| Field            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                  | <ul style="list-style-type: none"> <li>If the data is declared but not defined in the generated code — for example, if the data is resolved with an imported storage class — the field displays the identifier text prefixed with the label 'Imported data:'.</li> <li>If the data is neither defined nor declared in the generated code — for example, if <b>Reusable function</b> code interface packaging is selected for the model — the field displays the text 'Defined externally'.</li> </ul> |
| <b>Data Type</b> | Lists the data type of the data store.                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Scaling</b>   | <p>For fixed-point entries, lists the data type and fraction length using Simulink fixed-point data type notation.</p> <hr/> <p><b>Note:</b> You must have a Fixed-Point Designer license to see fixed-point scaling information in the report. For more information on how scaling is represented in the table, see “Fixed-Point Data Type and Scaling Notation”.</p>                                                                                                                                |
| <b>Dimension</b> | Lists the dimensions of the data store (for example, 1 or [ 1, 2]).                                                                                                                                                                                                                                                                                                                                                                                                                                   |

For example, here is the **Data Stores** subsection for the model `rtwdemo_basicsc` (with the **ExportedGlobal Storage Class** button selected in the model window).

### Data Stores

| Data Store Source                              | Code Identifier | Data Type | Dimension |
|------------------------------------------------|-----------------|-----------|-----------|
| <a href="#">&lt;Root&gt;/Data Store Memory</a> | mode            | boolean_T | 1         |

## Code Interface Report Limitations

The following limitations apply to the code interface section of the HTML code generation reports.

- The code interface report does not support the GRT interface with an ERT target or **C++ class** code interface packaging. For these configurations, the code interface report is not generated and does not appear in the HTML code generation report **Contents** pane.
- The code interface report supports data resolved with most custom storage classes (CSCs), except when the CSC properties are set in any of the following ways:

- The CSC property **Type** is set to **FlatStructure**. For example, the **BitField** and **Struct** CSCs in the Simulink package have **Type** set to **FlatStructure**.
- The CSC property **Type** is set to **Other**. For example, the **GetSet** CSC in the Simulink package has **Type** set to **Other**.
- The CSC property **Data access** is set to **Pointer**, indicating that imported symbols are declared as pointer variables rather than simple variables. This property is accessible only when the CSC property **Data scope** is set to **Imported** or **Instance-specific**.

In these cases, the report displays empty **Data Type** and **Dimension** fields.

- For outports, the code interface report cannot describe the associated memory (data type and dimensions) if the memory is optimized. In these cases, the report displays empty **Data Type** and **Dimension** fields.
- The code interface report does not support data type replacement using the **Code Generation > Data Type Replacement** pane of the Configuration Parameters dialog box. The data types listed in the report will link to built-in data types rather than their specified replacement data types.

## Static Code Metrics

### In this section...

“About Static Code Metrics” on page 35-34

“Static Code Metrics Analysis” on page 35-35

“View Static Code Metrics and Definitions Within the Generated Code” on page 35-36

### About Static Code Metrics

The code generator performs static analysis of the generated C or C++ code and provides these metrics in the **Static Code Metrics Report** section of the HTML Code Generation Report.

You can use the information in the report to:

- Find the number of files and lines of code in each file.
- Estimate the number of lines of code and stack usage per function.
- Compare the difference in terms of how many files, functions, variables, and lines of code are generated every time you change the model or MATLAB algorithm.
- Determine a target platform and allocation of RAM to the stack, based on the size of global variables plus the estimated stack size.
- Determine possible performance slow points, such as the largest global variables or the most costly call path in terms of stack usage.
- View the cyclomatic complexity of a function, which counts the number of linearly independent paths through a function.
- View the function call tree. Determine the longest call path to estimate the worst case execution timing.
- View how target functions, provided by the selected code replacement library, are used in the generated code.

For examples, see

- “Generate Static Code Metrics Report for Simulink Model” on page 35-38
- “Generate a Static Code Metrics Report for MATLAB Code” on page 35-43

## Static Code Metrics Analysis

Static analysis of the generated code is performed only on the source code without executing the program. The results of the static code metrics analysis are included in the **Static Code Metrics** section of the HTML Code Generation Report. The report is not available if you generate a MEX function from MATLAB code.

Static analysis of the generated source code files:

- Uses the specified C data types. For Simulink models, you specify these data types in the **Hardware Implementation > Production hardware** pane of the Configuration Parameters dialog box. For code generation from MATLAB code, you specify them in the **Hardware** tab of the MATLAB Coder project settings dialog box or using a code generation configuration object. Actual object code metrics might differ due to target-specific compiler and platform settings.
- Includes custom code only if you specify it. For Simulink models, you specify custom code on the **Code Generation > Custom Code** pane in the model configuration. For code generation from MATLAB code, you specify it on the **Debugging** tab of the MATLAB Coder project settings dialog box or using a code generation configuration object. An error report is generated if the generated code includes platform-specific files not contained in the standard C run-time library.
- For Simulink models, includes the generated code from referenced models.
- Uses 1-byte alignment for all members of a structure for estimating global and local data structure sizes. The size of a structure is calculated by summing the sizes of all of its fields. This estimation represents the smallest possible size for a structure.
- Calculates the self stack size of a function as the size of local data within a function, excluding input arguments. The accumulated stack size of a function is the self stack size plus the maximum of the accumulated stack sizes of its called functions. For example, if the accumulated stack sizes for the called functions are represented as `accum_size1...accum_sizeN`, then the accumulated stack size for a function is

$$\text{accumulated\_stack\_size} = \text{self\_stack\_size} + \max(\text{accum\_size1}, \dots, \text{accum\_sizeN})$$

- When estimating the stack size of a function, static analysis stops at the first instance of a recursive call. The **Function Information** table indicates when recursion occurs in a function call path. Code generation generates only recursive code for Stateflow event broadcasting and for graphical functions if it is written as a recursive function.
- Calculates the cyclomatic complexity of a function as the number of decisions plus one:

$$CC = \text{Number of decisions} + 1$$

The following constructs add a decision:

- If statement
- Else-If statement
- Switch statement (1 decision for each case branch)
- Loop statements: While, For, Do-while

---

**Note:** Boolean operators in the above constructs do not add extra decisions.

---

- Does not include `ert_main.c`, because you have the option to provide your own `main.c`.

## View Static Code Metrics and Definitions Within the Generated Code

When you view code in the code generation report, to get access to code metrics and definitions, you can use the following tools:

- On the **Code Generation > Report** pane, if you select the **Static code metrics** check box you can hover your cursor over global variables and functions in the code window to see code metrics information.

```

141 * UnitDelay: '<Root>/X'
142 */
143 /* Gateway: Chart */
144 if (rtDWork.temporalCounter_i1 < 7U) {
145 rtDWork: Global Variable: rtDWork (19 byte)
146 }
147 ...

```

- In the code window, if you click linked variables or functions, the code inspect window is displayed. The window provides links to definitions for the variables or functions. On the **Code Generation > Report** pane, if you selected the **Static code metrics** check box, you can also see code metrics information for the variable or function.

```
29 /* Block states (auto storage) */
30 D_Work rtDWork;
31
32 /* External outputs (root outports fed by signals with auto storage) */
33 ExternalOutputs rtY;
```

Global Variable: *rtDWork* (19 byte)  
*rtDWork* defined at [rtwdemo\\_hyperlinks.c line 30](#)

## Generate Static Code Metrics Report for Simulink Model

The **Static Code Metrics Report** is a section included in the HTML Code Generation Report. For more information on the static analysis of the generated code, see “Static Code Metrics Analysis” on page 35-35.

- 1 Before generating the HTML Code Generation Report, open the Configuration Parameters dialog box for your model. On the **Code Generation > Report** pane, select the “Static code metrics” check box.

If your model includes referenced models, select the **Static code metrics** check box in each referenced model’s configuration set. Otherwise, you cannot view a separate static code metrics report for a referenced model.

- 2 Press **Ctrl+B** to build your model and generate the HTML code generation report. For more information, see “Traceability in Code Generation Report” on page 35-15.
- 3 If the HTML Code Generation Report is not already open, open the report. On the left navigation pane, in the **Contents** section, select **Static Code Metrics Report**.

- 4 To see the generated files and how many lines of code are generated per file, look at the **File Information** section.

**1. File Information** [\[hide\]](#)

(-) Summary (excludes ert\_main.c)

Number of .c files : 2  
 Number of .h files : 4  
 Lines of code : 1,132  
 Lines : 1,958

(-) File details

| File Name                                   | Lines of Code | Lines | Generated On       |
|---------------------------------------------|---------------|-------|--------------------|
| <a href="#">fuel_rate_control.c</a>         | 665           | 1,107 | 06/10/2016 4:17 PM |
| <a href="#">fuel_rate_control_data.c</a>    | 253           | 342   | 06/10/2016 4:17 PM |
| <a href="#">rtwtypes.h</a>                  | 97            | 177   | 06/10/2016 4:17 PM |
| <a href="#">fuel_rate_control.h</a>         | 88            | 249   | 06/10/2016 4:17 PM |
| <a href="#">fuel_rate_control_types.h</a>   | 22            | 52    | 06/10/2016 4:17 PM |
| <a href="#">fuel_rate_control_private.h</a> | 7             | 31    | 06/10/2016 4:17 PM |

- 5 Hover your cursor over column titles and some column values to see a description of the corresponding data.
- 6 If your model includes referenced models, the File information section includes a **Referenced Model** column. In this column, click the referenced model name to open its static code metrics report. If the static code metrics report is not available for a referenced model, specify the **Static code metrics** parameter in the referenced model's configuration set and rebuild your model.
- 7 To view the global variables in the generated code, their size, and the number of accesses, see the **Global Variables** section.

**2. Global Variables** [\[hide\]](#)

| <b>Total</b>                             | <b>72</b>    | <b>248</b>     |                              |

\* The global variable is not directly used in any function.

The **Reads/Writes** column displays the total number of read and write accesses to the global variable. The **Reads/Writes in a Function** column displays the maximum number of read and write accesses to the global variable within a function. You use this information is to estimate the benefit of turning on optimizations, which

reduce the number of global references. For more information, see “Optimize Global Variable Usage” on page 55-2.

Click [ + ] to expand structures.

| <a href="#">fuel_rate_control_terminate</a>    |                                                                                      | 0                              | 0                       | 0             | 4     | 1          |
| <a href="#">look2_iff_linlca</a>               | <a href="#">fuel_rate_control_step</a> (5)                                           | 36                             | 36                      | 55            | 100   | 12         |
| <code>memset</code>                            | <a href="#">fuel_rate_control_initialize</a> (2)                                     | <i>Not available</i>           | -                       | -             | -     | -          |

The second column, **Called By**, lists functions that call the function listed in the first column, using the following criteria:

- If a function is called by multiple functions, all functions are listed.
- If a function has no called function, this column is empty.

For example, `Fueling_Mode` is called by `Fail` and `fuel_rate_control_step`. The number of call sites is included in parentheses. `Fail` calls `Fueling_Mode` twice.

# Generate a Static Code Metrics Report for MATLAB Code

## Generate a Static Code Metrics Report Using the MATLAB Coder App

This example shows how to generate a static code metrics report for a static C library that is generated from MATLAB code using the MATLAB Coder app.

By default, if you have an Embedded Coder license, when you use MATLAB Coder to generate standalone C/C++ code, the code generation report includes a static code metrics report. The static code metrics report is not available for generated MEX functions.

### Create the Example Files

- 1 In a local, writable folder, create a MATLAB file, `moving_average.m`, that contains:

```
function [avg,z] = moving_average(x,z)
 %#codegen
 z(2:end) = z(1:end-1); % Update buffer
 z(1) = x; % Add new value
 avg = mean(z); % Compute moving average
end
```

- 2 In the same local, writable folder, create a test file, `moving_average_test.m`, that contains:

```
function moving_average_test()
 z = zeros(10,1);
 for i = 1:10
 [avg, z] = moving_average(i,z);
 end
 disp(avg)
end
```

### Set Up the MATLAB Coder Project

- 1 To open the MATLAB Coder app and set up a project, at the command line, enter:

```
coder -new moving_average.prj
```

The app adds `moving_average` to the list of entry-point functions.

- 2 Click **Next** to go to the **Define Input Types** step.

### Define Input Types

- 1 To automatically define the input types, select or enter the test file `moving_average_test.m`. Click **Autodefine Input Types**.

The app determines that `x` is `double(1x1)` and `z` is `double(10x1)`.

- 2 Click **Next** to go to the **Check for Run-Time Issues** step.

The **Check for Run-Time Issues** step generates a MEX file from your entry-point functions, runs the MEX function, and reports issues. This step is optional. However, it is a best practice to perform this step. You can detect and fix run-time errors that are harder to diagnose in the generated C code.

### Check for Run-Time Issues

- 1 To open the **Check for Run-Time Issues** dialog box, click the **Check for Issues** arrow .

The app populates the test file field with `moving_average_test.m`, the test file that you used to define input types.

- 2 Click **Check for Issues**.

The app does not detect issues.

- 3 Click **Next** to go to the **Generate Code** step.

### Configure the Build Settings

- 1 On the **Generate Code** page, to open the **Generate** dialog box, click the **Generate** arrow .

- 2 Set **Build type** to `Static library`.

The default output file name is `moving_average`.

- 3 Click **More Settings**.

- 4 On the **Debugging** tab, verify that the **Static code metrics** check box is selected.

- 5 Click **Close**.

### Generate C Code

- 1 To generate the library, click **Generate**.

MATLAB Coder generates a C static library and supporting files in the default folder, `codegen/lib/moving_average`.

- 2 Click **Next** to go to the **Finish Workflow** step.

#### **View the Static Code Metrics Report**

- 1 To open the code generation report, under **Generated Output**, click **Code Generation Report**.
- 2 In the code generation report, click **Static Code Metrics Report**.
- 3 To see the generated files and the number of lines of code per file, click **File Information**.

Static Code Metrics Report

## Static Code Metrics Report

The static code metrics report provides statistics of the generated code. Metrics are estimated from static analysis of the generated code using the C data type specified in the **Hardware**: **char** 8, **short** 16, **int** 32, **long** 32, **float** 32, **double** 64, **pointer** 64 bits. Actual object code metrics might differ due to target specific compiler and platform settings.

| rtGetInfF                 | rtGetInf<br>rt_InitInfAndNaN     | 4                              | 4                       | 3             | 6     | 1          |
| rtGetMinusInf             | rt_InitInfAndNaN                 | 38                             | 34                      | 36            | 43    | 5          |

The second column, **Called By**, lists functions that call the function listed in the first column. If multiple functions call the function, all functions are listed. If no functions call the function, this column is empty.

## Enable a Static Code Metrics Report at the Command Line

To enable a static code metrics report at the command line:

- 1 Create a code generation configuration object for standalone code generation. For example, to generate a static library, use:

```
cfg = coder.config('lib', 'ecoder', true);
```

- 2 Generate code, passing the configuration object as a parameter and specifying the `-report` option. For example:

```
codegen -config cfg -report foo
```

Alternatively, you can:

- 1 Create a code generation configuration object for standalone code generation. For example, to generate a static library:

```
cfg = coder.config('lib', 'ecoder', true);
```

- 2 Set the configuration object `GenerateReport` and `GenerateCodeMetricsReport` parameters to `true`.

```
cfg.GenerateReport = true;
```

```
cfg.GenerateCodeMetricsReport = true;
```

- 3** Generate code, passing the configuration object as a parameter. For example:

```
codegen -config cfg foo
```

## Analyze Code Replacements in the Generated Code

When you select the check box **Summarize which blocks triggered code replacements** for an ERT-based model, a Code Replacements Report section is automatically included in the generated HTML report. The Code Replacements Report section documents the code replacement library (CRL) functions that were used for code replacements during code generation, providing a mapping between each replacement instance and the Simulink block that triggered the replacement. To enable display of the Simulink block information, select the **Code Generation > Comments** check box **Include comments**. On the same pane, select either the **Simulink block / Stateflow object comments** check box or the **Simulink block descriptions** check box if present, or both.

You can use the report to:

- Determine which replacement functions were used in the generated code.
- Trace each replacement instance back to the block that triggered the replacement.

The figure below shows a Code Replacements Report generated for the CRL model `rtwdemo_crladdsub`. Each replacement function used is listed with a link to the block that triggered the replacement.

## Code replacements in rtwdemo\_crladddsub

Code replacements for library 'Addition & Subtraction Examples'. The library comprises:

- Addition & Subtraction Examples
  - crl\_table\_addsub

To see the replacements and misses in the Code Replacement Viewer, look [here](#).

### 1. Addition operator replacements [\[hide\]](#)

The following table provides a mapping from the addition operators used from the selected Code Replacement Library to the blocks in the model that triggered the replacement.

| Function        | Block                              |
|-----------------|------------------------------------|
| s16_add_s16_s16 | <a href="#">&lt;S1&gt;:1</a>       |
| u8_add_u8_u8    | <a href="#">&lt;Root&gt;/Add8</a>  |
| u16_add_u16_u16 | <a href="#">&lt;Root&gt;/Add16</a> |

### 2. Subtraction operator replacements [\[hide\]](#)

The following table provides a mapping from the subtraction operators used from the selected Code Replacement Library to the blocks in the model that triggered the replacement.

| Function        | Block                                 |
|-----------------|---------------------------------------|
| u32_sub_u32_u32 | <a href="#">&lt;Root&gt;/EmbSub32</a> |
| s8_sub_s8_s8    | <a href="#">&lt;Root&gt;/Sub8</a>     |
| s32_sub_s32_s32 | <a href="#">&lt;Root&gt;/Sub32</a>    |

OK Help

If you click a block path in the report, the block that triggered the replacement is highlighted in the model diagram. If the replacement was triggered by a Stateflow chart or a MATLAB function, a window opens to display the chart or function.

For more information, see Trace Code Replacements Generated Using Your Code Replacement Library on page 51-82.

## Document Generated Code with Simulink Report Generator

| In this section...                                        |
|-----------------------------------------------------------|
| “Generate Code for the Model” on page 35-53               |
| “Open the Report Generator” on page 35-53                 |
| “Set Report Name, Location, and Format” on page 35-55     |
| “Include Models and Subsystems in a Report” on page 35-56 |
| “Customize the Report” on page 35-57                      |
| “Generate the Report” on page 35-58                       |

The Simulink Report Generator software creates documentation from your model in multiple formats, including HTML, PDF, RTF, Microsoft Word, and XML. This example shows one way to document a code generation project in Microsoft Word. The generated report includes:

- System snapshots (model and subsystem diagrams)
- Block execution order list
- Simulink Coder and model version information for generated code
- List of generated files
- Optimization configuration parameter settings
- System target file selection and build process configuration parameter settings
- Subsystem map
- File name, path, and generated code listings for the source code

To adjust Simulink Report Generator settings to include custom code and then generate a report for a model, complete the following tasks:

- 1 “Generate Code for the Model” on page 35-53
- 2 “Open the Report Generator” on page 35-53
- 3 “Set Report Name, Location, and Format” on page 35-55
- 4 “Include Models and Subsystems in a Report” on page 35-56
- 5 “Customize the Report” on page 35-57
- 6 “Generate the Report” on page 35-58

A Simulink Report Generator license is required for the following report formats: PDF, RTF, Microsoft Word, and XML. For more information on generating reports in these formats, see the Simulink Report Generator documentation.

## Generate Code for the Model

Before you use the Report Generator to document your project, generate code for the model.

- 1 In the MATLAB Current Folder browser, navigate to a folder where you have write access.
- 2 Create a working folder from the MATLAB command line by typing:  

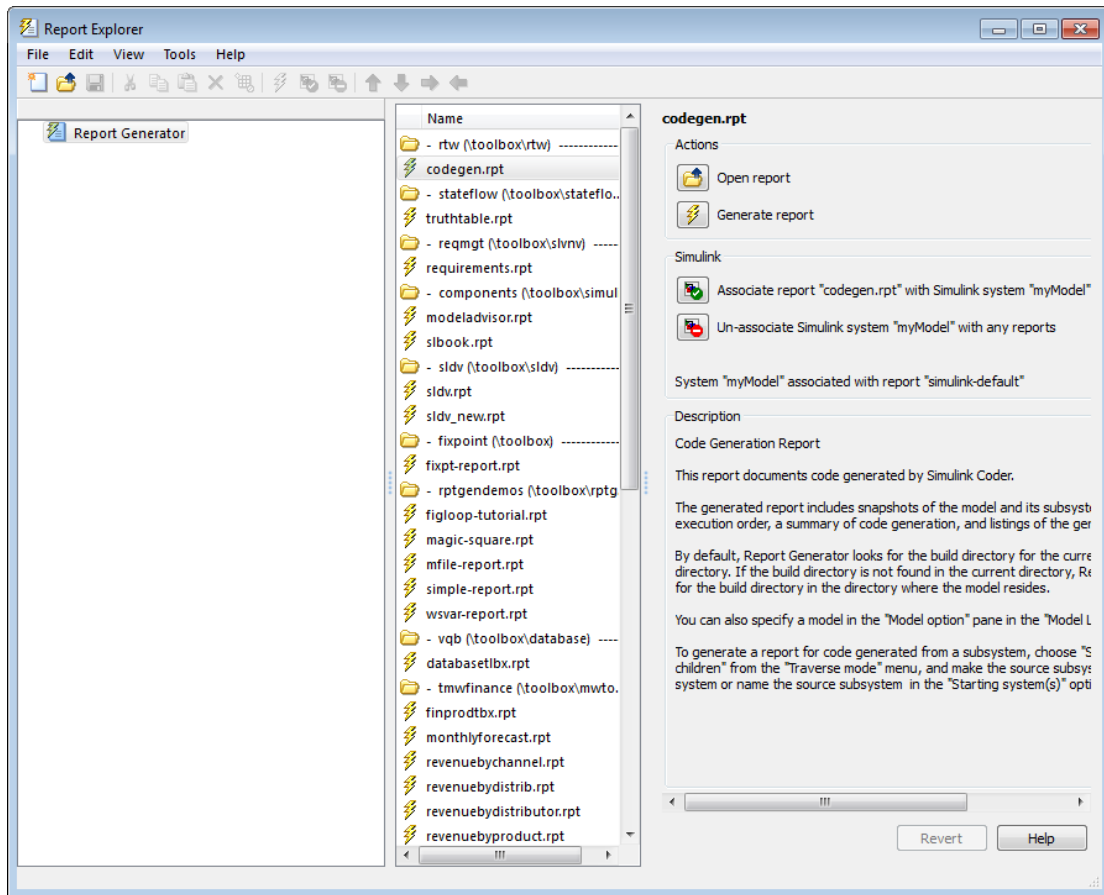

```
mkdir report_ex
```
- 3 Make `report_ex` your working folder:  

```
cd report_ex
```
- 4 Open the `slexAircraftExample` model by entering the model name on the MATLAB command line.
- 5 In the model window, choose **File > Save As**, navigate to the working folder, `report_ex`, and save a copy of the `slexAircraftExample` model as `myModel`.
- 6 Open the Configuration Parameters dialog box by selecting **Model Configuration Parameters** from the **Simulation** menu.
- 7 Select the **Solver** pane. In the **Solver options** section, specify the **Type** parameter as `Fixed-step`.
- 8 Select the **Code Generation** pane. Select **Generate code only**.
- 9 Click **Apply**.
- 10 In the model window, press **Ctrl+B**. The build process generates code for the model.

## Open the Report Generator

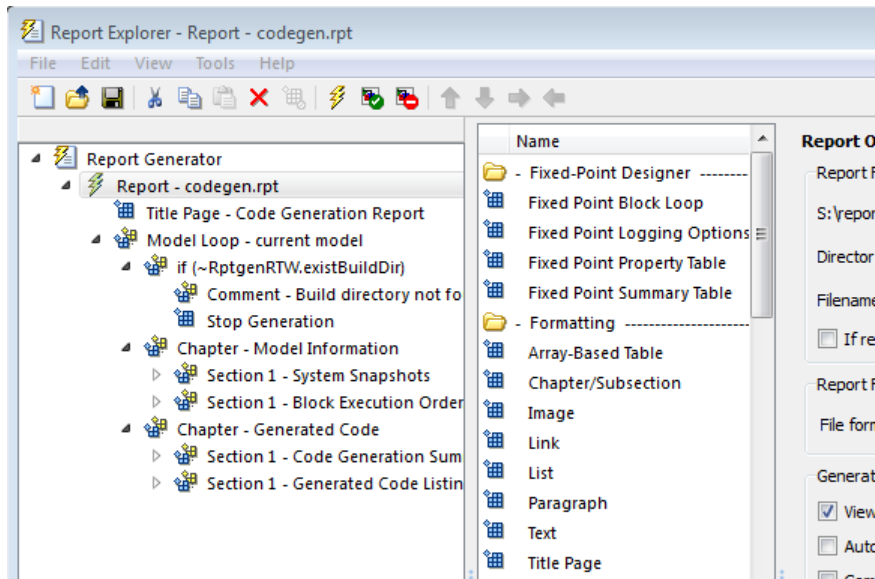

After you generate the code, open the Report Generator.

- 1 In the model diagram window, select **Tools > Report Generator**.
- 2 In the Report Explorer window, in the options pane (center), click the folder `rtw` (`\toolbox\rtw`). Click the setup file that it contains, `codegen.rpt`.

3

Double-click **codegen.rpt** or select it and click the **Open report** button . The Report Explorer displays the structure of the setup file in the outline pane (left).

## Set Report Name, Location, and Format

Before generating a report, you can specify report output options, such as the folder, file name, and format. For example, to generate a Microsoft Word report named `MyCGModelReport.rtf`:

- 1 In the properties pane, under **Report Options**, review the options listed.

- 2 Leave the **Directory** field set to **Present working directory**.
- 3 For **Filename**, select **Custom:** and replace **index** with the name **MyModel1CGreport**.
- 4 For **File format**, specify **Rich Text Format** and replace **Standard Print** with **Numbered Chapters & Sections**.

## Include Models and Subsystems in a Report

Specify the models and subsystems that you want to include in the generated report by setting options in the Model Loop component.

- 1 In the outline pane (left), select **Model Loop**. Report Generator displays Model Loop component options in the properties pane.
- 2 If not already selected, select **Current block diagram** for the **Model name** option.
- 3 In the outline pane, click **Report - codegen.rpt\***.

## Customize the Report

After specifying the models and subsystems to include in the report, you can customize the sections included in the report.

- 1 In the outline pane (left), expand the node **Chapter - Generated Code**. By default, the report includes two sections, each containing one of two report components.
- 2 Expand the node **Section 1 — Code Generation Summary**.
- 3 Select **Code Generation Summary**. Options for the component are displayed in the properties pane.
- 4 Click **Help** to review the report customizations that you can make with the Code Generation Summary component. For this example, do not customize the component.
- 5 In the Report Explorer window, expand the node **Section 1 — Generated Code Listing**.
- 6 Select **Import Generated Code**. Options for the component are displayed in the properties pane.
- 7 Click **Help** to review the report customizations that you can make with the Import Generated Code component.

## Generate the Report

After you adjust the report options, from the **Report Explorer** window, generate the report by clicking **File > Report**. A **Message List** dialog box opens, which displays messages that you can monitor as the report is generated. Model snapshots also appear during report generation. The **Message List** dialog box might be hidden behind other dialog boxes.

When the report is complete, open the report, `MyModelCGReport.rtf` in the folder `report_ex` (in this example).

## Add Custom Comments to Generated Code

You can include auto-generated comments in the generated code as described in “Configure Code Comments”. For ERT targets, include additional custom comments by setting parameters on the **Code Generation > Comments** pane in the Configuration Parameters dialog box. With these parameters, you can enable or suppress generation of descriptive information in comments for blocks and other model elements.

| Goal                                                                                                                                                                                                                    | Specify                                   |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------|
| Include the text specified in the <b>Description</b> field of a block's Block Properties dialog box as comments in the code generated for each block.                                                                   | <b>Simulink block descriptions</b>        |
| Add a comment that includes the block name at the start of the code for each block.                                                                                                                                     | <b>Simulink block descriptions</b>        |
| Include the text specified in the <b>Description</b> field of a Simulink data object (such as a signal, parameter, data type, or bus) in the Simulink Model Explorer as comments in the code generated for each object. | <b>Simulink data object descriptions</b>  |
| Include comments just above signals and parameter identifiers in the generated code as specified in the MATLAB or TLC function.                                                                                         | <b>Custom comments (MPT objects only)</b> |
| Include the text specified in the <b>Description</b> field in the Properties dialog box for a Stateflow object as comments just above the code generated for each object.                                               | <b>Stateflow object descriptions</b>      |
| Include requirements assigned to Simulink blocks in the generated code comments (for more information, see “Generate Code for Models with Requirements Links”).                                                         | <b>Requirements in block comments</b>     |

When you select **Simulink block descriptions**:

- The code generator includes strings for model parameters, block names, signal names, and Stateflow object names in the generated code comments. If those strings are unrepresented in the character set encoding for the model, the code generator replaces the strings with XML escape sequences. For example, the code generator replaces the

Japanese full-width Katakana letter `ア` with the escape sequence `&#x30A2;`. For more information, see “Internationalization and Code Generation”.

- The code generation software automatically inserts comments into the generated code for custom blocks. Therefore, you do not need to include block comments in the associated TLC file for a custom block.

---

**Note:** If you have existing TLC files with manually inserted comments for block descriptions, the code generation process emits these comments instead of the automatically generated comments. Consider removing existing block comments from your TLC files. Manually inserted comments might be poorly formatted in the generated code and code-to-model traceability might not work.

---

- For virtual blocks or blocks that have been removed due to block reduction, comments are not generated.

For more information, see “Model Configuration Parameters: Code Generation Comments”.

## Add Custom Comments for Variables in the Generated Code

To control code generation options for signals, states, and parameters in a model, you can create data objects in a workspace or data dictionary. You can generate comments in the code that help you to document the purpose and properties of the data in each object. Associate handwritten comments with each object, or write a function that generates comments based on the properties of the object.

For more information about data objects, see “Data Objects”.

### In this section...

“Embed Handwritten Comments for Signals or Parameters” on page 36-5

“Generate Dynamic Comments Based on Data Properties” on page 36-6

### Embed Handwritten Comments for Signals or Parameters

To embed handwritten comments in the generated code near the definition of a signal, state, or parameter:

- 1 Create a data object to represent a signal, state, or parameter. You can use a data object from any package. For example, use a data object of the classes `Simulink.Signal` or `Simulink.Parameter`, which are defined in the package `Simulink`.

```
myParam = Simulink.Parameter(15.23);
```

- 2 Set the storage class of the data object so that optimizations do not eliminate the signal or parameter from the generated code. For example, use the storage class `ExportedGlobal`.

```
myParam.StorageClass = 'ExportedGlobal';
```

- 3 Set the `Description` property of the object. The description that you specify appears in the generated code as lines of comments.

```
myParam.Description = 'This parameter represents wind speed.';
```

- 4 Set **Configuration Parameters > Code Generation > System target file** to an ERT-based target such as `ert.tlc`.

To generate comments from data object descriptions, you must use an ERT-based target.

- 5 Select **Configuration Parameters > Code Generation > Comments > Simulink data object descriptions**.
- 6 Generate code from the model. In the code, the data object description appears near the definition of the corresponding variable.

```
/* Exported block parameters */
real_T myParam = 15.23; /* Variable: myParam
 * Referenced by: '<S1>/Gain'
 * This parameter represents wind speed.
 */
```

## Generate Dynamic Comments Based on Data Properties

You can generate dynamic comments that include the properties of the data object such as data type, units, and dimensions. If you change the properties of the data object in Simulink, the code generator maintains the accuracy of the comments. For example, this comment displays some of the property values for a data object named MAP:

```
/* Unit: psi */
/* Owner: */ */
/* DefinitionFile: specialDef */
real_T MAP = 0.0;
```

- 1 Create a data object from the package `mpt` and apply a custom storage class to the object. The default storage class for objects that you create from the package `mpt` is the custom storage class `Global (Custom)`.

```
MAP = mpt.Signal;
```

To generate dynamic comments, you must use a data object from the package `mpt`, and you must apply a custom storage class to the object.

- 2 Write a MATLAB or TLC function that generates the comment text. For an example MATLAB function, see the function `matlabroot/toolbox/rtw/rtwdemos/rtwdemo_comments_mptfun.m`.

The function must accept three input arguments that correspond to `objectName`, `modelName`, and `request`. If you write a TLC file, you can use the library function `LibGetSLDataObjectInfo` to get all of the property values of the data object.

- 3 Save the function as a MATLAB file or a TLC file, and place the file in a folder that is on your MATLAB path.

- 4 In the model, select **Configuration Parameters > Code Generation > Comments > Custom comments (MPT objects only)**.
- 5 Set **Custom comments function** to the name of the MATLAB file or TLC file that you created.
- 6 Generate code from the model. The comments that your function generates appear near the code that represents each data object.

### Limitations

- To generate comments by using the **Custom comments (MPT objects only)** and **Custom comments function** options, you must create data objects from the package `mpt`. The data objects must use a custom storage class.
- Only the custom storage classes from the `mpt` package that create unstructured variables support a custom comments function.

### Related Examples

## Add Global Comments

| In this section...                                         |
|------------------------------------------------------------|
| “Use a Simulink DocBlock to Add a Comment” on page 36-8    |
| “Use a Simulink Annotation to Add a Comment” on page 36-11 |
| “Use a Stateflow Note to Add a Comment” on page 36-11      |
| “Use Sorted Notes to Add Comments” on page 36-12           |

The following examples show how to add a global comment to a Simulink model so that the comment text appears in the generated file or files where you want. Specify a template symbol name with a Simulink DocBlock, a Simulink annotation, or a Stateflow note. You can also use a sorted-notes capability that works with Simulink annotations or Stateflow notes (but not DocBlocks). For more information about template symbols, see “Template Symbols and Rules” on page 36-89.

---

**Note** Template symbol names `Description` and `ModifiedHistory` also are fields in the Model Properties dialog box. If you use one of these symbol names for global comment text, and its Model Properties field also has text in it, both names appear in the generated files.

---

### Use a Simulink DocBlock to Add a Comment

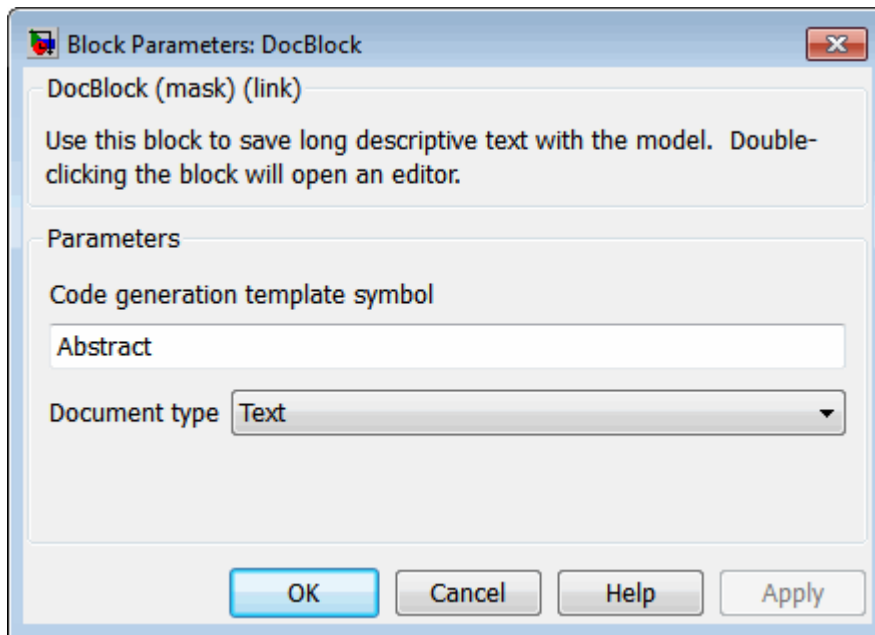

- 1 With the model open, from the **View** menu, select **Library Browser**.
- 2 Drag the DocBlock from **Model-Wide Utilities** in the Simulink library into the model.
- 3 Double-click the DocBlock and type the comment that you want in the editor. Save and close the editor.
- 4 Right-click the DocBlock and select **Mask > Mask Parameters**.
- 5 In the **Code generation template symbol** box, type one of the following:
  - `Abstract`
  - `Description`
  - `History`
  - `ModifiedHistory`

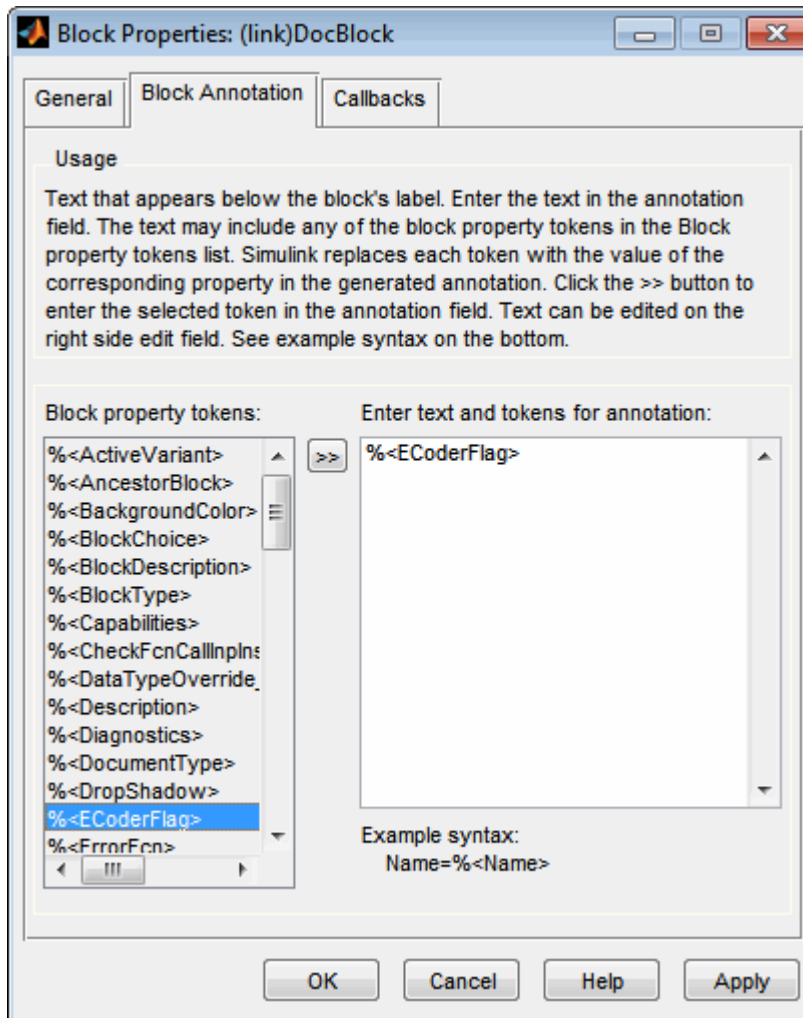

- Notes

Click **OK**. Template symbol names are case sensitive.

If you are using a DocBlock to add comments to your code, set the **Document type** to **Text**. If you set **Document type** to **RTF** or **HTML**, your comments will not appear in the code.

- 6 In the Block Properties dialog box, on the **Block Annotation** tab, select `%<ECoderFlag>` and click **OK**. The symbol name that you typed in the previous step now appears under the DocBlock in the model.

- 7 Save the model. After you generate code, the code generator places the comment in each generated file whose template has the symbol name that you typed. The code generator places the comment in the generated file at the location that corresponds to where the symbol name is located in the template file.
- 8 To add more comments to the generated files, repeat steps 1–7.

## Use a Simulink Annotation to Add a Comment

- 1 Double-click the unoccupied area on the model where you want to place the comment. See “Describe Models Using Annotations”.
- 2 Type `<S:Symbol_name>` followed by the comment. `Symbol_name` is one of the following:
  - Abstract
  - Description
  - History
  - ModifiedHistory
  - Notes

For example, type `<S:Description>This is the description I want.` Template symbol names are case sensitive. (The "S" before the colon indicates "symbol.") If you want the code generator to sort multiple comments for the **Notes** symbol name, replace the next step with “Use Sorted Notes to Add Comments” on page 36-12.

- 3 Click outside the rectangle and save the model. After you generate code, the code generator places the comment in each generated file whose template has the symbol name that you typed. The code generator places the comment in the generated file at the location that corresponds to where the symbol name is located in the template file. If you want the code generator to sort multiple comments for the **Notes** symbol name, replace the next step with “Use Sorted Notes to Add Comments” on page 36-12.
- 4 To add one or more other comments to the generated files, repeat steps 1–3.

## Use a Stateflow Note to Add a Comment

- 1 Right-click the unoccupied area on the Stateflow chart where you want to place the comment.
- 2 Select the annotation icon from the palette.
- 3 Type `<S:Symbol_name>` followed by the comment. `Symbol_name` is one of the following:
  - Abstract
  - Description

- History
- ModifiedHistory
- Notes

For example, type `<S:Description>This is the description I want.` Template symbol names are case sensitive. If you want the code generator to sort multiple comments for the `Notes` symbol name, replace the next step with “Use Sorted Notes to Add Comments” on page 36-12.

- 4 Click outside the note and save the model. After you generate code, the code generator places the comment in each generated file whose template has the symbol name that you typed. The code generator places the comment in the generated file at the location that corresponds to where the symbol name is located in the template file.
- 5 To add one or more other comments to the generated files, repeat steps 1–4.

## Use Sorted Notes to Add Comments

The sorted-notes capability allows you to add automatically sorted comments to the generated files. The code generator places these comments in each generated file at the location that corresponds to where the `Notes` symbol is located in the template file.

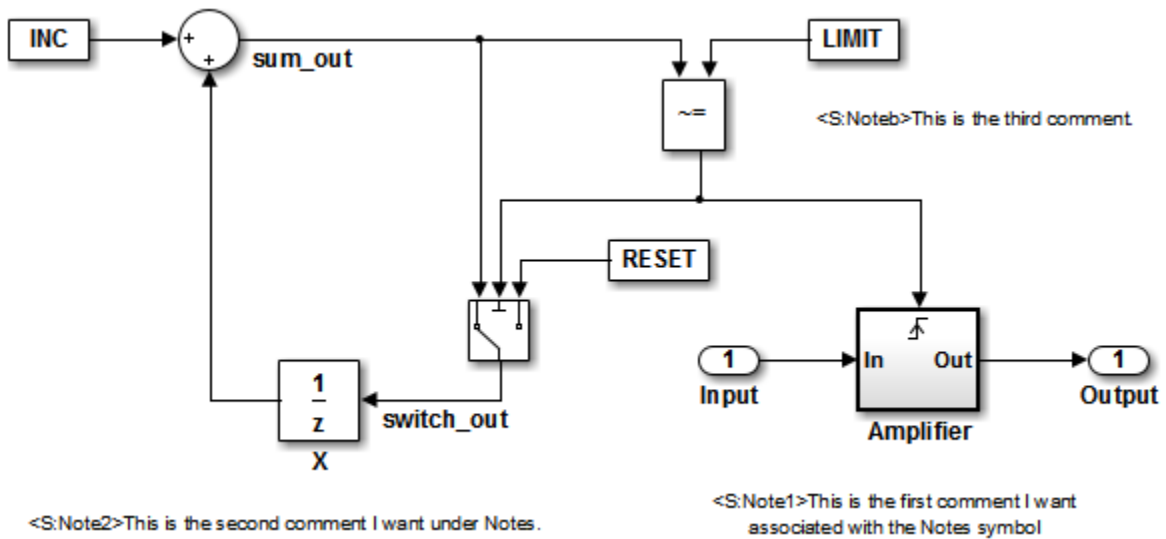

The code generator uses the following sorting order:

- Numbers before letters.
- Among numbers, 0 is first.
- Among letters, uppercase are before lowercase.

You can use sorted notes with a Simulink annotation or a Stateflow note, but not with a DocBlock.

- In the Simulink annotation or the Stateflow note, type `<S:NoteY>` followed by the first comment. Y is a number or a letter.
- Repeat for as many additional comments you want. Replace Y with a subsequent number or letter.

The figure illustrates sorted notes on a model, and where the code generator places each note in a generated file.

The relevant fragment from the generated file for this model is:

\*\* NOTES

\*\* Note1: This is the first comment I want associated with the Notes symbol.  
 Note2: This is the second comment I want under Notes.  
 Noteb: This is the third comment.

\*\*

## Specify Comment Style

For ERT-based models, the comment style used in generated code is determined by the programming language selected for the model:

- C code uses `/* . . . */` notation for both single-line and multiple-line comments.
- C++ code uses `// . . .` notation and contains only single-line comments.

If you have an Embedded Coder license, you can modify the comment style for generated code using the command-line parameter `CommentStyle`. The parameter takes the following values:

| Value          | Description                                                                                                                                                              |
|----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Auto (default) | For C, generate single or multiple-line comments delimited by <code>/*</code> and <code>*/</code> . For C++, generate single-line comments preceded by <code>//</code> . |
| Multi-line     | Generate single or multiple-line comments delimited by <code>/*</code> and <code>*/</code> .                                                                             |
| Single-line    | Generate single-line comments preceded by <code>//</code> .                                                                                                              |

For example, the following command sets the comment style to single-line comments:

```
>> set_param('rtwdemo_counter','CommentStyle','Single-line')
```

Here is an example of code generated using the single-line comment style:

```
// Sum: '<Root>/Sum' incorporates:
// Constant: '<Root>/INC'
// UnitDelay: '<Root>/X'

rtb_sum_out = (uint8_T)(1U + rtwdemo_counter_DW.X);
```

---

**Note:** For C code generation, select `Single-line` only if your compiler supports it

---

## Customize Generated Identifier Naming Rules

### In this section...

“Apply Naming Rules to Identifiers Globally” on page 36-15

“Apply Naming Rules to Simulink Data Objects” on page 36-16

For GRT and RSim targets, the code generator constructs identifiers for variables and functions in the generated code. For ERT targets, you can customize the naming of identifiers in the generated code by specifying parameters on the **Code Generation > Symbols** pane in the Configuration Parameters dialog box. You can also specify parameters that control identifiers generated from Simulink data objects. For detailed information about these parameters, see “Model Configuration Parameters: Code Generation Symbols”.

### Apply Naming Rules to Identifiers Globally

| Goal                                                                                                                                                                                                                                                                                                                                                                                                 | Specify                                                                                                                                                                                                                                                                                                                                                           |
|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Set the maximum number of characters that the code generator uses for function, <code>typedef</code> , and variable names (default 31) .                                                                                                                                                                                                                                                             | An integer value for the “Maximum identifier length” parameter. For more information, see “Specify Identifier Length to Avoid Naming Collisions”. If you expect your model to generate lengthy identifiers (due to use of long signal or parameter names, for example), or if identifiers are mangled more than you expect, increase the value of this parameter. |
| Define a macro that specifies certain text included within generated identifiers for: <ul style="list-style-type: none"> <li>• Global variables</li> <li>• Global types</li> <li>• Field names of global types</li> <li>• Subsystem methods</li> <li>• Subsystem method arguments</li> <li>• Local temporary variables</li> <li>• Local block output variables</li> <li>• Constant macros</li> </ul> | A macro for the <b>Identifier format control</b> parameters. For more information, see “Identifier Format Control” on page 36-22. See also “Exceptions to Identifier Formatting Conventions” on page 36-32 and “Identifier Format Control Parameters Limitations” on page 36-33.                                                                                  |

| Goal                                                                                                         | Specify                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|--------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <ul style="list-style-type: none"> <li>Shared utilities</li> </ul>                                           |                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Set the minimum number of characters that the code generator uses for the mangling text.                     | An integer value for the “Minimum mangle length” parameter. For more information, see “Control Name Mangling in Generated Identifiers” on page 36-27                                                                                                                                                                                                                                                                                    |
| Control whether the software uses shortened names for system-generated identifiers.                          | <p>Shortened for the “System-generated identifiers” parameter. This setting:</p> <ul style="list-style-type: none"> <li>Provides more space for user names.</li> <li>Provides a more predictable and consistent naming system that uses camel case.</li> <li>Does not include underscores or plurals.</li> <li>Provides consistent abbreviations for both a type and a variable.</li> </ul>                                             |
| Control whether the generated code expresses scalar inlined parameter values as literal values or as macros. | <p>The value <b>Literals</b> or <b>Macros</b> for the “Generate scalar inlined parameters as” parameter.</p> <ul style="list-style-type: none"> <li><b>Literals:</b> If you set <b>Default parameter behavior</b> to <b>Inlined</b>, parameters are expressed as numeric constants.</li> <li><b>Macros:</b> Parameters are expressed as variables (with <code>#define</code> macros). This setting makes code more readable.</li> </ul> |

## Apply Naming Rules to Simulink Data Objects

When your model uses Simulink data objects from the `Simulink` package, identifiers in generated code copy the names of the objects by default. For example, a `Simulink.Signal` object named `Speed` appears as the identifier `Speed` in generated code.

You can control these identifiers by specifying naming rules that are specific to Simulink data objects. On the **Code Generation > Symbols** pane of the Configuration Parameters dialog box, adjust the settings in the **Simulink data object naming rules** section .

When you specify naming rules for generated code, follow ANSI C<sup>7</sup>/C++ rules for naming identifiers.

### Specify Naming Rule Using a Function

This example shows how to customize identifiers in generated code by defining a MATLAB function.

- 1 Write a MATLAB function that returns an identifier by modifying a data object name, and save the function in your working folder. For example, the following function returns an identifier name by appending the text `_param` to a data object name.

```
function revisedName = append_text(name, object)
% APPEND_TEXT: Returns an identifier for generated
% code by appending text to a data object name.
%
% Input arguments:
% name: data object name as spelled in model
% object: target data object
%
% Output arguments:
% revisedName: altered identifier returned for use in
% generated code.
%
%
text = '_param';

revisedName = [name,text];
```

- 2 Open the model `rtwdemo_namerules`.
- 3 Double-click the yellow box labeled **View Symbols Configuration** to open the **Code Generation > Symbols** pane in the Configuration Parameters dialog box.
- 4 From the **Parameter naming** drop-down list, select **Custom M-function**.

---

7. ANSI is a registered trademark of the American National Standards Institute, Inc.

- 5 In the **M-function** field, type the name of the file that defines the MATLAB function, `append_text.m`.
- 6 Click **Apply**.
- 7 Generate code for the model.
- 8 Inspect the code generation report to confirm the parameter object naming rule. For example, the generated file `rtwdemo_namerules.h` represents the parameter objects `G1`, `G2`, and `G3` with the variables `G1_param`, `G2_param`, and `G3_param`.

### Specify Naming Rule for Storage Class Define

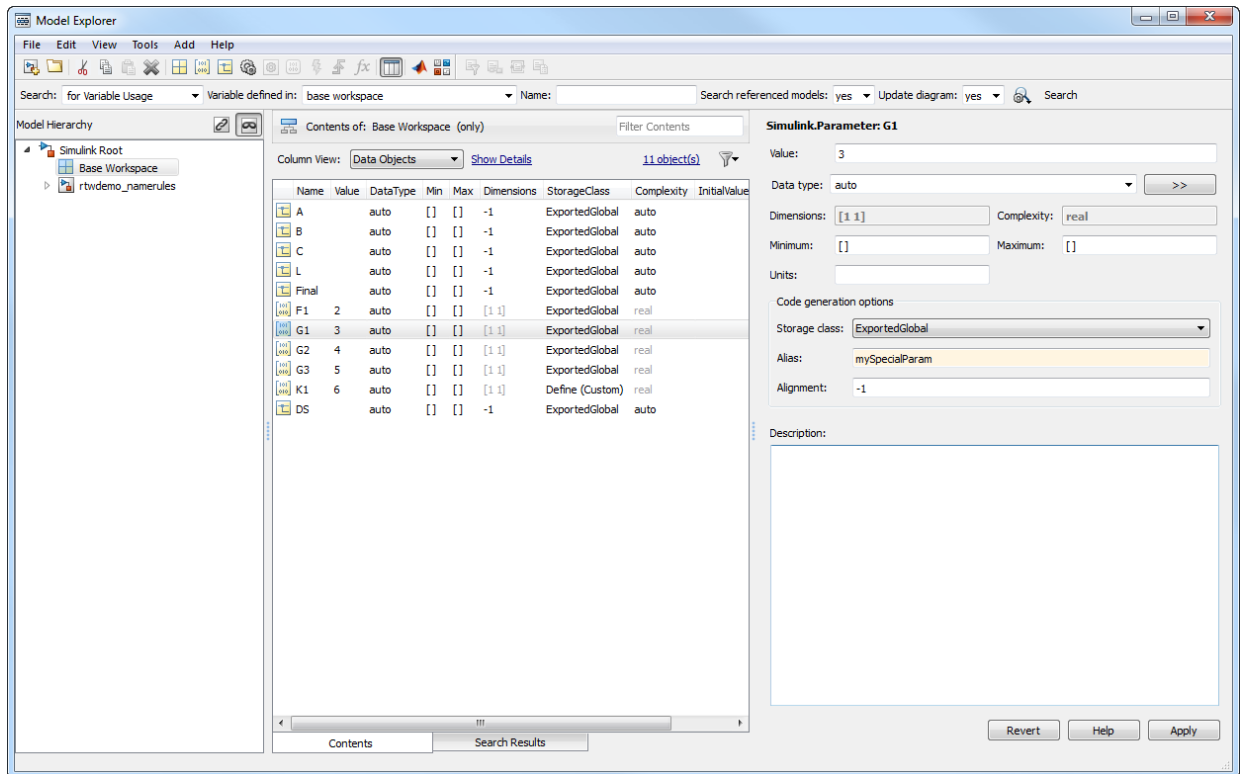

You can specify a naming rule that applies only to Simulink data objects whose storage class you set to **Define**. For these data objects, the specified naming rule overrides the other parameter and signal object naming rules. On the **Code Generation > Symbols** pane in the Configuration Parameters dialog box, adjust the **#define naming** setting.

### Override Data Object Naming Rules

This example shows how to override a data object naming rule for a single data object.

You can override data object naming rules by specifying the **Alias** property of an individual Simulink data object. Generated code uses the text that you specify as the identifier to represent the data object, regardless of naming rules.

- 1 Open the model `rtwdemo_namerules`.
- 2 Open Model Explorer and navigate to the base workspace.
- 3 Click the parameter object `G1` and specify the **Alias** property as `mySpecialParam`. Click **Apply**.

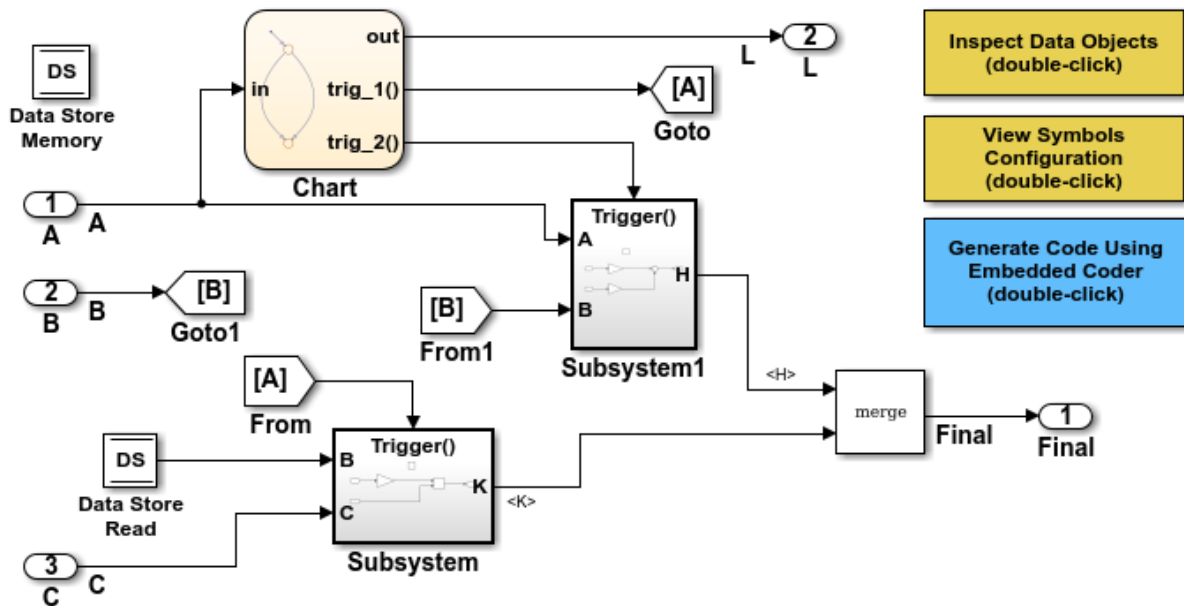

- 4 Generate code for the model.
- 5 In the code generation report, confirm the alias for the parameter object G1. The generated file `rtwdemo_namerules.h` represents G1 with the variable `mySpecialParam`.

### Apply Custom Naming Conventions to Identifiers

This example shows how to apply uniform naming rules for Simulink® data objects, including signals, parameters, and data store memory variables.

```
model='rtwdemo_namerules';
open_system(model)
```

**Description**

Many organizations employ coding standards that include naming rules for variables. This model shows how to apply uniform naming rules for Simulink data objects, including signals, parameters, and data store memory variables. Predefined conventions exist to apply upper and lower case naming, and arbitrary custom rules can be defined in a user-supplied MATLAB script.

**Instructions**

1. Double-click the yellow View Symbols Configuration button to inspect the "Simulink data object naming rules."
2. Double-click the yellow Inspect Data Objects button to inspect the data objects for this model.
3. Generate code using the blue button in the upper right of the diagram. An HTML report automatically appears.
4. Inspect the data that is defined toward the top of `rtwdemo_namerules.c`.

**Note**

The model is configured to "Force lower case." Therefore, the variables in the code are defined in lower case even though the data is declared upper case in the model.

Copyright 1994-2012 The MathWorks, Inc.

```
% Cleanup
rtwdemoclean;
```

```
close_system(model,0)
```

## Identifier Format Control

You can customize generated identifiers by specifying the **Identifier format control** parameters on the **Code Generation > Symbols** pane in the Configuration Parameters dialog box. For each parameter, you can enter a macro that specifies whether, and in what order, certain text is included within generated identifiers. For example, you can specify that the root model name be inserted into each identifier using the **\$R** token.

The macro can include:

- Valid tokens, which are listed in Identifier Format Tokens. You can use or omit tokens depending on what you want to include in the identifier name. The **Shared utilities** parameter requires you to specify the checksum token, **\$C**. The other parameters require the mangling token, **\$M**. For more information, see “Control Name Mangling in Generated Identifiers” on page 36-27. The mangling token is subject to the use and ordering restrictions noted in Identifier Format Control Parameter Values.
- Valid C or C++ language identifier characters (a-z, A-Z, **\_**, 0-9).

The build process generates each identifier by expanding tokens and inserting the resultant text into the identifier. The tokens are expanded in the order listed in Identifier Format Tokens. Groups of characters are inserted in the positions that you specify around tokens directly into the identifier. Contiguous token expansions are separated by the underscore (**\_**) character.

### Identifier Format Tokens

| Token | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| \$C   | This token is required for <b>Shared utilities</b> . If the identifier exceeds the <b>Maximum identifier length</b> , the code generator inserts an 8-character checksum to avoid naming collisions. The position of the <b>\$C</b> token in the <b>Identifier format control</b> parameter specification determines the position of the checksum in the generated identifier. For example, if you use the specification <b>\$N\$C</b> , the checksum is appended to the end of the identifier. This token is available only for shared utilities. |
| \$M   | This token is required. If necessary, the code generator inserts name-mangling text to avoid naming collisions. The position of the <b>\$M</b> token in the <b>Identifier format control</b> parameter specification determines the position of the name-mangling text in the generated identifier. For example, if you use the specification <b>\$R\$N\$M</b> , the name-mangling text is                                                                                                                                                         |

| Token | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|       | appended (if required) to the end of the identifier. For more information, see “Control Name Mangling in Generated Identifiers” on page 36-27<br>.                                                                                                                                                                                                                                                                                                                           |
| \$U   | Insert text that you specify for the \$U token. Use the <b>Custom token text</b> parameter to specify this text. This parameter is on the <b>All Parameters</b> tab of the Configuration Parameters dialog box.                                                                                                                                                                                                                                                              |
| \$F   | Insert method name (for example, <code>_Update</code> for update method). This token is available only for subsystem methods.                                                                                                                                                                                                                                                                                                                                                |
| \$N   | Insert name of object (block, signal or signal object, state, parameter, shared utility function or parameter object) for which identifier is being generated.                                                                                                                                                                                                                                                                                                               |
| \$R   | Insert root model name into identifier, replacing unsupported characters with the underscore ( <code>_</code> ) character. When you use referenced models, this token is required in addition to \$M (see “Avoid Identifier Name Collisions with Referenced Models” on page 36-29).<br><br><b>Note:</b> This token replaces the <b>Prefix model name to global identifiers</b> option in previous releases.                                                                  |
| \$H   | Insert tag indicating system hierarchy level. For root-level blocks, the tag is the text <code>root_</code> . For blocks at the subsystem level, the tag is of the form <code>SN_</code> . N is a unique system number assigned by the Simulink software. This token is available only for subsystem methods and field names of global types.<br><br><b>Note:</b> This token replaces the <b>Include System Hierarchy Number in Identifiers</b> option in previous releases. |
| \$A   | Insert data type acronym (for example, <code>i32</code> for integers) to signal and work vector identifiers. This token is available for local block output variables, local temporary variables, and field names of global types.<br><br><b>Note:</b> This token replaces the <b>Include data type acronym in identifier</b> option in previous releases.                                                                                                                   |
| \$I   | <ul style="list-style-type: none"> <li>• Insert <code>u</code> if the argument is an input.</li> <li>• Insert <code>y</code> if the argument is an output.</li> <li>• Insert <code>uy</code> if the argument is an input and output.</li> </ul>                                                                                                                                                                                                                              |

| Token | Description                                                                                                                                                                                                           |

Identifier Format Control Parameter Values lists the default macro value, the supported tokens, and the applicable restrictions for each **Identifier format control** parameter.

### Identifier Format Control Parameter Values

| Parameter                           | Default Value            | Supported Tokens                          | Restrictions                                                                                                                    |
|-------------------------------------|--------------------------|-------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------|
| <b>Global variables</b>             | <code>rt\$N\$M</code>    | <code>\$R, \$N, \$M, \$U</code>           | <code>\$F, \$H, \$A, and \$I</code> are not allowed.                                                                            |
| <b>Global types</b>                 | <code>\$N\$R\$M_T</code> | <code>\$N, \$R, \$M, \$U</code>           | <code>\$F, \$H, \$A, and \$I</code> are not allowed.                                                                            |
| <b>Field name of global types</b>   | <code>\$N\$M</code>      | <code>\$N, \$M, \$H, \$A, \$U</code>      | <code>\$R, \$F, and \$I</code> are not allowed.                                                                                 |
| <b>Subsystem methods</b>            | <code>\$F\$N\$M</code>   | <code>\$R, \$N, \$M, \$F, \$H, \$U</code> | <code>\$F</code> and <code>\$H</code> are empty for Stateflow functions; <code>\$A</code> and <code>\$I</code> are not allowed. |
| <b>Subsystem method arguments</b>   | <code>rt\$I\$N\$M</code> | <code>\$N, \$M, \$I, \$U</code>           | <code>\$R, \$F, \$H, and \$A</code> are not allowed.                                                                            |
| <b>Local temporary variables</b>    | <code>\$N\$M</code>      | <code>\$N, \$M, \$R, \$A, \$U</code>      | <code>\$F, \$H, and \$I</code> are not allowed.                                                                                 |
| <b>Local block output variables</b> | <code>rtb_ \$N\$M</code> | <code>\$N, \$M, \$A, \$U</code>           | <code>\$R, \$F, \$H, and \$I</code> are not allowed.                                                                            |
| <b>Constant macros</b>              | <code>\$R\$N\$M</code>   | <code>\$R, \$N, \$M, \$U</code>           | <code>\$F, \$H, \$A, and \$I</code> are not allowed.                                                                            |
| <b>Shared utilities</b>             | <code>\$N\$C</code>      | <code>\$N, \$C, \$R, \$U</code>           | <code>\$C</code> is required. <code>\$M, \$F, \$H, \$A</code> , and <code>\$I</code> are not allowed.                           |

Non-ERT-based targets (such as the GRT target) implicitly use a default `$R$N$M` specification. This default specification consists of the root model name, followed by the name of the generating object (signal, parameter, state, and so on), followed by name-mangling text.

For limitations that apply to **Identifier format control** parameters, see “Exceptions to Identifier Formatting Conventions” on page 36-32 and “Identifier Format Control Parameters Limitations” on page 36-33.

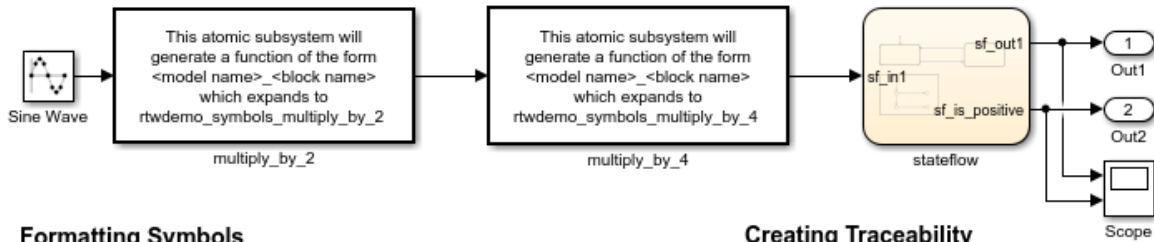

## Control Formatting of Identifiers

This example shows how you can customize generated identifiers by specifying the **Identifier format control** parameters on the **Code Generation > Symbols** pane in the Configuration Parameters dialog box.

```
model='rtwdemo_symbols';
open_system(model)
```

## Embedded Coder(R) Symbol Naming and Traceability

### Formatting Symbols

Symbols in Embedded Coder(R) can be formatted via the "Identifier format control" option group. These options can be composed of predefined macros and C-language literal characters.

Common macros include

- \$R** = Root model name
- \$N** = Name of object (block, signal, state, etc.)
- \$M** = Mangle used to uniquely symbol

For a complete list of macros and the rules by which they are expanded, see the Symbol format help link below.

Different identifier format control strings control different types of identifiers. Double-click the yellow buttons at the bottom to modify the format control strings for global variable names and global type names. Double-click the blue button to generate and inspect code for the change.

- ▶ [Double-click to view symbol format](#)
- ▶ [Double-click to view symbol format help](#)

**Global variable names  
contain model name.

rtwdemoclean;
close_system(model,0)
```

### Creating Traceability

One aspect of traceability is making sure that incremental revisions to a model have minimal impact on the symbol names that appear in generated code. There are two ways of achieving this in Simulink:

- 1) Name objects in Simulink (blocks, signals, states, etc.) as uniquely as possible.
- 2) Make use of name mangling when conflicts cannot be avoided.

For a complete discussion of how name mangling can be used to create traceable code, see the help link below.

- ▶ [Double-click to view mangle settings](#)
- ▶ [Double-click to view traceability help](#)

## Control Name Mangling in Generated Identifiers

The position of the \$M token in the **Identifier format control** parameter specification determines the position of the name-mangling text in the generated identifiers. For example, if you use the specification \$R\$N\$M, the name-mangling text is appended (if required) to the end of the identifier. For more information, see “Identifier Format Control” on page 36-22.

### Name-Mangling Text Per Object

| Object Type        | Source of Mangling Text                                                                       |
|--------------------|-----------------------------------------------------------------------------------------------|
| Block diagram      | Name of block diagram                                                                         |
| Simulink block     | Simulink identifier (for details, see “Locate Diagram Components Using Simulink Identifiers”) |
| Simulink parameter | Full name of parameter owner (model or block) and parameter name                              |
| Simulink signal    | Signal name, full name of source block, and port number                                       |
| Stateflow objects  | Complete path to Stateflow block and Stateflow computed name (unique within chart)            |

The length of the name-mangling text is specified by the **Minimum mangle length** parameter. The default value is 1, but this automatically increases during code generation as a function of the number of collisions. To minimize disturbance to the generated code during development, specify a larger **Minimum mangle length**. A **Minimum mangle length** of 4 is a conservative value. A value of 4 allows for over 1.5 million collisions for a particular identifier before the mangle length is increased.

### Minimize Name Mangling

The length of generated identifiers is limited by the **Maximum identifier length** parameter. When a name collision exists, the \$M token is expanded to the minimum number of characters required to avoid the collision. Other tokens are expanded in the order listed in Identifier Format Tokens. If the **Maximum identifier length** is not large enough to accommodate full expansions of the other tokens, partial expansions are used. To avoid partial expansions, it is good practice to:

- Avoid name collisions. One way to avoid name collisions is to not use default block names (for example, Gain1, Gain2...) when there are many blocks of the same type in the model.

- Where possible, increase the **Maximum identifier length** to accommodate the length of the identifiers that you expect to generate.
- Set the **Maximum identifier length** parameter to reserve at least three characters for the name-mangling text. The length of the name-mangling text increases as the number of name collisions increases.

If changes to the model create more or fewer collisions, existing name-mangling text increases or decreases in length. If the length of the name-mangling text increases, additional characters are appended to the existing text. For example, the mangling text 'xyz' can change to 'xyzQ'. For fewer collisions, the name-mangling text 'xyz' changes to 'xy'.

## Avoid Identifier Name Collisions with Referenced Models

Within a model that uses referenced models, collisions between the names of the models are not allowed. When generating code from a model that uses model referencing:

- You must include the **\$R** token in the **Identifier format control** parameter specifications (in addition to the **\$M** token).
- The **Maximum identifier length** must be large enough to accommodate full expansions of the **\$R** and **\$M** tokens. If **Maximum identifier length** is too small, a code generation error occurs.

When a name conflict occurs between an identifier within the scope of a higher-level model and an identifier within the scope of a referenced model, the identifier from the referenced model is preserved. Name mangling is performed on the identifier from the higher-level model.

If your model contains two referenced models with the same input or output port names, and one of the referenced models contains an atomic subsystem with “Function packaging” set to **Nonreuseable function**, a name conflict can occur and the build process produces an error.

### Use Model Advisor to Detect Identifier Names Changed During Code Generation

For a referenced model, if the following **Configuration Parameters > Code Generation > Symbols** parameters have settings that do not contain a **\$R** token (which represents the name of the reference model), code generation prepends the **\$R** token to the identifier format.

- **Global variables**
- **Global types**
- **Subsystem methods**
- **Constant macros**

You can use the Model Advisor to identify referenced models in a model referencing hierarchy for which code generation changes these configuration parameter settings.

- 1 In the Simulink Editor, select **Analysis > Model Advisor**.
- 2 Select **By Task**.

- 3** Run the **Check code generation identifier formats used for model reference** check.

## Maintain Traceability for Generated Identifiers

To verify your model, you can trace back and forth between generated identifiers and corresponding entities within the model. To maintain traceability, it is important that incremental revisions to a model have minimal impact on the identifier names that appear in generated code. There are two ways to minimally impact the identifier names:

- Choose unique names for Simulink objects (blocks, signals, states, and so on) as much as possible.
- Use name mangling when conflicts cannot be avoided.

The position of the name-mangling text is specified by the placement of the **\$M** token in the **Identifier format control** parameters. Mangle characters consist of alphanumeric characters that are unique to each object. For more information, see “Control Name Mangling in Generated Identifiers” on page 36-27.

## Exceptions to Identifier Formatting Conventions

There are some exceptions to the identifier formatting conventions described in “Identifier Format Control” on page 36-22.

- Type name generation: name mangling conventions do not apply to type names (that is, `typedef` statements) generated for global data types. If the `$R` token is included in the **Identifier format control** parameter specification, the model name is included in the `typedef`. When generating type definitions, the **Maximum identifier length** parameter is not respected.
- Non-`Auto` storage classes: the **Identifier format control** parameters specification does not affect objects (such as signals and parameters) that have a storage class other than `Auto` (such as `ImportedExtern` or `ExportedGlobal`).
- For shared utilities, code generation inserts the checksum specified by `$C` to prevent name collisions in the following situations:
  - `$C` is specified without `$N`.
  - The length of `$N` plus the length of the text that you specify exceeds the **Maximum identifier length**. Code generation truncates `$N` and inserts an 8-character checksum where you specified `$C` in the formatting scheme.

## Identifier Format Control Parameters Limitations

The following limitations apply to the **Identifier format control** parameters:

- The following autogenerated identifiers currently do not fully comply with the setting of the **Maximum identifier length** parameter on the **Code Generation > Symbols** pane of the Configuration Parameters dialog box.
  - Model methods
    - The applicable format scheme is `$R$F`, and the longest `$F` is `_derivatives`, which is 12 characters long. The model name can be up to 19 characters without exceeding the default **Maximum identifier length** of 31.
  - Local functions generated by S-functions or by add-on products such as DSP System Toolbox that rely on S-functions
  - Local variables generated by S-functions or by add-on products such as DSP System Toolbox that rely on S-functions
  - DW identifiers generated by S-functions in referenced models
  - Fixed-point shared utility macros or shared utility functions
  - Simulink `rtm` macros
    - Most are within the default **Maximum identifier length** of 31, but some exceed the limit. Examples are `RTMSpecAccsGetStopRequestedValStoredAsPtr`, `RTMSpecAccsGetErrorStatusPointer`, and `RTMSpecAccsGetErrorStatusPointerPointer`.
  - Define protection guard macros
    - Header file guards, such as `_RTW_HEADER_(filename)_h_`, which can exceed the default **Maximum identifier length** of 31 given a filename such as `$R_private.h`.
    - Include file guards, such as `_$R_COMMON_INCLUDES_`.
    - `typedef` guards, such as `_CSCI_$R_CHARTSTRUCT_`.
- In some situations, the following identifiers potentially can conflict with others.
  - Model methods
  - Reentrant model function arguments

- Local functions generated by S-functions or by add-on products such as DSP System Toolbox that rely on S-functions
- Local variables generated by S-functions or by add-on products such as DSP System Toolbox that rely on S-functions
- Fixed-point shared utility macros or shared utility functions
- Include header guard macros
- The following external identifiers that are unknown to the Simulink software might conflict with autogenerated identifiers.
  - Identifiers defined in custom code
  - Identifiers defined in custom header files
  - Identifiers introduced through a non-ANSI C standard library
  - Identifiers defined by custom TLC code
- Identifiers generated for simulation targets might exceed the **Maximum identifier length**. Simulation targets include the model reference simulation target, the accelerated simulation target, the RSim target, and the S-function target.
- Identifiers generated using a model name and bus object data type name, which are both long names, might exceed the **Maximum identifier length**. For example, a ground value variable name is generated as `<model_name>_rtZ<bus_name>`. If the *model\_name* and *bus\_name* are close to the maximum identifier length, the name exceeds the maximum identifier length.

## Control Code Style

### In this section...

“Control Parentheses in Generated Code” on page 36-36

“Optimize Code by Reordering Commutable Operands” on page 36-38

“Suppress Generation of Default Cases for Unreachable Stateflow Switch Statements” on page 36-39

“Replace Multiplication by Powers of Two with Signed Bitwise Shifts” on page 36-42

“Generate Code with Right Shifts on Signed Integers” on page 36-44

“Control Indentation Style in Generated Code” on page 36-45

“Control Cast Expressions in Generated Code” on page 36-47

You can change the code style, cast expressions, and indentation of your generated code to conform to certain coding standards. Modify style options by setting parameters on the **Code Generation > Code Style** pane.

In the generated code, you can control the following style aspects:

- Level of parenthesization, see “Control Parentheses in Generated Code” on page 36-36.
- Order of operands in expressions, see “Optimize Code by Reordering Commutable Operands” on page 36-38.
- Empty primary condition expressions in `if` statements, see “Preserve condition expression in if statement”.
- Whether to generate code for `if-elseif-else` decision logic as `switch-case` statements, see “Convert if-elseif-else patterns to switch-case statements”.
- Whether to include the `extern` keyword in function declarations, see “Preserve extern keyword in function declarations”.
- Whether to generate `default` cases for `switch-case` statements in the code for Stateflow charts, see “Suppress Generation of Default Cases for Unreachable Stateflow Switch Statements” on page 36-39.
- Whether to replace multiplications by powers of two with signed bitwise shifts, see “Replace Multiplication by Powers of Two with Signed Bitwise Shifts” on page 36-42. Whether to allow right shifts on signed integers, see “Generate Code with Right Shifts on Signed Integers” on page 36-44. Some coding standards, such

as MISRA, do not allow bitwise operations on signed integers. Clearing this option increases the likelihood of generating MISRA C:2012 compliant code.

- Cast expressions, see “Control Cast Expressions in Generated Code” on page 36-47.
- Indentation style, see “Control Indentation Style in Generated Code” on page 36-45.

## Control Parentheses in Generated Code

C code contains some syntactically required parentheses, and can contain additional parentheses that change semantics by overriding default operator precedence. C code can also contain optional parentheses that have no functional significance, but only increase the readability of the code. Optional C parentheses vary between two stylistic extremes:

- Include the minimum parentheses required by C syntax and precedence overrides so that C precedence rules specify all semantics unless overridden by parentheses.
- Include the maximum parentheses that can exist without duplication so that C precedence rules become irrelevant. Parentheses alone completely specify all semantics.

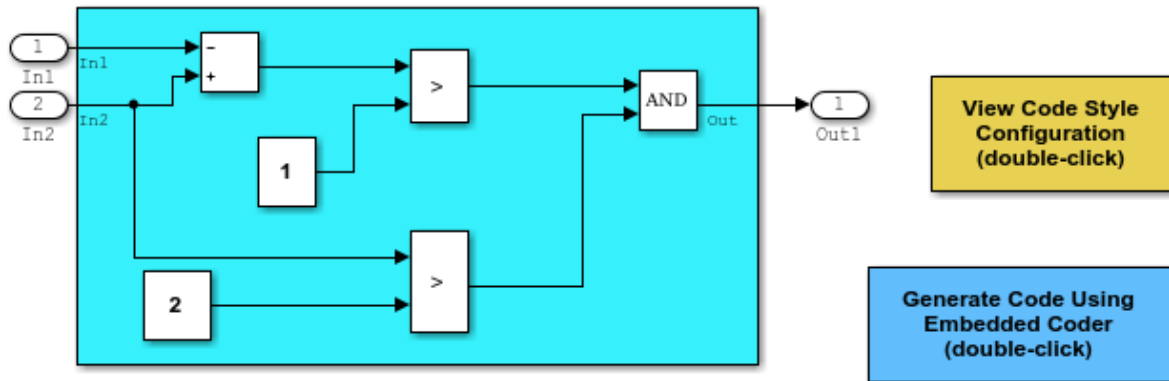

Understanding code with minimum parentheses can require applying nonobvious precedence rules. Maximum parentheses can hinder code reading by belaboring obvious precedence rules. Various parenthesization standards exist that specify one or the other extreme, or define an intermediate style useful to people who read code.

For more information on this parameter, see “Parentheses level”.

### Control Use of Parentheses

This example shows that Embedded Coder® provides three levels of control for parentheses in the generated code.

```
model='rtwdemo_parentheses';
open_system(model)
```

Parentheses level "Minimum": `Out = ln2 - ln1 > 1.0 && ln2 > 2.0;`

Parentheses level "Nominal": `Out = ((ln2 - ln1 > 1.0) && (ln2 > 2.0));`

Parentheses level "Maximum": `Out = (((ln2 - ln1) > 1.0) && (ln2 > 2.0));`

### Description

Embedded Coder(R) provides three levels of control for parentheses in the generated code. The control level "Minimum" generates the most compact code, with the smallest number of parentheses allowed under C syntax rules. The control level "Nominal" adds parentheses as needed to optimize readability. The control level "Maximum" generates the largest number of parentheses. The parentheses explicitly define the sequence of operations in an expression without relying on C precedence rules. Specifying control level "Maximum" provides full compliance with the MISRA-C(TM) standard.

### Instructions

1. View and set the parentheses level by double-clicking the yellow button to the right.
2. Generate code by double-clicking the blue button to the right.  
An HTML report is displayed automatically.
3. Inspect the generated source files, comparing them with the three code examples above.

```
rtwdemoclean;
```

```
close_system(model,0)
```

## Optimize Code by Reordering Commutable Operands

This example shows how to reorder commutable operands to make expressions left-recursive. This optimization improves code efficiency.

### Example Model

To reorder commutable operands, create the following model and name it `operand_order`. In this model, the output signal is the result of multiplying the signal from Inport block In1 by the sum of the signals from Inport blocks In2 and In3.

### Generate Code

- 1 Open the Model Configuration Parameters dialog box. On the **Code Style** tab, select the **Preserve operand order in expression** parameter.
- 2 Generate code for the model.

In the `operand_order.c` file, the `operand_order_step` function contains the following code:

```
operand_order_Y.Out1 = operand_order_U.In1 * (operand_order_U.In2 +
```

```
operand_order_U.In3);
```

The code generator preserves the specified expression order in the model. Preserving the specified expression order increases the readability of the code for code traceability purposes.

### Generate Code with Optimization

- 1 Open the Model Configuration Parameters dialog box. On the **Code Style** tab, clear the **Preserve operand order in expression** parameter.
- 2 Generate code for the model.

In the `operand_order.c` file, the `operand_order_step` function contains the following code:

```
operand_order_Y.Out1 = (operand_order_U.In2 + operand_order_U.In3) *
 operand_order_U.In1;
```

The code generator optimizes the code by reordering the commutable operands to make the expression left-recursive. Left-recursive expressions improve code efficiency.

For more information on the **Preserve operand order in expression** parameter, see “Preserve operand order in expression”.

## Suppress Generation of Default Cases for Unreachable Stateflow Switch Statements

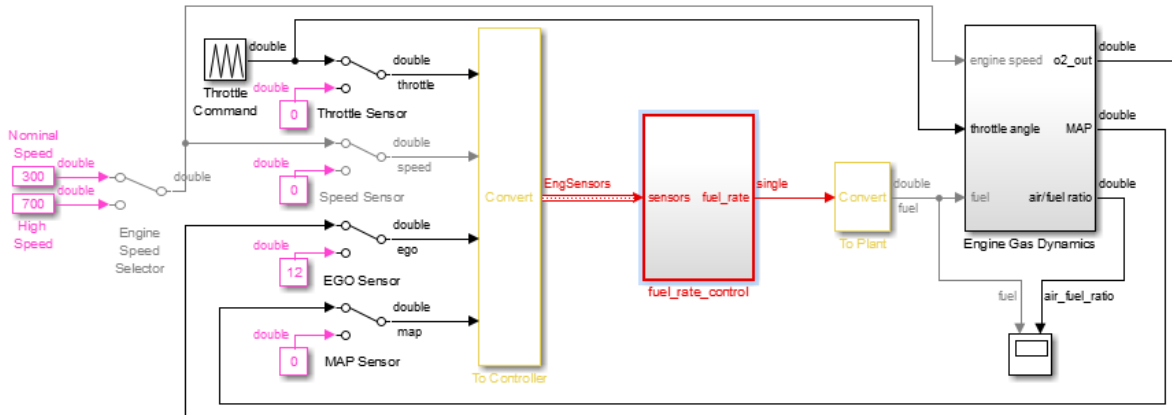

This example shows how to specify whether to generate default cases for switch-case statements in the code for Stateflow charts. Generated code that does not contain default cases conserves ROM consumption and enables better code coverage because every branch in the generated code is falsifiable.

Some coding standards, such as MISRA, require the default case for switch-case statements. If you want to increase your chances of producing MISRA C compliant code, generate default cases for unreachable Stateflow switch statements.

### Example

Figures 1, 2, and 3 show relevant portions of the `sldemo_fuelsys` model, a closed-loop system containing a plant and controller. The Air-fuel rate controller logic is a Stateflow chart that specifies the different operation modes.

### Fault-Tolerant Fuel Control System

The sensor switches simulate any combination of sensor failures. The Engine Speed Selector switch simulates different engine speeds (rad/sec).

Copyright 1990-2014 The MathWorks, Inc.

Figure 1: Top-level model of the plant and controller

### Fuel Rate Control Subsystem

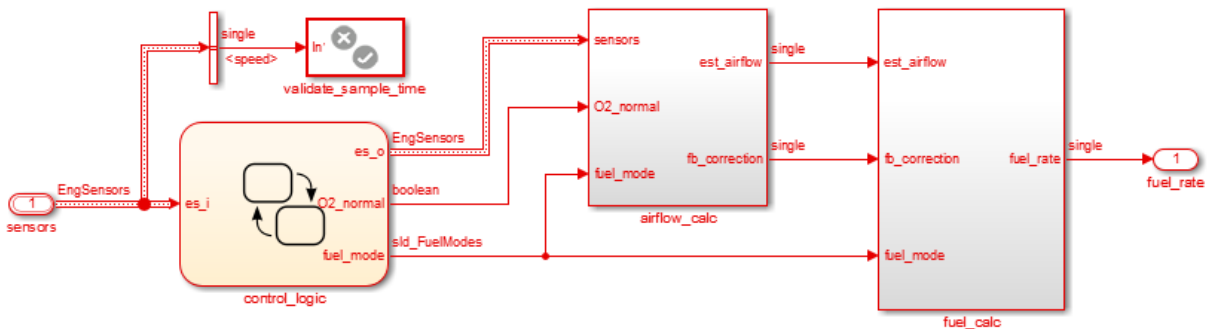

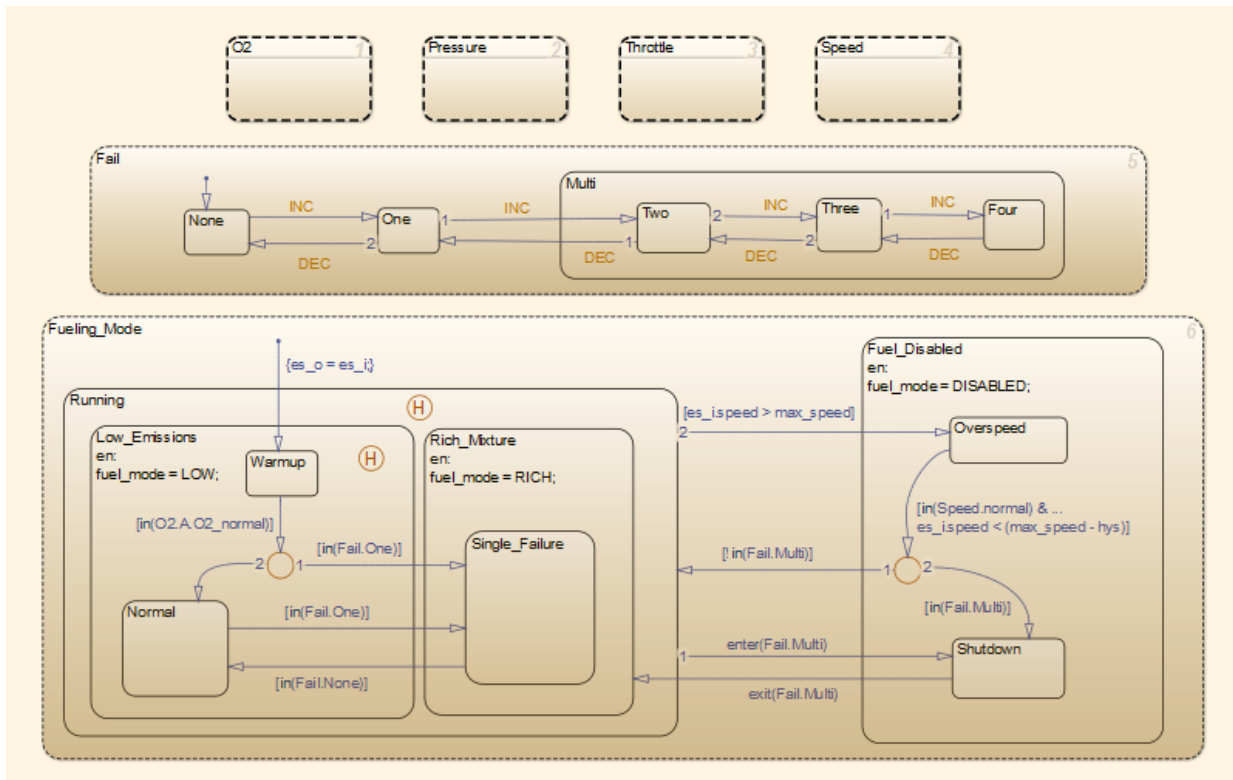

Figure 2: Fuel rate controller subsystem

**Figure 3: Fuel rate controller logic**

### Generate Code with Default Cases for Unreachable Stateflow Switch Statements

- 1 In the MATLAB Command Window, to open `sldemo_fuelsys` via `rtwdemo_fuelsys` enter:

```
rtwdemo_fuelsys
```

- 2 Open the Model Configuration parameters dialog box. On the **Code Generation > Code Style** tab, clear the **Suppress generation of default cases for Stateflow statements if unreachable** parameter.

- 3 In the MATLAB Command Window, to build the model, enter:

```
rtwbuild('sldemo_fuelsys/fuel_rate_control');
```

For the different operation modes, the `fuel_rate_control.c` file contains default cases for unreachable switch statements. For example, for the Shutdown operation mode, the generated code contains this default statement:

```
default:
 /* Unreachable state, for coverage only */
 rtDWork.bitsForTIDO.is_Fuel_Disabled = IN_NO_ACTIVE_CHILD;
 break;
```

For the Warmup operation mode, the generated code contains this default statement:

```
default:
 /* Unreachable state, for coverage only */
 rtDWork.bitsForTIDO.is_Low_Emissions = IN_NO_ACTIVE_CHILD;
 break;
```

### Suppress Default Cases for Unreachable Stateflow Switch Statements

- 1 Open the Model Configuration parameters dialog box. On the **Code Generation > Code Style** tab, select the **Suppress generation of default cases for Stateflow statements if unreachable** parameter.
- 2 Build the model.

Read through the `fuel_rate_control.c` file. The default cases for unreachable switch statements are not in the generated code.

For more information on the **Suppress generation of default cases for Stateflow statements if unreachable** parameter, see “Suppress generation of default cases for Stateflow switch statements if unreachable”.

### Replace Multiplication by Powers of Two with Signed Bitwise Shifts

This example shows how to generate code that replaces multiplication by powers of two with signed bitwise shifts. Code that contains bitwise shifts is more efficient than code that contains multiplication by powers of two.

Some coding standards, such as MISRA, do not allow bitwise operations on signed integers. If you want to increase your chances of producing MISRA C compliant code, do not replace multiplication by powers of two with bitwise shifts.

#### Example

To replace multiplication by powers of two with bitwise shifts, create the following model. In this model, a signal of **Data type** `int16` feeds into a Shift Arithmetic block. In the

Shift Arithmetic Block Parameters dialog box, the **Bits to shift > Direction** parameter is set to **Left**. The **Bits to shift > Number** parameter is set to 3. This parameter corresponds to a value of 8, or raising 2 to the power of 3.

### Generate Code with Signed Bitwise Shifts

- 1 Open the Model Configuration Parameters dialog box and select the **Code Style** tab. The **Replace multiplications by powers of two with signed bitwise shifts** parameter is on by default.
- 2 Generate code for the model.

In the `bitwise_multiplication.c` file, the `bitwise_multiplication` step function contains this code:

```
bitwise_multiplication_Y.Out1 = (int16_T)(bitwise_multiplication_U.In1 << 3);
```

The signed integer, `bitwise_multiplication_U.In1`, is shifted three bits to the left.

### Generate Code with Multiplication by Powers of Two

- 1 Open the Model Configuration Parameters dialog box and select the **Code Style** tab.
- 2 Clear the **Replace multiplications by powers of two with signed bitwise shifts** parameter.
- 3 Generate code for the model.

In the `bitwise_multiplication.c` file, the `bitwise_multiplication` step function contains this code:

```
bitwise_multiplication_Y.Out1 = (int16_T)(bitwise_multiplication_U.In1 * 8);
```

The signed integer `bitwise_multiplication_U.In1` is multiplied by 8.

For more information on the **Replace multiplications by powers of two with signed bitwise shifts** parameter, see “Replace multiplications by powers of two with signed bitwise shifts”.

## Generate Code with Right Shifts on Signed Integers

This example shows how to control whether the generated code contains right shifts on signed integers. Generated code that does not contain right shifts on signed integers first casts the signed integers to unsigned integers, and then right shifts the unsigned integers.

Some coding standards, such as MISRA, do not allow right shifts on signed integers because different hardware can store negative integers differently. For negative integers, you can get different answers depending on the hardware. If you want to increase your chances of producing MISRA C compliant code, do not allow right shifts on signed integers.

### Example Model

To generate code with right shifts on signed integers, create the following model. In this model, a signal of **Data type** `int16` feeds into a Shift Arithmetic block. In the Shift Arithmetic Block Parameters dialog box, the **Bits to shift > Direction** parameter is set to Right. The **Bits to shift > Number** parameter is set to 3.

### Generate Code with Right Shifts on Signed Integers

- 1 Open the Model Configuration Parameters dialog box and select the **Code Style** tab. The **Allow right shifts on signed integers** parameter is on by default.
- 2 Generate code for the model.

In the `rightshift.c` file, the `rightshift_step` function contains this code:

```
rightshift_Y.Out1 = (int16_T)(rightshift_U.In1 >> 3);
```

The signed integer `rightshift_U.In1` is shifted three bits to the right.

### Generate Code That Does Not Allow Right Shifts on Signed Integers

- 1 Open the Model Configuration Parameters dialog box and select the **Code Style** tab. Clear the **Allow right shifts on signed integers** parameter.
- 2 Generate code for the model.

In the `rightshift.c` file, the `rightshift_step` function contains this code:

```
rightshift_Y.Out1 = (int16_T)asr_s32(rightshift_U.In1, 3U);
```

When you clear the **Allow right shifts on signed integers** parameter, the generated code contains a function call instead of a right shift on a signed integer. The function `asr_s32` contains this code:

```
int32_T asr_s32(int32_T u, uint32_T n)
{
 int32_T y;
 if (u >= 0) {
 y = (int32_T)((uint32_T)u >> n);
 } else {
 y = -(int32_T)((uint32_T)-(u + 1) >> n) - 1;
 }

 return y;
}
```

The `asr_s32` function casts a signed integer to an unsigned integer, and then right shifts the unsigned integer.

For more information on the **Allow right shifts on signed integers** parameter, see “Allow right shifts on signed integers”.

## Control Indentation Style in Generated Code

For code indentation, you can set the following parameters:

- “Indent style” controls the placement of braces in generated code.

- “Indent size” controls the number of characters per indent level in generated code (2–8 characters).

You can set **Indent style** to K&R or Allman style.

### **K&R**

K&R stands for Kernighan and Ritchie. Each function has the opening and closing brace on its own line at the same level of indentation as the function header. Code within the function is indented according to the **Indent size**.

For blocks within a function, opening braces are on the same line as the control statement. Closing braces are on a new line at the same level of indentation as the control statement. Code within the block is indented according to the **Indent size**.

For example, here is generated code with the **Indent style** set to K&R with an **Indent size** of 2:

```
void rt_OneStep(void)
{
 static boolean_T OverrunFlag = 0;
 if (OverrunFlag) {
 rtmSetErrorStatus(rtwdemo_counter_M, "Overrun");
 return;
 }

 OverrunFlag = TRUE;
 rtwdemo_counter_step();
 OverrunFlag = FALSE;
}
```

### **Allman**

Each function has the opening and closing brace on its own line at the same level of indentation as the function header. Code within the function is indented according to the **Indent size**.

For blocks within a function, opening and closing braces for control statements are on a new line at the same level of indentation as the control statement. This is the key difference between K&R and Allman styles. Code within the block is indented according to the **Indent size**.

For example, here is generated code with the **Indent style** set to Allman with an **Indent size** of 4:

```
void rt_OneStep(void)
{
 static boolean_T OverrunFlag = 0;
 if (OverrunFlag)
 {
 rtmSetErrorStatus(rtwdemo_counter_M, "Overrun");
 return;
 }

 OverrunFlag = TRUE;
 rtwdemo_counter_step();
 OverrunFlag = FALSE;
}
```

## Control Cast Expressions in Generated Code

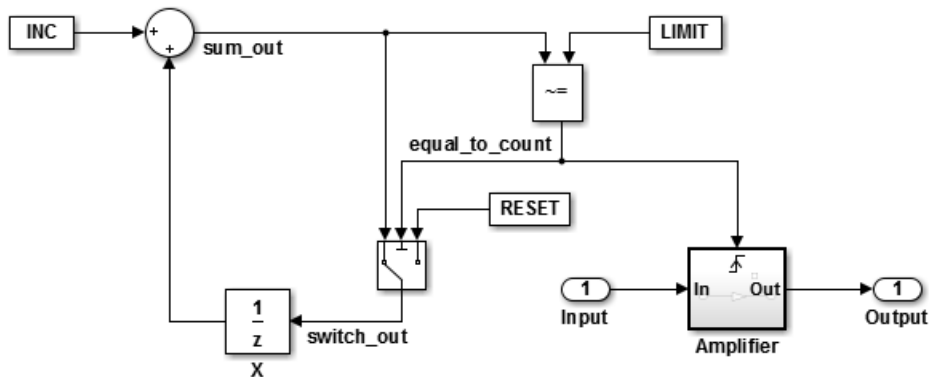

You can choose how the code generator specifies data type casts in the generated code. In the Configuration Parameters dialog box, select **Code Generation > Code Style**. From the **Casting modes** drop-down list, three parameter options control how the code generator casts data types.

- **Nominal** instructs the code generator to generate code that has minimal data type casting. When you do not have special data type information requirements, choose **Nominal**.
- **Standards Compliant** instructs the code generator to cast data types to conform to MISRA standards when it generates code. The MISRA data type casting eliminates common MISRA standard violations, including address arithmetic and assignment. It reduces 10.1, 10.2, 10.3, and 10.4 violations.

For more information, see “MISRA C Guidelines” on page 11-5.

- **Explicit** instructs the code generator to cast data type values explicitly when it generates code. You can see how a value is stored, which tells you how much memory space the code uses for the variable. The data type informs you how much precision is possible in calculations involving the variable.

Open the example model `rtwdemo_rtwecintro`.

### Enable Nominal Casting Mode and Generate Code

When you choose **Nominal** casting mode, the code generator does not create data type casts for variables in the generated code.

- 1 On the **Code Generation > Code Style** pane, from the **Casting modes** drop-down list, select **Nominal**.
- 2 On the **Code Generation > Report** pane, select **Create code generation report**.
- 3 On the **Code Generation** pane, select **Generate code only**.
- 4 Click **Apply**.
- 5 In the model window, press **Ctrl+B** to generate code.
- 6 In the Code Generation report left pane, click `rtwdemo_rtweccintro.c` to see the code.

```

/* Model step function */
void rtwdemo_rtweccintro_step(void)
{
 boolean_T rtb_equal_to_count;

 /* Sum: 'XRootX/Sum' incorporates:
 * Constant: 'XRootX/INC'
 * UnitDelay: 'XRootX/X'
 */
 rtDWork.X++;

 /* RelationalOperator: 'XRootX/RelOpt' incorporates:
 * Constant: 'XRootX/LIMIT'
 */

```

```

rtb_equal_to_count = (rtDWork.X != 16);

/* Outputs for Triggered SubSystem: 'XRootX/Amplifier' incorporates:
 * TriggerPort: 'XS1X/Trigger'
 */
if (rtb_equal_to_count && (rtPrevZCSigState.Amplifier_Trig_ZCE != POS_ZCSIG))
{
 /* Output: 'XRootX/Output' incorporates:
 * Gain: 'XS1X/Gain'
 * Inport: 'XRootX/Input'
 */
 rtY.Output = rtU.Input << 1;
}

rtPrevZCSigState.Amplifier_Trig_ZCE = (uint8_T)(rtb_equal_to_count ? (int32_T)
POS_ZCSIG : (int32_T)ZERO_ZCSIG);

/* End of Outputs for SubSystem: 'XRootX/Amplifier' */

/* Switch: 'XRootX/Switch' */
if (!rtb_equal_to_count) {
 /* Update for UnitDelay: 'XRootX/X' incorporates:
 * Constant: 'XRootX/RESET'
 */
 rtDWork.X = 0U;
}

/* End of Switch: 'XRootX/Switch' */
}

```

### Enable Standards Compliant Casting Mode and Generate Code

When you choose **Standards Compliant** casting mode, the code generator creates MISRA standards compliant data type casts for variables in the generated code.

- 1 On the **Code Style** pane, from the **Casting modes** drop-down list, select **Standards Compliant**.
- 2 On the **Code Generation** pane, click **Apply**.
- 3 In the model window, press **Ctrl+B** to generate code.
- 4 In the Code Generation report left pane, click `rtwdemo_rtweccintro.c` to see the code.

```
void rtwdemo_rtweccintro_step(void)
```

```

{
 boolean_T rtb_equal_to_count;

 /* Sum: '<Root>/Sum' incorporates:
 * Constant: '<Root>/INC'
 * UnitDelay: '<Root>/X'
 */
 rtDWork.X++;

 /* RelationalOperator: '<Root>/RelOpt' incorporates:
 * Constant: '<Root>/LIMIT'
 */
 rtb_equal_to_count = (boolean_T)(int32_T)((int32_T)rtDWork.X != (int32_T)16);

 /* Outputs for Triggered SubSystem: '<Root>/Amplifier' incorporates:
 * TriggerPort: '<S1>/Trigger'
 */
 if (((int32_T)rtb_equal_to_count) && (rtPrevZCSigState.Amplifier_Trig_ZCE !=
 POS_ZCSIG)) {
 /* Outport: '<Root>/Output' incorporates:
 * Gain: '<S1>/Gain'
 * Inport: '<Root>/Input'
 */
 rtY.Output = (int32_T)(uint32_T)((uint32_T)rtU.Input << (uint32_T)(int8_T)1);
 }

 rtPrevZCSigState.Amplifier_Trig_ZCE = (uint8_T)(int32_T)(rtb_equal_to_count ?
 (int32_T)(uint8_T)POS_ZCSIG : (int32_T)(uint8_T)ZERO_ZCSIG);

 /* End of Outputs for SubSystem: '<Root>/Amplifier' */

 /* Switch: '<Root>/Switch' */
 if (!rtb_equal_to_count) {
 /* Update for UnitDelay: '<Root>/X' incorporates:
 * Constant: '<Root>/RESET'
 */
 rtDWork.X = 0U;
 }

 /* End of Switch: '<Root>/Switch' */
}

```

## Enable Explicit Casting Mode and Generate Code

When you choose `Explicit` casting mode, the code generator creates explicit data type casts for variables in the generated code.

- 1 On the **Code Style** pane, from the **Casting modes** drop-down list, select `Explicit`.
- 2 On the **Code Generation** pane, click **Apply**.
- 3 In the model window, press **Ctrl+B** to generate code.
- 4 In the Code Generation report left pane, click `rtwdemo_rtweccintro.c` to see the code.

```

/* Model step function */
void rtwdemo_rtweccintro_step(void)
{
 boolean_T rtb_equal_to_count;

 /* Sum: '<Root>/Sum' incorporates:
 * Constant: '<Root>/INC'
 * UnitDelay: '<Root>/X'
 */
 rtDWork.X = (uint8_T)(1U + (uint32_T)(int32_T)rtDWork.X);

 /* RelationalOperator: '<Root>/RelOpt' incorporates:
 * Constant: '<Root>/LIMIT'
 */
 rtb_equal_to_count = (boolean_T)((int32_T)rtDWork.X != 16);

 /* Outputs for Triggered SubSystem: '<Root>/Amplifier' incorporates:
 * TriggerPort: '<S1>/Trigger'
 */
 if (((int32_T)rtb_equal_to_count) && ((int32_T)((int32_T)
 rtPrevZCSigState.Amplifier_Trig_ZCE != (int32_T)POS_ZCSIG))) {
 /* Output: '<Root>/Output' incorporates:
 * Gain: '<S1>/Gain'
 * Inport: '<Root>/Input'
 */
 rtY.Output = rtU.Input << 1;
 }

 rtPrevZCSigState.Amplifier_Trig_ZCE = (uint8_T)(rtb_equal_to_count ? (int32_T)
 POS_ZCSIG : (int32_T)ZERO_ZCSIG);

 /* End of Outputs for SubSystem: '<Root>/Amplifier' */

```

```
/* Switch: '<Root>/Switch' */
if (!(int32_T)rtb_equal_to_count) {
 /* Update for UnitDelay: '<Root>/X' incorporates:
 * Constant: '<Root>/RESET'
 */
 rtDWork.X = 0U;
}

/* End of Switch: '<Root>/Switch' */
}
```

## More About

- “Model Configuration Parameters: Code Generation Code Style”

## Customize Code Organization and Format

### In this section...

“Custom File Processing Components” on page 36-53

“Custom File Processing Configuration” on page 36-54

Custom file processing (CFP) tools allow you to customize the organization and formatting of your generated code. With these tools, you can:

- Generate a source (.c or .cpp) or header (.h) file. Using a *custom file processing template* (CFP template), you can control how code emits to the standard generated model files (for example, *model.c* or *.cpp*, *model.h*) or generate files that are independent of model code.
- Organize generated code into sections (such as includes, **typedefs**, functions, and more). Your CFP template can emit code (for example, functions), directives (such as **#define** or **#include** statements), or comments into each section.
- Generate custom *file banners* (comment sections) at the start and end of generated code files and custom *function banners* that precede functions in the generated code.
- Generate code to call model functions, such as *model\_initialize*, *model\_step*, and so on.
- Generate code to read and write model inputs and outputs.
- Generate a main program module.
- Obtain information about the model and the generated files from the model.

### Custom File Processing Components

The custom file processing features are based on the following interrelated components:

- *Code generation template* (CGT) files: a CGT file defines the top-level organization and formatting of generated code. See “Code Generation Template (CGT) Files” on page 36-56.
- The *code template API*: a high-level Target Language Compiler (TLC) API that provides functions with which you can organize code into named sections and subsections of generated source and header files. The code template API also provides utilities that return information about generated files, generate standard model calls, and perform other functions. See “Code Template API Summary” on page 36-78.

- *Custom file processing (CFP) templates*: a CFP template is a TLC file that manages the process of custom code generation. A CFP template assembles code to be generated into buffers. A CFP template also calls the code template API to emit the buffered code into specified sections of generated source and header files. A CFP template interacts with a CGT file, which defines the ordering of major sections of the generated code. See “Custom File Processing (CFP) Templates” on page 36-62.

To use CFP templates, you must understand TLC programming, for more information, see “Target Language Compiler”.

## Custom File Processing Configuration

Customize generated code by specifying code and data templates on the **Code Generation > Templates** pane:

| Goal                                                                                                                  | Action                                                                                                                                                                                                                                                                                                                                                                  |
|-----------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Specify a template that defines the top-level organization and formatting of generated source code (.c or .cpp) files | Enter a code generation template (CGT) file for the <b>Source file (*.c) template</b> parameter.                                                                                                                                                                                                                                                                        |
| Specify a template that defines the top-level organization and formatting of generated header (.h) files              | Enter a CGT file for the <b>Header file (*.h) template</b> parameter. This template file can be the same template file that you specify for <b>Source file (.c) template</b> . If you use the same template file, source and header files contain identical banners. The default template is <code>matlabroot/toolbox/rtw/targets/ecoder/ert_code_template.cgt</code> . |
| Specify a template that organizes generated code into sections (such as includes, typedefs, functions, and more)      | Enter a custom file processing (CFP) template file for the “File customization template” parameter. A CFP template can emit code, directives, or comments into each section. For more information, see “Custom File Processing (CFP) Templates” on page 36-62.                                                                                                          |
| Generate a model-specific example main program module                                                                 | Select <b>Generate an example main program</b> . For more information, see “Generate a Standalone Program” on page 49-2.                                                                                                                                                                                                                                                |

---

**Note:** Place the template files that you specify on the MATLAB path.

---

## Specify Templates For Code Generation

To use custom file processing features, create CGT files and CFP templates. These files are based on default templates provided by the code generation software. Once you have created your templates, you must integrate them into the code generation process.

Select and edit CGT files and CFP templates, and specify their use in the code generation process in the **Code Generation > Templates** pane of a model configuration set. The following figure shows options configured for their defaults.

The options related to custom file processing are:

- The **Source file (.c) template** field in the **Code templates** and **Data templates** sections. This field specifies the name of a CGT file to use when generating source (.c or .cpp) files. You must place this file on the MATLAB path.
- The **Header file (.h) template** field in the **Code templates** and **Data templates** sections. This field specifies the name of a CGT file to use when generating header (.h) files. You must place this file on the MATLAB path.

By default, the template for both source and header files is matlabroot/toolbox/rtw/targets/ecoder/ert\_code\_template.cgt.

- The **File customization template** edit field in the **Custom templates** section. This field specifies the name of a CFP template file to use when generating code files. You must place this file on the MATLAB path. The default CFP template is matlabroot/toolbox/rtw/targets/ecoder/example\_file\_process.tlc.

In each of these fields, click **Browse** to navigate to and select an existing CFP template or CGT file. Click **Edit** to open the specified file into the MATLAB editor where you can customize it.

## Code Generation Template (CGT) Files

Code Generation Template (CGT) files define the top-level organization and formatting of generated source code and header files. CGT files have the following applications:

- Generation of custom banners (comments sections) in code files. See “Generate Custom File and Function Banners” on page 36-81.
- Generation of custom code using a CFP template requires a CGT file. To use CFP templates, you must understand the CGT file structure. In many cases, however, you can use the default CGT file without modifying it.

### Default CGT file

The code generation software provides a default CGT file, `matlabroot/toolbox/rtw/targets/ecoder/ert_code_template.cgt`. Base your custom CGT files on the default file.

### CGT File Structure

A CGT file consists of one required section and four optional sections:

#### Code Insertion Section

(Required) This section contains tokens that define an ordered partitioning of the generated code into a number of sections (such as `Includes` and `Defines` sections). Tokens have the form of:

```
%<SectionName>
```

For example,

```
%<Includes>
```

The code generation software defines a minimal set of required tokens. These tokens generate C or C++ source or header code. They are *built-in* tokens (see “Built-In Tokens and Sections” on page 36-57). You can also define custom tokens and custom sections.

Each token functions as a placeholder for a corresponding section of generated code. The ordering of the tokens defines the order in which the corresponding sections appear in the generated code. If you do not include a token, then the corresponding section is not

generated. To generate code into a given section, explicitly call the code template API from a CFP template, as described in “Custom File Processing (CFP) Templates” on page 36-62.

The CGT tokens define the high-level organization of generated code. Using the code template API, you can partition each code section into named subsections, as described in “Subsections” on page 36-59.

In the code insertion section, you can also insert C or C++ comments between tokens. Such comments emit directly into the generated code.

### **File Banner Section**

(Optional) This section contains comments and tokens you use in generating a custom file banner.

### **Function Banner Section**

(Optional) This section contains comments and tokens for use in generating a custom function banner.

### **Shared Utility Function Banner Section**

(Optional) This section contains comments and tokens for use in generating a custom shared utility function banner.

### **File Trailer Section**

(Optional) This section contains comments for use in generating a custom trailer banner.

For more information on these sections, see “Generate Custom File and Function Banners” on page 36-81.

## **Built-In Tokens and Sections**

The following code extract shows the required code insertion section of the default CGT file with the required built-in tokens.

```

%%
%% Code insertion section (required)
%% These are required tokens. You can insert comments and other tokens in
%% between them, but do not change their order or remove them.
%%

```

```
%<Includes>
%<Defines>
%<Types>
%<Enums>
%<Definitions>
%<Declarations>
%<Functions>
```

Note the following requirements for customizing a CGT file:

- Do not remove required built-in tokens.
- Built-in tokens must appear in the order shown because each successive section has dependencies on previous sections.
- Only one token per line.
- Do not repeat tokens.
- You can add custom tokens and comments to the code insertion section as long as you do not violate the previous requirements.

---

**Note:** If you modify a CGT file and then rebuild your model, the code generation process does not force a top model build. To regenerate the code, see “Force Regeneration of Top Model Code”.

---

The following table summarizes the built-in tokens and corresponding section names, and describes the code sections.

### Built-In CGT Tokens and Corresponding Code Sections

| Token and Section Name | Description                                                                                 |
|------------------------|---------------------------------------------------------------------------------------------|
| Includes               | <code>#include</code> directives section                                                    |
| Defines                | <code>#define</code> directives section                                                     |
| Types                  | <code>typedef</code> section. <code>Typedefs</code> can depend on a previously defined type |
| Enums                  | Enumerated types section                                                                    |
| Definitions            | Data definitions (for example, <code>double x = 3.0;</code> )                               |
| Declarations           | Data declarations (for example, <code>extern double x;</code> )                             |
| Functions              | C or C++ functions                                                                          |

## Subsections

You can define one or more named subsections for any section. Some of the built-in sections have predefined subsections summarized in table Subsections Defined for Built-In Sections.

---

**Note:** Sections and subsections emit to the source or header file in the order listed in the CGT file.

---

Using the custom section feature, you can define additional sections. See “Generate a Custom Section” on page 36-71.

### Subsections Defined for Built-In Sections

| Section      | Subsections       | Subsection Description                                                                                                                                  |
|--------------|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------|
| Includes     | N/A               |                                                                                                                                                         |
| Defines      | N/A               |                                                                                                                                                         |
| Types        | IntrinsicTypes    | Intrinsic typedef section. Intrinsic types depend only on intrinsic C or C++ types.                                                                     |
| Types        | PrimitiveTypedefs | Primitive typedef section. Primitive typedefs depend only on intrinsic C or C++ types and on typedefs previously defined in the IntrinsicTypes section. |
| Types        | UserTop           | You can place any type of code in this section, including code that has dependencies on the previous sections.                                          |
| Types        | Typedefs          | typedef section. Typedefs can depend on previously defined types                                                                                        |
| Enums        | N/A               |                                                                                                                                                         |
| Definitions  | N/A               |                                                                                                                                                         |

## Format Generated Code Files Using Templates

This example shows how to use code generation templates to add custom code banners, rearrange data and functions, and insert additional code segments and documentation into generated code files.

```
model='rtwdemo_codetemplate';
open_system(model)
```

<S:Note>This Simulink annotation maps to the code template %<Note> symbol.

### Description

This model extracts text from the Model Description, a DOC block, and a Simulink annotation. The Simulink annotation maps to the code template %<Note> symbol. Many symbols are available that extract information from a model automatically. Refer to Module Packaging Features in the Embedded Coder documentation to see a complete list.

Many organizations employ coding standards that include consistent file layout and elaboration. Embedded Coder provides extensible code generation templates for formatting generated code. The layout and format of the code template file controls the output of the generated code.

Code generation templates (.cgt files) allow you to add custom code banners, rearrange data and functions, and insert additional code segments and documentation into generated code files. Code generation templates are picked up automatically from the MATLAB path and employed during the code generation process. For this model, the code generation template "rtwdemocodetemplate.cgt" is used.

### Instructions

1. Double-click the yellow View Templates Configuration button to view the templates configuration.
2. Click the Edit button to the right of the "rtwdemocodetemplate.cgt" template, and inspect the code template.
3. Double-click the blue button in the upper right to generate code. An HTML report appears automatically.
4. Open rtwdemo\_codetemplate.c to inspect the generated code for this model.

Copyright 1994-2012 The MathWorks, Inc.

```
rtwdemoclean;
close_system(model,0)
```

## Custom File Processing (CFP) Templates

The files provided to support custom file processing are:

- `matlabroot/rtw/c/tlc/mw/codetemplatelib.tlc`: A TLC function library that implements the code template API. `codetemplatelib.tlc` also provides the comprehensive documentation of the API in the comments headers preceding each function.
- `matlabroot/toolbox/rtw/targets/ecoder/example_file_process.tlc`: An example custom file processing (CFP) template, which you should use as the starting point for creating your own CFP templates. Guidelines and examples for creating a CFP template are provided in “Generate Source and Header Files with a Custom File Processing (CFP) Template” on page 36-66.
- TLC files supporting generation of single-rate and multirate main program modules (see “Customizing Main Program Module Generation” on page 36-70).

Once you have created a CFP template, you must integrate it into the code generation process, using the **File customization template** edit field. See “Specify Templates For Code Generation” on page 36-55.

### Custom File Processing (CFP) Template Structure

A custom file processing (CFP) template imposes a simple structure on the code generation process. The template, a code generation template (CGT) file, partitions the code generated for each file into a number of sections. These sections are summarized in Built-In CGT Tokens and Corresponding Code Sections and Subsections Defined for Built-In Sections.

Code for each section is assembled in buffers and then emitted, in the order listed, to the file being generated.

To generate a file section, your CFP template must first assemble the code to be generated into a buffer. Then, to emit the section, your template calls the TLC function

```
LibSetSourceFileSection(fileH, section, tmpBuf)
```

where

- `fileH` is a file reference to a file being generated.
- `section` is the code section or subsection to which code is to be emitted. `section` must be one of the section or subsection names listed in Subsections Defined for Built-In Sections.

Determine the `section` argument as follows:

- If Subsections Defined for Built-In Sections does not define subsections for a given section, use the section name as the `section` argument.
- If Subsections Defined for Built-In Sections defines one or more subsections for a given section, you can use either the section name or a subsection name as the `section` argument.
- If you have defined a custom token denoting a custom section, do not call `LibSetSourceFileSection`. Special API calls are provided for custom sections (see “Generate a Custom Section” on page 36-71).
- `tmpBuf` is the buffer containing the code to be emitted.

There is no requirement to generate all of the available sections. Your template need only generate the sections you require in a particular file.

Note that legality or syntax checking is not performed on the custom code within each section.

See “Generate Source and Header Files with a Custom File Processing (CFP) Template” on page 36-66, for typical usage examples.

## Change the Organization of a Generated File

The files created during code generation are organized according to the general code generation template. This template has the filename `ert_code_template.cgt`, and is specified by default in **Code Generation > Templates** pane of the Configuration Parameters dialog box.

The following fragment shows the `rtwdemo_mpf.c` file header that is generated using this default template:

```
/*
 * File: rtwdemo_mpf.c
 *
 * Code generated for Simulink model 'rtwdemo_mpf'.
 *
 * Model version : 1.88
 * Simulink Coder version : 8.0 (R2011a) 26-Aug-2010
 * TLC version : 7.6 (Sep 3 2010)
 * C/C++ source code generated on : Thu Sep 09 10:10:14 2010
 *
 * Target selection: ert.tlc
 * Embedded hardware selection: Generic->32-bit Embedded Processor
 * Code generation objectives: Unspecified
 * Validation result: Not run
 */
```

You can change the organization of generated files using code templates and data templates. Code templates organize the files that contain functions, primarily. Data templates organize the files that contain identifiers. In this procedure, you organize the generated files, using the supplied code and data templates:

- 1 Display the active **Templates** configuration parameters.
- 2 In the **Code templates** section of the **Templates** pane, type `code_c_template.cgt` into the **Source file (\*.c) templates** text box.
- 3 Type `code_h_template.cgt` into the **Header file (\*.h) templates** text box.
- 4 In the **Data templates** section, type `data_c_template.cgt` into the **Source file (\*.c) templates** text box.
- 5 Type `data_h_template.cgt` into the **Header file (\*.h) templates** text box, and click **Apply**.
- 6 In the model window, press **Ctrl+B**. Now the files are organized using the templates you specified. For example, the `rtwdemo_mpf.c` file header now is organized like this:

```
/**
```

```

** FILE INFORMATION:

## Generate Source and Header Files with a Custom File Processing (CFP) Template

### In this section...

“Generate Code with a CFP Template” on page 36-66

“Analysis of the Example CFP Template and Generated Code” on page 36-68

“Generate a Custom Section” on page 36-71

“Custom Tokens” on page 36-73

This example shows you the process of generating a simple source (.c or .cpp) and header (.h) file using the example CFP template. Then, it examines the template and the code generated by the template.

The example CFP template, `matlabroot/toolbox/rtw/targets/ecoder/example_file_process.tlc`, demonstrates some of the capabilities of the code template API, including

- Generation of simple source (.c or .cpp) and header (.h) files
- Use of buffers to generate file sections for includes, functions, and so on
- Generation of includes, defines, into the standard generated files (for example, `model.h`)
- Generation of a main program module

### Generate Code with a CFP Template

This section sets up a CFP template and configures a model to use the template in code generation. The template generates (in addition to the standard model files) a source file (`timestwo.c` or `.cpp`) and a header file (`timestwo.h`).

Follow the steps below to become acquainted with the use of CFP templates:

- 1 Copy the example CFP template, `matlabroot/toolbox/rtw/targets/ecoder/example_file_process.tlc`, to a folder outside of the MATLAB folder structure (that is, not under `matlabroot`). If the folder is not on the MATLAB path or the TLC path, then add it to the MATLAB path. It is good practice to locate the CFP template in the same folder as your system target file, which is on the TLC path.

- 2 Rename the copied `example_file_process.tlc` to `test_example_file_process.tlc`.
- 3 Open `test_example_file_process.tlc` into the MATLAB editor.
- 4 Uncomment the following line:

```
%% %assign ERTCustomFileTest = TLC_TRUE
```

It now reads:

```
%assign ERTCustomFileTest = TLC_TRUE
```

If `ERTCustomFileTest` is not assigned as shown, the CFP template is ignored in code generation.

- 5 Save your changes to the file. Keep `test_example_file_process.tlc` open, so you can refer to it later.
- 6 Open the `rtwdemo_udt` model.
- 7 Open the Simulink Model Explorer. Select the active configuration set of the model, and open the **Code Generation** pane of the active configuration set.
- 8 On the **Templates** tab, in the **File customization template** field, specify `test_example_file_process.tlc`. This is the file you previously edited and is now the specified CFP template for your model.
- 9 On the **General** tab, select the **Generate code only** check box.
- 10 Click **Apply**.
- 11 In the model window, press **Ctrl+B**. During code generation, notice the following message in the **Diagnostic Viewer**:

```
Warning: Overriding example ert_main.c!
```

This message is displayed because `test_example_file_process.tlc` generates the main program module, overriding the default action of the ERT target. This is explained in greater detail below.

- 12 The `rtwdemo_udt` model is configured to generate an HTML code generation report. After code generation is complete, view the report.

Notice that the **Generated Code** list contains the following files:

- Under **Main file**, `ert_main.c`.
- Under **Other files**, `timestwo.c` and `timestwo.h`.

The files were generated by the CFP template. The next section examines the template to learn how this was done.

- 13 Keep the model, the code generation report, and the `test_example_file_process.tlc` file open so you can refer to them in the next section.

## Analysis of the Example CFP Template and Generated Code

This section examines excerpts from `test_example_file_process.tlc` and some of the code it generates. Refer to the comments in `matlabroot/rtw/c/tlc/mw/codetemplatelib.tlc` while reading the following discussion.

### Generating Code Files

Source (`.c` or `.cpp`) and header (`.h`) files are created by calling `LibCreateSourceFile`, as in the following excerpts:

```
%assign cFile = LibCreateSourceFile("Source", "Custom", "timestwo")
...
%assign hFile = LibCreateSourceFile("Header", "Custom", "timestwo")
```

Subsequent code refers to the files by the file reference returned from `LibCreateSourceFile`.

### File Sections and Buffers

The code template API lets you partition the code generated to each file into sections, tagged as `Definitions`, `Includes`, `Functions`, `Banner`, and so on. You can append code to each section as many times as required. This technique gives you a great deal of flexibility in the formatting of your custom code files.

Subsections Defined for Built-In Sections describes the available file sections and their order in the generated file.

For each section of a generated file, use `%openfile` and `%closefile` to store the text for that section in temporary buffers. Then, to write (append) the buffer contents to a file section, call `LibSetSourceFileSection`, passing in the desired section tag and file reference. For example, the following code uses two buffers (`typesBuf` and `tmpBuf`) to generate two sections (tagged `"Includes"` and `"Functions"`) of the source file `timestwo.c` or `.cpp` (referenced as `cFile`):

```

%openfile typesBuf
#include "rtwtypes.h"
%closefile typesBuf
%<LibSetSourceFileSection(cFile,"Includes",typesBuf)>

%openfile tmpBuf

/* Times two function */
real_T timestwofcn(real_T input) {
 return (input * 2.0);
}

%closefile tmpBuf

%<LibSetSourceFileSection(cFile,"Functions",tmpBuf)>

```

These two sections generate the entire `timestwo.c` or `.cpp` file:

```

#include "rtwtypes.h"

/* Times two function */
FLOAT64 timestwofcn(FLOAT64 input)
{
 return (input * 2.0);
}

```

### Adding Code to Standard Generated Files

The `timestwo.c` or `.cpp` file generated in the previous example was independent of the standard code files generated from a model (for example, `model.c` or `.cpp`, `model.h`, and so on). You can use similar techniques to generate custom code within the model files. The code template API includes functions to obtain the names of the standard models files and other model-related information. The following excerpt calls `LibGetMdlPubHdrBaseName` to obtain the name for the `model.h` file. It then obtains a file reference and generates a definition in the `Defines` section of `model.h`:

```

%% Add a #define to the model's public header file model.h

%assign pubName = LibGetMdlPubHdrBaseName()
%assign modelH = LibCreateSourceFile("Header", "Simulink", pubName)

%openfile tmpBuf

```

```
#define ACCELERATION 9.81

%closefile tmpBuf

%<LibSetSourceFileSection(modelH, "Defines", tmpBuf)>
```

Examine the generated `rtwdemo_udd.h` file to see the generated `#define` directive.

### Customizing Main Program Module Generation

Normally, the ERT target determines whether and how to generate an `ert_main.c` or `.cpp` module based on the settings of the **Generate an example main program** and **Target operating system** options on the **Templates** pane of the Configuration Parameters dialog box. You can use a CFP template to override the normal behavior and generate a main program module customized for your target environment.

To support generation of main program modules, two TLC files are provided:

- `bareboard_srmain.tlc`: TLC code to generate an example single-rate main program module for a bareboard target environment. Code is generated by a single TLC function, `FcnSingleTaskingMain`.
- `bareboard_mrmain.tlc`: TLC code to generate a multirate main program module for a bareboard target environment. Code is generated by a single TLC function, `FcnMultiTaskingMain`.

In the example CFP template file `matlabroot/toolbox/rtw/targets/ecoder/example_file_process.tlc`, the following code generates either a single- or multitasking `ert_main.c` or `.cpp` module. The logic depends on information obtained from the code template API calls `LibIsSingleRateModel` and `LibIsSingleTasking`:

```
%% Create a simple main. Files are located in MATLAB/rtw/c/tlc/mw.

%if LibIsSingleRateModel() || LibIsSingleTasking()
 %include "bareboard_srmain.tlc"
 %<FcnSingleTaskingMain(>
%else
 %include "bareboard_mrmain.tlc"
 %<FcnMultiTaskingMain(>
%endif
```

Note that `bareboard_srmain.tlc` and `bareboard_mrmain.tlc` use the code template API to generate `ert_main.c` or `.cpp`.

When generating your own main program module, you disable the default generation of `ert_main.c` or `.cpp`. The TLC variable `GenerateSampleERTMain` controls generation

of `ert_main.c` or `.cpp`. You can directly force this variable to `TLC_FALSE`. The examples `bareboard_mrmain.tlc` and `bareboard_srmain.tlc` use this technique, as shown in the following excerpt from `bareboard_srmain.tlc`.

```
%if GenerateSampleERTMain
 %assign CompiledModel.GenerateSampleERTMain = TLC_FALSE
 %warning Overriding example ert_main.c!
%endif
```

Alternatively, you can implement a `SelectCallback` function for your target. A `SelectCallback` function is a MATLAB function that is triggered during model loading, and also when the user selects a target with the System Target File browser. Your `SelectCallback` function should deselect and disable the **Generate an example main program** option. This prevents the TLC variable `GenerateSampleERTMain` from being set to `TLC_TRUE`.

See the “rtwgensettings Structure” section for information on creating a `SelectCallback` function.

The following code illustrates how to deselect and disable the **Generate an example main program** option in the context of a `SelectCallback` function.

```
slConfigUISetVal(hDlg, hSrc, 'GenerateSampleERTMain', 'off');
slConfigUISetEnabled(hDlg, hSrc, 'GenerateSampleERTMain', 0);
```

---

**Note** Creation of a main program for your target environment requires some customization; for example, in a bareboard environment you need to attach `rt_OneStep` to a timer interrupt. It is expected that you will customize either the generated code, the generating TLC code, or both. See “Guidelines for Modifying the Main Program” on page 49-4 and “Guidelines for Modifying `rt_OneStep`” on page 49-9 for further information.

---

## Generate a Custom Section

You can define custom tokens in a CGT file and direct generated code into an associated built-in section. This feature gives you additional control over the formatting of code within each built-in section. For example, you could add subsections to built-in sections that do not already define subsections. Custom sections must be associated with one of the built-in sections: `Includes`, `Defines`, `Types`, `Enums`, `Definitions`, `Declarations`, or `Functions`. To create custom sections, you must

- Add a custom token to the code insertion section of your CGT file.
- In your CFP file:
  - Assemble code to be generated to the custom section into a buffer.
  - Declare an association between the custom section and a built-in section, with the code template API function `LibAddSourceFileCustomSection`.
  - Emit code to the custom section with the code template API function `LibSetSourceFileCustomSection`.

The following code examples illustrate the addition of a custom token, `Myincludes`, to a CGT file, and the subsequent association of the custom section `Myincludes` with the built-in section `Includes` in a CFP file.

---

**Note:** If you have not already created custom CGT and CFP files for your model, copy the default template files `matlabroot/toolbox/rtw/targets/ecoder/ert_code_template.cgt` and `matlabroot/toolbox/rtw/targets/ecoder/example_file_process.tlc` to a work folder that is outside the MATLAB folder structure but on the MATLAB or TLC path, rename them (for example, add the prefix `test_` to each file), and update the **Templates** pane of the Configuration Parameters dialog box to reference them.

---

First, add the token `Myincludes` to the code insertion section of your CGT file. For example:

```
%<Includes>
%<Myincludes>
%<Defines>
%<Types>
%<Enums>
%<Definitions>
%<Declarations>
%<Functions>
```

Next, in the CFP file, add code to generate `include` directives into a buffer. For example, in your copy of the example CFP file, you could insert the following section between the `Includes` section and the `Create a simple main` section:

```
%% Add a custom section to the model's C file model.c

%openfile tmpBuf
#include "moretables1.h"
```

```
#include "moretables2.h"
%closefile tmpBuf

%<LibAddSourceFileCustomSection(modelC, "Includes", "Myincludes")>
%<LibSetSourceFileCustomSection(modelC, "Myincludes", tmpBuf)>
```

The `LibAddSourceFileCustomSection` function call declares an association between the built-in section `Includes` and the custom section `Myincludes`. `Myincludes` is a subsection of `Includes`. The `LibSetSourceFileCustomSection` function call directs the code in the `tmpBuf` buffer to the `Myincludes` section of the generated file. `LibSetSourceFileCustomSection` is syntactically identical to `LibSetSourceFileSection`.

In the generated code, the include directives generated to the custom section appear after other code directed to `Includes`.

```
#include "rtwdemo_udt.h"
#include "rtwdemo_udt_private.h"

/* #include "mytables.h" */
#include "moretables1.h"
#include "moretables2.h"
```

---

**Note:** The placement of the custom token in this example CGT file is arbitrary. By locating `%<Myincludes>` after `%<Includes>`, the CGT file specifies only that the `Myincludes` code appears after `Includes` code.

---

## Custom Tokens

Custom tokens are automatically translated to TLC syntax as a part of the build process. To escape a token, that is to prepare it for normal TLC expansion, use the `!` character. For example, the token `%<!TokenName>` is expanded to `%<TokenName>` by the template conversion program. You can specify valid TLC code, including TLC function calls: `%<!MyTLCFcn()>`.

## Comparison of a Template and Its Generated File

This figure shows part of a user-modified custom file processing (CFP) template and the resulting generated code. The figure illustrates how you can use a template to:

- Define what code the code generation software should add to the generated file
- Control the location of code in the file
- Optionally insert comments in the generated file

Notice %<Includes>, for example, on the template. The term **Includes** is a symbol name. A percent sign and brackets (%< >) must enclose every symbol name. You can add the desired symbol name (within the %< > delimiter) at a particular location in the template. This is how you control where the code generator places an item in the generated file.

## Template and Generated File

### Mapping Template Specification to Code Generation

| This part of the template... |                                                       | Generates in the file... |                                                                                     | Explanation                                                                                                                                                                                                                                                                                                     |
|------------------------------|-------------------------------------------------------|--------------------------|-------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                              |                                                       | Line                     | Description                                                                         |                                                                                                                                                                                                                                                                                                                 |
| (1)                          | <code>/*#INCLUDES*/<br/>%&lt;Includes&gt;</code>      | 26–28                    | An <code>/*#INCLUDES*/</code> comment, followed by <code>#include</code> statements | The code generator adds the C/C++ comment as a header, and then interprets the <code>%&lt;Includes&gt;</code> template symbol to list the required <code>#include</code> statements in the file. This code is first in this section of the file because the template entries are first.                         |
| (2)                          | <code>/*#DEFINES*/<br/>%&lt;Defines&gt;</code>        | 30                       | A <code>/*#DEFINES*/</code> comment, but no <code>#define</code> statements         | Next, the code generator places the comment as a header for <code>#define</code> statements, but the file does not need <code>#define</code> . No code is added.                                                                                                                                                |
| (3)                          | <code>#pragma string1</code>                          | 31                       | <code>#pragma</code> statements                                                     | While the code generator requires <code>%&lt;&gt;</code> delimiters for template symbols, it can also interpret C/C++ statements in the template without delimiters. In this case, the generator adds the specified statements to the code, following the order in which the statements appear in the template. |
| (5)                          | <code>#pragma string2</code>                          | 42                       |                                                                                     |                                                                                                                                                                                                                                                                                                                 |
| (4)                          | <code>/*DEFINITIONS*/<br/>%&lt;Definitions&gt;</code> | 32–41                    | <code>/*DEFINITIONS*/</code> comment, followed by definitions                       | The code generator places the comment and definitions in the file between the <code>#pragma</code> statements, according to the order in the template. It also inserts comments (lines 33 and 36) that are preset in the model's Configuration Parameters dialog box.                                           |
| (6)                          | <code>%&lt;Declarations&gt;</code>                    | 43                       | No declarations                                                                     | The file needs no declarations, so the code generator does not generate declarations for this file. The template does not have                                                                                                                                                                                  |

| This part of the template... |              | Generates in the file... |             | Explanation                                                                                                                                                                                                                                                                               |
|------------------------------|--------------|--------------------------|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                              |              | Line                     | Description |                                                                                                                                                                                                                                                                                           |
|                              |              |                          |             | a comment to provide a header. Line 43 is left blank.                                                                                                                                                                                                                                     |
| (7)                          | %<Functions> | 44-74                    | Functions   | Finally, the code generator adds functions from the model, plus comments that are preset in the Configuration Parameters dialog box. But it adds no comments as a header for the functions, because the template does not have one. This code is last because the template entry is last. |

For a list of template symbols and the rules for using them, see “Template Symbol Groups” on page 36-89, “Template Symbols” on page 36-92, and “Rules for Modifying or Creating a Template” on page 36-95. To set comment options, from the **Simulation** menu, select **Model Configuration Parameters**. On the Configuration Parameters dialog box, select the **Code Generation > Comments** pane. For details, see “Configure Code Comments”.

## Code Template API Summary

Code Template API Functions summarizes the code template API. See the source code in `matlabroot/rtw/c/tlc/mw/codetemplatelib.tlc` for detailed information on the arguments, return values, and operation of these calls.

### Code Template API Functions

| Function                             | Description                                                                                                                                                                       |
|--------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>LibGetNumSourceFiles</code>    | Returns the number of created source files (.c or .cpp and .h).                                                                                                                   |
| <code>LibGetSourceFileTag</code>     | Returns <code>&lt;filename&gt;_h</code> and <code>&lt;filename&gt;_c</code> for header and source files, respectively, where <code>filename</code> is the name of the model file. |
| <code>LibCreateSourceFile</code>     | Creates a new C or C++ file and returns its reference. If the file already exists, simply returns its reference.                                                                  |
| <code>LibGetFileRecordName</code>    | Returns a model file name (including the path) without the extension.                                                                                                             |
| <code>LibGetSourceFileFromIdx</code> | Returns a model file reference based on its index. This is useful for a common operation on all files, such as to set the leading file banner of all files.                       |
| <code>LibSetSourceFileSection</code> | Adds to the contents of a specified section within a specified file (see also “Custom File Processing (CFP) Template Structure” on page 36-62).                                   |
| <code>LibIndentSourceFile</code>     | Indents a file (from within the TLC environment).                                                                                                                                 |
| <code>LibCallModelInitialize</code>  | Returns code for calling the model's <code>model_initialize</code> function (valid for ERT only).                                                                                 |
| <code>LibCallModelStep</code>        | Returns code for calling the model's <code>model_step</code> function (valid for ERT only).                                                                                       |

| Function                       | Description                                                                                                   |
|--------------------------------|---------------------------------------------------------------------------------------------------------------|
| LibCallModelTerminate          | Returns code for calling the model's <i>model_terminate</i> function (valid for ERT only).                    |
| LibCallSetEventForThisBaseStep | Returns code for calling the model's set events function (valid for ERT only).                                |
| LibWriteModelData              | Returns data for the model (valid for ERT only).                                                              |
| LibSetRTModelErrorStatus       | Returns the code to set the model error status.                                                               |
| LibGetRTModelErrorStatus       | Returns the code to get the model error status.                                                               |
| LibIsSingleRateModel           | Returns true if model is single rate and false otherwise.                                                     |
| LibGetModelName                | Returns name of the model (without an extension).                                                             |
| LibGetMdlSrcBaseName           | Returns the name of model's main source file (for example, <i>model.c</i> or <i>.cpp</i> ).                   |
| LibGetMdlPubHdrBaseName        | Returns the name of model's public header file (for example, <i>model.h</i> ).                                |
| LibGetMdlPrvHdrBaseName        | Returns the name of the model's private header file (for example, <i>model_private.h</i> ).                   |
| LibIsSingleTasking             | Returns <b>true</b> if the model is configured for single-tasking execution.                                  |
| LibWriteModelInput             | Returns the code to write to a particular root input (that is, a model inport block). (valid for ERT only).   |
| LibWriteModelOutput            | Returns the code to write to a particular root output (that is, a model outport block). (valid for ERT only). |
| LibWriteModelInputs            | Returns the code to write to root inputs (that is, all model inport blocks). (valid for ERT only)             |

| Function                        | Description                                                                                                                                                                                                 |
|---------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| LibWriteModelOutputs            | Returns the code to write to root outputs (that is, all model output blocks). (valid for ERT only).                                                                                                         |
| LibNumDiscreteSampleTimes       | Returns the number of discrete sample times in the model.                                                                                                                                                   |
| LibSetSourceFileCodeTemplate    | Set the code template to be used for generating a specified source file.                                                                                                                                    |
| LibSetSourceFileOutputDirectory | Set the folder into which a specified source file is to be generated.                                                                                                                                       |
| LibAddSourceFileCustomSection   | Add a custom section to a source file. The custom section must be associated with one of the built-in (required) sections: <b>Includes, Defines, Types, Enums, Definitions, Declarations, or Functions.</b> |
| LibSetSourceFileCustomSection   | Adds to the contents of a specified custom section within a specified file. The custom section must have been previously created with <b>LibAddSourceFileCustomSection.</b>                                 |

## Generate Custom File and Function Banners

Using code generation template (CGT) files, you can specify custom file banners and function banners for the generated code files. File banners are comment sections in the header and trailer sections of a generated file. Function banners are comment sections for each function in the generated code. Use these banners to add a company copyright statement, specify a special version symbol for your configuration management system, remove time stamps, and for many other purposes. These banners can contain characters, which propagate to the generated code.

To specify banners, create a custom CGT file with customized banner sections. The build process creates an executable TLC file from the CGT file. The code generation process then invokes the TLC file.

You do not need to be familiar with TLC programming to generate custom banners. You can modify example files that are supplied with the ERT target.

---

**Note** Prior releases supported direct use of customized TLC files as banner templates. You specified these with the **Source file (.c) banner template** and **Header file (.h) banner template** options of the ERT target. You can still use a custom TLC file banner templates, however, you can now use CGT files instead.

---

ERT template options on the **Code Generation > Templates** pane of a configuration set, in the **Code templates** section, support banner generation.

The options for function and file banner generation are:

- “Code templates: Source file (\*.c) template”: CGT file to use when generating source (.c or .cpp) files. Place this file on the MATLAB path.
- “Code templates: Header file (\*.h) template”: CGT file to use when generating header (.h) files. You must place this file on the MATLAB path. This file can be the same template specified in the **Code templates: Source file (\*.c) template** field, in which case identical banners are generated in source and header files.

By default, the template for both source and header files is matlabroot/toolbox/rtw/targets/ecoder/ert\_code\_template.cgt.

- In each of these fields, click **Browse** to navigate to and select an existing CGT file for use as a template. Click **Edit** to open the specified file into the MATLAB editor, where you can customize it.

## Create a Custom File and Function Banner Template

To customize a CGT file for custom banner generation, make a local copy of the default code template and edit it, as follows:

- 1 Activate the configuration set that you want to work with.
- 2 Open the **Code Generation** pane of the active configuration set.
- 3 Click the **Templates** tab.
- 4 By default, the code template specified in the **Code templates: Source file (\*.c) template** and **Code templates: Header file (\*.h) template** fields is `matlabroot/toolbox/rtw/targets/ecoder/ert_code_template.cgt`.
- 5 If you want to use a different template as your starting point, click **Browse** to locate and select a CGT file.
- 6 Click **Edit** button to open the CGT file into the MATLAB editor.
- 7 Save a local copy of the CGT file. Store the copy in a folder that is outside of the MATLAB folder structure, but on the MATLAB path. If required, add the folder to the MATLAB path.
- 8 If you intend to use the CGT file with a custom target, locate the CGT file in a folder under your target root folder.
- 9 Rename your local copy of the CGT file. When you rename the CGT file, update the associated **Code templates: Source file (\*.c) template** or **Code templates: Header file (\*.h) template** field to match the new file name.
- 10 Edit and customize the local copy of the CGT file for banner generation, using the information provided in “Customize a Code Generation Template (CGT) File for File and Function Banner Generation” on page 36-83.
- 11 Save your changes to the CGT file.
- 12 Click **Apply** to update the configuration set.
- 13 Save your model.
- 14 Generate code. Examine the generated source and header files to confirm that they contain the banners specified by the template or templates.

## Customize a Code Generation Template (CGT) File for File and Function Banner Generation

This section describes how to edit a CGT file for custom file and function banner generation. For a description of CGT files, see “Code Generation Template (CGT) Files” on page 36-56.

### Components of the File and Function Banner Sections in the CGT file

In a CGT file, you can modify the following sections: file banner, function banner, shared utility function banner, and file trailer. Each section is defined by open and close tags. The tags specific to each section are shown in the following table.

| CGT File Section      | Open Tag              | Close Tag              |
|-----------------------|-----------------------|------------------------|
| File Banner           | <FileBanner>          | </FileBanner>          |
| Function Banner       | <FunctionBanner>      | </FunctionBanner>      |
| Shared-utility Banner | <SharedUtilityBanner> | </SharedUtilityBanner> |
| File Trailer          | <FileTrailer>         | </FileTrailer>         |

You can customize your banners by including tokens and comments between the open and close tag for each section. Tokens are typically TLC variables, for example <ModelVersion>, which are replaced with values in the generated code.

---

**Note:** Including C comment indicators, `/*` or `*/`, in the contents of your banner might introduce an error in the generated code.

---

An open tag includes tag attributes. Enclose the value of the attribute in double quotes. The attributes available for an open tag are:

- **width:** specifies the width of the file or function banner comments in the generated code. The default value is 80.
- **style:** specifies the boundary for the file or function banner comments in the generated code.

The open tag syntax is as follows:

```
<OpenTag style = "style_value" width = "num_width">
```

**Note:** If the **Configuration Parameters > Code Generation > Language** parameter is set to C++, to select a comment style that uses C comment notation (*/\* . . . \*/*), you must also set the **Configuration Parameters > All Parameters > Comment style** parameter to **Multi-line**. For more information, see “Specify Comment Style” on page 36-14.

---

The built-in style options for the `style` attribute are:

- `classic`

```
/* single line comments */
/*
 * multiple line comments
 * second line
 */
```

- `classic_cpp`

```
// single line comments
//
// multiple line comments
// second line
//
```

- `box`

```

/* banner contents */

```

- `box_cpp`

```
////////////////////////////////////
// banner contents //
////////////////////////////////////
```

- `open_box`

```

 * banner contents

```

- `open_box_cpp`

```
////////////////////////////////////
// banner contents
```

```
////////////////////////////////////
• doxygen
/** single line comments */

/**
 * multiple line comments
 * second line
 */
• doxygen_cpp
/// single line comments

///
/// multiple line comments
/// second line
///
• doxygen_qt
/*! single line comments */

/*!
 * multiple line comments
 * second line
 */
• doxygen_qt_cpp
/*! single line comments

/*!
/*! multiple line comments
/*! second line
/*!
```

### File Banner

This section contains comments and tokens for use in generating a custom file banner. The file banner precedes C or C++ code generated by the model. If you omit the file banner section from the CGT file, then no file banner emits to the generated code.

---

**Note:** If you customize your file banner, the software does not emit the customized banner for the file `const_params.c`.

---

The following section is the file banner section provided with the default CGT file, matlabroot/toolbox/rtw/targets/ecoder/ert\_code\_template.cgt.

```

%%
%% Custom file banner section (optional)
%%
<FileBanner style="classic">
File: %<FileName>

Code generated for Simulink model %<ModelName>.

Model version : %<ModelVersion>
Simulink Coder version : %<RTWFileVersion>
TLC version : %<TLCVersion>
C/C++ source code generated on : %<SourceGeneratedOn>
%<CodeGenSettings>
</FileBanner>

```

**Summary of Tokens for File Banner Generation**

FileName	Name of the generated file (for example, "rtwdemo_udt.c").
FileType	Either "source" or "header". Designates whether generated file is a .c or .cpp file or an .h file.
FileTag	Given file names file.c or .cpp and file.h; the file tags are "file_c" and "file_h", respectively.
ModelName	Name of generating model.
ModelVersion	Version number of model.
RTWFileVersion	Version number of <i>model</i> .rtw file.
RTWFileGeneratedOn	Timestamp of <i>model</i> .rtw file.
TLCVersion	Version of Target Language Compiler.
SourceGeneratedOn	Timestamp of generated file.
CodeGenSettings	Code generation settings for model: target language, target selection, production hardware selection, test hardware selection, code generation objectives (in priority order), and Code Generation Advisor validation result.

**Function Banner**

This section contains comments and tokens for use in generating a custom function banner. The function banner precedes C or C++ function generated during the build

process. If you omit the function banner section from the CGT file, the default function banner emits to the generated code. The following section is the default function banner section provided with the default CGT file, matlabroot/toolbox/rtw/targets/ecoder/ert\_code\_template.cgt.

```

%%
%% Custom function banner section (optional)
%% Customize function banners by using the following predefined tokens:
%% %<ModelName>, %<FunctionName>, %<FunctionDescription>, %<Arguments>,
%% %<ReturnType>, %<GeneratedFor>, %<BlockDescription>.
%%
<FunctionBanner style="classic">
%<FunctionDescription>
%<BlockDescription>
</FunctionBanner>

```

**Summary of Tokens for Function Banner Generation**

FunctionName	Name of function
Arguments	List of function arguments
ReturnType	Return type of function
ModelName	Name of generating model
FunctionDescription	Short abstract about the function
GeneratedFor	Full block path for the generated function
BlockDescription	User input from the <b>Block Description</b> parameter of the block properties dialog box. <b>BlockDescription</b> contains an optional token attribute, <b>style</b> . The only valid value for <b>style</b> is <b>content_only</b> , which is case-sensitive and enclosed in double quotes. Use the <b>content_only</b> style when you want to include only the block description content that you entered in the block parameter dialog. The syntax for the token attribute <b>style</b> is:  %<BlockDescription style = "content_only">

**Shared Utility Function Banner**

The shared utility function banner section contains comments and tokens for use in generating a custom shared utility function banner. The shared utility function banner precedes C or C++ shared utility function generated during the build process. If you omit the shared utility function banner section from the CGT file, the default shared utility function banner emits to the generated code. The following section is the default shared

utility function banner section provided with the default CGT file, matlabroot/toolbox/rtw/targets/ecoder/ert\_code\_template.cgt.

```

%%
%% Custom shared utility function banner section (optional)
%% Customize banners for functions generated in shared location by using the
%% following predefined tokens: %<FunctionName>, %<FunctionDescription>,
%% %<Arguments>, %<ReturnType>.
%%
<SharedUtilityBanner style="classic">
%<FunctionDescription>
</SharedUtilityBanner>

```

**Summary of Tokens for Shared Utility Function Banner Generation**

FunctionName	Name of function
Arguments	List of function arguments
ReturnType	Return type of function
FunctionDescription	Short abstract about function

**File Trailer**

The file trailer section contains comments for generating a custom file trailer. The file trailer follows C or C++ code generated from the model. If you omit the file trailer section from the CGT file, no file trailer emits to the generated code. The following section is the default file trailer provided in the default CGT file.

```

%%
%% Custom file trailer section (optional)
%%
<FileTrailer style="classic">
File trailer for generated code.

[EOF]
</FileTrailer>

```

Tokens available for the file banner are available for the file trailer. See Summary of Tokens for File Banner Generation.

## Template Symbols and Rules

### In this section...

“Introduction” on page 36-89

“Template Symbol Groups” on page 36-89

“Template Symbols” on page 36-92

“Rules for Modifying or Creating a Template” on page 36-95

### Introduction

“Template Symbol Groups” on page 36-89 and “Template Symbols” on page 36-92 describe custom file processing (CFP) template symbols and rules for using them. The location of a symbol in one of the supplied template files (`code_c_template.cgt`, `code_h_template.cgt`, `data_c_template.cgt`, or `data_h_template.cgt`) determines where the items associated with that symbol are located in the corresponding generated file. “Template Symbol Groups” on page 36-89 identifies the symbol groups, starting with the parent (“Base”) group, followed by the children of each parent. “Template Symbols” on page 36-92 lists the symbols alphabetically.

---

**Note:** If you are using custom CGT sections, for files generated to the `_sharedutils` folder, you can only use symbol names in the Base symbol group.

---

### Template Symbol Groups

Symbol Group	Symbol Names in This Group
Base (Parents)	Declarations Defines Definitions Documentation Enums Functions

## Template Symbols

Symbol Name*	Symbol Group	Symbol Scope	Symbol Description (What the symbol puts in the generated file)
Abstract	Documentation	N/A	User-supplied description of the model or file. Placed in the generated file based on the Stateflow note, Simulink annotation, or DocBlock on the model.**
Banner	Documentation	N/A	Comments located near top of the file. Contains information that includes model and software versions, and date file was generated.
CFunctionCode	Functions	File	C/C++ functions. Must be at the bottom of the template.
Created	Documentation	N/A	Date when model was created. From <b>Created on</b> field on Model Properties dialog box.
Creator	Documentation	N/A	User who created model. From <b>Created by</b> field on Model Properties dialog box.
Date	Documentation	N/A	Date file was generated. Taken from computer clock.
Declarations	Base		Data declaration of a signal or parameter. For example, <code>extern real_T globalvar;</code>
Defines	Base	File	Required <code>#defines</code> of <code>.h</code> files.
Definitions	Base	File	Data definitions of signals or parameters.
Description	Documentation	N/A	Description of model. From <b>Model description</b> field on Model Properties dialog box.**

Symbol Name*	Symbol Group	Symbol Scope	Symbol Description (What the symbol puts in the generated file)
Documentation	Base	N/A	Comments about how to interpret the generated files.
Enums	Base	File	Enumerated data type definitions.
ExternalCalibrationLookup1D	Declarations	External	***
ExternalCalibrationLookup2D	Declarations	External	***
ExternalCalibrationScalar	Declarations	External	***
ExternalVariableScalar	Declarations	External	***
FileName	Documentation	N/A	Name of the generated file.
FilescopeCalibrationLookup1D	Definitions	File	***
FilescopeCalibrationLookup2D	Definitions	File	***
FilescopeCalibrationScalar	Definitions	File	***
FilescopeVariableScalar	Definitions	File	***
Functions	Base	File	Generated function code.
GlobalCalibrationLookup1D	Definitions	Global	***
GlobalCalibrationLookup2D	Definitions	Global	***
GlobalCalibrationScalar	Definitions	Global	***
GlobalVariableScalar	Definitions	Global	***
History	Documentation	N/A	User-supplied revision history of the generated files. Placed in the generated file based on the Stateflow note, Simulink annotation, or DocBlock on the model.**
Includes	Base	File	<code>#include</code> preprocessor directives.
LastModifiedDate	Documentation	N/A	Date when model was last saved. From <b>Last saved on</b> field on Model Properties dialog box.

Symbol Name*	Symbol Group	Symbol Scope	Symbol Description (What the symbol puts in the generated file)
LastModifiedBy	Documentation	N/A	User who last saved model. From <b>Last saved by</b> field on Model Properties dialog box.
LocalDefines	Defines	File	<b>#define</b> preprocessor directives from code-generation data objects.
LocalMacros	Defines	File	C/C++ macros local to the file.
ModelName	Documentation	N/A	Name of the model.
ModelVersion	Documentation	N/A	Version number of the Simulink model. From <b>Model version</b> field on Model Properties dialog box.
ModifiedBy	Documentation	N/A	Name of user who last modified the model.
ModifiedComment	Documentation	N/A	Comment user enters in the <b>Modified Comment</b> field on the Log Change dialog box. For more information, see “Log Comments History”.
ModifiedHistory	Documentation	N/A	Text from <b>Model history</b> field on Model Properties dialog box.**
Notes	Documentation	N/A	User-supplied miscellaneous notes about the model or generated files. Placed in the generated file based on the Stateflow note, Simulink annotation, or DocBlock on the model.**
ToolVersion	Documentation	N/A	A list of the versions of the toolboxes used in generating the code.
Types	Base		Data types of generated code.

\* Symbol names must be enclosed between %< >. For example, %<Functions>.

\*\* This symbol can be used to add a comment to the generated files. See “Add Global Comments” on page 36-8. The code generator places the comment in each generated file whose template has this symbol name. The code generator places the comment at the location that corresponds to where the symbol name is located in the template file.

\*\*\* The description can be deduced from the symbol name. For example, GlobalCalibrationScalar is a symbol that identifies a scalar. It contains data of global scope that you can calibrate .

## Rules for Modifying or Creating a Template

The following are the rules for creating a MPF template. “Comparison of a Template and Its Generated File” on page 36-74 illustrates several of these rules.

- 1 Place a symbol on a template within the %< > delimiter. For example, the symbol named `Includes` should look like this on a template: %<Includes>. *Note that symbol names are case sensitive.*
- 2 Place a symbol on a template where desired. Its location on the template determines where the item associated with this symbol is located in the generated file. If no item is associated with it, the symbol is ignored.
- 3 Place a C/C++ statement outside of the %< > delimiter, and on a different line than a %< > delimiter, for that statement to appear in the generated file. For example, `#pragma message ("my text")` in the template results in `#pragma message ("my text")` at the corresponding location in the generated file. Note that the statement must be compatible with your C/C++ compiler.
- 4 Use the `.cgt` extension for every template filename. (“cgt” stands for code generation template.)
- 5 Note that `%% $Revision: 1.1.4.10.4.1 $` appears at the top of the MathWorks supplied templates. This is for internal MathWorks use only. It does not need to be placed on a user-defined template and does not show in a generated file.
- 6 Place a comment on the template between `/* */` as in standard ANSI C<sup>8</sup>. This results in `/*comment*/` on the generated file.
- 7 Each MPF template must have all of the Base group symbols, in predefined order. They are listed in “Template Symbol Groups” on page 36-89. Each symbol in the Base group is a parent. For example, `Declarations` is a parent symbol.

---

8. ANSI is a registered trademark of the American National Standards Institute, Inc.

- 8** Each symbol in a non-Base group is a child. For example, `LocalMacros` is a child.
- 9** Except for Documentation children, children must be placed after their parent, before the next parent, and before the `FUNCTIONS` symbol.
- 10** Documentation children can be located before or after their parent in any order anywhere in the template.
- 11** If a non-Documentation child is missing from the template, the code generator places the information associated with this child at its parent location in the generated file.
- 12** If a Documentation child is missing from the template, the code generator omits the information associated with that child from the generated file.

## Annotate Code for Justifying Polyspace Checks

With the Polyspace Code Prover™ product you can apply Polyspace verification to Embedded Coder generated code. The software detects run-time errors in the generated code and helps you to locate and fix model faults.

Polyspace might highlight overflows for certain operations that are legitimate because of the way the code generator implements these operations. Consider the following model and the corresponding generated code.

```

32 /* Sum: '<Root>/Sum' incorporates:
33 * Inport: '<Root>/In1'
34 * Inport: '<Root>/In2'
35 */
36 qY_0 = sat_add_U.In1 + sat_add_U.In2;
37 if ((sat_add_U.In1 < 0) && ((sat_add_U.In2 < 0) && (qY_0 >= 0))) {
38 qY_0 = MIN_int32_T;
39 } else {
40 if ((sat_add_U.In1 > 0) && ((sat_add_U.In2 > 0) && (qY_0 <= 0))) {
41 qY_0 = MAX_int32_T;
42 }
43 }

```

The code generator recognizes that the largest built-in data type is 32-bit. It is not possible to saturate the results of the additions and subtractions using `MIN_INT32` and `MAX_INT32` and a bigger single-word integer data type. Instead the software detects the results overflow and the direction of the overflow, and saturates the result.

If you do not provide justification for the addition operator on line 36, Polyspace verification generates an orange check that indicates a potential overflow. The verification does not take into account the saturation function of lines 37 to 43. In addition, the trace-back functionality of Polyspace Code Prover does not identify the reason for the orange check.

To justify overflows from operators that are legitimate, on the **Configuration Parameters > Code Generation > Comments** pane:

- Under **Overall control**, select the **Include comments** check box.
- Under **Auto generate comments**, select the **Operator annotations check box**.

The code generator annotates generated code with comments for Polyspace. For example:

```
32 /* Sum: '<Root>/Sum' incorporates:
33 * Inport: '<Root>/In1'
34 * Inport: '<Root>/In2'
35 */
36 qY_0 = sat_add_U.In1 +/*MW:0v0k*/ sat_add_U.In2;
```

When you run a verification using Polyspace Code Prover, the Polyspace software uses the annotations to justify the operator-related orange checks and assigns the **Not a defect** classification to the checks.

## Manage Placement of Data Definitions and Declarations

### In this section...

“Overview of Data Placement” on page 36-99

“Priority and Usage” on page 36-100

“Ownership Settings” on page 36-105

“Memory Section Settings” on page 36-106

“Data Placement Rules” on page 36-106

“Settings for a Data Object” on page 36-106

“Data Placement Rules and Results” on page 36-114

“Specify Default #include Syntax for Data Header Files” on page 36-124

### Overview of Data Placement

This chapter focuses on module packaging features (MPF) settings that are interdependent. Their combined values, along with Simulink partitioning, determine the file placement of data definitions and declarations, or *data placement*. This includes

- The number of files generated.
- Whether or not the generated files contain definitions for a model's global identifiers. And, if a definition exists, the settings determine the files in which MPF places them.
- Where MPF places global data declarations (`extern`).

The following six MPF settings are distributed among the main procedures and form an important interdependency:

- The **Data definition** field on the **Code Placement** pane of the Configuration Parameters dialog box.
- The **Data declaration** field on the **Code Placement** pane of the Configuration Parameters dialog box.
- The **Owner** field of the data object in the Model Explorer and the checkbox for **Use owner from data object for data definition placement** on the **Code Placement** pane of the Configuration Parameters dialog box. The term "ownership settings" refers to these fields together.
- The **Definition file** field of the data object on the Model Explorer.
- The **Header file** field of the data object on the Model Explorer.

- The **Memory section** field of the data object on the Model Explorer.

## Priority and Usage

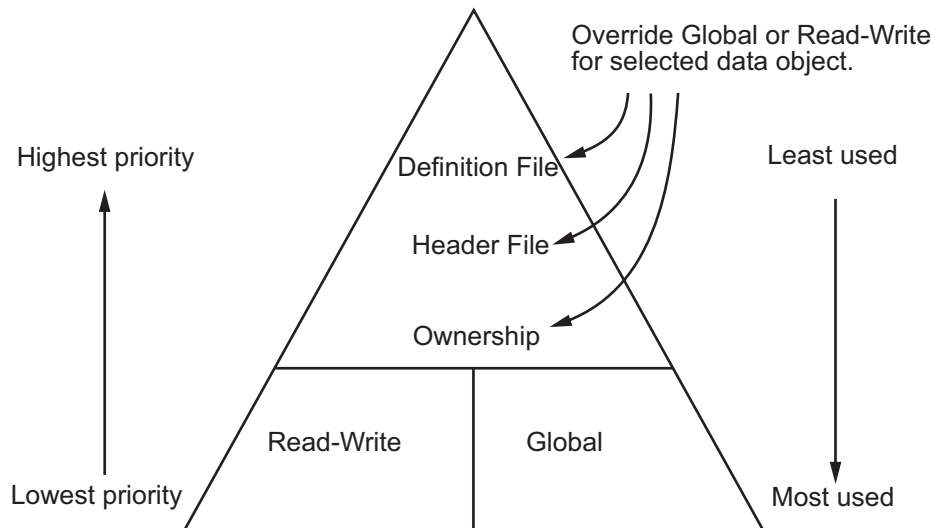

- “Overview” on page 36-100
- “Read-Write Priority” on page 36-101
- “Global Priority” on page 36-104
- “Definition File, Header File, and Ownership Priorities” on page 36-105

### Overview

There is a priority order among interdependent MPF settings. From highest to lowest, the priorities are

- Definition File priority
- Header File priority
- Ownership priority
- Read-Write priority or Global priority

Priority order varies inversely with frequency of use, as illustrated below. For example, Definition File is highest priority but least used.

### MPF Settings Priority and Usage

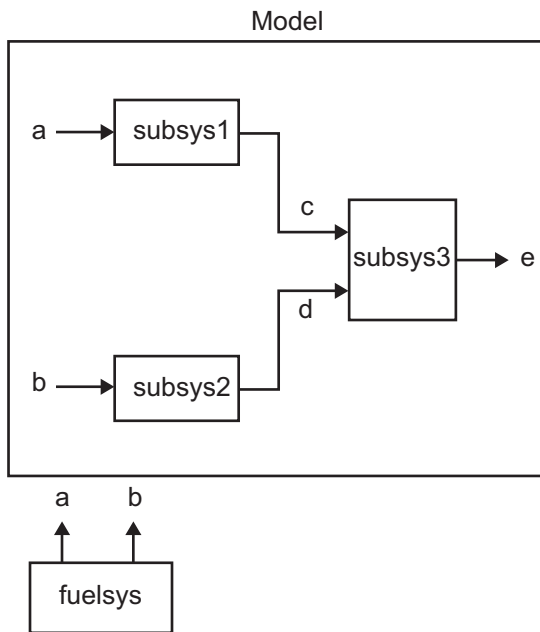

Unless they are overridden, the Read-Write and Global priorities place in the generated files all of the model's MPF-derived data objects that you selected using Data Object Wizard. (See “Create Data Objects for Code Generation with Data Object Wizard” on page 23-2 for details.) Before generating the files, you can use the higher priority Definition file, Header file, and Ownership, as desired, to override Read-Write or Global priorities for single data objects. Most users will employ Read-Write or Global, without an override. A few users, however, will want to do an override for certain data objects. We expect that those users whose applications include multiple modules will want to use the Ownership priority.

The priorities are used only for those data objects that are derived from `Simulink.Signal` and `Simulink.Parameter`, and whose custom storage classes are specified using the Custom Storage Class Designer. (For details, see “Design Custom Storage Classes and Memory Sections” on page 22-27.) Otherwise, the build process determines the data placement.

### **Read-Write Priority**

This is the lowest priority. Consider that a model consists of one or more Simulink blocks or Stateflow diagrams. There can be subsystems within these. For the purpose of illustration, think of a model with one top-level block called `fuelsys`. You double-clicked the block and now see three subsystems labeled `subsys1`, `subsys2` and `subsys3`, as shown in the next figure. Signals `a` and `b` are outputs from the top-level block (`fuelsys`). Signal `a` is an input to `subsys1` and `b` is input to `subsys2`. Signal `c` is an output from `subsys1`. Notice the other inputs and outputs (`d` and `e`). Signals `a` through `e` have corresponding data objects.

As explained in “Data Definition and Declaration Management”, MPF provides you with the means of selecting a data object that you want defined as an identifier in the generated code. MPF also allows you to specify property values for each data object.

### The Generated Files

We generate code for this model. As shown in the figure below, this results in a `.c` source file corresponding to each of the subsystems. (In actual applications, there could be more than one `.c` source file for a subsystem. This is based on the file partitioning previously selected for the model. But for our illustration, we only need to show one for each subsystem.) Data objects `a` through `e` have corresponding identifiers in the generated files.

A `.c` source file has one or more functions in it, depending on the internal operations (functions) of its corresponding subsystem. An identifier in a generated `.c` file has local scope when it is used only in one function of that `.c` file. An identifier has file scope when more than one function in the same `.c` file uses it. An identifier has global scope when more than one of the generated files uses it.

A subsystem's source file contains the definitions for that subsystem's data objects that have local scope or file scope. (These definitions are not shown in the figure.) But where are the definitions and declarations for data objects of global scope? These are shown in the next figure.

For the Read-Write priority, this source file contains the definitions for the subsystem's global data objects, if this is the file that first writes to the data object's address. Other files that read (use) that data object only include a reference to it. This is why this priority is called Read-Write. Since a read and a write of a file are analogous to input and output of a model's block, respectively, there is another way of saying this. The definitions of a block's global data objects are located in the corresponding generated file, if that data object is an output from that block. The declarations (`extern`) of a block's global data objects are located in the corresponding generated file, if that data object is an input to that block.

### Settings for Read-Write Priority

The generated files and what they include, as just described, occur when the Read-Write priority is used. For this to be the case, the other priorities are turned off. That is,

- The **Data definition** field on the **Code Placement** pane is set to **Data defined in source file**.
- The **Data declaration** field on the **Code Placement** pane is set to **Data declared in source file**.

- The **Owner** field on the Model Explorer is blank, and the checkbox for the **Use owner from data object for data definition placement** field on the **Code Placement** pane is not checked.
- **Definition file** and **Header file** on the Model Explorer are blank.

### Global Priority

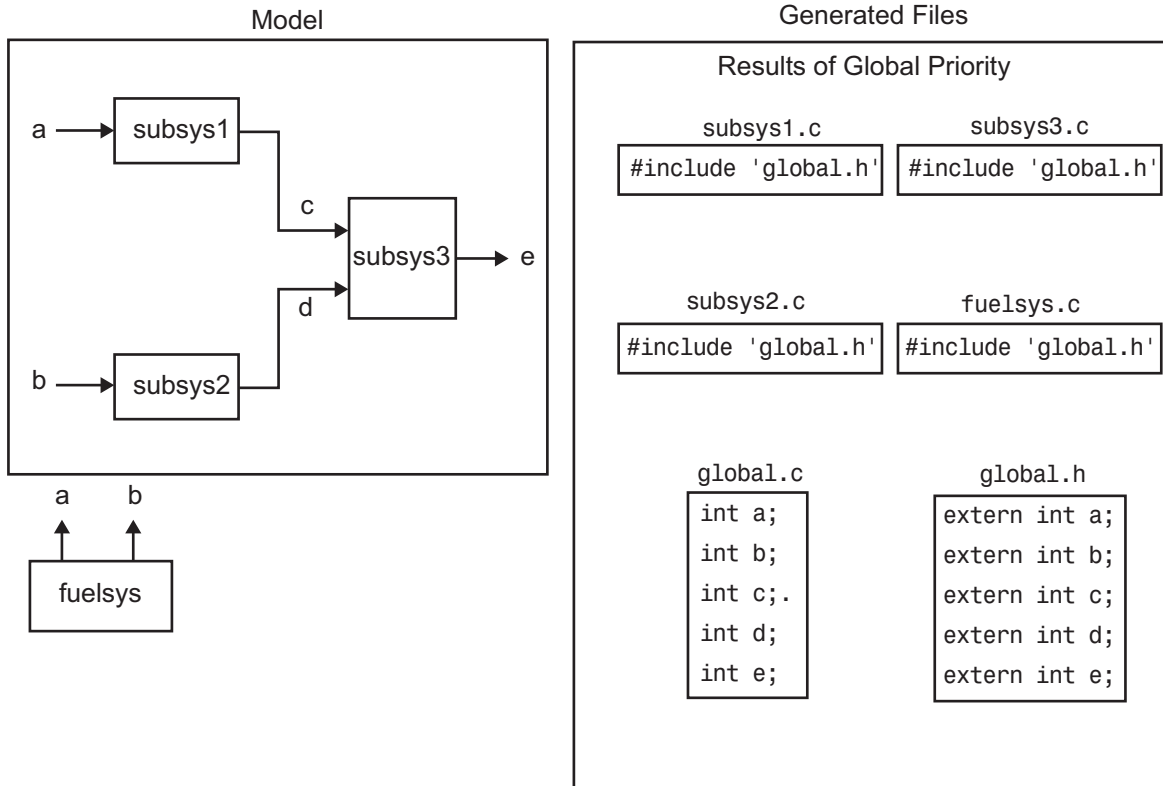

This has the same priority as Read-Write (the lowest) priority. The settings for this are the same as for Read-Write Priority, except

- The **Data definition** field on the **Code Placement** pane is set to `Data defined in single separate source file`.
- The **Data declaration** field on the **Code Placement** pane is set to `Data declared in single separate header file`.

The generated files that result are shown in the next figure. A subsystem's data objects of local or file scope are defined in the `.c` source file where the subsystem's functions are located (not shown). The data objects of global scope are defined in another `.c` file (called `global.c` in the figure). The declarations for the subsystem's data objects of global scope are placed in a `.h` file (called `global.h`).

For example, data objects of local and file scope for `subsys1` are defined in `subsys1.c`. Signal `c` in the model is an output of `subsys1` and an input to `subsys2`. So `c` is used by more than one subsystem and thus is a global data object. Because of the global priority, the definition for `c` (`int c;`) is in `global.c`. The declaration for `c` (`extern int c;`) is in `global.h`. Since `subsys2` uses (reads) `c`, `#include "global.h"` is in `subsys2.c`.

### Definition File, Header File, and Ownership Priorities

While the Read-Write and Global priorities operate on all MPF-derived data objects that you want defined in the generated code, the remaining priorities allow you to override the Read-Write or Global priorities for one or more particular data objects. There is a high-to-low priority among these remaining priorities — Definition File, Header File, and Ownership — for a particular data object, as shown in MPF Settings Priority and Usage

### Ownership Settings

*Ownership settings* refers to the **on** or **off** setting specified using the **Use owner from data object for data definition placement** checkbox on the **Code Placement** pane of the Configuration Parameters dialog box, and the **Owner** field of a data object in the Model Explorer. These settings control the file placement of data definition and

initialization by specifying a model that owns the data. The settings do not control what files are generated. There are four possible configurations, as shown in “Ownership Settings” on page 36-115.

## Memory Section Settings

Memory sections allow you to specify storage directives for a data object. As shown in Parameter and Signal Property Values, the possible values for the **Memory section** property of a parameter or signal object are **Default**, **MemConst**, **MemVolatile** or **MemConstVolatile**.

If you specify a filename for **Definition file**, and select **Default**, **MemConst**, **MemVolatile** or **MemConstVolatile** for the **Memory section** property, the code generation software generates a **.c** file and an **.h** file. The **.c** file contains the definition for the data object with the **pragma** statement or qualifier associated with the **Memory section** selection. The **.h** file contains the declaration for the data object. The **.h** file can be included, using the preprocessor directive **#include**, in files that need to reference the data object.

You can add more memory sections. For more information, see “Design Custom Storage Classes and Memory Sections” on page 22-27 and “Control Data and Function Placement in Memory by Inserting Pragmas” on page 26-2.

## Data Placement Rules

For a complete set of data placement rules in convenient tabular form, based on the priorities discussed in this chapter, see “Data Placement Rules and Results” on page 36-114.

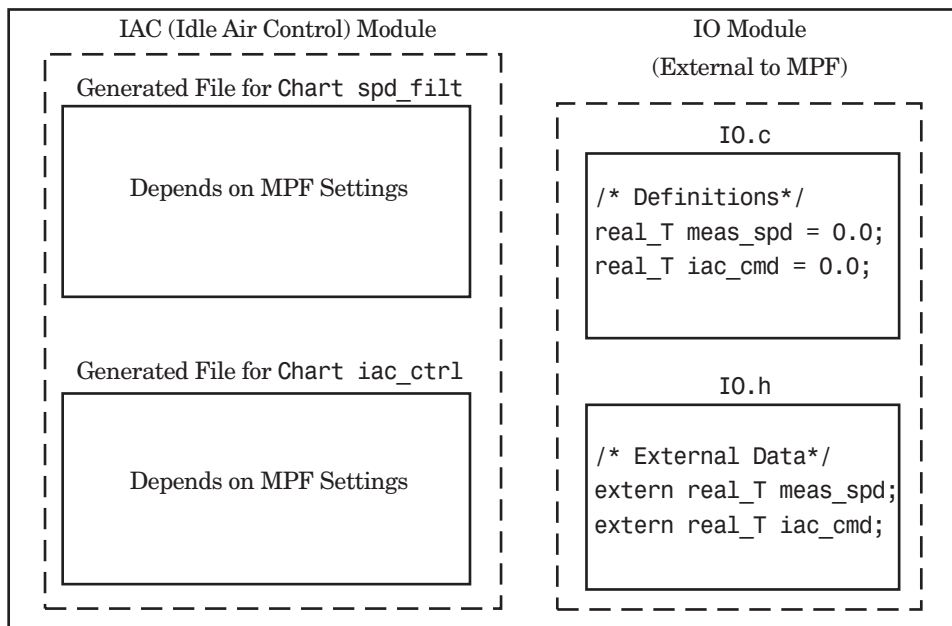

## Settings for a Data Object

- “Introduction” on page 36-107
- “Read-Write” on page 36-108
- “Ownership” on page 36-110
- “Header File” on page 36-111
- “Definition File” on page 36-113

## Introduction

“Settings and Resulting Generated Files” on page 36-115 provides example settings for one data object of a model. Eight examples are listed so that you can see the generated files that result from a wide variety of settings. Four examples from this table are discussed below in more detail. These discussions provide information for understanding settings you might choose. For illustration purposes, the four examples assume that we are dealing with an overall system that controls engine idle speed.

The next figure shows that the software component of this example system consists of two modules, IAC (Idle Air Control), and IO (Input-Output).

Engine Idle Speed Control System

The code in the IO module controls the system's IO hardware. Code is generated only for the IAC module. (Some other means produced the code for the IO module, such as hand-coding.) So the code in IO is external to MPF, and can illustrate legacy code. To simplify matters, the IO code contains one source file, called `IO.c`, and one header file, called `IO.h`.

The IAC module consists of two Stateflow charts, `spd_filt` and `iac_ctrl`. The `spd_filt` chart has two signals (`meas_spd` and `filt_spd`), and one parameter (`a`). The `iac_ctrl` chart also has two signals (`filt_spd` and `iac_cmd`) and a parameter (`ref_spd`). (The parameters are not visible in the top-level charts.) One file for each chart is generated. This example system allows us to illustrate referencing from file to file within the MPF module, and model to external module. It also illustrates the case where there is no such referencing.

Proceed to the discussion of the desired example settings:

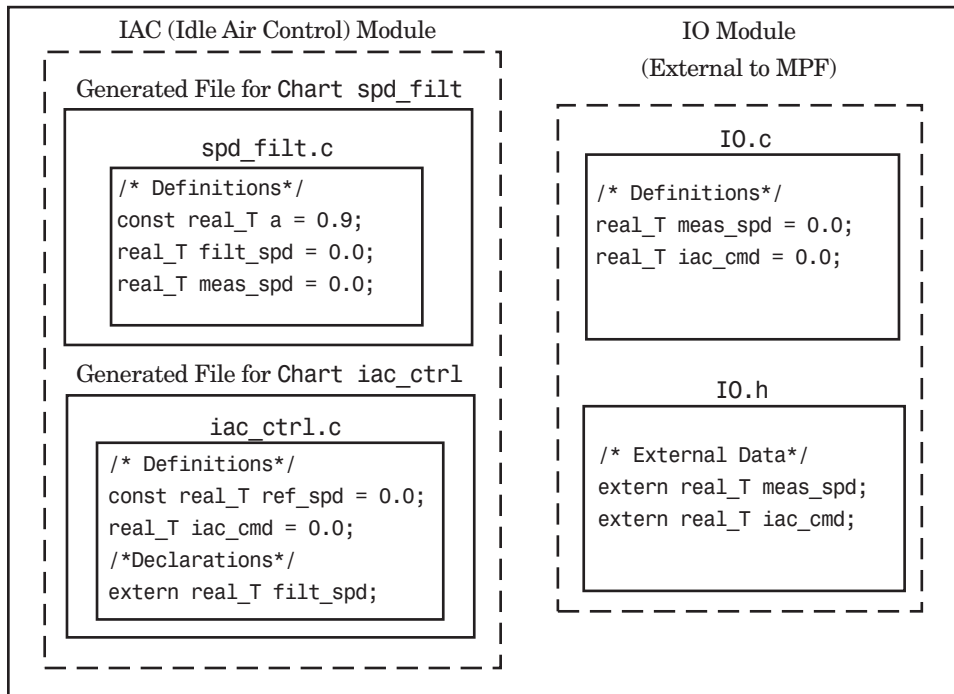

- “Read-Write” on page 36-108
- “Ownership” on page 36-110
- “Header File” on page 36-111
- “Definition File” on page 36-113

### Read-Write

These settings and the generated files that result are shown as Example Settings 1 in “Settings and Resulting Generated Files” on page 36-115. As you can see from the table, this example illustrates the case in which only one `.c` source file (for each chart) is generated.

So, for the IAC model, select the following settings. Accept the `Data` defined in source file in the **Data definition** field and the `Data` declared in source file in the **Data declaration** field on the **Code Placement** pane of the Configuration

Parameters dialog box. Accept the default unchecked **Use owner from data object for data definition placement** field. Accept the default blank settings for the **Owner**, **Definition file** and **Header file** fields on the Model Explorer. For **Memory section**, accept **Default**. Now the Read-Write priority is active. Generate code. The next figure shows the results in terms of definition and declaration statements.

Engine Idle Speed Control System (Read-Write Example)

The code generator generated a `spd_filt.c` for the `spd_filt` chart and `iac_ctrl.c` for the `iac_ctrl` chart. As you can see, MPF placed definitions of data objects for the `spd_filt` chart in `spd_filt.c`. It placed definitions of data objects for the `iac_ctrl` chart in `iac_ctrl.c`.

However, notice `real_T filt_spd`. This data object is defined in `spd_filt.c` and declared in `iac_ctrl.c`. That is, since the Read-Write priority is active, `filt_spd` is defined in the file that first writes to its address. And, it is declared in the file that reads (uses) it. Further, `real_T meas_spd` is defined in both `spd_filt.c` and the external `IO.c`. And, `real_T iac_cmd` is defined in both `iac_ctrl.c` and `IO.c`.

## Ownership

See tables “Ownership Settings” on page 36-115 and “Settings and Resulting Generated Files” on page 36-115. In the “Read-Write” on page 36-108, there are several instances where the same data object is defined in more than one .c source file, and there is no declaration (`extern`) statement. This would result in compiler errors during link time. But in this example, we configure MPF Ownership rules so that linking can take place. Notice the Example Settings 2 row in “Settings and Resulting Generated Files” on page 36-115. Except for the ownership settings, assume these are the settings you made for the model in the IAC module. Since this example has no **Definition file** or **Header file** specified, now Ownership takes priority. (If you specified a **Definition file** or **Header file**, MPF ignores the ownership settings.)

On the **Code Placement** pane of the Configuration Parameters dialog box, check the box for the **Use owner from data object for data definition placement** field. Open the Model Explorer (by issuing the MATLAB command `daexplr`) and, for all data objects except `meas_spd` and `iac_cmd`, type IAC in the **Owner** field (case sensitive). Then, only for the `meas_spd` and `iac_cmd` data objects, type IO as their **Owner** (case sensitive). Generate code.

The results are shown in the next figure. Notice the `extern real_T meas_spd` statement in `spd_filt.c`, and `extern real_T iac_cmd` in `iac_ctrl.c`. MPF placed these declaration statements in the files where these data objects are used. This allows the generated source files (`spd_filt.c` and `iac_ctrl.c`) to be compiled and linked with `IO.c`.

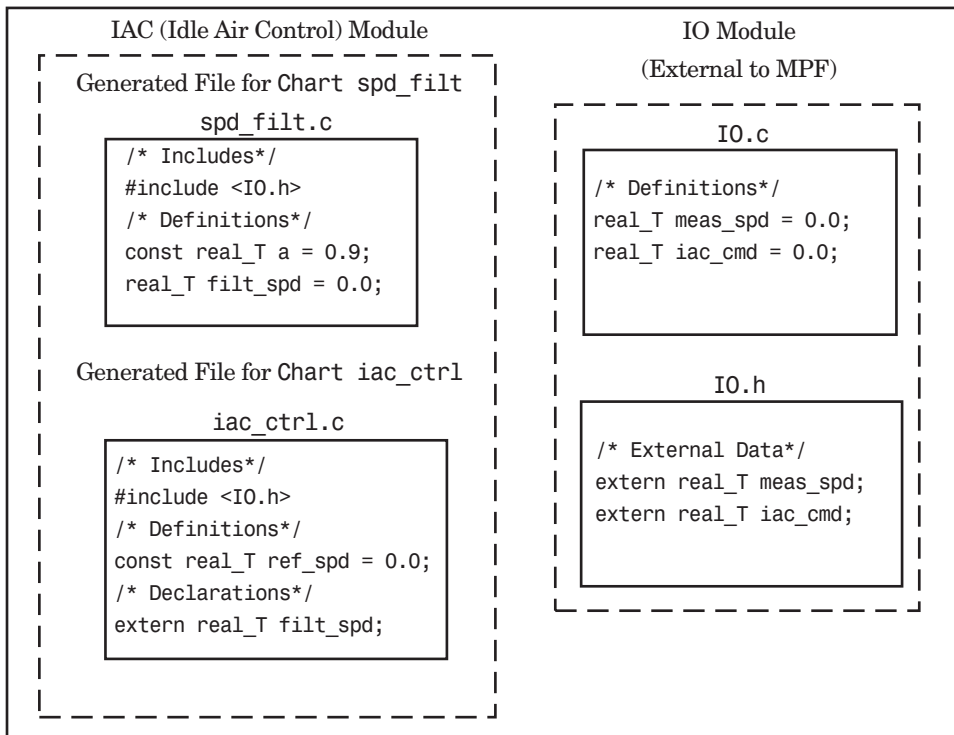

Engine Idle Speed Control System (Ownership Example)

## Header File

These settings and the generated files that result are shown as Example Settings 3 in “Settings and Resulting Generated Files” on page 36-115. This example has no **Definition file** specified. If you specified a **Definition file**, MPF ignores the **Header file** setting. The focus of this example is to show how the **Header file** settings result in the linking of the two chart source files to the external IO files, shown in the next figure. (Also, ownership settings will be used to link the two chart files with each other.)

As you can see in the figure, the `meas_spd` and `iac_cmd` identifiers are defined in `IO.c` and declared in `IO.h`. Both of these identifiers are external to the generated `.c` files. You open the Model Explorer and select both the `meas_spd` and `iac_cmd` data objects. For each of these data objects, in the **Header file** field, specify `IO.h`, since this is where these two objects are declared. This setting allows the `spd_filt.c` source file to compile and link with the external `IO.c` file.

Now we configure the ownership settings. In the Model Explorer, select the `filt_spd` data object and set its **Owner** field to **IAC**. Then, on the **Code Placement** pane of the Configuration Parameters dialog box, check the box for the **Use owner from data object for data definition placement** field. Now the `spd_filt` source file links to the `iac_ctrl` source file. Generate code. See the figure below.

Engine Idle Speed Control System (Header File Example)

Since you specified the `IO.h` filename for the **Header file** field for the `meas_spd` and `iac_ctrl` objects, the code generator assumed that their declarations are in `IO.h`. So the code generator placed `#include IO.h` in each source file: `spd_filt.c` and `iac_ctrl.c`. So these two files will link with the external IO files. Also, due to the ownership settings that were specified, the code generator places the `real_T filt_spd = 0.0;` definition in `spd_filt.c` and declares the `filt_spd` identifier in `iac_ctrl.c` with `extern real_T iac_cmd;`. Consequently, the two source files will link together.

## Definition File

These settings and the generated files that result are shown as Example Settings 4 in “Settings and Resulting Generated Files” on page 36-115. Notice that a definition filename is specified. The settings in the table only apply to the data object called **a**. You have decided that you do not want this object defined in `spd_filt.c`, the generated source file for the `spd_filt` chart. (There are many possible organizational reasons one might want an object declared in another file. It is not important for this example to specify the reason.)

For this example, assume the settings for all data objects are the same as those indicated in “Header File” on page 36-111, except for the data object **a**. The description below identifies only the differences that result from this.

Open the Model Explorer, and select data object **a**. In the **Definition file** field specify a filename. Choose `filter_constants.c`. Generate code. The results are shown in the next figure.

Engine Idle Speed Control System (Definition File Example)

The code generator generates the same files as in the “Header File” on page 36-111, and adds a new file, `filter_constants.c`. Data object `a` now is defined in `filter_constants.c`, rather than in the source file `spd_filt.c`, as it is in the example. This data object is declared with an `extern` statement in `global.h`

## Data Placement Rules and Results

- “Ownership Settings” on page 36-115

- “Settings and Resulting Generated Files” on page 36-115
- “Data Placement Rules” on page 36-117

### Ownership Settings

Row Number	Enable Data Ownership Checkbox	Owner Setting	Result*
1	Off**	Blank**	The code generator determines whether the current model defines and initializes data.
2	Off**	A name is specified.	The code generator determines whether the current model defines and initializes data.
3	On	Blank**	The code generator determines whether the current model defines and initializes data.
4	On	A name is specified.	The model specified in the <b>Owner</b> setting defines and initializes data.

\* See also “Ownership Settings” on page 36-105.\*\* Default.

### Settings and Resulting Generated Files

	Data Defined In...	Data Declared In...	Owner-ship*	Defined File**	Header File	Generated Files
Example Settings 1 (Rd-Write Example)	Source file	Source file	Blank	Blank	Blank	.c / .cpp source file
Example Settings 2 (Owner-ship Example)	Source file	Source file	Name of module specified	Blank	Blank	.c / .cpp source file
Example Settings 3 (Header File Example)	Source file	Source file	Blank	Blank	Desired include filename specified.	.c / .cpp source file .h definition file

	Data Defined In...	Data Declared In...	Ownership*	Defined File**	Header File	Generated Files
Example Settings 4 (Def. File Example)	Source file	Source file	Blank	Desired definition filename specified.	Desired include filename specified.	.c/.cpp source file .c/.cpp definition file* .h definition file*
Example Settings 5	Single separate source file	Source file	Blank	Blank	Blank	.c/.cpp source file global.c/.cpp
Example Settings 6	Single separate source file	Single separate header file	Blank	Blank	Blank	.c/.cpp source file global.c/.cpp global.h
Example Settings 7	Single separate source file	Single separate header file	Name of module specified	Blank	Blank	.c/.cpp source file global.c/.cpp global.h
Example Settings 8	Single separate source file	Single separate header file	Blank	Blank	Desired include filename specified.	.c/.cpp source file global.c/.cpp global.h .h definition file

\* "Blank" in ownership setting means that the check box for the **Use owner from data object for data definition placement** field on the **Code Placement** pane is **Off** and the **Owner** field on the Model Explorer is blank. "Name of module specified" can be a variety of ownership settings as defined in "Ownership Settings" on page 36-115.

\*\* The code generator generates a definition `.c/.cpp` file for every data object for which you specified a definition filename (unless you selected **#DEFINE** for the **Memory section** field). For example, if you specify the same definition filename for all data objects, only one definition `.c/.cpp` file is generated. The code generator places declarations in `model.h` by default, unless you specify **Data declared in single separate header file** for the **Data declaration** option on the **Code Generation > Code Placement** pane of the Configuration Parameter dialog box. If you select that data placement option, the code generator places declarations in `global.h`. If you specify a definition filename for each data object, the code generator generates one definition `.c/.cpp` file for each data object and places declarations in `model.h` by default, unless you specify **Data declared in single separate header file** for **Data declaration**. If you select that data placement option, the code generator places declarations in `global.h`.

**Note:** If you generate C++ rather than C code, the .c files listed in the following table will be .cpp files.

### Data Placement Rules

Storage Class Setting	Global Settings:		Override Settings for Specific Data Object:			Results in Generated Files:

### Notes

In the previous table:

- A Declaration Inclusion Approach is a file in which the header file that contains the data declarations is included.
- D/C stands for don't care.
- Dec stands for declaration.
- Def stands for definition.
- gbl stands for global.
- hdr stands for header.
- N/A stands for not applicable.
- null stands for field is blank.
- sep stands for separate.

**Note 1:** `model.h` is included directly in all source files.

**Note 2:** `model_private.h` is included directly in all source files.

**Note 3:** `extern` is included in `model_private.h`, which is in `source.c`.

**Note 4:** `header.h` is included in `model_private.h`, which is in `source.c`.

**Note 5:** `model.h` is included directly in all source files that use `#define`.

**Note 6:** `header.h` is included in `model.h`, which is in source files that use `#define`.

**Note 7:** `model.h` is included in all `source.c` files.

**Note 8:** `extern` is inlined in source files where data is used.

**Note 9:** `global.h` is included in `model.h`, which is in all source files.

**Note 10:** When you specify a definition filename for a data object, a header file is not generated for that data object. The code generator declares the data object according to the data placement priorities.

**Note 11:** `header.h` is included in `model.h`, which is in all source files.

**Note 12:** Signal: Either not defined because it is expression folded, or local data, or defined in a structure in `model.c`, all depending on model's code generation settings. Parameter: Either inlined in the code, or defined in `model_data.c`.

**Note 13:** Signal: In a structure that is defined in `model.c`. Parameter: In a structure that is defined in `model_data.c`.

## Specify Default `#include` Syntax for Data Header Files

To control the file placement of a data item such as a signal line or block state in the generated code, you can apply a custom storage class to the data item (see “Introduction to Custom Storage Classes” on page 22-2). You then use the `HeaderFile` custom attribute to specify the generated or custom header file that contains the declaration of the data.

To reduce maintenance effort and data entry, when you specify `HeaderFile`, you can omit delimiters (`"` or `<>`) and use only the file name. You can then control the default delimiters that the generated code uses for the corresponding `#include` directives. To use angle brackets by default, set **Configuration Parameters > Code Generation > Code Placement > #include file delimiters** to `#include <header.h>`.

## Enhance Readability of Code for Flow Charts

In this section...
“Appearance of Generated Code for Flow Charts” on page 36-126
“Convert If-Elseif-Else Code to Switch-Case Statements” on page 36-129
“Example of Converting Code to Switch-Case Statements” on page 36-131

### Appearance of Generated Code for Flow Charts

If you have an Embedded Coder license and you generate code for models that include Stateflow objects, the code from a flow chart resembles the samples that follow.

The following characteristics apply:

- By default, the generated code uses `if-elseif-else` statements to represent `switch` patterns. To convert the code to use `switch-case` statements, see “Convert If-Elseif-Else Code to Switch-Case Statements” on page 36-129.
- By default, variables that appear in the flow chart do not retain their names in the generated code. Modified identifiers guarantee that no naming conflicts occur.
- Traceability comments for the transitions appear between each set of `/*` and `*/` markers. To learn more about traceability, see “Trace Stateflow Objects in Generated Code” on page 61-10.

```

if (modelName_U.In1 == 1.0) {
 /* Transition: '<S1>:11' */
 /* Transition: '<S1>:12' */
 modelName_Y.Out1 = 10.0;

 /* Transition: '<S1>:15' */
 /* Transition: '<S1>:16' */
} else {
 /* Transition: '<S1>:10' */
 if (modelName_U.In1 == 2.0) {
 /* Transition: '<S1>:13' */
 /* Transition: '<S1>:14' */
 modelName_Y.Out1 = 20.0;

 /* Transition: '<S1>:16' */
 } else {
 /* Transition: '<S1>:17' */
 modelName_Y.Out1 = 30.0;
 }
}
}

```

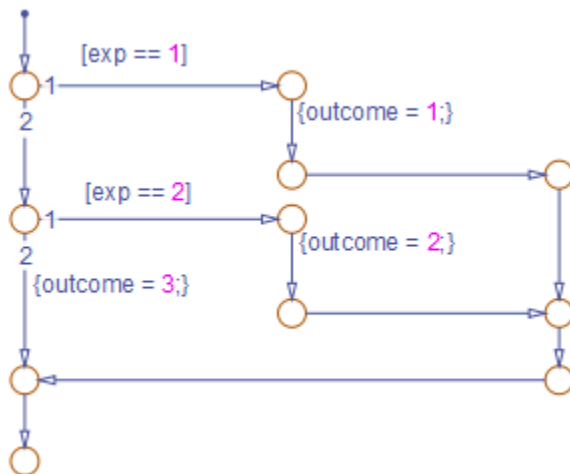

### Sample Code for a Decision Logic Pattern

```
for (sf_i = 0; sf_i < 10; sf_i++) {
 /* Transition: '<S1>:40' */
 /* Transition: '<S1>:41' */
 modelName_B.y = modelName_B.y +
 modelName_U.In1;

 /* Transition: '<S1>:39' */
}
```

**Sample Code for an Iterative Loop Pattern**

```
if (modelName_U.In1 == 1.0) {
 /* Transition: '<S1>:149' */
 /* Transition: '<S1>:150' */
 modelName_Y.Out1 = 1.0;

 /* Transition: '<S1>:151' */
 /* Transition: '<S1>:152' */
 /* Transition: '<S1>:158' */
 /* Transition: '<S1>:159' */
} else {
 /* Transition: '<S1>:156' */
 if (modelName_U.In1 == 2.0) {
 /* Transition: '<S1>:153' */
 /* Transition: '<S1>:154' */
 modelName_Y.Out1 = 2.0;

 /* Transition: '<S1>:155' */
 /* Transition: '<S1>:158' */
 /* Transition: '<S1>:159' */
 } else {
 /* Transition: '<S1>:161' */
 modelName_Y.Out1 = 3.0;
 }
}
```

### Sample Code for a Switch Pattern

## Convert If-Elseif-Else Code to Switch-Case Statements

When you generate code for embedded real-time targets, you can choose to convert `if-elseif-else` code to `switch-case` statements. This conversion can enhance readability of the code. For example, when a flow chart contains a long list of conditions, the `switch-case` structure:

- Reduces the use of parentheses and braces
- Minimizes repetition in the generated code

### How to Convert If-Elseif-Else Code to Switch-Case Statements

The following procedure describes how to convert generated code for the flow chart from `if-elseif-else` to `switch-case` statements.

Step	Task	Reference
1	Verify that your flow chart follows the rules for conversion.	“Verify the Contents of the Flow Chart” on page 36-133
2	Enable the conversion.	“Enable the Conversion” on page 36-134
3	Generate code for your model.	“Generate Code for Your Model” on page 36-135
4	Troubleshoot the generated code. <ul style="list-style-type: none"> <li>• If you see <code>switch-case</code> statements for your flow chart, you can stop.</li> <li>• If you see <code>if-elseif-else</code> statements for your flow chart, update the chart and repeat the previous step.</li> </ul>	“Troubleshoot the Generated Code” on page 36-135

### Rules of Conversion

For the conversion to occur, the following rules must hold. LHS and RHS refer to the left-hand side and right-hand side of a condition, respectively.

Construct	Rules to Follow
Flow chart	Must have two or more <i>unique</i> conditions, in addition to a default.  For more information, see “How the Conversion Handles Duplicate Conditions” on page 36-131.
Each condition	Must test equality only.
	Must use the same variable or expression for the LHS.
	<b>Note:</b> You can reverse the LHS and RHS.
Each LHS	Must be a single variable or expression.
	Cannot be a constant.
	Must have an integer or enumerated data type.
	Cannot have any side effects on simulation.

Construct	Rules to Follow
	For example, the LHS can read from but not write to global variables.
Each RHS	Must be a constant.
	Must have an integer or enumerated data type.

### How the Conversion Handles Duplicate Conditions

If a flow chart has duplicate conditions, the conversion preserves only the first condition. The code discards all other instances of duplicate conditions.

After removal of duplicates, two or more unique conditions must exist. If not, no conversion occurs and the code contains all duplicate conditions.

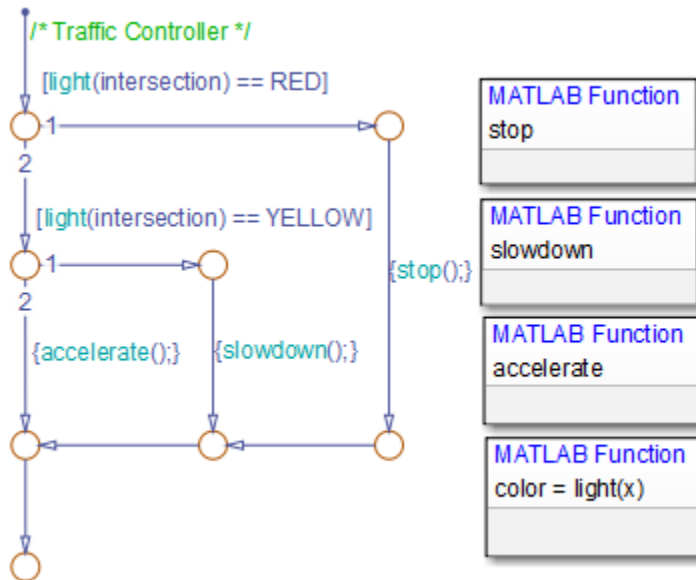

Example of Generated Code	Code After Conversion
<pre> if (x == 1) {     block1 } else if (x == 2) {     block2 } else if (x == 1) { // duplicate     block3 } else if (x == 3) {     block4 } else if (x == 1) { // duplicate     block5 } else {     block6 } </pre>	<pre> switch (x) {     case 1:         block1; break;     case 2:         block2; break;     case 3:         block4; break;     default:         block6; break; } </pre>
<pre> if (x == 1) {     block1 } else if (x == 1) { // duplicate     block2 } else {     block3 } </pre>	No change, because only one unique condition exists

### Example of Converting Code to Switch-Case Statements

Suppose that you have the following model with a single chart.

The chart contains a flow chart and four MATLAB functions:

The MATLAB functions in the chart contain the code in the following table. In each case, the **Function Inline Option** is **Auto**. For more information about function inlining, see “Specify Graphical Function Properties”.

MATLAB Function	Code
stop	<pre>function stop  %#codegen  coder.extrinsic('disp');  disp('Not moving.')</pre>

MATLAB Function	Code
	<code>traffic_speed = 0;</code>
<code>slowdown</code>	<pre>function slowdown %#codegen coder.extrinsic('disp') disp('Slowing down.')  traffic_speed = 1;</pre>
<code>accelerate</code>	<pre>function accelerate %#codegen coder.extrinsic('disp'); disp('Moving along.')  traffic_speed = 2;</pre>
<code>light</code>	<pre>function color = light(x) %#codegen if (x &lt; 20)     color = TrafficLights.GREEN; elseif (x &gt;= 20 &amp;&amp; x &lt; 25)     color = TrafficLights.YELLOW; else     color = TrafficLights.RED; end</pre>

The output `color` of the function `light` uses the enumerated type `TrafficLights`. The enumerated type definition in `TrafficLights.m` is:

```
classdef TrafficLights < Simulink.IntEnumType
 enumeration
 RED(0)
 YELLOW(5)
 GREEN(10)
 end
end
```

For more information, see “Define Enumerated Data in a Chart”.

### Verify the Contents of the Flow Chart

Check that the flow chart in your chart follows all the rules in “Rules of Conversion” on page 36-130.

Construct	How the Construct Follows the Rules
Flow chart	Two unique conditions exist, in addition to the default: <ul style="list-style-type: none"> <li>• <code>[light(intersection) == RED]</code></li> <li>• <code>[light(intersection) == YELLOW]</code></li> </ul>
Each condition	Each condition: <ul style="list-style-type: none"> <li>• Tests equality</li> <li>• Uses the same function call <code>light(intersection)</code> for the LHS</li> </ul>
Each LHS	Each LHS: <ul style="list-style-type: none"> <li>• Contains a single expression</li> <li>• Is the output of a function call and therefore not a constant</li> <li>• Is of enumerated type <code>TrafficLights</code>, which you define in <code>TrafficLights.m</code> on the MATLAB path (see “Define Enumerated Data in a Chart”)</li> <li>• Uses a function call that has no side effects</li> </ul>
Each RHS	Each RHS: <ul style="list-style-type: none"> <li>• Is an enumerated value and therefore a constant</li> <li>• Is of enumerated type <code>TrafficLights</code></li> </ul>

### Enable the Conversion

- 1 Open the Model Configuration Parameters dialog box.
- 2 In the **Code Generation** pane, select `ert.tlc` for the **System target file**.

This step specifies an ERT-based target for your model.

- 3 In the **Code Generation > Code Style** pane, select the **Convert if-elseif-else patterns to switch-case statements** check box.

---

**Tip** This conversion works on a per-model basis. If you select this check box, the conversion applies to:

- Flow charts in all charts of a model
- MATLAB functions in all charts of a model

- All MATLAB Function blocks in that model

---

## Generate Code for Your Model

In the model, select **Code > C/C++ Code > Build Model** to generate source code from the model.

## Troubleshoot the Generated Code

The generated code for the flow chart appears something like this:

```

if (sf_color == RED) {
 /* Transition: '<S1>:11' */
 /* Transition: '<S1>:12' */
 /* MATLAB Function 'stop': '<S1>:23' */
 /* '<S1>:23:6' */
 rtb_traffic_speed = 0;

 /* Transition: '<S1>:15' */
 /* Transition: '<S1>:16' */
} else {
 /* Transition: '<S1>:10' */
 /* MATLAB Function 'light': '<S1>:19' */
 if (ifelse_using_enums_U.In1 < 20.0) {
 /* '<S1>:19:3' */
 /* '<S1>:19:4' */
 sf_color = GREEN;
 } else if ((ifelse_using_enums_U.In1 >= 20.0) &&
 (ifelse_using_enums_U.In1 < 25.0)) {
 /* '<S1>:19:5' */
 /* '<S1>:19:6' */
 sf_color = YELLOW;
 } else {
 /* '<S1>:19:8' */
 sf_color = RED;
 }
}

if (sf_color == YELLOW) {
 /* Transition: '<S1>:13' */
 /* Transition: '<S1>:14' */
 /* MATLAB Function 'slowdown': '<S1>:24' */
 /* '<S1>:24:6' */
 rtb_traffic_speed = 1;
}

```

```
 /* Transition: '<S1>:16' */
 } else {
 /* Transition: '<S1>:17' */
 /* MATLAB Function 'accelerate': '<S1>:25' */
 /* '<S1>:25:6' */
 rtb_traffic_speed = 2;
 }
}
```

Because the MATLAB function `light` appears inlined, inequality comparisons appear in these lines of code:

```
if (ifelse_using_enums_U.In1 < 20.0) {

} else if ((ifelse_using_enums_U.In1 >= 20.0) &&
 (ifelse_using_enums_U.In1 < 25.0)) {

}
```

Because inequalities appear in the body of the `if-elseif-else` code for the flow chart, the conversion to `switch-case` statements does not occur. To prevent this behavior, do one of the following:

- Specify that the function `light` does not appear inlined. See “Change the Inlining Property for the Function” on page 36-136.
- Modify the flow chart. See “Modify the Flow Chart to Ensure Switch-Case Statements” on page 36-138.

### Change the Inlining Property for the Function

If you do not want to modify your flow chart, change the inlining property for the function `light`:

- 1 Right-click the function box for `light` and select **Properties**.

The properties dialog box appears.

- 2 For **Function Inline Option**, select **Function**.
- 3 Click **OK** to close the dialog box.

---

**Note:** You do not have to change the inlining property for the other three MATLAB functions in the chart. Because the flow chart does not call those functions during evaluation of conditions, the inlining property for those functions can remain **Auto**.

---

When you regenerate code for your model, the code for the flow chart now appears something like this:

```
switch (ifelse_using_enums_light(ifelse_using_enums_U.In1)) {
 case RED:
 /* Transition: '<S1>:11' */
 /* Transition: '<S1>:12' */
 /* MATLAB Function 'stop': '<S1>:23' */
 /* '<S1>:23:6' */
 ifelse_using_enums_Y.Out1 = 0.0;

 /* Transition: '<S1>:15' */
 /* Transition: '<S1>:16' */
 break;

 case YELLOW:
 /* Transition: '<S1>:10' */
 /* Transition: '<S1>:13' */
 /* Transition: '<S1>:14' */
 /* MATLAB Function 'slowdown': '<S1>:24' */
 /* '<S1>:24:6' */
 ifelse_using_enums_Y.Out1 = 1.0;

 /* Transition: '<S1>:16' */
 break;

 default:
 /* Transition: '<S1>:17' */
 /* MATLAB Function 'accelerate': '<S1>:25' */
 /* '<S1>:25:6' */
 ifelse_using_enums_Y.Out1 = 2.0;
 break;
}
```

Because the MATLAB function `light` no longer appears inlined, the conversion to `switch-case` statements occurs. The `switch-case` statements provide the following benefits to enhance readability:

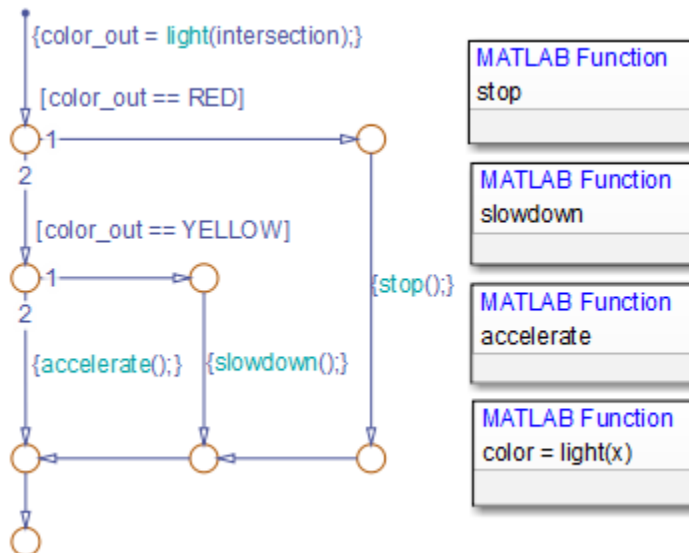

- The code reduces the use of parentheses and braces.
- The LHS expression `ifelse_using_enums_light(ifelse_using_enums_U.In1)` appears only once, minimizing repetition in the code.

### Modify the Flow Chart to Ensure Switch-Case Statements

If you do not want to change the inlining property for the function `light`, modify your flow chart:

- 1 Add chart local data `color_out` with the enumerated type `TrafficLights`.
- 2 Replace each instance of `light(intersection)` with `color_out`.
- 3 Add the action `{color_out = light(intersection)}` to the default transition of the flow chart.

The chart should now look something like this:

When you regenerate code for your model, the code for the flow chart uses `switch-case` statements.

## Generate Inlined Subsystem Code

You can configure a nonvirtual subsystem to inline the subsystem code with the model code. In the Subsystem Parameters dialog box, the **Function packaging** parameter specifies the format of the subsystem's generated code. This parameter has four settings: **Auto**, **Inline**, **Nonreusable function**, and **Reusable function**. The code generator can generate inlined code for the **Auto** or **Inline** settings.

The **Inline** setting explicitly directs the code generator to inline the subsystem code unconditionally.

The default **Auto** setting directs the code generator to generate the most efficient code for the subsystem based on the type and number of instances of the subsystem that exist in the model. When there is only one instance of a subsystem, the **Auto** setting inlines the subsystem code. When there are multiple instances of a subsystem, that is not too complex, the **Auto** setting inlines the code for each subsystem. Otherwise, the **Auto** setting generates a single copy of the function (as a reusable function). For a function-call subsystem with multiple callers, the **Auto** setting generates subsystem code that is consistent with the **Nonreusable function** setting.

### Configure Subsystem to Inline Code

To configure your subsystem for inlining:

- 1 Right-click the Subsystem block. From the context menu, select **Block Parameters (Subsystem)**.
- 2 In the Subsystem Parameters dialog box, if the subsystem is virtual, select **Treat as atomic unit**. This option makes the subsystem nonvirtual. On the **Code Generation** tab, the **Function packaging** option is now available.
- 3 Click the **Code Generation** tab and select **Auto** or **Inline** from the **Function packaging** parameter.
- 4 Click **Apply** and close the dialog box.

The border of the subsystem thickens, indicating that it is nonvirtual.

When you generate code from your model, the code generator inlines subsystem code within *model.c* or *model.cpp* (or in its parent system's source file). You can identify this code by system/block identification tags, such as:

```
/* Atomic SubSystem Block: <Root>/AtomicSubsys1 */
```

## Exceptions to Inlining

There are certain cases in which the code generator does not inline a nonvirtual subsystem, even though you select the `Inline` setting.

- If a noninlined S-function calls a function-call subsystem, the code generator ignores the `Inline` setting. Because noninlined S-functions use function pointers to make function calls, the code generator must generate a function with all arguments present.
- In a feedback loop involving function-call subsystems, the code generator generates a function instead of inlined code for one of the subsystems. Based on the internal, sorted order of the subsystems, the code generator selects which subsystem to generate a function.
- If an S-function, an Async Interrupt, or a Task Sync block with the option `SS_OPTION_FORCE_NONINLINED_FCNCALL` set to `TRUE` calls a subsystem, the code generator generates a function instead of inlined code for the subsystem. The VxWorks block library (`vxlib1`), contains the user-defined Async Interrupt and Task Sync blocks.<sup>9</sup>

# Code Replacement in Simulink Coder

---

- “What Is Code Replacement?” on page 37-2
- “Choose a Code Replacement Library” on page 37-8
- “Replace Code Generated from Simulink Models” on page 37-10

## What Is Code Replacement?

Code replacement is a technique to change the code that the code generator produces for functions and operators to meet application code requirements. For example, you can replace generated code to meet requirements such as:

- Optimization for a specific run-time environment, including, but not limited to, specific target hardware.
- Integration with existing application code.
- Compliance with a standard, such as AUTOSAR.
- Modification of code behavior, such as enabling or disabling nonfinite or inline support.
- Application- or project-specific code requirements, such as:
  - Elimination of `math.h`.
  - Elimination of system header files.
  - Elimination of calls to `memcpy` or `memset`.
  - Use of BLAS.
  - Use of a specific BLAS.

To apply this technique, configure the code generator to apply a code replacement library (CRL) during code generation. By default, the code generator does not apply a code replacement library. You can choose from the following libraries that MathWorks provides:

- GNU C99 extensions—GNU<sup>10</sup> gcc math library, which provides C99 extensions as defined by compiler option `-std=gnu99`.
- AUTOSAR 4.0—Produces code that more closely aligns with the AUTOSAR standard. Requires an Embedded Coder license.
- Intel IPP for x86-64 (Windows)—Generates calls to the Intel<sup>®</sup> Performance Primitives (IPP) library for the x86-64 Windows platform.
- Intel IPP/SSE for x86-64 (Windows)—Generates calls to the IPP and Streaming SIMD Extensions (SSE) libraries for the x86-64 Windows platform.
- Intel IPP for x86-64 (Windows using MinGW compiler)—Generates calls to the IPP library for the x86-64 Windows platform and MinGW compiler.

---

10. GNU is a registered trademark of the Free Software Foundation.

- Intel IPP/SSE for x86-64 (Windows using MinGW compiler)—Generates calls to the IPP and SSE libraries for the x86-64 Windows platform and MinGW compiler.
- Intel IPP for x86/Pentium (Windows)—Generates calls to the IPP library for the x86/Pentium Windows platform.
- Intel IPP/SSE for x86/Pentium (Windows)—Generates calls to the Intel Performance IPP and SSE libraries for the x86/Pentium Windows platform.
- Intel IPP for x86-64 (Linux)—Generates calls to the IPP library for the x86-64 Linux platform.
- Intel IPP/SSE with GNU99 extensions for x86-64 (Linux)—Generates calls to the GNU libraries for IPP and SSE, with GNU C99 extensions, for the x86-64 Linux platform.

Libraries that include GNU99 extensions are intended for use with the GCC compiler. If use one of those libraries with another compiler, generated code might not compile.

Depending on the product licenses that you have, other libraries might be available. If you have an Embedded Coder license, you can view and choose from other libraries and you can create custom code replacement libraries.

## Code Replacement Libraries

A *code replacement library* consists of one or more code replacement tables that specify application-specific implementations of functions and operators. For example, a library for a specific embedded processor specifies function and operator replacements that optimize generated code for that processor.

A *code replacement table* contains one or more *code replacement entries*, with each entry representing a potential replacement for a function or operator. Each entry maps a *conceptual representation* of a function or operator to an *implementation representation* and priority.

Table Entry Component	Description
Conceptual representation	<p>Identifies the table entry and contains match criteria for the code generator. Consists of:</p> <ul style="list-style-type: none"> <li>• Function name or a key. The function name identifies most functions. For operators and some functions, a series of characters, called a key identifies a function or operator. For example, function name 'COS' and operator key 'RTW_OP_ADD'.</li> <li>• Conceptual arguments that observe code generator naming ('y1', 'u1', 'u2', ...), with corresponding I/O types (output or input) and data types.</li> <li>• Other attributes, such as an algorithm, fixed-point saturation, and rounding modes, which identify matching criteria for the function or operator.</li> </ul>
Implementation representation	<p>Specifies replacement code. Consists of:</p> <ul style="list-style-type: none"> <li>• Function name. For example, 'cos_db1' or 'u8_add_u8_u8'.</li> <li>• Implementation arguments, with corresponding I/O types (output or input) and data types.</li> <li>• Parameters that provide additional implementation details, such as header and source file names and paths of build resources.</li> </ul>

Table Entry Component	Description
Priority	Defines the entry priority relative to other entries in the table. The value can range from 0 to 100, with 0 being the highest priority. If multiple entries have the same priority, the code generator uses the first match with that priority.

When the code generator looks for a match in a code replacement library, it creates and populates a *call site object* with the function or operator conceptual representation. If a match exists, the code generator uses the matched code replacement entry populated with the implementation representation and uses it to generate code.

The code generator searches the tables in a code replacement library for a match in the order that the tables appear in the library. If the code generator finds multiple matches within a table, the priority determines the match. The code generator uses a higher-priority entry over a similar entry with a lower priority.

## Code Replacement Terminology

Term	Definition
Cache hit	A code replacement entry for a function or operator, defined in the specified code replacement library, for which the code generator finds a match.
Cache miss	A conceptual representation of a function or operator for which the code generator does not find a match.
Call site object	Conceptual representation of a function or operator that the code generator uses when it encounters a call site for a function or operator. The code generator uses the object to query the code replacement library for a conceptual representation match. If a match exists, the code generator returns a code replacement object, fully populated with the conceptual representation, implementation representation, and priority, and uses that object to generate replacement code.
Code replacement library	One or more code replacement tables that specify application-specific implementations of functions

Term	Definition
	and operators. When configured to use a code replacement library, the code generator uses criteria defined in the library to search for matches. If a match is found, the code generator replaces code that it generates by default with application-specific code defined in the library.
Code replacement table	One or more code replacement table entries. Provides a way to group related or shared entries for use in different libraries.
Code replacement entry	Represents a potential replacement for a function or operator. Maps a conceptual representation of a function or operator to an implementation representation and priority.
Conceptual argument	Represents an input or output argument for a function or operator being replaced. Conceptual arguments observe naming conventions ('y1', 'u1', 'u2', ...) and data types familiar to the code generator.
Conceptual representation	Represents match criteria that the code generator uses to qualify functions and operators for replacement. Consists of: <ul style="list-style-type: none"> <li>• Function or operator name or key</li> <li>• Conceptual arguments with type, dimension, and complexity specification for inputs and output</li> <li>• Attributes, such as an algorithm and fixed-point saturation and rounding modes</li> </ul>
Implementation argument	Represents an input or output argument for a C or C++ replacement function. Implementation arguments observe C/C++ name and data type specifications.

Term	Definition
Implementation representation	<p>Specifies C or C++ replacement function prototype. Consists of:</p> <ul style="list-style-type: none"> <li>• Function name (for example, 'cos_db1' or 'u8_add_u8_u8')</li> <li>• Implementation arguments specifying type, type qualifiers, and complexity for the function inputs and output</li> <li>• Parameters that provide build information, such as header and source file names and paths of build resources and compile and link flags</li> </ul>
Key	<p>Identifies a function or operator that is being replaced. A function name or key appears in the conceptual representation of a code replacement entry. The key RTW_OP_ADD identifies the addition operator.</p>
Priority	<p>Defines the match priority for a code replacement entry relative to other entries, which have the same name and conceptual argument list, within a code replacement library. The priority can range from 0 to 100, with 0 being the highest priority. The default is 100. If a library provides two implementations for a function or operator, the implementation with the higher priority shadows the one with the lower priority.</p>

## Code Replacement Limitations

Code replacement verification — It is possible that code replacement behaves differently than you expect. For example, data types that you observe in code generator input might not match what the code generator uses as intermediate data types during an operation. Verify code replacements by examining generated code.

## Choose a Code Replacement Library

### In this section...

“About Choosing a Code Replacement Library” on page 37-8

“Explore Available Code Replacement Libraries” on page 37-8

“Explore Code Replacement Library Contents” on page 37-8

### About Choosing a Code Replacement Library

By default, the code generator does not use a code replacement library.

If you are considering using a code replacement library:

- 1 Explore available libraries. Identify one that best meets your application needs.
  - Consider the lists of application code replacement requirements and libraries that MathWorks provides in “What Is Code Replacement?” on page 38-2.
  - See “Explore Available Code Replacement Libraries” on page 37-8.
- 2 Explore the contents of the library. See “Explore Code Replacement Library Contents” on page 37-8.

If you do not find a suitable library and you have an Embedded Coder license, you can create a custom code replacement library.

### Explore Available Code Replacement Libraries

Select the “Code replacement library” to use for code generation from the **Configuration Parameters > Code Generation > Interface** pane. To view a description of a library, select and hover your cursor over the library name. A tooltip describes the library and lists the tables that it contains. The tooltip lists the tables in the order that the code generator searches for a function or operator match.

### Explore Code Replacement Library Contents

Use the Code Replacement Viewer to explore the content of a code replacement library.

- 1 At the command prompt, type `crviewer`.

```
>> crviewer
```

The viewer opens. To view the content of a specific library, specify the name of the library as an argument in single quotes. For example:

```
>> crviewer('GNU C99 extensions')
```

- 2** In the left pane, select the name of a library. The viewer displays information about the library in the right pane.
- 3** In the left pane, expand the library, explore the list of tables it contains, and select a table from the list. In the middle pane, the viewer displays the function and operator entries that are in that table, along with abbreviated information for each entry.
- 4** In the middle pane, select a function or operator. The viewer displays information from the table entry in the right pane.

If you select an operator entry that specifies net slope fixed-point parameters (instantiated from entry class `RTW.Tf1COperationEntryGenerator` or `RTW.Tf1COperationEntryGenerator_NetSlope`), the viewer displays an additional tab that shows fixed-point settings.

See Code Replacement Viewer for details on what the viewer displays.

- “Replace Code Generated from Simulink Models”

## Replace Code Generated from Simulink Models

This example shows how to replace generated code, using a code replacement library. Code replacement is a technique you can use to change the code that the code generator produces for functions and operators to meet application code requirements.

### Prepare for Code Replacement

- 1 Make sure that MATLAB, Simulink, Simulink Coder, and a C compiler are installed on your system. Some code replacement libraries available in your development environment can also require Embedded Coder.

To install MathWorks products, see the MATLAB installation documentation. If you have installed MATLAB and want to see which other MathWorks products are installed, in the Command Window, enter `ver`.

- 2 Identify an existing or create a Simulink model for which you want the code generator to replace code.

### Choose a Code Replacement Library

If you are not sure which library to use, explore the available libraries.

### Configure Code Generator To Use Code Replacement Library

- 1 Configure the code generator to apply a code replacement library during code generation for the model. Do one of the following:
  - In the Configuration Parameters dialog box, on the **Code Generation > Interface** pane, select a library for the “Code replacement library” parameter.
  - Set the `CodeReplacementLibrary` parameter at the command line or programmatically.
- 2 Configure the code generator to produce code only (not build an executable) so you can verify your code replacements before building an executable. Do one of the following:
  - In the Configuration Parameters dialog box, on the **Code Generation** pane, select “Generate code only”.
  - Set the `GenCodeOnly` parameter at the command line or programmatically.

## Include Code Replacement Information In Code Generation Report

If you have an Embedded Coder license, you can configure the code generator to include a code replacement section in the code generation report. The additional information can help you verify code replacements.

- 1 Configure the code generator to generate a report. In the Configuration Parameters dialog box, on the **Code Generation > Report** pane, select “Create code generation report”. Consider having the report open automatically. Select “Open report automatically”.
- 2 Include the code replacement section in the report. On the **All Parameters** tab, select “Summarize which blocks triggered code replacements”.

## Generate Replacement Code

Generate C/C++ code from the model and, if you configured the code generator accordingly, a code generation report. For example, in the model window, press **Ctrl+B**.

The code generator produces the code and displays the report.

## Verify Code Replacements

Verify code replacements by examining the generated code. It is possible that code replacement behaves differently than you expect. For example, data types that you observe in the code generator input might not match what the code generator uses as intermediate data types during an operation.

# Code Replacement for Simulink Models in Embedded Coder

---

- “What Is Code Replacement?” on page 38-2
- “Choose a Code Replacement Library” on page 38-8
- “Replace Code Generated from Simulink Models” on page 38-10

## What Is Code Replacement?

Code replacement is a technique to change the code that the code generator produces for functions and operators to meet application code requirements. For example, you can replace generated code to meet requirements such as:

- Optimization for a specific run-time environment, including, but not limited to, specific target hardware.
- Integration with existing application code.
- Compliance with a standard, such as AUTOSAR.
- Modification of code behavior, such as enabling or disabling nonfinite or inline support.
- Application- or project-specific code requirements, such as:
  - Elimination of `math.h`.
  - Elimination of system header files.
  - Elimination of calls to `memcpy` or `memset`.
  - Use of BLAS.
  - Use of a specific BLAS.

To apply this technique, configure the code generator to apply a code replacement library (CRL) during code generation. By default, the code generator does not apply a code replacement library. You can choose from the following libraries that MathWorks provides:

- GNU C99 extensions—GNU<sup>11</sup> gcc math library, which provides C99 extensions as defined by compiler option `-std=gnu99`.
- AUTOSAR 4.0—Produces code that more closely aligns with the AUTOSAR standard. Requires an Embedded Coder license.
- Intel IPP for x86-64 (Windows)—Generates calls to the Intel Performance Primitives (IPP) library for the x86-64 Windows platform.
- Intel IPP/SSE for x86-64 (Windows)—Generates calls to the IPP and Streaming SIMD Extensions (SSE) libraries for the x86-64 Windows platform.
- Intel IPP for x86-64 (Windows using MinGW compiler)—Generates calls to the IPP library for the x86-64 Windows platform and MinGW compiler.

---

11. GNU is a registered trademark of the Free Software Foundation.

- Intel IPP/SSE for x86-64 (Windows using MinGW compiler)—Generates calls to the IPP and SSE libraries for the x86-64 Windows platform and MinGW compiler.
- Intel IPP for x86/Pentium (Windows)—Generates calls to the IPP library for the x86/Pentium Windows platform.
- Intel IPP/SSE for x86/Pentium (Windows)—Generates calls to the Intel Performance IPP and SSE libraries for the x86/Pentium Windows platform.
- Intel IPP for x86-64 (Linux)—Generates calls to the IPP library for the x86-64 Linux platform.
- Intel IPP/SSE with GNU99 extensions for x86-64 (Linux)—Generates calls to the GNU libraries for IPP and SSE, with GNU C99 extensions, for the x86-64 Linux platform.

Libraries that include GNU99 extensions are intended for use with the GCC compiler. If use one of those libraries with another compiler, generated code might not compile.

Depending on the product licenses that you have, other libraries might be available. If you have an Embedded Coder license, you can view and choose from other libraries and you can create custom code replacement libraries.

## Code Replacement Libraries

A *code replacement library* consists of one or more code replacement tables that specify application-specific implementations of functions and operators. For example, a library for a specific embedded processor specifies function and operator replacements that optimize generated code for that processor.

A *code replacement table* contains one or more *code replacement entries*, with each entry representing a potential replacement for a function or operator. Each entry maps a *conceptual representation* of a function or operator to an *implementation representation* and priority.

Table Entry Component	Description
Conceptual representation	<p>Identifies the table entry and contains match criteria for the code generator. Consists of:</p> <ul style="list-style-type: none"> <li>• Function name or a key. The function name identifies most functions. For operators and some functions, a series of characters, called a key identifies a function or operator. For example, function name 'COS' and operator key 'RTW_OP_ADD'.</li> <li>• Conceptual arguments that observe code generator naming ('y1', 'u1', 'u2', ...), with corresponding I/O types (output or input) and data types.</li> <li>• Other attributes, such as an algorithm, fixed-point saturation, and rounding modes, which identify matching criteria for the function or operator.</li> </ul>
Implementation representation	<p>Specifies replacement code. Consists of:</p> <ul style="list-style-type: none"> <li>• Function name. For example, 'cos_db1' or 'u8_add_u8_u8'.</li> <li>• Implementation arguments, with corresponding I/O types (output or input) and data types.</li> <li>• Parameters that provide additional implementation details, such as header and source file names and paths of build resources.</li> </ul>

Table Entry Component	Description
Priority	Defines the entry priority relative to other entries in the table. The value can range from 0 to 100, with 0 being the highest priority. If multiple entries have the same priority, the code generator uses the first match with that priority.

When the code generator looks for a match in a code replacement library, it creates and populates a *call site object* with the function or operator conceptual representation. If a match exists, the code generator uses the matched code replacement entry populated with the implementation representation and uses it to generate code.

The code generator searches the tables in a code replacement library for a match in the order that the tables appear in the library. If the code generator finds multiple matches within a table, the priority determines the match. The code generator uses a higher-priority entry over a similar entry with a lower priority.

## Code Replacement Terminology

Term	Definition
Cache hit	A code replacement entry for a function or operator, defined in the specified code replacement library, for which the code generator finds a match.
Cache miss	A conceptual representation of a function or operator for which the code generator does not find a match.
Call site object	Conceptual representation of a function or operator that the code generator uses when it encounters a call site for a function or operator. The code generator uses the object to query the code replacement library for a conceptual representation match. If a match exists, the code generator returns a code replacement object, fully populated with the conceptual representation, implementation representation, and priority, and uses that object to generate replacement code.
Code replacement library	One or more code replacement tables that specify application-specific implementations of functions

Term	Definition
	and operators. When configured to use a code replacement library, the code generator uses criteria defined in the library to search for matches. If a match is found, the code generator replaces code that it generates by default with application-specific code defined in the library.
Code replacement table	One or more code replacement table entries. Provides a way to group related or shared entries for use in different libraries.
Code replacement entry	Represents a potential replacement for a function or operator. Maps a conceptual representation of a function or operator to an implementation representation and priority.
Conceptual argument	Represents an input or output argument for a function or operator being replaced. Conceptual arguments observe naming conventions ('y1', 'u1', 'u2', ...) and data types familiar to the code generator.
Conceptual representation	Represents match criteria that the code generator uses to qualify functions and operators for replacement. Consists of: <ul style="list-style-type: none"> <li>• Function or operator name or key</li> <li>• Conceptual arguments with type, dimension, and complexity specification for inputs and output</li> <li>• Attributes, such as an algorithm and fixed-point saturation and rounding modes</li> </ul>
Implementation argument	Represents an input or output argument for a C or C++ replacement function. Implementation arguments observe C/C++ name and data type specifications.

Term	Definition
Implementation representation	<p>Specifies C or C++ replacement function prototype. Consists of:</p> <ul style="list-style-type: none"> <li>• Function name (for example, 'cos_dbl' or 'u8_add_u8_u8')</li> <li>• Implementation arguments specifying type, type qualifiers, and complexity for the function inputs and output</li> <li>• Parameters that provide build information, such as header and source file names and paths of build resources and compile and link flags</li> </ul>
Key	<p>Identifies a function or operator that is being replaced. A function name or key appears in the conceptual representation of a code replacement entry. The key RTW_OP_ADD identifies the addition operator.</p>
Priority	<p>Defines the match priority for a code replacement entry relative to other entries, which have the same name and conceptual argument list, within a code replacement library. The priority can range from 0 to 100, with 0 being the highest priority. The default is 100. If a library provides two implementations for a function or operator, the implementation with the higher priority shadows the one with the lower priority.</p>

## Code Replacement Limitations

Code replacement verification — It is possible that code replacement behaves differently than you expect. For example, data types that you observe in code generator input might not match what the code generator uses as intermediate data types during an operation. Verify code replacements by examining generated code.

## Related Examples

## Choose a Code Replacement Library

### In this section...

“About Choosing a Code Replacement Library” on page 38-8

“Explore Available Code Replacement Libraries” on page 38-8

“Explore Code Replacement Library Contents” on page 38-8

### About Choosing a Code Replacement Library

By default, the code generator does not use a code replacement library.

If you are considering using a code replacement library:

- 1 Explore available libraries. Identify one that best meets your application needs.
  - Consider the lists of application code replacement requirements and libraries that MathWorks provides in “What Is Code Replacement?” on page 38-2.
  - See “Explore Available Code Replacement Libraries” on page 37-8.
- 2 Explore the contents of the library. See “Explore Code Replacement Library Contents” on page 37-8.

If you do not find a suitable library and you have an Embedded Coder license, you can create a custom code replacement library.

### Explore Available Code Replacement Libraries

Select the “Code replacement library” to use for code generation from the **Configuration Parameters > Code Generation > Interface** pane. To view a description of a library, select and hover your cursor over the library name. A tooltip describes the library and lists the tables that it contains. The tooltip lists the tables in the order that the code generator searches for a function or operator match.

### Explore Code Replacement Library Contents

Use the Code Replacement Viewer to explore the content of a code replacement library.

- 1 At the command prompt, type `crviewer`.

```
>> crviewer
```

The viewer opens. To view the content of a specific library, specify the name of the library as an argument in single quotes. For example:

```
>> crviewer('GNU C99 extensions')
```

- 2** In the left pane, select the name of a library. The viewer displays information about the library in the right pane.
- 3** In the left pane, expand the library, explore the list of tables it contains, and select a table from the list. In the middle pane, the viewer displays the function and operator entries that are in that table, along with abbreviated information for each entry.
- 4** In the middle pane, select a function or operator. The viewer displays information from the table entry in the right pane.

If you select an operator entry that specifies net slope fixed-point parameters (instantiated from entry class `RTW.Tf1COperationEntryGenerator` or `RTW.Tf1COperationEntryGenerator_NetSlope`), the viewer displays an additional tab that shows fixed-point settings.

See Code Replacement Viewer for details on what the viewer displays.

## Replace Code Generated from Simulink Models

This example shows how to replace generated code, using a code replacement library. Code replacement is a technique you can use to change the code that the code generator produces for functions and operators to meet application code requirements.

### Prepare for Code Replacement

- 1 Make sure that MATLAB, Simulink, Simulink Coder, and a C compiler are installed on your system. Some code replacement libraries available in your development environment can also require Embedded Coder.

To install MathWorks products, see the MATLAB installation documentation. If you have installed MATLAB and want to see which other MathWorks products are installed, in the Command Window, enter `ver`.

- 2 Identify an existing or create a Simulink model for which you want the code generator to replace code.

### Choose a Code Replacement Library

If you are not sure which library to use, explore the available libraries.

### Configure Code Generator To Use Code Replacement Library

- 1 Configure the code generator to apply a code replacement library during code generation for the model. Do one of the following:
  - In the Configuration Parameters dialog box, on the **Code Generation > Interface** pane, select a library for the “Code replacement library” parameter.
  - Set the `CodeReplacementLibrary` parameter at the command line or programmatically.
- 2 Configure the code generator to produce code only (not build an executable) so you can verify your code replacements before building an executable. Do one of the following:
  - In the Configuration Parameters dialog box, on the **Code Generation** pane, select “Generate code only”.
  - Set the `GenCodeOnly` parameter at the command line or programmatically.

## Include Code Replacement Information In Code Generation Report

If you have an Embedded Coder license, you can configure the code generator to include a code replacement section in the code generation report. The additional information can help you verify code replacements.

- 1 Configure the code generator to generate a report. In the Configuration Parameters dialog box, on the **Code Generation > Report** pane, select “Create code generation report”. Consider having the report open automatically. Select “Open report automatically”.
- 2 Include the code replacement section in the report. On the **All Parameters** tab, select “Summarize which blocks triggered code replacements”.

## Generate Replacement Code

Generate C/C++ code from the model and, if you configured the code generator accordingly, a code generation report. For example, in the model window, press **Ctrl+B**.

The code generator produces the code and displays the report.

## Verify Code Replacements

Verify code replacements by examining the generated code. It is possible that code replacement behaves differently than you expect. For example, data types that you observe in the code generator input might not match what the code generator uses as intermediate data types during an operation.

## About External Code Integration

The code generator includes a variety of approaches for integrating legacy or custom code with generated code. *Legacy code* is existing handwritten code or code for environments that you need to integrate with code produced by the code generator. *Custom code* is legacy code or other user-specified lines of code that you need to include in the code generator build process. Collectively, legacy and custom code are called *external code*.

You can achieve external code integration in two ways. You can import existing external code into code produced by code generation technology or you can export generated code into an existing external code base. For example, you might want to use generated code as a plug-in function.

See “Choose External Code Integration Approach” for guidance on choosing an approach based on your application.

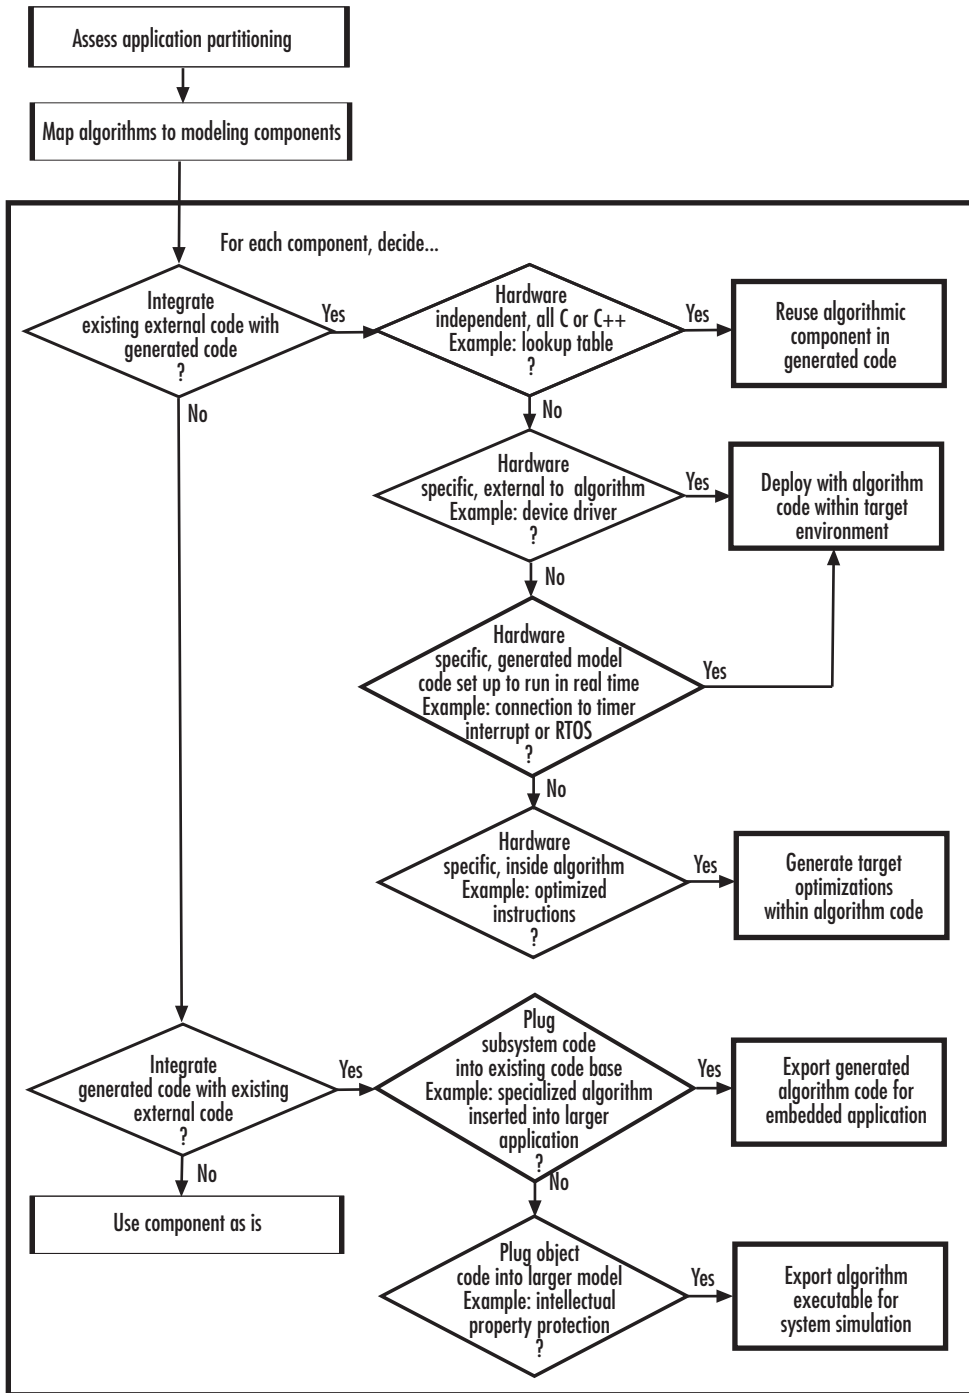

## Choose External Code Integration Approach

Based on application goals, external code integration can be characterized as follows:

- Import external code into generated code
  - Reuse of an algorithmic component in generated code
  - Deploy an application with algorithm code within the target environment
  - Generate target optimizations within algorithm code
- Export generated code into external code
  - Export generated algorithm code for an embedded application
  - Export an algorithm executable for system simulation

Use the following flow diagram to prepare for integration and choose integration paths that best map to your application components. As the diagram shows, before you make integration decisions, assess your application architecture and partition it as much as possible. Working with smaller units makes it easier to map algorithms to modeling components and decide how to integrate the components. For each component, use the highlighted area of the flow diagram to identify the most applicable type of integration. Then, see the information provided for the corresponding type.

**In this section...**

- “Export Generated Algorithm Code for Embedded Applications” on page 39-18
- “Export Algorithm Executables for System Simulation” on page 39-20
- “Modify External Code for Language Compatibility” on page 39-20

## Reuse Algorithmic Components in Generated Code

The approach you choose to reuse algorithmic components in generated code depends on the language used to program the components.

- “Reusable Algorithmic Components” on page 39-5
- “Integrate External MATLAB Code” on page 39-6
- “Integrate External C or C++ Code” on page 39-8
- “Integrate Fortran Code” on page 39-12
- “Integration Considerations for Reusable Algorithmic Components” on page 39-12

### Reusable Algorithmic Components

You have several options for integrating reusable algorithmic components with the generated code. Such components are hardware-independent and can be verified with Simulink simulation. Examples of such components include:

- Lookup tables
- Math utilities
- Digital filters
- Special integrators
- Proportional–integral–derivative (PID) control modules

Some integration options allow you to integrate external code for a reusable component directly, while other options convert external code to modeling elements. To take full advantage of Model-Based Design, convert code to modeling elements which you can then use in the Simulink or Stateflow simulation environment. Doing so enables you to simulate and generate code for an integrated component and, for example, use software-

in-the-loop (SIL) or processor-in-the-loop (PIL) testing to verify whether algorithm behavior is the same in both environments.

### **Integrate External MATLAB Code**

The following diagram identifies common characteristics or requirements for reusable algorithmic components written in MATLAB code and recommends solutions in each case. The table that follows the diagram provides more detail. Collectively, the diagram and table help you choose the best solution for your application and find more related information.

	If...	Then...	For More Information, See...
1	The algorithm must model continuous state dynamics	Write a MATLAB S-function and, for generating code, a corresponding TLC	<ul style="list-style-type: none"> <li>• “MATLAB S-Functions”</li> <li>• “Target Language Compiler”</li> </ul>

	If...	Then...	For More Information, See...
		file for the algorithm and add the S-function to your model	
2	You want to embed MATLAB code directly in the model	Add a MATLAB Function block to the model and embed the MATLAB code in that block	MATLAB Function
3	You need to optimize runtime performance or prepare to deploy the code in an embedded system	Use MATLAB Coder software to generate a C source code, executable, or library file	“Getting Started with MATLAB Coder”
4	You have C or C++ programming experience and the external MATLAB code is compact and primarily uses C or C++ constructs	Convert the MATLAB code to C or C++ code manually and choose an option for integrating the C or C++ code	“Integrate External C or C++ Code” on page 39-8
5	Sections of the external MATLAB code map to built-in blocks	Develop the algorithm in the context of a model, using the applicable built in blocks	<ul style="list-style-type: none"> <li>• “Model Editing Fundamentals” and “Component-Based Modeling”</li> <li>• “Supported Products and Block Usage”</li> </ul>

To embed external MATLAB code in a MATLAB Function block or generate C or C++ code from MATLAB code with the MATLAB Coder software, the MATLAB code must use functions suitable for code generation.

### Integrate External C or C++ Code

The following diagram identifies common characteristics or requirements for reusable algorithmic components written in C or C++ code and recommends solutions in each case. The table that follows the diagram provides more detail. Collectively, the diagram and table will help you choose the best solution for your application and find more related information.

	If...	Then...	For More Information, See...
1	The external code will simulate in a Stateflow environment	Use the Stateflow custom code interface	<ul style="list-style-type: none"> <li>sf_custom</li> <li>“Call Custom C Code Functions” in the Stateflow documentation</li> </ul>
2	Performance is not an issue and you want to quickly embed a call to external C or C++ code in a model	Call the C or C++ code with the <code>coder.ceval</code> function from a MATLAB Function block	<ul style="list-style-type: none"> <li><code>coder.ceval</code> function description</li> <li>MATLAB Function block</li> </ul>
3	You want maximum flexibility and the	Write an S-function and TLC file manually	<ul style="list-style-type: none"> <li>“C S-Function Examples” and “C++ S-Function Examples”</li> </ul>

	<b>If...</b>	<b>Then...</b>	<b>For More Information, See...</b>
	ability to control what code is generated; the application requires function overloading or you need to format data definitions such that they are compatible with a function		<ul style="list-style-type: none"> <li>• “S-Function Basics”</li> <li>• “S-Functions and Code Generation” on page 39-99</li> </ul>
4	You want ease of use with moderate flexibility to control what code gets generated, typically for discrete applications; you have C or C++ programming experience, but prefer to generate the files that add the code to a model; optimizing generated code is essential	Use the Legacy Code Tool to generate the S-function and TLC files; optionally, you can fine-tune the generated files manually to better meet application needs	<ul style="list-style-type: none"> <li>• “Integrate External C Functions That Implement N-Dimensional Table Lookups”</li> <li>• “Integrate C Functions Using Legacy Code Tool” in the Simulink documentation</li> <li>• “Build S-Function With Legacy Code Tool”</li> </ul>
5	You want ease of use with basic flexibility to control what code gets generated, typically for mixed discrete and continuous-time applications; programming experience is limited or the external code requires a Fixed-Point block interface	Use the S-Function Builder to generate the S-function and TLC files; optionally, you can fine-tune the generated files manually to better meet application needs	“Build S-Functions Automatically” in the Simulink documentation

If you must control how code generation technology declares, stores, and represents data in generated code, you can do so by designing (creating) and applying custom storage classes (CSCs) if you have an Embedded Coder license. For information on CSCs, see

the examples `rtwdemo_cscpredef`, `rtwdemo_importstruct`, `rtwdemo_advsc`, and “Custom Storage Classes” in the Embedded Coder documentation.

## Integrate Fortran Code

The following diagram shows that to integrate external Fortran code as reusable algorithmic components you must integrate the code by writing an S-function and corresponding TLC file.

For information, see “Fortran S-Function Examples” and “Fortran S-Functions”.

## Integration Considerations for Reusable Algorithmic Components

---

**Note:** Solutions marked with *EC only* require an Embedded Coder license.

If...	Consider...	For More Information, See...
Generated code must use math functions and operators that are consistent with imported external code	<i>EC only</i> —Using the Code Replacement Tool, code replacement library (CRL) API, and Code Replacement Viewer to create, examine, validate, and register function and operator code replacement tables	<ul style="list-style-type: none"> <li>“Code Replacement Customization”</li> <li>“Optimize Generated Code By Developing and Using Code Replacement Libraries - Simulink®”</li> </ul>
Generated code must share data with imported external code	Using data creation and management technologies, such as Simulink data objects,	<ul style="list-style-type: none"> <li>“Data Representation”</li> </ul>

If...	Consider...	For More Information, See...
	alias and numeric data types, and data type replacement to match data type, formatting, and storage that is consistent with that used by the imported external code	<ul style="list-style-type: none"> <li>• “Exchange and Reuse Parameter Data Between Generated Code and Existing Code” on page 22-11</li> <li>• “Introduction to Custom Storage Classes” on page 22-2</li> <li>• “Configure Generated Code According to Interface Control Document” on page 22-98</li> </ul>
Style and format of identifiers in generated code must be consistent with style and format applied in imported external code	In the Configuration Parameters dialog box, on the <b>Symbols</b> pane, configure identifier naming for the generated code	<ul style="list-style-type: none"> <li>• <code>rtwdemo_symbols</code></li> <li>• <code>rtwdemo_namerules</code></li> <li>• “Construction of Generated Identifiers” and “Customize Generated Identifier Naming Rules” on page 36-15 in the Embedded Coder documentation</li> </ul>
Use of comments in generated code must match the use of comments in imported external code	In the Configuration Parameters dialog box, on the <b>Comments</b> pane, configure comments for the generated code	<ul style="list-style-type: none"> <li>• <code>rtwdemo_comments</code></li> <li>• “Configure Code Comments” and “Add Custom Comments to Generated Code” on page 36-3 in the Embedded Coder documentation</li> </ul>
Style of code, such as style and usage of parentheses, must be match the style used in imported external code	<i>EC only</i> —In the Configuration Parameters dialog box, on the <b>Code Style</b> pane, configure the style for the generated code	<ul style="list-style-type: none"> <li>• <code>rtwdemo_parentheses</code></li> <li>• “Control Code Style” on page 36-35 in the Embedded Coder documentation</li> </ul>

## Deploy Algorithm Code Within a Target Environment

Code generation technology can generate a single set of application source files from an algorithm model and integrated external C or C++ code that supports the target environment hardware. For example, you might have a working device driver that you

want to integrate with algorithmic code that has to read data from and write data to the I/O device the driver supports. Typically, a deployed model algorithm calls out to the external code.

The following diagram identifies common characteristics or requirements for a target environment in which generated algorithm code might be deployed and recommends solutions. The table that follows the diagram provides more detail. Collectively, the diagram and table help you choose the best solution for your application and find more related information.

---

**Note:** Solutions marked with *EC only* require an Embedded Coder license.

---

	If You Need To...	Then...	For More Information, See...
1	Embed a call to hardware-specific code, such as a device driver, within generated algorithm code	Use the Legacy Code Tool	<ul style="list-style-type: none"> <li>• “Device Drivers”</li> <li>• “Integrate C Functions Using Legacy Code Tool” in the Simulink documentation</li> <li>• “Build S-Function With Legacy Code Tool”</li> </ul>
2	Insert target-specific C or C++ code into entry-point functions that the code generator produces for a model with a high level of control over code placement; for example, inserting startup, initialization, or termination code	Use Custom Code blocks	<ul style="list-style-type: none"> <li>• <code>rtwdemo_slcustcode</code></li> <li>• “Insert Code into Model Custom Code Blocks”</li> </ul>
3	Insert application-specific C or C++ code—near the top of the generated source code or header file or inside the model initialization or termination function—or files for the build process—source, header, library—for the external code	Configure files and data for the external code environment by entering code and file specifications for parameters on the <b>Code Generation &gt; Interface</b> pane of the Configuration Parameters dialog box	<ul style="list-style-type: none"> <li>• “Integrate Generated Code with Custom Code in External Environment”</li> <li>• “Configure Model for External Code Integration”</li> </ul>

	If You Need To...	Then...	For More Information, See...
4	Control the organization and format of code files generated for a model—for example, placement of code in sections, inclusion of banners, calls to generated entry-point functions, generation of a main program module	<i>EC only</i> —Use the custom file processing components—code generation template (CGT) files, code template API, and custom file processing (CFP) templates (the API and CFP templates require TLC programming knowledge)	<ul style="list-style-type: none"> <li>• <code>rtwdemo_codetemplate</code></li> <li>• “Customize Code Organization and Format” on page 36-53 in the Embedded Coder documentation</li> </ul>
5	Control how the code generator declares, stores, and represents signals, tunable parameters, block states, and data objects in generated code	<i>EC only</i> — Design (create) and apply custom storage classes	<ul style="list-style-type: none"> <li>• “Introduction to Custom Storage Classes” on page 22-2</li> <li>• “Control Signals and States in Code by Applying Storage Classes” on page 18-120</li> <li>• “Block Parameter Representation in the Generated Code” on page 18-43</li> </ul>
6	Insert comments or <b>pragmas</b> in generated code to identify memory for custom storage classes or model- or subsystem-level functions and internal data	<i>EC only</i> — Use the memory section capability	<ul style="list-style-type: none"> <li>• <code>rtwdemo_memsec</code></li> <li>• “Control Data and Function Placement in Memory by Inserting Pragmas” on page 26-2</li> </ul>
7	Set up generated algorithmic code to run in real time—within the context of a real-time operating system (RTOS) or on hardware that is not running an operating system (bare board)	<i>EC only</i> —Generate and customize an ERT target main (harness) program module ( <code>ert_main.c</code> or <code>ert_main.cpp</code> ) for the model	<ul style="list-style-type: none"> <li>• “Deployment”</li> <li>• “Deploy Generated Standalone Executables To Target Hardware” on page 49-2</li> </ul>

## Export Generated Algorithm Code for Embedded Applications

You have multiple options for configuring and preparing a model or subsystem so that you can plug its generated source code into an existing external code base.

Scan the first column of the following table to identify tasks that apply to the algorithm code you want to export. For each task that applies, the information in the corresponding row describes how to achieve the goal, using code generation technology.

---

**Note:** Solutions marked with *EC only* require an Embedded Coder license.

---

If You Need To...	Then...	For More Information, See...
Insert C or C++ code into specific entry-point functions that the code generator produces for interfacing with the external code	Use Custom Code blocks	<ul style="list-style-type: none"> <li>• <code>rtwdemo_slcstcode</code></li> <li>• “Insert Code into Model Custom Code Blocks”</li> </ul>
Pass composite data	Represent the data in the model as a vector or structure	<ul style="list-style-type: none"> <li>• <code>rtwdemo_scalarrep</code></li> <li>• <code>rtwdemo_slbus</code></li> <li>• “Group Signals into Structures in the Generated Code Using Buses”</li> <li>• “Use memcpy Function to Optimize Generated Code for Vector Assignments”</li> </ul>
Read from or write to a specific region or area of memory	<i>EC only</i> — Set up a Data Store Memory block in the model to represent the area of memory and define the area with the built-in advanced custom storage class (CSC) <code>GetSet</code>	“Data Stores in Generated Code” on page 18-31
Generate a C++ class interface to the model code — encapsulating model data as properties	Select <code>C++ class</code> code interface packaging in the Configuration Parameters dialog box or	• “Simple Use of C++ Class Control” on page 25-24

If You Need To...	Then...	For More Information, See...
and model entry-point functions as methods	programmatically with MATLAB commands — customizing the generated C++ class interface is <i>EC only</i>	<ul style="list-style-type: none"> <li>• “Control Generation of C++ Class Interfaces” on page 25-23 in the Embedded Coder documentation</li> </ul>
Control how the code generator produces function prototypes — arguments, argument order, and data types—for a model (for example, so the prototypes match the external code)	<i>EC only</i> — Configure function prototypes for the model by clicking the <b>Configure Model Functions</b> button on the <b>Code Generation &gt; Interface</b> pane of the Configuration Parameters dialog box and entering data in the Model Interface dialog box; alternatively, configure the function prototypes programmatically in the MATLAB command window or with a script	<ul style="list-style-type: none"> <li>• “Sample Procedure for Configuring Function Prototypes” on page 25-11</li> <li>• “Control Generation of Function Prototypes” on page 25-2 in the Embedded Coder documentation</li> </ul>
Insert application-specific C or C++ code —near the top of the generated source code or header file or inside the model initialization or termination function—or files for the build process —source, header, library—for the external code	Configure files and data for the external code environment by entering code and file specifications for parameters on the <b>Code Generation &gt; Interface</b> pane of the Configuration Parameters dialog box	<ul style="list-style-type: none"> <li>• “Integrate Generated Code with Custom Code in External Environment”</li> <li>• “Configure Model for External Code Integration”</li> </ul>

If You Need To...	Then...	For More Information, See...
Generate code, which is to be integrated with an existing C code base, for a function-call or virtual subsystem	<i>EC only</i> — Review and adjust for exported subsystem requirements, configure the parent model to use an ERT target, and right-click build the subsystem block using the <b>C/C++ Code &gt; Export Functions</b> menu item	<ul style="list-style-type: none"> <li>• “Techniques for Exporting Function-Call Subsystems” on page 50-4</li> <li>• <code>rtwdemo_exporting_functions</code></li> <li>• “Export Function-Call Subsystems” on page 50-2 in the Embedded Coder documentation</li> </ul>

## Export Algorithm Executables for System Simulation

If you have an Embedded Coder license, you can use an ERT shared library target (`ert_shrlib.tlc`) to build a Windows dynamic link library (`.dll`), a UNIX shared object (`.so`) file, or a Macintosh OS X dynamic library (`.dylib`) file from a model. An application, which runs on a Windows, UNIX, or Macintosh OS X system, can then load the shared library file. You can upgrade a shared library without having to recompile applications that use it.

Uses of shared library files include:

- Adding a software component to an application for system simulation
- Reusing off-the-shelf software modules among applications on a host system
- Hiding source code (intellectual property) for software shared with a vendor

For an example, see `rtwdemo_shrlib`. For more information, see “Package Generated Code as Shared Object Libraries” on page 47-2 in the Embedded Coder documentation.

## Modify External Code for Language Compatibility

If you need to integrate external C code with generated C++ code or vice versa, you must modify your external code to be language compatible with the generated code. Options for making the code language compatible include:

- Writing or rewriting the legacy or custom code in the same language as the generated code.

- If the generated code is in C++ and your legacy or custom code is in C, for each C function, create a header file that prototypes the function, using the following format:

```
#ifdef __cplusplus
extern "C" {
#endif
int my_c_function_wrapper();
#ifdef __cplusplus
}
#endif
```

The prototype serves as a function wrapper. If your compiler supports C++ code, the value `__cplusplus` is defined. The linkage specification `extern "C"` specifies C linkage with no name mangling.

- If the generated code is in C and your legacy or custom code is in C++, include an `extern "C"` linkage specification in each `.cpp` file. For example, the following shows a portion of C++ code in the file `my_func.cpp`:

```
extern "C" {

int my_cpp_function()
{
 ...
}
}
```

## Automate S-Function Generation with S-Function Builder

The **Generate S-function** feature automates the process of generating an S-function from a subsystem. In addition, the **Generate S-function** feature presents a display of parameters used within the subsystem, and lets you declare selected parameters tunable.

As an example, consider `SourceSubsys`, the same subsystem illustrated in the example “Create S-Function Blocks from a Subsystem” on page 46-36. The objective is to automatically extract `SourceSubsys` from the model and build an S-Function block from it, as in the previous example. In addition, the workspace variable `K`, which is the gain factor of the Gain block within `SourceSubsys` (as shown in the Gain block parameter dialog box below), is declared and generated as a tunable variable.

To auto-generate an S-function from `SourceSubsys` with tunable parameter `K`,

- 1 With the `SourceSubsys` model open, click the subsystem to select it.
- 2 From the **Code** menu, select **C/C++ Code** > **Generate S-Function**. This menu item is enabled when a subsystem is selected in the current model.

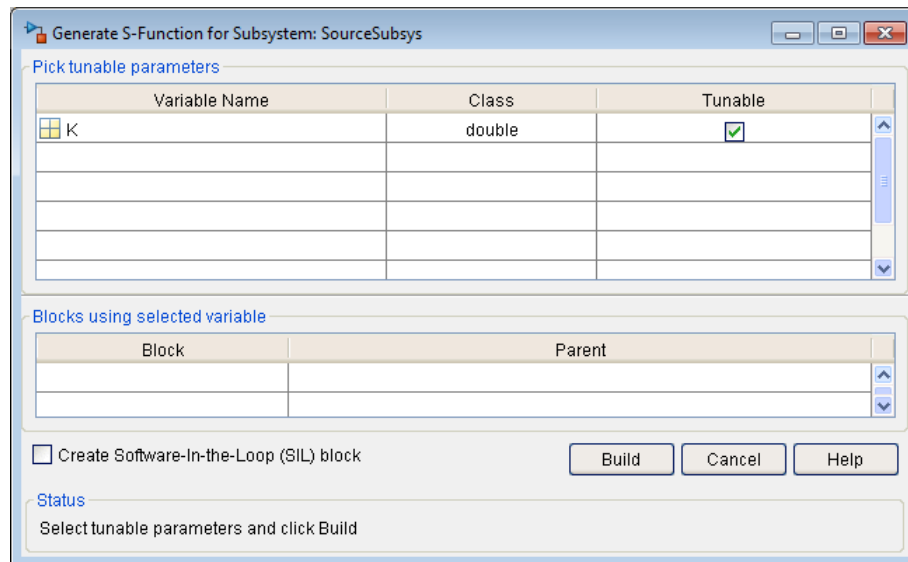

Alternatively, you can right-click the subsystem and select **C/C++ Code** > **Generate S-Function** from the subsystem block's context menu.

- 3 The **Generate S-Function** window is displayed (see the next figure). This window shows variables (or data objects) that are referenced as block parameters in the subsystem, and lets you declare them as tunable.

The upper pane of the window displays three columns:

- **Variable Name:** name of the parameter.
- **Class:** If the parameter is a workspace variable, its data type is shown. If the parameter is a data object, its name and class is shown
- **Tunable:** Lets you select tunable parameters. To declare a parameter tunable, select the check box. In the next figure, the parameter K is declared tunable.

When you select a parameter in the upper pane, the lower pane shows the blocks that reference the parameter, and the parent system of each such block.

### Generate S-Function Window

- 4 After selecting tunable parameters, click the **Build** button. This initiates code generation and compilation of the S-function, using the S-function target. The **Create New Model** option is automatically enabled.
- 5 The build process displays status messages in the MATLAB Command Window. When the build completes, the tunable parameters window closes, and a new untitled model window opens.

- 6 The model window contains an S-Function block with the same name as the subsystem from which the block was generated (in this example, `SourceSubsys`). Optionally, you can save the generated model containing the generated block.
- 7 The generated code for the S-Function block is stored in the current working folder. The following files are written to the top level folder:
  - `subsys_sf.c` or `.cpp`, where *subsys* is the subsystem name (for example, `SourceSubsys_sf.c`)
  - `subsys_sf.h`
  - `subsys_sf.mexext`, where *mexext* is a platform-dependent MEX-file extension (for example, `SourceSubsys_sf.mexw64`)

The source code for the S-function is written to the subfolder `subsys_sfcn_rtw`. The top-level `.c` or `.cpp` file is a stub file that simply contains an include directive that you can use to interface other C/C++ code to the generated code.

---

**Note:** For a list of files required to deploy your S-Function block for simulation or code generation, see “Required Files for S-Function Deployment” on page 46-34.

---

- 8 The generated S-Function block has inports and outports whose widths and sample times correspond to those of the original model.

The following code, from the `mdlOutputs` routine of the generated S-function code (in `SourceSubsys_sf.c`), shows how the tunable variable `K` is referenced by using calls to the MEX API.

```
static void mdlOutputs(SimStruct *S, int_T tid)
```

```

...
/* Gain: '<S1>/Gain' incorporates:
 * Sum: '<S1>/Sum'
 */
rtb_Gain_n[0] = (rtb_Product_p + (((const
real_T**)ssGetInputPortSignalPtrs(S, 2))[0]))) * ((real_T
*)(mxGetData(K(S))));
rtb_Gain_n[1] = (rtb_Product_p + (((const
real_T**)ssGetInputPortSignalPtrs(S, 2))[1]))) * ((real_T
*)(mxGetData(K(S))));

```

- In automatic S-function generation, the **Use Value for Tunable Parameters** option is cleared or at the command line is set to 'off'.
- Use a MEX S-function wrapper only in the MATLAB version in which the wrapper is created.

If you specify paths and files with absolute

## Macro Parameters

Suppose that you apply a custom storage class such as `Define` to a `Simulink.Parameter` object so that the parameter appears as a macro in the generated code. If you use the parameter object inside a subsystem from which you generate an ERT S-function, you cannot select the parameter object as a tunable parameter. Instead, the S-function code generator applies the custom storage class to the parameter object. This generation of macros in the S-function code allows you to generate S-functions from subsystems that contain variant elements, such as Variant Subsystem blocks, that you configure to produce preprocessor conditionals in the generated code. However, you cannot change the value of the parameter during simulation of the S-function.

To select the parameter object as a tunable parameter, apply a different storage class or custom storage class. Custom storage classes that treat parameters as macros include `Define`, `ImportedDefine`, `CompilerFlag`, and custom storage classes that you create by setting **Data initialization** to **Macro** in the Custom Storage Class Designer. If you use a non-macro storage class or custom storage class, you cannot use the parameter object as a variant control variable and generate preprocessor conditionals.

If you apply a custom storage class that treats the parameter object as an imported macro, provide the macro definition before you generate the ERT S-function. For example, suppose you apply the custom storage class `ImportedDefine` to a `Simulink.Parameter` object, and use the parameter object as a variant control variable in the subsystem. If you set the custom attribute `HeaderFile` to 'myHdr.h', when you

generate the S-function, place the custom header file `myHdr.h` in the current folder. The generated S-function uses the macro value from your header file instead of the value from the `Value` property of the parameter object.

To use a macro that you define through a compiler option, for example by applying the custom storage class `CompilerFlag`, use the model configuration parameter **Configuration Parameters > Code Generation > Custom Code > Additional build information > Defines** to specify the compiler option. For more information, see [Code Generation Pane: Custom Code: Additional Build Information: Defines](#).

# Build S-Function With Legacy Code Tool

## Legacy Code Tool and Code Generation

You can use the Simulink Legacy Code Tool to automatically generate fully inlined C MEX S-functions for legacy or custom code that is optimized for embedded components, such as device drivers and lookup tables, that call existing C or C++ functions.

---

**Note:** The Legacy Code Tool can interface with C++ functions, but not C++ objects. For a work around so that the tool can interface with C++ objects, see “Legacy Code Tool Limitations” in the Simulink documentation.

---

You can use the tool to:

- Compile and build the generated S-function for simulation.
- Generate a masked S-Function block that is configured to call the existing external code.

If you want to include these types of S-functions in models for which you intend to generate code, you must use the tool to generate a TLC block file. The TLC block file specifies how the generated code for a model calls the existing C or C++ function.

If the S-function depends on files in folders other than the folder containing the S-function dynamically loadable executable file, and you want to maintain those dependencies for building a model that includes the S-function, use the tool to also generate an `rtwmakecfg.m` file for the S-function. For example, for some applications, such as custom targets, you might want to locate files in a target-specific location. The build process looks for the generated file `rtwmakecfg.m` in the same folder as the S-function dynamically loadable executable and calls the `rtwmakecfg` function if the software finds the file.

For more information, see “Integrate C Functions Using Legacy Code Tool” in the Simulink documentation.

## Generate Inlined S-Function Files for Code Generation

Depending on your application's code generation requirements, to generate code for a model that uses the S-function, you can choose to do either of the following:

- Generate one `.cpp` file for the inlined S-function. In the Legacy Code Tool data structure, set the value of the `Options.singleCPPMexFile` field to `true` before generating the S-function source file from your existing C function. For example:

```
def.Options.singleCPPMexFile = true;
legacy_code('sfcn_cmex_generate', def);
```

- Generate a source file and a TLC block file for the inlined S-function. For example:

```
def.Options.singleCPPMexFile = false;
legacy_code('sfcn_cmex_generate', def);
legacy_code('sfcn_tlc_generate', def);
```

### **singleCPPMexFile Limitations**

You cannot set the `singleCPPMexFile` field to `true` if

- `Options.language='C++'`
- You use one of the following Simulink objects with the `IsAlias` property set to `true`:
  - `Simulink.Bus`
  - `Simulink.AliasType`
  - `Simulink.NumericType`
- The Legacy Code Tool function specification includes a `void*` or `void**` to represent scalar work data for a state argument
- `HeaderFiles` field of the Legacy Code Tool structure specifies multiple header files

## **Apply Code Style Settings to Legacy Functions**

To apply the model configuration parameters for code style to a legacy function:

- 1 Initialize the Legacy Code Tool data structure. For example:

```
def = legacy_code('initialize');
```

- 2 In the data structure, set the value of the `Options.singleCPPMexFile` field to `true`. For example:

```
def.Options.singleCPPMexFile = true;
```

To verify the setting, enter:

```
def.Options.singleCPPMexFile
```

### singleCPPMexFile Limitations

You cannot set the `singleCPPMexFile` field to `true` if

- `Options.language='C++'`
- You use one of the following Simulink objects with the `IsAlias` property set to `true`:
  - `Simulink.Bus`
  - `Simulink.AliasType`
  - `Simulink.NumericType`
- The Legacy Code Tool function specification includes a `void*` or `void**` to represent scalar work data for a state argument
- `HeaderFiles` field of the Legacy Code Tool structure specifies multiple header files

### Address Dependencies on Files in Different Locations

By default, the Legacy Code Tool assumes that files on which an S-function depends reside in the same folder as the dynamically loadable executable file for the S-function. If your S-function depends on files that reside elsewhere and you are using the template makefile build process, you must generate an `rtwmakecfg.m` file for the S-function. For example, it is likely that you need to generate this file if your Legacy Code Tool data structure defines compilation resources as path names.

To generate the `rtwmakecfg.m` file, call the `legacy_code` function with `'rtwmakecfg_generate'` as the first argument, and the name of the Legacy Code Tool data structure as the second argument.

```
legacy_code('rtwmakecfg_generate', lct_spec);
```

If you use multiple registration files in the same folder and generate an S-function for each file with a single call to `legacy_code`, the call to `legacy_code` that specifies `'rtwmakecfg_generate'` must be common to all registration files. For more information, see “Handling Multiple Registration Files” in the Simulink documentation

For example, if you define `defs` as an array of Legacy Code Tool structures, you call `legacy_code` with `'rtwmakecfg_generate'` once.

```
defs = [defs1(:);defs2(:);defs3(:)];
legacy_code('rtwmakecfg_generate', defs);
```

For more information, see “Build Support for S-Functions”.

## Deploy S-Functions for Simulation and Code Generation

You can deploy the S-functions that you generate with the Legacy Code Tool so that other people can use them. To deploy an S-function for simulation and code generation, share the following files:

- Registration file
- Compiled dynamically loadable executable
- TLC block file
- `rtwmakecfg.m` file
- Header, source, and include files on which the generated S-function depends

Users of the deployed files must be aware that:

- Before using the deployed files in a Simulink model, they must add the folder that contains the S-function files to the MATLAB path.
- If the Legacy Code Tool data structure registers required files as absolute paths and the location of the files changes, they must regenerate the `rtwmakecfg.m` file.

# Use C++ Object Methods and Objects with Legacy Code Tool

## Integrate External C++ Object Methods

Integrate legacy C++ object methods by using the Legacy Code Tool.

With the Legacy Code Tool, you can:

- Provide the legacy function specification.
- Generate a C++ MEX S-function that calls the legacy code during simulation.
- Compile and build the generated S-function for simulation.
- Generate a block TLC file and optional rtwmakecfg.m file that calls the legacy code during code generation.

## Provide the Legacy Function Specification

Functions provided with the Legacy Code Tool take a specific data structure or array of structures as the argument. The data structure is initialized by calling the function `legacy_code()` using 'initialize' as the first input. After initializing the structure, assign its properties to values corresponding to the legacy code being integrated. For detailed help on the properties, call `legacy_code('help')`. The definition of the legacy C++ class in this example is:

```
class adder {
private:
 int int_state;
public:
 adder();
 int add_one(int increment);
 int get_val();
};
```

The legacy source code is in the files `adder_cpp.h` and `adder_cpp.cpp`.

```
% rtwdemo_sfun_adder_cpp
def = legacy_code('initialize');
def.SFunctionName = 'rtwdemo_sfun_adder_cpp';
def.StartFcnSpec = 'createAdder()';
def.OutputFcnSpec = 'int32 y1 = adderOutput(int32 u1)';
def.TerminateFcnSpec = 'deleteAdder()';
```

```

def.HeaderFiles = {'adder_cpp.h'};
def.SourceFiles = {'adder_cpp.cpp'};
def.IncPaths = {'rtwdemo_lct_src'};
def.SrcPaths = {'rtwdemo_lct_src'};
def.Options.language = 'C++';
def.Options.useTlcWithAccel = false;

```

### Generate an S-Function for Simulation

To generate a C-MEX S-function according to the description provided by the input argument 'def', call the function `legacy_code()` again with the first input set to 'sfcn\_cmex\_generate'. The S-function calls the legacy functions during simulation. The source code for the S-function is in the file `rtwdemo_sfun_adder_cpp.cpp`.

```
legacy_code('sfcn_cmex_generate', def);
```

### Compile the Generated S-Function for Simulation

After you generate the C-MEX S-function source file, to compile the S-function for simulation with Simulink®, call the function `legacy_code()` again with the first input set to 'compile'.

```
legacy_code('compile', def);
```

```

Start Compiling rtwdemo_sfun_adder_cpp
 mex('-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src', '-IC:\TEMP\Bdoc16b_437511_1');
Building with 'Microsoft Visual C++ 2013 Professional'.
MEX completed successfully.
 mex('rtwdemo_sfun_adder_cpp.cpp', '-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src');
Building with 'Microsoft Visual C++ 2013 Professional'.
MEX completed successfully.
Finish Compiling rtwdemo_sfun_adder_cpp
Exit

```

### Generate a TLC Block File for Code Generation

After you compile the S-function and use it in simulation, you can call the function `legacy_code()` again. Set the first input to 'sfcn\_tlc\_generate' to generate a TLC block file that supports code generation through Simulink® Coder™. If the TLC block file is not created and you try to generate code for a model that includes the S-function, code generation fails. The TLC block file for the S-function is: `rtwdemo_sfun_adder_cpp.tlc`.

```
legacy_code('sfcn_tlc_generate', def);
```

### Generate an `rtwmakecfg.m` File for Code Generation

After you create the TLC block file, you can call the function `legacy_code()` again. Set the first input to `'rtwmakecfg_generate'` to generate an `rtwmakecfg.m` file that supports code generation through Simulink® Coder™. If the required source and header files for the S-function are not in the same folder as the S-function, and you want to add these dependencies in the makefile produced during code generation, generate the `rtwmakecfg.m` file.

```
legacy_code('rtwmakecfg_generate', def);
```

### Generate a Masked S-Function Block for Calling the Generated S-Function

After you compile the C-MEX S-function source, you can call the function `legacy_code()` again. Set the first input to `'slblock_generate'` to generate a masked S-function block that is configured to call that S-function. The software places the block in a new model. You can copy the block to an existing model.

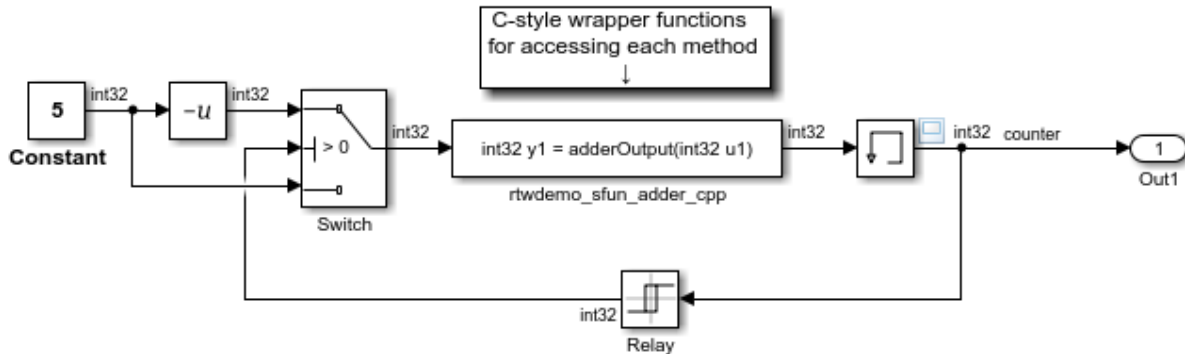

```
% legacy_code('slblock_generate', def);
```

### Show the Generated Integration with Legacy Code

The model `rtwdemo_lct_cpp` shows integration with the legacy code.

```
open_system('rtwdemo_lct_cpp')
sim('rtwdemo_lct_cpp')
```

This example illustrates how the Legacy Code Tool is used to call C++ object member functions

For this example to run you must go to the MATLAB command prompt and enter: `>> mex -setup` then select a C++ compiler.

To view the sources for this example click the links below.

- open legacy files `adder_cpp.h` and `adder_cpp.cpp`
- open registration script `rtwdemo_lct_cpp_script.m`
- open generated S-Function `rtwdemo_sfund_adder_cpp.cpp`
- open generated TLC file `rtwdemo_sfund_adder_cpp.tlc`

Generate Code Using  
Embedded Coder  
(double-click)

Copyright 1990-2012 The MathWorks, Inc.

## Integrate External C++ Objects

The Legacy Code Tool can interface with C++ functions, but not C++ objects. Using the previous example as a starting point, here is an example of how you can work around this limitation.

- Modify the class definition for `adder` in a new file `adder_cpp.hpp`. Add three new macros that dynamically allocate a new `adder` object, invoke the method `add_one()`, and free the memory allocated. Each macro takes a pointer to an `adder` object. Because each function called by the Legacy Code Tool must have a C-like signature,

the pointer is cached and passed as a `void*`. Then you must explicitly cast to `adder*` in the macro. The new class definition for `adder`:

```
#ifndef _ADDER_CPP_
#define _ADDER_CPP_

class adder {
private:
 int int_state;
public:
 adder(): int_state(0) {};
 int add_one(int increment);
 int get_val() {return int_state;};
};

// Method wrappers implemented as macros
#define createAdder(work1) \
 *(work1) = new adder

#define deleteAdder(work1) \
 delete(static_cast<adder*>(*(work1)))

#define adderOutput(work1, u1) \
 (static_cast<adder*> (*(work1)))->add_one(u1)

#endif /* _ADDER_CPP_ */
```

- Update `adder_cpp.cpp`. With the class modification, instead of one global instance, each generated S-function manages its own `adder` object.

```
#include "adder_cpp.hpp"

int adder::add_one(int increment)
{
 int_state += increment;
 return int_state;
}
```

- Update `rtwdemo_sfun_adder_cpp.cpp` with the following changes:
  - `StartFcnSpec` calls the macro that allocates a new `adder` object and caches the pointer.

```
def.StartFcnSpec = 'createAdder(void **work1)';
```

- `OutputFcnSpec` calls the macro that invokes the method `add_one()` and provides the S-function specific `adder` pointer object.

```
def.OutputFcnSpec = 'int32 y1 = adderOutput(void *work1, int32 u1)';
```

- `TerminateFcnSpec` calls the macro that frees the memory.

```
def.TerminateFcnSpec = 'deleteAdder(void **work1)';
```

## Integrate External C Functions That Pass Input Arguments By Value Versus Address

This example shows how to use the Legacy Code Tool to integrate legacy C functions that pass their input arguments by value versus address.

With the Legacy Code Tool, you can:

- Provide the legacy function specification.
- Generate a C-MEX S-function that calls the legacy code during simulation.
- Compile and build the generated S-function for simulation.
- Generate a TLC block file and optional `rtwmakecfg.m` file that specifies how the generated code for a model calls the legacy code.

### Provide the Legacy Function Specification

Legacy Code Tool functions take a specific data structure or array of structures as the argument. You can initialize the data structure by calling the function `legacy_code()` using 'initialize' as the first input. After initializing the structure, assign its properties to values corresponding to the legacy code being integrated. For detailed help on the properties, call `legacy_code('help')`. The prototypes of the legacy functions being called in this example are:

- `FLT filterV1(const FLT signal, const FLT prevSignal, const FLT gain)`
- `FLT filterV2(const FLT* signal, const FLT prevSignal, const FLT gain)`

FLT is a typedef to float. The legacy source code is in the files `your_types.h`, `myfilter.h`, `filterV1.c`, and `filterV2.c`.

Note the difference in the `OutputFcnSpec` defined in the two structures; the first case specifies that the first input argument is passed by value, while the second case specifies pass by pointer.

```
defs = [];
```

```
% rtwdemo_sfunk_filterV1
def = legacy_code('initialize');
def.SFunctionName = 'rtwdemo_sfunk_filterV1';
def.OutputFcnSpec = 'single y1 = filterV1(single u1, single u2, single p1)';
```

```

def.HeaderFiles = {'myfilter.h'};
def.SourceFiles = {'filterV1.c'};
def.IncPaths = {'rtwdemo_lct_src'};
def.SrcPaths = {'rtwdemo_lct_src'};
defs = [defs; def];

% rtwdemo_sfun_filterV2
def = legacy_code('initialize');
def.SFunctionName = 'rtwdemo_sfun_filterV2';
def.OutputFcnSpec = 'single y1 = filterV2(single u1[1], single u2, single p1)';
def.HeaderFiles = {'myfilter.h'};
def.SourceFiles = {'filterV2.c'};
def.IncPaths = {'rtwdemo_lct_src'};
def.SrcPaths = {'rtwdemo_lct_src'};
defs = [defs; def];

```

### Generate S-Functions for Simulation

To generate C-MEX S-functions according to the description provided by the input argument 'defs', call the function `legacy_code()` again with the first input set to 'sfcn\_cmex\_generate'. The S-functions call the legacy functions in simulation. The source code for the S-functions is in the files `rtwdemo_sfun_filterV1.c` and `rtwdemo_sfun_filterV2.c`.

```
legacy_code('sfcn_cmex_generate', defs);
```

### Compile the Generated S-Functions for Simulation

After you generate the C-MEX S-function source files, to compile the S-functions for simulation with Simulink®, call the function `legacy_code()` again with the first input set to 'compile'.

```
legacy_code('compile', defs);
```

```

Start Compiling rtwdemo_sfun_filterV1
 mex('-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src', '-IC:\TEMP\Bdoc16b_437511_')
Building with 'Microsoft Visual C++ 2013 Professional (C)'.
MEX completed successfully.
 mex('rtwdemo_sfun_filterV1.c', '-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src',
Building with 'Microsoft Visual C++ 2013 Professional (C)'.
MEX completed successfully.
Finish Compiling rtwdemo_sfun_filterV1
Exit

```

```
Start Compiling rtwdemo_sfun_filterV2
 mex('-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src', '-IC:\TEMP\Bdoc16b_437511_
Building with 'Microsoft Visual C++ 2013 Professional (C)'.
MEX completed successfully.
 mex('rtwdemo_sfun_filterV2.c', '-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src',
Building with 'Microsoft Visual C++ 2013 Professional (C)'.
MEX completed successfully.
Finish Compiling rtwdemo_sfun_filterV2
Exit
```

### Generate TLC Block Files for Code Generation

After you compile the S-functions and use them in simulation, you can call the function `legacy_code()` again with the first input set to `'sfcn_tlc_generate'` to generate TLC block files. Block files specify how the generated code for a model calls the legacy code. If you do not generate TLC block files and you try to generate code for a model that includes the S-functions, code generation fails. The TLC block files for the S-functions are `rtwdemo_sfun_filterV1.tlc` and `rtwdemo_sfun_filterV2.tlc`.

```
legacy_code('sfcn_tlc_generate', defs);
```

### Generate an `rtwmakecfg.m` File for Code Generation

After you create the TLC block files, you can call the function `legacy_code()` again with the first input set to `'rtwmakecfg_generate'` to generate an `rtwmakecfg.m` file to support code generation. If the required source and header files for the S-functions are not in the same folder as the S-functions, and you want to add these dependencies in the makefile produced during code generation, generate the `rtwmakecfg.m` file.

```
legacy_code('rtwmakecfg_generate', defs);
```

### Generate Masked S-Function Blocks for Calling the Generated S-Functions

After you compile the C-MEX S-function source, you can call the function `legacy_code()` again with the first input set to `'slblock_generate'` to generate masked S-function blocks that call the S-functions. The software places the blocks in a new model. From there you can copy them to an existing model.

```
legacy_code('slblock_generate', defs);
```

### Show the Generated Integration with Legacy Code

The model `rtwdemo_lct_filter` shows integration of the model with the legacy code. The subsystem `TestFilter` serves as a harness for the calls to the legacy C functions via the generate S-functions, with unit delays serving to store the previous output values.

```
open_system('rtwdemo_lct_filter')
open_system('rtwdemo_lct_filter/TestFilter')
sim('rtwdemo_lct_filter')
```

## Integrate External C Functions That Pass the Output Argument As a Return Argument

This example shows how to use the Legacy Code Tool to integrate legacy C functions that pass their output as a return argument.

With the Legacy Code Tool, you can:

- Provide the legacy function specification.
- Generate a C-MEX S-function that calls the legacy code during simulation.
- Compile and build the generated S-function for simulation.
- Generate a TLC block file and optional `rtwmakecfg.m` file that specifies how the generated code for a model calls the legacy code.

## Provide the Legacy Function Specification

Legacy Code Tool functions take a specific data structure or array of structures as the argument. You can initialize the data structure by calling the function `legacy_code()` using 'initialize' as the first input. After initializing the structure, assign its properties to values corresponding to the legacy code being integrated. For detailed help on the properties, call `legacy_code('help')`. The prototype of the legacy functions being called in this example is:

```
FLT gainScalar(const FLT in, const FLT gain)
```

FLT is a typedef to float. The legacy source code is in the files `your_types.h`, `gain.h`, and `gainScalar.c`.

```
% rtwdemo_sfun_gain_scalar
def = legacy_code('initialize');
def.SFunctionName = 'rtwdemo_sfun_gain_scalar';
def.OutputFcnSpec = 'single y1 = gainScalar(single u1, single p1)';
def.HeaderFiles = {'gain.h'};
def.SourceFiles = {'gainScalar.c'};
def.IncPaths = {'rtwdemo_lct_src'};
def.SrcPaths = {'rtwdemo_lct_src'};
```

## Generate an S-Function for Simulation

To generate a C-MEX S-function according to the description provided by the input argument 'def', call the function `legacy_code()` again with the first input set to 'sfcn\_cmex\_generate'. The S-function calls the legacy functions during simulation. The source code for the S-function is in the file `rtwdemo_sfun_gain_scalar.c`.

```
legacy_code('sfcn_cmex_generate', def);
```

## Compile the Generated S-Function for Simulation

After you generate the C-MEX S-function source file, to compile the S-function for simulation with Simulink®, call the function `legacy_code()` again with the first input set to 'compile'.

```
legacy_code('compile', def);
```

```
Start Compiling rtwdemo_sfun_gain_scalar
mex('-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src', '-IC:\TEMP\Bdoc16b_437511_
```

```

Building with 'Microsoft Visual C++ 2013 Professional (C)'.
MEX completed successfully.
 mex('rtwdemo_sfund_gain_scalar.c', '-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_sro
Building with 'Microsoft Visual C++ 2013 Professional (C)'.
MEX completed successfully.
Finish Compiling rtwdemo_sfund_gain_scalar
Exit

```

### Generate a TLC Block File for Code Generation

After you compile the S-function and use it in simulation, you can call the function `legacy_code()` again with the first input set to `'sfcn_tlc_generate'` to generate a TLC block file. The block file specifies how the generated code for a model calls the legacy code. If you do not generate a TLC block file and you try to generate code for a model that includes the S-function, code generation fails. The TLC block file for the S-function is: `rtwdemo_sfund_gain_scalar.tlc`.

```
legacy_code('sfcn_tlc_generate', def);
```

### Generate an `rtwmakecfg.m` File for Code Generation

After you create the TLC block file, you can call the function `legacy_code()` again with the first input set to `'rtwmakecfg_generate'` to generate an `rtwmakecfg.m` file to support code generation. If the required source and header files for the S-function are not in the same folder as the S-function, and you want to add these dependencies in the makefile produced during code generation, generate the `rtwmakecfg.m` file.

```
legacy_code('rtwmakecfg_generate', def);
```

### Generate a Masked S-Function Block for Calling the Generated S-Function

After you compile the C-MEX S-function source, you can call the function `legacy_code()` again with the first input set to `'slblock_generate'` to generate a masked S-function block that calls that S-function. The software places the block in a new model. From there you can copy it to an existing model.

```
legacy_code('slblock_generate', def);
```

## Show the Generated Integration with Legacy Code

The model `rtwdemo_lct_gain` shows integration of the model with the legacy code. The subsystem `TestGain` serves as a harness for the call to the legacy C function via the generate S-function.

```
open_system('rtwdemo_lct_gain')
open_system('rtwdemo_lct_gain/TestGain')
sim('rtwdemo_lct_gain')
```

## Integrate External C Functions That Pass Input and Output Arguments as Signals with a Fixed-Point Data Type

This example shows how to use the Legacy Code Tool to integrate legacy C functions that pass their inputs and outputs by using parameters of fixed-point data type.

With the Legacy Code Tool, you can:

- Provide the legacy function specification.
- Generate a C-MEX S-function that calls the legacy code during simulation.
- Compile and build the generated S-function for simulation.
- Generate a TLC block file and optional `rtwmakecfg.m` file that specifies how the generated code for a model calls the legacy code.

### Provide the Legacy Function Specification

Legacy Code Tool functions take a specific data structure or array of structures as the argument. You can initialize the data structure by calling the function `legacy_code()` using 'initialize' as the first input. After initializing the structure, assign its properties to values corresponding to the legacy code being integrated. For detailed help on the properties, call `legacy_code('help')`. The prototype of the legacy functions being called in this example is:

```
myFixpt timesS16(const myFixpt in1, const myFixpt in2, const uint8_T fracLength)
```

myFixpt is logically a fixed-point data type, which is physically a typedef to a 16-bit integer:

```
myFixpt = Simulink.NumericType;
myFixpt.DataTypeMode = 'Fixed-point: binary point scaling';
myFixpt.Signed = true;
myFixpt.WordLength = 16;
myFixpt.FractionLength = 10;
myFixpt.IsAlias = true;
myFixpt.HeaderFile = 'timesFixpt.h';
```

The legacy source code is in the files timesFixpt.h, and timesS16.c.

```
% rtwdemo_sfun_times_s16
def = legacy_code('initialize');
def.SFunctionName = 'rtwdemo_sfun_times_s16';
def.OutputFcnSpec = 'myFixpt y1 = timesS16(myFixpt u1, myFixpt u2, uint8 p1)';
def.HeaderFiles = {'timesFixpt.h'};
def.SourceFiles = {'timesS16.c'};
def.IncPaths = {'rtwdemo_lct_src'};
def.SrcPaths = {'rtwdemo_lct_src'};
```

### Generate an S-Function for Simulation

To generate a C-MEX S-function according to the description provided by the input argument 'def', call the function legacy\_code() again with the first input set to 'sfcn\_cmex\_generate'. The S-function calls the legacy functions during simulation. The source code for the S-function is in the file rtwdemo\_sfun\_times\_s16.c.

```
legacy_code('sfcn_cmex_generate', def);
```

### Compile the Generated S-Function for Simulation

After you generate the C-MEX S-function source file, to compile the S-function for simulation with Simulink®, call the function legacy\_code() again with the first input set to 'compile'.

```
legacy_code('compile', def);
```

```
Start Compiling rtwdemo_sfun_times_s16
mex('-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src', '-IC:\TEMP\Bdoc16b_437511_
```

```

Building with 'Microsoft Visual C++ 2013 Professional (C)'.
MEX completed successfully.
 mex('rtwdemo_sfun_times_s16.c', '-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src
Building with 'Microsoft Visual C++ 2013 Professional (C)'.
MEX completed successfully.
Finish Compiling rtwdemo_sfun_times_s16
Exit

```

### Generate a TLC Block File for Code Generation

After you compile the S-function and use it in simulation, you can call the function `legacy_code()` again with the first input set to `'sfcn_tlc_generate'` to generate a TLC block file. The block file specifies how the generated code for a model calls the legacy code. If you do not generate a TLC block file and you try to generate code for a model that includes the S-function, code generation fails. The TLC block file for the S-function is: `rtwdemo_sfun_times_s16.tlc`.

```
legacy_code('sfcn_tlc_generate', def);
```

### Generate an `rtwmakecfg.m` File for Code Generation

After you create the TLC block file, you can call the function `legacy_code()` again with the first input set to `'rtwmakecfg_generate'` to generate an `rtwmakecfg.m` file to support code generation. If the required source and header files for the S-function are not in the same folder as the S-function, and you want to add these dependencies in the makefile produced during code generation, generate the `rtwmakecfg.m` file.

```
legacy_code('rtwmakecfg_generate', def);
```

### Generate a Masked S-Function Block for Calling the Generated S-Function

After you compile the C-MEX S-function source, you can call the function `legacy_code()` again with the first input set to `'slblock_generate'` to generate a masked S-function block that calls that S-function. The software places the block in a new model. From there you can copy it to an existing model.

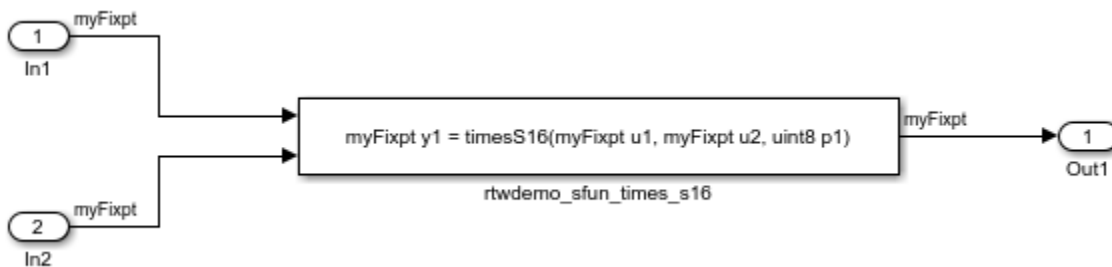

```
legacy_code('slblock_generate', def);
```

### Show the Integration of the Model with Legacy Code

The model `rtwdemo_lct_fixpt_signals` shows integration of the model with the legacy code. The subsystem `TestFixpt` serves as a harness for the call to the legacy C function via the generated S-function.

```
open_system('rtwdemo_lct_fixpt_signals')
open_system('rtwdemo_lct_fixpt_signals/TestFixpt')
sim('rtwdemo_lct_fixpt_signals')
```

### Integrate External C Functions with Instance-Specific Persistent Memory

Integrate legacy C functions that use instance-specific persistent memory by using the Legacy Code Tool.

With the Legacy Code Tool, you can:

- Provide the legacy function specification.
- Generate a C-MEX S-function that calls the legacy code during simulation.
- Compile and build the generated S-function for simulation.
- Generate a TLC block file and optional `rtwmakecfg.m` file that specifies how the generated code for a model calls the legacy code.

#### Provide the Legacy Function Specification

Legacy Code Tool functions take a specific data structure or array of structures as the argument. You can initialize the data structure by calling the function `legacy_code()` using 'initialize' as the first input. After initializing the structure, assign its properties to values corresponding to the legacy code being integrated. For detailed help on the

properties, call `legacy_code('help')`. The prototypes of the legacy functions being called in this example are:

```
void memory_bus_init(COUNTERBUS *mem, int32_T upper_sat, int32_T lower_sat);
```

```
void memory_bus_step(COUNTERBUS *input, COUNTERBUS *mem, COUNTERBUS *output);
```

`mem` is an instance-specific persistent memory for applying a one integration step delay. `COUNTERBUS` is a struct typedef defined in `counterbus.h` and implemented with a Simulink.Bus object in the base workspace. The legacy source code is in the files `memory_bus.h`, and `memory_bus.c`.

```
evalin('base', 'load rtwdemo_lct_data.mat')

% rtwdemo_sfunk_work
def = legacy_code('initialize');
def.SFunctionName = 'rtwdemo_sfunk_work';
def.InitializeConditionsFcnSpec = ...
 'void memory_bus_init(COUNTERBUS work1[1], int32 p1, int32 p2)';
def.OutputFcnSpec = ...
 'void memory_bus_step(COUNTERBUS u1[1], COUNTERBUS work1[1], COUNTERBUS y1[1])';
def.HeaderFiles = {'memory_bus.h'};
def.SourceFiles = {'memory_bus.c'};
def.IncPaths = {'rtwdemo_lct_src'};
def.SrcPaths = {'rtwdemo_lct_src'};
```

### Generate an S-Function for Simulation

To generate a C-MEX S-function according to the description provided by the input argument `def`, call the function `legacy_code()` again with the first input set to `'sfcn_cmex_generate'`. The S-function calls the legacy functions during simulation. The source code for the S-function is in the file `rtwdemo_sfunk_work.c`.

```
legacy_code('sfcn_cmex_generate', def);
```

### Compile the Generated S-Function for Simulation

After you generate the C-MEX S-function source file, to compile the S-function for simulation with Simulink®, call the function `legacy_code()` again with the first input set to `'compile'`.

```
legacy_code('compile', def);
```

```

Start Compiling rtwdemo_sfun_work
 mex('-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src', '-IC:\TEMP\Bdoc16b_437511
Building with 'Microsoft Visual C++ 2013 Professional (C)'.
MEX completed successfully.
 mex('rtwdemo_sfun_work.c', '-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src', '-I
Building with 'Microsoft Visual C++ 2013 Professional (C)'.
MEX completed successfully.
Finish Compiling rtwdemo_sfun_work
Exit

```

### Generate a TLC Block File for Code Generation

After you compile the S-function and use it in simulation, you can call the function `legacy_code()` again with the first input set to `'sfcn_tlc_generate'` to generate a TLC block file. The block file specifies how the generated code for a model calls the legacy code. If you do not generate a TLC block file and you try to generate code for a model that includes the S-function, code generation fails. The TLC block file for the S-function is: `rtwdemo_sfun_work.tlc`.

```
legacy_code('sfcn_tlc_generate', def);
```

### Generate an `rtwmakecfg.m` File for Code Generation

After you create the TLC block file, you can call the function `legacy_code()` again with the first input set to `'rtwmakecfg_generate'` to generate an `rtwmakecfg.m` file to support code generation. If the required source and header files for the S-function are not in the same folder as the S-function, and you want to add these dependencies in the makefile produced during code generation, generate the `rtwmakecfg.m` file.

```
legacy_code('rtwmakecfg_generate', def);
```

### Generate a Masked S-Function Block for Calling the Generated S-Function

After you compile the C-MEX S-function source, you can call the function `legacy_code()` again with the first input set to `'slblock_generate'` to generate a masked S-function block that calls that S-function. The software places the block in a new model. From there you can copy it to an existing model.

```
legacy_code('slblock_generate', def);
```

## Show the Integration of the Model with Legacy Code

The model `rtwdemo_lct_work` shows integration of the model with the legacy code. The subsystem `memory_bus` serves as a harness for the call to the legacy C function.

```
open_system('rtwdemo_lct_work')
open_system('rtwdemo_lct_work/memory_bus')
sim('rtwdemo_lct_work')
```

This legacy function apply a one integration step delay. The output is the previous input value. The parameters P1 and P2 set the initial values of the sub structure fields "upper\_saturation\_limit" and "lower\_saturation\_limit"

## Integrate External C Functions That Use Structure Arguments

Integrate legacy C functions with structure arguments that use Simulink® buses with the Legacy Code Tool.

With the Legacy Code Tool, you can:

- Provide the legacy function specification.
- Generate a C-MEX S-function that calls the legacy code during simulation.
- Compile and build the generated S-function for simulation.
- Generate a TLC block file and optional `rtwmakecfg.m` file that specifies how the generated code for a model calls the legacy code.

### Provide the Legacy Function Specification

Legacy Code Tool functions take a specific data structure or array of structures as the argument. You can initialize the data structure by calling the function `legacy_code()` using 'initialize' as the first input. After initializing the structure, assign its properties to values corresponding to the legacy code being integrated. For detailed help on the properties, call `legacy_code('help')`. The prototype of the legacy functions being called in this example is:

```
counterbusFcn(COUNTERBUS *u1, int32_T u2, COUNTERBUS *y1, int32_T *y2)
```

COUNTERBUS is a struct typedef defined in counterbus.h and implemented with a Simulink.Bus object in the base workspace. The legacy source code is in the files counterbus.h, and counterbus.c.

```
evalin('base', 'load rtwdemo_lct_data.mat')

% rtwdemo_sfun_counterbus
def = legacy_code('initialize');
def.SFunctionName = 'rtwdemo_sfun_counterbus';
def.OutputFcnSpec = ...
 'void counterbusFcn(COUNTERBUS u1[1], int32 u2, COUNTERBUS y1[1], int32 y2[1])';
def.HeaderFiles = {'counterbus.h'};
def.SourceFiles = {'counterbus.c'};
def.IncPaths = {'rtwdemo_lct_src'};
def.SrcPaths = {'rtwdemo_lct_src'};
```

### Generate an S-Function for Simulation

To generate a C-MEX S-function according to the description provided by the input argument 'def', call the function legacy\_code() again with the first input set to 'sfcn\_cmex\_generate'. The S-function calls the legacy functions during simulation. The source code for the S-function is in the file rtwdemo\_sfun\_counterbus.c.

```
legacy_code('sfcn_cmex_generate', def);
```

### Compile the Generated S-Function for Simulation

After you generate the C-MEX S-function source file, to compile the S-function for simulation with Simulink®, call the function legacy\_code() again with the first input set to 'compile'.

```
legacy_code('compile', def);
```

```
Start Compiling rtwdemo_sfun_counterbus
mex('-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src', '-IC:\TEMP\Bdoc16b_437511_1');
Building with 'Microsoft Visual C++ 2013 Professional (C)'.
MEX completed successfully.
mex('rtwdemo_sfun_counterbus.c', '-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src');
Building with 'Microsoft Visual C++ 2013 Professional (C)'.
MEX completed successfully.
Finish Compiling rtwdemo_sfun_counterbus
```

```
Exit
```

### Generate a TLC Block File for Code Generation

After you compile the S-function and use it in simulation, you can call the function `legacy_code()` again with the first input set to `'sfcn_tlc_generate'` to generate a TLC block file. The block file specifies how the generated code for a model calls the legacy code. If you do not generate a TLC block file and you try to generate code for a model that includes the S-function, code generation fails. The TLC block file for the S-function is: `rtwdemo_sfun_counterbus.tlc`.

```
legacy_code('sfcn_tlc_generate', def);
```

### Generate an `rtwmakecfg.m` File for Code Generation

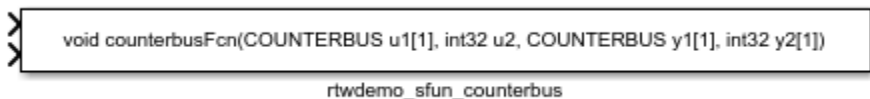

After you create the TLC block file, you can call the function `legacy_code()` again with the first input set to `'rtwmakecfg_generate'` to generate an `rtwmakecfg.m` file to support code generation. If the required source and header files for the S-function are not in the same folder as the S-function, and you want to add these dependencies in the makefile produced during code generation, generate the `rtwmakecfg.m` file.

```
legacy_code('rtwmakecfg_generate', def);
```

### Generate a Masked S-Function Block for Calling the Generated S-Function

After you compile the C-MEX S-function source, you can call the function `legacy_code()` again with the first input set to `'slblock_generate'` to generate a masked S-function block that calls that S-function. The software places the block in a new model. From there you can copy it to an existing model.

```
legacy_code('slblock_generate', def);
```

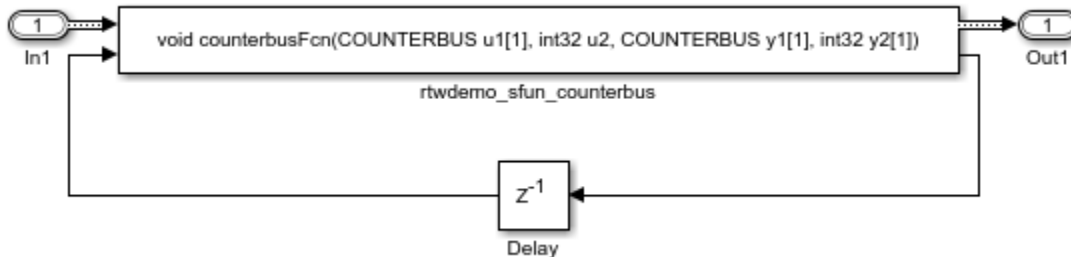

```
void counterbusFcn(COUNTERBUS u1[1], int32 u2, COUNTERBUS y1[1], int32 y2[1])
rtwdemo_sfun_counterbus
```

### Show the Integration of the Model with Legacy Code

The model `rtwdemo_lct_bus` shows integration of the model with the legacy code. The subsystem `TestCounter` serves as a harness for the call to the legacy C function.

```
open_system('rtwdemo_lct_bus')
```

```
open_system('rtwdemo_lct_bus/TestCounter')
sim('rtwdemo_lct_bus')
```

## Integrate External C Functions That Pass Input and Output Arguments as Signals with Complex Data

Integrate legacy C functions using complex signals with the Legacy Code Tool.

With the Legacy Code Tool, you can:

- Provide the legacy function specification.
- Generate a C-MEX S-function that calls the legacy code during simulation.
- Compile and build the generated S-function for simulation.
- Generate a TLC block file and optional `rtwmakecfg.m` file that specifies how the generated code for a model calls the legacy code.

### Provide the Legacy Function Specification

Legacy Code Tool functions take a specific data structure or array of structures as the argument. You can initialize the data structure by calling the function `legacy_code()` using 'initialize' as the first input. After initializing the structure, assign its properties to values corresponding to the legacy code being integrated. For detailed help on the properties, call `legacy_code('help')`. The prototype of the legacy functions being called in this example is:

```
void cplx_gain(creal_T *input, creal_T *gain, creal_T *output);
```

`creal_T` is the complex representation of a double. The legacy source code is in the files `cplxgain.h`, and `cplxgain.c`.

```

% rtwdemo_sfun_gain_scalar
def = legacy_code('initialize');
def.SFunctionName = 'rtwdemo_sfun_cplx_gain';
def.OutputFcnSpec = ...
 'void cplx_gain(complex<double> u1[1], complex<double> p1[1], complex<double> y1[1]';
def.HeaderFiles = {'cplxgain.h'};
def.SourceFiles = {'cplxgain.c'};
def.IncPaths = {'rtwdemo_lct_src'};
def.SrcPaths = {'rtwdemo_lct_src'};

```

### Generate an S-Function for Simulation

To generate a C-MEX S-function according to the description provided by the input argument 'def', call the function `legacy_code()` again with the first input set to 'sfcn\_cmex\_generate'. The S-function calls the legacy functions during simulation. The source code for the S-function is in the file `rtwdemo_sfun_cplx_gain.c`.

```
legacy_code('sfcn_cmex_generate', def);
```

### Compile the Generated S-Function for Simulation

After you generate the C-MEX S-function source file, to compile the S-function for simulation with Simulink®, call the function `legacy_code()` again with the first input set to 'compile'.

```
legacy_code('compile', def);
```

```

Start Compiling rtwdemo_sfun_cplx_gain
 mex('-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src', '-IC:\TEMP\Bdoc16b_437511_');
Building with 'Microsoft Visual C++ 2013 Professional (C)'.
MEX completed successfully.
 mex('rtwdemo_sfun_cplx_gain.c', '-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src');
Building with 'Microsoft Visual C++ 2013 Professional (C)'.
MEX completed successfully.
Finish Compiling rtwdemo_sfun_cplx_gain
Exit

```

### Generate a TLC Block File for Code Generation

After you compile the S-function and use it in simulation, you can call the function `legacy_code()` again with the first input set to 'sfcn\_tlc\_generate' to generate a TLC block file. The block file specifies how the generated code for a model calls the legacy code. If you do not generate a TLC block file and you try to generate code for a model that

includes the S-function, code generation fails. The TLC block file for the S-function is: `rtwdemo_sfncplx_gain.tlc`.

```
legacy_code('sfnc_tlc_generate', def);
```

### Generate an `rtwmakecfg.m` File for Code Generation

After you create the TLC block file, you can call the function `legacy_code()` again with the first input set to `'rtwmakecfg_generate'` to generate an `rtwmakecfg.m` file to support code generation. If the required source and header files for the S-function are not in the same folder as the S-function, and you want to add these dependencies in the makefile produced during code generation, generate the `rtwmakecfg.m` file.

```
legacy_code('rtwmakecfg_generate', def);
```

### Generate a Masked S-Function Block for Calling the Generated S-Function

After you compile the C-MEX S-function source, you can call the function `legacy_code()` again with the first input set to `'slblock_generate'` to generate a masked S-function block that calls that S-function. The software places the block in a new model. From there you can copy it to an existing model.

```
legacy_code('slblock_generate', def);
```

### Show the Integration of the Model with Legacy Code

The model `rtwdemo_lct_cplxgain` shows integration of the model with the legacy code. The subsystem `complex_gain` serves as a harness for the call to the legacy C function via the generate S-function.

```
if isempty(find_system('SearchDepth',0,'Name','rtwdemo_lct_cplxgain'))
 open_system('rtwdemo_lct_cplxgain')
 open_system('rtwdemo_lct_cplxgain/complex_gain')
 sim('rtwdemo_lct_cplxgain')
end
```

## Integrate External C Functions That Pass Arguments That Have Inherited Dimensions

This example shows how to use the Legacy Code Tool to integrate legacy C functions whose arguments have inherited dimensions.

With the Legacy Code Tool, you can:

- Provide the legacy function specification.
- Generate a C-MEX S-function that calls the legacy code during simulation.
- Compile and build the generated S-function for simulation.
- Generate a TLC block file and optional `rtwmakecfg.m` file that specifies how the generated code for a model calls the legacy code.

### Provide the Legacy Function Specification

Legacy Code Tool functions take a specific data structure or array of structures as the argument. You can initialize the data structure by calling the function `legacy_code()` using 'initialize' as the first input. After initializing the structure, assign its properties to values corresponding to the legacy code being integrated. For detailed help on the properties, call `legacy_code('help')`. The prototypes of the legacy functions being called in this example are:

- `void mat_add(real_T *u1, real_T *u2, int32_T nbRows, int32_T nbCols, real_T *y1)`
- `void mat_mult(real_T *u1, real_T *u2, int32_T nbRows1, int32_T nbCols1, int32_T nbCols2, real_T *y1)`

`real_T` is a typedef to `double`, and `int32_T` is a typedef to a 32-bit integer. The legacy source code is in the files `mat_ops.h`, and `mat_ops.c`.

```
defs = [];
```

```
% rtwdemo_sfun_mat_add
def = legacy_code('initialize');
def.SFunctionName = 'rtwdemo_sfun_mat_add';
```

```

def.OutputFcnSpec = ['void mat_add(double u1[][], double u2[][], ' ...
 'int32 u3, int32 u4, double y1[size(u1,1)][size(u1,2)])'];
def.HeaderFiles = {'mat_ops.h'};
def.SourceFiles = {'mat_ops.c'};
def.IncPaths = {'rtwdemo_lct_src'};
def.SrcPaths = {'rtwdemo_lct_src'};
defs = [defs; def];

% rtwdemo_sfun_mat_mult
def = legacy_code('initialize');
def.SFunctionName = 'rtwdemo_sfun_mat_mult';
def.OutputFcnSpec = ['void mat_mult(double u1[p1][p2], double u2[p2][p3], ' ...
 'int32 p1, int32 p2, int32 p3, double y1[p1][p3])'];
def.HeaderFiles = {'mat_ops.h'};
def.SourceFiles = {'mat_ops.c'};
def.IncPaths = {'rtwdemo_lct_src'};
def.SrcPaths = {'rtwdemo_lct_src'};
defs = [defs; def];

```

### Generate S-Functions for Simulation

To generate C-MEX S-functions according to the description provided by the input argument 'defs', call the function `legacy_code()` again with the first input set to 'sfcn\_cmex\_generate'. The S-functions call the legacy functions during simulation. The source code for the S-function is in the files `rtwdemo_sfun_mat_add.c` and `rtwdemo_sfun_mat_mult.c`.

```
legacy_code('sfcn_cmex_generate', defs);
```

### Compile the Generated S-Functions for Simulation

After you generate the C-MEX S-function source files, to compile the S-functions for simulation with Simulink®, call the function `legacy_code()` again with the first input set to 'compile'.

```
legacy_code('compile', defs);
```

```

Start Compiling rtwdemo_sfun_mat_add
 mex('-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src', '-IC:\TEMP\Bdoc16b_437511_
Building with 'Microsoft Visual C++ 2013 Professional (C)'.
MEX completed successfully.
 mex('rtwdemo_sfun_mat_add.c', '-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src',
Building with 'Microsoft Visual C++ 2013 Professional (C)'.
MEX completed successfully.

```

```

Finish Compiling rtwdemo_sfun_mat_add
Exit

Start Compiling rtwdemo_sfun_mat_mult
 mex('-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src', '-IC:\TEMP\Bdoc16b_437511_')
Building with 'Microsoft Visual C++ 2013 Professional (C)'.
MEX completed successfully.
 mex('rtwdemo_sfun_mat_mult.c', '-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src',
Building with 'Microsoft Visual C++ 2013 Professional (C)'.
MEX completed successfully.

### Generate TLC Block Files for Code Generation

After you compile the S-functions and use them in simulation, you can call the function `legacy_code()` again with the first input set to `'sfcn_tlc_generate'` to generate TLC block files. Block files specify how the generated code for a model calls the legacy code. If you do not generate TLC block files and you try to generate code for a model that includes the S-functions, code generation fails. The TLC block files for the S-functions are `rtwdemo_sfun_mat_add.tlc` and `rtwdemo_sfun_mat_mult.tlc`.

```
legacy_code('sfcn_tlc_generate', defs);
```

### Generate an `rtwmakecfg.m` File for Code Generation

After you create the TLC block files, you can call the function `legacy_code()` again with the first input set to `'rtwmakecfg_generate'` to generate an `rtwmakecfg.m` file to support code generation. If the required source and header files for the S-functions are not in the same folder as the S-functions, and you want to add these dependencies in the makefile produced during code generation, generate the `rtwmakecfg.m` file.

```
legacy_code('rtwmakecfg_generate', defs);
```

### Generate Masked S-Function Blocks for Calling the Generated S-Functions

After you compile the C-MEX S-function source, you can call the function `legacy_code()` again with the first input set to `'slblock_generate'` to generate masked S-function blocks that call the S-functions. The software places the blocks in a new model. From there you can copy them to an existing model

```
legacy_code('slblock_generate', defs);
```

```
void mat_add(double u1[], double u2[], int32 u3, int32 u4, double y1[size(u1,1)][size(u1,2)])
```

rtwdemo\_sfun\_mat\_add

```
void mat_mult(double u1[p1][p2], double u2[p2][p3], int32 p1, int32 p2, int32 p3, double y1[p1][p3])
```

rtwdemo\_sfun\_mat\_mult

### Show the Generated Integration with Legacy Code

The model `rtwdemo_lct_inherit_dims` shows integration of the model with the legacy code. The subsystem `TestMatOps` serves as a harness for the calls to the legacy C functions, with unit delays serving to store the previous output values.

```
open_system('rtwdemo_lct_inherit_dims')
open_system('rtwdemo_lct_inherit_dims/TestMatOps')
sim('rtwdemo_lct_inherit_dims')
```

## Integrate External C Functions That Implement Start and Terminate Actions

Integrate legacy C functions that have start and terminate actions by using the Legacy Code Tool.

With the Legacy Code Tool, you can:

- Provide the legacy function specification.
- Generate a C-MEX S-function that calls the legacy code during simulation.
- Compile and build the generated S-function for simulation.
- Generate a TLC block file and optional `rtwmakecfg.m` file that specifies how the generated code for a model calls the legacy code.

### Provide the Legacy Function Specification

Legacy Code Tool functions take a specific data structure or array of structures as the argument. You can initialize the data structure by calling the function `legacy_code()` using 'initialize' as the first input. After initializing the structure, assign its properties

to values corresponding to the legacy code being integrated. For detailed help on the properties, call `legacy_code('help')`. The prototypes of the legacy functions being called in this example are:

- `void initFaultCounter(unsigned int *counter)`
- `void openLogFile(void **fid)`
- `void incAndLogFaultCounter(void *fid, unsigned int *counter, double time)`
- `void closeLogFile(void **fid)`

The legacy source code is in the files `your_types.h`, `fault.h`, and `fault.c`.

```
% rtwdemo_sfun_fault
def = legacy_code('initialize');
def.SFunctionName = 'rtwdemo_sfun_fault';
def.InitializeConditionsFcnSpec = 'initFaultCounter(uint32 work2[1])';
def.StartFcnSpec = 'openLogFile(void **work1)';
def.OutputFcnSpec = ...
 'incAndLogFaultCounter(void *work1, uint32 work2[1], double u1)';
def.TerminateFcnSpec = 'closeLogFile(void **work1)';
def.HeaderFiles = {'fault.h'};
def.SourceFiles = {'fault.c'};
def.IncPaths = {'rtwdemo_lct_src'};
def.SrcPaths = {'rtwdemo_lct_src'};
def.Options.useTlcWithAccel = false;
```

### Generate an S-Function for Simulation

To generate a C-MEX S-function according to the description provided by the input argument `def`, call the function `legacy_code()` again with the first input set to `'sfcn_cmex_generate'`. The S-function calls the legacy functions during simulation. The source code for the S-function is in the file `rtwdemo_sfun_fault.c`.

```
legacy_code('sfcn_cmex_generate', def);
```

### Compile the Generated S-Function for Simulation

After you generate the C-MEX S-function source file, to compile the S-function for simulation with Simulink®, call the function `legacy_code()` again with the first input set to `'compile'`.

```
legacy_code('compile', def);

Start Compiling rtwdemo_sfun_fault
```

```

 mex('-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src', '-IC:\TEMP\Bdoc16b_437511_
Building with 'Microsoft Visual C++ 2013 Professional (C)'.
MEX completed successfully.
 mex('rtwdemo_sfun_fault.c', '-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src', '-
Building with 'Microsoft Visual C++ 2013 Professional (C)'.
MEX completed successfully.
Finish Compiling rtwdemo_sfun_fault
Exit

```

### Generate a TLC Block File for Code Generation

After you compile the S-function and use it in simulation, you can call the function `legacy_code()` again with the first input set to `'sfcn_tlc_generate'` to generate a TLC block file. The block file specifies how the generated code for a model calls the legacy code. If you do not generate a TLC block file and you try to generate code for a model that includes the S-function, code generation fails. The TLC block file for the S-function is: `rtwdemo_sfun_fault.tlc`.

```
legacy_code('sfcn_tlc_generate', def);
```

### Generate an `rtwmakecfg.m` File for Code Generation

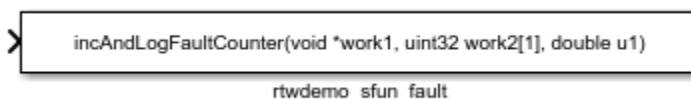

After you create the TLC block file, you can call the function `legacy_code()` again with the first input set to `'rtwmakecfg_generate'` to generate an `rtwmakecfg.m` file to support code generation. If the required source and header files for the S-function are not in the same folder as the S-function, and you want to add these dependencies in the makefile produced during code generation, generate the `rtwmakecfg.m` file.

```
legacy_code('rtwmakecfg_generate', def);
```

### Generate a Masked S-Function Block for Calling the Generated S-Function

After you compile the C-MEX S-function source, you can call the function `legacy_code()` again with the first input set to `'slblock_generate'` to generate a masked S-function block that calls that S-function. The software places the block in a new model. From there you can copy it to an existing model.

```
legacy_code('slblock_generate', def);
```

```

> incAndLogFaultCounter(void *work1, uint32 work2[1], double u1)
 rtwdemo_sfun_fault

```

### Showing the Generated Integration with Legacy Code

The model `rtwdemo_lct_start_term` shows integration of the model with the legacy code. The subsystem `TestFixpt` serves as a harness for the call to the legacy C function, and the scope compares the output of the function with the output of the built-in Simulink® product block; the results should be identical.

```
open_system('rtwdemo_lct_start_term')
open_system('rtwdemo_lct_start_term/TestFault')
sim('rtwdemo_lct_start_term')
```

### Integrate External C Functions That Pass Arguments as Multi-Dimensional Signals

This example shows how to use the Legacy Code Tool to integrate legacy C functions with multi-dimensional Signals.

With the Legacy Code Tool, you can:

- Provide the legacy function specification.
- Generate a C-MEX S-function that calls the legacy code during simulation.
- Compile and build the generated S-function for simulation.
- Generate a TLC block file and optional `rtwmakecfg.m` file that specifies how the generated code for a model calls the legacy code.

#### Provide the Legacy Function Specification

Legacy Code Tool functions take a specific data structure or array of structures as the argument. You can initialize the data structure by calling the function `legacy_code()` using 'initialize' as the first input. After initializing the structure, assign its properties

to values corresponding to the legacy code being integrated. For detailed help on the properties, call `legacy_code('help')`. The prototype of the legacy functions being called in this example is:

```
void array3d_add(real_T *y1, real_T *u1, real_T *u2, int32_T nbRows, int32_T nbCols,
int32_T nbPages);
```

`real_T` is a typedef to `double`, and `int32_T` is a typedef to a 32-bit integer. The legacy source code is in the files `ndarray_ops.h`, and `ndarray_ops.c`.

```
% rtwdemo_sfun_ndarray_add
def = legacy_code('initialize');
def.SFunctionName = 'rtwdemo_sfun_ndarray_add';
def.OutputFcnSpec = ['void array3d_add(double y1[size(u1,1)][size(u1,2)][size(u1,3)],
 'double u1[][][], double u2[][][], ' ...
 'int32 size(u1,1), int32 size(u1,2), int32 size(u1,3))'];
def.HeaderFiles = {'ndarray_ops.h'};
def.SourceFiles = {'ndarray_ops.c'};
def.IncPaths = {'rtwdemo_lct_src'};
def.SrcPaths = {'rtwdemo_lct_src'};
```

`y1` is a 3-D output signal of same dimensions as the 3-D input signal `u1`. Note that the last 3 arguments passed to the legacy function correspond to the number of element in each dimension of the 3-D input signal `u1`.

### Generate an S-Function for Simulation

To generate a C-MEX S-function according to the description provided by the input argument `def`, call the function `legacy_code()` again with the first input set to `'sfcn_cmex_generate'`. The S-function calls the legacy functions during simulation. The source code for the S-function is in the file `rtwdemo_sfun_ndarray_add.c`.

```
legacy_code('sfcn_cmex_generate', def);
```

### Compile the Generated S-Function for Simulation

After you generate the C-MEX S-function source file, to compile the S-function for simulation with Simulink®, call the function `legacy_code()` again with the first input set to `'compile'`.

```
legacy_code('compile', def);
```

```
Start Compiling rtwdemo_sfun_ndarray_add
```

```

 mex('-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src', '-IC:\TEMP\Bdoc16b_437511_
Building with 'Microsoft Visual C++ 2013 Professional (C)'.
MEX completed successfully.
 mex('rtwdemo_sfun_ndarray_add.c', '-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src
Building with 'Microsoft Visual C++ 2013 Professional (C)'.
MEX completed successfully.
Finish Compiling rtwdemo_sfun_ndarray_add
Exit

```

### Generate a TLC Block File for Code Generation

After you compile the S-function and use it in simulation, you can call the function `legacy_code()` again with the first input set to `'sfcn_tlc_generate'` to generate a TLC block file. The block file specifies how the generated code for a model calls the legacy code. If you do not generate a TLC block file and you try to generate code for a model that includes the S-function, code generation fails. The TLC block file for the S-function is: `rtwdemo_sfun_ndarray_add.tlc`.

```
legacy_code('sfcn_tlc_generate', def);
```

### Generate an `rtwmakecfg.m` File for Code Generation

After you create the TLC block file, you can call the function `legacy_code()` again with the first input set to `'rtwmakecfg_generate'` to generate an `rtwmakecfg.m` file to support code generation. If the required source and header files for the S-function are not in the same folder as the S-function, and you want to add these dependencies in the makefile produced during code generation, generate the `rtwmakecfg.m` file.

```
legacy_code('rtwmakecfg_generate', def);
```

### Generate a Masked S-Function Block for Calling the Generated S-Function

After you compile the C-MEX S-function source, you can call the function `legacy_code()` again with the first input set to `'slblock_generate'` to generate a masked S-function block that calls that S-function. The software places the block in a new model. From there you can copy it to an existing model.

```
legacy_code('slblock_generate', def);
```

## Showing the Generated Integration with Legacy Code

The model `rtwdemo_lct_ndarray` shows integration of the model with the legacy code. The subsystem `ndarray_add` serves as a harness for the call to the legacy C function.

```
open_system('rtwdemo_lct_ndarray')
open_system('rtwdemo_lct_ndarray/ndarray_add')
sim('rtwdemo_lct_ndarray')
```

This legacy function computes the addition of the 2 input signals:

- Input1 and Input2 are dynamically sized 3D arrays
- Output1 is a dynamically sized 3D array of same size as Input1
- the last 3 function's arguments allow to pass the Input1's dimensions to the legacy function

## Integrate External C Functions with a Block Sample Time Specified, Inherited, and Parameterized

This example shows how to use the Legacy Code Tool to integrate legacy C functions with the block's sample time specified, inherited and parameterized.

With the Legacy Code Tool, you can:

- Provide the legacy function specification.
- Generate a C-MEX S-function that calls the legacy code during simulation.
- Compile and build the generated S-function for simulation.
- Generate a TLC block file and optional `rtwmakecfg.m` file that specifies how the generated code for a model calls the legacy code.

### Provide the Legacy Function Specification

Legacy Code Tool functions take a specific data structure or array of structures as the argument. You can initialize the data structure by calling the function `legacy_code()`

using 'initialize' as the first input. After initializing the structure, assign its properties to values corresponding to the legacy code being integrated. For detailed help on the properties, call `legacy_code('help')`. The prototype of the legacy functions being called in this example is:

```
FLT gainScalar(const FLT in, const FLT gain)
```

FLT is a typedef to float. The legacy source code is in the files `your_types.h`, `gain.h`, and `gainScalar.c`.

```
defs = [];

% rtwdemo_sfun_st_inherited
def = legacy_code('initialize');
def.SFunctionName = 'rtwdemo_sfun_st_inherited';
def.OutputFcnSpec = 'single y1 = gainScalar(single u1, single p1)';
def.HeaderFiles = {'gain.h'};
def.SourceFiles = {'gainScalar.c'};
def.IncPaths = {'rtwdemo_lct_src'};
def.SrcPaths = {'rtwdemo_lct_src'};
defs = [defs; def];

% rtwdemo_sfun_st_fixed
def = legacy_code('initialize');
def.SFunctionName = 'rtwdemo_sfun_st_fixed';
def.OutputFcnSpec = 'single y1 = gainScalar(single u1, single p1)';
def.HeaderFiles = {'gain.h'};
def.SourceFiles = {'gainScalar.c'};
def.IncPaths = {'rtwdemo_lct_src'};
def.SrcPaths = {'rtwdemo_lct_src'};
def.SampleTime = [2 1];
defs = [defs; def];

% rtwdemo_sfun_st_parameterized
def = legacy_code('initialize');
def.SFunctionName = 'rtwdemo_sfun_st_parameterized';
def.OutputFcnSpec = 'single y1 = gainScalar(single u1, single p1)';
def.HeaderFiles = {'gain.h'};
def.SourceFiles = {'gainScalar.c'};
def.IncPaths = {'rtwdemo_lct_src'};
def.SrcPaths = {'rtwdemo_lct_src'};
def.SampleTime = 'parameterized';
defs = [defs; def];
```

## Generate S-Functions for Simulation

To generate C-MEX S-functions according to the description provided by the input argument 'defs', call the function `legacy_code()` again with the first input set to 'sfcn\_cmex\_generate'. The S-functions call the legacy functions during simulation. The source code for the S-functions is in the files `rtwdemo_sfun_st_inherited.c` and `rtwdemo_sfun_st_fixed.c`, `rtwdemo_sfun_st_parameterized.c`.

```
legacy_code('sfcn_cmex_generate', defs);
```

## Compile the Generated S-Functions for Simulation

After you generate the C-MEX S-function source files, to compile the S-functions for simulation with Simulink®, call the function `legacy_code()` again with the first input set to 'compile'.

```
legacy_code('compile', defs);
```

```
Start Compiling rtwdemo_sfun_st_inherited
 mex('-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src', '-IC:\TEMP\Bdoc16b_437511_1')

### **Generate TLC Block Files for Code Generation**

After you compile the S-functions and use them in simulation, you can call the function `legacy_code()` again with the first input set to `'sfcn_tlc_generate'` to generate TLC block files. Block files specify how the generated code for a model calls the legacy code. If you do not generate TLC block files and you try to generate code for a model that includes the S-functions, code generation fails. The TLC block files for the S-functions are `rtwdemo_sfun_st_inherited.tlc` and `rtwdemo_sfun_st_fixed.tlc`. `rtwdemo_sfun_st_parameterized.tlc`.

```
legacy_code('sfcn_tlc_generate', defs);
```

### **Generate an `rtwmakecfg.m` File for Code Generation**

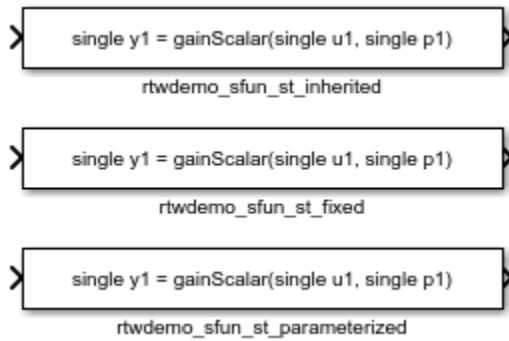

After you create the TLC block files, you can call the function `legacy_code()` again with the first input set to `'rtwmakecfg_generate'` to generate an `rtwmakecfg.m` file to support code generation. If the required source and header files for the S-functions are not in the same folder as the S-functions, and you want to add these dependencies in the makefile produced during code generation, generate the `rtwmakecfg.m` file.

```
legacy_code('rtwmakecfg_generate', defs);
```

### **Generate Masked S-Function Blocks for Calling the Generated S-Functions**

After you compile the C-MEX S-function source, you can call the function `legacy_code()` again with the first input set to `'slblock_generate'` to generate masked S-function blocks that call the S-functions. The software places the blocks in a new model. From there you can copy them to an existing model.

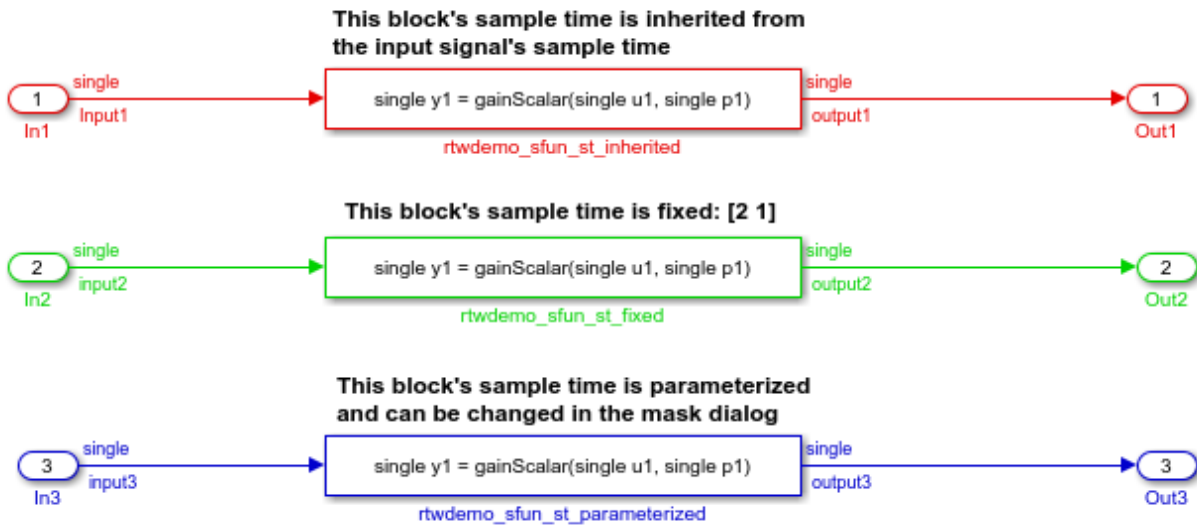

```
legacy_code('slblock_generate', defs);
```

### Show the Generated Integration with Legacy Code

The model `rtwdemo_lct_sampletime` shows integration of the model with the legacy code. The subsystem `sample_time` serves as a harness for the calls to the legacy C functions, with unit delays serving to store the previous output values.

```
open_system('rtwdemo_lct_sampletime')
open_system('rtwdemo_lct_sampletime/sample_time')
sim('rtwdemo_lct_sampletime')
```

## Insert External C and C++ Code Into Stateflow Charts for Code Generation

This example shows how to use Stateflow® to integrate external code into a model.

### Open Model

```
model='rtwdemo_sfcustom';
open_system(model);
```

## Integrating c-code into model

Custom written c-files can be easily integrated into Stateflow models. This code can be used to augment Stateflow's capabilities or to take advantage of legacy code.

To add custom c-files open the Stateflow simulation target and enter the following:

**Include Code** - Header that defines functions, structures, and data to be accessible by Stateflow.

**Include Path** - Path to this include file.

**Source Files** - c-files that define the functions and data accessible by Stateflow.

### ▶ Open Stateflow simulation custom code settings

If generating code via Simulink Coder, these same settings must also be added to the Model's configuration parameters custom code settings.

### ▶ Open Code Generation custom code settings

### ▶ Build model using Simulink Coder

## Calling c-code from Stateflow

### Functions

Custom c-code functions can be called from Stateflow using the same syntax as graphical function calls. The statement takes the form:

```
result = my_custom_function(in_args);
```

### Structures

Variables of structure type can be accessed in Stateflow via the "dot" notation. The expression takes the form:

```
result = my_var.my_field;
```

To view the custom source for this exemplenstration double click the links below.

### ▶ Open my\_header.h

### ▶ Open my\_function.c

## Calling C++ code from Stateflow

Custom C++ code can also be integrated into Stateflow and Simulink Coder. Double-click below for an example.

### ▶ Open rtwdemo\_sfcpp

## Additional documentation

Additional documentation is available for integrating C and C++ code in your model by double-clicking the link below.

### ▶ C-Code integration

### ▶ C++-Code integration

Copyright 1994-2012 The MathWorks, Inc.

## Integrate Code

1. The example includes the custom header file `my_header.c` and the custom source file `my_function.c`.

```
%Open files my_header.h and my_function.c
eval('edit my_header.h')
eval('edit my_function.c')
```

2. On the Configuration Parameters dialog box **Simulation Target** pane, enter the custom source file and header file. Also enter additional include directories and source files.

In this example, the custom header file `my_header.c` and source file `my_function.c` are entered on the **Simulation Target** pane.

```
%Open Configuration Parameters dialog box
slCfgPrmDlg(model, 'Open');
slCfgPrmDlg(bdroot, 'TurnToPage', 'Simulation Target');
```

3. If you generate code with Simulink Coder®, on the Configuration Parameters dialog box **Code Generation > Custom Code** pane, enter the same custom source file and header file. Also enter the same additional include directories and source files.

In this example, the custom header file `my_header.c` and source file `my_function.c` are entered on the **Code Generation > Custom Code** pane.

```
%Open Configuration Parameters dialog box
slCfgPrmDlg(model, 'Open');
slCfgPrmDlg(bdroot, 'TurnToPage', 'Code Generation/Custom Code');
```

### Generate Code

```
rtwbuild('rtwdemo_sfcustom')

Starting build procedure for model: rtwdemo_sfcustom
Successful completion of build procedure for model: rtwdemo_sfcustom
```

### Call C Code from Stateflow

To call custom C code functions from Stateflow, use the same syntax as graphical function calls: `result = my_custom_function(in_args);`

To call variables of structure type, use the dot notation: `result = my_var.my_field;`

### See Also

- Include Custom C Code in Simulation Targets for Library Models

### Close Model

```
rtwdemoclean;
close_system('rtwdemo_sfcustom',0);
```

## Integrate External C Code Into Generated Code Using Custom Code Blocks and Model Configuration Parameters

The model shows how to integrate external code into generated code by using Simulink® Coder™ custom code blocks and model configuration parameters.

**Open Example Model**

Open the example model `rtwdemo_slcustcode`.

```
open_system('rtwdemo_slcustcode')
```

Several techniques exist for incorporating custom code into Simulink Coder. This model shows the use of the Simulink Coder custom code blocks and the Configuration Parameters Code Generation Custom Code page:

1. The Model Source custom code block declares an integer GLOBAL\_INT1 in <model>.c.
2. The Subsystem Outputs custom code block (inside subsystem Amplifier) uses GLOBAL\_INT1.
3. The variable GLOBAL\_INT2 is declared and set from the Configuration Parameters Code Generation Custom Code page, from the "Source file" and "Initialize function," respectively.

Some overlap exists between custom code blocks and custom code specified using configuration parameters, but custom code blocks provide much finer granularity of code placement, and have the advantage of being graphical.

Several techniques exist for integrating external code into code that Simulink® Coder™ generates for a model. This model shows how to integrate external C code by using Simulink® Coder™ custom code blocks and model configuration parameters.

In the model:

- Custom code block Model Source declares integer GLOBAL\_INT1. The declaration appears in the generated file `model.c`.
- Triggered subsystem Amplifier includes the custom code block System Outputs, which uses GLOBAL\_INT1. The System Outputs block declares code for the nearest parent atomic subsystem. In this case, the code appears in the output for the triggered subsystem.
- Model configuration parameters **Source file** and **Initialize function**, on the **Code Generation > Custom Code** pane, declare and set the variable GLOBAL\_INT2.

Some overlap exists between custom code blocks and the custom code model configuration parameters. Custom code blocks provide finer granularity of code placement and are graphical.

To view the custom code blocks, double click **View Custom Code Library**. To view the custom code configuration parameters, double click **View Custom Code Configuration**.

```

### Integrating c-code into model

Custom written c-files can be easily integrated into Stateflow models. This code can be used to augment Stateflow's capabilities or to take advantage of legacy code.

To add custom c-files open the Stateflow simulation target and enter the following:

**Include Code** - Header that defines functions, structures, and data to be accessible by Stateflow.

**Include Path** - Path to this include file.

**Source Files** - c-files that define the functions and data accessible by Stateflow.

▶ **Open Stateflow simulation custom code settings**

If generating code via Simulink Coder, these same settings must also be added to the Model's configuration parameters custom code settings.

▶ **Open Code Generation custom code settings**

▶ **Build model using Simulink Coder**

### Calling c-code from Stateflow

#### Functions

Custom c-code functions can be called from Stateflow using the same syntax as graphical function calls. The statement takes the form:

```
result = my_custom_function(in_args);
```

#### Structures

Variables of structure type can be accessed in Stateflow via the "dot" notation. The expression takes the form:

```
result = my_var.my_field;
```

To view the custom source for this exemplenstration double click the links below.

▶ **Open my\_header.h**

▶ **Open my\_function.c**

### Calling C++ code from Stateflow

Custom C++ code can also be integrated into Stateflow and Simulink Coder. Double-click below for an example.

▶ **Open rtwdemo\_sfcpp**

### Additional documentation

Additional documentation is available for integrating C and C++ code in your model by double-clicking the link below.

▶ **C-Code integration**

▶ **C++-Code integration**

Copyright 1994-2012 The MathWorks, Inc.

## Integrate Code

1. The example includes the custom header file `my_header.c` and the custom source file `my_function.c`.

```
%Open files my_header.h and my_function.c
eval('edit my_header.h')
eval('edit my_function.c')
```

2. On the Configuration Parameters dialog box **Simulation Target** pane, enter the custom source file and header file. Also enter additional include directories and source files.

In this example, the custom header file `my_header.c` and source file `my_function.c` are entered on the **Simulation Target** pane.

```
%Open Configuration Parameters dialog box
slCfgPrmDlg(model, 'Open');
slCfgPrmDlg(bdroot, 'TurnToPage', 'Simulation Target');
```

3. If you generate code with Simulink Coder®, on the Configuration Parameters dialog box **Code Generation > Custom Code** pane, enter the same custom source file and header file. Also enter the same additional include directories and source files.

In this example, the custom header file `my_header.c` and source file `my_function.c` are entered on the **Code Generation > Custom Code** pane.

```
%Open Configuration Parameters dialog box
slCfgPrmDlg(model, 'Open');
slCfgPrmDlg(bdroot, 'TurnToPage', 'Code Generation/Custom Code');
```

### Generate Code

```
rtwbuild('rtwdemo_sfcustom')

Starting build procedure for model: rtwdemo_sfcustom
Successful completion of build procedure for model: rtwdemo_sfcustom
```

### Call C Code from Stateflow

To call custom C code functions from Stateflow, use the same syntax as graphical function calls: `result = my_custom_function(in_args);`

To call variables of structure type, use the dot notation: `result = my_var.my_field;`

## Configure Model for External Code Integration

Configure a model using the **Custom Code** pane such that the code generator includes external code such as headers, files, and functions. You can also include additional files and paths in the build process.

To...	Select...
Insert custom code near the top of the generated <i>model.c</i> or <i>model.cpp</i> file, outside of any function	<p><b>Source file</b> and enter the custom code to insert.</p> <hr/> <p><b>Note:</b> If you generate subsystem code into separate files, this code does not have access to custom code specified as a <b>Source file</b> setting. For example, if you specify an include file as a <b>Source file</b> setting, the software inserts the <b>#include</b> near the top of the <i>model.c</i> or <i>model.cpp</i> file. Subsystem code generated to a separate file does not have access to declarations inside that include file. In this case, consider specifying your custom code as a <b>Header file</b> setting instead.</p>
Insert custom code near the top of the generated <i>model.h</i> file	<b>Header file</b> and enter the custom code to insert.
Insert custom code inside the model's initialize function in the <i>model.c</i> or <i>model.cpp</i> file	<b>Initialize function</b>
Insert custom code inside the model's terminate function in the <i>model.c</i> or <i>model.cpp</i> file.	<b>Terminate function</b> and enter the custom code to insert. Also select the <b>Terminate function required</b> parameter on the <b>Interface</b> pane.
Add include folders, which contain header files, to the build process	<b>Include directories</b> and enter the absolute or relative paths to the folders. If you specify relative paths, the paths must be relative to the folder containing your model files, not relative to the build folder. The order in which you specify the folders is the order in which they are searched for header, source, and library files.
Add source files to be compiled and linked	<b>Source files</b> and enter the full paths or just the file names for the files. Enter just the file name if the file is in the current MATLAB folder or in

To...	Select...
	<p>one of the include folders. For each additional source that you specify, the build process expands a generic rule in the template makefile for the folder in which the source file is found. For example, if a source file is found in folder <code>inc</code>, the build process adds a rule similar to the following:</p> <pre>%.obj: builddir\inc\%.c     \$(CC) -c -Fo\$(@F) \$(CFLAGS) \$&lt;</pre> <p>The build process adds the rules in the order you list the source files.</p>
Add libraries to be linked	<b>Libraries</b> and enter the full paths or just the file names for the libraries. Enter just the file name if the library is located in the current MATLAB folder or in one of the include folders.
Add preprocessor macro definitions	<b>Defines</b> and enter a space-separated list of preprocessor macro definitions to be added to the generated code. The list can include both simple definitions (for example, <code>-DEF1</code> ) and definitions with a value (for example, <code>-DDEF2=1</code> ). Definitions may omit the <code>-D</code> (for example, <code>-DFOO=1</code> and <code>FOO=1</code> are equivalent). If used, the <code>-D</code> may be overridden by the toolchain if it uses a different flag for defines.
Use the same custom code settings as those specified for simulation of MATLAB Function blocks, Stateflow charts, and Truth Table blocks	<p><b>Use the same custom code settings as Simulation Target</b></p> <hr/> <p><b>Note:</b> This option refers to the <b>Simulation Target</b> pane in the Configuration Parameters dialog box.</p>
Enable a library model to use custom code settings unique from the parent model to which the library is linked	<p><b>Use local custom code settings (do not inherit from main model)</b></p> <hr/> <p><b>Note:</b> This option is available only for library models that contain MATLAB Function blocks, Stateflow charts, or Truth Table blocks.</p>

If you are including a header file, in your custom header file add `#ifndef` code. This avoids multiple inclusions. For example, in `rtwtypes.h` the following `#include` guards are added:

```
#ifndef RTW_HEADER_rtwtypes_h_
#define RTW_HEADER_rtwtypes_h_
```

```
...
#endif /* RTW_HEADER_rtwtypes_h_ */
```

---

**Note** Custom code that you include in a configuration set is ignored when building S-function targets, accelerated simulation targets, and model reference simulation targets.

---

For more information about **Custom Code** pane parameters, see “Model Configuration Parameters: Code Generation Custom Code”.

### **More About**

- “About External Code Integration”

## Insert Code into Model Custom Code Blocks

The following topics explain how to use blocks in the Custom Code block library to insert custom code into the code generated for a model.

In this section...
“Custom Code Library” on page 39-86
“Embed Custom Code Directly Into MdlStart Function” on page 39-90
“Custom Code in Subsystems” on page 39-92
“Preserve User Files in Build Folder” on page 39-93

### Custom Code Library

The Custom Code library contains blocks that enable you to insert your own C or C++ code into specific functions within code produced by the code generator for root models and subsystems. These blocks are a superset of code customization capabilities built into the **Custom Code** Configuration Parameters dialog box, and provide greater flexibility in terms of code placement than the controls on the dialog box.

The Custom Code library is part of the Simulink Coder block library. You can access the block library by using the Simulink Library Browser. You can access Custom Code blocks by using the Simulink Coder block library or by entering the MATLAB command `rtwlib` and then double-clicking the Custom Code Library block within it. Alternatively, you can enter the command `custcode`.

These blocks allow you to insert custom code into specific files and functions.

---

**Note:** If you need to integrate custom C++ code with generated C code or vice versa, see “Modify External Code for Language Compatibility”.

---

All Custom Code blocks except for Model Header and Model Source can be dragged into either root models or atomic subsystems. Model Header and Model Source blocks can only be placed in root models.

---

**Note** You can use models containing Custom Code blocks as models referenced by Model blocks. The code generator ignores the blocks when producing code for a simulation target. When producing code for a code generation target, the code generator includes and compiles the custom code.

---

The Custom Code library contains ten blocks that insert custom code into the generated model files and functions. You can view the blocks either by

- Expanding the Custom Code node (under Simulink Coder block library) in the Simulink Library Browser

- Right-clicking the Custom Code sublibrary icon in the right pane of the Simulink Library Browser

The two blocks on the top row contain text fields for inserting custom code at the top and bottom of

- `model.h` — Model Header File block
- `model.c` or `model.cpp` — Model Source File block

Each block contains two fields, in which you type or paste code and comments:

- Top of Model Source/Header
- Bottom of Model Source/Header

The next figure shows the Model Source block dialog box.

The eight function blocks in the second and third rows contain text fields to insert custom code sections at the top and bottom of these designated model functions:

- `SystemStart` — `System Start` function block
- `SystemInitialize` — `System Initialize` function block
- `SystemTerminate` — `System Terminate` function block
- `SystemEnable` — `System Enable` function block
- `SystemDisable` — `System Disable` function block
- `SystemOutputs` — `System Outputs` function block
- `SystemUpdate` — `System Update` function block
- `SystemDerivatives` — `System Derivatives` function block

Each of these blocks provides a System Outputs Function Custom Code dialog box that contains three fields:

- Declaration code
- Execution code
- Exit code

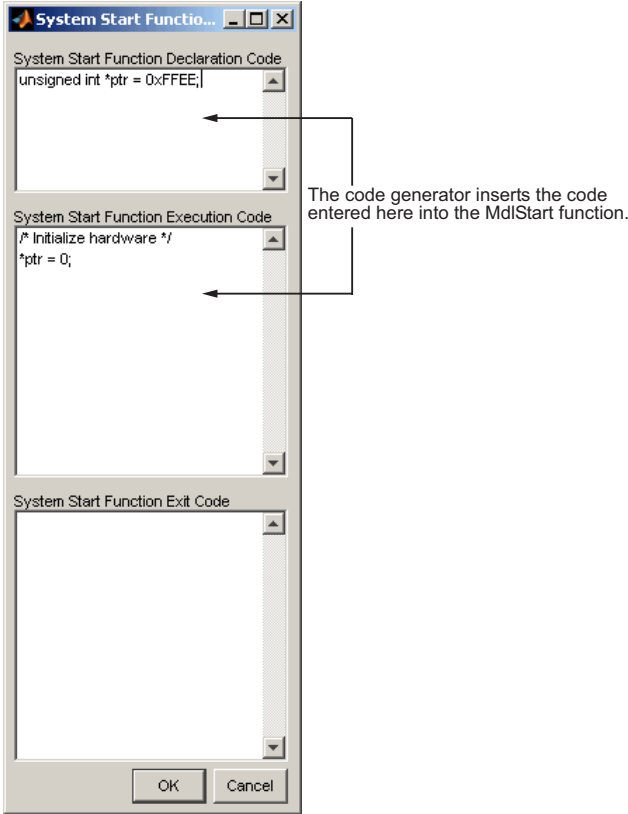

## Embed Custom Code Directly Into MdlStart Function

The following example uses a System Start Function block to introduce code into the MdlStart function. The next figure shows a simple model with the System Start Function block inserted.

Double-clicking the System Start Function block opens the System Start Function Custom Code dialog box.

You can insert custom code into the available text fields.

The code below is the `MdlStart` function for this example (`mymodel`).

```
void MdlStart(void)
{
 {
 {
 /* user code (Start function Header) */
 /* System '<Root>' */
 unsigned int *ptr = 0xFFEE;

 /* user code (Start function Body) */
 /* System '<Root>' */
 /* Initialize hardware */
 *ptr = 0;
 }
 }
}

MdlInitialize();
}
```

The custom code entered in the System Start Function Custom Code dialog box is embedded directly in the generated code. Each block of custom code is tagged with a comment such as

```
/* user code (Start function Header) */
```

## Custom Code in Subsystems

The location of a Custom Code block in your model determines the location of the code it contains. You can use System Custom Code blocks either at root level or within atomic subsystems; the code is local to the subsystem in which you place the blocks. For example, the System Outputs block places code in `mdlOutputs` when the code block resides in the root model. If the System Outputs block resides in a triggered or enabled subsystem, however, the code is placed in the subsystem's `Outputs` function.

The ordering for a triggered or enabled system is

- 1 Output entry
- 2 Output exit
- 3 Update entry
- 4 Update exit

---

**Note** If a root model or atomic subsystem does not need to generate a function for which a Custom Code block has been supplied, either the code in the block is not

used or an error is generated. The software does not have a diagnostic setting to control this. To eliminate the error, remove the Custom Code block.

---

## Preserve User Files in Build Folder

Foreign source files are by default deleted during builds, but can be preserved by following the guidelines given below.

If you put a `.c/.cpp` or `.h` source file in a build folder, and you want to prevent the code generator from deleting it during the TLC code generation process, insert the text `target specific file` in the first line of the `.c/.cpp` or `.h` file. For example,

```
/* COMPANY-NAME target specific file
 *
 * This file is created for use with the
 * COMPANY-NAME target.
 * It is used for ...
 */
...
```

Make sure you spell the text “target specific file” as shown in the preceding example, and that the text is in the first line of the source file. Other text can appear before or after this text.

In addition to preserving them, flagging user files in this manner prevents postprocessing them to indent them along with generated source files. Auto-indenting occurred in previous releases to build folder files with names having the pattern `model_*.c/.cpp` (where `*` could be text). The indenting is harmless, but can cause differences to be detected by source control software that might trigger unnecessary updates.

## Insert External Code into Stateflow Charts

“External Code Integration Examples” includes examples that show how to integrate external code in models for code generation by inserting the code into Stateflow charts.

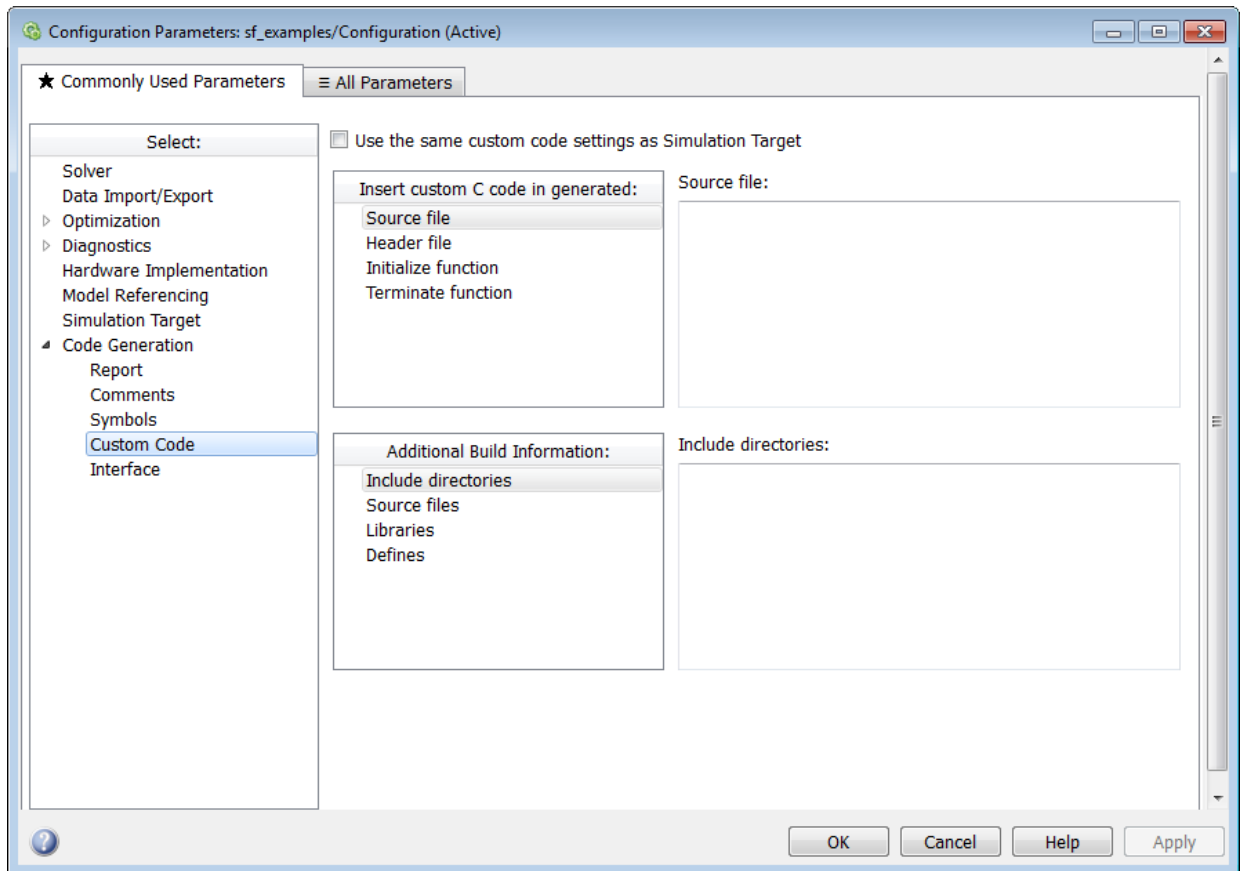

In this section...
“Integrate External Code for Library Charts” on page 39-94
“Integrate External Code for All Charts” on page 39-96

### Integrate External Code for Library Charts

To integrate external code that applies only to Stateflow library charts for code generation, complete the following steps for each library model that contributes a chart to your main model. Then, generate code.

- 1 In the Stateflow Editor, select **Code > C/C++ Code > Code Generation Options**.

The Model Configuration Parameters dialog box appears.

- 2 In the **Code Generation** pane, select **Use local custom code settings (do not inherit from main model)**.

This causes each library model to retain its own custom code settings during code generation.

- 3 Specify your custom code in the subpanes.

Follow the guidelines in “Specify Relative Paths for Custom Code”.

---

**Note:** If you specified custom code settings for simulation, you can apply these settings to code generation. To avoid entering the same information twice, select **Use the same custom code settings as Simulation Target**.

---

- 4 Click **OK**.

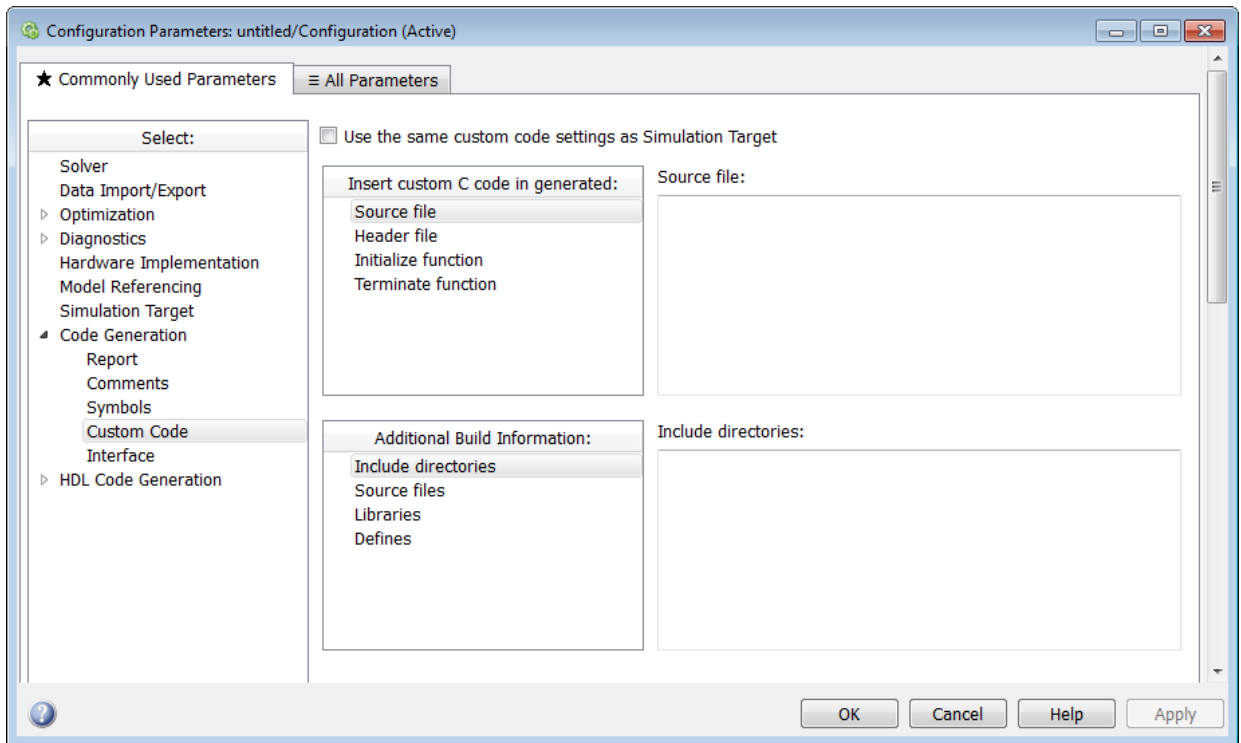

After completing these steps for each library model generate code.

## **Integrate External Code for All Charts**

To integrate external code that applies to all charts for code generation, complete the following steps.

- 1 Specify custom code options for code generation of your main model.
  - a In the Model Configuration Parameters dialog box, select **Code Generation > Custom Code**.

The custom code options appear.

- b** Specify your custom code in the subpanes.

Follow the guidelines in “Specify Relative Paths for Custom Code”.

---

**Note:** If you specified custom code settings for simulation, you can apply these settings to code generation. To avoid entering the same information twice, select **Use the same custom code settings as Simulation Target**.

---

- 2** Configure code generation for each library model that contributes a chart to your main model.
  - a** In the Stateflow Editor, select **Code > C/C++ Code > Code Generation Options**.
  - b** In the **Code Generation** pane, clear the **Use local custom code settings (do not inherit from main model)** check box.

This causes library charts to inherit the custom code settings of your main model.

- c** Click **OK**.
- 3** Generate code.

## S-Functions and Code Generation

This topic describes types of S-functions and provides examples of how you can use them with the code generator.

This topic assumes that you understand the following concepts:

- Level 2 S-functions
- Target Language Compiler (TLC) scripting
- How the code generator produces and builds C/C++ code

---

**Note** When this topic refers to actions performed by the Target Language Compiler, including parsing, caching, and creating buffers, the name Target Language Compiler is spelled out fully. When referring to code written in the Target Language Compiler syntax, this topic uses the abbreviation TLC.

---

---

**Note** The guidelines presented in this topic are for code generator users. Even if you do not currently use the code generator, follow the practices in this topic when writing S-functions, especially if you are creating general-purpose S-functions.

---

### In this section...

“Classes of Problems Solved by S-Functions” on page 39-99

“Types of S-Functions” on page 39-100

“Basic Files Required for Implementation” on page 39-102

“Guidelines for Writing S-Functions” on page 39-103

## Classes of Problems Solved by S-Functions

S-functions help solve various kinds of problems you might face when working with the Simulink and code generator products. These problems include:

- Extending the set of algorithms (blocks) provided by the Simulink and code generator products
- Interfacing external code with the Simulink and code generator products
- Interfacing to hardware through device driver S-functions

- Generating highly optimized code for embedded systems
- Verifying code generated for a subsystem as part of a Simulink simulation

S-functions are written using an application program interface (API) that allows you to implement generic algorithms in the Simulink environment with a great deal of flexibility. This flexibility cannot always be maintained when you use S-functions with the code generator. For example, it is not possible to access the MATLAB workspace from an S-function that is used with the code generator. However, using the techniques presented in this topic, you can create S-functions for most applications that work with the generated code.

Although S-functions provide a generic and flexible solution for implementing complex algorithms in a model, the underlying API incurs overhead in terms of memory and computation resources. Most often the additional resources are acceptable for real-time rapid prototyping systems. In many cases, though, additional resources are unavailable in real-time embedded applications. You can minimize memory and computational requirements by using the Target Language Compiler technology provided with the code generator to inline your S-functions. If you are producing an S-function for existing code, consider using the Legacy Code Tool.

## Types of S-Functions

The implementation of S-functions changes based on your requirements. This topic discusses the typical problems that you may face and how to create S-functions for applications that need to work with the Simulink and code generator products. These are some (informally defined) common situations:

- 1 “I’m not concerned with efficiency. I just want to write one version of my algorithm and have it work in the Simulink and code generator products automatically.”
- 2 “I want to implement a highly optimized algorithm in the Simulink and code generator products that looks like a built-in block and generates very efficient code.”
- 3 “I have a lot of hand-written code that I need to interface. I want to call my function from the Simulink and code generator products in an efficient manner.”

MathWorks products have adopted terminology for these different requirements. Respectively, the situations described above map to this terminology:

- 1 Noninlined S-function
- 2 Inlined S-function

### 3 Autogenerated S-function for legacy or custom code

#### Noninlined S-Functions

A noninlined S-function is a C or C++ MEX S-function that is treated identically by the Simulink engine and generated code. In general, you implement your algorithm once according to the S-function API. The Simulink engine and generated code call the S-function routines (for example, `mdlOutputs`) during model execution.

Additional memory and computation resources are required for each instance of a noninlined S-Function block. However, this routine of incorporating algorithms into models and code generation applications is typical during the prototyping phase of a project where efficiency is not important. The advantage gained by forgoing efficiency is the ability to change model parameters and structures rapidly.

Writing a noninlined S-function does not involve TLC coding. Noninlined S-functions are the default case for the build process in the sense that once you build a MEX S-function in your model, there is no additional preparation prior to pressing **Ctrl+B** to build your model.

Some restrictions exist concerning the names and locations of noninlined S-function files when generating makefiles. See “Write Noninlined S-Function and TLC Files” on page 39-104.

#### Inlined S-Functions

For S-functions to work in the Simulink environment, some overhead code is generated. When the code generator produces code from models that contain S-functions (without `sfunction.tlc` files), it embeds some of this overhead code in the generated code. If you want to optimize your real-time code and eliminate some of the overhead code, you must *inline* (or embed) your S-functions. This involves writing a TLC (`sfunction.tlc`) file that eliminates overhead code from the generated code. The Target Language Compiler processes `sfunction.tlc` files to define how to inline your S-function algorithm in the generated code.

---

**Note** The term *inline* should not be confused with the C++ *inline* keyword. Inline means to specify text in place of the call to the general S-function API routines (for example, `mdlOutputs`). For example, when a TLC file is used to inline an S-function, the generated code contains the C/ C++ code that would normally appear within the S-function routines and the S-function itself has been removed from the build process.

---

A fully inlined S-function builds your algorithm (block) into generated code in a manner that is indistinguishable from a built-in block. Typically, a fully inlined S-function requires you to implement your algorithm twice: once for the Simulink model (C/C++ MEX S-function) and once for code generation (TLC file). The complexity of the TLC file depends on the complexity of your algorithm and the level of efficiency you're trying to achieve in the generated code. TLC files vary from simple to complex in structure.

### Autogenerated S-Functions for Legacy or Custom Code

If you need to invoke hand-written C/C++ code in your model, consider using the Simulink Legacy Code Tool. The Legacy Code Tool can automate the generation of a fully inlined S-function and a corresponding TLC file based on information that you register in a Legacy Code Tool data structure.

For more information, see “Integrate C Functions Using Legacy Code Tool” in the Simulink Writing S-Functions documentation and “Build S-Function With Legacy Code Tool” on page 39-27.

### Basic Files Required for Implementation

This topic briefly describes what files and functions you need to create noninlined and inlined S-functions.

- Noninlined S-functions require the C or C++ MEX S-function source code (*sfunction.c* or *sfunction.cpp*).
- Fully inlined S-functions require an *sfunction.tlc* file. Fully inlined S-functions produce the optimal code for a parameterized S-function. This is an S-function that operates in a specific mode dependent upon fixed S-function parameters that do not change during model execution. For a given operating mode, the *sfunction.tlc* file specifies the exact code that is generated to implement the algorithm for that mode. For example, the direct-index lookup table S-function in “Write Fully Inlined S-Functions with mdlRTW Routine” on page 39-116 contains two operating modes — one for evenly spaced *x-data* and one for unevenly spaced *x-data*.

---

**Note:** Fully-inlined S-functions that are generated to invoke legacy or custom C/C++ code also require an *sfunction.tlc* file, which is generated by Legacy Code Tool.

---

Fully inlined S-functions might require the placement of the mdlRTW routine in your S-function MEX-file *sfunction.c* or *sfunction.cpp*. The mdlRTW routine lets you

place information in *model.rtw*, the record file that specifies a model, and which the code generator invokes the Target Language Compiler to process prior to executing *sfunction.tlc* when generating code.

Including a `mdlRTW` routine is useful when you want to introduce nontunable parameters into your TLC file. Such parameters are generally used to determine which operating mode is active in a given instance of the S-function. Based on this information, the TLC file for the S-function can generate highly efficient, optimal code for that operating mode.

## Guidelines for Writing S-Functions

- You can use C/C++ MEX, MATLAB language, and Fortran MEX S-functions with code generation.
- You can inline S-functions for code generation by providing an inlining TLC file. See S-Function Inlining in “Target Language Compiler”. MATLAB and Fortran MEX S-functions must be inlined. C/C++ MEX S-functions can be inlined for code efficiency, or noninlined.
- To automatically generate a fully inlined C MEX S-function for invoking legacy or custom code, use the Legacy Code Tool. For more information, see “Integrate C Functions Using Legacy Code Tool” in the Simulink documentation and “Build S-Function With Legacy Code Tool”.
- If code efficiency is not an overriding consideration, for example, if you are rapid prototyping, you can choose not to inline a C/C++ MEX S-function. For more information, see “Write Noninlined S-Function and TLC Files” on page 39-104.

- “Build S-Function With Legacy Code Tool” on page 39-27
- “Inlining S-Functions”

## Write S-Function and TLC Files By Hand

You can choose from several approaches for writing S-function and TLC files by hand.

### Write Noninlined S-Function and TLC Files

- “About Noninlined S-Functions” on page 39-104
- “Guidelines for Writing Noninlined S-Functions” on page 39-104
- “Noninlined S-Function Parameter Type Limitations” on page 39-105

#### About Noninlined S-Functions

Noninlined S-functions are identified by the *absence* of an `sfunction.tlc` file for your S-function. The filename varies depending on your platform. For example, on a 64-bit Microsoft Windows system, the file name would be `sfunction.mexw64`. Type `mexext` in the MATLAB Command Window to see which extension your system uses.

#### Guidelines for Writing Noninlined S-Functions

- The MEX-file cannot call MATLAB functions.
- If the MEX-file uses functions in the MATLAB External Interface libraries, include the header file `cg_sfun.h` instead of `mex.h` or `simulink.c`. To handle this case, include the following lines at the end of your S-function:

```
#ifdef MATLAB_MEX_FILE /* Is this file being compiled as a MEX-file? */
#include "simulink.c" /* MEX-file interface mechanism */
#else
#include "cg_sfun.h" /* Code generation registration function */
#endif
```

- Use only MATLAB API function that the code generator supports, which include:

```
mxGetEps
mxGetInf
mxGetM
mxGetN
mxGetNaN
mxGetPr
mxGetScalar
mxGetString
mxIsEmpty
mxIsFinite
mxIsInf
```

- MEX library calls are not supported in generated code. To use such calls in MEX-file and not in the generated code, conditionalize the code as follows:

```
#ifdef MATLAB_MEX_FILE
#endif
```

- Use only full matrices that contain only real data.
- Do not specify a return value for calls to `mxGetString`. If you do specify a return value, the MEX-file will not compile. Instead, use the function's second input argument, which returns a pointer to a character vector.
- Make sure that the `#define s-function_name` statement is correct. The S-function name that you specify must match the S-function's filename.
- Use the data types `real_T` and `int_T` instead of `double` and `int`, if possible. The data types `real_T` and `int_T` are more generic and can be used in multiple environments.
- Provide the build process with the names of the modules used to build the S-function. You can do this by using a template make file, the `set_param` function, or the `S-function modules` field of the S-Function block parameters dialog box. For example, suppose you build your S-function with the following command:

```
mex sfun_main.c sfun_module1.c sfun_module2.c
```

You can then use the following call to `set_param` to include the required modules:

```
set_param(sfun_block, "SFunctionModules", "sfun_module1 sfun_module2")
```

When you are ready to generate code, force the code generator to rebuild the top model, as explained in “Control Regeneration of Top Model Code”.

### Noninlined S-Function Parameter Type Limitations

Parameters to noninlined S-functions can be of the following types only:

- Double precision
- Characters in scalars, vectors, or 2-D matrices

For more flexibility in the type of parameters you can supply to S-functions or the operations in the S-function, inline your S-function and consider using an `mdlRTW` S-function routine.

Use of other functions from the MATLAB `matrix.h` API or other MATLAB APIs, such as `mex.h` and `mat.h`, is not supported. If you call unsupported APIs from an S-function

source file, compiler errors occur. See the files `matlabroot/rtw/c/src/rt_matrix.h` and `matlabroot/rtw/c/src/rt_matrix.c` for details on supported MATLAB API functions.

If you use `mxGetPr` on an empty matrix, the function does not return `NULL`; rather, it returns a random value. Therefore, you should protect calls to `mxGetPr` with `mxIsEmpty`.

## Write Wrapper S-Function and TLC Files

This topic describes how to create S-functions that work seamlessly with the Simulink and code generator products using the *wrapper* concept. This topic begins by describing how to interface your algorithms in Simulink models by writing MEX S-function wrappers (`sfunction.mex`). It finishes with a description of how to direct the code generator to insert your algorithm into the generated code by creating a TLC S-function wrapper (`sfunction.tlc`).

- “MEX S-Function Wrapper” on page 39-106
- “TLC S-Function Wrapper” on page 39-111
- “Code Overhead for Noninlined S-Functions” on page 39-111
- “How to Inline” on page 39-112
- “The Inlined Code” on page 39-114

### MEX S-Function Wrapper

Creating S-functions using an S-function wrapper allows you to insert C/C++ code algorithms in Simulink models and the generated code with little or no change to your original C/C++ function. A *MEX S-function wrapper* is an S-function that calls code that resides in another module. A *TLC S-function wrapper* is a TLC file that specifies how the code generator should call your code (the same code that was called from the C MEX S-function wrapper).

---

**Note:** A MEX S-function wrapper must only be used in the MATLAB version in which the wrapper is created.

---

Suppose you have an algorithm (that is, a C function) called `my_alg` that resides in the file `my_alg.c`. You can integrate `my_alg` into a Simulink model by creating a MEX S-

function wrapper (for example, `wrapsfcn.c`). Once this is done, a Simulink model can call `my_alg` from an S-Function block. However, the Simulink S-function contains a set of empty functions that the Simulink engine requires for various API-related purposes. For example, although only `mdlOutputs` calls `my_alg`, the engine calls `mdlTerminate` as well, even though this S-function routine performs no action.

You can integrate `my_alg` into generated code (that is, embed the call to `my_alg` in the generated code) by creating a TLC S-function wrapper (for example, `wrapsfcn.tlc`). The advantage of creating a TLC S-function wrapper is that the empty function calls can be eliminated and the overhead of executing the `mdlOutputs` function and then the `my_alg` function can be eliminated.

Wrapper S-functions are useful when you are creating new algorithms that are procedural in nature or when you are integrating legacy code into a Simulink model. However, if you want to create code that is

- Interpretive in nature (that is, highly parameterized by operating modes)
- Heavily optimized (that is, no extra tests to decide what mode the code is operating in)

then you must create a *fully inlined TLC file* for your S-function.

The next figure shows the wrapper S-function concept.

**Simulink**

Place the name of your S-function in the S-Function block dialog box.

In Simulink, the S-function calls mdlOutputs, which in turn calls my\_alg.

```

wrapsfcn.c
...
mdlOutputs(...)
{
 ...
 my_alg();
}

```

mdlOutputs in wrapsfcn.mex calls external function my\_alg.

```

my_alg.c
...
real_T my_alg(real_T u)
{
 ...
 y=f(u);
}

```

**Simulink Coder**

wrapper.c, the generated code, calls mdlOutputs, which then calls my\_alg.

```

wrapper.c
...
mdlOutputs(...)
{
 ...
 my_alg();
}

```

In the TLC wrapper version of the S-function, mdlOutputs in wrapper.exe calls my\_alg.

\*See note below

\*The dotted line is the path taken if the S-function does not have a TLC wrapper file. If there is no TLC wrapper file, the generated code calls mdlOutputs.

Using an S-function wrapper to import algorithms in your Simulink model means that the S-function serves as an interface that calls your C/C++ algorithms from mdlOutputs. S-function wrappers have the advantage that you can quickly integrate large standalone C /C++ programs into your model without having to make changes to the code.

The following sample model includes an S-function wrapper.

There are two files associated with the `wrapsfcn` block, the S-function wrapper and the C/C++ code that contains the algorithm. The S-function wrapper code for `wrapsfcn.c` appears below. The first three statements do the following:

- 1 Defines the name of the S-function (what you enter in the Simulink S-Function block dialog).
- 2 Specifies that the S-function is using the level 2 format.
- 3 Provides access to the `SimStruct` data structure, which contains pointers to data used during simulation and code generation and defines macros that store data in and retrieve data from the `SimStruct`.

For more information, see “Templates for C S-Functions” in the Simulink documentation.

```
#define S_FUNCTION_NAME wrapsfcn
#define S_FUNCTION_LEVEL 2
#include "simstruc.h"

extern real_T my_alg(real_T u); /* Declare my_alg as extern */

/*
 * mdlInitializeSizes - initialize the sizes array
 */
static void mdlInitializeSizes(SimStruct *S)
{
 ssSetNumSFcnParams(S, 0); /*number of input arguments*/

 if (!ssSetNumInputPorts(S, 1)) return;
 ssSetInputPortWidth(S, 0, 1);
 ssSetInputPortDirectFeedThrough(S, 0, 1);

 if (!ssSetNumOutputPorts(S,1)) return;
 ssSetOutputPortWidth(S, 0, 1);

 ssSetNumSampleTimes(S, 1);
}
```

```

/*
 * mdlInitializeSampleTimes - indicate that this S-function runs
 * at the rate of the source (driving block)
 */
static void mdlInitializeSampleTimes(SimStruct *S)
{
 ssSetSampleTime(S, 0, INHERITED_SAMPLE_TIME);
 ssSetOffsetTime(S, 0, 0.0);
}

/*
 * mdlOutputs - compute the outputs by calling my_alg, which
 * resides in another module, my_alg.c
 */
static void mdlOutputs(SimStruct *S, int_T tid)
{
 InputRealPtrsType uPtrs = ssGetInputPortRealSignalPtrs(S,0);
 real_T *y = ssGetOutputPortRealSignal(S,0);
 *y = my_alg(*uPtrs[0]); /* Call my_alg in mdlOutputs */
}
/*
 * mdlTerminate - called when the simulation is terminated.
 */
static void mdlTerminate(SimStruct *S)
{
}

#ifdef MATLAB_MEX_FILE /* Is this file being compiled as a MEX-file? */
#include "simulink.c" /* MEX-file interface mechanism */
#else
#include "cg_sfuns.h" /* Code generation registration function */
#endif

```

The S-function routine `mdlOutputs` contains a function call to `my_alg`, which is the C function containing the algorithm that the S-function performs. This is the code for `my_alg.c`:

```

#ifdef MATLAB_MEX_FILE
#include "tmwtypes.h"
#else
#include "rtwtypes.h"
#endif
real_T my_alg(real_T u)
{
 return(u * 2.0);
}

```

For more information, see the topic “Dependencies When Interfacing Custom and Generated Code” on page 33-39.

The wrapper S-function `wrapsfcn` calls `my_alg`, which computes `u * 2.0`. To build `wrapsfcn.mex`, use the following command:

```
mex wrapsfcn.c my_alg.c
```

## TLC S-Function Wrapper

This topic describes how to inline the call to `my_alg` in the `mdlOutputs` section of the generated code. In the above example, the call to `my_alg` is embedded in the `mdlOutputs` section as

```
*y = my_alg(*uPtrs[0]);
```

When you are creating a TLC S-function wrapper, the goal is to embed the same type of call in the generated code.

It is instructive to look at how the code generator executes S-functions that are not inlined. A noninlined S-function is identified by the absence of the file `sfunction.tlc` and the existence of `sfunction.mex`. When generating code for a noninlined S-function, the code generator produces a call to `mdlOutputs` through a function pointer that, in this example, then calls `my_alg`.

The wrapper example contains one S-function, `wrapsfcn.mex`. You must compile and link an additional module, `my_alg`, with the generated code. To do this, specify

```
set_param('wrapper/S-Function', 'SFunctionModules', 'my_alg')
```

## Code Overhead for Noninlined S-Functions

The code generated when using `grt.tlc` as the system target file *without* `wrapsfcn.tlc` is

<Generated code comments for wrapper model with **noninlined** wrapsfcn S-function>

```
#include <math.h>
#include <string.h>
#include "wrapper.h"
#include "wrapper.prm"

/* Start the model */
void mdlStart(void)
{
 /* (start code not required) */
}

/* Compute block outputs */
void mdlOutputs(int_T tid)
{
 /* Sin Block: <Root>/Sin */
 rtB.Sin = rtP.Sin.Amplitude *
 sin(rtP.Sin.Frequency * ssGetT(rtS) + rtP.Sin.Phase);
```

```

/* Level2 S-Function Block: <Root>/S-Function (wrapsfcn) */
{
 /* Noninlined S-functions create a SimStruct object and
 * generate a call to S-function routine mdlOutputs
 */
 SimStruct *rts = ssGetSFunction(rtS, 0);
 sfcnOutputs(rts, tid);
}

/* Outport Block: <Root>/Out */
rtY.Out = rtB.S_Function;
}

/* Perform model update */
void mdlUpdate(int_T tid)
{
 /* (update code not required) */
}

/* Terminate function */
void mdlTerminate(void)
{
 /* Level2 S-Function Block: <Root>/S-Function (wrapsfcn) */
 {
 /* Noninlined S-functions require a SimStruct object and
 * the call to S-function routine mdlTerminate
 */
 SimStruct *rts = ssGetSFunction(rtS, *0);
 sfcnTerminate(rts);
 }
}

#include "wrapper.reg"

/* [EOF] wrapper.c */

```

In addition to the overhead outlined above, the `wrapper.reg` generated file contains the initialization of the `SimStruct` for the wrapper S-Function block. There is one child `SimStruct` for each S-Function block in your model. You can significantly reduce this overhead by creating a TLC wrapper for the S-function.

### How to Inline

The generated code makes the call to your S-function, `wrapsfcn.c`, in `mdlOutputs` by using this code:

```

SimStruct *rts = ssGetSFunction(rtS, 0);
sfcnOutputs(rts, tid);

```

This call has computational overhead associated with it. First, the Simulink engine creates a `SimStruct` data structure for the S-Function block. Second, the code generator

constructs a call through a function pointer to execute `mdlOutputs`, then `mdlOutputs` calls `my_alg`. By inlining the call to your C/C++ algorithm, `my_alg`, you can eliminate both the `SimStruct` and the extra function call, thereby improving the efficiency and reducing the size of the generated code.

Inlining a wrapper S-function requires an `sfunction.tlc` file for the S-function (see the “Target Language Compiler” for details). The TLC file must contain the function call to `my_alg`. The following figure shows the relationships between the algorithm, the wrapper S-function, and the `sfunction.tlc` file.

The `wrapsfcn.tlc` file tells Simulink Coder how to inline the call to `my_alg` using this statement.

To inline this call, you have to place your function call in an `sfunction.tlc` file with the same name as the S-function (in this example, `wrapsfcn.tlc`). This causes the Target Language Compiler to override the default method of placing calls to your S-function in the generated code.

This is the `wrapsfcn.tlc` file that inlines `wrapsfcn.c`.

```

%% File : wrapsfcn.tlc
%% Abstract:
%% Example inlined tlc file for S-function wrapsfcn.c
%%

%implements "wrapsfcn" "C"

%% Function: BlockTypeSetup =====
%% Abstract:
%% Create function prototype in model.h as:
%% "extern real_T my_alg(real_T u);"
%%
%%function BlockTypeSetup(block, system) void
 %openfile buffer
 extern real_T my_alg(real_T u); /* This line is placed in wrapper.h */

```

```

 %closefile buffer
 %<LibCacheFunctionPrototype(buffer)>
%endfunction %% BlockTypeSetup

%% Function: Outputs =====
%% Abstract:
%% y = my_alg(u);
%%
%function Outputs(block, system) Output
/* %<Type> Block: %<Name> */
%assign u = LibBlockInputSignal(0, "", "", 0)
%assign y = LibBlockOutputSignal(0, "", "", 0)
%% PROVIDE THE CALLING STATEMENT FOR "algorithm"
%% The following line is expanded and placed in mdlOutputs within wrapper.c
%<y> = my_alg(%<u>);

%endfunction %% Outputs

```

The first section of this code inlines the `wrapsfcn` S-Function block and generates the code in C:

```
%implements "wrapsfcn" "C"
```

The next task is to tell the code generator that the routine `my_alg` needs to be declared external in the generated `wrapper.h` file for any `wrapsfcn` S-Function blocks in the model. You only need to do this once for all `wrapsfcn` S-Function blocks, so use the `BlockTypeSetup` function. In this function, you tell the Target Language Compiler to create a buffer and cache the `my_alg` as `extern` in the `wrapper.h` generated header file.

The final step is the inlining of the call to the function `my_alg`. This is done by the `Outputs` function. In this function, you access the block's input and output and place a direct call to `my_alg`. The call is embedded in `wrapper.c`.

### The Inlined Code

The code generated when you inline your wrapper S-function is similar to the default generated code. The `mdlTerminate` function does not contain a call to an empty function and the `mdlOutputs` function now directly calls `my_alg`.

```

void mdlOutputs(int_T tid)
{
 /* Sin Block: <Root>/Sin */
 rtB.Sin = rtP.Sin.Amplitude *
 sin(rtP.Sin.Frequency * ssGetT(rtS) + rtP.Sin.Phase);

 /* S-Function Block: <Root>/S-Function */
 rtB.S_Function = my_alg(rtB.Sin); /* Inlined call to my_alg */
}

```

```

/* Output Block: <Root>/Out */
rtY.Out = rtB.S_Function;
}

```

In addition, `wrapper.reg` does not create a child `SimStruct` for the S-function because the generated code is calling `my_alg` directly. This eliminates over 1 KB of memory usage.

## Write Fully Inlined S-Functions

Using the example from “Write Wrapper S-Function and TLC Files”, you could eliminate the call to `my_alg` entirely by specifying the explicit code (that is, `2.0 * u`) in `wrapsfcn.tlc`. This is referred to as a *fully inlined S-function*. While this can improve performance, if you are working with a large amount of C/C++ code, this can be a lengthy task. In addition, you now have to maintain your algorithm in two places, the C/C++ S-function itself and the corresponding TLC file. However, the performance gains might outweigh the disadvantages. To inline the algorithm used in this example, in the Outputs section of your `wrapsfcn.tlc` file, instead of writing

```

%<y> = my_alg(%<u>);

use

%<y> = 2.0 * %<u>;

```

This is the code produced in `mdlOutputs`:

```

void mdlOutputs(int_T tid)
{
/* Sin Block: <Root>/Sin */
rtB.Sin = rtP.Sin.Amplitude *
 sin(rtP.Sin.Frequency * ssGetT(rtS) + rtP.Sin.Phase);

/* S-Function Block: <Root>/S-Function */
rtB.S_Function = 2.0 * rtB.Sin; /* Explicit embedding of algorithm */

/* Output Block: <Root>/Out */
rtY.Out = rtB.S_Function;
}

```

The Target Language Compiler has replaced the call to `my_alg` with the algorithm itself.

## Multiport S-Function

A more advanced multiport inlined S-function example is `sfun_multiport.c` and `sfun_multiport.tlc`. This S-function illustrates how to create a fully inlined TLC

file for an S-function that contains multiple ports. You might find that looking at this example helps you to understand fully inlined TLC files.

## Write Fully Inlined S-Functions with mdlRTW Routine

You can inline more complex S-functions that use the S-function `mdlRTW` routine. The purpose of the `mdlRTW` routine is to provide the code generation process with more information about how the S-function is to be inlined, by creating a parameter record of a nontunable parameter for use with a TLC file. The `mdlRTW` routine does this by placing information in the `model.rtw` file. The `mdlRTW` function is described in the text file `matlabroot/simulink/src/sfuntmpl_doc.c`.

As an example of how to use the `mdlRTW` function, this topic discusses the steps you must take to create a direct-index lookup S-function. Lookup tables are collections of ordered data points of a function. Typically, these tables use some interpolation scheme to approximate values of the associated function between known data points. To incorporate the example lookup table algorithm into a Simulink model, the first step is to write an S-function that executes the algorithm in `mdlOutputs`. To produce the most efficient code, the next step is to create a corresponding TLC file to eliminate computational overhead and improve the speed of the lookup computations.

For your convenience, the Simulink product provides support for two general-purpose lookup 1-D and 2-D algorithms. You can use these algorithms as they are or create a custom lookup table S-function to fit your requirements. This topic illustrates how to create a 1-D lookup S-function, `sfun_directlook.c`, and its corresponding inlined `sfun_directlook.tlc` file (see “Target Language Compiler” for more details). This 1-D direct-index lookup table example illustrates the following concepts that you need to know to create your own custom lookup tables:

- Error checking of S-function parameters
- Caching of information for the S-function that doesn't change during model execution
- How to use the `mdlRTW` function to customize the code generator to produce the optimal code for a given set of block parameters
- How to generate an inlined TLC file for an S-function in a combination of the fully inlined form and/or the wrapper form
- “S-Function RTWdata” on page 39-117
- “Direct-Index Lookup Table Algorithm” on page 39-117

- “Direct-Index Lookup Table Example” on page 39-119

### S-Function RTWdata

There is a property of blocks called `RTWdata`, which can be used by the Target Language Compiler when inlining an S-function. `RTWdata` is a structure of character vectors that you can attach to a block. It is saved with the model and placed in the `model.rtw` file when generating code. For example, this set of MATLAB commands,

```
mydata.field1 = 'information for field1';
mydata.field2 = 'information for field2';
set_param(gcf,'RTWdata',mydata)
get_param(gcf,'RTWdata')
```

produces this result:

```
ans =

 field1: 'information for field1'
 field2: 'information for field2'
```

Inside the `model.rtw` file for the associated S-Function block is this information.

```
Block {
 Type "S-Function"
 RTWdata {
 field1 "information for field1"
 field2 "information for field2"
 }
}
```

---

**Note:** `RTWdata` is saved in the model file for S-functions that are not linked to a library. However, `RTWdata` is **not persistent** for S-Function blocks that are linked to a library.

---

### Direct-Index Lookup Table Algorithm

The 1-D lookup table block provided in the Simulink library uses interpolation or extrapolation when computing outputs. This extra accuracy might not be required. In this example, you create a lookup table that directly indexes the output vector ( $y$ -data vector) based on the current input ( $x$ -data) point.

This direct 1-D lookup example computes an approximate solution  $p(x)$  to a partially known function  $f(x)$  at  $x=x_0$ , given data point pairs  $(x,y)$  in the form of an  $x$ -data vector and a  $y$ -data vector. For a given data pair (for example, the  $i$ 'th pair),  $y_i = f(x_i)$ . It is assumed that the  $x$ -data values are monotonically increasing. If  $x_0$  is outside the range of the  $x$ -data vector, the first or last point is returned.

The parameters to the S-function are

XData, YData, XEvenlySpaced

XData and YData are double vectors of equal length representing the values of the unknown function. XDataEvenlySpaced is a scalar, 0.0 for false and 1.0 for true. If the XData vector is evenly spaced, XDataEvenlySpaced is 1.0 and more efficient code is generated.

The following graph shows how the parameters XData=[1:6] and YData=[1,2,7,4,5,9] are handled. For example, if the input ( $x$ -value) to the S-Function block is 3, the output ( $y$ -value) is 7.

## Direct-Index Lookup Table Example

This topic shows how to improve the lookup table by inlining a direct-index S-function with a TLC file. This direct-index lookup table S-function does not require a TLC file. Here the example uses a TLC file for the direct-index lookup table S-function to reduce the code size and increase efficiency of the generated code.

Implementation of the direct-index algorithm with inlined TLC file requires the S-function main module, `sfun_directlook.c`, and a corresponding `lookup_index.c` module. The `lookup_index.c` module contains the `GetDirectLookupIndex` function that is used to locate the index in the `XData` for the current `x` input value when the `XData` is unevenly spaced. The `GetDirectLookupIndex` routine is called from both the S-function and the generated code. Here the example uses the wrapper concept for sharing C/C++ code between Simulink MEX-files and the generated code.

If the `XData` is evenly spaced, then both the S-function main module and the generated code contain the lookup algorithm (not a call to the algorithm) to compute the `y`-value of a given `x`-value, because the algorithm is short. This illustrates the use of a fully inlined S-function for generating optimal code.

The inlined TLC file, which either performs a wrapper call or embeds the optimal C/C++ code, is `sfun_directlook.tlc` (see the example in “mdlRTW Usage” on page 39-120).

### Error Handling

In this example, the `mdlCheckParameters` routine verifies that

- The new parameter settings are valid.
- `XData` and `YData` are vectors of the same length containing real finite numbers.
- `XDataEvenlySpaced` is a scalar.
- The `XData` vector is a monotonically increasing vector and evenly spaced.

The `mdlInitializeSizes` function explicitly calls `mdlCheckParameters` after it verifies the number of parameters passed to the S-function. After the Simulink engine calls `mdlInitializeSizes`, it then calls `mdlCheckParameters` whenever you change the parameters or there is a need to reevaluate them.

### User Data Caching

The `mdlStart` routine shows how to cache information that does not change during the simulation (or while the generated code is executing). The example caches the value

of the `XDataEvenlySpaced` parameter in `UserData`, a field of the `SimStruct`. The following line in `mdlInitializeSizes` tells the Simulink engine to disallow changes to `XDataEvenlySpaced`.

```
ssSetSFcnParamTunable(S, iParam, SS_PRM_NOT_TUNABLE);
```

During execution, `mdlOutputs` accesses the value of `XDataEvenlySpaced` from `UserData` rather than calling the `mxGetPr` MATLAB API function.

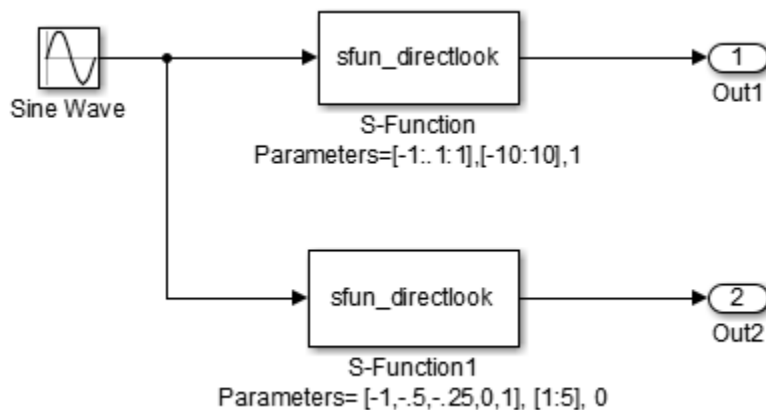

### mdlRTW Usage

The code generator calls the `mdlRTW` routine while generating the `model.rtw` file. To produce optimal code for your Simulink model, you can add information to the `model.rtw` file about the mode in which your S-Function block is operating.

The following example adds parameter settings to the `model.rtw` file. The parameter settings do not change during execution. In this case, the `XDataEvenlySpaced` S-function parameter cannot change during execution (`ssSetSFcnParamTunable` was specified as false (0) for it in `mdlInitializeSizes`). The example writes it out as a parameter setting (`XSpacing`) using the function `ssWriterTWParamSettings`.

Because `xData` and `yData` are registered as run-time parameters in `mdlSetWorkWidths`, the code generator handles writing to the `model.rtw` file automatically.

Before examining the S-function and the inlined TLC file, consider the generated code for the following model.

The model uses evenly spaced XData in the top S-Function block and unevenly spaced XData in the bottom S-Function block. When creating this model, you need to specify the following for each S-Function block.

```
set_param('sfun_directlook_ex/S-Function','SFunctionModules','lookup_index')
set_param('sfun_directlook_ex/S-Function1','SFunctionModules','lookup_index')
```

This informs the build process to use the module `lookup_index.c` when creating the executable.

When generating code for this model, the code generator uses the S-function `mdlRTW` method to generate a `model.rtw` file with the value `EvenlySpaced` for the `XSpacing` parameter for the top S-Function block, and the value `UnEvenlySpaced` for the `XSpacing` parameter for the bottom S-Function block. The TLC-file uses the value of `XSpacing` to determine what algorithm to include in the generated code. The generated code contains the lookup algorithm when the XData is evenly spaced, but calls the `GetDirectLookupIndex` routine when the XData is unevenly spaced. The generated `model.c` or `model.cpp` code for the lookup table example model is similar to the following:

```
/*
 * sfun_directlook_ex.c
 *
 * Code generation for Simulink model
 * "sfun_directlook_ex.slx".
 *
...
 */

#include "sfun_directlook_ex.h"
#include "sfun_directlook_ex_private.h"

/* External outputs (root outputs fed by signals with auto storage) */
ExtY_sfun_directlook_ex_T sfun_directlook_ex_Y;

/* Real-time model */
RT_MODEL_sfun_directlook_ex_T sfun_directlook_ex_M;

## Guidelines for Writing Inlined S-Functions

- Consider using the block property `RTWdata` (see “S-Function `RTWdata`”). This property is a structure of character vectors that you can associate with a block. The code generator saves the structure with the model in the `model.rtw` file and makes the `.rtw` file more readable. For example, suppose you enter the following commands in the MATLAB Command Window:

```
mydata.field1 = 'information for field1';
mydata.field2 = 'information for field2';
set_param(sfun_block, 'RTWdata', mydata);
```

The `.rtw` file that the code generator produces for the block includes the comments specified in the structure `mydata`.

- Consider using the `mdlRTW` function to inline your C MEX S-function in the generated code. This is useful when you want to
  - Rename tunable parameters in the generated code
  - Introduce nontunable parameters into a TLC file

## S-Functions That Support Expression Folding

- “About S-Functions that Support Expression Folding” on page 39-135
- “Categories of Output Expressions” on page 39-136
- “Acceptance or Denial of Requests for Input Expressions” on page 39-140
- “Expression Folding in a TLC Block Implementation” on page 39-142

### About S-Functions that Support Expression Folding

This topic describes how you can take advantage of expression folding to increase the efficiency of code generated by your own inlined S-Function blocks, by calling macros provided in the S-Function API. This topic assumes that you are familiar with:

- Writing inlined S-functions (see “S-Function Basics”).
- “Target Language Compiler”

The S-Function API lets you specify whether a given S-Function block should nominally accept expressions at a given input port. A block should not always accept expressions. For example, if the address of the signal at the input is used, expressions should not be accepted at that input, because it is not possible to take the address of an expression.

The S-Function API also lets you specify whether an expression can represent the computations associated with a given output port. When you request an expression at a block's input or output port, the Simulink engine determines whether or not it can honor that request, given the block's context. For example, the engine might deny a block's request to output an expression if the destination block does not accept expressions at its input, if the destination block has an update function, or if multiple output destinations exist.

The decision to honor or deny a request to output an expression can also depend on the category of output expression the block uses (see “Categories of Output Expressions” on page 39-136).

The topics that follow explain

- When and how you can request that a block accept expressions at an input port
- When and how you can request that a block generate expressions at an output port
- The conditions under which the Simulink engine will honor or deny such requests

To take advantage of expression folding in your S-functions, you should understand when to request acceptance and generation of expressions for specific blocks. You do not have to understand the algorithm by which the Simulink engine chooses to accept or deny these requests. However, if you want to trace between the model and the generated code, it is helpful to understand some of the more common situations that lead to denial of a request.

### Categories of Output Expressions

When you implement a C MEX S-function, you can specify whether the code corresponding to a block's output is to be generated as an expression. If the block generates an expression, you must specify that the expression is *constant*, *trivial*, or *generic*.

A *constant* output expression is a direct access to one of the block's parameters. For example, the output of a Constant block is defined as a constant expression because the output expression is simply a direct access to the block's `Value` parameter.

A *trivial* output expression is an expression that can be repeated, without a performance penalty, when the output port has multiple output destinations. For example, the output of a Unit Delay block is defined as a trivial expression because the output expression is simply a direct access to the block's state. Because the output expression does not have computations, it can be repeated more than once without degrading the performance of the generated code.

A *generic* output expression is an expression that should be assumed to have a performance penalty if repeated. As such, a generic output expression is not suitable for repeating when the output port has multiple output destinations. For instance, the output of a Sum block is a generic rather than a trivial expression because it is costly to recompute a Sum block output expression as an input to multiple blocks.

### Examples of Trivial and Generic Output Expressions

Consider the following block diagram. The Delay block has multiple destinations, yet its output is designated as a trivial output expression, so that it can be used more than once without degrading the efficiency of the code.

The following code excerpt shows code generated from the Unit Delay block in this block diagram. The three root outputs are directly assigned from the state of the Unit Delay block, which is stored in a field of the global data structure `rtDWork`. Since the assignment is direct, without expressions, there is no performance penalty associated with using the trivial expression for multiple destinations.

```
void MdlOutputs(int_T tid)
{
 ...
 /* Output: <Root>/Out1 incorporates:
 * UnitDelay: <Root>/Unit Delay */
 rtY.Out1 = rtDWork.Unit_Delay_DSTATE;

 /* Output: <Root>/Out2 incorporates:
 * UnitDelay: <Root>/Unit Delay */
 rtY.Out2 = rtDWork.Unit_Delay_DSTATE;

 /* Output: <Root>/Out3 incorporates:
 * UnitDelay: <Root>/Unit Delay */
 rtY.Out3 = rtDWork.Unit_Delay_DSTATE;
}
```

```

}
...
}

```

On the other hand, consider the Sum blocks in the following model:

The upper Sum block in the preceding model generates the signal labeled `non_triv`. Computation of this output signal involves two multiplications and an addition. If the Sum block's output were permitted to generate an expression even when the block had multiple destinations, the block's operations would be duplicated in the generated code. In the case illustrated, the generated expressions would proliferate to four multiplications and two additions. This would degrade the efficiency of the program. Accordingly the output of the Sum block is not allowed to be an expression because it has multiple destinations

The code generated for the previous block diagram shows how code is generated for Sum blocks with single and multiple destinations.

The Simulink engine does not permit the output of the upper Sum block to be an expression because the signal `non_triv` is routed to two output destinations. Instead, the result of the multiplication and addition operations is stored in a temporary variable (`rtb_non_triv`) that is referenced twice in the statements that follow, as seen in the code excerpt below.

In contrast, the lower Sum block, which has only a single output destination (`Out2`), does generate an expression.

```

void MdlOutputs(int_T tid)
{
 /* local block i/o variables */
 real_T rtb_non_triv;

```

```

real_T rtb_Sine_Wave;

/* Sum: <Root>/Sum incorporates:
 * Gain: <Root>/Gain
 * Inport: <Root>/u1
 * Gain: <Root>/Gain1
 * Inport: <Root>/u2
 *
 * Regarding <Root>/Gain:
 * Gain value: rtP.Gain_Gain
 *
 * Regarding <Root>/Gain1:
 * Gain value: rtP.Gain1_Gain
 */
rtb_non_triv = (rtP.Gain_Gain * rtU.u1) + (rtP.Gain1_Gain *
rtU.u2);

/* Outport: <Root>/Out1 */
rtY.Out1 = rtb_non_triv;

/* Sin Block: <Root>/Sine Wave */

rtb_Sine_Wave = rtP.Sine_Wave_Amp *
sin(rtP.Sine_Wave_Freq * rtmGetT(rtM_model) +
rtP.Sine_Wave_Phase) + rtP.Sine_Wave_Bias;

/* Outport: <Root>/Out2 incorporates:
 * Sum: <Root>/Sum1
 */
rtY.Out2 = (rtb_non_triv + rtb_Sine_Wave);
}

```

### Specify the Category of an Output Expression

The S-Function API provides macros that let you declare whether an output of a block should be an expression, and if so, to specify the category of the expression. The following table specifies when to declare a block output to be a constant, trivial, or generic output expression.

#### Types of Output Expressions

Category of Expression	When to Use
Constant	Use only if block output is a direct memory access to a block parameter.
Trivial	Use only if block output is an expression that can appear multiple times in the code without reducing efficiency (for example, a direct memory access to a field of the DWORK vector, or a literal).
Generic	Use if output is an expression, but not constant or trivial.

You must declare outputs as expressions in the `mdlSetWorkWidths` function using macros defined in the S-Function API. The macros have the following arguments:

- `SimStruct *S`: pointer to the block's `SimStruct`.
- `int idx`: zero-based index of the output port.
- `bool value`: pass in `TRUE` if the port generates output expressions.

The following macros are available for setting an output to be a constant, trivial, or generic expression:

- `void ssSetOutputPortConstOutputExprInRTW(SimStruct *S, int idx, bool value)`
- `void ssSetOutputPortTrivialOutputExprInRTW(SimStruct *S, int idx, bool value)`
- `void ssSetOutputPortOutputExprInRTW(SimStruct *S, int idx, bool value)`

The following macros are available for querying the status set by prior calls to the macros above:

- `bool ssGetOutputPortConstOutputExprInRTW(SimStruct *S, int idx)`
- `bool ssGetOutputPortTrivialOutputExprInRTW(SimStruct *S, int idx)`
- `bool ssGetOutputPortOutputExprInRTW(SimStruct *S, int idx)`

The set of generic expressions is a superset of the set of trivial expressions, and the set of trivial expressions is a superset of the set of constant expressions.

Therefore, when you query an output that has been set to be a constant expression with `ssGetOutputPortTrivialOutputExprInRTW`, it returns `True`. A constant expression is considered a trivial expression, because it is a direct memory access that can be repeated without degrading the efficiency of the generated code.

Similarly, an output that has been configured to be a constant or trivial expression returns `True` when queried for its status as a generic expression.

### **Acceptance or Denial of Requests for Input Expressions**

A block can request that its output be represented in code as an expression. Such a request can be denied if the destination block cannot accept expressions at its input port. Furthermore, conditions independent of the requesting block and its destination blocks can prevent acceptance of expressions.

This topic discusses block-specific conditions under which requests for input expressions are denied. For information on other conditions that prevent acceptance of expressions, see “Denial of Block Requests to Output Expressions” on page 39-142.

A block should not be configured to accept expressions at its input port under the following conditions:

- The block must take the address of its input data. It is not possible to take the address of most types of input expressions.
- The code generated for the block references the input more than once (for example, the Abs or Max blocks). This would lead to duplication of a potentially complex expression and a subsequent degradation of code efficiency.

If a block refuses to accept expressions at an input port, then a block that is connected to that input port is not permitted to output a generic or trivial expression.

A request to output a constant expression is not denied, because there is no performance penalty for a constant expression, and the software can take the parameter’s address.

### **S-Function API to Specify Input Expression Acceptance**

The S-Function API provides macros that let you:

- Specify whether a block input should accept nonconstant expressions (that is, trivial or generic expressions)
- Query whether a block input accepts nonconstant expressions

By default, block inputs do not accept nonconstant expressions.

You should call the macros in your `mdlSetWorkWidths` function. The macros have the following arguments:

- `SimStruct *S`: pointer to the block's `SimStruct`.
- `int idx`: zero-based index of the input port.
- `bool value`: pass in `TRUE` if the port accepts input expressions; otherwise pass in `FALSE`.

The macro available for specifying whether or not a block input should accept a nonconstant expression is as follows:

```
void ssSetInputPortAcceptExprInRTW(SimStruct *S, int portIdx, bool value)
```

The corresponding macro available for querying the status set by any prior calls to `ssSetInputPortAcceptExprInRTW` is as follows:

```
bool ssGetInputPortAcceptExprInRTW(SimStruct *S, int portIdx)
```

### Denial of Block Requests to Output Expressions

Even after a specific block requests that it be allowed to generate an output expression, that request can be denied for generic reasons. These reasons include, but are not limited to

- The output expression is nontrivial, and the output has multiple destinations.
- The output expression is nonconstant, and the output is connected to at least one destination that does not accept expressions at its input port.
- The output is a test point.
- The output has been assigned an external storage class.
- The output must be stored using global data (for example is an input to a merge block or a block with states).
- The output signal is complex.

You do not need to consider these generic factors when deciding whether or not to utilize expression folding for a particular block. However, these rules can be helpful when you are examining generated code and analyzing cases where the expression folding optimization is suppressed.

### Expression Folding in a TLC Block Implementation

To take advantage of expression folding, you must modify the TLC block implementation of an inlined S-Function such that it informs the Simulink engine whether it generates or accepts expressions at its

- Input ports, as explained in “S-Function API to Specify Input Expression Acceptance” on page 39-141.
- Output ports, as explained in “Categories of Output Expressions” on page 39-136.

This topic discusses required modifications to the TLC implementation.

### Expression Folding Compliance

In the `BlockInstanceSetup` function of your S-function, register your block to be compliant with expression folding. Otherwise, expression folding requested or allowed at the block's outputs or inputs will be disabled, and temporary variables will be used.

To register expression folding compliance, call the TLC library function `LibBlockSetIsExpressionCompliant(block)`, which is defined in `matlabroot/rtw/c/tlc/lib/utllib.tlc`. For example:

```
%% Function: BlockInstanceSetup =====
%%
%function BlockInstanceSetup(block, system) void
 %%
 %<LibBlockSetIsExpressionCompliant(block)>
 %%
%endfunction
```

You can conditionally disable expression folding at the inputs and outputs of a block by making the call to this function conditionally.

If you override one of the TLC block implementations provided by the code generator with your own implementation, you should not make the preceding call until you have updated your implementation, as described by the guidelines for expression folding in the following topics.

### Output Expressions

The `BlockOutputSignal` function is used to generate code for a scalar output expression or one element of a nonscalar output expression. If your block outputs an expression, you should add a `BlockOutputSignal` function. The prototype of the `BlockOutputSignal` is

```
%function BlockOutputSignal(block,system,portIdx,ucv,lcx,idx,retType) void
```

The arguments to `BlockOutputSignal` are as follows:

- **block**: the record for the block for which an output expression is being generated
- **system**: the record for the system containing the block
- **portIdx**: zero-based index of the output port for which an expression is being generated
- **ucv**: user control variable defining the output element for which code is being generated
- **lcx**: loop control variable defining the output element for which code is being generated
- **idx**: signal index defining the output element for which code is being generated
- **retType**: character vector defining the type of signal access desired:
  - "Signal" specifies the contents or address of the output signal.

"SignalAddr" specifies the address of the output signal

The `BlockOutputSignal` function returns a character vector for the output signal or address. The character vector should enforce the precedence of the expression by using opening and terminating parentheses, unless the expression consists of a function call. The address of an expression can only be returned for a constant expression; it is the address of the parameter whose memory is being accessed. The code implementing the `BlockOutputSignal` function for the Constant block is shown below.

```
%% Function: BlockOutputSignal =====
%% Abstract:
%% Return the reference to the parameter. This function *may*
%% be used by Simulink when optimizing the Block IO data structure.
%%
%%function BlockOutputSignal(block,system,portIdx,ucv,lcv,idx,retType) void
%switch retType
%case "Signal"
%return LibBlockParameter(Value,ucv,lcv,idx)
%case "SignalAddr"
%return LibBlockParameterAddr(Value,ucv,lcv,idx)
%default
%assign errTxt = "Unsupported return type: %<retType>"
%<LibBlockReportError(block,errTxt)>
%endswitch
%endfunction
```

The code implementing the `BlockOutputSignal` function for the Relational Operator block is shown below.

```
%% Function: BlockOutputSignal =====
%% Abstract:
%% Return an output expression. This function *may*
%% be used by Simulink when optimizing the Block IO data structure.
%%
%%function BlockOutputSignal(block,system,portIdx,ucv,lcv,idx,retType) void
%switch retType
%case "Signal"
%assign logicOperator = ParamSettings.Operator
%if ISEQUAL(logicOperator, "~=")
%assign op = "!="
elseif ISEQUAL(logicOperator, "==") %assign op = "=="
%else
%assign op = logicOperator
%endif
%assign u0 = LibBlockInputSignal(0, ucv, lcv, idx)
%assign u1 = LibBlockInputSignal(1, ucv, lcv, idx)
%return "(%<u0> %<op> %<u1>)"
%default
%assign errTxt = "Unsupported return type: %<retType>"
%<LibBlockReportError(block,errTxt)>
%endswitch
```

```
%endfunction
```

### Expression Folding for Blocks with Multiple Outputs

When a block has a single output, the `Outputs` function in the block's TLC file is called only if the output port is not an expression. Otherwise, the `BlockOutputSignal` function is called.

If a block has multiple outputs, the `Outputs` function is called if any output port is not an expression. The `Outputs` function should guard against generating code for output ports that are expressions. This is achieved by guarding sections of code corresponding to individual output ports with calls to `LibBlockOutputSignalIsExpr()`.

For example, consider an S-Function with two inputs and two outputs, where

- The first output, `y0`, is equal to two times the first input.
- The second output, `y1`, is equal to four times the second input.

The `Outputs` and `BlockOutputSignal` functions for the S-function are shown in the following code excerpt.

```
%% Function: BlockOutputSignal =====
%% Abstract:
%% Return an output expression. This function *may*
%% be used by Simulink when optimizing the Block IO data structure.
%%
%function BlockOutputSignal(block,system,portIdx,ucv,lcx,idx,retType) void
%switch retType
%case "Signal"
 %assign u = LibBlockInputSignal(portIdx, ucv, lcx, idx)
 %case "Signal"
 %if portIdx == 0
 %return "(2 * %<u>)"
 %elseif portIdx == 1
 %return "(4 * %<u>)"
 %endif
%default
%assign errTxt = "Unsupported return type: %<retType>"
%<LibBlockReportError(block,errTxt)>
%endswitch
%endfunction
%%
%% Function: Outputs =====
%% Abstract:
%% Compute output signals of block
%%
%function Outputs(block,system) Output
%assign rollVars = ["U", "Y"]
%roll sigIdx = RollRegions, lcv = RollThreshold, block, "Roller", rollVars
%assign u0 = LibBlockInputSignal(0, "", lcv, sigIdx)
%assign u1 = LibBlockInputSignal(1, "", lcv, sigIdx)
```

```

%assign y0 = LibBlockOutputSignal(0, "", lcv, sigIdx)
%assign y1 = LibBlockOutputSignal(1, "", lcv, sigIdx)
%if !LibBlockOutputSignalIsExpr(0)
%<y0> = 2 * %<u0>;
%endif
%if !LibBlockOutputSignalIsExpr(1)
%<y1> = 4 * %<u1>;
%endif
%endroll
%endfunction

```

### Comments for Blocks That Are Expression-Folding-Compliant

In the past, blocks preceded their outputs code with comments of the form

```
/* %<Type> Block: %<Name> */
```

When a block is expression-folding-compliant, the initial line shown above is generated automatically. You should not include the comment as part of the block's TLC implementation. Additional information should be registered using the `LibCacheBlockComment` function.

The `LibCacheBlockComment` function takes a character vector as an input, defining the body of the comment, except for the opening header, the final newline of a single or multiline comment, and the closing trailer.

The following TLC code illustrates registering a block comment. Note the use of the function `LibBlockParameterForComment`, which returns a character vector, suitable for a block comment, specifying the value of the block parameter.

```

%openfile commentBuf
$c(*) Gain value: %<LibBlockParameterForComment(Gain)>
%closefile commentBuf
%<LibCacheBlockComment(block, commentBuf)>

```

### S-Functions That Specify Port Scope and Reusability

You can use the following `SimStruct` macros in the `mdlInitializeSizes` method to specify the scope and reusability of the memory used for your S-function's input and output ports:

- `ssSetInputPortOptimOpts`: Specify the scope and reusability of the memory allocated to an S-function input port
- `ssSetOutputPortOptimOpts`: Specify the scope and reusability of the memory allocated to an S-function output port
- `ssSetInputPortOverWritable`: Specify whether one of your S-function's input ports can be overwritten by one of its output ports

- `ssSetOutputPortOverwritesInputPort`: Specify whether an output port can share its memory buffer with an input port

You declare an input or output as local or global, and indicate its reusability, by passing one of the following four options to the `ssSetInputPortOptimOpts` and `ssSetOutputPortOptimOpts` macros:

- `SS_NOT_REUSABLE_AND_GLOBAL`: Indicates that the input and output ports are stored in separate memory locations in the global block input and output structure
- `SS_NOT_REUSABLE_AND_LOCAL`: Indicates that the code generator can declare individual local variables for the input and output ports
- `SS_REUSABLE_AND_LOCAL`: Indicates that the code generator can reuse a single local variable for these input and output ports
- `SS_REUSABLE_AND_GLOBAL`: Indicates that these input and output ports are stored in a single element in the global block input and output structure

---

**Note** Marking an input or output port as a local variable does not imply that the code generator uses a local variable in the generated code. If your S-function accesses the inputs and outputs only in its `mdlOutputs` routine, the code generator declares the inputs and outputs as local variables. However, if the inputs and outputs are used elsewhere in the S-function, the code generator includes them in the global block input and output structure.

---

The reusability setting indicates if the memory associated with an input or output port can be overwritten. To reuse input and output port memory:

- 1 Indicate the ports are reusable using either the `SS_REUSABLE_AND_LOCAL` or `SS_REUSABLE_AND_GLOBAL` option in the `ssSetInputPortOptimOpts` and `ssSetOutputPortOptimOpts` macros
- 2 Indicate the input port memory is overwritable using `ssSetInputPortOverWritable`
- 3 If your S-function has multiple input and output ports, use `ssSetOutputPortOverwritesInputPort` to indicate which output and input ports share memory

The following example shows how different scope and reusability settings affect the generated code. The following model contains an S-function block pointing to the C

MEX S-function `matlabroot/toolbox/simulink/simdemos/simfeatures/src/sfun_directlook.c`, which models a direct 1-D lookup table.

The S-function's `mdlInitializeSizes` method declares the input port as reusable, local, and overwritable and the output port as reusable and local, as follows:

```
static void mdlInitializeSizes(SimStruct *S)
{
 /* snip */
 ssSetInputPortOptimOpts(S, 0, SS_REUSABLE_AND_LOCAL);
 ssSetInputPortOverWritable(S, 0, TRUE);

 /* snip */
 ssSetOutputPortOptimOpts(S, 0, SS_REUSABLE_AND_LOCAL);

 /* snip */
}
```

The generated code for this model stores the input and output signals in a single local variable `rtb_SFunction`, as shown in the following output function:

```
static void sl_directlook_output(int_T tid)
{
 /* local block i/o variables */
 real_T rtb_SFunction[2];

 /* Sin: '<Root>/Sine Wave' */
 rtb_SFunction[0] = sin(((real_T)sl_directlook_DWork.counter[0] +
 sl_directlook_P.SineWave_Offset) * 2.0 * 3.1415926535897931E+000 /
 sl_directlook_P.SineWave_NumSamp) * sl_directlook_P.SineWave_Amp[0] +
 sl_directlook_P.SineWave_Bias;
 rtb_SFunction[1] = sin(((real_T)sl_directlook_DWork.counter[1] +
 sl_directlook_P.SineWave_Offset) * 2.0 * 3.1415926535897931E+000 /
 sl_directlook_P.SineWave_NumSamp) * sl_directlook_P.SineWave_Amp[1] +
 sl_directlook_P.SineWave_Bias;

 /* S-Function Block: <Root>/S-Function */
 {
 const real_T *xData = &sl_directlook_P.SFunction_XData[0];
 const real_T *yData = &sl_directlook_P.SFunction_YData [0];
 real_T spacing = xData[1] - xData[0];
 if (rtb_SFunction[0] <= xData[0]) {
 rtb_SFunction[0] = yData[0];
 } else if (rtb_SFunction[0] >= yData[20]) {
```

```

 rtb_SFunction[0] = yData[20];
} else {
 int_T idx = (int_T)((rtb_SFunction[0] - xData[0]) / spacing);
 rtb_SFunction[0] = yData[idx];
}

if (rtb_SFunction[1] <= xData[0]) {
 rtb_SFunction[1] = yData[0];
} else if (rtb_SFunction[1] >= yData[20]) {
 rtb_SFunction[1] = yData[20];
} else {
 int_T idx = (int_T)((rtb_SFunction[1] - xData[0]) / spacing);
 rtb_SFunction[1] = yData[idx];
}
}

/* Outport: '<Root>/Out1' */
sl_directlook_Y.Out1[0] = rtb_SFunction[0];
sl_directlook_Y.Out1[1] = rtb_SFunction[1];
UNUSED_PARAMETER(tid);
}

```

The following table shows variations of the code generated for this model when using the generic real-time target (GRT). Each row explains a different setting for the scope and reusability of the S-function's input and output ports.

Scope and reusability	S-function mdlInitializeSizes code	Generated code
<b>Inputs:</b> Local, reusable, overwriteable  <b>Outputs:</b> Local, reusable	<pre> ssSetInputPortOptimOpts(S, 0, SS_REUSABLE_AND_LOCAL);  ssSetInputPortOverWritable(S, 0, TRUE);  ssSetOutputPortOptimOpts(S, 0, SS_REUSABLE_AND_LOCAL); </pre>	<p>The <i>model.c</i> file declares a local variable in the output function.</p> <pre> /* local block i/o variables */ real_T rtb_SFunction[2]; </pre>
<b>Inputs:</b> Global, reusable, overwriteable  <b>Outputs:</b> Global, reusable	<pre> ssSetInputPortOptimOpts(S, 0, SS_REUSABLE_AND_GLOBAL);  ssSetInputPortOverWritable(S, 0, TRUE);  ssSetOutputPortOptimOpts(S, 0, SS_REUSABLE_AND_GLOBAL); </pre>	<p>The <i>model.h</i> file defines a block signals structure with a single element to store the S-function's input and output.</p> <pre> /* Block signals (auto storage) */ typedef struct {     real_T SFunction[2]; } BlockIO_sl_directlook; </pre> <p>The <i>model.c</i> file uses this element of the structure in calculations of the S-function's input and output signals.</p> <pre> /* Sin: '&lt;Root&gt;/Sine Wave' */ </pre>

Scope and reusability	S-function mdlInitializeSizes code	Generated code
		<pre>sl_directlook_B.SFunction[0] = sin ... /* snip */ /*S-Function Block:&lt;Root&gt;/S-Function*/ { const real_T *xData =     &amp;sl_directlook_P.SFunction_XData[0]</pre>
<p><b>Inputs:</b> Local, not reusable</p> <p><b>Outputs:</b> Local, not reusable</p>	<pre>ssSetInputPortOptimOpts(S, 0, SS_NOT_REUSABLE_AND_LOCAL);  ssSetInputPortOverWritable(S, 0, FALSE);  ssSetOutputPortOptimOpts(S, 0, SS_NOT_REUSABLE_AND_LOCAL);</pre>	<p>The <i>model.c</i> file declares local variables for the S-function's input and output in the output function</p> <pre>/* local block i/o variables */ real_T rtb_SineWave[2]; real_T rtb_SFunction[2];</pre>
<p><b>Inputs:</b> Global, not reusable</p> <p><b>Outputs:</b> Global, not reusable</p>	<pre>ssSetInputPortOptimOpts(S, 0, SS_NOT_REUSABLE_AND_GLOBAL);  ssSetInputPortOverWritable(S, 0, FALSE);  ssSetOutputPortOptimOpts(S, 0, SS_NOT_REUSABLE_AND_GLOBAL);</pre>	<p>The <i>model.h</i> file defines a block signal structure with individual elements to store the S-function's input and output.</p> <pre>/* Block signals (auto storage) */ typedef struct {     real_T SineWave[2];     real_T SFunction[2]; } BlockIO_sl_directlook;</pre> <p>The <i>model.c</i> file uses the different elements in this structure when calculating the S-function's input and output.</p> <pre>/* Sin: '&lt;Root&gt;/Sine Wave' */ sl_directlook_B.SineWave[0] = sin ... /* snip */ /*S-Function Block:&lt;Root&gt;/S-Function*/ { const real_T *xData =     &amp;sl_directlook_P.SFunction_XData[0]</pre>

## S-Functions That Specify Sample Time Inheritance Rules

For the Simulink engine to determine whether a model can inherit a sample time, the S-functions in the model need to specify how they use sample times. You can specify this information by calling the macro `ssSetModelReferenceSampleTimeInheritanceRule` from `mdlInitializeSizes` or `mdlSetWorkWidths`. To use this macro:

- 1 Check whether the S-function calls any of the following macros:

- `ssGetSampleTime`
- `ssGetInputPortSampleTime`
- `ssGetOutputPortSampleTime`
- `ssGetInputPortOffsetTime`
- `ssGetOutputPortOffsetTime`
- `ssGetSampleTimePtr`
- `ssGetInputPortSampleTimeIndex`
- `ssGetOutputPortSampleTimeIndex`
- `ssGetSampleTimeTaskID`
- `ssGetSampleTimeTaskIDPtr`

**2** Check for the following in your S-function TLC code:

- `LibBlockSampleTime`
- `CompiledModel.SampleTime`
- `LibBlockInputSignalSampleTime`
- `LibBlockInputSignalOffsetTime`
- `LibBlockOutputSignalSampleTime`
- `LibBlockOutputSignalOffsetTime`

**3** Depending on your search results, use `ssSetModelReferenceSampleTimeInheritanceRule` as indicated in the following table.

If...	Use...
None of the macros or functions are present, the S-function does not preclude the model from inheriting a sample time.	<code>ssSetModelReferenceSampleTimeInheritanceRule(S, USE_DEFAULT_FOR_DISCRETE_INHERITANCE)</code>
Any of the macros or functions are used for <ul style="list-style-type: none"> <li>• Throwing errors if sample time is inherited, continuous, or constant</li> </ul>	<code>ssSetModelReferenceSampleTimeInheritanceRule... (S,USE_DEFAULT_FOR_DISCRETE_INHERITANCE)</code>

If...	Use...
<ul style="list-style-type: none"> <li>• Checking <code>ssIsSampleHit</code></li> <li>• Checking whether sample time is inherited in either <code>mdlSetInputPortSampleTime</code> or <code>mdlSetOutputPortSampleTime</code> before setting</li> </ul>	
The S-function uses its sample time for computing parameters, outputs, and so on	<code>ssSetModelReferenceSampleTimeInheritanceRule(S, DISALLOW_SAMPLE_TIME_INHERITANCE)</code>

---

**Note** If an S-function does not set the `ssSetModelReferenceSampleTimeInheritanceRule` macro, by default the Simulink engine assumes that the S-function does not preclude the model containing that S-function from inheriting a sample time. However, the engine issues a warning indicating that the model includes S-functions for which this macro is not set.

---

You can use settings on the **All Parameters** pane of the Configuration Parameters dialog box or Model Explorer to control how the Simulink engine responds when it encounters S-functions that have unspecified sample time inheritance rules. Toggle the **Unspecified inheritability of sample time** diagnostic to none, warning, or error. The default is warning.

## S-Functions That Support Code Reuse

You can reuse the generated code for identical subsystems that occur in multiple instances within a model and across referenced models. For more information about code generation of subsystems for code reuse, see “Code Generation of Subsystems”. If you want your S-function to support code reuse for a subsystem, the S-function must meet the following requirements:

- The S-function must be inlined.
- Code generated from the S-function must not use static variables.
- The S-function must initialize its pointer work vector in `mdlStart` and not before.
- The S-function must not be a sink that logs data to the workspace.

- The S-function must register its parameters as run-time parameters in `mdlSetWorkWidths`. (It must not use `ssWriteRTWParameters` in its `mdlRTW` function for this purpose.)
- The S-function must not be a device driver.

In addition to meeting the preceding requirements, your S-function must set the `SS_OPTION_WORKS_WITH_CODE_REUSE` flag (see the description of `ssSetOptions` in the Simulink Writing S-Function documentation). This flag indicates that your S-function meets the requirements for subsystem code reuse.

## S-Functions for Multirate Multitasking Environments

- “About S-Functions for Multirate Multitasking Environments” on page 39-153
- “Rate Grouping Support in S-Functions” on page 39-153
- “Create Multitasking, Multirate, Port-Based Sample Time S-Functions” on page 39-154

### About S-Functions for Multirate Multitasking Environments

S-functions can be used in models with multiple sample rates and deployed in multitasking target environments. Likewise, S-functions themselves can have multiple rates at which they operate. The code generator produces code for multirate multitasking models using an approach called *rate grouping*. In code generated for ERT-based targets, rate grouping generates separate `model_step` functions for the base rate task and each subrate task in the model. Although rate grouping is a code generation feature found in ERT targets only, your S-functions can use it in other contexts when you code them as explained below.

### Rate Grouping Support in S-Functions

To take advantage of rate grouping, you must inline your multirate S-functions if you have not done so. You need to follow certain Target Language Compiler protocols to exploit rate grouping. Coding TLC to exploit rate grouping does not prevent your inlined S-functions from functioning properly in GRT. Likewise, your inlined S-functions will still generate valid ERT code even if you do not make them rate-grouping-compliant. If you do so, however, they will generate more efficient code for multirate models.

For instructions and examples of Target Language Compiler code illustrating how to create and upgrade S-functions to generate rate-grouping-compliant code, see “Rate

Grouping Compliance and Compatibility Issues” on page 49-17 in the Embedded Coder documentation.

For each multirate S-function that is not rate grouping-compliant, the code generator issues the following warning when you build:

```
Warning: Simulink Coder: Code of output function for multirate block
'<Root>/S-Function' is guarded by sample hit checks rather than being rate
grouped. This will generate the same code for all rates used by the block,
possibly generating dead code. To avoid dead code, you must update the TLC
file for the block.
```

You will also find a comment such as the following in code generated for each noncompliant S-function:

```
/* Because the output function of multirate block
<Root>/S-Function is not rate grouped,
the following code might contain unreachable blocks of code.
To avoid this, you must update your block TLC file. */
```

The words “update function” are substituted for “output function” in these warnings.

### **Create Multitasking, Multirate, Port-Based Sample Time S-Functions**

The following instructions show how to support both data determinism and data integrity in multirate S-functions. They do not cover cases where there is no determinism nor integrity. Support for frame-based processing does not affect the requirements.

---

**Note** The slow rates must be multiples of the fastest rate. The instructions do not apply when two rates being interfaced are not multiples or when the rates are not periodic.

---

#### **Rules for Properly Handling Fast-to-Slow Transitions**

The rules that multirate S-functions should observe for inputs are

- The input should only be read at the rate that is associated with the input port sample time.
- Generally, the input data is written to DWork, and the DWork can then be accessed at the slower (downstream) rate.

The input can be read at every sample hit of the input rate and written into DWork memory, but this DWork memory cannot then be directly accessed by the slower rate. DWork memory that will be read by the slow rate must only be written by the fast rate

when there is a *special sample hit*. A special sample hit occurs when both this input port rate and rate to which it is interfacing have a hit. Depending on their requirements and design, algorithms can process the data in several locations.

The rules that multirate S-functions should observe for outputs are

- The output should not be written by a rate other than the rate assigned to the output port, except in the optimized case described below.
- The output should always be written when the sample rate of the output port has a hit.

If these conditions are met, the S-Function block can specify that the input port and output port can both be made local and reusable.

You can include an optimization when little or no processing needs to be done on the data. In such cases, the input rate code can directly write to the output (instead of by using `DWork`) when there is a special sample hit. If you do this, however, you must declare the output port to be *global* and *not reusable*. This optimization results in one less `memcpy` but does introduce nonuniform processing requirements on the faster rate.

Whether you use this optimization or not, the most recent input data, as seen by the slower rate, is the value when both the faster and slower rate had their hits (and possible earlier input data as well, depending on the algorithm). Subsequent steps by the faster rate and the associated input data updates are not seen by the slower rate until the next hit for the slow rate occurs.

### Pseudocode Examples of Fast-to-Slow Rate Transition

The pseudocode below abstracts how you should write your C MEX code to handle fast-to-slow transitions, illustrating with an input rate of 0.1 second driving an output rate of one second. A similar approach can be taken when inlining the code. The block has following characteristics:

- File: `sfun_multirate_zoh.c`, Equation:  $y = u(\text{tslow})$
- Input: local and reusable
- Output: local and reusable
- DirectFeedthrough: yes

```
OutputFcn
if (ssIsSampleHit(".1")) {
 if (ssIsSpecialSampleHit("1")) {
 DWork = u;
```

```

 }
}
if (ssIsSampleHit("1")) {
 y = DWork;
}

```

An alternative, slightly optimized approach for simple algorithms:

- Input: local and reusable
- Output: global and not reusable because it needs to persist between special sample hits
- DirectFeedthrough: yes

```

OutputFcn
if (ssIsSampleHit(".1")) {
 if (ssIsSpecialSampleHit("1")) {
 y = u;
 }
}

```

Example adding a simple algorithm:

- File: `sfun_multirate_avg.c`; Equation:  $y = \text{average}(u)$
- Input: local and reusable
- Output: local and reusable
- DirectFeedthrough: yes

(Assume `DWork[0:10]` and `DWork[mycounter]` are initialized to zero)

```

OutputFcn
if (ssIsSampleHit(".1")) {
 /* In general, processing on 'u' could be done here,
 it runs on every hit of the fast rate. */
 DWork[DWork[mycounter]++] = u;
 if (ssIsSpecialSampleHit("1")) {
 /* In general, processing on DWork[0:10] can be done
 here, but it does cause the faster rate to have
 nonuniform processing requirements (every 10th hit,
 more code needs to be run).*/
 DWork[10] = sum(DWork[0:9])/10;
 DWork[mycounter] = 0;
 }
}
if (ssIsSampleHit("1")) {
 /* Processing on DWork[10] can be done here before
 outputting. This code runs on every hit of the
 slower task. */
 y = DWork[10];
}

```

### Rules for Properly Handling Slow-to-Fast Transitions

When output rates are faster than input rates, input should only be read at the rate that is associated with the input port sample time, observing the following rules:

- Always read input from the update function.
- Use no special sample hit checks when reading input.
- Write the input to a DWork.
- When there is a special sample hit between the rates, copy the DWork into a second DWork in the output function.
- Write the second DWork to the output at every hit of the output sample rate.

The block can request that the input port be made local but it cannot be set to reusable. The output port can be set to local and reusable.

As in the fast-to-slow transition case, the input should not be read by a rate other than the one assigned to the input port. Similarly, the output should not be written to at a rate other than the rate assigned to the output port.

An optimization can be made when the algorithm being implemented is only required to run at the slow rate. In such cases, you use only one DWork. The input still writes to the DWork in the update function. When there is a special sample hit between the rates, the output function copies the same DWork directly to the output. You must set the output port to be global and not reusable in this case. This optimization results in one less `memcpy` operation per special sample hit.

In either case, the data that the fast rate computations operate on is always delayed, that is, the data is from the previous step of the slow rate code.

### Pseudocode Examples of Slow-to-Fast Rate Transition

The pseudocode below abstracts what your S-function needs to do to handle slow-to-fast transitions, illustrating with an input rate of one second driving an output rate of 0.1 second. The block has following characteristics:

- File: `sfun_multirate_delay.c`, Equation:  $y = u(ts_{slow}-1)$
- Input: Set to local, will be local if output/update are combined (ERT) otherwise will be global. Set to not reusable because input needs to be preserved until the update function runs.
- Output: local and reusable

- DirectFeedthrough: no

```
OutputFcn
if (ssIsSampleHit(".1")) {
 if (ssIsSpecialSampleHit("1")) {
 DWork[1] = DWork[0];
 }
 y = DWork[1];
}
UpdateFcn
if (ssIsSampleHit("1")) {
 DWork[0] = u;
}
```

An alternative, optimized approach can be used by some algorithms:

- Input: Set to local, will be local if output/update are combined (ERT) otherwise will be global. Set to not reusable because input needs to be preserved until the update function runs.
- Output: global and not reusable because it needs to persist between special sample hits.
- DirectFeedthrough: no

```
OutputFcn
if (ssIsSampleHit(".1")) {
 if (ssIsSpecialSampleHit("1")) {
 y = DWork;
 }
}
UpdateFcn
if (ssIsSampleHit("1")) {
 DWork = u;
}
```

Example adding a simple algorithm:

- File: `sfun_multirate_modulate.c`, Equation:  $y = \sin(\text{tfast}) + u(\text{tslow}-1)$
- Input: Set to local, will be local if output/update are combined (an ERT feature) otherwise will be global. Set to not reusable because input needs to be preserved until the update function runs.
- Output: local and reusable
- DirectFeedthrough: no

```
OutputFcn
if (ssIsSampleHit(".1")) {
 if (ssIsSpecialSampleHit("1")) {
 /* Processing not likely to be done here. It causes
 * the faster rate to have nonuniform processing
```

```
 * requirements (every 10th hit, more code needs to
 * be run).*/
 DWork[1] = DWork[0];
}
/* Processing done at fast rate */
y = sin(ssGetTaskTime(".1")) + DWork[1];
}
UpdateFcn
if (ssIsSampleHit("1")) {
 /* Processing on 'u' can be done here. There is a delay of
 one slow rate period before the fast rate sees it.*/
 DWork[0] = u;}
```

## Build Support for S-Functions

### About Build Support for S-Functions

User-written S-Function blocks provide a powerful way to incorporate external code into the Simulink development environment. In most cases, you use S-functions to integrate existing external code with generated code. Several approaches to writing S-functions are available:

- “Write Noninlined S-Function and TLC Files” on page 39-104
- “Write Wrapper S-Function and TLC Files” on page 39-106
- “Write Fully Inlined S-Functions” on page 39-115
- “Write Fully Inlined S-Functions with mdlRTW Routine” on page 39-116
- “S-Functions That Support Code Reuse” on page 39-152
- “S-Functions for Multirate Multitasking Environments” on page 39-153

S-functions also provide the most flexible and capable way of including build information for legacy and custom code files in the build process.

There are a number of different ways of adding S-functions to the build process.

### Implicit Build Support

When building models with S-functions, the build process adds rules, include paths, and source file names to the generated makefile. The source files (`.h`, `.c`, and `.cpp`) for the S-function must be in the same folder as the S-function MEX-file. Whether using the toolchain approach or template makefile approach for builds, the build process propagates this information through the toolchain or template makefile.

The implicit build support includes:

- If the file `sfcnname.h` exists in the same folder as the S-function MEX-file (for example, `sfcnname.mexext`), the folder is added to the include path.
- If the file `sfcnname.c` or `sfcnname.cpp` exists in the same folder as the S-function MEX-file, the build process adds a makefile rule for compiling files from that folder.
- When an S-function is not inlined with a TLC file, the build process must compile the S-function source file. To determine the name of the source file to add to the list

of files to compile, the build process searches for `sfcname.cpp` on the MATLAB path. If the source file is found, the build process adds the source file name to the makefile. If `sfcname.cpp` is not found on the path, the build process adds the file name `sfcname.c` to the makefile, whether or not it is on the MATLAB path.

---

**Note:** For the Simulink engine to find the MEX-file for simulation and code generation, it must exist on the MATLAB path or be in your current MATLAB working folder.

---

## Specify Additional Source Files for an S-Function

If your S-function has additional source file dependencies, you must add the names of the additional modules to the build process. Specify the filenames:

- In the **S-function modules** field of the S-Function block parameter dialog box
- With the `SFunctionModules` parameter in a call to the `set_param` function

For example, suppose you build your S-function with multiple modules.

```
mex sfun_main.c sfun_module1.c sfun_module2.c
```

You can then add the modules to the build process by doing one of the following:

- In the S-function block dialog box, specify `sfun_main`, `sfun_module1`, and `sfun_module2` in the **S-function modules** field.
- At the MATLAB command prompt, enter:

```
set_param(sfun_block, 'SFunctionModules', 'sfun_module1 sfun_module2')
```

Alternatively, you can define a variable to represent the parameter value.

```
modules = 'sfun_module1 sfun_module2'
set_param(sfun_block, 'SFunctionModules', modules)
```

---

**Note:** The **S-function modules** field and `SFunctionModules` parameter do not support complete source file path specifications. To use the parameter, the code generator must be able to find the additional source files when executing the makefile. For the code generator to locate the additional files, place them in the same folder as the S-function MEX-file. You can then leverage the implicit build support described in “Implicit Build Support” on page 39-160.

---

When you are ready to generate code after using the **S-function modules** field or `SFunctionModules` parameter, you must force the code generator to rebuild the top model, as described in “Control Regeneration of Top Model Code”.

For more complicated S-function file dependencies, such as specifying source files in other locations or specifying libraries or object files, use the `rtwmakecfg.m` API, as described in “Use `rtwmakecfg.m` API to Customize Generated Makefiles” on page 70-24.

## Use TLC Library Functions

If you inline your S-function by writing a TLC file, you can add source file names to the build process by using the TLC library function `LibAddToModelSources`. For details, see “`LibAddSourceFileCustomSection(file, builtInSection, newSection)`” in the Target Language Compiler documentation.

---

**Note:** This function does not support complete source file path specifications and assumes that the code generator can find the additional source files when executing the makefile.

---

Another useful TLC library function is `LibAddToCommonIncludes`. Use this function in a `#include` statement to include S-function header files in the generated `model.h` header file. For details, see “`LibAddToCommonIncludes(incFileName)`” in the Target Language Compiler documentation.

For more complicated S-function file dependencies, such as specifying source files in other locations or specifying libraries or object files, use the `rtwmakecfg.m` API, as described in “Use `rtwmakecfg.m` API to Customize Generated Makefiles” on page 70-24.

## Precompile S-Function Libraries

You can precompile new or updated S-function libraries (MEX-files) for a model by using the MATLAB language function `rtw_precompile_libs`. Using a specified model and a library build specification, this function builds and places the libraries in a precompiled library folder.

By precompiling S-function libraries, you can optimize system builds. Once your precompiled libraries exist, the build process can omit library compilation from

subsequent builds. For models that use numerous libraries, the time savings for build processing can be significant.

To use `rtw_precompile_libs`:

- 1 Set the library file suffix, including the file type extension, based on the platform in use.
- 2 Set the precompiled library folder.
- 3 Define a build specification.
- 4 Issue a call to `rtw_precompile_libs`.

The procedure describes these steps in more detail.

- 1 Set the library file suffix, including the file type extension, based on the platform.

Consider determining the type of platform and then use the `TargetLibSuffix` parameter to set the library suffix accordingly. For example, when applying a suffix for a GRT target, you might set the suffix to `_std.a` for a UNIX platform and `_vcx64.lib` for a Windows platform.

```
if isunix
 suffix = '_std.a';
else
 suffix = '_vcx64.lib';
end
```

```
set_param(my_model, 'TargetLibSuffix', suffix);
```

There are a number of factors that influence the precompiled library suffix and extension. The following table provides examples for typical selections of system target file, the compiler toolchain, and other options that affect your choice of suffix and extension. For more information, examine the template make files in the `matlab/rtw/c/grt` folder or `matlab/rtw/c/ert` folder.

TMF File	COMPILER _TOOL_CHAIN Value	Precompiler Libraries (PRECOMP_LIBRARIES)			
		Library Suffix S-Function (EXPAND _LIBRARY _NAME Value)	Library Suffix Integer- Only Code (EXPAND _LIBRARY _NAME Value)	Library Suffix Optimize for Speed (EXPAND _LIBRARY _NAME Value)	Library Extension (EXPAND _LIBRARY _NAME Value)
ert_lcc64.tmf	lcc	_rtwsfcn_lcc	_int_ert_lcc	_ert_lcc	.lib

TMF File	COMPILER _TOOL_CHAIN Value	Precompiler Libraries (PRECOMP_LIBRARIES)			
		Library Suffix S-Function (EXPAND _LIBRARY _NAME Value)	Library Suffix Integer- Only Code (EXPAND _LIBRARY _NAME Value)	Library Suffix Optimize for Speed (EXPAND _LIBRARY _NAME Value)	Library Extension (EXPAND _LIBRARY _NAME Value)
ert_vcx64.tmf	vcx64	_rtwsfcn_vcx64	_int_ert_vcx64	_ert_vcx64	.lib
ert_unix.tmf	unix	_rtwsfcn	_int_ert	_ert	.a
grt_lcc64.tmf	lcc	n/a	n/a	_lcc	.lib
grt_vcx64.tmf	vcx64	n/a	n/a	_vcx64	.lib
grt_unix.tmf	unix	n/a	n/a	_std	.a

## 2 Set the precompiled library folder.

Use one of the following methods to set the precompiled library folder.

- Set the `TargetPreCompLibLocation` parameter, as explained in “Specify the Location of Precompiled Libraries” on page 70-9.
- Set the `makeInfo.precompile` field in an `rtwmakecfg.m` function file. (For more information, see “Use `rtwmakecfg.m` API to Customize Generated Makefiles” on page 70-24.)

If you set both `TargetPreCompLibLocation` and `makeInfo.precompile`, the setting for `TargetPreCompLibLocation` takes precedence.

The following command sets the precompiled library folder for model `my_model` to folder `lib` under the current working folder.

```
set_param(my_model, 'TargetPreCompLibLocation', fullfile(pwd, 'lib'));
```

---

**Note:** If you set both the target folder for the precompiled library files and a target library file suffix, the build process detects whether any precompiled library files are missing while processing builds.

---

## 3 Define a build specification.

Set up a structure that defines a build specification. The following table describes fields that you can define in the structure. These fields are optional, except for `rtwmakecfgDirs`.

Field	Description
<code>rtwmakecfgDirs</code>	<p>A cell array of character vectors that name the folders containing <code>rtwmakecfg</code> files for libraries to be precompiled. The function uses the <code>Name</code> and <code>Location</code> elements of <code>makeInfo.library</code>, as returned by <code>rtwmakecfg</code>, to specify the name and location of the precompiled libraries. If you set the <code>TargetPreCompLibLocation</code> parameter to specify the library folder, that setting overrides the <code>makeInfo.library.Location</code> setting.</p> <p><b>Note:</b> The specified model must contain blocks that use precompiled libraries specified by the <code>rtwmakecfg</code> files because the TMF-to-makefile conversion generates the library rules only if the libraries are used.</p>
<code>libSuffix</code>	<p>A character vector that specifies the suffix, including the file type extension, to be appended to the name of each library (for example, <code>.a</code> or <code>_vc.lib</code>). The character vector must include a period (<code>.</code>). You must set the suffix with either this field or the <code>TargetLibSuffix</code> parameter. If you specify a suffix with both mechanisms, the <code>TargetLibSuffix</code> setting overrides the setting of this field.</p>
<code>intOnlyBuild</code>	<p>A Boolean flag. When set to true, the flag indicates the libraries are to be optimized such that they are compiled from integer code only. This field applies to ERT targets only.</p>
<code>makeOpts</code>	<p>A character vector that specifies an option to be included in the <code>rtwMake</code> command line.</p>
<code>addLibs</code>	<p>A cell array of structures that specify libraries to be built that are not specified by an <code>rtwmakecfg</code> function. Each structure must be defined with two fields that are character arrays:</p> <ul style="list-style-type: none"> <li><code>libName</code> — the name of the library without a suffix</li> <li><code>libLoc</code> — the location for the precompiled library</li> </ul> <p>The TMF can specify other libraries and how those libraries are to be built. Use this field if you need to precompile those libraries.</p>

The following commands set up build specification `build_spec`, which indicates that the files to be compiled are in folder `src` under the current working folder.

```
build_spec = [];
build_spec.rtwmakecfgDirs = {fullfile(pwd,'src')};
```

#### 4 Issue a call to `rtw_precompile_libs`.

Issue a call to `rtw_precompile_libs` that specifies the model for which you want to build the precompiled libraries and the build specification. For example:

```
rtw_precompile_libs(my_model,build_spec);
```

## Change Programming Language

By default, the code generator produces C code.

To change the language setting:

- 1 In the Configuration Parameters dialog box, on the **Code Generation** pane, select **C** or **C++** from the **Language** menu in the **Target selection** section. Alternatively, set the `TargetLang` parameter at the command line.

The code generator produces `.c` or `.cpp` files, depending on your selection, and places the generated files in your build folder.

For more information, see “Language”.

- 2 Check whether you must choose and configure a compiler. If you select C++, you must choose and configure a compiler. For details, see “Select and Configure Compiler or IDE”.
- 3 Check whether the standard math library is configured for your compiler. By default, the code generator uses the ISO/IEC 9899:1999 C (**C99 (ISO)**) library for the C language and the ISO/IEC 14882:2003 C++ (**C++03 (ISO)**) library for the C++ language.

For more information, see “Standard math library”.

### More About

- “Select and Configure Compiler or IDE”
- “Troubleshoot Compiler Issues”

# Select and Configure Compiler or IDE

## Compilers and the Build Process

The build process requires a supported compiler. *Compiler*, in this context, refers to a development environment containing a linker and make utility, in addition to a high-level language compiler. For details on supported compiler versions, see

[http://www.mathworks.com/support/compilers/current\\_release](http://www.mathworks.com/support/compilers/current_release)

When creating an executable program, the build process must be able to access a supported compiler. The build process can automatically find a compiler to use based on your default MEX compiler.

The build process also requires the selection of a toolchain or template makefile. The toolchain or template makefile determines which compiler runs, during the make phase of the build, to compile the generated code.

To determine which templates makefiles are available for your compiler and target, see System Target Files Available from the System Target File Browser.

For both generated files and user-supplied files, the file extension, `.c` or `.cpp`, determines whether the build process uses a C or a C++ compiler. If the file extension is `.c`, the build process uses C compiler to compile the file, and the symbols use the C linkage convention. If the file extension is `.cpp`, the build process uses a C++ compiler to compile the file, and the symbols use the C++ linkage specification.

## Language Standards Compliance

The code generator produces code that is compliant with the following standards:

Language	Supported Standard
C	ISO/IEC 9899:1990, also known as C89/C90
C++	ISO/IEC 14882:2003

Code that the code generator produces from these sources is ANSI C/C++ compliant:

- Simulink built-in block algorithmic code
- Generated system level code (task ID [TID] checks, management, functions, and so on)

- Code from other blocksets, including the Fixed-Point Designer product, the Communications System Toolbox product, and so on
- Code from other code generators, such as MATLAB functions

Additionally, the code generator can incorporate code from

- Embedded targets (for example, startup code, device driver blocks)
- User-written S-functions or TLC files

---

**Note:** Coding standards for these two sources are beyond the control of the code generator, and can be a source for compliance problems, such as code that uses C99 features not supported in the ANSI C, C89/C90 subset.

---

## Programming Language Considerations

The code generator produces C and C++ code. Consider the following as you choose a programming language:

- Whether you need to configure the code generator to use a specific compiler. This is required to generate C++ code on Windows. See “Select and Configure Compiler or IDE” on page 40-3.
- The language configuration setting for the model. See “Change Programming Language” on page 40-2.
- Whether you need to integrate legacy or custom code with generated code. For a summary of integration options, see “About External Code Integration”.
- Whether you need to integrate C and C++ code. If so, see “About External Code Integration”.

---

**Note:** You can mix C and C++ code when integrating generated code with custom code. However, you must be aware of the differences between C and default C++ linkage conventions, and add the `extern "C"` linkage specifier where required. For the details of the differing linkage conventions and how to apply `extern "C"`, refer to a C++ programming language reference book.

---

- “C++ Language Limitations” on page 40-5.

For an example, enter `sfndemo_cppcount` in the MATLAB Command Window. For a Stateflow example, enter `sf_cpp`.

## C++ Language Considerations

To use the C++ target language support, you might need to configure the code generator to use a specific compiler. For example, if a supported compiler is not installed on your Microsoft Windows computer, the default compiler is the lcc C compiler shipped with the MATLAB product. This compiler does not support C++. If you do not configure the code generator to use a C++ compiler before you specify C++ for code generation, the software produces an error message.

## C++ Language Limitations

- The code generator does not support C++ code generation for the following:
  - Simscape Driveline
  - Simscape Multibody First Generation (Simscape Multibody Second Generation is supported)
  - Simscape Power Systems
  - Embedded Targets in Embedded Coder
  - Simulink Real-Time
- The following Embedded Coder dialog box fields currently do not accept the `.cpp` extension. However, the code generator produces a `.cpp` file if you specify a filename without an extension in these fields, with C++ selected as the target language for your generated code.
  - **Data definition filename** field on the **Data Placement** pane of the Configuration Parameters dialog box
  - **Definition file** field for a data object in Model Explorer. Data objects are objects of the class `Simulink.Signal`, `Simulink.Parameter`, and subclasses.

These restrictions on specifying `.cpp` will be removed in a future release.

## Code Generator Optimizes Code by Relying on Undefined Behavior of C Language for Signed Integer Overflows

The code generator reduces memory usage and enhances performance of code that it produces by assuming signed integer C operations wrap on overflow. A signed integer overflow occurs when the result of an arithmetic operation is outside the range of values that the output data type can represent. The C programming language does not define the results of such operations. Some C compilers aggressively optimize signed operations for in-range values at the expense of overflow conditions. Other compilers preserve the

full wrap-on-overflow behavior. For example, the gcc and MinGW compilers provide an option to reliably wrap overflow on signed integer overflows. The generated program image for a model can produce results that differ from model simulation results because the handling of overflows varies, depending on your compiler.

When you generate code, if you use a supported compiler with the default options configured by the code generator, the compiler preserves the full wrap-on-overflow behavior. If you change the compiler options or compile the code in another development environment, it is possible that the compiler does not preserve the full wrap-on-overflow behavior. In this case, the executable program can produce unpredictable results.

If this issue is a concern for your application, consider one or more of the following actions:

- Verify that the compiled code produces expected results.
- If your compiler has an option to force wrapping behavior, turn it on. For example, for the gcc compiler or a compiler based on gcc, such as MinGW, configure the build process to use the compiler option `-fwrapv`.
- Choose a compiler that wraps on integer overflow.
- If you have Embedded Coder installed, develop and apply a custom code replacement library to replace code generated for signed integers. For more information, see “Code Replacement Customization”.

## Choose and Configure Compiler on Microsoft Windows

On a Windows computer, you can install supported compilers. MATLAB automatically selects a default compiler, which is used by the build process. Alternatively, you can use the lcc C compiler that is shipped with the MATLAB product.

The compiler that the code generator requires is determined primarily by the specified system target file:

- If you select a toolchain-based system target file such as `grt.tlc` (Generic Real-Time Target), `ert.tlc` (Embedded Coder), or `autosar.tlc` (Embedded Coder for AUTOSAR), the **Build process** subpane displays toolchain parameters for configuring the build process. Use the **Toolchain** parameter to select a compiler and associated tools for your model build. Click on the **All Parameters > Toolchain > Validate** button to validate the selected toolchain.
- If you select a template makefile (TMF) based system target file, such as a desktop or embedded target, `rsim.tlc`, or a Visual C++ Solution File target, the **Build process**

subpane displays template makefile parameters for configuring the build process. The **Template makefile** parameter displays the default TMF file for the selected target. If the target supports compiler-specific template makefiles (for example, Rapid Simulation or S-Function target), you can set **Template makefile** to a compiler-specific TMF, such as `rsim_lcc.tmf`. (See “Available System Target Files” for valid TMF names.) If the template makefile is not compiler-specific, you can change the default compiler through the following command:

```
mex -setup
```

## Choose and Configure Compiler on UNIX

On a UNIX platform, the build process uses the default compiler. The default compiler is GNU `gcc/g++` for GNU or Xcode for Mac. For more information, see supported compilers. The compiler for your model build is indicated in the **Build process** parameters located on the **Code Generation** pane of the Configuration Parameters dialog box. The type of display depends on the **System target file** selected for your model build:

- If you select a toolchain-based system target file, such as `grt.tlc` (Generic Real-Time Target), `ert.tlc` (Embedded Coder), or `autosar.tlc` (Embedded Coder for AUTOSAR), the **Build process** subpane displays toolchain parameters for configuring the build process. You can use the **Toolchain** parameter to examine and validate the compiler and associated tool settings for your model build.
- If you select a template makefile (TMF) based system target file, such as a desktop or embedded target or `rsim.tlc`, the **Build process** subpane displays template makefile parameters for configuring the build process. The **Template makefile** parameter displays the default TMF file for the selected target. If the target supports compiler-specific template makefiles (for example, Rapid Simulation or S-Function target), set **Template makefile** to the UNIX TMF for your target. For example, for the Rapid Simulation target, enter `rsim_unix.tmf`. (See “Available System Target Files” for valid UNIX TMF names.) You can display the UNIX compiler with the following command:

```
mex -setup
```

## Include S-Function Source Code

When the code generator builds models with S-functions, source code for the S-functions can be either in the current folder or in the same folder as their MEX-file. The code

generator adds an include path to the generated makefiles whenever it finds a file named *sfncname*.h in the same folder that the S-function MEX-file is in. This folder must be on the MATLAB path.

Similarly, the code generator adds a rule for the folder when it finds a file *sfncname*.c (or .cpp) in the same folder as the S-function MEX-file is in.

# Troubleshoot Compiler Issues

## Compiler Version Mismatch Errors

### Description

The build process produces a compiler version mismatch error.

### Action

- 1 Check the list of supported and compatible compilers available at [www.mathworks.com/support/compilers/current\\_release/](http://www.mathworks.com/support/compilers/current_release/).
- 2 Upgrade or change your compiler. For more information, see “Choose and Configure Compiler on Microsoft Windows” on page 40-6 or “Choose and Configure Compiler on UNIX” on page 40-7.
- 3 Rebuild the model.

## Executable Program Generated for Model Produces Different Results from Model Simulation Results

### Description

The generated source code includes an arithmetic operation that produces a signed integer overflow. Your compiler might not implement wrapping behavior for signed integer overflow conditions, or you are using an appropriate compiler, but you did not configure it to use the `-fwrapv` option.

For more information, see “Code Generator Relies on Undefined Behavior of C Language for Integer Overflows.”

### Action

- If your compiler has an option to force wrapping behavior, turn it on. For example, for the gcc compiler or a compiler based on gcc, such as MinGW, specify the compiler option `-fwrapv`.
- Choose a compiler that checks for integer overflows.
- If you have an Embedded Coder license, develop and apply a code replacement library to replace code generated for signed integers.

## Build Process Generates Expected Source Code But Executable Program Produces Incorrect Results

### Description

The generated source code appears as expected. However, the executable program produces incorrect results.

### Action

Do one of the following:

- Lower the compiler optimization level.
  - 1 Select **Custom** for the Model Configuration parameter **Code Generation > Compiler optimization level**.
  - 2 In the **Custom compiler optimization flags** field, specify a lower optimization level.
  - 3 Rebuild the model.
- Disable compiler optimizations.
  - 1 Select **Optimizations off (faster builds)** for the Model Configuration parameter **Code Generation > Compiler optimization level**.
  - 2 Rebuild the model.

For more information, see “Control Compiler Optimizations” and your compiler documentation.

## Compile-Time Issues

Issue	Action
You see a compiler configuration error.	Make sure that MATLAB supports the compiler and version that you want to use. For a list of currently supported and compatible compilers, see <a href="http://www.mathworks.com/support/compilers/current_release/">www.mathworks.com/support/compilers/current_release/</a> . If necessary, upgrade or change your compiler (see “Choose and Configure Compiler on Microsoft Windows”

Issue	Action
	on page 40-6 or “Choose and Configure Compiler on UNIX” on page 40-7).
<p>Environment variables for your make utility, compiler, or linker are set up incorrectly. For example, installation of Cygwin tools on a Windows platform affects environment variables used by other compilers.</p>	<p>Review the environment variable settings for your system by using the <code>set</code> command on a Windows platform or <code>setenv</code> on a UNIX platform. Make sure that the settings match what is required for the tools you are using.</p>
<p>Custom code specified as an S-function block or in the <b>Code Generation &gt; Custom Code</b> pane of the Configuration Parameters dialog box includes errors. For example, the code refers to a header file that the compiler cannot find.</p>	<p>Remove the custom code from the model to isolate the source of the problem, debug, and rebuild the model.</p>
<p>The model includes a block, such as a device driver block, which is not intended for use with the currently selected target.</p>	<p>Remove the target-specific block or configure the model for use with the another target.</p>
<p>All of these conditions are true:</p> <ul style="list-style-type: none"> <li>• You represent signal, state, or parameter data by creating a data object such as <code>Simulink.Signal</code>. You use the object in a model reference hierarchy.</li> <li>• You use a custom storage class with the data object. Custom storage classes require an Embedded Coder license.</li> <li>• You set the owner of the object to a model that does not directly access the data.</li> <li>• You use the toolchain <code>lcc-win64</code>.</li> </ul> <p>When you generate an executable from the model reference hierarchy, you see a linker error about an undefined reference to the data.</p>	<p>To resolve the issue, choose one of these methods:</p> <ul style="list-style-type: none"> <li>• In the data object, clear the <code>Owner</code> property. Alternatively, set the owner to a model that directly accesses the data.</li> <li>• Use a different toolchain, such as <code>gcc</code>, instead of <code>lcc</code>.</li> </ul>

## LCC Compiler Does Not Support Ampersands in Source Folder Paths

### Description

If you use the LCC compiler and your model folder path contains an ampersand (&), the build process produces an error.

### Action

Remove the ampersand from the model folder path. Then, rebuild the model.

# Configure Build Process

## Choose a Build Process

The code generator supports two processes for building code generated from Simulink models:

- *Toolchain approach* — A newer build process that generates optimized makefiles and supports custom toolchains. The benefits of this approach include:
  - Provide control of your build process with toolchain information objects. These objects can be defined using MATLAB scripts.
  - Supports model referencing, PIL, SIL, and Rapid Accelerator builds.
  - Supported by MATLAB Coder.
  - Provides added flexibility to configure the build process for individual models.
- *Template makefile approach* — An older build process that uses template makefiles

The “System target file” parameter, located on the **Code Generation** pane in the Configuration Parameters dialog box, determines the build process for a model. When the **System target file** is set to:

- `ert.tlc`, `ert_shrplib.tlc`, `grt.tlc`, or any toolchain-compliant system target file, the build process uses the *toolchain approach*. For more information, see “Toolchain Approach” on page 40-13 and see “Support Toolchain Approach with Custom Target” on page 71-81.
- Any non-toolchain-compliant system target files. The build process uses the *template makefile approach*. For more information, see “Template Makefile Approach” on page 40-19.

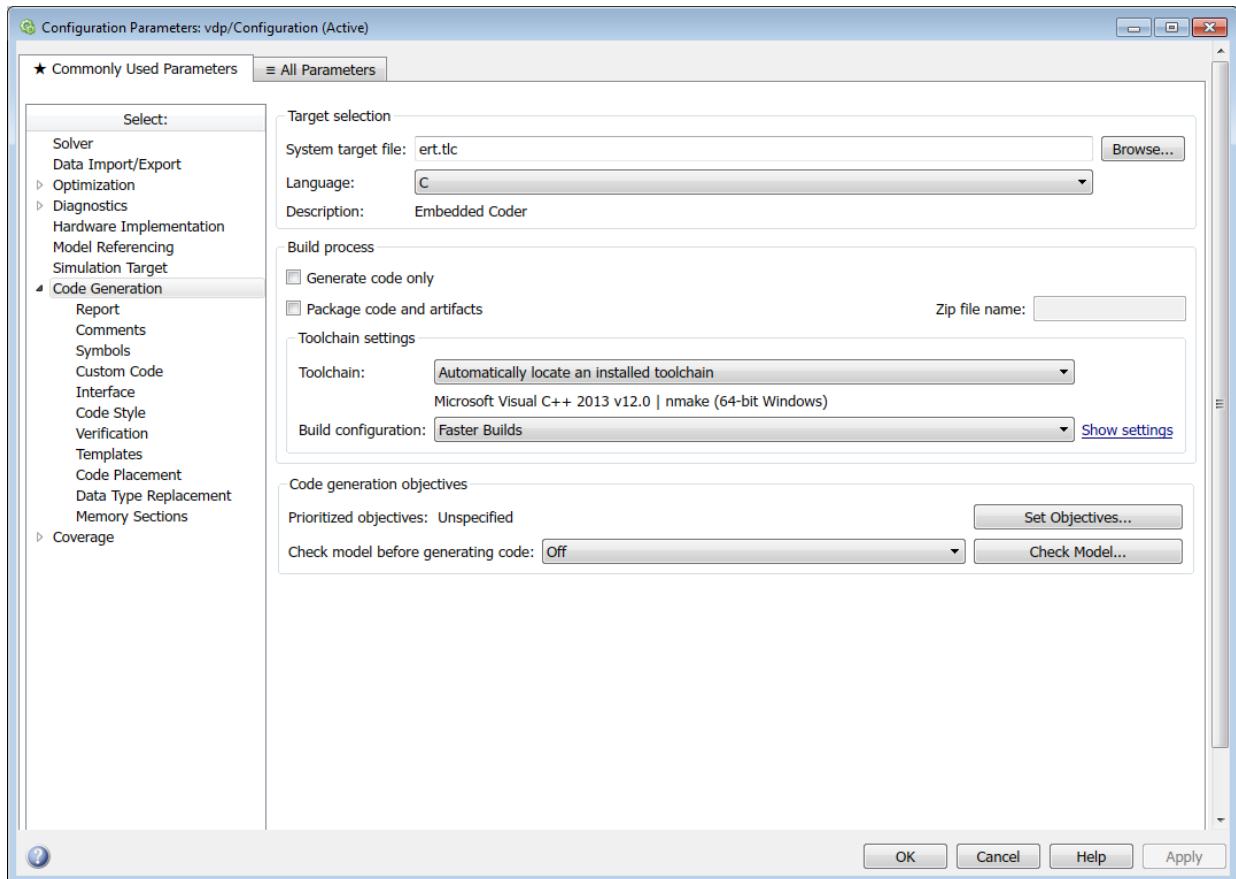

## Toolchain Approach

The *toolchain approach* is named for the **Toolchain settings** that appear under **Build process** when you set **System target file** to:

- `grt.tlc` – Generic Real-Time Target
- `ert.tlc` – Embedded Coder (requires the Embedded Coder product)
- `ert_shrplib.tlc` – Embedded Coder (host-based shared library target) (requires the Embedded Coder product)

- Any toolchain-compliant target (If ERT-based, requires the Embedded Coder product)

For more information about toolchain-compliant targets, see “Support Toolchain Approach with Custom Target”.

The **Toolchain settings** include:

- The “Toolchain” parameter specifies the collection of third-party software tools that builds the generated code. A toolchain can include a compiler, linker, archiver, and other prebuild or postbuild tools that download and run the executable on the target hardware.

The default value of **Toolchain** is `Automatically locate an installed toolchain`. The **Toolchain** parameter displays name of the automatically located toolchain just below `Automatically locate an installed toolchain`.

Click the **All Parameters > Toolchain > Validate** button to check that the toolchain is present and validate that the code generator has the information required to use the toolchain. The resulting Validation Report gives a pass/fail for the selected toolchain, and identifies issues to resolve.

- The “Build configuration” parameter lets you choose or customize the optimization settings. By default, **Build Configuration** is set to `Faster Builds`. You can also select `Faster Runs`, `Debug`, and `Specify`. When you select `Specify` and click **Apply**, you can customize the toolchain options for each toolchain. These custom toolchain settings only apply to the current model.

---

**Note:** The following system target files, which use the template makefile approach, have the same names but different descriptions from system target files that use the toolchain approach:

- `ert.tlc` – Create Visual C/C++ Solution File for Embedded Coder
- `grt.tlc` – Create Visual C/C++ Solution File for Simulink Coder

To avoid confusion, click **Browse** to select the system target file and look at the description of each file.

---

## Upgrade Model to Use Toolchain Approach

When you open a model created before R2013b that uses the following system target files, the software automatically tries to upgrade the model from using template makefile settings to using the toolchain settings:

- `ert.tlc` – Embedded Coder
- `ert_shrlib.tlc` – Embedded Coder (host-based shared library target)
- `grt.tlc` – Generic Real-Time Target

---

**Note:** To upgrade models using a custom system target file to use the toolchain approach, see “Support Toolchain Approach with Custom Target” on page 71-81.

---

However, some model configuration parameter values prevent the software from automatically upgrading a model to use toolchain settings. The following instructions show you ways to complete the upgrade process.

We recommend upgrading your models, but doing so is not required. You can continue generating code from a model that has not been upgraded.

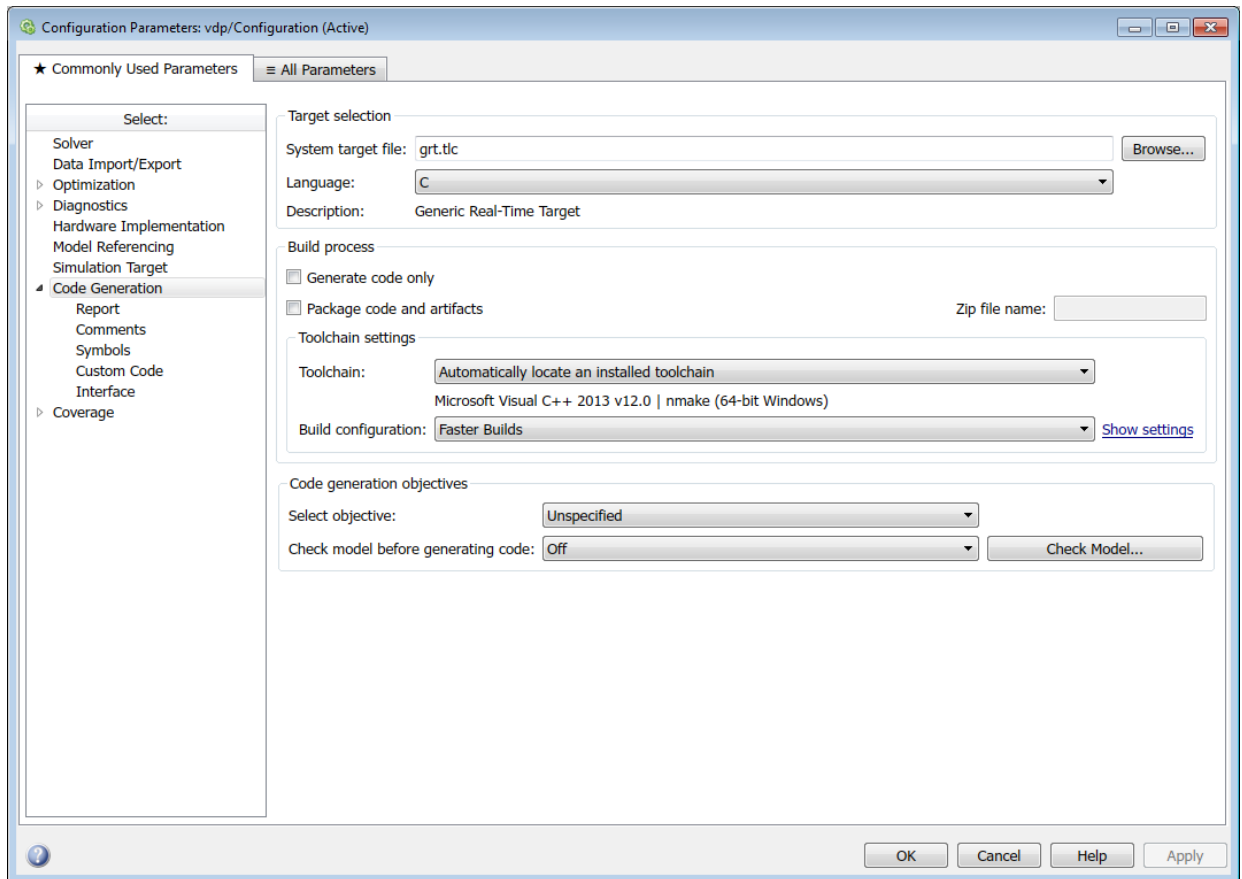

---

**Note:** The software does not upgrade models that use the following system target files:

- `ert.tlc` – Create Visual C/C++ Solution File for Embedded Coder
  - `grt.tlc` – Create Visual C/C++ Solution File for Simulink Coder
- 

To see if a model was upgraded:

- 1** Open the model configuration parameters by pressing **Ctrl+E**.
- 2** Select the **Code Generation** pane.
- 3** If the **Build process** area contains the **Toolchain** and **Build configuration** parameters, the model has already been upgraded.

If the **Build process** area displays **Makefile configuration** parameters, such as **Generate makefile**, **Make command**, and **Template makefile**, the software has not upgraded the model.

Start by creating a working copy of the model using **File > Save As**. This action preserves the original model and configuration parameters, in case you need to refer back to them.

Try to upgrade the model using Upgrade Advisor:

- 1 In your model, select **Analysis > Model Advisor > Upgrade Advisor**.

- 2 In Upgrade Advisor, select **Check and update model to use toolchain approach to build generated code** and click **Run This Check**.
- 3 Perform the recommended actions and/or click **Update Model**.

When you cannot upgrade the model using Upgrade Advisor, one or more of the following parameters is not set to its default value, shown here:

- **Compiler optimization level** — Optimizations off (faster builds)
- **Generate makefile** — Enabled
- **Template makefile** — Target-specific template makefile
- **Make command** — `make_rtw` without arguments

In some cases, a model cannot be upgraded, however, try the following procedure:

- If **Generate makefile** is disabled, this case might not be upgradable. However, you can try enabling it and try upgrading the model using Upgrade Advisor.
- If **Compiler optimization level** is set to **Optimizations on (faster runs)**:
  - 1 Set **Compiler optimization level** is to **Optimizations off (faster builds)**.
  - 2 Upgrade the model using Upgrade Advisor.
  - 3 Set **Build configuration** to **Faster Runs**.
- If **Compiler optimization level** is set to **Custom**:
  - 1 Copy the **Custom compiler optimization flags** to a text file.
  - 2 Set **Compiler optimization level** to **Optimizations off (faster builds)**.
  - 3 Upgrade the model using Upgrade Advisor.
  - 4 Set **Build configuration** to **Specify**.
  - 5 Edit the compiler options to perform the same optimizations.
- If **Template makefile** uses a customized template makefile, this case might not be upgradable. However, you can try the following:
  - 1 Update **Template makefile** to use the default makefile for the system target file.

---

**Note:** To get the default makefile name, change the **System target file**, click **Apply**, change it back, and click **Apply** again.

---

- 2 Upgrade the model using Upgrade Advisor.
- 3 If the template makefile contains build tool options, such as compiler optimization flags, set **Build configuration** to **Specify** and update the options.
- 4 If the template makefile uses custom build tools, create and register a custom toolchain, as described in “Custom Toolchain Registration” . Then, set the **Toolchain** parameter to use the custom toolchain.

---

**Note:** After registering the custom toolchain, update **Toolchain** to use the custom toolchain.

---

- 5 If the template makefile contains custom rules and logic, these cannot be applied to the upgraded model.

## Template Makefile Approach

When the **System target file** is set to a `tlc` file that uses the template makefile approach, the software displays **Compiler optimization level**, **Generate makefile**, **Make command**, and **Template makefile** parameters.

## Specify Whether To Generate a Makefile

The **Generate makefile** option specifies whether the build process is to generate a makefile for a model. By default, the build process generates a makefile. Suppress generation of a makefile, for example in support of custom build processing that is not based on makefiles, by clearing **Generate makefile**. When you clear this parameter:

- The **Make command** and **Template makefile** options are unavailable.
- You must set up post code generation build processing using a user-defined command, as explained in “Customize Post-Code-Generation Build Processing” on page 70-14.

## Specify a Make Command

Each template makefile based target has an associated `make` command, an internal MATLAB command used by code generation software to control the build process. The command displayed in the **Make command** field is invoked when you start a build.

Most targets use the default command, `make_rtw`. Third-party targets might supply another `make` command. See the vendor's documentation.

In addition to the name of the `make` command, you can supply makefile options in the **Make command** field. These options might include compiler-specific options, include paths, and other parameters. When the build process invokes the `make` utility, these options are passed on the `make` command line, which adds them to the overall flags passed to the compiler.

“Template Makefiles and Make Options” on page 29-26 lists the **Make command** options you can use with each supported compiler.

## Specify the Template Makefile

The **Template makefile** field has these functions:

- If you have selected a target configuration using the System Target File Browser, this field displays the name of a MATLAB language file that selects a template makefile for your development environment. For example, in “Model Configuration Parameters: Code Generation”, the **Template makefile** field displays `grt_default_tmf`, indicating that the build process invokes `grt_default_tmf.m`.

“Template Makefiles and Make Options” on page 29-26 gives a detailed description of the logic by which the build process selects a template makefile.

- Alternatively, you can explicitly enter the name of a specific template makefile (including the extension) or a MATLAB language file that returns a template makefile in this field. You must do this if you are using a target configuration that does not appear in the System Target File Browser. For example, do this if you have written your own template makefile for a custom target environment.

If you specify your own template makefile, be sure to include the filename extension. If you omit the extension, the build process attempts to find and execute a file with the extension `.m` (that is, a MATLAB language file). The template make file (or a MATLAB language file that returns a template make file) must be on the MATLAB path. To determine whether the file is on the MATLAB path, enter the following command in the MATLAB Command Window:

which *tmf\_filename*

## Specify TLC Options

You can specify Target Language Compiler (TLC) command line options and arguments for code generation using the model parameter `TLCOptions` in a `set_param` function call. For example,

```
>> set_param(gcs,'TLCOptions','-p0 -aWarnNonSaturatedBlocks=0')
```

Some common uses of TLC options include the following:

- `-aVarName=1` to declare a TLC variable and/or assign a value to it
- `-IC:\Work` to specify an include path
- `-v` to obtain verbose output from TLC processing (for example, when debugging)

TLC options that you specify for code generation are listed in the summary section of the generated HTML code generation report.

Specifying TLC command-line options does not add flags to the make command line.

For additional information, see “Target Language Compiler Overview”.

- “Target Language Compiler Overview”
- “How Executable Programs Are Built From Models” on page 40-39
- “Executable Program Generation” on page 40-63

# Build a Generic Real-Time Program

## Building a Program

Building a program means generating C or C++ code from an example model and then building an executable program from the generated code. This example uses a Generic Real-Time (GRT) target for code generation. The resulting standalone program runs on your workstation, independent of external timing and events.

## Working Folder

This example uses a local copy of the `slexAircraftExample` model, stored in its own folder, `aircraftexample`. Set up your *working folder* as follows:

- 1 In the MATLAB Current Folder browser, navigate to a folder to which you have write access.
- 2 Enter the following MATLAB command to create the working folder:

```
mkdir aircraftexample
```

- 3 Make `aircraftexample` your working folder:

```
cd aircraftexample
```

- 4 Open the `slexAircraftExample` model:

```
slexAircraftExample
```

The model appears in the Simulink Editor model window.

- 5 In the model window, choose **File > Save As**. Navigate to your working folder, `aircraftexample`. Save a copy of the `slexAircraftExample` model as `myAircraftExample`.

## Build Folder and Code Generation Folders

While producing code, the code generator creates a *build folder* within your working folder. The build folder name is `model_target_rtw`, derived from the name of the source model and the chosen target. The build folder stores generated source code and other files created during the build process. You examine the build folder contents at the end of this example.

When a model contains Model blocks (references to other models), special *code generation folders* are created in your code generation folder to organize code for the referenced models. Code generation folders exist alongside product build folders and are named `slprj`. “Generate Code for Referenced Models” on page 4-4 describes navigating code generation folder structures in Model Explorer.

Under the `slprj` folder, a subfolder named `_sharedutils` contains generated code that can be shared between models.

## Set Simulation Parameters

To generate code from your model, you must change some of the simulation parameters. In particular, the generic real-time (GRT) target and most other targets require that the model specify a fixed-step solver.

---

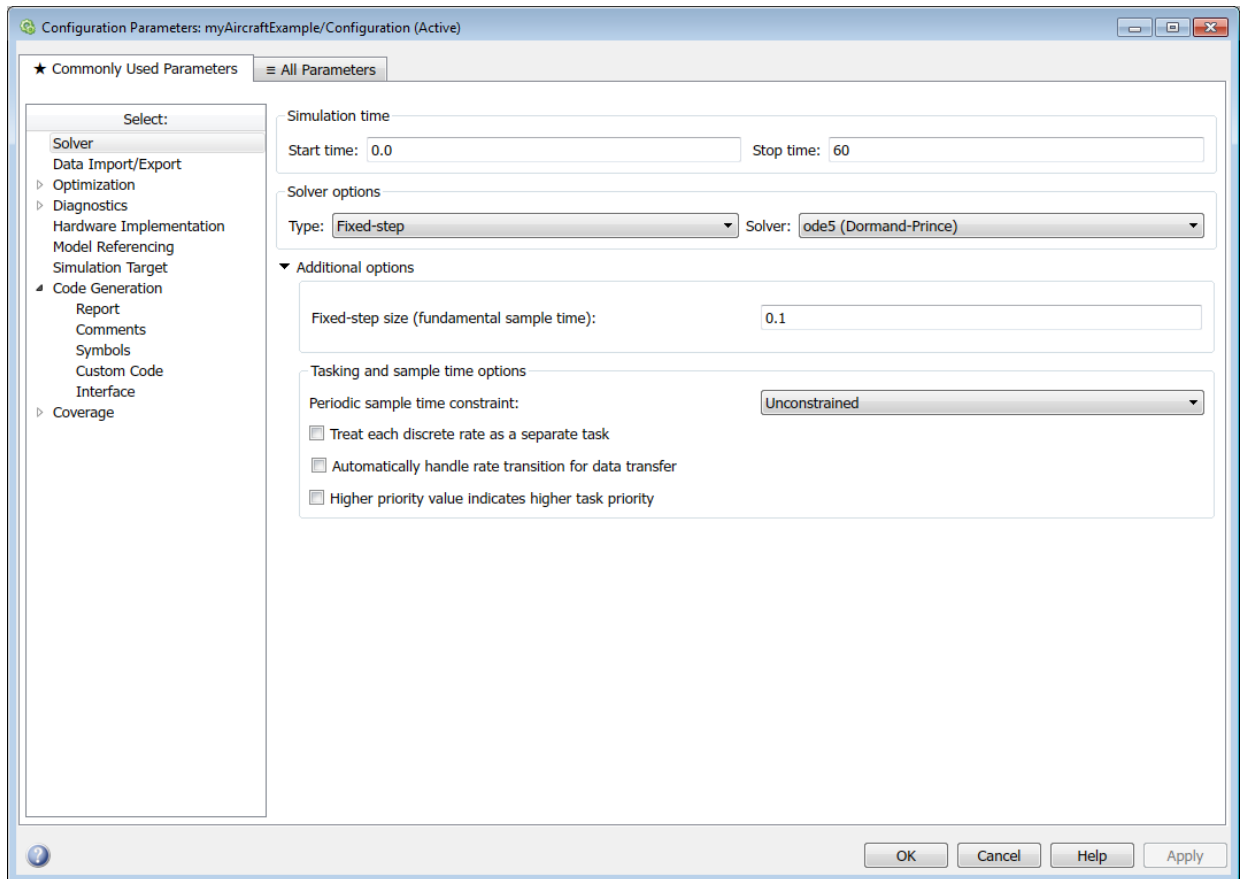

**Note** The code generator produces code for models, using variable-step solvers, for rapid simulation (`rsim`) and S-function system target files only.

---

To set simulation parameters using the Configuration Parameters dialog box:

- 1 Open the `myAircraftExample` model if it is not already open.
- 2 From the model window, open the Configuration Parameters dialog box by selecting **Simulation > Model Configuration Parameters**.
- 3 Select the **Solver** pane. Enter the following parameter values (some might already be set):
  - **Start time:** 0.0
  - **Stop time:** 60
  - **Type:** Fixed-step
  - **Solver:** ode5 (Dormand-Prince)
  - **Fixed step size (fundamental sample time):** 0.1
  - **Treat each discrete rate as a separate task:** Off

The background color of the controls you just changed is tan. The color also appears on fields that were set automatically by your choices in other fields. Use this visual feedback to verify that what you set is what you intended. When you apply your changes, the background color reverts to white.

- 4 Click **Apply** to register your changes.
- 5 Save the model. Simulation parameters persist with the model for use in future sessions.

## Select a Target Configuration

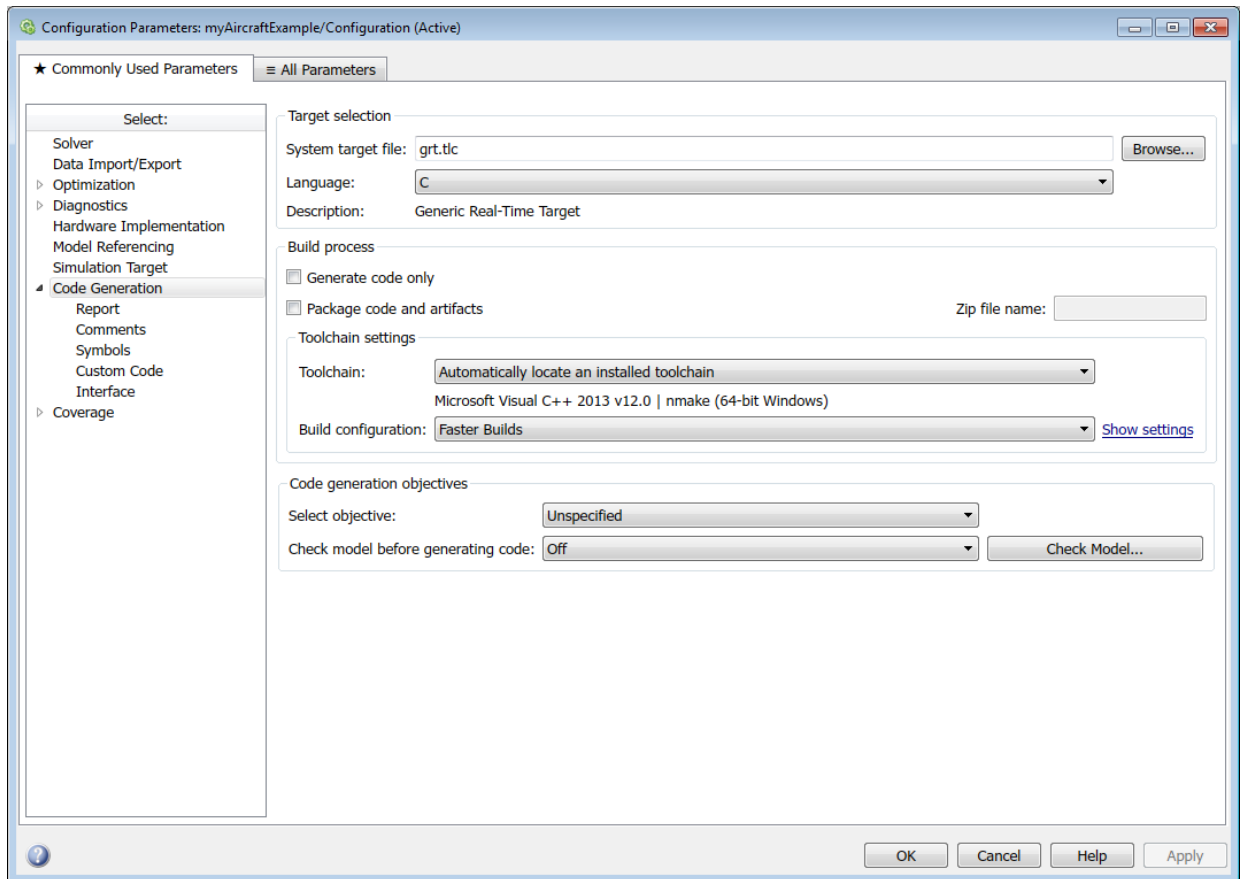

To specify a target configuration for your model, you choose a system target file, a toolchain or template makefile, and a make command.

In these examples and in most applications, you do not need to specify these parameters individually. Here, you use the ready-to-run generic real-time target (GRT) configuration. The GRT target builds a standalone executable program that runs on your workstation.

To select the GRT target using the Configuration Parameters dialog box:

- 1** With the `myAircraftExample` model open, select **Simulation > Model Configuration Parameters** to open the Configuration Parameters dialog box.
- 2** Select the **Code Generation** pane.
- 3** For **System target file**, enter `grt.tlc`, and click **Apply**.

The **Code Generation** pane displays the **System target file** (`grt.tlc`), **Toolchain** (Automatically locate an installed toolchain), and **Build Configuration** (Faster Builds).

**Note** If you click **Browse**, a System Target File Browser opens and displays the system target files on the MATLAB path. Some system target files require additional licensed products. For example, `ert.tlc` requires the Embedded Coder product.

- 4 Save the model.

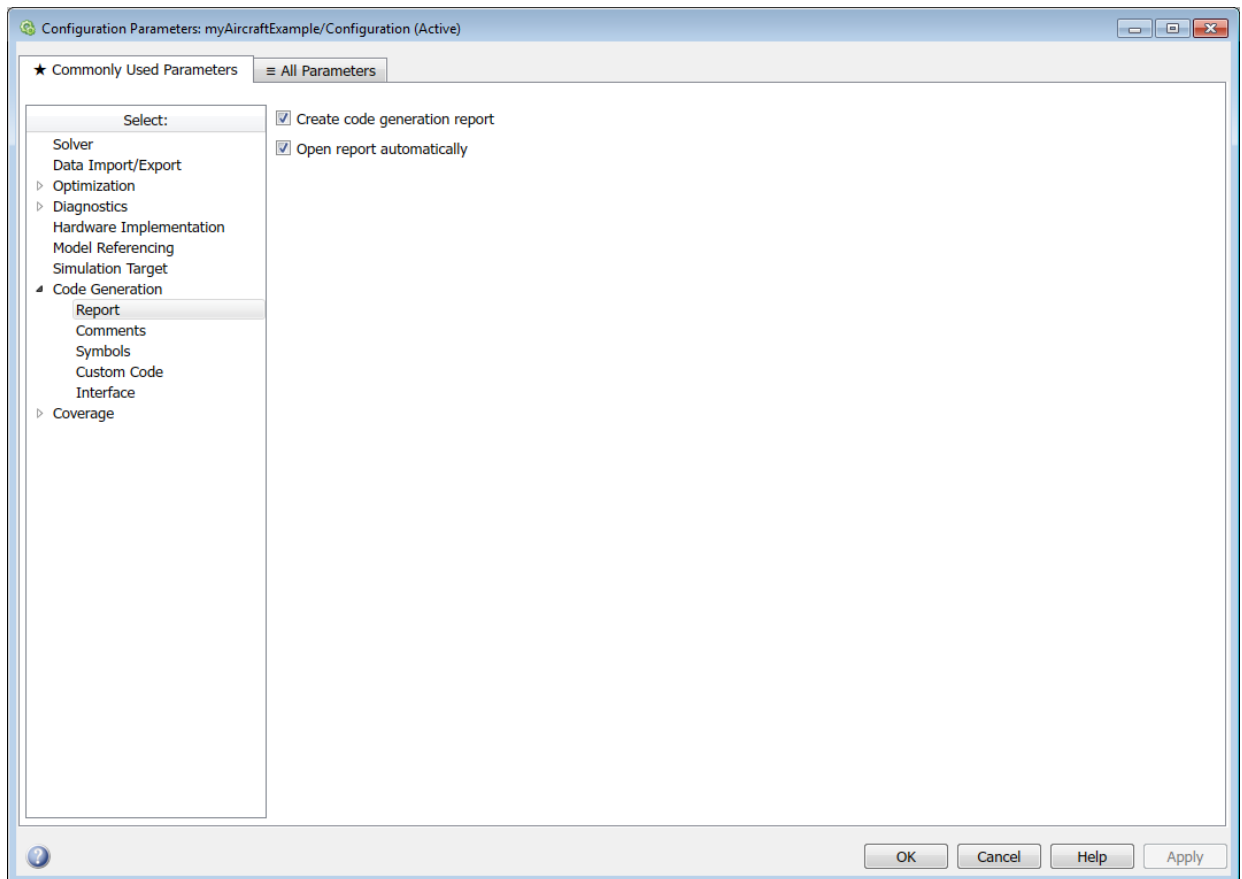

## Set Code Generation Parameters

Before you generate code from your model for the first time, inspect the code generation parameters for the model. Some of the steps in this topic do not require you to make

changes. They are included to help you familiarize yourself with the user interface. As you work with the model parameters, you can place the mouse pointer on a parameter to see a tool tip describing its function.

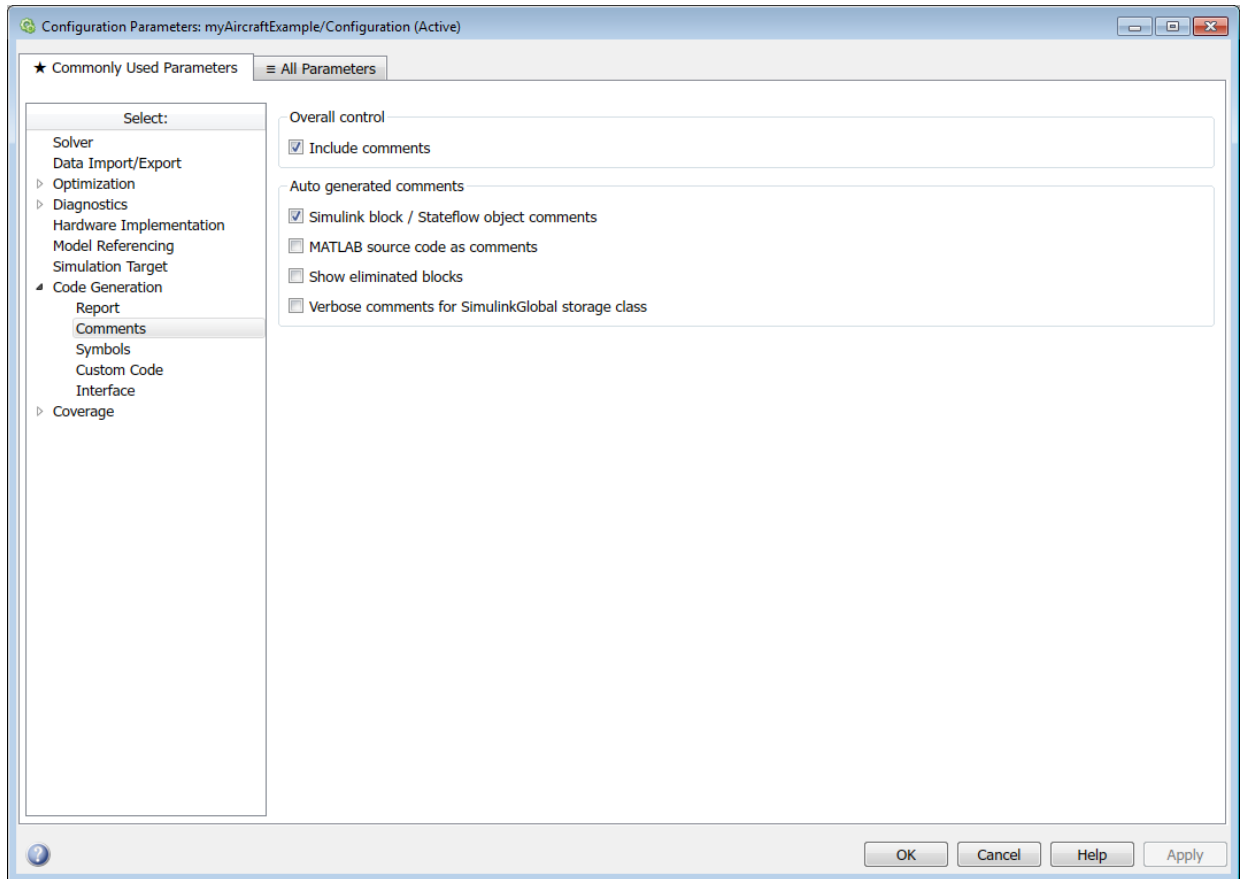

To set code generation parameters using the Configuration Parameters dialog box:

- 1 With the `myAircraftExample` model open, select **Simulation > Model Configuration Parameters** to open the Configuration Parameters dialog box.
- 2 Select **Code Generation > Report > Create code generation report**. This action enables the software to create and display a code generation report for the `myAircraftExample` model.

- 3 Select the **Code Generation > Comments** pane. The options displayed here control the types of comments included in generated code. Leave the options set to their defaults.

- 4 Select the **Code Generation > Symbols** pane. The options on this pane control the look and feel of generated code.

5 Select the **All Parameters** tab. The following parameters in the **Code Generation** category control build verbosity and debugging support. These parameter are common to all target configurations.

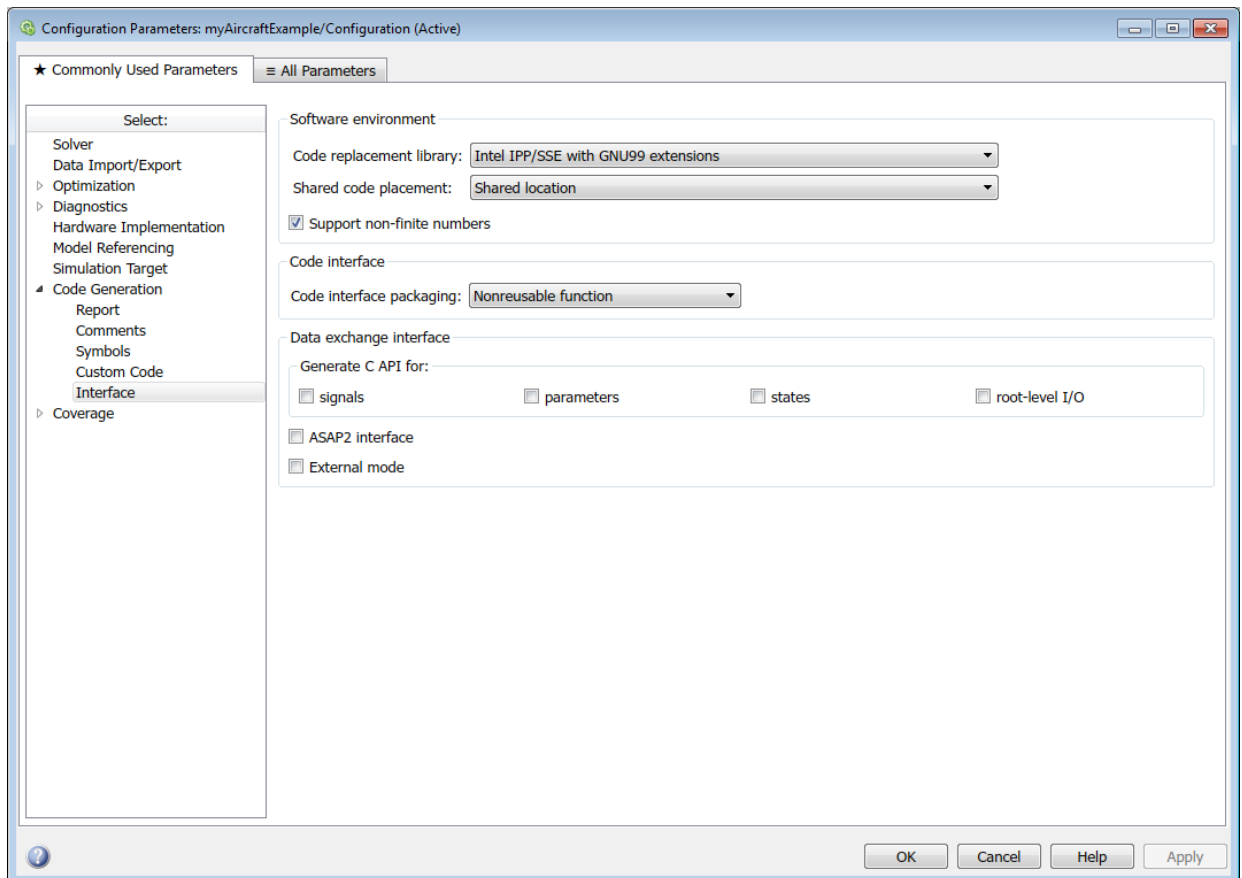

- Verbose build (`RTWVerbose` parameter)
- Retain .rtw file (`RetainRTWFile` parameter)
- Profile TLC (`ProfileTLC` parameter)
- Start TLC debugger when generating code (`TLCDebug` parameter)
- Start TLC coverage when generating code (`TLCCoverage` parameter)

- Enable TLC assertion (TLCAssert parameter)

Leave the options set to their defaults.

**6** Select the **Code Generation > Interface** pane.

- For the **Shared code placement** parameter, select **Shared location**. The build process will place generated code for utilities at a shared location within the `slprj` folder in your code generation folder.
- If it is not already cleared, switch to the **All Parameters** tab and clear the **Code Generation > Classic call interface** option.

- 7 Click **Apply** and save the model.

## Build and Run a Program

The build process generates C code from the model. It then compiles and links the generated program to create an executable image. To build and run the program:

- 1 With the `myAircraftExample` model open, go to the Configuration Parameters dialog box. In the **Code Generation** pane, click **Build** to start the build process.

A number of messages concerning code generation and compilation appear in the Command Window. The initial message is:

```
Starting build procedure for model: myAircraftExample
```

The contents of many of the succeeding messages depends on your compiler and operating system. The final messages include:

```
Created executable myAircraftExample.exe
Successful completion of build procedure for model: myAircraftExample
Creating HTML report file myAircraftExample_codegen_rpt.html
```

The code generation folder now contains an executable, `myAircraftExample.exe` (Microsoft Windows platforms) or `myAircraftExample` (UNIX platforms). In addition, the build process has created an `slprj` folder and a `myAircraftExample_grt_rtw` folder in your code generation folder.

---

**Note:** After generating the code for the `myAircraftExample` model, the build process displays a code generation report. See “Report Generation” for more information about how to create and use a code generation report.

---

- 2 To see the contents of the working folder after the build, enter the `dir` or `ls` command:

```
>> dir

.
..
myAircraftExample.exe
myAircraftExample.slx
myAircraftExample.slx.autosave
myAircraftExample_grt_rtw
slprj
```

- 3 To run the executable from the Command Window, type `!myAircraftExample`. The `!` character passes the command that follows it to the operating system, which runs the standalone `myAircraftExample` program.

```
>> !myAircraftExample
```

```
** starting the model **
** created myAircraftExample.mat **
```

- 4 To see the files created in the build folder, use the `dir` or `ls` command again. The exact list of files produced varies among MATLAB platforms and versions. Here is a sample list from a Windows platform:

```
>> dir myAircraftExample_grt_rtw

. rt_main.obj myAircraftExample_data.c
.. rtmodel.h myAircraftExample_data.obj
buildInfo.mat rtw_proj.tmw myAircraftExample_private.h
codeInfo.mat myAircraftExample.bat myAircraftExample_ref.rsp
defines.txt myAircraftExample.c myAircraftExample_types.h
html myAircraftExample.h
modelsources.txt myAircraftExample.mk
rt_logging.obj myAircraftExample.obj
```

## Contents of the Build Folder

The build process creates a build folder and names it *model\_target\_rtw*, where *model* is the name of the source model and *target* is the target selected for the model. In this example, the build folder is named `myAircraftExample_grt_rtw`.

The build folder includes the following generated files.

File	Description
<code>myAircraftExample.c</code>	Standalone C code that implements the model
<code>myAircraftExample.h</code>	An include header file containing definitions of parameters and state variables
<code>myAircraftExample_private.h</code>	Header file containing common include definitions
<code>myAircraftExample_types.h</code>	Forward declarations of data types used in the code
<code>rtmodel.h</code>	Master header file for including generated code in the static main program (its name does not change, and it simply includes <code>myAircraftExample.h</code> )

The code generation report that you created for the `myAircraftExample` model displays a link for each of these files. You can click the link explore the file contents.

The build folder contains other files used in the build process. They include:

- `myAircraftExample.mk` — Makefile for building executable using the specified Toolchain.
- Object (`.obj`) files
- `myAircraftExample.bat` — Batch control file
- `rtw_proj.tmw` — Marker file
- `buildInfo.mat` — Build information for relocating generated code to another development environment
- `defines.txt` — Preprocessor definitions required for compiling the generated code
- `myAircraftExample_ref.rsp` — Data to include as command-line arguments to `mex` (Windows systems only)

The build folder also contains a subfolder, `html`, which contains the files that make up the code generation report. For more information, see “Reports for Code Generation”.

## More About

- “Configure Build Process” on page 40-13
- “Initiate the Build Process” on page 40-35
- “Build and Run a Program” on page 40-36
- “Reports for Code Generation”
- “Select and Configure Compiler or IDE” on page 40-3

## Initiate the Build Process

You can initiate code generation and the build process by using the following options:

- Press **Ctrl+B**.
- Select **Code > C/C++ Code > Build Model**.
- Invoke the `rtwbuild` command from the MATLAB command line.
- Invoke the `slbuild` command from the MATLAB command line.

### More About

- `rtwbuild`
- “Build a Generic Real-Time Program” on page 40-23
- “Rebuild a Model” on page 40-41
- “Build and Run a Program” on page 40-36

## Build and Run a Program

The build process generates C code from a model, and then compiles and links the generated program to create an executable image. To build and run a sample program, use the example model `slexAircraftExample`.

- 1 In the Command Window, enter `slexAircraftExample` to open the model.
- 2 Save a copy of the model to your working folder and name it `myAircraftExample`.
- 3 Open the Configuration Parameters dialog box by selecting **Simulation > Model Configuration Parameters**. Set the following parameters.
  - Select the **Solver** pane. Enter the following parameter values on the **Solver** pane (some may already be set):
    - **Start time:** 0.0
    - **Stop time:** 60
    - **Type:** Fixed-step
    - **Solver:** ode5 (Dormand-Prince)
    - **Fixed step size (fundamental sample time):** 0.1
    - **Treat each discrete rate as a separate task:** Off
  - Select the **Code Generation > Report** pane, and select the **Create code generation report** parameter. This causes the build process to display a code generation report after generating the code for the `myAircraftExample` model.
  - Select the **Code Generation > Interface** pane. For the **Shared code placement** parameter, select `Shared location`. This causes generated code for utilities to be placed at a shared location within the `slprj` folder in the code generation folder.
  - Select the **All Parameters** tab.
    - If it is not already cleared, clear the **Classic call interface** option.
    - If it is not already set, set the **Single output/update function** option.

Click **Apply**.

- 4 In the **Code Generation** pane, click the **Build** button to start the build process.

A number of messages concerning code generation and compilation appear in the MATLAB Command Window. The initial message is

```
Starting build procedure for model: myAircraftExample
```

The contents of many of the succeeding messages depends on your compiler and operating system. The final messages include

```
Created executable slxAircraftExample.exe
Successful completion of build procedure for model: myAircraftExample
Creating HTML report file myAircraftExample_codegen_rpt.html
```

The code generation folder now contains an executable, `myAircraftExample.exe` (Microsoft Windows platforms) or `myAircraftExample` (UNIX platforms). In addition, the build process has created an `slprj` folder and a `myAircraftExample_grt_rtw` folder in the code generation folder .

---

**Note:** The build process displays a code generation report after generating the code for the `myAircraftExample` model. See “Report Generation” for more information about how to create and use a code generation report.

---

- 5 To observe the contents of the working folder after the build, type the `dir` or `ls` command from the Command Window.

```
>> dir
```

```
. myAircraftExample.exe myAircraftExample_grt_rtw
.. myAircraftExample.slx slprj
```

- 6 To run the executable from the Command Window, type `!slxAircraftExample`. The `!` character passes the command that follows it to the operating system, which runs the standalone `slxAircraftExample` program.

```
>> !myAircraftExample
```

```
** starting the model **
** created myAircraftExample.mat **
```

- 7 To see the files created in the build folder, use the `dir` or `ls` command again. The exact list of files produced varies among MATLAB platforms and versions. Here is a sample list from a Windows platform.

```
>> dir myAircraftExample_grt_rtw
```

```
. rt_main.obj myAircraftExample_data.c
.. rtmodel.h myAircraftExample_data.obj
buildInfo.mat rtw_proj.tmw myAircraftExample_private.h
codeInfo.mat myAircraftExample.bat myAircraftExample_ref.rsp

- “Rebuild a Model” on page 40-41
- “Report Generation”

## How Executable Programs Are Built From Models

The code generator produces C code only or generates the C code and produces an executable image, depending on the level of processing you choose. By default, the software generates the C code and produces an executable image. If you select the **Generate code only** check box, the software generates code only.

### Build Process Steps

When you press **Ctrl+B**, the code generator performs the following build process. If the software detects code generation constraints for your model, it issues warning or error messages.

- 1 “Model Compilation” on page 33-71
- 2 “Code Generation” on page 33-71
- 3 “Customized Makefile Generation” on page 40-39
- 4 “Executable Program Generation” on page 40-63

For more information, see “Generate a Code Generation Report”. You can also view an HTML report in Model Explorer.

### Customized Makefile Generation

After producing code, the code generator produces a customized makefile, *model.mk*. The generated makefile instructs the **make** system utility to compile and link source code generated from the model, as well as any required harness program, libraries, or user-provided modules. The code generator produces the file *model.mk* whether you are using the toolchain approach or template makefile approach for build process control. For more information about these approaches, see “Configure Build Process” on page 40-13.

If you are using the template makefile approach, the code generator creates *model.mk* from a system template file, *system.tmf* (where *system* stands for the selected target name). The system template makefile is designed for your target environment. You have the option of modifying the template makefile to specify compilers, compiler options, and additional information used during the creation of the executable. For more information, see “Template Makefile Approach” on page 40-19.

If you are using the toolchain approach, the code generator creates *model.mk* based on the model **Toolchain settings**. You can modify generation of the makefile through the `rtwmakecfg.m` API. For more information, see “Toolchain Approach” on page 40-13.

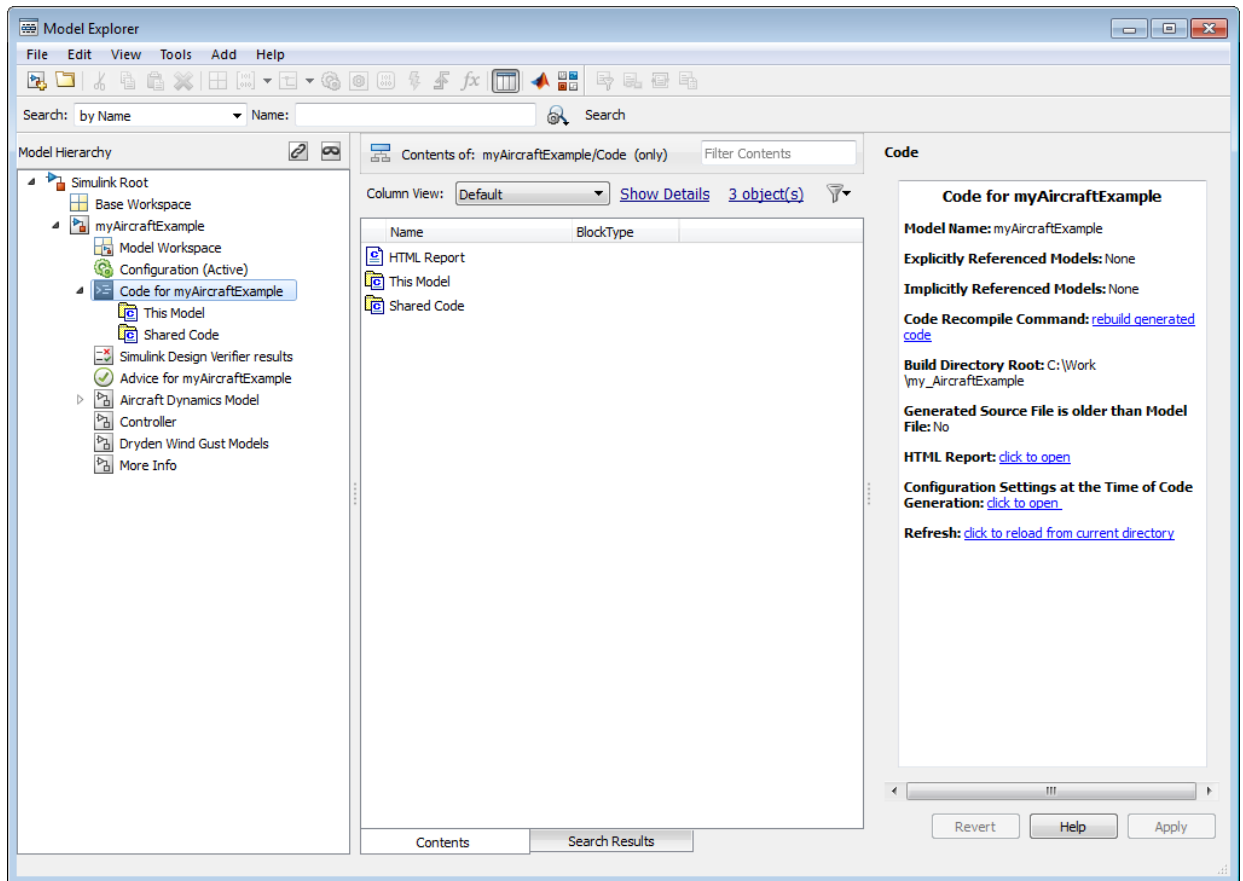

## **More About**

- “Build and Run a Program” on page 40-36

## Rebuild a Model

If you update generated source code or makefiles manually to add customizations, you can rebuild the files with the `rtwrebuild` command. This command recompiles the modified files by invoking the generated makefile. Alternatively, you can use this command from the Model Explorer:

- 1 Open the top model. Select **View > Model Explorer** to open the Model Explorer window.
- 2 In the **Model Hierarchy** pane, expand the node for the model.
- 3 Click the **Code for *model*** node.
- 4 In the **Code** pane, next to **Code Recompile Command**, click **rebuild generated code**.

## More About

- `rtwrebuild`
- “Initiate the Build Process” on page 40-35
- “Build and Run a Program” on page 40-36

## Control Regeneration of Top Model Code

When you rebuild a model, by default, the build process performs checks to determine whether changes to the model or relevant settings require regeneration of the top model code. Top model code is regenerated if any of the following conditions is true:

- The structural checksum of the model has changed.
- The top-model-only checksum has changed. The top-model-only checksum provides information about top model parameters, such as application lifespan, maximum stack size, make command, verbose and `.rtw` file debug settings, and `TLCOptions`.
- Any of the following TLC debugging model options, located on the **All Parameters** tab of the Configuration Parameters dialog box, is on:
  - **Start TLC debugger when generating code** (`TLCDebug`)
  - **Start TLC coverage when generating code** (`TLCCoverage`)
  - **Enable TLC assertion** (`TLCAssert`)
  - **Profile TLC** (`ProfileTLC`)

If the checks determine that top model code generation is required, the build process fully regenerates and compiles the model code.

If the checks indicate that the top model generated code is current with respect to the model, and no model settings require full regeneration, the build process omits regeneration of the top model code. This can significantly reduce model build times.

---

**Note:** With an Embedded Coder license, if you modify a code generation template (CGT) file and then rebuild your model, the code generation process does not force a top model build. In this case, see “Force Regeneration of Top Model Code” on page 40-44.

---

Regardless of whether the top model code is regenerated, the build process subsequently calls the build process hooks, including `STF_make_rtw_hook` functions and the post code generation command, and reruns the makefile so that external dependencies are recompiled and relinked.

---

**Note:** Target authors can perform actions related to code regeneration, including forcing or reacting to code regeneration, in the `STF_make_rtw_hook` functions that are called

by the build process. For more information, see “Control Code Regeneration Using `STF_make_rtw_hook.m`” on page 70-34.

---

## Force Regeneration of Top Model Code

If you want to control or override the default top model build behavior, use one of the following command-line options:

- To ignore the checksum and force regeneration of the top model code:
  - `rtwbuild(model, 'ForceTopModelBuild', true)`
  - `slbuild(model, 'StandaloneRTWTarget', 'ForceTopModelBuild', true)`
- To clean the model build area enough to trigger regeneration of the top model code at the next build (slbuild only):
  - `slbuild(model, 'CleanTopModel')`

---

**Note:** You can also force regeneration of the top model code by deleting the `slprj` folder or the generated model code folder from the code generation folder .

---

## More About

- `rtwrebuild`

- “Rebuild a Model” on page 40-41
- “Reduce Build Time for Referenced Models” on page 40-45

## Reduce Build Time for Referenced Models

In a parallel computing environment, you can increase the speed of code generation and compilation for models containing large model reference hierarchies by building referenced models in parallel whenever conditions allow. For example, if you have Parallel Computing Toolbox™ software, code generation and compilation for each referenced model can be distributed across the cores of a multicore host computer. If you additionally have MATLAB Distributed Computing Server™ software, code generation and compilation for each referenced model can be distributed across remote workers in your MATLAB Distributed Computing Server configuration.

### Parallel Building For Large Model Reference Hierarchies

The performance gain realized by using parallel builds for referenced models depends on several factors, including how many models can be built in parallel for a given model referencing hierarchy, the size of the referenced models, and parallel computing resources such as number of local and/or remote workers available and the hardware attributes of the local and remote machines (amount of RAM, number of cores, and so on).

For configuration requirements that might apply to your parallel computing environment, see “Parallel Building Configuration Requirements” on page 40-46.

For a description of the general workflow for building referenced models in parallel whenever conditions allow, see “Build Models In a Parallel Computing Environment” on page 40-46.

For information on how to configure a custom embedded target to support parallel builds, see “Support Model Referencing” on page 71-83.

---

**Note:** In a MATLAB Distributed Computing Server parallel computing configuration, parallel building is designed to work interactively with the software. You can initiate builds from the Simulink user interface or from the MATLAB Command Window using commands such as `slbuild`. You cannot initiate builds using `batch` or other batch mode workflows.

---

## Parallel Building Configuration Requirements

The following requirements apply to configuring your parallel computing environment for building model reference hierarchies in parallel whenever conditions allow:

- For local pools, the host machine must have enough RAM to support the number of local workers (MATLAB sessions) that you plan to use. For example, using `parpool(4)` to create a parallel pool with four workers results in five MATLAB sessions on your machine, each using the amount of memory required for MATLAB and the code generator at startup. For memory requirements, see System Requirements for MATLAB & Simulink.
- Remote MATLAB Distributed Computing Server workers participating in a parallel build and the client machine must use a common platform and compiler.
- A consistent MATLAB environment must be set up in each MATLAB worker session as in the MATLAB client session — for example, shared base workspace variables, MATLAB path settings, and so forth. One approach is to use the `PreLoadFcn` callback of the top model. If you configure your model to load the top model with each MATLAB worker session, its preload function can be used for any MATLAB worker session setup.

## Build Models In a Parallel Computing Environment

To take advantage of parallel building for a model reference hierarchy:

- 1 Set up a pool of local and/or remote MATLAB workers in your parallel computing environment.
  - a Make sure that Parallel Computing Toolbox software is licensed and installed.
  - b To use remote workers, make sure that MATLAB Distributed Computing Server software is licensed and installed.
  - c Issue MATLAB commands to set up the parallel pool, for example, `parpool(4)`.
- 2 From the top model of the model reference hierarchy, open the Configuration Parameters dialog box. Go to the **Model Referencing** pane and select the **Enable parallel model reference builds** option. This selection enables the parameter **MATLAB worker initialization for builds**.

For **MATLAB worker initialization for builds**, select one of the following values:

- **None** if the software should not perform special worker initialization. Specify this value if the child models in the model reference hierarchy do not rely on anything in the base workspace beyond what they explicitly set up (for example, with a model load function).
- **Copy base workspace** if the software should attempt to copy the base workspace to each worker. Specify this value if you use a setup script to prepare the base workspace for multiple models to use.

- `Load top model` if the software should load the top model on each worker. Specify this value if the top model in the model reference hierarchy handles the base workspace setup (for example, with a model load function).

---

**Note:** You only need to set **Enable parallel model reference builds** for the top model of the model reference hierarchy to which it applies.

---

- 3 Optionally, turn on verbose messages for simulation builds, code generation builds, or both. If you select verbose builds, the build messages report the progress of each parallel build with the name of the model.
  - To turn on verbose messages for simulation target builds, go to the **All Parameters** tab of the Configuration Parameters dialog box and select **Verbose accelerator builds**.
  - To turn on verbose messages for code generation target builds, go to the **Debug** pane of the Configuration Parameters dialog box and select **Verbose build**

Both options control the verbosity of build messages both in the MATLAB Command Window and in parallel build log files.

- 4 Optionally, inspect the model reference hierarchy to determine, based on model dependencies, which models will be built in parallel. For example, you can use the Model Dependency Viewer from the Simulink **Analysis > Model Dependencies** menu.
- 5 Build your model. Messages in the MATLAB Command Window record when each parallel or serial build starts and finishes. The order in which referenced models build is nondeterministic. They might build in a different order each time the model is built.

If you need more information about a parallel build, for example, if a build fails, see “Locate Parallel Build Logs” on page 40-48.

## Locate Parallel Build Logs

When you build a model for which referenced models are built in parallel, if verbose builds are turned on, messages in the MATLAB Command Window record when each parallel or serial build starts and finishes. For example,

```
Initializing parallel workers for parallel model reference build.
Parallel worker initialization complete.
Starting parallel model reference SIM build for 'bot_model1001'
```

```

Starting parallel model reference SIM build for 'bot_model002'
Starting parallel model reference SIM build for 'bot_model003'
Starting parallel model reference SIM build for 'bot_model004'
Finished parallel model reference SIM build for 'bot_model001'
Finished parallel model reference SIM build for 'bot_model002'
Finished parallel model reference SIM build for 'bot_model003'
Finished parallel model reference SIM build for 'bot_model004'
Starting parallel model reference RTW build for 'bot_model001'
Starting parallel model reference RTW build for 'bot_model002'
Starting parallel model reference RTW build for 'bot_model003'
Starting parallel model reference RTW build for 'bot_model004'
Finished parallel model reference RTW build for 'bot_model001'
Finished parallel model reference RTW build for 'bot_model002'
Finished parallel model reference RTW build for 'bot_model003'
Finished parallel model reference RTW build for 'bot_model004'

```

To obtain more detailed information about a parallel build, you can examine the parallel build log. For each referenced model built in parallel, the build process generates a file named *model\_buildlog.txt*, where *model* is the name of the referenced model. This file contains the full build log for that model.

If a parallel build completes, you can find the build log file in the build subfolder corresponding to the referenced model. For example, for a build of referenced model *bot\_model004*, look for the build log file *bot\_model004\_buildlog.txt* in a referenced model subfolder such as *build\_folder/slprj/grt/bot\_model004*, *build\_folder/slprj/ert/bot\_model004*, or *build\_folder/slprj/sim/bot\_model004*. The build log (diagnostic viewer) provides a relative path to the location of each build log file.

If a parallel builds fails, you might see output similar to the following:

```

Initializing parallel workers for parallel model reference build.
Parallel worker initialization complete.
...
Starting parallel model reference RTW build for 'bot_model002'
Starting parallel model reference RTW build for 'bot_model003'
Finished parallel model reference RTW build for 'bot_model002'
Finished parallel model reference RTW build for 'bot_model003'
Starting parallel model reference RTW build for 'bot_model001'
Starting parallel model reference RTW build for 'bot_model004'
Finished parallel model reference RTW build for 'bot_model004'
The following error occurred during the parallel model reference RTW build for
'bot_model001':

Error(s) encountered while building model "bot_model001"

Cleaning up parallel workers.

```

If a parallel build fails, you can find the build log file in a referenced model subfolder under the build subfolder */par\_md1\_ref/model*. For example, for a failed parallel build of model *bot\_model001*, look for the build log file *bot\_model001\_buildlog.txt*

in a subfolder such as *build\_folder/par\_md1\_ref/bot\_model001/slprj/grt/bot\_model001*, *build\_folder/par\_md1\_ref/bot\_model001/slprj/ert/bot\_model001*, or *build\_folder/par\_md1\_ref/bot\_model001/slprj/sim/bot\_model001*.

## Relocate Code to Another Development Environment

If you need to relocate the static and generated code files for a model to another development environment, such as a system or an integrated development environment (IDE) that does not include MATLAB and Simulink products, use the pack-and-go utility.

### Code Relocation

The pack-n-go utility uses the tools for customizing the build process after code generation and a `packNGo` function to find and package files for building an executable image. The files are packaged in a compressed file that you can relocate and unpack using a standard `zip` utility.

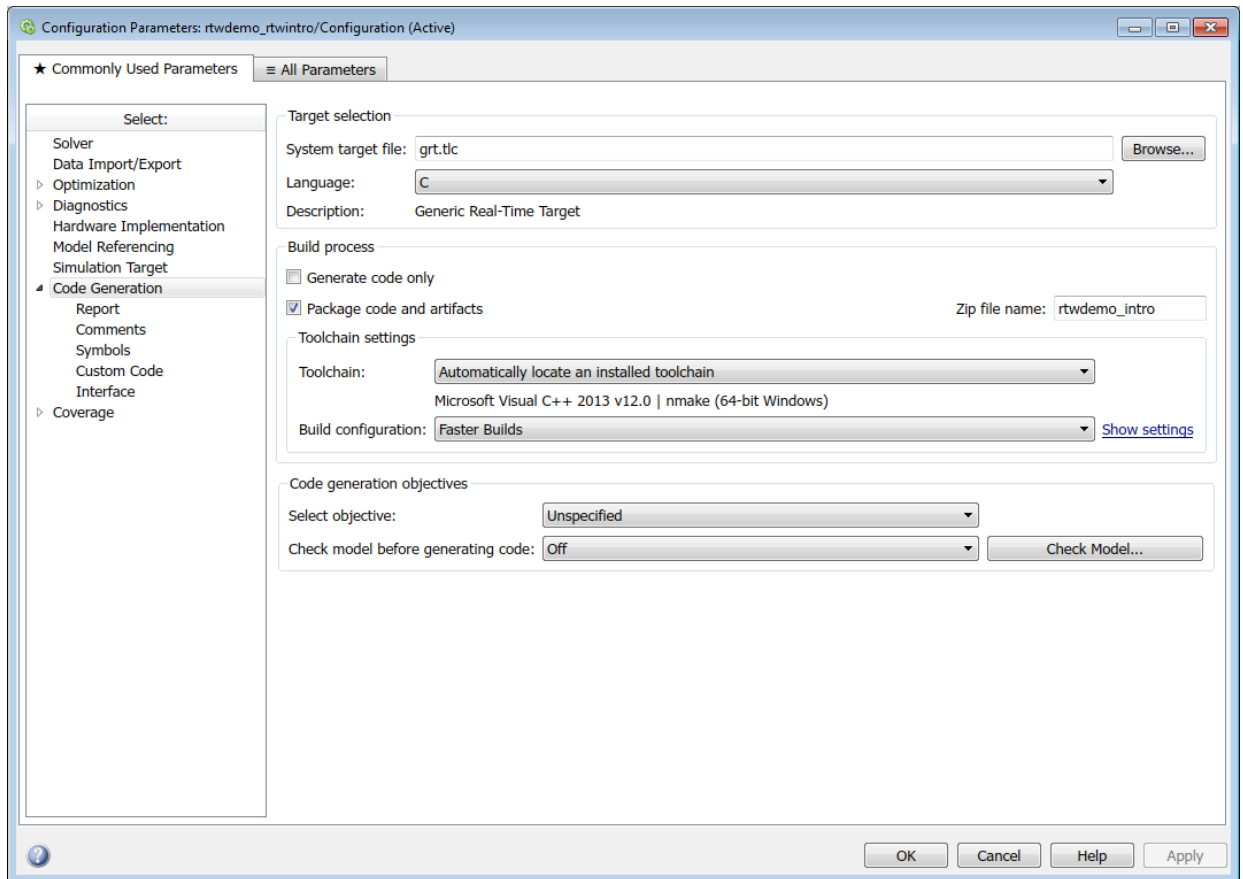

To package model code files, you can do either of the following:

- Use the model option **Package code and artifacts** on the **Code Generation** pane of the Configuration Parameters dialog box. See “Package Code Using the Graphical User Interface” on page 40-51.
- Use MATLAB commands to configure a `PostCodeGenCommand` parameter with a call to the `packNGo` function. See “Package Code Using the Command-Line Interface” on page 40-52. The command-line interface provides more control over the details of code packaging.

### Package Code Using the Graphical User Interface

To package and relocate code for your model using the graphical user interface:

- 1 Open the Configuration Parameters dialog box and select the **Code Generation** pane.
- 2 Select the option **Package code and artifacts**. This option configures the build process to run the `packNGo` function after code generation to package generated code and artifacts for relocation.
- 3 In the **Zip file name** field, enter the name of the `zip` file in which to package generated code and artifacts for relocation. You can specify the file name with or without the `.zip` extension. If you specify no extension or an extension other than `.zip`, the `zip` utility adds the `.zip` extension. If you do not specify a value, the build process uses the name `model.zip`, where `model` is the name of the top model for which code is being generated.

- 4 Apply changes and generate code for your model. Inspect the resulting zip file to verify that it is ready for relocation. Depending on the zip tool that you use, you might be able to open and inspect the file without unpacking it.
- 5 Relocate the zip file to the destination development environment and unpack the file.

## Package Code Using the Command-Line Interface

To package and relocate code for your model using the command-line interface:

- 1 Select a structure for the zip file.

- 2 Select a name for the zip file.
- 3 Package the model code files in the zip file.
- 4 Inspect the generated zip file.
- 5 Relocate and unpack the zip file.

### Select a Structure for the Zip File

Before you generate and package the files for a model build, decide whether you want the files to be packaged in a flat or hierarchical folder structure. By default, the `packNGo` function packages the files in a single, flat folder structure.

If...	Then Use a...
You are relocating files to an IDE that does not use the generated makefile, or the code is not dependent on the relative location of required static files	Single, flat folder structure
The target development environment must maintain the folder structure of the source environment because it uses the generated makefile, or the code is dependent on the relative location of files	Hierarchical structure

If you use a hierarchical structure, the `packNGo` function creates two levels of zip files, a primary zip file, which in turn contains the following secondary zip files:

- `mlrFiles.zip` — files in your *matlabroot* folder tree
- `sDirFiles.zip` — files in and under your build folder where you initiated the model's code generation
- `otherFiles.zip` — required files not in the *matlabroot* or *start* folder trees

Paths for the secondary zip files are relative to the root folder of the primary zip file, maintaining the source development folder structure.

### Select a Name for the Zip File

By default, the `packNGo` function names the primary zip file *model*.. You have the option of specifying a different name. If you specify a file name and omit the file type extension, the function appends `.zip` to the name that you specify.

### Package Model Code in a Zip File

You package model code files by using the `PostCodeGenCommand` configuration parameter, `packNGo` function, and the model's build information object. You can set up the packaging operation to use:

- A system generated build information object.

In this case, before generating the model code, use `set_param` to set the configuration parameter `PostCodeGenCommand` to an explicit call to the `packNGo` function. For example:

```
set_param(bdroot, 'PostCodeGenCommand', 'packNGo(buildInfo);');
```

This command instructs the build process to evaluate the call to `packNGo`, using the system generated build information object for the currently selected model, after generating and writing the model code to disk and before generating a makefile.

- A build information object that you construct programmatically.

In this case, you might use other build information functions to selectively include paths and files in the build information object that you then specify with the `packNGo` function. For example:

```
.
.
.
myModelBuildInfo = RTW.BuildInfo;
addSourceFiles(myModelBuildInfo, {'test1.c' 'test2.c' 'driver.c'});
.
.
.
packNGo(myModelBuildInfo);
```

The following examples show how you can change the default behavior of `packNGo`.

To...	Specify...
Change the structure of the file packaging to hierarchical	<code>packNGo(buildInfo, {'packType' 'hierarchical'});</code>
Rename the primary zip file	<code>packNGo(buildInfo, {'fileName' 'zippedsrcs'});</code>
Change the structure of the file packaging to hierarchical and rename the primary zip file	<code>packNGo(buildInfo, {'packType' 'hierarchical' ...</code>

To...	Specify...
	<code>'fileName' 'zippedsrcs'});</code>
Include header files found on the include path in the zip file	<code>packNGO(buildInfo, {'minimalHeaders' false});</code>
Generate warnings for parse errors and missing files	<code>packNGO(buildInfo, {'ignoreParseError' true... 'ignoreFileMissing' true});</code>

---

**Note:** The `packNGO` function can potentially modify the build information passed in the first `packNGO` argument. As part of packaging model code, `packNGO` might find additional files from source and include paths recorded in the model's build information and add them to the build information.

---

### Inspect a Generated Zip File

Inspect the generated zip file to verify that it is ready for relocation. Depending on the zip tool that you use, you might be able to open and inspect the file without unpacking it. If you need to unpack the file and you packaged the model code files as a hierarchical structure, you will need to unpack the primary and secondary zip files. When you unpack the secondary zip files, relative paths of the files are preserved.

### Relocate and Unpack a Zip File

Relocate the generated zip file to the destination development environment and unpack the file.

### Code Packaging Example

This example shows how to package code files generated for the example model `rtwdemo_rtwinintro` using the command-line interface:

- 1 Set your working folder to a writable folder.
- 2 Open the model `rtwdemo_rtwinintro` and save a copy to your working folder.
- 3 Enter the following MATLAB command:

```
set_param('rtwdemo_rtwinintro', 'PostCodeGenCommand', ...
'packNGO(buildInfo, {'packType' 'hierarchical'}));
```

You must double the single-quotes due to the nesting of character arrays 'packType' and 'hierarchical' within the character array that specifies the call to packNGo.

- 4 Generate code for the model.
- 5 Inspect the generated zip file, `rtwdemo_rtwintr0.zip`. The zip file contains the two secondary zip files, `mlrFiles.zip` and `sDirFiles.zip`.
- 6 Inspect the zip files `mlrFiles.zip` and `sDirFiles.zip`.
- 7 Relocate the zip file to a destination environment and unpack it.

## Integrate Generated Code with Custom Code in External Environment

Identify required files and interfaces for calling generated code in an external build process.

Learn how to:

- Collect files required for building outside of Simulink®
- Interface with external variables and functions

For information about the example model and other examples in this series, see “Generate C Code from a Control Algorithm for an Embedded System”.

### Collect and Build Required Data and Files

The code that Embedded Coder® generates requires support files that are provided by MathWorks®. To relocate the generated code to another development environment, such as a dedicated build system, you must also relocate these support files. You can package all of these files in a zip file by using the `packNGo` utility. This utility finds and packages the files that you need to build an executable image. The utility uses tools for customizing the build process after code generation, which include a `buildinfo_data` structure, as well as a `packNGo` function. These files include external files that you identify in the **Code Generation > Custom Code** pane in the Model Configuration Parameters dialog box. The utility saves the `buildinfo` MAT-file in the `model_ert_rtw` folder.

Open the example model, `rtwdemo_PCG_Eval_P5`.

This model is configured to run `packNGo` after code generation.

Generate code from the entire model.

To generate the zip file manually:

- 1 Load the file `buildInfo.mat` (located in the `rtwdemo_PCG_Eval_P5_ert_rtw` subfolder).
- 2 At the command prompt, enter the command `packNGo(buildInfo)`.

The number of files in the zip file depends on the version of Embedded Coder® and on the configuration of the model that you use. The compiler does not require all of the files in the zip file. The compiled executable size (RAM/ROM) depends on the link process. The linker likely includes only the object files that are necessary.

### **Integrating the Generated Code into an Existing System**

This example shows how to integrate the generated code into an existing code base. The example uses the Eclipse™ IDE and the Cygwin™/gcc compiler. The required integration tasks are common to all integration environments.

### **Overview of Integration Environment**

A full embedded controls system consists of multiple hardware and software components. Control algorithms are just one type of component. Other components can be:

- An operating system (OS)
- A scheduling layer
- Physical hardware I/O
- Low-level hardware device drivers

Typically, you do not use the generated code in these components. Instead, the generated code includes interfaces that connect with these components. MathWorks® provides hardware interface block libraries for many common embedded controllers. For examples, see the Embedded Targets block library.

This example provides files to show how you can build a full system. The main file is `example_main.c`, which contains a simple main function that performs only basic actions to exercise the code.

View `example_main.c`.

```
int_T main(void)
{
 /* Initialize model */
 rt_Pos_Command_Arbitration_Init(); /* Set up the data structures for chart*/
 rtwdemo_PCG__Define_Throt_Param(); /* SubSystem: '<Root>/Define_Throt_Param' */
 defineImportData(); /* Defines the memory and values of inputs */

 do /* This is the "Schedule" loop.
 Functions would be called based on a scheduling algorithm */
 {
 /* HARDWARE I/O */

 /* Call control algorithms */
 PI_Cntrl_Reusable((*pos_rqst),fbk_1,&rtwdemo_PCG_Eval_P5_B.PI_ctrl_1,
 &rtwdemo_PCG_Eval_P5_DWork.PI_ctrl_1);
 PI_Cntrl_Reusable((*pos_rqst),fbk_2,&rtwdemo_PCG_Eval_P5_B.PI_ctrl_2,
 &rtwdemo_PCG_Eval_P5_DWork.PI_ctrl_2);
 pos_cmd_one = rtwdemo_PCG_Eval_P5_B.PI_ctrl_1.Saturation1;
 pos_cmd_two = rtwdemo_PCG_Eval_P5_B.PI_ctrl_2.Saturation1;

 rtwdemo_Pos_Command_Arbitration(pos_cmd_one, &Throt_Param, pos_cmd_two,
 &rtwdemo_PCG_Eval_P5_B.sf_Pos_Command_Arbitration);
 }
}
```

The file:

- Defines function interfaces (function prototypes)
- Includes files that declare external data
- Defines extern data
- Initializes data
- Calls simulated hardware
- Calls algorithmic functions

The order of function execution matches the order of subsystem execution in the test harness model and in `rtwdemo_PCG_Eval_P5.h`. If you change the order of execution in `example_main.c`, results that the executable image produces differ from simulation results.

## Match System Interfaces

Integration requires matching both the *Data* and *Function* interfaces of the generated code and the existing system code. In this example, the `example_main.c` file imports and exports the data through `#include` statements and `extern` declarations. The file also calls the functions from the generated code.

## Connect Input Data

The system has three input signals: `pos_rqst`, `fbk_1`, and `fbk_2`. The generated code accesses the two feedback signals through direct reference to imported global variables (storage class `ImportedExtern`). The code accesses the position signal through an imported pointer (storage class `ImportedExternPointer`).

The handwritten file `defineImportedData.c` defines the variables and the pointer. The generated code does not define the variables and the pointer because the handwritten code defines them. Instead, the generated code declares the imported data (`extern`) in the file `rtwdemo_PCG_Eval_P5_Private.h`. In a real system, the data typically come from other software components or from hardware devices.

View `defineImportedData.c`.

```
/* Define imported data */
#include "rtwtypes.h"
#include "defineImportedData.h"

real_T fbk_1;
real_T fbk_2;
real_T dummy_pos_value = 10.0;
real_T *pos_rqst;
void defineImportData(void)
{
 pos_rqst = &dummy_pos_value;
}
```

View `rtwdemo_PCG_Eval_P5_Private.h`.

```

/* Imported (extern) block signals */
extern real_T fbk_1; /* '<Root>/fbk_1' */
extern real_T fbk_2; /* '<Root>/fbk_2' */

/* Imported (extern) pointer block signals */
extern real_T *pos_rqst; /* '<Root>/pos_rqst' */

```

### Connect Output Data

In this example, you do not access the output data of the system. The example “Test Generated Code” shows how you can save the output data to a standard log file. You can access the output data by referring to the file `rtwdemo_PCG_Eval_P5.h`.

View `rtwdemo_PCG_Eval_P5.h`.

### Access Additional Data

The generated code contains several structures that store commonly used data including:

- Block state values (integrator, transfer functions)
- Local parameters
- Time

The table lists the common data structures. Depending on the configuration of the model, some or all of these structures appear in the generated code. The data is declared in the file `rtwdemo_PCG_Eval_P5.h`, but in this example, you do not access this data.

Data Type	Data Name	Data Purpose
Constants	model_cP	Constant parameters
Constants	model_cB	Constant block I/O
Output	model_U	Root and atomic subsystem input
Output	model_Y	Root and atomic subsystem output
Internal data	model_B	Value of block output
Internal data	model_D	State information vectors
Internal data	model_M	Time and other system level data
Internal data	model_Zero	Zero-crossings
Parameters	model_P	Parameters

### Match Function Call Interfaces

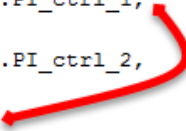

By default, functions that the code generator generates have a `void Func(void)` interface. If you configure the model or atomic subsystem to generate reentrant code,

the code generator creates a more complex function prototype. In this example, the `example_main` function calls the generated functions with the correct input arguments.

```
PI_Cntrl_Reusable((*pos_rqst),fbk_1,&rtwdemo_PCG_Eval_P5_B.PI_ctrl_1,
 &rtwdemo_PCG_Eval_P5_DWork.PI_ctrl_1);
PI_Cntrl_Reusable((*pos_rqst),fbk_2,&rtwdemo_PCG_Eval_P5_B.PI_ctrl_2,
 &rtwdemo_PCG_Eval_P5_DWork.PI_ctrl_2);
pos_cmd_one = rtwdemo_PCG_Eval_P5_B.PI_ctrl_1.Saturation1;
pos_cmd_two = rtwdemo_PCG_Eval_P5_B.PI_ctrl_2.Saturation1;

rtwdemo_Pos_Command_Arbitration(pos_cmd_one, &Throt_Param, pos_cmd_two,
 &rtwdemo_PCG_Eval_P5_B.sf_Pos_Command_Arbitration);
```

Calls to the function `PI_Cntrl_Reusable` use a mixture of separate, unstructured global variables and Simulink® Coder™ data structures. The handwritten code defines these variables. The structure types are defined in `rtwdemo_PCG_Eval_P5.h`.

### Build Project in Eclipse™ Environment

This example uses the Eclipse™ IDE and the Cygwin™ GCC debugger to build the embedded system. The example provides installation files for both programs. Software components and versions numbers are:

- Eclipse™ SDK 3.2
- Eclipse™ CDT 3.3
- Cygwin™/GCC 3.4.4-1
- Cygwin™/GDB 20060706-2

To install and use Eclipse™ and GCC, see “Install and Use Cygwin and Eclipse”.

You can install the files for this example automatically by clicking this [hyperlink](#).

Set up the build folder.

Alternatively, to install the files manually:

- 1 Create a build folder (`Eclipse_Build_P5`).
- 2 Unzip the file `rtwdemo_PCG_Eval_P5.zip` into the build folder.
- 3 Delete the files `rtwdemo_PCG_Eval_P5.c`, `ert_main.c` and `rt_logging.c`, which are replaced by `example_main.c`.

**Note:** Before continuing to the next example in the series, if you have not generated code for the model or if the zip file does not exist, complete the steps in **Collect and Build Required Data and Files**.

You can use the Eclipse™ debugger to step through and evaluate the execution behavior of the generated C code. See the example “Install and Use Cygwin and Eclipse”.

The next example in this series, “Test Generated Code”, shows how to exercise the model with input data.

## **packNGo Function Limitations**

The following limitations apply to the `packNGo` function:

- The function operates on source files, such as `*.c`, `*.cpp`, and `*.h` files, only. The function does not support compile flags, defines, or makefiles.
- Unnecessary files might be included. The function might find additional files from source and include paths recorded in the model's build information and include them, even if they are not used.

## **More About**

- `packNGo`
- “Configure Build Process” on page 40-13
- “Build and Run a Program” on page 40-36
- “How Executable Programs Are Built From Models” on page 40-39
- “Executable Program Generation” on page 40-63

## Executable Program Generation

The following figure shows how the process for automatic program building.

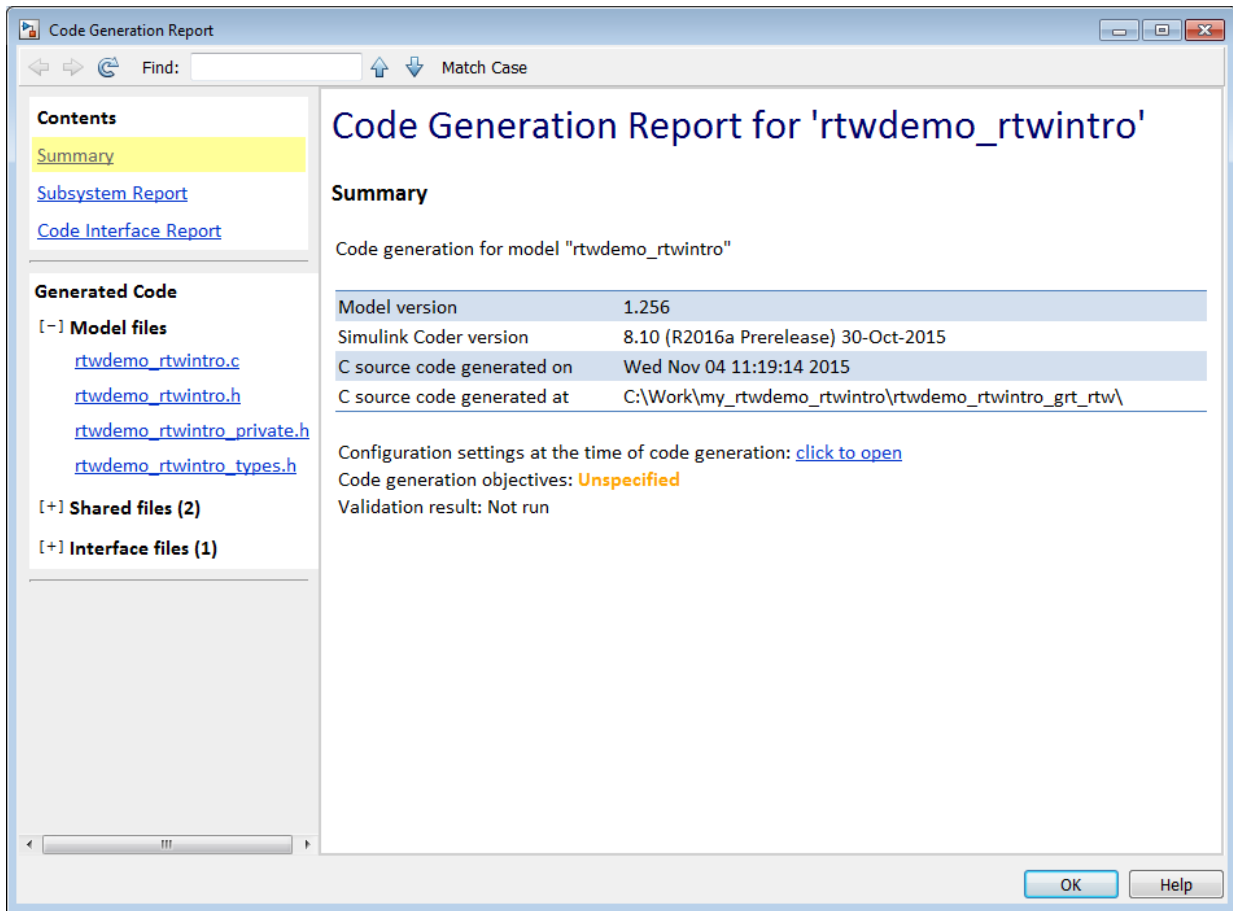

During the final stage of processing, the build process invokes the generated makefile, *model.mk*, which in turn compiles and links the generated code. On PC platforms, a batch file is created to invoke the generated makefile. The batch file sets up the environment for invoking the `make` utility and related compiler tools. To avoid recompiling C files, the `make` utility performs date checking on the dependencies between the object and C files; only out-of-date source files are compiled. Optionally, the makefile can download the resulting executable image to your target hardware.

This stage is optional, as illustrated by the control logic in the preceding figure. You might choose to omit this stage, for example, if you are targeting an embedded microcontroller or a digital signal processing (DSP) board.

To omit this stage of processing, select the **Generate code only** check box on the **Code Generation** pane of the Configuration Parameters dialog box. You can then cross-compile your code and download it to your target hardware.

If you select **Create code generation report** on the **Code Generation > Report** pane, a navigable summary of source files is produced when the model is built. The report files occupy a folder called `html` within the build folder. The following display shows an example of an HTML code generation report for a generic real-time (GRT) target.

## More About

- “Configure Build Process” on page 40-13

- “Build and Run a Program” on page 40-36
- “Executable Program Generation” on page 40-63

## Profile Code Performance

By profiling the performance of generated code, you can help verify that the code meets performance requirements.

### About Profiling Code Performance

Profiling can be especially important early in the development cycle for identifying potential architectural issues that can be more expensive to address later in the process. Profiling can also identify bottlenecks and procedural issues that indicate a need for optimization, for example, with an inner loop or inline code.

---

**Note:** If you have an Embedded Coder license, see “Code Execution Profiling” for an alternative and simpler approach based on software-in-the-loop (SIL) or processor-in-the-loop (PIL) simulations.

---

### How to Profile Code Performance

You can profile code generated with code generation technology by using a Target Language Compiler (TLC) hook function interface.

To use the profile hook function interface:

- 1 For your target, create a TLC file that defines the following hook functions. Write the functions so that they specify profiling code. The code generator adds the hook function code to code generated for atomic systems in the model.

Function	Input Arguments	Output Type	Description
ProfilerHeaders	void	Array of header file names	Return an array of the header file names to be included in the generated code.
ProfilerTypedefs	void	typedefs	Generate code statements for profiler type definitions.
ProfilerGlobal-Data	system	Global data for the specified system	Generate code statements that declare global data.

Function	Input Arguments	Output Type	Description
ProfilerExtern-DataDecls	system	extern declarations for the specified system	Generate code statements that create global extern declarations.
ProfilerSystem-Decls	system, functionType	Declarations for the specified system for the specified functionType	Generate code for required variable declarations within the scope of an atomic subsystem Output, Update, OutputUpdate, or Derivatives function.
ProfilerSystem-Start	system, functionType	Profiler start commands for the specified system and functionType	Generate code that starts the profiler within the scope of an atomic subsystem Output, Update, OutputUpdate, or Derivatives function.
ProfilerSystem-Finish	system, functionType	Profiler end commands for the specified system and functionType	Generate code that stops the profiler within the scope of an atomic subsystem's Output, Update, OutputUpdate, or Derivatives function.
ProfilerSystem-Terminate	system	Profiler termination code for the specified system	Generate code that terminates profiling (and possibly reports results) for an atomic subsystem.

For an example TLC file, see `matlabroot/toolbox/rtw/rtwdemos/rtwdemo_profile_hook.tlc`.

- 2 In your `target.tlc` file, define the following global variables.

Define...	To Be...
ProfileGenCode	TLC_TRUE or 1 to turn on profiling (TLC_FALSE or 0 to turn off profiling)
ProfilerTLC	The name of the TLC file that you created in step 1

A quick way to define global variables is to define the parameters with the `-a` option. You can do this by using the `set_param` command to set the model configuration parameter `TLCOptions`. For example,

```
>> set_param(gcs, 'TLCOptions', '-aProfileGenCode=1 -aProfilerTLC="rtwdemo_profile_hook.tlc"')
```

- 3 Consider setting configuration parameters for generating a code generation report. You can then examine the profiling code in the context of the code generated for the model.
- 4 Build the model. The build process embeds the profiling code in the hook function locations in the generated code for the model.
- 5 Run the generated executable file. In the MATLAB Command Window, enter `!model -name`. You see the profiling report you programmed in the profiling TLC file that you created. For example, a profile report might list the number of calls made to each system in a model and the number of CPU cycles spent in each system.

For an example, see “Run Profiling Hooks for Generated Code” on page 40-69. For details on programming a `.tlc` file and defining TLC configuration variables, see “Target Language Compiler”.

## Embed Profiling Commands In Generated Code

This model shows the hooks provided by Simulink® Coder™ to profile generated code. In this model, the subsystems that perform averaging are profiled. Use the blue buttons in the model to generate and inspect code. The code contains profiling commands. To learn more about how profiler code was added for this example, look at the file `rtwdemo_profile_hook.tlc`.

```
open_system('rtwdemo_profile')
```

This model shows the hooks provided by Simulink Coder to profile generated code. In this model, the subsystems that perform averaging are profiled. Use the blue buttons below to generate code for this model and inspect the generated code. The code contains profiling commands. To learn more about how profiler code was added for this example, look at the file `rtwdemo_profile_hook.tlc`.

`matlabroot\toolbox\rtw\rtwdemos\rtwdemo_profile_hook.tlc`

## Run Profiling Hooks for Generated Code

The example model `rtwdemo_profile` shows how to use special hooks provided by the code generator to add profiling code snippets to the generated code for your models.

The basis for this example is the Target Language Compiler (TLC) hook function interface described in “How to Profile Code Performance” on page 40-66. The hooks

allow you to add profiling code snippets within nonvirtual (atomic) systems in the model, which allow you to profile those atomic systems. For this example, the file `matlabroot/toolbox/rtw/rtwdemos/rtwdemo_profile_hook.tlc` implements the required profiling functions. You can inspect this file for more information on each of the profiling functions.

Run the example as follows:

- 1 Open the model `rtwdemo_profile`; for example, you can enter the command `rtwdemo_profile` in the MATLAB Command Window.
- 2 Change your working folder to one for which you have write permission.
- 3 Double-click one of the Generate Code blocks. This configures the selected code generation target options with the profiling hooks and builds the model. When the build process is completed, a window opens with a display of the generated code. Browse through the code to see the profile-specific C code that has been generated.
- 4 Enter `!rtwdemo_profile` in the MATLAB Command Window to run the generated executable file. This command displays a textual report of the number of calls made to each system in the example model and the number of CPU cycles that were spent in each system.

## Profiling Limitation

The TLC hook function interface for profiling code performance does not support the S-function target (`rtwsfcn.tlc`).

# Host/Target Communication in Simulink Coder

---

## Set Up and Use Host/Target Communication Channel

External mode allows two separate systems, a *host* and a *target*, to communicate. The host is the computer where the MATLAB and Simulink environments execute. The target is the computer where the executable created by the code generation and build process runs.

The host (the Simulink environment) transmits messages requesting the target to accept parameter changes or to upload signal data. The target responds by executing the request. External mode communication is based on a *client/server* architecture, in which the Simulink environment is the client and the target is the server.

### In this section...

“What You Can Do With a Host/Target Communication Channel” on page 41-2

“Set Up an External Mode Communication Channel” on page 41-3

“Configure and Use External Mode” on page 41-14

“External Mode Compatible Blocks and Subsystems” on page 41-34

“External Mode Communication” on page 41-37

“External Mode Limitations” on page 41-55

## What You Can Do With a Host/Target Communication Channel

You can use a host/target communication channel to:

- Modify, or *tune*, block parameters in real time. In external mode, whenever you change parameters in the block diagram, the Simulink engine downloads them to the executing target program. You can tune your program parameters without recompiling.
- View and log block outputs in many types of blocks and subsystems. You can monitor and store signal data from the executing target program, without writing special interface code. You can define the conditions under which data is uploaded from target to host. For example, data uploading can be triggered by a selected signal crossing zero in a positive direction. Alternatively, you can manually trigger data uploading.

External mode establishes a communication channel between the Simulink engine and generated code. The channel's low-level *transport layer* handles the physical transmission of messages. The Simulink engine and the generated model code are independent of this layer. The transport layer and the code directly interfacing to it are isolated in separate modules that format, transmit, and receive messages and data packets.

This design allows for different targets to use different transport layers. For example:

- ERT, GRT, and RSim targets support external mode host/target communication by using TCP/IP and serial (RS-232) communication.
- The Simulink Real-Time product uses a customized transport layer.
- The Simulink Desktop Real-Time product uses shared memory communication.
- Target hardware platforms supported by Simulink use serial or TCP/IP communication.

For an example of using external mode, see “Set Up an External Mode Communication Channel” on page 41-3.

## Set Up an External Mode Communication Channel

- “External Mode Communication Channel Setup” on page 41-3
- “Set Up the Model” on page 41-4
- “Build the Target Executable” on page 41-6
- “Run the External Mode Target Program” on page 41-8
- “Tune Parameters” on page 41-12

### External Mode Communication Channel Setup

External mode is a very useful environment for rapid prototyping. This example consists of four parts, each of which depends on completion of the preceding ones, in order. The four parts correspond to the steps that you follow in simulating, building, running, and tuning an actual real-time application.

- 1 Set up the model.
- 2 Build the target executable.
- 3 Run the external mode target program.
- 4 Tune parameters.

The example uses the GRT target. It does not require hardware other than the computer on which you run the Simulink and Simulink Coder software. The generated executable in this example runs on the host computer in a separate process from MATLAB and Simulink.

### Set Up the Model

In this part of the example, you create a simple model, `ex_extModeExample`. You also create a folder called `ext_mode_example` to store the model and the generated executable.

To create the folder and the model:

- 1 From the MATLAB command line, type:

```
mkdir ext_mode_example
```

- 2 Make `ext_mode_example` your working folder:

```
cd ext_mode_example
```

- 3 Create a model in Simulink with a Sine Wave block for the input signal, two Gain blocks in parallel, and two Scope blocks. Be sure to label the Gain and Scope blocks as shown below.

- 4 Define and assign two MATLAB workspace variables, A and B, as follows:

```
A = 2;
B = 3;
```

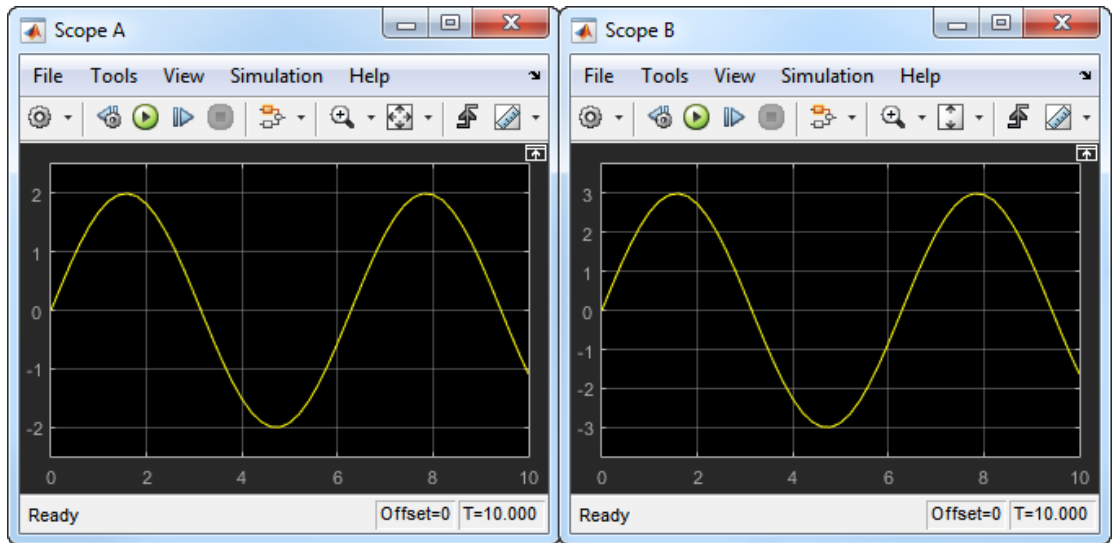

- 5 Open Gain block A and set its **Gain** parameter to the variable A.

- 6 Open Gain block B and set its **Gain** parameter to the variable B.

When the target program is built and connected to Simulink in external mode, you can download new gain values to the executing target program. To do this, you can assign new values to workspace variables A and B, or edit the values in the block parameters dialog box. For more information, see “Tune Parameters” on page 41-12.

- 7 Verify operation of the model. Open the Scope blocks and run the model. When A = 2 and B = 3, the output appears as shown below.

- 8 Save the model as `ex_extModeExample`.

### Build the Target Executable

Set up the model and code generation parameters required for an external mode compatible target program. Then, generate code and build the target executable.

- 1 Open the Configuration Parameters dialog box by selecting **Simulation > Model Configuration Parameters**.
- 2 Select the **Solver** pane.
- 3 In the **Solver options** subpane:
  - a In the **Type** field, select **Fixed-step**.
  - b In the **Solver** field, select **discrete (no continuous states)**.
  - c Open **Additional options**. In the **Fixed-step size** field, specify **0.1**. (Otherwise, when you generate code, the Simulink Coder build process posts a warning and supplies a value.)

Leave **Start time** set to the default value of **0.0**.

Click **Apply**.

- 4 Select the **Data Import/Export** pane, and clear the **Time** and **Output** check boxes. In this example, data is not logged to the workspace or to a MAT-file. Click **Apply**.
- 5 Select the **Optimization > Signals and Parameters** pane. Make sure that **Default parameter behavior** is set to **Tunable**. Inlined parameters are not part of this example. If you have made changes, click **Apply**.
- 6 Select the **Code Generation** pane. By default, the generic real-time (GRT) target is selected.
- 7 Select the **Code Generation > Interface** pane. In the **Data exchange interface** section, select **External mode**. This selection enables generation of external mode support code and displays additional external mode configuration parameters.
- 8 In the **External mode configuration** section, make sure that the default value **tcpip** is selected for the **Transport layer** parameter.

External mode

External mode configuration

Transport layer: tcpip MEX-file name: `ext_comm`

MEX-file arguments:

Static memory allocation

External mode supports communication via TCP/IP, serial, and custom transport protocols. The **MEX-file name** field specifies the name of a MEX-file that implements host and target communication on the host side. The default for TCP/IP is `ext_comm`, a MEX-file provided with the Simulink Coder software. You can override this default by supplying other files. If you need to support other transport layers, see “Create a Transport Layer for External Communication”.

The **MEX-file arguments** field lets you specify arguments, such as a TCP/IP server port number, to be passed to the external interface program. These arguments are specific to the external interface that you are using. For information on setting these arguments, see “MEX-File Optional Arguments for TCP/IP Transport” and “MEX-File Optional Arguments for Serial Transport” in the Simulink Coder documentation.

This example uses the default arguments. Leave the **MEX-file arguments** field blank.

- 9 Click **Apply** to save the external mode settings.

- 10** Save the model.
- 11** Select the **Code Generation** pane. Make sure that **Generate code only** is cleared, and then, in the model window, press **Ctrl+B** to generate code and create the target program. The software creates the `ex_extModeExample` target executable in your working folder.

### Run the External Mode Target Program

You now run the `ex_extModeExample` target executable and use Simulink as an interactive front end to the running target program. The executable file is in your working folder. Run the target program and establish communication between Simulink and the target.

---

**Note:** An external mode program like `ex_extModeExample` is a host-based executable. Its execution is not tied to a real-time operating system (RTOS) or a periodic timer interrupt, and it does not run in real time. The program just runs as fast as possible, and the time units it counts off are simulated time units that do not correspond to time in the world outside the program.

---

The External Signal & Triggering dialog box (accessed from the External Mode Control Panel) displays a list of blocks in your model that support external mode signal monitoring and logging. In the dialog box, you can configure the signals that are viewed, how they are acquired, and how they are displayed.

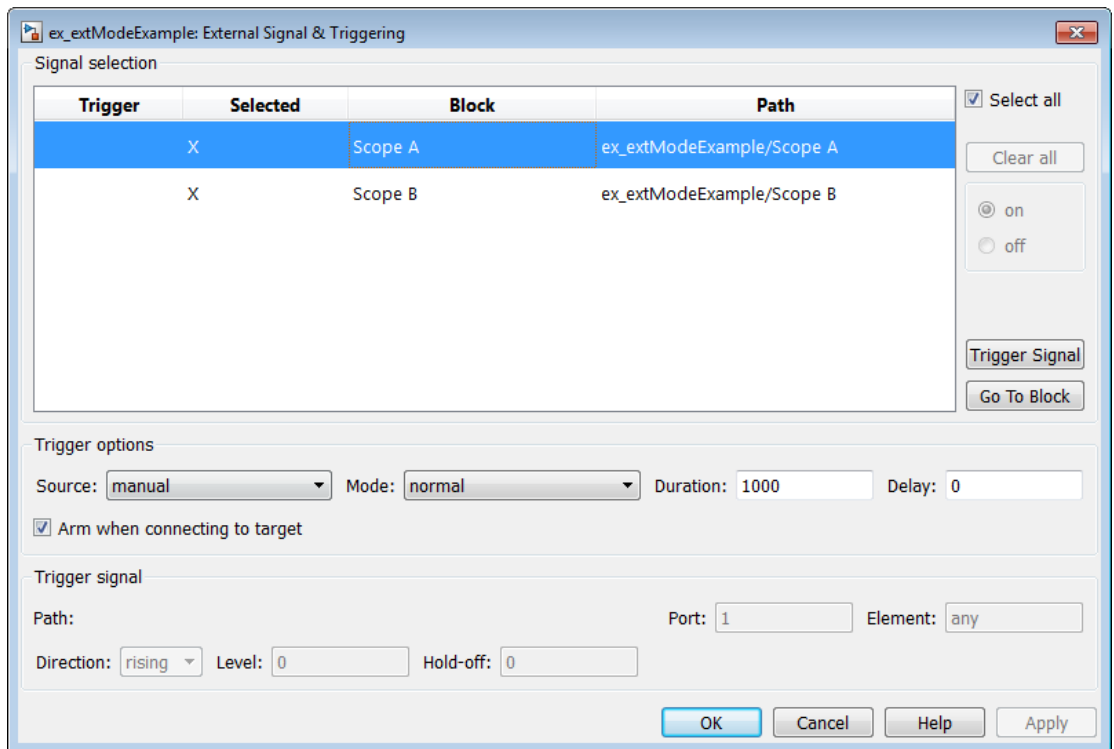

In this example, you observe and use the default settings of the External Signal & Triggering dialog box.

- 1** From the **Code** menu of the model diagram, select **External Mode Control Panel**. This control panel is where you configure signal monitoring and data archiving. You can also connect to the target program, and start and stop execution of the model code.

- You use the top row of buttons after the target program has started.
- The **Signal & Triggering** button opens the External Signal & Triggering dialog box. Use this dialog box to select the signals that are collected from the target system and viewed in external mode. You can also select a signal that triggers uploading of data when certain signal conditions are met, and define the triggering conditions.
- The **Data Archiving** button opens the Enable Data Archiving dialog box. Use data archiving to save data sets generated by the target program for future analysis. This example does not use data archiving. See “Configure Host Archiving of Target Program Signal Data” on page 41-31 for more information.

- Click the **Signal & Triggering** button to open the External Signal & Triggering dialog box. The default configuration selects all signals for monitoring and sets signal monitoring to begin as soon as the host and target programs have connected.

- Check that the External Signal & Triggering dialog box is set to the following defaults:

- Select all** check box is selected. Signals in the **Signal selection** list are marked with an X in the **Selected** column.
- Under **Trigger options**:
  - Source:** manual
  - Mode:** normal
  - Duration:** 1000
  - Delay:** 0

- **Arm when connecting to target:** selected

Click **OK** to close the External Signal & Triggering dialog box, and then close the External Mode Control Panel.

For descriptions of the External Signal & Triggering dialog box parameters, see “Configure Host Monitoring of Target Program Signal Data” on page 41-23.

---

**Note:** At the conclusion of this example, when Simulink is connected to a running target executable, you can modify signal and triggering options without disconnecting from the target. For more information, see “Modify Signal and Triggering Options While Connected” on page 41-30.

---

- 4 To run the target program, open an operating system command window (on UNIX systems, a terminal emulator window). At the command prompt, use `cd` to navigate to the `ext_mode_example` folder to which you generated the target program executable.

Enter the following command:

```
ex_extModeExample -tf inf -w
```

---

**Note** Alternatively, you can run the target program from the MATLAB Command Window, using the following syntax.

```
!ex_extModeExample -tf inf -w &
```

---

The target program begins execution, and enters a wait state.

The `-tf` switch overrides the stop time set for the model in Simulink. The `inf` value directs the model to run indefinitely. The model code runs until the target program receives a stop message from Simulink.

The `-w` switch instructs the target program to enter a wait state until it receives a **Start Real-Time Code** message from the host. If you want to view data from time step 0 of the target program execution, or if you want to modify parameters before the target program begins execution of model code, this switch is required.

- 5 Open the Scope blocks in the model. Signals are not visible on the scopes. When you connect Simulink to the target program and begin model execution, the signals generated by the target program become visible on the scope displays.
- 6 Before communication between the model and the target program can begin, the model must be in external mode. To enable external mode, from the **Simulation > Mode** menu, select **External**.
- 7 Reopen the External Mode Control Panel (found in the **Code** menu) and click **Connect**. This action initiates a handshake between Simulink and the target program. When Simulink and the target are connected, the **Start Real-Time Code** button becomes enabled, and the label of the **Connect** button changes to **Disconnect**.
- 8 Click **Start Real-Time Code**. The outputs of Gain blocks A and B are displayed on the two scopes in your model.

You have established communication between Simulink and the running target program. You can now tune block parameters in Simulink and observe the effects the parameter changes have on the target program.

### Tune Parameters

You can change the gain factor of either Gain block by assigning a new value to the variable **A** or **B** in the MATLAB workspace. When you change block parameter values in the workspace during a simulation, you must explicitly update the block diagram with these changes. When you update the block diagram, the new values are downloaded to the target program.

Under certain conditions, you can also tune the expressions that you use to specify block parameter values. To change an expression during simulation, open the block dialog box.

- 1 At the command prompt, assign new values to both variables, for example:  

```
A = 0.5;
B = 3.5;
```
- 2 Open the `ex_extModeExample` model window. From the **Simulation** menu, select **Update Diagram**. As soon as Simulink has updated the block parameters, the new gain values are downloaded to the target program, and the scopes are changed because of the gain change.
- 3 In the Sine Wave block dialog box, set **Amplitude** to **0.5**. Click **Apply** or **OK**.

When you click **Apply** or **OK**, the simulation downloads the new block parameter value to the target program. The Scope block displays the change to reflect the new amplitude value.

- 4 To simultaneously disconnect host/target communication and end execution of the target program, from the **Simulation** menu, select **Stop**. Alternatively, in the External Mode Control Panel, click **Stop Real-Time Code**.

You cannot change the sample time of the Sine Wave block during simulation. Block sample times are part of the structural definition of the model and are part of the generated code. Therefore, if you want to change a block sample time, you must stop the external mode simulation, reset the sample time of the block, and rebuild the executable.

Block parameter tunability during external mode simulation depends on the way that the generated code represents block parameters.

For example, in the Gain A block dialog box, you cannot change the expression A in the **Gain** parameter during simulation. Instead, you must change the value of the variable A in the base workspace. You cannot change the expression because the generated code does not allocate storage in memory for the **Gain** parameter. Instead, the code creates a field A in a structure:

```
/* Parameters (auto storage) */
struct P_ex_extModeExample_T_ {
 real_T A; /* Variable: A
 */
 real_T B; /* Variable: B
 */
 real_T SineWave_Amp; /* Expression: 1
 */
 real_T SineWave_Bias; /* Expression: 0
 */
 real_T SineWave_Freq; /* Expression: 1
 */
 real_T SineWave_Phase; /* Expression: 0
 */
};
```

The generated code algorithm uses that field in the code that represents the block Gain A. In this case, the global structure variable `ex_extModeExample_P` uses the type `P_ex_extModeExample_T_`:

```
ex_extModeExample_B.GainA = ex_extModeExample_P.A * rtb_SineWave;
```

When you change the value of **A** in the base workspace, the simulation downloads the new value to the field **A** in the target program.

However, you can change the expressions in the Sine Wave block parameters during simulation. You can change these expressions because the generated code creates a field in the global structure `ex_extModeExample_P` to represent each parameter in the block. When you change an expression in the block dialog box, the simulation first evaluates the new expression. The simulation then downloads the resulting numeric value to the corresponding structure field in the target program.

For more information about controlling parameter representation in the generated code, see “Block Parameter Representation in the Generated Code”.

## Configure and Use External Mode

- “Configure External Mode Options for Code Generation” on page 41-14
- “Target Interfacing” on page 41-16
- “Control Host and Target Execution” on page 41-18
- “Control External Mode Operations” on page 41-19
- “Configure Host Monitoring of Target Program Signal Data” on page 41-23
- “Configure Host Archiving of Target Program Signal Data” on page 41-31

### Configure External Mode Options for Code Generation

The list of targets and products that support external mode includes the ERT, GRT, and RSim targets, the Simulink Desktop Real-Time product, and Simulink target hardware platforms. Code generation targets that support external mode provide a set of external mode options in the Configuration Parameters dialog box, on the **Code Generation > Interface** pane or their respective target pane.

For targets that support the ability to build target code, connect to the target, and run an application in external mode by clicking **Run** in the model window toolbar, note the following:

- You select external mode from the model window by clicking **Simulation > Mode > External**.
- External mode parameters continue to appear for the target in the Configuration Parameters dialog box.
- By default, the code generator produces code that is *not* set up for external mode if you build the code by using one of following methods:

- Press **Ctrl+B**
- At the MATLAB command line, enter `rtwbuild`

The following figure shows external mode parameters from the GRT and ERT target views of the **Code Generation > Interface** pane.

External mode

External mode configuration

Transport layer:  MEX-file name: `ext_comm`

MEX-file arguments:

Static memory allocation

---

**Note** The Simulink Real-Time product also uses external mode communication. External mode in the Simulink Real-Time product is always on, and does not have interface options.

---

The **Data exchange interface** section in the **Code Generation > Interface** pane includes the following external mode parameters:

- **External mode** option: Includes the external mode data exchange interface in the generated C code.

When you select **External mode**, the following parameters appear:

- **Transport layer** menu: Identifies the messaging protocol for host/target communication; typically, the choices are `tcpip` and `serial`.

The default is `tcpip`. When you select a protocol, the MEX-file name that implements the protocol is shown to the right of the menu.

- **MEX-file arguments** text field: Optionally enter a list of arguments to be passed to the transport layer MEX-file for communicating with executing targets. The arguments vary according to the protocol that you use.

For more information on the transport options, see “Target Interfacing” on page 41-16 and “Choose Communication Protocol for Client and Server” on page 41-40.

- **Static memory allocation** check box: Controls how memory is allocated for external mode communication buffers in the target. Selecting this option enables the **Static memory buffer size** parameter.
- **Static memory buffer size** text field: Number of bytes to preallocate for external mode communication buffers in the target.

---

**Note** Selecting **External mode** does not cause the Simulink model to operate in external mode (see “Control Host and Target Execution” on page 41-18). The **External mode** option instruments the code generated for the target to support external mode.

---

The **Static memory allocation** check box (for GRT and ERT targets) directs the Simulink Coder software to generate code for external mode that uses only static memory allocation (“malloc-free” code). Selecting **Static memory allocation** enables the **Static memory buffer size** edit field, which you use to specify the size of the static memory buffer used by external mode. The default value is 1,000,000 bytes. If you enter too small a value for your application, external mode issues an out-of-memory error when it tries to allocate more memory than you allowed. In such cases, increase the value in the **Static memory buffer size** field and regenerate the code.

To determine how much memory to allocate, enable verbose mode on the target (by including `OPTS=" -DVERBOSE "` on the `make` command line). As it executes, external mode displays the amount of memory it tries to allocate and the amount of memory available to it each time it attempts an allocation. If an allocation fails, you can use this console log to adjust the size in the **Static memory buffer size** field.

---

**Note** When you create an ERT target, external mode can generate pure integer code. Select pure integer code by clearing the **Support floating-point numbers** option on the **Code Generation > Interface** pane of the Configuration Parameters dialog box. Clearing this option makes the code, including external mode support code, free of doubles and floats. For more information, see “Model Configuration Parameters: Code Generation Interface”.

---

## Target Interfacing

The Simulink Coder product lets you implement client and server transport for external mode using either TCP/IP or serial protocols. If your target system supports TCP/IP, you can use the socket-based external mode implementation provided by the Simulink Coder

product with the generated code. Otherwise, use or customize the serial transport layer option.

A low-level *transport layer* handles physical transmission of messages. Both the Simulink engine and the model code are independent of this layer. Both the transport layer and code directly interfacing to the transport layer are isolated in separate modules that format, transmit, and receive messages and data packets.

You specify the transport mechanism using the **Transport layer** menu in the **External mode configuration** section of the **Code Generation > Interface** pane of the Configuration Parameters dialog box.

External mode

External mode configuration

Transport layer:  MEX-file name: ext\_comm

MEX-file arguments:

Static memory allocation

To the right of the **Transport layer** menu, **MEX-file name** displays the name of an external interface MEX-file. This MEX-file implements host/target communication for the selected external mode transport layer. The default is `ext_comm`, the TCP/IP-based external interface file for use with the GRT, ERT, and RSim targets. If you select the serial transport option, the MEX-file name `ext_serial_win32_com` is displayed in this location.

---

**Note:** Custom or third-party targets can use a custom transport layer and a different external interface MEX-file. For more information, see “Create a Transport Layer for External Communication”. For more information on specifying a TCP/IP or serial transport layer for a custom target, see “Using the TCP/IP Implementation” on page 41-41 or “Using the Serial Implementation” on page 41-44.

---

In the **MEX-file arguments** edit field, you can optionally specify arguments that are passed to the external mode interface MEX-file for communicating with executing targets. The meaning of the MEX-file arguments depends on the MEX-file implementation.

For TCP/IP interfaces, `ext_comm` allows three optional arguments:

- Network name of your target (for example, 'myPuter' or '148.27.151.12')
- Verbosity level (0 for no information or 1 for detailed information)
- TCP/IP server port number (an integer value between 256 and 65535, with a default of 17725)

For serial transport, `ext_serial_win32_comm` allows three optional arguments:

- Verbosity level (0 for no information or 1 for detailed information)
- Serial port ID (for example, 1 for COM1, and so on)
- Baud rate (selected from the set 1200, 2400, 4800, 9600, 14400, 19200, 38400, 57600, and 115200, with a default baud rate of 57600)

For more information on MEX-file transport architecture and arguments, see “Choose Communication Protocol for Client and Server” on page 41-40.

### Control Host and Target Execution

Simulink software provides multiple ways to control external mode host and target execution. The following table lists common steps in the external mode workflow and the ways in which they can be initiated.

External Mode Action	Toolbar Control	Menu Control	External Mode Control Panel Button
Set the simulation mode of your model to external mode	From the simulation mode drop-down list, select <b>External</b>	<b>Simulation &gt; Mode &gt; External</b>	<b>Connect</b> (if the model simulation mode is not already set, sets the simulation mode to external mode)
Connect your model to a waiting or running target program	<b>Connect to Target</b> button 	<b>Simulation &gt; Connect to Target</b>	<b>Connect</b>
Start running real-time code in the target environment	<b>Run</b> button	<b>Simulation &gt; Run</b> (keyboard shortcut <b>Ctrl +T</b> )	<b>Start Real-Time Code</b>
Disconnect your model from the target	<b>Disconnect from Target</b> button 	<b>Simulation &gt;</b>	<b>Disconnect</b>

External Mode Action	Toolbar Control	Menu Control	External Mode Control Panel Button
environment (does not halt running real-time code)		<b>Disconnect from Target</b>	
Stop target program execution and disconnect your model from the target environment	<b>Stop</b> button	<b>Simulation &gt; Stop</b> (keyboard shortcut <b>Ctrl+Shift+T</b> )	<b>Stop Real-Time Code</b>

---

**Note** Setting the simulation mode of your model to external mode affects execution only, and does *not* cause the Simulink Coder software to generate code instrumented for external mode. See “Configure External Mode Options for Code Generation” on page 41-14.

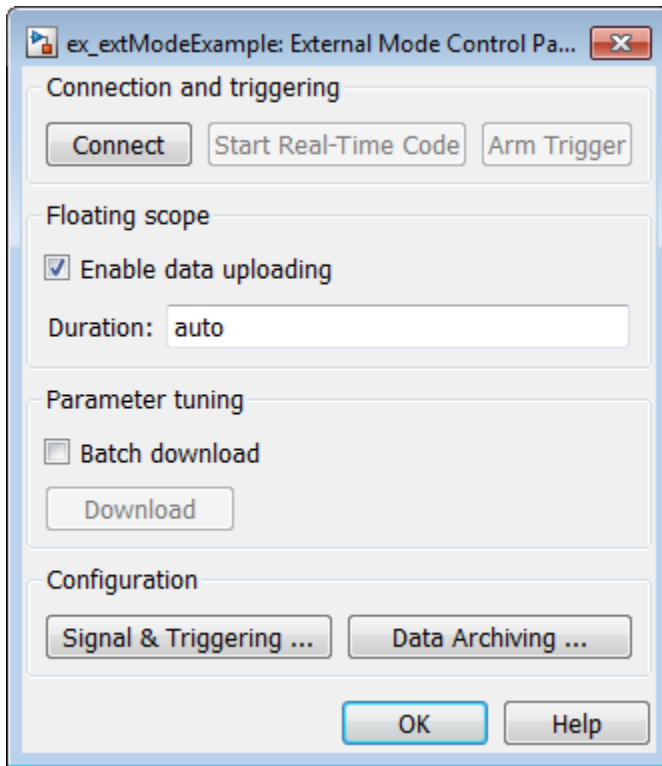

---

### Control External Mode Operations

The External Mode Control Panel provides centralized control of external mode operations, including:

- “Connect, Start, and Stop” on page 41-20
- “Upload Target Program Signal Data to Host” on page 41-21
- “Download Parameters to Target Program” on page 41-22
- “Configure Host Monitoring of Target Program Signal Data” on page 41-23
- “Configure Host Archiving of Target Program Signal Data” on page 41-31

To open the External Mode Control Panel dialog box, in the model window, select **Code > External Mode Control Panel**.

### Connect, Start, and Stop

The External Mode Control Panel performs the same connect/disconnect and start/stop functions found in the **Simulation** menu and the Simulink toolbar (see “Control Host and Target Execution” on page 41-18).

Clicking the **Connect** button connects your model to a waiting or running target program. While you are connected, the button changes to a **Disconnect** button.

**Disconnect** disconnects your model from the target environment, but does not halt real-time code running in the target environment.

**Connect** sets the model simulation mode to external mode.

Clicking the **Start Real-Time Code** button commands the target to start running real-time code. While real-time code is running in the target environment, the button changes

to a **Stop Real-Time Code** button. **Stop Real-Time Code** stops target program execution and disconnects your model from the target environment.

### Upload Target Program Signal Data to Host

The External Mode Control Panel allows you to trigger and cancel data uploads to the host. The destination for the uploaded data can be a scope block, Display block, To Workspace block, or another block or subsystem listed in “External Mode Compatible Blocks and Subsystems” on page 41-34.

The **Arm Trigger** and **Cancel Trigger** buttons provide manual control of data uploading to compatible blocks or subsystems, except floating scopes. (For floating scopes, use the **Floating scope** section of the External Mode Control Panel.)

- To trigger data uploading to compatible blocks or subsystems, click the **Arm Trigger** button. The button changes to **Cancel Trigger**.
- To cancel data uploading, click the **Cancel Trigger** button. The button reverts to **Arm Trigger**.

You can trigger data uploads manually or automatically. To configure signals and triggers for data uploads, see “Configure Host Monitoring of Target Program Signal Data” on page 41-23.

A subset of external mode compatible blocks, including Scope, Time Scope, and To Workspace, allow you to log uploaded data to disk. To configure data archiving, see “Configure Host Archiving of Target Program Signal Data” on page 41-31.

The **Floating scope** section of the External Mode Control Panel controls when and for how long data is uploaded to Floating Scope blocks. When used in external mode, floating scopes:

- Do not appear in the External Signal & Triggering dialog box.
- Do not log data to external mode archiving.
- Support manual triggering only.

The **Floating scope** section contains the following parameters:

- **Enable data uploading** option, which functions as an **Arm Trigger** button for floating scopes. When the target is disconnected, the option controls whether to arm the trigger when connecting the floating scopes. When the target is connected, the option acts as a toggle button to arm or cancel the trigger.

- To trigger data uploading to floating scopes, select **Enable data uploading**.
- To cancel data uploading to floating scopes, clear **Enable data uploading**.
- **Duration** edit field, which specifies the number of base-rate steps for which external mode logs floating scopes data after a trigger event. By default, it is set to **auto**, which causes the duration value set in the External Signal & Triggering dialog box to be used. The default duration value is 1000 base rate steps.

### **Download Parameters to Target Program**

The **Batch download** option on the External Mode Control Panel enables or disables batch parameter changes.

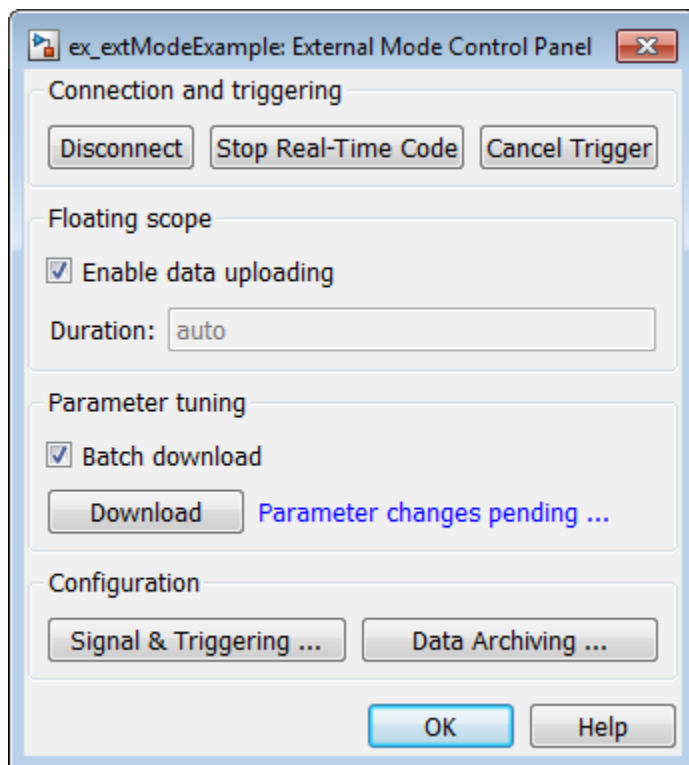

By default, batch download is disabled. If batch download is disabled, when you click **OK** or **Apply**, changes made directly to block parameters by editing block parameter dialog boxes are sent to the target. When you perform an **Update Diagram**, changes to MATLAB workspace variables are sent.

If you select **Batch download**, the **Download** button is enabled. Until you click **Download**, changes made to block parameters are stored locally. When you click **Download**, the changes are sent in a single transmission.

When parameter changes are awaiting batch download, the External Mode Control Panel displays the message **Parameter changes pending...** to the right of the **Download** button. This message remains visible until the Simulink engine receives notification that the new parameters have been installed in the parameter vector of the target system.

The next figure shows the External Mode Control Panel with the **Batch download** option activated and parameter changes pending.

### Configure Host Monitoring of Target Program Signal Data

- “Role of Trigger in Signal Data Uploading” on page 41-24
- “Configure Signal Data Uploading” on page 41-24
- “Default Trigger Options” on page 41-25
- “Select Signals to Upload” on page 41-26
- “Configure Trigger Options” on page 41-26
- “Select Trigger Signal” on page 41-28
- “Set Trigger Conditions” on page 41-29
- “Modify Signal and Triggering Options While Connected” on page 41-30

### **Role of Trigger in Signal Data Uploading**

In external mode, uploading target program signal data to the host depends on a *trigger*. The trigger is a set of conditions that must be met for data uploading to begin. The trigger can be armed or not armed.

- When the trigger is armed, the software checks for the trigger conditions that allow data uploading to begin.
- If the trigger is not armed, the software does not check for the trigger conditions and data uploading cannot begin.
- The trigger can be armed automatically, when the host connects to the target, or manually, by clicking the **Arm Trigger** button on the External Mode Control Panel.

When the trigger is armed and the trigger conditions are met, the trigger fires and data uploading begins.

When data has been collected for a defined duration, the trigger event completes and data uploading stops. The trigger can then rearm, or remain unarmed until you click the **Arm Trigger** button.

To select the target program signals to upload and configure how uploads are triggered, see “Configure Signal Data Uploading” on page 41-24.

### **Configure Signal Data Uploading**

Clicking the **Signal & Triggering** button of the External Mode Control Panel opens the External Signal & Triggering dialog box.

The External Signal & Triggering dialog box displays a list of blocks and subsystems in your model that support external mode signal uploading. For information on which types of blocks are external mode compatible, see “External Mode Compatible Blocks and Subsystems” on page 41-34.

In the External Signal & Triggering dialog box, you can select the signals that are collected from the target system and viewed in external mode. You can also select a trigger signal, which triggers uploading of data based on meeting certain signal conditions, and define the triggering conditions.

### Default Trigger Options

The preceding figure shows the default settings of the External Signal & Triggering dialog box. The default operation of the External Signal & Triggering dialog box simplifies monitoring the target program. If you use the default settings, you do not need to preconfigure signals and triggers. You start the target program and connect the

Simulink engine to it. External mode compatible blocks are selected and the trigger is armed. Signal uploading begins immediately upon connection to the target program.

The default configuration of trigger options is:

- **Select all:** on
- **Source:** manual
- **Mode:** normal
- **Duration:** 1000
- **Delay:** 0
- **Arm when connecting to target:** on

### **Select Signals to Upload**

External mode compatible blocks in your model appear in the **Signal selection** list of the External Signal & Triggering dialog box. You use this list to select signals that you want to view. In the **Selected** column, an X appears for each selected block.

The **Select all** check box selects all signals. By default, **Select all** is selected.

If **Select all** is cleared, you can select or clear individual signals using the **on** and **off** options. To select a signal, click its list entry and select the **on** option. To clear a signal, click its list entry and select the **off** option.

The **Clear all** button clears all signals.

### **Configure Trigger Options**

As described in “Role of Trigger in Signal Data Uploading” on page 41-24, signal data uploading depends on a trigger. The trigger defines conditions that must be met for uploading to begin. Also, the trigger must be armed for data uploading to begin. When the trigger is armed and trigger conditions are met, the trigger fires and uploading begins. When data has been collected for a defined duration, the trigger event completes and data uploading stops.

To control when and how signal data is collected (uploaded) from the target system, configure the following **Trigger options** in the External Signal & Triggering dialog box.

- **Source:** manual or signal. Controls whether a button or a signal triggers data uploading.

Selecting **manual** directs external mode to use the **Arm Trigger** button on the External Mode Control Panel as the trigger to start uploading data. When you click **Arm Trigger**, data uploading begins.

Selecting **signal** directs external mode to use a trigger signal as the trigger to start uploading data. When the trigger signal satisfies trigger conditions (that is, the signal crosses the trigger level in the specified direction), a *trigger event* occurs. (Specify trigger conditions in the **Trigger signal** section.) If the trigger is *armed*, external mode monitors for the occurrence of a trigger event. When a trigger event occurs, data uploading begins.

- **Mode:** **normal** or **one-shot**. Controls whether the trigger rearms after a trigger event completes.

In **normal** mode, external mode automatically rearms the trigger after each trigger event. The next data upload begins when the trigger fires.

In **one-shot** mode, external mode collects only one buffer of data each time you arm the trigger.

For more information on the **Mode** setting, see “Configure Host Archiving of Target Program Signal Data” on page 41-31.

- **Duration:** Specifies the number of base rate steps for which external mode uploads data after a trigger event (default is 1000). For example, if **Duration** is set to 1000, and the base (fastest) rate of the model is one second:
  - For a signal sampled at the base rate, one second (1.0 Hz), external mode collects 1000 contiguous samples during a trigger event.
  - For a signal sampled at two seconds (0.5 Hz), external mode collects 500 samples during a trigger event.
- **Delay:** Specifies a delay to be applied to data collection. The delay represents the amount of time that elapses between a trigger event and the start of data collection. The delay is expressed in base rate steps. It can be positive or negative (default is 0). A negative delay corresponds to pretriggering. When the delay is negative, data from the time preceding the trigger event is collected and uploaded.
- **Arm when connecting to target:** Selected or cleared. Whether a button or a signal triggers data uploading (as defined by **Source**), the trigger must be armed to allow data uploading to begin.

If you select this option, connecting to the target arms the trigger.

- If the trigger **Source** is `manual`, data uploading begins immediately.
- If the trigger **Source** is `signal`, monitoring of the trigger signal begins immediately. Data uploading begins when the trigger signal satisfies trigger conditions (as defined in the **Trigger signal** section).

If you clear **Arm when connecting to target**, manually arm the trigger by clicking the **Arm Trigger** button on the External Mode Control Panel.

When simulating in external mode, each rate in the model creates a buffer on the target. Each entry in the buffer is big enough to hold all of the data required of every signal in that rate for one time step (time plus data plus external mode indices identifying the signal). The number of entries in the circular buffer is determined by the external mode trigger **Duration** parameter (`ExtModeTrigDuration`). The memory allocated on the target for buffering signals is proportional to the **Duration** and the number of signals uploading. The **Duration** also provides an indication of the number of base rate steps with log data after a trigger event in external mode.

The **Duration** value specifies the number of contiguous points of data to be collected in each buffer of data. You should enter a **Duration** value equal to the number of continuous sample points that you need to collect rather than relying on a series of buffers to be continuous. If you enter a value less than the total number of sample points, you may lose sample points during the time spent transferring values from the data buffer to the MATLAB workspace. The Simulink software maintains point continuity only within one buffer. Between buffers, because of transfer time, some samples may be omitted.

The **Duration** value is related to the **Limit data points to last** value in the **Scope parameters** dialog box. The smaller of either value limits the number of sample points saved to the MATLAB workspace. You should not select the **Limit data points to last** check box; instead, use the **Duration** value to set the number of sample points saved.

### Select Trigger Signal

You can designate one signal as a trigger signal. To select a trigger signal, from the **Source** menu in the **Trigger options** section, select `signal`. This action enables the parameters in the **Trigger signal** section. Then, select a signal in the **Signal selection** list, and click the **Trigger Signal** button.

When you select a signal to be a trigger, a T appears in the **Trigger** column of the **Signal selection** list. In the next figure, the **Scope A** signal is the trigger. **Scope B** is also selected for viewing, as indicated by the X in the **Selected** column.

After selecting the trigger signal, you can use the **Trigger signal** section to define the trigger conditions and set the trigger signal **Port** and **Element** parameters.

### Set Trigger Conditions

Use the **Trigger signal** section of the External Signal & Triggering dialog box to set trigger conditions and attributes.

---

**Note** The **Trigger signal** parameters are enabled only when the trigger parameter **Source** is set to **signal** in the **Trigger options** section.

---

By default, any element of the first input port of a specified trigger block can cause the trigger to fire (that is, Port 1, any element). You can modify this behavior by adjusting the **Port** and **Element** values in the **Trigger signal** section. The **Port** field accepts a number or the keyword **last**. The **Element** field accepts a number or the keywords **any** or **last**.

In the **Trigger signal** section, you also define the conditions under which a trigger event occurs.

- **Direction:** `rising`, `falling`, or `either`. The direction in which the signal must be traveling when it crosses the threshold value. The default is `rising`.
- **Level:** A value indicating the threshold the signal must cross in a designated direction to fire the trigger. By default, the level is 0.
- **Hold-off:** Applies only to `normal` mode. Expressed in base rate steps, **Hold-off** is the time between the termination of one trigger event and the rearming of the trigger.

### Modify Signal and Triggering Options While Connected

After you configure signal data uploading, and connect Simulink to a running target executable, you can modify signal and triggering options without disconnecting from the target.

If the trigger is armed (for example, if the trigger option **Arm when connecting to the target** is selected, which is the default), the External Signal & Triggering dialog box cannot be modified. To modify signal and triggering options:

- 1 Open the External Mode Control Panel.
- 2 Click **Cancel Trigger**. Triggering and display of uploaded data stops.
- 3 Open the External Signal & Triggering dialog box and modify signal and trigger options as required. For example, in the **Signal selection** section, you can enable or disable a scope, and in the **Trigger options** section, change the trigger **Mode**, for example, from `normal` to `one-shot`.
- 4 Click **Arm Trigger**. Triggering and display of uploaded data resumes, with your modifications.

### Configure Host Archiving of Target Program Signal Data

In external mode, you can use the Simulink Scope and To Workspace blocks to archive data to disk.

To understand how the archiving features work, consider the handling of data when archiving is not enabled. There are two cases, one-shot mode and normal mode.

- In one-shot mode, after a trigger event occurs, each selected block writes its data to the workspace, as it would at the end of a simulation. If another one-shot is triggered, the existing workspace data is overwritten.
- In normal mode, external mode automatically rearms the trigger after each trigger event. Consequently, you can think of normal mode as a series of one-shots. Each one-shot in this series, except for the last, is referred to as an *intermediate result*. Because

the trigger can fire at any time, writing intermediate results to the workspace can result in unpredictable overwriting of the workspace variables. For this reason, the default behavior is to write only the results from the final one-shot to the workspace. The intermediate results are discarded. If you know that enough time exists between triggers for inspection of the intermediate results, you can override the default behavior by selecting the **Write intermediate results to workspace** option. This option does not protect the workspace data from being overwritten by subsequent triggers.

If you use a Simulink Scope block to archive data to disk, open the Scope parameters dialog box and select the option **Log data to workspace**. This is required for the following reasons:

- The data is first transferred from the scope data buffer to the MATLAB workspace, before being written to a MAT-file.
- The **Variable name** entered in the Scope parameters dialog box is the same as the one in the MATLAB workspace and the MAT-file. Enabling the data to be saved enables a variable named with the **Variable name** parameter to be saved to a MAT-file.

---

**Note:** If you do not select the Scope block option **Log data to workspace**, the MAT-files for data logging are created, but they are empty.

---

The Enable Data Archiving dialog box supports the following capabilities:

- Folder notes
- File notes
- Automated data archiving

On the External Mode Control Panel, click the **Data Archiving** button to open the Enable Data Archiving dialog box. If your model is connected to the target environment, disconnect it while you configure data archiving. Select **Enable archiving** to enable the other controls in the dialog box.

The operations supported by the Enable Data Archiving dialog box are as follows.

#### Folder Notes

Use the **Edit Directory Note** button to add annotations for a collection of related data files in a folder. In the Enable Data Archiving dialog box, click **Edit Directory Note** to open the MATLAB editor. Place comments that you want saved to a file in the specified folder in this window. By default, the comments are saved to the folder last written to by data archiving.

#### File Notes

Use the **Edit File Note** button to add annotations for an individual data file. In the Enable Data Archiving dialog box, click **Edit File Note** to open a file finder window that is, by default, set to the last file to which you have written. Selecting a MAT-file opens an edit window. In this window, add or edit comments that you want saved with your individual MAT-file.

### Automated Data Archiving

Use the **Enable archiving** option and the controls it enables to configure automatic writing of logging results, optionally including intermediate results, to disk. The dialog box provides the following related controls:

- **Directory:** Specifies the folder in which data is saved. If you select **Increment directory when trigger armed**, external mode appends a suffix.
- **File:** Specifies the name of the file in which data is saved. If you select **Increment file after one-shot**, external mode appends a suffix.
- **Increment directory when trigger armed:** Each time that you click the **Arm Trigger** button, external mode uses a different folder for writing log files. The folders are named incrementally, for example, `dirname1`, `dirname2`, and so on.
- **Increment file after one-shot:** New data buffers are saved in incremental files: `filename1`, `filename2`, and so on. File incrementing happens automatically in normal mode.
- **Append file suffix to variable names:** Whenever external mode increments file names, each file contains variables with identical names. Selecting **Append file suffix to variable name** results in each file containing unique variable names. For example, external mode saves a variable named `xdata` in incremental files (`file_1`, `file_2`, and so on) as `xdata_1`, `xdata_2`, and so on. This approach supports loading the MAT-files into the workspace and comparing variables at the MATLAB command prompt. Without the unique names, each instance of `xdata` would overwrite the previous one in the MATLAB workspace.
- **Write intermediate results to workspace:** If you want the Simulink Coder software to write intermediate results to the workspace, select this option.

### External Mode Compatible Blocks and Subsystems

- “Compatible Blocks” on page 41-34
- “Signal Viewing Subsystems” on page 41-35
- “Supported Blocks for Data Archiving” on page 41-37

### Compatible Blocks

In external mode, you can use the following types of blocks to receive and view signals uploaded from the target program:

- Floating Scope and Scope blocks

- Spectrum Analyzer, Time Scope, and Vector Scope blocks from the DSP System Toolbox product
- Display blocks
- To Workspace blocks
- User-written S-Function blocks

An external mode method is built into the S-function API. This method allows user-written blocks to support external mode. See `matlabroot/simulink/include/simstruc.h`.

- XY Graph blocks

In addition to these types of blocks, you can designate certain subsystems as Signal Viewing Subsystems and use them to receive and view signals uploaded from the target program. See “Signal Viewing Subsystems” on page 41-35 for more information.

You select external mode compatible blocks and subsystems, and arm the trigger, by using the External Signal & Triggering dialog box. By default, such blocks in a model are selected, and a manual trigger is set to be armed when connected to the target program.

### Signal Viewing Subsystems

A Signal Viewing Subsystem is an atomic subsystem that encapsulates processing and viewing of signals received from the target system. A Signal Viewing Subsystem runs only on the host, and does not generate code in the target system. Signal Viewing Subsystems run in Normal, Accelerator, Rapid Accelerator, and External simulation modes.

---

**Note:** Signal Viewing Subsystems are inactive if placed inside a SIL or PIL component, such as a top model in SIL or PIL mode, a Model block in SIL or PIL mode, or a SIL or PIL block. However, a SIL or PIL component can feed a Signal Viewing Subsystem running in a supported mode.

---

Signal Viewing Subsystems are useful in situations where you want to process or condition signals before viewing or logging them, but you do not want to perform these tasks on the target system. By using a Signal Viewing Subsystem, you can generate smaller and more efficient code on the target system.

Like other external mode compatible blocks, Signal Viewing Subsystems are displayed in the External Signal & Triggering dialog box.

To declare a subsystem to be a Signal Viewing Subsystem,

- 1 Select the **Treat as atomic unit** option in the Block Parameters dialog box.

For more information on atomic subsystems, see “Code Generation of Subsystems”.

- 2 Use the following `set_param` command to turn the `SimViewingDevice` property on,

```
set_param('blockname', 'SimViewingDevice', 'on')
```

where 'blockname' is the name of the subsystem.

- 3 Make sure the subsystem meets the following requirements:

- It must be a pure Sink block. That is, it must not contain Outport blocks or Data Store blocks. It can contain Goto blocks only if the corresponding From blocks are contained within the subsystem boundaries.
- It must not have continuous states.

The following model, `sink_examp`, contains an atomic subsystem, `theSink`.

The subsystem `theSink`, shown in the next figure, applies a gain and an offset to its input signal and displays it on a Scope block.

If `theSink` is declared as a Signal Viewing Subsystem, the generated target program includes only the code for the Sine Wave block. If `theSink` is selected and armed in

the External Signal & Triggering dialog box, the target program uploads the sine wave signal to theSink during simulation. You can then modify the parameters of the blocks within theSink and observe the uploaded signal.

If theSink were not declared as a Signal Viewing Subsystem, its Gain, Constant, and Sum blocks would run as subsystem code on the target system. The Sine Wave signal would be uploaded to the Simulink engine after being processed by these blocks, and viewed on sink\_examp/theSink/Scope2. Processing demands on the target system would be increased by the additional signal processing, and by the downloading of changes in block parameters from the host.

### Supported Blocks for Data Archiving

In external mode, you can use the following types of blocks to archive data to disk:

- Scope blocks
- To Workspace blocks

You configure data archiving by using the Enable Data Archiving dialog box, as described in “Configure Host Archiving of Target Program Signal Data” on page 41-31.

## External Mode Communication

- “About External Mode Communication” on page 41-37
- “Download Mechanism” on page 41-37
- “Inlined and Tunable Parameters” on page 41-39

### About External Mode Communication

Depending on the setting of the **Default parameter behavior** option when the target program is generated, there are differences in the way parameter updates are handled. “Download Mechanism” on page 41-37 describes the operation of external mode communication with **Default parameter behavior** set to Tunable. “Inlined and Tunable Parameters” on page 41-39 describes the operation of external mode with **Default parameter behavior** set to Inlined.

### Download Mechanism

In external mode, the Simulink engine does not simulate the system represented by the block diagram. By default, when external mode is enabled, the Simulink engine

downloads parameters to the target system. After the initial download, the engine remains in a waiting mode until you change parameters in the block diagram or until the engine receives data from the target.

When you change a parameter in the block diagram, the Simulink engine calls the external interface MEX-file, passing new parameter values (along with other information) as arguments. The external interface MEX-file contains code that implements one side of the interprocess communication (IPC) channel. This channel connects the Simulink process (where the MEX-file executes) to the process that is executing the external program. The MEX-file transfers the new parameter values by using this channel to the external program.

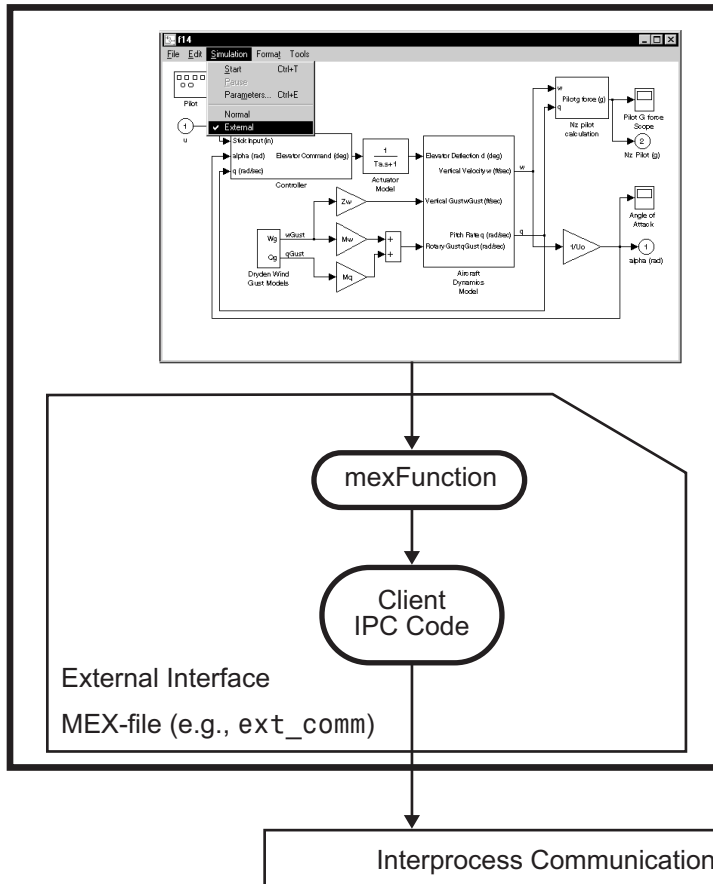

The other side of the communication channel is implemented within the external program. This side writes the new parameter values into the target's parameter structure (*model\_P*).

The Simulink side initiates the parameter download operation by sending a message containing parameter information to the external program. In the terminology of client/server computing, the Simulink side is the client and the external program is the server. The two processes can be remote, or they can be local. Where the client and server are remote, a protocol such as TCP/IP is used to transfer data. Where the client and server are local, a serial connection or shared memory can be used to transfer data.

The next figure shows this relationship. The Simulink engine calls the external interface MEX-file whenever you change parameters in the block diagram. The MEX-file then downloads the parameters to the external program by using the communication channel.

## Simulink Process

## External Program Process

## External Mode Architecture

## Inlined and Tunable Parameters

By default, parameters (except those listed in “External Mode Limitations” on page 41-55) in an external mode program are tunable; that is, you can change them by using the download mechanism described in this section.

If you set **Default parameter behavior** to **Inlined** (on the **Optimization > Signals and Parameters** pane of the Configuration Parameters dialog box), the Simulink Coder code generator embeds the numerical values of model parameters (constants), instead of

symbolic parameter names, in the generated code. Inlining parameters generates smaller and more efficient code. However, inlined parameters, because they effectively become constants, are not tunable.

The Simulink Coder software lets you improve overall efficiency by inlining most parameters, while at the same time retaining the flexibility of run-time tuning for selected parameters that are important to your application. When you inline parameters, you can use `Simulink.Parameter` objects to remove individual parameters from inlining and declare them to be tunable. In addition, you can use these objects to control how parameters are represented in the generated code.

For more information on tunable parameters, see “Block Parameter Representation in the Generated Code”.

### **Automatic Parameter Uploading on Host/Target Connection**

Each time the Simulink engine connects to a target program that was generated with **Default parameter behavior** set to `Inlined`, the target program uploads the current value of its tunable parameters to the host. These values are assigned to the corresponding MATLAB workspace variables. This procedure synchronizes the host and target with respect to parameter values.

Workspace variables required by the model must be initialized at the time of host/target connection. Otherwise the uploading cannot proceed and an error results. Once the connection is made, these variables are updated to reflect the current parameter values on the target system.

Automatic parameter uploading takes place only if the target program was generated with **Default parameter behavior** set to `Inlined`. “Download Mechanism” on page 41-37 describes the operation of external mode communication with **Default parameter behavior** set to `Tunable`.

## **Choose Communication Protocol for Client and Server**

- “Introduction” on page 41-41
- “Using the TCP/IP Implementation” on page 41-41
- “Using the Serial Implementation” on page 41-44
- “Run the External Program” on page 41-46
- “Implement an External Mode Protocol Layer” on page 41-48

## Introduction

The Simulink Coder product provides code to implement both the client and server side of external mode communication using either TCP/IP or serial protocols. You can use the socket-based external mode implementation provided by the Simulink Coder product with the generated code, provided that your target system supports TCP/IP. If not, use or customize the serial transport layer option provided.

A low-level *transport layer* handles physical transmission of messages. Both the Simulink engine and the model code are independent of this layer. Both the transport layer and code directly interfacing to the transport layer are isolated in separate modules that format, transmit, and receive messages and data packets.

See “Target Interfacing” on page 41-16 for information on selecting a transport layer.

## Using the TCP/IP Implementation

You can use TCP/IP-based client/server implementation of external mode with real-time programs on The Open Group UNIX or PC systems. For help in customizing external mode transport layers, see “Create a Transport Layer for External Communication”.

To use Simulink external mode over TCP/IP:

- Make sure that the external interface MEX-file for your target's TCP/IP transport is specified.

Targets provided by MathWorks specify the name of the external interface MEX-file in `matlabroot/toolbox/simulink/simulink/extmode_transports.m`. The name of the interface appears as uneditable text in the **External mode configuration** section of the **Interface** pane of the Configuration Parameters dialog box. The TCP/IP default is `ext_comm`.

To specify a TCP/IP transport for a custom target, you must add an entry of the following form to an `sl_customization.m` file on the MATLAB path:

```
function sl_customization(cm)
 cm.ExtModeTransports.add('stf.tlc', 'transport', 'mexfile', 'Level1');
%end function
```

where

- `stf.tlc` is the name of the system target file for which you are registering the transport (for example, `'mytarget.tlc'`)

- *transport* is the transport name to display in the **Transport layer** menu on the **Interface** pane of the Configuration Parameters dialog box (for example, 'tcpip')
- *mexfile* is the name of the transport's associated external interface MEX-file (for example, 'ext\_comm')

You can specify multiple targets and/or transports with additional `cm.ExtModeTransports.add` lines, for example:

```
function sl_customization(cm)
 cm.ExtModeTransports.add('mytarget.tlc', 'tcpip', 'ext_comm', 'Level1');
 cm.ExtModeTransports.add('mytarget.tlc', 'serial', ...
 'ext_serial_win32_comm', 'Level1');
%end function
```

- Be sure that the template makefile is configured to link the source files for the TCP/IP server code and that it defines the compiler flags when building the generated code.
- Build the external program.
- Run the external program.
- Set the Simulink model to external mode and connect to the target.

The next figure shows the structure of the TCP/IP-based implementation.

### TCP/IP-Based Client/Server Implementation for External Mode

#### MEX-File Optional Arguments for TCP/IP Transport

In the External Target Interface dialog box, you can specify optional arguments that are passed to the external mode interface MEX-file for communicating with executing targets.

- Target network name: the network name of the computer running the external program. By default, this is the computer on which the Simulink product is running, for example, 'myComputer'. You can also use the IP address, for example, '148.27.151.12'.

- **Verbosity level:** controls the level of detail of the information displayed during the data transfer. The value is either 0 or 1 and has the following meaning:
  - 0 — No information
  - 1 — Detailed information
- **TCP/IP server port number:** The default value is 17725. You can change the port number to a value between 256 and 65535 to avoid a port conflict.

The arguments are positional and must be specified in the following order:

```
<TargetNetworkName> <VerbosityLevel> <ServerPortNumber>
```

For example, if you want to specify the verbosity level (the second argument), then you must also specify the target network name (the first argument). Arguments can be delimited by white space or commas. For example:

```
'148.27.151.12' 1 30000
```

You can specify command-line options to the external program when you launch it. See “Run the External Program” on page 41-46 for more information.

### Using the Serial Implementation

Controlling host/target communication on a serial channel is similar to controlling host/target communication on a TCP/IP channel.

To use Simulink external mode over a serial channel, you must

- Make sure that the external interface MEX-file for your target's serial transport is specified.

Targets provided by MathWorks specify the name of the external interface MEX-file in `matlabroot/toolbox/simulink/simulink/extmode_transports.m`.

The name of the interface appears as uneditable text in the **External mode configuration** section of the **Interface** pane of the Configuration Parameters dialog box. The serial default is `serial`.

To specify a serial transport for a custom target, you must add an entry of the following form to an `sl_customization.m` file on the MATLAB path:

```
function sl_customization(cm)
 cm.ExtModeTransports.add('stf.tlc', 'transport', 'mexfile', 'Level1');
%end function
```

where

- *stf.tlc* is the name of the system target file for which you are registering the transport (for example, 'mytarget.tlc')
- *transport* is the transport name to display in the **Transport layer** menu on the **Interface** pane of the Configuration Parameters dialog box (for example, 'serial')
- *mexfile* is the name of the transport's associated external interface MEX-file (for example, 'ext\_serial\_win32\_comm')

You can specify multiple targets and/or transports with additional `cm.ExtModeTransports.add` lines, for example:

```
function sl_customization(cm)
 cm.ExtModeTransports.add('mytarget.tlc', 'tcpip', 'ext_comm', 'Level1');
 cm.ExtModeTransports.add('mytarget.tlc', 'serial', ...
 'ext_serial_win32_comm', 'Level1');
%end function
```

- Be sure that the template makefile is configured to link the source files for the serial server code and that it defines the compiler flags when building the generated code.
- Build the external program.
- Run the external program.
- Set the Simulink model to external mode and connect to the target.

### MEX-File Optional Arguments for Serial Transport

In the **MEX-file arguments** field of the **Interface** pane of the Configuration Parameters dialog box, you can specify arguments that are passed to the external mode interface MEX-file for communicating with the executing targets. For serial transport, the optional arguments to `ext_serial_win32_comm` are as follows:

- Verbosity level: This argument controls the level of detail of the information displayed during data transfer. The value of this argument is
  - 0 (no information), or
  - 1 (detailed information)
- Serial port ID: The port ID of the host, specified as an integer or character vector. For example, specify the port ID of a USB to serial converter as '/dev/ttyusb0'.

---

**Note:** Simulink Coder prefixes integer port IDs with '\\.\COM' on Windows and by '/dev/ttyS' on Unix.

---

When you start the target program using a serial connection, you must specify the port ID to use to connect it to the host. Do this by including the `-port` command-line option. For example,

```
mytarget.exe -port 2 -w
```

- Baud rate: Specify an integer value. The default value is 57600.

The MEX-file options arguments are positional and must be specified in the following order:

```
<VerbosityLevel> <SerialPortID> <BaudRate>
```

For example, if you want to specify the serial port ID (the second argument), then you must also specify the verbosity level (the first argument). Arguments can be delimited by white space or commas. For example:

```
1 '/dev/ttyusb0' 57600
```

You can specify command-line options to the external program when you launch it. The following section provides more information on using command-line arguments.

### Run the External Program

The external program must be running before you can use the Simulink product in external mode.

If the target program is executing on the same machine as the host and communication is through a loopback serial cable, the target's port ID must differ from that of the host (as specified in the **MEX-file arguments** edit field).

To run the external program, you type a command of the form

```
model -opt1 ... -optN
```

where *model* is the name of the external program and *-opt1 ... -optN* are options. (See “Command-Line Options for the External Program” on page 41-47.) In the examples in this section, the name of the external program is assumed to be `ext_example`.

### Running the External Program Under the Windows Environment

In the Windows environment, you can run the external programs in either of the following ways:

- Open a Command Prompt window. At the command prompt, type the name of the target executable, followed by possible options, such as:

```
ext_example -tf inf -w
```

- Alternatively, you can launch the target executable from the MATLAB Command Window. The command must be preceded by an exclamation point (!) and followed by an ampersand (&), as in the following example:

```
!ext_example -tf inf -w &
```

The ampersand (&) causes the operating system to spawn another process to run the target executable. If you do not include the ampersand, the program still runs, but you cannot enter commands at the MATLAB command prompt or manually terminate the executable.

### Running the External Program Under the UNIX Environment

In the UNIX environment, you can run the external programs in either of the following ways:

- Open an Xterm window. At the command prompt, type the name of the target executable, followed by possible options, such as:

```
./ext_example -tf inf -w
```

- Alternatively, you can launch the target executable from the MATLAB Command Window. You must run it in the background so that you can still access the Simulink environment. The command must be preceded by an exclamation point (!), dot slash (./ indicating the current directory), and followed by an ampersand (&), as in the following example:

```
!./ext_example -tf inf -w &
```

The ampersand (&) causes the operating system to spawn another process to run the target executable.

### Command-Line Options for the External Program

External mode target executables generated by the Simulink Coder code generator support the following command-line options:

- -tf n

The `-tf` option overrides the stop time set in the Simulink model. The argument `n` specifies the number of seconds the program will run. The value `inf` directs the model to run indefinitely. In this case, the model code will run until the target program receives a stop message from the Simulink engine.

The following example sets the stop time to 10 seconds.

```
ext_example -tf 10
```

When integer-only ERT targets are built and executed in external mode, the stop time parameter (`-tf`) is interpreted by the target as the number of base rate ticks rather than the number of seconds to execute.

- `-w`

Instructs the target program to enter a wait state until it receives a message from the host. At this point, the target is running, but not executing the model code. The start message is sent when you select **Start Real-Time Code** from the **Simulation** menu or click the **Start Real-Time Code** button in the External Mode Control Panel.

Use the `-w` option if you want to view data from time step 0 of the target program execution, or if you want to modify parameters before the target program begins execution of model code.

- `-port n`

Specifies the TCP/IP port number or the serial port ID, `n`, for the target program. The port number of the target program must match that of the host for TCP/IP transport. The port number depends on the type of transport.

- For TCP/IP transport: Port number is an integer between 256 and 65535, with the default value being 17725.
- For serial transport: Port ID is an integer or a character vector. For example, specify the port ID of a USB to serial converter as `'/dev/ttyusb0'`

- `-baud r`

Specified as an integer, this option is only available for serial transport.

### Implement an External Mode Protocol Layer

If you want to implement your own transport layer for external mode communication, you must modify certain code modules provided by the Simulink Coder product and

create a new external interface MEX-file. This advanced topic is addressed in “Create a Transport Layer for External Communication”.

## Use External Mode Programmatically

You can run external-mode applications from the MATLAB command line or programmatically in scripts. Use the `get_param` and `set_param` commands to retrieve and set the values of model simulation command-line parameters, such as `SimulationMode` and `SimulationCommand`, and external mode command-line parameters, such as `ExtModeCommand` and `ExtModeTrigType`.

The following model simulation commands assume that a Simulink model is open and that you have loaded a target program to which the model will connect using external mode.

- 1 Change the Simulink model to external mode:  

```
set_param(gcs, 'SimulationMode', 'external')
```
- 2 Connect the open model to the loaded target program:  

```
set_param(gcs, 'SimulationCommand', 'connect')
```
- 3 Start running the target program:  

```
set_param(gcs, 'SimulationCommand', 'start')
```
- 4 Stop running the target program:  

```
set_param(gcs, 'SimulationCommand', 'stop')
```
- 5 Disconnect the target program from the model:  

```
set_param(gcs, 'SimulationCommand', 'disconnect')
```

To tune a workspace parameter, change its value at the command prompt. If the workspace parameter is a `Simulink.Parameter` object, assign the new value to the `Value` property.

```
myVariable = 5.23;
myParamObj.Value = 5.23;
```

To download the workspace parameter in external mode, you update the model diagram. The following model simulation command initiates a model update:

```
set_param(gcs, 'SimulationCommand', 'update')
```

To trigger or cancel data uploading to scopes, use the ExtModeCommand values armFloating and cancelFloating, or armWired and cancelWired. For example, to trigger and then cancel data uploading to wired (nonfloating) scopes:

```
set_param(gcs, 'ExtModeCommand', 'armWired')
set_param(gcs, 'ExtModeCommand', 'cancelWired')
```

The next table lists external mode command-line parameters that you can use in get\_param and set\_param commands. The table provides brief descriptions, valid values (bold type highlights defaults), and a mapping to External Mode dialog box equivalents.

---

**Note:** For external mode parameters that are equivalent to **Interface** pane options in the Configuration Parameters dialog box, see “Model Configuration Parameters: Code Generation Interface”.

---

### External Mode Command-Line Parameters

Parameter and Values	Dialog Box Equivalent	Description
ExtModeAddSuffixToVar <b>off</b> , on	Enable Data Archiving: <b>Append file suffix to variable names</b> check box	Increment variable names for each incremented filename.
ExtModeArchiveDirName <i>character vector</i>	Enable Data Archiving: <b>Directory</b> text field	Save data in specified folder.
ExtModeArchiveFileName <i>character vector</i>	Enable Data Archiving: <b>File</b> text field	Save data in specified file.
ExtModeArchiveMode <i>character vector</i> - <b>off</b> , on	Enable Data Archiving: <b>Enable archiving</b> check box	Activate automated data archiving features.
ExtModeArmWhenConnect <b>off</b> , <b>on</b>	External Signal & Triggering: <b>Arm when connecting to target</b> check box	Arm the trigger as soon as the Simulink Coder software connects to the target.
ExtModeAutoIncOneShot <b>off</b> , on	Enable Data Archiving: <b>Increment file after one-shot</b> check box	Save new data buffers in incremental files.
ExtModeAutoUpdateStatusClock (Microsoft Windows platforms only)	Not available	Continuously upload and display target time on the model window status bar.

Parameter and Values	Dialog Box Equivalent	Description
off, on		
ExtModeBatchMode off, on	External Mode Control Panel: <b>Batch download</b> check box	Enable or disable downloading of parameters in batch mode.
ExtModeChangesPending off, on	Not available	When ExtModeBatchMode is enabled, indicates whether parameters remain in the queue of parameters to be downloaded to the target.
ExtModeCommand <i>character vector</i> - armFloating, armWired, cancelFloating, cancelWired	<ul style="list-style-type: none"> <li>• armFloating and cancelFloating are equivalent to selecting and clearing External Mode Control Panel check box <b>Floating scope &gt; Enable data uploading</b></li> <li>• armWired and cancelWired are equivalent to External Mode Control Panel buttons <b>Arm Trigger</b> and <b>Cancel Trigger</b></li> </ul>	Issue an external mode command to the target program.
ExtModeConnected off, on	External Mode Control Panel: <b>Connect/Disconnect</b> button	Indicate the state of the connection with the target program.
ExtModeEnableFloating off, on	External Mode Control Panel: <b>Enable data uploading</b> check box	Enable or disable the arming and canceling of triggers when a connection is established with floating scopes.
ExtModeIncDirWhenArm off, on	Enable Data Archiving: <b>Increment directory when trigger armed</b> check box	Write log files to incremental folders each time the trigger is armed.

Parameter and Values	Dialog Box Equivalent	Description
ExtModeLogAll off, on	External Signal & Triggering: <b>Select all</b> check box	Upload available signals from the target to the host.
ExtModeParamChangesPending off, on	Not available	When the Simulink Coder software is connected to the target and ExtModeBatchMode is enabled, indicates whether parameters remain in the queue of parameters to be downloaded to the target. More efficient than ExtModeChangesPending, because it checks for a connection to the target.
ExtModeSkipDownloadWhenConnect off, on	Not available	Connect to the target program without downloading parameters.
ExtModeTrigDelay integer (0)	External Signal & Triggering: <b>Delay</b> text field	Specify the amount of time (expressed in base rate steps) that elapses between a trigger occurrence and the start of data collection.
ExtModeTrigDirection character vector - rising, falling, either	External Signal & Triggering: <b>Direction</b> menu	Specify the direction in which the signal must be traveling when it crosses the threshold value.
ExtModeTrigDuration integer (1000)	External Signal & Triggering: <b>Duration</b> text field	Specify the number of base rate steps for which external mode is to log data after a trigger event.
ExtModeTrigDurationFloating character vector - integer (auto)	External Mode Control Panel: <b>Duration</b> text field	Specify the duration for floating scopes. If auto is specified, the value of ExtModeTrigDuration is used.

Parameter and Values	Dialog Box Equivalent	Description
ExtModeTrigElement <i>character vector - integer, any, last</i>	External Signal & Triggering: <b>Element</b> text field	Specify the elements of the input port of the specified trigger block that can cause the trigger to fire.
ExtModeTrigHoldOff <i>integer (0)</i>	External Signal & Triggering: <b>Hold-off</b> text field	Specify the base rate steps between when a trigger event terminates and the trigger is rearmed.
ExtModeTrigLevel <i>integer (0)</i>	External Signal & Triggering: <b>Level</b> text field	Specify the threshold value the trigger signal must cross to fire the trigger.
ExtModeTrigMode <i>character vector - normal, oneshot</i>	External Signal & Triggering: <b>Mode</b> menu	Specify whether the trigger is to rearm automatically after each trigger event or whether only one buffer of data is to be collected each time the trigger is armed.
ExtModeTrigPort <i>character vector - integer (1), last</i>	External Signal & Triggering: <b>Port</b> text field	Specify the input port of the specified trigger block for which elements can cause the trigger to fire.
ExtModeTrigType <i>character vector - manual, signal</i>	External Signal & Triggering: <b>Source</b> menu	Specify whether to start logging data when the trigger is armed or when a specified trigger signal satisfies trigger conditions.
ExtModeUploadStatus <i>character vector - inactive, armed, uploading</i>	Not available	Return the status of the external mode upload mechanism — inactive, armed, or uploading.
ExtModeWriteAllDataToWs <b>off</b> , on	Enable Data Archiving: <b>Write intermediate results to workspace</b> check box	Write intermediate results to the workspace.

## Animate Stateflow Charts in External Mode

If you have a Stateflow license, you can animate a chart in external mode. In external mode, you can animate states in a chart, and view test point signals in a floating scope or signal viewer.

- “Animate States During Simulation in External Mode” on page 41-54
- “View Test Point Data in Floating Scopes and Signal Viewers” on page 41-55

### Animate States During Simulation in External Mode

To animate states in a chart in external mode:

- 1 Load the chart you want to animate to the target machine.
- 2 Open the Model Configuration Parameters dialog box.
- 3 In the left Select pane, select **Code Generation > Interface**.
- 4 In the right pane, **Data exchange interface** section, select **External mode** and click **OK**.
- 5 In the Simulink Editor, select **Code > External Mode Control Panel**.
- 6 In the External Mode Control Panel dialog box, click **Signal & Triggering**.
- 7 In the External Signal & Triggering dialog box, set these parameters:

In:	Select:
Signal selection pane	Chart you want to animate
Trigger pane	<b>Arm when connecting to target</b> check box
Trigger pane	normal from drop-down menu in <b>Mode</b> field

- 8 Build the model to generate an executable file.
- 9 Start the target in the background by typing this command at the MATLAB prompt:

```
!model_name.exe -w &
```

For example, if the name of your model is `my_control_sys`, enter this command:

```
!my_control_sys.exe -w &
```

---

**Note:** `-w` allows the target code to wait for the Simulink model connection.

---

- 10 In the Model Editor, select **Simulation > Mode > External**, and then select **Simulation > Connect to Target**.
- 11 Start simulation.

The chart highlights states as they execute.

### View Test Point Data in Floating Scopes and Signal Viewers

When you simulate a chart in external mode, you can designate chart data of local scope to be test points and view the test point data in floating scopes and signal viewers.

To view test point data during simulation in external mode:

- 1 Open the Model Explorer and for each data you want to view, follow these steps:
  - a In the middle **Contents** pane, select the state or local data of interest.
  - b In the right **Dialog** pane, select the **Logging** tab and select **Test point** check box.
- 2 From a floating scope or signal viewer, click the signal selection button:

The Signal Selector dialog box opens.

- 3 In the Signal Selector **Model hierarchy** pane, select the chart.
- 4 In the Signal Selector **List contents** menu, select **Testpointed/Logged signals only** and then select the signals you want to view.
- 5 Simulate the model in external mode as described in “Animate States During Simulation in External Mode” on page 41-54.

The scope or viewer displays the values of the test point signals as the simulation runs.

For more information, see “Behavior of Scopes and Viewers with Rapid Accelerator Mode” in the Simulink documentation.

### External Mode Limitations

- “Limitation on Changing Parameters” on page 41-56
- “Limitation on Mixing 32-bit and 64-bit Architectures” on page 41-57

- “Limitation on Uploading Data” on page 41-57
- “Limitation on Uploading Variable-Size Signals” on page 41-57
- “Limitation on Signal Value Display in Simulation” on page 41-57
- “Limitation on Tunable Structure Parameters” on page 41-57
- “Limitation on Archiving Data” on page 41-57
- “Limitation on Scopes in Referenced Models” on page 41-58
- “Limitation on Simulation Start Time” on page 41-58
- “Limitation on File-Scoped Data” on page 41-58

### **Limitation on Changing Parameters**

In general, you cannot change a parameter if doing so results in a change in the structure of the model. For example, you cannot change

- The number of states, inputs, or outputs of a block
- The sample time or the number of sample times
- The integration algorithm for continuous systems
- The name of the model or of a block
- The parameters to the Fcn block

If you make these changes to the block diagram, then you must rebuild the program with newly generated code.

However, you can change parameters in transfer function and state space representation blocks in specific ways:

- The parameters (numerator and denominator polynomials) for the Transfer Fcn (continuous and discrete) and Discrete Filter blocks can be changed (as long as the number of states does not change).
- Zero entries in the State-Space and Zero Pole (both continuous and discrete) blocks in the user-specified or computed parameters (that is, the A, B, C, and D matrices obtained by a zero-pole to state-space transformation) cannot be changed once external simulation is started.
- In the State-Space block, if you specify the matrices in the controllable canonical realization, then all changes to the A, B, C, D matrices that preserve this realization and the dimensions of the matrices are allowed.

If the Simulink block diagram does not match the external program, the Simulink engine displays an error informing you that the checksums do not match (that is, the model has

changed since you generated code). This means that you must rebuild the program from the new block diagram (or reload another one) to use external mode.

If the external program is not running, the Simulink engine displays an error informing you that it cannot connect to the external program.

### **Limitation on Mixing 32-bit and 64-bit Architectures**

When you use external mode, the machine running the Simulink product and the machine running the target executable must have matching bit architectures, either 32-bit or 64-bit. This is because the Simulink Coder software varies a model's checksum based on whether it is configured for a 32-bit or 64-bit platform.

If you attempt to connect from a 32-bit machine to a 64-bit machine or vice versa, the external mode connection fails.

### **Limitation on Uploading Data**

External mode does not support uploading data values for fixed-point or enumerated types into workspace parameters.

### **Limitation on Uploading Variable-Size Signals**

External mode does not support uploading variable-size signals for the following targets:

- Simulink Real-Time
- Texas Instruments™ C2000™

### **Limitation on Signal Value Display in Simulation**

External mode does not support graphical display of signal values in models (described in “Displaying Signal Values in Model Diagrams”). For example, you cannot use the **Data Display in Simulation** menu selections **Show Value Labels When Hovering**, **Toggle Value Labels When Clicked**, and **Show Value Label of Selected Port**.

### **Limitation on Tunable Structure Parameters**

External mode does not support uploading or downloading tunable structure parameters.

### **Limitation on Archiving Data**

External mode supports the Scope and To Workspace blocks for archiving data to disk. However, external mode does not support scopes other than the Scope block for archiving

data. For example, you cannot use Floating Scope blocks or Signal and Scope Manager viewer objects to archive data in external mode.

### **Limitation on Scopes in Referenced Models**

In a model hierarchy, if the top model simulates in external mode and a referenced model simulates in Normal or Accelerator mode, scopes in the referenced model do not display.

However, if the top model is changed to simulate in Normal mode, the behavior of scopes in the referenced models differs between Normal and Accelerator mode. Scopes in a referenced model simulating in Normal mode display, while scopes in a referenced model simulating in Accelerator mode do not display.

### **Limitation on Simulation Start Time**

External mode does not support nonzero simulation start times. In the Configuration Parameters dialog box, **Solver** pane, leave **Start time** set to the default value of **0.0**.

### **Limitation on File-Scoped Data**

External mode does not support file-scoped data, for example, data items to which you apply the built-in custom storage class `FileScope`. File-scoped data are not externally accessible.

### **Related Examples**

- “Use External Mode with the ERT Target” on page 54-7

# Logging in Simulink Coder

---

## Log Program Execution Results

Multiple techniques are available by which a program generated by the Simulink Coder software can save data to a MAT-file for analysis. A generated executable can save system states, outputs, and simulation time at each model execution time step. The data is written to a MAT-file, named (by default) *model.mat*, where *model* is the name of your model. See “Log Data for Analysis” on page 42-2 for a data logging tutorial.

---

**Note:** Data logging is available only for system target files that have access to a file system. In addition, only the RSim target executables are capable of accessing MATLAB workspace data.

For MAT-file logging limitations, see the configuration parameter “MAT-file logging”.

---

“Configure State, Time, and Output Logging” on page 42-9
“Log Data with Scope and To Workspace Blocks” on page 42-11
“Log Data with To File Blocks” on page 42-11
“Data Logging Differences Between Single- and Multitasking” on page 42-12

### Log Data for Analysis

- “Set Up and Configure Model” on page 42-2
- “Data Logging During Simulation” on page 42-4
- “Data Logging from Generated Code” on page 42-7

### Set Up and Configure Model

This example shows how data generated by a copy of the model `slexAircraftExample` is logged to the file `myAircraftExample.mat`. Refer to “Build a Generic Real-Time Program” on page 40-23 for instructions on setting up a copy of `slexAircraftExample` `asmAircraftExample` in a working folder if you have not done so already.

**Note:** When you configure the code generator to produce code that includes support for data logging during execution, the code generator can include text for block names in the block paths included in the log file. If the text includes characters that are unrepresented in the character set encoding for the model, the code generator replaces the characters with XML escape sequences. For example, the code generator replaces the Japanese full-width Katakana letter `㍑` with the escape sequence `&#x30A2;`. For more information, see “Internationalization and Code Generation”.

---

To configure data logging, open the Configuration Parameters dialog box and select the **Data Import/Export** pane. The process is the same as configuring a Simulink model to save output to the MATLAB workspace. For each workspace return variable you define and enable, the Simulink Coder software defines a parallel MAT-file variable. For example, if you save simulation time to the variable `tout`, your generated program logs the same data to a variable named `rt_tout`. You can change the prefix `rt_` to a suffix (`_rt`), or eliminate it entirely. You do this by setting **Configuration Parameters > All Parameters > MAT-file variable name modifier**.

Simulink lets you log signal data from anywhere in a model. In the Simulink Editor, select the signals that you want to log and then in the **Simulation Data Inspector** button dropdown, select **Log Selected Signals to Workspace**. However, the Simulink Coder software does not use this method of signal logging in generated code. To log signals in generated code, you must either use the **Data Import/Export** options described below or include To File or To Workspace blocks in your model.

---

**Note:** If you enable MAT-file and signal logging (through the **Data Import/Export** pane) and select signals for logging (through the Simulink Editor), you see the following warning when you build the model:

```
Warning: MAT-file logging does not support signal logging.
When your model code executes, the signal logging variable 'rt_logout' will
not be saved to the MAT-file.
```

To avoid this warning, clear the **Data Import/Export > Signal logging** check box.

---

In this example, you modify the `myAircraftExample` model so that the generated program saves the simulation time and system outputs to the file `myAircraftExample.mat`. Then you load the data into the base workspace and plot simulation time against one of the outputs. The `myAircraftExample` model should be configured as described in “Build a Generic Real-Time Program” on page 40-23.

### Data Logging During Simulation

To use the data logging feature:

- 1 Open the `myAircraftExample` model if it is not already open.
- 2 Open the Configuration Parameters dialog box by selecting **Simulation > Model Configuration Parameters** from the model window.
- 3 Select the **Data Import/Export** pane. The **Data Import/Export** pane lets you specify which output data is to be saved to the workspace and what variable names to use for it.
- 4 Set **Format** to **Structure with time**. When you select this format, Simulink saves the model states and outputs in structures that have their names specified in the **Save to workspace or file** area. By default, the structures are `xout` for states and `yout` for output. The structure used to save output has two top-level fields: `time` and `signals`. The `time` field contains a vector of simulation times and `signals` contains an array of substructures, each of which corresponds to a model output port.
- 5 Select the **Output** option. This tells Simulink to save output signal data during simulation as a variable named `yout`. Selecting **Output** enables the code generator to create code that logs the root Output block (`alpha`, `rad`) to a MAT-file.
- 6 Set **Decimation** to 1.
- 7 If other options are enabled, clear them. The figure below shows how the dialog box should appear.

Load from workspace

Input:

Initial state:

Save to workspace or file

Time:

States:  Format:

Output:

Final states:   Save complete SimState in final state

Signal logging:

Data stores:

Log Dataset data to file:

Single simulation output:  Logging intervals:

Simulation Data Inspector

Record logged workspace data in Simulation Data Inspector

Write streamed signals to workspace

► Additional parameters

- 8 Click **Apply** and **OK** to register your changes and close the dialog box.
- 9 Save the model.
- 10 In the model window, double-click the scope symbol next to the Aircraft Dynamics Model block, then run the model by choosing **Simulation > Run** in the model window. The resulting scope display is shown below.

- 11** Verify that the simulation time and outputs have been saved to the base workspace in MAT-files. At the MATLAB prompt, type:

```
whos yout
```

Simulink displays:

Name	Size	Bytes	Class	Attributes
yout	1x1	10756	struct	

- 12** Verify that `alpha, rad` was logged by plotting simulation time versus that variable. In the Command Window, type:

```
plot(yout.time,yout.signals.values)
```

The resulting plot is shown below.

### Data Logging from Generated Code

In the second part of this example, you build and run a Simulink Coder executable of the `myAircraftExample` model that outputs a MAT-file containing the simulation time and output you previously examined. Even though you have already generated code for the `myAircraftExample` model, you must now regenerate that code because you have changed the model by enabling data logging. The steps below explain this procedure.

To avoid overwriting workspace data with data from simulation runs, the code generator modifies identifiers for variables logged by Simulink. You can control these modifications.

- 1 Set **Configuration Parameters** > **All Parameters** > **MAT-file variable name modifier** to `_rt`. This adds the suffix `_rt` to each variable that you selected to be logged in the first part of this example.
- 2 Click **Apply** and **OK** to register your changes and close the dialog box.
- 3 Save the model.
- 4 Build an executable.
- 5 When the build concludes, run the executable with the command:  

```
!myAircraftExample
```
- 6 The program now produces two message lines, indicating that the MAT-file has been written.

```
** starting the model **
** created myAircraftExample.mat **
```

- 7 Load the MAT-file data created by the executable and look at the workspace variables from simulation and the generated program by typing:

```
load myAircraftExample.mat
whos yout*
```

Simulink displays:

Name	Size	Bytes	Class	Attributes
yout	1x1	10756	struct	
yout_rt	1x1	10756	struct	

Note the size and bytes of the structures resulting from the simulation run and generated code are the same.

- 8 Plot the generated code output by entering the following command in the Command Window:

```
plot(yout_rt.time,yout_rt.signals.values)
```

The plot should be identical to the plot that you produced in the previous part of this example.

---

**Tip** For UNIX platforms, run the executable in the Command Window with the syntax `!./executable_name`. If preferred, run the executable from an OS shell with the syntax `./executable_name`. For more information, see “Run External Commands, Scripts, and Programs”.

---

## Configure State, Time, and Output Logging

The **Data Import/Export** pane enables a generated program to save system states, outputs, and simulation time at each model execution time step. The data is written to a MAT-file, named (by default) `model.mat`.

Before using this data logging feature, you should learn how to configure a Simulink model to return output to the MATLAB workspace. This is discussed in “Export Simulation Data”.

For each workspace return variable that you define and enable, the code generator defines a MAT-file variable. For example, if your model saves simulation time to the workspace variable `tout`, your generated program logs the same data to a variable named (by default) `rt_tout`.

The code generated by the code generator logs the following data:

- Root Outport blocks

The default MAT-file variable name for system outputs is `rt_yout`.

The sort order of the `rt_yout` array is based on the port number of the Outport block, starting with 1.

- Continuous and discrete states in the model

The default MAT-file variable name for system states is `rt_xout`.

- Simulation time

The default MAT-file variable name for simulation time is `rt_tout`.

- “Override Default MAT-File Variable Names” on page 42-10

- “Override Default MAT-File Name or Buffer Size” on page 42-10

### Override Default MAT-File Variable Names

By default, the code generation software prefixes the text `rt_` to the variable names for system outputs, states, and simulation time to form MAT-file variable names. To change this prefix for a model, select a prefix (`rt_`), a suffix (`_rt`), or no modifier (`none`) for **Configuration Parameters > All Parameters > MAT-file variable name modifier**. Other system target files might not support this parameter.

### Override Default MAT-File Name or Buffer Size

You can specify compiler options to override the following MAT-file attributes in generated code:

MAT-File Attribute	Default	Compiler Option
Name	<code>model.mat</code>	<code>-DSAVEFILE=<i>filename</i></code>
Size of data logging buffer	1024 bytes	<code>-DDEFAULT_BUFFER_SIZE=<i>n</i></code>

**Note:** Valid option syntax can vary among compilers. For example, Microsoft Visual C++ compilers typically accept `/DSAVEFILE=filename` as well as `-DSAVEFILE=filename`.

For a template makefile (TMF) based target, append the compiler option to the **Make command** field on the **Code Generation** pane of the Configuration Parameters dialog box. For example:

Make command: `make_rtw OPTS="-DSAVEFILE=myCodeLog.mat"`

For a toolchain-based target such as GRT or ERT, add the compiler option to the **Build configuration** settings on the **Code Generation** pane of the Configuration Parameters dialog box. Set **Build configuration** to **Specify**, and add the compiler option to the **C Compiler** row of the **Tool/Options** table. For example:

Tool	Options
C Compiler	<code>\$(cflags) \$(CFLAGS) \$(CFLAGS_ADDITIONAL) -DSAVEFILE=myCodeLog.mat /Od /Oy-</code>

To add the compiler option to a custom toolchain, you can modify and reregister the custom toolchain using the procedures shown in the example “Adding a Custom

Toolchain”. For example, to add the compiler option to the MATLAB source file for the custom toolchain, you could define `myCompilerOpts` as follows:

```

optimsOffOpts = {'/c /Od'};
optimsOnOpts = {'/c /O2'};
cCompilerOpts = '$(cflags) $(CVARSFLAG) $(CFLAGS_ADDITIONAL)';
cppCompilerOpts = '$(cflags) $(CVARSFLAG) $(CPPFLAGS_ADDITIONAL)';
myCompilerOpts = {' -DSAVEFILE=myCodeLog.mat '};
...

```

Then you can add `myCompilerOpts` to the flags for each configuration and compiler to which it applies, for example:

```

cfg = tc.getBuildConfiguration('Faster Builds');
cfg.setOption('C Compiler', horzcat(cCompilerOpts, myCompilerOpts, optimsOffOpts));

```

As shown in “Adding a Custom Toolchain”, after modifying the custom toolchain, you save the configuration to a MAT-file and refresh the target registry.

## Log Data with Scope and To Workspace Blocks

The code generated by the code generator also logs data from these sources:

- Scope blocks that have the **Log data to workspace** parameter enabled
  - You must specify the variable name and data format in each Scope block's dialog box.
- To Workspace blocks in the model
  - You must specify the variable name and data format in each To Workspace block's dialog box.

The variables are written to `model.mat`, along with variables logged from the **Workspace I/O** pane.

## Log Data with To File Blocks

You can also log data to a To File block. The generated program creates a separate MAT-file (distinct from `model.mat`) for each To File block in the model. The file contains the block time and input variable(s). You must specify the filename, variable names, decimation, and sample time in the To File block dialog box.

---

**Note:** Models referenced by Model blocks do not perform data logging in that context except for states, which you can include in the state logged for top models. Code

generated by the Simulink Coder software for referenced models does not perform data logging to MAT-files.

---

### Data Logging Differences Between Single- and Multitasking

When logging data in single-tasking and multitasking systems, you will notice differences in the logging of

- Noncontinuous root Outport blocks
- Discrete states

In multitasking mode, the logging of states and outputs is done after the first task execution (and not at the end of the first time step). In single-tasking mode, the code generated by the build procedure logs states and outputs after the first time step.

See [Data Logging in Single-Tasking and Multitasking Model Execution](#) for more details on the differences between single-tasking and multitasking data logging.

---

**Note:** The rapid simulation target (RSim) provides enhanced logging options. See “Accelerate, Refine, and Test Hybrid Dynamic System on Host Computer by Using RSim System Target File” for more information.

---

# Data Interchange Using the C API in Simulink Coder

---

- “Exchange Data Between Generated and External Code Using C API” on page 43-2
- “Use C API to Access Model Signals and States” on page 43-24
- “Use C API to Access Model Parameters” on page 43-30

## Exchange Data Between Generated and External Code Using C API

Some Simulink Coder applications must interact with signals, states, root-level inputs/outputs, or parameters in the generated code for a model. For example, calibration applications monitor and modify parameters. Signal monitoring or data logging applications interface with signal, state, and root-level input/output data. Using the Simulink Coder C API, you can build target applications that log signals, states, and root-level inputs/outputs, monitor signals, states, and root-level inputs/outputs, and tune parameters, while the generated code executes.

The C API minimizes its memory footprint by sharing information common to signals, states, root-level inputs/outputs, and parameters in smaller structures. Signal, state, root-level input/output, and parameter structures include an index into the structure map, allowing multiple signals, states, root-level inputs/outputs, or parameters to share data.

To get started with an example, see “Use C API to Access Model Signals and States” on page 43-24 or “Use C API to Access Model Parameters” on page 43-30.

### In this section...

“Generated C API Files” on page 43-2

“Generate C API Files” on page 43-3

“Description of C API Files” on page 43-5

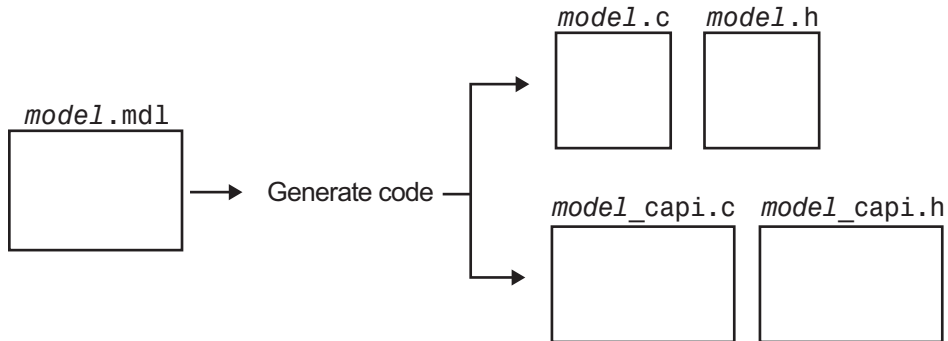

“Generate C API Data Definition File for Exchanging Data with a Target System” on page 43-20

“C API Limitations” on page 43-22

## Generated C API Files

When you configure a model to use the C API, the Simulink Coder code generator generates two additional files, *model\_capi.c* (or *.cpp*) and *model\_capi.h*, where *model* is the name of the model. The code generator places the two C API files in the build folder, based on settings in the Configuration Parameters dialog box. The C API source code file contains information about global block output signals, states, root-level inputs/outputs, and global parameters defined in the generated code model source code. The C API header file is an interface header file between the model source code and

the generated C API. You can use the information in these C API files to create your application. Among the files generated are those shown in the next figure.

### Generated Files with C API Selected

---

**Note:** When you configure the code generator to produce code that includes support for the C API interface and data logging, the code generator can include text for block names in the block paths logged to C API files *model\_capi.c* (or *.cpp*) and *model\_capi.h*. If the text includes characters that are unrepresented in the character set encoding for the model, the code generator replaces the characters with XML escape sequences. For example, the code generator replaces the Japanese full-width Katakana letter  $\text{ア}$  with the escape sequence `&#x30A2`; . For more information, see “Internationalization and Code Generation”.

---

## Generate C API Files

To generate C API files for your model:

- 1 Select the C API interface for your model. There are two ways to select the C API interface for your model, as described in the following sections.
  - “Select C API with Configuration Parameters Dialog” on page 43-4
  - “Select C API from the Command Line” on page 43-4
- 2 Generate code for your model.

After generating code, you can examine the files *model\_capi.c* (or *.cpp*) and *model\_capi.h* in the model build folder.

### Select C API with Configuration Parameters Dialog

- 1 Open your model, and open the Configuration Parameters dialog box.
- 2 Go to the **Code Generation > Interface** pane and, in the **Data exchange interface** subgroup, select one or more C API options. Based on the options you select, support for accessing signals, parameters, states, and root-level I/O will appear in the C API generated code.
  - If you want to generate C API code for global block output signals, select **Generate C API for: signals**.
  - If you want to generate C API code for global block parameters, select **Generate C API for: parameters**.
  - If you want to generate C API code for discrete and continuous states, select **Generate C API for: states**.
  - If you want to generate C API code for root-level inputs and outputs, select **Generate C API for: root-level I/O**.

### Select C API from the Command Line

From the MATLAB command line, you can use the `set_param` function to select or clear the C API check boxes on the **Interface** pane of the Configuration Parameters dialog box. At the MATLAB command line, enter one or more of the following commands, where `modelName` is the name of your model.

To select **Generate C API for: signals**, enter:

```
set_param('modelName', 'RTWCAPISignals', 'on')
```

To clear **Generate C API for: signals**, enter:

```
set_param('modelName', 'RTWCAPISignals', 'off')
```

To select **Generate C API for: parameters**, enter:

```
set_param('modelName', 'RTWCAPIParams', 'on')
```

To clear **Generate C API for: parameters**, enter:

```
set_param('modelName', 'RTWCAPIParams', 'off')
```

To select **Generate C API for: states**, enter:

```
set_param('modelName', 'RTWCAPISStates', 'on')
```

To clear **Generate C API for: states**, enter:

```
set_param('modelName', 'RTWCAPISStates', 'off')
```

To select **Generate C API for: root-level I/O**, enter:

```
set_param('modelName', 'RTWCAPIRootIO', 'on')
```

To clear **Generate C API for: root-level I/O**, enter:

```
set_param('modelName', 'RTWCAPIRootIO', 'off')
```

## Description of C API Files

- “About C API Files” on page 43-5
- “Structure Arrays Generated in C API Files” on page 43-8
- “Generate Example C API Files” on page 43-9
- “C API Signals” on page 43-11
- “C API States” on page 43-14
- “C API Root-Level Inputs and Outputs” on page 43-15
- “C API Parameters” on page 43-16
- “Map C API Data Structures to rtModel” on page 43-18

### About C API Files

The `model_capi.c` (or `.cpp`) file provides external applications with a consistent interface to model data. Depending on your configuration settings, the data could be a signal, state, root-level input or output, or parameter. In this document, the term *data item* refers to either a signal, a state, a root-level input or output, or a parameter. The C API uses structures that provide an interface to the data item properties. The interface packages the properties of each data item in a data structure. If the model contains multiple data items, the interface generates an array of data structures. The members of a data structure map to data properties.

To interface with data items, an application requires the following properties for each data item:

- Name

- Block path
- Port number (for signals and root-level inputs/outputs only)
- Address
- Data type information: native data type, data size, complexity, and other attributes
- Dimensions information: number of rows, number of columns, and data orientation (scalar, vector, matrix, or  $n$ -dimensional)
- Fixed-point information: slope, bias, scale type, word length, exponent, and other attributes
- Sample-time information (for signals, states, and root-level inputs/outputs only): sample time, task identifier, frames

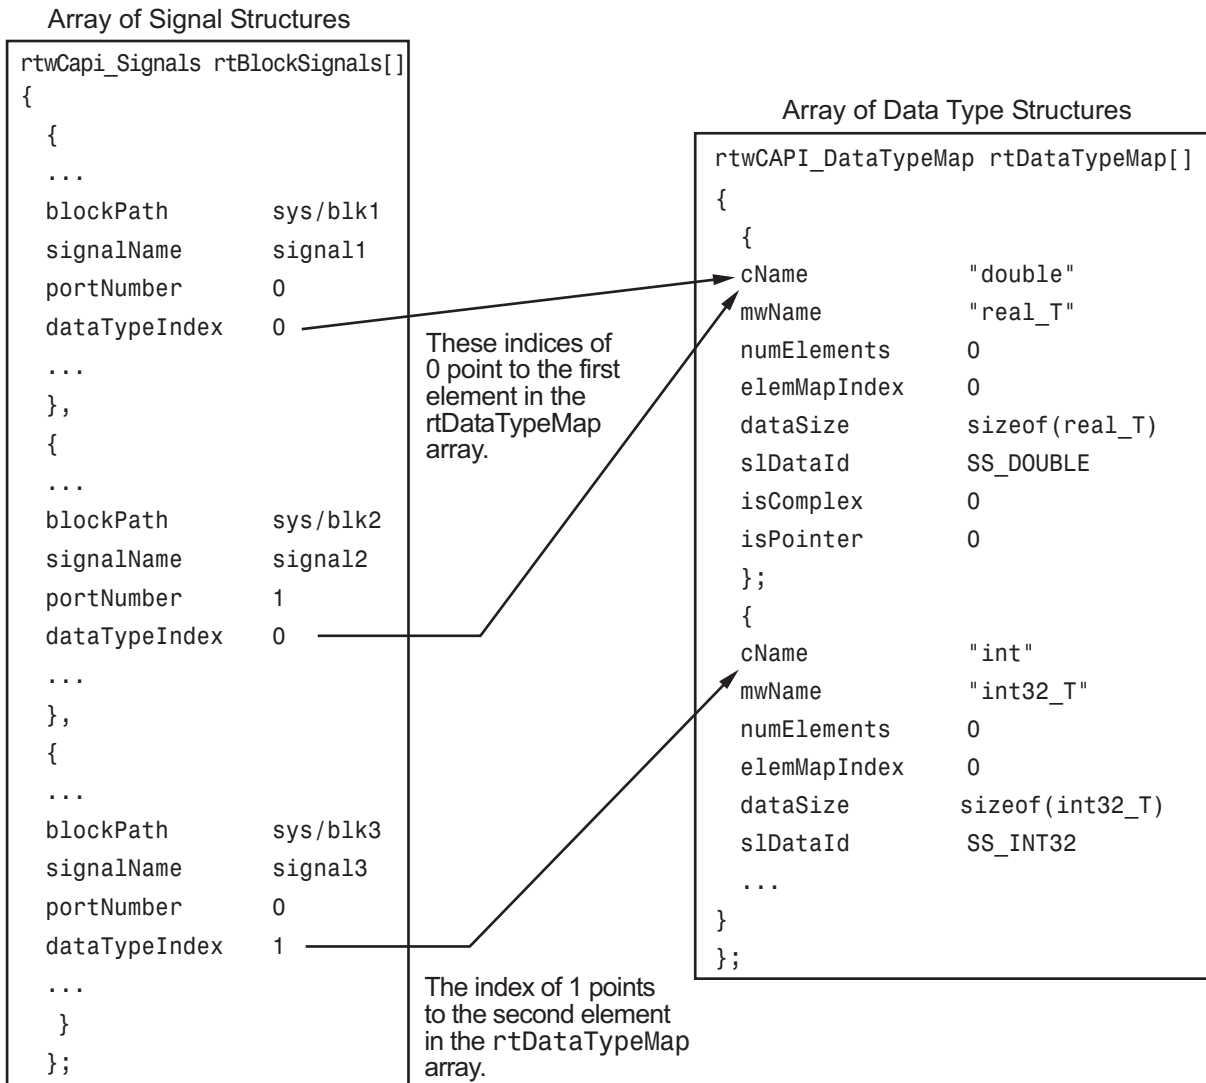

As illustrated in the next figure, the properties of data item A, for example, are located in data structure DS\_A. The properties of data item B are located in data structure DS\_B.

Some property *values* can be unique to each data item, and there are some property values that several data items can share in common. Name, for example, has a unique value for each data item. The interface places the unique property values directly in the structure for the data item. The name value of data item A is in DS\_A, and the name value of data item B is in DS\_B.

But data type could be a property whose value several data items have in common. The ability of some data items to share a property allows the C API to have a reuse feature. In this case, the interface places only an index value in DS\_A and an index value in

DS\_B. These indices point to a different data structure, DS\_C, that contains the actual data type value. The next figure shows this scheme with more detail.

The figure shows three signals. **signal1** and **signal2** share the same data type, **double**. Instead of specifying this data type value in each signal data structure, the

interface provides only an index value, 0, in the structure. "double" is described by entry 0 in the `rtDataTypeMap` array, which is referenced by both signals. Additionally, property values can be shared between signals, states, root-level inputs/outputs, and parameters, so states, root-level inputs/outputs, and parameters also might reference the `double` entry in the `rtDataTypeMap` array. This reuse of information reduces the memory size of the generated interface.

### Structure Arrays Generated in C API Files

As with data type, the interface maps other common properties (such as address, dimension, fixed-point scaling, and sample time) into separate structures and provides an index in the structure for the data item. For a complete list of structure definitions, refer to the file `matlabroot/rtw/c/src/rtw_capi.h`. This file also describes each member in a structure. The structure arrays generated in the `model_capi.c` (or `.cpp`) file are of structure types defined in the `rtw_capi.h` file. Here is a brief description of the structure arrays generated in `model_capi.c` (or `.cpp`):

- **rtBlockSignals** is an array of structures that contains information about global block output signals in the model. Each element in the array is of type `struct rtwC_API_Signals`. The members of this structure provide the signal name, block path, block port number, address, and indices to the data type, dimension, fixed-point, and sample-time structure arrays.
- **rtBlockParameters** is an array of structures that contains information about the tunable block parameters in the model by block name and parameter name. Each element in the array is of type `struct rtwC_API_BlockParameters`. The members of this structure provide the parameter name, block path, address, and indices to data type, dimension, and fixed-point structure arrays.
- **rtBlockStates** is an array of structures that contains information about discrete and continuous states in the model. Each element in the array is of type `struct rtwC_API_States`. The members of this structure provide the state name, block path, type (continuous or discrete), and indices to the address, data type, dimension, fixed-point, and sample-time structure arrays.
- **rtRootInputs** is an array of structures that contains information about root-level inputs in the model. Each element in the array is of type `struct rtwC_API_Signals`. The members of this structure provide the root-level input name, block path, block port number, address, and indices to the data type, dimension, fixed-point, and sample-time structure arrays.
- **rtRootOutputs** is an array of structures that contains information about root-level outputs in the model. Each element in the array is of type `struct`

`rtwC_API_Signals`. The members of this structure provide the root-level output name, block path, block port number, address, and indices to the data type, dimension, fixed-point, and sample-time structure arrays.

- **`rtModelParameters`** is an array of structures that contains information about workplace variables that one or more blocks or Stateflow charts in the model reference as block parameters. Each element in the array is of data type `rtwC_API_ModelParameters`. The members of this structure provide the variable name, address, and indices to data type, dimension, and fixed-point structure arrays.
- **`rtDataAddrMap`** is an array of base addresses of signals, states, root-level inputs/outputs, and parameters that appear in the `rtBlockSignals`, `rtBlockParameters`, `rtBlockStates`, and `rtModelParameters` arrays. Each element of the `rtDataAddrMap` array is a pointer to `void (void*)`.
- **`rtDataTypeMap`** is an array of structures that contains information about the various data types in the model. Each element of this array is of type `struct rtwC_API_DataTypeMap`. The members of this structure provide the data type name, size of the data type, and information on whether or not the data is complex.
- **`rtDimensionMap`** is an array of structures that contains information about the various data dimensions in the model. Each element of this array is of type `struct rtwC_API_DimensionMap`. The members of this structure provide information on the number of dimensions in the data, the orientation of the data (whether it is scalar, vector, or a matrix), and the actual dimensions of the data.
- **`rtFixPtMap`** is an array of structures that contains fixed-point information about the signals, states, root-level inputs/outputs, and parameters. Each element of this array is of type `struct rtwC_API_FixPtMap`. The members of this structure provide information about the data scaling, bias, exponent, and whether or not the fixed-point data is signed. If the model does not have fixed-point data (signal, state, root-level input/output, or parameter), the Simulink Coder software assigns NULL or zero values to the elements of the `rtFixPtMap` array.
- **`rtSampleTimeMap`** is an array of structures that contains sampling information about the global signals, states, and root-level inputs/outputs in the model. (This array does not contain information about parameters.) Each element of this array is of type `struct rtwC_API_SampleTimeMap`. The members of this structure provide information about the sample period, offset, and whether or not the data is frame-based or sample-based.

### Generate Example C API Files

Subtopics “C API Signals” on page 43-11, “C API States” on page 43-14, “C API Root-Level Inputs and Outputs” on page 43-15, and “C API Parameters” on page

43-16 discuss generated C API structures using the example model `rtwdemo_capi`. To generate code from the example model, do the following:

- 1 Open the model by clicking the `rtwdemo_capi` link above or by typing `rtwdemo_capi` on the MATLAB command line.
- 2 If you want to generate C API structures for root-level inputs/outputs in `rtwdemo_capi`, open the Configuration Parameters dialog box, go to the **Code Generation** > **Interface** pane, and select **Generate C API for: root-level I/O**.

---

**Note:** The setting of **Generate C API for: root-level I/O** must match between the top model and the referenced model. If you modify the option, save the top model and the referenced model to the same writable work folder.

---

- 3 Generate code for the model by double-clicking **Generate Code Using Simulink Coder**.

---

**Note:** The C API code examples in the next subtopics are generated with C as the target language.

---

This model has three global block output signals that will appear in C API generated code:

- `top_sig1`, which is a test point at the output of the Gain1 block in the top model
- `sig2_eg`, which appears in the top model and is defined in the base workspace as a `Simulink.Signal` object having storage class `ExportedGlobal`
- `bot_sig1`, which appears in the referenced model `rtwdemo_capi_bot` and is defined as a `Simulink.Signal` object having storage class `SimulinkGlobal`

The model also has two discrete states that will appear in the C API generated code:

- `top_state`, which is defined for the Delay1 block in the top model
- `bot_state`, which is defined for the Discrete Filter block in the referenced model

The model has root-level inputs/outputs that will appear in the C API generated code if you select the option **Generate C API for: root-level I/O**:

- Four root-level inputs, `In1` through `In4`
- Six root-level outputs, `Out1` through `Out6`

Additionally, the model has five global block parameters that will appear in C API generated code:

- Kp (top model Gain1 block and referenced model Gain2 block share)
- Ki (referenced model Gain3 block)
- p1 (lookup table lu1d)
- p2 (lookup table lu2d)
- p3 (lookup table lu3d)

### C API Signals

The `rtwCAPI_Signals` structure captures signal information including the signal name, address, block path, output port number, data type information, dimensions information, fixed-point information, and sample-time information.

Here is the section of code in `rtwdemo_capi_capi.c` that provides information on C API signals for the top model in `rtwdemo_capi`:

```
/* Block output signal information */
static const rtwCAPI_Signals rtBlockSignals[] = {
 /* addrMapIndex, sysNum, blockPath,
 * signalName, portNumber, dataTypeIndex, dimIndex, fxpIndex, sTimeIndex
 */
 { 0, 0, "rtwdemo_capi/Gain1",
 "top_sig1", 0, 0, 0, 0, 0 },

 { 1, 0, "rtwdemo_capi/lu2d",
 "sig2_eg", 0, 0, 1, 0, 0 },

 {
 0, 0, (NULL), (NULL), 0, 0, 0, 0, 0
 }
};
```

**Note** To better understand the code, read the comments in the file. For example, notice the comment that begins on the third line in the preceding code. This comment lists the members of the `rtwCAPI_Signals` structure, in order. This tells you the order in which the assigned values for each member appear for a signal. In this example, the comment tells you that `signalName` is the fourth member of the structure. The following lines describe the first signal:

```
{ 0, 0, "rtwdemo_capi/Gain1",
 "top_sig1", 0, 0, 0, 0, 0 },
```

From these lines you infer that the name of the first signal is `top_sig1`.

Each array element, except the last, describes one output port for a block signal. The final array element is a sentinel, with all elements set to null values. For example, examine the second signal, described by the following code:

```
{ 1, 0, "rtwdemo_capi/lu2d",
 "sig2_eg", 0, 0, 1, 0, 0 },
```

This signal, named `sig2_eg`, is the output signal of the first port of the block `rtwdemo_capi/lu2d`. (This port is the first port because the zero-based index for `portNumber` displayed on the second line is assigned the value 0.)

The address of this signal is given by `addrMapIndex`, which, in this example, is displayed on the first line as 1. This provides an index into the `rtDataAddrMap` array, found later in `rtwdemo_capi_capi.c`:

```
/* Declare Data Addresses statically */
static void* rtDataAddrMap[] = {
 &rtwdemo_capi_B.top_sig1, /* 0: Signal */
 &sig2_eg[0], /* 1: Signal */
 &rtwdemo_capi_DWork.top_state, /* 2: Discrete State */
 &rtP_Ki, /* 3: Model Parameter */
 &rtP_Kp, /* 4: Model Parameter */
 &rtP_p1[0], /* 5: Model Parameter */
 &rtP_p2[0], /* 6: Model Parameter */
 &rtP_p3[0], /* 7: Model Parameter */
};
```

The index of 1 points to the second element in the `rtDataAddrMap` array. From the `rtDataAddrMap` array, you can infer that the address of this signal is `&sig2_eg[0]`.

This level of indirection supports multiple code instances of the same model. For multiple instances, the signal information remains constant, except for the address. In this case, the model is a single instance. Therefore, the `rtDataAddrMap` is declared statically. If you choose to generate reusable code, an initialize function is generated that initializes the addresses dynamically per instance. (For details on generating reusable code, see “Entry-Point Functions and Scheduling” and, in the Embedded Coder documentation, “Set Up Support for Code Reuse” on page 30-10.)

The `dataTypeIndex` provides an index into the `rtDataTypeMap` array, found later in `rtwdemo_capi_capi.c`, indicating the data type of the signal:

```
/* Data Type Map - use dataTypeMapIndex to access this structure */
static const rtwCAPI_DataTypeMap rtDataTypeMap[] = {
 /* cName, mwName, numElements, elemMapIndex, dataSize, slDataId, *
 * isComplex, isPointer */
 { "double", "real_T", 0, 0, sizeof(real_T), SS_DOUBLE, 0, 0 }
};
```

Because the index is 0 for `sig2_eg`, the index points to the first structure element in the array. You can infer that the data type of the signal is `double`. The value of `isComplex` is 0, indicating that the signal is not complex. Rather than providing the data type information directly in the `rtwCAPI_Signals` structure, a level of indirection is introduced. The indirection allows multiple signals that share the same data type to point to one map structure, saving memory for each signal.

The `dimIndex` (dimensions index) provides an index into the `rtDimensionMap` array, found later in `rtwdemo_capi_capi.c`, indicating the dimensions of the signal. Because this index is 1 for `sig2_eg`, the index points to the second element in the `rtDimensionMap` array:

```
/* Dimension Map - use dimensionMapIndex to access elements of ths structure*/
static const rtwCAPI_DimensionMap rtDimensionMap[] = {
 /* dataOrientation, dimArrayIndex, numDims, vardimsIndex */
 { rtwCAPI_SCALAR, 0, 2, 0 },

 { rtwCAPI_VECTOR, 2, 2, 0 },
 ...
};
```

From this structure, you can infer that this is a nonscalar signal having a dimension of 2. The `dimArrayIndex` value, 2, provides an index into `rtDimensionArray`, found later in `rtwdemo_capi_capi.c`:

```
/* Dimension Array- use dimArrayIndex to access elements of this array */
static const uint_T rtDimensionArray[] = {
 1, /* 0 */
 1, /* 1 */
 2, /* 2 */
 ...
};
```

The `fxpIndex` (fixed-point index) provides an index into the `rtFixPtMap` array, found later in `rtwdemo_capi_capi.c`, indicating fixed-point information about the signal. Your code can use the scaling information to compute the real-world value of the signal, using the equation  $V = SQ + B$ , where  $V$  is “real-world” (that is, base-10) value,  $S$  is user-specified slope,  $Q$  is “quantized fixed-point value” or “stored integer,” and  $B$  is user-specified bias. (For details, see “Scaling” in the Fixed-Point Designer documentation.)

Because this index is 0 for `sig2_eg`, the signal does not have fixed-point information. A fixed-point map index of zero means that the signal does not have fixed-point information.

The `sTimeIndex` (sample-time index) provides the index to the `rtSampleTimeMap` array, found later in `rtwdemo_capi_capi.c`, indicating task information about the

signal. If you log multirate signals or conditionally executed signals, the sampling information can be useful.

---

**Note:** `model_capi.c` (or `.cpp`) includes `rtw_capi.h`. A source file that references the `rtBlockSignals` array also must include `rtw_capi.h`.

---

### C API States

The `rtwCAPI_States` structure captures state information including the state name, address, block path, type (continuous or discrete), data type information, dimensions information, fixed-point information, and sample-time information.

Here is the section of code in `rtwdemo_capi_capi.c` that provides information on C API states for the top model in `rtwdemo_capi`:

```
/* Block states information */
static const rtwCAPI_States rtBlockStates[] = {
 /* addrMapIndex, contStateStartIndex, blockPath,
 * stateName, pathAlias, dWorkIndex, dataTypeIndex, dimIndex,
 * fixPtIdx, sTimeIndex, isContinuous
 */
 { 2, -1, "rtwdemo_capi/Delay1",
 "top_state", "", 0, 0, 0, 0, 0, 0 },

 {
 0, -1, (NULL), (NULL), (NULL), 0, 0, 0, 0, 0, 0
 }
};
```

Each array element, except the last, describes a state in the model. The final array element is a sentinel, with all elements set to null values. In this example, the C API code for the top model displays one state:

```
{ 2, -1, "rtwdemo_capi/Delay1",
 "top_state", "", 0, 0, 0, 0, 0, 0 },
```

This state, named `top_state`, is defined for the block `rtwdemo_capi/Delay1`. The value of `isContinuous` is zero, indicating that the state is discrete rather than continuous. The other fields correspond to the like-named signal equivalents described in “C API Signals” on page 43-11, as follows:

- The address of the signal is given by `addrMapIndex`, which, in this example, is 2. This is an index into the `rtDataAddrMap` array, found later in

`rtwdemo_capi_capi.c`. Because the index is zero based, 2 corresponds to the third element in `rtDataAddrMap`, which is `&rtwdemo_capi_DWork.top_state`.

- The `dataTypeIndex` provides an index into the `rtDataTypeMap` array, found later in `rtwdemo_capi_capi.c`, indicating the data type of the parameter. The value 0 corresponds to a double, noncomplex parameter.
- The `dimIndex` (dimensions index) provides an index into the `rtDimensionMap` array, found later in `rtwdemo_capi_capi.c`. The value 0 corresponds to the first entry, which is `{ rtwCAPI_SCALAR, 0, 2, 0 }`.
- The `fixPtIndex` (fixed-point index) provides an index into the `rtFixPtMap` array, found later in `rtwdemo_capi_capi.c`, indicating fixed-point information about the parameter. As with the corresponding signal attribute, a fixed-point map index of zero means that the parameter does not have fixed-point information.

## C API Root-Level Inputs and Outputs

The `rtwCAPI_Signals` structure captures root-level input/output information including the input/output name, address, block path, port number, data type information, dimensions information, fixed-point information, and sample-time information. (This structure also is used for block output signals, as previously described in “C API Signals” on page 43-11.)

Here is the section of code in `rtwdemo_capi_capi.c` that provides information on C API root-level inputs/outputs for the top model in `rtwdemo_capi`:

```
/* Root Inputs information */
static const rtwCAPI_Signals rtRootInputs[] = {
 /* addrMapIndex, sysNum, blockPath,
 * signalName, portNumber, dataTypeIndex, dimIndex, fixpIndex, sTimeIndex
 */
 { 3, 0, "rtwdemo_capi/In1",
 "", 1, 0, 0, 0, 0, 0 },

 { 4, 0, "rtwdemo_capi/In2",
 "", 2, 0, 0, 0, 0, 0 },

 { 5, 0, "rtwdemo_capi/In3",
 "", 3, 0, 0, 0, 0, 0 },

 { 6, 0, "rtwdemo_capi/In4",
 "", 4, 0, 0, 0, 0, 0 },

 {
 0, 0, (NULL), (NULL), 0, 0, 0, 0, 0, 0
 }
};
```

```

/* Root Outputs information */
static const rtwCAPI_Signals rtRootOutputs[] = {
/* addrMapIndex, sysNum, blockPath,
 * signalName, portNumber, dataTypeIndex, dimIndex, fxpIndex, sTimeIndex
 */
{ 7, 0, "rtwdemo_capi/Out1",
 "", 1, 0, 0, 0, 0 },

{ 8, 0, "rtwdemo_capi/Out2",
 "", 2, 0, 0, 0, 0 },

{ 9, 0, "rtwdemo_capi/Out3",
 "", 3, 0, 0, 0, 0 },

{ 10, 0, "rtwdemo_capi/Out4",
 "", 4, 0, 0, 0, 0 },

{ 11, 0, "rtwdemo_capi/Out5",
 "sig2_eg", 5, 0, 1, 0, 0 },

{ 12, 0, "rtwdemo_capi/Out6",
 "", 6, 0, 1, 0, 0 },

{
 0, 0, (NULL), (NULL), 0, 0, 0, 0, 0
}
};

```

For information about interpreting the values in the `rtwCAPI_Signals` structure, see the previous section “C API Signals” on page 43-11.

### C API Parameters

The `rtwCAPI_BlockParameters` and `rtwCAPI_ModelParameters` structures capture parameter information including the parameter name, block path (for block parameters), address, data type information, dimensions information, and fixed-point information.

The `rtModelParameters` array contains entries for workspace variables that are referenced as tunable Simulink block parameters or Stateflow data of machine scope. For example, tunable parameters include `Simulink.Parameter` objects that use a storage class other than `Auto`. The Simulink Coder software assigns its elements only `NULL` or zero values in the absence of such data.

The setting that you choose for **Configuration Parameters > Optimization > Signals and Parameters > Default parameter behavior** determines how information is generated into the `rtBlockParameters` array in `model_capi.c` (or `.cpp`).

- If you set **Default parameter behavior** to `Tunable`, the `rtBlockParameters` array contains an entry for every modifiable parameter of every block in the model.

However, if you use a MATLAB variable or a tunable parameter to specify a block parameter, the block parameter does not appear in `rtBlockParameters`. Instead, the variable or tunable parameter appears in `rtModelParameters`.

- If you set **Default parameter behavior** to **Inlined**, the `rtBlockParameters` array is empty. The Simulink Coder software assigns its elements only `NULL` or zero values.

The last member of each array is a sentinel, with all elements set to null values.

Here is the `rtBlockParameters` array that is generated by default in `rtwdemo_capi_capi.c`:

```
/* Individual block tuning is not valid when inline parameters is *
 * selected. An empty map is produced to provide a consistent *
 * interface independent of inlining parameters. *
 */
static const rtwCAPI_BlockParameters rtBlockParameters[] = {
 /* addrMapIndex, blockPath,
 * paramName, dataTypeIndex, dimIndex, fixPtIdx
 */
 {
 0, (NULL), (NULL), 0, 0, 0
 }
};
```

In this example, only the final, sentinel array element is generated, with all members of the structure `rtwCAPI_BlockParameters` set to `NULL` and zero values. This is because **Default parameter behavior** is set to **Inlined** by default for the `rtwdemo_capi` example model. If you set **Default parameter behavior** to **Tunable**, the block parameters are generated in the `rtwCAPI_BlockParameters` structure. However, MATLAB variables and tunable parameters appear in the `rtwCAPI_ModelParameters` structure.

Here is the `rtModelParameters` array that is generated by default in `rtwdemo_capi_capi.c`:

```
/* Tunable variable parameters */
static const rtwCAPI_ModelParameters rtModelParameters[] = {
 /* addrMapIndex, varName, dataTypeIndex, dimIndex, fixPtIndex */
 { 2, TARGET_STRING("Ki"), 0, 0, 0 },

 { 3, TARGET_STRING("Kp"), 0, 0, 0 },

 { 4, TARGET_STRING("p1"), 0, 2, 0 },

 { 5, TARGET_STRING("p2"), 0, 3, 0 },
};
```

```
{ 6, TARGET_STRING("p3"), 0, 4, 0 },
{ 0, (NULL), 0, 0, 0 }
};
```

In this example, the `rtModelParameters` array contains entries for each variable that is referenced as a tunable Simulink block parameter.

For example, the `varName` (variable name) of the fourth parameter is `p2`. The other fields correspond to the like-named signal equivalents described in “C API Signals” on page 43-11, as follows:

- The address of the fourth parameter is given by `addrMapIndex`, which, in this example, is 5. This is an index into the `rtDataAddrMap` array, found later in `rtwdemo_capi_capi.c`. Because the index is zero based, 5 corresponds to the sixth element in `rtDataAddrMap`, which is `rtP_p2`.
- The `dataTypeIndex` provides an index into the `rtDataTypeMap` array, found later in `rtwdemo_capi_capi.c`, indicating the data type of the parameter. The value 0 corresponds to a double, noncomplex parameter.
- The `dimIndex` (dimensions index) provides an index into the `rtDimensionMap` array, found later in `rtwdemo_capi_capi.c`. The value 3 corresponds to the fourth entry, which is `{ rtwCAPI_MATRIX_COL_MAJOR, 6, 2, 0 }`.
- The `fixPtIndex` (fixed-point index) provides an index into the `rtFixPtMap` array, found later in `rtwdemo_capi_capi.c`, indicating fixed-point information about the parameter. As with the corresponding signal attribute, a fixed-point map index of zero means that the parameter does not have fixed-point information.

For more information about tunable parameter storage in the generated code, see “Block Parameter Representation in the Generated Code”.

### Map C API Data Structures to `rtModel`

The real-time model data structure encapsulates model data and associated information that describes the model fully. When you select the C API feature and generate code, the Simulink Coder code generator adds another member to the real-time model data structure generated in `model.h`:

```
/*
 * DataMapInfo:
 * The following substructure contains information regarding
 * structures generated in the model's C API.
```

```

*/
struct {
 rtwCAPI_ModelMappingInfo mmi;
} DataMapInfo;

```

This member defines `mmi` (for model mapping information) of type `struct rtwCAPI_ModelMappingInfo`. The structure is located in `matlabroot/rtw/c/src/rtw_modelmap.h`. The `mmi` substructure defines the interface between the model and the C API files. More specifically, members of `mmi` map the real-time model data structure to the structures in `model_capi.c` (or `.cpp`).

Initializing values of `mmi` members to the arrays accomplishes the mapping, as shown in Map Model to C API Arrays of Structures. Each member points to one of the arrays of structures in the generated C API file. For example, the address of the `rtBlockSignals` array of structures is allocated to the first member of the `mmi` substructure in `model.c` (or `.cpp`), using the following code in the `rtw_modelmap.h` file:

```

/* signals */
struct {
 rtwCAPI_Signals const *signals; /* Signals Array */
 uint_T numSignals; /* Num Signals */
 rtwCAPI_Signals const *rootInputs; /* Root Inputs array */
 uint_T numRootInputs; /* Num Root Inputs */
 rtwCAPI_Signals const *rootOutputs; /* Root Outputs array */
 uint_T numRootOutputs; /* Num Root Outputs */
} Signals;

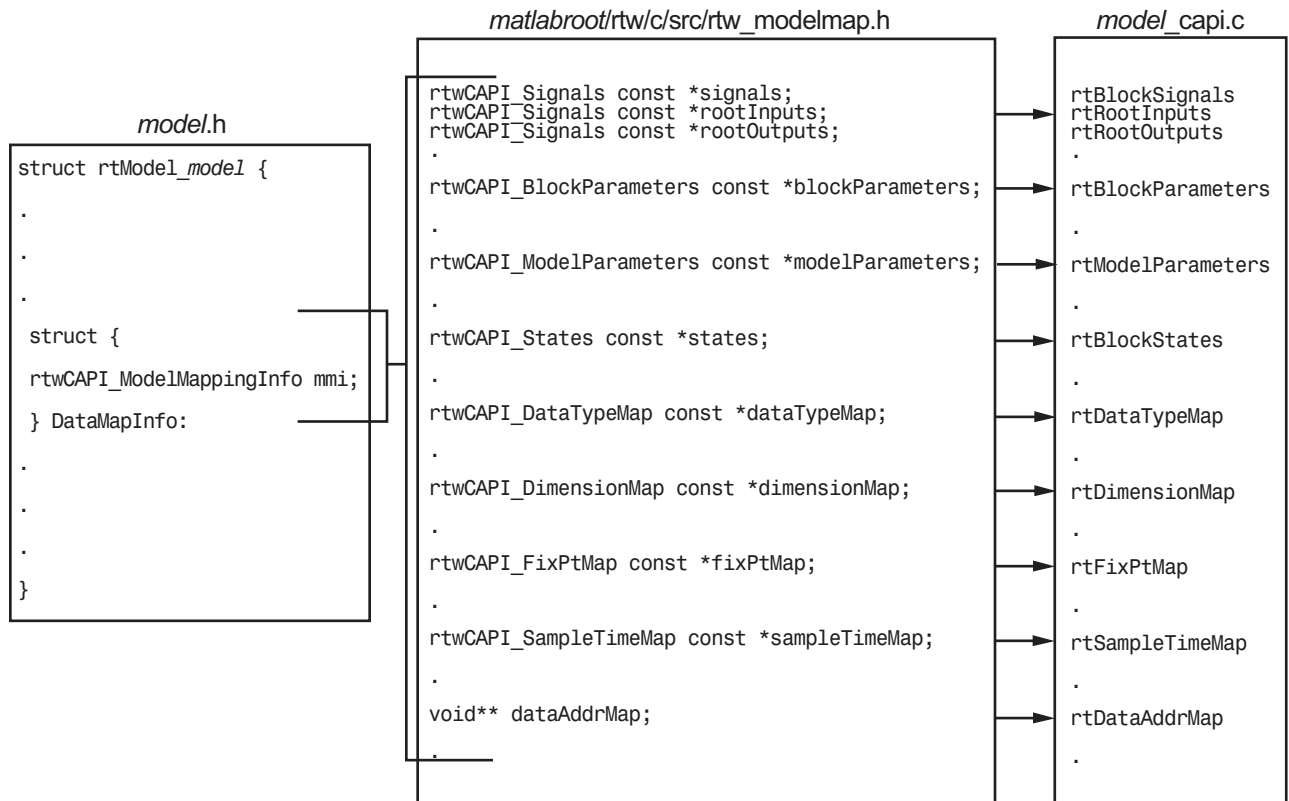

```

The model initialize function in `model.c` (or `.cpp`) performs the initializing by calling the C API initialize function. For example, the following code is generated in the model initialize function for example model `rtwdemo_capi`:

```

/* Initialize DataMapInfo substructure containing ModelMap for C API */
rtwdemo_capi_InitializeDataMapInfo(rtwdemo_capi_M);

```

### Map Model to C API Arrays of Structures

**Note:** This figure lists the arrays in the order that their structures appear in `rtw_modelmap.h`, which differs slightly from their generated order in `model_capi.c`.

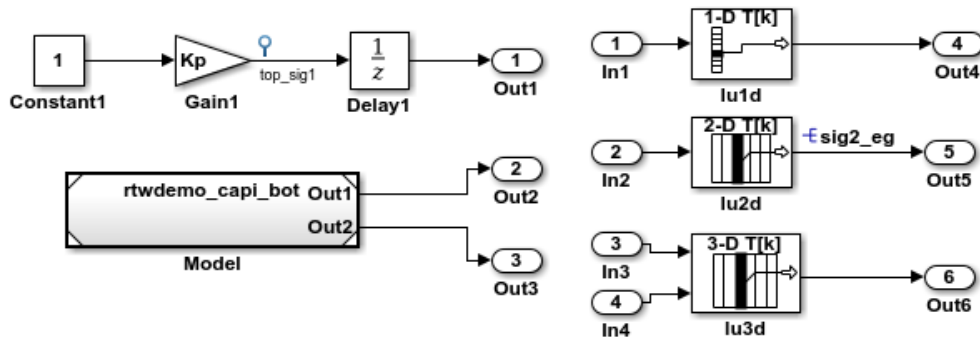

## Generate C API Data Definition File for Exchanging Data with a Target System

This model illustrates the target-based C API for interfacing signals, parameters, and states in the generated code.

## Open Example Model

Open the example model `rtwdemo_capi`.

```
open_system('rtwdemo_capi');
```

This model illustrates the target-based C API for interfacing signals, parameters and states in the generated code. The C API is useful for real-time interaction with the data, without having to stop execution or recompile the generated code. Typically, a client/server protocol is set up from a host to a target using serial, TCP/IP, or dual-port memory connection. The purpose of this example is not the client/server protocol. Rather, this model shows the necessary data interface required by the C client/server programs.

You can enable the C API by selecting one or more C API options on the "Code Generation > Interface" pane of the Configuration Parameters dialog box. Any signal or parameter or state with an addressable storage class is placed in the C API data structure in `<model>_capi.c`. Note that signals, states and parameters in the referenced model can be accessed using C-API. So make sure that C-API is enabled for the referenced model.

Copyright 1994-2012 The MathWorks, Inc.

The C API is useful for real-time interaction with application data, without having to stop execution or recompile the generated code. Typically, a client/server protocol is set up from a host to a target using serial, TCP/IP, or dual-port memory connection. The

purpose of this example is not the client/server protocol. Rather, this model shows the necessary data interface required by the C client/server programs.

You enable the C API by selecting one or more C API options on the **Code Generation > Interface** pane of the Configuration Parameters dialog box. Any signal or parameter or state with an addressable storage class is placed in the C API data structure in *model\_capi.c*. Note that signals, states, and parameters in the referenced model can be accessed using C API. So make sure that C API is enabled for the referenced model.

## C API Limitations

The C API feature has the following limitations.

- The C API does not support the following values for the **CodeFormat** TLC variable:
  - **S-Function**
  - **Accelerator\_S-Function** (for accelerated simulation)
- For ERT-based targets, the C API requires that support for floating-point code be enabled.
- Local block output signals are not supported.
- Local Stateflow parameters are not supported.
- The following custom storage class objects are not supported:
  - Objects without the package **csc\_registration** file
  - Grouped custom storage classes
  - Objects defined by using macros
  - **BitField** objects
  - **FileScope** objects
- Customized data placement is disabled when you are using the C API. The interface looks for global data declaration in *model.h* and *model\_private.h*. Declarations placed in any other file by customized data placement result in code that does not compile.

---

**Note** Custom Storage Class objects work in code generation, only if you use the ERT target and clear the **Ignore custom storage classes** check box in the Configuration Parameters dialog box.

## Use C API to Access Model Signals and States

This example helps you get started writing application code to interact with model signals and states. To get started writing application code to interact with model parameters, see “Use C API to Access Model Parameters” on page 43-30.

The C API provides you with the flexibility of writing your own application code to interact with model signals, states, root-level inputs/outputs, and parameters. Your target-based application code is compiled with the Simulink Coder generated code into an executable. The target-based application code accesses the C API structure arrays in *model\_capi.c* (or *.cpp*). You might have host-based code that interacts with your target-based application code. Or, you might have other target-based code that interacts with your target-based application code. The files *rtw\_modelmap.h* and *rtw\_capi.h*, located in *matlabroot/rtw/c/src* (open), provide macros for accessing the structures in these arrays and their members.

Here is an example application that logs global signals and states in a model to a text file. This code is intended as a starting point for accessing signal and state addresses. You can extend the code to perform signal logging and monitoring, state logging and monitoring, or both.

This example uses the following macro and function interfaces:

- `rtmGetDataMapInfo` macro

Accesses the model mapping information (MMI) substructure of the real-time model structure. In the following macro call, `rtM` is the pointer to the real-time model structure in *model.c* (or *.cpp*):

```
rtwCAPI_ModelMappingInfo* mmi = &(rtmGetDataMapInfo(rtM).mmi);
```

- `rtmGetTPtr` macro

Accesses the absolute time information for the base rate from the timing substructure of the real-time model structure. In the following macro call, `rtM` is the pointer to the real-time model structure in *model.c* (or *.cpp*):

```
rtmGetTPtr(rtM)
```

- Custom functions `capi_StartLogging`, `capi_UpdateLogging`, and `capi_TerminateLogging`, provided via the files *rtwdemo\_capi\_datalog.h* and *rtwdemo\_capi\_datalog.c*. These files are located in *matlabroot/toolbox/rtw/rtwdemos* (open).

- `capi_StartLogging` initializes signal and state logging.
- `capi_UpdateLogging` logs a signal and state value at each time step.
- `capi_TerminateLogging` terminates signal and state logging and writes the logged values to a text file.

You can integrate these custom functions into generated model code using one or more of the following methods:

- **Code Generation > Custom Code** pane of the Configuration Parameters dialog box
- Custom Code library blocks
- TLC custom code functions

This tutorial uses the **Code Generation > Custom Code** pane and the System Outputs block from the Custom Code library to insert calls to the custom functions into `model.c` (or `.cpp`), as follows:

- `capi_StartLogging` is called in the `model_initialize` function.
- `capi_UpdateLogging` is called in the `model_step` function.
- `capi_TerminateLogging` is called in the `model_terminate` function.

The following excerpts of generated code from `model.c` (rearranged to reflect their order of execution) show how the function interfaces are used.

```
void rtwdemo_capi_initialize(void)
{
...
/* user code (Initialize function Body) */

/* C API Custom Logging Function: Start Signal and State logging via C API.
 * capi_StartLogging: Function prototype in rtwdemo_capi_datalog.h
 */
{
rtwCAPI_ModelMappingInfo *MMI = &(rtmGetDataMapInfo(rtwdemo_capi_M).mmi);
printf("*** Started state/signal logging via C API **\n");
capi_StartLogging(MMI, MAX_DATA_POINTS);
}
...
}
...
/* Model step function */
void rtwdemo_capi_step(void)
{
...
/* user code (Output function Trailer) */

/* System '<Root>' */
```

```

/* C API Custom Logging Function: Update Signal and State logging buffers.
 * capi_UpdateLogging: Function prototype in rtwdemo_capi_datalog.h
 */
{
 rtwCAPI_ModelMappingInfo *MMI = &(rtmGetDataMapInfo(rtwdemo_capi_M).mmi);
 capi_UpdateLogging(MMI, rtmGetTPtr(rtwdemo_capi_M));
}
...
}
...
/* Model terminate function */
void rtwdemo_capi_terminate(void)
{
 /* user code (Terminate function Body) */

 /* C API Custom Logging Function: Dump Signal and State buffers into a text file.
 * capi_TerminateLogging: Function prototype in rtwdemo_capi_datalog.h
 */
 {
 capi_TerminateLogging("rtwdemo_capi_ModelLog.txt");
 printf("** Finished state/signal logging. Created rtwdemo_capi_ModelLog.txt **\n");
 }
}

```

The following procedure illustrates how you can use the C API macro and function interfaces to log global signals and states in a model to a text file.

- 1 At the MATLAB command line, enter `rtwdemo_capi` to open the example model.
- 2 Save the top model `rtwdemo_capi` and the referenced model `rtwdemo_capi_bot` to the same writable work folder.
- 3 Open the Configuration Parameters dialog box.
- 4 If you are licensed for Embedded Coder software and you want to use the `ert.tlc` target instead of the default `grt.tlc`, go to the **Code Generation** pane and use the **System target file** field to select an `ert.tlc` target. Make sure that you also select `ert.tlc` for the referenced model `rtwdemo_capi_bot`.
- 5 In the top model, go to the **Code Generation > Interface** pane.
  - a In the **Data exchange interface** subgroup, verify that the model options **Generate C API for: signals** and **Generate C API for: states** are selected. This example also leaves **Generate C API for: parameters** selected.
  - b If you are using the `ert.tlc` system target file, verify that the option **Support: complex numbers** is selected.
  - c Click the **All Parameters** tab, and select the **MAT-file logging** option.
  - d Click **Apply**.
  - e Update configuration parameter settings in the referenced model, `rtwdemo_capi_bot`, to match changes you made in the top model.

- 6 Use the **Custom Code** pane to embed your custom application code in the generated code. Select the **Custom Code** pane, and then click **Include directories**. The **Include directories** input field is displayed.
- 7 In the **Include directories** field, type `matlabroot/toolbox/rtw/rtwdemos`, where `matlabroot` represents the root of your MATLAB installation folder. (If you are specifying a Windows path that contains a space, place the text inside double quotes.)
- 8 In the **Additional Build Information** subpane, click **Source files**, and type `rtwdemo_capi_datalog.c`.

- 9 In the **Include custom C code in generated** subpane, click **Source file**, and type or copy and paste the following include statement:

```
#include "rtwdemo_capi_datalog.h"
```

- 10 In the **Initialize function** field, type or copy and paste the following application code:

```
/* C API Custom Logging Function: Start Signal and State logging via C API.
 * capi_StartLogging: Function prototype in rtwdemo_capi_datalog.h
 */
{
 rtwCAPI_ModelMappingInfo *MMI = &(rtmGetDataMapInfo(rtwdemo_capi_M).mmi);
 printf("*** Started state/signal logging via C API **\n");
 capi_StartLogging(MMI, MAX_DATA_POINTS);
}
```

---

**Note:** If you renamed the top model `rtwdemo_capi`, update the name `rtwdemo_capi_M` in the application code to reflect the new model name.

---

- 11 In the **Terminate function** field, type or copy and paste the following application code:

```
/* C API Custom Logging Function: Dump Signal and State buffers into a text file.
 * capi_TerminateLogging: Function prototype in rtwdemo_capi_datalog.h
 */
```

```

{
capi_TerminateLogging("rtwdemo_capi_ModelLog.txt");
printf("** Finished state/signal logging. Created rtwdemo_capi_ModelLog.txt **\n");
}

```

Click **Apply**.

- 12 In the MATLAB Command Window, enter `custcode` to open the Simulink Coder Custom Code library. At the top level of the `rtwdemo_capi` model, add a System Outputs block.
- 13 Double-click the System Outputs block to open the System Outputs Function Custom Code dialog box. In the **System Outputs Function Exit Code** field, type or copy and paste the following application code:

```

/* C API Custom Logging Function: Update Signal and State logging buffers.
 * capi_UpdateLogging: Function prototype in rtwdemo_capi_dataLog.h
 */
{
 rtwCAPI_ModelMappingInfo *MMI = &(rtmGetDataMapInfo(rtwdemo_capi_M).mmi);
 capi_UpdateLogging(MMI, rtmGetTPtr(rtwdemo_capi_M));
}

```

---

**Note:** If you renamed the top model `rtwdemo_capi`, update two instances of the name `rtwdemo_capi_M` in the application code to reflect the new model name.

---

Click **OK**.

- 14 On the **Code Generation** pane, verify that the **Generate code only** check box is *cleared*.

Press **Ctrl+B** to build the model and generate an executable file. For example, on a Windows system, the build generates the executable file `rtwdemo_capi.exe` in your current working folder.

- 15 In the MATLAB Command Window, enter the command `!rtwdemo_capi` to run the executable file. During execution, signals and states are logged using the C API and then written to the text file `rtwdemo_capi_ModelLog.txt` in your current working folder.

```

>> !rtwdemo_capi

** starting the model **
** Started state/signal logging via C API **
** Logging 2 signal(s) and 1 state(s). In this demo, only scalar named
 signals/states are logged **
** Finished state/signal logging. Created rtwdemo_capi_ModelLog.txt **

```

- 16** Examine the text file in the MATLAB editor or other text editor. Here is an excerpt of the signal and state logging output.

```

## Use C API to Access Model Parameters

This example helps you get started writing application code to interact with model parameters. To get started writing application code to interact with model signals and states, see “Use C API to Access Model Signals and States” on page 43-24.

The C API provides you with the flexibility of writing your own application code to interact with model signals, states, root-level inputs/outputs, and parameters. Your target-based application code is compiled with the Simulink Coder generated code into an executable. The target-based application code accesses the C API structure arrays in *model\_capi.c* (or *.cpp*). You might have host-based code that interacts with your target-based application code. Or, you might have other target-based code that interacts with your target-based application code. The files *rtw\_modelmap.h* and *rtw\_capi.h*, located in *matlabroot/rtw/c/src* (open), provide macros for accessing the structures in these arrays and their members.

Here is an example application that prints the parameter values of tunable parameters in a model to the standard output. This code is intended as a starting point for accessing parameter addresses. You can extend the code to perform parameter tuning. The application:

- Uses the `rtmGetDataMapInfo` macro to access the mapping information in the `mmi` substructure of the real-time model structure

```
rtwCAPI_ModelMappingInfo* mmi = &(rtmGetDataMapInfo(rtM).mmi);
```

where `rtM` is the pointer to the real-time model structure in *model.c* (or *.cpp*).

- Uses `rtwCAPI_GetNumModelParameters` to get the number of model parameters in mapped C API:

```
uint_T nModelParams = rtwCAPI_GetNumModelParameters(mmi);
```

- Uses `rtwCAPI_GetModelParameters` to access the array of model parameter structures mapped in C API:

```
rtwCAPI_ModelParameters* capiModelParams = \
 rtwCAPI_GetModelParameters(mmi);
```

- Loops over the `capiModelParams` array to access individual parameter structures. A call to the function `capi_PrintModelParameter` displays the value of the parameter.

The example application code is provided below:

```

{
/* Get CAPI Mapping structure from Real-Time Model structure */
rtwCAPI_ModelMappingInfo* capiMap = \
&(rtmGetDataMapInfo(rtwdemo_capi_M).mmi);

/* Get number of Model Parameters from capiMap */
uint_T nModelParams = rtwCAPI_GetNumModelParameters(capiMap);
printf("Number of Model Parameters: %d\n", nModelParams);

/* If the model has Model Parameters, print them using the
application capi_PrintModelParameter */
if (nModelParams == 0) {
 printf("No Tunable Model Parameters in the model \n");
}
else {
 unsigned int idx;

 for (idx=0; idx < nModelParams; idx++) {
 /* call print utility function */
 capi_PrintModelParameter(capiMap, idx);
 }
}
}
}

```

The print utility function is located in *matlabroot/rtw/c/src/rtw\_capi\_examples.c*. This file contains utility functions for accessing the C API structures.

To become familiar with the example code, try building a model that displays the tunable block parameters and MATLAB variables. You can use *rtwdemo\_capi*, the C API example model. The following steps apply to both *grt.tlc* and *ert.tlc* targets, unless otherwise indicated.

- 1 At the MATLAB command line, enter *rtwdemo\_capi* to open the example model.
- 2 Save the top model *rtwdemo\_capi* and the referenced model *rtwdemo\_capi\_bot* to the same writable work folder.
- 3 If you are licensed for Embedded Coder software and you want to use the *ert.tlc* target instead of the default *grt.tlc*, go to the **Code Generation** pane of the Configuration Parameters dialog box and use the **System target file** field to select an *ert.tlc* target. Make sure that you also select *ert.tlc* for the referenced model *rtwdemo\_capi\_bot*.
- 4 Go to the **Code Generation > Interface** pane.

- a** In the **Data exchange interface** subgroup, verify that the model option **Generate C API for: parameters** is selected.
  - b** If you are using the `ert.tlc` system target file, verify that the option **Support: complex numbers** is selected.
  - c** Click the **All Parameters** tab, and select the **MAT-file logging** option.
  - d** Click **Apply**.
  - e** Update configuration parameter settings in the referenced model, `rtwdemo_capi_bot`, to match changes you made in the top model.
- 5** Use the **Custom Code** pane to embed your custom application code in the generated code. Select the **Custom Code** pane, and then click **Initialize function**. The **Initialize function** input field is displayed.
  - 6** In the **Initialize function** input field, type or copy and paste the example application code shown above step 1. This embeds the application code in the `model_initialize` function.

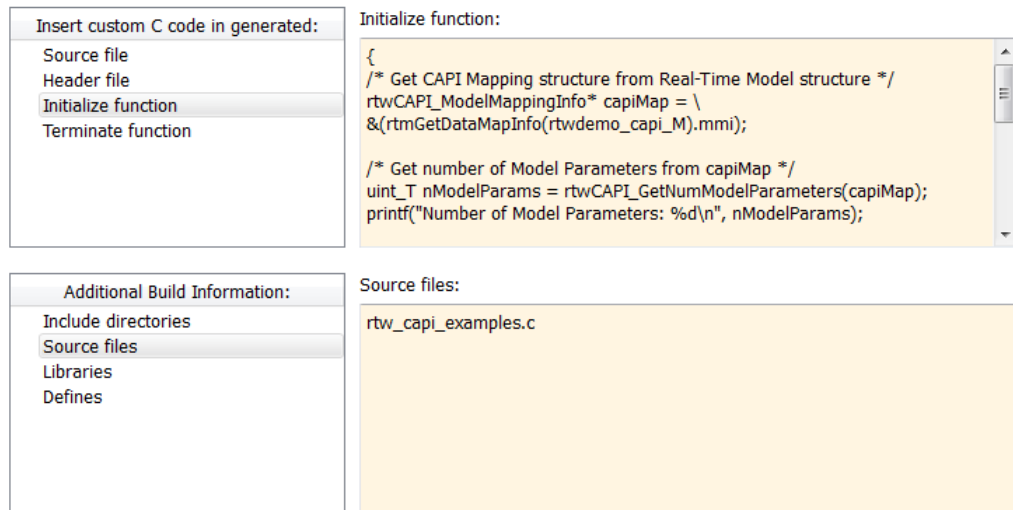

---

**Note:** If you renamed the top model `rtwdemo_capi`, update the name `rtwdemo_capi_M` in the application code to reflect the new model name.

---

- 7** Click **Include directories**, and type `matlabroot/rtw/c/src`, where *matlabroot* represents the root of your MATLAB installation folder. (If you are specifying a Windows path that contains a space, place the text inside double quotes.)
- 8** In the **Additional Build Information** subpane, click **Source files**, and type `rtw_capi_examples.c`.

Click **Apply**.

- On the **Code Generation** pane, verify that the **Generate code only** check box is *cleared*.

Press **Ctrl+B** to build the model and generate an executable file. For example, on a Windows system, the build generates the executable file `rtwdemo_capi.exe` in your current working folder.

- In the MATLAB Command Window, enter `!rtwdemo_capi` to run the executable file. Running the program displays parameter information in the Command Window.

```
>> !rtwdemo_capi

# ASAP2 Data Measurement and Calibration in Simulink Coder

---

## Export ASAP2 File for Data Measurement and Calibration

The ASAM MCD-2 MC standard, also known as ASAP2, is a data definition standard proposed by the Association for Standardization of Automation and Measuring Systems (ASAM). ASAP2 is a non-object-oriented description of the data used for measurement, calibration, and diagnostic systems. For more information on ASAM and the ASAM MCD-2 MC (ASAP2) standard, see the ASAM Web site at <http://www.asam.net>.

The Simulink Coder product lets you export an ASAP2 file containing information about your model during the code generation process.

You can run an interactive example of ASAP2 file generation. To open the example at the MATLAB command prompt, enter the following command:

```
rtwdemo_asap2
```

---

**Note:** Simulink Coder support for ASAP2 file generation is version-neutral. By default, the software generates ASAP2 version 1.31 format, but the generated model information is generally compatible with all ASAP2 versions. ASAP2 file generation also is neutral with respect to the specific needs of ASAP2 measurement and calibration tools. The software provides customization APIs that you can use to customize ASAP2 file generation to generate any ASAP2 version and to meet the specific needs of your ASAP2 tools.

---

“Targets Supporting ASAP2” on page 44-3

“Define ASAP2 Information” on page 44-3

“Generate an ASAP2 File” on page 44-9

“Structure of the ASAP2 File” on page 44-12

“Create a Host-Based ASAM-ASAP2 Data Definition File for Data Measurement and Calibration” on page 44-13

## What You Should Know

To make use of ASAP2 file generation, you should become familiar with the following topics:

- ASAM and the ASAP2 standard and terminology. See the ASAM Web site at <http://www.asam.net>.
- Simulink data objects. Data objects are used to supply information not contained in the model. For an overview, see “Data Objects”.
- Storage and representation of signals and parameters in generated code. See “Data Representation”.
- If you are licensed for Embedded Coder, see also the Embedded Coder topic “Data Representation”.

## Targets Supporting ASAP2

ASAP2 file generation is available to all Simulink Coder target configurations. You can select these target configurations from the System Target File Browser. For example,

- The **Generic Real-Time Target (grt.tlc)** lets you generate an ASAP2 file as part of the code generation and build process.
- The **Embedded Coder (ert.tlc)** target selections also lets you generate an ASAP2 file as part of the code generation and build process.
- The **ASAM-ASAP2 Data Definition Target (asap2.tlc)** lets you generate only an ASAP2 file, without building an executable.

Procedures for generating ASAP2 files by using these target configurations are given in “Generate an ASAP2 File” on page 44-9.

## Define ASAP2 Information

- “Define ASAP2 Information for Parameters and Signals” on page 44-3
- “Memory Address Attribute” on page 44-4
- “Automatic ECU Address Replacement for ASAP2 Files (Embedded Coder)” on page 44-6
- “Define ASAP2 Information for Lookup Tables” on page 44-7

### Define ASAP2 Information for Parameters and Signals

The ASAP2 file generation process requires information about parameters and signals in your model. Some of this information is contained in the model itself. You must supply the rest by using Simulink data objects and corresponding properties.

You can use built-in Simulink data objects to provide the information. For example, you can use `Simulink.Signal` objects to provide MEASUREMENT information and `Simulink.Parameter` objects to provide CHARACTERISTIC information. Also, you can use data objects from data classes that are derived from `Simulink.Signal` and `Simulink.Parameter` to provide the information. For details, see “Data Objects”.

The following table contains the minimum set of data attributes required for ASAP2 file generation. Some data attributes are defined in the model; others are supplied in the properties of objects. For attributes that are defined in `Simulink.Signal` or `Simulink.Parameter` objects, the table gives the associated property name.

Data Attribute	Defined In	Property Name
Name (symbol)	Data object	Inherited from the handle of the data object to which parameter or signal name resolves
Description	Data object	Description
Data type	Model	Not applicable
Scaling (if fixed-point data type)	Model	Data type (for signals)  Inherited from value (for parameters)
Minimum allowable value	Data object	Min
Maximum allowable value	Data object	Max
Unit	Data object	Unit
Memory address (optional)	Data object	MemoryAddress_ASAP2 (optional; see “Memory Address Attribute” on page 44-4.)

### Memory Address Attribute

If the memory address attribute is unknown before code generation, the code generator inserts ECU Address placeholder text in the generated ASAP2 file. You can substitute an actual address for the placeholder by postprocessing the generated file. See the file `matlabroot/toolbox/rtw/targets/asap2/asap2/asap2post.m` for an example. `asap2post.m` parses through the linker map file that you provide and replaces the

ECU Address placeholders in the ASAP2 file with the actual memory addresses. Since linker map files vary from compiler to compiler, you might need to modify the regular expression code in `asap2post.m` to match the format of the linker map you use.

---

**Note:** If Embedded Coder is licensed and installed on your system, and if you are generating ELF (Executable and Linkable Format) files for your embedded target, you can use the `rtw.asap2SetAddress` function to automate ECU address replacement. For more information, see “Automatic ECU Address Replacement for ASAP2 Files (Embedded Coder)” on page 44-6.

---

If the memory address attribute is known before code generation, it can be defined in the data object. By default, the `MemoryAddress_ASAP2` property does not exist in the `Simulink.Signal` or `Simulink.Parameter` data object classes. If you want to add the attribute, add a property called `MemoryAddress_ASAP2` to a custom class that is a subclass of the `Simulink` or `ASAP2` class. For information on subclassing Simulink data classes, see “Define Data Classes” in the Simulink documentation.

---

**Note** In previous releases, for ASAP2 file generation, you had to define objects explicitly as `ASAP2.Signal` and `ASAP2.Parameter`. This is no longer a limitation. As explained above, you can use built-in Simulink objects for generating an ASAP2 file. If you have been using an earlier release, you can continue to use the ASAP2 objects. If one of these ASAP2 objects was created in the previous release, and you use it in this release, the MATLAB Command Window displays a warning the first time the objects are loaded.

---

The following table indicates the Simulink object properties that have replaced the ASAP2 object properties of the previous release:

#### Differences Between ASAP2 and Simulink Parameter and Signal Object Properties

ASAP2 Object Properties (Previous)	Simulink Object Properties (Current)
<code>LONGIG_ASAP2</code>	Description
<code>PhysicalMin_ASAP2</code>	Min
<code>PhysicalMax_ASAP2</code>	Max
<code>Units_ASAP2</code>	Unit

### Automatic ECU Address Replacement for ASAP2 Files (Embedded Coder)

If Embedded Coder is licensed and installed on your system, and if you are generating ELF (Executable and Linkable Format) files for your embedded target, you can use the `rtw.asap2SetAddress` function to automate the replacement of `ECU Address` placeholder memory address values with actual addresses in the generated ASAP2 file.

If the memory address attribute is unknown before code generation, the code generator inserts `ECU Address` placeholder text in the generated ASAP2 file, as shown in the example below.

```
/begin CHARACTERISTIC
/* Name */ Ki
/* Long Identifier */ ""
/* Type */ VALUE
/* ECU Address */ 0x0
 /*ECU_Address@Ki@ */
```

To substitute actual addresses for the `ECU Address` placeholders, process the generated ASAP2 file using the `rtw.asap2SetAddress` function. The general syntax is as follows:

```
rtw.asap2SetAddress(ASAP2File, InfoFile)
```

where the arguments are character vectors specifying the name of the generated ASAP2 file and the name of the generated executable ELF file or DWARF debug information file for the model. When called, `rtw.asap2SetAddress` extracts the actual ECU address from the specified ELF or DWARF file and replaces the placeholder in the ASAP2 file with the actual address, for example:

```
/begin CHARACTERISTIC
/* Name */ Ki
/* Long Identifier */ ""
/* Type */ VALUE
/* ECU Address */ 0x40009E60
```

## Define ASAP2 Information for Lookup Tables

Simulink Coder software generates ASAP2 descriptions for lookup table data and its breakpoints. The software represents 1-D table data as **CURVE** information, 2-D table data as **MAP** information, and breakpoints as **AXIS\_DESCR** and **AXIS\_PTS** information. You can model lookup tables using one of the following Simulink Lookup Table blocks:

- Direct Lookup Table (n-D) — 1 and 2 dimensions
- Interpolation Using Prelookup — 1 and 2 dimensions
- 1-D Lookup Table
- 2-D Lookup Table
- n-D Lookup Table — 1 and 2 dimensions

The software supports the following types of lookup table breakpoints (axis points):

Breakpoint Type	Generates
Tunable and shared among multiple table axes (common axis)	COM_AXIS
Fixed and nontunable (fixed axis)	One of these variants of FIX_AXIS: <ul style="list-style-type: none"> <li>• FIX_AXIS_PAR if breakpoints are integers with equidistant spacing and the equidistant spacing is a power of two</li> <li>• FIX_AXIS_PAR_DIST if breakpoints are integers with equidistant spacing</li> <li>• FIX_AXIS_PAR_LIST if breakpoints are integers with non-equidistant spacing</li> </ul>
Tunable but not shared among multiple tables (standard axis)	STD_AXIS

When you configure the blocks for ASAP2 code generation:

- For table data, use a `Simulink.Parameter` data object with a non-`Auto` storage class.
- For tunable breakpoint data that is shared among multiple table axes (`COM_AXIS`), use a `Simulink.Parameter` data object with a non-`Auto` storage class.
- For fixed, nontunable breakpoint data (`FIX_AXIS`), use workspace variables or arrays specified in the block parameters dialog box. The breakpoints should be stored as integers in the code, so the data type should be a built-in integer type (`int8`, `int16`, `int32`, `uint8`, `uint16`, or `uint32`), a fixed-point data type, or an equivalent alias type.
- For tunable breakpoint data that is not shared among multiple tables (`STD_AXIS`):
  - 1 Create a `Simulink.Bus` object to define the `struct` packaging (names and order of the fields). The fields of the parameter structure must correspond to the lookup table data and each axis of the lookup table block. For example, in an n-D Lookup Table block with 2 dimensions, the structure must contain only three fields. This bus object describes the record layout for the lookup characteristic.
  - 2 Create a `Simulink.Parameter` object to represent a tunable parameter.
  - 3 Create table and axis values.
  - 4 Optionally, specify the **Units**, **Minimum**, and **Maximum** properties for the parameter object. The properties will be applied to table data only.

Here is an example of an n-D Lookup Table record generated into an ASAP2 file in Standard Axis format:

```
/begin CHARACTERISTIC
 /* Name */ STDAxisParam
 ...
 /* Record Layout */ Lookup1D_X_WORD_Y_FLOAT32_IEEE
 ...
 begin AXIS_DESCR
 /* Description of X-Axis Points */
 /* Axis Type */ STD_AXIS
 ...
 /end AXIS_DESCR
/end CHARACTERISTIC

/begin RECORD_LAYOUT Lookup1D_X_WORD_Y_FLOAT32_IEEE
 AXIS_PTS_X 1 WORD INDEX_INCR DIRECT
```

```
FNC_VALUES 2 FLOAT32_IEEE COLUMN_DIR DIRECT
/end RECORD_LAYOUT
```

---

**Note:** The example model `rtwdemo_asap2` illustrates ASAP2 file generation for Lookup Table blocks, including both tunable (COM\_AXIS) and fixed (FIX\_AXIS) lookup table breakpoints.

---

## Generate an ASAP2 File

- “About Generating ASAP2 Files” on page 44-9
- “Use GRT or ERT Target” on page 44-9
- “Use the ASAM-ASAP2 Data Definition Target” on page 44-10
- “Generate ASAP2 Files for Referenced Models” on page 44-11
- “Merge ASAP2 Files for Top and Referenced Models” on page 44-12

### About Generating ASAP2 Files

You can generate an ASAP2 file from your model in one of the following ways:

- Use the Generic Real-Time Target or a Embedded Coder target to generate an ASAP2 file as part of the code generation and build process.
- Use the ASAM-ASAP2 Data Definition Target to generate only an ASAP2 file, without building an executable.

This section discusses how to generate an ASAP2 file by using the targets that have built-in ASAP2 support. For an example, see the ASAP2 example model `rtwdemo_asap2`.

### Use GRT or ERT Target

The procedure for generating the ASAP2 data definition for a model using the Generic Real-Time Target or an Embedded Coder target is as follows:

- 1 Create the desired model. Use parameter names and signal labels to refer to corresponding CHARACTERISTIC records and MEASUREMENT records, respectively.
- 2 Create `Simulink.Parameter` and `Simulink.Signal` objects in the MATLAB workspace and reference them from parameters and signals in the model. A convenient way of creating multiple signal and parameter data objects is to use the Data Object Wizard. Alternatively, you can create data objects one at a time from

the MATLAB command line. For details on how to use the Data Object Wizard, see “Create Data Objects for a Model Using Data Object Wizard” in the Simulink documentation.

- 3 For each data object, configure the **Storage class** property to a setting other than **Auto**, **FileScope**, or **SimulinkGlobal**. This setting declares the data object as global in the generated code. For example, a storage class setting of **ExportedGlobal** configures the data object as unstructured global in the generated code.

---

**Note:** The data object is not represented in the ASAP2 file if any of the following conditions exist:

- You set the storage class to **Auto**, **FileScope**, or **SimulinkGlobal**.
- You set the storage class to **Custom** and custom storage class settings cause the code generator to generate a macro or non-addressable variable.

- 
- 4 Configure the remaining properties as desired for each data object.
  - 5 On the **Code Generation** pane, click **Browse** to open the System Target File Browser. In the browser, select `grt.tlc` or an ERT based target file and click **OK**.
  - 6 On the **Code Generation > Interface** pane, in the **Data exchange interface** subgroup, select **ASAP2 interface**.
  - 7 Select the **Generate code only** check box on the **Code Generation** pane.
  - 8 Click **Apply**.
  - 9 Press **Ctrl+B** to build the model.

The Simulink Coder code generator writes the ASAP2 file to the build folder. By default, the file is named `model.a2l`, where `model` is the name of the model. The ASAP2 setup file controls the ASAP2 file name. For details, see “Customize Generated ASAP2 File” on page 69-2.

### Use the ASAM-ASAP2 Data Definition Target

The procedure for generating the ASAP2 data definition for a model using the ASAM-ASAP2 Data Definition Target is as follows:

- 1 Create the desired model. Use parameter names and signal labels to refer to corresponding CHARACTERISTIC records and MEASUREMENT records, respectively.

- 2 Create `Simulink.Parameter` and `Simulink.Signal` objects in the MATLAB workspace and reference them from parameters and signals in the model. A convenient way of creating multiple signal and parameter data objects is to use the Data Object Wizard. Alternatively, you can create data objects one at a time from the MATLAB command line. For details on how to use the Data Object Wizard, see “Create Data Objects for a Model Using Data Object Wizard” in the Simulink documentation.
- 3 For each data object, configure the **Storage class** property to a setting other than `Auto`, `FileScope`, or `SimulinkGlobal`. This setting declares the data object as global in the generated code. For example, a storage class setting of `ExportedGlobal` configures the data object as unstructured global in the generated code.

---

**Note:** The data object is not represented in the ASAP2 file if any of the following conditions exist:

- You set the storage class to `Auto`, `FileScope`, or `SimulinkGlobal`.
- You set the storage class to `Custom` and custom storage class settings cause the code generator to generate a macro or non-addressable variable.

- 
- 4 Configure the remaining properties as desired for each data object.
  - 5 On the **Code Generation** pane, click **Browse** to open the System Target File Browser. In the browser, select `asap2.tlc` and click **OK**.
  - 6 Select the **Generate code only** check box on the **Code Generation** pane.
  - 7 Click **Apply**.
  - 8 Press **Ctrl+B**.

The Simulink Coder code generator writes the ASAP2 file to the build folder. By default, the file is named `model.a2l`, where `model` is the name of the model. The ASAP2 setup file controls the ASAP2 file name. For details, see “Customize Generated ASAP2 File” on page 69-2.

### Generate ASAP2 Files for Referenced Models

The build process can generate an ASAP2 file for each referenced model in a model reference hierarchy. In the generated ASAP2 file, MEASUREMENT records represent signals and states inside the referenced model.

To generate ASAP2 files for referenced models, select ASAP2 file generation for the top model and for each referenced model in the reference hierarchy. For example, if you are using the Generic Real-Time Target or an Embedded Coder target, follow the procedure described in “Use GRT or ERT Target” on page 44-9 for the top model and each referenced model.

### Merge ASAP2 Files for Top and Referenced Models

Use function `rtw.asap2MergeMdlRefs` to merge the ASAP2 files generated for top and referenced models. The function has the following syntax:

```
[status,info]=rtw.asap2MergeMdlRefs(topModelName,asap2FileName)
```

- `topModelName` is the name of the model containing one or more referenced models.
- `asap2FileName` is the name you specify for the merged ASAP2 file.
- *Optional*:: `status` returns false (logical 0) if the merge completes and true (logical 1) otherwise.
- *Optional*:: `info` returns additional information about merge failure if `status` is true. Otherwise, it returns an empty character vector.

Consider the following example.

```
[status,info]=rtw.asap2MergeMdlRefs('myTopMdl','merged.a21')
```

This command merges the ASAP2 files generated for the top model `myTopMdl` and its referenced models in the file `merged.a21`.

The example model `rtwdemo_asap2` includes an example of merging ASAP2 files.

### Structure of the ASAP2 File

The following table outlines the basic structure of the ASAP2 file and describes the Target Language Compiler (TLC) functions and files used to create each part of the file:

- Static parts of the ASAP2 file are shown in **bold**.
- Function calls are indicated by `%<FunctionName(>`.

File Section	Contents of <code>asap2main.tlc</code>	TLC File Containing Function Definition
File header	<code>%&lt;ASAP2UserFcnWriteFileHead(&gt;</code>	<code>asap2userlib.tlc</code>
<b>/begin PROJECT</b> " "	<b>/begin PROJECT</b> <code>"%&lt;ASAP2ProjectName&gt;"</code>	<code>asap2setup.tlc</code>

File Section	Contents of asap2main.tlc	TLC File Containing Function Definition
/begin HEADER " " HEADER contents	/begin HEADER "%<ASAP2HeaderName>" %<ASAP2UserFcnWriteHeader()>	asap2setup.tlc asap2userlib.tlc

## Create a Host-Based ASAM-ASAP2 Data Definition File for Data Measurement and Calibration

This model shows ASAP2 data export. ASAP2 is a data definition standard proposed by the Association for Standardization of Automation and Measuring Systems (ASAM).

### Open Example Model

Open the example model `rtwdemo_asap2`.

```
open_system('rtwdemo_asap2');
```

This model shows ASAP2 data export. ASAP2 is a data definition standard proposed by the Association for Standardization of Automation and Measuring Systems (ASAM). ASAP2 is a non-object-oriented description of the data used for measurement, calibration, and diagnostics systems. For more information on ASAM and the ASAP2 standard, see the ASAM Web site: <http://www.asam.de>.

ASAP2 data definition is achieved with Simulink data objects and test point signals. Using the Target Language Compiler (TLC), you can create highly customized solutions for your application. See the Simulink Coder documentation for details on ASAP2 file generation.

You can configure ASAP2 file generation from "Code Generation > Interface > ASAP2 interface" in the Configuration Parameters dialog box.

**Generate Code Using  
Simulink Coder

# Direct Memory Access to Generated Code for Simulink Coder

---

## Access Memory in Generated Code Using Global Data Map

Simulink Coder provides a Target Language Compiler (TLC) function library that lets you create a *global data map record*. The global data map record, when generated, is added to the `CompiledModel` structure in the `model.rtw` file. The global data map record is a database containing information required for accessing memory in the generated code, including

- Signals (Block I/O)
- Parameters
- Data type work vectors (DWork)
- External inputs
- External outputs

Use of the global data map requires knowledge of the Target Language Compiler and of the structure of the `model.rtw` file. See “Target Language Compiler Overview” for information on these topics.

The TLC functions that are required to generate and access the global data map record are contained in `matlabroot/rtw/c/tlc/mw/globalmaplib.tlc`. The comments in the source code fully document the global data map structures and the library functions.

The global data map structures and functions might be modified or enhanced in future releases.

- “Accelerate, Refine, and Test Hybrid Dynamic System on Host Computer by Using RSim System Target File” on page 46-2
- “Accelerate Simulation, Reuse Code, or Protect Intellectual Property by Using S-Function Target” on page 46-33

## Accelerate, Refine, and Test Hybrid Dynamic System on Host Computer by Using RSim System Target File

After you create a model, you can use the rapid simulation (RSim) system target file to characterize model behavior. The executable program that results from the build process is for non-real-time execution on your development computer. The executable program is highly optimized for simulating models of hybrid dynamic systems, including models that use variable-step solvers and zero-crossing detection. The speed of the generated code makes the RSim system target file ideal for building programs for batch or Monte Carlo simulations.

### About Rapid Simulation

Use the RSim target to generate an executable that runs fast, standalone simulations. You can repeat simulations with varying data sets, interactively or programmatically with scripts, without rebuilding the model. This can accelerate the characterization and tuning of model behavior and code generation testing.

Using command-line options:

- Define parameter values and input signals in one or more MAT-files that you can load and reload at the start of simulations without rebuilding your model.
- Redirect logging data to one or more MAT-files that you can then analyze and compare.
- Control simulation time.
- Specify external mode options.

---

**Note:** To run an RSim executable, configure your computer to run MATLAB and have the MATLAB and Simulink installation folders accessible. To deploy a standalone host executable ( i.e., without MATLAB and Simulink installed), consider using the Host-Based Shared Library target (ert\_shrlib)."

---

### Rapid Simulation Advantage

The advantage that you gain from rapid simulation varies. Larger simulations achieve speed improvements of up to 10 times faster than standard Simulink simulations. Some

models might not show noticeable improvement in simulation speed. To determine the speed difference for your model, time your standard Simulink simulation and compare the results with a rapid simulation. In addition, test the model simulation in Rapid Accelerator simulation mode.

## General Rapid Simulation Workflow

Like other stages of Model-Based Design, characterization and tuning of model behavior is an iterative process, as shown in the general workflow diagram in the figure. Tasks in the workflow are:

- 1 Identify your rapid simulation requirements.
- 2 Configure Inport blocks that provide input source data for rapid simulations.
- 3 Configure the model for rapid simulation.
- 4 Set up simulation input data.
- 5 Run the rapid simulations.

## Identify Rapid Simulation Requirements

The first step to setting up a rapid simulation is to identify your simulation requirements.

Question...	For More Information, See...
How long do you want simulations to run?	“Configure and Build Model for Rapid Simulation” on page 46-6
Are there solver requirements? Do you expect to use the same solver for which the model is configured for your rapid simulations?	“Configure and Build Model for Rapid Simulation” on page 46-6

Question...	For More Information, See...
Do your rapid simulations need to accommodate flexible custom code interfacing? Or, do your simulations need to retain storage class settings?	“Configure and Build Model for Rapid Simulation” on page 46-6
Will you be running simulations with multiple data sets?	“Set Up Rapid Simulation Input Data” on page 46-8
Will the input data consist of global parameters, signals, or both?	“Set Up Rapid Simulation Input Data” on page 46-8
What type of source blocks provide input data to the model — From File, Inport, From Workspace?	“Set Up Rapid Simulation Input Data” on page 46-8
Will the model's parameter vector ( <i>model_P</i> ) be used as input data?	“Create a MAT-File That Includes a Model Parameter Structure” on page 46-9
What is the data type of the input parameters and signals?	“Set Up Rapid Simulation Input Data” on page 46-8
Will the source data consist of one variable or multiple variables?	“Set Up Rapid Simulation Input Data” on page 46-8
Does the input data include tunable parameters?	“Create a MAT-File That Includes a Model Parameter Structure” on page 46-9
Do you need to gain access to tunable parameter information — model checksum and parameter data types, identifiers, and complexity?	“Create a MAT-File That Includes a Model Parameter Structure” on page 46-9
Will you have a need to vary the simulation stop time for simulation runs?	“Configure and Build Model for Rapid Simulation” on page 46-6 and “Override a Model Simulation Stop Time” on page 46-21
Do you want to set a time limit for the simulation? Consider setting a time limit if your model experiences frequent zero crossings and has a small minor step size.	“Set a Clock Time Limit for a Rapid Simulation” on page 46-21
Do you need to preserve the output of each simulation run?	“Specify a New Output File Name for a Simulation” on page 46-29 and “Specify New Output File Names for To File Blocks” on page 46-29

Question...	For More Information, See...
Do you expect to run the simulations interactively or in batch mode?	“Scripts for Batch and Monte Carlo Simulations” on page 46-18

## Configure Inports to Provide Simulation Source Data

You can use Inport blocks as a source of input data for rapid simulations. To do so, configure the blocks so that they can import data from external MAT-files. By default, the Inport block inherits parameter settings from downstream blocks. In most cases, to import data from an external MAT-file, you must explicitly set the following parameters to match the source data in the MAT-file.

- **Main > Interpolate data**
- **Signal Attributes > Port dimensions**
- **Signal Attributes > Data type**
- **Signal Attributes > Signal type**

If you do not have control over the model content, you might need to modify the data in the MAT-file to conform to what the model expects for input. Input data characteristics and specifications of the Inport block that receives the data must match.

For details on adjusting these parameters and on creating a MAT-file for use with an Inport block, see “Create a MAT-File for an Inport Block” on page 46-14. For descriptions of the preceding block parameters, see the description of the Inport block in the Simulink documentation.

## Configure and Build Model for Rapid Simulation

After you identify your rapid simulation requirements, configure the model for rapid simulation.

- 1 Open the Configuration Parameters dialog box.
- 2 Go to the **Code Generation** pane.
- 3 On the **Code Generation** pane, click **Browse**. The System Target File Browser opens.
- 4 Select `rsim.tlc` (Rapid Simulation Target) and click **OK**.

On the **Code Generation** pane, the code generator populates the **Make command** and “Template makefile” fields with default settings and adds the **RSim Target** pane under **Code Generation**.

- 5 Click **RSim Target** to view the **RSim Target** pane.

The screenshot shows the RSim Target configuration pane with the following settings:

- Parameter loading:**  Enable RSim executable to load parameters from a MAT-file
- Solver:** Solver selection: auto
- Storage classes:**  Force storage classes to AUTO

- 6 Set the RSim target configuration parameters to your rapid simulation requirements.

If You Want to...	Then...
Generate code that allows the RSim executable to load parameters from a MAT-file	Select <b>Enable RSim executable to load parameters from a MAT-file</b> (default).
Let the target choose a solver based on the solver already configured for the model	Set <b>Solver selection</b> to <b>auto</b> (default). The code generator uses a built-in solver if a fixed-step solver is specified on the <b>Solver</b> pane or calls the Simulink solver module (a shared library) if a variable-step solver is specified.
Explicitly instruct the target to use a fixed-step solver	Set <b>Solver selection</b> to <b>Use fixed-step solvers</b> . In the Configuration Parameters dialog box, on the <b>Solver</b> pane, specify a fixed-step solver.
Explicitly instruct the target to use a variable-step solver	Set <b>Solver selection</b> to <b>Use Simulink solver module</b> . In the Configuration Parameters dialog box, on the <b>Solver</b> pane, specify a variable-step solver.
Force storage classes to <b>Auto</b> for flexible custom code interfacing	Select <b>Force storage classes to AUTO</b> (default).
Retain storage class settings, such as <b>ExportedGlobal</b> or <b>ImportedExtern</b> , due to application requirements	Clear <b>Force storage classes to AUTO</b> .

- 7 Set up data import and export options. On the **Data Import/Export** pane, in the **Save to Workspace** section, select the **Time**, **States**, **Outputs**, and **Final States** options, as they apply. By default, the code generator saves simulation logging results to a file named *model.mat*. For more information, see “Export Simulation Data”.
- 8 If you are using external mode communication, set up the interface, using the **Code Generation > Interface** pane. See “What You Can Do With a Host/Target Communication Channel” on page 41-2 for details.
- 9 Press **Ctrl+B**. The code generator builds a highly optimized executable program that you can run on your development computer with varying data, without rebuilding.

For more information on compilers that are compatible with the Simulink Coder product, see “Select and Configure Compiler or IDE” on page 40-3 and “Template Makefiles and Make Options” on page 29-26 .

## Set Up Rapid Simulation Input Data

- “About Rapid Simulation Data Setup” on page 46-8
- “Create a MAT-File That Includes a Model Parameter Structure” on page 46-9
- “Create a MAT-File for a From File Block” on page 46-13
- “Create a MAT-File for an Inport Block” on page 46-14

### About Rapid Simulation Data Setup

The format and setup of input data for a rapid simulation depends on your requirements.

If the Input Data Source Is...	Then...
The model's global parameter vector ( <i>model_P</i> )	Use the <code>rsimgetrtp</code> function to get the vector content and then save it to a MAT-file.
The model's global parameter vector and you want a mapping between the vector and tunable parameters	Call the <code>rsimgetrtp</code> function to get the global parameter structure and then save it to a MAT-file.
Provided by a From File block	Create a MAT-file that a From File block can read.
Provided by an Inport block	Create a MAT-file that adheres to one of the three data file formats that the Inport block can read.

If the Input Data Source Is...	Then...
Provided by a From Workspace block	Create structure variables in the MATLAB workspace.

The RSim target requires that MAT-files used as input for From File and Inport blocks contain data. The `grt` target inserts MAT-file data directly into the generated code, which is then compiled and linked as an executable. In contrast, RSim allows you to replace data sets for each successive simulation. A MAT-file containing From File or Inport block data must be present if a From File block or Inport block exists in your model.

### Create a MAT-File That Includes a Model Parameter Structure

To create a MAT-file that includes a model global parameter structure (*model\_P*),

- 1 Get the structure by calling the function `rsimgetrtp`.
- 2 Save the parameter structure to a MAT-file.

If you want to run simulations over varying data sets, consider converting the parameter structure to a cell array and saving the parameter variations to a single MAT-file.

#### Get the Parameter Structure for a Model

Get the global parameter structure (*model\_P*) for a model by calling the function `rsimgetrtp`.

```
param_struct = rsimgetrtp('model')
```

Argument	Description
<i>model</i>	The model for which you are running the rapid simulations.

The `rsimgetrtp` function forces an update diagram action for the specified model and returns a structure that contains the following fields.

Field	Description
<code>modelChecksum</code>	A four-element vector that encodes the structure of the model. The code generator uses the checksum to check whether the structure of the model has changed since the RSim executable was generated. If you delete or add a block, and then generate a new <i>model_P</i> vector, the new checksum does not match the

Field	Description
	original checksum anymore. The RSim executable detects this incompatibility in parameter vectors and exits to avoid returning incorrect simulation results. If the model structure changes, you must regenerate the code for the model.
parameters	A structure that contains the model's global parameters.

The parameter structure contains the following information.

Field	Description
dataTypeName	The name of the parameter data type, for example, <code>double</code>
dataTypeID	Internal data type identifier used by the code generator
complex	The value 0 if real; 1 if complex
dtTransIdx	Internal data index used by the code generator
values	A vector of the parameter values associated with this structure
map	This field contains the mapping information that correlates the 'values' to the tunable parameters of the model. This mapping information, in conjunction with <code>rsimsetrtpparam</code> , is useful for creating subsequent rtP structures without compiling the block diagram.

The code generator reports a tunable fixed-point parameter according to its stored value. For example, an `sfix(16)` parameter value of 1.4 with a scaling of  $2^{-8}$  has a value of 358 as an `int16`.

In the following example, `rsimgetrtpp` returns the parameter structure for the example model `rtwdemo_rsimtf` to `param_struct`.

```
param_struct = rsimgetrtpp('rtwdemo_rsimtf')

param_struct =

 modelChecksum: [1.7165e+009 3.0726e+009 2.6061e+009 2.3064e+009]
 parameters: [1x1 struct]
```

#### Save the Parameter Structure to a MAT-File

After you issue a call to `rsimgetrtpp`, save the return value of the function call to a MAT-file. Using a command-line option, you can then specify that MAT-file as input for rapid simulations.

The following example saves the parameter structure returned for `rtwdemo_rsimtf` to the MAT-file `myrsimdemo.mat`.

```
save myrsimdemo.mat param_struct;
```

For information on using command-line options to specify required files, see “Run Rapid Simulations” on page 46-18.

### Convert the Parameter Structure for Running Simulations on Varying Data Sets

To use rapid simulations to test changes to specific parameters, you can convert the model parameter structure to a cell array. You can then access a specific parameter set by using the `@` operator to specify the index for a specific parameter set in the file.

To convert the structure to a cell array:

- 1 Use the function `rsimgetrtpt` to get a structure containing parameter information for the example model `rtwdemo_rsimtf`. Store the structure in a variable `param_struct`.

```
param_struct = rsimgetrtpt('rtwdemo_rsimtf');
```

The `parameters` field of the structure is a substructure that contains parameter information. The `values` field of the `parameters` substructure contains the numeric values of the parameters that you can tune during execution of the simulation code.

- 2 Use the function `rsimsetrtpparam` to expand the structure so that it contains more parameter sets. In this case, create two more parameter sets (for a total of three sets).

```
param_struct = rsimsetrtpparam(param_struct,3);
```

The function converts the `parameters` field to a cell array with three elements. Each element contains information for a single parameter set. By default, the function creates the second and third elements of the cell array by copying the first element. Therefore, all of the parameter sets use the same parameter values.

- 3 Specify new values for the parameters in the second and third parameter sets.

```
param_struct.parameters{2}.values = [-150 -5000 0 4950];
param_struct.parameters{3}.values = [-170 -5500 0 5100];
```

- 4 Save the structure containing the parameter set information to a MAT-file.

```
save rtwdemo_rsimtf.mat param_struct;
```

Alternatively, you can modify the block parameters in the model, and use `rsimgetrtp` to create multiple parameter sets:

- 1 Use the function `rsimgetrtp` to get a structure containing parameter information for the example model `rtwdemo_rsimtf`. Store the structure in a variable `param_struct`.

```
param_struct = rsimgetrtp('rtwdemo_rsimtf');
```

- 2 Use the function `rsimsetrtpparam` to expand the structure so that it contains more parameter sets. In this case, create two more parameter sets (for a total of three sets).

```
param_struct = rsimsetrtpparam(param_struct,3);
```

The function converts the `parameters` field to a cell array with three elements. Each element contains information for a single parameter set. By default, the function creates the second and third elements of the cell array by copying the first element. Therefore, all of the parameter sets use the same parameter values.

- 3 Change the values of block parameters or workspace variables. For example, change the value of the variable `w` from 70 to 72.

```
w = 72;
```

- 4 Use `rimsgetrtp` to get another structure containing parameter information. Store the structure in a temporary variable `rtp_temp`.

```
rtp_temp = rimsgetrtp('rtwdemo_rsimtf');
```

- 5 Assign the value of the `parameters` field of `rtp_temp` to the structure `param_struct` as a second parameter set.

```
param_struct.parameters{2} = rtp_temp.parameters;
```

- 6 Change the value of the variable `w` from 72 to 75.

```
w = 75;
```

- 7 Use `rimsgetrtp` to get another structure containing parameter information. Then, assign the value of the `parameters` field to `param_struct` as a third parameter set.

```
rtp_temp = rimsgetrtp('rtwdemo_rsimtf');
param_struct.parameters{3} = rtp_temp.parameters;
```

- 8 Save the structure containing the parameter set information to a MAT-file.

```
save rtwdemo_rsimtf.mat param_struct;
```

For more information on how to specify each parameter set when you run the simulations, see “Change Block Parameters for an RSim Simulation” on page 46-27.

### Create a MAT-File for a From File Block

You can use a MAT-file as the input data source for a **From File** block. The format of the data in the MAT-file must match the data format expected by that block. For example, if you are using a matrix as an input for the MAT file, this cannot be different from the matrix size for the executable.

To create a MAT-file for a **From File** block:

- 1 For array format data, in the workspace create a matrix that consists of two or more rows. The first row must contain monotonically increasing time points. Other rows contain data points that correspond to the time point in that column. The time and data points must be data of type **double**.

For example:

```
t=[0:0.1:2*pi]';
Ina1=[2*sin(t) 2*cos(t)];
Ina2=sin(2*t);
Ina3=[0.5*sin(3*t) 0.5*cos(3*t)];
var_matrix=[t Ina1 Ina2 Ina3]';
```

For other supported data types, such as **int16** or fixed-point, the time data points must be of type **double**, just as for array format data. However, the sample data can be of any dimension.

For more information on setting up the input data, see the description of the **From File** block in the Simulink documentation.

- 2 Save the matrix to a MAT-file.

The following example saves the matrix `var_matrix` to the MAT-file `myrsimdemo.mat` in Version 7.3 format.

```
save '-v7.3' myrsimdemo.mat var_matrix;
```

Using a command-line option, you can then specify that MAT-file as input for rapid simulations.

### Create a MAT-File for an Inport Block

You can use a MAT-file as the input data source for an Inport block.

The format of the data in the MAT-file must adhere to one of the three column-based formats listed in the following table. The table lists the formats in order from least flexible to most flexible.

Format	Description
Single time/data matrix	<ul style="list-style-type: none"> <li>• Least flexible.</li> <li>• One variable.</li> <li>• Two or more <i>columns</i>. Number of columns must equal the sum of the dimensions of all root Inport blocks plus 1. First column must contain monotonically increasing time points. Other columns contain data points that correspond to the time point in a given row.</li> <li>• Data of type <code>double</code>.</li> </ul> <p>For an example, see Single time/data matrix in the following procedure, step 4. For more information, see “Create Data Arrays for Root-Level Inports” in the Simulink documentation.</p>
Signal-and-time structure	<ul style="list-style-type: none"> <li>• More flexible than the single time/data matrix format.</li> <li>• One variable.</li> <li>• Must contain two top-level fields: <code>time</code> and <code>signals</code>. The <code>time</code> field contains a <i>column</i> vector of the simulation times. The <code>signals</code> field contains an array of substructures, each of which corresponds to an Inport block. The substructure index corresponds to the Inport block number. Each <code>signals</code> substructure must contain a field named <code>values</code>. The <code>values</code> field must contain an array of inputs for the corresponding Inport block, where each input corresponds to a time point specified by the <code>time</code> field.</li> <li>• If the <code>time</code> field is set to an empty value, clear the check box for the Inport block <b>Interpolate data</b> parameter.</li> <li>• Data type must match Inport block settings.</li> </ul> <p>For an example, see Signal-and-time structure in the following procedure, step 4. For more information on this format, see “Create Data Structures for Root Inports” in the Simulink documentation.</p>

Format	Description
Per-port structure	<ul style="list-style-type: none"> <li>• Most flexible</li> <li>• Multiple variables. Number of variables must equal the number of Inport blocks.</li> <li>• Consists of a separate structure-with-time or structure-without-time for each Inport block. Each Inport block data structure has only one <b>signals</b> field. To use this format, in the <b>Input</b> text field, enter the names of the structures as a comma-separated list, <b>in1, in2, ..., inN</b>, where <b>in1</b> is the data for your model's first port, <b>in2</b> for the second port, and so on.</li> <li>• Each variable can have a different time vector.</li> <li>• If the <b>time</b> field is set to an empty value, clear the check box for the Inport block <b>Interpolate data</b> parameter.</li> <li>• Data type must match Inport block settings.</li> <li>• To save multiple variables to the same data file, you must save them in the order expected by the model, using the <b>-append</b> option.</li> </ul> <p>For an example, see Per-port structure in the following procedure, step 4. For more information, see “Create Data Structures for Root Inports” in the Simulink documentation.</p>

The supported formats and the following procedure are illustrated in `rtwdemo_rsim_i`.

To create a MAT-file for an Inport block:

- 1** Choose one of the preceding data file formats.
- 2** Update Inport block parameter settings and specifications to match specifications of the data to be supplied by the MAT-file.

By default, the Inport block inherits parameter settings from downstream blocks. To import data from an external MAT-file, explicitly set the following parameters to match the source data in the MAT-file.

- **Main > Interpolate data**
- **Signal Attributes > Port dimensions**
- **Signal Attributes > Data type**
- **Signal Attributes > Signal type**

If you choose to use a structure format for workspace variables and the `time` field is empty, you must clear **Interpolate data** or modify the field so that it is set to a nonempty value. Interpolation requires time data.

For descriptions of the preceding block parameters, see the description of the **Inport** block in the Simulink documentation.

- 3 Build an RSim executable program for the model. The build process creates and calculates a structural checksum for the model and embeds it in the generated executable. The RSim target uses the checksum to verify that data being passed into the model is consistent with what the model executable expects.
- 4 Create the MAT-file that provides the source data for the rapid simulations. You can create the MAT-file from a workspace variable. Using the specifications in the preceding format comparison table, create the workspace variables for your simulations.

An example of each format follows:

#### Single time/data matrix

```
t=[0:0.1:2*pi]';
Ina1=[2*sin(t) 2*cos(t)];
Ina2=sin(2*t);
Ina3=[0.5*sin(3*t) 0.5*cos(3*t)];
var_matrix=[t Ina1 Ina2 Ina3];
```

#### Signal-and-time structure

```
t=[0:0.1:2*pi]';
var_single_struct.time=t;
var_single_struct.signals(1).values(:,1)=2*sin(t);
var_single_struct.signals(1).values(:,2)=2*cos(t);
var_single_struct.signals(2).values=sin(2*t);
var_single_struct.signals(3).values(:,1)=0.5*sin(3*t);
var_single_struct.signals(3).values(:,2)=0.5*cos(3*t);
v=[var_single_struct.signals(1).values...
var_single_struct.signals(2).values...
var_single_struct.signals(3).values];
```

#### Per-port structure

```
t=[0:0.1:2*pi]';
Inb1.time=t;
```

```
Inb1.signals.values(:,1)=2*sin(t);
Inb1.signals.values(:,2)=2*cos(t);
t=[0:0.2:2*pi]';
Inb2.time=t;
Inb2.signals.values(:,1)=sin(2*t);
t=[0:0.1:2*pi]';
Inb3.time=t;
Inb3.signals.values(:,1)=0.5*sin(3*t);
Inb3.signals.values(:,2)=0.5*cos(3*t);
```

- 5 Save the workspace variables to a MAT-file.

### Single time/data matrix

The following example saves the workspace variable `var_matrix` to the MAT-file `rsim_i_matrix.mat`.

```
save rsim_i_matrix.mat var_matrix;
```

### Signal-and-time structure

The following example saves the workspace structure variable `var_single_struct` to the MAT-file `rsim_i_single_struct.mat`.

```
save rsim_i_single_struct.mat var_single_struct;
```

### Per-port structure

To order data when saving per-port structure variables to a single MAT-file, use the `save` command's `-append` option. Be sure to append the data in the order that the model expects it.

The following example saves the workspace variables `Inb1`, `Inb2`, and `Inb3` to MAT-file `rsim_i_multi_struct.mat`.

```
save rsim_i_multi_struct.mat Inb1;
save rsim_i_multi_struct.mat Inb2 -append;
save rsim_i_multi_struct.mat Inb3 -append;
```

The `save` command does not preserve the order in which you specify your workspace variables in the command line when saving data to a MAT-file. For example, if you specify the variables `v1`, `v2`, and `v3`, in that order, the order of the variables in the MAT-file could be `v2 v1 v3`.

Using a command-line option, you can then specify the MAT-files as input for rapid simulations.

## Scripts for Batch and Monte Carlo Simulations

The RSim target is for batch simulations in which parameters and input signals vary for multiple simulations. New output file names allow you to run new simulations without overwriting prior simulation results. You can set up a series of simulations to run by creating a `.bat` file for use on a Microsoft Windows platform.

Create a file for the Windows platform with a text editor and execute it by typing the file name, for example, `mybatch`, where the name of the text file is `mybatch.bat`.

```
rtwdemo_rsimtf -f rtwdemo_rsimtf.mat=run1.mat -o results1.mat -tf 10.0
rtwdemo_rsimtf -f rtwdemo_rsimtf.mat=run2.mat -o results2.mat -tf 10.0
rtwdemo_rsimtf -f rtwdemo_rsimtf.mat=run3.mat -o results3.mat -tf 10.0
rtwdemo_rsimtf -f rtwdemo_rsimtf.mat=run4.mat -o results4.mat -tf 10.0
```

In this case, batch simulations run using four sets of input data in files `run1.mat`, `run2.mat`, and so on. The RSim executable saves the data to the files specified with the `-o` option.

The variable names containing simulation results in each of the files are identical. Therefore, loading consecutive sets of data without renaming the data once it is in the MATLAB workspace results in overwriting the prior workspace variable with new data. To avoid overwriting, you can copy the result to a new MATLAB variable before loading the next set of data.

You can also write MATLAB scripts to create new signals and new parameter structures, as well as to save data and perform batch runs using the bang command (!).

For details on running simulations and available command-line options, see “Run Rapid Simulations” on page 46-18. For an example of a rapid simulation batch script, see the example “Run Batch Simulations Without Recompiling Generated Code”.

## Run Rapid Simulations

- “Rapid Simulations” on page 46-19
- “Requirements for Running Rapid Simulations” on page 46-20
- “Set a Clock Time Limit for a Rapid Simulation” on page 46-21
- “Override a Model Simulation Stop Time” on page 46-21

- “Read the Parameter Vector into a Rapid Simulation” on page 46-22
- “Specify New Signal Data File for a From File Block” on page 46-22
- “Specify Signal Data File for an Inport Block” on page 46-25
- “Change Block Parameters for an RSim Simulation” on page 46-27
- “Specify a New Output File Name for a Simulation” on page 46-29
- “Specify New Output File Names for To File Blocks” on page 46-29

### Rapid Simulations

Using the RSim target, you can build a model once and run multiple simulations to study effects of varying parameter settings and input signals. You can run a simulation directly from your operating system command line, redirect the command from the MATLAB command line by using the bang (!) character, or execute commands from a script.

From the operating system command line, use

```
rtwdemo_rsimgtf
```

From the MATLAB command line, use

```
!rtwdemo_rsimgtf
```

The following table lists ways you can use RSim target command-line options to control a simulation.

To...	Use...
Read input data for a From File block from a MAT-file other than the MAT-file used for the previous simulation	<code>model -f oldfilename.mat=newfilename.mat</code>
Print a summary of the options for RSim executable targets	<code>executable filename -h</code>
Read input data for an Inport block from a MAT-file	<code>model -i filename.mat</code>
Time out after $n$ clock time seconds, where $n$ is a positive integer value	<code>model -L n</code>
Write MAT-file logging data to file <code>filename.mat</code>	<code>model -o filename.mat</code>
Read a parameter vector from file <code>filename.mat</code>	<code>model -p filename.mat</code>

To...	Use...
Override the default TCP port (17725) for external mode	<code>model -port TCPport</code>
Write MAT-file logging data to a MAT-file other than the MAT-file used for the previous simulation	<code>model -t oldfilename.mat=newfilename.mat</code>
Run the simulation until the time value <i>stoptime</i> is reached	<code>model -tf stoptime</code>
Run in verbose mode	<code>model -v</code>
Wait for the Simulink engine to start the model in external mode	<code>model -w</code>

The following sections use the `rtwdemo_rsimtf` example model in examples to illustrate some of these command-line options. In each case, the example assumes you have already done the following:

- Created or changed to a working folder.
- Opened the example model.
- Copied the data file `matlabroot/toolbox/rtw/rtwdemos/rsimdemos/rsim_tfdata.mat` to your working folder. You can perform this operation using the command:

```
copyfile(fullfile(matlabroot,'toolbox','rtw','rtwdemos',...
'rsimdemos','rsim_tfdata.mat'),pwd);
```

### Requirements for Running Rapid Simulations

The following requirements apply to both fixed and variable step executables.

- You must run the RSim executable on a computer configured to run MATLAB. Also, the `RSim.exe` file must be able to access the MATLAB and Simulink installation folders on this machine. To obtain that access, your `PATH` environment variable must include `/bin` and `/bin/($ARCH)`, where `($ARCH)` represents your operating system architecture. For example, for a personal computer running on a Windows platform, `($ARCH)` is “win64”, whereas for a Linux machine, `($ARCH)` is “glnxa64”.
- On GNU Linux platforms, to run an RSim executable, define the `LD_LIBRARY_PATH` environment variable to provide the path to the MATLAB installation folder, as follows:

```
% setenv LD_LIBRARY_PATH /matlab/sys/os/glnx64:$LD_LIBRARY_PATH
```

- On the Apple Macintosh OS X platform, to run RSim target executables, you must define the environment variable `DYLD_LIBRARY_PATH` to include the folders `bin/mac` and `sys/os/mac` under the MATLAB installation folder. For example, if your MATLAB installation is under `/MATLAB`, add `/MATLAB/bin/mac` and `/MATLAB/sys/os/mac` to the definition for `DYLD_LIBRARY_PATH`.

### Set a Clock Time Limit for a Rapid Simulation

If a model experiences frequent zero crossings and the model's minor step size is small, consider setting a time limit for a rapid simulation. To set a time limit, specify the `-L` option with a positive integer value. The simulation aborts after running for the specified amount of clock time (not simulation time). For example,

```
!rtwdemo_rsimgtf -L 20
```

Based on your clock, after the executable runs for 20 seconds, the program terminates. You see a message similar to one of the following:

- On a Microsoft Windows platform,
 

```
Exiting program, time limit exceeded
Logging available data ...
```
- On The Open Group UNIX platform,
 

```
** Received SIGALRM (Alarm) signal @ Fri Jul 25 15:43:23 2003
** Exiting model 'vdp' @ Fri Jul 25 15:43:23 2003
```

You do not need to do anything to your model or to its configuration to use this option.

### Override a Model Simulation Stop Time

By default, a rapid simulation runs until the simulation time reaches the time specified the Configuration Parameters dialog box, on the **Solver** pane. You can override the model simulation stop time by using the `-tf` option. For example, the following simulation runs until the time reaches 6.0 seconds.

```
!rtwdemo_rsimgtf -tf 6.0
```

The RSim target stops and logs output data using MAT-file data logging rules.

If the model includes a From File block, the end of the simulation is regulated by the stop time setting specified in the Configuration Parameters dialog box, on the **Solver** pane, or with the RSim target option `-tf`. The values in the block's time vector are ignored.

However, if the simulation time exceeds the endpoints of the time and signal matrix (if the final time is greater than the final time value of the data matrix), the signal data is extrapolated to the final time value.

### Read the Parameter Vector into a Rapid Simulation

To read the model parameter vector into a rapid simulation, you must first create a MAT-file that includes the parameter structure as described in “Create a MAT-File That Includes a Model Parameter Structure” on page 46-9. You can then specify the MAT-file in the command line with the `-p` option.

For example:

- 1 Build an RSim executable for the example model `rtwdemo_rsimtf`.
- 2 Modify parameters in your model and save the parameter structure.

```
param_struct = rsimgetrtp('rtwdemo_rsimtf');
save myrsimdata.mat param_struct
```

- 3 Run the executable with the new parameter set.

```
!rtwdemo_rsimtf -p myrsimdata.mat
```

```
** Starting model 'rtwdemo_rsimtf' @ Tue Dec 27 12:30:16 2005
** created rtwdemo_rsimtf.mat **
```

- 4 Load workspace variables and plot the simulation results by entering the following commands:

```
load myrsimdata.mat
plot(rt_yout)
```

### Specify New Signal Data File for a From File Block

If your model's input data source is a `From File` block, you can feed the block with input data during simulation from a single MAT-file or you can change the MAT-file from one simulation to the next. Each MAT-file must adhere to the format described in “Create a MAT-File for a From File Block” on page 46-13.

To change the MAT-file after an initial simulation, you specify the executable with the `-f` option and an `oldfile.mat=newfile.mat` parameter, as shown in the following example.

- 1 Set some parameters in the MATLAB workspace. For example:

```
w = 100;
```

```
theta = 0.5;
```

- 2 Build an RSim executable for the example model `rtwdemo_rsimtf`.
- 3 Run the executable.

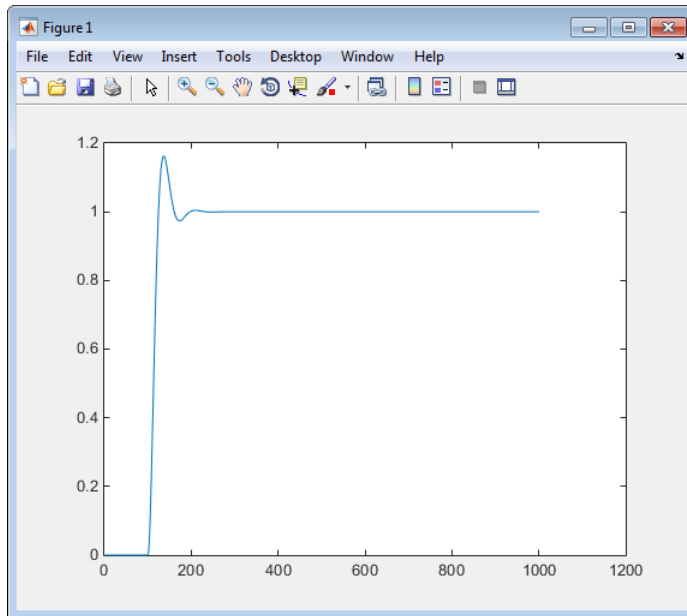

```
!rtwdemo_rsimtf
```

The RSim executable runs a set of simulations and creates output MAT-files containing the specific simulation result.

- 4 Load the workspace variables and plot the simulation results by entering the following commands:

```
load rtwdemo_rsimtf.mat
plot(rt_yout)
```

The resulting plot shows simulation results based on default input data.

- 5 Create a new data file, `newfrom.mat`, that includes the following data:

```
t=[0:.001:1];
u=sin(100*t.*t);
tu=[t;u];
```

```
save newfrom.mat tu;
```

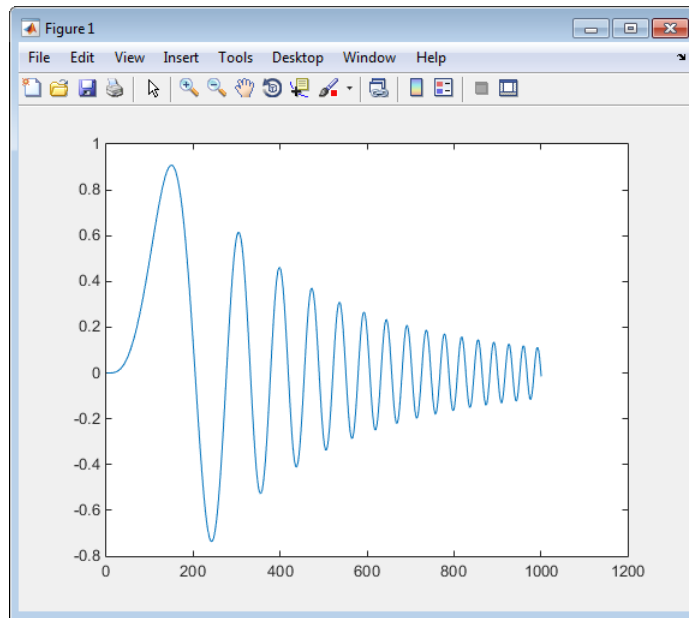

- 6 Run a rapid simulation with the new data by using the `-f` option to replace the original file, `rsim_tfdata.mat`, with `newfrom.mat`.

```
!rtwdemo_rsimtf -f rsim_tfdata.mat=newfrom.mat
```

- 7 Load the data and plot the new results by entering the following commands:

```
load rtwdemo_rsimtf.mat
plot(rt_yout)
```

The next figure shows the resulting plot.

From File blocks require input data of type **double**. If you need to import signal data of a data type other than **double**, use an Inport block (see “Create a MAT-File for an Inport Block” on page 46-14) or a From Workspace block with the data specified as a structure.

Workspace data must be in the format:

```
variable.time
variable.signals.values
```

If you have more than one signal, use the following format:

```
variable.time
variable.signals(1).values
variable.signals(2).values
```

### Specify Signal Data File for an Inport Block

If your model's input data source is an Inport block, you can feed the block with input data during simulation from a single MAT-file or you can change the MAT-file from one simulation to the next. Each MAT-file must adhere to one of the three formats described in “Create a MAT-File for an Inport Block” on page 46-14.

To specify the MAT-file after a simulation, you specify the executable with the `-i` option and the name of the MAT-file that contains the input data. For example:

- 1 Open the model `rtwdemo_rsim_i`.
- 2 Check the Inport block parameter settings. The following Inport block data parameter settings and specifications that you specify for the workspace variables must match settings in the MAT-file, as indicated in “Configure Inports to Provide Simulation Source Data” on page 46-6:
  - **Main > Interpolate data**
  - **Signal Attributes > Port dimensions**
  - **Signal Attributes > Data type**
  - **Signal Attributes > Signal type**
- 3 Build the model.
- 4 Set up the input signals. For example:

```
t=[0:0.01:2*pi]';
s1=[2*sin(t) 2*cos(t)];
s2=sin(2*t);
s3=[0.5*sin(3*t) 0.5*cos(3*t)];
plot(t, [s1 s2 s3])
```

- 5 Prepare the MAT-file by using one of the three available file formats described in “Create a MAT-File for an Inport Block” on page 46-14. The following example defines a signal-and-time structure in the workspace and names it `var_single_struct`.

```
t=[0:0.1:2*pi]';
var_single_struct.time=t;
var_single_struct.signals(1).values(:,1)=2*sin(t);
var_single_struct.signals(1).values(:,2)=2*cos(t);
var_single_struct.signals(2).values=sin(2*t);
var_single_struct.signals(3).values(:,1)=0.5*sin(3*t);
var_single_struct.signals(3).values(:,2)=0.5*cos(3*t);
v=[var_single_struct.signals(1).values...
var_single_struct.signals(2).values...
var_single_struct.signals(3).values];
```

- 6 Save the workspace variable `var_single_struct` to MAT-file `rsim_i_single_struct`.

```
save rsim_i_single_struct.mat var_single_struct;
```

- 7 Run a rapid simulation with the input data by using the `-i` option. Load and plot the results.

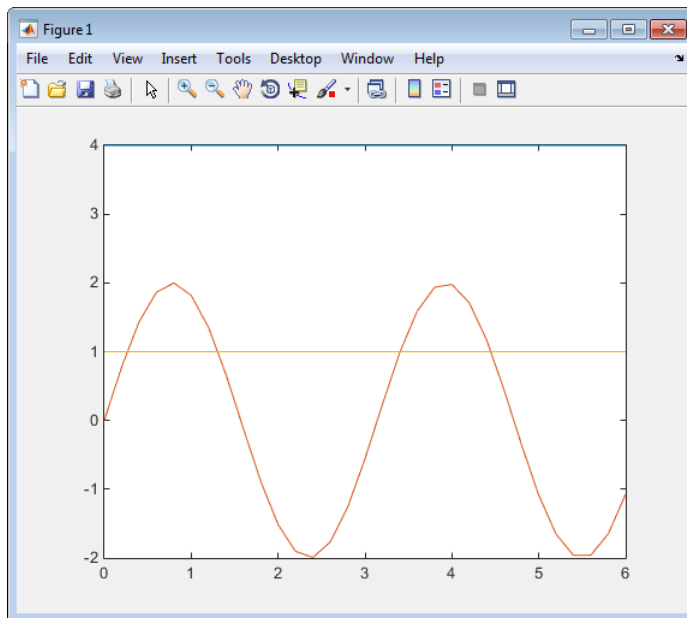

```
!rtwdemo_rsim_i -i rsim_i_single_struct.mat

** Starting model 'rtwdemo_rsim_i' @ Tue Aug 19 10:26:53 2014
*** rsim_i_single_struct.mat is successfully loaded! ***
** created rtwdemo_rsim_i.mat **

** Execution time = 0.02024185130718954s
```

- 8 Load and plot the results.

```
load rtwdemo_rsim_i.mat
plot(rt_tout, rt_yout);
```

### Change Block Parameters for an RSim Simulation

As described in “Create a MAT-File That Includes a Model Parameter Structure” on page 46-9, after you alter one or more parameters in a Simulink block diagram, you can extract the parameter vector, `model_P`, for the entire model. You can then save the parameter vector, along with a model checksum, to a MAT-file. This MAT-file can be read directly by the standalone RSim executable, allowing you to replace the entire parameter

vector or individual parameter values, for running studies of variations of parameter values representing coefficients, new data for input signals, and so on.

RSim can read the MAT-file and replace the entire *model\_P* structure whenever you change one or more parameters, without recompiling the entire model.

For example, assume that you changed one or more parameters in your model, generated the new *model\_P* vector, and saved *model\_P* to a new MAT-file called *mymatfile.mat*. To run the same *rtwdemo\_rsimtf* model and use these new parameter values, use the `-p` option, as shown in the following example:

```
!rtwdemo_rsimtf -p mymatfile.mat
load rtwdemo_rsimtf
plot(rt_yout)
```

If you have converted the parameter structure to a cell array for running simulations on varying data sets, as described in “Convert the Parameter Structure for Running Simulations on Varying Data Sets” on page 46-11, you must add an `@n` suffix to the MAT-file specification. *n* is the element of the cell array that contains the specific input that you want to use for the simulation.

The following example converts *param\_struct* to a cell array, changes parameter values, saves the changes to MAT-file *mymatfile.mat*, and then runs the executable using the parameter values in the second element of the cell array as input.

```
param_struct = rsimgetrtp('rtwdemo_rsimtf');
param_struct = rsimsetrtpparam(param_struct,2);
param_struct.parameters{1}

ans =

 dataTypeName: 'double'
 dataTypeId: 0
 complex: 0
 dtTransIdx: 0
 values: [-140 -4900 0 4900]
 map: []
 structParamInfo: []

param_struct.parameters{2}.values=[-150 -5000 0 4950];
save mymatfile.mat param_struct;
!rtwdemo_rsimtf -p mymatfile.mat@2 -o rsim2.mat
```

## Specify a New Output File Name for a Simulation

If you have specified one or more of the **Save to Workspace** options — **Time**, **States**, **Outputs**, or **Final States** — in the Configuration Parameters dialog box, on the **Data Import/Export** pane, the default is to save simulation logging results to the file `model.mat`. For example, the example model `rtwdemo_rsimtf` normally saves data to `rtwdemo_rsimtf.mat`, as follows:

```
!rtwdemo_rsimtf
created rtwdemo_rsimtf.mat
```

You can specify a new output file name for data logging by using the `-o` option when you run an executable.

```
!rtwdemo_rsimtf -o rsim1.mat
```

In this case, the set of parameters provided at the time of code generation, including From File block data parameters, is run.

## Specify New Output File Names for To File Blocks

In much the same way as you can specify a new system output file name, you can also provide new output file names for data saved from one or more To File blocks. To do this, specify the original file name at the time of code generation with a new name, as shown in the following example:

```
!rtwdemo_rsimtf -t rtwdemo_rsimtf_data.mat=mynewrsimdata.mat
```

In this case, assume that the original model wrote data to the output file `rtwdemo_rsimtf_data.mat`. Specifying a new file name forces RSim to write to the file `mynewrsimdata.mat`. With this technique, you can avoid overwriting an existing simulation run.

## Tune Parameters Interactively During Rapid Simulation

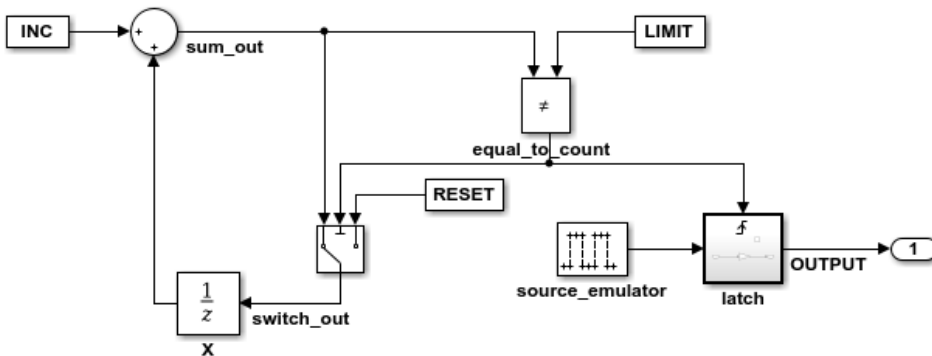

The RSim target was designed to let you run batch simulations at the fastest possible speed. Using variable-step or fixed-step solvers with RSim combined with the use of a tunable parameter data structure, whether you set **Default parameter behavior** to **Tunable** or to **Inlined**, you can create multiple parameter sets to run with the RSim target's standalone executable file (.exe on Windows) generated using Simulink Coder. Each invocation of the executable allows specification of the file name to use for results.

For this example, **Default parameter behavior** is set to **Inlined**. The model declares workspace variables as tunable parameters. To use RSim with **Default parameter behavior** set to **Tunable**, and without explicitly declaring tunable parameters, see “Run Batch Simulations Without Recompiling Generated Code”.

### **Open Example Model**

Open the example model `rtwdemo_rsim_param_tuning`.

```
open_system('rtwdemo_rsim_param_tuning');
```

1. Build Model with RSim Target

2. Run RSIMGETRTP

3. Save RTP structure in a MAT-File

4. Open the MATLAB RSim GUI Example

Copyright 1994-2012 The MathWorks, Inc.

The RSim target was designed to let you run batch simulations at the fastest possible speed. Using variable-step or fixed-step solvers with RSim combined with the use of a tunable parameter data structure, you can create multiple parameter sets to run with the RSim target's standalone executable file (.exe on Windows) generated using Simulink Coder. Each invocation of the executable allows specification of the filename to use for results.

This model uses the RSim target to allow a non-real-time executable to be passed new data without the need to recompile the Simulink model. This feature allows you to easily get a map of the tunable parameters declared in a model and save it in a MAT-file. You can then create your own MATLAB GUI or a standalone GUI (independent of MATLAB) to read and write the MAT-file and rerun the executable to produce new output files.

Double-click the buttons at the upper right sequentially to run the example. To review the code used to create both the MATLAB GUI and standalone GUI, double-click the View MATLAB programs button.

For more information, you can also refer to the "Rapid Simulation Target" section in the Simulink Coder documentation.

View MATLAB programs

This model uses the RSim target and the `rsimgetrtpt` function to allow a non real time executable to be passed new data without the need to recompile the Simulink model. This feature allows you to get a map of the tunable parameters declared in a model and save it in a MAT-file. You can then create your own MATLAB GUI or a standalone GUI (independent of MATLAB) to read and write the MAT-file and rerun the executable to produce new output files.

Double-click the buttons at the upper right sequentially to run the example.

To review the code used to create both the MATLAB GUI and standalone GUI, double-click the View MATLAB programs button.

For more information, you can also refer to the "Rapid Simulation Target" section in the Simulink Coder documentation.

## Rapid Simulation Target Limitations

The RSim target has the following limitations:

- Does not support algebraic loops.
- Does not support Interpreted MATLAB Function blocks.
- Does not support noninlined MATLAB language or Fortran S-functions.
- If an RSim build includes referenced models (by using Model blocks), set up these models to use fixed-step solvers to generate code for them. The top model, however, can use a variable-step solver as long as the blocks in the referenced models are discrete.
- In certain cases, changing block parameters can result in structural changes to your model that change the model checksum. An example of such a change is changing the number of delays in a DSP simulation. In such cases, you must regenerate the code for the model.

# Accelerate Simulation, Reuse Code, or Protect Intellectual Property by Using S-Function Target

S-functions are an important class of system target file for which the code generator can produce code. The ability to encapsulate a subsystem into an S-function allows you to increase its execution efficiency and facilitate code reuse.

The following sections describe the properties of S-function targets and illustrate how to generate them. For more details on the structure of S-functions, see “Host-Specific Code”.

## In this section...

- “About the S-Function Target” on page 46-33
- “Create S-Function Blocks from a Subsystem” on page 46-36
- “Tunable Parameters in Generated S-Functions” on page 46-40
- “System Target File” on page 46-42
- “Checksums and the S-Function Target” on page 46-42
- “Generated S-Function Compatibility” on page 46-43
- “S-Function Target Limitations” on page 46-43

## About the S-Function Target

Using the S-function target, you can build an S-function component and use it as an S-Function block in another model. The following sections describe deployment considerations for the S-function target.

- “Required Files for S-Function Deployment” on page 46-34
- “Sample Time Propagation in Generated S-Functions” on page 46-35
- “Choose a Solver Type” on page 46-35
- “Solver Type Overrides” on page 46-36

The ‘S-Function’ value for CodeFormat TLC variable used by the S-function target generates code that conforms to the Simulink C MEX S-function application programming interface (API). Applications of this format include

- Conversion of a model to a component. You can generate an S-Function block for a model, `m1`. Then, you can place the generated S-Function block in another model, `m2`. Regenerating code for `m2` does not require regenerating code for `m1`.

- Conversion of a subsystem to a component. By extracting a subsystem to a separate model and generating an S-Function block from that model, you can create a reusable component from the subsystem. See “Create S-Function Blocks from a Subsystem” on page 46-36 for an example of this procedure.
- Speeding up simulation. Often, an S-function generated from a model performs more efficiently than the original model.
- Code reuse. You can incorporate multiple instances of one model inside another without replicating the code for each instance. Each instance continues to maintain its own unique data.

You can place a generated S-function block into another model from which you can generate another S-function. This approach allows any level of nested S-functions. For limitations related to nesting, see “Limitations on Nesting S-Functions” on page 46-47.

---

**Note:** While the S-function target provides a means to deploy an application component for reuse while shielding its internal logic from inspection and modification, the preferred solutions for protecting intellectual property in distributed components are:

- The protected model, a referenced model that hides all block and line information. For more information, see “Protected Model” in the Simulink documentation.
  - The shared library system target file, used to generate a shared library for a model or subsystem for use in a system simulation external to Simulink. For more information, see “Package Generated Code as Shared Object Libraries” on page 47-2 in the Embedded Coder documentation.
- 

### Required Files for S-Function Deployment

There are different files required to deploy a generated S-Function block for simulation versus code generation.

To deploy your generated S-Function block for inclusion in other models *for simulation*, you need only provide the binary MEX-file object that was generated in the current working folder when the S-Function block was created. The required file is:

- `subsys_sf.mexext`

where `subsys` is the subsystem name and `mexext` is a platform-dependent MEX-file extension (see `mexext`). For example, `SourceSubsys_sf.mexw64`.

To deploy your generated S-Function block for inclusion in other models *for code generation*, you must provide all of the files that were generated in the current working folder when the S-Function block was created. The required files are:

- `subsys_sf.c` or `.cpp`, where `subsys` is the subsystem name (for example, `SourceSubsys_sf.c`)
- `subsys_sf.h`
- `subsys_sf.mexext`, where `mexext` is a platform-dependent MEX-file extension (see `mexext`)
- Subfolder `subsys_sfcn_rtw` and its contents

---

**Note:** The generated S-function code uses **Configuration Parameters > Hardware Implementation** parameter values that match the host system on which the function was built. When you use the S-function in a model for code generation, make sure that these parameter values for the model match the parameter values of the S-function.

---

### Sample Time Propagation in Generated S-Functions

A generated S-Function block can inherit its sample time from the model in which it is placed if certain criteria are met. Conditions that govern sample time propagation for both Model blocks and generated S-Function blocks are described in “Sample Times for Model Referencing” in the Simulink documentation and “Inherited Sample Time for Referenced Models” on page 4-25.

To generate an S-Function block that meets the criteria for inheriting sample time, you must constrain the solver for the model from which the S-Function block is generated. On the **Solver** configuration parameters dialog box pane, set **Type** to **Fixed-step** and **Periodic sample time constraint** to **Ensure sample time independent**. If the model is unable to inherit sample times, this setting causes the Simulink software to display an error message when building the model. See “Periodic sample time constraint” in the Simulink documentation for more information about this option.

### Choose a Solver Type

The table shows the possible combinations of top-level model solver types as these types relate to subsystem build types and solver types for generated S-functions.

### Top-level Model Solver Options and Subsystem Build Types

	Model Configuration Parameters: top-level model configuration	
Subsystem Build Type	Solver options, Type: Variable-step	Solver options, Type: Fixed-step
Build This Subsystem	Generated S-function does NOT require variable-step solver	Generated S-function does NOT require variable-step solver
Generate S-Function	Generated S-function requires variable-step solver	Generated S-function does NOT require variable-step solver

**Note:** S-functions generated from a subsystem have parameters that are hard coded into the block. Simulink calculates parameters such as sample time when it generates the block, not during simulation run time. Hence, it is important to verify whether the generated S-Function block works as expected in the destination model.

### Solver Type Overrides

There are instances when the subsystem build type selection produces an override of the subsystem solver type. The table summarizes the relationships between subsystem build types and the applied subsystem solver types.

#### Top-level Model Solver Type Overrides of Subsystem Solver Types by Build Type

	Model Configuration Parameters: top-level model configuration	
Subsystem Build Type	Solver options, Type: Variable-step	Solver options, Type: Fixed-step
Build This Subsystem	Subsystem uses fixed-step solver type	Subsystem uses fixed-step solver type
Generate S-Function	Subsystem uses variable-step solver type	Subsystem uses fixed-step solver type

### Create S-Function Blocks from a Subsystem

This section illustrates how to extract a subsystem from a model and generate a reusable S-function component from it.

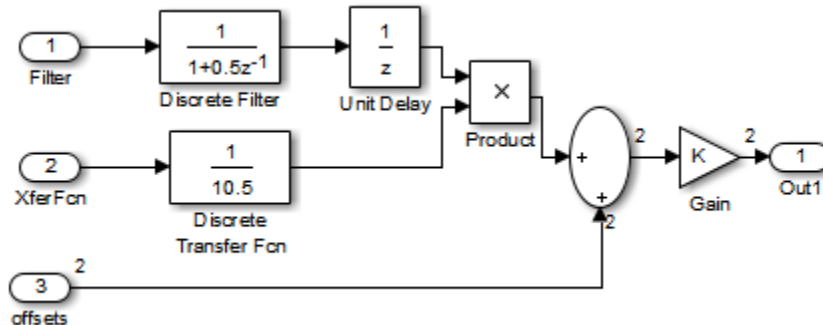

The next figure shows **SourceModel1**, a simple model that inputs signals to a subsystem. The subsequent figure shows the subsystem, **SourceSubsys**. The signals, which have different widths and sample times, are:

- A Step block with sample time 1
- A Sine Wave block with sample time 0.5
- A Constant block whose value is the vector [-2 3]

### SourceModel

### SourceSubsys

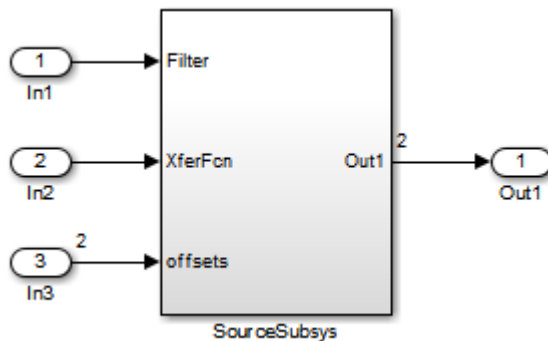

The objective is to extract `SourceSubsys` from the model and build an S-Function block from it, using the S-function target. The S-Function block must perform identically to the subsystem from which it was generated.

In this model, `SourceSubsys` inherits sample times and signal widths from its input signals. However, S-Function blocks created from a model using the S-function target has all signal attributes (such as signal widths or sample times) hard-wired. (The sole exception to this rule concerns sample times, as described in “Sample Time Propagation in Generated S-Functions” on page 46-35.)

In this example, you want the S-Function block to retain the properties of `SourceSubsys` as it exists in `SourceModel`. Therefore, before you build the subsystem as a separate S-function component, you must set the inport sample times and widths explicitly. In addition, the solver parameters of the S-function component must be the same as those parameters of the original model. The generated S-function component operates identically to the original subsystem (see “Choose a Solver Type” on page 46-35 for more information).

To build `SourceSubsys` as an S-function component,

- 1 Create a new model and copy/paste the `SourceSubsys` block into the empty window.
- 2 Set the signal widths and sample times of inports inside `SourceSubsys` such that they match those of the signals in the original model. Inport 1, `Filter`, has a width of 1 and a sample time of 1. Inport 2, `XferFcn`, has a width of 1 and a sample time of 0.5. Inport 3, `offsets`, has a width of 2 and a sample time of 0.5.
- 3 The generated S-Function block should have three inports and one output. Connect inports and an output to `SourceSubsys`, as shown in the next figure.

The signal widths and sample times are propagated to these ports.

- 4 Set the solver type, mode, and other solver parameters such that they are identical to those of the source model. This is easiest to do if you use Model Explorer.
- 5 In the Configuration Parameters dialog box, go to the **Code Generation** pane.
- 6 Click **Browse** to open the System Target File Browser.
- 7 In the System Target File Browser, select the S-function target, `rtwsfcn.tlc`, and click **OK**.
- 8 Select the **S-Function Target** pane. Make sure that **Create new model** is selected, as shown in the next figure:

When this option is selected, the build process creates a new model after it builds the S-function component. The new model contains an S-Function block, linked to the S-function component.

Click **Apply**.

- 9 Save the new model containing your subsystem, for example as `SourceSubsys`.
- 10 Build the model.
- 11 The build process produces the S-function component in the working folder. After the build, a new model window is displayed.

Optionally you can save the generated model, for example as `SourceSubsys_Sfunction`.

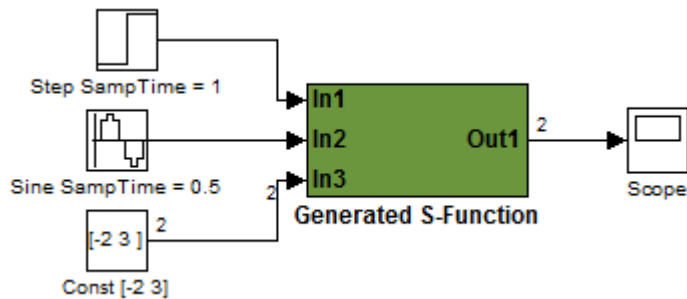

- 12 You can now copy the S-Function block generated from the new model and use it in other models or in a library.

---

**Note:** For a list of files required to deploy your S-Function block for simulation or code generation, see “Required Files for S-Function Deployment” on page 46-34.

---

The next figure shows the S-Function block plugged into the original model. Given identical input signals, the S-Function block performs identically to the original subsystem.

### Generated S-Function Configured Like SourceModel

The speed at which the S-Function block executes is typically faster than the original model. This difference in speed is more pronounced for larger and more complicated models. By using generated S-functions, you can increase the efficiency of your modeling process.

## Tunable Parameters in Generated S-Functions

You can use tunable parameters in generated S-functions in two ways:

- Use the **Generate S-function** feature (see “Automate S-Function Generation with S-Function Builder” on page 39-22).

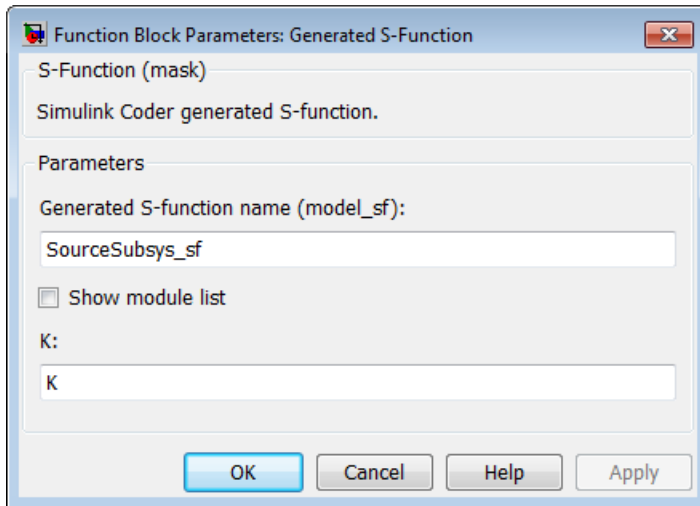

or

- Use the Model Parameter Configuration dialog box (see “Block Parameter Representation in the Generated Code” on page 18-43) to declare desired block parameters tunable.

Block parameters that are declared tunable with the `auto` storage class in the source model become tunable parameters of the generated S-function. These parameters do not become part of a generated `model_P` (formerly `rtP`) parameter data structure, as they would in code generated from other targets. Instead, the generated code accesses these parameters by using MEX API calls such as `mxGetPr` or `mxGetData`. Your code should access these parameters in the same way.

For more information on MEX API calls, see “About C S-Functions” and “MATLAB API for Other Languages”.

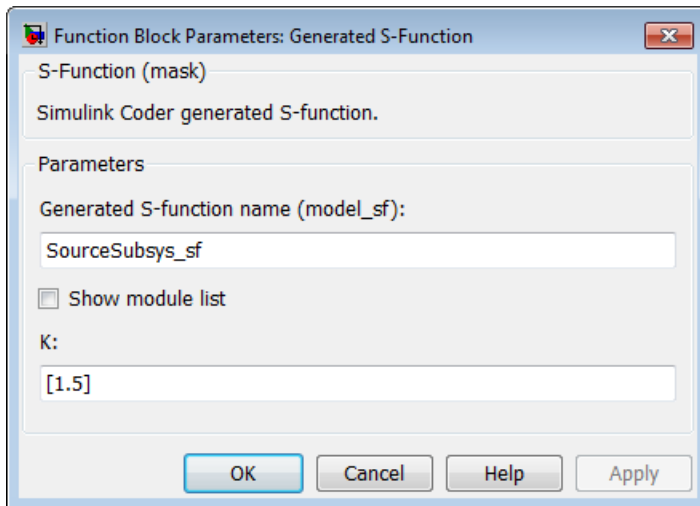

S-Function blocks created by using the S-function target are automatically masked. The mask displays each tunable parameter in an edit field. By default, the edit field displays the parameter by variable name, as in the following example.

You can choose to display the value of the parameter rather than its variable name by selecting **Use value for tunable parameters** on the **Code Generation > S-Function Target** pane of the Configuration Parameters dialog box.

When this option is chosen, the value of the variable (at code generation time) is displayed in the edit field, as in the following example.

## System Target File

The `rtwsfcn.tlc` system target file is provided for use with the S-function target.

## Checksums and the S-Function Target

The code generator creates a checksum for a model and uses the checksum during the build process for code reuse, model reference, and external mode features.

The code generator calculates a model checksum by

- 1 Calculating a checksum for each subsystem in the model. A subsystem's checksum is the combination of properties (data type, complexity, sample time, port dimensions, and so forth) of the subsystem's blocks.
- 2 Combining the subsystem checksums and other model-level information.

An S-function can add additional information, not captured during the block property analysis, to a checksum by calling the function `ssSetChecksumVal`. For the S-Function target, the value that gets added to the checksum is the checksum of the model or subsystem from which the S-function is generated.

The code generator applies the subsystem and model checksums as follows:

- Code reuse — If two subsystems in a model have the same checksum, the code generator produces code for one function only.
- Model reference — If the current model checksum matches the checksum when the model was built, the build process does not rebuild referenced models.
- External mode — If the current model checksum does not match the checksum of the code that is running on the target hardware, the build process generates an error.

## Generated S-Function Compatibility

When you build a MEX S-function from your model, the code generator builds a level 2 noninlined S-function. Cross-release usage limitations on the generated code and binary MEX file (for example, \*.mexw64) include:

- S-function target generated code from previous MATLAB release software is not compatible with newer releases. Do not recompile the generated code from a previous release with newer MATLAB release software. Use the same MATLAB release software to generate code for the S-function target and compile the code into a MEX file.
- You can use binary S-function MEX files generated from previous MATLAB release software with the same or newer releases with the same compatibility considerations as handwritten S-functions. For more information, see “S-Function Compatibility”.
- The code generator can generate code and build an executable from a model that contains generated S-functions. This support requires that the S-functions are built with the same MATLAB release software that builds the model. It is not possible to incorporate a generated S-function MEX file from previous MATLAB release software into a model and build the model with newer releases.

## S-Function Target Limitations

- “Unsupported Blocks” on page 46-47
- “SimState Not Supported for Code Generation” on page 46-47

- “Profiling Code Performance Not Supported” on page 46-47
- “Limitations on Nesting S-Functions” on page 46-47
- “Limitations on User-Defined Data Types” on page 46-48
- “Limitation on Right-Click Generation of an S-Function Target” on page 46-48
- “Limitation on S-Functions with Bus I/O Signals” on page 46-48
- “Limitation on Subsystems with Function-Call I/O Signals” on page 46-49
- “Data Store Access” on page 46-49
- “Cannot Specify Outport Dimensions Through Subsystem Mask” on page 46-49

### Limitations on Using Tunable Variables in Expressions

Certain limitations apply to the use of tunable variables in expressions. When the code generator encounters an unsupported expression while producing code, a warning appears and the equivalent numeric value is generated in the code. For a list of the limitations, see “Tunable Expression Limitations” on page 18-49.

### Parameter Tuning

The S-Function block does not support tuning of tunable parameters with:

- Complex values.
- Values or data types that are transformed to a constant (by setting the model configuration parameter **Optimization > Signals and Parameters > Default parameter behavior** to **Inlined**).
- Data types that are not built-in.

If you select these tunable parameters (through the Generate S-Function for Subsystem dialog box):

- The software produces warnings during the build process.
- The generated S-Function block mask does not display these parameters.

### Run-Time Parameters and S-Function Compatibility Diagnostics

If you set the **S-function upgrades needed** option on the **Diagnostics > Compatibility** pane of the Configuration Parameters dialog box to **warning** or **error**, the code generator instructs you to upgrade S-functions that you create with the **Generate S-function** feature. This is because the S-function system target file does

not register run-time parameters. Run-time parameters are only supported for inlined S-Functions and the generated S-Function supports features that prevent it from being inlined (for example, it can call or contain other noninlined S-functions).

You can work around this limitation by setting the **S-function upgrades needed** option to none.

### Limitations on Using Goto and From Block

When using the S-function system target file, the code generator restricts I/O to correspond to the root model Inport and Outport blocks (or the Inport and Outport blocks of the Subsystem block from which the S-function target was generated). No code is generated for Goto or From blocks.

To work around this restriction, create your model and subsystem with the required Inport and Outport blocks, instead of using Goto and From blocks to pass data between the root model and subsystem. In the model that incorporates the generated S-function, you would then add Goto and From blocks.

### Example Before Work Around

- Root model with a From block and subsystem, `Subsystem1`

- `Subsystem1` with a Goto block, which has global visibility and passes its input to the `From` block in the root model

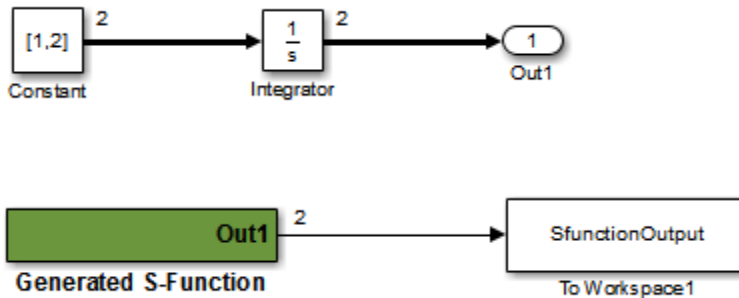

- `Subsystem1` replaced with an S-function generated with the S-Function target — a warning results when you run the model because the generated S-function does not implement the Goto block

### Example After Work Around

An Outport block replaces the GoTo block in `Subsystem1`. When you plug the generated S-function into the root model, its output connects directly to the To Workspace block.

### Limitations on Building and Updating S-Functions

The following limitations apply to building and updating S-functions using the S-function system target file:

- You cannot build models that contain Model blocks using the S-function system target file. This also means that you cannot build a subsystem module by right-clicking (or by using **Code > C/C++ Code > Build Selected Subsystem**) if the subsystem contains Model blocks. This restriction applies only to S-functions generated using the S-function target, not to ERT S-functions.
- If you modify the model that generated an S-Function block, the build process does not automatically rebuild models containing the generated S-Function block. This is in contrast to the practice of automatically rebuilding models referenced by Model blocks when they are modified (depending on the Model Reference **Rebuild** configuration setting).

- Handwritten S-functions without corresponding TLC files must contain exception-free code. For more information on exception-free code, see “Exception Free Code” in the Simulink documentation.

### **Unsupported Blocks**

The S-function format does not support the following built-in blocks:

- Interpreted MATLAB Function block
- S-Function blocks containing any of the following:
  - MATLAB language S-functions (unless you supply a TLC file for C code generation)
  - Fortran S-functions (unless you supply a TLC file for C code generation)
  - C/C++ MEX S-functions that call into the MATLAB environment
- Scope block
- To Workspace block

The S-function format does not support blocks from the `embeddedtargetslib` block library.

### **SimState Not Supported for Code Generation**

You can use `SimState` within C-MEX and Level-2 MATLAB language S-functions to save and restore the simulation state (see “S-Function Compliance with the `SimState`” in the Simulink documentation). However, `SimState` is not supported for code generation, including with the S-function system target file.

### **Profiling Code Performance Not Supported**

Profiling the performance of generated code using the Target Language Compiler (TLC) hook function interface described by the example model `rtwdemo_profile` is not supported for the S-function target.

### **Limitations on Nesting S-Functions**

The following limitations apply to nesting a generated S-Function block in a model or subsystem from which you generate another S-function:

- The software does not support nonvirtual bus input and output signals for a nested S-function.

- You should avoid nesting an S-function in a model or subsystem having the same name as the S-function (possibly several levels apart). In such situations, the S-function can be called recursively. The software currently does not detect such loops in S-function dependency, which can result in aborting or hanging your MATLAB session. To prevent this from happening, be sure to name the subsystem or model to be generated as an S-function target uniquely, to avoid duplicating existing MEX filenames on the MATLAB path.

### Limitations on User-Defined Data Types

The S-function system target file does not support the `HeaderFile` property that can be specified on user-defined data types, including those based on `Simulink.AliasType`, `Simulink.Bus`, and `Simulink.NumericType` objects. If a user-defined data type in your model uses the `HeaderFile` property to specify an associated header file, code generation with the S-function system target file disregards the value and does not generate a corresponding include statement.

### Limitation on Right-Click Generation of an S-Function Target

If you generate an S-function target by right-clicking a Function-Call Subsystem block, the original subsystem and the generated S-function might not be consistent. An inconsistency occurs when the **States when enabling** parameter of the Trigger Port block inside the Function-Call Subsystem block is set to **inherit**. You must set the **States when enabling** parameter to **reset** or **held**, otherwise Simulink reports an error.

### Limitation on S-Functions with Bus I/O Signals

If an S-function generated using the S-function target has bus input or output signals, the generated bus data structures might include padding to align fields of the bus elements with the Simulink representation used during simulation. However, if you insert the S-function in a model and generate code using a model target such as `grt.tlc`, the bus structure alignment generated for the model build might be incompatible with the padding generated for the S-function and might affect the numerical results of code execution. To make the structure alignment consistent between model simulation and execution of the model code, for each `Simulink.Bus` object, you can modify the `HeaderFile` property to remove the unpadded bus structure header file. This will cause the bus typedefs generated for the S-function to be reused in the model code.

### Limitation on Subsystems with Function-Call I/O Signals

The S-function target does not support creating an S-Function block from a subsystem that has a function-call trigger input or a function-call output.

### Data Store Access

When an S-Function in your model accesses a data store during simulation, Simulink disables data store diagnostics.

- If you created the S-Function from a model, the diagnostic is disabled for global data stores as well.
- If you created the S-Function from a subsystem, the diagnostic is disabled for the following data stores:
  - Global data stores
  - Data stores placed outside the subsystem, but accessed by Data Store Read or Data Store Write blocks.

### Cannot Specify Output Dimensions Through Subsystem Mask

You cannot specify **Port dimensions** for an Outport block through a subsystem mask if you want to generate an S-Function block from the subsystem. The software produces an error when you try to run a simulation that uses the S-Function block, for example:

```
Invalid setting in 'testSystem/Subsystem/__OutputSSForSFun__/Out2'
for parameter 'PortDimensions'
...
```

## Package Generated Code as Shared Object Libraries

The Embedded Coder product provides the system target file `ert_shrlib.tlc` for generating a shared library version of model code for your development platform. The shared library file can be a Windows dynamic link library (`.dll`) file, a UNIX shared object (`.so`) file, or a Macintosh OS X dynamic library (`.dylib`) file. Package your source code for easy distribution and shared use. The generated `.dll`, `.so`, or `.dylib` file is shareable among different applications and upgradeable without having to recompile the applications that use it.

### About Generated Shared Libraries

Code generation for the `ert_shrlib.tlc` target exports

- Variables and signals of type `ExportedGlobal` as data
- Real-time model structure (`model_M`) as data
- Functions essential to executing your model code

To view a list of symbols contained in a generated shared library file, you can

- On Windows, use the Dependency Walker utility, downloadable from <http://www.dependencywalker.com>
- On UNIX, use `nm -D model.so`
- On Macintosh OS X, use `nm -g model.dylib`

To generate and use a host-based shared library, you

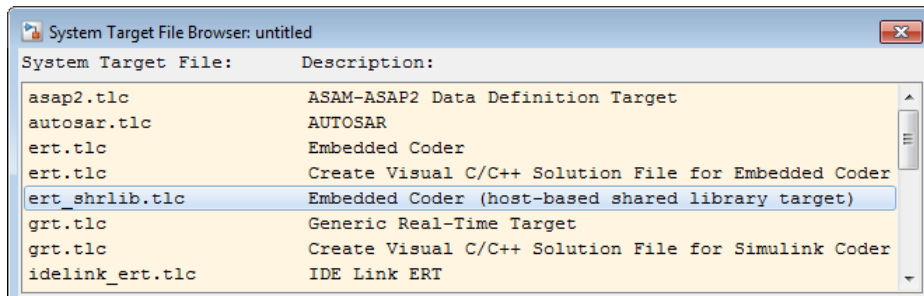

- 1 Generate a shared library version of your model code
- 2 Create application code to load and use your shared library file

### Generate Shared Library Version of Model Code

This section summarizes the steps to generate a shared library version of your model code.

- 1 To configure your model code for shared use by applications, open your model and select the `ert_shrlib.tlc` target on the **Code Generation** pane of the Configuration Parameters dialog box. Click **OK**.

Selecting the `ert_shrplib.tlc` target causes the build process to generate a shared library version of your model code into your current working folder. The selection does not change the code that is generated for your model.

- 2 Build the model.
- 3 After the build completes, you can examine the generated code in the model subfolder and examine the `.dll`, `.so`, or `.dylib` file that has been generated into your current folder.

## Create Application Code to Use Shared Library

To illustrate how application code can load an ERT shared library file and access its functions and data, MathWorks provides the model `rtwdemo_shrplib`. Clicking the blue button in the model runs a script that:

- 1 Builds a shared library file from the model (for example, `rtwdemo_shrplib_win64.dll` on 64-bit Windows)
- 2 Compiles and links an example application, `rtwdemo_shrplib_app`, that will load and use the shared library file
- 3 Executes the example application

---

**Note:** Change directory to a writable working folder before running the `rtwdemo_shrplib` script.

---

---

**Tip** Explicit linking is preferred for portability. But, on Windows systems, the `ert_shrplib` target generates and retains the `.lib` file to support implicit linking.

---

To use implicit linking, the generated `model.h` file needs a small modification to be used together with the generated `ert_main.c`. For example, if you are using Visual C++, you need to declare `__declspec(dllimport)` in front of data to be imported implicitly from the shared library file.

The model uses the following example application files, which are located in the folder `matlabroot/toolbox/rtw/rtwdemos/shrplib_demo` (open).

File	Description
<code>rtwdemo_shrplib_app.h</code>	Example application header file
<code>rtwdemo_shrplib_app.c</code>	Example application that loads and uses the shared library file generated for the model
<code>run_rtwdemo_shrplib_app.m</code>	Script to compile, link, and execute the example application

You can view each of these files by clicking white buttons in the model window. Additionally, running the script places the relevant source and generated code files in your current folder. The files can be used as templates for writing application code for your own ERT shared library files.

The following sections present key excerpts of the example application files.

### Example Application Header File

The example application header file `rtwdemo_shrplib_app.h` contains type declarations for the model's external input and output.

```
#ifndef _APP_MAIN_HEADER_
#define _APP_MAIN_HEADER_

typedef struct {
 int32_T Input;
} ExternalInputs_rtwdemo_shrplib;

typedef struct {
 int32_T Output;
} ExternalOutputs_rtwdemo_shrplib;

#endif /* _APP_MAIN_HEADER_ */
```

## Example Application C Code

The example application `rtwdemo_shrllib_app.c` includes the following code for dynamically loading the shared library file. Notice that, depending on platform, the code invokes Windows or UNIX library commands.

```

#if defined(_WIN32)||defined(_WIN64) /* WINDOWS */
#include <windows.h>
#define GETSYMBOLADDR GetProcAddress
#define LOADLIB LoadLibrary
#define CLOSELIB FreeLibrary

#else /* UNIX */
#include <dlfcn.h>
#define GETSYMBOLADDR dlsym
#define LOADLIB dlopen
#define CLOSELIB dlclose

#endif

int main()
{
 void* handleLib;
 ...
 #if defined(_WIN64)
 handleLib = LOADLIB("./rtwdemo_shrllib_win64.dll");
 #else
 #if defined(_WIN32)
 handleLib = LOADLIB("./rtwdemo_shrllib_win32.dll");
 #else /* UNIX */
 handleLib = LOADLIB("./rtwdemo_shrllib.so", RTLD_LAZY);
 #endif
 #endif
 ...
 return(CLOSELIB(handleLib));
}

```

The following code excerpt shows how the C application accesses the model's exported data and functions. Notice the hooks for adding user-defined initialization, step, and termination code.

```

 int32_T i;
 ...
 void (*mdl_initialize)(boolean_T);
 void (*mdl_step)(void);
 void (*mdl_terminate)(void);

 ExternalInputs_rtwdemo_shrllib (*mdl_Uptr);
 ExternalOutputs_rtwdemo_shrllib (*mdl_Yptr);

 uint8_T (*sum_outptr);
 ...
 #if (defined(LCCDLL)||defined(BORLANDCDLL))

```

```

/* Exported symbols contain leading underscores when DLL is linked with
LCC or BORLANDC */
mdl_initialize = (void(*) (boolean_T))GETSYMBOLADDR(handleLib ,
 "_rtwdemo_shrplib_initialize");
mdl_step = (void(*) (void))GETSYMBOLADDR(handleLib ,
 "_rtwdemo_shrplib_step");
mdl_terminate = (void(*) (void))GETSYMBOLADDR(handleLib ,
 "_rtwdemo_shrplib_terminate");
mdl_Uptr = (ExternalInputs_rtwdemo_shrplib*)GETSYMBOLADDR(handleLib ,
 "_rtwdemo_shrplib_U");
mdl_Yptr = (ExternalOutputs_rtwdemo_shrplib*)GETSYMBOLADDR(handleLib ,
 "_rtwdemo_shrplib_Y");
sum_outptr = (uint8_T*)GETSYMBOLADDR(handleLib , "_sum_out");
#else
mdl_initialize = (void(*) (boolean_T))GETSYMBOLADDR(handleLib ,
 "rtwdemo_shrplib_initialize");
mdl_step = (void(*) (void))GETSYMBOLADDR(handleLib ,
 "rtwdemo_shrplib_step");
mdl_terminate = (void(*) (void))GETSYMBOLADDR(handleLib ,
 "rtwdemo_shrplib_terminate");
mdl_Uptr = (ExternalInputs_rtwdemo_shrplib*)GETSYMBOLADDR(handleLib ,
 "rtwdemo_shrplib_U");
mdl_Yptr = (ExternalOutputs_rtwdemo_shrplib*)GETSYMBOLADDR(handleLib ,
 "rtwdemo_shrplib_Y");
sum_outptr = (uint8_T*)GETSYMBOLADDR(handleLib , "sum_out");
#endif

if ((mdl_initialize && mdl_step && mdl_terminate && mdl_Uptr && mdl_Yptr &&
 sum_outptr)) {
 /* === user application initialization function === */
 mdl_initialize(1);
 /* insert other user defined application initialization code here */

 /* === user application step function === */
 for(i=0;i<=12;i++){
 mdl_Uptr->Input = i;
 mdl_step();
 printf("Counter out(sum_out): %d\tAmplifier in(Input): %d\tout(Output): %d\n",
 *sum_outptr, i, mdl_Yptr->Output);
 /* insert other user defined application step function code here */
 }

 /* === user application terminate function === */
 mdl_terminate();
 /* insert other user defined application termination code here */
}
else {
 printf("Cannot locate the specified reference(s) in the shared library.\n");
 return(-1);
}

```

## Example Application Script

The application script `run_rtwdemo_shrlib_app` loads and rebuilds the model, and then compiles, links, and executes the model's shared library target file. You can view the script source file by opening `rtwdemo_shrlib` and clicking a white button to view source code. The script constructs platform-dependent command character vectors for compilation, linking, and execution that may apply to your development environment. To run the script, click the blue button.

---

**Note:** To run the `run_rtwdemo_shrlib_app` script without first opening the `rtwdemo_shrlib` model, change directory to a writable working folder and issue the following MATLAB command:

```
addpath(fullfile(matlabroot, 'toolbox', 'rtw', 'rtwdemos', 'shrlib_demo'))
```

---

## Host-Based Shared Library Limitations

The following limitations apply to using ERT host-based shared libraries:

- Code generation for the `ert_shrlib.tlc` target exports only the following as data:
  - Variables and signals of type `ExportedGlobal`
  - Real-time model structure (`model_M`)
- Code generation for the `ert_shrlib.tlc` target supports the C language only (not C++). When you select the `ert_shrlib.tlc` target, language selection is greyed out on the **Code Generation** pane of the Configuration Parameters dialog box.
- To reconstruct a model simulation using a generated host-based shared library, the application author must maintain the timing between system and shared library function calls in the original application. The timing needs to be consistent so that you can compare the simulation and integration results. Additional simulation considerations apply if generating a shared object library from a model that enables parameters **Support: continuous time** and **Single output/update function**. For more information, see “Single output/update function” dependencies.

- “Deploy Environment Model for Real-Time Hardware-In-the-Loop (HIL) Simulation” on page 48-5

## Deploy Algorithm Model for Real-Time Rapid Prototyping

Use the code generator to deploy algorithm models for real-time rapid prototyping.

### In this section...

“About Real-Time Rapid Prototyping” on page 48-2

“Goals of Real-Time Rapid Prototyping” on page 48-2

“Refine Code With Real-Time Rapid Prototyping” on page 48-3

### About Real-Time Rapid Prototyping

Real-time rapid prototyping requires the use of a real-time simulator, potentially connected to system hardware (for example, physical plant or vehicle) being controlled. You generate, deploy, and tune code as it runs on the real-time simulator or embedded microprocessor. This design step is crucial for verifying whether a component can adequately control the system, and allows you to assess, interact with, and optimize code.

The following figure shows a typical approach for real-time rapid prototyping.

### Goals of Real-Time Rapid Prototyping

Assuming that you have documented functional requirements, refined concept models, system hardware for the physical plant or vehicle being controlled, and access to target

products you intend to use (for example, for example, the Simulink Real-Time or Simulink Desktop Real-Time product), you can use real-time prototyping to:

- Refine component and environment model designs by rapidly iterating between algorithm design and prototyping
- Validate whether a component can adequately control the physical system in real time
- Evaluate system performance before laying out hardware, coding production software, or committing to a fixed design
- Test hardware

## Refine Code With Real-Time Rapid Prototyping

To perform real-time rapid prototyping:

- 1 Create or acquire a real-time system that runs in real time on rapid prototyping hardware. The Simulink Real-Time product facilitates real-time rapid prototyping. This product provides a real-time operating system that makes PCs run in real time. It also provides device driver blocks for numerous hardware I/O cards. You can then create a rapid prototyping system using inexpensive commercial-off-the-shelf (COTS) hardware. In addition, third-party vendors offer products based on the Simulink Real-Time product or other code generation technology that you can integrate into a development environment.
- 2 Use provided system target files to generate code that you can deploy onto a real-time simulator. See the following information.

Engineering Tasks	Related Product Information	Examples
Generate code for real-time rapid prototyping	“System Target Files and Code Generation Features”  “Event-Based Scheduling”  — Embedded Coder  “Support for Standards and Guidelines” on page 11-2 — Embedded Coder	rtwdemo_counter

Engineering Tasks	Related Product Information	Examples

## Deploy Environment Model for Real-Time Hardware-In-the-Loop (HIL) Simulation

### In this section...

“About Hardware-In-the-Loop Simulation” on page 48-5

“Set Up and Run HIL Simulations” on page 48-6

### About Hardware-In-the-Loop Simulation

Hardware-in-the-loop (HIL) simulation tests and verifies an embedded system or control unit in the context of a software test platform. Examples of test platforms include real-time target systems and instruction set simulators (IISs). You use Simulink software to develop and verify a model that represents the test environment. Using the code generator, you produce, build, and download an executable program for the model to the HIL simulation platform. After you set up the environment, you can run the executable to validate the embedded system or control unit in real time.

During HIL simulation, you gradually replace parts of a system environment with hardware components as you refine and fabricate the components. HIL simulation offers an efficient design process that eliminates costly iterations of part fabrication.

The code that you build for the system simulator provides real-time system capabilities. For example, the code can include VxWorks from Wind River or another real-time operating system (RTOS).

The following figure shows a typical HIL setup.

The HIL platform available from MathWorks is the Simulink Real-Time product. Several third-party products are also available for use as HIL platforms. The Simulink Real-Time product offers hard real-time performance for PCs with Intel or AMD<sup>®</sup> 32-bit processors functioning as your real-time target. The Simulink Real-Time product enables you to add I/O interface blocks to your models and automatically generate code with code generation technology. The Simulink Real-Time product can download the code to a second PC running the Simulink Real-Time real-time kernel. System integrator solutions that are based on Simulink Real-Time are also available.

## **Set Up and Run HIL Simulations**

To set up and run HIL simulations iterate through the following steps:

- 1** Develop a model that represents the environment or system under development. For more information, see:
  - “System Target Files and Code Generation Features”
- 2** Generate an executable for the environment model.
- 3** Download the executable for the environment model to the HIL simulation platform.
- 4** Replace software representing a system component with corresponding hardware.
- 5** Test the hardware in the context of the HIL system.
- 6** Repeat steps 4 and 5 until you can simulate the system after including components that require testing.

# Real-Time and Embedded Systems in Embedded Coder

---

- “Deploy Generated Standalone Executables To Target Hardware” on page 49-2
- “Deploy Generated Embedded System Software to Application Target Platforms” on page 49-22

## Deploy Generated Standalone Executables To Target Hardware

By default, the Embedded Coder software generates *standalone* executable programs that do not require an external real-time executive or operating system. A standalone program requires minimal modification to be adapted to the target hardware. The standalone program architecture supports execution of models with either single or multiple sample rates.

### In this section...

“Generate a Standalone Program” on page 49-2

“Standalone Program Components” on page 49-3

“Main Program” on page 49-3

“rt\_OneStep and Scheduling Considerations” on page 49-4

“Static Main Program Module” on page 49-10

“Rate Grouping Compliance and Compatibility Issues” on page 49-17

## Generate a Standalone Program

To generate a standalone program:

- 1 In the **Custom templates** section of the **Code Generation > Templates** pane of the Configuration Parameters dialog box, select the **Generate an example main program** option (which is on by default). This enables the **Target operating system** menu.
- 2 From the **Target operating system** menu, select **BareBoardExample** (the default selection).
- 3 Generate the code.

Different code is generated for multirate models depending on the following factors:

- Whether the model executes in single-tasking or multitasking mode.
- Whether or not reusable code is being generated.

These factors affect the scheduling algorithms used in generated code, and in some cases affect the API for the model entry point functions. The following sections discuss these variants.

## Standalone Program Components

The core of a standalone program is the main loop. On each iteration, the main loop executes a background or null task and checks for a termination condition.

The main loop is periodically interrupted by a timer. The function `rt_OneStep` is either installed as a timer interrupt service routine (ISR), or called from a timer ISR at each clock step.

The execution driver, `rt_OneStep`, sequences calls to the `model_step` functions. The operation of `rt_OneStep` differs depending on whether the generating model is single-rate or multirate. In a single-rate model, `rt_OneStep` simply calls the `model_step` function. In a multirate model, `rt_OneStep` prioritizes and schedules execution of blocks according to the rates at which they run.

## Main Program

- “Overview of Operation” on page 49-3
- “Guidelines for Modifying the Main Program” on page 49-4

### Overview of Operation

The following pseudocode shows the execution of a main program.

```
main()
{
 Initialization (including installation of rt_OneStep as an
 interrupt service routine for a real-time clock)
 Initialize and start timer hardware
 Enable interrupts
 While(not Error) and (time < final time)
 Background task
 EndWhile
 Disable interrupts (Disable rt_OneStep from executing)
 Complete any background tasks
 Shutdown
}
```

The pseudocode is a design for a harness program to drive your model. The main program only partially implements this design. You must modify it according to your specifications.

### Guidelines for Modifying the Main Program

This section describes the minimal modifications you should make in your production version of the main program module to implement your harness program.

- 1 Call `model_initialize`.
- 2 Initialize target-specific data structures and hardware, such as ADCs or DACs.
- 3 Install `rt_OneStep` as a timer ISR.
- 4 Initialize timer hardware.
- 5 Enable timer interrupts and start the timer.

---

**Note** `rtModel` is not in a valid state until `model_initialize` has been called. Servicing of timer interrupts should not begin until `model_initialize` has been called.

---

- 6 Optionally, insert background task calls in the main loop.
- 7 On termination of the main loop (if applicable):
  - Disable timer interrupts.
  - Perform target-specific cleanup such as zeroing DACs.
  - Detect and handle errors. Note that even if your program is designed to run indefinitely, you may need to handle severe error conditions, such as timer interrupt overruns.

You can use the macros `rtmGetErrorStatus` and `rtmSetErrorStatus` to detect and signal errors.

### rt\_OneStep and Scheduling Considerations

- “Overview of Operation” on page 49-4
- “Single-Rate Single-Tasking Operation” on page 49-5
- “Multirate Multitasking Operation” on page 49-6
- “Multirate Single-Tasking Operation” on page 49-8
- “Guidelines for Modifying `rt_OneStep`” on page 49-9

### Overview of Operation

The operation of `rt_OneStep` depends upon

- Whether your model is single-rate or multirate. In a single-rate model, the sample times of all blocks in the model, and the model's fixed step size, are the same. A model in which the sample times and step size do not meet these conditions is termed multirate.
- Your model's solver mode (`SingleTasking` versus `MultiTasking`)

Permitted Solver Modes for Embedded Real-Time System Target Files summarizes the permitted solver modes for single-rate and multirate models. Note that for a single-rate model, only `SingleTasking` solver mode is allowed.

### Permitted Solver Modes for Embedded Real-Time System Target Files

Mode	Single-Rate	Multirate
<code>SingleTasking</code>	Allowed	Allowed
<code>MultiTasking</code>	Disallowed	Allowed
<code>Auto</code>	Allowed (defaults to <code>SingleTasking</code> )	Allowed (defaults to <code>MultiTasking</code> )

The generated code for `rt_OneStep` (and associated timing data structures and support functions) is tailored to the number of rates in the model and to the solver mode. The following sections discuss each possible case.

#### Single-Rate Single-Tasking Operation

The only valid solver mode for a single-rate model is `SingleTasking`. Such models run in “single-rate” operation.

The following pseudocode shows the design of `rt_OneStep` in a single-rate program.

```
rt_OneStep()
{
 Check for interrupt overflow or other error
 Enable "rt_OneStep" (timer) interrupt
 Model_Step() -- Time step combines output, logging, update
}
```

For the single-rate case, the generated `model_step` function is

```
void model_step(void)
```

Single-rate `rt_OneStep` is designed to execute `model_step` within a single clock period. To enforce this timing constraint, `rt_OneStep` maintains and checks a timer overrun flag. On entry, timer interrupts are disabled until the overrun flag and other error conditions have been checked. If the overrun flag is clear, `rt_OneStep` sets the flag, and proceeds with timer interrupts enabled.

The overrun flag is cleared only upon successful return from `model_step`. Therefore, if `rt_OneStep` is reinterrupted before completing `model_step`, the reinterrupt is detected through the overrun flag.

Reinterruption of `rt_OneStep` by the timer is an error condition. If this condition is detected `rt_OneStep` signals an error and returns immediately. (Note that you can change this behavior if you want to handle the condition differently.)

Note that the design of `rt_OneStep` assumes that interrupts are disabled before `rt_OneStep` is called. `rt_OneStep` should be noninterruptible until the interrupt overflow flag has been checked.

### **Multirate Multitasking Operation**

In a multirate multitasking system, code generation uses a prioritized, preemptive multitasking scheme to execute the different sample rates in your model.

The following pseudocode shows the design of `rt_OneStep` in a multirate multitasking program.

```
rt_OneStep()
{
 Check for base-rate interrupt overrun
 Enable "rt_OneStep" interrupt
 Determine which rates need to run this time step

 Model_Step0() -- run base-rate time step code

 For N=1:NumTasks-1 -- iterate over sub-rate tasks
 If (sub-rate task N is scheduled)
 Check for sub-rate interrupt overrun
 Model_StepN() -- run sub-rate time step code
 EndIf
 EndFor
}
```

### Task Identifiers

The execution of blocks having different sample rates is broken into tasks. Each block that executes at a given sample rate is assigned a *task identifier* (`tid`), which associates it with a task that executes at that rate. Where there are `NumTasks` tasks in the system, the range of task identifiers is `0..NumTasks-1`.

### Prioritization of Base-Rate and Subrate Tasks

Tasks are prioritized, in descending order, by rate. The *base-rate* task is the task that runs at the fastest rate in the system (the hardware clock rate). The base-rate task has highest priority (`tid 0`). The next fastest task (`tid 1`) has the next highest priority, and so on down to the slowest, lowest priority task (`tid NumTasks-1`).

The slower tasks, running at multiples of the base rate, are called *subrate* tasks.

### Rate Grouping and Rate-Specific `model_step` Functions

In a single-rate model, the block output computations are performed within a single function, `model_step`. For multirate, multitasking models, the code generator tries to use a different strategy. This strategy is called *rate grouping*. Rate grouping generates separate `model_step` functions for the base rate task and each subrate task in the model. The function naming convention for these functions is

`model_stepN`

where `N` is a task identifier. For example, for a model named `my_model` that has three rates, the following functions are generated:

```
void my_model_step0 (void);
void my_model_step1 (void);
void my_model_step2 (void);
```

Each `model_stepN` function executes the blocks sharing `tid N`; in other words, the block code that executes within task `N` is grouped into the associated `model_stepN` function.

### Scheduling `model_stepN` Execution

On each clock tick, `rt_OneStep` maintains scheduling counters and *event flags* for each subrate task. The counters are implemented as `taskCounter` arrays indexed on `tid`. The event flags are implemented as arrays indexed on `tid`.

The scheduling counters and task flags for sub-rates are maintained by `rt_OneStep`. The scheduling counters are basically clock rate dividers that count up the sample period

associated with each sub-rate task. A pair of tasks that exchanges data maintains an interaction flag at the faster rate. Task interaction flags indicate that both fast and slow tasks are scheduled to run.

The event flags indicate whether or not a given task is scheduled for execution. `rt_OneStep` maintains the event flags based on a task counter that is maintained by code in the main program module for the model. When a counter indicates that a task's sample period has elapsed, the main code sets the event flag for that task.

On each invocation, `rt_OneStep` updates its scheduling data structures and steps the base-rate task (`rt_OneStep` calls `model_step0` because the base-rate task must execute on every clock step). Then, `rt_OneStep` iterates over the scheduling flags in `tid` order, unconditionally calling `model_stepN` for any task whose flag is set. The tasks are executed in order of priority.

### Preemption

Note that the design of `rt_OneStep` assumes that interrupts are disabled before `rt_OneStep` is called. `rt_OneStep` should be noninterruptible until the base-rate interrupt overflow flag has been checked (see pseudocode above).

The event flag array and loop variables used by `rt_OneStep` are stored as local (stack) variables. Therefore, `rt_OneStep` is reentrant. If `rt_OneStep` is reinterrupted, higher priority tasks preempt lower priority tasks. Upon return from interrupt, lower priority tasks resume in the previously scheduled order.

### Overrun Detection

Multirate `rt_OneStep` also maintains an array of timer overrun flags. `rt_OneStep` detects timer overrun, per task, by the same logic as single-rate `rt_OneStep`.

---

**Note** If you have developed multirate S-functions, or if you use a customized static main program module, see “Rate Grouping Compliance and Compatibility Issues” on page 49-17 for information about how to adapt your code for rate grouping compatibility. This adaptation lets your multirate, multitasking models generate more efficient code.

---

### Multirate Single-Tasking Operation

In a multirate single-tasking program, by definition, sample times in the model must be an integer multiple of the model's fixed-step size.

In a multirate single-tasking program, blocks execute at different rates, but under the same task identifier. The operation of `rt_OneStep`, in this case, is a simplified version of multirate multitasking operation. Rate grouping is not used. The only task is the base-rate task. Therefore, only one `model_step` function is generated:

```
void model_step(void)
```

On each clock tick, `rt_OneStep` checks the overrun flag and calls `model_step`. The scheduling function for a multirate single-tasking program is `rate_scheduler` (rather than `rate_monotonic_scheduler`). The scheduler maintains scheduling counters on each clock tick. There is one counter for each sample rate in the model. The counters are implemented in an array (indexed on `tid`) within the `Timing` structure within `rtModel`.

The counters are clock rate dividers that count up the sample period associated with each subrate task. When a counter indicates that a sample period for a given rate has elapsed, `rate_scheduler` clears the counter. This condition indicates that blocks running at that rate should execute on the next call to `model_step`, which is responsible for checking the counters.

### Guidelines for Modifying `rt_OneStep`

`rt_OneStep` does not require extensive modification. The only required modification is to reenable interrupts after the overrun flags and error conditions have been checked. If applicable, you should also

- Save and restore your FPU context on entry and exit to `rt_OneStep`.
- Set model inputs associated with the base rate before calling `model_step0`.
- Get model outputs associated with the base rate after calling `model_step0`.

---

**Note:** If you modify `rt_OneStep` to read a value from a continuous output port after each base-rate model step, see the relevant cautionary guideline below.

---

- In a multirate, multitasking model, set model inputs associated with subrates before calling `model_stepN` in the subrate loop.
- In a multirate, multitasking model, get model outputs associated with subrates after calling `model_stepN` in the subrate loop.

Comments in `rt_OneStep` indicate the place to add your code.

In multirate `rt_OneStep`, you can improve performance by unrolling `for` and `while` loops.

In addition, you may choose to modify the overrun behavior to continue execution after error recovery is complete.

Also observe the following cautionary guidelines:

- You should not modify the way in which the counters, event flags, or other timing data structures are set in `rt_OneStep`, or in functions called from `rt_OneStep`. The `rt_OneStep` timing data structures (including `rtModel`) and logic are critical to the operation of the generated program.
- If you have customized the main program module to read model outputs after each base-rate model step, be aware that selecting model options **Support: continuous time** and **Single output/update function** together may cause output values read from `main` for a continuous output port to differ slightly from the corresponding output values in the model's logged data. This is because, while logged data is a snapshot of output at major time steps, output read from `main` after the base-rate model step potentially reflects intervening minor time steps. To eliminate the discrepancy, either separate the generated output and update functions (clear the **Single output/update function** option) or place a Zero-Order Hold block before the continuous output port.
- It is possible to observe a mismatch between results from simulation and logged MAT file results from generated code if you do not set model inputs before each time you call the model step function. In the generated example main program, the following comments show the locations for setting the inputs and stepping the model with your code:

```
/* Set model inputs here */
/* Step the model */
```

If your model applies signal reuse and you are using `MatFileLogging` for comparing results from simulation against generated code, modify `rt_OneStep` to write model inputs in every time step as directed by these comments. Alternatively, you could “Choose a SIL or PIL Approach” on page 64-11 for verification.

## Static Main Program Module

- “Overview” on page 49-11
- “Rate Grouping and the Static Main Program” on page 49-12
- “Modify the Static Main Program” on page 49-13
- “Modify Static Main to Allocate and Access Model Instance Data” on page 49-14

## Overview

In most cases, the easiest strategy for deploying generated code is to use the **Generate an example main program option** to generate the `ert_main.c` or `.cpp` module (see “Generate a Standalone Program” on page 49-2).

However, if you turn the **Generate an example main program** option off, you can use a static main module as an example or template for developing your embedded applications. Static main modules provided by MathWorks include:

- `matlabroot/rtw/c/src/common/rt_main.c` — Supports Nonreusable function code interface packaging.
- `matlabroot/rtw/c/src/common/rt_malloc_main.c` — Supports Reusable function code interface packaging. The model option **Use dynamic memory allocation for model initialization** must be on and model parameter **Pass root-level I/O as** must be set to `Part of model data structure`.
- `matlabroot/rtw/c/src/common/rt_cppclass_main.cpp` — Supports C++ class code interface packaging.

The static main module is not part of the generated code; it is provided as a basis for your custom modifications, and for use in simulation. If your existing applications depend upon a static `ert_main.c` (developed in releases before R2012b), `rt_main.c`, `rt_malloc_main.c`, or `rt_cppclass_main.cpp`, you may need to continue using a static main program module.

When developing applications using a static main module, you should copy the module to your working folder and rename it before making modifications. For example, you could rename `rt_main.c` to `model_rt_main.c`. Also, you must modify the template makefile or toolchain settings such that the build process creates a corresponding object file, such as `model_rt_main.obj` (on UNIX, `model_rt_main.o`), in the build folder.

The static main module contains

- `rt_OneStep`, a timer interrupt service routine (ISR). `rt_OneStep` calls `model_step` to execute processing for one clock period of the model.
- A skeletal `main` function. As provided, `main` is useful in simulation only. You must modify `main` for real-time interrupt-driven execution.

For single-rate models, the operation of `rt_OneStep` and the main function are essentially the same in the static main module as they are in the automatically generated version described in “Deploy Generated Standalone Executables To Target

Hardware” on page 49-2. For multirate, multitasking models, however, the static and generated code are slightly different. The next section describes this case.

### Rate Grouping and the Static Main Program

Targets based on the ERT target sometimes use a static main module and disallow use of the **Generate an example main program** option. This is done because target-specific modifications have been added to the static main module, and these modifications would not be preserved if the main program were regenerated.

Your static main module may or may not use rate grouping compatible *model\_stepN* functions. If your main module is based on the static *rt\_main.c*, *rt\_malloc\_main.c*, or *rt\_cppclass\_main.cpp* module, it does not use rate-specific *model\_stepN* function calls. It uses the old-style *model\_step* function, passing in a task identifier:

```
void model_step(int_T tid);
```

By default, when the **Generate an example main program** option is off, the ERT target generates a *model\_step* “wrapper” for multirate, multitasking models. The purpose of the wrapper is to interface the rate-specific *model\_stepN* functions to the old-style call. The wrapper code dispatches to the *model\_stepN* call with a `switch` statement, as in the following example:

```
void mymodel_step(int_T tid) /* Sample time: */
{
 switch(tid) {
 case 0 :
 mymodel_step0();
 break;
 case 1 :
 mymodel_step1();
 break;
 case 2 :
 mymodel_step2();
 break;
 default :
 break;
 }
}
```

The following pseudocode shows how *rt\_OneStep* calls *model\_step* from the static main program in a multirate, multitasking model.

```

rt_OneStep()
{
 Check for base-rate interrupt overflow
 Enable "rt_OneStep" interrupt
 Determine which rates need to run this time step

 ModelStep(tid=0) --base-rate time step

 For N=1:NumTasks-1 -- iterate over sub-rate tasks
 Check for sub-rate interrupt overflow
 If (sub-rate task N is scheduled)
 ModelStep(tid=N) --sub-rate time step
 EndIf
 EndFor
}

```

You can use the TLC variable `RateBasedStepFcn` to specify that only the rate-based step functions are generated, without the wrapper function. If your target calls the rate grouping compatible `model_stepN` function directly, set `RateBasedStepFcn` to 1. In this case, the wrapper function is not generated.

You should set `RateBasedStepFcn` prior to the `%include "codegenentry.tlc"` statement in your system target file. Alternatively, you can set `RateBasedStepFcn` in your `target_settings.tlc` file.

### Modify the Static Main Program

As with the generated `ert_main.c` or `.cpp`, you should make a few modifications to the main loop and `rt_OneStep`. See “Guidelines for Modifying the Main Program” on page 49-4 and “Guidelines for Modifying `rt_OneStep`” on page 49-9.

Also, you should replace the `rt_OneStep` call in the main loop with a background task call or null statement.

Other modifications you may need to make are

- If applicable, follow comments in the code regarding where to add code for reading/writing model I/O and saving/restoring FPU context.

---

**Note:** If you modify `rt_main.c`, `rt_malloc_main.c`, or `rt_cppclass_main.cpp` to read a value from a continuous output port after each base-rate model step, see the relevant cautionary guideline in “Guidelines for Modifying `rt_OneStep`” on page 49-9.

---

- When the **Generate an example main program** option is off, `rtmodel.h` is generated to provide an interface between the main module and generated model code. If you create your own static main program module, you would normally include `rtmodel.h`.

Alternatively, you can suppress generation of `rtmodel.h`, and include `model.h` directly in your main module. To suppress generation of `rtmodel.h`, use the following statement in your system target file:

```
%assign AutoBuildProcedure = 0
```

- If you have cleared the **Terminate function required** option, remove or comment out the following in your production version of `rt_main.c`, `rt_malloc_main.c`, or `rt_cppclass_main.cpp`:
  - The `#if TERMFCN...` compile-time error check
  - The call to `MODEL_TERMINATE`
- For `rt_main.c` (not applicable to `rt_cppclass_main.cpp`): If you do *not* want to combine output and update functions, clear the **Single output/update function** option and make the following changes in your production version of `rt_main.c`:
  - Replace calls to `MODEL_STEP` with calls to `MODEL_OUTPUT` and `MODEL_UPDATE`.
  - Remove the `#if ONESTEPFCN...` error check.
- The static `rt_main.c` module does not support **Reusable** function code interface packaging. The following error check raises a compile-time error if **Reusable** function code interface packaging is used illegally.

```
#if MULTI_INSTANCE_CODE==1
```

### Modify Static Main to Allocate and Access Model Instance Data

If you are using a static main program module, and your model is configured for **Reusable** function code interface packaging, but the model option **Use dynamic memory allocation for model initialization** is not selected, model instance data must be allocated either statically or dynamically by the calling main code. Pointers to the individual model data structures (such as Block IO, DWork, and Parameters) must be set up in the top-level real-time model data structure.

To support main modifications, the build process generates a subset of the following real-time model (RTM) macros, based on the data requirements of your model, into `model.h`.

RTM Macro Syntax	Description
<code>rtmGetBlockIO(rtm)</code>	Get the block I/O data structure
<code>rtmSetBlockIO(rtm, val)</code>	Set the block I/O data structure
<code>rtmGetContStates(rtm)</code>	Get the continuous states data structure
<code>rtmSetContStates(rtm, val)</code>	Set the continuous states data structure
<code>rtmGetDefaultParam(rtm)</code>	Get the default parameters data structure
<code>rtmSetDefaultParam(rtm, val)</code>	Set the default parameters data structure
<code>rtmGetPrevZCSigState(rtm)</code>	Get the previous zero-crossing signal state data structure
<code>rtmSetPrevZCSigState(rtm, val)</code>	Set the previous zero-crossing signal state data structure
<code>rtmGetRootDWork(rtm)</code>	Get the DWork data structure
<code>rtmSetRootDWork(rtm, val)</code>	Set the DWork data structure
<code>rtmGetU(rtm)</code>	Get the root inputs data structure (when root inputs are passed as part of the model data structure)
<code>rtmSetU(rtm, val)</code>	Set the root inputs data structure (when root inputs are passed as part of the model data structure)
<code>rtmGetY(rtm)</code>	Get the root outputs data structure (when root outputs are passed as part of the model data structure)
<code>rtmSetY(rtm, val)</code>	Set the root outputs data structure (when root outputs are passed as part of the model data structure)

Use these macros in your static main program to access individual model data structures within the RTM data structure. For example, suppose that the example model `rtwdemo_reusable` is configured with **Reusable** function code interface packaging, **Use dynamic memory allocation for model initialization** cleared, **Pass root-level I/O as set to Individual** arguments, and **Optimization** pane option **Remove root level I/O zero initialization** cleared. Building the model generates the following model data structures and model entry-points into `rtwdemo_reusable.h`:

```
/* Block states (auto storage) for system '<Root>' */
typedef struct {
 real_T Delay_DSTATE; /* '<Root>/Delay' */
} D_Work;
```

```
/* Parameters (auto storage) */
struct Parameters_ {
 real_T k1;
};

/* Real-time Model Data Structure */
struct tag_RTM {
 /*
 * ModelData:
 * The following substructure contains information regarding
 * the data used in the model.
 */
 struct {
 Parameters *defaultParam;
 D_Work *dwork;
 } ModelData;
};

/* Model entry point functions */
extern void rtwdemo_reusable_initialize(RT_MODEL *const rtM, real_T *rtU_In1,
 real_T *rtU_In2, real_T *rtY_Out1);
extern void rtwdemo_reusable_step(RT_MODEL *const rtM, real_T rtU_In1, real_T
 rtU_In2, real_T *rtY_Out1);
```

Additionally, if **Generate an example main program** is not selected for the model, `rtwdemo_reusable.h` contains definitions for the RTM macros `rtmGetDefaultParam`, `rtmsetDefaultParam`, `rtmGetRootDWork`, and `rtmSetRootDWork`.

Also, for reference, the generated `rtmodel.h` file contains an example parameter definition with initial values (non-executing code):

```
#if 0

/* Example parameter data definition with initial values */
static Parameters rtP = {
 2.0
};

#endif

/* Variable: k1
 * Referenced by: '<Root>/Gain'
 */
/* Modifiable parameters */
```

In the definitions section of your static main file, you could use the following code to statically allocate the real-time model data structures and arguments for the `rtwdemo_reusable` model:

```
static RT_MODEL rtM;
static RT_MODEL *const rtM = &rtM; /* Real-time model */
static Parameters rtP = {
```

```

 2.0 /* Variable: k1
 * Referenced by: '<Root>/Gain'
 */
}; /* Modifiable parameters */

static D_Work rtDWork; /* Observable states */

/* '<Root>/In1' */
static real_T rtU_In1;

/* '<Root>/In2' */
static real_T rtU_In2;

/* '<Root>/Out1' */
static real_T rtY_Out1;

```

In the body of your main function, you could use the following RTM macro calls to set up the model parameters and DWork data in the real-time model data structure:

```

int_T main(int_T argc, const char *argv[])
{
 ...
 /* Pack model data into RTM */

 rtmSetDefaultParam(rtm, &rtP);
 rtmSetRootDWork(rtm, &rtDWork);

 /* Initialize model */
 rtwdemo_reusable_initialize(rtm, &rtU_In1, &rtU_In2, &rtY_Out1);
 ...
}

```

Follow a similar approach to set up multiple instances of model data, where the real-time model data structure for each instance has its own data. In particular, the parameter structure (rtP) should be initialized, for each instance, to the desired values, either statically as part of the rtP data definition or at run time.

## Rate Grouping Compliance and Compatibility Issues

- “Main Program Compatibility” on page 49-17
- “Make Your S-Functions Rate Grouping Compliant” on page 49-18

### Main Program Compatibility

When the **Generate an example main program** option is off, code generation produces slightly different rate grouping code, for compatibility with the older static `ert_main.c` module. See “Rate Grouping and the Static Main Program” on page 49-12 for details.

## Make Your S-Functions Rate Grouping Compliant

Built-in Simulink blocks, as well as DSP System Toolbox blocks, are compliant with the requirements for generating rate grouping code. However, user-written multirate inlined S-functions may not be rate grouping compliant. Noncompliant blocks generate less efficient code, but are otherwise compatible with rate grouping. To take full advantage of the efficiency of rate grouping, your multirate inlined S-functions must be upgraded to be fully rate grouping compliant. You should upgrade your TLC S-function implementations, as described in this section.

Use of noncompliant multirate blocks to generate rate-grouping code generates dead code. This can cause two problems:

- Reduced code efficiency.
- Warning messages issued at compile time. Such warnings are caused when dead code references temporary variables before initialization. Since the dead code does not run, this problem does not affect the run-time behavior of the generated code.

To make your S-functions rate grouping compliant, you can use the following TLC functions to generate `ModelOutputs` and `ModelUpdate` code, respectively:

```
OutputsForTID(block, system, tid)
UpdateForTID(block, system, tid)
```

The code listings below illustrate generation of output computations without rate grouping (Listing 1) and with rate grouping (Listing 2). Note the following:

- The `tid` argument is a task identifier (`0..NumTasks-1`).
- Only code guarded by the `tid` passed in to `OutputsForTID` is generated. The `if (%<LibIsSFcnSampleHit(portName)>)` test is not used in `OutputsForTID`.
- When generating rate grouping code, `OutputsForTID` and/or `UpdateForTID` is called during code generation. When generating non-rate-grouping code, `Outputs` and/or `Update` is called.
- In rate grouping compliant code, the top-level `Outputs` and/or `Update` functions call `OutputsForTID` and/or `UpdateForTID` functions for each rate (`tid`) involved in the block. The code returned by `OutputsForTID` and/or `UpdateForTID` must be guarded by the corresponding `tid` guard:

```
if (%<LibIsSFcnSampleHit(portName)>)
```

as in Listing 2.

Launch example

#### Description

The script loads and runs an application on the target DSP. To begin, the example asks you to choose the processor to run the example on. Your target selection is displayed by invoking `ccsboardinfo` and `boardprocel` functions.

Through `ticcs`, you create a handle to the processor. Using this handle, you perform CCS IDE-specific tasks such as

- Build the CCS project
- Load the application
- Run, halt, and restart the processor

You can also do other operations such as

- Insert and delete breakpoints
- Toggle the CCS IDE visibility

You can query the target for information using the methods

- `isrunning`
- `address`
- `info`

You can access target memory and registers using the methods

- read
- write
- regread
- regwrite

### **Supported Processor Families**

- C2000™ (C28x™, C27x™, C24x™)
- TMS470 (R1x, R2x)

### **To Run the Example**

- At the MATLAB® command prompt, enter `ccstutorial`.

## **Read From and Write To DSP Target Using RTDX™ Component of IDE Link Component**

Read and write data to and from a DSP target using the RTDX™ component of the IDE Link component.

Launch example

### **Description**

The example script loads and runs an application on the target. This application uses RTDX to transfer data messages between MATLAB® (the host application) and the target.

This tutorial writes the integers 1 through 10 to the target DSP. The target takes the array of integers, increments each array element by one, and writes the resultant array back to the host. The read and write process is performed 20 successive times, with each iteration incrementing the previous array result by one. The host application uses `readmsg` and `readmat` to read the data in a variety of data formats.

### **Supported Processor Families**

- C2000™ (C28x™)

**To Run the Example**

- At the MATLAB™ command prompt, enter `rtdxtutorial`.

**Build Executables for Multiprocessor Platform Using IDE Link Component**

This example shows how to use IDE Link component with platforms consisting of multiple processors using MATLAB® commands.

Launch example

**Description**

The tutorial shows how to use IDE Link methods to connect to and control multiple processors simultaneously.

**Supported Processor**

- OMAP™

**To Run the Example**

- At the MATLAB® command prompt, enter `multiproctutorial`.

**Interface to an Example Real-Time Operating System (VxWorks®)**

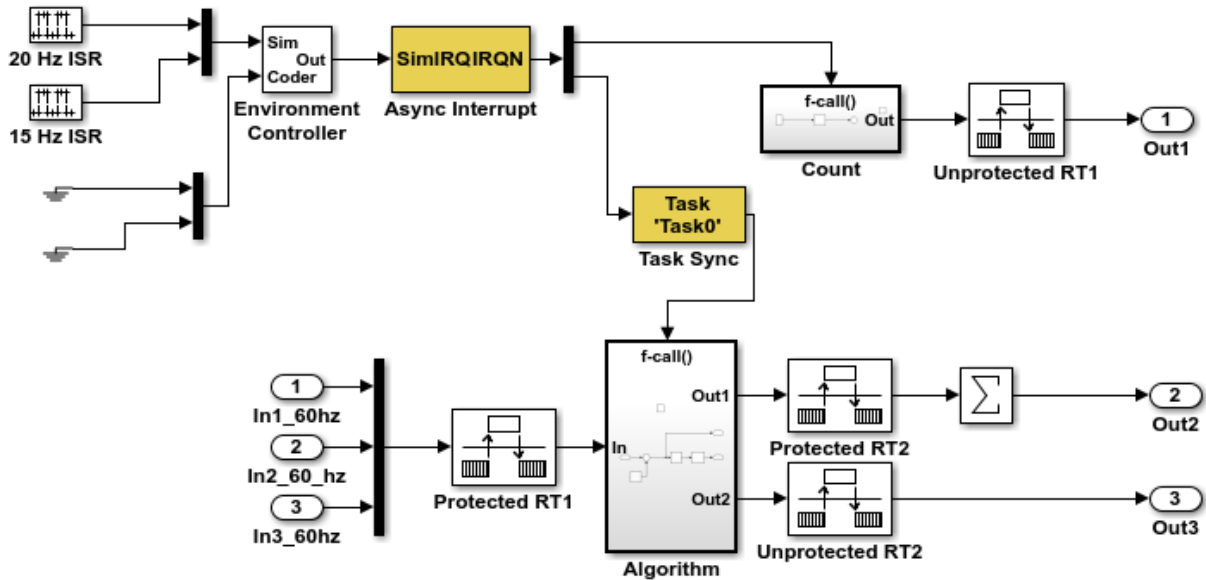

This example shows how to simulate and generate code for asynchronous events on an example RTOS (VxWorks).

The operating system integration techniques that are demonstrated in this example use one or more blocks the blocks in the `vxlib1` library. These blocks provide starting point examples to help you develop custom blocks for your target environment.

**Example Model**

Open the `rtwdemo_vxworks` model.

```
model = 'rtwdemo_vxworks';
open_system(model);
%
```

This model shows how to simulate and generate code for asynchronous events on a real-time multitasking system. This model contains two asynchronously executed subsystems, "Count" and "Algorithm." "Count" is executed at interrupt level, whereas "Algorithm" is executed in an asynchronous task. The code generated for these blocks is specifically tailored for the VxWorks operating system. However, you can modify the Async Interrupt and Task Sync blocks to generate code specific to your environment whether you are using an operating system or not.

## Model Description

The example model contains two asynchronously executed subsystems, Count and Algorithm. Count executes at interrupt level. Algorithm executes in an asynchronous task. The generated code for these blocks is tailored for the VxWorks® operating system. However, you can modify the Async Interrupt and Task Sync blocks to generate code for your run-time environment whether you are using an operating system or not.

### Multirate Modeling in Multitasking Mode (VxWorks® OS)

This example generates code for a multirate discrete-time model configured for a multitasking operating system target (VxWorks®). The model contains two sample times. Inport block 1 and Inport block 2 specify 1-second and 2-second sample times, respectively, which are enforced by the **Periodic sample time constraint** solver configuration parameter setting. The solver is set for multitasking operation, which means a Rate Transition block is required to ensure that data integrity is enforced when the 1-second task preempts the 2-second task. Simulink® and the code generator enforce proper rate transitions. This model specifies an explicit Rate Transition block. Alternatively, you can instruct Simulink® to insert this block for you by setting the **Automatically handle data transfers between tasks** solver configuration parameter.

The model is configured to display sample-time colors upon diagram update. Red represents the fastest discrete sample time in the model, green represents the second fastest, and yellow represents mixed sample times. Click the **Display Sample Time Colors** button to update the diagram and show sample-time colors.

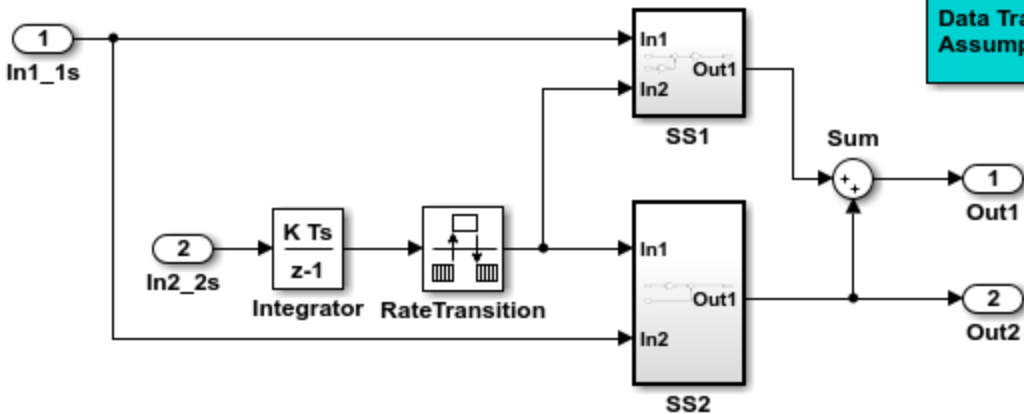

### Example Model

```
model = 'rtwdemo_mrmtos';
open_system(model);
```

The model is configured to display sample-time colors upon diagram update. Red represents the fastest discrete sample time in the model, green represents the second fastest, and yellow represents mixed sample times. Click the yellow button to the right to update the diagram and show sample-time colors.

Display Sample Time Colors (double-click)

Data Transfer Assumptions ...

This model shows the code generated for a multirate discrete-time model configured for a multitasking operating system target (VxWorks). The model contains two sample times. Inport block 1 and Inport block 2 specify 1-second and 2-second sample times, respectively, which are enforced by the "Periodic sample time constraint" option on the Solver configuration page. The solver is set for multitasking operation, which means a rate transition block is required to ensure that data integrity is enforced when the 1-second task preempts the 2-second task. Proper rate transitions are always enforced by Simulink and Simulink Coder. This model specifies an explicit rate transition block. Alternatively, this block could be automatically inserted by Simulink using the "Automatically handle data transfers between tasks" option on the Solver configuration page.

This example uses an Embedded Coder feature to generate an example VxWorks main (i.e., "Target operating system" on the Template configuration page.) Simulink Coder also supports VxWorks via the Tornado target.

# Export Code Generated from Model to External Application in Embedded Coder

---

- “Export Function-Call Subsystems” on page 50-2
- “Control Generation of Function Prototypes” on page 50-16
- “Control Generation of C++ Class Interfaces” on page 50-18

## Export Function-Call Subsystems

Export a function-call subsystem when you want the code generator to produce function code that includes no supporting scheduling code. You might refer to the resulting code as a standalone function.

### Exporting Function-Call Subsystems

Embedded Coder software provides code export capabilities that you can use to

- Automatically generate code for
  - A function-call subsystem that contains only blocks that support code generation
  - A virtual subsystem that contains only such subsystems and a few other types of blocks
- Create a SIL block that represents generated code

You can use these capabilities only if the subsystem and its interface to the Simulink model conform to certain requirements and constraints, as described in “Requirements for Exporting Function-Call Subsystems” on page 50-3. For limitations that apply, see “Function-Call Subsystems Export Limitations” on page 50-14. To see an example of exported function-call subsystems, type `rtwdemo_export_functions` in the MATLAB Command Window.

---

**Note:** For models designed in earlier releases, Embedded Coder software also supports the ability to export functions from triggered subsystems. In general, the requirements and limitations stated for exporting functions from function-call subsystems also apply to exporting functions from triggered subsystems, with the following exceptions:

- Triggered subsystems from which you intend to export functions must be encapsulated in a single top-level virtual subsystem.
  - Triggered subsystems do not have to meet the requirements in “Requirements for Exported Virtual Subsystems” on page 50-4.
  - The section “Export Functions That Depend on Elapsed Time” on page 50-7 is not applicable to exporting functions from triggered subsystems.
-

## Requirements for Exporting Function-Call Subsystems

To be exportable as code, a function-call subsystem, or a virtual subsystem that contains such subsystems, must meet certain requirements. Most requirements are similar for either type of export, but some apply only to virtual subsystems. The requirements for Simulink code generation also apply.

For brevity, *exported subsystem* in this section means only an exported function-call subsystem or an exported virtual subsystem that contains such subsystems. The requirements listed do not necessarily apply to other types of exported subsystems.

### Requirements for Exported Subsystems

These requirements apply to both exported function-call subsystems and exported virtual subsystems that contain such subsystems.

- Blocks must support code generation.

All blocks within an exported subsystem must support code generation. However, blocks outside the subsystem need not support code generation unless they will be converted to code in some other context.

- Blocks must not use absolute time.

Some blocks use absolute time. Blocks that use absolute time are not supported in exported function-call subsystems. For a complete list of such blocks, see “Absolute Time Limitations” in the Simulink Coder documentation.

- Blocks must not depend on elapsed time.

Some blocks, like the Sine Wave and Discrete Integrator blocks, depend on elapsed time. If an exported function-call subsystem contains a block that depends on elapsed time, the subsystem must specify periodic execution. See “Export Functions That Depend on Elapsed Time” on page 50-7 in the Simulink Coder documentation.

- Trigger signals require a common source.

If multiple trigger signals cross the boundary of an exported system, all of the trigger signals must be periodic and originate from the same function-call initiator.

- Trigger signals must be scalar.

A trigger signal that crosses the boundary of an exported subsystem must be scalar. Input and output data signals that do not act as triggers need not be scalar.

- Data signals must be nonvirtual.

A data signal that crosses the boundary of an exported system cannot be a virtual bus, and cannot be implemented as a `Goto-From` connection. Every data signal crossing the export boundary must be scalar, muxed, or a nonvirtual bus.

### Requirements for Exported Virtual Subsystems

These requirements apply only to exported virtual subsystems that contain function-call subsystems.

- Virtual subsystem must use only permissible blocks.

The top level of an exported virtual subsystem that contains function-call subsystem blocks can contain only the following other types of blocks:

- Input and Output blocks (ports)
- Constant blocks (including blocks that resolve to constants, such as Add)
- Merge blocks
- Virtual connection blocks (Mux, Demux, Bus Creator, Bus Selector, Signal Specification)
- Signal-viewer blocks, such as Scope blocks

These restrictions do *not* apply within function-call subsystems, whether or not they appear in a virtual subsystem. They apply only at the top level of an exported virtual subsystem that contains one or more function-call subsystems.

- Constant blocks must be inlined.

When a constant block appears at the top level of an exported virtual subsystem, the containing model must set **Default parameter behavior** to **Inlined** on the **Optimization > Signals and Parameters** pane of the Configuration Parameters dialog box.

- Constant outputs must specify a storage class.

When a constant signal drives an output port of an exported virtual subsystem, the signal must specify a storage class.

### Techniques for Exporting Function-Call Subsystems

- “General Workflow” on page 50-5

- “Specify a Custom Initialize Function Name” on page 50-5
- “Specify a Custom Description” on page 50-6

## General Workflow

To export a function-call subsystem, or a virtual subsystem that contains function-call subsystems,

- 1 Check that the subsystem to be exported satisfies the “Requirements for Exporting Function-Call Subsystems” on page 50-3.
- 2 In the Configuration Parameters dialog box:
  - a On the **Code Generation** pane, specify an ERT code generation target such as `ert.tlc`.
  - b If you want a SIL block with the generated code, from the **Configuration Parameters > All Parameters > Create block** drop-down list, select **SIL**.
  - c Click **OK** or **Apply**.
- 3 Right-click the subsystem block and choose **C/C++ Code > Export Functions** from the context menu.

The **Build code for subsystem: *Subsystem*** dialog box appears. This dialog box is not specific to exporting function-call subsystems, and generating code does not require entering information in the box.

- 4 Click **Build**.

The MATLAB Command Window displays messages similar to the code generation sequence. Simulink generates code and places it in the working folder.

If you set **Create block** to **SIL** in step 2b, Simulink opens a new window that contains an S-function block that represents the generated code. This block has the same size, shape, and connectors as the original subsystem.

Code generation and optional block creation are now complete. You can test and use the code and optional block as you could for generated ERT code and S-function block.

## Specify a Custom Initialize Function Name

You can specify a custom name for the initialize function of your exported function as an argument to the `rtwbuild` command. When used for this purpose, the command takes the following form:

```
blockHandle = rtwbuild('subsystem', 'Mode', 'ExportFunctionCalls',...
 'ExportFunctionInitializeFunctionName', 'fcnname')
```

where *fcnname* specifies the desired function name. For example, if you specify the name 'myinitfcn', the build process emits code similar to the following:

```
/* Model initialize function */
void myinitfcn(void){
 ...
}
```

### Specify a Custom Description

You can enter a custom description for an exported function using the Block Properties dialog box of an Inport block. To do this, go to the subsystem that is to be exported as a function, right-click on the Inport block that drives the control port of the subsystem, and select **Properties**. In the **General** tab, use the **Description** field to enter your descriptive text. During function export, the text you enter is emitted to the generated code in the header for the Inport block. For example, if you open the example program `rtwdemo_exporting_functions` and enter a description in the Block Properties dialog box for port `t_1tic_A`, code similar to the following is emitted:

```
/*
 * Output and update for exported function: t_1tic_A
 *
 * My custom description of the exported function
 */
void t_1tic_A(void)
{
 ...
}
```

### Optimize Exported Function-Call Subsystems

To optimize the code generated for a function-call subsystem or virtual block that contains such subsystems, you can

- Specify a storage class for every input signal and output signal that crosses the boundary of the subsystem.
- For each function-call subsystem to be exported (whether directly or within a virtual subsystem):
  - 1 Right-click the subsystem and choose **Block Parameters (Subsystem)** from the context menu.

- 2 Select the **Code Generation** tab and set the **Function packaging** parameter to Auto.
- 3 Click **OK** or **Apply**.

## Export Functions That Depend on Elapsed Time

Some blocks, such as the Sine Wave block (if sample-based) and the Discrete-Time Integrator block, depend on elapsed time. See “Absolute and Elapsed Time Computation” in the Simulink Coder documentation for more information.

When a block that depends on elapsed time exists in a function-call subsystem, the subsystem cannot be exported unless it specifies periodic execution. To specify for this:

- 1 Right-click the Trigger block in the function-call subsystem and choose **Block Parameters** from the context menu.
- 2 Specify **periodic** in the **Sample time type** field.
- 3 Set the **Sample time** to the same granularity specified (directly or by inheritance) in the function-call initiator.
- 4 Click **OK** or **Apply**.

## Generate Code for Functions Exported to a Larger System

This example shows how to generate function code for individual Simulink function blocks or function-call subsystems without generating scheduling code.

To generate function code for export:

- 1 Create a model that contains the functions for export.
- 2 Create a test harness model that schedules execution of the functions during simulation.
- 3 Simulate the model that contains the functions by using the test harness model.
- 4 Generate code for the model that contains the functions.

### Create Model That Contains Functions for Export

The model with functions for export must satisfy architectural constraints at the model root level. Blocks that are valid at the root level are:

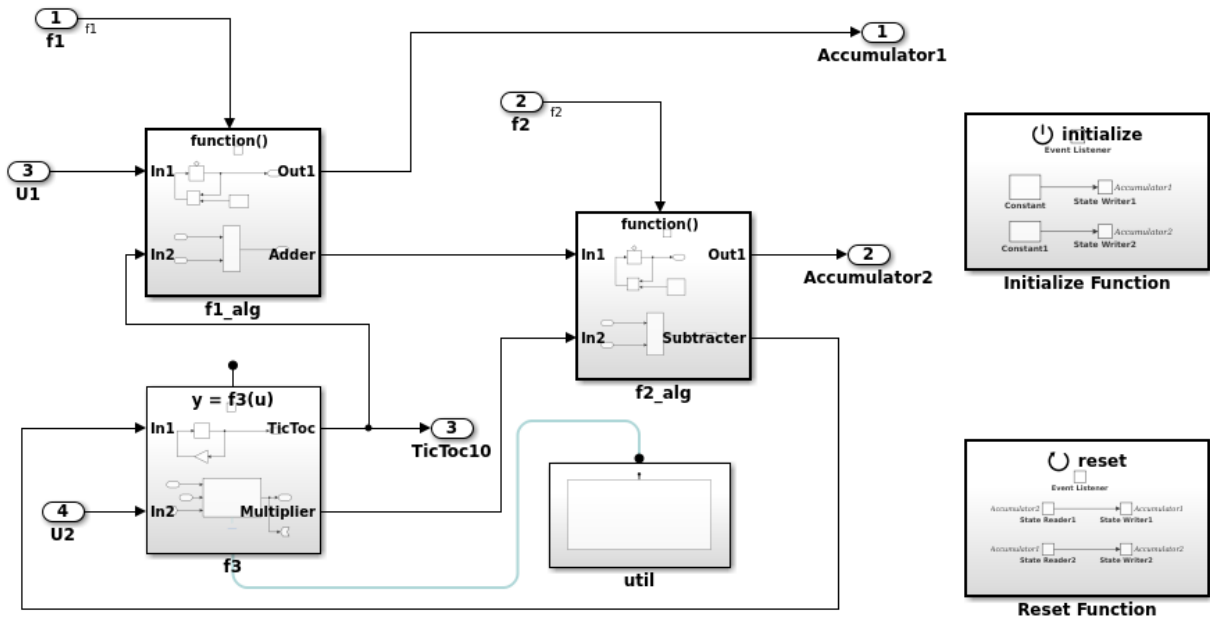

- Inport
- Outport
- Function-Call Subsystem
- Simulink Function
- Goto
- From
- Merge

The code generator produces function code for Function-Call Subsystem and Simulink Function blocks as well as Initialize and Reset Function blocks. For a Function-call Subsystem block, you connect the block input ports to root Inport blocks that assert function-call signals. The subsystem executes based on the function-call signal that it receives. A Simulink Function block executes in response to the execution of a corresponding Function Caller block or Stateflow chart. An Initialize Function block executes on a model initialize event and a Reset Function block executes on a user-defined reset event.

Model `rtwdemo_functions` contains two function-call subsystems (`f1_alg` and `f2_alg`) and a Simulink Function block (`f3_alg`) for exporting functions. The model also contains an Initialize Function block (`Initialize Function`) and a Reset Function block (`Reset Function`). The State Writer blocks are used inside the Initialize and Reset Function blocks to calculate initial conditions for blocks with state in other parts of the model.

```
open_system('rtwdemo_functions')
```

Copyright 2014-2016 The MathWorks, Inc.

## Create Model That Contains Function Caller

Use a Function Caller block to invoke a Simulink Function block. The Function Caller block can be in the same model as the Simulink Function block or in a different model.

Multiple Function Caller blocks can invoke a Simulink Function block. You can place the Function Caller block inside a function-call subsystem. During code generation, the code generator exports a function from the function-call subsystem.

The model `rtwdemo_caller` exports a function-call subsystem that contains a Function Caller block.

```
open_system('rtwdemo_caller')
```

Copyright 2014 The MathWorks, Inc.

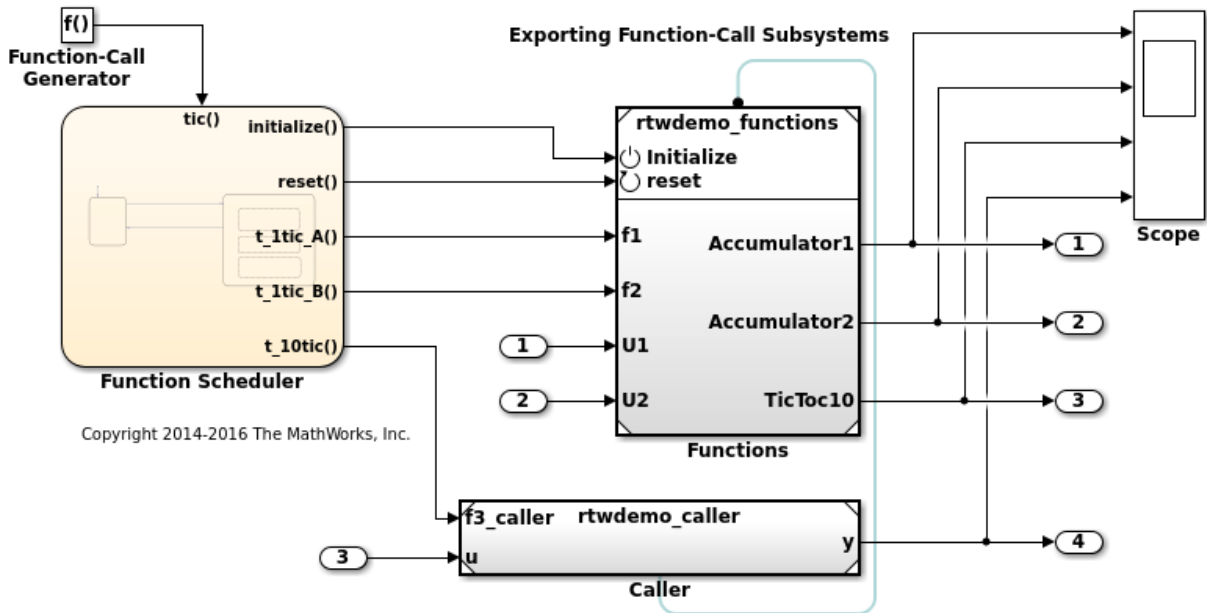

### Create Test Harness Model for Simulation

When you export functions, the generated code does not include a scheduler. Create a test harness model to handle scheduling during simulation. Do not use the test harness model to generate code that you deploy.

Model `rtwdemo_export_functions` is a test harness. The model:

- Schedules the Simulink Function block with the Function Caller block in `rtwdemo_caller`.
- Provides function-call signals to other models in this example to schedule the model contents, including the model initialize and reset events.

```
open_system('rtwdemo_export_functions')
```

Copyright 2014-2016 The MathWorks, Inc.

### Simulate the Test Harness Model

Verify that the model containing the functions that you want to export executes as you expect by simulating the test harness model. For example, simulate `rtwdemo_export_functions`.

```
sim('rtwdemo_export_functions')
```

### Generate Function Code and Report

Generate code and a code generation report for the functions that you want to export. For example, generate code for `rtwdemo_functions`.

```
rtwbuild('rtwdemo_functions')
```

```
Starting build procedure for model: rtwdemo_functions
Generated code for 'rtwdemo_functions' is up to date because no structural, parameter, or code changes were detected
Successful completion of code generation for model: rtwdemo_functions
```

### Review Generated Code

From the code generation report, review the generated code.

- `ert_main.c` is an example main program (execution framework) for the model. This code shows how to call the exported functions. The code also shows how to initialize and execute the generated code.
- `rtwdemo_functions.c` calls the initialization function, including `Initialize Function`, and exported functions for model components `f1_alg`, `f2_alg`, and `f3_alg`.
- `rtwdemo_functions.h` declares model data structures and a public interface to the exported entry-point functions and data structures.
- `f3.h` is a shared file that declares the call interface for the Simulink function `f3_alg`.
- `rtwtypes.h` defines data types, structures, and macros that the generated code requires.

### Code Interface

Open and review the Code Interface Report. To write the interface code for your execution framework, use the information in that report.

- 1 Include the generated header files by adding directives `#include rtwdemo_functions.h`, `#include f3.h`, and `#include rtwtypes.h`.
- 2 Write input data to the generated code for model Inport blocks.
- 3 Call the generated entry-point functions.
- 4 Read data from the generated code for model Outport blocks.

Input ports:

- `rtU.U1` of type `real_T` with dimension 1
- `rtU.U2` of type `real_T` with dimension 1

Entry-point functions:

- Initialize entry-point function, `void rtwdemo_functions_initialize(void)`. At startup, call this function once.
- Reset entry-point function, `void rtwdemo_functions_reset(void)`. Call this function as needed.
- Exported function, `void f1(void)`. Call this function as needed.
- Exported function, `void f2(void)`. Call this function as needed.

- Simulink function, `void f3(real_T rtu_u, real_T *rtty_y)`. Call this function as needed.

Output ports:

- `rtY.Accumulator1` of type `int8_T` with dimension [2]
- `rtY.Accumulator2` of type `int8_T` with dimension [2]
- `rtY.TicToc10` of type `int8_T` with dimension 1

### **Create Model with Functions for Export with C++ Class Generation**

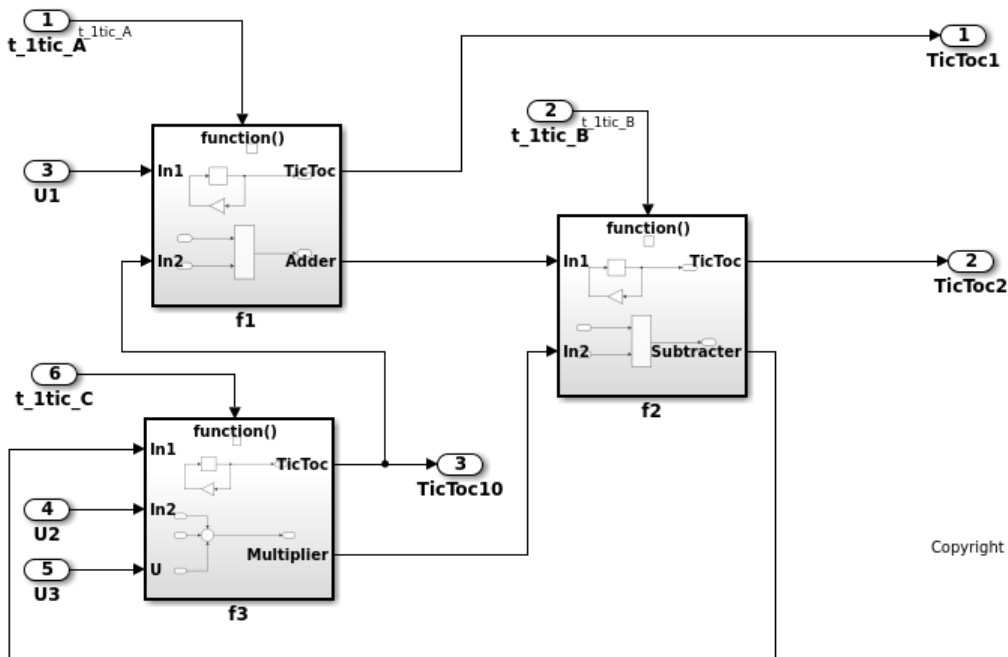

You can use exported functions with a C++ model class interface. For C++ class generation, blocks that are valid at the model root level are:

- Inport
- Outport
- Function-Call Subsystem
- Goto
- From
- Merge

When generating C++ code, the code generator produces public class methods for Function-Call Subsystem blocks. For a Function-call Subsystem block, you connect the block input ports to root Inport blocks that produce function-call signals.

Model `rtwdemo_cppclass_functions` exports functions as C++ code. The model is a modified version of `rtwdemo_functions`.

```
open_system('rtwdemo_cppclass_functions');
```

```

### Function-Call Subsystems Export Limitations

The function-call subsystem export has the following limitations:

- Subsystem block parameters do not control the names of the files containing the generated code. Such file names begin with the name of the exported subsystem.
- Subsystem block parameters do not control the names of top-level functions in the generated code. Each function name reflects the name of the signal that triggers the function or (for an unnamed signal) reflects the block from which the signal originates.
- The software cannot export reusable code for a function-call subsystem. The **Code interface packaging** value `Reusable` function does not apply for a function-call subsystem.
- You can export function-call systems for the C++ class code interface packaging only when its function specification is set to **Default step method**. For more information, see “Control Generation of C++ Class Interfaces” on page 25-23. The exported function is compatible with single-threaded execution. To avoid potential data race conditions for shared signals, all members for the class should be invoked from the same execution thread.
- The software supports a SIL or PIL block in accelerator mode only if its function-call initiator is noninlined in accelerator mode. Examples of noninlined initiators include Stateflow charts.
- The SIL block must be driven by a Level-2 S-function initiator block, such as a Stateflow chart or the built-in Function-Call Generator block.
- An asynchronous (sample-time) function-call system can be exported, but the software does not support the SIL or PIL block for an asynchronous system.
- The software does not support MAT-file logging for exported function calls. Specifications that enable MAT-file logging are ignored.
- The use of the TLC function `LibIsFirstInit` has been removed for exported function calls.

## Control Generation of Function Prototypes

The Embedded Coder software provides a **Configure Model Functions** button, located on the **Code Generation > Interface** pane of the Configuration Parameters dialog box, that allows you to control the model function prototypes that are generated for ERT-based models.

By default, the function prototype of an ERT-based model's generated *model\_step* function resembles the following:

```
void model_step(void);
```

The function prototype of an ERT-based model's generated *model\_initialize* function resembles the following:

```
void model_initialize(void);
```

(For more detailed information about the default calling interface for the *model\_step* function, see the *model\_step* reference page.)

The **Configure Model Functions** button on the **Interface** pane provides you flexible control over the model function prototypes that are generated for your model. Clicking **Configure Model Functions** launches a Model Interface dialog box. Based on the **Function specification** value you specify for your model function (supported values include `Default model initialize and step functions` and `Model specific C prototypes`), you can preview and modify the function prototypes. Once you validate and apply your changes, you can generate code based on your function prototype modifications.

For more information about using the **Configure Model Functions** button and the Model Interface dialog box, see “Sample Procedure for Configuring Function Prototypes” on page 25-11 and the example model `rtwdemo_fcncnprotoctrl`, which is preconfigured to demonstrate function prototype control.

Alternatively, you can use function prototype control functions to programmatically control model function prototypes. For more information, see “Configure Function Prototypes Programmatically” on page 25-16 “Configure Function Prototypes Programmatically” on page 25-16.

You can also control model function prototypes for nonvirtual subsystems, if you generate subsystem code using right-click build. To launch the **Model Interface for subsystem** dialog box, use the `RTW.configSubsystemBuild` function.

Right-click building the subsystem generates the step and initialization functions according to the customizations you make. For more information, see “Configure Function Prototypes for Nonvirtual Subsystems” on page 25-9.

For limitations that apply, see “Function Prototype Control Limitations” on page 25-21.

## **More About**

- “Export-Function Models”

## Control Generation of C++ Class Interfaces

Using the **Code interface packaging** option `C++ class`, on the **Code Generation > Interface** pane of the Configuration Parameters dialog box, you can generate a C++ class interface to model code. The generated interface encapsulates required model data into C++ class attributes and model entry point functions into C++ class methods. The benefits of C++ class encapsulation include:

- Greater control over access to model data
- Ability to multiply instantiate model classes
- Easier integration of model code into C++ programming environments

C++ class encapsulation also works for right-click builds of nonvirtual subsystems. (For information on requirements that apply, see “Configure C++ Class Interfaces for Nonvirtual Subsystems” on page 25-44.)

The general procedure for generating C++ class interfaces to model code is as follows:

- 1 Configure your model to use an `ert.tlc` system target file provided by MathWorks.
- 2 Select the C++ language for your model.
- 3 Select `C++ class` code interface packaging for your model.
- 4 Optionally, configure related C++ class interface settings for your model code, using either a graphical user interface (GUI) or application programming interface (API).
- 5 Generate model code and examine the results.

To get started with an example, see “Simple Use of C++ Class Control” on page 25-24. For more details about configuring C++ class interfaces for your model code, see “Customize C++ Class Interfaces Using Graphical Interfaces” on page 25-31 and “Customize C++ Class Interfaces Programmatically” on page 25-45. For limitations that apply, see “C++ Class Interface Control Limitations” on page 25-50.

---

**Note:** For an example of C++ class code generation, see the example model `rtwdemo_cppclass`.

- “Shift Left Operations and Code Replacement” on page 51-226

## What Is Code Replacement Customization?

Customize how and when the code generator replaces C/C++ code that it generates by default for functions and operators by developing a custom code replacement library. You can develop libraries interactively with the Code Replacement Tool or programmatically.

- Develop libraries tailored to specific application requirements
- Add identifiers to the list of reserved keywords the code generator considers during code replacement
- Customize the code generator's match and replacement process for functions

To get started, “Quick Start Library Development” on page 51-28.

### Code Replacement Match and Replacement Process

When the code generator encounters a call site for a function or operator, it:

- 1** Creates and partially populates a code replacement entry object with the function or operator name or key and conceptual arguments.
- 2** Uses the entry object to query the configured code replacement library for a conceptual representation match. The code generator searches the tables in a code replacement library for a match in the order that the tables appear in the library. When searching for a match, the code generator takes into account:
  - Conceptual name or key
  - Arguments, including quantity, type, type qualifiers, and complexity
  - Algorithm (computation method)
  - Fixed-point saturation and rounding modes
  - Priority
- 3** When a match exists, the code generator returns a code replacement object, fully populated with the conceptual representation, implementation representation, and priority. If the code generator finds multiple matches within a table, the entry priority determines the match. The priority can range from 0 to 100. The highest priority is 0. The code generator uses a higher-priority entry over a similar entry with a lower priority.
- 4** Uses the C or C++ replacement function prototype in the code replacement object to generate code.

## Code Replacement Customization Limitations

- Code replacement verification — It is possible that code replacement behaves differently than you expect. For example, data types that you observe in code generator input might not match what the code generator uses as intermediate data types during an operation. Verify code replacements by examining generated code. See “Verify Code Replacements” on page 51-76.
- Tokens in file paths—You can include tokens in file paths when specifying build information for a code replacement entry by using the programming interface only. The ability to include tokens is not available from the Code Replacement Tool. See “Specify Build Information for Replacement Code” on page 51-59.
- Addition and subtraction operation replacements—See “Addition and Subtraction Operator Code Replacement” on page 51-170 for relevant limitations.
- Data alignment—
  - Not supported for
    - Arguments associated with a built-in custom storage class with **DataScope** set to **Exported** or the imported built-in custom storage class **GetSet**
    - Software-in-the-loop (SIL)
    - Processor-in-the-loop (PIL)
    - Model reference parameters
    - Exported functions in Stateflow charts
    - Replaced functions that are generated with C function prototype control or C++ class I/O arguments step method and that use root-level I/O variables
    - Replaced functions that are generated with the AUTOSAR system target file and that use root-level I/O or AUTOSAR inter-runnable access functions
  - If the following conditions exist, the code generator includes data alignment directives for root-level I/O variables in the `ert_main.c` or `ert_main.cpp` file it produces:
    - Compiler supports global variable alignment
    - Generate an example main program (select **Configuration Parameters > All Parameters > Generate an example main program**)
    - Generate a reusable function interface for the model (set **Configuration Parameters > Code Generation > Interface > Code interface packaging to Reusable function**)

- Function uses root-level I/O variables that are passed in as individual arguments (set **Configuration Parameters > Code Generation > Interface > Pass root-level I/O** as to Individual arguments)
- Replaced function uses a root-level I/O variable
- Replaced function imposes alignment requirements

If you discard the generated example main program, align used root-level I/O variables correctly.

If you choose not to generate an example main program in this case, the code generator does not replace the function.

- If a replacement imposes alignment requirements on the shared utility interface arguments, the code generator does not honor data alignment. Under these conditions, replacement does not occur. Replacement is allowed if the registered data alignment type specification supports alignment of local variables, and the replacement involves only local variables.
- For `Simulink.Bus`:
  - If user registered alignment specifications do not support structure field alignment, aligning `Simulink.Bus` objects is not supported unless the `Simulink.Bus` is imported.
  - When aligning a `Simulink.Bus` data object, the elements in the bus object are aligned on the same boundary. The boundary is the lowest common multiple of the alignment requirements for each individual bus element.
- When you specify alignment for functions that occur in a model reference hierarchy, and multiple models in the hierarchy operate on the same function data, the bottommost model dictates alignment for the rest of the hierarchy. If the alignment requirement for a function in a model higher in the hierarchy cannot be honored due to the alignment set by a model lower in the hierarchy, the replacement in the higher model does not occur. In some cases, an error message is generated. To work around this issue, if the shared data is represented by a bus or signal object, manually set the alignment property on the shared data by setting the alignment property of the `Simulink.Bus` or `Simulink.Signal` object.
- It is your responsibility to honor the `Alignment` property setting for custom storage classes that you create.

See “Data Alignment for Code Replacement” on page 51-133.

- `coder.replace` function — See `coder.replace` for relevant limitations.

## Code You Can Replace From Simulink Models

Code that the code generator replaces depends on the code replacement library (CRL) that you use. By default, the code generator does not apply a code replacement library. Your choice of libraries is dependent on product licensing and whether you have access to custom libraries.

For information on how to explore functions and operators that a code replacement library supports, see “Choose a Code Replacement Library” on page 38-8 license and want to develop a custom code replacement library, see Code Replacement Customization.

<sup>1</sup> Wrap on integer overflow only. Clear block parameter <b>Saturate on integer overflow</b> . <sup>2</sup> Only when used with the MATLAB Function block. <sup>3</sup> Supports the CORDIC approximation method. <sup>4</sup> Stateflow support only.			

## Math Functions – Stateflow Support

When generating C/C++ code from Stateflow charts, depending on code replacement libraries available in your development environment, you can configure the code generator to replace instances of the following math functions with application-specific implementations.

Function	Data Type Support	Scalar, Vector, Matrix Support	Real, Complex Support
abs <sup>1</sup>	Integer Floating point	Scalar	Real
acos <sup>2</sup>	Floating point	Scalar Vector Matrix	Real Complex Complex input/complex output

Function	Data Type Support	Scalar, Vector, Matrix Support	Real, Complex Support
			Real input/complex output
$\text{acosd}^3$	Floating point	Scalar Vector Matrix	Real Complex
$\text{acot}^3$	Floating point	Scalar Vector Matrix	Real Complex
$\text{acotd}^3$	Floating point	Scalar Vector Matrix	Real Complex
$\text{acoth}^{3,5}$	Floating point	Scalar Vector Matrix	Real Complex
$\text{acsc}^3$	Floating point	Scalar Vector Matrix	Real Complex
$\text{acscd}^3$	Floating point	Scalar Vector Matrix	Real Complex
$\text{acsch}^3$	Floating point	Scalar Vector Matrix	Real Complex
$\text{asec}^3$	Floating point	Scalar Vector Matrix	Real Complex
$\text{asecd}^3$	Floating point	Scalar Vector Matrix	Real Complex
$\text{asech}^3$	Floating point	Scalar Vector Matrix	Real Complex

Function	Data Type Support	Scalar, Vector, Matrix Support	Real, Complex Support
$\text{asin}^2$	Floating point	Scalar Vector Matrix	Real Complex Complex input/complex output Real input/complex output
$\text{asind}^3$	Floating point	Scalar Vector Matrix	Real Complex
$\text{atan}^2$	Floating point	Scalar Vector Matrix	Real Complex Complex input/complex output Real input/complex output
$\text{atan2}^2$	Floating point	Scalar Vector Matrix	Real
$\text{atan2d}^3$	Floating point	Scalar Vector Matrix	Real
$\text{atand}^3$	Floating point	Scalar Vector Matrix	Real Complex
$\text{ceil}$	<ul style="list-style-type: none"> <li>• Floating-point</li> <li>• Scalar</li> </ul>	<ul style="list-style-type: none"> <li>• Floating-point</li> <li>• Scalar</li> </ul>	<ul style="list-style-type: none"> <li>• Floating-point</li> <li>• Scalar</li> </ul>
$\text{cos}^3$	Floating point	Scalar Vector Matrix	Real Complex Complex input/complex output Real input/complex output
$\text{cosd}^3$	Floating point	Scalar Vector Matrix	Real Complex

Function	Data Type Support	Scalar, Vector, Matrix Support	Real, Complex Support
$\cosh^2$	Floating point	Scalar Vector Matrix	Real Complex Complex input/complex output Real input/complex output
$\cot^3$	Floating point	Scalar Vector Matrix	Real Complex
$\cotd^3$	Floating point	Scalar Vector Matrix	Real Complex
$\coth^3$	Floating point	Scalar Vector Matrix	Real Complex

$\log_{10}^2$	Floating point	Scalar Vector Matrix	Real Complex
$\log_2^3$	Floating point	Scalar Vector Matrix	Real Complex
max	Integer Floating point	Scalar	Real
min	Integer Floating point	Scalar	Real
pow	Floating point	Scalar	Real
$\sec^3$	Floating point	Scalar Vector Matrix	Real Complex
$\secd^3$	Floating point	Scalar Vector Matrix	Real Complex
$\sech^3$	Floating point	Scalar Vector Matrix	Real Complex
$\sin^2$	Floating point	Scalar Vector Matrix	Real Complex Complex input/complex output Real input/complex output
$\sind^3$	Floating point	Scalar Vector Matrix	Real Complex

Function	Data Type Support	Scalar, Vector, Matrix Support	Real, Complex Support
$\sinh^2$	Floating point	Scalar Vector Matrix	Real Complex Complex input/complex output Real input/complex output
$\sqrt{\phantom{x}}$	Floating point	Scalar	Real
$\tan^2$	Floating point	Scalar Vector Matrix	Real Complex Complex input/complex output Real input/complex output
$\tand^3$	Floating point	Scalar Vector Matrix	Real Complex
$\tanh^2$	Floating point	Scalar Vector Matrix	Real Complex Complex input/complex output Real input/complex output
<sup>1</sup> Wrap on integer overflow only. <sup>2</sup> For models involving vectors or matrices, the code generator replaces only functions coded in the MATLAB action language. <sup>3</sup> The code generator replaces only functions coded in the MATLAB action language.			

## Memory Functions

Depending on code replacement libraries available in your development environment, you can configure the code generator to replace instances of the following memory functions with application-specific implementations.

Function	Data Type Support	Scalar, Vector, Matrix Support	Real, Complex Support
memcmp	Void pointer (void*)	Scalar	Real

Function	Data Type Support	Scalar, Vector, Matrix Support	Real, Complex Support
		Vector Matrix	Complex
memcpy	Void pointer (void*)	Scalar Vector Matrix	Real Complex
memset	Void pointer (void*)	Scalar Vector Matrix	Real Complex
memset2zero	Void pointer (void*)	Scalar Vector Matrix	Real Complex

Some target processors provide optimized functions to set memory to zero. Use the code replacement library programming interface to replace the `memset2zero` function with more efficient target-specific functions.

## Nonfinite Functions

Depending on code replacement libraries available in your development environment, you can configure the code generator to replace instances of the following nonfinite functions with application-specific implementations.

Function	Data Type Support	Scalar, Vector, Matrix Support	Real, Complex Support
getInf	Floating point	Scalar	Real
getMinusInf	Floating point	Scalar	Real
getNaN	Floating point	Scalar	Real
rtIsInf	Floating point	Scalar	Real Complex
rtIsNaN	Floating point	Scalar	Real Complex

## Mutex and Semaphore Functions

Mutex and semaphore functions control access to resources shared by multiple processes in multicore target environments. MathWorks provides code replacement libraries that support mutex and semaphore replacement for Rate Transition and Task Transition blocks on Windows, Linux, Mac, and VxWorks platforms.

Generated mutex and semaphore code typically consists of:

- In model initialization code, an initialization function call to create a mutex or semaphore to control entry to a critical section of code.
- In model step code:
  - Before code for a data transfer between tasks enters the critical section, mutex lock or semaphore wait function calls to reserve a critical section of code.
  - After code for a data transfer between tasks finishes executing the critical section, mutex unlock or semaphore post function calls to release the critical section of code.
- In model termination code, an optional destroy function call to explicitly delete the mutex or semaphore.

Depending on code replacement libraries available in your development environment, you can configure the code generator to replace instances of the following mutex and semaphore functions with application-specific implementations.

Function	Key
Mutex Destroy	RTW_MUTEX_DESTROY
Mutex Init	RTW_MUTEX_INIT
Mutex Lock	RTW_MUTEX_LOCK
Mutex Unlock	RTW_MUTEX_UNLOCK
Semaphore Destroy	RTW_SEM_DESTROY
Semaphore Init	RTW_SEM_INIT
Semaphore Post	RTW_SEM_POST
Semaphore Wait	RTW_SEM_WAIT

## Operators

When generating C/C++ code from a Simulink model, depending on code replacement libraries available in your development environment, you can configure the code generator to replace instances of the following operators with application-specific implementations.

Mixed data type support indicates that you can specify different data types for different inputs.

Operator	Key	Data Type Support	Scalar, Vector, Matrix Support	Real, Complex Support
Addition (+) <sup>1</sup>	RTW_OP_ADD	Integer Floating point Fixed-point Mixed	Scalar Vector Matrix	Real Complex
Subtraction (-) <sup>1</sup>	RTW_OP_MINUS	Integer Floating point Fixed-point Mixed	Scalar Vector Matrix	Real Complex
Multiplication (*) <sup>2</sup>	RTW_OP_MUL	Integer Floating point Fixed-point Mixed	Scalar Vector Matrix	Real Complex
Division (/)	RTW_OP_DIV	Integer Floating point Fixed-point Mixed	Scalar	Real Complex
Data type conversion (cast)	RTW_OP_CAST	Integer Floating point <sup>3</sup> Fixed-point Mixed	Scalar Vector Matrix	Real Complex
Shift left (<<)	RTW_OP_SL	Integer Fixed-point Mixed	Scalar Vector Matrix <sup>4</sup>	Real

<b>Operator</b>	<b>Key</b>	<b>Data Type Support</b>	<b>Scalar, Vector, Matrix Support</b>	<b>Real, Complex Support</b>
Shift right arithmetic (>>) <sup>5</sup>	RTW_OP_SRA	Integer Fixed-point Mixed	Scalar Vector Matrix <sup>4</sup>	Real
Shift right logical (>>)	RTW_OP_SRL	Integer Fixed-point Mixed	Scalar Vector Matrix <sup>4</sup>	Real
Element-wise matrix multiplication (.*) <sup>6</sup>	RTW_OP_ELEM_MUL	Integer Floating point Fixed-point Mixed	Vector Matrix	Real Complex
Matrix right division (/)	RTW_OP_RDIV	Integer Floating point Fixed-point Mixed	Vector Matrix	Real Complex
Matrix left division (\)	RTW_OP_LDIV	Integer Floating point Fixed-point Mixed	Vector Matrix	Real Complex
Matrix inversion (inv)	RTW_OP_INV	Integer Floating point Fixed-point Mixed	Vector Matrix	Real Complex
Complex conjugation	RTW_OP_CONJUGATE	Integer Floating point Fixed-point Mixed	Scalar Vector Matrix	Real Complex
Transposition (.')	RTW_OP_TRANS	Integer Floating point Fixed-point Mixed	Vector Matrix	Real Complex

Operator	Key	Data Type Support	Scalar, Vector, Matrix Support	Real, Complex Support
Hermitian (complex conjugate) transposition (')	RTW_OP_HERMITIAN	Integer Floating point Fixed-point Mixed	Vector Matrix	Real Complex
Multiplication with transposition <sup>2</sup>	RTW_OP_TRMUL	Integer Floating point Fixed-point Mixed	Vector Matrix	Real Complex
Multiplication with Hermitian transposition <sup>2</sup>	RTW_OP_HMMUL	Integer Floating point Fixed-point Mixed	Vector Matrix	Real Complex
Multiplication followed by shift right arithmetic ( $u1 * u2 \gg u3$ ) <sup>7</sup>	RTW_OP_MUL_SRA	Integer Fixed-point	Scalar	Real
Multiplication followed by division ( $u1 * u2 / u3$ ) <sup>8</sup>	RTW_OP_MULDIV	Integer Fixed-point	Scalar	Real
Greater than (>)	RTW_OP_GREATER_THAN	Integer Floating point Fixed-point Mixed	Scalar Vector Matrix	Real Complex
Greater than or equal (>=)	RTW_OP_GREATER_THAN_OR_EQUAL	Integer Floating point Fixed-point Mixed	Scalar Vector Matrix	Real Complex
Less than (<)	RTW_OP_LESS_THAN	Integer Floating point Fixed-point Mixed	Scalar Vector Matrix	Real Complex

<b>Operator</b>	<b>Key</b>	<b>Data Type Support</b>	<b>Scalar, Vector, Matrix Support</b>	<b>Real, Complex Support</b>
Less than or equal (<=)	RTW_OP_LESS_THAN_OR_EQUAL	Integer Floating point Fixed-point Mixed	Scalar Vector Matrix	Real Complex
Equal (==)	RTW_OP_EQUAL	Integer Floating point Fixed-point Mixed	Scalar Vector Matrix	Real Complex
Not equal (!=)	RTW_OP_NOT_EQUAL	Integer Floating point Fixed-point Mixed	Scalar Vector Matrix	Real Complex

Operator	Key	Data Type Support	Scalar, Vector, Matrix Support	Real, Complex Support
<p><sup>1</sup> See “Addition and Subtraction Operator Code Replacement” on page 51-170 for details to consider when defining mappings for addition and subtraction code replacements.</p> <p><sup>2</sup> Can map to Basic Linear Algebra Subroutine (BLAS) multiplication functions.</p> <p><sup>3</sup> Scaled floating point is not supported.</p> <p><sup>4</sup> Shift operator replacement with matrix data is supported for shift values that you specify with an input port. Replacement is not supported for shift values that you specify in a block parameter dialog.</p> <p><sup>5</sup> The code generator converts some arithmetic shift rights to logical shift rights. ## Develop a Code Replacement Library

Iterate through the following steps, as necessary, to develop a code replacement library:

- 1 “Identify Code Replacement Requirements” on page 51-38
- 2 “Prepare for Code Replacement Library Development” on page 51-41
- 3 “Define Code Replacement Mappings” on page 51-42
- 4 “Specify Build Information for Replacement Code” on page 51-59
- 5 “Register Code Replacement Mappings” on page 51-68
- 6 “Verify Code Replacements” on page 51-76
- 7 “Deploy Code Replacement Library” on page 51-93

To get started, see “Identify Code Replacement Requirements” on page 51-38.

To experiment with the process and tools, see “Quick Start Library Development” on page 51-28.

### More About

- “Code You Can Replace From Simulink Models” on page 51-7
- “Identify Code Replacement Requirements” on page 51-38
- “Quick Start Library Development” on page 51-28
- “What Is Code Replacement Customization?” on page 51-3

## Quick Start Library Development

This example shows how to develop a code replacement library that includes an entry for generating replacement code for the math function `sin`. You use the Code Replacement Tool.

### Prerequisites

To complete this example, install the following software:

- MATLAB
- Simulink
- Simulink Coder
- Embedded Coder

For instructions on installing MathWorks products, see the . If you have installed MATLAB and want to see what other MathWorks products are installed, in the Command Window, enter `ver`.

For a list of supported compilers, see [http://www.mathworks.com/support/compilers/current\\_release/](http://www.mathworks.com/support/compilers/current_release/).

### Open the Code Replacement Tool

- 1 Start a new MATLAB session.
- 2 Create or navigate (`cd`) to an empty folder.
- 3 At the command prompt, enter the `crtool` command. The Code Replacement Tool window opens.

### Create Code Replacement Table

- 1 In the Code Replacement Tool window, select **File > New table**.
- 2 In the right pane, name the table `cr1_table_sinfcn` and click **Apply**. Later, when you save the table, the tool saves it with the file name `cr1_table_sinfcn.m`.

### Create Table Entry

Create a table entry that maps a `sin` function with `double` input and `double` output to a custom implementation function.

- 1 In the left pane, select table `crl_table_sinfcn`. Then, select **File > New entry > Function**. The new entry appears in the middle pane, initially without a name.
- 2 In the middle pane, select the new entry.
- 3 In the right pane, on the **Mapping Information** tab, from the **Function** menu, select `sin`.
- 4 Leave **Algorithm** set to `Unspecified`, and leave parameters in the **Conceptual function** group set to default values.
- 5 In the **Replacement function** group, name the replacement function `sin_dbl`.
- 6 Leave the remaining parameters in the **Replacement function** group set to default values.

- 7 Click **Apply**. The tool updates the **Function signature preview** to reflect the specified replacement function name.
- 8 Scroll to the bottom of the **Mapping Information** tab and click **Validate entry**. The tool validates your entry.

The following figure shows the completed mapping information.

Mapping Information **Build Information**

Function: **sin**

Entry information

Algorithm: **Unspecified**

Conceptual function

*Used by code generation process for matching purposes*

Conceptual arguments: **y1**  
**u1**

Argument properties

Data type: **double**

Complex

Argument type: **Scalar**

Make conceptual and implementation argument types the same

Replacement function

Function prototype

Name: **sin\_dbl** C++ namespace:

Function returns void

Function arguments: **y1(return arg)**  
**u1**

Argument properties

Data type: **double** I/O type: **OUTPUT**

Const  Pointer  Complex

Function signature preview

```
double sin_dbl(double u1);
```

Implementation attributes

Integer saturation mode: **Unspecified Saturation**

Rounding mode: **Unspecified Rounding**  
Floor  
Ceil  
...

Allow expressions as inputs

Function modifies internal or global state

[Click here to add Build Information](#)

Validation

**Validate entry** Status: **Validated**

**Help** **Apply**

### Specify Build Information for Replacement Code

- 1 On the **Build Information** tab, for the **Implementation header file** parameter, enter `sin_dbl.h`.
- 2 Leave the remaining parameters set to default values.
- 3 Click **Apply**.

- 4 Optionally, you can revalidate the entry. Return to the **Mapping Information** tab and click **Validate entry**.

### Create Another Table Entry

Create an entry that maps a `sin` function with `single` input and `double` output to a custom implementation function named `sin_sgl`. Create the entry by copying and pasting the `sin_dbl` entry.

- 1 In the middle pane, select the `sin_dbl` entry.
- 2 Select **Edit > Copy**
- 3 Select **Edit > Paste**
- 4 On the **Mapping Information** tab, in the **Conceptual function** section, set the data type of input argument `u1` to `single`.
- 5 In the **Replacement function** section, name the function `sin_sgl`. Set the data type of input argument `u1` to `single`.
- 6 Click **Apply**. Note the changes that appear for the **Function signature preview**.
- 7 On the **Build Information** tab, for the **Implementation header file** parameter, enter `sin_sgl.h`. Leave the remaining parameters set to default values and click **Apply**.

### Validate the Code Replacement Table

- 1 Select **Actions > Validate table**.

- 2 If the tool reports errors, fix them, and rerun the validation. Repeat fixing and validating errors until the tool does not report errors. The following figure shows a validation report.

Name	Implementation	NumIn	In1Type	In2Type	Out1Type	Out2Type	Priority
✓ sin	sin_dbl	1	double		double		100
✓ sin	sin_sgl	1	single		double		100

### Save the Code Replacement Table

Save the code replacement table to a MATLAB file in your working folder. Select **File > Save table**. By default, the tool uses the table name to name the file. For this example, the tool saves the table in the file `crl_table_sinfcn.m`.

### Review the Code Replacement Table Definition

Consider reviewing the MATLAB code for your code replacement table definition. After using the tool to create an initial version of a table definition file, you can update, enhance, or copy the file in a text editor.

To review it, in MATLAB or another text editor, open the file `crl_table_sinfcn.m`.

### Generate a Registration File

Before you can use your code replacement table, you must register it as part of a code replacement library. Use the Code Replacement Tool to generate a registration file.

- 1 In the Code Replacement Tool, select **File > Generate registration file**.
- 2 In the **Generate registration file** dialog box, edit the dialog box fields to match the following figure, and then click **OK**.

- 3 In the **Select location** dialog box, specify a location for the registration file. The location must be on the MATLAB path or in the current working folder. Save the file. The tool saves the file as `rtwTargetInfo.m`.

### Register the Code Replacement Table

At the command prompt, enter:

```
sl_refresh_customizations
```

### Review and Test Code Replacements

Apply your code replacement library. Verify that the code generator makes code replacements that you expect.

- 1 Check for errors. At the command line, invoke the table definition file. For example:

```
tbl = crl_table_sinfcn
```

```
tbl =
```

```
Tf1Table with properties:
```

```
 Version: '1.0'
 ReservedSymbols: []
StringResolutionMap: []
 AllEntries: [2x1 RTW.Tf1CFunctionEntry]
 EnableTrace: 1
```

If an error exists in the definition file, the invocation triggers a message. Fix the error and try again.

- 2 Use the Code Replacement Viewer to check your code replacement entries. For example:

```
crviewer('Sin Function Example')
```

In the viewer, select entries in your table and verify that the content is what you expect. The viewer can help you detect issues such as:

- Incorrect argument order.
- Conceptual argument names that do not match what the code generator expects.
- Incorrect priority settings.

- Identify an existing model or create a new model that includes a Trigonometric Function block that is set to the `sin` function. For example:

- Open the model and configure it for code generation with an Embedded Coder (ERT-based) target.
- See whether your library is listed as an available option for the **Code Generation > Interface > Code replacement library** model configuration parameter. If it is, select it.

If it is not listed, open the registration file, `rtwTargetInfo.m`. See whether you entered the correct code replacement table name when you created the file. If you hover the cursor over the selected library, a tool tip appears. This tip contains information derived from your code replacement library registration file, such as the library description and the list of tables it contains.

- Configure the code generation report for code replacement analysis by setting the following parameters:
  - On the **Code Generation > Report** pane, select **Create code generation report** and **Open report automatically**.
  - On the **Code Generation > Comments** pane, select **Include comments**, **Simulink block / Stateflow object comments**, and **Simulink block descriptions**.
  - On the **All Parameters** tab, select **Code-to-model**, **Model-to-code**, and **Summarize which blocks triggered code replacements**.
- Configure the model to generate code only. Before you build an executable, confirm that the code generator is replacing code as expected.
- Generate code for the model.
- Review code replacement results in the Code Replacement Report section of the code generation report.

The report indicates that the code generator found a match and applied the replacement code for the function `sin_dbl`.

- Review the code replacements. In the model window, right-click the Trigonometric Function block. Select **C/C++ Code > Navigate to C/C++ Code**. The code generation report opens and highlights the code replacement in `my_sin_func.c`. In this case, the code generator replaced `sin` with `sin_dbl`.

## More About

- “Code You Can Replace From Simulink Models” on page 51-7
- “Develop a Code Replacement Library” on page 51-27
- “What Is Code Replacement Customization?” on page 51-3

## Identify Code Replacement Requirements

The first step to developing a code replacement library is to consider the following types of requirements for the library.

### Mapping Information Requirements

- Are you defining a code replacement mapping for the first time?
- Are you updating code replacement entries in an existing library? Or, are you creating a new library?
- Are you rapid prototyping code replacements?
- Can you base your mappings on existing mappings?
- What type of code do you want to replace? Options include:
  - Math operation
  - Function
  - BLAS operation
  - CBLAS operation
  - Net slope fixed-point operation
  - Semaphore or mutex functions
- Do you want to change the inline or nonfinite behavior for functions?
- What specific functions and operations do you want to replace?
- What input and output arguments does the function or operator that you are replacing take? For each argument, what is the data type, complexity, and dimensionality?
- What does the prototype for your replacement code look like?
  - What is the replacement function name?
  - What are the input and output arguments?
  - Are there return values?
  - What is the data type, complexity, and dimensionality of each argument and return value?

## Build Information Requirements

- Does your replacement function implementation require a header file? If yes, specify the header file.
- If the replacement function implementation requires a header file, what is the path for that file?
- Is the source file for the replacement function in your working folder? If not, you can explicitly specify the source file name and extension. For example, if the file is required in the generated makefile or specified in a build information object, specify the source file.
- Does the replacement function use additional include files? If yes, what are they and what are the paths for those files?
- Does the replacement function use additional source files? If yes, what are they and what are the paths for those files?
- What compiler flags are required for compiling code that includes the replacement code?
- What linker flags are required for building an executable that includes the replacement code?
- Are the required header, source, and object files for building an executable that includes your replacement code in the working folder for your project? If not, before starting the build process, do you want the code generator to copy required files to the build folder?

## Registration Information Requirements

- What do you want to name your code replacement library?
- What code replacement tables do you want to include in the library? What are the file names and paths for the tables?
- What is the purpose of the library? You can document the purpose as the library description.
- Does the library apply to specific hardware devices? If yes, what devices?
- Are you developing a hierarchy of code replacement libraries? Is the library that you are developing based (dependent) on another library? For example, you can specify a general `TI device library` as the base library for a more specific `TI C28x device library`.

- Do you need to specify data alignment for the library? What data alignments are required? For each specification, what type of alignment is required and for what programming language?

Next, prepare for developing a library by reviewing a code replacement library development checklist.

### **More About**

- “Code You Can Replace From Simulink Models” on page 51-7
- “Develop a Code Replacement Library” on page 51-27
- “Prepare for Code Replacement Library Development” on page 51-41
- “What Is Code Replacement Customization?” on page 51-3

## Prepare for Code Replacement Library Development

After you identify your code replacement requirements, prepare for library development by reviewing this checklist:

- Get familiar with the library development process.
- Decide whether to define code replacement mappings and produce a registration file interactively with the Code Replacement Tool or programmatically.
- Identify or develop MATLAB code and Simulink models to test your code replacement library.
- Consider the hierarchy and organization of your library. A library can consist of multiple tables and each table can include multiple entries. How do you want to organize the library to optimize reuse of tables and entries? For example, a registration file can define code replacement tables organized in a hierarchy of code replacement libraries based on entries that increase in specificity:
  - Common entries
  - Entries for TI devices
  - Entries for TI C6xx devices
  - Entries specific to the TI C67x device
- If support files, such as header files, additional source files, and dynamically linked libraries are not in your current working folder, note their location. You need to specify the paths for such files.

Next, based on your requirements and preparation, define code replacement mappings.

### More About

- “Code You Can Replace From Simulink Models” on page 51-7
- “Identify Code Replacement Requirements” on page 51-38
- “Define Code Replacement Mappings” on page 51-42
- “Develop a Code Replacement Library” on page 51-27
- “What Is Code Replacement Customization?” on page 51-3

## Define Code Replacement Mappings

After you prepare for library development, use your requirements to define code replacement mappings. A code replacement mapping associates a conceptual representation of a function or operator that is familiar to the code generator with a custom implementation representation that specifies a C or C++ replacement function prototype. You capture a mapping as an entry in a code replacement table:

- Interactively, by using the Code Replacement Tool.
- Programmatically, by using a MATLAB programming interface.

### Choose an Approach for Defining Code Replacement Mappings

The following table lists situations to help you decide when to use the interactive or programmatic approach.

Situation	Approach
Defining mappings for the first time.	Code Replacement Tool.
Rapid prototyping mappings.	Code Replacement Tool to quickly generate, register, and test mappings.
Developing a mapping as a template or starting point for defining similar mappings.	Code Replacement Tool to generate definition code that you can copy and modify.
Modifying a registration file, including copying and pasting content.	MATLAB Editor to update the programming interface directly.
Defining mappings that specify attributes not available from the Code Replacement Tool (for example, sets of algorithm parameters).	Programming interface.
Reusing existing code for new mappings by copying, pasting, and editing existing mappings.	Programming interface.

## Define Mappings Interactively with the Code Replacement Tool

This example shows how to use the Code Replacement Tool to develop code replacement mappings. The tool is ideal for getting started with developing mappings, rapid prototyping, and developing a mapping to use as a starting point for defining similar mappings.

### Open the Code Replacement Tool

Do one of the following:

- In the Command Window, enter the command `crtool`.
- In the Configuration Parameters dialog box, navigate to **All Parameters > Code Generation > Code replacement library** and click **Custom**.

An Embedded Coder license is not required to create a custom code replacement library. However, you must have an Embedded Coder license to use a such a library.

By default, the tool displays, left to right, a root pane, a list pane, and a dialog pane. You can manipulate the display:

- Drag boundaries to widen, narrow, shorten, or lengthen panes, and to resize table columns.
- Select **View > Show dialog pane** to hide or display the right-most pane.
- Click a table column heading to sort the table based on contents of the selected column.
- Right-click a table column heading and select **Hide** to remove the column from the display. (You cannot hide the **Name** column.)

### Create a Code Replacement Table

- 1 In the Code Replacement Tool window, select **File > New table**.
- 2 In the right pane, name the table and click **Apply**. Later, when you save the table, the tool uses the table name that you specify to name the file. For example, if you enter the name `my_sinfcn`, the tool names the file `my_sinfcn.m`.

### Create Table Entries

Create one or more table entries. Each entry maps the conceptual representation of a function or operator to your implementation representation. The information that you enter depends on the type of entry you create. Enter the following information:

- 1 In the left pane, select the table to which you want to add the entry.
- 2 Select **File > New entry > entry-type**, where **entry-type** is one of:
  - Math Operation
  - Function
  - BLAS Operation
  - CBLAS Operation
  - Net Slope Fixed-Point Operation
  - Semaphore entry
  - Customization entry

The new entry appears in the middle pane, initially without a name.

- 3 In the middle pane, select the new entry.
- 4 In the right pane, on the **Mapping Information** tab, from the **Function** or **Operation** menu, select the function or operation that you want the code generator to replace. Regardless of the entry type, make a selection from this menu. Your selection determines what other information you specify.

Except for customization entries, you also specify information for your replacement function prototype. You can also specify implementation attributes, such as the rounding modes to apply.

- 5 If prompted, specify additional entry information that you want the code generator to use when searching for a match. For example, when you select an addition or subtraction operation, the tool prompts you to specify an algorithm (**Cast before operation** or **Cast after operation**).
- 6 Review the conceptual argument information that the tool populates for the function or operation. Conceptual input and output arguments represent arguments for the function or operator being replaced. Conceptual arguments observe naming conventions ('y1', 'u1', 'u2', ...) and data types familiar to the code generator.

If you do not want the data types for your implementation to be the same as the conceptual argument types, clear the **Make the conceptual and implementation argument types the same** check box. For example, most ANSI-C functions operate on and return `double` data. Clear the check box if want to map a conceptual representation of the function to an implementation representation that specifies an argument and return value. For example, clear the check box to map the conceptual representation of the function `sin` to an implementation representation that

specifies an argument and return value of type `single` (`single sin(single)`), of type `double` (`double sin(double)`). In this case, the code generator produces the following code:

```
y = (single) sin(u1);
```

If you select **Custom** for a function entry, specify only conceptual argument information.

- 7 Specify the name and argument information for your replacement function. As you enter the information and click **Apply**, the tool updates the **Function signature preview**.
- 8 Specify additional implementation attributes that apply. For example, depending on the type and name of the entry that you specify, the tool prompts you to specify:
  - Integer saturation mode
  - Rounding modes
  - Whether to allow inputs that include expressions
  - Whether a function modifies internal or global state
- 9 Click **Apply**.

### Validate Tables and Entries

The Code Replacement Tool provides a way to validate the syntax of code replacement tables and table entries as you define them. If the tool finds validation errors, you can address them and retry the validation. Repeat the process until the tool does not report errors.

To	Do
Validate table entries	Select an entry, scroll to the bottom of the <b>Mapping Information</b> tab, and click <b>Validate entry</b> . Alternatively, select one or more entries, right-click, and select <b>Validate entries</b> .
Validate a table	Select the table. Then, select <b>Actions &gt; Validate table</b> .

### Save a Table

When you save a table, the tool validates unvalidated content.

- 1 Select **File > Save table**.
- 2 In the Browse For Folder dialog box, specify a location and name for the file. Typically, you select a location on the MATLAB path. By default, the tool names the file using the name that you specify for the table with the extension `.m`.
- 3 Click **Save**.

### Open and Modify Tables

After saving a code replacement table, to make changes in the table:

- 1 Select **File > Open table**.
- 2 In the Import file dialog box, browse to the MATLAB file that contains the table.

Repeat the sequence to open and work on multiple tables.

If you open multiple tables, you can manage the tables together. For example, use the tool to:

- Create new table entries.
- Delete entries.
- Copy and paste or cut and paste information between tables.

### Define Mappings Programmatically

This example shows how to define a code replacement mapping programmatically. The programming interface for defining code replacement table mappings is ideal for

- Modifying tables that you create with the Code Replacement Tool.
- Defining mappings for specialized entries that you cannot create with the Code Replacement Tool.
- Replicating and modifying similar entries and tables.

Steps for defining a mapping programmatically are:

#### Create Code Replacement Table

- 1 Create a table definition file that contains a function definition. For example:  

```
function hTable = crl_table_sinfcn()
```
- 2 Within the function body, create the table by calling the function `RTW.Tf1Table`.

```
hTable = RTW.Tf1Table;
```

## Create Table Entry

For each function or operator that you want the code generator to replace, map a conceptual representation of the function or operator to an implementation representation as a table entry.

- 1 Within the body of a table definition file, create a code replacement entry object. Call one of the following functions.

Entry Type	Function
Math operation	RTW.Tf1COperationEntry
Function	RTW.Tf1CFunctionEntry
BLAS operation	RTW.Tf1BlasEntryGenerator
CBLAS operation	RTW.Tf1CBlasEntryGenerator
Fixed-point addition and subtraction operations (support for <code>SlopesMustBeTheSame</code> and <code>ZeroNetBias</code> parameters)	RTW.Tf1COperationEntryGenerator
Net slope fixed-point operation	RTW.Tf1COperationEntryGenerator_NetSlope
Semaphore or mutex entry	RTW.Tf1CSemaphoreEntry
Custom function entry	<i>MyCustomFunctionEntry</i> (where <i>MyCustomFunctionEntry</i> is a class derived from RTW.Tf1CFunctionEntryML)
Custom operation entry	<i>MyCustomOperationEntry</i> (where <i>MyCustomOperationEntry</i> is a class derived from RTW.Tf1COperationEntryML)

For example:

```
hEnt = RTW.Tf1CFunctionEntry;
```

You can combine steps of creating the entry, setting entry parameters, creating conceptual and implementation arguments, and adding the entry to a table with a

single function call to `registerCFunctionEntry`, `registerCPPFunctionEntry`, or `registerCPromotableMacroEntry` if you are creating an entry for a function and the function implementation meets the following criteria:

- Implementation argument names and order match the names and order of corresponding conceptual arguments.
- Input arguments are of the same type.
- The return and input argument names follow the code generator's default naming conventions:
  - Return argument is `y1`.
  - Input arguments are `u1`, `u2`, ..., `un`.

For example:

```
registerCFunctionEntry(hTable, 100, 1, 'sin', 'double', ...
 'sin_dbl', 'double', 'sin_dbl.h', '', '');
```

As another alternative, you can significantly reduce the amount of code that you write by combining the steps of creating the entry and conceptual and implementation arguments with a call to the `createCRLEntry` function. In this case, specify the conceptual and implementation information as character vector specifications.

For example:

```
hEnt = createCRLEntry(hTable, ...
 'double y1 = sin(double u1)', ...
 'mySin');
```

This approach does not support:

- C++ implementations
- Data alignment
- Operator replacement with net slope arguments
- Entry parameter specifications (for example, priority, algorithm, building information)
- Semaphore and mutex function replacements

## Set Entry Parameters

Set entry parameters, such as the priority, algorithm information, and implementation (replacement) function name. Call the function listed in the following table for the entry type that you created.

Entry Type	Function
Math operation	setTf1COperationEntryParameters
Function	setTf1CFunctionEntryParameters
BLAS operation	setTf1COperationEntryParameters
CBLAS operation	setTf1COperationEntryParameters
Fixed-point addition and subtraction operations where there is a many-to-one mapping, such as a mapping for a range of fixed-point types to the same replacement function (support for SlopesMustBeTheSame and ZeroNetBias parameters)	setTf1COperationEntryParameters
Net slope fixed-point operation	setTf1COperationEntryParameters
Semaphore or mutex entry	setTf1CSemaphoreEntryParameters
Custom function entry	setTf1CFunctionEntryParameters
Custom operation entry	setTf1COperationEntryParameters

To see a list of the parameters that you can set, at the command line, create a new entry and omit the semicolon at the end of the command. For example:

```
hEnt = RTW.Tf1CFunctionEntry
```

```
hEnt =
```

```
Tf1CFunctionEntry with properties:
```

```

 Implementation: [1x1 RTW.CImplementation]
 SlopesMustBeTheSame: 0
 BiasMustBeTheSame: 0
 AlgorithmParams: []
 ImplType: 'FCN_IMPL_FUNCT'
 AdditionalHeaderFiles: {0x1 cell}
 AdditionalSourceFiles: {0x1 cell}

```

```
AdditionalIncludePaths: {0x1 cell}
AdditionalSourcePaths: {0x1 cell}
AdditionalLinkObjs: {0x1 cell}
AdditionalLinkObjsPaths: {0x1 cell}
AdditionalLinkFlags: {0x1 cell}
AdditionalCompileFlags: {0x1 cell}
 SearchPaths: {0x1 cell}
 Key: ''
 Priority: 100
 ConceptualArgs: [0x1 handle]
 EntryInfo: []
 GenCallback: ''
 GenFileName: ''
 SaturationMode: 'RTW_SATURATE_UNSPECIFIED'
 RoundingModes: {'RTW_ROUND_UNSPECIFIED'}
 TypeConversionMode: 'RTW_EXPLICIT_CONVERSION'
 AcceptExprInput: 1
 SideEffects: 0
 UsageCount: 0
 RecordedUsageCount: 0
 Description: ''
 StoreFcnReturnInLocalVar: 0
 TraceManager: [1x1 RTW.Tf1TraceManager]
```

To see the implementation parameters, enter:

```
hEnt.Implementation
```

```
ans =
```

```
CImplementation with properties:
```

```
HeaderFile: ''
SourceFile: ''
HeaderPath: ''
SourcePath: ''
Return: []
StructFieldMap: []
Name: ''
Arguments: [0x1 handle]
ArgumentDescriptor: []
```

For example, to set entry parameters for the `sin` function and name your replacement function `sin_dbl`, use the following function call:

```
setTf1CFunctionEntryParameters(hEnt, ...
 'Key', 'sin', ...
 'ImplementationName', 'sin_dbl');
```

## Create Conceptual Arguments

Create conceptual arguments and add them to the entry's array of conceptual arguments.

- Specify output arguments before input arguments.
- Specify argument names that comply with code generator argument naming conventions:
  - $y_1$  for a return argument
  - $u_1, u_2, \dots, u_n$  for input arguments
- Specify data types that are familiar to the code generator.
- The function signature, including argument naming, order, and attributes, must fulfill the signature match sought by function or operator callers.
- The code generator determines the size of the value for an argument with an unsized type, such as integer, based on hardware implementation configuration settings.

For each argument:

- 1 Identify whether the argument is for input or output, the name, and data type. If you do not know what arguments to specify for a supported function or operation, use the Code Replacement Tool to find them. For example, to find the conceptual arguments for the `sin` function, open the tool, create a table, create a function entry, and in the **Function** menu select `sin`.
- 2 Create and add the conceptual argument to an entry. You can choose a method from the methods listed in this table.

If	Then
You want simpler code or want to explicitly specify whether the argument is scalar or nonscalar (vector or matrix).	Call the function <code>createAndAddConceptualArg</code> . For example: <pre>createAndAddConceptualArg(hEnt, ...     'RTW.Tf1ArgNumeric', ...     'Name', 'y1', ...     'IOType', 'RTW_IO_OUTPUT', ...     'DataTypeMode', 'double');</pre>

If	Then
	The second argument specifies whether the argument is scalar ( <code>RTW.TflArgNumeric</code> or <code>RTW.TflArgMatrix</code> ).
You want to create an argument based on a built-in argument definition (for example, scalar or nonscalar).	<p>Call <code>getTflArgFromString</code> to create the argument. Then, call <code>addConceptualArg</code> to add the argument to the entry.</p> <pre data-bbox="624 496 1299 578">arg = getTflArgFromString(hEnt, 'y1','double'); arg.IOType = 'RTW_IO_OUTPUT'; addConceptualArg(hEnt, arg);</pre>
You need to define several similar mappings, you want to minimize the code to write, and the entries do not require data alignment, use net slope arguments, or involve semaphore or mutex replacements.	<p>Call <code>createCRLEntry</code> to create the entry and specify conceptual and implementation arguments in a single function call.</p> <pre data-bbox="624 713 1151 795">hEnt = createCRLEntry(hTable, ...     'double y1 = sin(double u1)', ...     'mySin');</pre>

The following code shows the second approach listed in the table for specifying the conceptual output and input argument definitions for the `sin` function.

#### % Conceptual Args

```
arg = getTflArgFromString(hEnt, 'y1','double');
arg.IOType = 'RTW_IO_OUTPUT';
addConceptualArg(hEnt, arg);
```

```
arg = getTflArgFromString(hEnt, 'u1','double');
addConceptualArg(hEnt, arg);
```

#### Create Implementation Arguments

Create implementation arguments for the C or C++ replacement function and add them to the entry.

- When replacing code, the code generator uses the argument names to determine how it passes data to the implementation function.

- For function replacements, the order of implementation argument names must match the order of the conceptual argument names.
- For operator replacements, the order of implementation argument names do not have to match the order of the conceptual argument names. For example, for an operator replacement for addition,  $y1=u1+u2$ , the conceptual arguments are  $y1$ ,  $u1$ , and  $u2$ , in that order. If the signature of your implementation function is `t myAdd(t u2, t u1)`, where `t` is a valid C type, based on the argument name matches, the code generator passes the value of the first conceptual argument,  $u1$ , to the second implementation argument of `myAdd`. The code generator passes the value of the second conceptual argument,  $u2$ , to the first implementation argument of `myAdd`.
- For operator replacements, you can remap operator output arguments to implementation function input arguments.

For each argument:

- 1 Identify whether the argument is for input or output, the name, and the data type.
- 2 Create and add the implementation argument to an entry. You can choose a method from the methods listed in this table.

If	Then
You want to populate implementation arguments as copies of previously created matching conceptual arguments	Call the function <code>copyConceptualArgsToImplementation</code> . For example:  <code>copyConceptualArgsToImplementation(hEnt);</code>
You want to create and add implementation arguments individually, or vary argument attributes, while maintaining conceptual argument order	Call functions <code>createAndSetCImplementationReturn</code> and <code>createAndAddImplementationArg</code> . For example:  <code>createAndSetCImplementationReturn(hEnt,     'RTW.TflArgNumeric', ...     'Name',              'y1', ...     'IOType',           'RTW_IO_OUTPUT', ...     'IsSigned',       true, ...     'WordLength',      32, ...     'FractionLength',  0);</code>  <code>createAndAddImplementationArg(op_entry,     'RTW.TflArgNumeric',...     'Name',              'u1', ...</code>

If	Then
	<pre data-bbox="672 296 1129 414">'IOType', 'RTW_IO_INPUT',... 'IsSigned', true,... 'WordLength', 32, ... 'FractionLength', 0 );</pre>

If	Then
<p>You want to minimize the amount of code, or specify constant arguments to pass to the implementation function</p>	<p>Create the argument with a call to the function <code>getTf1ArgFromString</code>. Then, use the convenience method <code>setReturn</code> or <code>addArgument</code> to specify whether an argument is a return value or argument and to add the argument to the entry's array of implementation arguments. For example:</p> <pre>arg = getTf1ArgFromString(hEnt, 'y1', 'double'); arg.IOType = 'RTW_IO_OUTPUT'; hEnt.Implementation.setReturn(arg);</pre> <p>arg = getTf1ArgFromString(hEnt, 'u1', 'double'); hEnt.Implementation.addArgument(arg);</p> <p>The following call to <code>getTf1ArgFromString</code> passes the constant 0 to argument u2:</p> <pre>arg = getTf1ArgFromString(hEnt, 'u2', 'int16', 0); hEnt.Implementation.addArgument(arg);</pre> <p>For semaphore and mutex entries, use the functions <code>getTf1DWorkFromString</code> and <code>addDWorkArg</code> to create and add a DWork argument to the entry. Then create implementation arguments as shown above with <code>getTf1ArgFromString</code> and the convenience methods <code>setReturn</code> and <code>addArgument</code>. For example:</p> <pre>arg = getTf1DWorkFromString('d1', 'void*'); hEnt.addDWorkArg(arg);</pre> <pre>arg = hEnt.getTf1ArgFromString('y1', 'void'); arg.IOType = 'RTW_IO_OUTPUT'; hEnt.Implementation.setReturn(arg);</pre> <pre>arg = hEnt.getTf1ArgFromString('u1', 'integer'); hEnt.Implementation.addArgument(arg);</pre> <pre>arg = hEnt.getTf1ArgFromString('d1', 'void**'); hEnt.Implementation.addArgument(arg);</pre>

If	Then
<p>You need to define several similar mappings, you want to minimize the code to write, and the entries do not require data alignment, use net slope arguments, or involve semaphore or mutex replacements.</p>	<p>Call <code>createCRLEntry</code> to create the entry and specify conceptual and implementation arguments in a single function call.</p> <pre data-bbox="612 421 1144 505"> hEnt = createCRLEntry(hTable, ...     'double y1 = sin(double u1)', ...     'mySin');</pre>

The following code shows the third approach listed in the table for specifying the implementation output and input argument definitions for the `sin` function:

```

% Implementation Args

arg = hEnt.getTf1ArgFromString('y1','double');
arg.IOType = 'RTW_IO_OUTPUT';
hEnt.Implementation.setReturn(arg);

arg = hEnt.getTf1ArgFromString('u1','double');
hEnt.Implementation.addArgument(arg);
```

### Add Entry to Table

Add an entry to a code replacement table by calling the function `addEntry`.

```

addEntry(hTable, hEnt);
```

### Validate Entry

After you create or modify a code replacement table entry, validate it by invoking it at the MATLAB command line. For example:

```

hTbl = crl_table_sinfcn

hTbl =

RTW.Tf1Table
 Version: '1.0'
 AllEntries: [2x1 RTW.Tf1CFunctionEntry]
ReservedSymbols: []
```

```
StringResolutionMap: []
```

If the table includes errors, MATLAB reports them. The following examples shows how MATLAB reports a typo in a data type name:

```
hTbl = crl_table_sinfcn
??? RTW_CORE:tf1:TflTable: Unsupported data type, 'dooble'.

Error in ==> crl_table_sinfcn at 7
hTable.registerCFunctionEntry(100, 1, 'sin', 'dooble', 'sin_dbl', ...
```

### Save Table

Save the table definition file. Use the name of the table definition function to name the file, for example, `crl_table_sinfcn.m`.

Next, from your requirements, determine whether you need to specify build information for your replacement code.

## Specify Build Information for Replacement Code

After you define code replacement mappings, determine whether you need to specify build information for your replacement code. A code replacement table entry can specify build information for the code generator to use when replacing code for a match. For example, specify files for implementation replacement code if you are using a generated makefile and the code generation software compiles the code.

Add build information to an entry:

- Interactively, by using the **Build Information** tab in the Code Replacement Tool.
- Programmatically, by using a MATLAB programming interface.

### Build Information

The build information can include:

- Paths and file names for header files
- Paths and file names for source files
- Paths and file names for object files
- Compile flags
- Link flags

### Choose an Approach for Specifying Build Information

The following table lists situations to help you decide when to use an interactive or programmatic approach to specifying build information:

Situation	Approach
Creating code replacement entries for the first time.	Code Replacement Tool.
You used the Code Replacement Tool to create the entries for which the build information applies.	Code Replacement Tool to specify the build information quickly .
Rapid prototyping entries.	Code Replacement Tool to generate, register, and test entries quickly.

Situation	Approach
Developing an entry to use as a template or starting point for defining similar entries.	Code Replacement Tool to generate entry code that you can copy and modify.
Modifying existing mappings.	MATLAB Editor to update the programming interface directly.

- If an entry uses header, source, or object files, consider whether to make the files accessible to the code generator. You can copy files to the build folder or you can specify individual file names and paths explicitly.
- If you specify *additional* header files/include paths or source files/paths and you copy files, the compiler and utilities such as `packNGO` might find duplicate instances of files (an instance in the build folder and an instance in the original folder).
- If you choose to copy files to the build folder and you are using the `packNGO` function to relocate static and generated code files to another development environment:
  - In the call to `packNGO`, specify the property-value pair `'minimalHeaders' true` (the default). That setting instructs the function to include the minimal header files required to build the code in the zip file.
  - Do not collocate files that you copy with files that you do not copy. If the `packNGO` function finds multiple instances of the same file, the function returns an error.
- If you use the programming interface, paths that you specify can include tokens. A token is a variable defined as a character vector or cell array of character vectors in the MATLAB workspace that you enclose with dollar signs (`$variable$`). The code generator evaluates and replaces a token with the defined value. For example, consider the path `$myfolder$folder1`, where `myfolder` is a character vector variable defined in the MATLAB workspace as `'d:\work\source\module1'`. The code generator generates the custom path as `d:\work\source\module1\folder1`.

## Specify Build Information Interactively with the Code Replacement Tool

The Code Replacement Tool provides a quick, easy way for you to specify build information for code replacement table entries. It is ideal for getting started with defining a table entry, rapid prototyping, and developing table entries to use as a starting point for defining similar mappings.

- 1 Determine the information that you must specify.

- 2 Open the Code Replacement Tool.
- 3 Select the code replacement table entry for which you want to specify the build information. In the left pane, select the table that contains the entry. In the middle pane, select the entry that you want to modify.
- 4 In the right pane, select the **Build Information** tab.
- 5 On the **Build Information** tab, specify your build information.

Parameter	Specify
<b>Implementation header file</b>	File name and extension for the header file the code generator needs to generate the replacement code. For example, <code>sin_dbl.h</code> .
<b>Implementation source file</b>	File name and extension for the C or C++ source file the code generator needs to generate the replacement code. For example, <code>sin_dbl.c</code> .
<b>Additional header files/include paths</b>	Paths and file names for additional header files the code generator needs to generate the replacement code. For example, <code>C:\libs\headerFiles</code> and <code>C:\libs\headerFiles\common.h</code> . This parameter adds <code>-I</code> to the compile line in the generated makefile.
<b>Additional source files/ paths</b>	Paths and file names for additional source files the code generator needs to generate the replacement code. For example, <code>C:\libs\srcFiles</code> and <code>C:\libs\srcFiles\common.c</code> . This parameter adds <code>-I</code> to the compile line in the generated makefile.
<b>Additional object files/ paths</b>	Paths and file names for additional object files the linker needs to build the replacement code. For example, <code>C:\libs\objFiles</code> and <code>C:\libs\objFiles\common.obj</code> .
<b>Additional link flags</b>	Flags the linker needs to generate an executable file for the replacement code.
<b>Additional compile flags</b>	Flags the compiler needs to generate object code for the replacement code.
<b>Copy files to build directory</b>	Whether to copy header, source, or object files, which are required to generate replacement

Parameter	Specify
	code, to the build folder before code generation. If you specify files with <b>Additional header files/include paths</b> or <b>Additional source files/ paths</b> and you copy files, the compiler and utilities such as packNGo might find duplicate instances of files.

- 6 Click **Apply**.
- 7 Select the **Mapping Information** tab. Scroll to the bottom of that table and click **Validate entry**. The tool validates the changes that you made to the entry.
- 8 Save the table that includes the entry that you just modified.

## Specify Build Information Programmatically

The programming interface for specifying build information for a code replacement entry is ideal for:

- Modifying entries created with the Code Replacement Tool.
- Replicating and then modifying similar entries and tables.

The basic workflow for specifying build information programmatically is:

- 1 Identify or create the code replacement entry that you want to specify the build information.
- 2 Determine what information to specify.
- 3 Specify your build information.

Specify	Action
Implementation header file	<p>Use one of the following:</p> <ul style="list-style-type: none"> <li>• Set properties <code>ImplementationHeaderFile</code> and <code>ImplementationHeaderPath</code> in a call to <code>setTf1CFunctionEntryParameters</code>, <code>setTf1COperationEntryParameters</code>, or <code>setTf1CSemaphoreEntryParameters</code>. For example:</li> </ul> <pre>setTf1CFunctionEntryParameters(hEnt, ...     'ImplementationHeaderFile', 'sin_dbl.h', ...</pre>

Specify	Action
	<pre data-bbox="501 296 1184 383">'ImplementationHeaderPath', 'D:/lib/headerFiles' 'Key', 'sin', ... 'ImplementationName', 'sin_dbl');</pre> <ul data-bbox="402 395 1233 487" style="list-style-type: none"> <li>• Set argument <code>headerFile</code> in a call to <code>registerCFunctionEntry</code>, <code>registerCPPFunctionEntry</code>, or <code>registerCPromotableMacroEntry</code></li> </ul>
Implementation source file	<p data-bbox="397 505 966 661">Set properties <code>ImplementationSourceFile</code> and <code>ImplementationSourcePath</code> in a call to <code>setTf1CFunctionEntryParameters</code>, <code>setTf1COperationEntryParameters</code>, or <code>setTf1CSemaphoreEntryParameters</code>. For example:</p> <pre data-bbox="397 690 1144 835">setTf1CFunctionEntryParameters(hEnt, ... 'ImplementationHeaderFile', 'sin_dbl.c', ... 'ImplementationHeaderPath', 'D:/lib/sourceFiles' 'Key', 'sin', ... 'ImplementationName', 'sin_dbl');</pre>
Additional header files/include paths	<p data-bbox="397 847 1273 939">For each file, specify the file name and path in calls to the functions <code>addAdditionalHeaderFile</code> and <code>addAdditionalIncludePath</code>. For example:</p> <pre data-bbox="397 968 1173 1142">libdir = fullfile('\$MATLAB_ROOT','..', '..', 'lib');  hEnt = RTW.Tf1CFunctionEntry;  addAdditionalHeaderFile(hEnt, 'common.h'); addAdditionalIncludePath(hEnt, fullfile(libdir, 'include'));  These functions add -I to the compile line in the generated makefile.</pre>

Specify	Action
Additional source files/paths	<p>For each file, specify the file name and path in calls to the functions <code>addAdditionalSourceFile</code> and <code>addAdditionalSourcePath</code>. For example:</p> <pre>libdir = fullfile('\$<b>MATLAB_ROOT</b>','..', '..', 'lib');  hEnt = RTW.Tf1CFunctionEntry;  addAdditionalSourceFile(hEnt, 'common.c'); addAdditionalSourcePath(hEnt, fullfile(libdir, 'src'));</pre> <p>These functions add <code>-I</code> to the compile line in the generated makefile.</p>
Additional object files/paths	<p>For each file, specify the file name and path in calls to the functions <code>addAdditionalLinkObj</code> and <code>addAdditionalLinkObjPath</code>. For example:</p> <pre>libdir = fullfile('\$<b>MATLAB_ROOT</b>','..', '..', 'lib');  hEnt = RTW.Tf1CFunctionEntry;  addAdditionalLinkObj(hEnt, 'sin.o'); addAdditionalLinkObjPath(hEnt, fullfile(libdir, 'bin'));</pre>
Compile flags	<p>Set the entry property <code>AdditionalCompileFlags</code> to a cell array of character vectors representing the required compile flags. For example:</p> <pre>hEnt = RTW.Tf1CFunctionEntry;  hEnt.AdditionalCompileFlags = {'-Zi -Wall', '-O3'};</pre>
Link flags	<p>Set the entry property <code>AdditionalLinkFlags</code> to a cell array of character vectors representing the required link flags. For example:</p> <pre>hEnt = RTW.Tf1CFunctionEntry;  hEnt.AdditionalCompileFlags = {'-MD -Gy', '-T'};</pre>

Specify	Action
Whether to copy header, source, or object files, which are required to generate replacement code, to the build folder before code generation	<p>Use one of the following:</p> <ul style="list-style-type: none"> <li>Set property <code>GenCallback</code> to <code>'RTW.copyFileToBuildDir'</code> in a call to <code>setTf1CFunctionEntryParameters</code>, <code>setTf1COperationEntryParameters</code>, or <code>setTf1CSemaphoreEntryParameters</code>. For example: <pre>setTf1CFunctionEntryParameters(hEnt, ...     'ImplementationHeaderFile', 'sin_dbl.h', ...     'ImplementationHeaderPath', 'D:/lib/headerFiles'     'Key', 'sin', ...     'ImplementationName', 'sin_dbl'     'GenCallback', 'RTW.copyFileToBuildDir');</pre> </li> <li>Set argument <code>genCallback</code> in a call to <code>registerCFunctionEntry</code>, <code>registerCPPFunctionEntry</code>, or <code>registerCPromotableMacroEntry</code> to <code>'RTW.copyFileToBuildDir'</code>.</li> </ul> <p>If a match occurs for a table entry, a call to the function <code>RTW.copyFileToBuildDir</code> copies required files to the build folder.</p> <p>If you specify additional header files/include paths or additional source files/paths and you copy files, the compiler and utilities such as <code>packNGO</code> might find duplicate instances of files.</p>

#### 4 Save the table that includes the entry that you added or modified.

The following example defines a table entry for an optimized multiplication function that takes signed 32-bit integers and returns a signed 32-bit integer, taking saturation into account. Multiplications in the generated code are replaced with calls to the optimized function. The optimized function does not reside in the build folder. For the code generator to access the files, copy them into the build folder to be compiled and linked into the application.

The table entry specifies the source and header file names and paths. To request the copy operation, the table entry sets the `genCallback` property to `'RTW.copyFileToBuildDir'` in the call to the `setTf1COperationEntryParameters` function. In this example, the header file `s32_mul.h` contains an inlined function that invokes assembly functions contained in `s32_mul.s`. If a match occurs for the table

entry, the function `RTW.copyFileToBuildDir` copies the specified source and header files to the build folder for use during the remainder of the build process.

```
function hTable = make_my_crl_table

hTable = RTW.Tf1Table;

op_entry = RTW.Tf1COperationEntry;
setTf1COperationEntryParameters(op_entry, ...
 'Key', 'RTW_OP_MUL', ...
 'Priority', 100, ...
 'SaturationMode', 'RTW_SATURATE_ON_OVERFLOW', ...
 'RoundingModes', {'RTW_ROUND_UNSPECIFIED'}, ...
 'ImplementationName', 's32_mul_s32_sat', ...
 'ImplementationHeaderFile', 's32_mul.h', ...
 'ImplementationSourceFile', 's32_mul.s', ...
 'ImplementationHeaderPath', {fullfile('${MATLAB_ROOT}','crl')}, ...
 'ImplementationSourcePath', {fullfile('${MATLAB_ROOT}','crl')}, ...
 'GenCallback', 'RTW.copyFileToBuildDir');
.
.
.
addEntry(hTable, op_entry);
```

The following example uses the functions `addAdditionalHeaderFile`, `addAdditionalIncludePath`, `addAdditionalSourceFile`, `addAdditionalSourcePath`, `addAdditionalLinkObj`, and `addAdditionalLinkObjPath` in addition to the code generation callback function `RTW.copyFileToBuildDir`.

```
hTable = RTW.Tf1Table;

% Path to external source, header, and object files
libdir = fullfile('${MATLAB_ROOT}','..', '..', 'lib');

op_entry = RTW.Tf1COperationEntry;
setTf1COperationEntryParameters(op_entry, ...
 'Key', 'RTW_OP_ADD', ...
 'Priority', 90, ...
 'SaturationMode', 'RTW_SATURATE_UNSPECIFIED', ...
 'RoundingModes', {'RTW_ROUND_UNSPECIFIED'}, ...
 'ImplementationName', 's32_add_s32_s32', ...
 'ImplementationHeaderFile', 's32_add_s32_s32.h', ...
 'ImplementationSourceFile', 's32_add_s32_s32.c'...
 'GenCallback', 'RTW.copyFileToBuildDir');

addAdditionalHeaderFile(op_entry, 'all_additions.h');
addAdditionalIncludePath(op_entry, fullfile(libdir, 'include'));
addAdditionalSourceFile(op_entry, 'all_additions.c');
addAdditionalSourcePath(op_entry, fullfile(libdir, 'src'));
addAdditionalLinkObj(op_entry, 'addition.o');
addAdditionalLinkObjPath(op_entry, fullfile(libdir, 'bin'));
.
```

```
.
.br/>addEntry(hTable, op_entry);
```

Next, include your code replacement table in a code replacement library and register the library with the code generator.

## **More About**

- “Code You Can Replace From Simulink Models” on page 51-7
- “Define Code Replacement Mappings” on page 51-42
- “Register Code Replacement Mappings” on page 51-68
- “Develop a Code Replacement Library” on page 51-27
- “What Is Code Replacement Customization?” on page 51-3

## Register Code Replacement Mappings

After you define code replacement entries and specify build information in a code replacement table, you can include the table in a code replacement library that you register with the code generator. When registered, a library appears in the list of available code replacement libraries that you can choose from when configuring the code generator.

Register a code replacement table as a code replacement library:

- Interactively, by using the Code Replacement Tool
- Programmatically, by using a MATLAB programming interface

### Choose an Approach for Creating the Registration File

The following table lists situations to help you decide when to use an interactive or programmatic approach to creating a registration file:

If...	Then...
Registering a code replacement table for the first time	Use the Code Replacement Tool.
You used the Code Replacement Tool to create the table	Use the Code Replacement Tool to quickly register the table.
Rapid prototyping code replacement	Use the Code Replacement Tool to quickly generate, register, and test entries.
Creating registration file to use as a template or starting point for defining similar registration files	Use the Code Replacement Tool to generate code that you can copy and modify.
Modifying existing registration files	Use the MATLAB Editor to update the registration file.
Defining multiple code replacement libraries in one registration file	Use the MATLAB Editor to create a new or extend an existing registration file.
Defining code replacement library hierarchy in a registration file	Use the MATLAB Editor to create a new or extend an existing registration file.

## Create Registration File Interactively with the Code Replacement Tool

The Code Replacement tool provides a quick, easy way for you to create a registration file for a code replacement table. It is ideal for getting started, rapid prototyping, and generating a registration file that you want to use as a starting point for similar registrations.

- 1 After you validate and save a code replacement table, select **File > Generate registration file** to open the **Generate registration file** dialog box.

- 2 Enter the registration information. Minimally, specify:

For...	Specify...
<b>Registry name</b>	Text naming the code replacement library. For example, <code>Sin Function Example</code> .
<b>Table list</b>	Text naming one or more code replacement tables to include in the library. Specify each table as one of the following: <ul style="list-style-type: none"> <li>• Name of a table file on the MATLAB search path</li> <li>• Absolute path to a table file</li> <li>• Path to a table file relative to <code>\$(MATLAB_ROOT)</code></li> </ul>

For...	Specify...
	<p>You can specify multiple tables. If you do, separate the table specifications with a comma. For example:</p> <pre>crl_table_sinfcn, c:/work_crl/crl_table_muldiv</pre> <p>See “Registration Files That Define Multiple Code Replacement Libraries” on page 52-61 for examples of each type of table specification.</p>

Optionally, you can specify:

For...	Specify...
<b>Description</b>	Text that describes the purpose and content of the library.
<b>Target HW device</b>	Text naming one or more hardware devices the code replacement library supports. Separate names with a comma. To support all device types, enter an asterisk (*). For example, TI C28x, TI C62x.
<b>Base CRL</b>	Text naming a code replacement library that you want to serve as a base library for the library you are registering. Use this field to specify library hierarchies. For example, you can specify a general TI device library as the base library for a more specific TI C28x device library.
<b>Generate data alignment specification</b>	Flag that enables data alignment specification.

## Create Registration File Programmatically

The programming interface for creating a registration file for a code replacement table is ideal for:

- Modifying registration files created with the Code Replacement Tool
- Replicating and modifying similar registration files
- Defining multiple code replacement libraries in one registration file

The basic workflow for creating a registration file programmatically consists of the following steps:

- 1 Define an `rtwTargetInfo` function. The code generator recognizes this function as a customization file. The function definition must include at least the following content:

```
function rtwTargetInfo(cm)

cm.registerTargetInfo(@loc_register_crl);

function this = loc_register_crl

this(1) = RTW.Tf1Registry;
this(1).Name = 'crl-name';
this(1).TableList = {'table',...};
```

For...	Replace...
<code>this(1).Name = 'crl-name';</code>	<code>crl-name</code> with text naming the code replacement library. For example, <code>Sin Function Example</code> .
<code>this(1).TableList = {'table',...};</code>	<p><code>table</code> with text that identifies the code replacement table that contains your code replacement entries. Specify a table as one of the following:</p> <ul style="list-style-type: none"> <li>• Name of a table file on the MATLAB search path</li> <li>• Absolute path to a table file</li> <li>• Path to a table file relative to <code>\$(MATLAB_ROOT)</code></li> </ul> <p>You can specify multiple tables. If you do, separate the table specifications with commas.</p>

Optionally, you can specify:

For...	Replace...
<code>this(1).Description = 'text'</code>	<i>text</i> with text that describes the purpose and content of the library.
<code>this(1).TargetHWDeviceType = {'device-type',...}</code>	<i>device-type</i> with text that names a hardware device the code replacement library supports. You can specify multiple device types. Separate device types with a comma. For example, TI C28x, TI C62x. To support all device types, enter an asterisk (*).
<code>this(1).BaseTfl = 'base-lib'</code>	<i>base-lib</i> with text that names a code replacement library that you want to serve as a base library for the library you are registering. Use this field to specify library hierarchies. For example, you can specify a general TI device library as the base library for a TI C28x device library.  See “Registration Files That Define Code Replacement Library Hierarchies” on page 52-61 for an example.

For example:

```
function rtwTargetInfo(cm)

cm.registerTargetInfo(@loc_register_crl);

function this = loc_register_crl

this(1) = RTW.TflRegistry;
this(1).Name = 'Sin Function Example';
this(1).TableList = {'crl_table_sinfcn'};
this(1).TargetHWDeviceType = {'*'};
this(1).Description = 'Example - sin function replacement';
```

- 2 Save the file with the name `rtwTargetInfo.m`.
- 3 Place the file on the MATLAB path. When the file is on the MATLAB path, the code generator reads the file after starting and applies the customizations during the current MATLAB session.

## Register a Code Replacement Library

Before you can use the code replacement tables defined in a registration file, refresh Simulink customizations within the current MATLAB session. To initiate a refresh, enter the following command:

```
sl_refresh_customizations
```

## Register a Library that Includes Multiple Code Replacement Tables

Use the programming interface to create a registration file that defines a code replacement library that includes multiple code replacement tables. The following example defines a library that includes multiple tables. The `TableList` fields specify tables that reside at different locations. The tables reside on the MATLAB search path or at locations specified with a path.

```
function rtwTargetInfo(cm)

cm.registerTargetInfo(@locCrlRegFcn);

function thisCrl = locCrlRegFcn

% Register a code replacement library for use with model: rtwdemo_crladdsub
thisCrl(1) = RTW.TflRegistry;
thisCrl(1).Name = 'Addition & Subtraction Examples';
thisCrl(1).Description = 'Example of addition/subtraction op replacement';
thisCrl(1).TableList = {'crl_table_addsub'};
thisCrl(1).TargetHWDDeviceType = {'*'};

% Register a code replacement library for use with model: rtwdemo_crlmuldiv
thisCrl(2) = RTW.TflRegistry;
thisCrl(2).Name = 'Multiplication & Division Examples';
thisCrl(2).Description = 'Example of mult/div op repl for built-in integers';
thisCrl(2).TableList = {'c:/work_crl/crl_table_muldiv'};
thisCrl(2).TargetHWDDeviceType = {'*'};

% Register a code replacement library for use with model: rtwdemo_crlfixpt
thisCrl(3) = RTW.TflRegistry;
thisCrl(3).Name = 'Fixed-Point Examples';
thisCrl(3).Description = 'Example of fixed-point operator replacement';
thisCrl(3).TableList = {fullfile('$MATLAB_ROOT'), ...
 'toolbox', 'rtw', 'rtwdemos', 'crl_demo', 'crl_table_fixpt'};
thisCrl(3).TargetHWDDeviceType = {'*'};
```

## Registration Files That Define Code Replacement Library Hierarchies

Using the programming interface, you can organize multiple code replacement libraries in a hierarchy. The following example shows a registration file that defines four code

replacement tables organized in a hierarchy of four code replacement libraries. The tables include entries that increase in specificity: common entries, entries for TI devices, entries for TI C6xx devices, and entries specific to the TI C67x device.

```
function rtwTargetInfo(cm)

cm.registerTargetInfo(@locCr1RegFcn);

function thisCr1 = locCr1RegFcn

% Register a code replacement library that includes common entries
thisCr1(1) = RTW.TflRegistry;
thisCr1(1).Name = 'Common Replacements';
thisCr1(1).Description = 'Common code replacement entries shared by other libraries';
thisCr1(1).TableList = {'cr1_table_general'};
thisCr1(1).TargetHWDeviceType = {'*'};

% Register a code replacement library for TI devices
thisCr1(2) = RTW.TflRegistry;
thisCr1(2).Name = 'TI Device Replacements';
thisCr1(2).Description = 'Code replacement entries shared across TI devices';
thisCr1(2).TableList = {'cr1_table_TI_devices'};
thisCr1(2).TargetHWDeviceType = {'TI C28x', 'TI C55x', 'TI C62x', 'TI C64x', 'TI 67x'};
thisCr1(1).BaseTfl = 'Common Replacements'

% Register a code replacement library for TI c6xx devices
thisCr1(3) = RTW.TflRegistry;
thisCr1(3).Name = 'TI c6xx Device Replacements';
thisCr1(3).Description = 'Code replacement entries shared across TI C6xx devices';
thisCr1(3).TableList = {'cr1_table_TIC6xx_devices'};
thisCr1(3).TargetHWDeviceType = {'TI C62x', 'TI C64x', 'TI 67x'};

% Register a code replacement library for the TI c67x device
thisCr1(3) = RTW.TflRegistry;
thisCr1(3).Name = 'TI c67x Device Replacements';
thisCr1(3).Description = 'Code replacement entries for the TI C67x device';
thisCr1(3).TableList = {'cr1_table_TIC67x_device'};
thisCr1(3).TargetHWDeviceType = {'TI 67x'};
```

After registering your code replacement mappings, verify that code replacements occur.

## More About

- “Troubleshoot Code Replacement Library Registration” on page 51-75
- “Specify Build Information for Replacement Code” on page 51-59
- “Verify Code Replacements” on page 51-76
- “Develop a Code Replacement Library” on page 51-27
- “What Is Code Replacement Customization?” on page 51-3

## Troubleshoot Code Replacement Library Registration

If a code replacement library is not listed as a configuration option or does not appear in the Code Replacement Viewer:

- Refresh the library registration information within the current MATLAB session (`RTW.TargetRegistry.getInstance('reset')`; or for the Simulink environment, `sl_refresh_customizations`).
- See whether the registration file, `rtwTargetInfo.m`, contains an error.

### More About

- “Register Code Replacement Mappings” on page 51-68

## Verify Code Replacements

After you create or modify and register a code replacement table, use the following techniques to examine and verify the table and its entries.

- Invoke the table definition file at the command prompt.
- Use the Code Replacement Viewer to examine libraries, tables, and entries.
- Trace code replacements from the source where you applied the code replacement library.
- Examine code replacement hits and misses logged during code generation.

### Code Replacement Hits and Misses

The code generator logs code replacement table entries for which it finds and does not find matches in the hit cache and miss cache, respectively. When a code replacement entry match fails and code is not replaced, the code generator logs the call site object (CSO) for the miss in the miss cache. When an entry match succeeds, the code generator logs the matched entry in the hit cache.

The code generator overwrites the hit and miss cache data each time it produces code. The cache data reflects hits and misses for only the last application component (MATLAB code or Simulink model) for which you generate code.

You can use the Code Replacement Viewer to review trace information based on logged hit and miss trace data. The hit cache provides trace information that helps to verify code replacements.

The miss cache and related miss data collected and stored in code replacement tables provide trace information for misses. Use this information for misses to troubleshoot expected code replacements that do not occur. Trace information for a miss:

- Identifies the call site object.
- Provides a link to the relevant source location for the miss.
- Includes information about the reason for the miss.

### Validate Table Definition File

After you create or modify a code replacement table definition file, validate it. At the command prompt, specify the name of the table in a call to the `isvalid` function. For example:

```
invalid(crl_table_sinfcn)
```

```
ans =
```

```
1
```

MATLAB displays errors that occur. In the following example, MATLAB detects a typo in a data type name.

```
invalid(crl_table_sinfcn)
```

```
??? RTW_CORE:tf1:Tf1Table: Unsupported data type, 'dooble'.
```

```
Error in ==> crl_table_sinfcn at 7
```

```
hTable.registerCFunctionEntry(100, 1, 'sin', 'dooble', 'sin_dbl', ...
```

## Review Library Content

After you create or modify a code replacement library, use the Code Replacement Viewer to review and verify the list of tables in the library and the entries in each table.

- 1 Open the viewer to display the contents of your library. At the command prompt, enter the following command:

```
crviewer('library')
```

For example:

```
crviewer('Addition & Subtraction Examples')
```

- 2 Review the list of tables in the left pane. Are tables missing? Are the tables listed in the correct relative order? By default, the viewer displays tables in search order.
- 3 In the left pane, click each table and review the list of entries in the center pane. Are entries missing? Does the list include extraneous or unexpected entries?

## Review Table Content

After you create or modify a code replacement table, use the Code Replacement Viewer to review and verify table entries.

- 1 Open the viewer to display the contents of your table. At the command prompt, enter the following command. *table* is a MATLAB file that defines code replacement tables. The file must be in the current folder or on the MATLAB path.

```
crviewer(table)
```

For example:

```
crviewer(crl_table_addsub)
```

- 2 Review the list of entries in the center pane. Are entries missing? Does the list include extraneous or unexpected entries? By default, the viewer displays entries in search order.
- 3 In the center pane, click each entry and verify the entry information in the right pane.

The screenshot shows the Code Replacement Viewer interface. On the left, the Code Replacement Library contains a folder named 'Addition & Subtraction Examples' with a sub-entry 'cr1\_table\_addsub'. The main pane displays a list of replacements with columns for Name and Implementation. The replacement 'RTW\_OP\_ADD u16\_add\_u16\_u16' is selected. The right pane shows the details for this replacement, including a summary of key information and conceptual/implementation argument tables.

Name	Implementation
RTW_OP_ADD	u8_add_u8_u8
RTW_OP_ADD	u16_add_u16_u16
RTW_OP_ADD	s16_add_s16_s16
RTW_OP_ADD	s16_add_s16_s16
RTW_OP_ADD	s16_add_s16_s16_ml
RTW_OP_MINUS	s16_sub_s16_s16
RTW_OP_MINUS	s8_sub_s8_s8
RTW_OP_MINUS	s16_sub_s16_s16_ml
RTW_OP_MINUS	s32_sub_s32_s32
RTW_OP_MINUS	u32_sub_u32_u32
RTW_OP_MINUS	s8_cboSub_s16_s16
RTW_OP_MINUS	s8_caoSub_s16_s16

**RTW\_OP\_ADD**

General Information

Summary

Description:

Key: RTW\_OP\_ADD with

Implementation: u16\_add\_u16\_u16

Implementation type: FCN\_IMPL\_FUNCT

Saturation mode: RTW\_WRAP\_ON\_C

Rounding mode: RTW\_ROUND\_CEIL

EntryInfo: RTW\_CAST\_BEFOI

GenCallback file:

Implementation header: u16\_add\_u16\_u16.

Implementation source: u16\_add\_u16\_u16.

Priority: 90

Total usage count: 0

Entry class: RTW.TfICOperator

Entry argument(s)

**Conceptual argument(s):**

Name	I/O type	Data type
y1	RTW_IO_OUTPUT	uint16
u1	RTW_IO_INPUT	uint16
u2	RTW_IO_INPUT	uint16

**Implementation:**

Name	I/O type	Data type	Align
y1	RTW_IO_OUTPUT	uint16	none
u1	RTW_IO_INPUT	uint16	none
u2	RTW_IO_INPUT	uint16	none

Help

- Argument order is correct.

- Conceptual argument names match code generator naming conventions.
- Implementation argument names are correct.
- Algorithm properties (for example, saturation and rounding mode) are set correctly.
- Header or source file specification is not missing.
- I/O types are correct.
- Relative priority of entries is correct.

## Review Code Replacements

After you review the content of your code replacement library and tables, generate code and a code generation report. Verify that the code generator replaces code as you expect.

The Code Replacements Report details the code replacement library functions that the code generator uses for code replacements. The report provides a mapping between each replacement instance and the model element that triggered the replacement.

The following example illustrates two complementary approaches to reviewing code replacements:

- Check the Code Replacements Report section of the code generation report for expected replacements.
- Trace code replacements.

For models that consist of model hierarchies, repeat the following procedure for each model in the hierarchy. Generate code for and review the trace information of each referenced model separately. Logged cache hit and miss information captured in the Code Replacement Viewer is valid for the last model for which code was generated. As you generate code for each model in the hierarchy, the code generator overwrites logged information.

- 1 Open the model where you anticipate that a function or operator replacement occurs. This example uses the model `rtwdemo_crladdsub`.
- 2 Configure the code generator to use your code replacement library. For this example, set the library to **Addition & Subtraction Examples**.
- 3 Configure the code generation report to include the Code Replacements Report. On the **Code Generation > Report** pane, select **Create code generation report** and

**Open report automatically.** On the **All Parameters** tab, select **Model-to-code** and **Summarize which blocks triggered code replacements**.

- 4 Configure comments for the generated code. On the **Code Generation > Comments** pane, select:
  - **Include comments**
  - Either or both of **Simulink block / Stateflow object comments** and **Simulink block descriptions**

In the **Code Replacements Report**, these options include Simulink block information.

- 5 Configure the code generator to generate only code. Before you build an executable file, review your code replacements in the generated code.
- 6 Generate code and a report.
- 7 Open the **Code Replacements Report** section of the code generation report.

The report lists the replacement functions that the code generator used. It provides a mapping between each replacement instance and the Simulink block that triggered the replacement.

Review the report:

- Check whether expected function and operator code replacements occurred.
  - In the replacements sections, click each block link to see the source that triggered the reported code replacement.
- 8** In the Simulink model window, use model-to-code highlighting to trace code replacements. Identify and right-click a block where you expected code replacement to occur. Select **C/C++ Code > Navigate to C/C++ Code**. The code generation report appears with the corresponding replacement code highlighted. In the example model `rtwdemo_crladdsub`, right-click the `Add8` block and select **C/C++ Code > Navigate to C/C++ Code**.

```

24 /* Real-time model */
25 RT_MODEL rtM;
26 RT_MODEL *const rtM = &rtM;
27
28 /* Model step function */
29 void rtwdemo_crladdsub_step(void)
30 {
31 /* Output: '<Root>/Out1' incorporates:
32 * Inport: '<Root>/In1'
33 * Inport: '<Root>/In2'
34 * Sum: '<Root>/Add8'
35 */
36 rtY.Out1 = u8_add_u8_u8(rtU.In1, rtU.In2);
37
38 /* Output: '<Root>/Out2' incorporates:
39 * Inport: '<Root>/In3'
40 * Inport: '<Root>/In4'
41 * Sum: '<Root>/Add16'
42 */
43 rtY.Out2 = u16_add_u16_u16(rtU.In3, rtU.In4);

```

Inspect the generated code to see if the function or operator replacement occurred as you expected.

If a function or operator is not replaced as expected, the code generator used a higher-priority (lower-priority value) match or did not find a match.

To analyze and troubleshoot code replacement misses, use the trace information that the Code Replacement Viewer provides. See “Troubleshoot Code Replacement Misses” on page 51-86.

Next, deploy your code replacement library for others to use.

## **More About**

- “Troubleshoot Code Replacement Misses” on page 51-86
- “Register Code Replacement Mappings” on page 51-68
- “Deploy Code Replacement Library” on page 51-93
- “What Is Code Replacement Customization?” on page 51-3

## Troubleshoot Code Replacement Misses

Use miss reason messages that appear in the Code Replacement Viewer to analyze and correct code replacement misses.

### Miss Reason Messages

The Code Replacement Viewer displays miss reason messages in trace information for code replacement misses. A legend listing each message that appears in the miss report precedes the report details. A message consists of:

- Numeric identifier, which identifies the message in the report details.
- Message text, which in some cases includes placeholders for names of arguments, call site object values, table entry values, and property names.

For example:

1. Mismatched data types (argument name, CS0 value, table entry value)

The parenthetical information represents placeholders for actual values that appear in the report details.

In the **Miss Source Locations** table that lists the miss details, the **Reason** column includes:

- The message identifier, as listed in the legend.
- The placeholder values for that instance of the miss reason message.

The following **Reason** details indicate a data type mismatch because the call site object specifies data type `int8` for arguments `y1`, `u1`, and `u2`, while the code replacement table entry specifies `uint32`.

1. `y1, int8, uint32`  
`u1, int8, uint32`  
`u2, int8, uint32`

Depending on your situation and the reported miss reason, troubleshoot reported misses by looking for instances of the following:

- A typo in the code replacement table entry definition or a source parameter setting.
- Information missing from the code replacement table entry or a source parameter setting.

- Invalid or incorrect information in the code replacement table entry definition or a source parameter setting.
- Arguments incorrectly ordered in the code replacement table entry definition or the source being replaced with replacement code.
- Failed algorithm classification for an addition or subtraction operation due to:
  - An ideal accumulator not being calculated because the type of an input argument is not fixed-point or the slope adjustment factors of the input arguments are not equal.
  - Input or output casts with a floating-point cast type.
  - Input or output casts with cast types that have different slope adjustment factors or biases.
  - Output casts not being convertible to a single output cast.
  - Input casts resulting in loss of bits.

## Analyze and Correct Code Replacement Misses

The following example shows how to use Code Replacement Viewer trace information to troubleshoot code replacement misses. You must have already reviewed and tested code replacements for your model.

- 1 Review the code generated for a model element, looking for expected code replacements. For this example, examine the code generated for block Sub32 in model `rtwdemo_cr1addsub`. Right-click the block and select **C/C++ Code > Navigate to C/C++ Code**.

The Code Generation Report opens to the location of the generated code for that block.

```

63 /* Output: '<Root>/Out5' incorporates:
64 * Inport: '<Root>/In10'
65 * Inport: '<Root>/In9'
66 * Sum: '<Root>/Sub32'
67 */
68 rtY.Out5 = s32_sub_s32_s32(rtU.In9, rtU.In10);

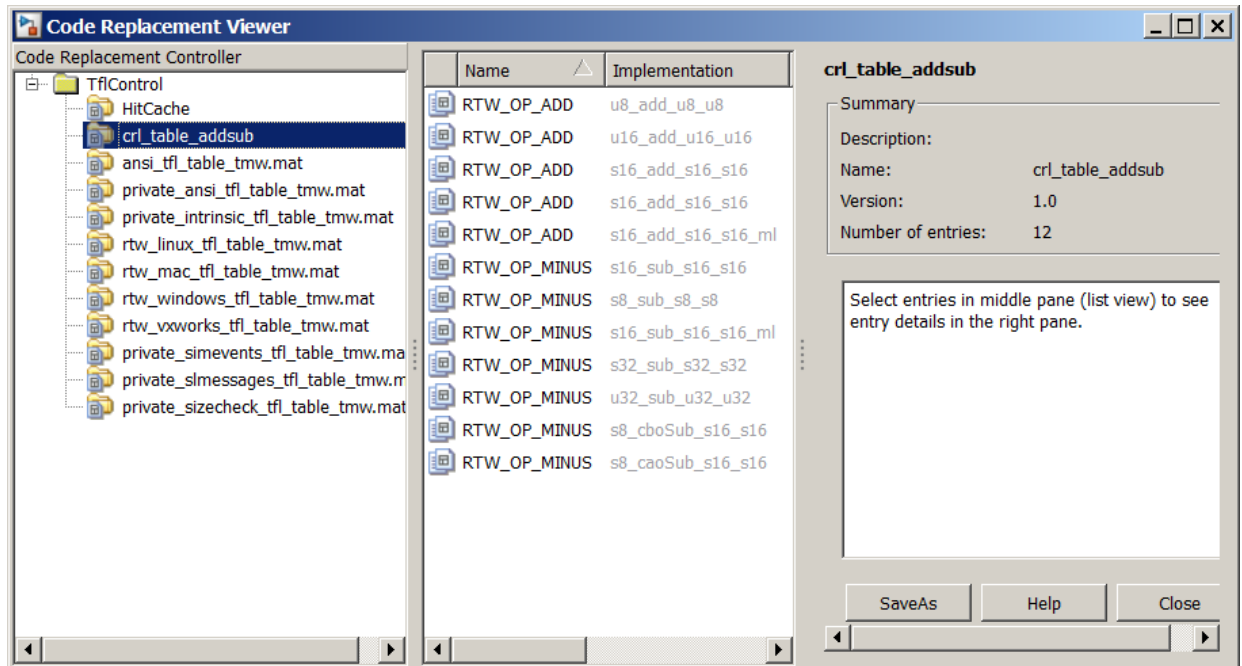

```

The code generator replaced code, but the replacement was for the signed version of the 32-bit subtraction operation. You expected an unsigned operation.

- 2 Regenerate or reopen the Code Replacements Report for your model. If you already generated the code generation report that includes the Code Replacements Report

for model `rtwdemo_crladdsub`, open the file `rtwdemo_crladdsub_ert_rtw/html/rtwdemo_crladdsub_codegen_rpt.html`. For information on how to regenerate the report, see “Review Code Replacements” on page 51-82.

- 3 Click the link to open the Code Replacement Viewer.
- 4 In the viewer left pane, select your code replacement table. The following display shows entries for code replacement table `crl_table_addsub`.

- 5 In the middle pane, select table entry `RTW_OP_MINUS` with implementation function `u32_sub_u32_u32`.
- 6 In the right pane, select the **Trace Information** tab.

The **Trace Information** is a table that lists the following information for each miss:

- Call site object preview. The call site object is the conceptual representation of a subtraction operator. The code generator uses this object to query the code replacement library for a match.

- A link to the source location in the model for which the code generator considered replacing code.
- The reasons that the miss occurred. For the list of reasons that misses occur, see “Miss Reason Messages” on page 51-86.

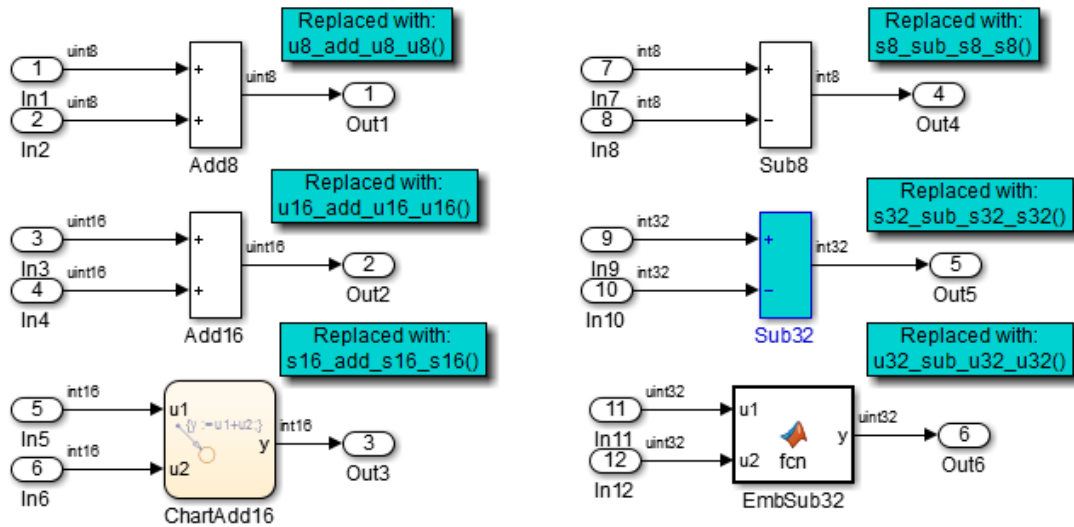

For this example, the report shows misses for two blocks: Sub32 and Sub8.

- 7** Find that source in the trace information. Depending on your situation and the reported miss reason, consider looking for a condition such as a typo in the code replacement table entry definition or in a source parameter setting. “Miss Reason Messages” on page 51-86 lists conditions to consider.

For this example, determine why code for the Sub32 block was not replaced with code for an unsigned 32-bit subtraction operation. The miss reason for the Sub32 block indicates a data type mismatch. The data type in the call site object for the three arguments is a signed 32-bit integer. The code replacement entry specifies an unsigned 32-bit integer.

- 8** Correct the model or code replacement table entry. If the issue is in the model, use the source location link in the trace information to find the model element to correct. For this example, you expected an unsigned subtraction operation for the Sub32 block. Click the link in the trace report for the Sub32 block.

The model opens with the Sub32 block highlighted.

Change the data type setting for the two input signals and the output signal for the Sub32 block to uint32.

- 9 Regenerate code. Use the Code Replacement Viewer trace information to verify that your model or code replacement table entry corrects the code replacement issue. In the following display, the trace information shows a hit for block Sub32.

## More About

- “Verify Code Replacements” on page 51-76

## Deploy Code Replacement Library

After you verify code replacements and are ready to package and deploy a code replacement library for others to use:

- 1** Move your code replacement table files to an area that is on the MATLAB search path and that is accessible to and shared by other users.
- 2** Move the `rtwTargetInfo.m` registration file, to an area that is on the MATLAB search path and that is accessible to and shared by other users. If you are deploying a library to a folder in a development environment that already contains a `rtwTargetInfo.m` file, copy the registration code from your code replacement library version of `rtwTargetInfo.m` and paste it into the shared version of that file.
- 3** Register the library customizations or restart MATLAB.
- 4** Verify that the libraries are available for configuring the code generator and that code replacements occur as expected.
- 5** Inform users that the libraries are available and provide direction on when and how to apply them.

### More About

## Math Function Code Replacement

This example shows how to define a code replacement mapping for a math function. The example defines a mapping for the `sin` function programmatically. Alternatively, you can use the Code Replacement Tool to define the same mapping.

- 1 Create a table definition file that contains a function definition. For example:

```
function hTable = crl_table_sinfcn2()
%CRL_TABLE_SINFCN2 - Define function entry for code replacement table.
```

- 2 Within the function body, create the table by calling the function `RTW.Tf1Table`.

```
hTable = RTW.Tf1Table;
```

- 3 Create an entry for the function mapping with a call to the `RTW.Tf1CFunctionEntry` function.

```
% Create entry for sin function replacement
fcn_entry = RTW.Tf1CFunctionEntry;
```

- 4 Set function entry parameters with a call to the `setTf1CFunctionEntryParameters` function.

```
setTf1CFunctionEntryParameters(fcn_entry, ...
 'Key', 'sin', ...
 'Priority', 30, ...
 'ImplementationName', 'mySin', ...
 'ImplementationHeaderFile', 'basicMath.h',...
 'ImplementationSourceFile', 'basicMath.c');
```

- 5 Create conceptual arguments `y1` and `u1`. There are multiple ways to set up the conceptual arguments. This example uses calls to the `createAndAddConceptualArg` function to create and add an argument with one function call.

```
createAndAddConceptualArg(fcn_entry, 'RTW.Tf1ArgNumeric', ...
 'Name', 'y1',...
 'IOType', 'RTW_IO_OUTPUT',...
 'DataTypeMode', 'double');
```

```
createAndAddConceptualArg(fcn_entry, 'RTW.Tf1ArgNumeric', ...
 'Name', 'u1', ...
 'IOType', 'RTW_IO_INPUT',...
 'DataTypeMode', 'double');
```

- 6 Copy the conceptual arguments to the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses a call to the `copyConceptualArgsToImplementation` function to create and add implementation arguments to the entry by copying matching conceptual arguments.

```
copyConceptualArgsToImplementation(fcn_entry);
```

- 7 Add the entry to a code replacement table with a call to the `addEntry` function.

```
addEntry(hTable, fcn_entry);
```

- 8 Save the table definition file. Use the name of the table definition function to name the file.

## Memory Function Code Replacement

This example shows how to define a code replacement mapping for a memory function. The example defines a mapping for the `memcpy` function programmatically. Alternatively, you can use the Code Replacement Tool to define the same mapping.

- 1 Create a table definition file that contains a function definition. For example:

```
function hTable = crl_table_memcpy()
```

- 2 Within the function body, create the table by calling the function `RTW.Tf1Table`.

```
hTable = RTW.Tf1Table;
```

- 3 Create an entry for the function mapping with a call to the `RTW.Tf1CFunctionEntry` function.

```
% Create entry for void* memcpy(void*, void*, size_t)
fcn_entry = RTW.Tf1CFunctionEntry;
```

- 4 Set function entry parameters with a call to the `setTf1CFunctionEntryParameters` function.

```
% Set SideEffects to 'true' for function returning void to prevent it from
% being optimized away.
setTf1CFunctionEntryParameters(fcn_entry, ...
 'Key', 'memcpy', ...
 'Priority', 90, ...
 'ImplementationName', 'memcpy_int', ...
 'ImplementationHeaderFile', 'memcpy_int.h', ...
 'SideEffects', true);
```

- 5 Create conceptual arguments `y1`, `u1`, `u2`, and `u3`. There are multiple ways to set up the conceptual arguments. This example uses calls to the `getTf1ArgFromString` and `addConceptualArg` functions to create and add the arguments.

```
arg = getTf1ArgFromString(hTable, 'y1', 'void*');
arg.IOType = 'RTW_IO_OUTPUT';
addConceptualArg(fcn_entry, arg);
```

```
arg = getTf1ArgFromString(hTable, 'u1', 'void*');
addConceptualArg(fcn_entry, arg);
```

```
arg = getTf1ArgFromString(hTable, 'u2', 'void*');
addConceptualArg(fcn_entry, arg);
```

```
arg = getTf1ArgFromString(hTable, 'u3', 'size_t');
addConceptualArg(fcn_entry, arg);
```

- 6 Copy the conceptual arguments to the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses a call

to the `copyConceptualArgsToImplementation` function to create and add implementation arguments to the entry by copying matching conceptual arguments.

```
copyConceptualArgsToImplementation(fcn_entry);
```

- 7 Add the entry to a code replacement table with a call to the `addEntry` function.

```
addEntry(hTable, fcn_entry);
```

- 8 Save the table definition file. Use the name of the table definition function to name the file.

To test this example:

- 1 Register the code replacement mapping.
- 2 Create a model that uses the `memcpy` function for vector assignments. For example, use In, Out, and Mux blocks to create the following model. (Alternatively, open the example model `rtwdemo_crlmath` and copy the contents of `Subsystem1` to a new model.)

- 3 Select the diagram and use **Edit > Subsystem** to make it a subsystem.

- 4 Configure the subsystem with the following settings:
  - On the **Solver** pane, select a fixed-step solver.
  - On the **Optimization > Signals and Parameters** pane, select **Use memcpy for vector assignment** and set **Memcpy threshold (bytes)** to 64.
  - On the **Code Generation** pane, select an ERT-based system target file.
  - On the **Code Generation > Interface** pane, select the code replacement library that contains your memory function entry.

- 5 In the Model Explorer, configure the **Signal Attributes** for the In1, In2, and In3 source blocks. For each, set **Port dimensions** to [ 1 , 100], and set **Data type** to int32. Apply the changes. Save the model.
- 6 Generate code and a code generation report.
- 7 Review the code replacements.

- “Develop a Code Replacement Library” on page 51-27

## Nonfinite Function Code Replacement

This example shows how to define a code replacement mapping for nonfinite utility functions.

- 1 Create a table definition file that contains a function definition. For example:

```
function hTable = crl_table_nonfinite()
```

- 2 Within the function body, create the table by calling the function `RTW.Tf1Table`.

```
hTable = RTW.Tf1Table;
```

- 3 Create entries for the function mappings. To minimize the size of this function, the example uses a local function, `locAddFcnEnt`, to group lines of code repeated for each entry. A call to the `RTW.Tf1CFunctionEntry` function creates an entry for the collection of local function entry definitions.

```
%% Create entries for nonfinite utility functions
% locAddFcnEnt(hTable, key, implName, out, in1, hdr)

locAddFcnEnt(hTable, 'getNaN', 'getNaN', 'double', 'void', 'nonfin.h');
locAddFcnEnt(hTable, 'getNaN', 'getNaNF', 'single', 'void', 'nonfin.h');
locAddFcnEnt(hTable, 'getInf', 'getInf', 'double', 'void', 'nonfin.h');
locAddFcnEnt(hTable, 'getInf', 'getInfF', 'single', 'void', 'nonfin.h');
locAddFcnEnt(hTable, 'getMinusInf', 'getMinusInf', 'double', 'void', 'nonfin.h');
locAddFcnEnt(hTable, 'getMinusInf', 'getMinusInfF', 'single', 'void', 'nonfin.h');
```

```
%% Local Function
function locAddFcnEnt(hTable, key, implName, out, in1, hdr)
 if isempty(hTable)
 return;
 end
```

```
 fcn_entry = RTW.Tf1CFunctionEntry;
```

- 4 Set function entry parameters with a call to the `setTf1CFunctionEntryParameters` function.

```
 setTf1CFunctionEntryParameters(fcn_entry, ...
 'Key', key, ...
 'Priority', 90, ...
 'ImplementationName', implName, ...
 'ImplementationHeaderFile', hdr);
```

- 5 Create conceptual arguments `y1` and `u1`. There are multiple ways to set up the conceptual arguments. This example uses calls to the `getTf1ArgFromString` and `addConceptualArg` functions to create and add the arguments.

```
 arg = getTf1ArgFromString(hTable, 'y1', out);
 arg.IOType = 'RTW_IO_OUTPUT';
 addConceptualArg(fcn_entry, arg);
```

```
arg = getTf1ArgFromString(hTable, 'u1', in1);
addConceptualArg(fcn_entry, arg);
```

- 6 Copy the conceptual arguments to the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses a call to the `copyConceptualArgsToImplementation` function to create and add implementation arguments to the entry by copying matching conceptual arguments.

```
copyConceptualArgsToImplementation(fcn_entry);
```

- 7 Add the entry to a code replacement table with a call to the `addEntry` function.

```
addEntry(hTable, fcn_entry);
```

- 8 Save the table definition file. Use the name of the table definition function to name the file.

To test this example:

- 1 Register the code replacement mapping.
- 2 Create a model that uses a nonfinite function. For example, create a model that includes a Math Function block that is set to the `rem` function. For example:

- 3 Configure the model with the following settings:
  - On the **Solver** pane, select a fixed-step solver.
  - On the **Code Generation** pane, select an ERT-based system target file.
  - On the **Code Generation > Interface** pane, select the code replacement library that contains your memory function entry and select **Support: non-finite numbers**.
- 4 In the Model Explorer, configure the **Signal Attributes** for the In1 and Constant source blocks. For each source block, set **Data type** to `double`. Apply the changes. Save the model.
- 5 Generate code and a code generation report.
- 6 Review the code replacements.

## Semaphore and Mutex Function Replacement

You can create a code replacement table for a custom target that supports concurrent execution. Create table entries that specify custom implementations of semaphore or mutex operations. The table must have four semaphore entries, four mutex entries, or both, and include the table in a custom code replacement library. (The semaphore or mutex entries are mutually dependent. Provide them in complete sets of four.)

---

**Note:** A custom target that supports concurrent multitasking must set the target configuration parameter `ConcurrentExecutionCompliant`. For more information, see “Support Concurrent Execution of Multiple Tasks” in the Simulink Coder documentation.

---

If the build process generates semaphore or mutex function calls for data transfer between tasks during code generation for a multicore target environment, use a custom library. The library can specify code replacements for custom semaphore or mutex implementations that are optimal for your target environment. Using the Code Replacement Tool (`crtool`) or equivalent code replacement functions, you can:

- Configure code replacement table entries for custom semaphore or mutex functions. During system startup, execution of the code for data transfer between tasks, and system shutdown the generated code calls these functions.
- Configure DWork arguments that represent global data, which the semaphore or mutex functions access. A DWork pointer is passed to the model entry functions.

Generated mutex and semaphore code typically consists of these elements:

Code	Generated Code
Model initialization	Initialization function call that creates a mutex or semaphore function to control entry to a critical section of code.
Model step	<ul style="list-style-type: none"> <li>• Before code for a data transfer between tasks enters the critical section, mutex lock or semaphore wait function calls reserve the critical section of code.</li> <li>• After code for a data transfer between tasks finishes executing the critical section, mutex unlock or semaphore post function calls release the critical section of code.</li> </ul>

Code	Generated Code
Model termination	Optional destroy function call to delete the mutex or semaphore explicitly.

This example shows how to create code replacement table entries for a mutex replacement scenario. You configure a multicore target model for concurrent execution and for data transfer between tasks of differing rates, which Rate Transition blocks handle. In the generated code for the model, each Rate Transition block has a separate, unique mutex. Mutex lock and unlock operations within the Rate Transition block generated code share access to the same global data. They achieve this by using the unique mutex created for that Rate Transition block.

- 1 Open the Code Replacement Tool.
- 2 Create and open a new table.
- 3 Name the table `cr1_table_rt_mutex`.
- 4 Create an entry for a mutex initialization function replacement.
  - a Select **File** > **New entry** > **Semaphore entry** to open a new table entry for configuring a semaphore or mutex replacement.
  - b In the **Mapping Information** tab, use the **Function** parameter to select `Mutex Init`. Initial default values for the table entry appear. In the **Conceptual function** section, typically you can leave the argument settings at their defaults.
  - c In the **DWork attributes** section, the **Allocate DWork** option is selected. The dialog box provides a unique entry tag for the DWork argument `d1`.

DWork attributes

Allocate DWork

DWork argument

Entry tag (unique):

DWork arguments

Argument properties

Data type:   Pointer

On the **DWork attributes** pane, configure a DWork argument to the replacement function. The DWork argument supports sharing of a semaphore or mutex between:

- Code that creates the semaphore or mutex
- Code that requests and relinquishes access
- Code that deletes the semaphore or mutex

In this example, the DWork argument for the `Mutex Init` function defines a unique entry tag, `entry_25576`. That function also defines DWork arguments for `Mutex Lock`, `Mutex Unlock`, and `Mutex Destroy`, which reference the entry tag to share the DWork data.

The only data type supported for the DWork **Data type** parameter is `void*`.

- d** In the **Replacement function** section, enter a function name in the **Name** field. This example uses `myMutexCreate`. In the list of **Function arguments**, leave the DWork argument `d1` data type as `void**`.

Replacement function

Function prototype

Name:  C++ namespace:

Function returns void

Function arguments

y1(return arg)	↑
d1	↓

Argument properties

Data type:  I/O type:

Const  Pointer  Pointer-Pointer

Function signature preview

```
void myMutexCreate (void** d1);
```

The C function signature preview is:

```
void myMutexCreate (void** d1);
```

- e In the **Replacement function** section, select **Function modifies internal or global state**. This option instructs the code generator not to optimize away the implementation function described by this entry because it accesses global memory values. Click **Apply**. Optionally, you can click **Validate entry** to validate the information entered in the **Mapping Information** tab.

To create a sample table entry, configure the replacement function signature without the replacement function and its build information. If header and source files for these functions are available, select the **Build Information** table to specify them.

- f The `Mutex Init` table entry is complete. Optionally, you can save the table to a file, and inspect the MATLAB code created for the table definition so far.
- 5 Repeat the following sequence to create the table entries for the mutex lock, unlock, and destroy function replacements. Each table entry references the DWork unique tag entry, `entry_25576`, defined in the `Mutex Init` table entry.
- a Select **File > New entry > Semaphore entry**.
  - b In the **Mapping Information** tab, use the **Function** parameter to select `Mutex Lock`, `Mutex Unlock`, or `Mutex Destroy`. Initial default values for the table entry appear. In the **Conceptual function** section, typically you can leave the argument settings at their defaults.
  - c For a Rate Transition block mutex, the wait, post, and destroy functions operate on the DWork allocated at system startup by the mutex initialization function. In the **DWork attributes** section, verify that the **Allocate DWork** option is cleared. From the **DWork Allocator entry** drop-down list, select the entry tag matching the value in the `Mutex Init` table entry. In this example, the entry tag is `entry_25576`.

DWork attributes

Allocate DWork

DWork Allocator entry: entry\_25576

- d In the **Replacement function** section, **Name** field, enter a function name. This example uses `myMutexLock`, `myMutexUnlock`, and `myMutexDelete`. In the list of **Function arguments**, leave the DWork argument `d1` data type as `void*`.

Replacement function

Function prototype

Name:  C++ namespace:

Function returns void

y1(return arg)	↑ ↓
d1	

Argument properties

Data type:  I/O type:

Const  Pointer  Pointer-Pointer

Alignment value:

Function signature preview

```
void myMutexLock (void* d1);
```

- e In the **Implementation attributes** section, select the option **Function modifies internal or global state**. This option instructs the code generator not to optimize away the implementation function described by this entry because it accesses global memory values.
  - f Optionally, supply build information for the replacement function on the **Build Information** tab.
  - g Click **Apply**. In the middle pane, right-click the table entry and select **Validate entry(s)**.
- 6 When you have added the table entries for **Mutex Lock**, **Mutex Unlock**, and **Mutex Destroy** to the entry for **Mutex Init**, the rate transition mutex replacement table is complete. In the left-most pane, right-click the table name and select **Validate table**. Address errors and repeat the table validation.

- 7 Save the table to a MATLAB file in your working folder, for example, using **File > Save table**. The name of the saved file is the table name, `crl_table_rt_mutex`, with an `.m` extension. Optionally, you can open the saved file and examine the MATLAB code for the code replacement table definition.

To test this example:

- 1 Register the code replacement mapping.
- 2 Create a model that contains a rate transition for which the build process generates mutex function calls. For example:

- 3 Configure the model for a multicore target environment and the following settings:
  - On the **Solver** pane, select a fixed-step solver.
  - On the **Code Generation** pane, select an ERT-based system target file.
  - On the **Code Generation > Interface** pane, select the code replacement library that contains your mutex entry.

- “Customize Match and Replacement Process” on page 51-153
- “Develop a Code Replacement Library” on page 51-27

## Algorithm-Based Code Replacement

For some math function blocks, you can control code replacement based on the computation or approximation algorithm configured for that block. For example, you can configure:

- The Reciprocal Sqrt block to use the **Newton-Raphson** or **Exact** computation method.
- The Trigonometric Function block, with **Function** set to **sin**, **cos**, or **sincos**, to use the approximation method **CORDIC** or **None**.

You can define code replacement entries to replace these functions for one or all of the available computation methods. For example, you can define an entry to replace only Newton-Raphson instances of the `rSqrt` function.

To set the algorithm for a function in an entry definition, use the `EntryInfoAlgorithm` property in a call to the function `setTf1CFunctionEntryParameters`. The following table lists arguments for specifying the computation method to match during code generation.

Function	Argument
<code>rSqrt</code>	<ul style="list-style-type: none"> <li>• 'RTW_DEFAULT' (match the default computation method, Exact)</li> <li>• 'RTW_NEWTON_RAPHSON'</li> <li>• 'RTW_UNSPECIFIED' (match any computation method)</li> </ul>
<code>sin</code> <code>cos</code> <code>sincos</code>	<ul style="list-style-type: none"> <li>• 'RTW_CORDIC'</li> <li>• 'RTW_DEFAULT' (match the default approximation method, None)</li> <li>• 'RTW_UNSPECIFIED' (match any approximation method)</li> </ul>

For example, to replace only Newton-Raphson instances of the `rSqrt` function, create an entry as follows:

- 1 Create a table definition file that contains a function definition. For example:
 

```
function hTable = crl_rsqr()
 %CRL_TABLE_RSQRT - Define function entry for code replacement table.
```
- 2 Within the function body, create the table by calling the function `RTW.Tf1Table`.

```
hTable = RTW.Tf1Table;
```

- 3 Create an entry for the function mapping with a call to the `RTW.Tf1CFunctionEntry` function.

```
% Create entry for rsqrt function replacement
fcn_entry = RTW.Tf1CFunctionEntry;
```

- 4 Set function entry parameters with a call to the `setTf1CFunctionEntryParameters` function.

```
setTf1CFunctionEntryParameters(fcn_entry, ...
 'Key', 'rSqrt', ...
 'Priority', 80, ...
 'ImplementationName', 'rsqrt_newton', ...
 'ImplementationHeaderFile', 'rsqrt.h', ...
 'EntryInfoAlgorithm', 'RTW_NEWTON_RAPHSON');
```

- 5 Create conceptual arguments `y1` and `u1`. This example uses calls to the `createAndAddConceptualArg` function to create and add an argument with one function call.

```
createAndAddConceptualArg(fcn_entry, 'RTW.Tf1ArgNumeric', ...
 'Name', 'y1', ...
 'IOType', 'RTW_IO_OUTPUT', ...
 'DataTypeMode', 'double');
```

```
createAndAddConceptualArg(e, 'RTW.Tf1ArgNumeric', ...
 'Name', 'u1', ...
 'DataTypeMode', 'double');
```

- 6 Copy the conceptual arguments to the implementation arguments. This example uses a call to the `copyConceptualArgsToImplementation` function to create and add implementation arguments to the entry by copying matching conceptual arguments.

```
copyConceptualArgsToImplementation(fcn_entry);
```

- 7 Add the entry to a code replacement table with a call to the `addEntry` function.

```
addEntry(hTable, fcn_entry);
```

- 8 Save the table definition file. Use the name of the table definition function to name the file.

The generated code for a Newton-Raphson instance of the `rSqrt` function looks like the following code:

```
/* Model step function */
```

```
void mrsqrt_step(void)
{
 /* Outport: '<Root>/Out1' incorporates:
 * Inport: '<Root>/In1'
 * Sqrt: '<Root>/rSqrtBlk'
 */
 mrsqrt_Y.Out1 = rsqrt_newton(mrsqrt_U.In1);
}
```

## Lookup Table Function Code Replacement

You can configure the algorithm for table lookup operations and index searches to better meet your application code requirements. Use the **Algorithm** tab of lookup table blocks. For example, you can specify the interpolation, extrapolation, and index search methods.

### Lookup Table Algorithm Replacement

If the code generated for available algorithm options does not meet requirements for your application, create custom code replacement table entries to replace generated algorithm code. You can create the table entries programmatically or interactively by using the Code Replacement Tool.

For more information about using lookup table blocks, see “Nonlinearity” in the Simulink documentation.

### Lookup Table Function Signatures

To create code replacement table entries for a function corresponding to a lookup table algorithm, you must have:

- Information about the conceptual function signature.
- Relevant algorithm parameters.

The following table provides the conceptual function signature information.

Conceptual Function Signature	Argument Summary
<code>y1 = interp1D(u1, u2, u3, u4)</code>	y1 – output u1 – index u2 – fraction u3 – table data u4 – table dimension length
<code>y1 = interp2D(u1, u2, u3, u4, u5, u6, u7)</code>	y1 – output u1, u3 – index u2, u4 – fraction u5 – table data u6, u7 – table dimension lengths
<code>y1 = interp3D(u1, u2, u3, u4, u5, u6, u7, u8, u9, u10)</code>	y1 – output u1, u3, u5 – index

Conceptual Function Signature	Argument Summary
	<p>u2, u4, u6 – fraction  u7 – table data  u8, u9, u10 – table dimension lengths</p>
<p>y1 = interp4D(u1, u2, u3, u4, u5, u6, u7, u8, u9, u10, u11, u12, u13)</p>	<p>y1 – output  u1, u3, u5, u7 – index  u2, u4, u6, u8 – fraction  u9 – table data  u10, u11, u12, u13 – table dimension lengths</p>
<p>y1 = interp5D(u1, u2, u3, u4, u5, u6, u7, u8, u9, u10, u11, u12, u13, u14, u15, u16)</p>	<p>y1 – output  u1, u3, u5, u7, u9 – index  u2, u4, u6, u8, u10 – fraction  u11 – table data  u12, u13, u14, u15, u16 – table dimension lengths</p>
<p>y1 = interpND({ui, uf,... ut, un...})</p>	<p>y1 – output  ui, uf is an index and fraction pair per dimension  ut – table data  un – table dimension lengths</p>
<p>Explicit values  y1 = lookup1D(u1, u2, u3, u4)</p>	<p>y1 – output  u1 – input  u2 – breakpoint data  u3 – table data  u4 – table dimension length</p>
<p>Even spacing  y1 = lookup1D(u1, u2, u3, u4, u5)</p>	<p>y1 – output  u1 – input  u2 – first point of breakpoint data  u3 – spacing of breakpoints  u4 – table data  u5 – table dimension length</p>

Conceptual Function Signature	Argument Summary
Explicit values <code>y1 = lookup2D(u1, u2, u3, u4, u5, u6, u7)</code>	y1 – output u1, u2 – input u3, u4 – breakpoint data u5 – table data u6, u7 – table dimension lengths
Even spacing <code>y1 = lookup2D(u1, u2, u3, u4, u5, u6, u7, u8, u9)</code>	y1 – output u1, u2 – input u3, u5 – first point of breakpoint data u4, u6 – spacing of breakpoints u7 – table data u8, u9 – table dimension lengths
Explicit spacing <code>y1 = lookup3D(u1, u2, u3, u4, u5, u6, u7, u8, u9, u10)</code>	y1 – output u1, u2, u3 – input u4, u5, u6 – breakpoint data u7 – table data u8, u9, u10 – table dimension lengths
Even spacing <code>y1 = lookup3D(u1, u2, u3, u4, u5, u6, u7, u8, u9, u10, u11, u12, u13)</code>	y1 – output u1, u2, u3 – input u4, u6, u8 – first point of breakpoint data u5, u7, u9 – spacing of breakpoints u10 – table data u11, u12, u13 – table dimension lengths
Explicit values <code>y1 = lookup4D(u1, u2, u3, u4, u5, u6, u7, u8, u9, u10, u11, u12, u13)</code>	y1 – output u1, u2, u3, u4 – input u5, u6, u7, u8 – breakpoint data u9 – table data u10, u11, u12, u13 – table dimension lengths

Conceptual Function Signature	Argument Summary
<p>Even spacing  <math>y1 = \text{lookup4D}(u1, u2, u3, u4, u5, u6, u7, u8, u9, u10, u11, u12, u13, u14, u15, u16, u17)</math></p>	<p><math>y1</math> – output  <math>u1, u2, u3, u4</math> – input  <math>u5, u7, u9, u11</math> – first point of breakpoint data  <math>u6, u8, u10, u12</math> – spacing of breakpoints  <math>u13</math> – table data  <math>u14, u15, u16, u17</math> – table dimension lengths</p>
<p>Explicit values  <math>y1 = \text{lookup5D}(u1, u2, u3, u4, u5, u6, u7, u8, u9, u10, u11, u12, u13, u14, u15, u16)</math></p>	<p><math>y1</math> – output  <math>u1, u2, u3, u4, u5</math> – input  <math>u6, u7, u8, u9, u10</math> – breakpoint data  <math>u11</math> – table data  <math>u12, u13, u14, u15, u16</math> – table dimension lengths</p>
<p>Even spacing  <math>y1 = \text{lookup5D}(u1, u2, u3, u4, u5, u6, u7, u8, u9, u10, u11, u12, u13, u14, u15, u16, u17, u18, u19, u20, u21)</math></p>	<p><math>y1</math> – output  <math>u1, u2, u3, u4, u5</math> – input  <math>u6, u8, u10, u12, u14</math> – first point of breakpoint data  <math>u7, u9, u11, u13, u15</math> – spacing of breakpoints  <math>u16</math> – table data  <math>u17, u18, u19, u20, u21</math> – table dimension lengths</p>
<p>Explicit values  <math>y1 = \text{lookupND}(u_n, \dots, u_b, \dots, u_t, u_n \dots)</math></p>	<p><math>y1</math> – output  <math>u_n</math>, input per dimension  <math>u_b</math>, breakpoint per dimension  <math>u_t</math> – table data  <math>u_n</math> – table dimension lengths</p>

Conceptual Function Signature	Argument Summary
Even spacing <code>y1 = lookupND(un,..., {ufn, usn,...} ut, un...)</code>	<code>y1</code> – output <code>un</code> – input per dimension <code>ufn</code> – first point of breakpoint data per dimension <code>usn</code> – spacing of breakpoint per dimension <code>ut</code> – table data <code>un</code> – table dimension lengths
<code>y1 = lookupND_Direct(u1, u2,...ui, ui+1)</code>	<code>y1</code> – output <code>u1...ui</code> – input <code>ui+1</code> – table data
Explicit values <code>y1, y2 = prelookup(u1, u2, u3)</code>	<code>y1</code> – index <code>y2</code> – fraction <code>u1</code> – input <code>u2</code> – breakpoint data <code>u3</code> – number of breakpoints
Evenly spaced <code>y1, y2 = prelookup(u1, u2, u3, u4)</code>	<code>y1</code> – index <code>y2</code> – fraction <code>u1</code> – input <code>u2</code> – first point of breakpoint data <code>u3</code> – spacing of breakpoints <code>u4</code> – number of breakpoints

When defining a table entry programmatically, you might also need to change the values of required (primary) and optional algorithm parameters.

- Set values for required parameters to achieve code replacement.
- If you do not set a value for an optional parameter, the algorithm parameter software applies `don't care`. The code replacement software ignores the parameter while searching for matches.

To look up algorithm parameter information for a lookup table function:

- 1 Create a table entry for a function.

```
tableEntry = RTW.Tf1CFunctionEntry;
```

- 2 Identify the lookup table function in the table entry. Use the **Key** table entry parameter in a call to `setTf1CFFunctionEntryParameters`. The following example identifies an entry for the `prelookup` function.

```
setTf1CFFunctionEntryParameters(tableEntry, ...
 'Key', 'prelookup', ...
 'Priority', 100, ...
 'ImplementationName', 'myPrelookup');
```

- 3 Get the algorithm parameter set for the entry with a call to `getAlgorithmParameters`.

```
algParams = getAlgorithmParameters(tableEntry);
algParams =
 Prelookup with properties:
 ExtrapMethod: [1x1 coder.algorithm.parameter.ExtrapMethod]
 RndMeth: [1x1 coder.algorithm.parameter.RndMeth]
 IndexSearchMethod: [1x1 coder.algorithm.parameter.IndexSearchMethod]
 UseLastBreakpoint: [1x1 coder.algorithm.parameter.UseLastBreakpoint]
 RemoveProtectionInput: [1x1 coder.algorithm.parameter.RemoveProtectionInput]
```

- 4 Examine information available for each parameter.

```
algParams.ExtrapMethod
```

```
ans =
```

```
ExtrapMethod with properties:
```

```
 Name: 'ExtrapMethod'
 Options: {'Linear' 'Clip'}
 Primary: 1
 Value: {'Linear'}
```

```
algParams.RndMeth
```

```
ans =
```

```
RndMeth with properties:
```

```
 Name: 'RndMeth'
 Options: {1x7 cell}
 Primary: 0
 Value: {1x7 cell}
```

```
algParams.RndMeth.Value
```

```
ans =
```

```
Columns 1 through 6
```

```
 'Ceiling' 'Convergent' 'Floor' 'Nearest' 'Round' 'Simplest'
```

```
Column 7
```

```
 'Zero'
```

```
algParams.IndexSearchMethod
```

```
ans =

IndexSearchMethod with properties:

 Name: 'IndexSearchMethod'
 Options: {'Linear search' 'Binary search' 'Evenly spaced points'}
 Primary: 0
 Value: {'Binary search' 'Evenly spaced points' 'Linear search'}

algParams.UseLastBreakpoint

ans =

UseLastBreakpoint with properties:

 Name: 'UseLastBreakpoint'
 Options: {'off' 'on'}
 Primary: 0
 Value: {'off' 'on'}

algParams.RemoveProtectionInput

ans =

RemoveProtectionInput with properties:

 Name: 'RemoveProtectionInput'
 Options: {'off' 'on'}
 Primary: 0
 Value: {'off' 'on'}
```

## Interactive Mapping with Code Replacement Tool

This example shows how to specify a code replacement table entry for a lookup table algorithm by using the Code Replacement Tool.

### Open and Examine Example Replacement Function

Identify or create the C or C++ replacement function for the algorithm that you want to use in place of a Simulink software algorithm.

This example uses the following C replacement function header and source files, which are in the folder `matlab/toolbox/rtw/rtwdemos/cr1_demo`:

- `myLookup1D.h`
- `myLookup1D.c`

Place a copy of these files in your working folder.

Open and examine the code for `myLookup1D.h`.

```
#include "rtwtypes.h"
real_T my_Lookup1D_Repl(real_T u0, const real_T *bp0, const real_T *table, uint32_T td1);
```

Open and examine the code in `myLookup1D.c`. Note the function signature. When you enter the implementation argument specification in the Code Replacement Tool, specify argument properties.

```
#include "myLookup1D.h"
real_T my_Lookup1D_Repl(real_T u0, const real_T *bp0, const real_T *table, uint32_T td1)
{
 real_T y;
 uint16_T frac;
 uint32_T bpIdx;
 uint32_T maxIndex=td1-1;

 if (u0 <= bp0[0U]) {
 bpIdx = 0U;
 frac = 0U;
 } else if (u0 < bp0[maxIndex]) {
 bpIdx = maxIndex >> 1U;
 while ((u0 < bp0[bpIdx]) && (bpIdx > 0U)) {
 bpIdx--;
 }

 while ((bpIdx < maxIndex - 1U) && (u0 >= bp0[bpIdx + 1U])) {
 bpIdx++;
 }

 frac = (uint16_T)((u0 - bp0[bpIdx]) / (bp0[bpIdx + 1U] -
 bp0[bpIdx]) * 32768.0);
 } else {
 bpIdx = maxIndex;
 frac = 0U;
 }

 if (bpIdx == maxIndex) {
 y = table[bpIdx];
 } else {
 y = (table[bpIdx + 1U] - table[bpIdx]) * ((real_T)frac * 3.0517578125E-5) +
 table[bpIdx];
 }

 return y;
}
```

## Open and Examine the Example Model

This example uses the model `rtwdemo_crllookup1D` to test your code replacement specification. Place a copy of the model in your working folder and name it `my_lookup1d.slx`.

Open and examine the model. Note input and output specifications and block parameter settings. To achieve a match, you must specify conceptual arguments based on how the 1-D Lookup Table block is configured in the example model.

### Create Code Replacement Table

- 1 At the command prompt, enter `crtool` to open the Code Replacement Tool.
- 2 Add a new table, select that table, and add a new function entry.
- 3 On the **Mapping Information** tab, select **Custom** for the **Function** parameter.
- 4 Look up the call signature and algorithm parameter information for the lookup table function that you want to update with an algorithm replacement. See “Lookup Table Function Signatures” on page 51-112.

For this example, you replace the algorithm for the conceptual function associated with the 1-D Lookup Table block. The signature for that function is:

```
y1 = lookup1D(u1, u2, u3, u4)
```

Arguments `u1`, `u2`, `u3`, `u4` represent input, breakpoint data, table data, and table dimension length, respectively. The function returns output to `y1`.

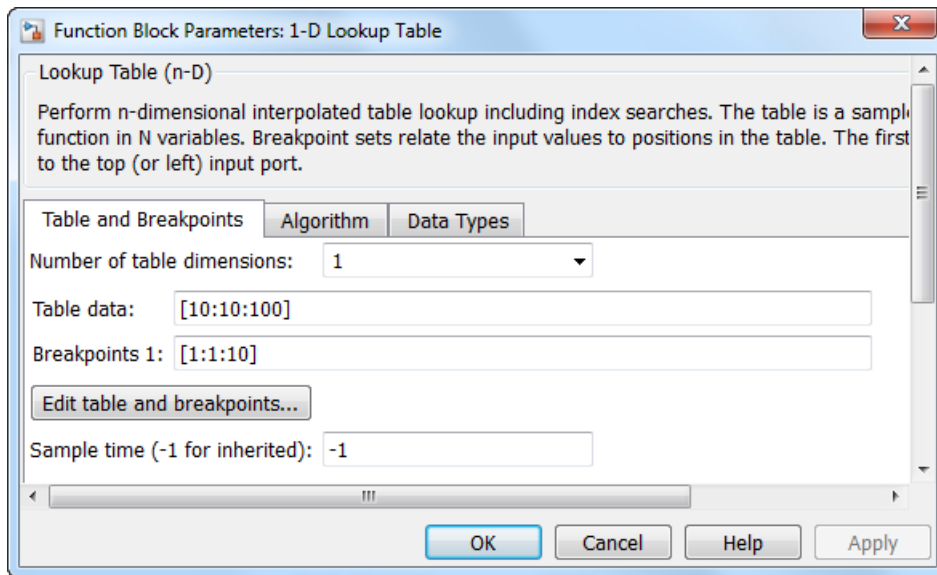

- 5 To the right of the **Function** drop-down list, in the function-name text box, enter the name of the Simulink lookup table function. For this example, type the name `lookup1D`. Type the name exactly as it appears in the documented signature, including character casing. Press **Enter**.

The tool displays algorithm parameter settings that trigger a match for the 1-D Lookup Table block in the example model. Required parameters appear with only one value. For this example, do not change the values. Optional parameters appear with multiple values. Changes to optional parameters do not affect the match process.

- 6 Specify the conceptual arguments. Under the **Conceptual arguments** list box, click **+** to add the arguments that are in the documented function signature. The `lookup1D` function takes one output argument and four input arguments. Click **+** five times.

The tool creates an output argument  $y1$  and four input arguments  $u1$ ,  $u2$ ,  $u3$ , and  $u4$ . By default, the four arguments are scalars of type `double`.

You can adjust the conceptual argument properties. For this example, you do not make changes for  $y1$  and  $u1$ . However, as the block parameter dialog box for the example model shows, you must adjust the argument properties for the breakpoint and table data arguments.

Adjust the conceptual argument properties by using the following table. Click **Apply**.

Signature Argument Name	Conceptual Argument Name	Data type	I/O type	Argument type	Lower range	Upper range
y	y1	double	OUTPUT	Scalar	Not applicable	Not applicable
u1	u1	double	INPUT	Scalar	Not applicable	Not applicable
bp1	u2	double	INPUT	Matrix	[0 0]	[Inf Inf]

Signature Argument Name	Conceptual Argument Name	Data type	I/O type	Argument type	Lower range	Upper range
table	u3	double	INPUT	Matrix	[0 0]	[Inf Inf]
td1	u4	uint32	INPUT	Scalar	Not applicable	Not applicable

- 7 Enter information for the replacement function prototype. The prototype for the example function is:

```
real_T my_Lookup1D_Repl(real_T u0, const real_T *bp0, const real_T *table, uint32_T td1)
```

In the **Replacement function > Function prototype** section, type the function name `my_Lookup1D_Repl` in the **Name** text box.

- 8 Specify the arguments for the replacement function. Under the **Function arguments** list box, click **+** five times to add five implementation arguments.

You might need to adjust the function argument properties. As the replacement function signature shows, adjust the argument properties for the breakpoint, table data, and table dimension length arguments. For `u2` (breakpoints) and `u3` (table), select the **Const** check box. For `u4`, set **Data type** to `uint32`.

The function signature preview should appear as follows:

```
double my_Lookup1D_Repl(double u1, const double* u2, const double* u3, uint32 u4)
```

- 9 Set relevant implementation attributes. Use the default settings.
- 10 Validate the entry. If the tool reports errors, fix them, and retry the validation. Repeat the procedure until the tool does not report errors.
- 11 Save the code replacement table in your working folder as `my_lookup_replacement_table.m`.

### Specify Build Information

On the **Build Information** tab, specify information relevant to generating C or C++ code and building an executable from the model. Enter `myLookup1D.h` for **Implementation Header File** and `myLookup1D.c` for **Implementation Source File**.

If you copied the example files to a folder other than the working folder containing the test model, `lookup1d.slx`, specify the source and header file paths. Otherwise, leave the other **Build Information** parameters set to default values. Click **Apply**.

### Test the Entry

To test this example:

- 1 Register the code replacement mapping.
- 2 Use the example model `rtwdemo_crllookup1D`.
- 3 Configure the model with the following settings:
  - On the **Solver** pane, select a fixed-step solver.
  - On the **Code Generation** pane, select an ERT-based system target file.
  - On the **Code Generation > Interface** pane, select the code replacement library that contains your lookup table function entry.

## Programmatic Specification

This example shows how to specify code replacement table entries for lookup table functions programmatically.

### Open and Examine Example Replacement Function

Identify or create the C or C++ replacement function for the algorithm that you want to use in place of a Simulink software algorithm.

This example uses the following C replacement function header and source files, which are in the folder `matlab/toolbox/rtw/rtwdemos/crl_demo`:

- `myLookup1D.h`
- `myLookup1D.c`

Place a copy of these files in your working folder.

Open and examine the code for `myLookup1D.h`.

```
#include "rtwtypes.h"
real_T my_Lookup1D_Repl(real_T u0, const real_T *bp0, const real_T *table, uint32_T td1);
```

Open and examine the code in `myLookup1D.c`. Note the function signature. When you enter the implementation argument specification in the Code Replacement Tool, specify argument properties.

```

#include "myLookup1D.h"
real_T my_Lookup1D_Repl(real_T u0, const real_T *bp0, const real_T *table, uint32_T td1)
{
 real_T y;
 uint16_T frac;
 uint32_T bpIdx;
 uint32_T maxIndex=td1-1;

 if (u0 <= bp0[0U]) {
 bpIdx = 0U;
 frac = 0U;
 } else if (u0 < bp0[maxIndex]) {
 bpIdx = maxIndex >> 1U;
 while ((u0 < bp0[bpIdx]) && (bpIdx > 0U)) {
 bpIdx--;
 }

 while ((bpIdx < maxIndex - 1U) && (u0 >= bp0[bpIdx + 1U])) {
 bpIdx++;
 }

 frac = (uint16_T)((u0 - bp0[bpIdx]) / (bp0[bpIdx + 1U] -
 bp0[bpIdx]) * 32768.0);
 } else {
 bpIdx = maxIndex;
 frac = 0U;
 }

 if (bpIdx == maxIndex) {
 y = table[bpIdx];
 } else {
 y = (table[bpIdx + 1U] - table[bpIdx]) * ((real_T)frac * 3.0517578125E-5) +
 table[bpIdx];
 }

 return y;
}

```

### Review Lookup Function Signature

Look up the call signature information for the lookup function that you want to update with an algorithm replacement. See “Lookup Table Function Signatures” on page 51-112.

Replace the algorithm for the function associated with the 1–D Lookup Table block. The signature for that function is:

$$y_1 = \text{lookup1D}(u_1, u_2, u_3, u_4)$$

Arguments  $u_1$ ,  $u_2$ ,  $u_3$ , and  $u_4$  represent input, breakpoint data, table data, and table dimension length, respectively. The function returns output to  $y_1$ .

## Create Code Replacement Entry

Create a code replacement table file as a MATLAB function, that describes the lookup table function code replacement table entries. Place a copy of the file `matlab/toolbox/rtw/rtwdemos/crl_demo/crl_table_lookup1D.m` in your working folder. This file defines a code replacement table for the C function `my_Lookup1D_Repl`.

Open `crl_table_lookup1D.m` and examine the definition.

- 1 Create a table definition file that contains a function definition. For example:

```
function hLib = my_lookup_replacement_table
```

- 2 Within the function body, create the table by calling the function `RTW.Tf1Table`.

```
hLib = RTW.Tf1Table;
```

- 3 Create an entry for the function mapping with a call to the `RTW.Tf1CFunctionEntry` function.

```
hEnt = RTW.Tf1CFunctionEntry;
```

- 4 Set function entry parameters with a call to the `setTf1CFunctionEntryParameters` function. The function key, implementation name, and header and source files in the function call identify the Simulink lookup table function name, `lookup1D`, and the following information for replacement function `my_Lookup1D_Repl`:
  - Function name
  - Header file
  - Source file

Specify the Simulink lookup table function name exactly as it appears in the documented signature, including character casing (see “Lookup Table Function Signatures” on page 51-112). If you copied the example files to a folder other than the working folder that contains the test model, `rtwdemo_crllookup1D`, specify the source and header file paths.

```
setTf1CFunctionEntryParameters(hEnt, ...
 'Key', 'lookup1D', ...
 'Priority', 100, ...
 'ImplementationName', 'my_Lookup1D_Repl', ...
 'ImplementationHeaderFile', 'myLookup1D.h', ...
 'ImplementationSourceFile', 'myLookup1D.c', ...
 'GenCallback', 'RTW.copyFileToBuildDir');
```

- 5 Create conceptual arguments and add them to the entry. This example uses calls to the `getTflArgFromString` and `addConceptualArg` functions to create and add the arguments.

The example defines five conceptual arguments for the `lookup1D` function, one output argument `y1` and four input arguments `u1`, `u2`, `u3`, and `u4`. Arguments `y1` and `u1` are defined as scalar `double` data. Arguments `u2` and `u3` represent `bp1` and `table` in the signature and are defined as 1x10 matrices of `double` data. Argument `u4` represents `td1` and is defined as scalar of `uint32` data. This definition triggers a match with the example model.

```
arg = hEnt.getTflArgFromString('y1','double');
arg.IOType = 'RTW_IO_OUTPUT';
addConceptualArg(hEnt, arg);

arg = hEnt.getTflArgFromString('u1','double');
addConceptualArg(hEnt, arg);

arg = RTW.TflArgMatrix('u2', 'RTW_IO_INPUT', 'double');
arg.DimRange = [0 0; Inf Inf];
addConceptualArg(hEnt, arg);

arg = RTW.TflArgMatrix('u3', 'RTW_IO_INPUT', 'double');
arg.DimRange = [0 0; Inf Inf];
addConceptualArg(hEnt, arg);

arg = hEnt.getTflArgFromString('u4','uint32');
addConceptualArg(hEnt, arg);
```

- 6 Review the algorithm parameter information for the lookup function that you want to update with an algorithm replacement. Use the `getAlgorithmParameters` function to display the parameter information.

```
algParams = getAlgorithmParameters(hEnt)

algParams =

Lookup with properties:

 InterpMethod: [1x1 coder.algorithm.parameter.InterpMethod]
 ExtrapMethod: [1x1 coder.algorithm.parameter.ExtrapMethod]
 RndMeth: [1x1 coder.algorithm.parameter.RndMeth]
 IndexSearchMethod: [1x1 coder.algorithm.parameter.IndexSearchMethod]
 UseLastTableValue: [1x1 coder.algorithm.parameter.UseLastTableValue]
 RemoveProtectionInput: [1x1 coder.algorithm.parameter.RemoveProtectionInput]
 SaturateOnIntegerOverflow: [1x1 coder.algorithm.parameter.SaturateOnIntegerOverflow]
 SupportTunableTableSize: [1x1 coder.algorithm.parameter.SupportTunableTableSize]
 BPPower2Spacing: [1x1 coder.algorithm.parameter.BPPower2Spacing]
```

Examine the information for each parameter. The `Options` property lists possible values. `Primary` indicates whether a parameter is required (1) or optional (0). The

**Value** property specifies the current value. For required parameters, initially, **Value** is set to the default value for a given lookup table function.

#### **algParams.InterpMethod**

ans =

InterpMethod with properties:

```
Name: 'InterpMethod'
Options: {'Linear' 'Flat' 'Nearest'}
Primary: 1
Value: {'Linear'}
```

#### **algParams.RndMeth**

ans =

RndMeth with properties:

```
Name: 'RndMeth'
Options: {1x7 cell}
Primary: 0
Value: {1x7 cell}
```

#### **algParams.RndMeth.Options**

ans =

Columns 1 through 5

```
'Ceiling' 'Convergent' 'Floor' 'Nearest' 'Round'
```

Columns 6 through 7

```
'Simplest' 'Zero'
```

#### **algParams.RndMeth**

ans =

RndMeth with properties:

```
Name: 'RndMeth'
Options: {1x7 cell}
```

```
Primary: 0
Value: {1x7 cell}
```

```
.
.
.
```

- 7 Set the algorithm properties for the `lookup1D` table entry. Assign a value to each parameter. Update the parameter settings for the entry by calling the function `setAlgorithmParameters`. The following parameter settings trigger a match with the example model.

```
algParams.InterpMethod = 'Linear';
algParams.ExtrapMethod = 'Clip';
algParams.RndMeth = 'Round';
algParams.IndexSearchMethod = 'Linear search';
algParams.UseLastTableValue = 'Evenly spaced point';
algParams.RemoveProtectionInput = 'off';
algParams.SaturateOnIntegerOverflow = 'off';
algParams.SupportTunableTableSize = 'off';
algParams.BPPower2Spacing = 'off';
setAlgorithmParameters(hEnt, algParams);
```

```
ans =
```

```
RndMeth with properties:
```

```
Name: 'RndMeth'
Options: {1x7 cell}
Primary: 0
Value: {1x7 cell}
```

```
.
.
.
```

To verify your changes, call `getAlgorithmParameters` to get the parameter set for the table entry. Examine the value of each parameter.

```
getAlgorithmParameters(hEnt, algParams);
algParams.InterpMethod.Value
```

```
ans =
```

```
'Linear'
```

```
algParams.ExtrapMethod.Value
```

```

ans =
 'Clip'
algParams.RndMeth.Value

```

```

ans =
 'Round'
.
.
.

```

- 8** Create the implementation arguments and add them to the entry. This example uses calls to the `getTflArgFromString` function to create five implementation arguments that map to arguments in the replacement function prototype: one output argument *y1* and four input arguments *u1*, *u2*, *u3*, and *u4*. The convenience methods `setReturn` and `addArgument` specify whether an argument is a return value or argument. The `addArgument` function also adds each argument to the entry's array of implementation arguments.

```

arg = hEnt.getTflArgFromString('y1', 'double');
arg.IOType = 'RTW_IO_OUTPUT';
hEnt.Implementation.setReturn(arg);

arg = hEnt.getTflArgFromString('u1', 'double');
hEnt.Implementation.addArgument(arg);

arg = hEnt.getTflArgFromString('u2', 'double*');
hEnt.Implementation.addArgument(arg);

arg = hEnt.getTflArgFromString('u3', 'double*');
hEnt.Implementation.addArgument(arg);

arg = hEnt.getTflArgFromString('u4', 'uint32');
hEnt.Implementation.addArgument(arg);

```

- 9** Add the entry to a code replacement table with a call to the `addEntry` function.

```

addEntry(hLib, hEnt);

```

- 10** Save the table definition file. Use the name of the table definition function to name the file.

## Test the Entry

To test this example:

- 1 Register the code replacement mapping.
- 2 Use the example model `rtwdemo_crlookup1D`.
- 3 Configure the model with the following settings:
  - On the **Solver** pane, select a fixed-step solver.
  - On the **Code Generation** pane, select an ERT-based system target file.
  - On the **Code Generation > Interface** pane, select the code replacement library that contains your lookup table function entry.

## Sample Code Replacement Definition for the `lookup2D` Function

The following code shows a replacement definition for the `lookup2D` function.

```
function hLib = my_2dlookup_replacement_table

hLib = RTW.Tf1Table;

hEnt = RTW.Tf1CFunctionEntry;
setTf1CFunctionEntryParameters(hEnt, ...
 'Key', 'lookup2D', ...
 'Priority', 100, ...

 'ImplementationName', 'custom_lookup2d', ...
 'ImplementationHeaderFile', 'custom_lookup2d.h', ...
 'ImplementationSourceFile', 'custom_lookup2d.c', ...
 'GenCallback', 'RTW.copyFileToBuildDir');

% Conceptual Args

arg = hEnt.getTf1ArgFromString('y1','double');
arg.IOType = 'RTW_IO_OUTPUT';
addConceptualArg(hEnt, arg);

arg = hEnt.getTf1ArgFromString('u1','double');
addConceptualArg(hEnt, arg);

arg = hEnt.getTf1ArgFromString('u2','double');
addConceptualArg(hEnt, arg);
```

```
arg = RTW.Tf1ArgMatrix('u3', 'RTW_IO_INPUT', 'double');
arg.DimRange = [1 1; 10 1];
addConceptualArg(hEnt, arg);

arg = RTW.Tf1ArgMatrix('u4', 'RTW_IO_INPUT', 'double');
arg.DimRange = [1 1; 10 1];
addConceptualArg(hEnt, arg);

arg = RTW.Tf1ArgMatrix('u5', 'RTW_IO_INPUT', 'double');
arg.DimRange = [1 1; 10 1];
addConceptualArg(hEnt, arg);

arg = hEnt.getTf1ArgFromString('u6','uint32');
addConceptualArg(hEnt, arg);

arg = hEnt.getTf1ArgFromString('u7','uint32');
addConceptualArg(hEnt, arg);

% Algorithm Parameters

addAlgorithmProperty(hEnt, 'ExtrapMethod','Clip');
addAlgorithmProperty(hEnt, 'IndexSearchMethod','Linear search');
addAlgorithmProperty(hEnt, 'InterpMethod','Linear');
addAlgorithmProperty(hEnt, 'RemoveProtectionInput','off');
addAlgorithmProperty(hEnt, 'UseLastTableValue','on');

% Implementation Args

arg = hEnt.getTf1ArgFromString('y1','double');
arg.IOType = 'RTW_IO_OUTPUT';
hEnt.Implementation.setReturn(arg);

arg = hEnt.getTf1ArgFromString('u1','double');
hEnt.Implementation.addArgument(arg);

arg = hEnt.getTf1ArgFromString('u2','double');
hEnt.Implementation.addArgument(arg);

arg = hEnt.getTf1ArgFromString('u3','double*');
arg.Type.BaseType.ReadOnly = true;
hEnt.Implementation.addArgument(arg);

arg = hEnt.getTf1ArgFromString('u4','double*');
```

```
arg.Type.BaseType.ReadOnly = true;
hEnt.Implementation.addArgument(arg);

arg = hEnt.getTflArgFromString('u5', 'double*');
arg.Type.BaseType.ReadOnly = true;
hEnt.Implementation.addArgument(arg);

arg = hEnt.getTflArgFromString('u6', 'uint32');
hEnt.Implementation.addArgument(arg);

arg = hEnt.getTflArgFromString('u7', 'uint32');
hEnt.Implementation.addArgument(arg);

hLib.addEntry(hEnt);
```

## Data Alignment for Code Replacement

Code replacement libraries can align data objects passed into a replacement function to a specified boundary.

### Code Replacement Data Alignment

You can take advantage of function implementations that require aligned data to optimize application performance. To configure data alignment for a function implementation:

- 1 Specify the data alignment requirements in a code replacement entry. Specify alignment separately for each implementation function argument or collectively for all function arguments. See “Specify Data Alignment Requirements for Function Arguments” on page 51-133.
- 2 Specify the data alignment capabilities and syntax for one or more compilers. Include the alignment specifications in a library registration entry in the `rtwTargetInfo.m` file. See “Provide Data Alignment Specifications for Compilers” on page 51-135.
- 3 Register the library containing the table entry and alignment specification object.
- 4 Configure the code generator to use the code replacement library and generate code. Observe the results.

For examples, see “Basic Example of Code Replacement Data Alignment” on page 51-139 and the “Data Alignment for Function Implementations” section of the “Optimize Generated Code By Developing and Using Code Replacement Libraries - Simulink®” example page.

### Specify Data Alignment Requirements for Function Arguments

To specify the data alignment requirement for an argument in a code replacement entry:

- If you are defining a replacement function in a code replacement table registration file, create an argument descriptor object (`RTW.ArgumentDescriptor`). Use its `AlignmentBoundary` property to specify the required alignment boundary and assign the object to the argument `Descriptor` property.
- If you are defining a replacement function using the Code Replacement Tool, on the **Mapping Information** tab, in the **Argument properties** section for the replacement function, enter a value for the **Alignment value** parameter.

The screenshot shows the 'Replacement function' dialog box. It is divided into several sections:

- Function prototype:**
  - Name:
  - C++ namespace:
  - Function returns void
- Function arguments:**
  - A list box containing 'y1(return arg)' and 'u1'. There are up and down arrow buttons to the right of the list.
- Argument properties:**
  - Data type:
  - I/O type:
  - Const
  - Pointer
  - Complex
  - Alignment value:

The `AlignmentBoundary` property (or **Alignment value** parameter) specifies the alignment boundary for data passed to a function argument, in number of bytes. The `AlignmentBoundary` property is valid only for addressable objects, including matrix and pointer arguments. It is not applicable for value arguments. Valid values are:

- -1 (default) — If the data is a `Simulink.Bus`, `Simulink.Signal`, or `Simulink.Parameter` object, specifies that the code generator determines an optimal alignment based on usage. Otherwise, specifies that there is not an alignment requirement for this argument.
- Positive integer that is a power of 2, not exceeding 128 — Specifies number of bytes in the boundary. The starting memory address for the data allocated for the function argument is a multiple of the specified value. If you specify an alignment boundary that is less than the natural alignment of the argument data type, the alignment directive is emitted in the generated code. However, the target compiler ignores the directive.

The following code specifies the `AlignmentBoundary` for an argument as 16 bytes.

```
hLib = RTW.Tf1Table;
entry = RTW.Tf1COperationEntry;
arg = getTf1ArgFromString(hLib, 'u1', 'single*');
desc = RTW.ArgumentDescriptor;
desc.AlignmentBoundary = 16;
arg.Descriptor = desc;
entry.Implementation.addArgument(arg);
```

The equivalent alignment boundary specification in the Code Replacement Tool dialog box is in this figure.

The figure shows a dialog box titled "Argument properties". It contains the following controls:

- "Data type:" dropdown menu with "single" selected.
- "I/O type:" dropdown menu with "INPUT" selected.
- Three checkboxes: "Const" (unchecked), "Pointer" (checked), and "Complex" (unchecked).
- "Alignment value:" text input field containing the number "16".

---

**Note:** If your model imports `Simulink.Bus`, `Simulink.Parameter`, or `Simulink.Signal` objects, specify an alignment boundary in the object properties, using the **Alignment** property. For more information, see `Simulink.Bus`, `Simulink.Parameter` class, and `Simulink.Signal`.

---

## Provide Data Alignment Specifications for Compilers

To support data alignment in generated code, describe the data alignment capabilities and syntax for your compilers in the code replacement library registration. Provide one or more alignment specifications for each compiler in a library registry entry.

To describe the data alignment capabilities and syntax for a compiler:

- If you are defining a code replacement library registration entry in a `rtwTargetInfo.m` customization file, add one or more `AlignmentSpecification` objects to an `RTW.DataAlignment` object. Attach the `RTW.DataAlignment` object to the `TargetCharacteristics` object of the registry entry.

The `RTW.DataAlignment` object also has the property `DefaultMallocAlignment`, which specifies the default alignment boundary, in bytes, that the compiler uses for dynamically allocated memory. If the code generator uses dynamic memory allocation for a data object involved in a code replacement, this value determines if the memory satisfies the alignment requirement of the replacement. If not, the code generator does not use the replacement. The default value for `DefaultMallocAlignment` is `-1`, indicating that the default alignment boundary used for dynamically allocated memory is unknown. In this case, the code generator uses the natural alignment of the data type to determine whether to allow a replacement.

Additionally, you can specify the alignment boundary for complex types by using the `addComplexTypeAlignment` function.

- If you are generating a customization file function using the Code Replacement Tool, fill out the following fields for each compiler.

Click the plus (+) symbol to add additional compiler specifications.

For each data alignment specification, provide the following information.

Alignment-Specification Property	Dialog Box Parameter	Description
AlignmentType	<b>Alignment type</b>	<p>Cell array of predefined enumerated strings, specifying which types of alignment this specification supports.</p> <ul style="list-style-type: none"> <li>• <code>DATA_ALIGNMENT_LOCAL_VAR</code> — Local variables.</li> <li>• <code>DATA_ALIGNMENT_GLOBAL_VAR</code> — Global variables.</li> <li>• <code>DATA_ALIGNMENT_STRUCT_FIELD</code> — Individual structure fields.</li> <li>• <code>DATA_ALIGNMENT_WHOLE_STRUCT</code> — Whole structure, with padding (individual structure field alignment, if</li> </ul>

Alignment-Specification Property	Dialog Box Parameter	Description
		<p>specified, is favored and takes precedence over whole structure alignment).</p> <p>Each alignment specification must specify at least <code>DATA_ALIGNMENT_GLOBAL_VAR</code> and <code>DATA_ALIGNMENT_STRUCT_FIELD</code>.</p>
AlignmentPosition	<b>Alignment position</b>	<p>Predefined enumerated string specifying the position in which you must place the compiler alignment directive for alignment type <code>DATA_ALIGNMENT_WHOLE_STRUCT</code>:</p> <ul style="list-style-type: none"> <li>• <code>DATA_ALIGNMENT_PREDIRECTIVE</code> — The alignment directive is emitted before <code>struct st_tag{...}</code>, as part of the type definition statement (for example, MSVC).</li> <li>• <code>DATA_ALIGNMENT_POSTDIRECTIVE</code> — The alignment directive is emitted after <code>struct st_tag{...}</code>, as part of the type definition statement (for example, gcc).</li> <li>• <code>DATA_ALIGNMENT_PRECEDING_STATEMENT</code> — The alignment directive is emitted as a standalone statement immediately preceding the definition of the structure type. A semicolon (;) must terminate the registered alignment syntax.</li> <li>• <code>DATA_ALIGNMENT_FOLLOWING_STATEMENT</code> — The alignment directive is emitted as a standalone statement immediately following the definition of the structure type. A semicolon (;) must terminate the registered alignment syntax.</li> </ul> <p>For alignment types other than <code>DATA_ALIGNMENT_WHOLE_STRUCT</code>, code generation uses alignment position <code>DATA_ALIGNMENT_PREDIRECTIVE</code>.</p>

Alignment-Specification Property	Dialog Box Parameter	Description
AlignmentSyntax-Template	Alignment syntax	<p>Specifies the alignment directive string that the compiler supports. The string is registered as a syntax template that has placeholders in it. These placeholders are supported:</p> <ul style="list-style-type: none"> <li>• %n — Replaced by the alignment boundary for the replacement function argument.</li> <li>• %s — Replaced by the aligned symbol, usually the identifier of a variable.</li> </ul> <p>For example, for the gcc compiler, you can specify <code>__attribute__((aligned(%n)))</code>, or for the MSVC compiler, <code>__declspec(align(%n))</code>.</p>
SupportedLanguage	Supported languages	<p>Cell array specifying the languages to which this alignment specification applies, among c and c++. Sometimes alignment syntax and position differ between languages for a compiler.</p> <p>.</p>

Here is a data alignment specification for the GCC compiler:

```

da = RTW.DataAlignment;

as = RTW.AlignmentSpecification;
as.AlignmentType = {'DATA_ALIGNMENT_LOCAL_VAR', ...
 'DATA_ALIGNMENT_STRUCT_FIELD', ...
 'DATA_ALIGNMENT_GLOBAL_VAR'};
as.AlignmentSyntaxTemplate = '__attribute__((aligned(%n)))';
as.AlignmentPosition = 'DATA_ALIGNMENT_PREDIRECTIVE';
as.SupportedLanguages = {'c', 'c++'};
da.addAlignmentSpecification(as);

tc = RTW.TargetCharacteristics;
tc.DataAlignment = da;

```

Here is the corresponding specification in the **Generate customization** dialog box of the Code Replacement Tool.

Generate data alignment specification

Alignment Specification 1

Alignment type: DATA\_ALIGNMENT\_LOCAL\_VAR  
DATA\_ALIGNMENT\_STRUCT\_FIELD  
DATA\_ALIGNMENT\_WHOLE\_STRUCT  
DATA\_ALIGNMENT\_GLOBAL\_VAR

Alignment position: DATA\_ALIGNMENT\_PREDIRECTIVE

Alignment syntax: \_\_attribute\_\_((aligned(%n)))

Supported languages: c, c++

## Basic Example of Code Replacement Data Alignment

A simple example of the complete workflow for data alignment specified for code replacement is:

- 1 Create and save the following code replacement table definition file, `cr1_table_mmul_4x4_single_align.m`. This table defines a replacement entry for the `*` (multiplication) operator, the `single` data type, and input dimensions `[4,4]`. The entry also specifies a data alignment boundary of 16 bytes for each replacement function argument. The entry expresses the requirement that the starting memory address for the data allocated for the function arguments during code generation is a multiple of 16.

```
function hLib = cr1_table_mmul_4x4_single_align
%CRL_TABLE_MMUL_4x4_SINGLE_ALIGN - Describe matrix operator entry with data alignment

hLib = RTW.Tf1Table;
entry = RTW.Tf1COperationEntry;
setTf1COperationEntryParameters(entry, ...
 'Key', 'RTW_OP_MUL', ...
 'Priority', 90, ...
 'ImplementationName', 'matrix_mul_4x4_s');

% conceptual arguments
createAndAddConceptualArg(entry, 'RTW.Tf1ArgMatrix', ...
 'Name', 'y1', ...
 'IOType', 'RTW_IO_OUTPUT', ...
 'BaseType', 'single', ...
 'DimRange', [4 4]);
```

```

createAndAddConceptualArg(entry, 'RTW.Tf1ArgMatrix',...
 'Name', 'u1', ...
 'BaseType', 'single', ...
 'DimRange', [4 4]);

createAndAddConceptualArg(entry, 'RTW.Tf1ArgMatrix',...
 'Name', 'u2', ...
 'BaseType', 'single', ...
 'DimRange', [4 4]);

% implementation arguments
arg = getTf1ArgFromString(hLib, 'y2', 'void');
arg.IOType = 'RTW_IO_OUTPUT';
entry.Implementation.setReturn(arg);

arg = getTf1ArgFromString(hLib, 'y1', 'single*');
desc = RTW.ArgumentDescriptor;
desc.AlignmentBoundary = 16;
arg.Descriptor = desc;
entry.Implementation.addArgument(arg);

arg = getTf1ArgFromString(hLib, 'u1', 'single*');
desc = RTW.ArgumentDescriptor;
desc.AlignmentBoundary = 16;
arg.Descriptor = desc;
entry.Implementation.addArgument(arg);

arg = getTf1ArgFromString(hLib, 'u2', 'single*');
desc = RTW.ArgumentDescriptor;
desc.AlignmentBoundary = 16;
arg.Descriptor = desc;
entry.Implementation.addArgument(arg);

hLib.addEntry(entry);

```

- 2 Create and save the following registration file, `rtwTargetInfo.m`. If you want to compile the code generated in this example, first modify the `AlignmentSyntaxTemplate` property for the compiler that you use. For example, for the MSVC compiler, replace the gcc template character vector `__attribute__((aligned(%n)))` with `__declspec(align(%n))`.

```

function rtwTargetInfo(cm)
% rtwTargetInfo function to register a code replacement library (CRL)
% for use with code generation

% Register the CRL defined in local function locCrlRegFcn
cm.registerTargetInfo(@locCrlRegFcn);

end % End of RTWTARGETINFO

% Local function to define a CRL containing crl_table_mmul_4x4_single_align
function thisCrl = locCrlRegFcn

% create an alignment specification object, assume gcc

```

```

as = RTW.AlignmentSpecification;
as.AlignmentType = {'DATA_ALIGNMENT_LOCAL_VAR', ...
 'DATA_ALIGNMENT_GLOBAL_VAR', ...
 'DATA_ALIGNMENT_STRUCT_FIELD'};
as.AlignmentSyntaxTemplate = '__attribute__((aligned(%n)))';
as.SupportedLanguages={'c', 'c++'};

% add the alignment specification object
da = RTW.DataAlignment;
da.addAlignmentSpecification(as);

% add the data alignment object to target characteristics
tc = RTW.TargetCharacteristics;
tc.DataAlignment = da;

% Instantiate a CRL registry entry
thisCrl = RTW.TflRegistry;

% Define the CRL properties
thisCrl.Name = 'Data Alignment Example';
thisCrl.Description = 'Example of replacement with data alignment';
thisCrl.TableList = {'crl_table_mmul_4x4_single_align'};
thisCrl.TargetCharacteristics = tc;

end % End of LOCCRLREGFCN

```

- 3 To register your library with code generator without having to restart MATLAB, enter this command:

```
RTW.TargetRegistry.getInstance('reset');
```

- 4 Configure the code generator to use your code replacement library.
- 5 Generate code and a code generation report.
- 6 Review the code replacements. For example, check whether a multiplication operation is replaced with a `matrix_mul_4x4_s` function call. In `mmalign.h`, check whether the gcc alignment directive `__attribute__((aligned(16)))` is generated to align the function variables.

## Replace MATLAB Functions with Custom Code Using `coder.replace`

The `coder.replace` function provides the ability to replace a specified MATLAB function with a code replacement function in generated code. Use `coder.replace` in MATLAB code from which you want to generate C code using:

- MATLAB Coder
- MATLAB code in a Simulink MATLAB Function block

You can replace MATLAB functions that have:

- Single or multiple inputs
- Single or multiple outputs
- Scalar and matrix inputs and outputs

Supported types include:

- `single`, `double` (complex and noncomplex)
- `int8`, `uint8` (complex and noncomplex)
- `int16`, `uint16` (complex and noncomplex)
- `int32`, `uint32` (complex and noncomplex)
- Fixed-point integers
- Mixed types (different type on each input)

## Replace `coder.ceval` Calls to External Functions

The `coder.ceval` function calls external C/C++ functions from code generated from MATLAB code. The code replacement software supports replacement of the function that you specify in a call to `coder.ceval`. An application of this code replacement scenario is to write generic MATLAB code that you can customize for different platforms with code replacements. A code replacement library can define hardware-specific code replacements for the function call. Use `coder.ceval` in MATLAB code from which you want to generate C code using:

- MATLAB Coder
- MATLAB code in a Simulink MATLAB Function block

### Example Files

For the examples in “Interactive External Function Call Replacement Specification with Code Replacement Tool” on page 52-93 and “Programmatic External Function Call Replacement Specification” on page 52-94 you must have set up the following:

- Custom C function `my_add.c`.

```
/* my_add.c */

#include "my_add.h"

double my_add(double in1, double in2)
{
 return in1 + in2;
}
```

- Custom C header file `my_add.h`.

```
/* my_add.h */

double my_add(double in1, double in2);
```

- MATLAB function `call_my_add.m`, which uses `coder.ceval` to invoke `my_add.c`.

```
function y = call_my_add(in1, in2) %#codegen

y=0.0;

if ~coder.target('Rtw')
% Executing in MATLAB, call MATLAB equivalent of C function my_add
```

```
 y= in1+in2;
else
% Executing in generated code, call C function my_add
 y = coder.ceval('my_add', in1, in2);
end
```

- MATLAB test function `call_my_add_test.m`, which calls `call_my_add.m`.

```
in1=10;
in2=20;
```

```
y = call_my_add(in1, in2);
```

```
disp('Output')
disp('y =')
disp(y);
```

- Replacement C function `my_add_replacement.c`.

```
/* my_add_replacement.c */
```

```
#include "my_add_replacement.h"
```

```
double my_add_replacement(double in1, double in2)
{
 return in1 + in2;
}
```

- Replacement C header file `my_add_replacement.h`.

```
/* my_add_replacement.h */
```

```
double my_add_replacement(double in1, double in2);
```

## Interactive External Function Call Replacement Specification with Code Replacement Tool

This example shows how to define a code replacement table entry for a MATLAB function that calls `coder.ceval` to invoke an external C function. The example shows how to define the entry interactively with the Code Replacement Tool.

- 1 Identify or create the C/C++ code and relevant header files, the MATLAB function that calls `coder.ceval`, a MATLAB test function, and the source and header files for your replacement code. To follow along with this example, set up the files identified in “Example Files” on page 52-92.

- 2 In the Code Replacement Tool, add a table, select that table, and add a function entry. For more information, see “Define Code Replacement Mappings” on page 52-30.
- 3 On the **Mapping Information** tab, select **Custom** for the **Function** parameter.
- 4 In the **function-name** text box, type the custom function name. For this example, type the name `my_add`.
- 5 Under the **Conceptual arguments** list box, click **+** to add three arguments. By default, the tool creates an output argument `y1` and input arguments `u1` and `u2` of type `double`.
- 6 In the **Replacement function > Function prototype** section, type the name `my_add_replacement` in the **Name** text box.
- 7 Under the **Function arguments** list box, click **+** to add three function implementation arguments. By default, the tool creates an output argument `y1` and input arguments `u1` and `u2` of type `double`. Use the default settings.
- 8 In the **Function signature preview** box, if you see the expected function signature, click **Apply**. The function signature for this example, appears as:  

```
double my_add_replacement(double u1, double u2);
```
- 9 On the **Build Information** tab, specify `my_add_replacement.h` for the **Implementation header file** parameter and `my_add_replacement.c` for the **Implementation source file**.
- 10 Click **Validate entry**.
- 11 Save the code replacement table in the same folder as `my_add_replacement.c`. Name the file `cr1_table_my_add.m`.

To test the example:

- 1 Register the table that contains the entry in a code replacement library.
- 2 Configure the code generator to use the code replacement library and to include the Code Replacements Report in the code generation report.
- 3 Generate code and the report.
- 4 Review the code replacements.

## Programmatic External Function Call Replacement Specification

This example shows how to define a code replacement table entry for a MATLAB function that calls `coder.ceval` to invoke an external C function. The example shows how to define the entry programmatically.

- 1 Identify or create the C/C++ code and relevant header files, the MATLAB function that calls `coder.ceval` to invoke the C/C++ function, a MATLAB test function, and the source and header files for your replacement code. To follow along with this example, set up the files identified in “Example Files” on page 52-92.

- 2 Create a table definition file that contains a function definition. For example:

```
function hLib = crl_table_my_add
```

- 3 Within the function body, create the table by calling the function `RTW.Tf1Table`.

- 4 Create an entry for the function mapping with a call to the `RTW.Tf1CFunctionEntry` function.

```
hEnt = RTW.Tf1CFunctionEntry;
```

- 5 Set function entry parameters with a call to the `setTf1CFunctionEntryParameters` function.

```
hEnt.setTf1CFunctionEntryParameters(...
 'Key', 'my_add', ...
 'Priority', 100, ...
 'ImplementationName', 'my_add_replacement', ...
 'ImplementationHeaderFile', 'my_add_replacement.h', ...
 'ImplementationSourceFile', 'my_add_replacement.c');
```

- 6 Create conceptual arguments `y1`, `u1`, and `u1`. This example uses calls to the `getTf1ArgFromString` and `addConceptualArg` functions to create and add the arguments.

```
arg = hEnt.getTf1ArgFromString('y1', 'double');
arg.IOType = 'RTW_IO_OUTPUT';
hEnt.addConceptualArg(arg);
```

```
arg = hEnt.getTf1ArgFromString('u1', 'double');
hEnt.addConceptualArg(arg);
```

```
arg = hEnt.getTf1ArgFromString('u2', 'double');
hEnt.addConceptualArg(arg);
```

- 7 Create the implementation arguments and add them to the entry. This example uses calls to the `getTf1ArgFromString` function to create implementation arguments. These functions map to arguments in the replacement function prototype: output argument `y1` and input arguments `u1` and `u2`. For each argument, the example uses the convenience method `setReturn` or `addArgument` to specify whether an argument is a return value or argument. For each argument, this example adds the argument to the entry array of implementation arguments.

```
arg = hEnt.getTflArgFromString('y1', 'double');
arg.IOType = 'RTW_IO_OUTPUT';
hEnt.Implementation.setReturn(arg);
```

```
arg = hEnt.getTflArgFromString('u1', 'double');
hEnt.Implementation.addArgument(arg);
```

```
arg = hEnt.getTflArgFromString('u2', 'double');
hEnt.Implementation.addArgument(arg);
```

- 8 Add the entry to a code replacement table with a call to the `addEntry` function.

```
hLib.addEntry(hEnt);
```

- 9 Save the table definition file. Use the name of the table definition function to name the file.

To test the example:

- 1 Register the table that contains the entry in a code replacement library.
- 2 Configure the code generator to use the code replacement library and to include the Code Replacements Report in the code generation report.
- 3 Generate code and the report.
- 4 Review the code replacements.

## Replace MATLAB Functions Specified in MATLAB Function Blocks

This example shows how to use code replacement to replace a **MATLAB** function specified in a MATLAB Function block.

- 1 Open the `ex_replace` model. At the command prompt, enter:

```
addpath(fullfile(docroot,'toolbox','ecoder','examples'))
ex_replace
```

- 2 View the MATLAB Function Block code. In the model, double-click the MATLAB Function block to view the code in the MATLAB editor.

```
function y = customFcn(u1, u2) %#codegen
% This block supports MATLAB for code generation.

% Replace this MATLAB function with CRL replacement function and if no
% CRL replacement is found, generate an error during code generation.
coder.replace('-errorifnoreplacement');

assert(isa(u1,'int32'));
assert(isa(u2,'int32'));

y = power(u1,u2);
```

The `coder.replace('-errorifnoreplacement')` statement instructs the code generator to replace this MATLAB function with a code replacement library function. The code generator produces an error if it does not find a match.

- 3 Create a table definition file that contains a function definition. For example:

```
function hTable = crl_table_coderreplace()
```

- 4 Within the function body, create the table by calling the function `RTW.Tf1Table`.

```
hTable = RTW.Tf1Table;
```

- 5 Create an entry for the function mapping with a call to the `RTW.Tf1CFunctionEntry` function.

```
hEnt = RTW.Tf1CFunctionEntry;
```

- 6 Set function entry parameters with a call to the `setTf1CFunctionEntryParameters` function.

```
setTf1CFunctionEntryParameters(hEnt, ...
 'Key', 'customFcn', ...
```

```

 'Priority', 100, ...
 'ImplementationName', 'scalarFcnReplacement', ...
 'ImplementationHeaderFile', 'MyMath.h', ...
 'ImplementationSourceFile', 'MyMath.c')

```

- 7 Create conceptual arguments `y1`, `u1`, and `u1`. This example uses calls to the `getTf1ArgFromString` and `addConceptualArg` functions to create and add the arguments.

```

arg = getTf1ArgFromString(hEnt, 'y1', 'int32');
arg.IOType = 'RTW_IO_OUTPUT';
addConceptualArg(hEnt, arg);

```

```

arg = getTf1ArgFromString(hEnt, 'u1', 'int32');
addConceptualArg(hEnt, arg);

```

```

arg = getTf1ArgFromString(hEnt, 'u2', 'int32');
addConceptualArg(hEnt, arg);

```

- 8 Create the implementation arguments and add them to the entry. This example uses calls to the `getTf1ArgFromString` function to create implementation arguments that map to arguments in the replacement function prototype: output argument `void`, input arguments `u1` and `u2`, and output argument `y1`. The convenience methods `setReturn` and `addArgument` specify whether an argument is a return value or argument. The `addArgument` function also adds each argument to the entry's array of implementation arguments.

```

arg = getTf1ArgFromString(hEnt, 'void', 'void');
arg.IOType = 'RTW_IO_OUTPUT';
hEnt.Implementation.setReturn(arg);

```

```

arg = getTf1ArgFromString(hEnt, 'u1', 'int32');
hEnt.Implementation.addArgument(arg);

```

```

arg = getTf1ArgFromString(hEnt, 'u2', 'int32');
hEnt.Implementation.addArgument(arg);

```

```

arg = getTf1ArgFromString(hEnt, 'y1', 'int32*');
arg.IOType = 'RTW_IO_OUTPUT';
hEnt.Implementation.addArgument(arg);

```

- 9 Add the entry to a code replacement table with a call to the `addEntry` function.

```

addEntry(hLib, hEnt);

```

- 10 Save the table definition file. Use the name of the table definition function to name the file.

To test the example:

- 1 Register the code replacement mapping.
- 2 Create files `MyMath.c` and `MyMath.h` that define the replacement function, `scalarFcnReplacement`, which has two `int32` inputs and one `int32` output.

`MyMath.c`

```
#include "MyMath.h"

void scalarFcnReplacement(int32_T u1, int32_T u2, int32_T* y1) {
 *y1 = u1^u2;
}
```

`MyMath.h`

```
#ifndef _ScalarMath_h
#define _ScalarMath_h

#include "rtwtypes.h"

#ifdef __cplusplus
extern "C" {
#endif

extern void scalarFcnReplacement(int32_T u1, int32_T u2, int32_T* y1);

#ifdef __cplusplus
}
#endif

#endif
```

- 3 Open the `ex_replace` model.
- 4 Configure the code generator to use the code replacement library and to include the Code Replacements Report in the code generation report.
- 5 Generate the replacement code and a code generation report.
- 6 Review the code replacements. In the code generation report, view the generated code for `ex_replace.c`.

```
void ex_replace_step(void)
{
 int32_T y;
 scalarFcnReplacement(ex_replace_U.In1, ex_replace_U.In2, &y);
 ex_replace_Y.Out1 = y;
}
```

}

## Reserved Identifiers and Code Replacement

The code generator and C programming language use, internally, reserved keywords for code generation. Do not use reserved keywords as identifiers or function names. Reserved keywords for code generation include many code replacement library identifiers, the majority of which are function names, such as `acos`.

To view a list of reserved identifiers for the code replacement library that you use to generate code, specify the name of the library in a call to the function `RTW.TargetRegistry.getInstance.getTf1ReservedIdentifiers`. For example:

```
cr1_ids = RTW.TargetRegistry.getInstance.getTf1ReservedIdentifiers('GNU99 (GNU)')
```

In a code replacement table, the code generator registers each function implementation name defined by a table entry as a reserved identifier. You can register additional reserved identifiers for the table on a per-header-file basis. Providing additional reserved identifiers can help prevent duplicate symbols and other identifier-related compile and link issues.

To register additional code replacement reserved identifiers, use the `setReservedIdentifiers` function. This function registers specified reserved identifiers to be associated with a code replacement table.

You can register up to four reserved identifier structures in a code replacement table. You can associate one set of reserved identifiers with a code replacement library, while the other three (if present) must be associated with ANSI C. The following example shows a reserved identifier structure that specifies two identifiers and the associated header file.

```
d{1}.LibraryName = 'ANSI_C';
d{1}.HeaderInfos{1}.HeaderName = 'math.h';
d{1}.HeaderInfos{1}.ReservedIds = {'y0', 'y1'};
```

The code generator adds the identifiers to the list of reserved identifiers and honors them during the build procedure.

### More About

- “Code You Can Replace From Simulink Models” on page 51-7
- “Customize Match and Replacement Process” on page 51-153
- “Define Code Replacement Mappings” on page 51-42
- “Develop a Code Replacement Library” on page 51-27

## Customize Match and Replacement Process

During the build process, the code generator uses:

- Preset match criteria to identify functions and operators for which application-specific implementations replace default implementations.
- Preset replacement function signatures.

It is possible that preset match criteria and preset replacement function signatures do not completely meet your function and operator replacement needs. For example:

- You want to replace an operator with a particular fixed-point implementation function only when fraction lengths are within a particular range.
- When a match occurs, you want to modify your replacement function signature based on compile-time information, such as passing fraction-length values into the function.

To add extra logic into the code replacement match and replacement process, create custom code replacement table entries. With custom entries, you can specify additional match criteria and modify the replacement function signature to meet application needs.

To create a custom code replacement entry:

- 1 Create a custom code replacement entry class, derived from `RTW.Tf1CFunctionEntryML` (for function replacement) or `RTW.Tf1COperationEntryML` (for operator replacement).
- 2 In your derived class, implement a `do_match` method with a fixed preset signature as a MATLAB function. In your `do_match` method, provide either or both of the following customizations that instantiate the class:
  - Add match criteria that the base class does not provide. The base class provides a match based on:
    - Argument number
    - Argument name
    - Signedness
    - Word size
    - Slope (if not specified with wildcards)
    - Bias (if not specified with wildcards)
    - Math modes, such as saturation and rounding

- Operator or function key
  - Modify the implementation signature by adding additional arguments or setting constant input argument values. You can inject a constant value, such as an input scaling value, as an additional argument to the replacement function.
- 3 Create code replacement entries that instantiate the custom entry class.
  - 4 Register a library containing the code replacement table that includes your entries.

During code generation, the code replacement match process tries to match function or operator call sites with the base class of your derived entry class. If the process finds a match, the software calls your `do_match` method to execute your additional match logic (if any) and your replacement function customizations (if any).

## Customize Code Match and Replacement for Functions

This example shows how to use custom code replacement table entries to refine the match and replacement logic for functions. The example shows how to:

- Modify a sine function replacement only if the integer size on the current target platform is 32 bits.
  - Change the replacement such that the implementation function passes in a degrees-versus-radians flag as an input argument.
- 1 To exercise the table entries that you create in this example, create an ERT-based model with a sine function block. For example:

In the Inport block parameters, set the signal **Data type** to **double**. If the value selected for **Configuration Parameters > Hardware Implementation > Device type** supports an integer size other than 32, do one of the following:

- Select a temporary target platform with a 32-bit integer size.
  - Modify the code to match the integer size of your target platform.
- 2 Create a class, for example `Tf1CustomFunctionEntry`, that is derived from the base class `RTW.Tf1CFunctionEntryML`. The derived class defines a `do_match` method with the signature:

```
function ent = do_match(hThis, ...
 hCSO, ...
 targetBitPerChar, ...
 targetBitPerShort, ...
 targetBitPerInt, ...
 targetBitPerLong, ...
 targetBitPerLongLong)
```

In the `do_match` signature:

- `ent` is the return handle, which is returned either as empty (indicating that the match failed) or as a `Tf1CFunctionEntry` handle.
- `hThis` is a handle to the class instance.
- `hCSO` is a handle to an object that the code generator creates for querying the library for a replacement.
- Remaining arguments are the number of bits for various data types of the current target.

The `do_match` method:

- Adds required additional match criteria that the base class does not provide.
- Makes required modifications to the implementation signature.

In this case, the `do_match` method must match only `targetBitPerInt`, representing the number of bits in the C `int` data type for the current target, to the value 32. If the code generator finds a match, the method sets the return handle and creates and adds an input argument. The input argument represents whether units are expressed as degrees or radians, to the replacement function signature.

Alternatively, create and add the additional implementation function argument for passing a units flag in each code replacement table definition file that instantiates this class. In that case, this class definition code does not create the argument. That code sets only the argument value. For an example of creating and adding additional implementation function arguments in a table definition file, see “Customize Code Match and Replacement for Scalar Operations” on page 51-161.

```
classdef Tf1CustomFunctionEntry < RTW.Tf1CFunctionEntryML
 methods
 function ent = do_match(hThis, ...
 hCSO, ... %#ok
 targetBitPerChar, ... %#ok
```

```

 targetBitPerShort, ... %#ok
 targetBitPerInt, ... %#ok
 targetBitPerLong, ... %#ok
 targetBitPerLongLong) %#ok
% DO_MATCH - Create a custom match function. The base class
% checks the types of the arguments prior to calling this
% method. This will check additional data and perhaps modify
% the implementation function.

ent = []; % default the return to empty, indicating the match failed.

% Match sine function only if the target int size is 32 bits
if targetBitPerInt == 32
 % Need to modify the default implementation, starting from a copy
 % of the standard TflCFunctionEntry.
 ent = RTW.TflCFunctionEntry(hThis);

 % If the target int size is 32 bits, the implementation function
 % takes an additional input flag argument indicating degrees vs.
 % radians. The additional argument can be created and added either
 % in the CRL table definition file that instantiates this class, or
 % here in the class definition, as follows:
 createAndAddImplementationArg(ent, 'RTW.TflArgNumericConstant', ...
 'Name', 'u2', ...
 'IsSigned', true, ...
 'WordLength', 32, ...
 'FractionLength', 0, ...
 'Value', 1);
end
end
end
end

```

Exit the class folder and return to the previous working folder.

- 3 Create and save the following code replacement table definition file, `crl_table_custom_sinfcn_double.m`. This file defines a code replacement table that contains a function table entry for sine with **double** input and output. This entry instantiates the derived class from the previous step, `TflCustomFunctionEntry`.

```

function hTable = crl_table_custom_sinfcn_double

hTable = RTW.TflTable;

%% Add TflCustomFunctionEntry
fcn_entry = TflCustomFunctionEntry;
setTflCFunctionEntryParameters(fcn_entry, ...
 'Key', 'sin', ...
 'Priority', 30, ...
 'ImplementationName', 'mySin', ...
 'ImplementationHeaderFile', 'mySin.h', ...
 'ImplementationSourceFile', 'mySin.c');

```

```

createAndAddConceptualArg(fcn_entry, 'RTW.Tf1ArgNumeric', ...
 'Name', 'y1', ...
 'IOType', 'RTW_IO_OUTPUT', ...
 'DataTypeMode', 'double');

createAndAddConceptualArg(fcn_entry, 'RTW.Tf1ArgNumeric', ...
 'Name', 'u1', ...
 'IOType', 'RTW_IO_INPUT', ...
 'DataTypeMode', 'double');

% Tf1CustomFunctionEntry class do_match method will create and add
% an implementation function argument during code generation if
% the supported integer size on the current target is 32 bits.
copyConceptualArgsToImplementation(fcn_entry);

addEntry(hTable, fcn_entry);

```

#### 4 Check the validity of the code replacement table entry.

- At the command prompt, invoke the table definition file.

```
tbl = crl_table_custom_sinfcn_double
```

- In the Code Replacement Viewer, view the table definition file.

```
crviewer(crl_table_custom_sinfcn_double)
```

## Customize Code Match and Replacement for Nonscalar Operations

This example shows how to create custom code replacement entries that add logic to the code match and replacement process for a nonscalar operation. Custom entries specify additional match criteria or modify the replacement function signature to meet application needs.

This example restricts the match criteria for an element-wise multiplication replacement to entries with a specific dimension range. When a match occurs, the custom `do_match` method modifies the replacement signature to pass the number of elements into the function.

Files for developing and testing this code replacement library example are available in `matlab/help/toolbox/ecoder/examples/code_replacement/custom_lemmult`:

- `do_match` method — `@MyElemMultEntry/MyElemMultEntry.m`
- Replacement function source and header files — `src/myMulImplLib.c` and `src/myMulImplLib.h`
- Model — `myElemMul.slx`

- Code replacement table definition — `myElemMultCr1Table.m`
- Registration file — `rtwTargetInfo.m`

To create custom code replacement entries that add logic to the code replacement match and replacement process:

- 1 Create a class, for example `MyElemMultEntry`, which is derived from the base class `RTW.Tf1COperationEntryML`. The derived class defines a `do_match` method with the following signature:

```
function ent = do_match(hThis, ...
 hCSO, ...
 targetBitPerChar, ...
 targetBitPerShort, ...
 targetBitPerInt, ...
 targetBitPerLong, ...
 targetBitPerLongLong)
```

In the `do_match` signature:

- `ent` is the return handle, which is returned as empty (indicating that the match failed) or as a `Tf1COperationEntry` handle.
- `hThis` is the handle to the derived instance.
- `hCSO` is a handle to an object that the code generator creates for querying the library for a replacement.
- Remaining arguments are the number of bits for various data types of the current target.

The `do_match` method:

- Adds match criteria that the base class does not provide.
- Makes changes to the implementation signature.

The `do_match` method relies on the base class for checking data types and dimension ranges. If the code generator finds a match, `do_match`:

- Sets the return handle.
- Uses the conceptual arguments to compute the number of elements in the array. In the replacement entry returned, sets the value of the constant implementation argument as the number of elements of the array.

- Updates the code replacement entry such that it matches CSOs that have the same argument dimensions.

```

classdef MyElemMulyEntry < RTW.Tf1COperationEntryML
 methods
 function obj = MyElemMultEntry(varargin)
 mlock;
 obj@RTW.Tf1COperationEntryML(varargin{:});
 end

 function ent = do_match(hThis, ...
 hCSO, ... %#ok
 targetBitPerChar, ... %#ok
 targetBitPerShort, ... %#ok
 targetBitPerInt, ... %#ok
 targetBitPerLong, ... %#ok
 targetBitPerLongLong) %#ok

 % Fourth implementation arg represents number of elements for producing matches.
 assert(strcmp(hThis.Implementation.Arguments(4).Name,'numElements'));

 ent = RTW.Tf1COperationEntry(hThis);

 % Calculate number of elements and set value of injected constant.
 ent.Implementation.Arguments(4).Value = prod(hCSO.ConceptualArgs(1).DimRange(1,:));

 % Since implementation has been modified for specific DimRange, update
 % returned entry to match similar CSOs only.
 for idx =1:3
 ent.ConceptualArgs(idx).DimRange = hCSO.ConceptualArgs(idx).DimRange;
 end
 end
 end
end
end

```

- 2 Create and save the following code replacement table definition file, `myElemMultCr1Table.m`. This file defines a code replacement table that contains an operator entry generator for element-wise multiplication. The table entry:

- Instantiates the derived class `myElemMultEntry` from the previous step.
- Sets operator entry parameters with the call to the `setTf1COperationEntryParameters` function.
- Creates conceptual arguments `y1`, `u1`, and `u2`. The argument class `RTW.Tf1ArgMatrix` specifies matrix arguments to match. The three arguments are set up to match 2-dimensional matrices with at least two elements in each dimension.

- Calls the `getTf1ArgFromString` function to create a return value and four implementation arguments. Arguments `u1` and `u2` are the operands, `y1` is the product, and the fourth argument is the number of elements.

Alternatively, the `do_match` method of the derived class `myElemMultEntry` can create and add the implementation arguments. When the number of additional implementation arguments required can vary based on compile-time information, use the alternative approach.

- Calls `addEntry` to add the entry to a code replacement table.

```
function hLib = myElemMultCr1Table

libPath = fullfile(fileparts(which(mfilename)), 'src');

hLib = RTW.Tf1Table;
%----- entry: RTW_OP_ELEM_MUL -----
hEnt = MyElemMultEntry;
hEnt.setTf1COperationEntryParameters(...
 'Key', 'RTW_OP_ELEM_MUL', ...
 'Priority', 100, ...
 'SaturationMode', 'RTW_WRAP_ON_OVERFLOW', ...
 'ImplementationName', 'myElemMul_s32', ...
 'ImplementationSourceFile', 'myMulImplLib.c', ...
 'ImplementationSourcePath', libPath, ...
 'ImplementationHeaderFile', 'myMulImplLib.h', ...
 'ImplementationHeaderPath', libPath, ...
 'SideEffects', true, ...
 'GenCallback', 'RTW.copyFileToBuildDir');

% Conceptual Args

arg = RTW.Tf1ArgMatrix('y1', 'RTW_IO_OUTPUT', 'int32');
arg.DimRange = [2 2; Inf Inf];
hEnt.addConceptualArg(arg);

arg = RTW.Tf1ArgMatrix('u1', 'RTW_IO_INPUT', 'int32');
arg.DimRange = [2 2; Inf Inf];
hEnt.addConceptualArg(arg);

arg = RTW.Tf1ArgMatrix('u2', 'RTW_IO_INPUT', 'int32');
arg.DimRange = [2 2; Inf Inf];
hEnt.addConceptualArg(arg);
```

```

% Implementation Args

arg = hEnt.getTf1ArgFromString('unused','void');
arg.IOType = 'RTW_IO_OUTPUT';
hEnt.Implementation.setReturn(arg);

arg = hEnt.getTf1ArgFromString('u1','int32*');
hEnt.Implementation.addArgument(arg);

arg = hEnt.getTf1ArgFromString('u2','int32*');
hEnt.Implementation.addArgument(arg);

arg = hEnt.getTf1ArgFromString('y1','int32*');
arg.IOType = 'RTW_IO_OUTPUT';
hEnt.Implementation.addArgument(arg);

arg = hEnt.getTf1ArgFromString('numElements','uint32',0);
hEnt.Implementation.addArgument(arg);

hLib.addEntry(hEnt);

```

### 3 Check the validity of the code replacement table entry.

- At the command prompt, invoke the table definition file.

```
tbl = myElemMultCr1Table
```

- In the Code Replacement Viewer, view the table definition file.

```
crviewer(myElemMultCr1Table)
```

## Customize Code Match and Replacement for Scalar Operations

This example shows how to create custom code replacement entries that add logic to the code match and replacement process for a scalar operation. Custom entries specify additional match criteria or modify the replacement function signature to meet application needs.

For example:

- When fraction lengths are within a specific range, replace an operator with a fixed-point implementation function.
- When a match occurs, modify the replacement function signature based on compile-time information, such as passing fraction-length values into the function.

This example modifies a fixed-point addition replacement such that the implementation function passes in the fraction lengths of the input and output data types as arguments.

To create custom code replacement entries that add logic to the code replacement match and replacement process:

- 1 Create a class, for example `Tf1CustomOperationEntry`, that is derived from the base class `RTW.Tf1COperationEntryML`. The derived class defines a `do_match` method with the following signature:

```
function ent = do_match(hThis, ...
 hCSO, ...
 targetBitPerChar, ...
 targetBitPerShort, ...
 targetBitPerInt, ...
 targetBitPerLong, ...
 targetBitPerLongLong)
```

In the `do_match` signature:

- `ent` is the return handle, which is returned as empty (indicating that the match failed) or as a `Tf1COperationEntry` handle.
- `hThis` is the handle to the class instance.
- `hCSO` is a handle to an object that the code generator creates for querying the library for a replacement.
- Remaining arguments are the number of bits for various data types of the current target.

The `do_match` method adds match criteria that the base class does not provide. The method makes modifications to the implementation signature. In this case, the `do_match` method relies on the base class for checking word size and signedness. `do_match` must match only the number of conceptual arguments to the value 3 (two inputs and one output) and the bias for each argument to value 0. If the code generator finds a match, `do_match`:

- Sets the return handle.
- Removes slope and bias wild cards from the conceptual arguments (the match is for specific slope and bias values).
- Writes fraction-length values for the inputs and output into replacement function arguments 3, 4, and 5.

You can create and add three additional implementation function arguments for passing fraction lengths in the class definition or in each code replacement entry definition that instantiates this class. This example creates the arguments, adds them to a code replacement table definition file, and sets them to specific values in the class definition code.

```

classdef TflCustomOperationEntry < RTW.TflCOperationEntryML
 methods
 function ent = do_match(hThis, ...
 hCSO, ... %#ok
 targetBitPerChar, ... %#ok
 targetBitPerShort, ... %#ok
 targetBitPerInt, ... %#ok
 targetBitPerLong, ... %#ok
 targetBitPerLongLong) %#ok

 % DO_MATCH - Create a custom match function. The base class
 % checks the types of the arguments prior to calling this
 % method. This class will check additional data and can
 % modify the implementation function.

 % The base class checks word size and signedness. Slopes and biases
 % have been wildcarded, so the only additional checking to do is
 % to check that the biases are zero and that there are only three
 % conceptual arguments (one output, two inputs)

 ent = []; % default the return to empty, indicating the match failed

 if length(hCSO.ConceptualArgs) == 3 && ...
 hCSO.ConceptualArgs(1).Type.Bias == 0 && ...
 hCSO.ConceptualArgs(2).Type.Bias == 0 && ...
 hCSO.ConceptualArgs(3).Type.Bias == 0

 % Modify the default implementation. Since this is a
 % generator entry, a concrete entry is created using this entry
 % as a template. The type of entry being created is a standard
 % TflCOperationEntry. Using the standard operation entry
 % provides required information, and you do not need
 % a custom match function.
 ent = RTW.TflCOperationEntry(hThis);

 % Since this entry is modifying the implementation for specific
 % fraction-length values (arguments 3, 4, and 5), the conceptual argument
 % wild cards must be removed (the wildcards were inherited from the
 % generator when it was used as a template for the concrete entry).
 % This concrete entry is now for a specific slope and bias.
 % hCSO holds the slope and bias values (created by the code generator).
 for idx=1:3
 ent.ConceptualArgs(idx).CheckSlope = true;
 ent.ConceptualArgs(idx).CheckBias = true;

 % Set the specific Slope and Biases

```

```

 ent.ConceptualArgs(idx).Type.Slope = hCSO.ConceptualArgs(idx).Type.Slope;
 ent.ConceptualArgs(idx).Type.Bias = 0;
 end

 % Set the fraction-length values in the implementation function.
 ent.Implementation.Arguments(3).Value = ...
 -1.0*hCSO.ConceptualArgs(2).Type.FixedExponent;
 ent.Implementation.Arguments(4).Value = ...
 -1.0*hCSO.ConceptualArgs(3).Type.FixedExponent;
 ent.Implementation.Arguments(5).Value = ...
 -1.0*hCSO.ConceptualArgs(1).Type.FixedExponent;
end
end
end
end

```

Exit the class folder and return to the previous working folder.

- 2 Create and save the following code replacement table definition file, `crl_table_custom_sinfcn_double.m`. This file defines a code replacement table that contains a single operator entry, an entry generator for unsigned 32-bit fixed-point addition operations, with arbitrary fraction-length values on the inputs and the output. The table entry:

- Instantiates the derived class `Tf1CustomOperationEntry` from the previous step. If you want to replace word sizes and signedness attributes, you can use the same derived class, but not the same entry, because you cannot use a wild card with the `WordLength` and `IsSigned` arguments. For example, to support `uint8`, `int8`, `uint16`, `int16`, and `int32`, add five other distinct entries. To use different implementation functions for saturation and rounding modes other than overflow and round to floor, add entries for those match permutations.
- Sets operator entry parameters with the call to the `setTf1COperationEntryParameters` function.
- Calls the `createAndAddConceptualArg` function to create conceptual arguments `y1`, `u1`, and `u2`.
- Calls `createAndSetCImplementationReturn` and `createAndAddImplementationArg` to define the signature for the replacement function. Three of the calls to `createAndAddImplementationArg` create implementation arguments to hold the fraction-length values for the inputs and output. Alternatively, the entry can omit those argument definitions. Instead, the `do_match` method of the derived class `Tf1CustomOperationEntry` can create and add the three implementation arguments. When the number of additional implementation arguments required can vary based on compile-time information, use the alternative approach.

- Calls `addEntry` to add the entry to a code replacement table.

```
function hTable = crl_table_custom_add_ufix32

hTable = RTW.Tf1Table;

%% Add Tf1CustomOperationEntry
op_entry = Tf1CustomOperationEntry;

setTf1CoperationEntryParameters(op_entry, ...
 'Key', 'RTW_OP_ADD', ...
 'Priority', 30, ...
 'SaturationMode', 'RTW_SATURATE_ON_OVERFLOW', ...
 'RoundingModes', {'RTW_ROUND_FLOOR'}, ...
 'ImplementationName', 'myFixptAdd', ...
 'ImplementationHeaderFile', 'myFixptAdd.h', ...
 'ImplementationSourceFile', 'myFixptAdd.c');

createAndAddConceptualArg(op_entry, 'RTW.Tf1ArgNumeric', ...
 'Name', 'y1', ...
 'IOType', 'RTW_IO_OUTPUT', ...
 'CheckSlope', false, ...
 'CheckBias', false, ...
 'DataType', 'Fixed', ...
 'Scaling', 'BinaryPoint', ...
 'IsSigned', false, ...
 'WordLength', 32);

createAndAddConceptualArg(op_entry, 'RTW.Tf1ArgNumeric', ...
 'Name', 'u1', ...
 'IOType', 'RTW_IO_INPUT', ...
 'CheckSlope', false, ...
 'CheckBias', false, ...
 'DataType', 'Fixed', ...
 'Scaling', 'BinaryPoint', ...
 'IsSigned', false, ...
 'WordLength', 32);

createAndAddConceptualArg(op_entry, 'RTW.Tf1ArgNumeric', ...
 'Name', 'u2', ...
 'IOType', 'RTW_IO_INPUT', ...
 'CheckSlope', false, ...
 'CheckBias', false, ...
 'DataType', 'Fixed', ...
```

```
 'Scaling', 'BinaryPoint', ...
 'IsSigned', false, ...
 'WordLength', 32);

% Specify replacement function signature
createAndSetCImplementationReturn(op_entry, 'RTW.TflArgNumeric', ...
 'Name', 'y1', ...
 'IOType', 'RTW_IO_OUTPUT', ...
 'IsSigned', false, ...
 'WordLength', 32, ...
 'FractionLength', 0);

createAndAddImplementationArg(op_entry, 'RTW.TflArgNumeric', ...
 'Name', 'u1', ...
 'IOType', 'RTW_IO_INPUT', ...
 'IsSigned', false, ...
 'WordLength', 32, ...
 'FractionLength', 0);

createAndAddImplementationArg(op_entry, 'RTW.TflArgNumeric', ...
 'Name', 'u2', ...
 'IOType', 'RTW_IO_INPUT', ...
 'IsSigned', false, ...
 'WordLength', 32, ...
 'FractionLength', 0);

% Add 3 fraction-length args. Actual values are set during code generation.
createAndAddImplementationArg(op_entry, 'RTW.TflArgNumericConstant', ...
 'Name', 'fl_in1', ...
 'IOType', 'RTW_IO_INPUT', ...
 'IsSigned', false, ...
 'WordLength', 32, ...
 'FractionLength', 0, ...
 'Value', 0);

createAndAddImplementationArg(op_entry, 'RTW.TflArgNumericConstant', ...
 'Name', 'fl_in2', ...
 'IOType', 'RTW_IO_INPUT', ...
 'IsSigned', false, ...
 'WordLength', 32, ...
 'FractionLength', 0, ...
 'Value', 0);

createAndAddImplementationArg(op_entry, 'RTW.TflArgNumericConstant', ...
```

```
'Name', 'fl_out', ...
'IOType', 'RTW_IO_INPUT', ...
'IsSigned', false, ...
'WordLength', 32, ...
'FractionLength', 0, ...
'Value', 0);
```

```
addEntry(hTable, op_entry);
```

### 3 Check the validity of the operator entry.

- At the command prompt, invoke the table definition file.

```
tbl = crl_table_custom_sinfcn_double
```

- In the Code Replacement Viewer, view the table definition file.

```
crviewer(crl_table_custom_sinfcn_double)
```

## Scalar Operator Code Replacement

This example shows how to define a code replacement mapping for a scalar operator. The example defines a mapping for the + (addition) operator programmatically. Alternatively, you can use the Code Replacement Tool to define the same mapping.

- 1 Create a table definition file that contains a function definition. For example:

```
function hTable = crl_table_add_uint8
```

- 2 Within the function body, create the table by calling the function `RTW.Tf1Table`.

```
hTable = RTW.Tf1Table;
```

- 3 Create an entry for the operator mapping with a call to the `RTW.Tf1COperationEntry` function.

```
% Create operation entry
op_entry = RTW.Tf1COperationEntry;
```

- 4 Set function entry parameters with a call to the `setTf1COperationEntryParameters` function.

```
% Define addition operation of built-in uint8 data type
% Saturation on, Rounding unspecified
setTf1COperationEntryParameters(op_entry, ...
 'Key', 'RTW_OP_ADD', ...
 'Priority', 90, ...
 'SaturationMode', 'RTW_SATURATE_ON_OVERFLOW', ...
 'RoundingModes', {'RTW_ROUND_UNSPECIFIED'}, ...
 'ImplementationName', 'u8_add_u8_u8', ...
 'ImplementationHeaderFile', 'u8_add_u8_u8.h', ...
 'ImplementationSourceFile', 'u8_add_u8_u8.c');
```

- 5 Create conceptual arguments `y1`, `u1`, and `u2`. There are multiple ways to set up the conceptual arguments. This example uses calls to the `getTf1ArgFromString` and `addConceptualArg` functions to create and add the arguments.

```
arg = getTf1ArgFromString(hTable, 'y1', 'uint8');
arg.IOType = 'RTW_IO_OUTPUT';
addConceptualArg(op_entry, arg);
```

```
arg = getTf1ArgFromString(hTable, 'u1', 'uint8');
addConceptualArg(op_entry, arg);
```

```
arg = getTf1ArgFromString(hTable, 'u2', 'uint8');
addConceptualArg(op_entry, arg);
```

- 6 Copy the conceptual arguments to the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses a call

to the `copyConceptualArgsToImplementation` function to create and add implementation arguments to the entry by copying matching conceptual arguments.

```
copyConceptualArgsToImplementation(op_entry);
```

- 7 Add the entry to a code replacement table with a call to the `addEntry` function.

```
addEntry(hTable, op_entry);
```

- 8 Save the table definition file. Use the name of the table definition function to name the file.

To test this example:

- 1 Register the code replacement mapping.
- 2 Create a model that includes an Add block, such as this model.

- 3 Configure the model with the following settings:
  - On the **Solver** pane, select a fixed-step solver.
  - On the **Code Generation** pane, select an ERT-based system target file.
  - On the **Code Generation > Interface** pane, select the code replacement library that contains your addition operation entry.
- 4 Generate code and a code generation report.
- 5 Review the code replacements.

## Addition and Subtraction Operator Code Replacement

Consider the following when defining mappings for addition and subtraction operator code replacements.

### Algorithm Options

When creating a code replacement table entry for an addition or subtraction operator, first determine the type of algorithm that your library function implements.

- **Cast-before-operation (CBO)**, default — Prior to performing the addition or subtraction operation, the algorithm type casts input values to the output type. If the output data type cannot exactly represent the input values, losses can occur as a result of the cast to the output type. Additional loss can occur when the result of the operation is cast to the final output type.

- **Cast-after-operation (CAO)** — The algorithm computes the ideal result of the addition or subtraction operation of the two inputs. The algorithm then type casts the result to the output data type. Loss occurs during the type cast. This algorithm behaves similarly to the C language except when the signedness of the operands does not match. For example, when you add a signed long operand to an unsigned long operand, standard C language rules convert the signed long operand to an unsigned long operand. The result is a value that is not ideal.

### Interactive Specification with Code Replacement Tool

When you use the Code Replacement Tool to create a code replacement table entry for an addition or subtraction operation, the tool displays an **Algorithm** menu. Use that menu to specify the **Cast before operation** or **Cast after operation** algorithm for that entry.

## Programmatic Specification

Create a code replacement table file, as a MATLAB function, that describes the addition or subtraction code replacement table entry. In the call to `setTf1COperationEntryParameters`, set at least these parameters:

- `Key` to `RTW_OP_ADD` or `RTW_OP_MINUS`
- `ImplementationName` to the name of your replacement function
- `EntryInfoAlgorithm` to `RTW_CAST_BFORE_OP` (cast-before-operation) or `RTW_CAST_AFTER_OP` (cast-after-operation)

This example sets parameters for a code replacement operator entry for a cast-after-operation implementation of a `uint8` addition.

```
op_entry = RTW.Tf1COperationEntry;
setTf1COperationEntryParameters(op_entry, ...
 'Key', 'RTW_OP_ADD', ...
 'EntryInfoAlgorithm', 'RTW_CAST_AFTER_OP', ...
 'ImplementationName', 'u8_add_u8_u8');
```

For more information, see `setTf1COperationEntryParameters`.

## Algorithm Classification

During code generation, the code generator examines addition and subtraction operations, including adjacent type cast operations, to determine the type of algorithm to compute the expression result. Based on the data types in the expression and the type of the accumulator (type used to hold the result of the addition or subtraction operation), the code generator uses these rules.

- Floating-point types only

Input 1 Data Type	Input 2 Data Type	Accumulator Data Type	Output Data Type	Classification
double	double	double	double	CBO, CAO
double	double	double	single	—
double	double	single	double	—
double	double	single	single	CBO
double	single	double	double	CBO, CAO

Input 1 Data Type	Input 2 Data Type	Accumulator Data Type	Output Data Type	Classification
double	single	double	single	—
double	single	single	double	—
double	single	single	single	CBO
single	single	single	single	CBO, CAO
single	single	single	double	—
single	single	double	single	—
single	single	double	double	CBO, CAO

- Floating-point and fixed-point types on the immediate addition or subtraction operation

Algorithm	Conditions
CBO	One of the following is true: <ul style="list-style-type: none"> <li>• Operation type is <b>double</b>.</li> <li>• Operation type is <b>single</b> and input types are <b>single</b> or <b>fixed-point</b>.</li> </ul>
CAO	Operation type is a superset of input types—that is, output type can represent values of input types without loss of data.

- Fixed-point types only

Algorithm	Conditions
CBO	At least one of the following is true: <ul style="list-style-type: none"> <li>• Accumulator type equals output type (<math>T_{acc} == T_{out}</math>).</li> <li>• Output type is a superset of input types (<math>T_{acc} \geq \{T_{in1}, T_{in2}\}</math>) and accumulator type is a superset of output type (<math>T_{acc} \geq T_{out}</math>).</li> <li>• Operation does not incur range or precision loss.</li> </ul>
CAO	Net bias is zero and the data types in the expression have equal slope adjustment factors. For more information on net bias, see “Addition” or “Subtraction” in “Fixed-Point Operator Code Replacement” on page 52-132 (for MATLAB code) or “Fixed-Point Operator Code Replacement” on page 51-195 (for Simulink models).

In many cases, the numerical result of a CBO operation is equal to that of a CAO operation. For example, if the input and output types are such that the operation produces the ideal result, as in the case of `int8 + int8 -> int16`. To maximize the probability of code replacement occurring in such cases, set the algorithm to cast-after-operation.

## Limitations

- The code generator does not replace operations with nonzero net bias.
- When classifying an operation as a CAO operation, the code generator includes the adjacent casts in the expression when the expression involves only fixed-point types. Otherwise, the code generator classifies and replaces only the immediate addition or subtraction operation. Casts that the code generator excludes from the classification appear in the generated code.
- To enable the code generator to include multiple cast operations, which follow an addition or subtraction of fixed-point data, in the classification of an expression, the rounding mode must be `simplest` or `floor`. Consider the expression `y=(cast A)(cast B)(u1+u2)`. If the rounding mode of `(cast A)`, `(cast B)`, and the addition operator (+) are set to `simplest` or `floor`, the code generator takes into account `(cast A)` and `(cast B)` when classifying the expression and performing the replacement only.

## Small Matrix Operation to Processor Code Replacement

This example shows how to define code replacement mappings that replace nonscalar small matrix operations with processor-specific intrinsic functions. The example defines a table containing two matrix operator replacement entries for the + (addition) operator and the `double` data type. The example defines the function mapping programmatically. Alternatively, you can use the Code Replacement Tool to define the same mapping.

- 1 Create a table definition file that contains a function definition. For example:

```
function hTable = crl_table_matrix_add_double
```

- 2 Within the function body, create the table by calling the function `RTW.Tf1Table`.

```
hTable = RTW.Tf1Table;
```

- 3 Create the entry for the first operator mapping with a call to the `RTW.Tf1COperationEntry` function.

```
% Create table entry for matrix_sum_2x2_double
op_entry = RTW.Tf1COperationEntry;
```

- 4 Set operator entry parameters with a call to the `setTf1COperationEntryParameters` function. The code generator ignores saturation and rounding modes for floating-point nonscalar addition and subtraction. For code replacement entries for nonscalar addition and subtraction operations that do not involve fixed-point data, in the call to `setTf1COperationEntryParameters`, specify `'RTW_SATURATE_UNSPECIFIED'` for the `SaturationMode` property and `{'RTW_ROUND_UNSPECIFIED'}` for `RoundingModes`.

```
setTf1COperationEntryParameters(op_entry, ...
 'Key', 'RTW_OP_ADD', ...
 'Priority', 30, ...
 'SaturationMode', 'RTW_WRAP_ON_OVERFLOW', ...
 'ImplementationName', 'matrix_sum_2x2_double', ...
 'ImplementationHeaderFile', 'MatrixMath.h', ...
 'ImplementationSourceFile', 'MatrixMath.c', ...
 'ImplementationHeaderPath', LibPath, ...
 'ImplementationSourcePath', LibPath, ...
 'AdditionalIncludePaths', {LibPath}, ...
 'GenCallback', 'RTW.copyFileToBuildDir', ...
 'SideEffects', true);
```

- 5 Create conceptual arguments `y1`, `u1`, and `u2`. There are multiple ways to set up the conceptual arguments. This example uses calls to the `createAndAddConceptualArg` function to create and add an argument with one function call. To specify a matrix argument in the function call, use the argument

class `RTW.Tf1ArgMatrix`. Specify the base type and the dimensions for which the argument is valid. The first table entry specifies `[2 2]` and the second table entry specifies `[3 3]`.

```
% Specify operands and result
createAndAddConceptualArg(op_entry, 'RTW.Tf1ArgMatrix', ...
 'Name', 'y1', ...
 'IOType', 'RTW_IO_OUTPUT', ...
 'BaseType', 'double', ...
 'DimRange', [2 2]);
createAndAddConceptualArg(op_entry, 'RTW.Tf1ArgMatrix',...
 'Name', 'u1', ...
 'BaseType', 'double', ...
 'DimRange', [2 2]);
createAndAddConceptualArg(op_entry, 'RTW.Tf1ArgMatrix',...
 'Name', 'u2', ...
 'BaseType', 'double', ...
 'DimRange', [2 2]);
```

- 6 Create the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses calls to the `getTf1ArgFromString` to create the arguments. The convenience methods `setReturn` and `addArgument` specify whether an argument is a return value or argument and adds the argument to the entry's array of implementation arguments.

```
arg = getTf1ArgFromString(hTable, 'y2', 'void');
arg.IOType = 'RTW_IO_OUTPUT';
op_entry.Implementation.setReturn(arg);

arg = getTf1ArgFromString(hTable, 'u1', ['double' '*']);
op_entry.Implementation.addArgument(arg);

arg = getTf1ArgFromString(hTable, 'u2', ['double' '*']);
op_entry.Implementation.addArgument(arg);

arg = getTf1ArgFromString(hTable, 'y1', ['double' '*']);
arg.IOType = 'RTW_IO_OUTPUT';
op_entry.Implementation.addArgument(arg);
```

- 7 Add the entry to a code replacement table with a call to the `addEntry` function.

```
addEntry(hTable, op_entry);
```

- 8 Create the entry for the second operator mapping.

```
% Create table entry for matrix_sum_3x3_double
op_entry = RTW.Tf1COperationEntry;
setTf1COperationEntryParameters(op_entry, ...
 'Key', 'RTW_OP_ADD', ...
 'Priority', 30, ...
 'SaturationMode', 'RTW_WRAP_ON_OVERFLOW', ...
 'ImplementationName', 'matrix_sum_3x3_double', ...
```

```

 'ImplementationHeaderFile', 'MatrixMath.h', ...
 'ImplementationSourceFile', 'MatrixMath.c', ...
 'ImplementationHeaderPath', LibPath, ...
 'ImplementationSourcePath', LibPath, ...
 'AdditionalIncludePaths', {LibPath}, ...
 'GenCallback', 'RTW.copyFileToBuildDir', ...
 'SideEffects', true);

% Specify operands and result
createAndAddConceptualArg(op_entry, 'RTW.Tf1ArgMatrix', ...
 'Name', 'y1', ...
 'IOType', 'RTW_IO_OUTPUT', ...
 'BaseType', 'double', ...
 'DimRange', [3 3]);
createAndAddConceptualArg(op_entry, 'RTW.Tf1ArgMatrix',...
 'Name', 'u1', ...
 'BaseType', 'double', ...
 'DimRange', [3 3]);
createAndAddConceptualArg(op_entry, 'RTW.Tf1ArgMatrix',...
 'Name', 'u2', ...
 'BaseType', 'double', ...
 'DimRange', [3 3]);

% Specify replacement function signature
arg = getTf1ArgFromString(hTable, 'y2', 'void');
arg.IOType = 'RTW_IO_OUTPUT';
op_entry.Implementation.setReturn(arg);
arg = getTf1ArgFromString(hTable, 'u1', ['double' '*']);
op_entry.Implementation.addArgument(arg);
arg = getTf1ArgFromString(hTable, 'u2', ['double' '*']);
op_entry.Implementation.addArgument(arg);
arg = getTf1ArgFromString(hTable, 'y1', ['double' '*']);
arg.IOType = 'RTW_IO_OUTPUT';
op_entry.Implementation.addArgument(arg);

addEntry(hTable, op_entry);

```

- 9 Save the table definition file. Use the name of the table definition function to name the file.

To test this example:

- 1 Register the code replacement mapping.
- 2 Create a model that includes an Add block.

- 3 Configure the model with the following settings:
  - On the **Solver** pane, select a fixed-step, discrete solver with a fixed-step size such as 0.1.
  - On the **Code Generation** pane, select an ERT-based system target file.
  - On the **Code Generation > Interface** pane, select the code replacement library that contains your addition operation entry.
- 4 In the Model Explorer, configure the **Signal Attributes** for the In1 and In2 source blocks. For each source block, set **Port dimensions** to [3,3], and set **Data type** to **double**. Apply the changes. Save the model.
- 5 Generate code and a code generation report.
- 6 Review the code replacements. The code generator replaces the + operator with `matrix_sum_3x3_double` in the generated code.
- 7 Reconfigure **Port dimensions** for In1 and In2 to [2 2], regenerate code. Observe that code containing the + operator is replaced with `matrix_sum_2x2_double`.

## Matrix Multiplication Operation to MathWorks BLAS Code Replacement

This example shows how to define code replacement mappings that replace nonscalar multiplication operations with Basic Linear Algebra Subroutine (BLAS) multiplication functions `xgemm` and `xgemv`. The example defines code replacement entries that map floating-point matrix/matrix and matrix/vector multiplication operations to MathWorks BLAS library multiplication functions `dgemm` and `dgemv`. The example defines the function mappings programmatically. Alternatively, you can use the Code Replacement Tool to define the same mappings.

BLAS libraries support matrix/matrix multiplication in the form of

$$C = a(\text{op}(A) * \text{op}(B)) + bC. \text{ op}(X) \text{ means } X, \text{ transposition of } X, \text{ or Hermitian}$$

transposition of  $X$ . However, code replacement libraries support only the limited case of

$$C = \text{op}(A) * \text{op}(B) \text{ (} a = 1.0, b = 0.0 \text{)}. \text{ Correspondingly, although BLAS libraries support}$$

matrix/vector multiplication in the form of  $y = a(\text{op}(A) * x) + by$ , code replacement

libraries support only the limited case of  $y = \text{op}(A) * x$  ( $a = 1.0, b = 0.0$ ).

- 1 Create a table definition file that contains a function definition. For example:

```
function hTable = crl_table_tmwblas_mmult_double
```

- 2 Within the function body, create the table by calling the function `RTW.Tf1Table`.

```
hTable = RTW.Tf1Table;
```

- 3 Define the path for the BLAS function library. If your replacement functions are on the MATLAB search path or are in your working folder, you can skip this step.

```
% Define library path for Windows or UNIX
arch = computer('arch');
if ~ispc
 LibPath = fullfile('$MATLAB_ROOT', 'bin', arch);
else
 % Use Stateflow to get the compiler info
 compilerInfo = sf('Private','compilerman','get_compiler_info');
 compilerName = compilerInfo.compilerName;
 if strcmp(compilerName, 'msvc90') || ...
 strcmp(compilerName, 'msvc80') || ...
 strcmp(compilerName, 'msvc71') || ...
 strcmp(compilerName, 'msvc60'), ...
 compilerName = 'microsoft';
end
LibPath = fullfile('$MATLAB_ROOT', 'extern', 'lib', arch, compilerName);
end
```

- 4 Create an entry for the first mapping with a call to the `RTW.Tf1BlasEntryGenerator` function.

```
% Create table entry for dgemm32
op_entry = RTW.Tf1BlasEntryGenerator;
```

- 5 Set operator entry parameters with a call to the `setTf1CFunctionEntryParameters` function. The function call sets matrix multiplication operator entry properties. The code generator ignores saturation and rounding modes for floating-point nonscalar addition and subtraction. For code replacement entries for nonscalar addition and subtraction operations that do not involve fixed-point data, in the call to `setTf1CFunctionEntryParameters`, specify `'RTW_SATURATE_UNSPECIFIED'` for the `SaturationMode` property and `{'RTW_ROUND_UNSPECIFIED'}` for `RoundingModes`.

```
if ispc
 libExt = 'lib';
elseif ismac
 libExt = 'dylib';
else
 libExt = 'so';
end
setTf1COperationEntryParameters(op_entry, ...
 'Key', 'RTW_OP_MUL', ...
 'Priority', 100, ...
 'ImplementationName', 'dgemm32', ...
 'ImplementationHeaderFile', 'blascompat32_cr1.h', ...
 'ImplementationHeaderPath', fullfile('${MATLAB_ROOT}','extern','include'), ...
 'AdditionalLinkObjs', {'libmwblascompat32.' libExt}, ...
 'AdditionalLinkObjsPaths', {LibPath}, ...
 'SideEffects', true);
```

- 6 Create conceptual arguments `y1`, `u1`, and `u2`. There are multiple ways to set up the conceptual arguments. This example uses calls to the `createAndAddConceptualArg` function to create and add an argument with one function call. To specify a matrix argument in the function call, use the argument class `RTW.Tf1ArgMatrix` and specify the base type and the dimensions for which the argument is valid. This type of table entry supports a range of dimensions specified in the format `[Dim1Min Dim2Min ... DimNMin; Dim1Max Dim2Max ... DimNMax]`. For example, `[2 2; inf inf]` means a two-dimensional matrix of size 2x2 or larger. The conceptual output argument for the `dgemm32` entry for matrix/matrix multiplication replacement specifies dimensions `[2 2; inf inf]`, while the conceptual output argument for the `dgemv32` entry for matrix/vector multiplication replacement specifies dimensions `[2 1; inf 1]`.

```
% Specify operands and result
createAndAddConceptualArg(op_entry, 'RTW.Tf1ArgMatrix', ...
 'Name', 'y1', ...
```

```

 'IOType', 'RTW_IO_OUTPUT', ...
 'BaseType', 'double', ...
 'DimRange', [2 2; inf inf]);
createAndAddConceptualArg(op_entry, 'RTW.Tf1ArgMatrix', ...
 'Name', 'u1', ...
 'BaseType', 'double', ...
 'DimRange', [2 2; inf inf]);
createAndAddConceptualArg(op_entry, 'RTW.Tf1ArgMatrix', ...
 'Name', 'u2', ...
 'BaseType', 'double', ...
 'DimRange', [1 1; inf inf]);

```

- 7 Create the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses calls to the `getTf1ArgFromString` and `RTW.Tf1ArgCharConstant` functions to create the arguments. The example code configures special implementation arguments that are required for `dgemm` and `dgemv` function replacements. The convenience methods `setReturn` and `addArgument` specify whether an argument is a return value or argument and adds the argument to the entry's array of implementation arguments.

```

% Using RTW.Tf1BlasEntryGenerator for xgemv requires the following
% implementation signature:
%
% void f(char* TRANSA, char* TRANSB, int* M, int* N, int* K,
% type* ALPHA, type* u1, int* LDA, type* u2, int* LDB,
% type* BETA, type* y, int* LDC)
%
% When a match occurs, the code generator computes the
% values for M, N, K, LDA, LDB, and LDC and inserts them into the
% generated code. TRANSA and TRANSB are set to 'N'.

% Specify replacement function signature

arg = getTf1ArgFromString(hTable, 'y2', 'void');
arg.IOType = 'RTW_IO_OUTPUT';
op_entry.Implementation.setReturn(arg);

arg = RTW.Tf1ArgCharConstant('TRANSA');
% Possible values for PassByType property are
% RTW_PASSBY_AUTO, RTW_PASSBY_POINTER,
% RTW_PASSBY_VOID_POINTER, RTW_PASSBY_BASE_POINTER
arg.PassByType = 'RTW_PASSBY_POINTER';
op_entry.Implementation.addArgument(arg);

arg = RTW.Tf1ArgCharConstant('TRANSB');
arg.PassByType = 'RTW_PASSBY_POINTER';
op_entry.Implementation.addArgument(arg);

arg = getTf1ArgFromString(hTable, 'M', 'integer', 0);
arg.PassByType = 'RTW_PASSBY_POINTER';
arg.Type.ReadOnly = true;
op_entry.Implementation.addArgument(arg);

```

```

arg = getTf1ArgFromString(hTable, 'N', 'integer', 0);
arg.PassByType = 'RTW_PASSBY_POINTER';
arg.Type.ReadOnly = true;
op_entry.Implementation.addArgument(arg);

op_entry.Implementation.addArgument(arg);

addEntry(hTable, op_entry);

```

- 10** Save the table definition file. Use the name of the table definition function to name the file.

To test this example:

- 1 Register the code replacement mapping.
- 2 Create a model that includes two Product blocks.

- 3 For each Product block, set the block parameter **Multiplication** to the value **Matrix(\*)**.
- 4 Configure the model with the following settings:
  - On the **Solver** pane, select a fixed-step, discrete solver with a fixed-step size such as 0.1.
  - On the **Code Generation** pane, select an ERT-based system target file.
  - On the **Code Generation > Interface** pane, select the code replacement library that contains your addition operation entry.
- 5 In the Model Explorer, configure the **Signal Attributes** for the In1, In2, and In3 source blocks. For In1 and In2, set **Port dimensions** to [3 3] and set the **Data type** to double. For In3, set **Port dimensions** to [3 1] and set the **Data type** to double.
- 6 Generate code and a code generation report.
- 7 Review the code replacements.

## Matrix Multiplication Operation to ANSI/ISO C BLAS Code Replacement

This example shows how to define code replacement mappings that replace nonscalar multiplication operations with ANSI/ISO C BLAS multiplication functions `xgemm` and `xgemv`. The example defines code replacement entries that map floating-point matrix/matrix and matrix/vector multiplication operations to ANSI/ISO C BLAS library multiplication functions `dgemm` and `dgemv`. The example defines the function mappings programmatically. Alternatively, you can use the Code Replacement Tool to define the same mappings.

BLAS libraries support matrix/matrix multiplication in the form of  $C = a(\text{op}(A) * \text{op}(B)) + bC$ . `op(X)` means X, transposition of X, or Hermitian transposition of X. However, code replacement libraries support only the limited case of  $C = \text{op}(A) * \text{op}(B)$  ( $a = 1.0, b = 0.0$ ). Correspondingly, although BLAS libraries support matrix/vector multiplication in the form of  $y = a(\text{op}(A) * x) + by$ , code replacement libraries support only the limited case of  $y = \text{op}(A) * x$  ( $a = 1.0, b = 0.0$ ).

- 1 Create a table definition file that contains a function definition. For example:

```
function hTable = crl_table_cblas_mmult_double
```

- 2 Within the function body, create the table by calling the function `RTW.Tf1Table`.

```
hTable = RTW.Tf1Table;
```

- 3 Define the path for the CBLAS function library. For example:

```
LibPath = fullfile(matlabroot, 'toolbox', 'rtw', 'rtwdemos', 'crl_demo');
```

- 4 Create an entry for the first mapping with a call to the `RTW.Tf1BlasEntryGenerator` function.

```
% Create table entry for cblas_dgemm
op_entry = RTW.Tf1CBlasEntryGenerator;
```

- 5 Set operator entry parameters with a call to the `setTf1COperationEntryParameters` function. The function call sets matrix multiplication operator entry properties. The code generator ignores saturation and rounding modes for floating-point nonscalar addition and subtraction.

```
setTf1COperationEntryParameters(op_entry, ...
 'Key', 'RTW_OP_MUL', ...
```

```

'Priority', 100, ...
'ImplementationName', 'cblas_dgemm', ...
'ImplementationHeaderFile', 'cblas.h', ...
'ImplementationHeaderPath', LibPath, ...
'AdditionalIncludePaths', {LibPath}, ...
'GenCallback', 'RTW.copyFileToBuildDir', ...
'SideEffects', true);

```

- 6 Create conceptual arguments `y1`, `u1`, and `u2`. There are multiple ways to set up the conceptual arguments. This example uses calls to the `createAndAddConceptualArg` function to create and add an argument with one function call. To specify a matrix argument in the function call, use the argument class `RTW.Tf1ArgMatrix` and specify the base type and the dimensions for which the argument is valid. This type of table entry supports a range of dimensions specified in the format `[Dim1Min Dim2Min ... DimNMin; Dim1Max Dim2Max ... DimNMax]`. For example, `[2 2; inf inf]` means a two-dimensional matrix of size 2x2 or larger. The conceptual output argument for the `dgemm32` entry for matrix/matrix multiplication replacement specifies dimensions `[2 2; inf inf]`. The conceptual output argument for the `dgemv32` entry for matrix/vector multiplication replacement specifies dimensions `[2 1; inf 1]`.

```

% Specify operands and result
createAndAddConceptualArg(op_entry, 'RTW.Tf1ArgMatrix', ...
 'Name', 'y1', ...
 'IOType', 'RTW_IO_OUTPUT', ...
 'BaseType', 'double', ...
 'DimRange', [2 2; inf inf]);
createAndAddConceptualArg(op_entry, 'RTW.Tf1ArgMatrix', ...
 'Name', 'u1', ...
 'BaseType', 'double', ...
 'DimRange', [2 2; inf inf]);
createAndAddConceptualArg(op_entry, 'RTW.Tf1ArgMatrix', ...
 'Name', 'u2', ...
 'BaseType', 'double', ...
 'DimRange', [1 1; inf inf]);

```

- 7 Create the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses calls to the `getTf1ArgFromString` function to create the arguments. The example code configures special implementation arguments that are required for `dgemm` and `dgemv` function replacements. The convenience methods `setReturn` and `addArgument` specify whether an argument is a return value or argument and adds the argument to the entry's array of implementation arguments.

```

% Using RTW.Tf1CBlasEntryGenerator for xgemm requires the following
% implementation signature:
%
% void f(enum ORDER, enum TRANSA, enum TRANSB, int M, int N, int K,
% type ALPHA, type* u1, int LDA, type* u2, int LDB,

```

```
% type BETA, type* y, int LDC)
%
% Since CRLs do not have the ability to specify enums, you must
% use integer. (This will cause problems with C++ code generation,
% so for C++, use a wrapper function to cast each int to the
% corresponding enumeration type.)
%
% When a match occurs, the code generator computes the
% values for M, N, K, LDA, LDB, and LDC and insert them into the
% generated code.

% Specify replacement function signature

arg = getTf1ArgFromString(hTable, 'y2', 'void');
arg.IOType = 'RTW_IO_OUTPUT';
op_entry.Implementation.setReturn(arg);

arg = getTf1ArgFromString(hTable, 'ORDER', 'integer', 102);
% arg.Type.ReadOnly=true;
op_entry.Implementation.addArgument(arg);

arg = getTf1ArgFromString(hTable, 'TRANSA', 'integer', 111);
% arg.Type.ReadOnly=true;
op_entry.Implementation.addArgument(arg);

arg = getTf1ArgFromString(hTable, 'TRANSB', 'integer', 111);
% arg.Type.ReadOnly=true;
op_entry.Implementation.addArgument(arg);

arg = getTf1ArgFromString(hTable, 'M', 'integer', 0);
op_entry.Implementation.addArgument(arg);

arg = getTf1ArgFromString(hTable, 'N', 'integer', 0);
op_entry.Implementation.addArgument(arg);

arg = getTf1ArgFromString(hTable, 'K', 'integer', 0);
op_entry.Implementation.addArgument(arg);

arg = getTf1ArgFromString(hTable, 'ALPHA', 'double', 1);
op_entry.Implementation.addArgument(arg);

arg = getTf1ArgFromString(hTable, 'u1', ['double' '*']);
op_entry.Implementation.addArgument(arg);

arg = getTf1ArgFromString(hTable, 'LDA', 'integer', 0);
op_entry.Implementation.addArgument(arg);

arg = getTf1ArgFromString(hTable, 'u2', ['double' '*']);
op_entry.Implementation.addArgument(arg);

arg = getTf1ArgFromString(hTable, 'LDB', 'integer', 0);
op_entry.Implementation.addArgument(arg);

arg = getTf1ArgFromString(hTable, 'BETA', 'double', 0);
op_entry.Implementation.addArgument(arg);
```

```
arg = getTf1ArgFromString(hTable, 'y1', ['double' '*']);
arg.IOType = 'RTW_IO_OUTPUT';
op_entry.Implementation.addArgument(arg);
```

```
arg = getTf1ArgFromString(hTable, 'LDC', 'integer', 0);
op_entry.Implementation.addArgument(arg);
```

- 8 Add the entry to a code replacement table with a call to the addEntry function.

```
addEntry(hTable, op_entry);
```

- 9 Create the entry for the second mapping.

```
% Create table entry for cblas_dgemv
op_entry = RTW.Tf1CBlasEntryGenerator;
setTf1COperationEntryParameters(op_entry, ...
 'Key', 'RTW_OP_MUL', ...
 'Priority', 100, ...
 'ImplementationName', 'cblas_dgemv', ...
 'ImplementationHeaderFile', 'cblas.h', ...
 'ImplementationHeaderPath', LibPath, ...
 'AdditionalIncludePaths', {LibPath}, ...
 'GenCallback', 'RTW.copyFileToBuildDir', ...
 'SideEffects', true);

% Specify operands and result
createAndAddConceptualArg(op_entry, 'RTW.Tf1ArgMatrix', ...
 'Name', 'y1', ...
 'IOType', 'RTW_IO_OUTPUT', ...
 'BaseType', 'double', ...
 'DimRange', [2 1; inf 1]);
createAndAddConceptualArg(op_entry, 'RTW.Tf1ArgMatrix', ...
 'Name', 'u1', ...
 'BaseType', 'double', ...
 'DimRange', [2 2; inf inf]);
createAndAddConceptualArg(op_entry, 'RTW.Tf1ArgMatrix', ...
 'Name', 'u2', ...
 'BaseType', 'double', ...
 'DimRange', [1 1; inf 1]);

% Using RTW.Tf1CBlasEntryGenerator for xgemv requires the following
% implementation signature:
%
% void f(enum ORDER, enum TRANSA, int M, int N,
% type ALPHA, type* u1, int LDA, type* u2, int INCX,
% type BETA, type* y, int INCY)
%
% Since CRLs do not have the ability to specify enums, you must
% use integer. (This will cause problems with C++ code generation,
% so for C++, use a wrapper function to cast each int to the
% corresponding enumeration type.)
%
% Upon a match, the CRL entry will compute the
% values for M, N, LDA, INCX, and INCY and insert them into the
% generated code.
```

```
% Specify replacement function signature

arg = getTf1ArgFromString(hTable, 'y2', 'void');
arg.IOType = 'RTW_IO_OUTPUT';
op_entry.Implementation.setReturn(arg);

arg = getTf1ArgFromString(hTable, 'ORDER', 'integer', 102);
% arg.Type.ReadOnly=true;
op_entry.Implementation.addArgument(arg);

arg = getTf1ArgFromString(hTable, 'TRANSA', 'integer', 111);
% arg.Type.ReadOnly=true;

## Remap Operator Output to Function Input

If your generated code must meet a specific coding pattern or you want more flexibility, for example, to further improve performance, you can remap operator outputs to input positions in an implementation function argument list.

---

**Note:** Remapping outputs to implementation function inputs is supported only for operator replacement.

---

For example, for a sum operation, the code generator produces code similar to:

```
add8_Y.Out1 = u8_add_u8_u8(add8_U.In1, add8_U.In2);
```

If you remap the output to the first input, the code generator produces code similar to:

```
u8_add_u8_u8(&add8_Y.Out1;, add8_U.In1, add8_U.In2);
```

The following table definition file for a sum operation remaps operator output `y1` as the first function input argument.

- 1 Create a table definition file that contains a function definition. For example:
 

```
function hTable = crl_table_add_uint8
```
- 2 Within the function body, create the table by calling the function `RTW.Tf1Table`.
 

```
hTable = RTW.Tf1Table;
```
- 3 Create an entry for the operator mapping with a call to the `RTW.Tf1COperationEntry` function.
 

```
% Create operation entry
op_entry = RTW.Tf1COperationEntry;
```
- 4 Set operator entry parameters with a call to the `setTf1COperationEntryParameters` function. In the function call, set the property `SideEffects` to `true`.
 

```
setTf1COperationEntryParameters(op_entry, ...
 'Key', 'RTW_OP_ADD', ...
 'Priority', 90, ...
 'ImplementationName', 'u8_add_u8_u8', ...
 'ImplementationHeaderFile', 'u8_add_u8_u8.h', ...
 'ImplementationSourceFile', 'u8_add_u8_u8.c', ...
 'SideEffects', true);
```

- 5 Create conceptual arguments `y1`, `u1`, and `u2`. There are multiple ways to set up the conceptual arguments. This example uses calls to the `getTf1ArgFromString` and `addConceptualArg` functions to create and add the arguments.

```
arg = getTf1ArgFromString(hTable, 'y1', 'uint8');
arg.IOType = 'RTW_IO_OUTPUT';
addConceptualArg(op_entry, arg);
```

```
arg = getTf1ArgFromString(hTable, 'u1', 'uint8');
addConceptualArg(op_entry, arg);
```

```
arg = getTf1ArgFromString(hTable, 'u2', 'uint8');
addConceptualArg(op_entry, arg);
```

- 6 Create the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses calls to the `getTf1ArgFromString` function to create the arguments. When defining the implementation function return argument, create a new `void` output argument, for example, `y2`. When defining the implementation function argument for the conceptual output argument (`y1`), set the operator output argument as an additional input argument. Mark its `IOType` as output. Make its type a pointer type. The convenience methods `setReturn` and `addArgument` specify whether an argument is a return value or argument and adds the argument to the entry's array of implementation arguments.

```
% Create new void output y2
arg = getTf1ArgFromString(hTable, 'y2', 'void');
arg.IOType = 'RTW_IO_OUTPUT';
op_entry.Implementation.setReturn(arg);
```

```
% Set y1 as first input arg, mark IOType as output, and use pointer type
arg=getTf1ArgFromString(hTable, 'y1', 'uint8*');
arg.IOType = 'RTW_IO_OUTPUT';
op_entry.Implementation.addArgument(arg);
```

```
arg=getTf1ArgFromString(hTable, 'u1', 'uint8');
op_entry.Implementation.addArgument(arg);
```

```
arg=getTf1ArgFromString(hTable, 'u2', 'uint8');
op_entry.Implementation.addArgument(arg);
```

- 7 Add the entry to a code replacement table with a call to the `addEntry` function.

```
addEntry(hTable, op_entry);
```

- 8 Save the table definition file. Use the name of the table definition function to name the file.

To test this example:

- 1 Register the code replacement mapping.

- 2 Create a model that includes an Add block.

- 3 Configure the model with the following settings:
  - On the **Solver** pane, select a fixed-step solver.
  - On the **Code Generation** pane, select an ERT-based system target file.
  - On the **Code Generation > Interface** pane, select the code replacement library that contains your addition operation entry.
  - On the **All Parameters** tab, set the **Optimize global data access** parameter to **Use global to hold temporary results** to reduce data copies in the generated code.
- 4 Generate code and a code generation report.
- 5 Review the code replacements.

## Fixed-Point Operator Code Replacement

If you have a Fixed-Point Designer license, you can define fixed-point operator code replacement entries to match:

- A binary-point-only scaling combination on the operator inputs and output.
- A slope bias scaling combination on the operator inputs and output.
- Relative scaling or net slope between multiplication or division operator inputs and output. Use one of these methods to map a range of slope and bias values to a replacement function for multiplication or division.
- Equal slope and zero net bias across addition or subtraction operator inputs and output. Use this method to disregard specific slope and bias values and map relative slope and bias values to a replacement function for addition or subtraction.

### Common Ways to Match Fixed-Point Operator Entries

The following table maps common ways to match fixed-point operator code replacement entries with the associated fixed-point parameters that you specify in a code replacement table definition file.

Match	Create entry	Minimally specify parameters
A specific binary-point-only scaling combination on the operator inputs and output.	RTW.Tf1COperationEntry	createAndAddConceptualArg function: <ul style="list-style-type: none"> <li>• CheckSlope: Specify the value true.</li> <li>• CheckBias: Specify the value true.</li> <li>• DataTypeMode (or DataType/Scaling equivalent): Specify fixed-point binary-point-only scaling.</li> <li>• FractionLength: Specify a fraction length (for example, 3).</li> </ul>
A specific slope bias scaling combination on the operator inputs and output.	RTW.Tf1COperationEntry	createAndAddConceptualArg function:

Match	Create entry	Minimally specify parameters
		<ul style="list-style-type: none"> <li>• <b>CheckSlope</b>: Specify the value <code>true</code>.</li> <li>• <b>CheckBias</b>: Specify the value <code>true</code>.</li> <li>• <b>DataTypeMode</b> (or <b>DataType/Scaling</b> equivalent): Specify fixed-point [slope bias] scaling.</li> <li>• <b>Slope</b> (or <b>SlopeAdjustmentFactor/FixedExponent</b> equivalent): Specify a slope value (for example, <code>15</code>).</li> <li>• <b>Bias</b>: Specify a bias value (for example, <code>2</code>).</li> </ul>
<p>Net slope between operator inputs and output (multiplication and division).</p>	<p><code>RTW.Tf1COperationEntry-Generator_NetSlope</code></p>	<p><code>setTf1COperationEntryParameters</code> function:</p> <ul style="list-style-type: none"> <li>• <b>NetSlopeAdjustmentFactor</b>: Specify the slope adjustment factor (F) part of the net slope, <math>F2^E</math> (for example, <code>1.0</code>).</li> <li>• <b>NetFixedExponent</b>: Specify the fixed exponent (E) part of the net slope, <math>F2^E</math> (for example, <code>-3.0</code>).</li> </ul> <p><code>createAndAddConceptualArg</code> function:</p> <ul style="list-style-type: none"> <li>• <b>CheckSlope</b>: Specify the value <code>false</code>.</li> <li>• <b>CheckBias</b>: Specify the value <code>false</code>.</li> <li>• <b>DataType</b>: Specify the value <code>'Fixed'</code>.</li> </ul>

Match	Create entry	Minimally specify parameters
Relative scaling between operator inputs and output (multiplication and division).	RTW.Tf1COperationEntry-Generator	<p>setTf1COperationEntryParameters function:</p> <ul style="list-style-type: none"> <li>• <b>RelativeScalingFactorF:</b> Specify the slope adjustment factor (F) part of the relative scaling factor, <math>F2^E</math> (for example, 1.0).</li> <li>• <b>RelativeScalingFactorE:</b> Specify the fixed exponent (E) part of the relative scaling factor, <math>F2^E</math> (for example, -3.0).</li> </ul> <p>createAndAddConceptualArg function:</p> <ul style="list-style-type: none"> <li>• <b>CheckSlope:</b> Specify the value false.</li> <li>• <b>CheckBias:</b> Specify the value false.</li> <li>• <b>DataType:</b> Specify the value 'Fixed'.</li> </ul>
Equal slope and zero net bias across operator inputs and output (addition and subtraction). ## Fixed-Point Numbers and Arithmetic

Fixed-point numbers use integers and integer arithmetic to represent real numbers and arithmetic with the following encoding scheme:

$$V = \tilde{V} = SQ + B$$

- $V$  is an arbitrarily precise real-world value.
- $\tilde{V}$  is the approximate real-world value that results from fixed-point representation.
- $Q$  is an integer that encodes  $\tilde{V}$ , referred to as the *quantized integer*.
- $S$  is a coefficient of  $Q$ , referred to as the *slope*.
- $B$  is an additive correction, referred to as the *bias*.

The general equation for an operation between fixed-point operands is:

$$(S_0Q_0 + B_0) = (S_1Q_1 + B_1) < op > (S_2Q_2 + B_2)$$

The objective of fixed-point operator replacement is to replace an operator that accepts and returns fixed-point or integer inputs and output with a function that accepts and returns built-in C numeric data types. The following sections provide additional programming information for each supported operator.

### Addition

The operation  $V_0 = V_1 + V_2$  implies that

$$Q_0 = \left( \frac{S_1}{S_0} \right) Q_1 + \left( \frac{S_2}{S_0} \right) Q_2 + \left( \frac{B_1 + B_2 - B_0}{S_0} \right)$$

If an addition replacement function is defined such that the scaling on the operands and sum are equal and the net bias

$$\left( \frac{B_1 + B_2 - B_0}{S_0} \right)$$

is zero (for example, a function `s8_add_s8_s8` that adds two signed 8-bit values and produces a signed 8-bit result), then the operator entry must set the operator entry parameters `SlopesMustBeTheSame` and `MustHaveZeroNetBias` to `true`. (For parameter descriptions, see the reference page for the function `setTf1COperationEntryParameters`.)

## Subtraction

The operation  $V_0 = V_1 - V_2$  implies that

$$Q_0 = \left( \frac{S_1}{S_0} \right) Q_1 - \left( \frac{S_2}{S_0} \right) Q_2 + \left( \frac{B_1 - B_2 - B_0}{S_0} \right)$$

If a subtraction replacement function is defined such that the scaling on the operands and difference are equal and the net bias

$$\left( \frac{B_1 - B_2 - B_0}{S_0} \right)$$

is zero (for example, a function `s8_sub_s8_s8` that subtracts two signed 8-bit values and produces a signed 8-bit result), then the operator entry must set the operator entry parameters `SlopesMustBeTheSame` and `MustHaveZeroNetBias` to `true`. (For parameter descriptions, see the reference page for the function `setTf1COperationEntryParameters`.)

## Multiplication

There are different ways to specify multiplication replacements. The most direct way is to specify an exact match of the input and output types. This is feasible if a model contains only a few (known) slope and bias combinations. Use the `Tf1COperationEntry` class

and specify the exact values of slope and bias on each argument. For scenarios where there are numerous slope/bias combinations, it is not feasible to specify each value with a different entry. Use a net slope entry or create a custom entry.

The operation  $V_0 = V_1 * V_2$  implies, for binary-point-only scaling, that

$$\begin{aligned}S_0 Q_0 &= (S_1 Q_1)(S_2 Q_2) \\ Q_0 &= \left( \frac{S_1 S_2}{S_0} \right) Q_1 Q_2 \\ Q_0 &= S_n Q_1 Q_2\end{aligned}$$

where  $S_n$  is the net slope.

It is common to replace all multiplication operations that have a net slope of 1.0 with a function that performs C-style multiplication. For example, to replace all signed 8-bit multiplications that have a net scaling of 1.0 with the `s8_mul_s8_u8` replacement function, the operator entry must define a net slope factor,  $F2^E$ . You specify the values for  $F$  and  $E$  using operator entry parameters `NetSlopeAdjustmentFactor` and `NetFixedExponent`. (For parameter descriptions, see the reference page for the function `setTf1COperationEntryParameters`.) For the `s8_mul_s8_u8` function, set `NetSlopeAdjustmentFactor` to 1 and `NetFixedExponent` to 0.0.

---

**Note:** When an operator entry specifies `NetSlopeAdjustmentFactor` and `NetFixedExponent`, matching entries must have arguments with zero bias.

---

## Division

There are different ways to specify division replacements. The most direct way is to specify an exact match of the input and output types. This is feasible if a model contains only a few (known) slope and bias combinations. For this, use the `Tf1COperationEntry` class and specify the exact values of slope and bias on each argument. For scenarios where there are numerous slope/bias combinations, it is not feasible to specify each value with a different entry. For this, use a net slope entry or create a custom entry (see “Customize Match and Replacement Process” on page 51-153).

The operation  $V_0 = (V_1 / V_2)$  implies, for binary-point-only scaling, that

$$S_0 Q_0 = \left( \frac{S_1 Q_1}{S_2 Q_2} \right)$$

$$Q_0 = S_n \left( \frac{Q_1}{Q_2} \right)$$

where  $S_n$  is the net slope.

It is common to replace all division operations that have a net slope of 1.0 with a function that performs C-style division. For example, to replace all signed 8-bit divisions that have a net scaling of 1.0 with the `s8_mul_s8_u8_` replacement function, the operator entry must define a net slope factor,  $F2^E$ . You specify the values for  $F$  and  $E$  using operator entry parameters `NetSlopeAdjustmentFactor` and `NetFixedExponent`. (For parameter descriptions, see the reference page for the function `setTf1COperationEntryParameters`.) For the `s16_netslope0p5_div_s16_s16` function, you would set `NetSlopeAdjustmentFactor` to 1 and `NetFixedExponent` to 0.0.

---

**Note:** When an operator entry specifies `NetSlopeAdjustmentFactor` and `NetFixedExponent`, matching entries must have arguments with zero bias.

---

## Data Type Conversion (Cast)

The data type conversion operation  $V_0 = V_1$  implies, for binary-point-only scaling, that

$$Q_0 = \left( \frac{S_1}{S_0} \right) Q_1$$

$$Q_0 = S_n Q_1$$

where  $S_n$  is the net slope.

## Shift

The shift left or shift right operation  $V_0 = (V_1 / 2^n)$  implies, for binary-point-only scaling, that

$$S_0 Q_0 = \left( \frac{S_1 Q_1}{2^n} \right)$$

$$Q_0 = \left( \frac{S_1}{S_0} \right) + \left( \frac{Q_1}{2^n} \right)$$

$$Q_0 = S_n \left( \frac{Q_1}{2^n} \right)$$

where  $S_n$  is the net slope.

## Binary-Point-Only Scaling Code Replacement

You can define code replacement entries for operations on fixed-point data types such that they match a binary-point-only scaling combination on operator inputs and output. These binary-point-only scaling entries can map the specified binary-point-scaling combination to a replacement function for addition, subtraction, multiplication, or division.

This example creates a code replacement entry for multiplication of fixed-point data types. You specify arguments using binary-point-only scaling. The example defines the function mapping programmatically. Alternatively, you can use the Code Replacement Tool to define the same mapping.

- 1 Create a table definition file that contains a function definition. For example:

```
function hTable = crl_table_fixed_binptscale
```

- 2 Within the function body, create the table by calling the function `RTW.Tf1Table`.

```
hTable = RTW.Tf1Table;
```

- 3 Create the entry for the operator mapping with a call to the `RTW.Tf1COperationEntry` function.

```
op_entry = RTW.Tf1COperationEntry;
```

- 4 Set operator entry parameters with a call to the `setTf1COperationEntryParameters` function. The parameters specify the type of operation as multiplication, the saturation mode as saturate on integer overflow, rounding modes as unspecified, and the name of the replacement function as `s32_mul_s16_s16_binarypoint`.

```
setTf1COperationEntryParameters(op_entry, ...
 'Key', 'RTW_OP_MUL', ...
 'Priority', 90, ...
 'SaturationMode', 'RTW_SATURATE_ON_OVERFLOW', ...
 'RoundingModes', {'RTW_ROUND_UNSPECIFIED'}, ...
 'ImplementationName', 's32_mul_s16_s16_binarypoint', ...
 'ImplementationHeaderFile', 's32_mul_s16_s16_binarypoint.h', ...
 'ImplementationSourceFile', 's32_mul_s16_s16_binarypoint.c');
```

- 5 Create conceptual arguments `y1`, `u1`, and `u2`. There are multiple ways to set up the conceptual arguments. This example uses calls to the `createAndAddConceptualArg` function to create and add an argument with one function call. Each argument specifies that the data type is fixed-point, the mode is binary-point-only scaling, and its derived slope and bias values must exactly match the call-site slope and bias values. The output argument is 32 bits, signed, with a

fraction length of 28. The input arguments are 16 bits, signed, with fraction lengths of 15 and 13.

```
createAndAddConceptualArg(op_entry, 'RTW.Tf1ArgNumeric',...
 'Name', 'y1', ...
 'IOType', 'RTW_IO_OUTPUT', ...
 'CheckSlope', true, ...
 'CheckBias', true, ...
 'DataTypeMode', 'Fixed-point: binary point scaling', ...
 'IsSigned', true, ...
 'WordLength', 32, ...
 'FractionLength', 28);

createAndAddConceptualArg(op_entry, 'RTW.Tf1ArgNumeric', ...
 'Name', 'u1', ...
 'IOType', 'RTW_IO_INPUT', ...
 'CheckSlope', true, ...
 'CheckBias', true, ...
 'DataTypeMode', 'Fixed-point: binary point scaling', ...
 'IsSigned', true, ...
 'WordLength', 16, ...
 'FractionLength', 15);

createAndAddConceptualArg(op_entry, 'RTW.Tf1ArgNumeric', ...
 'Name', 'u2', ...
 'IOType', 'RTW_IO_INPUT', ...
 'CheckSlope', true, ...
 'CheckBias', true, ...
 'DataTypeMode', 'Fixed-point: binary point scaling', ...
 'IsSigned', true, ...
 'WordLength', 16, ...
 'FractionLength', 13);
```

- 6 Create the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses calls to the `createAndSetCImplementationReturn` and `createAndAddImplementationArg` functions to create and add implementation arguments to the entry. Implementation arguments must describe fundamental numeric data types (not fixed-point data types). In this case, the output argument is 32 bits and signed (`int32`). The input arguments are 16 bits and signed (`int16`).

```
createAndSetCImplementationReturn(op_entry, 'RTW.Tf1ArgNumeric', ...
 'Name', 'y1', ...
 'IOType', 'RTW_IO_OUTPUT', ...
 'IsSigned', true, ...
 'WordLength', 32, ...
 'FractionLength', 0);

createAndAddImplementationArg(op_entry, 'RTW.Tf1ArgNumeric',...
 'Name', 'u1', ...
 'IOType', 'RTW_IO_INPUT', ...
 'IsSigned', true, ...
 'WordLength', 16, ...
```

```

 'FractionLength', 0);

createAndAddImplementationArg(op_entry, 'RTW.Tf1ArgNumeric',...
 'Name', 'u2', ...
 'IOType', 'RTW_IO_INPUT', ...
 'IsSigned', true, ...
 'WordLength', 16, ...
 'FractionLength', 0);

```

- 7 Add the entry to a code replacement table with a call to the `addEntry` function.

```
addEntry(hTable, op_entry);
```

- 8 Save the table definition file. Use the name of the table definition function to name the file.

To test this example:

- 1 Register the code replacement mapping.
- 2 Create a model.

- 3 For this model:

- Set the **Inport 1 Data type** to `fixdt(1,16,15)`.
- Set the **Inport 2 Data type** to `fixdt(1,16,13)`.
- In the **Product** block:
  - Set **Output data type** to `fixdt(1,32,28)`.
  - Select the option **Saturate on integer overflow**.

- 4 Configure the model with the following settings:

- On the **Solver** pane, select a fixed-step, discrete solver.
- On the **Code Generation** pane, select an ERT-based system target file.
- On the **Code Generation > Interface** pane, select the code replacement library that contains your addition operation entry.

- 5 Generate code and a code generation report.

- 6 Review the code replacements.

## Slope Bias Scaling Code Replacement

You can define code replacement for operations on fixed-point data types as matching a slope bias scaling combination on the operator inputs and output. The slope bias scaling entries can map the specified slope bias combination to a replacement function for addition, subtraction, multiplication, or division.

This example creates a code replacement entry for division of fixed-point data types. You specify arguments using slope bias scaling. The example defines the function mapping programmatically. Alternatively, you can use the Code Replacement Tool to define the same mapping.

- 1 Create a table definition file that contains a function definition. For example:

```
function hTable = crl_table_fixed_s16divslopebias
```

- 2 Within the function body, create the table by calling the function `RTW.Tf1Table`.

```
hTable = RTW.Tf1Table;
```

- 3 Create the entry for the operator mapping with a call to the `RTW.Tf1COperationEntry` function.

```
op_entry = RTW.Tf1COperationEntry;
```

- 4 Set operator entry parameters with a call to the `setTf1COperationEntryParameters` function. The parameters specify the type of operation as division, the saturation mode as saturate on integer overflow, rounding modes as round to ceiling, and the name of the replacement function as `s16_div_s16_s16_slopebias`.

```
setTf1COperationEntryParameters(op_entry, ...
 'Key', 'RTW_OP_DIV', ...
 'Priority', 90, ...
 'SaturationMode', 'RTW_SATURATE_ON_OVERFLOW', ...
 'RoundingModes', {'RTW_ROUND_CEILING'}, ...
 'ImplementationName', 's16_div_s16_s16_slopebias', ...
 'ImplementationHeaderFile', 's16_div_s16_s16_slopebias.h', ...
 'ImplementationSourceFile', 's16_div_s16_s16_slopebias.c');
```

- 5 Create conceptual arguments `y1`, `u1`, and `u2`. There are multiple ways to set up the conceptual arguments. This example uses calls to the `createAndAddConceptualArg` function to create and add an argument with one function call. Each argument specifies that the data type is fixed-point, the mode is slope bias scaling, and its specified slope and bias values must exactly match the call-site slope and bias values. The output argument and input arguments are 16 bits, signed, each with specific slope bias specifications.

```

createAndAddConceptualArg(op_entry, 'RTW.Tf1ArgNumeric', ...
 'Name', 'y1', ...
 'IOType', 'RTW_IO_OUTPUT', ...
 'CheckSlope', true, ...
 'CheckBias', true, ...
 'DataTypeMode', 'Fixed-point: slope and bias scaling', ...
 'IsSigned', true, ...
 'WordLength', 16, ...
 'Slope', 15, ...
 'Bias', 2);

createAndAddConceptualArg(op_entry, 'RTW.Tf1ArgNumeric', ...
 'Name', 'u1', ...
 'IOType', 'RTW_IO_INPUT', ...
 'CheckSlope', true, ...
 'CheckBias', true, ...
 'DataTypeMode', 'Fixed-point: slope and bias scaling', ...
 'IsSigned', true, ...
 'WordLength', 16, ...
 'Slope', 15, ...
 'Bias', 2);

createAndAddConceptualArg(op_entry, 'RTW.Tf1ArgNumeric', ...
 'Name', 'u2', ...
 'IOType', 'RTW_IO_INPUT', ...
 'CheckSlope', true, ...
 'CheckBias', true, ...
 'DataTypeMode', 'Fixed-point: slope and bias scaling', ...
 'IsSigned', true, ...
 'WordLength', 16, ...
 'Slope', 13, ...
 'Bias', 5);

```

- 6 Create the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses calls to the `createAndSetCImplementationReturn` and `createAndAddImplementationArg` functions to create and add implementation arguments to the entry. Implementation arguments must describe fundamental numeric data types (not fixed-point data types). In this case, the output and input arguments are 16 bits and signed (`int16`).

```

createAndSetCImplementationReturn(op_entry, 'RTW.Tf1ArgNumeric', ...
 'Name', 'y1', ...
 'IOType', 'RTW_IO_OUTPUT', ...
 'IsSigned', true, ...
 'WordLength', 16, ...
 'FractionLength', 0);

createAndAddImplementationArg(op_entry, 'RTW.Tf1ArgNumeric', ...
 'Name', 'u1', ...
 'IOType', 'RTW_IO_INPUT', ...
 'IsSigned', true, ...
 'WordLength', 16, ...

```

```

 'FractionLength', 0);

createAndAddImplementationArg(op_entry, 'RTW.Tf1ArgNumeric',...
 'Name', 'u2', ...
 'IOType', 'RTW_IO_INPUT', ...
 'IsSigned', true, ...
 'WordLength', 16, ...
 'FractionLength', 0);

```

- 7 Add the entry to a code replacement table with a call to the `addEntry` function.

```
addEntry(hTable, op_entry);
```

- 8 Save the table definition file. Use the name of the table definition function to name the file.

To test this example:

- 1 Register the code replacement mapping.
- 2 Create a model.

- 3 For this model:

- Set the Inport 1 **Data type** to `fixdt(1,16,15,2)`.
- Set the Inport 2 **Data type** to `fixdt(1,16,13,5)`.
- In the Divide block:
  - Set **Output data type** to `Inherit: Inherit via back propagation`.
  - Set **Integer rounding mode** to `Ceiling`.
  - Select the option **Saturate on integer overflow**.

- 4 Configure the model with the following settings:

- On the **Solver** pane, select a fixed-step, discrete solver.
- On the **Code Generation** pane, select an ERT-based system target file.
- On the **Code Generation > Interface** pane, select the code replacement library that contains your addition operation entry.

- 5 Generate code and a code generation report.
- 6 Review the code replacements.

# Net Slope Scaling Code Replacement

## Multiplication and Division with Saturation

You can define code replacement entries for operations on fixed-point data types as matching net slope between operator inputs and output. The net slope entries can map a range of slope and bias values to a replacement function for multiplication or division.

This example creates a code replacement entry for division of fixed-point data types, using wrap on overflow saturation mode and a net slope. The example defines the function mapping programmatically. Alternatively, you can use the Code Replacement Tool to define the same mapping.

- 1 Create a table definition file that contains a function definition. For example:

```
function hTable = crl_table_fixed_netslopesaturate
```

- 2 Within the function body, create the table by calling the function `RTW.Tf1Table`.

```
hTable = RTW.Tf1Table;
```

- 3 Create the entry for the operator mapping with a call to the `RTW.Tf1COperationEntryGenerator_Netslope` function, which provides access to the fixed-point parameters `NetSlopeAdjustmentFactor` and `NetFixedExponent`.

```
wv = [16,32];
for iy = 1:2
 for inum = 1:2
 for iden = 1:2
 hTable = getDivOpEntry(hTable, ...
 fixdt(1,wv(iy)),fixdt(1,wv(inum)),fixdt(1,wv(iden)));
 end
 end
end
```

```
%-----
function hTable = getDivOpEntry(hTable,dti,dtnum,dtden)
%-----
% Create an entry for division of fixed-point data types where
% arguments are specified using Slope and Bias scaling
% Saturation on, Rounding unspecified

funcStr = sprintf('user_div_%s_%s_%s',...
 typeStrFunc(dti),...
 typeStrFunc(dtnum),...
 typeStrFunc(dtden));
```

```
op_entry = RTW.Tf1COperationEntryGenerator_NetSlope;
```

- 4 Set operator entry parameters with a call to the `setTf1COperationEntryParameters` function. The parameters specify the type of operation as division, the saturation mode as wrap on overflow, rounding modes as unspecified, and the name of the replacement function as `user_div_*`. `NetSlopeAdjustmentFactor` and `NetFixedExponent` specify the F and E parts of the net slope  $F2^E$ .

```
setTf1COperationEntryParameters(op_entry, ...
 'Key', 'RTW_OP_DIV', ...
 'Priority', 90, ...
 'SaturationMode', 'RTW_WRAP_ON_OVERFLOW', ...
 'RoundingModes', {'RTW_ROUND_UNSPECIFIED'}, ...
 'NetSlopeAdjustmentFactor', 1.0, ...
 'NetFixedExponent', 0.0, ...
 'ImplementationName', funcStr, ...
 'ImplementationHeaderFile', [funcStr, '.h'], ...
 'ImplementationSourceFile', [funcStr, '.c']);
```

- 5 Create conceptual arguments `y1`, `u1`, and `u2`. There are multiple ways to set up the conceptual arguments. This example uses calls to the `createAndAddConceptualArg` function to create and add an argument with one function call. Specify each argument as fixed-point and signed. Also, for each argument, specify that code replacement request processing does *not* check for an exact match to the call-site slope and bias values.

```
createAndAddConceptualArg(op_entry, ...
 'RTW.Tf1ArgNumeric', ...
 'Name', 'y1', ...
 'IOType', 'RTW_IO_OUTPUT', ...
 'CheckSlope', false, ...
 'CheckBias', false, ...
 'DataTypeMode', 'Fixed-point: slope and bias scaling', ...
 'IsSigned', dtty.Signed, ...
 'WordLength', dtty.WordLength, ...
 'Bias', 0);
```

```
createAndAddConceptualArg(op_entry, ...
 'RTW.Tf1ArgNumeric', ...
 'Name', 'u1', ...
 'IOType', 'RTW_IO_INPUT', ...
 'CheckSlope', false, ...
 'CheckBias', false, ...
 'DataTypeMode', 'Fixed-point: slope and bias scaling', ...
 'IsSigned', dtnum.Signed, ...
 'WordLength', dtnum.WordLength, ...
 'Bias', 0);
```

```
createAndAddConceptualArg(op_entry, ...
 'RTW.Tf1ArgNumeric', ...
 'Name', 'u2', ...
```

```

'IOType', 'RTW_IO_INPUT',...
'CheckSlope', false,...
'CheckBias', false,...
'DataTypeMode', 'Fixed-point: slope and bias scaling',...
'IsSigned', dtden.Signed,...
'WordLength', dtden.WordLength,...
'Bias', 0);

```

- 6** Create the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses calls to the `getTf1ArgFromString` function to create the arguments. Implementation arguments must describe fundamental numeric data types (not fixed-point data types). The convenience methods `setReturn` and `addArgument` specify whether an argument is a return value or argument. These methods add the argument to the entry array of implementation arguments.

```

arg = getTf1ArgFromString(hTable, 'y1', typeStrBase(dty));
op_entry.Implementation.setReturn(arg);

```

```

arg = getTf1ArgFromString(hTable, 'u1', typeStrBase(dtnum));
op_entry.Implementation.addArgument(arg);

```

```

arg = getTf1ArgFromString(hTable, 'u2', typeStrBase(dtdden));
op_entry.Implementation.addArgument(arg);

```

- 7** Add the entry to a code replacement table with a call to the `addEntry` function.

```

addEntry(hTable, op_entry);

```

- 8** Define functions that determine the data type word length.

```

%-----
function str = typeStrFunc(dt)
%-----

if dt.Signed
 sstr = 's';
else
 sstr = 'u';
end
str = sprintf('%s%d',sstr,dt.WordLength);

%-----
function str = typeStrBase(dt)
%-----

if dt.Signed
 sstr = ;
else
 sstr = 'u';
end
str = sprintf('%sint%d',sstr,dt.WordLength);

```

- 9 Save the table definition file. Use the name of the table definition function to name the file.

## Multiplication and Division with Rounding Mode and Additional Implementation Arguments

You can define code replacement entries for multiplication and division operations on fixed-point data types such that they match the net slope between operator inputs and output. The net slope entries can map a range of slope and bias values to a replacement function for multiplication or division.

This example creates a code replacement entry for division of fixed-point data types, using the ceiling rounding mode and a net slope scaling factor. The example defines the function mapping programmatically. Alternatively, you can use the Code Replacement Tool to define the same mapping.

- 1 Create a table definition file that contains a function definition. For example:

```
function hTable = crl_table_fixed_netsloperound
```

- 2 Within the function body, create the table by calling the function `RTW.Tf1Table`.

```
hTable = RTW.Tf1Table;
```

- 3 Create the entry for the operator mapping with a call to the `RTW.Tf1COperationEntryGenerator_Netslope` function, which provides access to the fixed-point parameters `NetSlopeAdjustmentFactor` and `NetFixedExponent`.

```
op_entry = RTW.Tf1COperationEntryGenerator_NetSlope;
```

- 4 Set operator entry parameters with a call to the `setTf1COperationEntryParameters` function. The parameters specify the type of operation as division, the saturation mode as saturation off, rounding modes as round to ceiling, and the name of the replacement function as `s16_div_s16_s16`. `NetSlopeAdjustmentFactor` and `NetFixedExponent` specify the F and E parts of the relative scaling factor  $F2^E$ .

```
setTf1COperationEntryParameters(op_entry, ...
 'Key', 'RTW_OP_DIV', ...
 'Priority', 90, ...
 'SaturationMode', 'RTW_WRAP_ON_OVERFLOW', ...
 'RoundingModes', {'RTW_ROUND_CEILING'}, ...
 'NetSlopeAdjustmentFactor', 1.0, ...
 'NetFixedExponent', 0.0, ...
```

```

 'ImplementationName', 's16_div_s16_s16', ...
 'ImplementationHeaderFile', 's16_div_s16_s16.h', ...
 'ImplementationSourceFile', 's16_div_s16_s16.c');

```

- 5 Create conceptual arguments `y1`, `u1`, and `u2`. There are multiple ways to set up the conceptual arguments. This example uses calls to the `createAndAddConceptualArg` function to create and add an argument with one function call. Specify each argument as fixed-point, 16 bits, and signed. Also, for each argument, specify that code replacement request processing does *not* check for an exact match to the call-site slope and bias values.

```

createAndAddConceptualArg(op_entry, 'RTW.Tf1ArgNumeric', ...
 'Name', 'y1', ...
 'IOType', 'RTW_IO_OUTPUT', ...
 'CheckSlope', false, ...
 'CheckBias', false, ...
 'DataType', 'Fixed', ...
 'IsSigned', true, ...
 'WordLength', 16);

```

```

createAndAddConceptualArg(op_entry, 'RTW.Tf1ArgNumeric', ...
 'Name', 'u1', ...
 'IOType', 'RTW_IO_INPUT', ...
 'CheckSlope', false, ...
 'CheckBias', false, ...
 'DataType', 'Fixed', ...
 'IsSigned', true, ...
 'WordLength', 16);

```

```

createAndAddConceptualArg(op_entry, 'RTW.Tf1ArgNumeric', ...
 'Name', 'u2', ...
 'IOType', 'RTW_IO_INPUT', ...
 'CheckSlope', false, ...
 'CheckBias', false, ...
 'DataType', 'Fixed', ...
 'IsSigned', true, ...
 'WordLength', 16);

```

- 6 Create the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses calls to the `createAndSetCImplementationReturn` and `createAndAddImplementationArg` functions to create and add implementation arguments to the entry. Implementation arguments must describe fundamental numeric data types (not fixed-point data types). In this case, the output and input arguments are 16 bits and signed (`int16`).

```

createAndSetCImplementationReturn(op_entry, 'RTW.Tf1ArgNumeric', ...
 'Name', 'y1', ...
 'IOType', 'RTW_IO_OUTPUT', ...
 'IsSigned', true, ...
 'WordLength', 16, ...
 'FractionLength', 0);

```

```

createAndAddImplementationArg(op_entry, 'RTW.Tf1ArgNumeric',...
 'Name', 'u1', ...
 'IOType', 'RTW_IO_INPUT', ...
 'IsSigned', true, ...
 'WordLength', 16, ...
 'FractionLength', 0);

createAndAddImplementationArg(op_entry, 'RTW.Tf1ArgNumeric',...
 'Name', 'u2', ...
 'IOType', 'RTW_IO_INPUT', ...
 'IsSigned', true, ...
 'WordLength', 16, ...
 'FractionLength', 0);

```

- 7 Add the entry to a code replacement table with a call to the `addEntry` function.

```
addEntry(hTable, op_entry);
```

- 8 Save the table definition file. Use the name of the table definition function to name the file.

To test this example:

- 1 Register the code replacement mapping.
- 2 Create a model.

- 3 For this model:
  - Set the Inport 1 **Data type** to `int16`.
  - Set the Inport 2 **Data type** to `fixdt(1, 16, -5)`.
  - In the Divide block:
    - Set **Output data type** to `fixdt(1, 16, -13)`.
    - Set **Integer rounding mode** to `Ceiling`.
- 4 Configure the model with the following settings:
  - On the **Solver** pane, select a fixed-step, discrete solver.

- On the **Code Generation** pane, select an ERT-based system target file.
  - On the **Code Generation > Interface** pane, select the code replacement library that contains your addition operation entry.
- 5 Generate code and a code generation report.
  - 6 Review the code replacements.

## Equal Slope and Zero Net Bias Code Replacement

You can define code replacement entries for addition or subtraction of fixed-point data types such that they match relative slope and bias values (equal slope and zero net bias) across operator inputs and output. These entries allow you to disregard slope and bias values. Map relative slope and bias values to a replacement function for addition or subtraction.

This example creates a code replacement entry for addition of fixed-point data types. Slopes must be equal and net bias must be zero across the operator inputs and output. The example defines the function mapping programmatically. Alternatively, you can use the Code Replacement Tool to define the same mapping.

- 1 Create a table definition file that contains a function definition. For example:

```
function hTable = crl_table_fixed_slopeseq_netbiaszero
```

- 2 Within the function body, create the table by calling the function `RTW.Tf1Table`.

```
hTable = RTW.Tf1Table;
```

- 3 Create the entry for the operator mapping with a call to the `RTW.Tf1COperationEntryGenerator` function, which provides access to the fixed-point parameters `SlopesMustBeTheSame` and `MustHaveZeroNetBias`.

```
op_entry = RTW.Tf1COperationEntryGenerator;
```

- 4 Set operator entry parameters with a call to the `setTf1COperationEntryParameters` function. The parameters specify the type of operation as addition, the saturation mode as saturation off, rounding modes as unspecified, and the name of the replacement function as `u16_add_SameSlopeZeroBias`. `SlopesMustBeTheSame` and `MustHaveZeroNetBias` are set to `true`, indicating that slopes must be equal and net bias must be zero across the addition inputs and output.

```
setTf1COperationEntryParameters(op_entry, ...
 'Key', 'RTW_OP_ADD', ...
 'Priority', 90, ...
 'SaturationMode', 'RTW_WRAP_ON_OVERFLOW', ...
 'RoundingModes', {'RTW_ROUND_UNSPECIFIED'}, ...
 'SlopesMustBeTheSame', true, ...
 'MustHaveZeroNetBias', true, ...
 'ImplementationName', 'u16_add_SameSlopeZeroBias', ...
 'ImplementationHeaderFile', 'u16_add_SameSlopeZeroBias.h', ...
 'ImplementationSourceFile', 'u16_add_SameSlopeZeroBias.c');
```

- 5 Create conceptual arguments  $y_1$ ,  $u_1$ , and  $u_2$ . There are multiple ways to set up the conceptual arguments. This example uses calls to the `createAndAddConceptualArg` function to create and add an argument with one function call. Each argument is specified as 16 bits and unsigned. Each argument specifies that code replacement request processing does *not* check for an exact match to the call-site slope and bias values.

```
createAndAddConceptualArg(op_entry, 'RTW.Tf1ArgNumeric', ...
 'Name', 'y1', ...
 'IOType', 'RTW_IO_OUTPUT', ...
 'CheckSlope', false, ...
 'CheckBias', false, ...
 'IsSigned', false, ...
 'WordLength', 16);

createAndAddConceptualArg(op_entry, 'RTW.Tf1ArgNumeric', ...
 'Name', 'u1', ...
 'IOType', 'RTW_IO_INPUT', ...
 'CheckSlope', false, ...
 'CheckBias', false, ...
 'IsSigned', false, ...
 'WordLength', 16);

createAndAddConceptualArg(op_entry, 'RTW.Tf1ArgNumeric', ...
 'Name', 'u2', ...
 'IOType', 'RTW_IO_INPUT', ...
 'CheckSlope', false, ...
 'CheckBias', false, ...
 'IsSigned', false, ...
 'WordLength', 16);
```

- 6 Create the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses calls to the `createAndSetCImplementationReturn` and `createAndAddImplementationArg` functions to create and add implementation arguments to the entry. Implementation arguments must describe fundamental numeric data types (not fixed-point data types). In this case, the output and input arguments are 16 bits and unsigned (`uint16`).

```
createAndSetCImplementationReturn(op_entry, 'RTW.Tf1ArgNumeric', ...
 'Name', 'y1', ...
 'IOType', 'RTW_IO_OUTPUT', ...
 'IsSigned', false, ...
 'WordLength', 16, ...
 'FractionLength', 0);

createAndAddImplementationArg(op_entry, 'RTW.Tf1ArgNumeric', ...
 'Name', 'u1', ...
 'IOType', 'RTW_IO_INPUT', ...
 'IsSigned', false, ...
 'WordLength', 16, ...
```

```

 'FractionLength', 0);

createAndAddImplementationArg(op_entry, 'RTW.Tf1ArgNumeric',...
 'Name', 'u2', ...
 'IOType', 'RTW_IO_INPUT', ...
 'IsSigned', false, ...
 'WordLength', 16, ...
 'FractionLength', 0);

```

- 7 Add the entry to a code replacement table with a call to the `addEntry` function.

```
addEntry(hTable, op_entry);
```

- 8 Save the table definition file. Use the name of the table definition function to name the file.

To test this example:

- 1 Register the code replacement mapping.
- 2 Create a model.

- 3 For this model:

- Set the Inport 1 **Data type** to `fixdt(0, 16, 13)`.
- Set the Inport 2 **Data type** to `fixdt(0, 16, 13)`.
- In the Add block:
  - Verify that **Output data type** is set to its default, `Inherit` via `internal` rule.
  - Set **Integer rounding mode** to `Zero`.

- 4 Configure the model with the following settings:

- On the **Solver** pane, select a fixed-step, discrete solver.
- On the **Code Generation** pane, select an ERT-based system target file.
- On the **Code Generation > Interface** pane, select the code replacement library that contains your addition operation entry.

- 5 Generate code and a code generation report.

**6** Review the code replacements.

## Data Type Conversions (Casts) and Operator Code Replacement

You can use code replacement entries to replace code that the code generator produces for data type conversion (cast) operations.

### Casts from `int32` To `int16`

This example creates a code replacement entry that replaces `int32` to `int16` data type conversion (cast) operations. The example defines the function mapping programmatically. Alternatively, you can use the Code Replacement Tool to define the same mapping.

- 1 Create a table definition file that contains a function definition. For example:

```
function hTable = crl_table_cast_int32_to_int16
```

- 2 Within the function body, create the table by calling the function `RTW.Tf1Table`.

```
hTable = RTW.Tf1Table;
```

- 3 Create the entry for the operator mapping with a call to the `RTW.Tf1COperationEntry` function.

```
op_entry = RTW.Tf1COperationEntry;
```

- 4 Set operator entry parameters with a call to the `setTf1COperationEntryParameters` function. The parameters specify the type of operation as `cast`, the saturation mode as `saturate on integer overflow`, rounding modes as `toward negative infinity`, and the name of the replacement function as `my_sat_cast`.

```
setTf1COperationEntryParameters(op_entry, ...
 'Key', 'RTW_OP_CAST', ...
 'Priority', 50, ...
 'ImplementationName', 'my_sat_cast', ...
 'SaturationMode', 'RTW_SATURATE_ON_OVERFLOW', ...
 'RoundingModes', {'RTW_ROUND_FLOOR'}, ...
 'ImplementationHeaderFile', 'some_hdr.h', ...
 'ImplementationSourceFile', 'some_hdr.c');
```

- 5 Create the `int16` argument as conceptual argument `y1` and the implementation return value. There are multiple ways to set up the conceptual and implementation arguments. This example uses calls to the `getTf1ArgFromString` and `addConceptualArg` functions to create the conceptual argument and add it to the entry. Convenience method `setReturn` specifies the argument as the implementation return value.

```
arg = getTf1ArgFromString(hTable, 'y1', 'int16');
arg.IOType = 'RTW_IO_OUTPUT';
addConceptualArg(op_entry, arg);
op_entry.Implementation.setReturn(arg);
```

- 6 Create the `int32` argument as conceptual and implementation argument `u1`. This example uses calls to the `getTf1ArgFromString` and `addConceptualArg` functions to create the conceptual argument and add it to the entry. Convenience method `addArgument` specifies the argument as implementation input argument.

```
arg = getTf1ArgFromString(hTable, 'u1', 'int32');
addConceptualArg(op_entry, arg);
op_entry.Implementation.addArgument(arg);
```

- 7 Add the entry to a code replacement table with a call to the `addEntry` function.

```
addEntry(hLib, hEnt);
```
- 8 Save the table definition file. Use the name of the table definition function to name the file.

## Casts Using Net Slope

You can use code replacement entries to replace code that the code generator produces for data type conversion (cast) operations.

This example creates a code replacement entry to replace data type conversions (casts) of fixed-point data types by using a net slope. The example defines the function mapping programmatically. Alternatively, you can use the Code Replacement Tool to define the same mapping.

- 1 Create a table definition file that contains a function definition. For example:

```
function hTable = crl_table_cast_fixpt_net_slope
```
- 2 Within the function body, create the table by calling the function `RTW.Tf1Table`.

```
hTable = RTW.Tf1Table;
```
- 3 Create the entry for the operator mapping with a call to the `RTW.Tf1COperationEntryGenerator_Netslope` function, which provides access to the fixed-point parameters `NetSlopeAdjustmentFactor` and `NetFixedExponent`

```
op_entry = RTW.Tf1COperationEntryGenerator_NetSlope;
```
- 4 Set operator entry parameters with a call to the `setTf1COperationEntryParameters` function. The parameters specify the type

of operation as cast, the saturation mode as saturate on integer overflow, rounding modes as toward negative infinity, and the name of the replacement function as `my_fxp_cast`. `NetSlopeAdjustmentFactor` and `NetFixedExponent` specify the F and E parts of the net slope  $F2^E$ .

```
InFL = 2;
InWL = 16;
InSgn = true;
OutFL = 4;
OutWL = 32;
OutSgn = true;
setTf1COperationEntryParameters(op_entry, ...
 'Key', 'RTW_OP_CAST', ...
 'Priority', 50, ...
 'SaturationMode', 'RTW_SATURATE_ON_OVERFLOW', ...
 'RoundingModes', {'RTW_ROUND_FLOOR'}, ...
 'NetSlopeAdjustmentFactor', 1.0, ...
 'NetFixedExponent', (OutFL - InFL), ...
 'ImplementationName', 'my_fxp_cast', ...
 'ImplementationHeaderFile', 'some_hdr.h', ...
 'ImplementationSourceFile', 'some_hdr.c');
```

- 5 Create conceptual arguments `y1` and `u1`. There are multiple ways to set up the conceptual arguments. This example uses calls to the `createAndAddConceptualArg` function to create and add an argument with one function call. Each argument is specified as fixed-point and signed. Each argument specifies that code replacement request processing does *not* check for an exact match to the call-site slope and bias values.

```
createAndAddConceptualArg(op_entry, 'RTW.Tf1ArgNumeric', ...
 'Name', 'y1', ...
 'IOType', 'RTW_IO_OUTPUT', ...
 'CheckSlope', false, ...
 'CheckBias', false, ...
 'DataTypeMode', 'Fixed-point: binary point scaling', ...
 'IsSigned', OutSgn, ...
 'WordLength', OutWL, ...
 'FractionLength', OutFL);
```

```
createAndAddConceptualArg(op_entry, 'RTW.Tf1ArgNumeric', ...
 'Name', 'u1', ...
 'IOType', 'RTW_IO_INPUT', ...
 'CheckSlope', false, ...
 'CheckBias', false, ...
 'DataTypeMode', 'Fixed-point: binary point scaling', ...
 'IsSigned', InSgn, ...
 'WordLength', InWL, ...
 'FractionLength', InFL);
```

- 6 Create the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses calls to the `createAndSetCImplementationReturn` and

`createAndAddImplementationArg` functions to create and add implementation arguments to the entry. Implementation arguments must describe fundamental numeric data types (not fixed-point data types).

```
createAndSetCImplementationReturn(op_entry, 'RTW.Tf1ArgNumeric', ...
 'Name', 'y1', ...
 'IOType', 'RTW_IO_OUTPUT', ...
 'IsSigned', OutSgn, ...
 'WordLength', OutWL, ...
 'FractionLength', 0);

createAndAddImplementationArg(op_entry, 'RTW.Tf1ArgNumeric', ...
 'Name', 'u1', ...
 'IOType', 'RTW_IO_INPUT', ...
 'IsSigned', InSgn, ...
 'WordLength', InWL, ...
 'FractionLength', 0);
```

- 7 Add the entry to a code replacement table with a call to the `addEntry` function.

```
addEntry(hTable, op_entry);
```

- 8 Save the table definition file. Use the name of the table definition function to name the file.

## Shift Left Operations and Code Replacement

You can use code replacement entries to replace code that the code generator produces for shift (<<) operations.

### Shift Lefts for `int16` Data

This example creates a code replacement entry to replace shift left operations for `int16` data. The example defines the function mapping programmatically. Alternatively, you can use the Code Replacement Tool to define the same mapping.

- 1 Create a table definition file that contains a function definition. For example:

```
function hTable = crl_table_shift_left_int16
```

- 2 Within the function body, create the table by calling the function `RTW.Tf1Table`.

```
hTable = RTW.Tf1Table;
```

- 3 Create the entry for the operator mapping with a call to the `RTW.Tf1COperationEntry` function.

```
op_entry = RTW.Tf1COperationEntry;
```

- 4 Set operator entry parameters with a call to the `setTf1COperationEntryParameters` function. The parameters specify the type of operation as shift left and the name of the replacement function as `my_shift_left`.

```
setTf1COperationEntryParameters(op_entry, ...
 'Key', 'RTW_OP_SL', ...
 'Priority', 50, ...
 'ImplementationName', 'my_shift_left', ...
 'ImplementationHeaderFile', 'some_hdr.h', ...
 'ImplementationSourceFile', 'some_hdr.c');
```

- 5 Create the `int16` argument as conceptual argument `y1` and the implementation return value. There are multiple ways to set up the conceptual and implementation arguments. This example uses calls to the `getTf1ArgFromString` and `addConceptualArg` functions to create the conceptual argument and add it to the entry. Convenience method `setReturn` specifies the argument as the implementation return value.

```
arg = getTf1ArgFromString(hTable, 'y1', 'int16');
arg.IOType = 'RTW_IO_OUTPUT';
addConceptualArg(op_entry, arg);
op_entry.Implementation.setReturn(arg);
```

- 6 Create the `int16` argument as conceptual and implementation argument `u1`. This example uses calls to the `getTf1ArgFromString` and `addConceptualArg` functions to create the conceptual argument and add it to the entry. Convenience method `addArgument` specifies the argument as an implementation input argument.

```
arg = getTf1ArgFromString(hTable, 'u1', 'int16');
addConceptualArg(op_entry, arg);
op_entry.Implementation.addArgument(arg);
```

- 7 Create the `int8` argument as conceptual and implementation argument `u2`. This example uses calls to the `getTf1ArgFromString` and `addConceptualArg` functions to create the conceptual argument and add it to the entry. This argument specifies the number of bits to shift the previous input argument. Because the argument type is not relevant, the example disables type checking by setting the `CheckType` property to `false`. Convenience method `addArgument` specifies the argument as implementation input argument.

```
arg = getTf1ArgFromString(hTable, 'u2', 'int8');
arg.CheckType = false;
addConceptualArg(op_entry, arg);
op_entry.Implementation.addArgument(arg);
```

- The function `getTf1ArgFromString` is called to create an `int8` input argument. This argument is added to the operator entry both as the third conceptual argument and the second implementation input argument.
- Add the entry to a code replacement table with a call to the `addEntry` function.

```
addEntry(hTable, op_entry);
```

- Save the table definition file. Use the name of the table definition function to name the file.

## Shift Lefts Using Net Slope

You can use code replacement entries to replace code that the code generator produces for shift (`<<`) operations.

This example creates a code replacement entry to replace shift left operations for fixed-point data using a net slope. The example defines the function mapping programmatically. Alternatively, you can use the Code Replacement Tool to define the same mapping.

- 1 Create a table definition file that contains a function definition. For example:

```
function hTable = crl_table_shift_left_fixpt_net_slope
```

- 2 Within the function body, create the table by calling the function `RTW.Tf1Table`.

```
hTable = RTW.Tf1Table;
```

- 3 Create the entry for the operator mapping with a call to the `RTW.Tf1COperationEntryGenerator_Netslope` function. This function provides access to the fixed-point parameters `NetSlopeAdjustmentFactor` and `NetFixedExponent`.

```
op_entry = RTW.Tf1COperationEntryGenerator_NetSlope;
```

- 4 Set operator entry parameters with a call to the `setTf1COperationEntryParameters` function. The parameters specify the type of operation as shift left, the saturation mode as saturate on integer overflow, rounding modes as toward negative infinity, and the name of the replacement function as `my_fxp_shift_left`. `NetSlopeAdjustmentFactor` and `NetFixedExponent` specify the F and E parts of the net slope  $F2^E$ .

```
InFL = 2;
InWL = 16;
InSgn = true;
OutFL = 4;
OutWL = 32;
OutSgn = true;
setTf1COperationEntryParameters(op_entry, ...
 'Key', 'RTW_OP_SL', ...
 'Priority', 50, ...
 'SaturationMode', 'RTW_SATURATE_ON_OVERFLOW', ...
 'RoundingModes', {'RTW_ROUND_FLOOR'}, ...
 'NetSlopeAdjustmentFactor', 1.0, ...
 'NetFixedExponent', (OutFL - InFL), ...
 'ImplementationName', 'my_fxp_shift_left', ...
 'ImplementationHeaderFile', 'some_hdr.h', ...
 'ImplementationSourceFile', 'some_hdr.c');
```

- 5 Create conceptual arguments `y1` and `u1`. There are multiple ways to set up the conceptual arguments. This example uses calls to the `createAndAddConceptualArg` function to create and add an argument with one function call. Each argument is specified as fixed-point and signed. Each argument specifies that code replacement request processing does *not* check for an exact match to the call-site slope and bias values.

```
createAndAddConceptualArg(op_entry, 'RTW.Tf1ArgNumeric', ...
 'Name', 'y1', ...
 'IOType', 'RTW_IO_OUTPUT', ...
 'CheckSlope', false, ...
 'CheckBias', false, ...
 'DataTypeMode', 'Fixed-point: binary point scaling', ...
 'IsSigned', OutSgn, ...
 'WordLength', OutWL, ...
```

```

 'FractionLength', OutFL);

createAndAddConceptualArg(op_entry, 'RTW.Tf1ArgNumeric', ...
 'Name', 'u1', ...
 'IOType', 'RTW_IO_INPUT', ...
 'CheckSlope', false, ...
 'CheckBias', false, ...
 'DataTypeMode', 'Fixed-point: binary point scaling', ...
 'IsSigned', InSgn, ...
 'WordLength', InWL, ...
 'FractionLength', InFL);

```

- 6 Create the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses calls to the `createAndSetCImplementationReturn` and `createAndAddImplementationArg` functions to create and add implementation arguments to the entry. Implementation arguments must describe fundamental numeric data types (not fixed-point data types).

```

createAndSetCImplementationReturn(op_entry, 'RTW.Tf1ArgNumeric', ...
 'Name', 'y1', ...
 'IOType', 'RTW_IO_OUTPUT', ...
 'IsSigned', OutSgn, ...
 'WordLength', OutWL, ...
 'FractionLength', 0);

createAndAddImplementationArg(op_entry, 'RTW.Tf1ArgNumeric', ...
 'Name', 'u1', ...
 'IOType', 'RTW_IO_INPUT', ...
 'IsSigned', InSgn, ...
 'WordLength', InWL, ...
 'FractionLength', 0);

```

- 7 Create the `int8` argument as conceptual and implementation argument `u2`. This example uses calls to the `getTf1ArgFromString` and `addConceptualArg` functions to create the conceptual argument and add it to the entry. This argument specifies the number of bits to shift the previous input argument. Because the argument type is not relevant, type checking is disabled by setting the `CheckType` property to `false`. Convenience method `addArgument` specifies the argument as implementation input argument.

```

arg = getTf1ArgFromString(hTable, 'u2', 'uint8');
arg.CheckType = false;
addConceptualArg(op_entry, arg);
op_entry.Implementation.addArgument(arg);

```

- 8 Add the entry to a code replacement table with a call to the `addEntry` function.

```
addEntry(hTable, op_entry);
```

- 9 Save the table definition file. Use the name of the table definition function to name the file.

## What Is Code Replacement Customization?

Customize how and when the code generator replaces C/C++ code that it generates by default for functions and operators by developing a custom code replacement library. You can develop libraries interactively with the Code Replacement Tool or programmatically.

- Develop libraries tailored to specific application requirements
- Add identifiers to the list of reserved keywords the code generator considers during code replacement
- Customize the code generator's match and replacement process for functions

To get started, “Quick Start Library Development” on page 51-28.

### Code Replacement Match and Replacement Process

When the code generator encounters a call site for a function or operator, it:

- 1 Creates and partially populates a code replacement entry object with the function or operator name or key and conceptual arguments.
- 2 Uses the entry object to query the configured code replacement library for a conceptual representation match. The code generator searches the tables in a code replacement library for a match in the order that the tables appear in the library. When searching for a match, the code generator takes into account:
  - Conceptual name or key
  - Arguments, including quantity, type, type qualifiers, and complexity
  - Algorithm (computation method)
  - Fixed-point saturation and rounding modes
  - Priority
- 3 When a match exists, the code generator returns a code replacement object, fully populated with the conceptual representation, implementation representation, and priority. If the code generator finds multiple matches within a table, the entry priority determines the match. The priority can range from 0 to 100. The highest priority is 0. The code generator uses a higher-priority entry over a similar entry with a lower priority.
- 4 Uses the C or C++ replacement function prototype in the code replacement object to generate code.

## Code Replacement Customization Limitations

- Code replacement verification — It is possible that code replacement behaves differently than you expect. For example, data types that you observe in code generator input might not match what the code generator uses as intermediate data types during an operation. Verify code replacements by examining generated code. See “Verify Code Replacements” on page 52-64.
- Tokens in file paths—You can include tokens in file paths when specifying build information for a code replacement entry by using the programming interface only. The ability to include tokens is not available from the Code Replacement Tool. See “Specify Build Information for Replacement Code” on page 52-47.
- Addition and subtraction operation replacements—See “Addition and Subtraction Operator Code Replacement” on page 52-108 for relevant limitations.
- `coder.replace` function — See `coder.replace` for relevant limitations.

## Code You Can Replace from MATLAB Code

Code that the code generator replaces depends on the code replacement library (CRL) that you use. By default, the code generator does not apply a code replacement library. Your choice of libraries is dependent on product licensing and whether you have access to custom libraries.

“Operators” on page 52-10

## Math Functions

When generating C/C++ code from MATLAB code, depending on code replacement libraries available in your development environment, you can configure the code generator to replace instances of the following math functions with application-specific implementations.

Function	Data Type Support	Scalar, Vector, Matrix Support	Real, Complex Support
abs <sup>1</sup>	Floating point	Scalar	Real
acos	Floating point	Scalar Vector Matrix	Real Complex Complex input/complex output Real input/complex output
acosd	Floating point	Scalar Vector Matrix	Real Complex
acot	Floating point	Scalar Vector Matrix	Real Complex
acotd	Floating point	Scalar Vector Matrix	Real Complex
acoth	Floating point	Scalar	Real

Function	Data Type Support	Scalar, Vector, Matrix Support	Real, Complex Support
		Vector Matrix	Complex
acsc	Floating point	Scalar Vector Matrix	Real Complex
acscd	Floating point	Scalar Vector Matrix	Real Complex
acsch	Floating point	Scalar Vector Matrix	Real Complex
asec	Floating point	Scalar Vector Matrix	Real Complex
asecd	Floating point	Scalar Vector Matrix	Real Complex
asech	Floating point	Scalar Vector Matrix	Real Complex
asin	Floating point	Scalar Vector Matrix	Real Complex Complex input/complex output Real input/complex output
asind	Floating point	Scalar Vector Matrix	Real Complex
atan	Floating point	Scalar Vector Matrix	Real Complex Complex input/complex output Real input/complex output

Function	Data Type Support	Scalar, Vector, Matrix Support	Real, Complex Support
atan2	Floating point	Scalar Vector Matrix	Real
atan2d	Floating point	Scalar Vector Matrix	Real
atand	Floating point	Scalar Vector Matrix	Real Complex
cos	Floating point	Scalar Vector Matrix	Real Complex Complex input/complex output Real input/complex output
ceil	<ul style="list-style-type: none"> <li>• Floating-point</li> <li>• Scalar</li> </ul>	<ul style="list-style-type: none"> <li>• Floating-point</li> <li>• Scalar</li> </ul>	<ul style="list-style-type: none"> <li>• Floating-point</li> <li>• Scalar</li> </ul>
cosd	Floating point	Scalar Vector Matrix	Real Complex
cosh	Floating point	Scalar Vector Matrix	Real Complex Complex input/complex output Real input/complex output
cot	Floating point	Scalar Vector Matrix	Real Complex
cotd	Floating point	Scalar Vector Matrix	Real Complex
coth	Floating point	Scalar Vector Matrix	Real Complex

Function	Data Type Support	Scalar, Vector, Matrix Support	Real, Complex Support
csc	Floating point	Scalar Vector Matrix	Real Complex
cscd	Floating point	Scalar Vector Matrix	Real Complex
csch	Floating point	Scalar Vector Matrix	Real Complex
exp	Floating point	Scalar	Real
fix	Floating point	Scalar	Real
floor	<ul style="list-style-type: none"> <li>• Floating-point</li> <li>• Scalar</li> </ul>	<ul style="list-style-type: none"> <li>• Floating-point</li> <li>• Scalar</li> </ul>	<ul style="list-style-type: none"> <li>• Floating-point</li> <li>• Scalar</li> </ul>
hypot	Floating point	Scalar Vector Matrix	Real
ldexp	Floating point	Scalar	Real
log	Floating point	Scalar Vector Matrix	Real Complex
log10	Floating point	Scalar Vector Matrix	Real Complex
log2	Floating point	Scalar Vector Matrix	Real Complex
max	Integer Floating point	Scalar	Real
min	Integer Floating point	Scalar	Real
pow	Floating point	Scalar	Real

Function	Data Type Support	Scalar, Vector, Matrix Support	Real, Complex Support
rem	Floating point	Scalar	Real
round	Floating point	Scalar	Real
sec	Floating point	Scalar Vector Matrix	Real Complex
secd	Floating point	Scalar Vector Matrix	Real Complex
sech	Floating point	Scalar Vector Matrix	Real Complex
sign	Floating point	Scalar	Real
sin	Floating point	Scalar Vector Matrix	Real Complex Complex input/complex output Real input/complex output
sind	Floating point	Scalar Vector Matrix	Real Complex
sinh	Floating point	Scalar Vector Matrix	Real Complex Complex input/complex output Real input/complex output
sqrt	Floating point	Scalar	Real
tan	Floating point	Scalar Vector Matrix	Real Complex Complex input/complex output Real input/complex output
tand	Floating point	Scalar Vector Matrix	Real Complex

Function	Data Type Support	Scalar, Vector, Matrix Support	Real, Complex Support
tanh	Floating point	Scalar Vector Matrix	Real Complex Complex input/complex output Real input/complex output
<sup>1</sup> Wrap on integer overflow only			

## Memory Functions

Depending on code replacement libraries available in your development environment, you can configure the code generator to replace instances of the following memory functions with application-specific implementations.

Function	Data Type Support	Scalar, Vector, Matrix Support	Real, Complex Support
memcmp	Void pointer (void*)	Scalar Vector Matrix	Real Complex
memcpy	Void pointer (void*)	Scalar Vector Matrix	Real Complex
memset	Void pointer (void*)	Scalar Vector Matrix	Real Complex
memset2zero	Void pointer (void*)	Scalar Vector Matrix	Real Complex

Some target processors provide optimized functions to set memory to zero. Use the code replacement library programming interface to replace the `memset2zero` function with more efficient target-specific functions.

## Operators

When generating C/C++ code from MATLAB code, depending on code replacement libraries available in your development environment, you can configure the code

generator to replace instances of the following operators with application-specific implementations.

Mixed data type support indicates you can specify different data types of different inputs.

<b>Operator</b>	<b>Key</b>	<b>Data Type Support</b>	<b>Scalar, Vector, Matrix Support</b>	<b>Real, Complex Support</b>
Addition (+) <sup>1</sup>	RTW_OP_ADD	Integer Floating point Fixed-point Mixed	Scalar Vector Matrix	Real Complex
Subtraction (-) <sup>1</sup>	RTW_OP_MINUS	Integer Floating point Fixed-point Mixed	Scalar Vector Matrix	Real Complex
Multiplication (*) <sup>2</sup>	RTW_OP_MUL	Integer Floating point Fixed-point Mixed	Scalar Vector Matrix	Real Complex
Division (/)	RTW_OP_DIV	Integer Floating point Fixed-point Mixed	Scalar	Real Complex
Data type conversion (cast)	RTW_OP_CAST	Integer Floating point <sup>3</sup> Fixed-point Mixed	Scalar Vector Matrix	Real Complex
Shift left (<<)	RTW_OP_SL	Integer Fixed-point Mixed	Scalar Vector Matrix	Real
Shift right arithmetic (>>) <sup>4</sup>	RTW_OP_SRA	Integer Fixed-point Mixed	Scalar Vector Matrix	Real
Shift right logical (>>)	RTW_OP_SRL	Integer Fixed-point	Scalar Vector	Real

Operator	Key	Data Type Support	Scalar, Vector, Matrix Support	Real, Complex Support
		Mixed	Matrix	
Element-wise matrix multiplication ( $\cdot$ $\cdot$ ) <sup>5</sup>	RTW_OP_ELEM_MUL	Integer Floating point Fixed-point Mixed	Vector Matrix	Real Complex
Complex conjugation	RTW_OP_CONJUGATE	Integer Floating point Fixed-point Mixed	Scalar Vector Matrix	Real Complex
Transposition ( $\cdot$ $'$ )	RTW_OP_TRANS	Integer Floating point Fixed-point Mixed	Vector Matrix	Real Complex
Hermitian (complex conjugate) transposition ( $'$ )	RTW_OP_HERMITIAN	Integer Floating point Fixed-point Mixed	Vector Matrix	Real Complex
Multiplication with transposition <sup>2</sup>	RTW_OP_TRMUL	Integer Floating point Fixed-point Mixed	Vector Matrix	Real Complex
Multiplication with Hermitian transposition <sup>2</sup>	RTW_OP_HMMUL	Integer Floating point Fixed-point Mixed	Vector Matrix	Real Complex
Multiplication followed by shift right arithmetic ( $u1 * u2 \gg u3$ ) <sup>6</sup>	RTW_OP_MUL_SRA	Integer Fixed-point	Scalar	Real
Multiplication followed by division ( $u1 * u2 / u3$ ) <sup>7</sup>	RTW_OP_MULDIV	Integer Fixed-point	Scalar	Real

Operator	Key	Data Type Support	Scalar, Vector, Matrix Support	Real, Complex Support
Greater than (>)	RTW_OP_GREATER_THAN	Integer Floating point Fixed-point Mixed	Scalar Vector Matrix	Real Complex
Greater than or equal (>=)	RTW_OP_GREATER_THAN_OR_EQUAL	Integer Floating point Fixed-point Mixed	Scalar Vector Matrix	Real Complex
Less than (<)	RTW_OP_LESS_THAN	Integer Floating point Fixed-point Mixed	Scalar Vector Matrix	Real Complex
Less than or equal (<=)	RTW_OP_LESS_THAN_OR_EQUAL	Integer Floating point Fixed-point Mixed	Scalar Vector Matrix	Real Complex
Equal (==)	RTW_OP_EQUAL	Integer Floating point Fixed-point Mixed	Scalar Vector Matrix	Real Complex
Not equal (!=)	RTW_OP_NOT_EQUAL	Integer Floating point Fixed-point Mixed	Scalar Vector Matrix	Real Complex

Operator	Key	Data Type Support	Scalar, Vector, Matrix Support	Real, Complex Support
<p><sup>1</sup> See “Addition and Subtraction Operator Code Replacement” on page 52-108 for details to consider when defining mappings for addition and subtraction code replacements.</p> <p><sup>2</sup> Can map to Basic Linear Algebra Subroutine (BLAS) multiplication functions.</p> <p><sup>3</sup> Scaled floating point is not supported.</p> <p><sup>4</sup> Code replacement libraries that provide arithmetic shift right implementations should also provide logical shift right implementations, because some arithmetic shift rights are converted to logical shift rights during code generation.</p> <p><sup>5</sup> Use the multiplication (*) operator (RTW_OP_MUL) for scalar multiplication.</p> <p><sup>6</sup> Requires scalar, real, or fixed-point data types with zero bias; output type of the multiplication operation to accommodate all possible output values; shift operand is an unsigned integer; and net slope is equal to 1 (<math>U1\_slope * U2\_slope == Mul\_output\_slope</math> and <math>Mul\_output\_slope == output\_slope\_of\_shift\_operation</math>).</p> <p><sup>7</sup> Requires scalar, real, or fixed-point data types with zero bias; output type of the multiplication operation to accommodate all possible output values; and net slope is equal to 1 (<math>U1\_slope * U2\_slope == Mul\_output\_slope == U3\_slope * Div\_output\_slope</math>).</p>

- “What Is Code Replacement?”

## Develop a Code Replacement Library

Iterate through the following steps, as necessary, to develop a code replacement library:

- 1 “Identify Code Replacement Requirements” on page 52-26
- 2 “Prepare for Code Replacement Library Development” on page 52-29
- 3 “Define Code Replacement Mappings” on page 52-30
- 4 “Specify Build Information for Replacement Code” on page 52-47
- 5 “Register Code Replacement Mappings” on page 52-56
- 6 “Verify Code Replacements” on page 52-64
- 7 “Deploy Code Replacement Library” on page 52-81

To get started, see “Identify Code Replacement Requirements” on page 52-26.

To experiment with the process and tools, see “Quick Start Library Development” on page 52-16.

### More About

- “Identify Code Replacement Requirements” on page 52-26
- “Code You Can Replace from MATLAB Code” on page 52-5
- “Quick Start Library Development” on page 52-16
- “What Is Code Replacement Customization?” on page 52-3

## Quick Start Library Development

This example shows how to develop a code replacement library that includes an entry for generating replacement code for the math function `sin`. You use the Code Replacement Tool.

### Prerequisites

To complete this example, install the following software:

- MATLAB
- MATLAB Coder
- Embedded Coder
- C compiler

For instructions on installing MathWorks products, see [. If you have installed MATLAB and want to see what other MathWorks products are installed, in the Command Window, enter `ver`.](#)

For a list of supported compilers, see [http://www.mathworks.com/support/compilers/current\\_release/](http://www.mathworks.com/support/compilers/current_release/).

### Open the Code Replacement Tool

- 1 Start a new MATLAB session.
- 2 Create or navigate (`cd`) to an empty folder.
- 3 At the command prompt, enter the `crtool` command. The Code Replacement Tool window opens.

### Create Code Replacement Table

- 1 In the Code Replacement Tool window, select **File > New table**.
- 2 In the right pane, name the table `crl_table_sinfcn` and click **Apply**. Later, when you save the table, the tool saves it with the file name `crl_table_sinfcn.m`.

### Create Table Entry

Create a table entry that maps a `sin` function with `double` input and `double` output to a custom implementation function.

- 1 In the left pane, select table `crl_table_sinfcn`. Then, select **File > New entry > Function**. The new entry appears in the middle pane, initially without a name.
- 2 In the middle pane, select the new entry.
- 3 In the right pane, on the **Mapping Information** tab, from the **Function** menu, select `sin`.
- 4 Leave **Algorithm** set to `Unspecified`, and leave parameters in the **Conceptual function** group set to default values.
- 5 In the **Replacement function** group, name the replacement function `sin_dbl`.
- 6 Leave the remaining parameters in the **Replacement function** group set to default values.

- 7 Click **Apply**. The tool updates the **Function signature preview** to reflect the specified replacement function name.
- 8 Scroll to the bottom of the **Mapping Information** tab and click **Validate entry**. The tool validates your entry.

The following figure shows the completed mapping information.

Mapping Information    Build Information

Function:

Entry information

Algorithm:

Conceptual function

*Used by code generation process for matching purposes*

Conceptual arguments    Argument properties

y1 u1	Data type: <input type="text" value="double"/>
	<input type="checkbox"/> Complex
	Argument type: <input type="text" value="Scalar"/>

Make conceptual and implementation argument types the same

Replacement function

Function prototype

Name:     C++ namespace:

Function returns void

Function arguments    Argument properties

y1(return arg) u1	Data type: <input type="text" value="double"/> I/O type: <input type="text" value="OUTPUT"/>
	<input type="checkbox"/> Const <input type="checkbox"/> Pointer <input type="checkbox"/> Complex

Function signature preview

```
double sin_dbl(double u1);
```

Implementation attributes

Integer saturation mode:

Rounding mode:   
Floor  
Ceil  
...

Allow expressions as inputs

Function modifies internal or global state

[Click here to add Build Information](#)

Validation

   Status: *Validated*

### Specify Build Information for Replacement Code

- 1 On the **Build Information** tab, for the **Implementation header file** parameter, enter `sin_dbl.h`.
- 2 Leave the remaining parameters set to default values.
- 3 Click **Apply**.

- 4 Optionally, you can revalidate the entry. Return to the **Mapping Information** tab and click **Validate entry**.

### Create Another Table Entry

Create an entry that maps a `sin` function with `single` input and `double` output to a custom implementation function named `sin_sgl`. Create the entry by copying and pasting the `sin_dbl` entry.

- 1 In the middle pane, select the `sin_dbl` entry.
- 2 Select **Edit > Copy**
- 3 Select **Edit > Paste**
- 4 On the **Mapping Information** tab, in the **Conceptual function** section, set the data type of input argument `u1` to `single`.
- 5 In the **Replacement function** section, name the function `sin_sgl`. Set the data type of input argument `u1` to `single`.
- 6 Click **Apply**. Note the changes that appear for the **Function signature preview**.
- 7 On the **Build Information** tab, for the **Implementation header file** parameter, enter `sin_sgl.h`. Leave the remaining parameters set to default values and click **Apply**.

### Validate the Code Replacement Table

- 1 Select **Actions > Validate table**.

- 2 If the tool reports errors, fix them, and rerun the validation. Repeat fixing and validating errors until the tool does not report errors. The following figure shows a validation report.

Name	Implementation	NumIn	In1Type	In2Type	Out1Type	Out2Type	Priority
✓ sin	sin_dbl	1	double		double		100
✓ sin	sin_sgl	1	single		double		100

### Save the Code Replacement Table

Save the code replacement table to a MATLAB file in your working folder. Select **File > Save table**. By default, the tool uses the table name to name the file. For this example, the tool saves the table in the file `crl_table_sinfcn.m`.

### Review the Code Replacement Table Definition

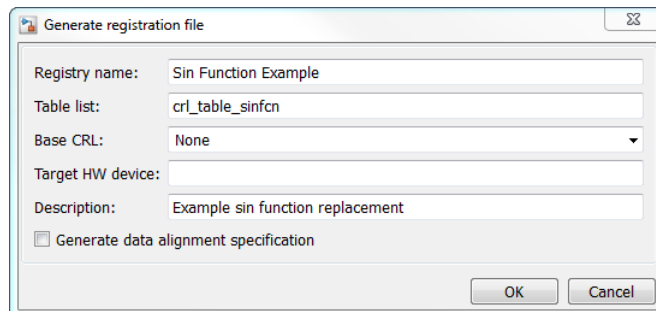

Consider reviewing the MATLAB code for your code replacement table definition. After using the tool to create an initial version of a table definition file, you can update, enhance, or copy the file in a text editor.

To review it, in MATLAB or another text editor, open the file `crl_table_sinfcn.m`.

### Generate a Registration File

Before you can use your code replacement table, you must register it as part of a code replacement library. Use the Code Replacement Tool to generate a registration file.

- 1 In the Code Replacement Tool, select **File > Generate registration file**.
- 2 In the **Generate registration file** dialog box, edit the dialog box fields to match the following figure, and then click **OK**.

- 3 In the **Select location** dialog box, specify a location for the registration file. The location must be on the MATLAB path or in the current working folder. Save the file. The tool saves the file as `rtwTargetInfo.m`.

### Register the Code Replacement Table

At the command prompt, enter:

```
RTW.TargetRegistry.getInstance('reset');
```

### Review and Test Code Replacements

Apply your code replacement library. Verify that the code generator makes code replacements that you expect.

- 1 Check for errors. At the command line, invoke the table definition file. For example:

```
tbl = crl_table_sinfcn
```

```
tbl =
```

```
Tf1Table with properties:
```

```
 Version: '1.0'
 ReservedSymbols: []
StringResolutionMap: []
 AllEntries: [2x1 RTW.Tf1CFunctionEntry]
 EnableTrace: 1
```

If an error exists in the definition file, the invocation triggers a message to appear. Fix the error and try again.

- 2 Use the Code Replacement Viewer to check your code replacement entries. For example:

```
crviewer('Sin Function Example')
```

In the viewer, select entries in your table and verify that the content is what you expect. The viewer can help you detect issues such as:

- Incorrect argument order.
- Conceptual argument names that do not match what is expected by the code generator.

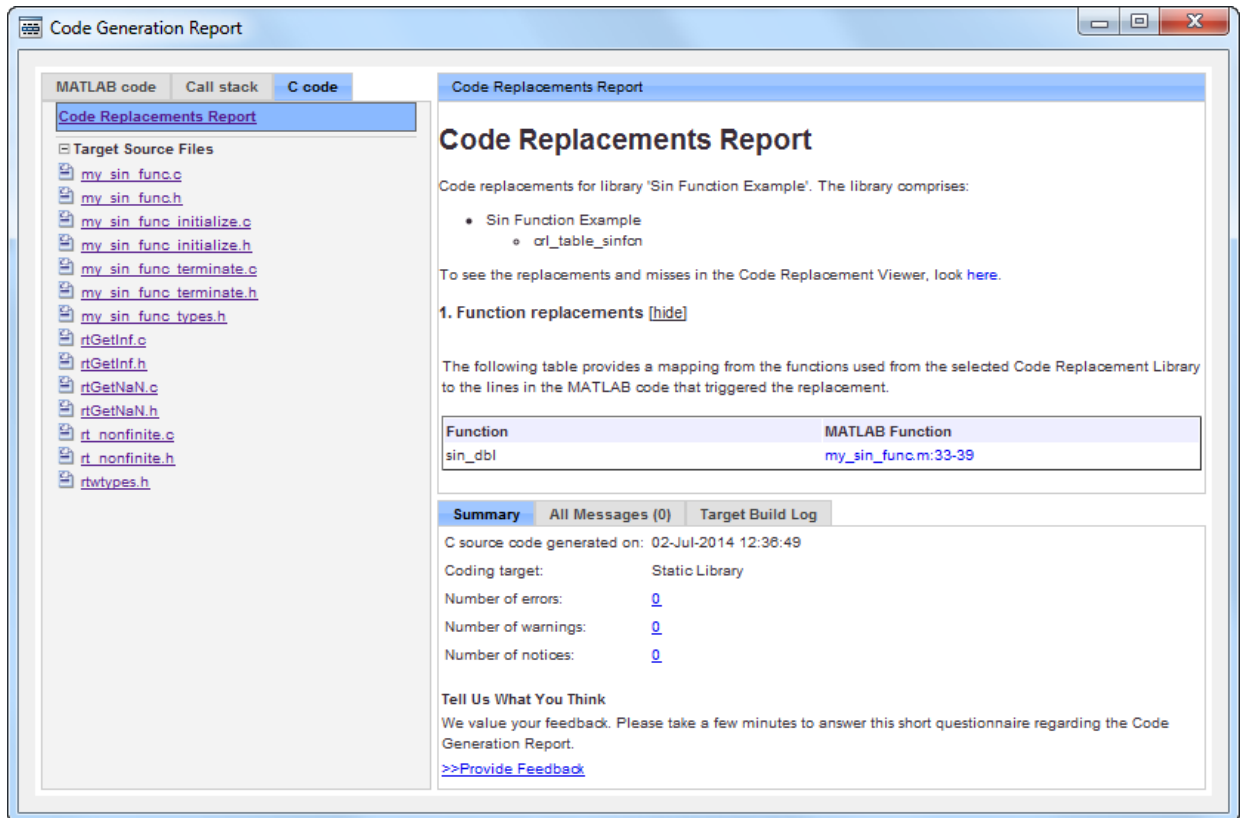

- Incorrect priority settings.

- 3 Identify existing or create new MATLAB code that calls the `sin` function. For example:

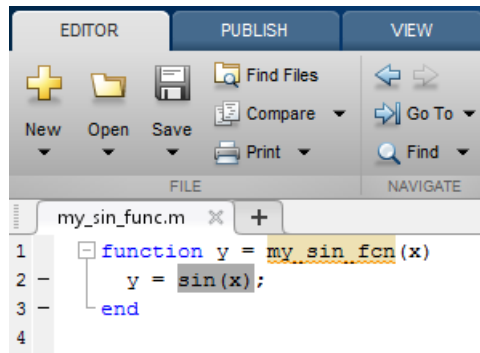

```
function y = my_sin_fnc(x)
 y = sin(x);
end
```

- 4 Open the MATLAB Coder app.
- 5 Add the function that includes a call to the `sin` function as an entry-point file. For example, add `my_sin_func.m`. The app creates a project named `my_sin_func.prj`.
- 6 Click **Next** to go to the **Define Input Type** step. Define the types for the entry-point function inputs.
- 7 Click **Next** to go to the **Check for Run-Time Issues** step. This step is optional. However, it is a best practice to perform this step. Provide a test file that calls your entry-point function. The app generates a MEX function from your entry-point function. Then, the app runs the test file, replacing calls to the MATLAB function with calls to the generated MEX function.
- 8 Click **Next** to go to the **Generate Code** step. To open the **Generate** dialog box, click the **Generate** arrow .
- 9 Set **Build type** to generate a library or executable.
- 10 Click **More Settings**.
- 11 Configure the code generator to use your code replacement library. On the **Custom Code** tab, set the **Code replacement library** parameter to the name of your library. For example, `Sin Function Example`.
- 12 Configure the code generation report. On the **Debugging** tab, set the **Always create a code generation report**, **Code replacements**, and **Automatically launch a report if one is generated** parameters.
- 13 Configure the code generator to generate code only. On the **Generate** dialog box, select the **Generate code only** check box. You want to review your code replacements in the generated code before building an executable.
- 14 Click **Generate** to generate C code and a report.
- 15 Review code replacement results in the Code Replacements Report section of the code generation report.

The report indicates that the code generator found a match and applied the replacement code for the function `sin_dbl`.

- 16 Review the code replacements. In the report, under **Function replacements**, click the MATLAB function that triggered the replacement, `my_sin_func.m`. The MATLAB Editor opens and highlights the function call that triggers the code replacement.

## More About

- “Develop a Code Replacement Library” on page 52-15
- “What Is Code Replacement Customization?” on page 52-3

## Identify Code Replacement Requirements

The first step to developing a code replacement library is to consider the following types of requirements for your code replacement library.

### Mapping Information Requirements

- Are you defining a code replacement mapping for the first time?
- Are you updating code replacement entries in an existing library? Or, are you creating a new library?
- Are you rapid prototyping code replacements?
- Can you base your mappings on existing mappings?
- What type of code do you want to replace? Options include:
  - Math operation
  - Function
  - BLAS operation
  - CBLAS operation
  - Net slope fixed-point operation
  - Semaphore or mutex functions
- Do you want to change the inline or nonfinite behavior for functions?
- What specific functions and operations do you want to replace?
- What input and output arguments does the function or operator that you are replacing take? For each argument, what is the data type, complexity, and dimensionality?
- What does the prototype for your replacement code look like?
  - What is the replacement function name?
  - What are the input and output arguments?
  - Are there return values?
  - What is the data type, complexity, and dimensionality of each argument and return value?

## Build Information Requirements

- Does your replacement function implementation require a header file? If yes, specify the header file.
- If the replacement function implementation requires a header file, what is the path for that file?
- Is the source file for the replacement function in your working folder? If not, you can explicitly specify the source file name and extension. For example, if the file is required in the generated makefile or specified in a build information object, specify the source file.
- Does the replacement function use additional include files? If yes, what are they and what are the paths for those files?
- Does the replacement function use additional source files? If yes, what are they and what are the paths for those files?
- What compiler flags are required for compiling code that includes the replacement code?
- What linker flags are required for building an executable that includes the replacement code?
- Are the required header, source, and object files for building an executable that includes your replacement code in the working folder for your project? If not, before starting the build process, do you want the code generator to copy required files to the build folder?

## Registration Information Requirements

- What do you want to name your code replacement library?
- What code replacement tables do you want to include in the library? What are the file names and paths for the tables?
- What is the purpose of the library? You can document the purpose as the library description.
- Does the library apply to specific hardware devices? If yes, what devices?
- Are you developing a hierarchy of code replacement libraries? Is the library that you are developing based (dependent) on another library? For example, you can specify a general `TI device library` as the base library for a more specific `TI C28x device library`.

- Do you need to specify data alignment for the library? What data alignments are required? For each specification, what type of alignment is required and for what programming language?

Next, prepare for developing a library by reviewing a code replacement library development checklist.

### **Related Examples**

- “Develop a Code Replacement Library” on page 52-15
- “Prepare for Code Replacement Library Development” on page 52-29
- “What Is Code Replacement Customization?” on page 52-3
- “Code You Can Replace from MATLAB Code” on page 52-5

## Prepare for Code Replacement Library Development

After you identify your code replacement requirements, prepare for library development by reviewing this checklist:

- Get familiar with the library development process.
- Decide whether to define code replacement mappings and produce a registration file interactively with the Code Replacement Tool or programmatically.
- Identify or develop MATLAB code and Simulink models to test your code replacement library.
- Consider the hierarchy and organization of your library. A library can consist of multiple tables and each table can include multiple entries. How do you want to organize the library to optimize reuse of tables and entries? For example, a registration file can define code replacement tables organized in a hierarchy of code replacement libraries based on entries that increase in specificity:
  - Common entries
  - Entries for TI devices
  - Entries for TI C6xx devices
  - Entries specific to the TI C67x device
- If support files, such as header files, additional source files, and dynamically linked libraries are not in your current working folder, note their location. You need to specify the paths for such files.

Next, based on your requirements and preparation, define code replacement mappings.

### More About

- “Identify Code Replacement Requirements” on page 52-26
- “Code You Can Replace from MATLAB Code” on page 52-5
- “Define Code Replacement Mappings” on page 52-30
- “Develop a Code Replacement Library” on page 52-15
- “What Is Code Replacement Customization?” on page 52-3

## Define Code Replacement Mappings

After you prepare for library development, use your requirements to define code replacement mappings. A code replacement mapping associates a conceptual representation of a function or operator that is familiar to the code generator with a custom implementation representation that specifies a C or C++ replacement function prototype. You capture a mapping as an entry in a code replacement table:

- Interactively, by using the Code Replacement Tool.
- Programmatically, by using a MATLAB programming interface.

### Choose an Approach for Defining Code Replacement Mappings

The following table lists situations to help you decide when to use the interactive or programmatic approach.

Situation	Approach
Defining mappings for the first time.	Code Replacement Tool.
Rapid prototyping mappings.	Code Replacement Tool to quickly generate, register, and test mappings.
Developing a mapping as a template or starting point for defining similar mappings.	Code Replacement Tool to generate definition code that you can copy and modify.
Modifying a registration file, including copying and pasting content.	MATLAB Editor to update the programming interface directly.
Defining mappings that specify attributes not available from the Code Replacement Tool (for example, sets of algorithm parameters).	Programming interface.
Reusing existing code for new mappings by copying, pasting, and editing existing mappings.	Programming interface.

## Define Mappings Interactively with the Code Replacement Tool

This example shows how to use the Code Replacement Tool to develop code replacement mappings. The tool is ideal for getting started with developing mappings, rapid prototyping, and developing a mapping to use as a starting point for defining similar mappings.

### Open the Code Replacement Tool

Do one of the following:

- In the Command Window, enter the command `crtool`.
- In the Configuration Parameters dialog box, navigate to **All Parameters > Code Generation > Code replacement library** and click **Custom**.

An Embedded Coder license is not required to create a custom code replacement library. However, you must have an Embedded Coder license to use a such a library.

By default, the tool displays, left to right, a root pane, a list pane, and a dialog pane. You can manipulate the display:

- Drag boundaries to widen, narrow, shorten, or lengthen panes, and to resize table columns.
- Select **View > Show dialog pane** to hide or display the right-most pane.
- Click a table column heading to sort the table based on contents of the selected column.
- Right-click a table column heading and select **Hide** to remove the column from the display. (You cannot hide the **Name** column.)

### Create a Code Replacement Table

- 1 In the Code Replacement Tool window, select **File > New table**.
- 2 In the right pane, name the table and click **Apply**. Later, when you save the table, the tool uses the table name that you specify to name the file. For example, if you enter the name `my_sinfcn`, the tool names the file `my_sinfcn.m`.

### Create Table Entries

Create one or more table entries. Each entry maps the conceptual representation of a function or operator to your implementation representation. The information that you enter depends on the type of entry you create. Enter the following information:

- 1 In the left pane, select the table to which you want to add the entry.
- 2 Select **File > New entry > entry-type**, where **entry-type** is one of:
  - Math Operation
  - Function
  - BLAS Operation
  - CBLAS Operation
  - Net Slope Fixed-Point Operation
  - Semaphore entry
  - Customization entry

The new entry appears in the middle pane, initially without a name.

- 3 In the middle pane, select the new entry.
- 4 In the right pane, on the **Mapping Information** tab, from the **Function** or **Operation** menu, select the function or operation that you want the code generator to replace. Regardless of the entry type, make a selection from this menu. Your selection determines what other information you specify.

Except for customization entries, you also specify information for your replacement function prototype. You can also specify implementation attributes, such as the rounding modes to apply.

- 5 If prompted, specify additional entry information that you want the code generator to use when searching for a match. For example, when you select an addition or subtraction operation, the tool prompts you to specify an algorithm (**Cast before operation** or **Cast after operation**).
- 6 Review the conceptual argument information that the tool populates for the function or operation. Conceptual input and output arguments represent arguments for the function or operator being replaced. Conceptual arguments observe naming conventions ('y1', 'u1', 'u2', ...) and data types familiar to the code generator.

If you do not want the data types for your implementation to be the same as the conceptual argument types, clear the **Make the conceptual and implementation argument types the same** check box. For example, most ANSI-C functions operate on and return **double** data. Clear the check box if want to map a conceptual representation of the function to an implementation representation that specifies an argument and return value. For example, clear the check box to map the conceptual representation of the function **sin** to an implementation representation that

specifies an argument and return value of type `single` (`single sin(single)`), of type `double` (`double sin(double)`). In this case, the code generator produces the following code:

```
y = (single) sin(u1);
```

If you select **Custom** for a function entry, specify only conceptual argument information.

- 7 Specify the name and argument information for your replacement function. As you enter the information and click **Apply**, the tool updates the **Function signature preview**.
- 8 Specify additional implementation attributes that apply. For example, depending on the type and name of the entry that you specify, the tool prompts you to specify:
  - Integer saturation mode
  - Rounding modes
  - Whether to allow inputs that include expressions
  - Whether a function modifies internal or global state
- 9 Click **Apply**.

### Validate Tables and Entries

The Code Replacement Tool provides a way to validate the syntax of code replacement tables and table entries as you define them. If the tool finds validation errors, you can address them and retry the validation. Repeat the process until the tool does not report errors.

To	Do
Validate table entries	Select an entry, scroll to the bottom of the <b>Mapping Information</b> tab, and click <b>Validate entry</b> . Alternatively, select one or more entries, right-click, and select <b>Validate entries</b> .
Validate a table	Select the table. Then, select <b>Actions &gt; Validate table</b> .

### Save a Table

When you save a table, the tool validates unvalidated content.

- 1 Select **File > Save table**.
- 2 In the Browse For Folder dialog box, specify a location and name for the file. Typically, you select a location on the MATLAB path. By default, the tool names the file using the name that you specify for the table with the extension `.m`.
- 3 Click **Save**.

### Open and Modify Tables

After saving a code replacement table, to make changes in the table:

- 1 Select **File > Open table**.
- 2 In the Import file dialog box, browse to the MATLAB file that contains the table.

Repeat the sequence to open and work on multiple tables.

If you open multiple tables, you can manage the tables together. For example, use the tool to:

- Create new table entries.
- Delete entries.
- Copy and paste or cut and paste information between tables.

## Define Mappings Programmatically

This example shows how to define a code replacement mapping programmatically. The programming interface for defining code replacement table mappings is ideal for

- Modifying tables that you create with the Code Replacement Tool.
- Defining mappings for specialized entries that you cannot create with the Code Replacement Tool.
- Replicating and modifying similar entries and tables.

Steps for defining a mapping programmatically are:

### Create Code Replacement Table

- 1 Create a table definition file that contains a function definition. For example:  

```
function hTable = cr1_table_sinfcn()
```
- 2 Within the function body, create the table by calling the function `RTW.Tf1Table`.

```
hTable = RTW.Tf1Table;
```

## Create Table Entry

For each function or operator that you want the code generator to replace, map a conceptual representation of the function or operator to an implementation representation as a table entry.

- 1 Within the body of a table definition file, create a code replacement entry object. Call one of the following functions.

Entry Type	Function
Math operation	RTW.Tf1COperationEntry
Function	RTW.Tf1CFunctionEntry
BLAS operation	RTW.Tf1BlasEntryGenerator
CBLAS operation	RTW.Tf1CBlasEntryGenerator
Fixed-point addition and subtraction operations (support for <code>SlopesMustBeTheSame</code> and <code>ZeroNetBias</code> parameters)	RTW.Tf1COperationEntryGenerator
Net slope fixed-point operation	RTW.Tf1COperationEntryGenerator_NetSlope
Semaphore or mutex entry	RTW.Tf1CSemaphoreEntry
Custom function entry	<i>MyCustomFunctionEntry</i> (where <i>MyCustomFunctionEntry</i> is a class derived from RTW.Tf1CFunctionEntryML)
Custom operation entry	<i>MyCustomOperationEntry</i> (where <i>MyCustomOperationEntry</i> is a class derived from RTW.Tf1COperationEntryML)

For example:

```
hEnt = RTW.Tf1CFunctionEntry;
```

You can combine steps of creating the entry, setting entry parameters, creating conceptual and implementation arguments, and adding the entry to a table with a

single function call to `registerCFunctionEntry`, `registerCPPFunctionEntry`, or `registerCPromotableMacroEntry` if you are creating an entry for a function and the function implementation meets the following criteria:

- Implementation argument names and order match the names and order of corresponding conceptual arguments.
- Input arguments are of the same type.
- The return and input argument names follow the code generator's default naming conventions:
  - Return argument is `y1`.
  - Input arguments are `u1`, `u2`, ..., `un`.

For example:

```
registerCFunctionEntry(hTable, 100, 1, 'sin', 'double', ...
 'sin_dbl', 'double', 'sin_dbl.h', '', '');
```

As another alternative, you can significantly reduce the amount of code that you write by combining the steps of creating the entry and conceptual and implementation arguments with a call to the `createCRLentry` function. In this case, specify the conceptual and implementation information as character vector specifications.

For example:

```
hEnt = createCRLentry(hTable, ...
 'double y1 = sin(double u1)', ...
 'mySin');
```

This approach does not support:

- C++ implementations
- Data alignment
- Operator replacement with net slope arguments
- Entry parameter specifications (for example, priority, algorithm, building information)
- Semaphore and mutex function replacements

## Set Entry Parameters

Set entry parameters, such as the priority, algorithm information, and implementation (replacement) function name. Call the function listed in the following table for the entry type that you created.

Entry Type	Function
Math operation	setTf1COperationEntryParameters
Function	setTf1CFunctionEntryParameters
BLAS operation	setTf1COperationEntryParameters
CBLAS operation	setTf1COperationEntryParameters
Fixed-point addition and subtraction operations where there is a many-to-one mapping, such as a mapping for a range of fixed-point types to the same replacement function (support for SlopesMustBeTheSame and ZeroNetBias parameters)	setTf1COperationEntryParameters
Net slope fixed-point operation	setTf1COperationEntryParameters
Semaphore or mutex entry	setTf1CSemaphoreEntryParameters
Custom function entry	setTf1CFunctionEntryParameters
Custom operation entry	setTf1COperationEntryParameters

To see a list of the parameters that you can set, at the command line, create a new entry and omit the semicolon at the end of the command. For example:

```
hEnt = RTW.Tf1CFunctionEntry
```

```
hEnt =
```

```
Tf1CFunctionEntry with properties:
```

```

 Implementation: [1x1 RTW.CImplementation]
 SlopesMustBeTheSame: 0
 BiasMustBeTheSame: 0
 AlgorithmParams: []
 ImplType: 'FCN_IMPL_FUNCT'
 AdditionalHeaderFiles: {0x1 cell}
 AdditionalSourceFiles: {0x1 cell}

```

```
AdditionalIncludePaths: {0x1 cell}
AdditionalSourcePaths: {0x1 cell}
AdditionalLinkObjs: {0x1 cell}
AdditionalLinkObjsPaths: {0x1 cell}
AdditionalLinkFlags: {0x1 cell}
AdditionalCompileFlags: {0x1 cell}
 SearchPaths: {0x1 cell}
 Key: ''
 Priority: 100
 ConceptualArgs: [0x1 handle]
 EntryInfo: []
 GenCallback: ''
 GenFileName: ''
 SaturationMode: 'RTW_SATURATE_UNSPECIFIED'
 RoundingModes: {'RTW_ROUND_UNSPECIFIED'}
 TypeConversionMode: 'RTW_EXPLICIT_CONVERSION'
 AcceptExprInput: 1
 SideEffects: 0
 UsageCount: 0
 RecordedUsageCount: 0
 Description: ''
 StoreFcnReturnInLocalVar: 0
 TraceManager: [1x1 RTW.Tf1TraceManager]
```

To see the implementation parameters, enter:

```
hEnt.Implementation
```

```
ans =
```

```
CImplementation with properties:
```

```
HeaderFile: ''
SourceFile: ''
HeaderPath: ''
SourcePath: ''
Return: []
StructFieldMap: []
Name: ''
Arguments: [0x1 handle]
ArgumentDescriptor: []
```

For example, to set entry parameters for the `sin` function and name your replacement function `sin_dbl`, use the following function call:

```
setTf1CFunctionEntryParameters(hEnt, ...
 'Key', 'sin', ...
 'ImplementationName', 'sin_dbl');
```

### Create Conceptual Arguments

Create conceptual arguments and add them to the entry's array of conceptual arguments.

- Specify output arguments before input arguments.
- Specify argument names that comply with code generator argument naming conventions:
  - $y_1$  for a return argument
  - $u_1, u_2, \dots, u_n$  for input arguments
- Specify data types that are familiar to the code generator.
- The function signature, including argument naming, order, and attributes, must fulfill the signature match sought by function or operator callers.
- The code generator determines the size of the value for an argument with an unsized type, such as integer, based on hardware implementation configuration settings.

For each argument:

- 1 Identify whether the argument is for input or output, the name, and data type. If you do not know what arguments to specify for a supported function or operation, use the Code Replacement Tool to find them. For example, to find the conceptual arguments for the `sin` function, open the tool, create a table, create a function entry, and in the **Function** menu select `sin`.
- 2 Create and add the conceptual argument to an entry. You can choose a method from the methods listed in this table.

If	Then
You want simpler code or want to explicitly specify whether the argument is scalar or nonscalar (vector or matrix).	Call the function <code>createAndAddConceptualArg</code> . For example:  <pre>createAndAddConceptualArg(hEnt, ...     'RTW.Tf1ArgNumeric', ...     'Name', 'y1', ...     'IOType', 'RTW_IO_OUTPUT', ...     'DataTypeMode', 'double');</pre>

If	Then
	The second argument specifies whether the argument is scalar ( <code>RTW.TflArgNumeric</code> or <code>RTW.TflArgMatrix</code> ).
You want to create an argument based on a built-in argument definition (for example, scalar or nonscalar).	Call <code>getTflArgFromString</code> to create the argument. Then, call <code>addConceptualArg</code> to add the argument to the entry.  <pre>arg = getTflArgFromString(hEnt, 'y1','double'); arg.IOType = 'RTW_IO_OUTPUT'; addConceptualArg(hEnt, arg);</pre>
You need to define several similar mappings, you want to minimize the code to write, and the entries do not require data alignment, use net slope arguments, or involve semaphore or mutex replacements.	Call <code>createCRLEntry</code> to create the entry and specify conceptual and implementation arguments in a single function call.  <pre>hEnt = createCRLEntry(hTable, ...     'double y1 = sin(double u1)', ...     'mySin');</pre>

The following code shows the second approach listed in the table for specifying the conceptual output and input argument definitions for the `sin` function.

#### % Conceptual Args

```
arg = getTflArgFromString(hEnt, 'y1','double');
arg.IOType = 'RTW_IO_OUTPUT';
addConceptualArg(hEnt, arg);
```

```
arg = getTflArgFromString(hEnt, 'u1','double');
addConceptualArg(hEnt, arg);
```

#### Create Implementation Arguments

Create implementation arguments for the C or C++ replacement function and add them to the entry.

- When replacing code, the code generator uses the argument names to determine how it passes data to the implementation function.

- For function replacements, the order of implementation argument names must match the order of the conceptual argument names.
- For operator replacements, the order of implementation argument names do not have to match the order of the conceptual argument names. For example, for an operator replacement for addition,  $y1=u1+u2$ , the conceptual arguments are  $y1$ ,  $u1$ , and  $u2$ , in that order. If the signature of your implementation function is `t myAdd(t u2, t u1)`, where `t` is a valid C type, based on the argument name matches, the code generator passes the value of the first conceptual argument,  $u1$ , to the second implementation argument of `myAdd`. The code generator passes the value of the second conceptual argument,  $u2$ , to the first implementation argument of `myAdd`.
- For operator replacements, you can remap operator output arguments to implementation function input arguments.

For each argument:

- 1 Identify whether the argument is for input or output, the name, and the data type.
- 2 Create and add the implementation argument to an entry. You can choose a method from the methods listed in this table.

If	Then
You want to populate implementation arguments as copies of previously created matching conceptual arguments	Call the function <code>copyConceptualArgsToImplementation</code> . For example:  <code>copyConceptualArgsToImplementation(hEnt);</code>
You want to create and add implementation arguments individually, or vary argument attributes, while maintaining conceptual argument order	Call functions <code>createAndSetCImplementationReturn</code> and <code>createAndAddImplementationArg</code> . For example:  <code>createAndSetCImplementationReturn(hEnt,     'RTW.TflArgNumeric', ...     'Name',              'y1', ...     'IOType',            'RTW_IO_OUTPUT', ...     'IsSigned',          true, ...     'WordLength',       32, ...     'FractionLength',   0);</code>  <code>createAndAddImplementationArg(op_entry,     'RTW.TflArgNumeric',...     'Name',              'u1', ...</code>

If	Then
	<pre>'IOType', 'RTW_IO_INPUT',... 'IsSigned', true,... 'WordLength', 32, ... 'FractionLength', 0 );</pre>

If	Then
<p>You want to minimize the amount of code, or specify constant arguments to pass to the implementation function</p>	<p>Create the argument with a call to the function <code>getTf1ArgFromString</code>. Then, use the convenience method <code>setReturn</code> or <code>addArgument</code> to specify whether an argument is a return value or argument and to add the argument to the entry's array of implementation arguments. For example:</p> <pre>arg = getTf1ArgFromString(hEnt, 'y1', 'double'); arg.IOType = 'RTW_IO_OUTPUT'; hEnt.Implementation.setReturn(arg);</pre> <pre>arg = getTf1ArgFromString(hEnt, 'u1', 'double'); hEnt.Implementation.addArgument(arg);</pre> <p>The following call to <code>getTf1ArgFromString</code> passes the constant 0 to argument u2:</p> <pre>arg = getTf1ArgFromString(hEnt, 'u2', 'int16', 0); hEnt.Implementation.addArgument(arg);</pre> <p>For semaphore and mutex entries, use the functions <code>getTf1DWorkFromString</code> and <code>addDWorkArg</code> to create and add a DWork argument to the entry. Then create implementation arguments as shown above with <code>getTf1ArgFromString</code> and the convenience methods <code>setReturn</code> and <code>addArgument</code>. For example:</p> <pre>arg = getTf1DWorkFromString('d1', 'void*'); hEnt.addDWorkArg(arg);</pre> <pre>arg = hEnt.getTf1ArgFromString('y1', 'void'); arg.IOType = 'RTW_IO_OUTPUT'; hEnt.Implementation.setReturn(arg);</pre> <pre>arg = hEnt.getTf1ArgFromString('u1', 'integer'); hEnt.Implementation.addArgument(arg);</pre> <pre>arg = hEnt.getTf1ArgFromString('d1', 'void**'); hEnt.Implementation.addArgument(arg);</pre>

If	Then
You need to define several similar mappings, you want to minimize the code to write, and the entries do not require data alignment, use net slope arguments, or involve semaphore or mutex replacements.	Call <code>createCRLEntry</code> to create the entry and specify conceptual and implementation arguments in a single function call. <pre data-bbox="612 421 1326 508"> hEnt = createCRLEntry(hTable, ...     'double y1 = sin(double u1)', ...     'mySin');</pre>

The following code shows the third approach listed in the table for specifying the implementation output and input argument definitions for the `sin` function:

```

% Implementation Args

arg = hEnt.getTf1ArgFromString('y1','double');
arg.IOType = 'RTW_IO_OUTPUT';
hEnt.Implementation.setReturn(arg);

arg = hEnt.getTf1ArgFromString('u1','double');
hEnt.Implementation.addArgument(arg);
```

### Add Entry to Table

Add an entry to a code replacement table by calling the function `addEntry`.

```

addEntry(hTable, hEnt);
```

### Validate Entry

After you create or modify a code replacement table entry, validate it by invoking it at the MATLAB command line. For example:

```

hTbl = crl_table_sinfcn

hTbl =

RTW.Tf1Table
 Version: '1.0'
 AllEntries: [2x1 RTW.Tf1CFunctionEntry]
ReservedSymbols: []
```

```
StringResolutionMap: []
```

If the table includes errors, MATLAB reports them. The following examples shows how MATLAB reports a typo in a data type name:

```
hTbl = crl_table_sinfcn
??? RTW_CORE:tf1:Tf1Table: Unsupported data type, 'dooble'.

Error in ==> crl_table_sinfcn at 7
hTable.registerCFFunctionEntry(100, 1, 'sin', 'dooble', 'sin_dbl', ...
```

### Save Table

Save the table definition file. Use the name of the table definition function to name the file, for example, `crl_table_sinfcn.m`.

Next, from your requirements, determine whether you need to specify build information for your replacement code.

## Specify Build Information for Replacement Code

After you define code replacement mappings, determine whether you need to specify build information for your replacement code. A code replacement table entry can specify build information for the code generator to use when replacing code for a match. For example, specify files for implementation replacement code if you are using a generated makefile and the code generation software compiles the code.

Add build information to an entry:

- Interactively, by using the **Build Information** tab in the Code Replacement Tool.
- Programmatically, by using a MATLAB programming interface.

### Build Information

The build information can include:

- Paths and file names for header files
- Paths and file names for source files
- Paths and file names for object files
- Compile flags
- Link flags

### Choose an Approach for Specifying Build Information

The following table lists situations to help you decide when to use an interactive or programmatic approach to specifying build information:

Situation	Approach
Creating code replacement entries for the first time.	Code Replacement Tool.
You used the Code Replacement Tool to create the entries for which the build information applies.	Code Replacement Tool to specify the build information quickly .
Rapid prototyping entries.	Code Replacement Tool to generate, register, and test entries quickly.

Situation	Approach
Developing an entry to use as a template or starting point for defining similar entries.	Code Replacement Tool to generate entry code that you can copy and modify.
Modifying existing mappings.	MATLAB Editor to update the programming interface directly.

- If an entry uses header, source, or object files, consider whether to make the files accessible to the code generator. You can copy files to the build folder or you can specify individual file names and paths explicitly.
- If you specify *additional* header files/include paths or source files/paths and you copy files, the compiler and utilities such as `packNGO` might find duplicate instances of files (an instance in the build folder and an instance in the original folder).
- If you choose to copy files to the build folder and you are using the `packNGO` function to relocate static and generated code files to another development environment:
  - In the call to `packNGO`, specify the property-value pair `'minimalHeaders' true` (the default). That setting instructs the function to include the minimal header files required to build the code in the zip file.
  - Do not collocate files that you copy with files that you do not copy. If the `packNGO` function finds multiple instances of the same file, the function returns an error.
- If you use the programming interface, paths that you specify can include tokens. A token is a variable defined as a character vector or cell array of character vectors in the MATLAB workspace that you enclose with dollar signs (`$variable$`). The code generator evaluates and replaces a token with the defined value. For example, consider the path `$myfolder$folder1`, where `myfolder` is a character vector variable defined in the MATLAB workspace as `'d:\work\source\module1'`. The code generator generates the custom path as `d:\work\source\module1\folder1`.

## Specify Build Information Interactively with the Code Replacement Tool

The Code Replacement Tool provides a quick, easy way for you to specify build information for code replacement table entries. It is ideal for getting started with defining a table entry, rapid prototyping, and developing table entries to use as a starting point for defining similar mappings.

- 1 Determine the information that you must specify.

- 2 Open the Code Replacement Tool.
- 3 Select the code replacement table entry for which you want to specify the build information. In the left pane, select the table that contains the entry. In the middle pane, select the entry that you want to modify.
- 4 In the right pane, select the **Build Information** tab.
- 5 On the **Build Information** tab, specify your build information.

Parameter	Specify
<b>Implementation header file</b>	File name and extension for the header file the code generator needs to generate the replacement code. For example, <code>sin_dbl.h</code> .
<b>Implementation source file</b>	File name and extension for the C or C++ source file the code generator needs to generate the replacement code. For example, <code>sin_dbl.c</code> .
<b>Additional header files/include paths</b>	Paths and file names for additional header files the code generator needs to generate the replacement code. For example, <code>C:\libs\headerFiles</code> and <code>C:\libs\headerFiles\common.h</code> . This parameter adds <code>-I</code> to the compile line in the generated makefile.
<b>Additional source files/ paths</b>	Paths and file names for additional source files the code generator needs to generate the replacement code. For example, <code>C:\libs\srcFiles</code> and <code>C:\libs\srcFiles\common.c</code> . This parameter adds <code>-I</code> to the compile line in the generated makefile.
<b>Additional object files/ paths</b>	Paths and file names for additional object files the linker needs to build the replacement code. For example, <code>C:\libs\objFiles</code> and <code>C:\libs\objFiles\common.obj</code> .
<b>Additional link flags</b>	Flags the linker needs to generate an executable file for the replacement code.
<b>Additional compile flags</b>	Flags the compiler needs to generate object code for the replacement code.
<b>Copy files to build directory</b>	Whether to copy header, source, or object files, which are required to generate replacement

Parameter	Specify
	code, to the build folder before code generation. If you specify files with <b>Additional header files/include paths</b> or <b>Additional source files/ paths</b> and you copy files, the compiler and utilities such as packNGo might find duplicate instances of files.

- 6 Click **Apply**.
- 7 Select the **Mapping Information** tab. Scroll to the bottom of that table and click **Validate entry**. The tool validates the changes that you made to the entry.
- 8 Save the table that includes the entry that you just modified.

## Specify Build Information Programmatically

The programming interface for specifying build information for a code replacement entry is ideal for:

- Modifying entries created with the Code Replacement Tool.
- Replicating and then modifying similar entries and tables.

The basic workflow for specifying build information programmatically is:

- 1 Identify or create the code replacement entry that you want to specify the build information.
- 2 Determine what information to specify.
- 3 Specify your build information.

Specify	Action
Implementation header file	<p>Use one of the following:</p> <ul style="list-style-type: none"> <li>• Set properties <code>ImplementationHeaderFile</code> and <code>ImplementationHeaderPath</code> in a call to <code>setTf1CFunctionEntryParameters</code>, <code>setTf1COperationEntryParameters</code>, or <code>setTf1CSemaphoreEntryParameters</code>. For example:</li> </ul> <pre>setTf1CFunctionEntryParameters(hEnt, ...     'ImplementationHeaderFile', 'sin_dbl.h', ...</pre>

Specify	Action
	<pre data-bbox="497 296 1184 383">'ImplementationHeaderPath', 'D:/lib/headerFiles' 'Key', 'sin', ... 'ImplementationName', 'sin_dbl');</pre> <ul data-bbox="402 395 1233 487" style="list-style-type: none"> <li>• Set argument headerFile in a call to registerCFunctionEntry, registerCPPFunctionEntry, or registerCPromotableMacroEntry</li> </ul>
Implementation source file	<p data-bbox="397 505 1069 661">Set properties ImplementationSourceFile and ImplementationSourcePath in a call to setTf1CFunctionEntryParameters, setTf1COperationEntryParameters, or setTf1CSemaphoreEntryParameters. For example:</p> <pre data-bbox="397 690 1144 829">setTf1CFunctionEntryParameters(hEnt, ... 'ImplementationHeaderFile', 'sin_dbl.c', ... 'ImplementationHeaderPath', 'D:/lib/sourceFiles' 'Key', 'sin', ... 'ImplementationName', 'sin_dbl');</pre>
Additional header files/include paths	<p data-bbox="397 847 1273 939">For each file, specify the file name and path in calls to the functions addAdditionalHeaderFile and addAdditionalIncludePath. For example:</p> <pre data-bbox="397 968 1262 1142">libdir = fullfile('\$ (MATLAB_ROOT)', '..', '..', 'lib');  hEnt = RTW.Tf1CFunctionEntry;  addAdditionalHeaderFile(hEnt, 'common.h'); addAdditionalIncludePath(hEnt, fullfile(libdir, 'include'));  These functions add -I to the compile line in the generated makefile.</pre>

Specify	Action
Additional source files/paths	<p>For each file, specify the file name and path in calls to the functions <code>addAdditionalSourceFile</code> and <code>addAdditionalSourcePath</code>. For example:</p> <pre>libdir = fullfile('\$MATLAB_ROOT','..', '..', 'lib');  hEnt = RTW.Tf1CFunctionEntry;  addAdditionalSourceFile(hEnt, 'common.c'); addAdditionalSourcePath(hEnt, fullfile(libdir, 'src'));</pre> <p>These functions add <code>-I</code> to the compile line in the generated makefile.</p>
Additional object files/paths	<p>For each file, specify the file name and path in calls to the functions <code>addAdditionalLinkObj</code> and <code>addAdditionalLinkObjPath</code>. For example:</p> <pre>libdir = fullfile('\$MATLAB_ROOT','..', '..', 'lib');  hEnt = RTW.Tf1CFunctionEntry;  addAdditionalLinkObj(hEnt, 'sin.o'); addAdditionalLinkObjPath(hEnt, fullfile(libdir, 'bin'));</pre>
Compile flags	<p>Set the entry property <code>AdditionalCompileFlags</code> to a cell array of character vectors representing the required compile flags. For example:</p> <pre>hEnt = RTW.Tf1CFunctionEntry;  hEnt.AdditionalCompileFlags = {'-Zi -Wall', '-O3'};</pre>
Link flags	<p>Set the entry property <code>AdditionalLinkFlags</code> to a cell array of character vectors representing the required link flags. For example:</p> <pre>hEnt = RTW.Tf1CFunctionEntry;  hEnt.AdditionalCompileFlags = {'-MD -Gy', '-T'};</pre>

Specify	Action
Whether to copy header, source, or object files, which are required to generate replacement code, to the build folder before code generation	<p>Use one of the following:</p> <ul style="list-style-type: none"> <li>Set property <code>GenCallback</code> to <code>'RTW.copyFileToBuildDir'</code> in a call to <code>setTf1CFunctionEntryParameters</code>, <code>setTf1COperationEntryParameters</code>, or <code>setTf1CSemaphoreEntryParameters</code>. For example: <pre>setTf1CFunctionEntryParameters(hEnt, ...     'ImplementationHeaderFile', 'sin_dbl.h', ...     'ImplementationHeaderPath', 'D:/lib/headerFiles'     'Key', 'sin', ...     'ImplementationName', 'sin_dbl'     'GenCallback', 'RTW.copyFileToBuildDir');</pre> </li> <li>Set argument <code>genCallback</code> in a call to <code>registerCFunctionEntry</code>, <code>registerCPPFunctionEntry</code>, or <code>registerCPromotableMacroEntry</code> to <code>'RTW.copyFileToBuildDir'</code>.</li> </ul> <p>If a match occurs for a table entry, a call to the function <code>RTW.copyFileToBuildDir</code> copies required files to the build folder.</p> <p>If you specify additional header files/include paths or additional source files/paths and you copy files, the compiler and utilities such as <code>packNGO</code> might find duplicate instances of files.</p>

#### 4 Save the table that includes the entry that you added or modified.

The following example defines a table entry for an optimized multiplication function that takes signed 32-bit integers and returns a signed 32-bit integer, taking saturation into account. Multiplications in the generated code are replaced with calls to the optimized function. The optimized function does not reside in the build folder. For the code generator to access the files, copy them into the build folder to be compiled and linked into the application.

The table entry specifies the source and header file names and paths. To request the copy operation, the table entry sets the `genCallback` property to `'RTW.copyFileToBuildDir'` in the call to the `setTf1COperationEntryParameters` function. In this example, the header file `s32_mul.h` contains an inlined function that invokes assembly functions contained in `s32_mul.s`. If a match occurs for the table

entry, the function `RTW.copyFileToBuildDir` copies the specified source and header files to the build folder for use during the remainder of the build process.

```
function hTable = make_my_crl_table

hTable = RTW.Tf1Table;

op_entry = RTW.Tf1COperationEntry;
setTf1COperationEntryParameters(op_entry, ...
 'Key', 'RTW_OP_MUL', ...
 'Priority', 100, ...
 'SaturationMode', 'RTW_SATURATE_ON_OVERFLOW', ...
 'RoundingModes', {'RTW_ROUND_UNSPECIFIED'}, ...
 'ImplementationName', 's32_mul_s32_sat', ...
 'ImplementationHeaderFile', 's32_mul.h', ...
 'ImplementationSourceFile', 's32_mul.s', ...
 'ImplementationHeaderPath', {fullfile('${MATLAB_ROOT}','crl')}, ...
 'ImplementationSourcePath', {fullfile('${MATLAB_ROOT}','crl')}, ...
 'GenCallback', 'RTW.copyFileToBuildDir');
.
.
.
addEntry(hTable, op_entry);
```

The following example uses the functions `addAdditionalHeaderFile`, `addAdditionalIncludePath`, `addAdditionalSourceFile`, `addAdditionalSourcePath`, `addAdditionalLinkObj`, and `addAdditionalLinkObjPath` in addition to the code generation callback function `RTW.copyFileToBuildDir`.

```
hTable = RTW.Tf1Table;

% Path to external source, header, and object files
libdir = fullfile('${MATLAB_ROOT}','..', '..', 'lib');

op_entry = RTW.Tf1COperationEntry;
setTf1COperationEntryParameters(op_entry, ...
 'Key', 'RTW_OP_ADD', ...
 'Priority', 90, ...
 'SaturationMode', 'RTW_SATURATE_UNSPECIFIED', ...
 'RoundingModes', {'RTW_ROUND_UNSPECIFIED'}, ...
 'ImplementationName', 's32_add_s32_s32', ...
 'ImplementationHeaderFile', 's32_add_s32_s32.h', ...
 'ImplementationSourceFile', 's32_add_s32_s32.c'...
 'GenCallback', 'RTW.copyFileToBuildDir');

addAdditionalHeaderFile(op_entry, 'all_additions.h');
addAdditionalIncludePath(op_entry, fullfile(libdir, 'include'));
addAdditionalSourceFile(op_entry, 'all_additions.c');
addAdditionalSourcePath(op_entry, fullfile(libdir, 'src'));
addAdditionalLinkObj(op_entry, 'addition.o');
addAdditionalLinkObjPath(op_entry, fullfile(libdir, 'bin'));
.
```

```
.
.br/>addEntry(hTable, op_entry);
```

Next, include your code replacement table in a code replacement library and register the library with the code generator.

## **More About**

- “Define Code Replacement Mappings” on page 52-30
- “Register Code Replacement Mappings” on page 52-56
- “Develop a Code Replacement Library” on page 52-15
- “What Is Code Replacement Customization?” on page 52-3
- “Code You Can Replace from MATLAB Code” on page 52-5

## Register Code Replacement Mappings

After you define code replacement entries in a code replacement table, you can include the table in a code replacement library that you register with the code generator. When registered, a library appears in the list of available code replacement libraries that you can choose from when configuring the code generator.

Register a code replacement table as a code replacement library:

- Interactively, by using the Code Replacement Tool
- Programmatically, by using a MATLAB programming interface

### Choose an Approach for Creating the Registration File

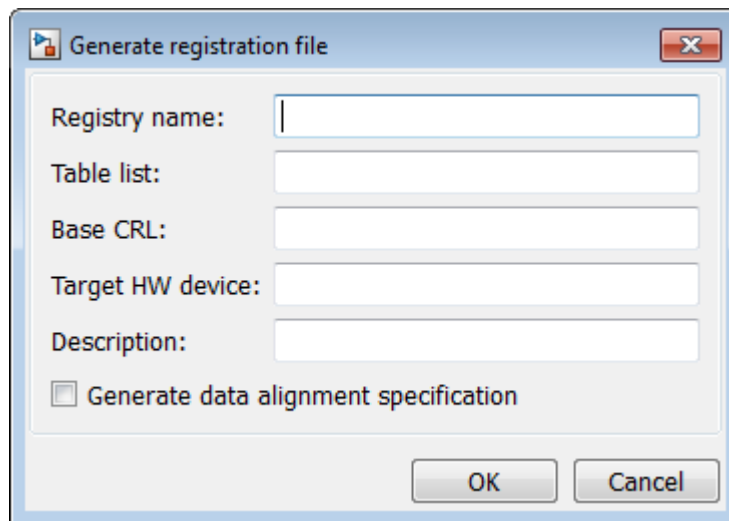

The following table lists situations to help you decide when to use an interactive or programmatic approach to creating a registration file:

If...	Then...
Registering a code replacement table for the first time	Use the Code Replacement Tool.
You used the Code Replacement Tool to create the table	Use the Code Replacement Tool to quickly register the table.
Rapid prototyping code replacement	Use the Code Replacement Tool to quickly generate, register, and test entries.
Creating registration file to use as a template or starting point for defining similar registration files	Use the Code Replacement Tool to generate code that you can copy and modify.
Modifying existing registration files	Use the MATLAB Editor to update the registration file.
Defining multiple code replacement libraries in one registration file	Use the MATLAB Editor to create a new or extend an existing registration file.
Defining code replacement library hierarchy in a registration file	Use the MATLAB Editor to create a new or extend an existing registration file.

## Create Registration File Interactively with the Code Replacement Tool

The Code Replacement tool provides a quick, easy way for you to create a registration file for a code replacement table. It is ideal for getting started, rapid prototyping, and generating a registration file that you want to use as a starting point for similar registrations.

- 1 After you validate and save a code replacement table, select **File > Generate registration file** to open the **Generate registration file** dialog box.

- 2 Enter the registration information. Minimally, specify:

For...	Specify...
<b>Registry name</b>	Text naming the code replacement library. For example, <code>Sin Function Example</code> .
<b>Table list</b>	Text naming one or more code replacement tables to include in the library. Specify each table as one of the following: <ul style="list-style-type: none"> <li>• Name of a table file on the MATLAB search path</li> <li>• Absolute path to a table file</li> <li>• Path to a table file relative to <code>\$(MATLAB_ROOT)</code></li> </ul>

For...	Specify...
	<p>You can specify multiple tables. If you do, separate the table specifications with a comma. For example:</p> <pre>crl_table_sinfcn, c:/work_crl/crl_table_muldiv</pre> <p>See “Registration Files That Define Multiple Code Replacement Libraries” on page 52-61 for examples of each type of table specification.</p>

Optionally, you can specify:

For...	Specify...
<b>Description</b>	Text that describes the purpose and content of the library.
<b>Target HW device</b>	Text naming one or more hardware devices the code replacement library supports. Separate names with a comma. To support all device types, enter an asterisk (*). For example, TI C28x, TI C62x.
<b>Base CRL</b>	Text naming a code replacement library that you want to serve as a base library for the library you are registering. Use this field to specify library hierarchies. For example, you can specify a general TI device library as the base library for a more specific TI C28x device library.
<b>Generate data alignment specification</b>	Flag that enables data alignment specification.

## Create Registration File Programmatically

The programming interface for creating a registration file for a code replacement table is ideal for:

- Modifying registration files created with the Code Replacement Tool
- Replicating and modifying similar registration files
- Defining multiple code replacement libraries in one registration file

The basic workflow for creating a registration file programmatically consists of the following steps:

- 1 Define an `rtwTargetInfo` function. The code generator recognizes this function as a customization file. The function definition must include at least the following content:

```
function rtwTargetInfo(cm)

cm.registerTargetInfo(@loc_register_crl);

function this = loc_register_crl

this(1) = RTW.Tf1Registry;
this(1).Name = 'crl-name';
this(1).TableList = {'table',...};
```

For...	Replace...
<code>this(1).Name = 'crl-name';</code>	<code>crl-name</code> with text naming the code replacement library. For example, <code>Sin Function Example</code> .
<code>this(1).TableList = {'table',...};</code>	<p><code>table</code> with text that identifies the code replacement table that contains your code replacement entries. Specify a table as one of the following:</p> <ul style="list-style-type: none"> <li>• Name of a table file on the MATLAB search path</li> <li>• Absolute path to a table file</li> <li>• Path to a table file relative to <code>\$(MATLAB_ROOT)</code></li> </ul> <p>You can specify multiple tables. If you do, separate the table specifications with commas.</p>

Optionally, you can specify:

For...	Replace...
<code>this(1).Description = 'text'</code>	<i>text</i> with text that describes the purpose and content of the library.
<code>this(1).TargetHWDeviceType = {'device-type',...}</code>	<i>device-type</i> with text that names a hardware device the code replacement library supports. You can specify multiple device types. Separate device types with a comma. For example, TI C28x, TI C62x. To support all device types, enter an asterisk (*).
<code>this(1).BaseTfl = 'base-lib'</code>	<i>base-lib</i> with text that names a code replacement library that you want to serve as a base library for the library you are registering. Use this field to specify library hierarchies. For example, you can specify a general TI device library as the base library for a TI C28x device library.  See “Registration Files That Define Code Replacement Library Hierarchies” on page 52-61 for an example.

For example:

```
function rtwTargetInfo(cm)

cm.registerTargetInfo(@loc_register_crl);

function this = loc_register_crl

this(1) = RTW.TflRegistry;
this(1).Name = 'Sin Function Example';
this(1).TableList = {'crl_table_sinfcn'};
this(1).TargetHWDeviceType = {'*'};
this(1).Description = 'Example - sin function replacement';
```

- 2 Save the file with the name `rtwTargetInfo.m`.
- 3 Place the file on the MATLAB path. When the file is on the MATLAB path, the code generator reads the file after starting and applies the customizations during the current MATLAB session.

## Register a Code Replacement Library

Before you can use the code replacement tables defined in a registration file, you must refresh Simulink customizations within the current MATLAB session. To initiate a refresh, enter the following command:

```
sl_refresh_customizations
```

## Registration Files That Define Multiple Code Replacement Libraries

Use the programming interface to create a registration file that defines a code replacement library that includes multiple code replacement tables. The following example defines a library that includes multiple tables. The `TableList` fields specify tables that reside at different locations. The tables reside on the MATLAB search path or at locations specified with a path.

```
function rtwTargetInfo(cm)

cm.registerTargetInfo(@locCr1RegFcn);

function thisCr1 = locCr1RegFcn

% Register a code replacement library for use with model: rtwdemo_crladdsub
thisCr1(1) = RTW.Tf1Registry;
thisCr1(1).Name = 'Addition & Subtraction Examples';
thisCr1(1).Description = 'Example of addition/subtraction op replacement';
thisCr1(1).TableList = {'crl_table_addsub'};
thisCr1(1).TargetHWDDeviceType = {'*'};

% Register a code replacement library for use with model: rtwdemo_crlmuldiv
thisCr1(2) = RTW.Tf1Registry;
thisCr1(2).Name = 'Multiplication & Division Examples';
thisCr1(2).Description = 'Example of mult/div op repl for built-in integers';
thisCr1(2).TableList = {'c:/work_crl/crl_table_muldiv'};
thisCr1(2).TargetHWDDeviceType = {'*'};

% Register a code replacement library for use with model: rtwdemo_crlfixpt
thisCr1(3) = RTW.Tf1Registry;
thisCr1(3).Name = 'Fixed-Point Examples';
thisCr1(3).Description = 'Example of fixed-point operator replacement';
thisCr1(3).TableList = {fullfile('$MATLAB_ROOT'), ...
 'toolbox', 'rtw', 'rtwdemos', 'crl_demo', 'crl_table_fixpt'};
thisCr1(3).TargetHWDDeviceType = {'*'};
```

## Registration Files That Define Code Replacement Library Hierarchies

Using the programming interface, you can organize multiple code replacement libraries in a hierarchy. The following example shows a registration file that defines four code

replacement tables organized in a hierarchy of four code replacement libraries. The tables include entries that increase in specificity: common entries, entries for TI devices, entries for TI C6xx devices, and entries specific to the TI C67x device.

```
function rtwTargetInfo(cm)

cm.registerTargetInfo(@locCr1RegFcn);

function thisCr1 = locCr1RegFcn

% Register a code replacement library that includes common entries
thisCr1(1) = RTW.TflRegistry;
thisCr1(1).Name = 'Common Replacements';
thisCr1(1).Description = 'Common code replacement entries shared by other libraries';
thisCr1(1).TableList = {'cr1_table_general'};
thisCr1(1).TargetHWDeviceType = {'*'};

% Register a code replacement library for TI devices
thisCr1(2) = RTW.TflRegistry;
thisCr1(2).Name = 'TI Device Replacements';
thisCr1(2).Description = 'Code replacement entries shared across TI devices';
thisCr1(2).TableList = {'cr1_table_TI_devices'};
thisCr1(2).TargetHWDeviceType = {'TI C28x', 'TI C55x', 'TI C62x', 'TI C64x', 'TI 67x'};
thisCr1(1).BaseTfl = 'Common Replacements'

% Register a code replacement library for TI c6xx devices
thisCr1(3) = RTW.TflRegistry;
thisCr1(3).Name = 'TI c6xx Device Replacements';
thisCr1(3).Description = 'Code replacement entries shared across TI C6xx devices';
thisCr1(3).TableList = {'cr1_table_TIC6xx_devices'};
thisCr1(3).TargetHWDeviceType = {'TI C62x', 'TI C64x', 'TI 67x'};

% Register a code replacement library for the TI c67x device
thisCr1(3) = RTW.TflRegistry;
thisCr1(3).Name = 'TI c67x Device Replacements';
thisCr1(3).Description = 'Code replacement entries for the TI C67x device';
thisCr1(3).TableList = {'cr1_table_TIC67x_device'};
thisCr1(3).TargetHWDeviceType = {'TI 67x'};
```

After registering your code replacement mappings, verify that code replacements occur.

## More About

- “Troubleshoot Code Replacement Library Registration” on page 52-63
- “Specify Build Information for Replacement Code” on page 52-47
- “Verify Code Replacements” on page 52-64
- “Develop a Code Replacement Library” on page 52-15
- “What Is Code Replacement Customization?” on page 52-3
- “Code You Can Replace from MATLAB Code” on page 52-5

## Troubleshoot Code Replacement Library Registration

If a code replacement library is not listed as a configuration option or does not appear in the Code Replacement Viewer:

- Refresh the library registration information within the current MATLAB session (`RTW.TargetRegistry.getInstance('reset')`; or for the Simulink environment, `sl_refresh_customizations`).
- See whether the registration file, `rtwTargetInfo.m`, contains an error.

### More About

- “Register Code Replacement Mappings” on page 52-56

## Verify Code Replacements

After you create or modify a code replacement table, use the following techniques to examine and validate the table and its entries.

- Invoke the table definition file at the command prompt.
- Use the Code Replacement Viewer to examine libraries, tables, and entries.
- Trace code replacements from the source where you applied the code replacement library.
- Examine code replacement hits and misses logged during code generation.

### Code Replacement Hits and Misses

The code generator logs code replacement table entries for which it finds and does not find matches in the hit cache and miss cache, respectively. When a code replacement entry match fails and code is not replaced, the code generator logs the call site object (CSO) for the miss in the miss cache. When an entry match succeeds, the code generator logs the matched entry in the hit cache.

The code generator overwrites the hit and miss cache data each time it produces code. The cache data reflects hits and misses for only the last application component (MATLAB code or Simulink model) for which you generate code.

You can use the Code Replacement Viewer to review trace information based on logged hit and miss trace data. The hit cache provides trace information that helps to verify code replacements.

The miss cache and related miss data collected and stored in code replacement tables provide trace information for misses. Use this information for misses to troubleshoot expected code replacements that do not occur. Trace information for a miss:

- Identifies the call site object.
- Provides a link to the relevant source location for the miss.
- Includes information about the reason for the miss.

### Validate a Table Definition File

After you create or modify a code replacement table definition file, validate it. At the command prompt, specify the name of the table in a call to the `isvalid` function. For example:

```
invalid(crl_table_sinfcn)
```

```
ans =
```

```
1
```

MATLAB displays errors that occur. In the following example, MATLAB detects a typo in a data type name.

```
invalid(crl_table_sinfcn)
```

```
??? RTW_CORE:tf1:Tf1Table: Unsupported data type, 'dooble'.
```

```
Error in ==> crl_table_sinfcn at 7
```

```
hTable.registerCFunctionEntry(100, 1, 'sin', 'dooble', 'sin_dbl', ...
```

## Review Library Content

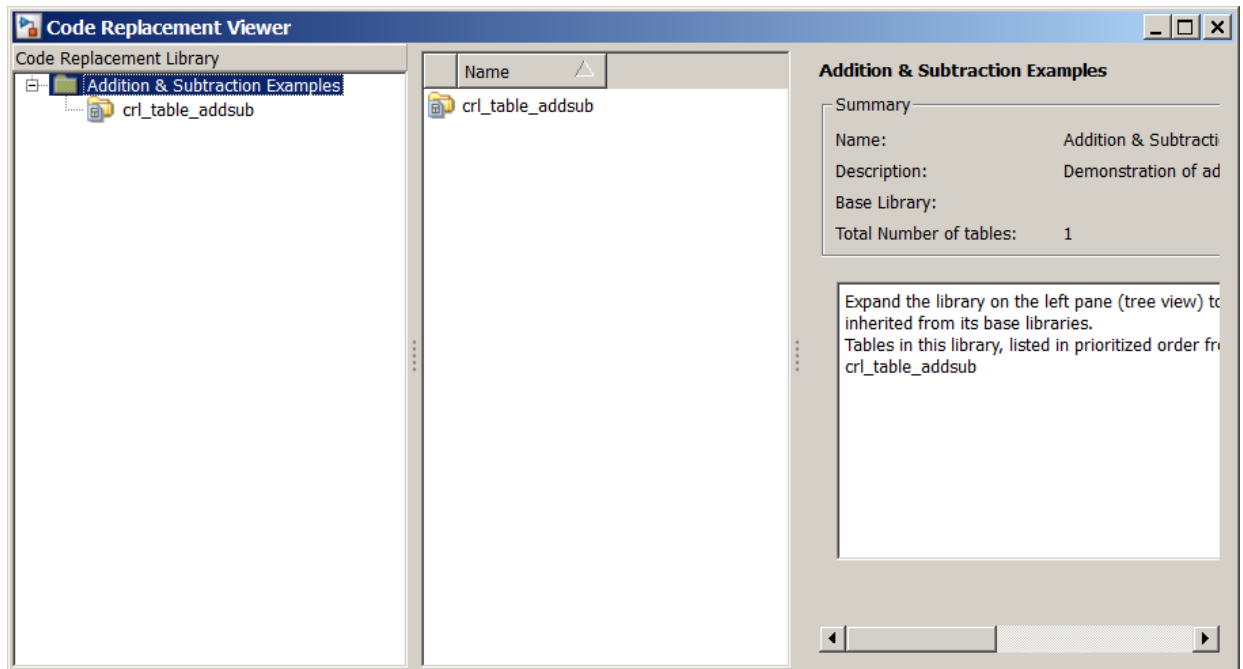

After you create or modify a code replacement library, use the Code Replacement Viewer to review and verify the list of tables in the library and the entries in each table.

- 1 Open the viewer to display the contents of your library. At the command prompt, enter the following command:

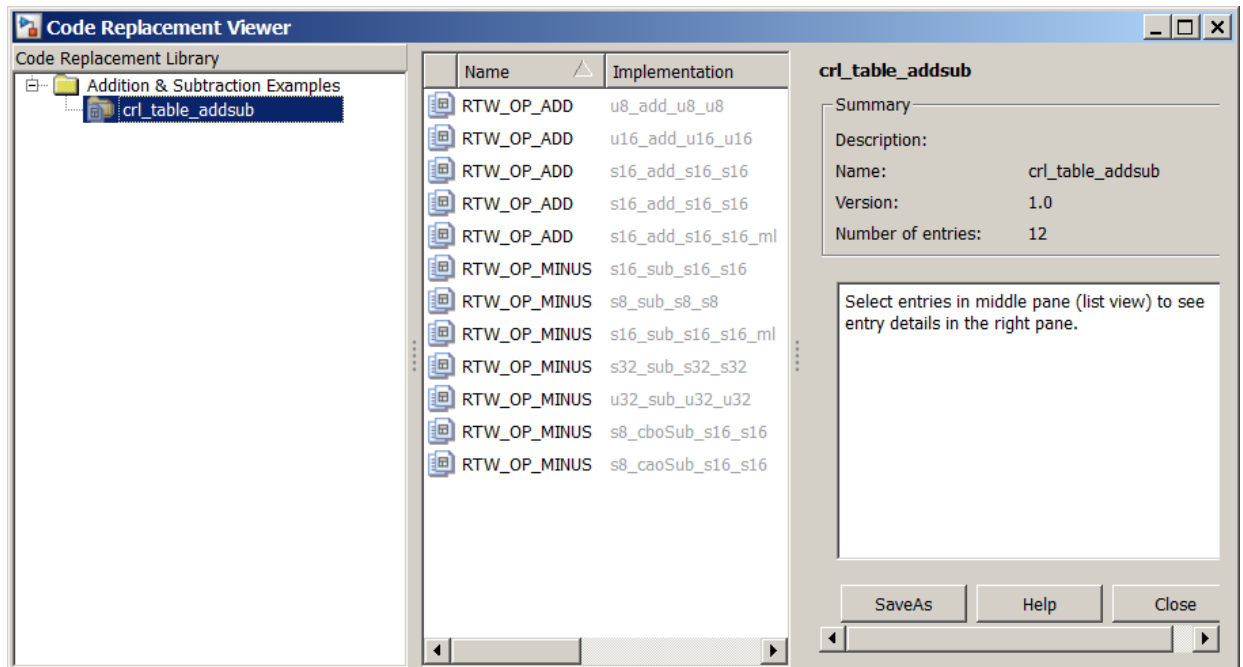

```
crviewer('library')
```

For example:

```
crviewer('Addition & Subtraction Examples')
```

- 2 Review the list of tables in the left pane. Are tables missing? Are the tables listed in the correct relative order? By default, the viewer displays tables in search order.
- 3 In the left pane, click each table and review the list of entries in the center pane. Are entries missing? Does the list include extraneous or unexpected entries?

## Review Table Content

After you create or modify a code replacement table, use the Code Replacement Viewer to review and verify table entries.

- 1 Open the viewer to display the contents of your table. At the command prompt, enter the following command. *table* is a MATLAB file that defines code replacement tables. The file must be in the current folder or on the MATLAB path.

```
crviewer(table)
```

For example:

```
crviewer(crl_table_addsub)
```

- 2 Review the list of entries in the center pane. Are entries missing? Does the list include extraneous or unexpected entries? By default, the viewer displays entries in search order.
- 3 In the center pane, click each entry and verify the entry information in the right pane.

The screenshot shows the Code Replacement Viewer interface. On the left, the Code Replacement Library contains a folder named 'Addition & Subtraction Examples' with a sub-entry 'cr1\_table\_addsub'. The main pane displays a list of replacements with columns for Name and Implementation. The selected entry is 'RTW\_OP\_ADD' with implementation 'u16\_add\_u16\_u16'. The right pane shows the details for this replacement, including a summary of key information and conceptual/implementation argument tables.

Name	Implementation
RTW_OP_ADD	u8_add_u8_u8
RTW_OP_ADD	u16_add_u16_u16
RTW_OP_ADD	s16_add_s16_s16
RTW_OP_ADD	s16_add_s16_s16
RTW_OP_ADD	s16_add_s16_s16_ml
RTW_OP_MINUS	s16_sub_s16_s16
RTW_OP_MINUS	s8_sub_s8_s8
RTW_OP_MINUS	s16_sub_s16_s16_ml
RTW_OP_MINUS	s32_sub_s32_s32
RTW_OP_MINUS	u32_sub_u32_u32
RTW_OP_MINUS	s8_cboSub_s16_s16
RTW_OP_MINUS	s8_caoSub_s16_s16

**RTW\_OP\_ADD**

General Information

Summary

Description:

Key: RTW\_OP\_ADD with

Implementation: u16\_add\_u16\_u16

Implementation type: FCN\_IMPL\_FUNCT

Saturation mode: RTW\_WRAP\_ON\_C

Rounding mode: RTW\_ROUND\_CEIL

EntryInfo: RTW\_CAST\_BEFOI

GenCallback file:

Implementation header: u16\_add\_u16\_u16.

Implementation source: u16\_add\_u16\_u16.

Priority: 90

Total usage count: 0

Entry class: RTW.TfICOperator

Entry argument(s)

**Conceptual argument(s):**

Name	I/O type	Data type
y1	RTW_IO_OUTPUT	uint16
u1	RTW_IO_INPUT	uint16
u2	RTW_IO_INPUT	uint16

**Implementation:**

Name	I/O type	Data type	Align
y1	RTW_IO_OUTPUT	uint16	none
u1	RTW_IO_INPUT	uint16	none
u2	RTW_IO_INPUT	uint16	none

Help

- Argument order is correct.

- Conceptual argument names match code generator naming conventions.
- Implementation argument names are correct.
- Algorithm properties (for example, saturation and rounding mode) are set correctly.
- Header or source file specification is not missing.
- I/O types are correct.
- Relative priority of entries is correct.

## Review Code Replacements

After you review the content of your code replacement library and tables, generate code and a code generation report. Verify that the code generator replaces code as you expect.

The Code Replacements Report details the code replacement library functions that the code generator uses for code replacements. The report provides a mapping between each replacement instance and the line of MATLAB code that triggered the replacement. The Code Replacements report is not available for generated MEX functions.

The following example illustrates two complementary approaches for reviewing code replacements:

- Check the Code Replacements Report section of the code generation report for expected replacements.
  - Trace code replacements.
- 1 Identify the MATLAB function where you anticipate that a function or operator replacement occurs. This example uses the function `matlabroot/toolbox/rtw/rtwdemos/crl_demo/addsub_two_int16.m`.

```
function [y1, y2] = addsub_two_int16(u1, u2)

y1 = int16(u1 + u2);
y2 = int16(u1 - u2);
```

- 2 Identify or create code or a script to exercise the function. For example, consider test file `addsub_to_int16_test.m`, which includes the following code:

```
disp('Input')
u1 = int16(10)
```

```
u2 = int16(10)

[y1, y2] = addsub_two_int16(u1, u2);

disp('Output')
disp('y1 =')
disp(y1);
disp('y2 =')
disp(y2);
```

- 3 Open the MATLAB Coder app.
- 4 On the **Select Source Files** page, add your function to the project. For this example, add function `addsub_two_int16`. Click **Next**.
- 5 On the **Define Input Types** page, use the test file `addsub_to_int16_test` to automatically define the input types. Click **Next**.
- 6 On the **Check for Run-Time Issues** page, specify the test file `addsub_to_int16_test`. The app runs the test file, replacing calls to `addsub_to_int16_test` with calls to a MEX version of `addsub_to_int16_test`. Click **Next**.
- 7 To open the **Generate** dialog box, on the **Generate Code** page, click the **Generate** arrow .
- 8 Set **Build type** to generate source code. Before you build an executable, you want to review your code replacements in the generated code.
- 9 In the Generate dialog box, click **More Settings**.
- 10 Configure the code generator to use your code replacement library. On the **Custom Code** tab, set the **Code replacement library** parameter to the name of your library. For this example, set the library to **Addition & Subtraction Examples**.
- 11 Configure the code generation report to include the Code Replacements Report. On the **Debugging** tab, select:
  - **Always create a code generation report**
  - **Code replacements**
  - **Automatically launch a report if one is generated**
- 12 To generate code and a report, click **Generate**.
- 13 Open the **Code Replacements Report** section of the code generation report.

That report lists the replacement functions that the code generator used. The report provides a mapping between each replacement instance and the MATLAB code that triggered the replacement.

Review the report:

- Check whether expected function and operator code replacements occurred.
- In the replacements sections, click each code link to see the source that triggered the reported code replacement.

If a function or operator is not replaced as expected, the code generator used a higher-priority (lower-priority value) match or did not find a match.

To analyze and troubleshoot code replacement misses, use the trace information that the Code Replacement Viewer provides. See “Troubleshoot Code Replacement Misses” on page 52-74.

## **More About**

- “Troubleshoot Code Replacement Misses” on page 52-74
- “Register Code Replacement Mappings” on page 52-56
- “Deploy Code Replacement Library” on page 52-81
- “Develop a Code Replacement Library” on page 52-15
- “What Is Code Replacement Customization?” on page 52-3

## Troubleshoot Code Replacement Misses

Use miss reason messages that appear in the Code Replacement Viewer to analyze and correct code replacement misses.

### Miss Reason Messages

The Code Replacement Viewer displays miss reason messages in trace information for code replacement misses. A legend listing each message that appears in the miss report precedes the report details. A message consists of:

- Numeric identifier, which identifies the message in the report details.
- Message text, which in some cases includes placeholders for names of arguments, call site object values, table entry values, and property names.

For example:

1. Mismatched data types (argument name, CS0 value, table entry value)

The parenthetical information represents placeholders for actual values that appear in the report details.

In the **Miss Source Locations** table that lists the miss details, the **Reason** column includes:

- The message identifier, as listed in the legend.
- The placeholder values for that instance of the miss reason message.

The following **Reason** details indicate a data type mismatch because the call site object specifies data type `int8` for arguments `y1`, `u1`, and `u2`, while the code replacement table entry specifies `uint32`.

1. `y1, int8, uint32`  
`u1, int8, uint32`  
`u2, int8, uint32`

Depending on your situation and the reported miss reason, troubleshoot reported misses by looking for instances of the following:

- A typo in the code replacement table entry definition or a source parameter setting.
- Information missing from the code replacement table entry or a source parameter setting.

- Invalid or incorrect information in the code replacement table entry definition or a source parameter setting.
- Arguments incorrectly ordered in the code replacement table entry definition or the source being replaced with replacement code.
- Failed algorithm classification for an addition or subtraction operation due to:
  - An ideal accumulator not being calculated because the type of an input argument is not fixed-point or the slope adjustment factors of the input arguments are not equal.
  - Input or output casts with a floating-point cast type.
  - Input or output casts with cast types that have different slope adjustment factors or biases.
  - Output casts not being convertible to a single output cast.
  - Input casts resulting in loss of bits.

## Analyze and Correct Code Replacement Misses

The following example shows how to use Code Replacement Viewer trace information to troubleshoot code replacement misses. You must have already reviewed and tested code replacements for your MATLAB code.

- 1 Review the code generated for a specific code element, looking for expected code replacement. Regenerate or reopen the code generation report for your MATLAB code. If you already generated the code generation report that includes the Code Replacements Report for `matlabroot/toolbox/rtw/rtwdemos/crl_demo/addsub_two_int16.m`, open the file `codegen/lib/addsub_two_int16/html/index.html`. For information on how to regenerate the report, see “Verify Code Replacements” on page 52-64.

To examine the code generated for function, from the code generation report, open the generated file `addsub_two_int16.c`.

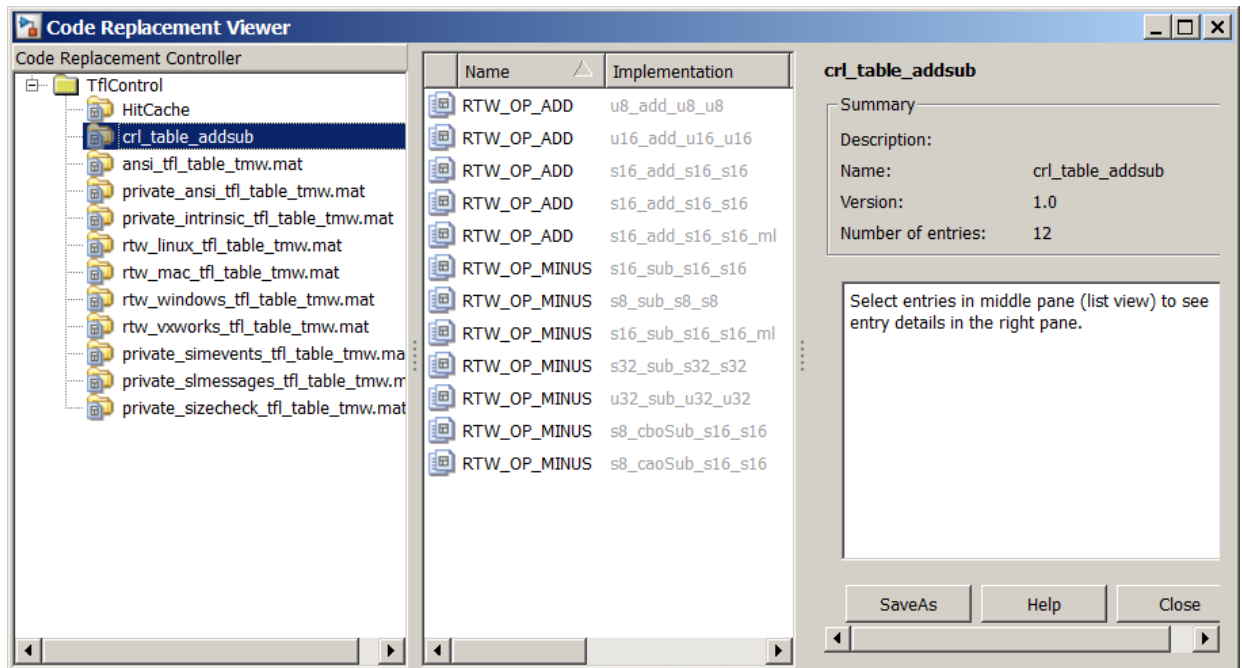

```

21 */
22 void addsub_two_int16(short u1, short u2, short *b_y1, short *y2)
23 {
24 *b_y1 = s16_add_s16_s16(u1, u2);
25 *y2 = s16_sub_s16_s16(u1, u2);
26 }
27 ~

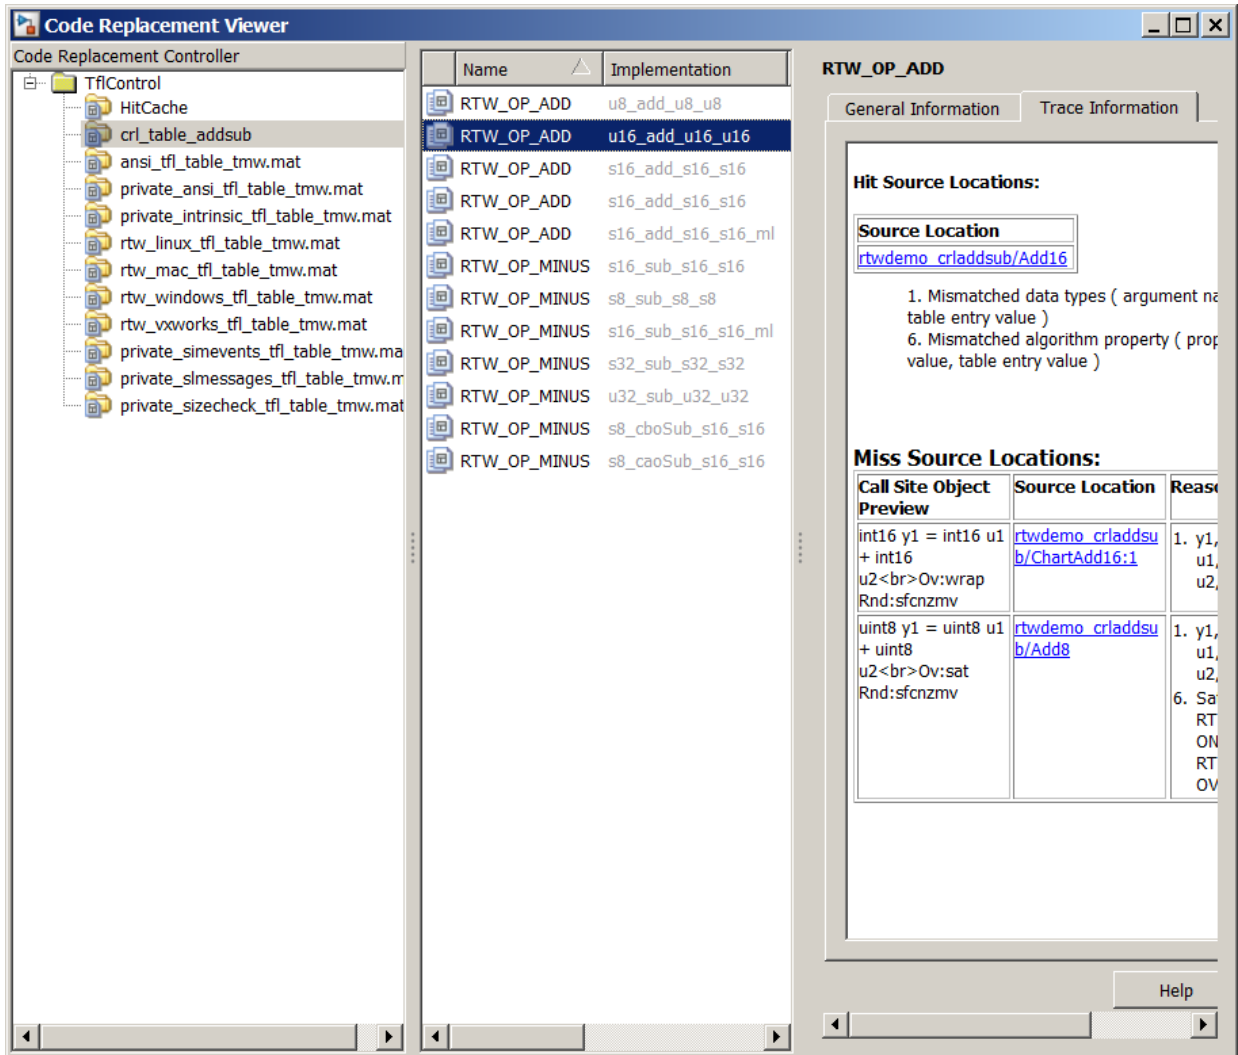

```

The code generator replaced code, but the replacement is for the signed version of the 16-bit addition and subtraction operations. You expected code replacements for operations on unsigned data.

- 2 Open the Code Replacements Report for the MATLAB code.
- 3 Click the link to open the Code Replacement Viewer.
- 4 In the viewer left pane, select your code replacement table. The following display shows entries for code replacement table `cr1_table_addsub`.

- 5 In the middle pane, select table entry `RTW_OP_ADD` with implementation function `u16_add_u16_u16`.
- 6 In the right pane, select the **Trace Information** tab.

The **Trace Information** is a table that lists the following information for each miss:

- Call site object preview. The call site object is the conceptual representation of addition operator. The code generator uses this object to query the code replacement library for a match.

- A link to the source location in the MATLAB function where the code generator considered replacing code.
- The reasons that the miss occurred. See “Miss Reason Messages” on page 52-74.

For this example, the report shows misses for function `addsub_two_int16.m`.

- 7 Find that source in the trace information. Depending on your situation and the reported miss reason, consider looking for a condition such as a typo in the code replacement table entry definition or a source parameter setting. For a list of conditions to consider, see “Miss Reason Messages” on page 52-74.

For this example, determine why code for function `addsub_two_int16` is not replaced with code for an unsigned 16-bit addition operation. The miss reasons for the function indicate data type and algorithm mismatches. For the three arguments:

- The data type in the call site object is a signed 16-bit integer. The code replacement entry specifies an unsigned 16-bit integer.
  - The algorithm property in the call site object is `RTW_SATURATE_ON_OVERFLOW` while the code replacement entry specifies `RTW_WRAP_ON_OVERFLOW`.
- 8 Correct the specified MATLAB code and relevant specifications or code replacement table entry. If the issue concerns the MATLAB code, use the source location in the trace information to find the code to correct. For this example, you expected an unsigned addition operation to occur for the `addsub_two_int16` function.

To fix the mismatches, in the test file `addsub_to_int16_test`, change the data types definitions for `u1` and `u2` as follows:

```
u1 = uint16(10)
u2 = uint16(10)
```

In the MATLAB Coder app:

- Open the project that contains the `addsub_to_int16` function.
- Use the updated test file `addsub_to_int16_test` to automatically redefine the input types.
- Run the test file.
- In the project settings dialog box, on the **Speed** tab, clear the check box for the **Saturate on integer overflow** parameter.

- Regenerate code and a report.
- 9 From the Code Replacements Report, open the Code Replacement Viewer. Use the Code Replacement Viewer trace information to verify that your MATLAB code or code replacement table entry corrects the code replacement issue. In the following display, the trace information shows a hit for function `addsub_two_int16`.

## **More About**

- “Verify Code Replacements” on page 52-64

## Deploy Code Replacement Library

After you verify code replacements and are ready to package and deploy a code replacement library for others to use:

- 1** Move your code replacement table files to an area that is on the MATLAB search path and that is accessible to and shared by other users.
- 2** Move the `rtwTargetInfo.m` registration file, to an area that is on the MATLAB search path and that is accessible to and shared by other users. If you are deploying a library to a folder in a development environment that already contains a `rtwTargetInfo.m` file, copy the registration code from your code replacement library version of `rtwTargetInfo.m` and paste it into the shared version of that file.
- 3** Register the library customizations or restart MATLAB.
- 4** Verify that the libraries are available for configuring the code generator and that code replacements occur as expected.
- 5** Inform users that the libraries are available and provide direction on when and how to apply them.

### More About

- “Verify Code Replacements” on page 52-64

## Math Function Code Replacement

This example shows how to define a code replacement mapping for a math function. The example defines a mapping for the `sin` function programmatically. Alternatively, you can use the Code Replacement Tool to define the same mapping.

- 1 Create a table definition file that contains a function definition. For example:

```
function hTable = crl_table_sinfcn2()
%CRL_TABLE_SINFCN2 - Define function entry for code replacement table.
```

- 2 Within the function body, create the table by calling the function `RTW.Tf1Table`.

```
hTable = RTW.Tf1Table;
```

- 3 Create an entry for the function mapping with a call to the `RTW.Tf1CFunctionEntry` function.

```
% Create entry for sin function replacement
fcn_entry = RTW.Tf1CFunctionEntry;
```

- 4 Set function entry parameters with a call to the `setTf1CFunctionEntryParameters` function.

```
setTf1CFunctionEntryParameters(fcn_entry, ...
 'Key', 'sin', ...
 'Priority', 30, ...
 'ImplementationName', 'mySin', ...
 'ImplementationHeaderFile', 'basicMath.h', ...
 'ImplementationSourceFile', 'basicMath.c');
```

- 5 Create conceptual arguments `y1` and `u1`. There are multiple ways to set up the conceptual arguments. This example uses calls to the `createAndAddConceptualArg` function to create and add an argument with one function call.

```
createAndAddConceptualArg(fcn_entry, 'RTW.Tf1ArgNumeric', ...
 'Name', 'y1', ...
 'IOType', 'RTW_IO_OUTPUT', ...
 'DataTypeMode', 'double');
```

```
createAndAddConceptualArg(fcn_entry, 'RTW.Tf1ArgNumeric', ...
 'Name', 'u1', ...
 'IOType', 'RTW_IO_INPUT', ...
 'DataTypeMode', 'double');
```

- 6 Copy the conceptual arguments to the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses a call to the `copyConceptualArgsToImplementation` function to create and add implementation arguments to the entry by copying matching conceptual arguments.

```
copyConceptualArgsToImplementation(fcn_entry);
```

- 7 Add the entry to a code replacement table with a call to the `addEntry` function.

```
addEntry(hTable, fcn_entry);
```

- 8 Save the table definition file. Use the name of the table definition function to name the file.

## More About

- “Define Code Replacement Mappings” on page 52-30
- “Specify In-Place Code Replacement” on page 52-86

- “Customize Match and Replacement Process” on page 52-98
- “Develop a Code Replacement Library” on page 52-15

## Memory Function Code Replacement

This example shows how to define a code replacement mapping for a memory function. The example defines a mapping for the `memcpy` function programmatically. Alternatively, you can use the Code Replacement Tool to define the same mapping.

- 1 Create a table definition file that contains a function definition. For example:

```
function hTable = crl_table_memcpy()
```

- 2 Within the function body, create the table by calling the function `RTW.Tf1Table`.

```
hTable = RTW.Tf1Table;
```

- 3 Create an entry for the function mapping with a call to the `RTW.Tf1CFunctionEntry` function.

```
% Create entry for void* memcpy(void*, void*, size_t)
fcn_entry = RTW.Tf1CFunctionEntry;
```

- 4 Set function entry parameters with a call to the `setTf1CFunctionEntryParameters` function.

```
% Set SideEffects to 'true' for function returning void to prevent it from
% being optimized away.
setTf1CFunctionEntryParameters(fcn_entry, ...
 'Key', 'memcpy', ...
 'Priority', 90, ...
 'ImplementationName', 'memcpy_int', ...
 'ImplementationHeaderFile', 'memcpy_int.h', ...
 'SideEffects', true);
```

- 5 Create conceptual arguments `y1`, `u1`, `u2`, and `u3`. There are multiple ways to set up the conceptual arguments. This example uses calls to the `getTf1ArgFromString` and `addConceptualArg` functions to create and add the arguments.

```
arg = getTf1ArgFromString(hTable, 'y1', 'void*');
arg.IOType = 'RTW_IO_OUTPUT';
addConceptualArg(fcn_entry, arg);
```

```
arg = getTf1ArgFromString(hTable, 'u1', 'void*');
addConceptualArg(fcn_entry, arg);
```

```
arg = getTf1ArgFromString(hTable, 'u2', 'void*');
addConceptualArg(fcn_entry, arg);
```

```
arg = getTf1ArgFromString(hTable, 'u3', 'size_t');
addConceptualArg(fcn_entry, arg);
```

- 6 Copy the conceptual arguments to the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses a call

to the `copyConceptualArgsToImplementation` function to create and add implementation arguments to the entry by copying matching conceptual arguments.

```
copyConceptualArgsToImplementation(fcn_entry);
```

- 7 Add the entry to a code replacement table with a call to the `addEntry` function.

```
addEntry(hTable, fcn_entry);
```

- 8 Save the table definition file. Use the name of the table definition function to name the file.

## Specify In-Place Code Replacement

In-place code replacement is an optimization technique that uses a single buffer, that is, the same memory, to store function input and output data, as in `x=f00(x)`.

When you generate C or C++ code from MATLAB code, the code generator supports in-place function argument code replacement. When you interactively create a code replacement table entry with the Code Replacement Tool, you can specify in-place function argument replacement. You can also specify in-place function argument replacement programmatically with the Code Replacement Library API.

### Argument Specification Requirements

- The argument must be a pointer.
- An argument can be in-place with only one other argument.
- Specify an input argument as in-place (shares memory) with an output argument or an output argument as in-place with an input argument.

### Interactive Argument Replacement Specification with Code Replacement Tool

This example shows how to specify in-place function argument replacement when replacing code for a MATLAB function with the Code Replacement Tool. The tool enforces in-place argument specification requirements as you add arguments and modify argument properties.

- 1 Create the following MATLAB function, `customFunction.m`.

```
function x = customFunction(x)
% Function that updates the input and returns it as an output

coder.replace('-errorifnoreplacement');
x = sin(x);
```

- 2 In the Code Replacement Tool, add a new table, select that table, and add a new function entry. For more information, see “Define Code Replacement Mappings” on page 52-30.
- 3 On the **Mapping Information** tab, select **Custom** for the **Function** parameter.
- 4 In the **function-name** text box, name the custom function. For this example, type the name `customFunction`.

- 5 Under the **Conceptual arguments** list box, click **+** to add two arguments. By default, the tool creates an output argument *y1* and an input argument *u1*, both of type double.
- 6 In the **Replacement function > Function prototype** section, type the name `custom_function_inplace_impl` in the **Name** text box.
- 7 Under the **Function arguments** list box, click **+** to add two function implementation arguments. By default, the tool creates an output argument *y1* and an input argument *u1*, both of type double.
- 8 For each input argument that you want to specify as in-place with a corresponding output argument, in the **Argument properties** box, select the **Pointer** check box. The **Argument properties** section of the dialog box expands to include an **In-place argument** drop-down list. For this example, in the **Function arguments** list, select input argument *u1*, and then select the **Pointer** check box.

Replacement function

Function prototype

Name:  C++ namespace:

Function returns void

Function arguments

y1(return arg)  
u1

Argument properties

Data type:  I/O type:

Const  Pointer  Complex

Alignment value:

In-place argument mapping

In-place argument

Make constant value

Function signature preview

```
double custom_function_inplace_impl(double u1);
```

- 9 From the **In-place argument** list, select *y1*, the output argument for the code replacement mapping. The **Function arguments** list box is updated to show possible in-place argument mappings.

Replacement function

Function prototype

Name:  C++ namespace:

Function returns void

Function arguments

```
void(return arg)
u1 <-> y1
y1 <-> u1
```

Argument properties

Data type:  I/O type:

Const  Pointer  Complex

Alignment value:

In-place argument mapping

In-place argument

Make constant value

Function signature preview

```
void custom_function_inplace_impl(double* u1, double* y1);
```

- 10 Select and delete one of the two possible argument mappings. For this example, delete the mapping `y1<->u1`.
- 11 In the **Function signature preview** box, if the function signature appears as expected, click **Apply**. Otherwise, make adjustments, and then click **Apply**. The function signature for this example, appears as
 

```
void custom_function_inplace_impl(double* u1);
```
- 12 Click **Validate entry**.
- 13 Save the code replacement table in the same folder as `customFunction.m`. Name the file `htfl_inplace_table.m`.

To test the example:

- 1 Register the table that contains the entry in a code replacement library.
- 2 Configure the code generator to use a code replacement library and to include the Code Replacements Report in the code generation report.
- 3 Generate the replacement code and a code generation report.
- 4 Review the code replacements.

## Programmatic Argument Replacement Specification

This example shows how to specify in-place function argument replacement when replacing code for a MATLAB function programmatically. For the input implementation argument that shares the memory buffer, the example:

- Sets the name of the implementation argument to the same name as the corresponding conceptual argument.
- Associates the corresponding implementation argument with the argument property `ArgumentForInPlaceUse`.

- 1 Create the following MATLAB function, `customFunction.m`.

```
function y = customFunction(x)
% Function that updates the input and returns it as an output

coder.replace('-errorifnoreplacement');
x = sin(x);
```

- 2 Create a table definition file that contains a function definition. For example:

```
function hTable = crl_table_inplace()
```

- 3 Within the function body, create the table by calling the function `RTW.Tf1Table`.

```
hTable = RTW.Tf1Table;
```

- 4 Create an entry for the function mapping with a call to the `RTW.Tf1CFunctionEntry` function.

```
hEnt = RTW.Tf1CFunctionEntry;
```

- 5 Set function entry parameters with a call to the `setTf1CFunctionEntryParameters` function.

```
setTf1CFunctionEntryParameters(hEnt, ...
 'Key', 'customFunction', ...
 'Priority', 100, ...
 'ImplementationName', 'custom_function_inplace_impl', ...
 'SideEffects', true);
```

- 6 Create conceptual arguments `y1` and `u1`. This example uses calls to the `getTf1ArgFromString` and `addConceptualArg` functions to create and add the arguments.

```
arg = getTf1ArgFromString(hEnt, 'y1', 'double');
arg.IOType = 'RTW_IO_OUTPUT';
addConceptualArg(hEnt, arg);
```

```
arg = getTf1ArgFromString(hEnt, 'u1', 'double');
addConceptualArg(hEnt, arg);
```

- 7 Create the implementation arguments and add them to the entry. This example uses calls to the `getTf1ArgFromString` function to create implementation arguments that map to arguments in the replacement function prototype: output argument `y1` and input argument `u1`. For each argument, the example uses the convenience method `setReturn` or `addArgument` to specify whether an argument is a return value or argument. For each argument, this example adds the argument to the entry array of implementation arguments.

```
arg = getTf1ArgFromString(hEnt, 'y2', 'void');
arg.IOType = 'RTW_IO_OUTPUT';
hEnt.Implementation.setReturn(arg);
```

```
arg = getTf1ArgFromString(hEnt, 'u1', 'double*');
arg.ArgumentForInPlaceUse = 'y1';
hEnt.Implementation.addArgument(arg);
```

- 8 Add the entry to a code replacement table with a call to the `addEntry` function.

```
addEntry(hLib, hEnt);
```

- 9 Save the table definition file. Use the name of the table definition function to name the file.

To test the example:

- 1 Register the table that contains the entry in a code replacement library.
- 2 Configure the code generator to use a code replacement library and to include the Code Replacements Report in the code generation report.
- 3 Generate the replacement code and a code generation report.
- 4 Review the code replacements.

## More About

- “Code You Can Replace from MATLAB Code” on page 52-5
- “Define Code Replacement Mappings” on page 52-30
- “Develop a Code Replacement Library” on page 52-15

## Replace MATLAB Functions with Custom Code Using `coder.replace`

The `coder.replace` function provides the ability to replace a specified MATLAB function with a code replacement function in generated code. Use `coder.replace` in MATLAB code from which you want to generate C code using:

- MATLAB Coder
- MATLAB code in a Simulink MATLAB Function block

You can replace MATLAB functions that have:

- Single or multiple inputs
- Single or multiple outputs
- Scalar and matrix inputs and outputs

Supported types include:

- `single`, `double` (complex and noncomplex)
- `int8`, `uint8` (complex and noncomplex)
- `int16`, `uint16` (complex and noncomplex)
- `int32`, `uint32` (complex and noncomplex)
- Fixed-point integers
- Mixed types (different type on each input)

### More About

- “Code You Can Replace from MATLAB Code” on page 52-5
- “Define Code Replacement Mappings” on page 52-30
- “Develop a Code Replacement Library” on page 52-15

## Replace `coder.ceval` Calls to External Functions

The `coder.ceval` function calls external C/C++ functions from code generated from MATLAB code. The code replacement software supports replacement of the function that you specify in a call to `coder.ceval`. An application of this code replacement scenario is to write generic MATLAB code that you can customize for different platforms with code replacements. A code replacement library can define hardware-specific code replacements for the function call. Use `coder.ceval` in MATLAB code from which you want to generate C code using:

- MATLAB Coder
- MATLAB code in a Simulink MATLAB Function block

### Example Files

For the examples in “Interactive External Function Call Replacement Specification with Code Replacement Tool” on page 52-93 and “Programmatic External Function Call Replacement Specification” on page 52-94 you must have set up the following:

- Custom C function `my_add.c`.

```
/* my_add.c */

#include "my_add.h"

double my_add(double in1, double in2)
{
 return in1 + in2;
}
```

- Custom C header file `my_add.h`.

```
/* my_add.h */

double my_add(double in1, double in2);
```

- MATLAB function `call_my_add.m`, which uses `coder.ceval` to invoke `my_add.c`.

```
function y = call_my_add(in1, in2) %#codegen

y=0.0;

if ~coder.target('Rtw')
 % Executing in MATLAB, call MATLAB equivalent of C function my_add
```

```

 y= in1+in2;
else
% Executing in generated code, call C function my_add
 y = coder.ceval('my_add', in1, in2);
end

```

- MATLAB test function `call_my_add_test.m`, which calls `call_my_add.m`.

```

in1=10;
in2=20;

y = call_my_add(in1, in2);

```

```

disp('Output')
disp('y =')
disp(y);

```

- Replacement C function `my_add_replacement.c`.

```

/* my_add_replacement.c */

#include "my_add_replacement.h"

double my_add_replacement(double in1, double in2)
{
 return in1 + in2;
}

```

- Replacement C header file `my_add_replacement.h`.

```

/* my_add_replacement.h */

double my_add_replacement(double in1, double in2);

```

## Interactive External Function Call Replacement Specification with Code Replacement Tool

This example shows how to define a code replacement table entry for a MATLAB function that calls `coder.ceval` to invoke an external C function. The example shows how to define the entry interactively with the Code Replacement Tool.

- 1 Identify or create the C/C++ code and relevant header files, the MATLAB function that calls `coder.ceval`, a MATLAB test function, and the source and header files for your replacement code. To follow along with this example, set up the files identified in “Example Files” on page 52-92.

- 2 In the Code Replacement Tool, add a table, select that table, and add a function entry. For more information, see “Define Code Replacement Mappings” on page 52-30.
- 3 On the **Mapping Information** tab, select **Custom** for the **Function** parameter.
- 4 In the **function-name** text box, type the custom function name. For this example, type the name `my_add`.
- 5 Under the **Conceptual arguments** list box, click **+** to add three arguments. By default, the tool creates an output argument `y1` and input arguments `u1` and `u2` of type `double`.
- 6 In the **Replacement function > Function prototype** section, type the name `my_add_replacement` in the **Name** text box.
- 7 Under the **Function arguments** list box, click **+** to add three function implementation arguments. By default, the tool creates an output argument `y1` and input arguments `u1` and `u2` of type `double`. Use the default settings.
- 8 In the **Function signature preview** box, if you see the expected function signature, click **Apply**. The function signature for this example, appears as:  

```
double my_add_replacement(double u1, double u2);
```
- 9 On the **Build Information** tab, specify `my_add_replacement.h` for the **Implementation header file** parameter and `my_add_replacement.c` for the **Implementation source file**.
- 10 Click **Validate entry**.
- 11 Save the code replacement table in the same folder as `my_add_replacement.c`. Name the file `cr1_table_my_add.m`.

To test the example:

- 1 Register the table that contains the entry in a code replacement library.
- 2 Configure the code generator to use the code replacement library and to include the Code Replacements Report in the code generation report.
- 3 Generate code and the report.
- 4 Review the code replacements.

## Programmatic External Function Call Replacement Specification

This example shows how to define a code replacement table entry for a MATLAB function that calls `coder.ceval` to invoke an external C function. The example shows how to define the entry programmatically.

- 1 Identify or create the C/C++ code and relevant header files, the MATLAB function that calls `coder.ceval` to invoke the C/C++ function, a MATLAB test function, and the source and header files for your replacement code. To follow along with this example, set up the files identified in “Example Files” on page 52-92.

- 2 Create a table definition file that contains a function definition. For example:

```
function hLib = crl_table_my_add
```

- 3 Within the function body, create the table by calling the function `RTW.Tf1Table`.

- 4 Create an entry for the function mapping with a call to the `RTW.Tf1CFunctionEntry` function.

```
hEnt = RTW.Tf1CFunctionEntry;
```

- 5 Set function entry parameters with a call to the `setTf1CFunctionEntryParameters` function.

```
hEnt.setTf1CFunctionEntryParameters(...
 'Key', 'my_add', ...
 'Priority', 100, ...
 'ImplementationName', 'my_add_replacement', ...
 'ImplementationHeaderFile', 'my_add_replacement.h', ...
 'ImplementationSourceFile', 'my_add_replacement.c');
```

- 6 Create conceptual arguments `y1`, `u1`, and `u1`. This example uses calls to the `getTf1ArgFromString` and `addConceptualArg` functions to create and add the arguments.

```
arg = hEnt.getTf1ArgFromString('y1', 'double');
arg.IOType = 'RTW_IO_OUTPUT';
hEnt.addConceptualArg(arg);
```

```
arg = hEnt.getTf1ArgFromString('u1', 'double');
hEnt.addConceptualArg(arg);
```

```
arg = hEnt.getTf1ArgFromString('u2', 'double');
hEnt.addConceptualArg(arg);
```

- 7 Create the implementation arguments and add them to the entry. This example uses calls to the `getTf1ArgFromString` function to create implementation arguments. These functions map to arguments in the replacement function prototype: output argument `y1` and input arguments `u1` and `u2`. For each argument, the example uses the convenience method `setReturn` or `addArgument` to specify whether an argument is a return value or argument. For each argument, this example adds the argument to the entry array of implementation arguments.

```
arg = hEnt.getTflArgFromString('y1','double');
arg.IOType = 'RTW_IO_OUTPUT';
hEnt.Implementation.setReturn(arg);
```

```
arg = hEnt.getTflArgFromString('u1','double');
hEnt.Implementation.addArgument(arg);
```

```
arg = hEnt.getTflArgFromString('u2','double');
hEnt.Implementation.addArgument(arg);
```

- 8 Add the entry to a code replacement table with a call to the `addEntry` function.

```
hLib.addEntry(hEnt);
```

- 9 Save the table definition file. Use the name of the table definition function to name the file.

To test the example:

- 1 Register the table that contains the entry in a code replacement library.
- 2 Configure the code generator to use the code replacement library and to include the Code Replacements Report in the code generation report.
- 3 Generate code and the report.
- 4 Review the code replacements.

- “Develop a Code Replacement Library” on page 52-15

## Reserved Identifiers and Code Replacement

The code generator and C programming language use, internally, reserved keywords for code generation. Do not use reserved keywords as identifiers or function names. Reserved keywords for code generation include many code replacement library identifiers, the majority of which are function names, such as `acos`.

To view a list of reserved identifiers for the code replacement library that you use to generate code, specify the name of the library in a call to the function `RTW.TargetRegistry.getInstance.getTf1ReservedIdentifiers`. For example:

```
cr1_ids = RTW.TargetRegistry.getInstance.getTf1ReservedIdentifiers('GNU99 (GNU)')
```

In a code replacement table, the code generator registers each function implementation name defined by a table entry as a reserved identifier. You can register additional reserved identifiers for the table on a per-header-file basis. Providing additional reserved identifiers can help prevent duplicate symbols and other identifier-related compile and link issues.

To register additional code replacement reserved identifiers, use the `setReservedIdentifiers` function. This function registers specified reserved identifiers to be associated with a code replacement table.

You can register up to four reserved identifier structures in a code replacement table. You can associate one set of reserved identifiers with a code replacement library, while the other three (if present) must be associated with ANSI C. The following example shows a reserved identifier structure that specifies two identifiers and the associated header file.

```
d{1}.LibraryName = 'ANSI_C';
d{1}.HeaderInfos{1}.HeaderName = 'math.h';
d{1}.HeaderInfos{1}.ReservedIds = {'y0', 'y1'};
```

The code generator adds the identifiers to the list of reserved identifiers and honors them during the build procedure.

### More About

- “Code You Can Replace from MATLAB Code” on page 52-5
- “Customize Match and Replacement Process” on page 52-98
- “Define Code Replacement Mappings” on page 52-30
- “Develop a Code Replacement Library” on page 52-15

## Customize Match and Replacement Process

During the build process, the code generator uses:

- Preset match criteria to identify functions and operators for which application-specific implementations replace default implementations.
- Preset replacement function signatures.

It is possible that preset match criteria and preset replacement function signatures do not completely meet your function and operator replacement needs. For example:

- You want to replace an operator with a particular fixed-point implementation function only when fraction lengths are within a particular range.
- When a match occurs, you want to modify your replacement function signature based on compile-time information, such as passing fraction-length values into the function.

To add extra logic into the code replacement match and replacement process, create custom code replacement table entries. With custom entries, you can specify additional match criteria and modify the replacement function signature to meet application needs.

To create a custom code replacement entry:

- 1 Create a custom code replacement entry class, derived from `RTW.Tf1CFunctionEntryML` (for function replacement) or `RTW.Tf1COperationEntryML` (for operator replacement).
- 2 In your derived class, implement a `do_match` method with a fixed preset signature as a MATLAB function. In your `do_match` method, provide either or both of the following customizations that instantiate the class:
  - Add match criteria that the base class does not provide. The base class provides a match based on:
    - Argument number
    - Argument name
    - Signedness
    - Word size
    - Slope (if not specified with wildcards)
    - Bias (if not specified with wildcards)
    - Math modes, such as saturation and rounding

- Operator or function key
  - Modify the implementation signature by adding additional arguments or setting constant input argument values. You can inject a constant value, such as an input scaling value, as an additional argument to the replacement function.
- 3** Create code replacement entries that instantiate the custom entry class.
  - 4** Register a library containing the code replacement table that includes your entries.

During code generation, the code replacement match process tries to match function or operator call sites with the base class of your derived entry class. If the process finds a match, the software calls your `do_match` method to execute your additional match logic (if any) and your replacement function customizations (if any).

## Customize Match and Replacement Process for Operators

This example shows how to create custom code replacement entries that add logic to the code match and replacement process for a scalar operation. Custom entries specify additional match criteria or modify the replacement function signature to meet application needs.

For example:

- When fraction lengths are within a specific range, replace an operator with a fixed-point implementation function.
- When a match occurs, modify the replacement function signature based on compile-time information, such as passing fraction-length values into the function.

This example modifies a fixed-point addition replacement such that the implementation function passes in the fraction lengths of the input and output data types as arguments.

To create custom code replacement entries that add logic to the code replacement match and replacement process:

- 1** Create a class, for example `Tf1CustomOperationEntry`, that is derived from the base class `RTW.Tf1COperationEntryML`. The derived class defines a `do_match` method with the following signature:

```
function ent = do_match(hThis, ...
 hCSO, ...
 targetBitPerChar, ...
 targetBitPerShort, ...
 targetBitPerInt, ...
```

```
targetBitPerLong, ...
targetBitPerLongLong)
```

In the `do_match` signature:

- `ent` is the return handle, which is returned as empty (indicating that the match failed) or as a `Tf1COperationEntry` handle.
- `hThis` is the handle to the class instance.
- `hCSO` is a handle to an object that the code generator creates for querying the library for a replacement.
- Remaining arguments are the number of bits for various data types of the current target.

The `do_match` method adds match criteria that the base class does not provide. The method makes modifications to the implementation signature. In this case, the `do_match` method relies on the base class for checking word size and signedness. `do_match` must match only the number of conceptual arguments to the value 3 (two inputs and one output) and the bias for each argument to value 0. If the code generator finds a match, `do_match`:

- Sets the return handle.
- Removes slope and bias wild cards from the conceptual arguments (the match is for specific slope and bias values).
- Writes fraction-length values for the inputs and output into replacement function arguments 3, 4, and 5.

You can create and add three additional implementation function arguments for passing fraction lengths in the class definition or in each code replacement entry definition that instantiates this class. This example creates the arguments, adds them to a code replacement table definition file, and sets them to specific values in the class definition code.

```
classdef Tf1CustomOperationEntry < RTW.Tf1COperationEntryML
 methods
 function ent = do_match(hThis, ...
 hCSO, ... %#ok
 targetBitPerChar, ... %#ok
 targetBitPerShort, ... %#ok
 targetBitPerInt, ... %#ok
 targetBitPerLong, ... %#ok
 targetBitPerLongLong) %#ok

 % DO_MATCH - Create a custom match function. The base class
```

```

% checks the types of the arguments prior to calling this
% method. This class will check additional data and can
% modify the implementation function.

% The base class checks word size and signedness. Slopes and biases
% have been wildcarded, so the only additional checking to do is
% to check that the biases are zero and that there are only three
% conceptual arguments (one output, two inputs)

ent = []; % default the return to empty, indicating the match failed

if length(hCSO.ConceptualArgs) == 3 && ...
 hCSO.ConceptualArgs(1).Type.Bias == 0 && ...
 hCSO.ConceptualArgs(2).Type.Bias == 0 && ...
 hCSO.ConceptualArgs(3).Type.Bias == 0

 % Modify the default implementation. Since this is a
 % generator entry, a concrete entry is created using this entry
 % as a template. The type of entry being created is a standard
 % Tf1COperationEntry. Using the standard operation entry
 % provides required information, and you do not need
 % a custom match function.
 ent = RTW.Tf1COperationEntry(hThis);

 % Since this entry is modifying the implementation for specific
 % fraction-length values (arguments 3, 4, and 5), the conceptual argument
 % wild cards must be removed (the wildcards were inherited from the
 % generator when it was used as a template for the concrete entry).
 % This concrete entry is now for a specific slope and bias.
 % hCSO holds the slope and bias values (created by the code generator).
 for idx=1:3
 ent.ConceptualArgs(idx).CheckSlope = true;
 ent.ConceptualArgs(idx).CheckBias = true;

 % Set the specific Slope and Biases
 ent.ConceptualArgs(idx).Type.Slope = hCSO.ConceptualArgs(idx).Type.Slope;
 ent.ConceptualArgs(idx).Type.Bias = 0;
 end

 % Set the fraction-length values in the implementation function.
 ent.Implementation.Arguments(3).Value = ...
 -1.0*hCSO.ConceptualArgs(2).Type.FixedExponent;
 ent.Implementation.Arguments(4).Value = ...
 -1.0*hCSO.ConceptualArgs(3).Type.FixedExponent;
 ent.Implementation.Arguments(5).Value = ...
 -1.0*hCSO.ConceptualArgs(1).Type.FixedExponent;
end
end
end
end
end

```

Exit the class folder and return to the previous working folder.

- 2 Create and save the following code replacement table definition file, `crl_table_custom_sinfcn_double.m`. This file defines a code replacement table

that contains a single operator entry, an entry generator for unsigned 32-bit fixed-point addition operations, with arbitrary fraction-length values on the inputs and the output. The table entry:

- Instantiates the derived class `Tf1CustomOperationEntry` from the previous step. If you want to replace word sizes and signedness attributes, you can use the same derived class, but not the same entry, because you cannot use a wild card with the `WordLength` and `IsSigned` arguments. For example, to support `uint8`, `int8`, `uint16`, `int16`, and `int32`, add five other distinct entries. To use different implementation functions for saturation and rounding modes other than overflow and round to floor, add entries for those match permutations.
- Sets operator entry parameters with the call to the `setTf1COperationEntryParameters` function.
- Calls the `createAndAddConceptualArg` function to create conceptual arguments `y1`, `u1`, and `u2`.
- Calls `createAndSetCImplementationReturn` and `createAndAddImplementationArg` to define the signature for the replacement function. Three of the calls to `createAndAddImplementationArg` create implementation arguments to hold the fraction-length values for the inputs and output. Alternatively, the entry can omit those argument definitions. Instead, the `do_match` method of the derived class `Tf1CustomOperationEntry` can create and add the three implementation arguments. When the number of additional implementation arguments required can vary based on compile-time information, use the alternative approach.
- Calls `addEntry` to add the entry to a code replacement table.

```
function hTable = crl_table_custom_add_ufix32

hTable = RTW.Tf1Table;

%% Add Tf1CustomOperationEntry
op_entry = Tf1CustomOperationEntry;

setTf1COperationEntryParameters(op_entry, ...
 'Key', 'RTW_OP_ADD', ...
 'Priority', 30, ...
 'SaturationMode', 'RTW_SATURATE_ON_OVERFLOW', ...
 'RoundingModes', {'RTW_ROUND_FLOOR'}, ...
 'ImplementationName', 'myFixptAdd', ...
 'ImplementationHeaderFile', 'myFixptAdd.h', ...
```

```
 'ImplementationSourceFile', 'myFixptAdd.c');

createAndAddConceptualArg(op_entry, 'RTW.Tf1ArgNumeric', ...
 'Name', 'y1', ...
 'IOType', 'RTW_IO_OUTPUT', ...
 'CheckSlope', false, ...
 'CheckBias', false, ...
 'DataType', 'Fixed', ...
 'Scaling', 'BinaryPoint', ...
 'IsSigned', false, ...
 'WordLength', 32);

createAndAddConceptualArg(op_entry, 'RTW.Tf1ArgNumeric', ...
 'Name', 'u1', ...
 'IOType', 'RTW_IO_INPUT', ...
 'CheckSlope', false, ...
 'CheckBias', false, ...
 'DataType', 'Fixed', ...
 'Scaling', 'BinaryPoint', ...
 'IsSigned', false, ...
 'WordLength', 32);

createAndAddConceptualArg(op_entry, 'RTW.Tf1ArgNumeric', ...
 'Name', 'u2', ...
 'IOType', 'RTW_IO_INPUT', ...
 'CheckSlope', false, ...
 'CheckBias', false, ...
 'DataType', 'Fixed', ...
 'Scaling', 'BinaryPoint', ...
 'IsSigned', false, ...
 'WordLength', 32);

% Specify replacement function signature
createAndSetCImplementationReturn(op_entry, 'RTW.Tf1ArgNumeric', ...
 'Name', 'y1', ...
 'IOType', 'RTW_IO_OUTPUT', ...
 'IsSigned', false, ...
 'WordLength', 32, ...
 'FractionLength', 0);

createAndAddImplementationArg(op_entry, 'RTW.Tf1ArgNumeric', ...
 'Name', 'u1', ...
 'IOType', 'RTW_IO_INPUT', ...
 'IsSigned', false, ...
```

```
 'WordLength', 32, ...
 'FractionLength', 0);

createAndAddImplementationArg(op_entry, 'RTW.Tf1ArgNumeric', ...
 'Name', 'u2', ...
 'IOType', 'RTW_IO_INPUT', ...
 'IsSigned', false, ...
 'WordLength', 32, ...
 'FractionLength', 0);

% Add 3 fraction-length args. Actual values are set during code generation.
createAndAddImplementationArg(op_entry, 'RTW.Tf1ArgNumericConstant', ...
 'Name', 'fl_in1', ...
 'IOType', 'RTW_IO_INPUT', ...
 'IsSigned', false, ...
 'WordLength', 32, ...
 'FractionLength', 0, ...
 'Value', 0);

createAndAddImplementationArg(op_entry, 'RTW.Tf1ArgNumericConstant', ...
 'Name', 'fl_in2', ...
 'IOType', 'RTW_IO_INPUT', ...
 'IsSigned', false, ...
 'WordLength', 32, ...
 'FractionLength', 0, ...
 'Value', 0);

createAndAddImplementationArg(op_entry, 'RTW.Tf1ArgNumericConstant', ...
 'Name', 'fl_out', ...
 'IOType', 'RTW_IO_INPUT', ...
 'IsSigned', false, ...
 'WordLength', 32, ...
 'FractionLength', 0, ...
 'Value', 0);

addEntry(hTable, op_entry);
```

**3** Check the validity of the operator entry.

- At the command prompt, invoke the table definition file.

```
tbl = crl_table_custom_sinfcn_double
```

- In the Code Replacement Viewer, view the table definition file.

```
crviewer(crl_table_custom_sinfcn_double)
```

## **More About**

- “Develop a Code Replacement Library” on page 52-15

## Scalar Operator Code Replacement

This example shows how to define a code replacement mapping for a scalar operator. The example defines a mapping for the + (addition) operator programmatically. Alternatively, you can use the Code Replacement Tool to define the same mapping.

- 1 Create a table definition file that contains a function definition. For example:

```
function hTable = crl_table_add_uint8
```

- 2 Within the function body, create the table by calling the function `RTW.Tf1Table`.

```
hTable = RTW.Tf1Table;
```

- 3 Create an entry for the operator mapping with a call to the `RTW.Tf1COperationEntry` function.

```
% Create operation entry
op_entry = RTW.Tf1COperationEntry;
```

- 4 Set function entry parameters with a call to the `setTf1COperationEntryParameters` function.

```
% Define addition operation of built-in uint8 data type
% Saturation on, Rounding unspecified
setTf1COperationEntryParameters(op_entry, ...
 'Key', 'RTW_OP_ADD', ...
 'Priority', 90, ...
 'SaturationMode', 'RTW_SATURATE_ON_OVERFLOW', ...
 'RoundingModes', {'RTW_ROUND_UNSPECIFIED'}, ...
 'ImplementationName', 'u8_add_u8_u8', ...
 'ImplementationHeaderFile', 'u8_add_u8_u8.h', ...
 'ImplementationSourceFile', 'u8_add_u8_u8.c');
```

- 5 Create conceptual arguments `y1`, `u1`, and `u2`. There are multiple ways to set up the conceptual arguments. This example uses calls to the `getTf1ArgFromString` and `addConceptualArg` functions to create and add the arguments.

```
arg = getTf1ArgFromString(hTable, 'y1', 'uint8');
arg.IOType = 'RTW_IO_OUTPUT';
addConceptualArg(op_entry, arg);
```

```
arg = getTf1ArgFromString(hTable, 'u1', 'uint8');
addConceptualArg(op_entry, arg);
```

```
arg = getTf1ArgFromString(hTable, 'u2', 'uint8');
addConceptualArg(op_entry, arg);
```

- 6 Copy the conceptual arguments to the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses a call

to the `copyConceptualArgsToImplementation` function to create and add implementation arguments to the entry by copying matching conceptual arguments.

```
copyConceptualArgsToImplementation(op_entry);
```

- 7 Add the entry to a code replacement table with a call to the `addEntry` function.

```
addEntry(hTable, op_entry);
```

- 8 Save the table definition file. Use the name of the table definition function to name the file.

## Addition and Subtraction Operator Code Replacement

Consider the following when defining mappings for addition and subtraction operator code replacements.

### Algorithm Options

When creating a code replacement table entry for an addition or subtraction operator, first determine the type of algorithm that your library function implements.

- **Cast-before-operation (CBO)**, default — Prior to performing the addition or subtraction operation, the algorithm type casts input values to the output type. If the output data type cannot exactly represent the input values, losses can occur as a result of the cast to the output type. Additional loss can occur when the result of the operation is cast to the final output type.

- **Cast-after-operation (CAO)** — The algorithm computes the ideal result of the addition or subtraction operation of the two inputs. The algorithm then type casts the result to the output data type. Loss occurs during the type cast. This algorithm behaves similarly to the C language except when the signedness of the operands does not match. For example, when you add a signed long operand to an unsigned long operand, standard C language rules convert the signed long operand to an unsigned long operand. The result is a value that is not ideal.

### Interactive Specification with Code Replacement Tool

When you use the Code Replacement Tool to create a code replacement table entry for an addition or subtraction operation, the tool displays an **Algorithm** menu. Use that menu to specify the **Cast before operation** or **Cast after operation** algorithm for that entry.

## Programmatic Specification

Create a code replacement table file, as a MATLAB function, that describes the addition or subtraction code replacement table entry. In the call to `setTf1COperationEntryParameters`, set at least these parameters:

- `Key` to `RTW_OP_ADD` or `RTW_OP_MINUS`
- `ImplementationName` to the name of your replacement function
- `EntryInfoAlgorithm` to `RTW_CAST_BFORE_OP` (cast-before-operation) or `RTW_CAST_AFTER_OP` (cast-after-operation)

This example sets parameters for a code replacement operator entry for a cast-after-operation implementation of a `uint8` addition.

```
op_entry = RTW.Tf1COperationEntry;
setTf1COperationEntryParameters(op_entry, ...
 'Key', 'RTW_OP_ADD', ...
 'EntryInfoAlgorithm', 'RTW_CAST_AFTER_OP', ...
 'ImplementationName', 'u8_add_u8_u8');
```

For more information, see `setTf1COperationEntryParameters`.

## Algorithm Classification

During code generation, the code generator examines addition and subtraction operations, including adjacent type cast operations, to determine the type of algorithm to compute the expression result. Based on the data types in the expression and the type of the accumulator (type used to hold the result of the addition or subtraction operation), the code generator uses these rules.

- Floating-point types only

Input 1 Data Type	Input 2 Data Type	Accumulator Data Type	Output Data Type	Classification
double	double	double	double	CBO, CAO
double	double	double	single	—
double	double	single	double	—
double	double	single	single	CBO
double	single	double	double	CBO, CAO

Input 1 Data Type	Input 2 Data Type	Accumulator Data Type	Output Data Type	Classification
double	single	double	single	—
double	single	single	double	—
double	single	single	single	CBO
single	single	single	single	CBO, CAO
single	single	single	double	—
single	single	double	single	—
single	single	double	double	CBO, CAO

- Floating-point and fixed-point types on the immediate addition or subtraction operation

Algorithm	Conditions
CBO	One of the following is true: <ul style="list-style-type: none"> <li>• Operation type is <code>double</code>.</li> <li>• Operation type is <code>single</code> and input types are <code>single</code> or fixed-point.</li> </ul>
CAO	Operation type is a superset of input types—that is, output type can represent values of input types without loss of data.

- Fixed-point types only

Algorithm	Conditions
CBO	At least one of the following is true: <ul style="list-style-type: none"> <li>• Accumulator type equals output type (<code>Tacc == Tout</code>).</li> <li>• Output type is a superset of input types (<code>Tacc &gt;= {Tin1, Tin2}</code>) and accumulator type is a superset of output type (<code>Tacc &gt;= Tout</code>).</li> <li>• Operation does not incur range or precision loss.</li> </ul>
CAO	Net bias is zero and the data types in the expression have equal slope adjustment factors. For more information on net bias, see “Addition” or “Subtraction” in “Fixed-Point Operator Code Replacement” on page 52-132 (for MATLAB code) or “Fixed-Point Operator Code Replacement” on page 51-195 (for Simulink models).

In many cases, the numerical result of a CBO operation is equal to that of a CAO operation. For example, if the input and output types are such that the operation produces the ideal result, as in the case of `int8 + int8 -> int16`. To maximize the probability of code replacement occurring in such cases, set the algorithm to cast-after-operation.

## Limitations

- The code generator does not replace operations with nonzero net bias.
- When classifying an operation as a CAO operation, the code generator includes the adjacent casts in the expression when the expression involves only fixed-point types. Otherwise, the code generator classifies and replaces only the immediate addition or subtraction operation. Casts that the code generator excludes from the classification appear in the generated code.
- To enable the code generator to include multiple cast operations, which follow an addition or subtraction of fixed-point data, in the classification of an expression, the rounding mode must be `simplest` or `floor`. Consider the expression `y=(cast A)(cast B)(u1+u2)`. If the rounding mode of `(cast A)`, `(cast B)`, and the addition operator (+) are set to `simplest` or `floor`, the code generator takes into account `(cast A)` and `(cast B)` when classifying the expression and performing the replacement only.

## Small Matrix Operation to Processor Code Replacement

This example shows how to define code replacement mappings that replace nonscalar small matrix operations with processor-specific intrinsic functions. The example defines a table containing two matrix operator replacement entries for the + (addition) operator and the `double` data type. The example defines the function mapping programmatically. Alternatively, you can use the Code Replacement Tool to define the same mapping.

- 1 Create a table definition file that contains a function definition. For example:

```
function hTable = cr1_table_matrix_add_double
```

- 2 Within the function body, create the table by calling the function `RTW.Tf1Table`.

```
hTable = RTW.Tf1Table;
```

- 3 Create the entry for the first operator mapping with a call to the `RTW.Tf1COperationEntry` function.

```
% Create table entry for matrix_sum_2x2_double
op_entry = RTW.Tf1COperationEntry;
```

- 4 Set operator entry parameters with a call to the `setTf1COperationEntryParameters` function. The code generator ignores saturation and rounding modes for floating-point nonscalar addition and subtraction. For code replacement entries for nonscalar addition and subtraction operations that do not involve fixed-point data, in the call to `setTf1COperationEntryParameters`, specify `'RTW_SATURATE_UNSPECIFIED'` for the `SaturationMode` property and `{'RTW_ROUND_UNSPECIFIED'}` for `RoundingModes`.

```
setTf1COperationEntryParameters(op_entry, ...
 'Key', 'RTW_OP_ADD', ...
 'Priority', 30, ...
 'SaturationMode', 'RTW_WRAP_ON_OVERFLOW', ...
 'ImplementationName', 'matrix_sum_2x2_double', ...
 'ImplementationHeaderFile', 'MatrixMath.h', ...
 'ImplementationSourceFile', 'MatrixMath.c', ...
 'ImplementationHeaderPath', LibPath, ...
 'ImplementationSourcePath', LibPath, ...
 'AdditionalIncludePaths', {LibPath}, ...
 'GenCallback', 'RTW.copyFileToBuildDir', ...
 'SideEffects', true);
```

- 5 Create conceptual arguments `y1`, `u1`, and `u2`. There are multiple ways to set up the conceptual arguments. This example uses calls to the `createAndAddConceptualArg` function to create and add an argument with one function call. To specify a matrix argument in the function call, use the argument

class `RTW.Tf1ArgMatrix`. Specify the base type and the dimensions for which the argument is valid. The first table entry specifies [2 2] and the second table entry specifies [3 3].

```
% Specify operands and result
createAndAddConceptualArg(op_entry, 'RTW.Tf1ArgMatrix', ...
 'Name', 'y1', ...
 'IOType', 'RTW_IO_OUTPUT', ...
 'BaseType', 'double', ...
 'DimRange', [2 2]);
createAndAddConceptualArg(op_entry, 'RTW.Tf1ArgMatrix',...
 'Name', 'u1', ...
 'BaseType', 'double', ...
 'DimRange', [2 2]);
createAndAddConceptualArg(op_entry, 'RTW.Tf1ArgMatrix',...
 'Name', 'u2', ...
 'BaseType', 'double', ...
 'DimRange', [2 2]);
```

- 6 Create the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses calls to the `getTf1ArgFromString` to create the arguments. The convenience methods `setReturn` and `addArgument` specify whether an argument is a return value or argument and adds the argument to the entry's array of implementation arguments.

```
arg = getTf1ArgFromString(hTable, 'y2', 'void');
arg.IOType = 'RTW_IO_OUTPUT';
op_entry.Implementation.setReturn(arg);

arg = getTf1ArgFromString(hTable, 'u1', ['double' '*']);
op_entry.Implementation.addArgument(arg);

arg = getTf1ArgFromString(hTable, 'u2', ['double' '*']);
op_entry.Implementation.addArgument(arg);

arg = getTf1ArgFromString(hTable, 'y1', ['double' '*']);
arg.IOType = 'RTW_IO_OUTPUT';
op_entry.Implementation.addArgument(arg);
```

- 7 Add the entry to a code replacement table with a call to the `addEntry` function.

```
addEntry(hTable, op_entry);
```

- 8 Create the entry for the second operator mapping.

```
% Create table entry for matrix_sum_3x3_double
op_entry = RTW.Tf1COperationEntry;
setTf1COperationEntryParameters(op_entry, ...
 'Key', 'RTW_OP_ADD', ...
 'Priority', 30, ...
 'SaturationMode', 'RTW_WRAP_ON_OVERFLOW', ...
 'ImplementationName', 'matrix_sum_3x3_double', ...
```

```

 'ImplementationHeaderFile', 'MatrixMath.h', ...
 'ImplementationSourceFile', 'MatrixMath.c', ...
 'ImplementationHeaderPath', LibPath, ...
 'ImplementationSourcePath', LibPath, ...
 'AdditionalIncludePaths', {LibPath}, ...
 'GenCallback', 'RTW.copyFileToBuildDir', ...
 'SideEffects', true);

% Specify operands and result
createAndAddConceptualArg(op_entry, 'RTW.Tf1ArgMatrix', ...
 'Name', 'y1', ...
 'IOType', 'RTW_IO_OUTPUT', ...
 'BaseType', 'double', ...
 'DimRange', [3 3]);
createAndAddConceptualArg(op_entry, 'RTW.Tf1ArgMatrix', ...
 'Name', 'u1', ...
 'BaseType', 'double', ...
 'DimRange', [3 3]);
createAndAddConceptualArg(op_entry, 'RTW.Tf1ArgMatrix', ...
 'Name', 'u2', ...
 'BaseType', 'double', ...
 'DimRange', [3 3]);

% Specify replacement function signature
arg = getTf1ArgFromString(hTable, 'y2', 'void');
arg.IOType = 'RTW_IO_OUTPUT';
op_entry.Implementation.setReturn(arg);
arg = getTf1ArgFromString(hTable, 'u1', ['double' '*']);
op_entry.Implementation.addArgument(arg);
arg = getTf1ArgFromString(hTable, 'u2', ['double' '*']);
op_entry.Implementation.addArgument(arg);
arg = getTf1ArgFromString(hTable, 'y1', ['double' '*']);
arg.IOType = 'RTW_IO_OUTPUT';
op_entry.Implementation.addArgument(arg);

addEntry(hTable, op_entry);

```

- 9 Save the table definition file. Use the name of the table definition function to name the file.

## Matrix Multiplication Operation to MathWorks BLAS Code Replacement

This example shows how to define code replacement mappings that replace nonscalar multiplication operations with Basic Linear Algebra Subroutine (BLAS) multiplication functions `xgemm` and `xgemv`. The example defines code replacement entries that map floating-point matrix/matrix and matrix/vector multiplication operations to MathWorks BLAS library multiplication functions `dgemm` and `dgemv`. The example defines the function mappings programmatically. Alternatively, you can use the Code Replacement Tool to define the same mappings.

BLAS libraries support matrix/matrix multiplication in the form of

$C = a(\text{op}(A) * \text{op}(B)) + bC$ . `op(X)` means X, transposition of X, or Hermitian

transposition of X. However, code replacement libraries support only the limited case of

$C = \text{op}(A) * \text{op}(B)$  ( $a = 1.0$ ,  $b = 0.0$ ). Correspondingly, although BLAS libraries support

matrix/vector multiplication in the form of  $y = a(\text{op}(A) * x) + by$ , code replacement

libraries support only the limited case of  $y = \text{op}(A) * x$  ( $a = 1.0$ ,  $b = 0.0$ ).

- 1 Create a table definition file that contains a function definition. For example:

```
function hTable = crl_table_tmwblas_mmult_double
```

- 2 Within the function body, create the table by calling the function `RTW.Tf1Table`.

```
hTable = RTW.Tf1Table;
```

- 3 Define the path for the BLAS function library. If your replacement functions are on the MATLAB search path or are in your working folder, you can skip this step.

```
% Define library path for Windows or UNIX
arch = computer('arch');
if ~ispc
 LibPath = fullfile('$MATLAB_ROOT', 'bin', arch);
else
 % Use Stateflow to get the compiler info
 compilerInfo = sf('Private','compilerman','get_compiler_info');
 compilerName = compilerInfo.compilerName;
 if strcmp(compilerName, 'msvc90') || ...
 strcmp(compilerName, 'msvc80') || ...
 strcmp(compilerName, 'msvc71') || ...
 strcmp(compilerName, 'msvc60'), ...
 compilerName = 'microsoft';
 end
 LibPath = fullfile('$MATLAB_ROOT', 'extern', 'lib', arch, compilerName);
end
```

- 4 Create an entry for the first mapping with a call to the `RTW.Tf1BlasEntryGenerator` function.

```
% Create table entry for dgemm32
op_entry = RTW.Tf1BlasEntryGenerator;
```

- 5 Set operator entry parameters with a call to the `setTf1CFunctionEntryParameters` function. The function call sets matrix multiplication operator entry properties. The code generator ignores saturation and rounding modes for floating-point nonscalar addition and subtraction. For code replacement entries for nonscalar addition and subtraction operations that do not involve fixed-point data, in the call to `setTf1CFunctionEntryParameters`, specify `'RTW_SATURATE_UNSPECIFIED'` for the `SaturationMode` property and `{'RTW_ROUND_UNSPECIFIED'}` for `RoundingModes`.

```
if ispc
 libExt = 'lib';
elseif ismac
 libExt = 'dylib';
else
 libExt = 'so';
end
setTf1COperationEntryParameters(op_entry, ...
 'Key', 'RTW_OP_MUL', ...
 'Priority', 100, ...
 'ImplementationName', 'dgemm32', ...
 'ImplementationHeaderFile', 'blascompat32_cr1.h', ...
 'ImplementationHeaderPath', fullfile('${MATLAB_ROOT}','extern','include'), ...
 'AdditionalLinkObjs', {'libmwblascompat32.' libExt}, ...
 'AdditionalLinkObjsPaths', {LibPath}, ...
 'SideEffects', true);
```

- 6 Create conceptual arguments `y1`, `u1`, and `u2`. There are multiple ways to set up the conceptual arguments. This example uses calls to the `createAndAddConceptualArg` function to create and add an argument with one function call. To specify a matrix argument in the function call, use the argument class `RTW.Tf1ArgMatrix` and specify the base type and the dimensions for which the argument is valid. This type of table entry supports a range of dimensions specified in the format `[Dim1Min Dim2Min ... DimNMin; Dim1Max Dim2Max ... DimNMax]`. For example, `[2 2; inf inf]` means a two-dimensional matrix of size 2x2 or larger. The conceptual output argument for the `dgemm32` entry for matrix/matrix multiplication replacement specifies dimensions `[2 2; inf inf]`, while the conceptual output argument for the `dgemv32` entry for matrix/vector multiplication replacement specifies dimensions `[2 1; inf 1]`.

```
% Specify operands and result
createAndAddConceptualArg(op_entry, 'RTW.Tf1ArgMatrix', ...
 'Name', 'y1', ...
```

```

 'IOType', 'RTW_IO_OUTPUT', ...
 'BaseType', 'double', ...
 'DimRange', [2 2; inf inf]);
createAndAddConceptualArg(op_entry, 'RTW.Tf1ArgMatrix', ...
 'Name', 'u1', ...
 'BaseType', 'double', ...
 'DimRange', [2 2; inf inf]);
createAndAddConceptualArg(op_entry, 'RTW.Tf1ArgMatrix', ...
 'Name', 'u2', ...
 'BaseType', 'double', ...
 'DimRange', [1 1; inf inf]);

```

- 7 Create the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses calls to the `getTf1ArgFromString` and `RTW.Tf1ArgCharConstant` functions to create the arguments. The example code configures special implementation arguments that are required for `dgemm` and `dgemv` function replacements. The convenience methods `setReturn` and `addArgument` specify whether an argument is a return value or argument and adds the argument to the entry's array of implementation arguments.

```

% Using RTW.Tf1BlasEntryGenerator for xgemm requires the following
% implementation signature:
%
% void f(char* TRANSA, char* TRANSB, int* M, int* N, int* K,
% type* ALPHA, type* u1, int* LDA, type* u2, int* LDB,
% type* BETA, type* y, int* LDC)
%
% When a match occurs, the code generator computes the
% values for M, N, K, LDA, LDB, and LDC and inserts them into the
% generated code. TRANSA and TRANSB are set to 'N'.

% Specify replacement function signature

arg = getTf1ArgFromString(hTable, 'y2', 'void');
arg.IOType = 'RTW_IO_OUTPUT';
op_entry.Implementation.setReturn(arg);

arg = RTW.Tf1ArgCharConstant('TRANSA');
% Possible values for PassByType property are
% RTW_PASSBY_AUTO, RTW_PASSBY_POINTER,
% RTW_PASSBY_VOID_POINTER, RTW_PASSBY_BASE_POINTER
arg.PassByType = 'RTW_PASSBY_POINTER';
op_entry.Implementation.addArgument(arg);

arg = RTW.Tf1ArgCharConstant('TRANSB');
arg.PassByType = 'RTW_PASSBY_POINTER';

## Matrix Multiplication Operation to ANSI/ISO C BLAS Code Replacement

This example shows how to define code replacement mappings that replace nonscalar multiplication operations with ANSI/ISO C BLAS multiplication functions `xgemm` and `xgemv`. The example defines code replacement entries that map floating-point matrix/matrix and matrix/vector multiplication operations to ANSI/ISO C BLAS library multiplication functions `dgemm` and `dgemv`. The example defines the function mappings programmatically. Alternatively, you can use the Code Replacement Tool to define the same mappings.

BLAS libraries support matrix/matrix multiplication in the form of  $C = a(\text{op}(A) * \text{op}(B)) + bC$ . `op(X)` means `X`, transposition of `X`, or Hermitian transposition of `X`. However, code replacement libraries support only the limited case of  $C = \text{op}(A) * \text{op}(B)$  ( $a = 1.0, b = 0.0$ ). Correspondingly, although BLAS libraries support matrix/vector multiplication in the form of  $y = a(\text{op}(A) * x) + by$ , code replacement libraries support only the limited case of  $y = \text{op}(A) * x$  ( $a = 1.0, b = 0.0$ ).

- 1 Create a table definition file that contains a function definition. For example:

```
function hTable = crl_table_cblas_mmult_double
```

- 2 Within the function body, create the table by calling the function `RTW.Tf1Table`.

```
hTable = RTW.Tf1Table;
```

- 3 Define the path for the CBLAS function library. For example:

```
LibPath = fullfile(matlabroot, 'toolbox', 'rtw', 'rtwdemos', 'crl_demo');
```

- 4 Create an entry for the first mapping with a call to the `RTW.Tf1BlasEntryGenerator` function.

```
% Create table entry for cblas_dgemm
op_entry = RTW.Tf1CBlasEntryGenerator;
```

- 5 Set operator entry parameters with a call to the `setTf1COperationEntryParameters` function. The function call sets matrix multiplication operator entry properties. The code generator ignores saturation and rounding modes for floating-point nonscalar addition and subtraction.

```
setTf1COperationEntryParameters(op_entry, ...
 'Key', 'RTW_OP_MUL', ...
```

```

'Priority', 100, ...
'ImplementationName', 'cblas_dgemm', ...
'ImplementationHeaderFile', 'cblas.h', ...
'ImplementationHeaderPath', LibPath, ...
'AdditionalIncludePaths', {LibPath}, ...
'GenCallback', 'RTW.copyFileToBuildDir', ...
'SideEffects', true);

```

- 6 Create conceptual arguments `y1`, `u1`, and `u2`. There are multiple ways to set up the conceptual arguments. This example uses calls to the `createAndAddConceptualArg` function to create and add an argument with one function call. To specify a matrix argument in the function call, use the argument class `RTW.Tf1ArgMatrix` and specify the base type and the dimensions for which the argument is valid. This type of table entry supports a range of dimensions specified in the format `[Dim1Min Dim2Min ... DimNMin; Dim1Max Dim2Max ... DimNMax]`. For example, `[2 2; inf inf]` means a two-dimensional matrix of size 2x2 or larger. The conceptual output argument for the `dgemm32` entry for matrix/matrix multiplication replacement specifies dimensions `[2 2; inf inf]`. The conceptual output argument for the `dgemv32` entry for matrix/vector multiplication replacement specifies dimensions `[2 1; inf 1]`.

```

% Specify operands and result
createAndAddConceptualArg(op_entry, 'RTW.Tf1ArgMatrix', ...
 'Name', 'y1', ...
 'IOType', 'RTW_IO_OUTPUT', ...
 'BaseType', 'double', ...
 'DimRange', [2 2; inf inf]);
createAndAddConceptualArg(op_entry, 'RTW.Tf1ArgMatrix', ...
 'Name', 'u1', ...
 'BaseType', 'double', ...
 'DimRange', [2 2; inf inf]);
createAndAddConceptualArg(op_entry, 'RTW.Tf1ArgMatrix', ...
 'Name', 'u2', ...
 'BaseType', 'double', ...
 'DimRange', [1 1; inf inf]);

```

- 7 Create the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses calls to the `getTf1ArgFromString` function to create the arguments. The example code configures special implementation arguments that are required for `dgemm` and `dgemv` function replacements. The convenience methods `setReturn` and `addArgument` specify whether an argument is a return value or argument and adds the argument to the entry's array of implementation arguments.

```

% Using RTW.Tf1CBlasEntryGenerator for xgemm requires the following
% implementation signature:
%
% void f(enum ORDER, enum TRANSA, enum TRANSB, int M, int N, int K,
% type ALPHA, type* u1, int LDA, type* u2, int LDB,

```

```
% type BETA, type* y, int LDC)
%
% Since CRLs do not have the ability to specify enums, you must
% use integer. (This will cause problems with C++ code generation,
% so for C++, use a wrapper function to cast each int to the
% corresponding enumeration type.)
%
% When a match occurs, the code generator computes the
% values for M, N, K, LDA, LDB, and LDC and insert them into the
% generated code.

% Specify replacement function signature

arg = getTf1ArgFromString(hTable, 'y2', 'void');
arg.IOType = 'RTW_IO_OUTPUT';
op_entry.Implementation.setReturn(arg);

arg = getTf1ArgFromString(hTable, 'ORDER', 'integer', 102);
% arg.Type.ReadOnly=true;
op_entry.Implementation.addArgument(arg);

arg = getTf1ArgFromString(hTable, 'TRANSA', 'integer', 111);
% arg.Type.ReadOnly=true;
op_entry.Implementation.addArgument(arg);

arg = getTf1ArgFromString(hTable, 'TRANSB', 'integer', 111);
% arg.Type.ReadOnly=true;
op_entry.Implementation.addArgument(arg);

arg = getTf1ArgFromString(hTable, 'M', 'integer', 0);
op_entry.Implementation.addArgument(arg);

arg = getTf1ArgFromString(hTable, 'N', 'integer', 0);
op_entry.Implementation.addArgument(arg);

arg = getTf1ArgFromString(hTable, 'K', 'integer', 0);
op_entry.Implementation.addArgument(arg);

arg = getTf1ArgFromString(hTable, 'ALPHA', 'double', 1);
op_entry.Implementation.addArgument(arg);

arg = getTf1ArgFromString(hTable, 'u1', ['double' '*']);
op_entry.Implementation.addArgument(arg);

arg = getTf1ArgFromString(hTable, 'LDA', 'integer', 0);
op_entry.Implementation.addArgument(arg);

arg = getTf1ArgFromString(hTable, 'u2', ['double' '*']);
op_entry.Implementation.addArgument(arg);

arg = getTf1ArgFromString(hTable, 'LDB', 'integer', 0);
op_entry.Implementation.addArgument(arg);

arg = getTf1ArgFromString(hTable, 'BETA', 'double', 0);
op_entry.Implementation.addArgument(arg);
```

```
arg = getTf1ArgFromString(hTable, 'y1', ['double' '*']);
arg.IOType = 'RTW_IO_OUTPUT';
op_entry.Implementation.addArgument(arg);
```

```
arg = getTf1ArgFromString(hTable, 'LDC', 'integer', 0);
op_entry.Implementation.addArgument(arg);
```

- 8 Add the entry to a code replacement table with a call to the `addEntry` function.

```
addEntry(hTable, op_entry);
```

- 9 Create the entry for the second mapping.

```
% Create table entry for cblas_dgemv
op_entry = RTW.Tf1CBlasEntryGenerator;
setTf1COperationEntryParameters(op_entry, ...
 'Key', 'RTW_OP_MUL', ...
 'Priority', 100, ...
 'ImplementationName', 'cblas_dgemv', ...
 'ImplementationHeaderFile', 'cblas.h', ...
 'ImplementationHeaderPath', LibPath, ...
 'AdditionalIncludePaths', {LibPath}, ...
 'GenCallback', 'RTW.copyFileToBuildDir', ...
 'SideEffects', true);

% Specify operands and result

```

```

% Specify replacement function signature

arg = getTf1ArgFromString(hTable, 'y2', 'void');
arg.IOType = 'RTW_IO_OUTPUT';
op_entry.Implementation.setReturn(arg);

arg = getTf1ArgFromString(hTable, 'ORDER', 'integer', 102);
% arg.Type.ReadOnly=true;
op_entry.Implementation.addArgument(arg);

arg = getTf1ArgFromString(hTable, 'TRANSA', 'integer', 111);
% arg.Type.ReadOnly=true;
op_entry.Implementation.addArgument(arg);

arg = getTf1ArgFromString(hTable, 'M', 'integer', 0);
op_entry.Implementation.addArgument(arg);

arg = getTf1ArgFromString(hTable, 'N', 'integer', 0);
op_entry.Implementation.addArgument(arg);

arg = getTf1ArgFromString(hTable, 'ALPHA', 'double', 1);
op_entry.Implementation.addArgument(arg);

arg = getTf1ArgFromString(hTable, 'u1', ['double' '*']);
op_entry.Implementation.addArgument(arg);

arg = getTf1ArgFromString(hTable, 'LDA', 'integer', 0);
op_entry.Implementation.addArgument(arg);

arg = getTf1ArgFromString(hTable, 'u2', ['double' '*']);
op_entry.Implementation.addArgument(arg);

arg = getTf1ArgFromString(hTable, 'INCX', 'integer', 0);
op_entry.Implementation.addArgument(arg);

arg = getTf1ArgFromString(hTable, 'BETA', 'double', 0);
op_entry.Implementation.addArgument(arg);

arg = getTf1ArgFromString(hTable, 'y1', ['double' '*']);
arg.IOType = 'RTW_IO_OUTPUT';
op_entry.Implementation.addArgument(arg);

arg = getTf1ArgFromString(hTable, 'INCY', 'integer', 0);
op_entry.Implementation.addArgument(arg);

addEntry(hTable, op_entry);

```

- 10** Save the table definition file. Use the name of the table definition function to name the file.

To test this example, create a model that uses two Product blocks. For example:

- 1** Create a model that includes two Product blocks, such as the following:

- 2 Configure the model with the following settings:
  - On the **Solver** pane, select a fixed-step, discrete solver with a fixed-step size such as 0.1.
  - On the **Code Generation** pane, select an ERT-based system target file.
  - On the **Code Generation > Interface** pane, select the code replacement library that contains your addition operation entry.
- 3 For each Product block, set the block parameter **Multiplication** to the value `Matrix(*)`.
- 4 In the Model Explorer, configure the **Signal Attributes** for the In1, In2, and In3 source blocks. For In1 and In2, set **Port dimensions** to [3 3] and set the **Data type** to double. For In3, set **Port dimensions** to [3 1] and set the **Data type** to double.
- 5 Generate code and a code generation report.
- 6 Review the code replacements.

## Remap Operator Output to Function Input

If your generated code must meet a specific coding pattern or you want more flexibility, for example, to further improve performance, you can remap operator outputs to input positions in an implementation function argument list.

---

**Note:** Remapping outputs to implementation function inputs is supported only for operator replacement.

---

For example, for a sum operation, the code generator produces code similar to:

```
add8_Y.Out1 = u8_add_u8_u8(add8_U.In1, add8_U.In2);
```

If you remap the output to the first input, the code generator produces code similar to:

```
u8_add_u8_u8(&add8_Y.Out1;, add8_U.In1, add8_U.In2);
```

The following table definition file for a sum operation remaps operator output `y1` as the first function input argument.

- 1 Create a table definition file that contains a function definition. For example:
 

```
function hTable = crl_table_add_uint8
```
- 2 Within the function body, create the table by calling the function `RTW.Tf1Table`.
 

```
hTable = RTW.Tf1Table;
```
- 3 Create an entry for the operator mapping with a call to the `RTW.Tf1COperationEntry` function.
 

```
% Create operation entry
op_entry = RTW.Tf1COperationEntry;
```
- 4 Set operator entry parameters with a call to the `setTf1COperationEntryParameters` function. In the function call, set the property `SideEffects` to `true`.
 

```
setTf1COperationEntryParameters(op_entry, ...
 'Key', 'RTW_OP_ADD', ...
 'Priority', 90, ...
 'ImplementationName', 'u8_add_u8_u8', ...
 'ImplementationHeaderFile', 'u8_add_u8_u8.h', ...
 'ImplementationSourceFile', 'u8_add_u8_u8.c', ...
 'SideEffects', true);
```

- 5 Create conceptual arguments `y1`, `u1`, and `u2`. There are multiple ways to set up the conceptual arguments. This example uses calls to the `getTf1ArgFromString` and `addConceptualArg` functions to create and add the arguments.

```
arg = getTf1ArgFromString(hTable, 'y1', 'uint8');
arg.IOType = 'RTW_IO_OUTPUT';
addConceptualArg(op_entry, arg);
```

```
arg = getTf1ArgFromString(hTable, 'u1', 'uint8');
addConceptualArg(op_entry, arg);
```

```
arg = getTf1ArgFromString(hTable, 'u2', 'uint8');
addConceptualArg(op_entry, arg);
```

- 6 Create the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses calls to the `getTf1ArgFromString` function to create the arguments. When defining the implementation function return argument, create a new `void` output argument, for example, `y2`. When defining the implementation function argument for the conceptual output argument (`y1`), set the operator output argument as an additional input argument. Mark its `IOType` as output. Make its type a pointer type. The convenience methods `setReturn` and `addArgument` specify whether an argument is a return value or argument and adds the argument to the entry's array of implementation arguments.

```
% Create new void output y2
arg = getTf1ArgFromString(hTable, 'y2', 'void');
arg.IOType = 'RTW_IO_OUTPUT';
op_entry.Implementation.setReturn(arg);
```

```
% Set y1 as first input arg, mark IOType as output, and use pointer type
arg=getTf1ArgFromString(hTable, 'y1', 'uint8*');
arg.IOType = 'RTW_IO_OUTPUT';
op_entry.Implementation.addArgument(arg);
```

```
arg=getTf1ArgFromString(hTable, 'u1', 'uint8');
op_entry.Implementation.addArgument(arg);
```

```
arg=getTf1ArgFromString(hTable, 'u2', 'uint8');
op_entry.Implementation.addArgument(arg);
```

- 7 Add the entry to a code replacement table with a call to the `addEntry` function.

```
addEntry(hTable, op_entry);
```

- 8 Save the table definition file. Use the name of the table definition function to name the file.

To test this example, create a model that uses an Add block. For example:

- 1 Create a model that includes an Add block, such as the following:

- 2 Configure the model with the following settings:
  - On the **Solver** pane, select a fixed-step solver.
  - On the **Code Generation** pane, select an ERT-based system target file.
  - On the **Code Generation > Interface** pane, select the code replacement library that contains your addition operation entry.
  - On the **All Parameters** tab, set the **Optimize global data access** parameter to `Use global to hold temporary results`. This reduces data copies in the generated code.
- 3 Generate code and a code generation report.
- 4 Review the code replacements.

## Fixed-Point Operator Code Replacement

If you have a Fixed-Point Designer license, you can define fixed-point operator code replacement entries to match:

- A binary-point-only scaling combination on the operator inputs and output.
- A slope bias scaling combination on the operator inputs and output.
- Relative scaling or net slope between multiplication or division operator inputs and output. Use one of these methods to map a range of slope and bias values to a replacement function for multiplication or division.
- Equal slope and zero net bias across addition or subtraction operator inputs and output. Use this method to disregard specific slope and bias values and map relative slope and bias values to a replacement function for addition or subtraction.

### Common Ways to Match Fixed-Point Operator Entries

The following table maps common ways to match fixed-point operator code replacement entries with the associated fixed-point parameters that you specify in a code replacement table definition file.

Match	Create entry	Minimally specify parameters
A specific binary-point-only scaling combination on the operator inputs and output.	RTW.Tf1COperationEntry	createAndAddConceptualArg function: <ul style="list-style-type: none"> <li>• CheckSlope: Specify the value true.</li> <li>• CheckBias: Specify the value true.</li> <li>• DataTypeMode (or DataType/Scaling equivalent): Specify fixed-point binary-point-only scaling.</li> <li>• FractionLength: Specify a fraction length (for example, 3).</li> </ul>
A specific slope bias scaling combination on the operator inputs and output.	RTW.Tf1COperationEntry	createAndAddConceptualArg function:

Match	Create entry	Minimally specify parameters
		<ul style="list-style-type: none"> <li>• <b>CheckSlope:</b> Specify the value true.</li> <li>• <b>CheckBias:</b> Specify the value true.</li> <li>• <b>DataTypeMode</b> (or <b>DataType/Scaling</b> equivalent): Specify fixed-point [slope bias] scaling.</li> <li>• <b>Slope</b> (or <b>SlopeAdjustmentFactor/FixedExponent</b> equivalent): Specify a slope value (for example, 15).</li> <li>• <b>Bias:</b> Specify a bias value (for example, 2).</li> </ul>
Net slope between operator inputs and output (multiplication and division).	RTW.Tf1COperationEntry-Generator_NetSlope	<b>setTf1COperationEntryParameters</b> function: <ul style="list-style-type: none"> <li>• <b>NetSlopeAdjustmentFactor:</b> Specify the slope adjustment factor (F) part of the net slope, <math>F2^E</math> (for example, 1.0).</li> <li>• <b>NetFixedExponent:</b> Specify the fixed exponent (E) part of the net slope, <math>F2^E</math> (for example, -3.0).</li> </ul> <b>createAndAddConceptualArg</b> function: <ul style="list-style-type: none"> <li>• <b>CheckSlope:</b> Specify the value false.</li> <li>• <b>CheckBias:</b> Specify the value false.</li> <li>• <b>DataType:</b> Specify the value 'Fixed'.</li> </ul>

## Fixed-Point Numbers and Arithmetic

Fixed-point numbers use integers and integer arithmetic to represent real numbers and arithmetic with the following encoding scheme:

$$V = \tilde{V} = SQ + B$$

- $V$  is an arbitrarily precise real-world value.
- $\tilde{V}$  is the approximate real-world value that results from fixed-point representation.
- $Q$  is an integer that encodes  $\tilde{V}$ , referred to as the *quantized integer*.
- $S$  is a coefficient of  $Q$ , referred to as the *slope*.
- $B$  is an additive correction, referred to as the *bias*.

The general equation for an operation between fixed-point operands is:

$$(S_0 Q_0 + B_0) = (S_1 Q_1 + B_1) < op > (S_2 Q_2 + B_2)$$

The objective of fixed-point operator replacement is to replace an operator that accepts and returns fixed-point or integer inputs and output with a function that accepts and returns built-in C numeric data types. The following sections provide additional programming information for each supported operator.

### Addition

The operation  $V_0 = V_1 + V_2$  implies that

$$Q_0 = \left( \frac{S_1}{S_0} \right) Q_1 + \left( \frac{S_2}{S_0} \right) Q_2 + \left( \frac{B_1 + B_2 - B_0}{S_0} \right)$$

If an addition replacement function is defined such that the scaling on the operands and sum are equal and the net bias

$$\left( \frac{B_1 + B_2 - B_0}{S_0} \right)$$

is zero (for example, a function `s8_add_s8_s8` that adds two signed 8-bit values and produces a signed 8-bit result), then the operator entry must set the operator entry parameters `SlopesMustBeTheSame` and `MustHaveZeroNetBias` to `true`. (For parameter descriptions, see the reference page for the function `setTf1COperationEntryParameters`.)

## Subtraction

The operation  $V_0 = V_1 - V_2$  implies that

$$Q_0 = \left( \frac{S_1}{S_0} \right) Q_1 - \left( \frac{S_2}{S_0} \right) Q_2 + \left( \frac{B_1 - B_2 - B_0}{S_0} \right)$$

If a subtraction replacement function is defined such that the scaling on the operands and difference are equal and the net bias

$$\left( \frac{B_1 - B_2 - B_0}{S_0} \right)$$

is zero (for example, a function `s8_sub_s8_s8` that subtracts two signed 8-bit values and produces a signed 8-bit result), then the operator entry must set the operator entry parameters `SlopesMustBeTheSame` and `MustHaveZeroNetBias` to `true`. (For parameter descriptions, see the reference page for the function `setTf1COperationEntryParameters`.)

## Multiplication

There are different ways to specify multiplication replacements. The most direct way is to specify an exact match of the input and output types. This is feasible if a model contains only a few (known) slope and bias combinations. Use the `Tf1COperationEntry` class

and specify the exact values of slope and bias on each argument. For scenarios where there are numerous slope/bias combinations, it is not feasible to specify each value with a different entry. Use a net slope entry or create a custom entry.

The operation  $V_0 = V_1 * V_2$  implies, for binary-point-only scaling, that

$$S_0 Q_0 = (S_1 Q_1)(S_2 Q_2)$$

$$Q_0 = \left( \frac{S_1 S_2}{S_0} \right) Q_1 Q_2$$

$$Q_0 = S_n Q_1 Q_2$$

where  $S_n$  is the net slope.

It is common to replace all multiplication operations that have a net slope of 1.0 with a function that performs C-style multiplication. For example, to replace all signed 8-bit multiplications that have a net scaling of 1.0 with the `s8_mul_s8_u8` replacement function, the operator entry must define a net slope factor,  $F2^E$ . You specify the values for  $F$  and  $E$  using operator entry parameters `NetSlopeAdjustmentFactor` and `NetFixedExponent`. (For parameter descriptions, see the reference page for the function `setTf1CoperationEntryParameters`.) For the `s8_mul_s8_u8` function, set `NetSlopeAdjustmentFactor` to 1 and `NetFixedExponent` to 0.0.

---

**Note:** When an operator entry specifies `NetSlopeAdjustmentFactor` and `NetFixedExponent`, matching entries must have arguments with zero bias.

---

## Division

There are different ways to specify division replacements. The most direct way is to specify an exact match of the input and output types. This is feasible if a model contains only a few (known) slope and bias combinations. For this, use the `Tf1CoperationEntry` class and specify the exact values of slope and bias on each argument. For scenarios where there are numerous slope/bias combinations, it is not feasible to specify each value with a different entry. For this, use a net slope entry or create a custom entry (see “Customize Match and Replacement Process” on page 51-153).

The operation  $V_0 = (V_1 / V_2)$  implies, for binary-point-only scaling, that

$$S_0 Q_0 = \left( \frac{S_1 Q_1}{S_2 Q_2} \right)$$
$$Q_0 = S_n \left( \frac{Q_1}{Q_2} \right)$$

where  $S_n$  is the net slope.

It is common to replace all division operations that have a net slope of 1.0 with a function that performs C-style division. For example, to replace all signed 8-bit divisions that have a net scaling of 1.0 with the `s8_mul_s8_u8_` replacement function, the operator entry must define a net slope factor,  $F2^E$ . You specify the values for  $F$  and  $E$  using operator entry parameters `NetSlopeAdjustmentFactor` and `NetFixedExponent`. (For parameter descriptions, see the reference page for the function `setTf1COperationEntryParameters`.) For the `s16_netslope0p5_div_s16_s16` function, you would set `NetSlopeAdjustmentFactor` to 1 and `NetFixedExponent` to 0.0.

---

**Note:** When an operator entry specifies `NetSlopeAdjustmentFactor` and `NetFixedExponent`, matching entries must have arguments with zero bias.

---

## Data Type Conversion (Cast)

The data type conversion operation  $V_0 = V_1$  implies, for binary-point-only scaling, that

$$Q_0 = \left( \frac{S_1}{S_0} \right) Q_1$$
$$Q_0 = S_n Q_1$$

where  $S_n$  is the net slope.

## Shift

The shift left or shift right operation  $V_0 = (V_1 / 2^n)$  implies, for binary-point-only scaling, that

$$S_0 Q_0 = \left( \frac{S_1 Q_1}{2^n} \right)$$

$$Q_0 = \left( \frac{S_1}{S_0} \right) + \left( \frac{Q_1}{2^n} \right)$$

$$Q_0 = S_n \left( \frac{Q_1}{2^n} \right)$$

where  $S_n$  is the net slope.

## Binary-Point-Only Scaling Code Replacement

You can define code replacement entries for operations on fixed-point data types such that they match a binary-point-only scaling combination on operator inputs and output. These binary-point-only scaling entries can map the specified binary-point-scaling combination to a replacement function for addition, subtraction, multiplication, or division.

This example creates a code replacement entry for multiplication of fixed-point data types. You specify arguments using binary-point-only scaling. The example defines the function mapping programmatically. Alternatively, you can use the Code Replacement Tool to define the same mapping.

- 1 Create a table definition file that contains a function definition. For example:

```
function hTable = crl_table_fixed_binptscale
```

- 2 Within the function body, create the table by calling the function `RTW.Tf1Table`.

```
hTable = RTW.Tf1Table;
```

- 3 Create the entry for the operator mapping with a call to the `RTW.Tf1COperationEntry` function.

```
op_entry = RTW.Tf1COperationEntry;
```

- 4 Set operator entry parameters with a call to the `setTf1COperationEntryParameters` function. The parameters specify the type of operation as multiplication, the saturation mode as saturate on integer overflow, rounding modes as unspecified, and the name of the replacement function as `s32_mul_s16_s16_binarypoint`.

```
setTf1COperationEntryParameters(op_entry, ...
 'Key', 'RTW_OP_MUL', ...
 'Priority', 90, ...
 'SaturationMode', 'RTW_SATURATE_ON_OVERFLOW', ...
 'RoundingModes', {'RTW_ROUND_UNSPECIFIED'}, ...
 'ImplementationName', 's32_mul_s16_s16_binarypoint', ...
 'ImplementationHeaderFile', 's32_mul_s16_s16_binarypoint.h', ...
 'ImplementationSourceFile', 's32_mul_s16_s16_binarypoint.c');
```

- 5 Create conceptual arguments `y1`, `u1`, and `u2`. There are multiple ways to set up the conceptual arguments. This example uses calls to the `createAndAddConceptualArg` function to create and add an argument with one function call. Each argument specifies that the data type is fixed-point, the mode is binary-point-only scaling, and its derived slope and bias values must exactly match the call-site slope and bias values. The output argument is 32 bits, signed, with a

fraction length of 28. The input arguments are 16 bits, signed, with fraction lengths of 15 and 13.

```
createAndAddConceptualArg(op_entry, 'RTW.Tf1ArgNumeric',...
 'Name', 'y1', ...
 'IOType', 'RTW_IO_OUTPUT', ...
 'CheckSlope', true, ...
 'CheckBias', true, ...
 'DataTypeMode', 'Fixed-point: binary point scaling', ...
 'IsSigned', true, ...
 'WordLength', 32, ...
 'FractionLength', 28);

createAndAddConceptualArg(op_entry, 'RTW.Tf1ArgNumeric', ...
 'Name', 'u1', ...
 'IOType', 'RTW_IO_INPUT', ...
 'CheckSlope', true, ...
 'CheckBias', true, ...
 'DataTypeMode', 'Fixed-point: binary point scaling', ...
 'IsSigned', true, ...
 'WordLength', 16, ...
 'FractionLength', 15);

createAndAddConceptualArg(op_entry, 'RTW.Tf1ArgNumeric', ...
 'Name', 'u2', ...
 'IOType', 'RTW_IO_INPUT', ...
 'CheckSlope', true, ...
 'CheckBias', true, ...
 'DataTypeMode', 'Fixed-point: binary point scaling', ...
 'IsSigned', true, ...
 'WordLength', 16, ...
 'FractionLength', 13);
```

- 6 Create the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses calls to the `createAndSetCImplementationReturn` and `createAndAddImplementationArg` functions to create and add implementation arguments to the entry. Implementation arguments must describe fundamental numeric data types (not fixed-point data types). In this case, the output argument is 32 bits and signed (`int32`). The input arguments are 16 bits and signed (`int16`).

```
createAndSetCImplementationReturn(op_entry, 'RTW.Tf1ArgNumeric', ...
 'Name', 'y1', ...
 'IOType', 'RTW_IO_OUTPUT', ...
 'IsSigned', true, ...
 'WordLength', 32, ...
 'FractionLength', 0);

createAndAddImplementationArg(op_entry, 'RTW.Tf1ArgNumeric',...
 'Name', 'u1', ...
 'IOType', 'RTW_IO_INPUT', ...
 'IsSigned', true, ...
 'WordLength', 16, ...
```

```
 'FractionLength', 0);
createAndAddImplementationArg(op_entry, 'RTW.Tf1ArgNumeric', ...
 'Name', 'u2', ...
 'IOType', 'RTW_IO_INPUT', ...
 'IsSigned', true, ...
 'WordLength', 16, ...
 'FractionLength', 0);
```

- 7 Add the entry to a code replacement table with a call to the `addEntry` function.

```
addEntry(hTable, op_entry);
```

- 8 Save the table definition file. Use the name of the table definition function to name the file.

## Slope Bias Scaling Code Replacement

You can define code replacement for operations on fixed-point data types as matching a slope bias scaling combination on the operator inputs and output. The slope bias scaling entries can map the specified slope bias combination to a replacement function for addition, subtraction, multiplication, or division.

This example creates a code replacement entry for division of fixed-point data types. You specify arguments using slope bias scaling. The example defines the function mapping programmatically. Alternatively, you can use the Code Replacement Tool to define the same mapping.

- 1 Create a table definition file that contains a function definition. For example:

```
function hTable = crl_table_fixed_s16divslopebias
```

- 2 Within the function body, create the table by calling the function `RTW.Tf1Table`.

```
hTable = RTW.Tf1Table;
```

- 3 Create the entry for the operator mapping with a call to the `RTW.Tf1COperationEntry` function.

```
op_entry = RTW.Tf1COperationEntry;
```

- 4 Set operator entry parameters with a call to the `setTf1COperationEntryParameters` function. The parameters specify the type of operation as division, the saturation mode as saturate on integer overflow, rounding modes as round to ceiling, and the name of the replacement function as `s16_div_s16_s16_slopebias`.

```
setTf1COperationEntryParameters(op_entry, ...
 'Key', 'RTW_OP_DIV', ...
 'Priority', 90, ...
 'SaturationMode', 'RTW_SATURATE_ON_OVERFLOW', ...
 'RoundingModes', {'RTW_ROUND_CEILING'}, ...
 'ImplementationName', 's16_div_s16_s16_slopebias', ...
 'ImplementationHeaderFile', 's16_div_s16_s16_slopebias.h', ...
 'ImplementationSourceFile', 's16_div_s16_s16_slopebias.c');
```

- 5 Create conceptual arguments `y1`, `u1`, and `u2`. There are multiple ways to set up the conceptual arguments. This example uses calls to the `createAndAddConceptualArg` function to create and add an argument with one function call. Each argument specifies that the data type is fixed-point, the mode is slope bias scaling, and its specified slope and bias values must exactly match the call-site slope and bias values. The output argument and input arguments are 16 bits, signed, each with specific slope bias specifications.

```

createAndAddConceptualArg(op_entry, 'RTW.Tf1ArgNumeric', ...
 'Name', 'y1', ...
 'IOType', 'RTW_IO_OUTPUT', ...
 'CheckSlope', true, ...
 'CheckBias', true, ...
 'DataTypeMode', 'Fixed-point: slope and bias scaling', ...
 'IsSigned', true, ...
 'WordLength', 16, ...
 'Slope', 15, ...
 'Bias', 2);

createAndAddConceptualArg(op_entry, 'RTW.Tf1ArgNumeric', ...
 'Name', 'u1', ...
 'IOType', 'RTW_IO_INPUT', ...
 'CheckSlope', true, ...
 'CheckBias', true, ...
 'DataTypeMode', 'Fixed-point: slope and bias scaling', ...
 'IsSigned', true, ...
 'WordLength', 16, ...

createAndAddConceptualArg(op_entry, 'RTW.Tf1ArgNumeric', ...
 'Name', 'u2', ...
 'IOType', 'RTW_IO_INPUT', ...
 'CheckSlope', true, ...
 'CheckBias', true, ...
 'DataTypeMode', 'Fixed-point: slope and bias scaling', ...
 'IsSigned', true, ...
 'WordLength', 16, ...
 'Slope', 13, ...
 'Bias', 5);

```

- 6 Create the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses calls to the `createAndSetCImplementationReturn` and `createAndAddImplementationArg` functions to create and add implementation arguments to the entry. Implementation arguments must describe fundamental numeric data types (not fixed-point data types). In this case, the output and input arguments are 16 bits and signed (`int16`).

```

createAndSetCImplementationReturn(op_entry, 'RTW.Tf1ArgNumeric', ...
 'Name', 'y1', ...
 'IOType', 'RTW_IO_OUTPUT', ...
 'IsSigned', true, ...
 'WordLength', 16, ...
 'FractionLength', 0);

createAndAddImplementationArg(op_entry, 'RTW.Tf1ArgNumeric', ...
 'Name', 'u1', ...
 'IOType', 'RTW_IO_INPUT', ...
 'IsSigned', true, ...
 'WordLength', 16, ...

```

```

 'FractionLength', 0);

createAndAddImplementationArg(op_entry, 'RTW.Tf1ArgNumeric',...
 'Name', 'u2', ...
 'IOType', 'RTW_IO_INPUT', ...
 'IsSigned', true, ...
 'WordLength', 16, ...
 'FractionLength', 0);

```

- 7 Add the entry to a code replacement table with a call to the `addEntry` function.

```
addEntry(hTable, op_entry);
```

- 8 Save the table definition file. Use the name of the table definition function to name the file.

## Net Slope Scaling Code Replacement

### Multiplication and Division with Saturation

You can define code replacement entries for operations on fixed-point data types as matching net slope between operator inputs and output. The net slope entries can map a range of slope and bias values to a replacement function for multiplication or division.

This example creates a code replacement entry for division of fixed-point data types, using wrap on overflow saturation mode and a net slope. The example defines the function mapping programmatically. Alternatively, you can use the Code Replacement Tool to define the same mapping.

- 1 Create a table definition file that contains a function definition. For example:

```
function hTable = crl_table_fixed_netslopesaturate
```

- 2 Within the function body, create the table by calling the function `RTW.Tf1Table`.

```
hTable = RTW.Tf1Table;
```

- 3 Create the entry for the operator mapping with a call to the `RTW.Tf1COperationEntryGenerator_Netslope` function, which provides access to the fixed-point parameters `NetSlopeAdjustmentFactor` and `NetFixedExponent`.

```
wv = [16,32];
for iy = 1:2
 for inum = 1:2
 for iden = 1:2
 hTable = getDivOpEntry(hTable, ...
 fixdt(1,wv(iy)),fixdt(1,wv(inum)),fixdt(1,wv(iden)));
 end
 end
end
```

```
%-----
function hTable = getDivOpEntry(hTable,dti,dtnum,dtden)
%-----
% Create an entry for division of fixed-point data types where
% arguments are specified using Slope and Bias scaling
% Saturation on, Rounding unspecified

funcStr = sprintf('user_div_%s_%s_%s',...
 typeStrFunc(dti),...
 typeStrFunc(dtnum),...
 typeStrFunc(dtden));
```

```
op_entry = RTW.Tf1COperationEntryGenerator_NetSlope;
```

- 4 Set operator entry parameters with a call to the `setTf1COperationEntryParameters` function. The parameters specify the type of operation as division, the saturation mode as wrap on overflow, rounding modes as unspecified, and the name of the replacement function as `user_div_*`. `NetSlopeAdjustmentFactor` and `NetFixedExponent` specify the F and E parts of the net slope  $F2^E$ .

```
setTf1COperationEntryParameters(op_entry, ...
 'Key', 'RTW_OP_DIV', ...
 'Priority', 90, ...
 'SaturationMode', 'RTW_WRAP_ON_OVERFLOW', ...
 'RoundingModes', {'RTW_ROUND_UNSPECIFIED'}, ...
 'NetSlopeAdjustmentFactor', 1.0, ...
 'NetFixedExponent', 0.0, ...
 'ImplementationName', funcStr, ...
 'ImplementationHeaderFile', [funcStr, '.h'], ...
 'ImplementationSourceFile', [funcStr, '.c']);
```

- 5 Create conceptual arguments `y1`, `u1`, and `u2`. There are multiple ways to set up the conceptual arguments. This example uses calls to the `createAndAddConceptualArg` function to create and add an argument with one function call. Specify each argument as fixed-point and signed. Also, for each argument, specify that code replacement request processing does *not* check for an exact match to the call-site slope and bias values.

```
createAndAddConceptualArg(op_entry, ...
 'RTW.Tf1ArgNumeric', ...
 'Name', 'y1', ...
 'IOType', 'RTW_IO_OUTPUT', ...
 'CheckSlope', false, ...
 'CheckBias', false, ...
 'DataTypeMode', 'Fixed-point: slope and bias scaling', ...
 'IsSigned', dtv.Signed, ...
 'WordLength', dtv.WordLength, ...
 'Bias', 0);
```

```
createAndAddConceptualArg(op_entry, ...
 'RTW.Tf1ArgNumeric', ...
 'Name', 'u1', ...
 'IOType', 'RTW_IO_INPUT', ...
 'CheckSlope', false, ...
 'CheckBias', false, ...
 'DataTypeMode', 'Fixed-point: slope and bias scaling', ...
 'IsSigned', dtnum.Signed, ...
 'WordLength', dtnum.WordLength, ...
 'Bias', 0);
```

```
createAndAddConceptualArg(op_entry, ...
 'RTW.Tf1ArgNumeric', ...
 'Name', 'u2', ...
```

```

'IOType', 'RTW_IO_INPUT',...
'CheckSlope', false,...
'CheckBias', false,...
'DataTypeMode', 'Fixed-point: slope and bias scaling',...
'IsSigned', dtten.Signed,...
'WordLength', dtten.WordLength,...
'Bias', 0);

```

- 6 Create the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses calls to the `getTf1ArgFromString` function to create the arguments. Implementation arguments must describe fundamental numeric data types (not fixed-point data types). The convenience methods `setReturn` and `addArgument` specify whether an argument is a return value or argument. These methods add the argument to the entry array of implementation arguments.

```

arg = getTf1ArgFromString(hTable, 'y1', typeStrBase(dt));
op_entry.Implementation.setReturn(arg);

```

```

arg = getTf1ArgFromString(hTable, 'u1', typeStrBase(dtnum));
op_entry.Implementation.addArgument(arg);

```

```

arg = getTf1ArgFromString(hTable, 'u2', typeStrBase(dtten));
op_entry.Implementation.addArgument(arg);

```

- 7 Add the entry to a code replacement table with a call to the `addEntry` function.

```

addEntry(hTable, op_entry);

```

- 8 Define functions that determine the data type word length.

```

%-----
function str = typeStrFunc(dt)
%-----

if dt.Signed
 sstr = 's';
else
 sstr = 'u';
end
str = sprintf('%s%d',sstr,dt.WordLength);

%-----
function str = typeStrBase(dt)
%-----

if dt.Signed
 sstr = ;
else
 sstr = 'u';
end
str = sprintf('%sint%d',sstr,dt.WordLength);

```

- 9 Save the table definition file. Use the name of the table definition function to name the file.

## Multiplication and Division with Rounding Mode and Additional Implementation Arguments

You can define code replacement entries for multiplication and division operations on fixed-point data types such that they match the net slope between operator inputs and output. The net slope entries can map a range of slope and bias values to a replacement function for multiplication or division.

This example creates a code replacement entry for division of fixed-point data types, using the ceiling rounding mode and a net slope scaling factor. The example defines the function mapping programmatically. Alternatively, you can use the Code Replacement Tool to define the same mapping.

- 1 Create a table definition file that contains a function definition. For example:

```
function hTable = crl_table_fixed_netsloperound
```

- 2 Within the function body, create the table by calling the function `RTW.Tf1Table`.

```
hTable = RTW.Tf1Table;
```

- 3 Create the entry for the operator mapping with a call to the `RTW.Tf1COperationEntryGenerator_Netslope` function, which provides access to the fixed-point parameters `NetSlopeAdjustmentFactor` and `NetFixedExponent`.

```
op_entry = RTW.Tf1COperationEntryGenerator_NetSlope;
```

- 4 Set operator entry parameters with a call to the `setTf1COperationEntryParameters` function. The parameters specify the type of operation as division, the saturation mode as saturation off, rounding modes as round to ceiling, and the name of the replacement function as `s16_div_s16_s16`. `NetSlopeAdjustmentFactor` and `NetFixedExponent` specify the F and E parts of the relative scaling factor  $F2^E$ .

```
setTf1COperationEntryParameters(op_entry, ...
 'Key', 'RTW_OP_DIV', ...
 'Priority', 90, ...
 'SaturationMode', 'RTW_WRAP_ON_OVERFLOW', ...
 'RoundingModes', {'RTW_ROUND_CEILING'}, ...
 'NetSlopeAdjustmentFactor', 1.0, ...
 'NetFixedExponent', 0.0, ...
```

```

 'ImplementationName', 's16_div_s16_s16', ...
 'ImplementationHeaderFile', 's16_div_s16_s16.h', ...
 'ImplementationSourceFile', 's16_div_s16_s16.c');

```

- 5 Create conceptual arguments `y1`, `u1`, and `u2`. There are multiple ways to set up the conceptual arguments. This example uses calls to the `createAndAddConceptualArg` function to create and add an argument with one function call. Specify each argument as fixed-point, 16 bits, and signed. Also, for each argument, specify that code replacement request processing does *not* check for an exact match to the call-site slope and bias values.

```

createAndAddConceptualArg(op_entry, 'RTW.Tf1ArgNumeric', ...
 'Name', 'y1', ...
 'IOType', 'RTW_IO_OUTPUT', ...
 'CheckSlope', false, ...
 'CheckBias', false, ...
 'DataType', 'Fixed', ...
 'IsSigned', true, ...
 'WordLength', 16);

```

```

createAndAddConceptualArg(op_entry, 'RTW.Tf1ArgNumeric', ...
 'Name', 'u1', ...
 'IOType', 'RTW_IO_INPUT', ...
 'CheckSlope', false, ...
 'CheckBias', false, ...
 'DataType', 'Fixed', ...
 'IsSigned', true, ...
 'WordLength', 16);

```

```

createAndAddConceptualArg(op_entry, 'RTW.Tf1ArgNumeric', ...
 'Name', 'u2', ...
 'IOType', 'RTW_IO_INPUT', ...
 'CheckSlope', false, ...
 'CheckBias', false, ...
 'DataType', 'Fixed', ...
 'IsSigned', true, ...
 'WordLength', 16);

```

- 6 Create the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses calls to the `createAndSetCImplementationReturn` and `createAndAddImplementationArg` functions to create and add implementation arguments to the entry. Implementation arguments must describe fundamental numeric data types (not fixed-point data types). In this case, the output and input arguments are 16 bits and signed (`int16`).

```

createAndSetCImplementationReturn(op_entry, 'RTW.Tf1ArgNumeric', ...
 'Name', 'y1', ...
 'IOType', 'RTW_IO_OUTPUT', ...
 'IsSigned', true, ...
 'WordLength', 16, ...
 'FractionLength', 0);

```

```

createAndAddImplementationArg(op_entry, 'RTW.Tf1ArgNumeric',...
 'Name', 'u1', ...
 'IOType', 'RTW_IO_INPUT', ...
 'IsSigned', true, ...
 'WordLength', 16, ...
 'FractionLength', 0);

createAndAddImplementationArg(op_entry, 'RTW.Tf1ArgNumeric',...
 'Name', 'u2', ...
 'IOType', 'RTW_IO_INPUT', ...
 'IsSigned', true, ...
 'WordLength', 16, ...
 'FractionLength', 0);

```

- 7 Add the entry to a code replacement table with a call to the `addEntry` function.

```
addEntry(hTable, op_entry);
```

- 8 Save the table definition file. Use the name of the table definition function to name the file.

## Equal Slope and Zero Net Bias Code Replacement

You can define code replacement entries for addition or subtraction of fixed-point data types such that they match relative slope and bias values (equal slope and zero net bias) across operator inputs and output. These entries allow you to disregard slope and bias values. Map relative slope and bias values to a replacement function for addition or subtraction.

This example creates a code replacement entry for addition of fixed-point data types. Slopes must be equal and net bias must be zero across the operator inputs and output. The example defines the function mapping programmatically. Alternatively, you can use the Code Replacement Tool to define the same mapping.

- 1 Create a table definition file that contains a function definition. For example:

```
function hTable = crl_table_fixed_slopeseq_netbiaszero
```

- 2 Within the function body, create the table by calling the function `RTW.Tf1Table`.

```
hTable = RTW.Tf1Table;
```

- 3 Create the entry for the operator mapping with a call to the `RTW.Tf1COperationEntryGenerator` function, which provides access to the fixed-point parameters `SlopesMustBeTheSame` and `MustHaveZeroNetBias`.

```
op_entry = RTW.Tf1COperationEntryGenerator;
```

- 4 Set operator entry parameters with a call to the `setTf1COperationEntryParameters` function. The parameters specify the type of operation as addition, the saturation mode as saturation off, rounding modes as unspecified, and the name of the replacement function as `u16_add_SameSlopeZeroBias`. `SlopesMustBeTheSame` and `MustHaveZeroNetBias` are set to `true`, indicating that slopes must be equal and net bias must be zero across the addition inputs and output.

```
setTf1COperationEntryParameters(op_entry, ...
 'Key', 'RTW_OP_ADD', ...
 'Priority', 90, ...
 'SaturationMode', 'RTW_WRAP_ON_OVERFLOW', ...
 'RoundingModes', {'RTW_ROUND_UNSPECIFIED'}, ...
 'SlopesMustBeTheSame', true, ...
 'MustHaveZeroNetBias', true, ...
 'ImplementationName', 'u16_add_SameSlopeZeroBias', ...
 'ImplementationHeaderFile', 'u16_add_SameSlopeZeroBias.h', ...
 'ImplementationSourceFile', 'u16_add_SameSlopeZeroBias.c');
```

- 5 Create conceptual arguments  $y_1$ ,  $u_1$ , and  $u_2$ . There are multiple ways to set up the conceptual arguments. This example uses calls to the `createAndAddConceptualArg` function to create and add an argument with one function call. Each argument is specified as 16 bits and unsigned. Each argument specifies that code replacement request processing does *not* check for an exact match to the call-site slope and bias values.

```
createAndAddConceptualArg(op_entry, 'RTW.Tf1ArgNumeric', ...
 'Name', 'y1', ...
 'IOType', 'RTW_IO_OUTPUT', ...
 'CheckSlope', false, ...
 'CheckBias', false, ...
 'IsSigned', false, ...
 'WordLength', 16);

createAndAddConceptualArg(op_entry, 'RTW.Tf1ArgNumeric', ...
 'Name', 'u1', ...
 'IOType', 'RTW_IO_INPUT', ...
 'CheckSlope', false, ...
 'CheckBias', false, ...
 'IsSigned', false, ...
 'WordLength', 16);

createAndAddConceptualArg(op_entry, 'RTW.Tf1ArgNumeric', ...
 'Name', 'u2', ...
 'IOType', 'RTW_IO_INPUT', ...
 'CheckSlope', false, ...
 'CheckBias', false, ...
 'IsSigned', false, ...
 'WordLength', 16);
```

- 6 Create the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses calls to the `createAndSetCImplementationReturn` and `createAndAddImplementationArg` functions to create and add implementation arguments to the entry. Implementation arguments must describe fundamental numeric data types (not fixed-point data types). In this case, the output and input arguments are 16 bits and unsigned (`uint16`).

```
createAndSetCImplementationReturn(op_entry, 'RTW.Tf1ArgNumeric', ...
 'Name', 'y1', ...
 'IOType', 'RTW_IO_OUTPUT', ...
 'IsSigned', false, ...
 'WordLength', 16, ...
 'FractionLength', 0);

createAndAddImplementationArg(op_entry, 'RTW.Tf1ArgNumeric', ...
 'Name', 'u1', ...
 'IOType', 'RTW_IO_INPUT', ...
 'IsSigned', false, ...
 'WordLength', 16, ...
```

```
 'FractionLength', 0);
createAndAddImplementationArg(op_entry, 'RTW.Tf1ArgNumeric', ...
 'Name', 'u2', ...
 'IOType', 'RTW_IO_INPUT', ...
 'IsSigned', false, ...
 'WordLength', 16, ...
 'FractionLength', 0);
```

- 7 Add the entry to a code replacement table with a call to the `addEntry` function.

```
addEntry(hTable, op_entry);
```

- 8 Save the table definition file. Use the name of the table definition function to name the file.

## Data Type Conversions (Casts) and Operator Code Replacement

You can use code replacement entries to replace code that the code generator produces for data type conversion (cast) operations.

This example creates a code replacement entry that replaces `int32` to `int16` data type conversion (cast) operations. The example defines the function mapping programmatically. Alternatively, you can use the Code Replacement Tool to define the same mapping.

- 1 Create a table definition file that contains a function definition. For example:

```
function hTable = crl_table_cast_int32_to_int16
```

- 2 Within the function body, create the table by calling the function `RTW.Tf1Table`.

```
hTable = RTW.Tf1Table;
```

- 3 Create the entry for the operator mapping with a call to the `RTW.Tf1COperationEntry` function.

```
op_entry = RTW.Tf1COperationEntry;
```

- 4 Set operator entry parameters with a call to the `setTf1COperationEntryParameters` function. The parameters specify the type of operation as `cast`, the saturation mode as `saturate on integer overflow`, rounding modes as `toward negative infinity`, and the name of the replacement function as `my_sat_cast`.

```
setTf1COperationEntryParameters(op_entry, ...
 'Key', 'RTW_OP_CAST', ...
 'Priority', 50, ...
 'ImplementationName', 'my_sat_cast', ...
 'SaturationMode', 'RTW_SATURATE_ON_OVERFLOW', ...
 'RoundingModes', {'RTW_ROUND_FLOOR'}, ...
 'ImplementationHeaderFile', 'some_hdr.h', ...
 'ImplementationSourceFile', 'some_hdr.c');
```

- 5 Create the `int16` argument as conceptual argument `y1` and the implementation return value. There are multiple ways to set up the conceptual and implementation arguments. This example uses calls to the `getTf1ArgFromString` and `addConceptualArg` functions to create the conceptual argument and add it to the entry. Convenience method `setReturn` specifies the argument as the implementation return value.

```
arg = getTf1ArgFromString(hTable, 'y1', 'int16');
arg.IOType = 'RTW_IO_OUTPUT';
addConceptualArg(op_entry, arg);
```

```
op_entry.Implementation.setReturn(arg);
```

- 6 Create the `int32` argument as conceptual and implementation argument `u1`. This example uses calls to the `getTf1ArgFromString` and `addConceptualArg` functions to create the conceptual argument and add it to the entry. Convenience method `addArgument` specifies the argument as implementation input argument.

```
arg = getTf1ArgFromString(hTable, 'u1', 'int32');
addConceptualArg(op_entry, arg);
op_entry.Implementation.addArgument(arg);
```

- 7 Add the entry to a code replacement table with a call to the `addEntry` function.

```
addEntry(hLib, hEnt);
```

- 8 Save the table definition file. Use the name of the table definition function to name the file.

You can use code replacement entries to replace code that the code generator produces for data type conversion (cast) operations.

This example creates a code replacement entry to replace data type conversions (casts) of fixed-point data types by using a net slope. The example defines the function mapping programmatically. Alternatively, you can use the Code Replacement Tool to define the same mapping.

- 1 Create a table definition file that contains a function definition. For example:

```
function hTable = crl_table_cast_fixpt_net_slope
```

- 2 Within the function body, create the table by calling the function `RTW.Tf1Table`.

```
hTable = RTW.Tf1Table;
```

- 3 Create the entry for the operator mapping with a call to the `RTW.Tf1COperationEntryGenerator_Netslope` function, which provides access to the fixed-point parameters `NetSlopeAdjustmentFactor` and `NetFixedExponent`

```
op_entry = RTW.Tf1COperationEntryGenerator_NetSlope;
```

- 4 Set operator entry parameters with a call to the `setTf1COperationEntryParameters` function. The parameters specify the type of operation as cast, the saturation mode as saturate on integer overflow, rounding modes as toward negative infinity, and the name of the replacement function as `my_fxp_cast`. `NetSlopeAdjustmentFactor` and `NetFixedExponent` specify the F and E parts of the net slope  $F2^E$ .

```

InFL = 2;
InWL = 16;
InSgn = true;
OutFL = 4;
OutWL = 32;
OutSgn = true;
setTf1COperationEntryParameters(op_entry, ...
 'Key', 'RTW_OP_CAST', ...
 'Priority', 50, ...
 'SaturationMode', 'RTW_SATURATE_ON_OVERFLOW', ...
 'RoundingModes', {'RTW_ROUND_FLOOR'}, ...
 'NetSlopeAdjustmentFactor', 1.0, ...
 'NetFixedExponent', (OutFL - InFL), ...
 'ImplementationName', 'my_fxp_cast', ...
 'ImplementationHeaderFile', 'some_hdr.h', ...
 'ImplementationSourceFile', 'some_hdr.c');

```

- 5 Create conceptual arguments `y1` and `u1`. There are multiple ways to set up the conceptual arguments. This example uses calls to the `createAndAddConceptualArg` function to create and add an argument with one function call. Each argument is specified as fixed-point and signed. Each argument specifies that code replacement request processing does *not* check for an exact match to the call-site slope and bias values.

```

createAndAddConceptualArg(op_entry, 'RTW.Tf1ArgNumeric', ...
 'Name', 'y1', ...
 'IOType', 'RTW_IO_OUTPUT', ...
 'CheckSlope', false, ...
 'CheckBias', false, ...
 'DataTypeMode', 'Fixed-point: binary point scaling', ...
 'IsSigned', OutSgn, ...
 'WordLength', OutWL, ...
 'FractionLength', OutFL);

```

```

createAndAddConceptualArg(op_entry, 'RTW.Tf1ArgNumeric', ...
 'Name', 'u1', ...
 'IOType', 'RTW_IO_INPUT', ...
 'CheckSlope', false, ...
 'CheckBias', false, ...
 'DataTypeMode', 'Fixed-point: binary point scaling', ...
 'IsSigned', InSgn, ...
 'WordLength', InWL, ...
 'FractionLength', InFL);

```

- 6 Create the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses calls to the `createAndSetCImplementationReturn` and `createAndAddImplementationArg` functions to create and add implementation arguments to the entry. Implementation arguments must describe fundamental numeric data types (not fixed-point data types).

```
createAndSetCImplementationReturn(op_entry, 'RTW.Tf1ArgNumeric', ...
 'Name', 'y1', ...
 'IOType', 'RTW_IO_OUTPUT', ...
 'IsSigned', OutSgn, ...
 'WordLength', OutWL, ...
 'FractionLength', 0);

createAndAddImplementationArg(op_entry, 'RTW.Tf1ArgNumeric', ...
 'Name', 'u1', ...
 'IOType', 'RTW_IO_INPUT', ...
 'IsSigned', InSgn, ...
 'WordLength', InWL, ...
 'FractionLength', 0);
```

- 7 Add the entry to a code replacement table with a call to the `addEntry` function.

```
addEntry(hTable, op_entry);
```

- 8 Save the table definition file. Use the name of the table definition function to name the file.

## Shift Left Operations and Code Replacement

You can use code replacement entries to replace code that the code generator produces for shift (<<) operations.

This example creates a code replacement entry to replace shift left operations for `int16` data. The example defines the function mapping programmatically. Alternatively, you can use the Code Replacement Tool to define the same mapping.

- 1 Create a table definition file that contains a function definition. For example:

```
function hTable = crl_table_shift_left_int16
```

- 2 Within the function body, create the table by calling the function `RTW.Tf1Table`.

```
hTable = RTW.Tf1Table;
```

- 3 Create the entry for the operator mapping with a call to the `RTW.Tf1COperationEntry` function.

```
op_entry = RTW.Tf1COperationEntry;
```

- 4 Set operator entry parameters with a call to the `setTf1COperationEntryParameters` function. The parameters specify the type of operation as shift left and the name of the replacement function as `my_shift_left`.

```
setTf1COperationEntryParameters(op_entry, ...
 'Key', 'RTW_OP_SL', ...
 'Priority', 50, ...
 'ImplementationName', 'my_shift_left', ...
 'ImplementationHeaderFile', 'some_hdr.h', ...
 'ImplementationSourceFile', 'some_hdr.c');
```

- 5 Create the `int16` argument as conceptual argument `y1` and the implementation return value. There are multiple ways to set up the conceptual and implementation arguments. This example uses calls to the `getTf1ArgFromString` and `addConceptualArg` functions to create the conceptual argument and add it to the entry. Convenience method `setReturn` specifies the argument as the implementation return value.

```
arg = getTf1ArgFromString(hTable, 'y1', 'int16');
arg.IOType = 'RTW_IO_OUTPUT';
addConceptualArg(op_entry, arg);
op_entry.Implementation.setReturn(arg);
```

- 6 Create the `int16` argument as conceptual and implementation argument `u1`. This example uses calls to the `getTf1ArgFromString` and `addConceptualArg`

functions to create the conceptual argument and add it to the entry. Convenience method `addArgument` specifies the argument as an implementation input argument.

```
arg = getTf1ArgFromString(hTable, 'u1', 'int16');
addConceptualArg(op_entry, arg);
op_entry.Implementation.addArgument(arg);
```

- 7 Create the `int8` argument as conceptual and implementation argument `u2`. This example uses calls to the `getTf1ArgFromString` and `addConceptualArg` functions to create the conceptual argument and add it to the entry. This argument specifies the number of bits to shift the previous input argument. Because the argument type is not relevant, the example disables type checking by setting the `CheckType` property to `false`. Convenience method `addArgument` specifies the argument as implementation input argument.

```
arg = getTf1ArgFromString(hTable, 'u2', 'int8');
arg.CheckType = false;
addConceptualArg(op_entry, arg);
op_entry.Implementation.addArgument(arg);
```

- The function `getTf1ArgFromString` is called to create an `int8` input argument. This argument is added to the operator entry both as the third conceptual argument and the second implementation input argument.
- Add the entry to a code replacement table with a call to the `addEntry` function.

```
addEntry(hTable, op_entry);
```

- Save the table definition file. Use the name of the table definition function to name the file.

You can use code replacement entries to replace code that the code generator produces for shift (`<<`) operations.

This example creates a code replacement entry to replace shift left operations for fixed-point data using a net slope. The example defines the function mapping programmatically. Alternatively, you can use the Code Replacement Tool to define the same mapping.

- 1 Create a table definition file that contains a function definition. For example:

```
function hTable = cr1_table_shift_left_fixpt_net_slope
```

- 2 Within the function body, create the table by calling the function `RTW.Tf1Table`.

```
hTable = RTW.Tf1Table;
```

- 3 Create the entry for the operator mapping with a call to the `RTW.Tf1COperationEntryGenerator_Netslope` function. This function provides access to the fixed-point parameters `NetSlopeAdjustmentFactor` and `NetFixedExponent`.

```
op_entry = RTW.Tf1COperationEntryGenerator_NetSlope;
```

- 4 Set operator entry parameters with a call to the `setTf1COperationEntryParameters` function. The parameters specify the type of operation as shift left, the saturation mode as saturate on integer overflow, rounding modes as toward negative infinity, and the name of the replacement function as `my_fxp_shift_left`. `NetSlopeAdjustmentFactor` and `NetFixedExponent` specify the F and E parts of the net slope  $F2^E$ .

```
InFL = 2;
InWL = 16;
InSgn = true;
OutFL = 4;
OutWL = 32;
OutSgn = true;
setTf1COperationEntryParameters(op_entry, ...
 'Key', 'RTW_OP_SL', ...
 'Priority', 50, ...
 'SaturationMode', 'RTW_SATURATE_ON_OVERFLOW', ...
 'RoundingModes', {'RTW_ROUND_FLOOR'}, ...
 'NetSlopeAdjustmentFactor', 1.0, ...
 'NetFixedExponent', (OutFL - InFL), ...
 'ImplementationName', 'my_fxp_shift_left', ...
 'ImplementationHeaderFile', 'some_hdr.h', ...
 'ImplementationSourceFile', 'some_hdr.c');
```

- 5 Create conceptual arguments `y1` and `u1`. There are multiple ways to set up the conceptual arguments. This example uses calls to the `createAndAddConceptualArg` function to create and add an argument with one function call. Each argument is specified as fixed-point and signed. Each argument specifies that code replacement request processing does *not* check for an exact match to the call-site slope and bias values.

```
createAndAddConceptualArg(op_entry, 'RTW.Tf1ArgNumeric', ...
 'Name', 'y1', ...
 'IOType', 'RTW_IO_OUTPUT', ...
 'CheckSlope', false, ...
 'CheckBias', false, ...
 'DataTypeMode', 'Fixed-point: binary point scaling', ...
 'IsSigned', OutSgn, ...
 'WordLength', OutWL, ...
 'FractionLength', OutFL);

createAndAddConceptualArg(op_entry, 'RTW.Tf1ArgNumeric', ...
 'Name', 'u1', ...
```

```

'IOType', 'RTW_IO_INPUT', ...
'CheckSlope', false, ...
'CheckBias', false, ...
'DataTypeMode', 'Fixed-point: binary point scaling', ...
'IsSigned', InSgn, ...
'WordLength', InWL, ...
'FractionLength', InFL);

```

- 6 Create the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses calls to the `createAndSetCImplementationReturn` and `createAndAddImplementationArg` functions to create and add implementation arguments to the entry. Implementation arguments must describe fundamental numeric data types (not fixed-point data types).

```

createAndSetCImplementationReturn(op_entry, 'RTW.Tf1ArgNumeric', ...
 'Name', 'y1', ...
 'IOType', 'RTW_IO_OUTPUT', ...
 'IsSigned', OutSgn, ...
 'WordLength', OutWL, ...
 'FractionLength', 0);

createAndAddImplementationArg(op_entry, 'RTW.Tf1ArgNumeric', ...
 'Name', 'u1', ...
 'IOType', 'RTW_IO_INPUT', ...
 'IsSigned', InSgn, ...
 'WordLength', InWL, ...
 'FractionLength', 0);

```

- 7 Create the `int8` argument as conceptual and implementation argument `u2`. This example uses calls to the `getTf1ArgFromString` and `addConceptualArg` functions to create the conceptual argument and add it to the entry. This argument specifies the number of bits to shift the previous input argument. Because the argument type is not relevant, type checking is disabled by setting the `CheckType` property to `false`. Convenience method `addArgument` specifies the argument as implementation input argument.

```

arg = getTf1ArgFromString(hTable, 'u2', 'uint8');
arg.CheckType = false;
addConceptualArg(op_entry, arg);
op_entry.Implementation.addArgument(arg);

```

- 8 Add the entry to a code replacement table with a call to the `addEntry` function.

```
addEntry(hTable, op_entry);
```

- 9 Save the table definition file. Use the name of the table definition function to name the file.

## Optimization Parameters for Code Generation

### In this section...

“Basic Optimization Parameters” on page 53-3

“Optimization Parameter Dependencies” on page 53-4

Many parameters, on the **All Parameters** tab and on the **Optimization and Optimization > Signals and Parameters** panes of the Configuration Parameters dialog box, depending on their setting, modify the generated code.

### Basic Optimization Parameters

Some basic optimization suggestions:

- Selecting the **Signal storage reuse** check box directs the code generator to store signals in reusable memory locations.

Disabling **Signal storage reuse** makes block outputs global and unique, which in many cases significantly increases RAM and ROM usage. For more information, see “Reduce Memory Requirements for Signals” on page 56-2.

- Setting **Default parameter behavior** to **Inlined** reduces global RAM usage, because parameters are not declared in the global parameters structure. You can override the inlining of individual parameters by creating parameter objects. For more information, see “Default parameter behavior” and “Block Parameter Representation in the Generated Code”.
- Selecting the **Enable local block outputs** check box declares block signals locally in functions instead of globally (when possible). You must select **Signal storage reuse** to enable **Enable local block outputs**.
- Selecting the **Reuse local block outputs** check box reduces stack size where signals are buffered in local variables. You must select **Signal storage reuse** to enable **Reuse local block outputs**.
- Selecting the **Inline invariant signals** check box directs the code generator to not generate code for blocks with a constant (invariant) sample time. You must set **Default parameter behavior** to **Inlined** to enable **Inline invariant signals**. For more information, see “Inline Invariant Signals” on page 53-43.
- Selecting the **Eliminate superfluous local variables (expression folding)** check box minimizes the computation of intermediate results at block outputs and the storage of such results in temporary buffers or variables. For more information, see

“Minimize Computations and Storage for Intermediate Results at Block Outputs” on page 53-40.

- Set a **Loop unrolling threshold**. The loop unrolling threshold determines when a wide signal should be wrapped into a `for` loop or when it should be generated as a separate statement for each element of the signal. For more information, see “Configure Loop Unrolling Threshold” on page 53-53.
- Specifying a **Maximum stack size (bytes)** provides control of the number of local and global variables, which determine the amount of stack space required for an application. For more information, see “Customize Stack Space Allocation” on page 53-93.
- If your target environment supports the `memcpy` function, and if your model uses signal vector assignments to move large amounts of data, selecting the **Use memcpy for vector assignment** check box can improve the execution speed of vector assignments by replacing `for` loops with `memcpy` function calls in the generated code. Set a **Memcpy threshold (bytes)**. For more information, see “Use memcpy Function to Optimize Generated Code for Vector Assignments” on page 53-56.

For more information on these parameters, see

- “Optimization Pane: General”
- “Optimization Pane: Signals and Parameters”

## Optimization Parameter Dependencies

Several parameters available on the **Optimization** panes and **All Parameters** tab are dependent on another configuration parameter setting. The following tables summarize the dependencies.

Optimization > General Pane	Dependency Details
Remove root level I/O zero initialization	ERT targets only
Remove internal data zero initialization	ERT targets only

Optimization > Signals and Parameters pane	Dependency Details
Inline invariant signals	Enabled when you set <b>Default parameter behavior</b> to <b>Inlined</b>
Simplify array indexing	ERT targets only

Optimization > Signals and Parameters pane	Dependency Details
Memcpy threshold (bytes)	Enabled by <b>Use memcpy for vector assignment</b>
Pack Boolean data into bitfields	ERT targets only
Bitfield declarator type specifier	<ul style="list-style-type: none"> <li>Enabled by <b>Pack Boolean data into bitfields</b></li> <li>ERT targets only</li> </ul>
Pass reusable subsystem output as	ERT targets only
Parameter structure	<ul style="list-style-type: none"> <li>Enabled when you set <b>Default parameter behavior</b> to <b>Inlined</b></li> <li>ERT targets only</li> </ul>

All Parameters Tab	Dependency Details
Remove code from floating-point to integer conversions with saturation that maps NaN to zero	For ERT targets, enabled by <b>Support floating-point numbers</b> and <b>Support non-finite numbers</b> in the <b>Code Generation &gt; Interface</b> pane
Remove code that protects against division arithmetic exceptions	ERT targets only
Remove reset function	ERT targets only
Remove disable function	ERT targets only
Enable local block outputs	Enabled by <b>Signal storage reuse</b>
Reuse local block outputs	Enabled by <b>Signal storage reuse</b>
Eliminate superfluous local variables (expression folding)	Enabled by <b>Signal storage reuse</b>

For more information on these parameters, see “Optimization Pane: General” and “Optimization Pane: Signals and Parameters”.

## Increase Code Generation Speed

### In this section...

“Build a Model in Increments” on page 53-7

“Build Large Model Reference Hierarchies in Parallel” on page 53-7

“Minimize Memory Requirements During Code Generation” on page 53-8

“Generate Only Code” on page 53-9

“No Creation of a Code Generation Report” on page 53-9

The amount of time it takes to generate code for a model depends on the size and configuration settings of the model. For instance, if you are working with a large model, it can take awhile to generate code. To decrease the amount of time for code generation of a model, try one or more of the following methods:

- Build a model in increments
- Build large model reference hierarchies in parallel
- Minimize memory requirements during code generation
- Generate only code
- Disable the creation of a code generation report

### Build a Model in Increments

You can use the `rtwbuild` command to build a model and generate code. By default, when rebuilding a model, `rtwbuild` provides an incremental model build, which only rebuilds a model or submodels that have changed since the most recent model build. Incremental model build saves code generation time. Use the **Rebuild** parameter on the **Model Referencing** pane to change the method that Simulink uses to determine when to rebuild code for referenced models. For more information on the **Rebuild** parameter, see “Rebuild”.

### Build Large Model Reference Hierarchies in Parallel

In a parallel computing environment, whenever conditions allow, you can increase the speed of code generation and compilation by building models containing large model reference hierarchies in parallel. For example, if you have Parallel Computing Toolbox software, you can distribute code generation and compilation for each referenced

model across the cores of a multicore host computer. If you have MATLAB Distributed Computing Server software, you can distribute code generation and compilation for each referenced model across remote workers in your MATLAB Distributed Computing Server configuration.

The performance gain realized by using parallel builds for referenced models depends on several factors, including:

- How many models can be built in parallel for a given model referencing hierarchy
- The size of the referenced models
- Parallel computing resources such as the number of local and remote workers available
- The hardware attributes of the local and remote machines (amount of RAM, number of cores, and so on)

For more information, see “Reduce Build Time for Referenced Models”.

## Minimize Memory Requirements During Code Generation

Models that have large amounts of parameter and constant data (such as lookup tables) can tax memory resources and slow code generation. The code generator copies this data to the *model.rtw* file. The *model.rtw* file is a partial representation of the model that the Target Language Compiler parses to transform block computations, parameters, signals, and constant data into a high-level language (for example, C). The Target Language Compiler (TLC) is an integral part of the code generator. The code generator copies parameters and data into *model.rtw*, whether they originate in the model or come from variables or objects in a workspace.

You can improve code generation speed by specifying the maximum number of elements that data vectors can have for the code generator to copy this data to *model.rtw*. When a data vector exceeds the specified size, the code generator places a reference key in *model.rtw*. The TLC uses this key to access the data from Simulink and format it into the generated code. Reference keys result in maintaining only one copy of large data vectors in memory.

The default value above which the code generator uses reference keys in place of actual data values is 10 elements. You can verify this value. In the Command Window, type the following command:

```
get_param(0, 'RTWDataReferencesMinSize')
```

To set the threshold to a different value, in the Command Window, type the following `set_param` function:

```
set_param(0, 'RTWDataReferencesMinSize', <size>)
```

Provide an integer value for `size` that specifies the number of data elements above which the code generator uses reference keys in place of actual data values.

## Generate Only Code

You can increase code generation speed by specifying that the build process generate code and a makefile, but not invoke the make command. When the code generator invokes the make command, the build process takes longer because the code generator generates code, compiles code, and creates an executable file.

On the **Code Generation** pane in the Model Configuration Parameters dialog box, you can specify that the build process generate only code by selecting the **Generate code only** parameter. You can specify that the code generation process build a makefile by selecting the **Generate makefile** parameter on the **All Parameters** tab.

## No Creation of a Code Generation Report

You can speed up code generation by not generating a code generation report as a part of the build process. To disable the creation of a code generation report, on the **Code Generation > Report** pane, clear the **Create code generation report** parameter. After the build process, you can generate a code generation report by doing this procedure, “Generate Code Generation Report After Build Process”.

## Design Tips for Optimizing Generated Code for Stateflow Objects

### In this section...

“Do Not Access Machine-Parented Data In a Graphical Function” on page 53-10

“Be Explicit About the Inline Option of a Graphical Function” on page 53-10

“Avoid Using Multiple Edge-Triggered Events in Stateflow Charts” on page 53-10

“Combine Input Signals of a Chart Into a Single Bus Object” on page 53-10

“Use Charts with Discrete Sample Times” on page 53-11

### Do Not Access Machine-Parented Data In a Graphical Function

This restriction prevents long parameter lists from appearing in the code generated for a graphical function. You can access local data that resides in the same chart as the graphical function.

For more information, see “Reuse Logic Patterns Using Graphical Functions”.

### Be Explicit About the Inline Option of a Graphical Function

When you use a graphical function in a Stateflow chart, select **Inline** or **Function** for the property **Function Inline Option**. Otherwise, the code generated for a graphical function may not appear as you want.

For more information, see “Specify Graphical Function Properties”.

### Avoid Using Multiple Edge-Triggered Events in Stateflow Charts

If you use more than one edge trigger, you generate multiple code statements to handle rising or falling edge detections. If multiple triggers are required, use function-call events instead.

For more information, see “How Events Work in Stateflow Charts”.

### Combine Input Signals of a Chart Into a Single Bus Object

When you use a bus object, you reduce the number of parameters in the parameter list of a generated function. This guideline also applies to output signals of a chart.

For more information, see “Define Stateflow Structures”.

## **Use Charts with Discrete Sample Times**

The code generated for discrete charts that are not inside a triggered or enabled subsystem uses integer counters to track time instead of Simulink provided time. This allows for more efficient code generation in terms of overhead and memory, as well as enabling this code for use in Software-in-the-Loop(SIL) and Processor-in-the-Loop(PIL) simulation modes.

## Control Compiler Optimizations

To control compiler optimizations for a makefile build at the GUI level, use the **Compiler optimization level** parameter. The **Compiler optimization level** parameter provides

- Target-independent values **Optimizations on (faster runs)** and **Optimizations off (faster builds)**, which allow you to easily toggle compiler optimizations on and off during code development
- The value **Custom** for entering custom compiler optimization flags at the Simulink GUI level, rather than editing compiler flags into template makefiles (TMFs) or supplying compiler flags to build process make commands

The default setting is **Optimizations off (faster builds)**. Selecting the value **Custom** enables the **Custom compiler optimization flags** field, in which you can enter custom compiler optimization flags (for example, `-O2`).

---

**Note:** If you specify compiler options for your makefile build using `OPT_OPTS`, `MEX_OPTS` (except `MEX_OPTS= " -v "`), or `MEX_OPT_FILE`, the value of **Compiler optimization level** is ignored and a warning is issued about the ignored parameter.

---

For more information about the **Compiler optimization level** parameter and its values, see “Compiler optimization level” and “Custom compiler optimization flags”.

## Optimization Tools and Techniques

Using the Model Advisor, you can analyze a model for code generation and identify aspects of your model that impede production deployment or limit code efficiency. You can select from a set of checks to run on a model's current configuration. The Model Advisor analyzes the model and generates check results providing suggestions for improvements in each area. Most Model Advisor diagnostics do not require the model to be in a compiled state; those that do are noted.

Before running the Model Advisor, select the target you plan to use for code generation. The Model Advisor works most effectively with ERT and ERT-based system target files.

Use the following examples to investigate optimizing models for code generation using the Model Advisor:

- `rtwdemo_advisor1`
- `rtwdemo_advisor2`
- `rtwdemo_advisor3`

---

**Note:** Example models `rtwdemo_advisor2` and `rtwdemo_advisor3` require Stateflow and Fixed-Point Designer software.

---

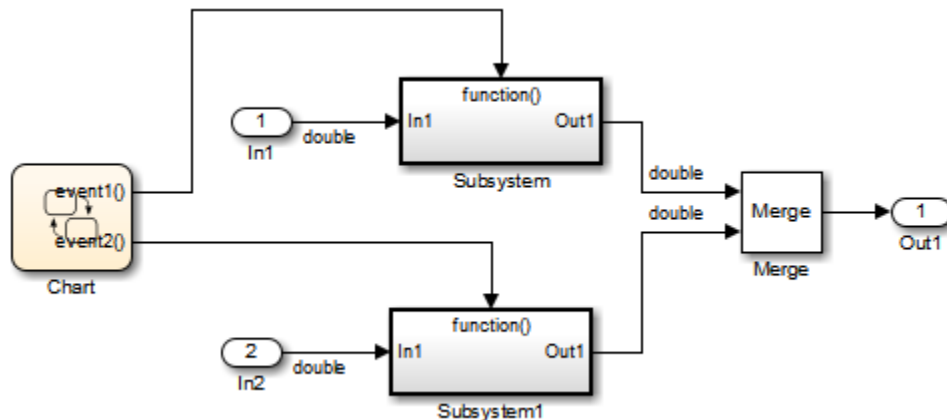

For more information on using the Model Advisor, see “Run Model Checks” in the Simulink documentation. For more information about the checks, see “Simulink Coder Checks” in the Simulink Coder documentation.

In addition to analyzing models with Model Advisor, you can also do the following:

- Use the Upgrade Advisor to upgrade older models (saved by prior versions or the current version) to use current features. For details, see “Model Upgrades”.
- Before building, set optimization flags for the compiler (for example, `-O2` for `gcc`, `-Ot` for the Microsoft Visual C++ compiler).
- Directly inline C/C++ S-functions into the generated code by writing a TLC file for the S-function. For more information, see “Accelerate Simulation, Reuse Code, or Protect Intellectual Property by Using S-Function Target” and the Target Language Compiler documentation.
- Use a Simulink data type other than `double` when possible. The available data types are `Boolean`, signed and unsigned 8-, 16-, and 32-bit integers, and 32- and 64-bit

floats (a `double` is a 64-bit float). For more information, see “About Data Types in Simulink”. For a block-by-block summary, click `showblockdatatypetable` or type the command in the Command Window.

- For tunable block parameters that you configure to store in memory in the generated code, you can match parameter data types with signal data types to eliminate unnecessary typecasts and C shifts. Where possible, store parameter values in small integer data types. See “Parameter Data Types in the Generated Code” on page 18-76.
- Remove repeated values in lookup table data.
- Use the Merge block to merge the output of signals wherever possible. This block is particularly helpful when you need to control the execution of function-call subsystems with a Stateflow chart. The following model shows an example of how to use the Merge block.

When more than one signal connected to a Merge block has a non-`Auto` storage class, all non-`Auto` signals connected to that block must *be identically labeled* and *have the same storage class*. When Merge blocks connect directly to one another, these rules apply to the signals connected to any of the Merge blocks in the group.

## Related Examples

- “Increase Code Generation Speed” on page 53-7
- “Execution Profiling for Generated Code” on page 53-16

## Control Memory Allocation for Time Counters

The **Application lifespan (days)** parameter lets you control the allocation of memory for absolute and elapsed time counters. Such counters exist in the code for blocks that use absolute or elapsed time. For a list of such blocks, see “Absolute Time Limitations”.

The size of the time counters in generated code is 8, 16, 32, or 64 bits. The size is set automatically to the minimum that can accommodate the duration value specified by **Application lifespan (days)** given the step size specified in the Configuration Parameters **Solver** pane. To minimize the amount of RAM used by time counters, specify the smallest lifespan possible and the largest step size possible.

An application runs to its specified lifespan. It may be able to run longer. For example, running a model with a step size of one millisecond (0.001 seconds) for one day requires a 32-bit timer, which could continue running without overflow for 49 days more.

To maximize application lifespan, specify **Application lifespan (days)** as `inf`. This value allocates 64 bits (two `uint32` words) for each timer. Using 64 bits to store timing data would allow a model with a step size of 0.001 microsecond (10E-09 seconds) to run for more than 500 years, which would rarely be required. 64-bit counters do not violate the usual code generator length limitation of 32 bits because the value of a time counter does not provide the value of a signal, state, or parameter.

### See Also

“Application lifespan (days)”

## Execution Profiling for Generated Code

Use code execution profiling to:

- Determine whether the generated code meets execution time requirements for real-time deployment on your target hardware.
- Identify code sections that require performance improvements.

The following tasks represent a general workflow that uses code execution profiling:

- 1** With the Simulink model, design and optimize your algorithm.
- 2** Configure the model for code execution profiling, and generate code.
- 3** Execute generated code on target. For example, you can:
  - Run a software-in-the-loop (SIL) simulation on your development computer.
  - Run a processor-in-the-loop (PIL) simulation using a target support package or custom PIL target.
  - Perform real-time execution with Simulink Real-Time or a target support package.
- 4** Analyze performance through code execution profiling plots and reports. For example, check that the algorithm code satisfies execution time requirements for real-time deployment:
  - If the algorithm code easily meets the requirements, consider enhancing your algorithm to exploit available processing power.
  - If the code cannot be executed in real time, look for ways to reduce execution time.

Identify the tasks that require the most time. For these tasks, investigate whether trade-offs between functionality and speed are possible.

If your target is a multicore processor, distribute the execution of algorithm code across available cores.

- 5** If required, refine the model and return to step 2.

To find information about code execution profiling with Simulink products, use the following table.

## Optimize Generated Code by Combining Multiple for Constructs

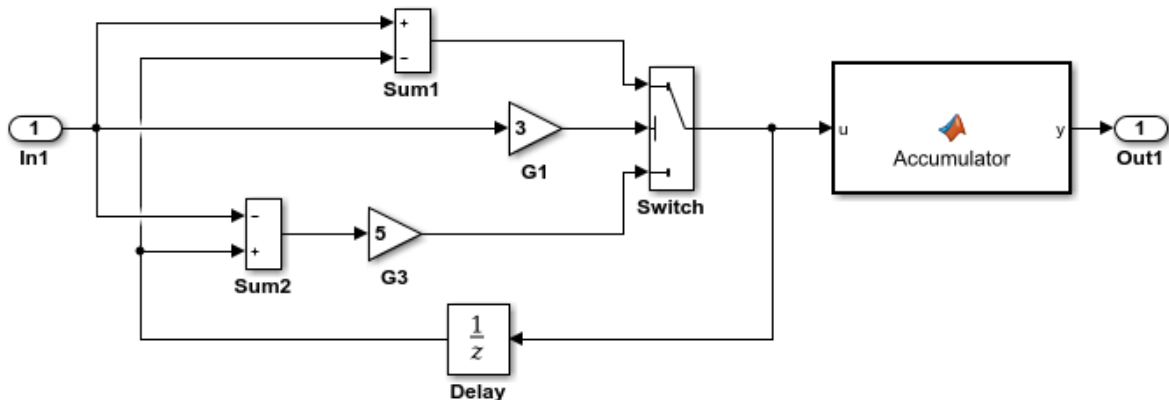

This example shows how the code generator combines for loops. The generated code uses for constructs to represent a variety of modeling patterns, such as a matrix signal or Iterator blocks. Using data dependency analysis, the code generator combines for constructs to reduce static code size and runtime branching.

The benefits of optimizing for loops are:

- Reducing ROM and RAM consumption.
- Increasing execution speed.

### for Loop Modeling Patterns

In the model, `rtwdemo_forloop`, the Switch block and MATLAB Function block represent for constructs. In the In1 Block Parameters dialog box, the **Port dimensions** parameter is set to 10.

This model shows how Simulink Coder optimizes for-loops by combining multiple blocks into the same for-loop, improving code efficiency and readability. The for-loop fusion optimization complements expression folding. To see the vector widths in this model, select Edit > Update Diagram.

## Generate Code

In the model, there are no data dependencies across the `for` loop iterations. Therefore, the code generator combines all `for` loops into one loop. Build the model and view the generated code.

```
Starting build procedure for model: rtwdemo_forloop
Successful completion of build procedure for model: rtwdemo_forloop
```

The generated file, `rtwdemo_forloop.c`, contains the code for the single `for` loop.

```
/* Model step function */
void rtwdemo_forloop_step(void)
{
 int32_T k;

 /* MATLAB Function: '<Root>/Accum' */
 /* MATLAB Function 'Accum': '<S1>:1' */
 /* '<S1>:1:3' */
 /* '<S1>:1:4' */
 rtwdemo_forloop_Y.Out1 = 0.0;

 /* '<S1>:1:5' */
 for (k = 0; k < 10; k++) {
 /* Switch: '<Root>/Switch' incorporates:
 * Gain: '<Root>/G1'
 * Gain: '<Root>/G3'
 * Inport: '<Root>/In1'
 * Sum: '<Root>/Sum1'
 * Sum: '<Root>/Sum2'
 * UnitDelay: '<Root>/Delay'
 */
 if (3.0 * rtwdemo_forloop_U.In1[k] >= 0.0) {
 rtwdemo_forloop_DW.Delay_DSTATE[k] = rtwdemo_forloop_U.In1[k] -
 rtwdemo_forloop_DW.Delay_DSTATE[k];
 } else {
 rtwdemo_forloop_DW.Delay_DSTATE[k] = (rtwdemo_forloop_DW.Delay_DSTATE[k] -
 rtwdemo_forloop_U.In1[k]) * 5.0;
 }

 /* End of Switch: '<Root>/Switch' */

 /* MATLAB Function: '<Root>/Accum' */
 /* '<S1>:1:5' */
 }
}
```

```
/* '<S1>:1:6' */
rtwdemo_forloop_Y.Out1 += (1.0 + (real_T)k) +
 rtwdemo_forloop_DW.Delay_DSTATE[k];
}
}
```

Close the model.

## Subnormal Number Performance

Subnormal numbers, formerly known as denormal numbers in floating-point literature, fill the underflow gap around zero in floating-point arithmetic. Subnormal values are a special category of floating-point values that are too close to 0.0 to be represented as a normalized value. The leading significand (mantissa) of a subnormal number is zero. When adding and subtracting floating-point numbers, subnormal numbers prevent underflow.

Using subnormal numbers provides precision beyond the normal representation by using leading zeros in the significand to represent smaller values after the representation reaches the minimum exponent. As the value approaches 0.0, you trade off precision for extended range. Subnormal numbers are useful if your application requires extra range.

However, in a real-time system, using subnormal numbers can dramatically increase execution latency, resulting in excessive design margins and real-time overruns. If the simulation or generated code performs calculations that produce or consume subnormal numbers, the execution of these calculations can be up to 50 times slower than similar calculations on normal numbers. The actual simulation or code execution time for subnormal number calculations depends on your computer operating environment. Typically, for desktop processors, the execution time for subnormal number calculations is five times slower than similar calculations on normal numbers.

To minimize the possibility of execution slowdowns or overruns due to subnormal number calculation latency, do one of the following:

- In your model, manually flush to zero any incoming or computed subnormal values at inputs and key operations, such as washouts and filters. For an example, see “Flush Subnormal Numbers to Zero” on page 53-24.

To detect a subnormal value for a single precision, 32-bit floating-point number:

- 1 Find the smallest normalized number on a MATLAB host. In the Command Window, type:

```
>> SmallestNormalSingle = realmin('single')
In the C language, FLT_MIN, defined in float.h, is equivalent to
realmin('single').
```

- 2 Look for values in range:

```
0 < fabsf(x) < SmallestNormalSingle
```

To detect a subnormal value for a double precision, 64-bit floating-point number:

- 1 Find the smallest normalized number on a MATLAB host. In the Command Window, type:

```
>> SmallestNormalDouble = realmin('double')
```

In the C language, `DBL_MIN`, defined in `float.h`, is equivalent to `realmin('double')`.

- 2 To detect a subnormal value, look for values in this range:

$$0 < \text{fabs}(x) < \text{SmallestNormalDouble}$$

- On your processor, set flush-to-zero mode or, with your compiler, specify an option to disable subnormal numbers. Flush-to-zero modes treat a subnormal number as 0 when it is an input to a floating-point operation. Underflow exceptions do not occur in flush-to-zero mode.

For example, in Intel® processors, the flush-to-zero (FTZ) and denormals-are-zero (DAZ) flags in the MXCSR register control floating-point calculations. For the gcc compiler on Linux, `-ffast-math` sets abrupt underflow (FTZ), flush-to-zero, while `-O3 -ffast-math` reverts to gradual underflow, using subnormal numbers.

For more information, see the IEEE Standard 754, *IEEE Standard for Floating-Point Arithmetic*.

## Simulation Time With and Without Subnormal Numbers

This model shows how using subnormal numbers increases simulation time by ~5 times.

- 1 Open the model `ex_subnormal`. The Gain is set to subnormal value `realmin('double')/2`.

- 2 To run a simulation, in the Command Window, type `for k=1:5, tic; sim('ex_subnormal'); toc,end`. Observe the elapsed times for simulation using subnormals, similar to the following:

```
>> for k=1:5, tic; sim('ex_subnormal'); toc,end
Elapsed time is 9.909326 seconds.
Elapsed time is 9.617966 seconds.
Elapsed time is 9.797183 seconds.
Elapsed time is 9.702397 seconds.
Elapsed time is 9.893946 seconds.
```

- 3 Set the Gain to a number, 2, that is not a subnormal value:

```
>> set_param('ex_subnormal/Gain', 'Gain', '2');
```

- 4 To run a simulation, in the Command Window, type `for k=1:5, tic; sim('ex_subnormal'); toc,end`. Observe elapsed times for simulations that do not use subnormal values, similar to the following:

```
>> for k=1:5, tic; sim('ex_subnormal'); toc,end
Elapsed time is 2.045123 seconds.
Elapsed time is 1.796598 seconds.
Elapsed time is 1.758458 seconds.
Elapsed time is 1.721721 seconds.
Elapsed time is 1.780569 seconds.
```

## Flush Subnormal Numbers to Zero

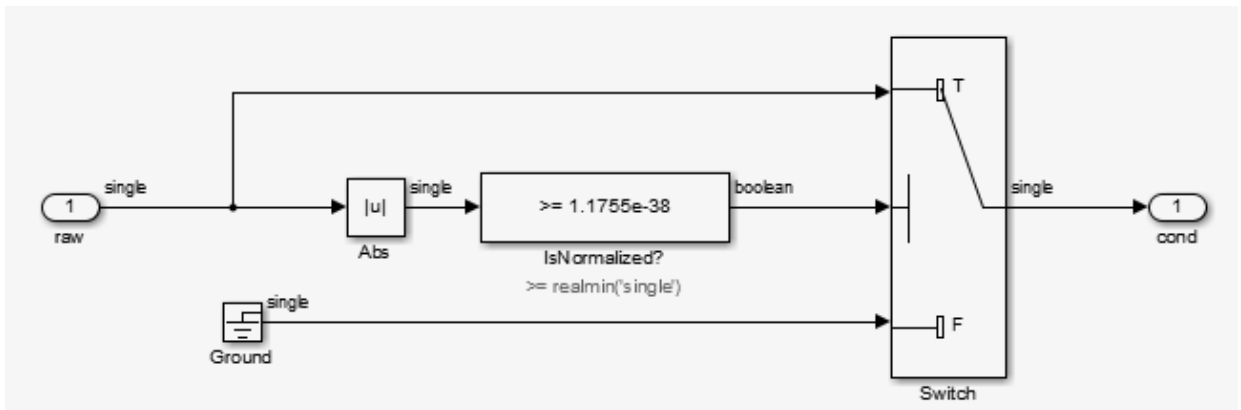

This example shows how to flush single precision subnormal numbers to zero.

- 1 Open the model `ex_flush_to_zero`:

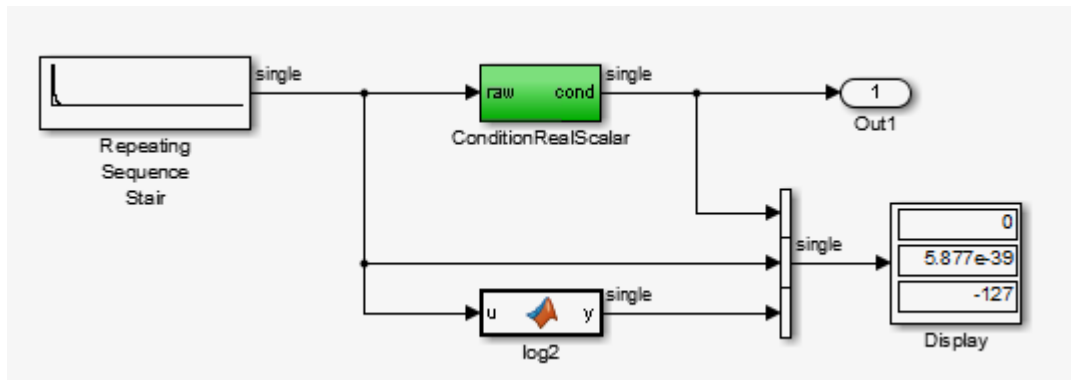

- Repeating Sequence Stair generates a sequence of numbers from two raised to the power of 0 through two raised to the power of -165. The sequence approaches zero.
- ConditionRealScalar flushes subnormal single precision values that are less than `realmin('single')` to zero.

- MATLAB function block `log2` generates the base 2 logarithm of the Repeating Sequence Stair output. Specifically, `log2` generates the numbers 0 through -165.
- 2** On the **Simulation > Stepping Options** pane:
- Select **Enable stepping back**.

- Select **Pause simulation when time reaches** and enter 121.
- 3 In the model window, run the simulation. The simulation pauses at T=121. The displayed values:
- ConditionRealScalar output approaches zero.
  - Repeating Sequence Stair output approaches zero.
- 4 Step the simulation forward to T=127. ConditionRealScalar flushes the subnormal value output from Repeating Sequence Stair to zero.

- 5 Continue stepping the simulation forward. ConditionRealScalar flushes the subnormal single precision values output from Repeating Sequence Stair to zero. When T=150, the output of Repeating Sequence Stair is itself zero.

## Remove Code From Floating-Point to Integer Conversions That Wraps Out-of-Range Values

### In this section...

“Example Model” on page 53-27

“Generate Code Without Optimization” on page 53-28

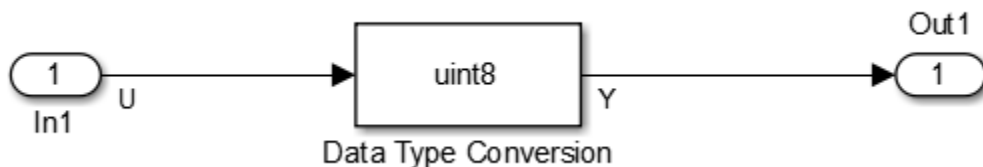

“Generate Code with Optimization” on page 53-29

This example shows how to remove code for out-of-range floating-point to integer conversions. Without this code, there might be a mismatch between simulation and code generation results. Standard C does not define the behavior of out-of-range floating-point to integer conversions, while these conversions are well-defined during simulation. In Standard C and during simulation, floating-point to integer conversions are well-defined for input values in the range of the output type.

If the input values in your application are in the range of the output type, remove code for out-of-range floating-point to integer conversions. Removing this code reduces the size and increases the speed of the generated code.

### Example Model

In this model, a Data Type Conversion block converts an input signal from a `double` to a `uint8`. A `uint8` can support values from 0 to 255. If the input signal has a value outside of this range, an out-of-range conversion occurs. In this example, the model is named `conversion_ex`.

- 1 Use Inport, Output, and Data Type Conversion blocks to create the example model.

- 2 Open the Inport Block Parameters dialog box and select the **Signal Attributes** tab. For the **Data Type** parameter, select **double**.
- 3 Open the Data Type Conversion dialog box. For the **Output data type** parameter, select **uint8**.
- 4 For the signal feeding into the Data Type Conversion block, open the Signal Properties dialog box. Enter the name **U**. On the **Code Generation** tab, for the **Storage Class** parameter, select **ImportedExtern**.
- 5 For the signal leaving the Data Type Conversion block, open the Signal Properties dialog box. Enter the name **Y**. On the **Code Generation** tab, for the **Storage Class** parameter, select **ImportedExtern**.

## Generate Code Without Optimization

- 1 Open the Model Configuration Parameters dialog box. On the **Solver** pane, for the **Type** parameter, select **Fixed-step**.
- 2 On the **Code Generation > Report** pane, select **Create code generation report**.
- 3 On the **Code Generation** pane, select **Generate code only**, and then, in the model window, press **Ctrl+B**. When code generation is complete, an HTML code generation report opens.
- 4 In the Code Generation report, select the `conversion_ex.c` file and view the model step function. The code generator applies the `fmod` function to handle out-of-range results.

```
/* Model step function */
void conversion_ex_step(void)
{
 real_T tmp;

 /* DataTypeConversion: '<Root>/Data Type Conversion' incorporates:
 * Inport: '<>/In1'
 */
 tmp = floor(U);
 if (rtIsNaN(tmp) || rtIsInf(tmp)) {
 tmp = 0.0;
 } else {
 tmp = fmod(tmp, 256.0);
 }

 Y = (uint8_T)(tmp < 0.0 ? (int32_T)(uint8_T)-(int8_T)(uint8_T)-tmp : (int32_T)
 (uint8_T)tmp);
}
```

## Generate Code with Optimization

- 1 Open the Configuration Parameters dialog box. On the **Optimization** pane, select **Remove code from floating-point to integer conversions that wraps out-of-range values**. Generate code.
- 2 In the code generation report, select the `conversion_ex.c` file and view the model step function. The generated code does not contain code that protects against out-of-range values.

```
/* Model step function */
void conversion_ex_step(void)
{
 /* DataTypeConversion: '<Root>/Data Type Conversion' incorporates:
 * Inport: '<Root>/In1'
 */
 Y = (uint8_T)U;
}
```

The generated code is more efficient without this protective code, but it is possible that the execution of generated code does not produce the same results as simulation for values not in the range of 0 to 255.

## Remove Code That Maps NaN to Integer Zero

### In this section...

“Example Model” on page 53-30

“Generate Code” on page 53-31

“Generate Code with Optimization” on page 53-32

This example shows how to remove code that maps NaN to integer zero. For floating-point to integer conversions involving saturation, Simulink converts NaN to integer zero during simulation. If your model contains an input value of NaN, you can specify that the code generator produce code that maps NaN to zero. Without this code, there is a mismatch between simulation and code generation results because in Standard C, every condition involving NaN evaluates to false.

If there are no input values of NaN in your application, you can remove code that maps NaN to integer zero. Removing this code reduces the size and increases the speed of the generated code.

### Example Model

In this model, a Data Type Conversion block converts an input signal from a double to a uint8. In this example, the model is named `conversion_ex`.

- 1 Use Inport, Outport, and Data Type Conversion blocks to create the example model.
- 2 Open the Inport Block Parameters dialog box and click the **Signal Attributes** tab. For the **Data Type** parameter, select `double`.
- 3 Open the Data Type Conversion dialog box. For the **Output data type** parameter, select `uint8`.

- 4 Select **Saturate on integer overflow**. Selecting this parameter specifies that an out-of-range signal value equals either the minimum or maximum value that the data type can represent.
- 5 For the signal feeding into the Data Type Conversion block, open the Signal Properties dialog box. Enter a name of U. On the **Code Generation** tab, for the **Storage Class** parameter, select **ImportedExtern**.
- 6 For the signal leaving the Data Type Conversion block, open the Signal Properties dialog box. Enter a name of Y. On the **Code Generation** tab, for the **Storage Class** parameter, select **ImportedExtern**.

## Generate Code

- 1 Open the Model Configuration Parameters dialog box. On the **Solver** pane, for the **Type** parameter, select **Fixed-step**.
- 2 Open the Model Configuration Parameters dialog box. On the **All Parameters** tab, clear **Remove code from floating-point to integer conversions with saturation that maps NaN to zero**.
- 3 On the **Code Generation > Report** pane, select **Create code generation report**.
- 4 On the **Code Generation** pane, select **Generate code only** and then, in the model window, press **Ctrl+B**. When code generation is complete, an HTML code generation report opens.
- 5 In the Code Generation report, select the `nan_int_ex.c` file and view the model step function. For an input value of NaN, there is agreement between the generated code and simulation because NaN maps to integer zero.

```

/* Model step function */
void nan_int_ex_step(void)
{
 /* DataTypeConversion: '<Root>/Data Type Conversion' incorporates:
 * Inport: '<Root>/In1'
 */
 if (U < 256.0) {
 if (U >= 0.0) {
 Y = (uint8_T)U;
 } else {
 Y = 0U;
 }
 } else if (U >= 256.0) {

```

```

 Y = MAX_uint8_T;
} else {
 Y = 0U;
}

```

## Generate Code with Optimization

- 1 Open the Configuration Parameters dialog box. On the **All Parameters** tab, select **Remove code from floating-point to integer conversions that wraps out-of-range values**. Generate code.
- 2 In the Code Generation report, select the `nan_int_ex.c` section and view the model step function. The generated code maps NaN to 255 and not integer zero. The generated code is more efficient without the extra code that maps NaN to integer zero, but the execution of the generated code does not produce the same results as simulation for NaN values.

```

/* Model step function */
void nan_int_ex_step(void)
{
 /* DataTypeConversion: '<Root>/Data Type Conversion' incorporates:
 * Inport: '<Root>/In1'
 */
 if (U < 256.0) {
 if (U >= 0.0) {
 Y = (uint8_T)U;
 } else {
 Y = 0U;
 }
 } else {
 Y = MAX_uint8_T;
 }

 /* End of DataTypeConversion: '<Root>/Data Type Conversion' */
}

```

## Disable Nonfinite Checks or Inlining for Math Functions

When the code generator produces code for math functions:

- If the model option **Support non-finite numbers** is selected, nonfinite number checking is generated uniformly for math functions, without the ability to specify that nonfinite number checking should be generated for some functions, but not for others.
- By default, inlining is applied uniformly for math functions, without the ability to specify that inlining should be generated for some functions, while invocations should be generated for others.

You can use code replacement library (CRL) customization entries to:

- Selectively disable nonfinite checks for math functions. This can improve the execution speed of the generated code.
- Selectively disable inlining of math functions. This can increase code readability and decrease code size.

The functions for which these customizations are supported include the following:

- Floating-point only: `atan2`, `copysign`, `fix`, `hypot`, `log`, `log10`, `round`, `sincos`, and `sqrt`
- Floating-point and integer: `abs`, `max`, `min`, `mod`, `rem`, `saturate`, and `sign`

The general workflow for disabling nonfinite number checking and/or inlining is as follows:

- 1 If you can disable nonfinite number checking for a particular math function, or if you want to disable inlining for a particular math function and instead generate a function invocation, you can copy the following MATLAB function code into a MATLAB file with an `.m` file name extension, for example, `crl_table_customization.m`.

```
function hTable = crl_table_customization

% Create an instance of the Code Replacement Library table for controlling
% function intrinsic inlining and nonfinite support

hTable = RTW.Tf1Table;

% Inline - true (if function needs to be inline)
% false (if function should not be inlined)
% SNF (support nonfinite) - ENABLE (if non-finite checking should be performed)
% DISABLE (if non-finite checking should NOT be performed)
% UNSPECIFIED (Default behavior)
```

```

% registerCustomizationEntry(hTable, ...

 100, 1, 'copysign', 'double', 'double', true, 'UNSPECIFIED');
registerCustomizationEntry(hTable, ...
 100, 1, 'copysign', 'single', 'single', true, 'UNSPECIFIED');

```

- 2 To reduce the size of the file, you can delete the `registerCustomizationEntry` lines for functions for which the default nonfinite number checking and inlining behavior is acceptable.
- 3 For each remaining entry,
  - Set the `Inline` argument to `true` if the function should be inlined or `false` if it should not be inlined.
  - Set the `SNF` argument to `ENABLE` if nonfinite checking should be generated, `DISABLE` if nonfinite checking should not be generated, or `UNSPECIFIED` to accept the default behavior based on the model option settings.

Save the file.

- 4 Optionally, perform a quick check of the syntactic validity of the customization table entries by invoking the table definition file at the MATLAB command line (`>> tbl = crl_table_customization`). Fix syntax errors that are flagged.
- 5 Optionally, view the customization table entries in the Code Replacement Viewer (`>> crviewer(crl_table_customization)`). For more information about viewing code replacement tables, see “Choose a Code Replacement Library”.
- 6 To register these changes and make them appear in the **Code replacement library** drop-down list located on the **Code Generation > Interface** pane of the Configuration Parameters dialog box, first copy the following MATLAB function code into an instance of the file `rtwTargetInfo.m`.

---

**Note:** For the example below, specify the argument `'RTW'` if a GRT target is selected for your model, otherwise omit the argument.

---

```

function rtwTargetInfo(cm)
% rtwTargetInfo function to register a code replacement library (CRL)

```

```

% Register the CRL defined in local function locCrlRegFcn
cm.registerTargetInfo(@locCrlRegFcn);

end % End of RTWTARGETINFO

% Local function to define a CRL containing crl_table_customization
function thisCrl = locCrlRegFcn

% Instantiate a CRL registry entry - specify 'RTW' for GRT
thisCrl = RTW.TflRegistry('RTW');

% Define the CRL properties
thisCrl.Name = 'CRL Customization Example';
thisCrl.Description = 'Example of CRL Customization';
thisCrl.TableList = {'crl_table_customization'};
thisCrl.TargetHWDeviceType = {'*'};

end % End of LOCCRLREGFCN

```

You can edit the **Name** field to specify the library name that appears in the **Code replacement library** drop-down list. Also, the file name in the **TableList** field must match the name of the file you created in step 1.

To register your changes, with both of the MATLAB files you created present in the MATLAB path, enter the following command at the MATLAB command line:

```
sl_refresh_customizations
```

- 7 Create or open a model that generates function code corresponding to one of the math functions for which you specified a change in nonfinite number checking or inlining behavior.
- 8 Open the Configuration Parameters dialog box, go to the **Code Generation** > **Interface** pane, and use the **Code replacement library** drop-down list to select the code replacement entry you registered in step 6, for example, **CRL Customization Example**.
- 9 Generate code for the model and examine the generated code to verify that the math functions are generated as expected.

## Minimize Computations and Storage for Intermediate Results at Block Outputs

### In this section...

“Expression Folding” on page 53-40

“Example Model” on page 53-40

“Generate Code” on page 53-41

“Enable Optimization” on page 53-41

“Generate Code with Optimization” on page 53-42

### Expression Folding

*Expression folding* optimizes code to minimize the computation of intermediate results at block outputs and the storage of such results in temporary buffers or variables. When expression folding is on, the code generator collapses (folds) block computations into a single expression, instead of generating separate code statements and storage declarations for each block in the model. Most Simulink blocks support expression folding.

Expression folding improves the efficiency of generated code, frequently achieving results that compare favorably to hand-optimized code. In many cases, entire groups of model computations fold into a single, highly optimized line of code.

You can use expression folding in your own inlined S-function blocks. For more information, see “S-Functions That Support Expression Folding”.

### Example Model

## Generate Code

With expression folding off, in the `explfld.c` file, the code generator generates this code.

```
/* Model step function */
void exprfld_step(void)
{
 /* Gain: '<Root>/Gain' incorporates:
 * Inport: '<Root>/In1'
 */
 exprfld_B.S1 = exprfld_P.Gain_Gain * exprfld_U.i1;

 /* Gain: '<Root>/Gain1' incorporates:
 * Inport: '<Root>/In2'
 */
 exprfld_B.S2 = exprfld_P.Gain1_Gain * exprfld_U.i2;

 /* Output: '<Root>/Out1' incorporates:
 * Product: '<Root>/Product'
 */
 exprfld_Y.Out1 = exprfld_B.S1 * exprfld_B.S2;
}
```

There are separate code statements for both Gain blocks. Before final output, these code statements compute temporary results for the Gain blocks.

## Enable Optimization

Expression folding is on by default. To see if expression folding is on for an existing model:

- 1 Open the Configuration Parameters dialog box and select the **All Parameters** tab.
- 2 Expression folding is available only when the **Signal storage reuse** parameter is set to **ON** because expression folding operates only on expressions involving local variables. On the **All Parameters** tab, select **Signal storage reuse**.
- 3 When you select **Signal storage reuse**, the **Enable local block outputs**, **Reuse local block outputs**, and **Eliminate superfluous local variables (expression folding)** parameters are all on by default.

## Generate Code with Optimization

With expression folding, the code generator generates a single-line output computation, as shown in the `exprfld.c` file. The generated comments document the block parameters that appear in the expression.

```
/* Model step function */
void exprfld_step(void)
{
 /* Outport: '<Root>/Out1' incorporates:
 * Gain: '<Root>/Gain'
 * Gain: '<Root>/Gain1'
 * Inport: '<Root>/In1'
 * Inport: '<Root>/In2'
 * Product: '<Root>/Product'
 */
 exprfld_Y.Out1 = exprfld_P.Gain_Gain * exprfld_U.i1 * (exprfld_P.Gain1_Gain *
 exprfld_U.i2);
}
```

For an example of expression folding in the context of a more complex model, click `rtwdemo_slexprfold`, or at the command prompt, type:

```
rtwdemo_slexprfold
```

For more information, see “Enable and Reuse Local Block Outputs in Generated Code”

## Inline Invariant Signals

You can optimize the generated code by selecting **Inline invariant signals** on the **Optimization > Signals and Parameters** pane. The generated code uses the numerical values of the invariant signals instead of their symbolic names.

An invariant signal is a block output signal that does not change during Simulink simulation. For example, the signal **S3** is an invariant signal. An *invariant signal* is not the same as an *invariant constant*. The two constants (1 and 2) and the gain value of 3 are invariant constants. To inline invariant constants, set **Default parameter behavior** to **Inlined**.

## Optimize Generated Code Using Inline Invariant Signals

This example shows how to use inline invariant signals to optimize the generated code. This optimization transforms symbolic names of invariant signals into constant values.

The `InlineInvariantSignals` optimization:

- Reduces ROM and RAM consumption.
- Improves execution speed.

### Example Model

Consider the model `matlab:rtwdemo_inline_invariant_signals`.

```
model = 'rtwdemo_inline_invariant_signals';
open_system(model);
```

Copyright 2014 The MathWorks, Inc.

### Generate Code

Create a temporary folder (in your system temporary folder) for the build and inspection process.

```
currentDir = pwd;
[~,cgDir] = rtwdemodir();
```

Build the model using Simulink Coder.

```
rtwbuild(model)
```

```
Starting build procedure for model: rtwdemo_inline_invariant_signals
Successful completion of build procedure for model: rtwdemo_inline_invariant_signals
```

View the generated code without the optimization. These lines of code are in `rtwdemo_inline_invariant_signals.c`.

```
cfile = fullfile(cgDir,'rtwdemo_inline_invariant_signals_grt_rtw',...
 'rtwdemo_inline_invariant_signals.c');
rtwdemodbtype(cfile,'/* Output and update for atomic system',...
 '/* Model output', 1, 0);

/* Output and update for atomic system: '<Root>/InlinedConstFcn' */
void rtwdemo_inline__InlinedConstFcn(int32_T rtu_In1,
 B_InlinedConstFcn_rtwdemo_inl_T *localB, const ConstB_InlinedConstFcn_rtwdem_T
 *localC)
{
 /* Product: '<S1>/Product' */
 localB->Product = rtu_In1 * localC->Sum_p;
}

```

## Enable Optimization

- 1 Open the Configuration Parameters dialog box.
- 2 On the **Optimization->Signals and Parameters** pane, select **Inline Invariant Signals**.

Alternatively, you can use the command-line API to enable the optimization:

```
set_param(model, 'InlineInvariantSignals', 'on');
```

## Generate Code with Optimization

The generated code uses the numerical values of the folded constants instead of creating an additional structure (rtwdemo\_inline\_invariant\_ConstB).

Build the model using Simulink Coder.

```
rtwbuild(model)
```

```
Starting build procedure for model: rtwdemo_inline_invariant_signals
Successful completion of build procedure for model: rtwdemo_inline_invariant_signals
```

View the generated code with the optimization. These lines of code are in `rtwdemo_minmax.c`.

```
rtwdemodbtype(cfile, '/* Output and update for atomic system', '/* Model output', 1, 0)
```

```
/* Output and update for atomic system: '<Root>/InlinedConstFcn' */
void rtwdemo_inline__InlinedConstFcn(int32_T rtu_In1,
 B_InlinedConstFcn_rtwdemo_inl_T *localB)
{
 /* Product: '<S1>/Product' */
 localB->Product = rtu_In1 << 5;
}

```

Close the model and code generation report.

```
bdclose(model)
rtwdemoclean;
cd(currentDir)
```

## See Also

“Inline invariant signals”

## **Related Examples**

- “Optimization Tools and Techniques” on page 53-13
- “Inline Numeric Values of Block Parameters” on page 53-47

## Inline Numeric Values of Block Parameters

This example shows how to optimize the generated code by inlining the numeric values of block parameters. *Block parameters* include the **Gain** parameter of a Gain block and the table data and breakpoint sets of an n-D Lookup Table block.

This optimization determines whether numeric block parameters occupy global memory in the generated code. The optimization can:

- Improve execution speed.
- Reduce RAM and ROM consumption.

### Explore Example Model

Open the example model `rtwdemo_paraminline`.

```
open_system('rtwdemo_paraminline')
```

<b>Generate Code Using Simulink Coder (double-click)</b>	<b>Generate Code Using Embedded Coder (double-click)</b>	<b>View Optimization Configuration (double-click)</b>	<b>Display Sample Time Colors (double-click)</b>
------------------------------------------------------------------	------------------------------------------------------------------	---------------------------------------------------------------	----------------------------------------------------------

Copyright 1994-2015 The MathWorks, Inc.

The model contains blocks that have these numeric parameters:

- The **Gain** parameters of the Gain blocks

- The **Constant value** parameters of the Constant blocks
- The table data and breakpoint sets of the n-D Lookup Table blocks

The output of the block G2, and the outputs of blocks upstream of G2, change only if you tune the values of the block parameters during simulation or during code execution. When you update the model diagram, these blocks and signal lines appear magenta in color.

Several blocks use `Simulink.Parameter` objects in the base workspace to set the values of their parameters. The parameter objects all use the storage class `Auto`, which means that you can configure the generated code to inline the parameter values.

### Generate Code Without Optimization

Create a temporary folder for the build and inspection process.

```
currentDir = pwd;
[~,cgDir] = rtwdemodir();
```

Disable the optimization by setting **Configuration Parameters > Optimization > Signals and Parameters > Default parameter behavior** to **Tunable**.

```
set_param('rtwdemo_paraminline', 'DefaultParameterBehavior', 'Tunable')
```

Generate code from the model.

```
rtwbuild('rtwdemo_paraminline')

Starting build procedure for model: rtwdemo_paraminline
Successful completion of build procedure for model: rtwdemo_paraminline
```

In the code generation report, view the source file `rtwdemo_paraminline_data.c`. The code defines a global structure that contains the block parameter values. Each block parameter in the model, such as a lookup table array, breakpoint set, or gain, appears as a field of the structure.

```
cfile = fullfile(cgDir, 'rtwdemo_paraminline_grt_rtw', 'rtwdemo_paraminline_data.c');
rtwdemodbtype(cfile, '/* Block parameters (auto storage) */', '}', '1, 1);

/* Block parameters (auto storage) */
P_rtwdemo_paraminline_T rtwdemo_paraminline_P = {
 10.0, /* Variable: MAX_LIFT
 * Referenced by: '<Root>/Constant'
 */
```

```

0.0, /* Variable: SLIDER_POS
 * Referenced by: '<Root>/Constant1'
 */

/* Variable: T1Break
 * Referenced by: '<Root>/1D Lookup'
 */
{ -5.0, -4.0, -3.0, -2.0, -1.0, 0.0, 1.0, 2.0, 3.0, 4.0, 5.0 },

/* Variable: T1Data
 * Referenced by: '<Root>/1D Lookup'
 */
{ -1.0, -0.99, -0.98, -0.96, -0.76, 0.0, 0.76, 0.96, 0.98, 0.99, 1.0 },

/* Variable: T2Break
 * Referenced by: '<Root>/2D Lookup'
 */
{ 1.0, 2.0, 3.0 },

/* Variable: T2Data
 * Referenced by: '<Root>/2D Lookup'
 */
{ 4.0, 16.0, 10.0, 5.0, 19.0, 18.0, 6.0, 20.0, 23.0 },
2.0, /* Expression: 2
 * Referenced by: '<Root>/G1'
 */
-2.0, /* Expression: -2
 * Referenced by: '<Root>/G2'
 */

/* Computed Parameter: uDLookup_maxIndex
 * Referenced by: '<Root>/2D Lookup'
 */
{ 2U, 2U }
};

```

You can tune the structure fields during code execution because they occupy global memory. However, at each step of the generated algorithm, the code must calculate the output of each block, including the outputs of the block G2 and the upstream blocks. View the algorithm in the model step function in the file `rtwdemo_paraminline.c`.

```

cfile = fullfile(cgDir,'rtwdemo_paraminline_grt_rtw','rtwdemo_paraminline.c');
rtwdemodbtype(cfile,'/* Model step function */','/* Model initialize function */',1,0)

```

```

/* Model step function */
void rtwdemo_paraminline_step(void)
{
 /* Outport: '<Root>/Out1' incorporates:
 * Constant: '<Root>/Constant'
 * Constant: '<Root>/Constant1'
 * Gain: '<Root>/G1'
 * Gain: '<Root>/G2'
 * Inport: '<Root>/In1'
 * Lookup_n-D: '<Root>/1D Lookup'
 * Lookup_n-D: '<Root>/2D Lookup'
 * Sum: '<Root>/Sum'
 */
 rtwdemo_paraminline_Y.Out1 = rtwdemo_paraminline_P.G1_Gain *
 rtwdemo_paraminline_U.In1 + rtwdemo_paraminline_P.G2_Gain * look2_binlx
 (rtwdemo_paraminline_P.MAX_LIFT, look1_binlx
 (rtwdemo_paraminline_P.SLIDER_POS, rtwdemo_paraminline_P.T1Break,
 rtwdemo_paraminline_P.T1Data, 10U), rtwdemo_paraminline_P.T2Break,
 rtwdemo_paraminline_P.T2Break, rtwdemo_paraminline_P.T2Data,
 rtwdemo_paraminline_P.uDLookup_maxIndex, 3U);
}

```

### Generate Code with Optimization

Set **Default parameter behavior** to **Inlined**.

```
set_param('rtwdemo_paraminline', 'DefaultParameterBehavior', 'Inlined')
```

Generate code from the model.

```
rtwbuild('rtwdemo_paraminline')
```

```
Starting build procedure for model: rtwdemo_paraminline
Successful completion of build procedure for model: rtwdemo_paraminline
```

In the code generation report, view the algorithm in the file `rtwdemo_paraminline.c`.

```
rtwdemodbtype(cfile, '/* Model step function */', '/* Model initialize function */', 1, 0)
```

```

/* Model step function */
void rtwdemo_paraminline_step(void)
{
 /* Outport: '<Root>/Out1' incorporates:
 * Gain: '<Root>/G1'

```

```

* Inport: '<Root>/In1'
* Sum: '<Root>/Sum'
*/
rtwdemo_paraminline_Y.Out1 = 2.0 * rtwdemo_paraminline_U.In1 + 150.0;
}

```

The code does not allocate memory for block parameters or for parameter objects that use the storage class `Auto`. Instead, the code generator uses the parameter values from the model, and from the parameter objects, to calculate and inline the constant output of the block G2, `150.0`. The generator also inlines the value of the **Gain** parameter of the Gain block G1, `2.0`.

With the optimization, the generated code leaves out computationally expensive algorithmic code for blocks such as the lookup tables. The optimized code calculates the output of a block only if the output can change during execution. For this model, only the outputs of the Inport block In1, the Gain block G1, and the Sum block can change.

Close the model and the code generation report.

```

bdclose('rtwdemo_paraminline')
rtwdemoclean;
cd(currentDir)

```

### Preserve Block Parameter Tunability

When you set **Default parameter behavior** to `Inlined`, you can preserve block parameter tunability by creating `Simulink.Parameter` objects for individual parameters. You can configure each object to appear in the code as a tunable field of the global parameter structure or as an individual global variable. You can change parameter values during code execution and interface the generated code with your own handwritten code. For more information, see “Block Parameter Representation in the Generated Code”.

### Inline Invariant Signals

You can select the **Inline invariant signals** code generation option (which also places constant values in the generated code) only when you set **Default parameter behavior** to `Inlined`. See “Inline Invariant Signals”.

### See Also

“Default parameter behavior”

## **Related Examples**

- “Block Parameter Representation in the Generated Code”

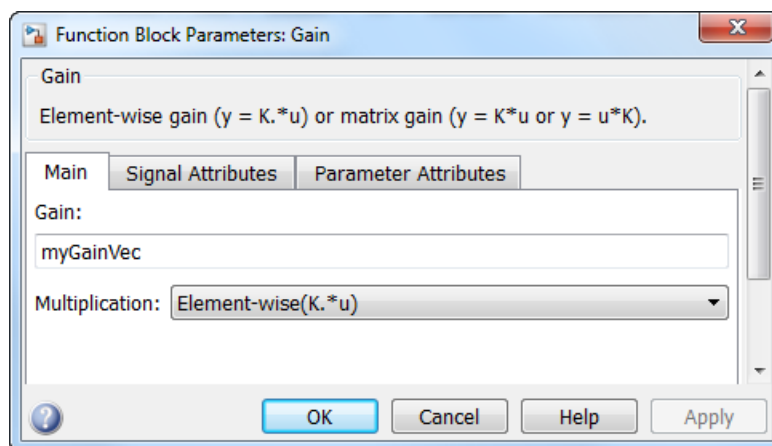

## Configure Loop Unrolling Threshold

The **Loop unrolling threshold** parameter on the **Optimization > Signals and Parameters** pane determines when a wide signal or parameter should be wrapped into a `for` loop and when it should be generated as a separate statement for each element of the signal. The default threshold value is 5.

For example, consider the model below:

The gain parameter of the Gain block is the vector `myGainVec`.

Assume that the loop unrolling threshold value is set to the default, 5.

If `myGainVec` is declared as

```
myGainVec = [1:10];
```

an array of 10 elements, `myGainVec_P.Gain_Gain[ ]`, is declared within the `Parameters_model` data structure. The size of the gain array exceeds the loop unrolling threshold. Therefore, the code generated for the Gain block iterates over the array in a `for` loop, as shown in the following code:

```
{
 int32_T i1;

 /* Gain: '<Root>/Gain' */
 for(i1=0; i1<10; i1++) {
 myGainVec_B.Gain_f[i1] = rtb_foo *
 myGainVec_P.Gain_Gain[i1];
 }
}
```

If myGainVec is declared as

```
myGainVec = [1:3];
```

an array of three elements, myGainVec\_P.Gain\_Gain[], is declared within the Parameters data structure. The size of the gain array is below the loop unrolling threshold. The generated code consists of inline references to each element of the array, as in the code below.

```
/* Gain: '<Root>/Gain' */
myGainVec_B.Gain_f[0] = rtb_foo * myGainVec_P.Gain_Gain[0];
myGainVec_B.Gain_f[1] = rtb_foo * myGainVec_P.Gain_Gain[1];
myGainVec_B.Gain_f[2] = rtb_foo * myGainVec_P.Gain_Gain[2];
```

See “Explore Variable Names and Loop Rolling” for more information on loop rolling.

---

**Note** When a model includes Stateflow charts or MATLAB Function blocks, you can apply a set of Stateflow optimizations on the **Optimization > Stateflow** pane. The settings you select for the Stateflow options also apply to MATLAB Function blocks in the model. This is because the MATLAB Function blocks and Stateflow charts are built on top of the same technology and share a code base. You do not need a Stateflow license to use MATLAB Function blocks.

---

## Use memcpy Function to Optimize Generated Code for Vector Assignments

### In this section...

“Example Model” on page 53-57

“Generate Code” on page 53-58

“Generate Code with Optimization” on page 53-58

You can use the **Use memcpy for vector assignment** parameter to optimize generated code for vector assignments by replacing **for** loops with **memcpy** function calls. The **memcpy** function is more efficient than **for**-loop controlled element assignment for large data sets. This optimization improves execution speed.

Selecting the **Use memcpy for vector assignment** parameter enables the associated parameter **Memcpy threshold (bytes)**, which allows you to specify the minimum array size in bytes for which **memcpy** function calls should replace **for** loops in the generated code. For more information, see “Use memcpy for vector assignment” and “Memcpy threshold (bytes)”. In considering whether to use this optimization,

- Verify that your target supports the **memcpy** function.
- Determine whether your model uses signal vector assignments (such as **Y=expression**) to move large amounts of data, for example, using the Selector block.

To apply this optimization,

- 1 Consider first generating code without this optimization and measuring its execution speed, to establish a baseline for evaluating the optimized assignment.
- 2 Select **Use memcpy for vector assignment** and examine the setting of **Memcpy threshold (bytes)**, which by default specifies 64 bytes as the minimum array size for which **memcpy** function calls replace **for** loops. Based on the array sizes used in your application's signal vector assignments, and target environment considerations that might bear on the threshold selection, accept the default or specify another array size.
- 3 Generate code, and measure its execution speed against your baseline or previous iterations. Iterate on steps 2 and 3 until you achieve an optimal result.

---

**Note:** The **memcpy** optimization may not occur under certain conditions, including when other optimizations have a higher precedence than the **memcpy** optimization, or when the

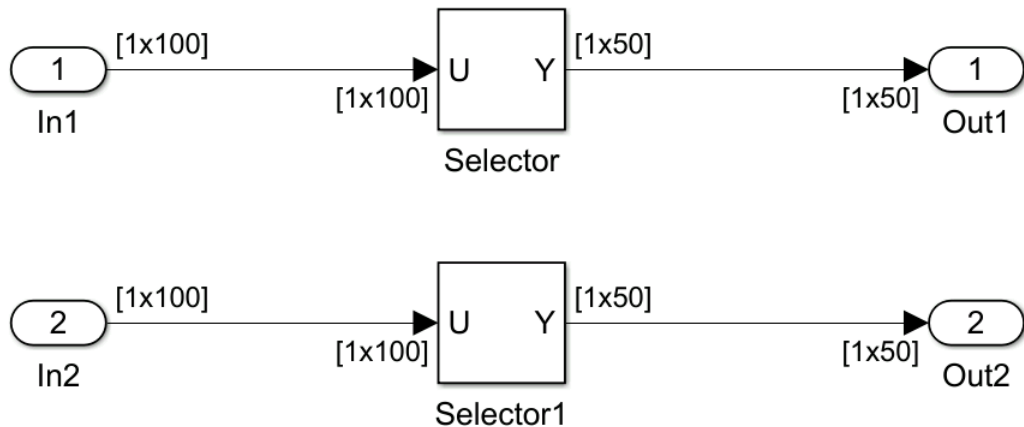

generated code is originating from Target Language Compiler (TLC) code, such as a TLC file associated with an S-function block.

**Note:** If you are licensed for Embedded Coder software, you can use a code replacement library (CRL) to provide your own custom implementation of the `memcpy` function to be used in generated model code. For more information, see “Memory Function Code Replacement” on page 51-96.

## Example Model

To examine the result of using the **Use memcpy for vector assignment** parameter on the generated vector assignment code, create a model that generates signal vector assignments. For example,

- 1 Use In, Out, and Selector blocks to create the following model.

- 2 Open Model Explorer and configure the **Signal Attributes** for the In1 and In2 source blocks. For each, set **Port dimensions** to [ 1 , 100 ], and set **Data type** to `int32`. Apply the changes and save the model. In this example, the model has the name `vectorassign`.
- 3 For each Selector block, set the **Index** parameter to 1 : 50. Set the **Input port size** parameter to 100.

## Generate Code

- 1 The **Use memcpy for vector assignment** parameter is on by default. To turn off the parameter, go to the **Optimization > Signals and Parameters** pane and clear the **Use memcpy for vector assignment** parameter.
- 2 Go to the **Code Generation > Report** pane of the Configuration Parameters dialog box and select the **Create code generation report**. Then go to the **Code Generation** pane, select the **Generate code only** option, and generate code for the model. When code generation completes, the HTML code generation report is displayed.
- 3 In the HTML code generation report, click the `vectorassign.c` section and inspect the model step function. Notice that the vector assignments are implemented using `for` loops.

```

/* Model step function */
void vectorassign_step(void)
{
 int32_T i;
 for (i = 0; i < 50; i++) {
 /* Output: '<Root>/Out1' incorporates:
 * Inport: '<Root>/In1'
 */
 vectorassign_Y.Out1[i] = vectorassign_U.In1[i];

 /* Output: '<Root>/Out2' incorporates:
 * Inport: '<Root>/In2'
 */
 vectorassign_Y.Out2[i] = vectorassign_U.In2[i];
 }
}

```

## Generate Code with Optimization

- 1 Go to the **Optimization > Signals and Parameters** pane of the Configuration Parameters dialog box and select the **Use memcpy for vector assignment** option. Leave the **Memcpy threshold (bytes)** option at its default setting of 64. Apply the changes and regenerate code for the model. When code generation completes, the HTML code generation report again is displayed.
- 2 In the HTML code generation report, click the `vectorassign.c` section and inspect the model output function. Notice that the vector assignments now are implemented using `memcpy` function calls.

```

/* Model step function */
void vectorassign_step(void)
{

```

```
/* Output: '<Root>/Out1' incorporates:
 * Inport: '<Root>/In1'
 */
memcpy(&vectorassign_Y.Out1[0], &vectorassign_U.In1[0], 50U * sizeof(real_T));

/* Output: '<Root>/Out2' incorporates:
 * Inport: '<Root>/In2'
 */
memcpy(&vectorassign_Y.Out2[0], &vectorassign_U.In2[0], 50U * sizeof(real_T));
}
```

## See Also

“Use memcpy for vector assignment”

## Generate Target Optimizations Within Algorithm Code

Some application components are hardware-specific and cannot simulate on a host system. For example, consider a component that includes pragmas and assembly code for enabling hardware instructions for saturate on add operations or a Fast Fourier Transform (FFT) function.

The following table lists integration options to customize generated algorithm code with target-specific optimizations.

---

**Note:** Solutions marked with *EC only* require an Embedded Coder license.

---

If...	Then...	For More Information, See
You want to optimize the execution speed and memory of the model code by replacing default math functions and operators with target-specific code	<i>EC only</i> —Implement function and operator replacements by using the Code Replacement Tool, code replacement library (CRL) API, and Code Replacement Viewer to create, examine, validate, and register hardware-specific replacement tables	“Optimize Generated Code By Developing and Using Code Replacement Libraries - Simulink®”
You want to control how code generation technology declares, stores, and represents signals, tunable parameters, block states, and data objects in generated code	<i>EC only</i> —Design (create) and apply custom storage classes	<ul style="list-style-type: none"> <li>• rtwdemo_cscpredef</li> <li>• rtwdemo_importstruct</li> <li>• rtwdemo_advsc</li> <li>• “Custom Storage Classes”</li> </ul>

---

**Note:** To simulate an algorithm that includes target-specific elements in a host environment, you must create code that is equivalent to the target code and can run in the host environment.

---

## Remove Code for Blocks That Have No Effect on Computational Results

This example shows how the code generator optimizes generated code by removing code that has no effect on computational results. This optimization:

- Increases execution speed.
- Reduces ROM consumption.

### Example

In the model `rtwdemo_blockreduction`, a Gain block of value `1.0` is in between Inport and Outport blocks.

```
model = 'rtwdemo_blockreduction';
open_system(model);
```

Copyright 2014 The Mathworks, Inc.

### Generate Code

Create a temporary folder for the build and inspection process.

```
currentDir=pwd;
[~,cgDir]=rtwdemodir();
```

Build the model.

```
set_param(model,'BlockReduction','off');
rtwbuild(model)
```

```
Starting build procedure for model: rtwdemo_blockreduction
Successful completion of build procedure for model: rtwdemo_blockreduction
```

Here is the code from `rtwdemo_blockreduction.c`.

```
cfile = fullfile(cgDir, 'rtwdemo_blockreduction_ert_rtw', 'rtwdemo_blockreduction.c');
rtwdemodbtype(cfile, '/* Model step function */', ...
 '/* Model initialize function */', 1, 0);

/* Model step function */
void rtwdemo_blockreduction_step(void)
{
 /* Outport: '<Root>/Out1' incorporates:
 * Gain: '<Root>/Gain'
 * Inport: '<Root>/In1'
 */
 rtwdemo_blockreduction_Y.Out1 = 1.0 * rtwdemo_blockreduction_U.In1;
}
```

### Enable Optimization

- 1 Open the Configuration Parameters dialog box.
- 2 On the **All Parameters** tab, select **Block reduction**. This optimization is on by default.

Alternately, use the command-line API to enable the optimization.

```
set_param(model, 'BlockReduction', 'on');
```

### Generate Code with Optimization

```
rtwbuild(model)

Starting build procedure for model: rtwdemo_blockreduction
Successful completion of build procedure for model: rtwdemo_blockreduction
```

Here is the optimized code from `rtwdemo_blockreduction.c`.

```
cfile = fullfile(cgDir, 'rtwdemo_blockreduction_ert_rtw', 'rtwdemo_blockreduction.c');
rtwdemodbtype(cfile, '/* Model step function */', ...
 '/* Model initialize function */', 1, 0);

/* Model step function */
void rtwdemo_blockreduction_step(void)
{
 /* Outport: '<Root>/Out1' incorporates:
```

```
* Inport: '<Root>/In1'
*/
rtwdemo_blockreduction_Y.Out1 = rtwdemo_blockreduction_U.In1;
}
```

Because multiplying the input signal by a value of 1.0 does not impact computational results, the code generator excludes the Gain block from the generated code. Close the model and clean up.

```
bdclose(model)
rtwdemoclean;
cd(currentDir)
```

## Eliminate Dead Code Paths in Generated Code

This example shows how the code generator eliminates dead (that is, unused) code paths from generated code. This optimization increases execution speed and conserves ROM and RAM consumption.

### Example

In the model `rtwdemo_deadpathElim`, the signal leaving the Sum block divides into two separate code paths. The top path is not a dead code path. If the user disables the Assertion block, the bottom path becomes a dead code path.

```
model = 'rtwdemo_deadpathElim';
open_system(model);
```

### Generate Code with an Enabled Assertion Block

- 1 For the Assertion block, open the block parameters dialog box.
- 2 Select the **Enable assertion** box. Alternatively, use the command-line API to enable the Assertion block.

```
set_param([model '/Assert1'], 'Enabled', 'on');
```

Create a temporary folder for the build and inspection process.

```
currentDir = pwd;
[~,cgDir] = rtwdemodir();
```

Build the model.

```
rtwbuild(model)
```

```
Starting build procedure for model: rtwdemo_deadpathElim
```

```
Successful completion of build procedure for model: rtwdemo_deadpathElim
```

Because the Assertion block is enabled, these lines of `rtwdemo_minmax.c` include code for the Gain and Assertion blocks.

```
cfile = fullfile(cgDir, 'rtwdemo_deadpathElim_grt_rtw', 'rtwdemo_deadpathElim.c');
rtwdemodbtype(cfile, '/* Model step', '/* Model initialize function */', 0, 1);
```

```
void rtwdemo_deadpathElim_step(void)
{
 /* Sum: '<Root>/Sum1' incorporates:
 * Constant: '<Root>/Constant1'
 * Inport: '<Root>/In1'
 */
 rtwdemo_deadpathElim_Y.Out1 = rtwdemo_deadpathElim_U.In1 + 1.0;

 /* Assertion: '<Root>/Assert1' incorporates:
 * Gain: '<Root>/G1'
 */
 utAssert(2.0 * rtwdemo_deadpathElim_Y.Out1 != 0.0);
}
```

### Generate Code with a Disabled Assertion Block

Disable the Assertion block to generate a dead code path. The code generator detects the dead code path and eliminates it from the generated code.

- 1 For the Assertion block, open the Block Parameters dialog box.
- 2 Deselect the **Enable assertion** box.

Alternatively, use the command-line API to disable the Assertion block.

```
set_param([model '/Assert1'], 'Enabled', 'off');
```

Build the model.

```
rtwbuild(model)
```

```
Starting build procedure for model: rtwdemo_deadpathElim
Successful completion of build procedure for model: rtwdemo_deadpathElim
```

Because the Assertion block is disabled, these lines of `rtwdemo_minmax.c` do not include code for the Gain and Assertion blocks.

```
rtwdemoDbType(cfile, '/* Model step', '/* Model initialize function */', 0, 1);

void rtwdemo_deadpathElim_step(void)
{
 /* Outport: '<Root>/Out1' incorporates:
 * Constant: '<Root>/Constant1'
 * Inport: '<Root>/In1'
 * Sum: '<Root>/Sum1'
 */
 rtwdemo_deadpathElim_Y.Out1 = rtwdemo_deadpathElim_U.In1 + 1.0;
}
```

### Close the model and clean-up.

```
bdclose(model)
rtwdemoclean;
cd(currentDir)
```

For another example of how the code generator eliminates dead code paths in the generated code, see `rtwdemo_deadpath`.

## Floating-Point Multiplication to Handle a Net Slope Correction

This example shows how to use floating-point multiplication to handle a net slope correction. When converting floating-point data types to fixed-point data types in the generated code, a net slope correction is one method of scaling fixed-point data types. Scaling the fixed-point data types avoids overflow conditions and minimizes quantization errors.

For processors that support efficient multiplication, using floating-point multiplication to handle a net slope correction improves code efficiency. If the net slope correction has a value that is not a power of two, using division improves precision.

**Note:** This example requires a Fixed-Point Designer™ license.

### Example

In the model `rtwdemo_float_mul_for_net_slope_correction`, a Convert block converts an input signal from a floating-point data type to a fixed-point data type. The net slope correction has a value of 3.

```
model = 'rtwdemo_float_mul_for_net_slope_correction';
open_system(model);
```

Copyright 2014 The MathWorks, Inc.

### Generate Code

Create a temporary folder for the build and inspection process.

```
currentDir = pwd;
[~,cgDir] = rtwdemodir();
```

Build the model.

```
rtwbuild(model)
```

```
Starting build procedure for model: rtwdemo_float_mul_for_net_slope_correction
Successful completion of build procedure for model: rtwdemo_float_mul_for_net_slope
```

In these lines of `rtwdemo_float_mul_for_net_slope_correction.c` code, the code generator divides the input signal by 3.0F .

```
cfile = fullfile(cgDir, 'rtwdemo_float_mul_for_net_slope_correction_ert_rtw', ...
 'rtwdemo_float_mul_for_net_slope_correction.c');
rtwdemodbtype(cfile, '/* Model step', '/* Model initialize', 1, 0);
```

```
/* Model step function */
void rtwdemo_float_mul_for_net_slope_correction_step(void)
{
 /* Output: '<Root>/Output' incorporates:
 * DataTypeConversion: '<Root>/Data Type Conversion'
 * Inport: '<Root>/Input'
 */
 rtY.Output = (int16_T)(real32_T)floor((real_T)(rtU.Input / 3.0F));
}
```

### Enable Optimization

- 1 Open the Configuration Parameters dialog box.
- 2 On the **Optimization** pane, select **Use floating-point multiplication to handle net slope corrections**. This optimization is on by default.

Alternatively, you can use the command-line API to enable the optimization.

```
set_param(model, 'UseFloatMulNetSlope', 'on');
```

### Generate Code with Optimization

```
rtwbuild(model)
```

```
Starting build procedure for model: rtwdemo_float_mul_for_net_slope_correction
Successful completion of build procedure for model: rtwdemo_float_mul_for_net_slope
```

In the optimized code, the code generator multiplies the input signal by the reciprocal of 3.0F , that is 0.333333343F .

```
rtwdemodbtype(cfile, '/* Model step', '/* Model initialize', 1, 0);
```

```
/* Model step function */
void rtwdemo_float_mul_for_net_slope_correction_step(void)
{
 /* Outport: '<Root>/Output' incorporates:
 * DataTypeConversion: '<Root>/Data Type Conversion'
 * Inport: '<Root>/Input'
 */
 rtY.Output = (int16_T)(real132_T)floor((real_T)(rtU.Input * 0.333333343F));
}
```

Close the model and the code generation report.

```
bdclose(model)
rtwdemoclean;
cd(currentDir)
```

## Use Conditional Input Branch Execution

This example shows how to optimize the generated code for a model that contains Switch and Multiplex blocks. When you select the model configuration parameter **Conditional input branch execution**, Simulink executes only blocks that compute the control input and data input that the control input selects. This optimization improves execution speed.

### Example Model

In this example, switch paths are conditionally executed. If `Switch1` control input is true, `Switch1` executes blocks grouped in the `Switch1:Path1` branch. If `Switch1` control input is false, `Switch1` executes blocks grouped in the `Switch1:Path2` branch. If `Switch1` executes blocks in the `Switch1:Path2` branch and `Switch2` control input is true, `Switch2` executes blocks in the `Switch2:Path1` branch. If `Switch2` control input is false, `Switch2` executes blocks in the `Switch2:Path2` branch. The pseudo code shows this logic.

```
model='rtwdemo_condinput';
open_system(model);
```

This model shows conditional input branch execution performed by Simulink and Simulink Coder. Conditional input branch execution improves simulation and code generation execution performance. In this example, switch paths are conditionally executed. That is, if Switch1's control input is true, Switch1 executes blocks grouped in the "Switch1:Path1" branch. Otherwise, it executes blocks grouped in the "Switch1:Path2" branch. If blocks in "Switch1:Path2" are executed, Switch2 executes the "Switch2:Path1" branch if its control input is true. Otherwise, it executes the "Switch2:Path2" branch. This logic is illustrated by the pseudo code above.

Generate Code Using  
Simulink Coder  
(double-click)

Generate Code Using  
Embedded Coder  
(double-click)

Copyright 1994-2012 The MathWorks, Inc.

## Generate Code

The **Conditional input branch execution** parameter is on by default. Enter the following command-line API to turn off the parameter.

```
set_param(model, 'ConditionallyExecuteInputs', 'off');
```

Create a temporary folder for the build and inspection process.

```
currentDir=pwd;
[~,cgDir]=rtwdemodir();
```

Build the model.

```
rtwbuild(model)

Starting build procedure for model: rtwdemo_condinput
Successful completion of build procedure for model: rtwdemo_condinput
```

View the generated code without the optimization. These lines of code are in the `rtwdemo_condinput.c` file.

```
cfile = fullfile(cgDir,'rtwdemo_condinput_grt_rtw','rtwdemo_condinput.c');
rtwdemodbtype(cfile,'/* Model step', '/* Model initialize', 1, 0);
```

```
/* Model step function */
void rtwdemo_condinput_step(void)
{
 /* Switch: '<Root>/ Switch2' incorporates:
 * Constant: '<Root>/ C_10'
 * Constant: '<Root>/C_5'
 * Gain: '<Root>/ G3'
 * Inport: '<Root>/input'
 * RelationalOperator: '<Root>/Relational Operator'
 * Sum: '<Root>/ Sum'
 */
 if (rtwdemo_condinput_U.input >= -5.0) {
 rtwdemo_condinput_Y.output = 3.0 * rtwdemo_condinput_U.input;
 } else {
 rtwdemo_condinput_Y.output = rtwdemo_condinput_U.input + -10.0;
 }

 /* End of Switch: '<Root>/ Switch2' */
}
```

```

/* Switch: '<Root>/Switch1' incorporates:
 * Constant: '<Root>/C5'
 * Inport: '<Root>/input'
 * RelationalOperator: '<Root>/Relational Operator1'
 */
if (rtwdemo_condinput_U.input >= 5.0) {
/* Outport: '<Root>/output' incorporates:
 * Constant: '<Root>/ C10'
 * Sum: '<Root>/ Sum1'
 */
rtwdemo_condinput_Y.output = rtwdemo_condinput_U.input + 10.0;
}

/* End of Switch: '<Root>/Switch1' */
}

```

The generated code contains an **if-else** statement for the **Switch1** block and an **if** statement for the **Switch2** block. Therefore, the generated code for **Switch1:Path2** executes even if the **if** statement for **Switch1:Path1** evaluates to true.

### Enable Optimization

- 1 Open the Configuration Parameters dialog box.
- 2 On the **All Parameters** tab, select **Conditional input branch execution**.  
Alternatively, you can use the command-line API to enable the optimization.

```
set_param(model, 'ConditionallyExecuteInputs', 'on');
```

### Generate Code with Optimization

```

rtwbuild(model)
cfile = fullfile(cgDir, 'rtwdemo_condinput_grt_rtw', 'rtwdemo_condinput.c');
rtwdemodbtype(cfile, '/* Model step', '/* Model initialize', 1, 0);

Starting build procedure for model: rtwdemo_condinput
Successful completion of build procedure for model: rtwdemo_condinput

/* Model step function */
void rtwdemo_condinput_step(void)
{
/* Switch: '<Root>/Switch1' incorporates:
 * Constant: '<Root>/C5'
 * Constant: '<Root>/C_5'
 * Inport: '<Root>/input'

```

```

* RelationalOperator: '<Root>/Relational Operator'
* RelationalOperator: '<Root>/Relational Operator1'
* Switch: '<Root>/ Switch2'
*/
if (rtwdemo_condinput_U.input >= 5.0) {
/* Outport: '<Root>/output' incorporates:
* Constant: '<Root>/ C10'
* Sum: '<Root>/ Sum1'
*/
rtwdemo_condinput_Y.output = rtwdemo_condinput_U.input + 10.0;
} else if (rtwdemo_condinput_U.input >= -5.0) {
/* Outport: '<Root>/output' incorporates:
* Gain: '<Root>/ G3'
* Switch: '<Root>/ Switch2'
*/
rtwdemo_condinput_Y.output = 3.0 * rtwdemo_condinput_U.input;
} else {
/* Outport: '<Root>/output' incorporates:
* Constant: '<Root>/ C_10'
* Sum: '<Root>/ Sum'
* Switch: '<Root>/ Switch2'
*/
rtwdemo_condinput_Y.output = rtwdemo_condinput_U.input + -10.0;
}

/* End of Switch: '<Root>/Switch1' */
}

```

The generated code contains one `if` statement. The generated code for `Switch1:Path2` only executes if the `if` statement evaluates to false.

### Close Model and Code Generation Report

```

bdclose(model)
rtwdemoclean;
cd(currentDir)

```

## Optimize Generated Code for Complex Signals

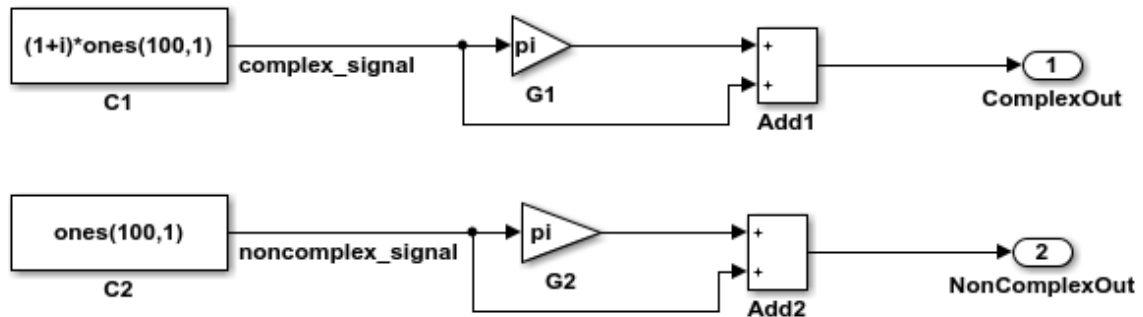

This example shows how Simulink Coder handles complex signals efficiently. To view the data types of the signals, update the model using **Simulation > Update Diagram**. Complex signals are represented as structures in generated code. Simulink Coder performs various optimizations on these structures. For example:

- Expression Folding: Gain and Sum operations on the complex signal are folded into a single expression.
- For-loop fusion: Two separate for-loops, one for the complex signal and one for noncomplex signal, are combined into a single for-loop.
- Inlined block parameters: The value of Gain block "pi" is inlined in the expression of the complex Gain-Sum.

Because of optimizations such as these, the code generated for complex and noncomplex signals is equally efficient.

### Example Model

```
model='rtwdemo_complex';
open_system(model);
```

This model shows how Simulink Coder handles complex signals efficiently. To view the data types of the signals, update the model using Simulation > Update Diagram. Complex signals are represented as structures in generated code. Simulink Coder performs various optimizations on these structures. For example,

- o Expression folding: Gain and Sum operations on the complex signal are folded into a single expression.
- o For-loop fusion: Two separate for-loops, one for the complex signal and one for the noncomplex signal, are combined into a single for-loop.
- o Inlined block parameters: The value of Gain block "pi" is inlined in the expression of the complex Gain-Sum.

Because of optimizations such as these, the code generated for complex and noncomplex signals is equally efficient.

## Speed Up Linear Algebra in Code Generated from a MATLAB Function Block

To improve the execution speed of code generated for certain linear algebra functions in a MATLAB Function block, specify that the code generator produce LAPACK calls. LAPACK is a software library for numerical linear algebra. The code generator uses the LAPACKE C interface to LAPACK. If you specify that you want to generate LAPACK calls, and the input arrays for the linear algebra functions meet certain criteria, the code generator produces the LAPACK calls. Otherwise, the code generator produces code for the linear algebra functions.

The code generator uses the LAPACK library that you specify. Specify a LAPACK library that is optimized for your execution environment. See [www.netlib.org/lapack/faq.html#\\_what\\_and\\_where\\_are\\_the\\_lapack\\_vendors\\_implementations](http://www.netlib.org/lapack/faq.html#_what_and_where_are_the_lapack_vendors_implementations).

### Specify LAPACK Library

To generate LAPACK calls, you must have access to a LAPACK callback class. A LAPACK callback class specifies the LAPACK library and LAPACKE header file for the LAPACK calls. To indicate that you want to generate LAPACK calls and that you want to use a specific LAPACK library, specify the name of the LAPACK callback class. In the Configuration Parameters dialog box, in the **Code Generation** category, on the **All Parameters** tab, set **Custom LAPACK library callback** to the name of the callback class, for example, `useMyLAPACK`.

### Write LAPACK Callback Class

To specify the locations of a particular LAPACK library and LAPACKE header file, write a LAPACK callback class. Share the callback class with others who want to use this LAPACK library for LAPACK calls in generated code.

The callback class must derive from the abstract class `coder.LAPACKCallback`. Use the following example callback class as a template.

```
classdef useMyLAPACK < coder.LAPACKCallback
 methods (Static)
 function hn = getHeaderFilename()
 hn = 'mylapacke_custom.h';
 end
 end
end
```

```

function updateBuildInfo(buildInfo, buildctx)
 buildInfo.addIncludePaths(fullfile(pwd, 'include'));
 libName = 'mylapack';
 libPath = fullfile(pwd, 'lib');
 [~, linkLibExt] = buildctx.getStdLibInfo();
 buildInfo.addLinkObjects([libName linkLibExt], libPath, ...
 '', true, true);
 buildInfo.addDefines('HAVE_LAPACK_CONFIG_H');
 buildInfo.addDefines('LAPACK_COMPLEX_STRUCTURE');
end
end
end

```

You must provide the `getHeaderFilename` and `updateBuildInfo` methods. The `getHeaderFilename` method returns the LAPACK header file name. In the example callback class, replace `mylapack_custom.h` with the name of your LAPACK header file. The `updateBuildInfo` method provides the information required for the build process to link to the LAPACK library. Use code like the code in the template to specify the location of header files and the full path name of the LAPACK library. In the example callback class, replace `mylapack` with the name of your LAPACK library.

If your compiler supports only complex data types that are represented as structures, include these lines in the `updateBuildInfo` method.

```

buildInfo.addDefines('HAVE_LAPACK_CONFIG_H');
buildInfo.addDefines('LAPACK_COMPLEX_STRUCTURE');

```

## Generate LAPACK Calls by Specifying a LAPACK Callback Class

This example shows how to generate code that calls LAPACK functions in a specific LAPACK library. For this example, assume that the LAPACK callback class `useMyLAPACK` specifies the LAPACK library that you want.

- 1 Create a Simulink model.
- 2 Add a MATLAB Function block to the model.
- 3 In the MATLAB Function block, add code that calls a linear algebra function. For example, add the function `mysvd` that calls the MATLAB function `svd`.

```

function s = mysvd(A)
 %#codegen
 s = svd(A);
end

```

- 4 Add a Constant block to the left of the MATLAB Function block. Set the value to `zeros(500)`.
- 5 Add an Outport block to the right of the MATLAB Function block.
- 6 Connect the blocks.

- 7 In the Configuration Parameters dialog box, in the **Code Generation** category, on the **All Parameters** tab, set **Custom LAPACK library callback** to `useMyLAPACK`.

The callback class must be on the MATLAB path.

- 8 Build the model.

If the input to `mysvd` is large enough, the code generator produces a LAPACK call for `svd`. Here is an example of a call to the LAPACK library function for `svd`.

```
info_t = LAPACKE_dgesvd(LAPACK_COL_MAJOR, 'N', 'N', (lapack_int)500,
 (lapack_int)500, &A[0], (lapack_int)500, &S[0], NULL, (lapack_int)1, NULL,
 (lapack_int)1, &superb[0]);
```

## Locate LAPACK Library in Execution Environment

The LAPACK library must be available in your execution environment. If your LAPACK library is shared, use environment variables or linker options to specify the location of the LAPACK library.

- On a Windows platform, modify the `PATH` environment variable.
- On a Linux platform, modify the `LD_LIBRARY_PATH` environment variable or use the `rpath` linker option.
- On a Mac OS X, modify the `DYLD_LIBRARY_PATH` environment variable or use the `rpath` linker option.

To specify the `rpath` linker option, you can use the build information `addLinkFlags` method in the `updateBuildInfo` method of your `coder.LAPACKCallback` class. For example, for a GCC compiler:

```
buildInfo.addLinkFlags(sprintf('-Wl,-rpath,"%s"', libPath));
```

## Optimize Memory Usage for Time Counters

This example shows how to optimize the amount of memory that the code generator allocates for time counters. The example optimizes the memory that stores elapsed time, the interval of time between two events.

The code generator represents time counters as unsigned integers. The word size of time counters is based on the setting of the model configuration parameter **Application lifespan (days)**, which specifies the expected maximum duration of time the application runs. You can use this parameter to prevent time counter overflows. The default size is 64 bits.

The number of bits that a time counter uses depends on the setting of the **Application lifespan (days)** parameter. For example, if a time counter increments at a rate of 1 kHz, to avoid an overflow, the counter has the following number of bits:

- Lifespan < 0.25 sec: 8 bits
- Lifespan < 1 min: 16 bits
- Lifespan < 49 days: 32 bits
- Lifespan > 50 days: 64 bits

A 64-bit time counter does not overflow for 590 million years.

### Open Example Model

Open the example model `rtwdemo_abstime`.

SS1 is clocked at 1 kHz, and contains a discrete-time integrator that requires elapsed time to compute its output. However, a counter is not required to compute elapsed time since the trigger port 'Sample time type' is set to 'periodic.' Instead, time is inlined as 1 kHz.

SS2 is clocked at 100 Hz, and contains a discrete-time integrator that requires elapsed time to compute its output. Since the application life span of the model is 1 day, a 32-bit counter is required to compute elapsed time for SS2.

SS3 is clocked at 0.5 Hz, and contains a discrete-time integrator that requires elapsed time to compute its output. Since the application life span of the model is 1 day, a 16-bit counter is required to compute elapsed time for SS3.

Simulink Coder optimizes how counters are employed to measure absolute and elapsed time:

- o Time is computed from unsigned integer counters.
- o Only tasks that require time are allocated a counter.
- o Elapsed time is computed by a subsystem if and only if a block in its hierarchy requires elapsed time.
- o Time is shared by all blocks within a triggered hierarchy.

Simulink Coder further optimizes counters based on the option "Application life span," whereby the number of bits used for a particular counter is optimized based on how long the application will run.

Did you know ...

Display Sample Time Colors (double-click)

Generate Code Using Simulink Coder (double-click)

Generate Code Using Embedded Coder (double-click)

Copyright 1994-2012 The MathWorks, Inc.

The model consists of three subsystems SS1, SS2, and SS3. On the **Optimization** tab, the **Application lifespan (days)** parameter is set to the default, which is **auto**.

The three subsystems contain a discrete-time integrator that requires elapsed time as input to compute its output value. The subsystems vary as follows:

- SS1 - Clocked at 1 kHz. Does not require a time counter. **Sample time type** parameter for trigger port is set to `periodic`. Elapsed time is inlined as 0.001.
- SS2 - Clocked at 100 Hz. Requires a time counter. Based on a lifespan of 1 day, a 32-bit counter stores the elapsed time.
- SS3 - Clocked at 0.5 Hz. Requires a time counter. Based on a lifespan of 1 day, a 16-bit counter stores the elapsed time.

### Simulate the Model

Simulate the model. By default, the model is configured to show sample times in different colors. Discrete sample times for the three subsystems appear red, green, and blue. Triggered subsystems are blue-green.

### Generate Code and Report

1. Create a temporary folder for the build and inspection process.
2. Configure the model for the code generator to use the GRT system target file and a lifespan of `inf` days.
3. Build the model.

```
Starting build procedure for model: rtwdemo_abstime
Successful completion of build procedure for model: rtwdemo_abstime
```

### Review Generated Code

Open the generated source file `rtwdemo_abstime.c`.

```
struct tag_RTM_rtwdemo_abstime_T {
 const char_T *errorStatus;

 /*
 * Timing:
 * The following substructure contains information regarding
 * the timing information for the model.
 */
 struct {
 uint32_T clockTick1;
 uint32_T clockTickH1;
 uint32_T clockTick2;
 uint32_T clockTickH2;
 struct {
```

```

 uint16_T TID[3];
 uint16_T cLimit[3];
 } TaskCounters;
} Timing;
};

```

Four 32-bit unsigned integers, `clockTick1`, `clockTickH1`, `clockTick2`, and `clockTickH2` are counters for storing the elapsed time of subsystems `SS2` and `SS3`.

### Enable Optimization and Regenerate Code

1. Reconfigure the model to set the lifespan to 1 day.
2. Build the model.

```

Starting build procedure for model: rtwdemo_abstime
Successful completion of build procedure for model: rtwdemo_abstime

```

### Review the Regenerated Code

```

struct tag_RTM_rtwdemo_abstime_T {
 const char_T *errorStatus;

 /*
 * Timing:
 * The following substructure contains information regarding
 * the timing information for the model.
 */
 struct {
 uint32_T clockTick1;
 uint16_T clockTick2;
 struct {
 uint16_T TID[3];
 uint16_T cLimit[3];
 } TaskCounters;
 } Timing;
};

```

The new setting for the **Application lifespan (days)** parameter instructs the code generator to set aside less memory for the time counters. The regenerated code includes:

- 32-bit unsigned integer, `clockTick1`, for storing the elapsed time of the task for `SS2`

- 16-bit unsigned integer, `clockTick2`, for storing the elapsed time of the task for SS3

### **Related Information**

## Minimize Memory Requirements During Code Generation

When the code generator produces code, it creates an partial representation of your model (called *model.rtw*), which the Target Language Compiler parses to transform block computations, parameters, signals, and constant data into a high-level language, (for example, C). Parameters and data are normally copied into the *model.rtw* file, whether they originate in the model itself or come from variables or objects in a workspace.

Models which have large amounts of parameter and constant data (such as lookup tables) can tax memory resources and slow down code generation because of the need to copy their data to *model.rtw*. You can improve code generation speed by limiting the size of data that is copied by using a `set_param` command, described below.

Data vectors such as those for parameters, lookup tables, and constant blocks whose sizes exceed a specified value are not copied into the *model.rtw* file. In place of the data vectors, the code generator places a special reference key in the *model.rtw* file that enables the Target Language Compiler to access the data directly from the Simulink software and format it directly into the generated code. This results in maintaining only one copy of large data vectors in memory.

You can specify the maximum number of elements that a parameter or other data source can have for the code generator to represent it literally in the *model.rtw* file. Whenever this threshold size is exceeded, the product writes a reference to the data to the *model.rtw* file, rather than its values. The default threshold value is 10 elements, which you can verify with

```
get_param(0, 'RTWDataReferencesMinSize')
```

To set the threshold to a different value, type the following `set_param` function in the MATLAB Command Window:

```
set_param(0, 'RTWDataReferencesMinSize', <size>)
```

Provide an integer value for `size` that specifies the number of data elements above which reference keys are to be used in place of actual data values.

### Related Examples

- “Increase Code Generation Speed” on page 53-7

## Optimize Generated Code Using Boolean Data for Logical Signals

Optimize generated code by storing logical signals as Boolean data. When you select the model configuration parameter **Implement logic signals as Boolean data (vs. double)**, blocks that generate logic signals output Boolean signals.

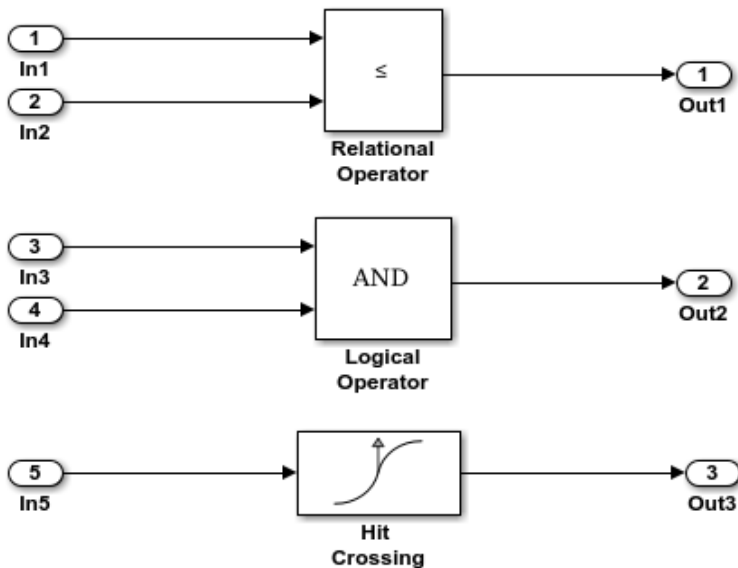

The optimization:

- Reduces the ROM and RAM consumption.
- Improves execution speed.

### Example Model

Consider the model `rtwdemo_logicalAsBoolean`. The outputs of the Relational Operator, Logical Operator and Hit Crossing blocks are double, even though they represent logical data.

```
model = 'rtwdemo_logicalAsBoolean';
open_system(model);
```

Copyright 1994-2012 The MathWorks, Inc.

## Generate Code

Create a temporary folder (in your system temporary folder) for the build and inspection process.

```
currentDir = pwd;
[~,cgDir] = rtwdemodir();
```

Build the model.

```
rtwbuild(model)

Starting build procedure for model: rtwdemo_logicalAsBoolean
Successful completion of build procedure for model: rtwdemo_logicalAsBoolean
```

View the generated code without the optimization. These lines of code are in `rtwdemo_logicalAsBoolean.h`.

```
hfile = fullfile(cgDir,'rtwdemo_logicalAsBoolean_ert_rtw',...
 'rtwdemo_logicalAsBoolean.h');
rtwdemodbtype(hfile,'/* External outputs','/* Parameters (auto storage) */',1,0);

/* External outputs (root outputs fed by signals with auto storage) */
typedef struct {
 real_T Out1; /* '<Root>/Out1' */
 real_T Out2; /* '<Root>/Out2' */
 real_T Out3; /* '<Root>/Out3' */
} ExtY_rtwdemo_logicalAsBoolean_T;
```

## Enable Optimization

- 1 Open the Configuration Parameters dialog box.
- 2 On the **All Parameters** tab, select **Implement logic signals as Boolean data (vs. double)**.

Alternatively, you can use the command-line API to enable the optimization:

```
set_param(model,'BooleanDataType','on');
```

## Generate Code with Optimization

The generated code stores the logical signal output as Boolean data.

Build the model.

```
rtwbuild(model)

Starting build procedure for model: rtwdemo_logicalAsBoolean
Successful completion of build procedure for model: rtwdemo_logicalAsBoolean

View the generated code with the optimization. These lines of code are in
rtwdemo_logicalAsBoolean.h.

rtwdemodbtype(hfile, '/* External outputs', '/* Parameters (auto storage) */', 1, 0);

/* External outputs (root outputs fed by signals with auto storage) */
typedef struct {
 boolean_T Out1; /* '<Root>/Out1' */
 boolean_T Out2; /* '<Root>/Out2' */
 boolean_T Out3; /* '<Root>/Out3' */
} ExtY_rtwdemo_logicalAsBoolean_T;
```

Close the model and code generation report.

```
bdclose(model)
rtwdemoclean;
cd(currentDir)
```

## Reduce Memory Usage for Boolean and State Configuration Variables

- 1 Open the Model Configuration Parameters dialog box.
- 2 In the Model Configuration Parameters dialog box, select the **Optimization > Stateflow** pane.
- 3 Choose from these options:
  - **Use bitsets for storing state configuration** — Reduces the amount of memory that stores state configuration variables. However, it can increase the amount of memory that stores target code if the target processor does not include instructions for manipulating bitsets.
  - **Use bitsets for storing Boolean data** — Reduces the amount of memory that stores Boolean variables. However, it can increase the amount of memory that stores target code if the target processor does not include instructions for manipulating bitsets.

---

**Note:** You cannot use bitsets when you generate code for these cases:

- An external mode simulation
  - A target that specifies an explicit structure alignment
-

## Customize Stack Space Allocation

Your application might be constrained by limited memory. Controlling the maximum allowable size for the stack is one way to modify whether data is defined as local or global in the generated code. You can limit the use of stack space by specifying a positive integer value for the “Maximum stack size (bytes)” parameter, on the **Optimization > Signals and Parameters** pane of the Configuration parameter dialog box. Specifying the maximum allowable stack size provides control over the number of local and global variables in the generated code. Specifically, lowering the maximum stack size might generate more variables into global structures. The number of local and global variables help determine the required amount of stack space for execution of the generated code.

The default setting for “Maximum stack size (bytes)” is **Inherit from target**. In this case, the value of the maximum stack size is the smaller value of the following: the default value set by the code generator (200,000 bytes) or the value of the TLC variable `MaxStackSize` found in the system target file (`ert.tlc`).

To specify a smaller stack size for your application, select the **Specify a value** option of the **Maximum stack size (bytes)** parameter and enter a positive integer value. To specify a smaller stack size at the command line, use:

```
set_param(model_name, 'MaxStackSize', 65000);
```

---

**Note:** For overall executable stack usage metrics, you might want to do a target-specific measurement, such as using runtime (empirical) analysis or static (code path) analysis with object code.

---

It is recommended that you use the **Maximum stack size (bytes)** parameter to control stack space allocation instead of modifying the TLC variable, `MaxStackSize`, in the system target file. However, a target author might want to set the TLC variable, `MaxStackSize`, for a target. To set `MaxStackSize`, use `assign` statements in the system target file (`ert.tlc`), as in the following example.

```
%assign MaxStackSize = 4096
```

Write your `%assign` statements in the **Configure RTW code generation settings** section of the system target file. The `%assign` statement is described in “Target Language Compiler”.

## **See Also**

## Optimize Generated Code Using memset Function

This example shows how to optimize the generated code by using the `memset` function to clear the internal storage. When you select the model configuration parameter **Use memset to initialize floats and doubles to 0.0**, the `memset` function clears internal storage, regardless of type, to the integer bit pattern 0 (that is, all bits are off).

If your compiler and target CPU both represent floating-point zero with the integer bit pattern 0, consider setting this parameter to gain execution and ROM efficiency.

**NOTE:** The command-line values are the reverse of the settings values. 'on' in the command line corresponds to clearing the setting. 'off' in the command line corresponds to selecting the setting.

This optimization:

- Reduces ROM consumption.
- Improves execution speed.

### Example Model

Consider the model `matlab:rtwdemo_memset`.

```
model = 'rtwdemo_memset';
open_system(model);
```

Copyright 2014 The MathWorks, Inc.

### Generate Code

The code generator uses a loop to initialize the Constant block values.

Create a temporary folder (in your system temporary folder) for the build and inspection process.

```
currentDir = pwd;
[~,cgDir] = rtwdemodir();
```

Build the model.

```
rtwbuild(model)
```

```
Starting build procedure for model: rtwdemo_memset
Successful completion of build procedure for model: rtwdemo_memset
```

View the generated code without the optimization. These lines of code are in `rtwdemo_memset.c`.

```
cfile = fullfile(cgDir, 'rtwdemo_memset_grt_rtw', 'rtwdemo_memset.c');
rtwdemodbtype(cfile, '/* Model initialize function */', ...
 '/* Model terminate function */', 1, 0);
```

```
/* Model initialize function */
void rtwdemo_memset_initialize(void)
{
 /* Registration code */

 /* initialize error status */
 rtmSetErrorStatus(rtwdemo_memset_M, (NULL));

 /* external outputs */
 {
 int32_T i;
 for (i = 0; i < 50; i++) {
 rtwdemo_memset_Y.Out1[i] = 0.0;
 }
 }

 {
 int32_T i;

 /* ConstCode for Outport: '<Root>/Out1' */
 for (i = 0; i < 50; i++) {
 rtwdemo_memset_Y.Out1[i] = 56.0;
 }

 /* End of ConstCode for Outport: '<Root>/Out1' */
 }
}
```

## Enable Optimization

- 1 Open the Configuration Parameters dialog box.
- 2 On the **All Parameters** tab, select **Use memset to initialize floats and doubles to 0.0**.

Alternatively, you can use the command-line API to enable the optimization:

```
set_param(model, 'InitFltsAndDblsToZero', 'off');
```

## Generate Code with Optimization

The code generator uses the `memset` function to initialize the Constant block values.

Build the model.

```
rtwbuild(model)
```

```
Starting build procedure for model: rtwdemo_memset
Successful completion of build procedure for model: rtwdemo_memset
```

View the generated code with the optimization. These lines of code are in `rtwdemo_memset.c`.

```
rtwdemodbtype(cfile, '/* Model initialize function */', ...
 '/* Model terminate function */', 1, 0);
```

```
/* Model initialize function */
void rtwdemo_memset_initialize(void)
{
 /* Registration code */

 /* initialize error status */
 rtmSetErrorStatus(rtwdemo_memset_M, (NULL));

 /* external outputs */
 (void) memset(&rtwdemo_memset_Y.Out1[0], 0,
 50U*sizeof(real_T));

 {
 int32_T i;

 /* ConstCode for Output: '<Root>/Out1' */
 for (i = 0; i < 50; i++) {
```

```
 rtwdemo_memset_Y.Out1[i] = 56.0;
 }

 /* End of ConstCode for Outport: '<Root>/Out1' */
}
}
```

Close the model and the code generation report.

```
bdclose(model)
rtwdemoclean;
cd(currentDir)
```

## Vector Operation Optimization

This example shows how Simulink® Coder™ optimizes generated code by setting block output that generates vectors to scalars, for blocks such as the Mux, Sum, Gain, and Bus. This optimization reduces stack memory by replacing temporary local arrays with local variables.

### Example Model

In the model, `rtwdemo_VectorOptimization`, the output of Gain blocks G1 and G2 are the vector signals `tmp1` and `tmp2`. These vectors have a width of 10.

```
model = 'rtwdemo_VectorOptimization';
open_system(model);
set_param(model, 'SimulationCommand', 'update')
```

Copyright 2014 The MathWorks, Inc.

### Generate Code

Create a temporary folder (in your system temporary folder) for the build and inspection process.

```
currentDir = pwd;
[~,cgDir] = rtwmoddir();
```

Build the model.

```
rtwbuild(model)
```

```
Starting build procedure for model: rtwdemo_VectorOptimization
Successful completion of build procedure for model: rtwdemo_VectorOptimization
```

The optimized code is in `rtwdemo_VectorOptimization.c`. The signals `tmp1` and `tmp2` are the local variables `rtb_tmp1` and `rtb_tmp2`.

```
cfile = fullfile(cgDir, 'rtwdemo_VectorOptimization_grt_rtw', ...
 'rtwdemo_VectorOptimization.c');
rtwdemodbtype(cfile, '/* Model step', '/* Model initialize', 1, 0);

/* Model step function */
void rtwdemo_VectorOptimization_step(void)
{
 int32_T i;
 real_T rtb_tmp2;
 real_T rtb_tmp1;
 real_T rtb_Sum3;
 for (i = 0; i < 10; i++) {
 /* Gain: '<Root>/G2' incorporates:
 * UnitDelay: '<Root>/X2'
 */
 rtb_tmp2 = 0.3 * rtwdemo_VectorOptimization_DW.X2_DSTATE[i];

 /* Gain: '<Root>/G1' incorporates:
 * UnitDelay: '<Root>/X1'
 */
 rtb_tmp1 = 0.2 * rtwdemo_VectorOptimization_DW.X1_DSTATE[i];

 /* Sum: '<Root>/Sum3' incorporates:
 * Gain: '<Root>/G3'
 * Inport: '<Root>/In2'
 * Sum: '<Root>/Sum1'
 * Sum: '<Root>/Sum2'
 * UnitDelay: '<Root>/X3'
 */
 rtb_Sum3 = ((rtwdemo_VectorOptimization_U.In2[i] - 0.4 *
 rtwdemo_VectorOptimization_DW.X3_DSTATE[i]) - rtb_tmp2) -
 rtb_tmp1;

 /* Output: '<Root>/Out2' */
 rtwdemo_VectorOptimization_Y.Out2[i] = rtb_Sum3;

 /* Update for UnitDelay: '<Root>/X3' */
 rtwdemo_VectorOptimization_DW.X3_DSTATE[i] = rtb_tmp2;
 }
}
```

```
/* Update for UnitDelay: '<Root>/X2' */
rtwdemo_VectorOptimization_DW.X2_DSTATE[i] = rtb_tmp1;

/* Update for UnitDelay: '<Root>/X1' */
rtwdemo_VectorOptimization_DW.X1_DSTATE[i] = rtb_Sum3;
}
}
```

Close the model and code generation report.

```
bdclose(model)
rtwdemoclean;
cd(currentDir)
```

## Enable and Reuse Local Block Outputs in Generated Code

### In this section...

“Example Model” on page 53-102

“Generate Code Without Optimization” on page 53-103

“Enable Local Block Outputs and Generate Code” on page 53-103

“Reuse Local Block Outputs and Generate Code” on page 53-104

This example shows how to specify block output as local variables. The code generator can potentially reuse these local variables in the generated code. Declaring block output as local variables conserves ROM consumption. Reusing local variables conserves RAM consumption and increases execution speed.

### Example Model

- 1 Use Inport, Outport, Gain, and Switch blocks to create the following model. In this example, the model is named `local_variable_ex`.

- 2 For G2, open the Gain Block Parameters dialog box. Enter a value of 2.
- 3 For G1, enter a value of 3.
- 4 For the Switch block, open the Block Parameters dialog box. For the **Criteria for passing first input** parameter, select `u2>=Threshold`.

## Generate Code Without Optimization

- 1 Open the Model Configuration Parameters dialog box. Select the **Solver** pane. For the **Type** parameter, select **Fixed-step**.
- 2 Select the **All Parameters** tab and clear **Signal Storage Reuse**.
- 3 Select the **Code Generation > Report** pane and select **Create code generation report**.
- 4 Select the **Code Generation** pane. Select **Generate code only**, and then, in the model window, press **Ctrl+B**. When code generation is complete, an HTML code generation report appears.
- 5 In the code generation report, select the `local_variable_ex.c` section and view the model step function. The Gain block outputs are the global variables `local_variable_ex_B.G2` and `local_variable_ex_B.G1`.

```

/* Model step function */
void local_variable_ex_step(void)
{
 /* Switch: '<Root>/Switch' incorporates:
 * Inport: '<Root>/In1'
 */
 if (local_variable_ex_U.In1 >= 0.0) {
 /* Gain: '<Root>/G2' */
 local_variable_ex_B.G2 = 2.0 * local_variable_ex_U.In1;

 /* Output: '<Root>/Out1' */
 local_variable_ex_Y.Out1 = local_variable_ex_B.G2;
 } else {
 /* Gain: '<Root>/G1' */
 local_variable_ex_B.G1 = 3.0 * local_variable_ex_U.In1;

 /* Output: '<Root>/Out1' */
 local_variable_ex_Y.Out1 = local_variable_ex_B.G1;
 }

 /* End of Switch: '<Root>/Switch' */
}

```

## Enable Local Block Outputs and Generate Code

- 1 Open the Model Configuration Parameters dialog box. On the **All Parameters** tab, select **Signal Storage Reuse**. **Signal Storage Reuse** enables the following optimization parameters:

- **Enable local block outputs**
  - **Reuse local block outputs**
  - **Eliminate superfluous local variables (expression folding)**
- 2 Clear **Reuse local block outputs** and **Eliminate superfluous local variables (expression folding)**.
  - 3 Generate code and view the model step function. There are three local variables in the model step function because you selected the optimization parameter **Enable Local Block Outputs**. The local variables `rtb_G2` and `rtb_G1` hold the outputs of the Gain blocks. The local variable `rtb_Switch` holds the output of the Switch block.

```

/* Model step function */
void local_variable_ex_step(void)
{
 real_T rtb_Switch;
 real_T rtb_G2;
 real_T rtb_G1;

 /* Switch: '<Root>/Switch' incorporates:
 * Inport: '<Root>/In1'
 */
 if (local_variable_ex_U.In1 >= 0.0) {
 /* Gain: '<Root>/G2' */
 rtb_G2 = 2.0 * local_variable_ex_U.In1;
 rtb_Switch = rtb_G2;
 } else {
 /* Gain: '<Root>/G1' */
 rtb_G1 = 3.0 * local_variable_ex_U.In1;
 rtb_Switch = rtb_G1;
 }

 /* End of Switch: '<Root>/Switch' */

 /* Output: '<Root>/Out1' */
 local_variable_ex_Y.Out1 = rtb_Switch;
}

```

## Reuse Local Block Outputs and Generate Code

- 1 Open the Model Configuration Parameters dialog box. On the **Optimization > Signals and Parameters** pane, select **Reuse local block outputs**.

- 2 Generate code. In the `local_variable_ex.c` section, view the model step function. There is one local variable, `rtb_G2`, that the code generator uses three times.

```
/* Model step function */
void local_variable_ex_step(void)
{
 real_T rtb_G2;

 /* Switch: '<Root>/Switch' incorporates:
 * Inport: '<Root>/In1'
 */
 if (local_variable_ex_U.In1 >= 0.0) {
 /* Gain: '<Root>/G2' */
 rtb_G2 = 2.0 * local_variable_ex_U.In1;
 } else {
 /* Gain: '<Root>/G1' */
 rtb_G2 = 3.0 * local_variable_ex_U.In1;
 }

 /* End of Switch: '<Root>/Switch' */

 /* Output: '<Root>/Out1' */
 local_variable_ex_Y.Out1 = rtb_G2;
}
```

## Configure Code Optimizations

Several parameters available on the **Optimization** panes configure your model to optimize code generation. The following table includes parameters on the **Optimization > General** pane:

To...	Select or Specify...
Remove initialization code for root-level inports and outports with a value of zero.	Select “Remove root level I/O zero initialization”.
Suppress the generation of code that initializes internal work structures (for example, block states and block outputs) to zero.	Select “Remove internal data zero initialization”.
Remove wrapping code that handles out-of-range floating-point to integer conversion results.	Select “Remove code from floating-point to integer conversions that wraps out-of-range values”. This reduces the size and increases the speed of the generated code at the cost of potentially producing results that do not match simulation in the case of out-of-range values.
Suppress generation of code that guards against fixed-point division by zero.	Select “Remove code that protects against division arithmetic exceptions”. When you select this parameter, simulation results and results from generated code may not be in bit-for-bit agreement.
To minimize the amount of memory allocated for absolute and elapsed time counters.	Specify an integer value for “Application lifespan (days)”. For more information on the allocation and operation of absolute and elapsed timers, see “Absolute and Elapsed Time Computation”, “Timers in Asynchronous Tasks”, and “Control Memory Allocation for Time Counters” in the Simulink Coder documentation.

The following table includes optimization parameters on the **Optimization > Signals and Parameters** pane:

To...	Select or Specify...
Control whether parameter data for reusable subsystems is generated in a	Select <b>Hierarchical</b> or <b>NonHierarchical</b> for “Parameter structure”.

To...	Select or Specify...
separate header file for each subsystem or in a single parameter data structure	
Store Boolean signals as one-bit bitfields instead of as a Boolean data type	Select “Pack Boolean data into bitfields”. Selecting this parameter enables the “Bitfield declarator type specifier”. To optimize your code further, select <code>uchar_T</code> , however this optimization benefit is dependent on your choice of target.
Pass each reusable subsystem output argument as an address of a local to reduce global memory usage and eliminate copying local variables back to global block I/O structures	Select <b>Individual arguments</b> for “Pass reusable subsystem outputs as”.

The following table includes optimization parameters on the **All Parameters** tab:

To	Select or Specify...
Generate additional code to set float and double storage explicitly to value <code>0.0</code> .	Select “Use <code>memset</code> to initialize floats and doubles to <code>0.0</code> ”. When you set this parameter, the <code>memset</code> function clears internal storage, regardless of type, to the integer bit pattern <code>0</code> (that is, all bits are off).  If your compiler and target CPU both represent floating-point zero with the integer bit pattern <code>0</code> , consider selecting this parameter to gain execution and ROM efficiency.
Replace multiply operations in array indices when accessing arrays in a loop	Select “Simplify array indexing”.

## Related Examples

- “Optimization Tools and Techniques” on page 53-13
- “Optimization Parameters for Code Generation” on page 53-3
- “Increase Code Generation Speed” on page 53-7

## Specify Global Variable Localization

When you generate code for a model, the code generator can optimize variable references by replacing global variables with local variables. Replacing global variables with local variables improves execution speed and reduces RAM/ROM. Creating more local variables can increase stack usage.

Some of the global variables that the code generator can localize include:

- Global signals that cross subsystem boundaries.
- Global signals across Simulink and Stateflow domains.
- Unused global state variables.
- Redundant local Data Store Memory block signals.

To enable the global variable localization analysis:

- 1 In the Configuration Parameters dialog box, on the **Code Generation** pane, in the **System target file** box, specify an ERT target.
- 2 Verify that the `OptimizeBlockIOStorage` parameter is set to 'on':

```
>> get_param(gcs, 'OptimizeBlockIOStorage')
ans =
 on
```

- 3 Verify that `AdvancedOptControl` is not set to '-SLCI':

```
>> get_param(gcs, 'AdvancedOptControl')
ans =
 ''
```

- 4 Set the storage class for signals to `Auto`.

The code generator does not localize global variables for MATLAB system objects or AUTOSAR.

## Set Hardware Implementation Parameters

Specification of target hardware device characteristics (such as word sizes for `char`, `short`, `int`, and `long` data types, or desired rounding behaviors in integer operations) for generated code can be critical in embedded systems development. The **Hardware Implementation** category of parameters in a configuration set provides a way to control such characteristics in simulation and code generation.

By configuring the **Hardware Implementation** parameters of the active configuration set for a model to match the behaviors of your compiler and hardware, you can generate more efficient code. For example, if you specify the **Byte ordering** parameter, you can avoid generation of extra code that tests the byte ordering of the target CPU.

Before generating and deploying code, get familiar with the **Hardware Implementation** pane of the Configuration Parameters dialog box. By default, target hardware microprocessor device details are hidden. To view the details, click the **Device details** arrow. See “Hardware Implementation Pane” in the Simulink documentation and “Platform Options for Development and Deployment” in the Simulink Coder documentation for more information.

You can use the example “Configure Target Hardware Characteristics” to determine characteristics of your C or C++ compiler and target hardware. By using the example model with your target development system and debugger, you can observe the behavior of the code as it executes on the target hardware. You can then use the information to refine hardware target device parameters for your model.

## Use External Mode with the ERT Target

Selecting the **External mode** option turns on generation of code to support external mode communication between host (Simulink) and target systems. The Embedded Coder software supports Simulink external mode simulation, as described in the Simulink Coder topic “Set Up and Use Host/Target Communication Channel”.

This section discusses external mode options that may be of special interest to embedded systems designers. The next figure shows the **External mode configuration** subpane of the Configuration Parameters dialog box, **Code Generation > Interface** pane, with **External mode** selected.

The screenshot shows the 'External mode configuration' subpane. It includes a checked checkbox for 'External mode'. Below it, the 'Transport layer' is set to 'tcpip' in a dropdown menu, and the 'MEX-file name' is 'ext\_comm'. There is an empty text field for 'MEX-file arguments'. At the bottom, the 'Static memory allocation' checkbox is unchecked.

### Memory Management

Consider the memory management option **Static memory allocation** before generating external mode code for an embedded target. Static memory allocation is generally desirable, as it reduces overhead and promotes deterministic performance.

When you select the **Static memory allocation** option, static external mode communication buffers are allocated in the target application. When **Static memory allocation** is deselected, communication buffers are allocated dynamically (with `malloc`) at run time.

## Generation of Pure Integer Code with External Mode

The Embedded Coder software supports generation of pure integer code when external mode code is generated. To do this, select the **External mode** option and deselect the **Support: floating-point numbers** option on the **Code Generation > Interface** pane.

This selection lets you generate external mode code that is free of storage definitions of double or float data type, and allows your code to run on integer-only processors.

If you intend to generate pure integer code with **External mode** on, note the following requirements:

- All trigger signals must be of data type `int32`. Use a Data Type Conversion block if needed.
- When pure integer code is generated, the simulation stop time specified in the **Solver** options is ignored. To specify a stop time, run your target application from the MATLAB command line and use the `-tf` option. (See “Run the External Program” in the Simulink Coder documentation.) If you do not specify this option, the application executes indefinitely (as if the stop time were `inf`).

When executing pure integer target applications, the stop time specified by the `-tf` command line option is interpreted as the number of base rate ticks to execute, rather than as an elapsed time in seconds. The number of ticks is computed as

```
stop time in seconds / base rate step size in seconds
```

## Optimize Global Variable Usage

In this section...
“Minimize Global Data Access” on page 55-2
“Use Global to Hold Temporary Results” on page 55-8

To tune your application and choose tradeoffs for execution speed and memory usage, you can choose a global variable reference optimization for the generated code.

In the Configuration Parameters dialog box, on the **All Parameters** tab, in the **Optimize global data access** drop-down list, three parameter options control global variable usage optimizations.

- **None.** Use default optimizations. This choice works well for most models. The code generator balances the use of local and global variables. It generates code which balances RAM and ROM consumption and execution speed.
- **Use global to hold temporary results.** Reusing global variables improves code efficiency and readability. This optimization reuses global variables, which results in the code generator defining fewer variables. It reduces RAM and ROM consumption and data copies.
- **Minimize global data access.** Using local variables to cache global data reduces ROM consumption by reducing code size in certain cases, such as when the global variables are scalars. This optimization improves execution speed because the code uses fewer instructions for local variable references than for global variable references.

Minimizing the use of global variables by using local variables interacts with stack usage control. For example, stack size can determine the number of local and global variables that the code generator can allocate in the generated code. For more information, see “Customize Stack Space Allocation”.

### Minimize Global Data Access

Generate optimized code that reads from and writes to global variables less frequently.

#### Example Model

In the model `matlab:rtwdemo_optimize_global`, five signals feed into a Multiport Switch block.

```
model = 'rtwdemo_optimize_global';
load_system('rtwdemo_optimize_global')
```

### Generate Code without Optimization

- 1 In the Configuration Parameters dialog box, on the **All Parameters** tab, verify that the **Signal storage reuse** parameter is selected.
- 2 In the Configuration Parameters dialog box, on the **All Parameters** tab, for the **Optimize global access** parameter, select **NONE** or enter the following command in the MATLAB Command Window:

```
set_param('rtwdemo_optimize_global','GlobalVariableUsage','None');
```

In your system's temporary folder, create a folder for the build and inspection process.

```
currentDir = pwd;
```

```
[~,cgDir] = rtwdemodir();
```

Build the model.

```
rtwbuild(model);
```

```
Starting build procedure for model: rtwdemo_optimize_global
```

```
Successful completion of build procedure for model: rtwdemo_optimize_global
```

View the generated code without the optimization. Here is a portion of `rtwdemo_optimize_global.c`.

```
cfile = fullfile(cgDir,'rtwdemo_optimize_global_ert_rtw',...
 'rtwdemo_optimize_global.c');
rtwdemodbtype(cfile,'/* Model step','/* Model initialize',1, 0);
```

```
/* Model step function */
void rtwdemo_optimize_global_step(void)
{
 /* MultiPortSwitch: '<Root>/Multiport Switch' incorporates:
 * Inport: '<Root>/In1'
 */
 switch ((int32_T)rtU.In1) {
 case 1:
 /* Outport: '<Root>/Out1' incorporates:
 * Constant: '<Root>/Constant'
 */
 rtY.Out1 = 1.0;
 break;

 case 2:
 /* Outport: '<Root>/Out1' incorporates:
 * Constant: '<Root>/Constant1'
 */
 rtY.Out1 = 2.0;
 break;

 case 3:
 /* Outport: '<Root>/Out1' incorporates:
 * Constant: '<Root>/Constant2'
 */
 rtY.Out1 = 3.0;
 break;
```

```

default:
 /* Outport: '<Root>/Out1' incorporates:
 * Constant: '<Root>/Constant3'
 */
 rtY.Out1 = 4.0;
 break;
}

/* End of MultiPortSwitch: '<Root>/Multiport Switch' */
}

```

In the Static Code Metrics Report, examine the **Global Variables** section.

- 1 In the Code Generation Report window, select **Static Code Metrics Report**.
- 2 Scroll down to the **Global Variables** section.
- 3 Select the **[+]** sign before each variable to expand it.

Global variables defined in the generated code.

Global Variable	Size (bytes)	Reads / Writes	Reads / Writes in a Function
<b>[ - ]</b> <a href="#">rtU</a>	8	1	1
In1	8	1	1
<b>[ - ]</b> <a href="#">rtY</a>	8	4	4
Out1	8	4	4
<b>[ - ]</b> <a href="#">rtM</a>	4	0 <sup>+</sup>	0 <sup>+</sup>
errorStatus	4	0	0
<b>Total</b>	<b>20</b>	<b>5</b>	

<sup>+</sup> The global variable is not directly used in any function.

The total number of reads and writes for global variables is 5.

### Enable Optimization and Generate Code

On the **All Parameters** tab, for the **Optimize global data access** parameter, select **Minimize global data access** or enter the following command in the MATLAB Command Window:

```
set_param('rtwdemo_optimize_global',...
```

```
'GlobalVariableUsage','Minimize global data access');
```

Build the model.

```
rtwbuild(model);
```

```
Starting build procedure for model: rtwdemo_optimize_global
Successful completion of build procedure for model: rtwdemo_optimize_global
```

View the generated code with the optimization. Here is a portion of `rtwdemo_optimize_global.c`.

```
cfile = fullfile(cgDir,'rtwdemo_optimize_global_ert_rtw',...
 'rtwdemo_optimize_global.c');
rtwdemodbtype(cfile,'/* Model step','/* Model initialize',1, 0);
```

```
/* Model step function */
void rtwdemo_optimize_global_step(void)
{
 real_T tmp_Out1;

 /* MultiPortSwitch: '<Root>/Multiport Switch' incorporates:
 * Inport: '<Root>/In1'
 */
 switch ((int32_T)rtU.In1) {
 case 1:
 /* Outport: '<Root>/Out1' incorporates:
 * Constant: '<Root>/Constant'
 */
 tmp_Out1 = 1.0;
 break;

 case 2:
 /* Outport: '<Root>/Out1' incorporates:
 * Constant: '<Root>/Constant1'
 */
 tmp_Out1 = 2.0;
 break;

 case 3:
 /* Outport: '<Root>/Out1' incorporates:
 * Constant: '<Root>/Constant2'
 */
 tmp_Out1 = 3.0;
```

```

 break;

 default:
 /* Outport: '<Root>/Out1' incorporates:
 * Constant: '<Root>/Constant3'
 */
 tmp_Out1 = 4.0;
 break;
 }

 /* End of MultiPortSwitch: '<Root>/Multiport Switch' */

 /* Outport: '<Root>/Out1' */
 rtY.Out1 = tmp_Out1;
}

```

In `rtwdemo_optimize_global.c`, the code assigns a constant value to the local variable `tmp_Out1` in each case statement. The last statement in the code copies the value of `tmp_Out1` to the global variable `rtY.Out1`. Fewer global variable references result in fewer instructions and improved execution speed.

In the **Static Code Metrics Report**, examine the **Global Variables** section. As a result of minimizing global data accesses, the total number of reads and writes for global variables has decreased from 5 to 2.

Global variables defined in the generated code.

Global Variable	Size (bytes)	Reads / Writes	Reads / Writes in a Function
[ - ] <a href="#">rtU</a>	8	1	1
In1	8	1	1
[ - ] <a href="#">rtY</a>	8	1	1
Out1	8	1	1
[ - ] <a href="#">rtM_</a>	4	0*	0*
errorStatus	4	0	0
<b>Total</b>	<b>20</b>	<b>2</b>	

\* The global variable is not directly used in any function.

Close the code generation report.

```
rtwdemoclean;
```

```
cd(currentDir)
```

## Use Global to Hold Temporary Results

The code generator uses global and local variables when you select **None** versus when you select **Use global** to hold temporary results.

### Example Model

In the model `matlab:rtwdemo_optimize_global_ebf`, an Assignment block assigns values coming from the Inport and Constant blocks to an output signal. The output signal feeds into a Gain block.

```
model = 'rtwdemo_optimize_global_ebf';
load_system('rtwdemo_optimize_global_ebf')
```

### Generate Code without Optimization

- 1 In the Configuration Parameters dialog box, on the All Parameters tab, verify that the **Signal storage reuse** parameter is selected.
- 2 In the Configuration Parameters dialog box, for the **Optimize global access parameter**, select **None** or enter the following command in the MATLAB Command Window:

```
set_param('rtwdemo_optimize_global_ebf', 'GlobalVariableUsage', 'None');
```

In your system's temporary folder, create a folder for the build and inspection process:

```
currentDir = pwd;
[~,cgDir] = rtwdemodir();
```

Build the model.

```
rtwbuild(model);

Starting build procedure for model: rtwdemo_optimize_global_ebf
Successful completion of build procedure for model: rtwdemo_optimize_global_ebf
```

View the generated code without the optimization. Here is a portion of `rtwdemo_optimize_global_ebf.c`.

```
cfile = fullfile(cgDir,'rtwdemo_optimize_global_ebf_ert_rtw',...
 'rtwdemo_optimize_global_ebf.c');
rtwdemodbtype(cfile,'/* Model step','/* Model initialize',1, 0);

/* Model step function */
void rtwdemo_optimize_global_ebf_step(void)
{
 real_T rtb_Assignment[5];
 int32_T i;

 /* Assignment: '<Root>/Assignment' incorporates:
 * Constant: '<Root>/Constant'
 * Inport: '<Root>/In1'
 */
 for (i = 0; i < 5; i++) {
 rtb_Assignment[i] = rtCP_Constant_Value[i];
 }

 rtb_Assignment[1] = rtU.In1;

 /* End of Assignment: '<Root>/Assignment' */

 /* Outport: '<Root>/Out1' incorporates:
 * Gain: '<Root>/Gain'
 */
 for (i = 0; i < 5; i++) {
 rtY.Out1[i] = 2.0 * rtb_Assignment[i];
 }

 /* End of Outport: '<Root>/Out1' */
}
```

The code assigns values to the local vector `rtb_Assignment`. The last statement copies the values in the local vector `rtb_Assignment` to the global vector `rtY.Out1`. Fewer global variable references result in improved execution speed. The code uses more instructions for global variable references than for local variable references.

In the Static Code Metrics Report, examine the Global Variables section.

- 1 In the Code Generation Report window, select **Static Code Metrics Report**.
- 2 Scroll down to the **Global Variables** section.
- 3 Select the **[+]** sign before each variable to expand it.

Global Variable	Size (bytes)	Reads / Writes	Reads / Writes in a Function
[-] <a href="#">rtY</a>	40	1	1
Out1	40	1	1
[-] <a href="#">rtU</a>	8	1	1
In1	8	1	1
[-] <a href="#">rtM_</a>	4	0*	0*
errorStatus	4	0	0
<b>Total</b>	<b>52</b>	<b>2</b>	

\* The global variable is not directly used in any function.

The total number of reads and writes for global variables is 2.

### Generate Code with Optimization

In the Configuration Parameters dialog box, for the **Optimize global access parameter**, select **Use global** to hold temporary results, or enter the following command in the MATLAB Command Window:

```
set_param('rtwdemo_optimize_global_ebf',...
 'GlobalVariableUsage','Use global to hold temporary results');
```

Build the model.

```
rtwbuild(model);
```

```
Starting build procedure for model: rtwdemo_optimize_global_ebf
Successful completion of build procedure for model: rtwdemo_optimize_global_ebf
```

View the generated code with the optimization. Here is a portion of `rtwdemo_optimize_global_ebf.c`.

```
cfile = fullfile(cgDir,'rtwdemo_optimize_global_ebf_ert_rtw',...
```

```
'rtwdemo_optimize_global_ebf.c');
rtwdemodbtype(cfile, '/* Model step', '/* Model initialize', 1, 0);

/* Model step function */
void rtwdemo_optimize_global_ebf_step(void)
{
 int32_T i;

 /* Assignment: '<Root>/Assignment' incorporates:
 * Constant: '<Root>/Constant'
 * Inport: '<Root>/In1'
 */
 for (i = 0; i < 5; i++) {
 rtY.Out1[i] = rtCP_Constant_Value[i];
 }

 rtY.Out1[1] = rtU.In1;

 /* End of Assignment: '<Root>/Assignment' */

 /* Output: '<Root>/Out1' incorporates:
 * Gain: '<Root>/Gain'
 */
 for (i = 0; i < 5; i++) {
 rtY.Out1[i] *= 2.0;
 }

 /* End of Output: '<Root>/Out1' */
}
```

The code assigns values to the global vector `rtY.Out1` without using a local variable. This assignment improves ROM and RAM consumption and reduces data copies. The code places the value in the destination variable for each assignment instead of copying the value at the end. In the Static Code Metrics Report, examine the Global Variables section.

Global Variable	Size (bytes)	Reads / Writes	Reads / Writes in a Function
[–] <a href="#">rtY</a>	40	4	4
Out1	40	4	4
[–] <a href="#">rtU</a>	8	1	1
In1	8	1	1
[–] <a href="#">rtM_</a>	4	0*	0*
errorStatus	4	0	0
<b>Total</b>	<b>52</b>	<b>5</b>	

\* The global variable is not directly used in any function.

As a result of using global variables to hold local results, the total number of reads and writes for global variables has increased from 2 to 5. This optimization reduces data copies by reusing global variables.

Close the code generation report.

```
rtwdemoclean;
cd(currentDir)
```

- “Customize Stack Space Allocation” on page 53-93
- “Reuse Global Block Outputs in the Generated Code” on page 55-13

## Reuse Global Block Outputs in the Generated Code

Reduce ROM and RAM consumption and data copies and increase execution speed of generated code. Configure the code generator to reuse global variables by selecting the model configuration parameter **Reuse global block outputs**.

### Example

In the Command Window, type `rtwdemo_reuse_global`.

### Generate Code without Optimization

- 1 In the Configuration Parameters dialog box, on the **All Parameters** tab, verify that **Signal storage reuse** is selected.
- 2 Clear **Reuse global block outputs** and click **Apply**.
- 3 On the **Code Generation > Report** pane, select **Static code metrics**.
- 4 In your system's temporary folder, create a folder for the build and inspection process.

Press **Ctrl+B** to generate code.

```
Starting build procedure for model: rtwdemo_reuse_global
```

```
Successful completion of build procedure for model: rtwdemo_reuse_global
```

View the generated code without the optimization. Here is a portion of `rtwdemo_reuse_global.c`.

```
/* Model step function */
void rtwdemo_reuse_global_step(void)
{
 /* Sum: '<Root>/Sum' incorporates:
 * Inport: '<Root>/In1'
 */
 rtDW.Delay_DSTATE += rtU.In1;

 /* Outport: '<Root>/Out1' */
 rtY.Out1 = rtDW.Delay_DSTATE;
}
```

The generated code contains a data copy to the global variable `rtDW.Delay_DSTATE`. Open the Static Code Metrics Report. The total number of reads and writes for global variables is 8. The total size is 32 bytes.

### Enable Optimization and Generate Code

- 1 On the **All Parameters** tab, select **Reuse global block outputs** and click **Apply**.
- 2 Generate code.
- 3 View the generated code with the optimization. Here is a portion of `rtwdemo_reuse_global.c`.

```
Starting build procedure for model: rtwdemo_reuse_global
Successful completion of build procedure for model: rtwdemo_reuse_global

/* Model step function */
void rtwdemo_reuse_global_step(void)
{
 /* Sum: '<Root>/Sum' incorporates:
 * Inport: '<Root>/In1'
 */
 rtY.Out1 += rtU.In1;
}
```

The code generator eliminates a data copy, reduces two statements to one statement and three global variables to two global variables.

Open the Static Code Metrics Report. For global variables, this optimization reduces the total number of reads and writes for global variables from 8 to 5 and the total size from 32 bytes to 24 bytes.

## See Also

## Virtualized Output Ports Optimization

The *virtualized output ports* optimization lets you store the signal entering the root output port as a global variable. Clearing the **MAT-file logging** option and setting the TLC variable `FullRootOutputVector` to 0, both defaults for Embedded Coder, eliminate code and data storage associated with root output ports.

Consider the model in the following block diagram. The signal `exportedSig` has `exportedGlobal` storage class.

In the default case, the output of the Gain block is written to the signal storage location, `exportedSig`. The code generator does not generate code or data for the `Out1` block, which has become a virtual block.

```
/* Gain Block: <Root>/Gain */
exportedSig = rtb_PulseGen * VirtOutPortLogOFF_P.Gain_Gain;
```

In cases where you enable **MAT-file logging** or set `FullRootOutputVector = 1`, the generated code represents root output ports as members of an external outputs vector.

The following code fragment was generated with **MAT-file logging** enabled. The output port is represented as a member of the external outputs vector `VirtOutPortLogON_Y`. The Gain block output value is copied to `exportedSig` and to the external outputs vector.

```
/* Gain Block: <Root>/Gain */
exportedSig = rtb_PulseGen * VirtOutPortLogON_P.Gain_Gain;

/* Output Block: <Root>/Out1 */
VirtOutPortLogON_Y.Out1 = exportedSig;
```

Data maintenance in the external outputs vector can be significant for smaller models that perform benchmarks.

You can force root output ports to be stored in the external outputs vector (regardless of the setting of **MAT-file logging**) by setting the TLC variable `FullRootOutputVector` to 1. Add the statement

```
%assign FullRootOutputVector = 1
```

to the Embedded Coder system target file. Alternatively, you can enter the assignment from the MATLAB command line using the `set_param` command, the model parameter `TLCOptions`, and the TLC option `-a`. For more information, see “Specify TLC Options” and “Configure TLC”.

For more information on how to control signal storage in generated code, see “Signal Representation in Generated Code”.

## Related Examples

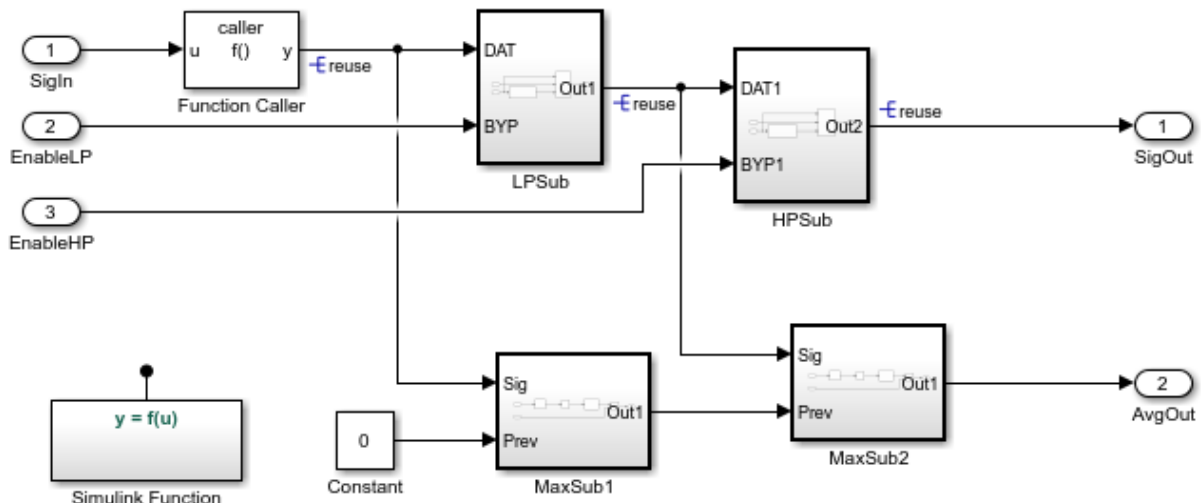

- “Optimization Tools and Techniques” on page 53-13
- “Specify Buffer Reuse for Multiple Signals in a Path” on page 55-18
- “Optimize Global Variable Usage” on page 55-2

## Specify Buffer Reuse for Multiple Signals in a Path

Use a Simulink signal object to specify buffer reuse for multiple signals in a path. The path can include a pair of root inport and outport signals. This optimization reduces ROM and RAM consumption because there are less global variables and data copies in the generated code. Code execution speed also increases.

### Example Model

The model `rtwdemo_reusable_csc_scheduling` contains the nonreusable subsystems `LPSub` and `HPSub` and the reusable subsystems `MaxSub1` and `MaxSub2`.

Copyright 2016 The MathWorks, Inc.

### Specify a Simulink Signal Object for Reuse

- 1 Open the base workspace. The Simulink signal object `reuse` is for specifying which buffers to reuse in the generated code. To use a Simulink signal object for buffer reuse, the object must have a **Storage class** of `Reusable (Custom)`.
- 2 Right-click one of the signal lines that has the signal name `reuse`.
- 3 Specify a name for the **Signal name** parameter and select the checkbox **Signal name must resolve to Simulink signal object**.

## Generate Code

Build the model.

```
Starting build procedure for model: rtwdemo_reusable_csc_scheduling
Successful completion of build procedure for model: rtwdemo_reusable_csc_scheduling
```

The `rtwdemo_reusable_csc_rescheduling.c` file contains this global variable for buffer reuse.

```
/* Definition for custom storage class: Reusable */
```

```
real_T reuse[256];
```

The `rtwdemo_reusable_csc_scheduling_step` function contains this code.

```
/* Model step function */
void rtwdemo_reusable_csc_scheduling_step(void)
{
 real_T rtb_MinMax_d[256];

 /* FunctionCaller: '<Root>/Function Caller' incorporates:
 * Inport: '<Root>/SigIn'
 */
 f(rtu.SigIn, reuse_1);

 /* Outputs for Atomic SubSystem: '<Root>/MaxSub1' */

 /* Constant: '<Root>/Constant' */
 MaxSub1(reuse_1, 0.0, rtb_MinMax_d);

 /* End of Outputs for SubSystem: '<Root>/MaxSub1' */

 /* Outputs for Atomic SubSystem: '<Root>/LPSub' */
 LPSub();

 /* End of Outputs for SubSystem: '<Root>/LPSub' */

 /* Outputs for Atomic SubSystem: '<Root>/MaxSub2' */
 MaxSub2(reuse_0, rtb_MinMax_d, rtY.AvgOut);

 /* End of Outputs for SubSystem: '<Root>/MaxSub2' */
}
```

```
/* Outputs for Atomic SubSystem: '<Root>/HPSub' */
HPSub();

/* End of Outputs for SubSystem: '<Root>/HPSub' */
}
```

All five functions in the `rtwdemo_reusable_csc_scheduling_step` function use the global variable `reuse`. In the functions `MaxSub1`, `MaxSub2`, and `f`, `reuse` is a function argument. In the functions `LPSub` and `HPSub`, `reuse` is in the function body.

### Buffer Reuse for Unit Delay and Delay Blocks

To reuse the signal of a Unit Delay or Delay block

- 1 Use the same reusable custom storage class specification for a pair of input and state arguments or a pair of output and state arguments of a Unit Delay block or a Delay block.
- 2 Open the Unit Delay or Delay block parameters dialog box.
- 3 On the **State Attributes** tab, set the **State name** parameter to the name of the `Simulink.signal` that you want to reuse.
- 4 On the **State Attributes** tab, select **Signal name must resolve to Simulink signal object**.
- 5 On the **Main** tab, the **Delay length** parameter must have a value of 1. The **Initial condition > Source parameter** must be set to `Dialog`.

### Limitations for Root Inport and Outport Signals

The following limitations apply to a model in which you specify buffer reuse for a pair of root inport and outport signals.

- The output ports cannot be conditional.
- If the code generator cannot reuse the same buffer in a top model, the generated code contains additional buffers. If the same model is a reference model, the code generator reports an error. To resolve the error, remove the `Simulink.signal` specification from the signal that connects to the outport port.
- When you run an executable produced by code generation, and you reuse a pair of root inport and outport signals, when the root input value is zero, the root output value must also be zero. If the output value is nonzero and you reuse the signals, then the results from the simulation can differ from the results produced by the executable.

## Limitations for the Model

The following limitations apply to a model in which you specify buffer reuse for signals.

- Signals that you specify for reuse must have the same data types and sampling rates.
- For user-specified buffer reuse, blocks that modify a signal specified for reuse must execute before blocks that use the original signal value. Sometimes the code generator has to change the block operation order so that buffer reuse can occur. For models in which the code generator is unable to reorder block operations, buffer reuse does not occur.
- For models in which the code generator reorders block operations so that **Simulink.Signal** reuse can occur, you can observe the difference in the sorted order. In the model window, select **Display > Blocks > Sorted Execution Order**. To display the sorted execution order during simulation, select **Simulation > Update Diagram**. To display the execution order in the generated code, select **Code > C/C++ Code > Build Model**.

## Reduce Memory Requirements for Signals

To reduce the memory requirements of your real-time program, select the configuration parameter **Signal storage reuse**. Selecting **Signal storage reuse** enables parameters that provide the capability to reuse memory allocated for signals: **Reuse local block outputs**, **Reuse global block outputs**, and **Optimize global data access**. Clearing **Signal storage reuse** makes all block outputs global and unique, which often significantly increases RAM and ROM usage.

When you select **Reuse local block outputs**, the code generator reuses local (function) variables for block outputs wherever possible. When you select **Reuse global block outputs**, the code generator reuses global (function) variables wherever possible.

The **Optimize global data access** parameter has the following settings **None**, **Use global to hold temporary results**, and **Minimize global data access**. When you select **None**, the code generator uses the default optimizations. The setting **Use global to hold temporary results** maximizes the use of global variables. The setting **Minimize global data access** minimizes the use of global variables by using local variables to hold intermediate values.

## Remove Initialization Code

Consider selecting the “Remove root level I/O zero initialization” and “Remove internal data zero initialization” options on the **Optimization > General** pane.

These options (both off by default) control whether internal data (block states and block outputs) and external data (root inports and outports whose value is zero) are initialized. Initializing the internal and external data whose value is zero is a precaution and your application might not require it. Many embedded application environments initialize RAM to zero at startup, making generation of initialization code redundant.

However, be aware that if you select **Remove internal data zero initialization**, memory might not be in a known state each time the generated code begins execution. If you turn the option on, running a model (or a generated S-function) multiple times can result in different answers for each run.

This behavior is sometimes desirable. For example, you can turn on **Remove internal data zero initialization** if you want to test the behavior of your design during a warm boot (that is, a restart without full system reinitialization).

In cases where you have turned on **Remove internal data zero initialization** but still want to get the same answer on every run from an S-function produced by the code generator, you can use either of the following MATLAB commands before each run:

```
clear SFcnName
```

where *SFcnName* is the name of the S-function, or

```
clear mex
```

A related option, **Use memset to initialize floats and doubles**, lets you control the representation of zero used during initialization. See “Use memset to initialize floats and doubles to 0.0” in the Simulink reference documentation.

Note that the code still initializes data structures whose value is not zero when **Remove internal data zero initialization** and **Remove root level I/O zero initialization** are selected.

Note also that data of `ImportedExtern` or `ImportedExternPointer` storage classes are not initialized, regardless of the settings of these options.

## Eliminate Zero Initialization Code for Internal Data

This example shows how to eliminate generated code that initializes internal data with zeroes, for example global DWork vectors, to reduce the size of the code and to accelerate model initialization.

### Overview

During model initialization, generated code can initialize internal data by using assignments to zero. DWork vectors are an example of internal data.

If the data are global variables in the generated code, and if the target environment already initializes global variables with zeroes, you can remove the corresponding lines of model initialization code.

This optimization removes unnecessary zero initialization code, providing these benefits:

- Reduction in size of generated code
- Increased execution speed of generated code

### Open Example Model

Open the model `rtwdemo_internal_init`. The model contains an enabled subsystem whose initial output is zero. The subsystem contains a Unit Delay block whose initial condition is 0.

Copyright 2014 The MathWorks, Inc.

### Generate Code Without Optimization

Build the model using Embedded Coder.

```
Starting build procedure for model: rtwdemo_internal_init
Successful completion of build procedure for model: rtwdemo_internal_init
```

View the following code from the generated file `rtwdemo_internal_init.c`.

```
/* Model initialize function */
void rtwdemo_internal_init_initialize(void)
{
 /* Registration code */

 /* initialize error status */
 rtmSetErrorStatus(rtm, (NULL));

 /* states (dwork) */
 (void) memset((void *)&rtDWork, 0,
 sizeof(D_Work));

 /* SystemInitialize for Enabled SubSystem: '<Root>/Enabled Subsystem' */
 /* InitializeConditions for UnitDelay: '<S1>/Unit Delay' */
 rtDWork.UnitDelay_DSTATE = 0.0;

 /* End of SystemInitialize for SubSystem: '<Root>/Enabled Subsystem' */
}
/*
```

### Enable Optimization

Open the Configuration Parameters dialog box. On the **Optimization** pane, select **Remove internal data zero initialization**.

Alternatively, you can use the command prompt to enable the optimization. To enable the optimization, set the model parameter `ZeroInternalMemoryAtStartup` to 'off'.

```
set_param(model, 'ZeroInternalMemoryAtStartup', 'off');
```

### Generate Code with Optimization

Build the model using Embedded Coder.

```
Starting build procedure for model: rtwdemo_internal_init
Successful completion of build procedure for model: rtwdemo_internal_init
```

View the following code from the file `rtwdemo_internal_init.c`. The generated code does not initialize internal data by assignment to zero.

```
/* Model initialize function */
void rtwdemo_internal_init_initialize(void)
{
 /* (no initialization code required) */
}

/*
```

## Generate Pure Integer Code If Possible

If your application uses only integer arithmetic, clear the **Support floating-point numbers** option in the **Software environment** section of the **Interface** pane so that the generated code contains no floating-point data or operations. When this option is cleared, an error is raised if noninteger data or expressions are encountered during code generation. The error message reports the offending blocks and parameters.

## Disable MAT-File Logging

Disable MAT-file logging by clearing **Configuration Parameters > All Parameters > MAT-file logging**. This setting is the default, and is recommended for embedded applications because it eliminates the extra code and memory usage required to initialize, update, and clean up logging variables. In addition to these efficiencies, clearing the **MAT-file logging** parameter lets you exploit further efficiencies under certain conditions. See “Virtualized Output Ports Optimization” on page 55-16 for information.

Note also that code generated to support MAT-file logging invokes `malloc`, which can be undesirable for your application.

## Simplify Multiply Operations in Array Indexing

### In this section...

“Example Model” on page 56-10

“Generate Code” on page 56-11

“Generate Code with Optimization” on page 56-11

The generated code might have multiply operations when indexing an element of an array. You can select the optimization parameter “Simplify array indexing” to replace multiply operations in the array index with a temporary variable. This optimization can improve execution speed by reducing the number of times the multiply operation executes.

### Example Model

If you have the following model:

The Constant blocks have the following **Constant value**:

- Const1: `reshape(1:30,[1 5 3 2])`
- Const2: `reshape(1:20,[1 5 2 2])`
- Const3: `reshape(1:90,[1 5 9 2])`

The Concatenate block parameter **Mode** is set to `Multidimensional` array. The Constant blocks **Sample time** parameter is set to `-1`.

## Generate Code

Building the model with the **Simplify array indexing** parameter turned off generates the following code:

```
int32_T i;
int32_T i_0;
int32_T i_1;

for (i = 0; i < 2; i++) {
 for (i_1 = 0; i_1 < 3; i_1++) {
 for (i_0 = 0; i_0 < 5; i_0++) {
 ex_arrayindex_Y.Out[(i_0 + 5 * i_1) + 70 * i] =
 ex_arrayindex_P.Constant1_Value[(5 * i_1 + i_0) + 15 * i];
 }
 }
}

for (i = 0; i < 2; i++) {
 for (i_1 = 0; i_1 < 2; i_1++) {
 for (i_0 = 0; i_0 < 5; i_0++) {
 ex_arrayindex_Y.Out[(i_0 + 5 * (i_1 + 3)) + 70 * i] =
 ex_arrayindex_P.Constant2_Value[(5 * i_1 + i_0) + 10 * i];
 }
 }
}

for (i = 0; i < 2; i++) {
 for (i_1 = 0; i_1 < 9; i_1++) {
 for (i_0 = 0; i_0 < 5; i_0++) {
 ex_arrayindex_Y.Out[(i_0 + 5 * (i_1 + 5)) + 70 * i] =
 ex_arrayindex_P.Constant3_Value[(5 * i_1 + i_0) + 45 * i];
 }
 }
}
```

## Generate Code with Optimization

Open the Configuration Parameters dialog box and select the **Simplify array indexing** parameter on the **All Parameters** tab. Build the model again. In the generated code,

$[(i\_0 + tmp\_1) + tmp]$  replaces a multiply operation in the array index,  $[(i\_0 + 5 * i\_1) + 70 * i]$ . The generated code is now:

```
int32_T i;
int32_T i_0;
int32_T i_1;
int32_T tmp;
int32_T tmp_0;
int32_T tmp_1;

tmp = 0;
tmp_0 = 0;
for (i = 0; i < 2; i++) {
 tmp_1 = 0;
 for (i_1 = 0; i_1 < 3; i_1++) {
 for (i_0 = 0; i_0 < 5; i_0++) {
 ex_arrayindex_Y.Out[(i_0 + tmp_1) + tmp] =
 ex_arrayindex_P.Constant1_Value[(i_0 + tmp_1) + tmp_0];
 }

 tmp_1 += 5;
 }

 tmp += 70;
 tmp_0 += 15;
}

tmp = 0;
tmp_0 = 0;
for (i = 0; i < 2; i++) {
 tmp_1 = 0;
 for (i_1 = 0; i_1 < 2; i_1++) {
 for (i_0 = 0; i_0 < 5; i_0++) {
 ex_arrayindex_Y.Out[((i_0 + tmp_1) + tmp) + 15] =
 ex_arrayindex_P.Constant2_Value[(i_0 + tmp_1) + tmp_0];
 }

 tmp_1 += 5;
 }

 tmp += 70;
 tmp_0 += 10;
}
```

```
tmp = 0;
tmp_0 = 0;
for (i = 0; i < 2; i++) {
 tmp_1 = 0;
 for (i_1 = 0; i_1 < 9; i_1++) {
 for (i_0 = 0; i_0 < 5; i_0++) {
 ex_arrayindex_Y.Out[((i_0 + tmp_1) + tmp) + 25] =
 ex_arrayindex_P.Constant3_Value[(i_0 + tmp_1) + tmp_0];
 }

 tmp_1 += 5;
 }

 tmp += 70;
 tmp_0 += 45;
}
```

## Replace `boolean` with Specific Integer Data Type

Depending on the architecture of the processor that your production hardware uses, you can improve the execution speed of generated code. Select a specific integer data type to use for the built-in type `boolean`. Using data type replacement, in the generated code you can replace the `boolean` built-in data type with one of these integer types:

- `int8`
- `uint8`
- `int $n$`

Replace  $n$  with `8`, `16`, or `32` to match the integer word size for the production hardware.

This example shows how to replace the data type `boolean` with the integer data type `int32` in the code generated for a 32-bit hardware target.

- 1 Define a `Simulink.AliasType` object with a base type of `int32`. Name the object using the replacement name that you want to appear in the generated code.

```
mybool = Simulink.AliasType;
mybool.BaseType = 'int32';
```

- 2 Open an ERT-based model. In the Configuration Parameters dialog box **Data Type Replacement** pane, specify the **Replacement Name** field for the data type `boolean` as `mybool`.

Data type names		
Simulink Name	Code Generation Name	Replacement Name
double	real_T	<input type="text"/>
single	real32_T	<input type="text"/>
int32	int32_T	<input type="text"/>
int16	int16_T	<input type="text"/>
int8	int8_T	<input type="text"/>
uint32	uint32_T	<input type="text"/>
uint16	uint16_T	<input type="text"/>
uint8	uint8_T	<input type="text"/>
boolean	boolean_T	mybool
int	int_T	<input type="text"/>
uint	uint_T	<input type="text"/>
char	char_T	<input type="text"/>

View the generated file `rtwtypes.h`. The code maps the identifier `mybool` to the native integer type of the target hardware by creating `typedef` statements.

```

/* Generic type definitions ... */
...
typedef int boolean_T;
...
/* Define Simulink Coder replacement data types. */
typedef boolean_T mybool; /* User defined replacement datatype for boolean_T */

```

View the generated file `model.c`. The code declares Boolean variables using the type `mybool`. For example, if the model has a Boolean output `Out1`, the generated code declares the corresponding variable using `mybool`.

```

mybool Out1; /* '<Root>/Out1' */

```

## Remove Code That Guards Against Division Exceptions for Integers and Fixed-Point Data

Optimize generated code by removing code that protects against division by zero and overflows in division `INT_MIN / -1` operations for integers and fixed-point data. If you are sure that these arithmetic exceptions do not occur during program execution, enable this optimization.

This optimization:

- Increases execution speed.
- Reduces ROM consumption.

**NOTE:** If you enable this optimization, it is possible that simulation results and results from generated code are not in bit-for-bit agreement. This example requires an Embedded Coder® license.

### Example Model

In the model `rtwdemo_nzcheck`, two signals of type `int8` feed into a divide block.

```
model = 'rtwdemo_nzcheck';
open_system(model);
```

Copyright 2014-2015 The MathWorks, Inc.

## Generate Code

In your system's temporary folder, create a temporary folder for the build and inspection process.

```
currentDir = pwd;
[~,cgDir] = rtwdemodir();
```

Build the model.

```
set_param(model, 'NoFixptDivByZeroProtection', 'off');
rtwbuild(model);

Starting build procedure for model: rtwdemo_nzcheck
Successful completion of code generation for model: rtwdemo_nzcheck
```

View the generated code without the optimization. Here is a portion of rtwdemo\_nzcheck.c.

```
cfile = fullfile(cgDir, 'rtwdemo_nzcheck_ert_rtw', 'rtwdemo_nzcheck.c');
rtwdemodbtype(cfile, '/* Real-time model', '/* Model step function', 1, 1);
```

```

/* Real-time model */
RT_MODEL_rtwdemo_nzcheck rtwdemo_nzcheck_M_;
RT_MODEL_rtwdemo_nzcheck *const rtwdemo_nzcheck_M = &rtwdemo_nzcheck_M_;
int32_T div_s32(int32_T numerator, int32_T denominator)
{
 int32_T quotient;
 uint32_T tempAbsQuotient;
 if (denominator == 0) {
 quotient = numerator >= 0 ? MAX_int32_T : MIN_int32_T;

 /* Divide by zero handler */
 } else {
 tempAbsQuotient = (numerator < 0 ? ~(uint32_T)numerator + 1U : (uint32_T)
 numerator) / (denominator < 0 ? ~(uint32_T)denominator +
 1U : (uint32_T)denominator);
 quotient = (numerator < 0) != (denominator < 0) ? -(int32_T)tempAbsQuotient :
 (int32_T)tempAbsQuotient;
 }

 return quotient;
}

```

### Enable Optimization

- 1 Open the Configuration Parameters dialog box.
- 2 On the **Optimization** pane, select **Remove code that protects against division arithmetic exceptions**.

Alternatively, you may use the command-line API to enable the optimization:

```
set_param(model, 'NoFixptDivByZeroProtection', 'on');
```

### Generate Code with Optimization

The optimized code does not contain code that checks for whether or not the divisor has a value of zero.

Build the model.

```
rtwbuild(model);
```

```
Starting build procedure for model: rtwdemo_nzcheck
Successful completion of code generation for model: rtwdemo_nzcheck
```

The following is a portion of `rtwdemo_nzcheck.c`. The code that protects against division arithmetic exceptions is not in the generated code.

```
rtwdemodbtype(cfile, '/* Real-time model', '/* Model step function', 1, 1);

/* Real-time model */
RT_MODEL_rtwdemo_nzcheck rtwdemo_nzcheck_M;
RT_MODEL_rtwdemo_nzcheck *const rtwdemo_nzcheck_M = &rtwdemo_nzcheck_M;
```

Close the model and code generation report.

```
bdclose(model)
rtwdemoclean;
cd(currentDir)
```

## Division Arithmetic Exceptions in Generated Code

The **Remove code that protects against division arithmetic exceptions** parameter in the **Optimization** pane of the Configuration Parameters dialog box controls the generation of code that protects against division arithmetic exceptions in integer and fixed-point operations. Division arithmetic exceptions include division by zero and `INT_MIN / -1`, which results in a quotient that cannot be represented.

When the parameter is selected, no code is generated to guard against these types of exceptions. This produces smaller, more efficient code, however it can affect numerical results. Select the parameter if you are sure that your model would not encounter these exceptions to optimize the efficiency of the generated code.

When the parameter is not selected, extra code will be generated to ensure that division arithmetic exceptions do not occur. The added protection code ensures numerical match between simulation and code generation for division operations at a cost of code size and performance.

### Division by Zero

Division by zero is undefined and results in a runtime error in the generated code. When the **Remove code that protects against division arithmetic exceptions** parameter is selected, the code generator does not produce code that protects against division by zero. Select this option only when you are sure that your model will not produce such a division operation.

### INT\_MIN/-1

When you divide the minimum representable value of a signed integer by negative one, the ideal result is equal to the maximum representable value plus one (`INT_MAX + 1`), which is not representable. This exception may cause the application to unexpectedly halt or crash at run-time. When the **Remove code that protects against division arithmetic exceptions** parameter is selected, the code generator does not produce code that protects against this situation. Select this option only when you are sure that your model will not produce such a division operation.

The following illustrates an example of this type of exception:

```
a = int32(-2147483648);
b = a / -1
```

The ideal quotient of this operation is 2147483648, but this is not representable in an `int32` data type, resulting in an exception at runtime.

## Other Factors Affecting Generated Code of Division Operations

In addition to the **Remove code that protects against division arithmetic exceptions** parameter, there are several other factors that can affect the appearance of code generated for division operations. The manner in which this parameter controls code generated from blocks containing MATLAB code with integer or fixed-point division operations differs from the built-in Divide block in Simulink. Blocks containing MATLAB code include MATLAB Function blocks and Stateflow charts using MATLAB action language. To balance the efficiency and semantics of fixed-point and integer divisions in these blocks, use `fi` objects and set the `fimath` properties to fit your needs. Usage of `fi` and `fimath` objects requires a Fixed-Point Designer license.

Rounding and overflow modes also affect the size and efficiency of the generated code. For more information, see “Optimize Generated Code with the Model Advisor”.

## Optimize Generated Code by Consolidating Redundant If-Else Statements

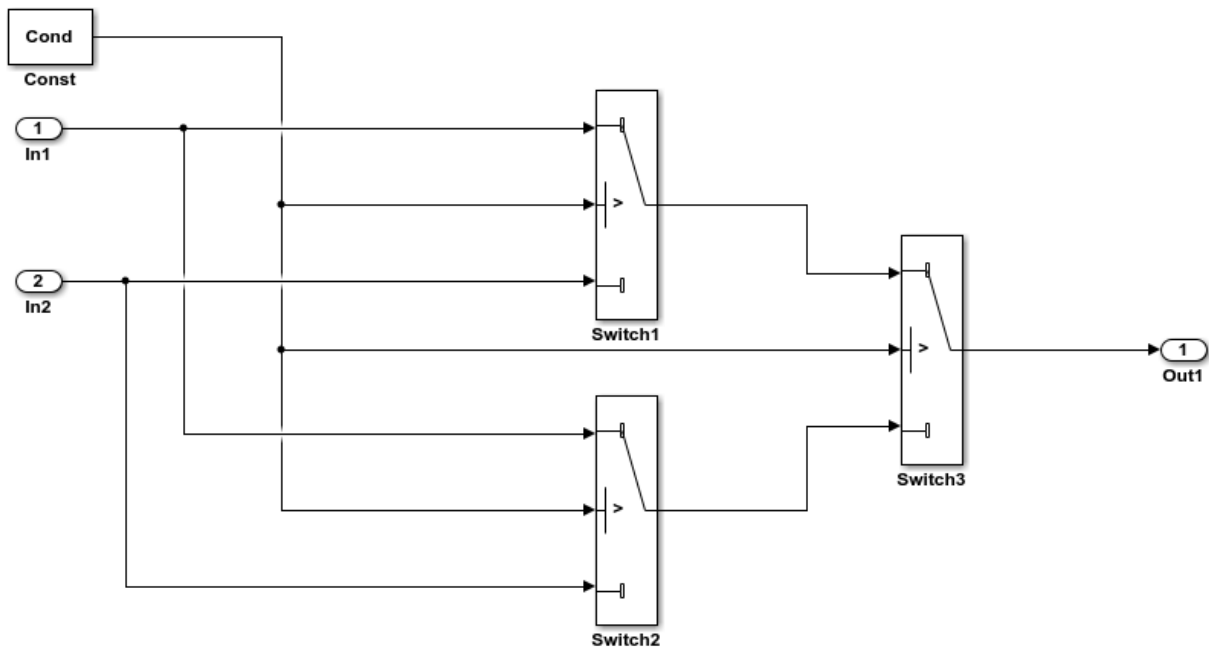

This example shows how to optimize generated code by combining `if - else` statements that share the same condition. This optimization:

- Improves control flow.
- Reduces code size.
- Reduces RAM consumption.
- Increases execution speed.

### Example

The model `rtwdemo_controlflow_opt` contains three Switch blocks. The Constant block provides the control input to the Switch blocks. The variable named `COND` determines the value of the Constant block.

```
model = 'rtwdemo_controlflow_opt';
open_system(model);
```

Copyright 2014 The MathWorks, Inc.

### Generate Code

Create a temporary folder for the build and inspection process.

```
currentDir = pwd;
[~,cgDir] = rtwdemodir();
```

Build the model.

```
rtwbuild(model)
```

```
Starting build procedure for model: rtwdemo_controlflow_opt
Successful completion of build procedure for model: rtwdemo_controlflow_opt
```

These lines of `rtwdemo_controlflow_opt.c` code show that in the generated code, two `if-else` statements and one `else-if` statement represent the three Switch blocks.

```
cfile = fullfile(cgDir,'rtwdemo_controlflow_opt_ert_rtw',...
 'rtwdemo_controlflow_opt.c');
rtwdemodbtype(cfile,'/* Model step', '/* Model initialize', 1, 0);

/* Model step function */
void rtwdemo_controlflow_opt_step(void)
{
 /* Switch: '<Root>/Switch3' incorporates:
 * Constant: '<Root>/Const'
 * Switch: '<Root>/Switch2'
 */
 if (Cond) {
 /* Switch: '<Root>/Switch1' */
 if (Cond) {
 /* Outport: '<Root>/Out1' incorporates:
 * Inport: '<Root>/In1'
 */
 rtY.Out1 = rtU.In1;
 } else {
 /* Outport: '<Root>/Out1' incorporates:
 * Inport: '<Root>/In2'
 */
 rtY.Out1 = rtU.In2;
 }

 /* End of Switch: '<Root>/Switch1' */
 } else if (Cond) {
 /* Switch: '<Root>/Switch2' incorporates:
 * Inport: '<Root>/In1'
 * Outport: '<Root>/Out1'
 */
 rtY.Out1 = rtU.In1;
 } else {
 /* Outport: '<Root>/Out1' incorporates:
 * Inport: '<Root>/In2'
 */
 rtY.Out1 = rtU.In2;
 }

 /* End of Switch: '<Root>/Switch3' */
}
```

### Enable Optimization

- 1 Open the Configuration Parameters dialog box.
- 2 On the **Code generation-> Code Style** pane, clear **Preserve condition expression in if statement**. This parameter is on by default.

Alternatively, use the command-line API to turn off the parameter:

```
set_param(model, 'PreserveIfCondition', 'off');
```

### Generate Code with Optimization

In the optimized code, the code generator consolidates the two **if-else** statements and one **else-if** statement into one **if-else** statement. The code generator consolidates these statements because they all share the same condition. There is no intervening code that affects the outcomes of these statements.

Build the model.

```
rtwbuild(model)
```

```
Starting build procedure for model: rtwdemo_controlflow_opt
Successful completion of build procedure for model: rtwdemo_controlflow_opt
```

Here is the `rtwdemo_controlflow_opt.c` optimized code.

```
rtwdemodbtype(cfile, '/* Model step', '/* Model initialize', 1, 0);
```

```
/* Model step function */
void rtwdemo_controlflow_opt_step(void)
{
 /* Switch: '<Root>/Switch1' incorporates:
 * Constant: '<Root>/Const'
 * Switch: '<Root>/Switch3'
 */
 if (Cond) {
 /* Output: '<Root>/Out1' incorporates:
 * Inport: '<Root>/In1'
 */
 rtY.Out1 = rtU.In1;
 } else {
 /* Output: '<Root>/Out1' incorporates:
 * Inport: '<Root>/In2'
 }
}
```

```
 */
 rtY.Out1 = rtU.In2;
}

/* End of Switch: '<Root>/Switch1' */
}
```

Close the model and clean up.

```
bdclose(model)
rtwdemoclean;
cd(currentDir)
```

## Remove Initialization Code for Root-Level Inports and Outports Set to Zero

This example shows how to optimize generated code by removing initialization code for root-level inports and outports set to zero. If your embedded application does not require generating initialization code for external data whose value is zero, you can enable this optimization. For example, many embedded application environments initialize RAM to zero at startup, making generation of initialization code redundant. This optimization:

- Increases execution speed.
- Reduces ROM consumption.

**Note:** This example requires an Embedded Coder® license.

### Example

In the model `rtwdemo_rootlevel_zero_initialization`, all of the input and output signals have a numeric value of zero. Because signals `sig1` and `sig2` have data types `int16` and `Boolean`, respectively, and all of the output signals have data type `double`, these signals also have initial values of bitwise zero. The signals have an integer bit pattern of 0, meaning that all bits are off. Signals `sig1_b` and `sig2_b` have a fixed-point data type with bias, so their initial value is not bitwise zero.

```
model = 'rtwdemo_rootlevel_zero_initialization';
open_system(model);
```

Copyright 2014 The MathWorks, Inc

### Generate Code

In your system temporary folder, create a temporary folder for the build and inspection process.

```
currentDir = pwd;
[~,cgDir] = rtwdemodir();
```

Build the model.

```
set_param(model, 'ZeroExternalMemoryAtStartup', 'on');
rtwbuild(model)
```

```
Starting build procedure for model: rtwdemo_rootlevel_zero_initialization
Successful completion of build procedure for model: rtwdemo_rootlevel_zero_initialization
```

These lines of `rtwdemo_rootlevel_zero_initialization.c` code show the initialization of root-level inports and outports without the optimization. The four input signals are individually initialized as global variables. The four output signals are members of a global structure that the `memset` function initializes to bitwise zero.

```
cfile = fullfile(cgDir, 'rtwdemo_rootlevel_zero_initialization_ert_rtw', ...
 'rtwdemo_rootlevel_zero_initialization.c');
rtwmodbtype(cfile, 'rtwdemo_rootlevel_zero_initialization_initialize', ...
 'trailer for generated code', 1, 0);
```

```
void rtwdemo_rootlevel_zero_initialization_initialize(void)
{
 /* Registration code */

 /* external inputs */
 sig1 = 0;
 sig2 = false;
 sig1_b = -3;
 sig2_b = -3;

 /* external outputs */
 (void) memset((void *)&rtY, 0,
 sizeof(ExternalOutputs));
}

/*
```

### Enable Optimization

- 1 Open the Configuration Parameters dialog box.
- 2 On the **Optimization** pane, select **Remove root level I/O zero initialization**.

Alternatively, use the command-line API to enable the optimization:

```
set_param(model, 'ZeroExternalMemoryAtStartup','off');
```

### Generate Code with Optimization

The optimized code does not contain initialization code for the input signals `sig1`, `sig2`, and the four output signals, because their initial values are bitwise zero.

Build the model.

```
rtwbuild(model)
```

```
Starting build procedure for model: rtwdemo_rootlevel_zero_initialization
Successful completion of build procedure for model: rtwdemo_rootlevel_zero_initialization
```

Here is the `rtwdemo_rootlevel_zero_initialization.c` optimized code in the initialization function.

```
cfile = fullfile(cgDir, 'rtwdemo_rootlevel_zero_initialization_ert_rtw', ...
 'rtwdemo_rootlevel_zero_initialization.c');
rtwdemodbtype(cfile, 'rtwdemo_rootlevel_zero_initialization_initialize', ...
 'trailer for generated code', 1, 0);
```

```
void rtwdemo_rootlevel_zero_initialization_initialize(void)
{
 /* Registration code */

 /* external inputs */
 sig1_b = -3;
 sig2_b = -3;
}

/*
```

Close the model and the code generation report.

```
bdclose(model)
rtwdemoclean;
cd(currentDir)
```

## Optimize Generated Code for Fixed-Point Data Operations

This model shows optimized fixed-point operations. An expensive division operation is avoided by precomputing the constant input of the Divide block and transforming the division to a highly efficient product operation. Note that the resulting operation also includes the adjustment in signal scaling from  $2^{-3}$  to  $2^{-5}$ .

### Description

This model shows optimized fixed-point operations. An expensive division operation is avoided by precomputing the constant input of the Divide block and transforming the division to a highly efficient product operation. The entire computation is realized with a single shift-right operation. Note that the resulting operation also includes the adjustment in signal scaling from  $2^{-3}$  to  $2^{-5}$ .

### Instructions

1. Double-click the yellow button below to view the signal data types.
2. Generate and inspect the code by double-clicking the blue button below. An HTML report detailing the code is displayed automatically.

This example requires a Fixed-Point Designer license

## Optimize Generated Code Using Minimum and Maximum Values

To optimize the generated code for your model, you can choose an option to use input range information, also known as *design minimum and maximum*, that you specify on signals and parameters. These minimum and maximum values usually represent environmental limits, such as temperature, or mechanical and electrical limits, such as output ranges of sensors.

In the Configuration Parameters dialog box, on the **Optimization** tab, when you select the **Optimize using specified minimum and maximum values** check box, the software uses the minimum and maximum values to derive range information for downstream signals in the model. It then uses this derived range information to determine if it is possible to streamline the generated code by:

- Reducing expressions to constants
- Removing dead branches of conditional statements
- Eliminating unnecessary mathematical operations

This optimization results in:

- Reduced ROM and RAM consumption
- Improved execution speed

### Configure Your Model

To make optimization more likely:

- Provide as much design minimum and maximum information as possible. Specify minimum and maximum values for signals and parameters in the model for:
  - Inport and Outport blocks
  - Block outputs
  - Block inputs, for example, for the MATLAB Function and Stateflow Chart blocks
  - `Simulink.Signal` objects
- Before generating code, test the minimum and maximum values for signals and parameters. Otherwise, optimization might result in numerical mismatch with simulation. You can simulate your model with simulation range checking enabled. If errors or warnings occur, fix these issues before generating code.

### Enable Simulation Range Checking

- 1 In your model, select **Simulation > Model Configuration Parameters** to open the Configuration Parameters dialog box.
  - 2 In the Configuration Parameters dialog box, select **Diagnostics > Data Validity**.
  - 3 On the **Data Validity** pane, under **Signals**, set **Simulation range checking** to **warning** or **error**.
- Provide design minimum and maximum information upstream of blocks as close to the inputs of the blocks as possible. If you specify minimum and maximum values for a block output, these values are most likely to affect the outputs of the blocks immediately downstream.

## Optimize Generated Code Using Specified Minimum and Maximum Values

This example shows how the minimum and maximum values specified on signals and parameters in a model are used to optimize the generated code.

### Overview

The specified minimum and maximum values usually represent environmental limits, such as temperature, or mechanical and electrical limits, such as output ranges of sensors.

This optimization uses these values to streamline the generated code. For example, it reduces expressions to constants or removes dead branches of conditional statements.

**NOTE:** Make sure the minimum and maximum values that you specify are valid limits. Otherwise, this optimization might result in numerical mismatch with simulation.

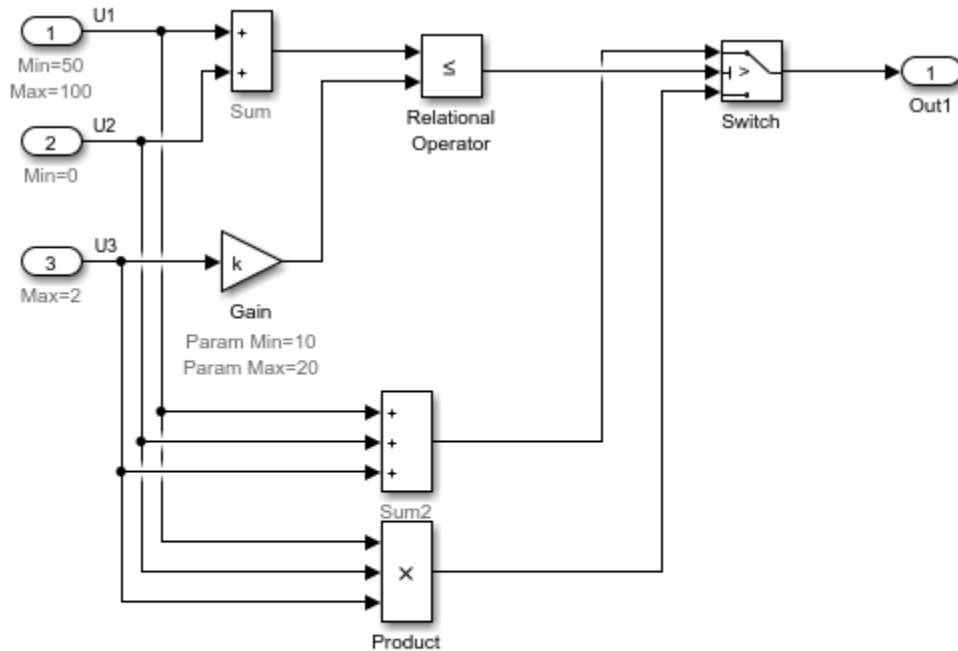

The benefits of optimizing the generated code are:

- Reducing the ROM and RAM consumption.
- Improving the execution speed.

### Review Minimum and Maximum Information

Consider the model `rtwdemo_minmax`. In this model, there are minimum and maximum values specified on Inports and on the gain parameter of the Gain block.

```
model = 'rtwdemo_minmax';
open_system(model);
```

Optimizing generated code using the specified minimum and maximum values

Copyright 2010-2011 The MathWorks, Inc.

### Generate Code Without This Optimization

First, generate code for this model without considering the min and max values.

```
currentDir = pwd;
[~,cgDir] = rtwdemodir();
rtwconfiguredemo(model,'ERT')
rtwbuild(model)
```

```
Starting build procedure for model: rtwdemo_minmax
Successful completion of build procedure for model: rtwdemo_minmax
```

A portion of `rtwdemo_minmax.c` is listed below.

```
cfile = fullfile(cgDir, 'rtwdemo_minmax_ert_rtw', 'rtwdemo_minmax.c');
rtwdemodbtype(cfile, '/* Model step', '/* Model initialize', 1, 0);
```

```
/* Model step function */
void rtwdemo_minmax_step(void)
{
 /* Switch: '<Root>/Switch' incorporates:
 * Gain: '<Root>/Gain'
 * Inport: '<Root>/U1'
 * Inport: '<Root>/U2'
 * Inport: '<Root>/U3'
 * RelationalOperator: '<Root>/Relational Operator'
 * Sum: '<Root>/Sum'
 */
 if (U1 + U2 <= k * U3) {
 /* Outport: '<Root>/Out1' incorporates:
 * Sum: '<Root>/Sum2'
 */
 rtY.Out1 = (U1 + U2) + U3;
 } else {
 /* Outport: '<Root>/Out1' incorporates:
 * Product: '<Root>/Product'
 */
 rtY.Out1 = U1 * U2 * U3;
 }

 /* End of Switch: '<Root>/Switch' */
}
}
```

### Enable This Optimization

- 1 Open the Configuration Parameters dialog box.
- 2 On the **Optimization** pane, select **Optimize using the specified minimum and maximum values**.

Alternatively, you can enable this optimization by setting the command-line parameter.

```
set_param(model, 'UseSpecifiedMinMax', 'on');
```

### Generate Code With This Optimization

In the model, with the specified minimum and maximum values for U1 and U2, the sum of U1 and U2 has a minimum value of 50. Considering the range of U3 and the specified minimum and maximum values for the Gain block parameter, the maximum value of the Gain block's output is 40.

The output of the Relational Operator block remains false, and the output of the Switch block remains the product of the three inputs.

Configure and build the model using Embedded Coder.

```
rtwconfiguredemo(model, 'ERT')
rtwbuild(model)

Starting build procedure for model: rtwdemo_minmax
Successful completion of build procedure for model: rtwdemo_minmax
```

View the optimized code from `rtwdemo_minmax.c`.

```
cfile = fullfile(cgDir, 'rtwdemo_minmax_ert_rtw', 'rtwdemo_minmax.c');
rtwdemodbtype(cfile, /* Model step', /* Model initialize', 1, 0);

/* Model step function */
void rtwdemo_minmax_step(void)
{
 /* Outport: '<Root>/Out1' incorporates:
 * Inport: '<Root>/U1'
 * Inport: '<Root>/U2'
 * Inport: '<Root>/U3'
 * Product: '<Root>/Product'
 * Switch: '<Root>/Switch'
 */
 rtY.Out1 = U1 * U2 * U3;
}
```

Close the model and cleanup.

```
bdclose(model)
rtwdemoclean;
```

```
cd(currentDir)
```

## Limitations

- This optimization does not take into account minimum and maximum values for:
  - Merge block inputs. To work around this issue, use a `Simulink.Signal` object on the Merge block output and specify the range on this object.
  - Bus elements.
  - Conditionally-executed subsystem (such as a triggered subsystem) block outputs that are directly connected to an Output block.

Output blocks in conditionally-executed subsystems can have an initial value specified for use only when the system is not triggered. In this case, the optimization cannot use the range of the block output because the range might not cover the initial value of the block.

- If you use Polyspace software to verify code generated using this optimization, it might mark code that was previously green as orange. For example, if your model contains a division where the range of the denominator does not include zero, the generated code does not include protection against division by zero. Polyspace might mark this code orange because it does not have information about the minimum and maximum values for the inputs to the division.

Polyspace Code Prover automatically captures some minimum and maximum values specified in the MATLAB workspace, for example, for `Simulink.Signal` and `Simulink.Parameter` objects. In this example, to provide range information to the Polyspace software, use a `Simulink.Signal` object on the input of the division and specify a range that does not include zero.

Polyspace Code Prover stores these values in a Data Range Specification (DRS) file. However, they do not capture all minimum and maximum values in your Simulink model. To provide additional minimum and maximum information to Polyspace, you can manually define a DRS file.

- If you are using double-precision data types and the **Code Generation > Interface > Support non-finite numbers** configuration parameter is selected, this optimization does not occur.
- If your model contains multiple instances of a reusable subsystem and each instance uses input signals with different minimum and maximum values, this optimization might result in different generated code for each subsystem so code reuse does not

occur. Without this optimization, code is generated once for the subsystem and shares this code among the multiple instances of the subsystem.

- The Model Advisor DO-178C/DO-331 check **Check safety-related optimization settings** generates a warning if this option is selected. For many safety-critical applications, removing dead code automatically is unacceptable because doing so might make code untraceable. For more information about using the check to comply with DO-178C/DO-331, see Check safety-related optimization settings.

## Flat Structures for Reusable Subsystem Parameters

This example shows how to increase the efficiency of code generated for reusable subsystems by generating a single flat parameter structure instead of a hierarchy of nested parameter structures.

By default, the code generated for reusable subsystems contains separate structures to define the parameters that each subsystem uses. If you use nested reusable subsystems, the generated code creates a hierarchy of nested parameter structures. Hierarchies of structures can reduce code efficiency due to compiler padding between word boundaries in memory.

This optimization is for only ERT-based targets. You must set the configuration parameter **Default parameter behavior** to **Inlined**.

### Explore Example Model

Open the example model `rtwdemo_paramstruct`.

```
model = 'rtwdemo_paramstruct';
open_system(model);
```

Copyright 2014 The MathWorks, Inc.

The model contains two nested reusable subsystems. Each subsystem uses two of the parameters A, B, C, and D that are defined in the base workspace.

## Generate Code with Hierarchical Parameter Structures

Create a temporary folder to contain the model build files. Generate code for the model using the default hierarchical data structure for reusable subsystems.

```
currentDir = pwd;
[~,cgDir] = rtwdemodir();
rtwbuild(model)

Starting build procedure for model: rtwdemo_paramstruct
Successful completion of build procedure for model: rtwdemo_paramstruct
```

In the code generation report, view the parameter structure definitions in the file `rtwdemo_paramstruct.h`.

```
cfile = fullfile(cgDir,'rtwdemo_paramstruct_ert_rtw','rtwdemo_paramstruct.h');
rtwdemodbtype(cfile,'/* Parameters for system: '<S1>/SubsysZ''',...
 '/* Parameters (auto storage)', 1, 0);

/* Parameters for system: '<S1>/SubsysZ' */
struct P_SubsysZ_ {
 uint16_T C; /* Variable: C
 * Referenced by: '<S2>/Gain3'
 */
 uint16_T D; /* Variable: D
 * Referenced by: '<S2>/Gain4'
 */
};

/* Parameters for system: '<S1>/SubsysZ' */
typedef struct P_SubsysZ_ P_SubsysZ;

/* Parameters for system: '<Root>/SubsysY' */
struct P_SubsysY_ {
 uint16_T A; /* Variable: A
 * Referenced by: '<S1>/Gain1'
 */
 uint16_T B; /* Variable: B
 * Referenced by: '<S1>/Gain2'
 */
 P_SubsysZ SubsysZ_m; /* '<S1>/SubsysZ' */
};

/* Parameters for system: '<Root>/SubsysY' */
```

```
typedef struct P_SubsysY_ P_SubsysY;
```

The code defines a parameter structure for each reusable subsystem and nests the structures.

### Enable Optimization

Open the Configuration Parameters dialog box. On the **Optimization > Signals and Parameters** pane, select **Nonhierarchical** in the **Parameter structure** drop-down list.

Alternatively, enable the optimization at the command prompt.

```
set_param(model, 'InlinedParameterPlacement', 'NonHierarchical');
```

### Generate Code with Flat Parameter Structure

Generate code for the model using a flat parameter structure for reusable subsystems.

```
rtwbuild(model)

Starting build procedure for model: rtwdemo_paramstruct
Successful completion of build procedure for model: rtwdemo_paramstruct
```

In the code generation report, view the parameter structure definition in the file `rtwdemo_paramstruct.h`.

```
rtwdemodbtype(cfile, '/* Parameters (auto storage) */', ...
 '/* Real-time Model Data Structure */', 1, 0);

/* Parameters (auto storage) */
struct P_ {
 uint16_T A; /* Variable: A
 * Referenced by: '<S1>/Gain1'
 */
 uint16_T B; /* Variable: B
 * Referenced by: '<S1>/Gain2'
 */
 uint16_T C; /* Variable: C
 * Referenced by: '<S2>/Gain3'
 */
 uint16_T D; /* Variable: D
 * Referenced by: '<S2>/Gain4'
 */
}
```

```
};

/* Parameters (auto storage) */
typedef struct P_ P;
```

The code stores all of the parameters for the reusable subsystems in a single flat structure.

Close the model and delete build files.

```
bdclose(model)
rtwdemoclean;
cd(currentDir)
```

## Reduce Global Variables in Nonreusable Subsystem Functions

### In this section...

“Generate void-void Function” on page 57-13

“Generate Function with Arguments” on page 57-14

Global variables can increase memory requirements and reduce execution speed. To reduce global RAM for a nonreusable subsystem, you can generate a function interface that passes data through arguments instead of global variables. The Subsystem block parameter “Function interface” provides this option. To compare the outputs for the **Function interface** options, first generate a function for a subsystem with a `void-void` interface, and then generate a function with arguments.

### Generate void-void Function

By default, when you configure a Subsystem block as a nonreusable function, it generates a `void-void` interface.

- 1 Open the example model `rtwdemo_roll`.
- 2 Right-click the subsystem `RollAngleReference`. From the list select **Block Parameter (Subsystem)**.
- 3 In the Block Parameter dialog box, confirm that the **Treat as atomic unit** check box is selected.
- 4 Click the **Code Generation** tab and set the **Function packaging** parameter to **Nonreusable function**.
- 5 The **Function interface** parameter is already set to `void_void`.
- 6 Click **Apply** and **OK**.
- 7 Repeat steps 2–6, for the other subsystems `HeadingMode` and `BasicRollMode`.
- 8 Generate code and the static code metrics report for `rtwdemo_roll`. This model is configured to generate a code generation report and to open the report automatically. For more information, see “Generate Static Code Metrics Report for Simulink Model” on page 35-38.

In the code generation report, in `rtwdemo_roll.c`, the generated code for subsystem `RollAngleReference` contains a `void-void` function definition:

```
void rtwdemo_roll_RollAngleReference(void)
```

```
{
 ...
}
```

In the static code metrics report, navigate to **Global Variables**. With the `void_void` option, the number of bytes for global variables is 59.

## 2. Global Variables [\[hide\]](#)

Global variables defined in the generated code.

Global Variable	Size (bytes)	Reads / Writes	Reads / Writes in a Function
[+] <a href="#">rtwdemo_roll_U</a>	26	14	6
[+] <a href="#">rtwdemo_roll_B</a>	16	16	8
[+] <a href="#">rtwdemo_roll_DW</a>	9	18	15
[+] <a href="#">rtwdemo_roll_M</a>	4	0*	0*
[+] <a href="#">rtwdemo_roll_Y</a>	4	2	2
<b>Total</b>	<b>59</b>	<b>50</b>	

\* The global variable is not directly used in any function.

Next, generate the same function with the `Allow arguments` option to compare the results.

## Generate Function with Arguments

To reduce global RAM, improve ROM usage and execution speed, generate a function that allows arguments:

- 1 Open the Subsystem Block Parameter dialog box for `RollAngleReference`.
- 2 Click the **Code Generation** tab. Set the **Function interface** parameter to `Allow arguments`.
- 3 Click **Apply** and **OK**.
- 4 Repeat steps 2 and 3, for the other subsystems `HeadingMode` and `BasicRollMode`.
- 5 Generate code and the static code metrics report for `rtwdemo_roll`.

In the code generation report, in `rtwdemo_roll.c`, the generated code for subsystem `RollAngleReference` now has arguments:

```

real32_T rtwdemo_roll_RollAngleReference(real32_T rtu_Turn_Knob,...
 boolean_T rtu_AP_Eng,...
 real32_T rtu_Phi)
{
 ...
}

```

In the static code metrics report, navigate to **Global Variables**. With the **Allow arguments** option set, the total number of bytes for global variables is now 47 bytes.

## 2. Global Variables [\[hide\]](#)

Global variables defined in the generated code.

Global Variable	Size (bytes)	Reads / Writes	Reads / Writes in a Function
[+] <a href="#">rtwdemo_roll_U</a>	26	11	8
[+] <a href="#">rtwdemo_roll_DW</a>	9	18	15
[+] <a href="#">rtwdemo_roll_B</a>	4	2	1
[+] <a href="#">rtwdemo_roll_M</a>	4	0*	0*
[+] <a href="#">rtwdemo_roll_Y</a>	4	2	2
<b>Total</b>	<b>47</b>	<b>33</b>	

\* The global variable is not directly used in any function.

## Optimize Generated Code By Packing Boolean Data Into Bitfields

This example shows how to optimize the generated code by packing Boolean data into bitfields. When you select the model configuration parameter **Pack Boolean data into bitfields**, Embedded Coder® packs the Boolean signals into 1-bit bitfields, reducing RAM consumption. By default, the optimization is enabled. This optimization reduces the RAM consumption. Be aware that this optimization can potentially increase code size and execution speed.

### Example Model

Consider the model `rtwdemo_pack_boolean`.

```
model = 'rtwdemo_pack_boolean';
open_system(model);
```

Copyright 2014 The MathWorks, Inc.

### Disable Optimization

- 1 Open the Configuration Parameters dialog box.
- 2 On the **Optimization > Signals and Parameters** pane, clear **Pack Boolean data into bitfields**.

Alternatively, you can use the command-line API to disable the optimization:

```
set_param(model, 'BooleansAsBitfields', 'off');
```

Create a temporary folder (in your system temporary folder) for the build and inspection process.

```
currentDir = pwd;
[~,cgDir] = rtwdemodir();
```

### Generate Code Without Optimization

Build the model using Embedded Coder®.

```
rtwbuild(model)
```

```
Starting build procedure for model: rtwdemo_pack_boolean
Successful completion of build procedure for model: rtwdemo_pack_boolean
```

View the generated code without the optimization. These lines of code are in `rtwdemo_pack_boolean.h`.

```
hfile = fullfile(cgDir, 'rtwdemo_pack_boolean_ert_rtw', 'rtwdemo_pack_boolean.h');
rtwdemodbtype(hfile, '/* Block signals and states', '/* External inputs', 1, 0);
```

```
/* Block signals and states (auto storage) for system '<Root>' */
typedef struct {
 boolean_T LogicalOp1; /* '<Root>/Logical Op1' */
 boolean_T LogicalOp2; /* '<Root>/Logical Op2' */
 boolean_T LogicalOp5; /* '<Root>/Logical Op5' */
 boolean_T LogicalOp3; /* '<Root>/Logical Op3' */
 boolean_T LogicalOp4; /* '<Root>/Logical Op4' */
 boolean_T RelationalOperator; /* '<Root>/Relational Operator' */
 boolean_T UnitDelay_DSTATE; /* '<Root>/Unit Delay' */
} DW;
```

### Enable Optimization

- 1 Open the Configuration Parameters dialog box.
- 2 On the **Optimization > Signals and Parameters** pane, select **Pack Boolean data into bitfields**.

Alternatively, you can use the command-line API to enable the optimization:

```
set_param(model, 'BooleansAsBitFields', 'on');
```

### Generate Code with Optimization

Build the model using Embedded Coder®.

```
rtwbuild(model)
```

```
Starting build procedure for model: rtwdemo_pack_boolean
Successful completion of build procedure for model: rtwdemo_pack_boolean
```

View the generated code with the optimization. These lines of code are in `rtwdemo_pack_boolean.h`.

```
hfile = fullfile(cgDir, 'rtwdemo_pack_boolean_ert_rtw', 'rtwdemo_pack_boolean.h');
rtwdemodbtype(hfile, '/* Block signals and states', '/* External inputs', 1, 0);
```

```
/* Block signals and states (auto storage) for system '<Root>' */
typedef struct {
 struct {
 uint_T LogicalOp1:1; /* '<Root>/Logical Op1' */
 uint_T LogicalOp2:1; /* '<Root>/Logical Op2' */
 uint_T LogicalOp5:1; /* '<Root>/Logical Op5' */
 uint_T LogicalOp3:1; /* '<Root>/Logical Op3' */
 uint_T LogicalOp4:1; /* '<Root>/Logical Op4' */
 uint_T RelationalOperator:1; /* '<Root>/Relational Operator' */
 uint_T UnitDelay_DSTATE:1; /* '<Root>/Unit Delay' */
 } bitsForTID0;
} DW;
```

Selecting **Pack Boolean data into bitfields** enables model configuration parameter **Bitfield declarator type specifier**. To optimize your code further, select `uchar_t`. However, the optimization benefit of the **Bitfield declarator type specifier** setting depends on your choice of target.

Close the model and code generation report.

```
bdclose(model)
rtwdemoclean;
cd(currentDir)
```

## Optimize Generated Code By Passing Reusable Subsystem Outputs as Individual Arguments

This example shows how passing reusable subsystem outputs as individual arguments can optimize the generated code.

### Overview

By default, the outputs of functions generated by reusable subsystems are passed as a pointer to a structure that is stored in global memory.

This optimization changes the function signature such that the outputs of the function are passed as pointers to local variables. This allows the reduction of global memory. The code generator also might remove data copies when global memory structures are passed into the function when outputs are not passed individually.

The benefits of this optimization are to:

- Reduce the RAM consumption.
- Improve the execution speed by removing data copies.

### Review the Model

Consider the model `rtwdemo_reusable_sys_outputs`. In this model, the reusable subsystem outputs feed the root outputs of the model.

```
model = 'rtwdemo_reusable_sys_outputs';
open_system(model);
```

Copyright 2014 The MathWorks, Inc.

### Generate Code Without This Optimization

Generate code for this model while passing subsystem outputs as a structure reference. Create a temporary folder (in your system's temporary folder) for the build and inspection process.

```
currentDir = pwd;
[~,cgDir] = rtwdemodir();
```

Build the model.

```
rtwbuild(model)
```

```
Starting build procedure for model: rtwdemo_reusable_sys_outputs
Successful completion of build procedure for model: rtwdemo_reusable_sys_outputs
```

Portions of `rtwdemo_reusable_sys_outputs.c` are listed below. Notice the global block I/O structure and in the model step function a data copy from this structure.

```
cfile = fullfile(cgDir,'rtwdemo_reusable_sys_outputs_ert_rtw',...
'rtwdemo_reusable_sys_outputs.c');
rtwdemodbtype(cfile,'/* Output and update for atomic system',...
'/* Model initialize', 1, 0);
```

```
/* Output and update for atomic system: '<Root>/ReusableSubsystem' */
void ReusableSubsystem(real_T rtu_In1, real_T rtu_In2, real_T rtu_In3,
 DW_ReusableSubsystem *localDW)
{
 /* Gain: '<S1>/Gain' */
 localDW->Gain = 5.0 * rtu_In1;

 /* Gain: '<S1>/Gain1' */
 localDW->Gain1 = 6.0 * rtu_In2;

 /* Gain: '<S1>/Gain2' */
 localDW->Gain2 = 7.0 * rtu_In3;
}

/* Model step function */
void rtwdemo_reusable_sys_outputs_step(void)
{
 /* Outputs for Atomic SubSystem: '<Root>/ReusableSubsystem' */

 /* Inport: '<Root>/In1' incorporates:
 * Inport: '<Root>/In2'
 * Inport: '<Root>/In3'
 */
 ReusableSubsystem(rtU.In1, rtU.In2, rtU.In3, &rtDW.ReusableSubsystem_d);

 /* End of Outputs for SubSystem: '<Root>/ReusableSubsystem' */

 /* Outport: '<Root>/Out1' */
 rtY.Out1 = rtDW.ReusableSubsystem_d.Gain;

 /* Outport: '<Root>/Out2' */
 rtY.Out2 = rtDW.ReusableSubsystem_d.Gain1;

 /* Outport: '<Root>/Out3' */
 rtY.Out3 = rtDW.ReusableSubsystem_d.Gain2;
}
```

### Enable This Optimization

- 1 Open the Configuration Parameters dialog box.
- 2 On the **Optimization > Signals and Parameters** pane, set **Pass reusable subsystem outputs as** to **Individual arguments**.

Alternatively, you can use the command-line API to enable the optimization:

```
set_param(model, 'PassReuseOutputArgsAs', 'Individual arguments');
```

### Generate Code With This Optimization

With this optimization, the `ReusableSubsystem` function takes three output arguments, which are direct references to the external outputs. The `rtDW` global structure no longer exists and the data copies from this structure to the `rtY` (external outputs) structure are removed.

Build the model.

```
rtwbuild(model)
```

```
Starting build procedure for model: rtwdemo_reusable_sys_outputs
Successful completion of build procedure for model: rtwdemo_reusable_sys_outputs
```

A portion of `rtwdemo_reusable_sys_outputs.c` is listed below. Observe the optimized code.

```
rtwdemodbtype(cfile, /* Output and update for atomic system' ,...
'/* Model initialize', 1, 0);

/* Output and update for atomic system: '<Root>/ReusableSubsystem' */
void ReusableSubsystem(real_T rtu_In1, real_T rtu_In2, real_T rtu_In3, real_T
 *rty_Out1, real_T *rty_Out2, real_T *rty_Out3)
{
 /* Gain: '<S1>/Gain' */
 *rty_Out1 = 5.0 * rtu_In1;

 /* Gain: '<S1>/Gain1' */
 *rty_Out2 = 6.0 * rtu_In2;

 /* Gain: '<S1>/Gain2' */
 *rty_Out3 = 7.0 * rtu_In3;
}

/* Model step function */
void rtwdemo_reusable_sys_outputs_step(void)
{
 /* Outputs for Atomic SubSystem: '<Root>/ReusableSubsystem' */

 /* Inport: '<Root>/In1' incorporates:
 * Inport: '<Root>/In2'
 * Inport: '<Root>/In3'
```

```
 */
 ReusableSubsystem(rtU.In1, rtU.In2, rtU.In3, &rtY.Out1, &rtY.Out2, &rtY.Out3);

 /* End of Outputs for SubSystem: '<Root>/ReusableSubsystem' */
}
```

Close the model and cleanup.

```
bdclose(model)
rtwdemoclean;
cd(currentDir)
```

## Convert Data Copies to Pointer Assignments

The code generator optimizes generated code for vector signal assignments by trying to replace `for` loop controlled element assignments and `memcpy` function calls with pointer assignments. Pointer assignments avoid expensive data copies. Therefore, they use less stack space and offer faster execution speed than `for` loop controlled element assignments and `memcpy` function calls. If you assign large data sets to vector signals, this optimization can result in significant improvements to code efficiency.

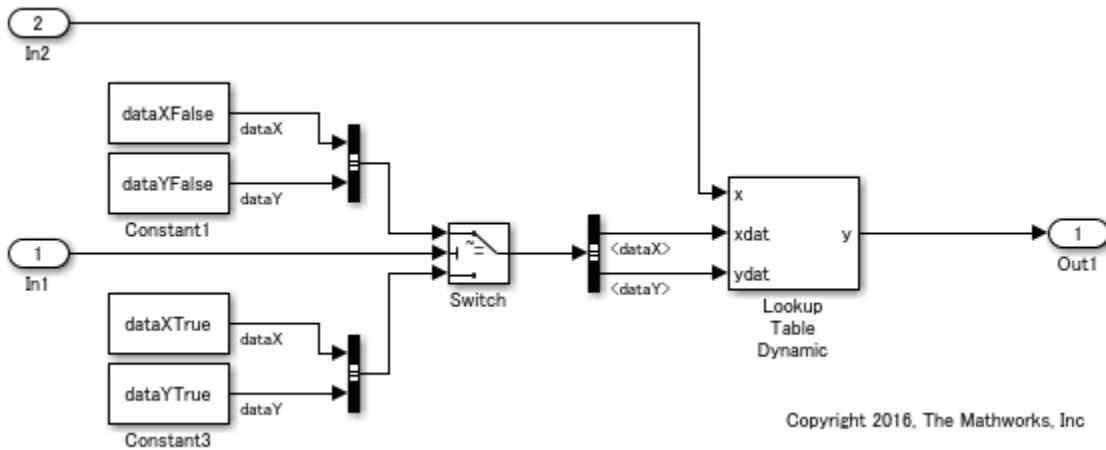

### Configure Model to Optimize Generated Code for Vector Signal Assignments

To apply this optimization:

- 1 Verify that your target supports the `memcpy` function.
- 2 Determine whether your model uses vector signal assignments (such as `Y=expression`) to move large amounts of data. For example, your model could use a Selector block to select input elements from a vector, matrix, or multidimension signal.
- 3 On the **Optimization > Signals and Parameters** pane, the **Use memcpy for vector assignment parameter**, which is on by default, enables the associated **Memcpy threshold (bytes)** parameter.
- 4 Examine the setting of **Memcpy threshold (bytes)**. By default, it specifies 64 bytes as the minimum array size for which `memcpy` function calls or pointer assignments can replace `for` loops in the generated code. Based on the array sizes in your application's vector signal assignments, and target environment considerations on the threshold selection, accept the default value or specify another array size.

### Example Model

Consider the following model named `rtwdemo_pointer_conversion`. This model uses a Switch block to assign data to a vector signal. This signal then feeds into a Bus Selector block.

### Generate Code without Optimization

- 1 In the Configuration Parameters dialog box, on the **All Parameters** tab, clear the **Use memcpy for vector assignment** parameter.
- 2 Create a temporary folder for the build and inspection process.
- 3 Press **Ctrl+B** to generate code.

```
Starting build procedure for model: rtwdemo_pointer_conversion
Successful completion of build procedure for model: rtwdemo_pointer_conversion
```

View the generated code without the optimization. Here is a portion of `rtwdemo_pointer_conversion.c`.

```
/* Model step function */
void rtwdemo_pointer_conversion_step(void)
{
 int16_T rtb_dataX[100];
 int16_T rtb_dataY[100];
 int32_T i;
 for (i = 0; i < 100; i++) {
 /* Switch: '<Root>/Switch' incorporates:
 * Constant: '<Root>/Constant'
 * Constant: '<Root>/Constant1'
 * Constant: '<Root>/Constant2'
 * Constant: '<Root>/Constant3'
 */
 }
}
```

```

 * Inport: '<Root>/In1'
 * Switch: '<Root>/Switch'
 */
 if (rtU.In1) {
 rtb_dataX[i] = rtCP_Constant_Value[i];
 rtb_dataY[i] = rtCP_Constant1_Value[i];
 } else {
 rtb_dataX[i] = rtCP_Constant2_Value[i];
 rtb_dataY[i] = rtCP_Constant3_Value[i];
 }

 /* End of Switch: '<Root>/Switch' */
}

/* Dynamic Look-Up Table Block: '<Root>/Lookup Table Dynamic'
 * Input0 Data Type: Integer S16
 * Input1 Data Type: Integer S16
 * Input2 Data Type: Integer S16
 * Output0 Data Type: Integer S16
 * Lookup Method: Linear_Endpoint
 *
 */
Lookup_S16_S16(&(rtY.Out1), &rtb_dataY[0], rtU.In2, &rtb_dataX[0], 99U);
}

```

Without the optimization, the generated code contains `for` loop controlled element assignments.

### Enable Optimization and Generate Code

- 1 In the Configuration Parameter dialog box, on the **All Parameters** tab, select the **Use memcpy for vector assignment** parameter.
- 2 Generate code.

```

Starting build procedure for model: rtwdemo_pointer_conversion
Successful completion of build procedure for model: rtwdemo_pointer_conversion

```

View the generated code without the optimization. Here is a portion of `rtwdemo_pointer_conversion.c`.

```

/* Model step function */
void rtwdemo_pointer_conversion_step(void)
{
 const int16_T *rtb_dataX_0;

```

```
const int16_T *rtb_dataY_0;

/* Switch: '<Root>/Switch' incorporates:
 * Inport: '<Root>/In1'
 */
if (rtU.In1) {
 /* Switch: '<Root>/Switch' incorporates:
 * Constant: '<Root>/Constant'
 */
 rtb_dataX_0 = &rtCP_Constant_Value[0];

 /* Switch: '<Root>/Switch' incorporates:
 * Constant: '<Root>/Constant1'
 */
 rtb_dataY_0 = &rtCP_Constant1_Value[0];
} else {
 /* Switch: '<Root>/Switch' incorporates:
 * Constant: '<Root>/Constant2'
 */
 rtb_dataX_0 = &rtCP_Constant2_Value[0];

 /* Switch: '<Root>/Switch' incorporates:
 * Constant: '<Root>/Constant3'
 */
 rtb_dataY_0 = &rtCP_Constant3_Value[0];
}

/* Dynamic Look-Up Table Block: '<Root>/Lookup Table Dynamic'
 * Input0 Data Type: Integer S16
 * Input1 Data Type: Integer S16
 * Input2 Data Type: Integer S16
 * Output0 Data Type: Integer S16
 * Lookup Method: Linear_Endpoint
 *
 */
Lookup_S16_S16(&(rtY.Out1), &rtb_dataY_0[0], rtU.In2, &rtb_dataX_0[0], 99U);
}
```

Because the setting of the **Memcpy threshold (bytes)** parameter is below the array sizes in the generated code, the optimized code contains pointer assignments for the vector signal assignments.

## Remove Reset and Disable Functions from the Generated Code

In this section...
“Example Model” on page 57-30
“Generate Code” on page 57-31
“Enable Optimization” on page 57-32

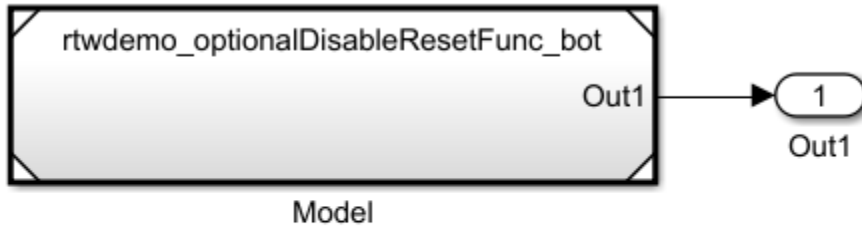

This example shows how the code generator removes unreachable (dead code) instances of the reset and disable functions from the generated code for ERT-based systems that include model referencing hierarchies. Optimizing the generated code to remove unreachable code is a requirement for safety-critical systems. This optimization also improves execution speed and reduces ROM consumption.

If a model contains blocks with states, the generated code contains reset and disable functions. If the model is not part of a conditionally executed system, such as an enabled subsystem, the code generator can remove the disable function because the generated code does not call it. If the model is not part of a conditionally executed system that can reset states when a control input enables it, the code generator can remove the reset function because the generated code does not call it.

### Example Model

A referenced model, `rtwdemo_optionalDisableResetFunc_bot`, is in `rtwdemo_optionalDisableResetFunc_top`. The referenced model contains two blocks with states, a Delay block and a Discrete-Time Integrator block.

Copyright 2016 The MathWorks, Inc

Copyright 2016 The MathWorks, Inc

## Generate Code

- 1 Open the models. In the Command Window, type `rtwdemo_optionalDisableResetFunc_bot` and `rtwdemo_optionalDisableResetFunc_top`.
- 2 In your system temporary folder, create a temporary folder for the build and inspection process.
- 3 Build the model.
- 4 Open the `rtwdemo_optionalDisableResetFunc_top.c` and `rtwdemo_optionalDisableResetFunc_bot.c` files.

The `rtwdemo_optionalDisableResetFunc_bot.c` file contains these reset and disable functions.

```
/* System reset for referenced model: 'rtwdemo_optionalDisableResetFunc_bot' */
void rtwdemo_optionalDisableResetFunc_bot_Reset
 (DW_rtwdemo_optionalDisableResetFunc_bot_f_T *localDW)
{
 /* InitializeConditions for Delay: '<Root>/Delay' */
 localDW->Delay_DSTATE = 0.0;

 /* InitializeConditions for DiscreteIntegrator: '<Root>/Discrete-Time Integrator' */
 localDW->DiscreteTimeIntegrator_DSTATE = 3.0;
}

/* Disable for referenced model: 'rtwdemo_optionalDisableResetFunc_bot' */
void rtwdemo_optionalDisableResetFunc_bot_Disable(real_T *rty_Out1,
 DW_rtwdemo_optionalDisableResetFunc_bot_f_T *localDW)
{
 /* Disable for DiscreteIntegrator: '<Root>/Discrete-Time Integrator' */
 localDW->DiscreteTimeIntegrator_DSTATE = *rty_Out1;
}
```

The `rtwdemo_optionalDisableResetFunc_top_step` function does not call the `rtwdemo_optionalDisableResetFunc_bot_Disable` function because the model is not part of a conditionally executed system. The `rtwdemo_optionalDisableResetFunc_top_step` function does not call the `rtwdemo_optionalDisableResetFunc_bot_Reset` function because the model is not part of a conditionally executed system that can reset states when a control input enables it.

## Enable Optimization

- 1 Open the Model Configuration Parameters dialog box for `rtwdemo_optionalDisableResetFunc_bot`.
- 2 On the **All Parameters** tab, select **Remove Disable Function** and **Remove Reset Function**.

Open the `rtwdemo_optionalDisableResetFunc_bot.c` file. The code does not contain the `rtwdemo_optionalDisableResetFunc_bot_Reset` function or the `rtwdemo_optionalDisableResetFunc_bot_Disable` function.

# Code Execution Profiling in Embedded Coder

---

- “Code Execution Profiling with SIL and PIL” on page 58-2
- “View and Compare Code Execution Times” on page 58-7
- “Analyze Code Execution Data” on page 58-18
- “Tips and Limitations” on page 58-21

## Code Execution Profiling with SIL and PIL

**In this section...**

“Configure Code Execution Profiling” on page 58-3

“Profiling for Atomic Subsystems and Model Reference Hierarchies” on page 58-4

You can configure a software-in-the-loop (SIL) or processor-in-the-loop (PIL) on page 64-2 simulation to produce execution-time metrics for tasks and functions in your generated code. The software calculates execution times from data that is obtained through code instrumentation added to the SIL or PIL application or the generated code under test. You can use the execution-time metrics to determine whether the generated code meets the requirements for real-time deployment on your target hardware.

For example, you can perform the following analysis:

- 1 Identify tasks that require the most time. Tasks are main entry points into the generated code. For example, the step function for a sample rate or the *model\_initialize* function.
- 2 In these tasks, investigate code sections that require the most time.
- 3 Identify variations in execution time over time steps.

If you are trying to reduce execution times, the analysis results help you to focus on the most critical code sections. To observe performance changes for an updated model, rerun the SIL or PIL simulation and compare the new metrics against previous metrics.

---

**Note:** Execution-time measurements depend greatly on the hardware that you use. For reliable results, collect execution-time metrics using hardware on which you plan to deploy the generated code, that is, run PIL simulations that execute code on your target hardware. SIL simulations, which execute code on your host computer, might not produce representative metrics.

---

When the SIL or PIL simulation is complete, you can:

- View execution-time metrics through a display window or report.
- Use the Simulation Data Inspector to view and compare the variation of execution times over a simulation.

- Analyze the measurements within the MATLAB environment.

## Configure Code Execution Profiling

To configure code execution profiling for a SIL or PIL simulation:

- 1 In your top model, open the Configuration Parameters dialog box, and select the **Code Generation > Verification** pane.
- 2 Select the **Measure task execution time** check box.
- 3 If you also want function execution times, select the **Measure function execution times** check box.
- 4 In the **Workspace variable** field, specify a name. When you run the simulation, the software generates a variable with this name in the MATLAB base workspace. The variable contains the execution-time measurements, and is an object of type `coder.profile.ExecutionTime`.

If you select the **Data Import/Export > Single simulation output** check box, the software creates the variable in the `Simulink.SimulationOutput` object that you specify.

- 5 From the **Save options** drop-down list, select one of the following:
  - **Summary data only** — If you want to generate only a report and reduce memory usage, for example, during a long simulation.
  - **All data** — Allows you to generate a report and store execution-time profiles in the base workspace. After the simulation, you can use methods from the `coder.profile.ExecutionTime` and `coder.profile.ExecutionTimeSection` classes to retrieve execution-time measurements for every call to each profiled section of code that occurs during the simulation.
- 6 Click **OK**.

For a PIL simulation, you must configure a hardware-specific timer. When you set up the connectivity configuration for your target, create a timer object. This action is not required for a SIL simulation.

If you select **All data** from the **Save options** drop-down list, the metrics display window and generated report display Simulation Data Inspector icons . When you click one of these icons, the software imports simulation results into the Simulation Data

Inspector. You can then plot execution times and manage and compare plots from various simulations.

## Profiling for Atomic Subsystems and Model Reference Hierarchies

To generate execution-time metrics for tasks only, on the **Code Generation > Verification** pane of the Configuration Parameters dialog box, select the **Measure task execution time** check box and clear the **Measure function execution times** check box.

To generate function execution data for atomic subsystems in the top model, on the **Code Generation > Verification** pane, select the **Measure task execution time** and **Measure function execution times** check boxes.

The generation of function execution data requires the insertion of measurement probes into the generated code. The software inserts measurement probes for an atomic subsystem only if you set the **Function packaging** field (on the **Code Generation** tab of the Function Block Parameters dialog box) to either **Nonreusable function** or **Reusable function**. If the field is set to **Auto**, then the insertion of probes depends on the packaging choice that results from the **Auto** setting. If the field is set to **Inline**, the software does not insert probes.

---

**Note:** In the generated code, the software wraps each function call with measurement probes except when:

- The call site cannot be wrapped because of expression folding (see “Minimize Computations and Storage for Intermediate Results at Block Outputs”).
  - The call site is located in the shared utility code (see “Sharing Utility Code”).
- 

You might not want to generate profiles for specific subsystems. To disable code execution profiling for a subsystem in the top model:

- 1 Right-click the subsystem.
- 2 From the context menu, select **Properties**.
- 3 In the Block Properties dialog box, select the **General** tab.
- 4 In the **Tag** field, enter `DoNotProfile`.
- 5 Click **OK**.

To generate function execution data for model reference hierarchies:

- 1 In the top model, open the Configuration Parameters dialog box, and select the **Code Generation > Verification** pane.
- 2 Select the **Measure task execution time** check box.
- 3 For each Model block that you want to profile, select **Measure function execution times** only at the reference level for which you require function execution data.

For example, consider a top model that has Model block A, which in turn contains Model block B.

If you want to generate execution times for functions from model B, select **Measure task execution time** for the top model and **Measure function execution times** for model B.

---

**Note:** By default, the Model block parameter **Code interface** is set to **Model reference**. If this block parameter is set to **Top model**, the configuration parameter **Measure task execution time** for the top model and the referenced model must be the same. Otherwise, the software produces an error.

---

If your top model has a PIL block, the execution profiling settings that apply to the PIL block are the settings from the original model that you used to create the PIL block. See “Simulation with Blocks From Subsystems” on page 64-18. The execution profiling settings of your top model do not apply to the PIL block.

## View and Compare Code Execution Times

During a software-in-the-loop (SIL) or processor-in-the-loop (PIL) simulation, you can use the Simulation Data Inspector to observe streamed execution times. At the end of the simulation, you can:

- View execution-time metrics for a profiled model component.
- Open a report of execution-time metrics for all profiled components.
- Use the Simulation Data Inspector to plot and compare execution times from various simulations.

Consider the model `rtwdemo_sil_topmodel`, which has two subsystems `CounterTypeA` and `CounterTypeB`.

To measure code execution times for the subsystems, on the **Configuration Parameters > Code Generation > Verification** pane:

- 1 Select the following check boxes:
  - **Measure task execution time**
  - **Measure function execution times**
- 2 Specify a **Workspace variable**, for example, `executionProfile`.
- 3 From the **Save options** drop-down list, select `All data`.

The simulation generates the variable `executionProfile` in the MATLAB base workspace.

---

**Note:** If you select the **Data Import/Export > Single simulation output** check box, the simulation creates the variable in your specified `Simulink.SimulationOutput` object.

---

To view streamed execution times during the simulation, open the Simulation Data Inspector. On the Simulink Editor toolbar, click the Simulation Data Inspector button.

When the simulation is complete, the profiled model components are colored blue. To view execution-time metrics for a profiled component, click the component. For example, subsystem `CounterTypeB`.

The display window also has links to:

- The complete profiling report, which provides execution-time metrics for all profiled code sections.
- The profiled code section in the code generation report.
- The Simulation Data Inspector, which allows you to plot and compare execution-time measurements for the profiled code section.

For top-model SIL or PIL simulations, the Simulink Editor background is also colored blue. When you click the background, the display window shows execution-time metrics for top-model tasks.

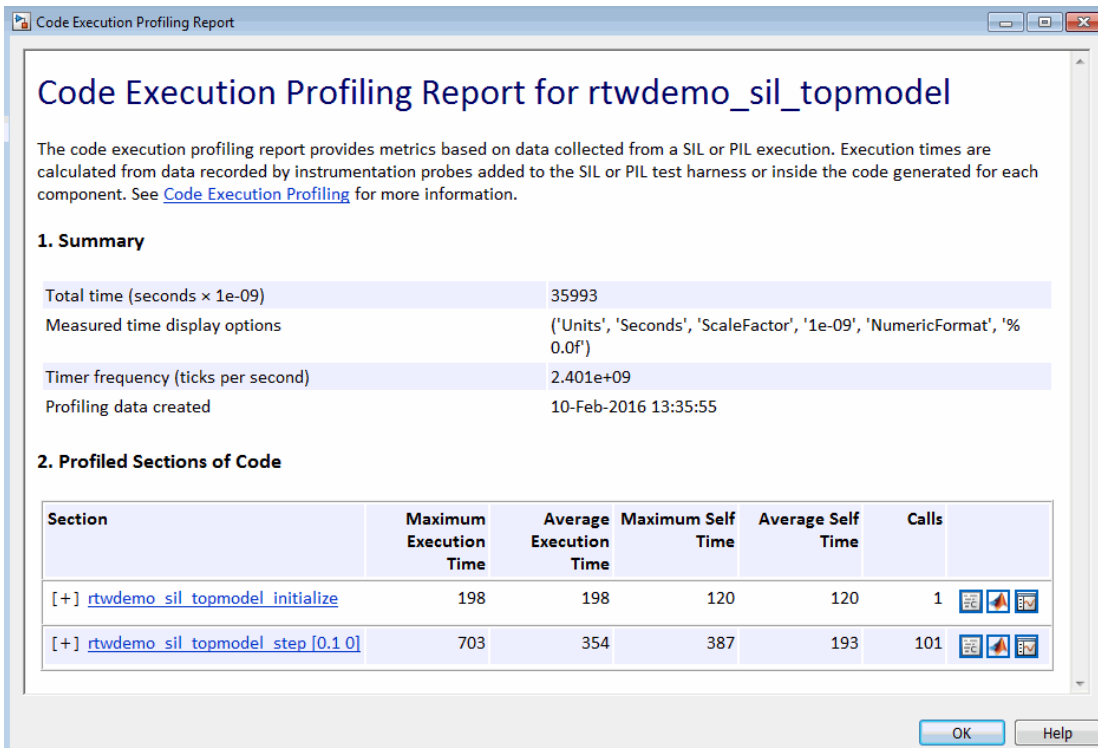

If you close the model or display window, you can reopen the colored model and display window with this line command:

```
>> annotate(executionProfile)
```

## Code Execution Profiling Report

At the end of the simulation, you can open this report through the metrics display window or with this line command:

```
>> report(executionProfile)
```

Part 1 provides a summary. Part 2 contains information about profiled code sections.

Expand and collapse profiled sections in Part 2 by clicking [+] and [-] respectively. This graphic shows fully expanded sections.

## 2. Profiled Sections of Code

Section	Maximum Execution Time	Average Execution Time	Maximum Self Time	Average Self Time	Calls	
[ - ] <a href="#">rtwdemo_sil_topmodel_initialize</a>	198	198	120	120	1	  
<a href="#">CounterTypeA</a>	52	52	52	52	1	  
<a href="#">CounterTypeB</a>	27	27	27	27	1	  
[ - ] <a href="#">rtwdemo_sil_topmodel_step [0.1 0]</a>	703	354	387	193	101	  
<a href="#">CounterTypeA</a>	257	116	257	116	101	  
<a href="#">CounterTypeB</a>	87	45	87	45	101	  

The report contains time measurements for:

- The model initialization function `rtwdemo_sil_topmodel_initialize`.
- A task represented by the step function `rtwdemo_sil_topmodel_step [0.1 0]`.
- Functions generated from the subsystems `CounterTypeA` and `CounterTypeB`.

You can go to a profiled code section in the Generated Code view of the Code Generation Report. In the Code Execution Profiling Report, on a code section row, click the icon . For example, if you click the icon for the `rtwdemo_sil_topmodel_initialize` task, you see the measurement probes around the call site in the SIL application.

```
66 XIL_INTERFACE_ERROR_CODE xilInitialize(uint32_T xilFcnId)
67 {
68 XIL_INTERFACE_ERROR_CODE errorCode = XIL_INTERFACE_SUCCESS;
69
70 /* initialize output storage owned by In-the-Loop */
71 /* Single In-the-Loop Component */
72 if (xilFcnId == 0) {
73 taskTimeStart_51c545e6ce8b10bf(1U);
74 rtwdemo_sil_topmodel_initialize();
75 taskTimeEnd_rt_38248ea98502ec29(1U);
76 } else {
77 errorCode = XIL_INTERFACE_UNKNOWN_FCNIID;
78 }
79
80 return errorCode;
81 }
```

If you click the icon for a function, the call site is highlighted.

```
147 /* Model step function */
148 void rtwdemo_sil_topmodel_step(void)
149 {
150 /* Logic: '<Root>/Logical Operator2' incorporates:
151 * Inport: '<Root>/count_enable'
152 * Inport: '<Root>/counter_mode'
153 * Logic: '<Root>/Logical Operator'
154 */
155 enableA = ((!rtU.counter_mode) && rtU.count_enable);
156
157 /* Outputs for Enabled SubSystem: '<Root>/CounterTypeA' */
158 CounterTypeA();
159
160 /* End of Outputs for SubSystem: '<Root>/CounterTypeA' */
```

From the Code Execution Profiling Report, you can trace the model component that produces a set of metrics. For example, in the **Section** column, if you click the CounterTypeA hyperlink, the Simulink Editor identifies the subsystem.

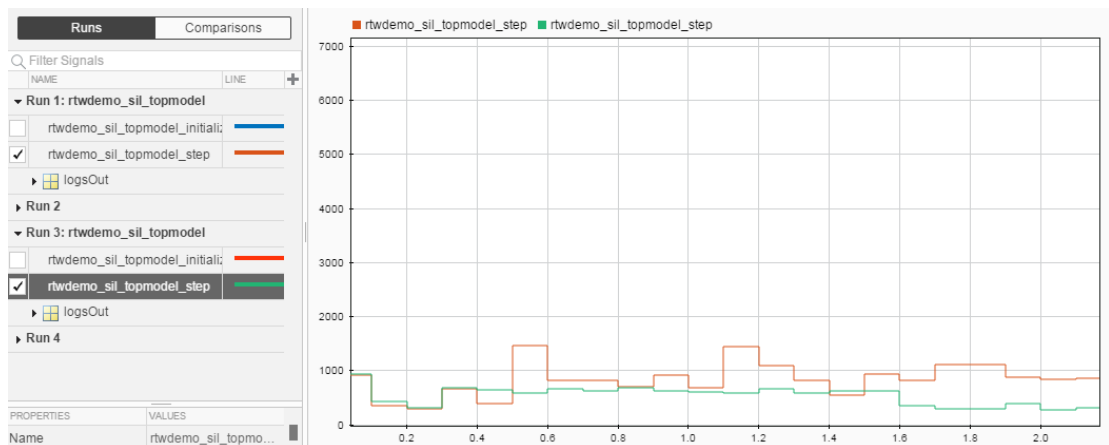

By default, the report displays time in nanoseconds ( $10^{-9}$  seconds). You can specify the time unit and numeric display format. For example, to display time in microseconds ( $10^{-6}$  seconds), use the following command:

```
>>report(executionProfile,'Units','Seconds','ScaleFactor','1e-06','NumericFormat','%0.3f')
```

The report displays time in seconds only if the timer is calibrated, that is, the number of timer ticks per second is known. On a Windows machine, the software determines this value for a SIL simulation. On a Linux machine, calibrate the timer manually. For example, if your processor speed is 1 GHz, specify the number of timer ticks per second:

```
>>executionProfile.TimerTicksPerSecond = 1e9;
```

To display measured execution times for a task or function, click the Simulation Data Inspector icon  on the corresponding row. Use the Simulation Data Inspector to manage and compare plots from various simulations.

**Note:** To observe how code sections are invoked over the execution timeline, use the `timeline` function.

The following table describes the information provided in the code section profiles.

Column	Description
Section	Name of task, top model, subsystem, or Model block. Click the link to go to the model.

Column	Description
	With a task, the sample period and sample offset are listed next to the task name. For example, <i>rtwdemo_sil_topmodel_step [0.1 0]</i> indicates that the sample period is 0.1 seconds and the sample offset is 0.
Maximum Execution Time	Maximum time between the start and the end of function execution. Includes time spent in child functions.
Average Execution Time	Average time between start and end of execution. Includes time spent in child functions.
Maximum Self Time	Longest time spent in the function. Excludes time spent in child functions.
Average Self Time	Average time spent in function. Excludes time spent in child functions.
Calls	Number of calls made to the task or function.
	Icon that you click to see the profiled code section in the Generated Code view of the Code Generation Report. The code section can be a task or a function.  The specified workspace variable, for example, <code>executionProfile</code> , must be present in the base workspace.
	Icon that you click to display the profiled code section in the Command Window. Equivalent to executing the command <code>executionProfile.Sections(i)</code> .  The specified workspace variable, for example, <code>executionProfile</code> , must be present in the base workspace.
	Icon that you click to display measured execution times with Simulation Data Inspector.  The specified workspace variable, for example, <code>executionProfile</code> , must be present in the base workspace.

## **More About**

- “Tips and Limitations” on page 58-21

## Analyze Code Execution Data

After a SIL or PIL simulation, you can analyze execution-time data using methods from the `coder.profile.ExecutionTime` and `coder.profile.ExecutionTimeSection` classes.

- 1 Open `rtwdemo_sil_topmodel`.
- 2 On the **Configuration Parameters > Code Generation > Verification** pane, specify profiling options:
  - Select the **Measure task execution time** check box.
  - Specify a **Workspace variable**, for example, `myExecutionProfile`.
  - From the **Save options** drop-down list, select **All data**.
- 3 Run a SIL simulation.

The software generates the workspace variable `myExecutionProfile`, an `coder.profile.ExecutionTime` object.

To get the total number of code sections that have profiling data, use the `Sections` method.

```
>> no_of_Sections = myExecutionProfile.Sections

no_of_Sections =

1x2 ExecutionTimeTaskSection array with properties:

Name
Number
ExecutionTimeInTicks
SelfTimeInTicks
TurnaroundTimeInTicks
TotalExecutionTimeInTicks
TotalSelfTimeInTicks
TotalTurnaroundTimeInTicks
MaximumExecutionTimeInTicks
MaximumExecutionTimeCallNum
MaximumSelfTimeInTicks
MaximumSelfTimeCallNum
MaximumTurnaroundTimeInTicks
MaximumTurnaroundTimeCallNum
NumCalls
ExecutionTimeInSeconds
Time
```

To get the `coder.profile.ExecutionTimeSection` object for a profiled code section, use the method `Sections`.

```

>> FirstSectionProfile = myExecutionProfile.Sections(1)
SecondSectionProfile = myExecutionProfile.Sections(2)

FirstSectionProfile =

 ExecutionTimeTaskSection with properties:

 Name: 'rtwdemo_sil_topmodel_initialize'
 Number: 1
 ExecutionTimeInTicks: 1188
 SelfTimeInTicks: 1188
 TurnaroundTimeInTicks: 1188
 TotalExecutionTimeInTicks: 1188
 TotalSelfTimeInTicks: 1188
 TotalTurnaroundTimeInTicks: 1188
 MaximumExecutionTimeInTicks: 1188
 MaximumExecutionTimeCallNum: 1
 MaximumSelfTimeInTicks: 1188
 MaximumSelfTimeCallNum: 1
 MaximumTurnaroundTimeInTicks: 1188
 MaximumTurnaroundTimeCallNum: 1
 NumCalls: 1
 ExecutionTimeInSeconds: 5.4000e-07
 Time: 0

SecondSectionProfile =

 ExecutionTimeTaskSection with properties:

 Name: 'rtwdemo_sil_topmodel_step [0.1 0]'
 Number: 2
 ExecutionTimeInTicks: [1×101 uint64]
 SelfTimeInTicks: [1×101 uint64]
 TurnaroundTimeInTicks: [1×101 uint64]
 TotalExecutionTimeInTicks: 70316
 TotalSelfTimeInTicks: 70316
 TotalTurnaroundTimeInTicks: 70316
 MaximumExecutionTimeInTicks: 2448
 MaximumExecutionTimeCallNum: 2
 MaximumSelfTimeInTicks: 2448
 MaximumSelfTimeCallNum: 2
 MaximumTurnaroundTimeInTicks: 2448
 MaximumTurnaroundTimeCallNum: 2
 NumCalls: 101
 ExecutionTimeInSeconds: [1×101 double]
 Time: [101×1 double]

```

Use `coder.profile.ExecutionTimeSection` methods to extract profiling information for a particular code section. For example, use `Name` to obtain the name of a profiled task.

```

>> name_of_section = SecondSectionProfile.Name

name_of_section =

```

```
rtwdemo_sil_topmodel_step [0.1 0]
```

If the timer is uncalibrated and you know the timer rate, for example 2.2 GHz, you can use the `coder.profile.ExecutionTime` method `TimerTicksPerSecond` to calibrate the timer:

```
>> myExecutionProfile.TimerTicksPerSecond = 2.2e9;
>> SecondSectionProfile = myExecutionProfile.Sections(2);
```

## Tips and Limitations

### In this section...

“Triggered Model Block” on page 58-21

“Outliers in Execution-Time Profiles” on page 58-21

“Hardware-Specific Timer” on page 58-23

“Task Context Switching Due to Preemption” on page 58-23

“Data Type Replacement Support” on page 58-24

“Subsystem Code Reuse” on page 58-24

“Cannot Load Execution-Time Measurements from Previous Release” on page 58-24

### Triggered Model Block

Consider the case where a triggered Model block is configured to run in the SIL or PIL simulation mode. The software generates one execution-time measurement each time the referenced model is triggered to run. If there are multiple triggers in a single time step, the software generates multiple measurements for the triggered Model block. Conversely, if there is no trigger in a given time step, the software generates no time measurements.

### Outliers in Execution-Time Profiles

When you run a SIL simulation with execution time profiling enabled, you might see spikes in execution-time measurements.

The spikes are due to process preemption that occurs with a multitasking host operating system. If the operating system preempts the SIL process and runs another process, the measured execution time includes the time during which the SIL process is suspended. With a PIL simulation, you do not see spikes because code execution on the target is not preempted.

Counter wrapping produces execution-time measurements that are smaller than expected. For SIL, the counter wraps when an execution-time period is greater than  $2^{64}$  ticks ( $2^{32}$  ticks if the MEX compiler is LCC). For PIL, the wrapping point depends on the timer you specify and can be  $2^8$ ,  $2^{16}$ ,  $2^{32}$ , or  $2^{64}$  ticks.

Consider a PIL example where the timer frequency is 20 MHz. For a 32-bit timer, wrapping occurs when the execution-time period is greater than  $1 / (20 \times 10^6) * (2^{32} - 1)$ , that is, 214.7 s. However, for a 16-bit timer, the point at which wrapping occurs is 0.0033 s.

For a real-time, multi-core application, the software accommodates synchronization discrepancies when recording timer values for different cores, which effectively reduces the timer measurement range.

## Hardware-Specific Timer

If your target configuration does not already specify a timer, create a timer object that provides details of the hardware-specific timer and associated source files:

- For SIL simulation, the timer word length is determined by your MEX compiler. The word length is 64 bits, unless your selected MEX compiler is LCC. In this case, the word length is 32 bits.
- For PIL simulation, you can specify an 8-, 16-, 32-, or 64-bit timer.

## Task Context Switching Due to Preemption

Profiling instrumentation is intrusive and affects the quantity that it is meant to measure. Therefore, the design goal is to maximize code understanding with a minimum of instrumentation. For example, with a real-time system, there can be task context switches due to preemption. These context switches are not explicitly instrumented. To record the start and end of each task, the software must infer context switches from instrumentation. As a result, the software reports behavior that is an estimate. The estimate is subject to error because of incomplete instrumentation within the kernel.

In some cases, when the software cannot accurately determine behavior, the software generates a warning:

```
Warning: Analysis unsuccessful for one or more profiling data points. ...
For example, the software might generate this warning when not all mutex take system
calls (associated with rate transitions) are instrumented. In the case of Simulink Real-
Time, this situation might arise if you generate code for a model reference hierarchy
without enabling function profiling for all referenced models (set_param(model,
'CodeProfilingInstrumentation', 'on')). If a mutex take system call is not
instrumented, a task context switch might occur that is not visible to the execution
profiling analysis.
```

In other cases, although the software cannot accurately determine behavior, the software does *not* generate a warning.

## Data Type Replacement Support

Data type replacement does not support the measurement of function execution times. For your model, clear one of the following check boxes:

- **Configuration Parameters > Code Generation > Verification > Measure function execution times**
- **Configuration Parameters > Code Generation > Data Type Replacement > Replace data type names in the generated code**

## Subsystem Code Reuse

You cannot generate execution-time profiles for function call sites within subsystem code that is reused across a model or multiple models. For information about subsystem code reuse, see “Code Reuse For Subsystems Shared Across Models”.

## Cannot Load Execution-Time Measurements from Previous Release

You cannot load execution-time measurements saved with a previous release. For example, using R2014a, you save workspace variables to a MAT-file. One of the workspace variables contains execution-time measurements. In R2015b, if you try to load the MAT-file, you see this error:

```
Format of execution profiling data is invalid. This error can occur if you load data from a previous release. Loading data from a previous release is not supported.
```

# Code Execution Profiling for MATLAB Coder

---

- “Execution Time Profiling for SIL and PIL” on page 59-2
- “Generate Execution Time Profile” on page 59-3
- “View Execution Times” on page 59-4
- “Analyze Execution Time Data” on page 59-7

## Execution Time Profiling for SIL and PIL

During a software-in-the-loop (SIL) or processor-in-the-loop (PIL) execution, you can produce a profile of execution times for code generated from entry-point functions. The software calculates execution times from data that is obtained through instrumentation probes added to the SIL or PIL application.

Use the execution time profile to check whether your code runs within the required time on your target hardware:

- If code execution overruns, look for ways to reduce execution time.
- If your code easily meets time requirements, consider enhancing functionality to exploit the unused processing power.

At the end of the SIL or PIL execution, you can:

- View a report of code execution times.
- Use the Simulation Data Inspector to view and compare plots of function execution times.
- Access and analyze execution time profiling data.

---

**Note:** SIL and PIL execution supports multiple entry-point functions. An entry-point function can call another entry-point function as a subfunction. However, the software generates execution time profiles only for functions that are called at the entry-point level. The software does not generate execution time profiles for entry-point functions that are called as subfunctions by other entry-point functions.

---

### Related Examples

- “Generate Execution Time Profile” on page 59-3
- “View Execution Times” on page 59-4
- “Analyze Execution Time Data” on page 59-7

## Generate Execution Time Profile

Before running a software-in-the-loop (SIL) or processor-in-the-loop (PIL) execution, enable execution time profiling:

- 1 To open the MATLAB Coder app, on the MATLAB Toolstrip **Apps** tab, under **Code Generation**, click the app icon.
- 2 To open your project, click  and then click **Open existing project**. Select the project.
- 3 On the **Generate Code** page, click **Verify Code**.
- 4 Select the **Enable entry point execution profiling for SIL/PIL** check box.

Or, from the Command Window, specify the `CodeExecutionProfiling` property of your `coder.EmbeddedCodeConfig` object. For example:

```
config.CodeExecutionProfiling = true;
```

### Related Examples

- “Software-in-the-Loop Execution with the MATLAB Coder App” on page 66-4
- “Processor-in-the-Loop Execution with the MATLAB Coder App” on page 66-25
- “View Execution Times” on page 59-4
- “Analyze Execution Time Data” on page 59-7

### More About

- “Execution Time Profiling for SIL and PIL” on page 59-2

## View Execution Times

When you run a SIL or PIL execution with execution time profiling enabled, the software generates a message in the **Test Output** tab. For example:

```
Current plot held
Starting SIL execution for 'kalman01'
 To terminate execution: clear kalman01_sil
 Execution profiling data is available for viewing. Open Simulation Data Inspector.
 Execution profiling report available after termination.
Current plot released
```

To observe streamed execution times while the execution runs, click the **Simulation Data Inspector** link.

To open the code execution profiling report:

- 1 Click the **Stop SIL Verification** link.

The software terminates the execution process and displays a new link.

```
Stopping SIL execution for 'kalman01'
 Execution profiling report: report(getCoderExecutionProfile('kalman01'))
```

- 2 Click the new link.

### Code Execution Profiling Report for kalman01

The code execution profiling report provides metrics based on data collected from a SIL or PIL execution. Execution times are calculated from data recorded by instrumentation probes added to the SIL or PIL test harness or inside the code generated for each component. See [Code Execution Profiling](#) for more information.

#### 1. Summary

Total time (seconds × 1e-09)	2206501
Measured time display options	('Units', 'Seconds', 'ScaleFactor', '1e-09', 'NumericFormat', '%0.0f')
Timer frequency (ticks per second)	3.06e+09
Profiling data created	01-Apr-2014 10:21:25

#### 2. Profiled Sections of Code

Section	Maximum Execution Time	Average Execution Time	Maximum Self Time	Average Self Time	Calls	
<a href="#">kalman01_initialize</a>	1076	1076	1076	1076	1	 
<a href="#">kalman01</a>	16009	7351	16009	7351	300	 
<a href="#">kalman01_terminate</a>	138	138	138	138	1	 

The first section provides a summary. The second section contains information about profiled code sections.

The report contains time measurements for:

- The `entry_point_fn_initialize` function, for example, `kalman01_initialize`.
- The entry-point function, for example, `kalman01`.
- The `entry_point_fn_terminate` function, for example, `kalman01_terminate`.

By default, the report displays time in nanoseconds ( $10^{-9}$  seconds). You can specify the time unit and numeric display format. For example, to display time in microseconds ( $10^{-6}$  seconds), use the `report` command:

```
executionProfile=getCoderExecutionProfile('kalman01'); % Create workspace var
report(executionProfile, ...
 'Units', 'Seconds', ...
 'ScaleFactor', '1e-06', ...
 'NumericFormat', '%0.3f')
```

The report displays time in seconds only if the timer is calibrated, that is, the number of timer ticks per second is established. On a Windows machine, the software determines this value for a SIL simulation. On a Linux machine, you must manually calibrate the timer. For example, if your processor speed is 1 GHz, specify the number of timer ticks per second:

```
executionProfile.TimerTicksPerSecond = 1e9;
```

To display measured execution times for a function, click the Simulation Data Inspector icon  on the corresponding row. You can use the Simulation Data Inspector to manage and compare plots from various executions.

The following table lists the information provided in the code section profiles.

Column	Description
Section	Name of function from which code is generated.
Maximum Execution Time	Maximum time between start and end of function execution. Includes time spent in child functions.
Average Execution Time	Average time between start and end of execution. Includes time spent in child functions.
Maximum Self Time	Longest time spent in function. Excludes time spent in child functions.

Column	Description
Average Self Time	Average time spent in function. Excludes time spent in child functions.
Calls	Number of calls made to function.
	Icon that you click to display the profiled code section.
	Icon that you click to display measured execution times with Simulation Data Inspector.

### Related Examples

- “Generate Execution Time Profile” on page 59-3
- “Analyze Execution Time Data” on page 59-7
- “Inspect Signal Data with Simulation Data Inspector”

## Analyze Execution Time Data

After a software-in-the-loop (SIL) or processor-in-the-loop (PIL) execution, you can analyze execution-time data using methods from the `coder.profile.ExecutionTime` and `coder.profile.ExecutionTimeSection` classes.

In the following example, you run a SIL execution and apply supplied methods to execution-time data.

### Extract Execution Time Data for Kalman Estimator Code

#### 1 Run SIL execution to generate execution time data

Copy MATLAB code to your working folder.

```
src_dir = ...
 fullfile(docroot, 'toolbox', 'coder', 'examples', 'kalman');

copyfile(fullfile(src_dir, 'kalman01.m'), '.')
copyfile(fullfile(src_dir, 'test01_ui.m'), '.')
copyfile(fullfile(src_dir, 'plot_trajectory.m'), '.')
copyfile(fullfile(src_dir, 'position.mat'), '.')
```

For a description of the Kalman estimator, see “C Code Generation at the Command Line”.

Create a `coder.EmbeddedCodeConfig` object.

```
config = coder.config('lib');
config.GenerateReport = true; % HTML report
```

Configure the object for SIL and enable execution time profiling.

```
config.VerificationMode = 'SIL';
config.CodeExecutionProfiling = true;
```

Generate library code for the `kalman01` MATLAB function and the SIL interface.

```
codegen('-config', config, '-args', {zeros(2,1)}, 'kalman01');
```

Run the MATLAB test file `test01_ui` with `kalman01_sil`. `kalman01_sil` is the SIL interface for `kalman01`.

```
coder.runTest('test01_ui', ['kalman01_sil.' mexext]);
```

You see the following message.

```
Starting SIL execution for 'kalman01'
To terminate execution: clear kalman01_sil
Execution profiling data is available for viewing. Go to Simulation Data Inspector.
Execution profiling report available after termination.
Current plot released
```

Terminate the SIL execution process. Click the link `clear kalman01_sil`.

```
Stopping SIL execution for 'kalman01'
Execution profiling report: report(getCoderExecutionProfile('kalman01'))
```

## 2 Create workspace variable that holds execution time data

Use the `getCoderExecutionProfile` function to create a workspace variable that holds execution time profiling data.

```
executionProfile=getCoderExecutionProfile('kalman01');
```

## 3 Extract code sections

Use the `Sections` method.

```
allSections = executionProfile.Sections
```

The software displays the number of code sections and a list of properties.

```
allSections =

1x3 ExecutionTimeTaskSection array with properties:

Name
Number
ExecutionTimeInTicks
SelfTimeInTicks
TurnaroundTimeInTicks
TotalExecutionTimeInTicks
TotalSelfTimeInTicks
TotalTurnaroundTimeInTicks
MaximumExecutionTimeInTicks
MaximumExecutionTimeCallNum
MaximumSelfTimeInTicks
MaximumSelfTimeCallNum
MaximumTurnaroundTimeInTicks
MaximumTurnaroundTimeCallNum
NumCalls
ExecutionTimeInSeconds
Time
```

#### 4 Extract execution time data from specific code section

Specify the code section that you want to examine.

```
secondSectionProfile = executionProfile.Sections(2)
```

The software displays profile data for the code section.

```
secondSectionProfile =
 ExecutionTimeTaskSection with properties:
 Name: 'kalman01'
 Number: 2
 ExecutionTimeInTicks: [1x300 uint64]
 SelfTimeInTicks: [1x300 uint64]
 TurnaroundTimeInTicks: [1x300 uint64]
 TotalExecutionTimeInTicks: 6641016
 TotalSelfTimeInTicks: 6641016
 TotalTurnaroundTimeInTicks: 6641016
 MaximumExecutionTimeInTicks: 48864
 MaximumExecutionTimeCallNum: 158
 MaximumSelfTimeInTicks: 48864
 MaximumSelfTimeCallNum: 158
 MaximumTurnaroundTimeInTicks: 48864
 MaximumTurnaroundTimeCallNum: 158
 NumCalls: 300
 ExecutionTimeInSeconds: [1x300 double]
 Time: [300x1 double]
```

You can extract specific properties, for example, the name of a profiled function.

```
nameOfSection = secondSectionProfile.Name
```

The software displays the name.

```
nameOfSection =
 kalman01
```

The following table lists the information that you can extract from each code section.

Property	Description
Name	Name of entry-point function
Number	Code section number

Property	Description
ExecutionTimeInTicks	Vector of execution times, measured in timer ticks. Each element contains the difference between the timer reading at the start and at the end of the code section. The data type is the same data type as the data type of the timer used on the target, which allows you to infer the maximum range of the timer measurements.
SelfTimeInTicks	Vector of timer tick numbers. Each element contains the number of ticks recorded for the code section, excluding the time spent in calls to child functions.
TurnaroundTimeInTicks	Vector of timer tick numbers. Each element contains the number of ticks recorded between the start and the finish of the code section. Unless the code is preempted, this number is the same number as the execution time.
TotalExecutionTimeInTicks	Total number of timer ticks recorded for the code section over the entire execution.
TotalSelfTimeInTicks	Total number of timer ticks recorded for the profiled code section over the entire execution. However, this number excludes the time spent in calls to child functions.
TotalTurnaroundTimeInTicks	Total number of timer ticks recorded between the start and the finish of the profiled code section over the entire execution. Unless the code is preempted, this number is the same as the total execution time.
MaximumExecutionTimeInTicks	Maximum number of timer ticks recorded for a single invocation of the code section over the execution.
MaximumExecutionTimeCallNum	Number of call in which MaximumExecutionTimeInTicks occurs.
MaximumSelfTimeInTicks	Maximum number of timer ticks recorded for a single code section invocation, but excluding the time spent in calls to child functions.
MaximumSelfTimeCallNum	Number of call in which MaximumSelfTimeInTicks occurs.
MaximumTurnaroundTimeInTicks	Maximum number of timer ticks recorded between the start and the finish of a single invocation of the profiled code section over the execution. Unless the code is preempted, this time is the same as the maximum execution time.

Property	Description
MaximumTurnaroundTimeCallNum	Number of call in which MaximumTurnaroundTimeInTicks occurs.
NumCalls	Total number of calls to the code section over the entire execution.
ExecutionTimeInSeconds	Vector of execution times, measured in seconds. Each element contains the difference between the timer reading at the start and at the end of the code section. Produced only if TimerTicksPerSecond is set.
Time	Vector of execution time measurements for the code section.

# Verification

# Simulation and Code Comparison in Simulink Coder

---

## Simulation and Code Comparison

### In this section...

“Configure Signal Data for Logging” on page 60-2

“Log Simulation Data” on page 60-3

“Run Executable and Load Data” on page 60-5

“Visualize and Compare Results” on page 60-6

“Compare States for Simulation and Code Generation” on page 60-8

This example shows how to verify the answers computed by code generated from the `slexAircraftExample` model. It shows how to capture and compare two sets of output data. Simulating the model produces one set of output data. Executing the generated code produces a second set of output data.

---

**Note** To obtain a valid comparison between model output and the generated code, use the same **Solver options** and **Step size** for the simulation run and the build process.

---

### Configure Signal Data for Logging

Configure the model for logging and recording signal data.

- 1 Make sure that `slexAircraftExample` is closed. Clear the base workspace to eliminate the results of previous simulation runs. In the Command Window, type:

```
clear
```

The clear operation clears variables created during previous simulations and all workspace variables, some of which are standard variables that the `slexAircraftExample` model requires.

- 2 In the Command Window, enter `slexAircraftExample` to open the model.
- 3 In the model window, choose **File > Save As**, navigate to the working folder, and save a copy of the `slexAircraftExample` model as `myAircraftExample`.
- 4 Set up your model to log signal data for signals: `Stick`, `alpha`, `rad`, and `q`, `rad/sec`. For each signal:
  - a Right-click the signal. From the context menu, select **Properties**.

- b** In the Signal Properties dialog box, select **Log signal data**.
- c** In the **Logging name** section, from the drop-down list, select **Custom**.
- d** In the text field, enter the logging name for the corresponding signal.

Signal Name	Logging Name
Stick	Stick_input
alpha, rad	Alpha
q, rad/sec	Pitch_rate

- e** Click **Apply** and **OK**.

For more information, see “Export Signal Data Using Signal Logging”.

- 5** Select **Simulation > Model Configuration Parameters** to open the Configuration Parameters dialog box.
- 6** Select the **Solver** pane and in the **Solver options** section, specify the **Type** parameter as **Fixed-step**.
- 7** On the **Data Import/Export** pane:
  - Specify the **Format** parameter as **Structure with time**.
  - Clear the **States** parameter check box.
  - Select the **Signal logging** parameter.
  - Select the **Record logged workspace data in Simulation Data Inspector** parameter to enable logged signal data to send to the Simulation Data Inspector after the simulation is finished.
- 8** Save the model.

Proceed to “Log Simulation Data” on page 60-3.

## Log Simulation Data

Run the simulation, log the signal data, and view the data in the Simulation Data Inspector.

- 1** Run the model. When the simulation is done, on the Simulink Editor toolbar, the **Simulation Data Inspector** button is highlighted to indicate that new simulation output is available in the Simulation Data Inspector.

- 2 Click the **Simulation Data Inspector** button to open the Simulation Data Inspector.
- 3 Group the signals:
  - a On the **Visualize** tab, click **Group Signals**.
  - b In the Group Signals dialog box, select **Data Hierarchy** from the **Then By** list.

- c Click **OK**.
- 4 Click the **logout** expander to view the logged signals.
- 5 Click the **Format** tab.
- 6 Click the **Subplots** button and select **3x1** to show three subplots.
- 7 For each signal:
  - a Click the top subplot. A blue border indicates the plot selection.
  - b Select the check box next to the **Alpha** signal name. The signal data appears in the subplot.
  - c Plot the **Pitch\_rate** signal in the middle subplot.
  - d Plot the **Stick\_input** signal in the bottom subplot.

Proceed to “Run Executable and Load Data” on page 60-5.

## Run Executable and Load Data

You must rebuild and run the `myAircraftExample` executable to obtain a valid data file because you have modified the model.

- 1 Select **Simulation > Model Configuration Parameters** to open the Configuration Parameters dialog box.
- 2 Select the **Code Generation > Interface** pane.
- 3 Set the **MAT-file variable name modifier** parameter to `rt_`. `rt_` is prefixed to each variable that you selected for logging in the first part of this example.
- 4 Click **Apply** and **OK**.
- 5 Save the model.
- 6 On the Simulink Editor toolbar, click the **Build Model** button to generate code.
- 7 When the build is finished, run the standalone program from the Command Window.

```
!myAircraftExample
```

The executing program writes the following messages to the Command Window.

```
** starting the model **
** created myAircraftExample.mat **
```

## 8 Load the data file myAircraftExample.mat.

```
load myAircraftExample
```

---

**Tip** For UNIX platforms, run the executable in the Command Window with the syntax `!./executable_name`. If preferred, run the executable from an OS shell with the syntax `./executable_name`. For more information, see “Run External Commands, Scripts, and Programs”.

---

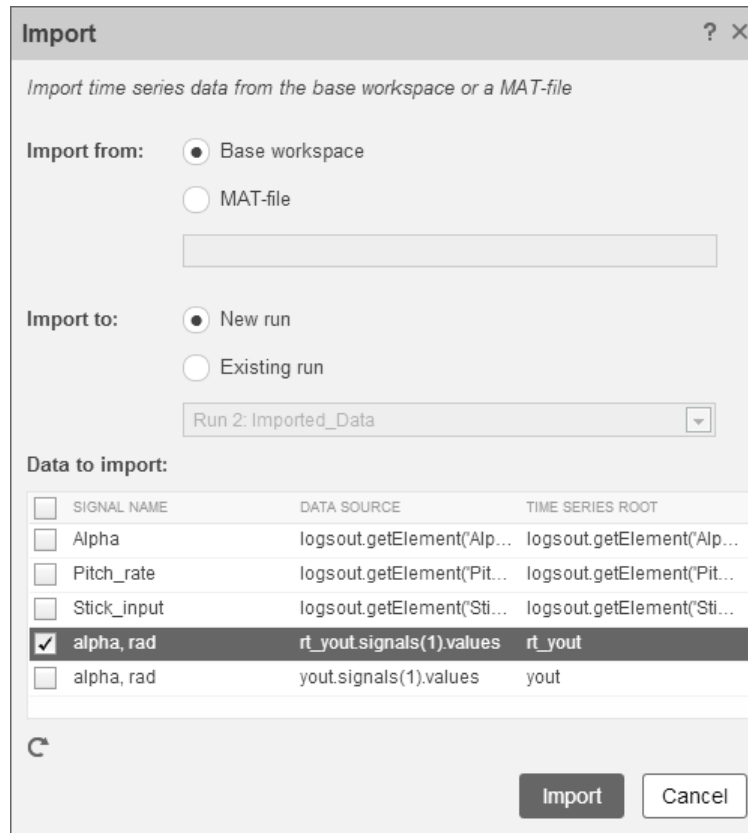

Proceed to “Visualize and Compare Results” on page 60-6.

## Visualize and Compare Results

When you follow the example sequence that began in “Configure Signal Data for Logging” on page 60-2, you obtain data from a Simulink run of the model and from a run of the program generated from the model.

- 1 To view the execution output for `alpha, rad`, import the data into the Simulation Data Inspector.
  - a On the Simulation Data Inspector **Visualize** tab, click the **Import** button to open the Import dialog.
  - b Specify **Import from** as **Base workspace**.
  - c Specify **Import to** as **New run**.
  - d To the left of **Signal Name**, click the check mark to clear the check boxes.
  - e Select the check box for the `alpha, rad` data where the **Time Series Root** is `rt_yout`.
  - f Click **Import**.

The selected data is now under **Run 2: Imported\_Data**.

- 2 View a plot of the executed data.
  - a Click the `rt_yout` expander.
  - b Click the top subplot and select the check box next to the `alpha, rad` signal name. The signal data appears in the top subplot.

The `alpha, rad` signal from Run 1 and Run 2 overlap in the subplot because the signals are equivalent.

It is possible to see a very small difference between simulation and code generation results. A slight difference can be caused by many factors, including:

- Different compiler optimizations
- Statement ordering
- Run-time libraries

For example, a function call such as `sin(2.0)` can return a slightly different value depending on which C library you use. Such variations can also cause differences between your results and these results.

## Compare States for Simulation and Code Generation

The order in which Simulink logs states during simulation is different than the order in which Simulink Coder logs states during code generation. If you want to compare states between simulation and code generation, sort the states by block name.

For example, by default, Simulink exports state data to the MATLAB variable, `xout`. Simulink Coder exports state data to the variable `rt_xout`. To sort the state data for these variables, enter the following commands in the MATLAB Command Window:

```
[~,idx1]=sort({xout.signals.blockName});
xout_sorted=[xout.signals(idx1).values];
[~,idx2]=sort({rt_xout.signals.blockName});
rt_xout_sorted=[rt_xout.signals(idx2).values];
```

You can confirm that the logging order is the same between code generation and simulation by entering the following command in the MATLAB Command Window:

```
isequal(xout_sorted, rt_xout_sorted)
```

# Code Tracing in Embedded Coder

---

- “What Is Code Tracing?” on page 61-2
- “Traceability Tags” on page 61-5
- “Trace Code to Model Objects by Using Hyperlinks” on page 61-6
- “Trace Model Objects to Generated Code” on page 61-8
- “Trace Stateflow Objects in Generated Code” on page 61-10
- “Link Generated Code to Requirements” on page 61-23
- “Reload Existing Traceability Information” on page 61-28
- “Customize Traceability Reports” on page 61-29
- “Generate a Traceability Matrix” on page 61-31
- “Traceability Limitations” on page 61-32

## What Is Code Tracing?

Code tracing (traceability) involves using hyperlinks to navigate between a line of generated code and its corresponding objects in a model. You can also right-click an object or objects in a model to find the lines of code to which they correspond. This two-way navigation is *bidirectional* traceability.

Code tracing provides a way to:

- Verify generated code. You can identify which model objects correspond to a line of code. You are able to keep track of code from different objects that you have or have not reviewed.
- Include comments in code generated for large-scale models. You can identify objects in generated code and avoid manually entering comments or descriptions.

The HTML code generation report that the code generator produces for a model includes resources that support code tracing:

- Code element hyperlinks (indicated with underlining) to trace through and toggle between generated source and header files.
- Tags in code comments that identify objects in a model from which lines of code are generated.
- Line number hyperlinks which link to the model component from which the line of code was generated.

## Traceable Objects

Bidirectional traceability is supported for blocks and the following Stateflow objects:

- States
- Transitions
- MATLAB functions (not supported for external code called from a MATLAB function)

---

**Note:** Traceability is not supported for external code that you call from a MATLAB function.

---

- Truth Table blocks and truth table functions
- Graphical functions

- Simulink functions
- State transition tables

Traceability in one direction is supported for these Stateflow objects:

- Events (code-to-model)

Code-to-model traceability works for explicit events, but not implicit events. Clicking a hyperlink for an explicit event in the generated code highlights that item in the **Contents** pane of the Model Explorer.

- Junctions (model-to-code)

Model-to-code traceability works for junctions with at least one outgoing transition. Right-clicking such a junction in the Stateflow Editor highlights the line of code that corresponds to the first outgoing transition for that junction.

---

**Note:** MATLAB Function blocks that you insert directly in a Simulink model are also traceable. For more information, see “Use Traceability in MATLAB Function Blocks” in the Simulink documentation.

---

## Workflow Traceability

The basic workflow for using traceability is:

- 1 Open your model, if necessary.
- 2 Define your system target file as an embedded real-time (**ert**) target.
- 3 Enable and configure the traceability options.
- 4 Generate the source code and header files for your model.
- 5 Do one or both of these steps:
  - Trace a line of generated code to the model.
  - Trace objects in the model to lines of code.

## Related Examples

- “Trace Code to Model Objects by Using Hyperlinks” on page 61-6
- “Trace Model Objects to Generated Code” on page 61-8

- “Reload Existing Traceability Information” on page 61-28
- “Customize Traceability Reports” on page 61-29

### **More About**

- “Traceability Tags” on page 61-5

## Traceability Tags

A traceability tag appears in a comment above the corresponding line of generated code. The format of the tags is `<system>/block_name`.

- *system* is one of the following:
  - The text `Root`
  - A unique system number assigned by the Simulink engine
- *block\_name* is the name of the source block

The code generator documents the tags for a model in the comments section of the generated header file `model.h`. For example, the following comment appears in the header file for a model, `foo`, that has a subsystem `Outer` and a nested subsystem `Inner`:

```
/* Here is the system hierarchy for this model.
 *
 * <Root> : foo
 * <S1> : foo/Outer
 * <S2> : foo/Outer/Inner
 */
```

This code shows a tag comment adjacent to a line of code. A Gain block at the root level of a source model generates this code:

```
/* Gain: '<Root>/UnDeadGain1' */
rtb_UnDeadGain1_h = dead_gain_U.In1 *
 dead_gain_P.UnDeadGain1_Gain;
```

The following code shows a tag comment adjacent to a line of code. A Gain block within a subsystem one level below the root level of the source model generates this code:

```
/* Gain: '<S1>/Gain' */
dead_gain_B.temp0 *= (dead_gain_P.s1_Gain_Gain);
```

## Trace Code to Model Objects by Using Hyperlinks

When using the Simulink Coder product, you can trace code to model objects by using the `hilite_system` command. The Embedded Coder product simplifies traceability with the use of hyperlinks in HTML code generation reports. The reports display hyperlinks in comment lines in generated code. To highlight the corresponding block or subsystem in the model diagram, click the hyperlinks.

To use hyperlinks for tracing code to model objects:

- 1 Open the model and make sure it is configured for an ERT target.
- 2 In the Configuration Parameters dialog box, on the **Code Generation > Report** pane, the **Create code generation report** parameter is selected by default. When selected, this parameter enables and selects **Open report automatically** and **Code-to-model**.
- 3 Build or generate code for the model. An HTML code generation report is displayed.
- 4 In the HTML report window, click hyperlinks to highlight source blocks. For example, generate an HTML report for model `rtwdemo_hyperlinks`. In the generated code for the model step function in `rtwdemo_hyperlinks.c`, click the first `UnitDelay` block hyperlink.

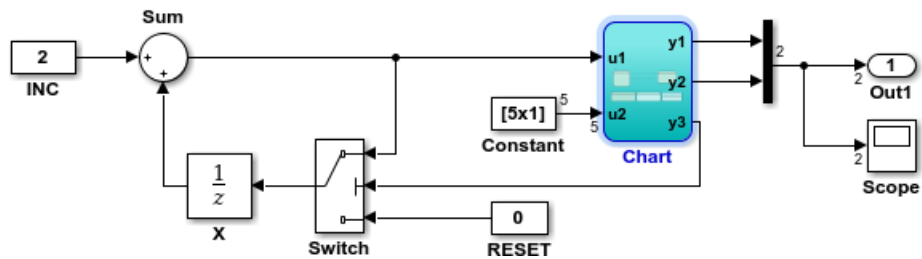

```
134 /* Model step function */
135 void rtwdemo_hyperlinks_step(void)
136 {
137 /* Chart: '<Root>/Chart' incorporates:
138 * Constant: '<Root>/Constant'
139 * Constant: '<Root>/INC'
140 * Sum: '<Root>/Sum'
141 */
142 /* Gateway: Chart */
143 if (rtDWork.temporalCounter_il < 7U) {
144 rtDWork.temporalCounter_il++;
145 }
```

In the model window, the corresponding `UnitDelay` block is highlighted.

To use line numbers for tracing code to model objects:

- 1 In the previous example, `rtwdemo_hyperlinks`, click the hyperlink at line number 144.
- 2 In the model window, the Chart subsystem is highlighted and contains the operation on line 144.

## Trace Model Objects to Generated Code

- 1 Open the model and make sure that it is configured for an ERT target.
- 2 In the Configuration Parameters dialog box, the **Code Generation > Report > Create code generation report** parameter is selected by default. When selected, the parameter enables and selects the **Open report automatically** and **Code-to-model** parameters.
- 3 On the **All Parameters** tab, select **Model-to-code**. This parameter:
  - Enables the **Configure** button, which opens a dialog box for loading existing trace information.
  - Enables and selects parameters for customizing the content of a traceability report.
- 4 Build or generate code for the model. An HTML code generation report is displayed.
- 5 In the model window, right-click a model object. To select multiple blocks, hold **Shift** and right-click additional blocks.
- 6 From the context menu, select **C/C++ Code > Navigate to C/C++ Code**. In the HTML code generation report, you see the first instance of highlighted code that is generated for the model object. In the left pane of the report, numbers that appear to the right of generated file names indicate the total number of highlighted lines in each file. The following figure shows the result of tracing the Unit Delay block in model `rtwdemo_hyperlinks`.

Highlight code for block: '<Root>/X'    <<    <    2 of 5    >    >>    Remove Highlights

```

227 }
228 }
229
230 /* End of Chart: '<Root>/Chart' */
231
232 /* Outputport: '<Root>/Out1' */
233 rtY.Out1[0] = rtDWork.y1;
234 rtY.Out1[1] = rtDWork.y2;
235
236 /* Switch: '<Root>/Switch' */
237 if (rtDWork.y3 >= 0.5) {
238 /* Update for UnitDelay: '<Root>/X' incorporates:
239 * Constant: '<Root>/INC'
240 * Sum: '<Root>/Sum'
241 * UnitDelay: '<Root>/X'
242 */
243 rtDWork.X += 2.0;
244 } else {
245 /* Update for UnitDelay: '<Root>/X' incorporates:
246 * Constant: '<Root>/RESET'
247 */
248 rtDWork.X = 0.0;
249 }
250
251 /* End of Switch: '<Root>/Switch' */
252 }

```

navigate to line 238

At the top of the code window, use the navigation bar to move forward and backward through multiple instances of highlighted lines. Use the navigation sidebar to go directly to a line of code.

If you close and reopen a model, the **Navigate to Code** context menu option might not be available because Embedded Coder cannot find a build folder for your model in the current working folder. Do one of the following:

- Reset the current working folder to the parent folder of the existing build folder.
- Select **Model-to-code** and rebuild the model. Rebuilding the model regenerates the build folder into the current working folder.
- Click **Configure**. In the Model-to-code navigation dialog box, reload the existing trace information.

“Model-to-Code Traceability for Junctions” on page 61-19

“Format of Traceability Comments for Stateflow Objects” on page 61-20

### Bidirectional Traceability for States and Transitions

See how bidirectional traceability works for states and transitions by following these steps:

- 1 At the command prompt, type `old_sf_car`.
- 2 Open the Model Configuration Parameters dialog box.
- 3 In the **Code Generation** pane, go to the **Target selection** section and enter `ert.tlc` for the system target file. Click **Apply** in the lower-right corner of the window. Traceability comments appear in generated code only for embedded real-time targets.
- 4 In the **Code Generation > Report** pane, the **Create code generation report** parameter is selected by default. This step automatically selects **Open report automatically** and **Code-to-model**.
- 5 On the **All Parameters** tab, select **Model-to-code**. Click **Apply**.
- 6 Go to the **Code Generation > Interface** pane. In the **Software environment** section, select **continuous time**. Click **Apply**. Before generating code, you must perform this step because this model contains a block with a continuous sample time.
- 7 Press **Ctrl+B**.

This step generates source code and header files for the `old_sf_car` model that contains the `shift_logic` chart. After the code generation process is complete, the code generation report appears.

- 8 In the report, click the `old_sf_car.c` hyperlink.

- 9 To see the traceability comments, scroll down through the code. The following line numbers can differ from the numbers that appear in your code generation report.

```

185 /* Function for Chart: '<Root>/shift_logic' */
186 static void old_sf_car_gear_state(const int32_T *sfEvent)
187 {
188 /* During 'gear_state': '<S5>:2' */
189 switch (old_sf_car_DW.is_gear_state) {
190 case old_sf_car_IN_first:
191 /* During 'first': '<S5>:6' */
192 if (*sfEvent == old_sf_car_event_UP) {
193 /* Transition: '<S5>:12' */
194 old_sf_car_DW.is_gear_state = old_sf_car_IN_second;
195
196 /* Entry 'second': '<S5>:4' */
197 old_sf_car_B.gear = 2.0;

```

- 10 To navigate to the corresponding model component, click the line number hyperlinks.

- 11 Click the [<S5>:2](#) hyperlink in this traceability comment:

```
/* During 'gear_state': '<S5>:2' */
```

The corresponding state appears highlighted in the chart.

- 12 Click the [<S5>:12](#) hyperlink in this traceability comment:

```
/* Transition: '<S5>:12' */
```

The corresponding transition appears highlighted in the chart. To remove highlighting from an object in the chart, select **Display > Remove Highlighting**.

- 13 You can also trace objects in the model to lines of generated code. In the chart, right-click the object `gear_state` and select **C/C++ Code > Navigate to C/C++ Code**.

The code for that state appears highlighted in `old_sf_car.c`.

```

188 /* Function for Stateflow: '<Root>/shift_logic' */
189 static void old_sf_car_gear_state(void)
190 {
191 /* During 'gear_state': '<S5>:2' */ ← Highlighted line of code
192 if (old_sf_car_DWork.is_active_gear_state != 0) {
193 switch (old_sf_car_DWork.is_gear_state) {
194 case old_sf_car_IN_first:
195 /* During 'first': '<S5>:6' */

```

- 14** In the chart, right-click the transition with the condition [ speed > up\_th ] and select **C/C++ Code > Navigate to C/C++ Code**.

The code for that transition appears highlighted in `old_sf_car.c`.

```

446 case old_sf_car_IN_steady_state:
447 /* During 'steady_state': '<S5>:9' */
448 if (old_sf_car_B.mph > old_sf_car_B.interp_up) {
449 /* Transition: '<S5>:18' */ ← Highlighted
450 /* Exit 'steady_state': '<S5>:9' */

```

line of code

---

**Note:** For a list of all Stateflow objects in your model that are traceable, click the [Traceability Report](#) hyperlink in the code generation report.

---

## Bidirectional Traceability for State Transition Tables

This example shows how to navigate bidirectionally between objects in a state transition table and the generated C/C++ and HDL code for traceability.

- 1** At the command prompt, type `sf_cdplayer_STT`. This model is already configured for traceability. For more information on these configurations, see “Traceability of Stateflow Objects in Generated Code”.
- 2** Press **Ctrl+B**.

This step generates source code and header files for the `sf_cdplayer_STT` model. After the code generation process is complete, the code generation report appears.

- 3** Click the `sf_cdplayer_STT.c` hyperlink in the report.
- 4** To see the traceability comments, scroll down through the code. The line numbers shown can differ from the numbers that appear in your code generation report.

```
60 /* Function for State Transition Table: '<Root>/CdPlayerModeManager' */
61 static void sf_cdplayer_S_enter_internal_ON(void)
62 {
63 /* Entry Internal 'ON': '<S2>:58' */
64 switch (sf_cdplayer_STT_DWork.bitsForTID1.was_ON) {
65 case sf_cdplayer_STT_IN_AMMode:
66 sf_cdplayer_STT_DWork.bitsForTID1.is_ON = sf_cdplayer_STT_IN_AMMode;
67 sf_cdplayer_STT_DWork.bitsForTID1.was_ON = sf_cdplayer_STT_IN_AMMode;
68
69 /* Entry 'AMMode': '<S2>:61' */
70 sf_cdplayer_STT_B.CurrentRadioMode = AM;
71 sf_cdplayer_STT_B.MechCmd = STOP;
72 break;
73 }
```

- 5 Click the <S2>:58 hyperlink in this traceability comment:

```
/* Entry Internal 'ON': '<S2>:58' */
```

The corresponding state 'ON' appears highlighted in the state transition table.

- 6 Right-click the highlighted state and select **View state object**. The state 'ON' also appears highlighted in the underlying state transition diagram.
- 7 You can also trace a state or transition from the state transition table to the generated code. Right-click the state Standby and select **C/C++ Code > Navigate to C/C++ Code**.

The entry code for the state Standby is highlighted in the generated code.

```

234 sf_cdplayer_STT_DWork.bitsForTID1.was_ModeManager =
235 sf_cdplayer_STT_IN_Standby;
236
237 /* Entry 'Standby': '<S2>:57' */
238 sf_cdplayer_STT_B.CurrentRadioMode = OFF;
239 sf_cdplayer_STT_B.MechCmd = STOP;
240 } else if (sf_cdplayer_STT_DWork.RadioReq_prev !=
241 sf_cdplayer_STT_DWork.RadioReq_start) {
242 /* Transition: '<S2>:75' */
243 if (sf_cdplayer_STT_P.RR_Value == CD) {

```

## Bidirectional Traceability for Truth Table Blocks

See how bidirectional traceability works for a Truth Table block by following these steps:

- 1 At the command prompt, type `sf_climate_control`
- 2 Complete steps 2 through 5 in “Bidirectional Traceability for States and Transitions” on page 61-10.
- 3 To build the model, press **Ctrl+B**.

The code generation report appears.

- 4 Click the `sf_climate_control.c` hyperlink in the report.
- 5 To see the traceability comments, scroll down through the code. The following line numbers can differ from the numbers that appear in your code.

```

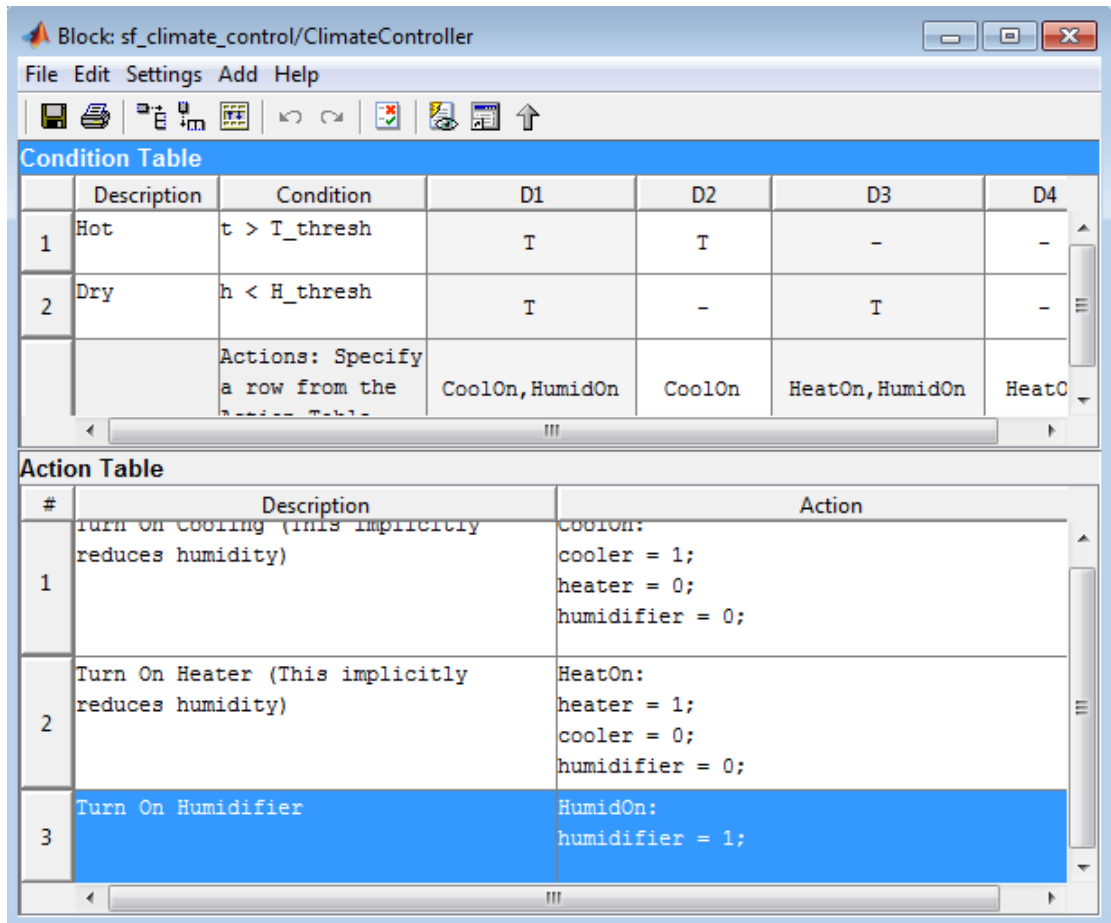

77 /* Turn On Humidifier */
78 /* Action '3': '<S1>:1:47' */ ← Traceability
79 rtb_humidifier = 1; comment for a
80 } else if (eml_aVarTruthTableCondition) { truth table action
81 /* Decision 'D2': '<S1>:1:18' */ ← Traceability
 comment for a
 truth table decision

```

- 6 Click the `<S1>:1:47` hyperlink in this traceability comment:

```
/* Action '3': '<S1>:1:47' */
```

In the Truth Table Editor, row 3 of the Action Table appears highlighted.

- 7 You can also trace a condition, decision, or action in the table to a line of generated code. For example, right-click a cell in the column D2 and select **C/C++ Code > Navigate to C/C++ Code**.

The code for that decision appears highlighted in `sf_climate_control.c`.

```

77 /* Turn On Humidifier */
78 /* Action '3': '<S1>:1:47' */
79 rtb_humidifier = 1;
80 } else if (eml_aVarTruthTableCondition) {
81 /* Decision 'D2': '<S1>:1:18' */

```

Highlighted  
line of code

**Tip** To select **C/C++ Code > Navigate to C/C++ Code** for a condition, decision, or action, right-click a cell in the row or column that corresponds to that truth table element.

## Bidirectional Traceability for Graphical Functions

See how bidirectional traceability works for graphical functions by following these steps:

- 1 At the command prompt, type `sf_clutch`.
- 2 Complete steps 2 through 6 in “Bidirectional Traceability for States and Transitions” on page 61-10.
- 3 In the Model Configuration Parameters dialog box, go to the **Solver** pane. In the **Solver options** section, select **Fixed-step** in the **Type** field. Click **Apply**. Before generating code, you must perform this step because the model does not work with variable step solvers.
- 4 To build the model, press **Ctrl+B**.

The code generation report appears.

- 5 Click the `sf_clutch.c` hyperlink in the report.
- 6 To see the traceability comments, scroll down through the code. The following line numbers can differ from the numbers that appear in your code generation report.

```

235 case sf_clutch_IN_Slipping:
236 /* Graphical Function 'detectLockup': '<S1>:10' */
237 /* Transition: '<S1>:28' */
238 /* Graphical Function 'getSlipTorque': '<S1>:3' */

```

Traceability  
comment for a  
graphical function

- 7 Click the `<S1>:3` hyperlink in this traceability comment:

```
/* Graphical Function 'getSlipTorque': '<S1>:3' */
```

In the chart, the graphical function `getSlipTorque` appears highlighted.

- You can also trace a graphical function in the chart to a line of generated code. For example, right-click the graphical function `detectSlip` and select **C/C++ Code > Navigate to C/C++ Code**.

The code for that graphical function appears highlighted in `sf_clutch.c`.

```
184 case sf_clutch_IN_Locked:
185 /* Graphical Function 'detectSlip': '<S1>:6' */ ← Highlighted
186 /* Transition: '<S1>:15' */ line of code
```

## Code-to-Model Traceability for Events

See how code-to-model traceability works for events by following these steps:

- At the command prompt, type `sf_security`.
- Complete steps 2 through 6 in “Bidirectional Traceability for States and Transitions” on page 61-10.
- To build the model, press **Ctrl+B**.

The code generation report appears.

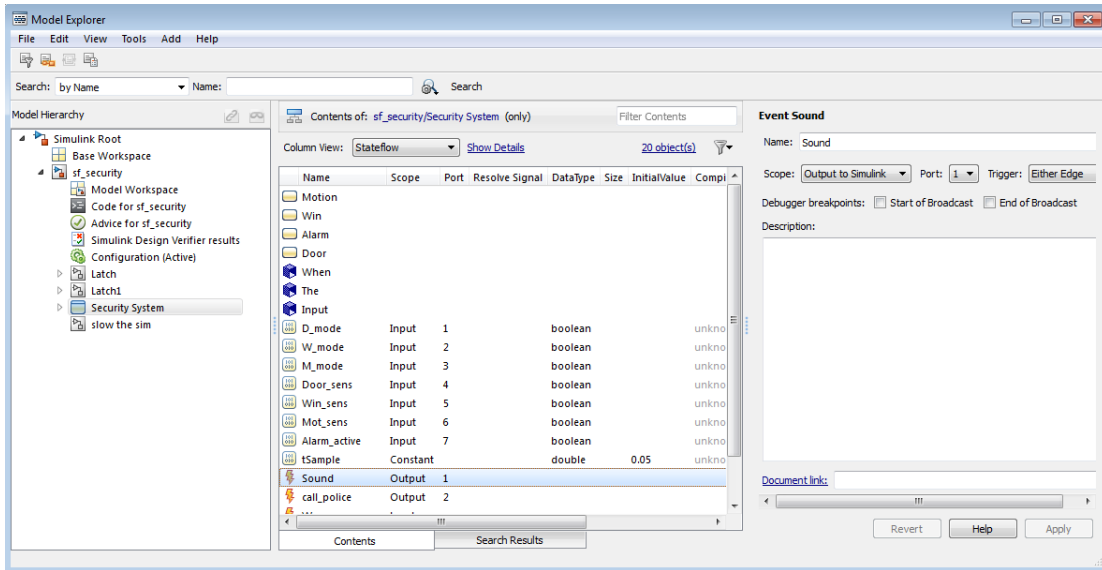

- Click the `sf_security.c` hyperlink in the report.
- To see the following traceability comment, scroll down through the code. The following line numbers can differ from the numbers that appear in your code generation report.

```
240 /* Event: '<S8>:56' */ ← Traceability
241 sf_security_DWork.SoundEventCounter = comment for
242 sf_security_DWork.SoundEventCounter + 1U; an event
```

- Click the `<S8>:56` hyperlink in this traceability comment:

```
/* Event: '<S8>:56' */
```

In the **Contents** pane of the Model Explorer, the event `Sound` appears highlighted.

## Model-to-Code Traceability for Junctions

See how model-to-code traceability works for junctions by following these steps:

- 1 At the command prompt, type `sf_abs`.
  - 2 Complete steps 2 through 6 in “Bidirectional Traceability for States and Transitions” on page 61-10.
  - 3 In the Model Configuration Parameters dialog box, go to the **Solver** pane. In the **Solver options** section, select **Fixed-step** in the **Type** field. Click **Apply**. Before generating code, you must perform this step because the model does not work with variable-step solvers.
  - 4 To build the model, press **Ctrl+B**.
- The code generation report appears.
- 5 Open the `AbsoluteValue` chart.
  - 6 Right-click the left junction and select **C/C++ Code > Navigate to C/C++ Code**.

The code for the first outgoing transition of that junction appears highlighted in `sf_abs.c`.

```

53 /* Gateway: AbsoluteValue */
54 /* During: AbsoluteValue */
55 if (sf_abs_DWork.is_active_c1_sf_abs == 0) {
56 /* Entry: AbsoluteValue */
57 sf_abs_DWork.is_active_c1_sf_abs = 1U;
58
59 /* Transition: '<S1>:5' */
60 if (sf_abs_B.SineWave1 >= 0.0) {
61 /* Transition: '<S1>:6' */ ← Highlighted line of code
62 /* Entry 'P': '<S1>:1' */

```

## Format of Traceability Comments for Stateflow Objects

The format of a traceability comment depends on the Stateflow object type.

### State

#### Syntax

```
/* <ActionType> '<StateName>': '<ObjectHyperlink>' */
```

#### Example

```
/* During 'gear_state': '<S5>:2' */
```

This comment refers to the during action of the state `gear_state`, which has the hyperlink `<S5>:2`.

### Transition

#### Syntax

```
/* Transition: '<ObjectHyperlink>' */
```

#### Example

```
/* Transition: '<S5>:12' */
```

This comment refers to a transition, which has the hyperlink `<S5>:12`.

### MATLAB Function

#### Syntax

```
/* MATLAB Function '<Name>': '<ObjectHyperlink>' */
```

Within the inlined code for a MATLAB function, comments that link to individual lines of the function have the following syntax:

```
/* '<ObjectHyperlink>' */
```

### Examples

```
/* MATLAB Function 'test_function': '<S50>:99' */
```

```
/* '<S50>:99:20' */
```

The first comment refers to the MATLAB function named `test_function`, which has the hyperlink `<S50>:99`.

The second comment refers to line 20 of the MATLAB function in your chart.

### Truth Table Block

#### Syntax

```
/* Truth Table Function '<Name>': '<ObjectHyperlink>' */
```

Within the inlined code for a Truth Table block, comments for conditions, decisions, and actions have the following syntax:

```
/* Condition '#<Num>': '<ObjectHyperlink>' */
```

```
/* Decision 'D<Num>': '<ObjectHyperlink>' */
```

```
/* Action '<Num>': '<ObjectHyperlink>' */
```

`<Num>` is the row or column number that appears in the Truth Table Editor.

### Examples

```
/* Truth Table Function 'truth_table_default': '<S10>:100' */
```

```
/* Condition '#1': '<S10>:100:8' */
```

```
/* Decision 'D1': '<S10>:100:16' */
```

```
/* Action '1': '<S10>:100:31' */
```

The first comment refers to a Truth Table block named `truth_table_default`, which has the hyperlink `<S10>:100`.

The other three comments refer to elements of that Truth Table block. Each condition, decision, and action in the Truth Table block has a unique hyperlink.

### Truth Table Function

For syntax and examples, see “Truth Table Block” on page 61-21.

### Graphical Function

#### Syntax

```
/* Graphical Function '<Name>': '<ObjectHyperlink>' */
```

#### Example

```
/* Graphical Function 'hello': '<S1>:123' */
```

This comment refers to a graphical function named `hello`, which has the hyperlink `<S1>:123`.

### Simulink Function

#### Syntax

```
/* Simulink Function '<Name>': '<ObjectHyperlink>' */
```

#### Example

```
/* Simulink Function 'simfcn': '<S4>:10' */
```

This comment refers to a Simulink function named `simfcn`, which has the hyperlink `<S4>:10`.

### Event

#### Syntax

```
/* Event: '<ObjectHyperlink>' */
```

#### Example

```
/* Event: '<S3>:33' */
```

This comment refers to an event, which has the hyperlink `<S3>:33`.

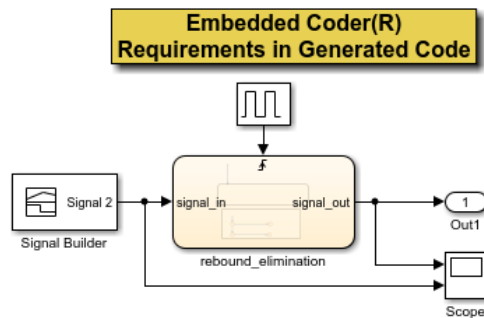

# Link Generated Code to Requirements

Link generated code to model object requirements. Using configuration parameters, you can specify whether to include requirement descriptions as comments in the generated code.

## Open Model

Open the `rtwdemo_requirements` model. The model contains Simulink® and Stateflow® objects with associated requirements.

```
model='rtwdemo_requirements';
open_system(model);
```

**!** This example requires a license for Simulink Verification and Validation

Generate Code Using Embedded Coder (double-click)

## Requirements in Generated Code

Requirements attached to various Simulink and Stateflow objects can appear in code generated by Embedded Coder(R) within their respective comments. The two steps are:

- 1) Add requirements to model.
- 2) Check option in configuration parameters.

## Step 1: Add Requirements to Model

Requirements can be added to numerous types of objects in Simulink and Stateflow using the Requirements entry from the context menu. The following are requirements entered in this model (double-click to open):

- ▶ Simulink Block
- ▶ Simulink Signal Builder
- ▶ Stateflow State
- ▶ Stateflow Transition
- ▶ Stateflow Graphical Function

## Step 2: Check Requirements Options

Open the model's configuration parameters and navigate to the Requirements section of the Code Generation settings. Double-click below to see these settings.

- ▶ [Open Requirements Settings](#)

## Additional Documentation

Additional documentation is available for integrating requirements into generated code by double-clicking the link below.

- ▶ [Requirements Documentation](#)

## View Requirements

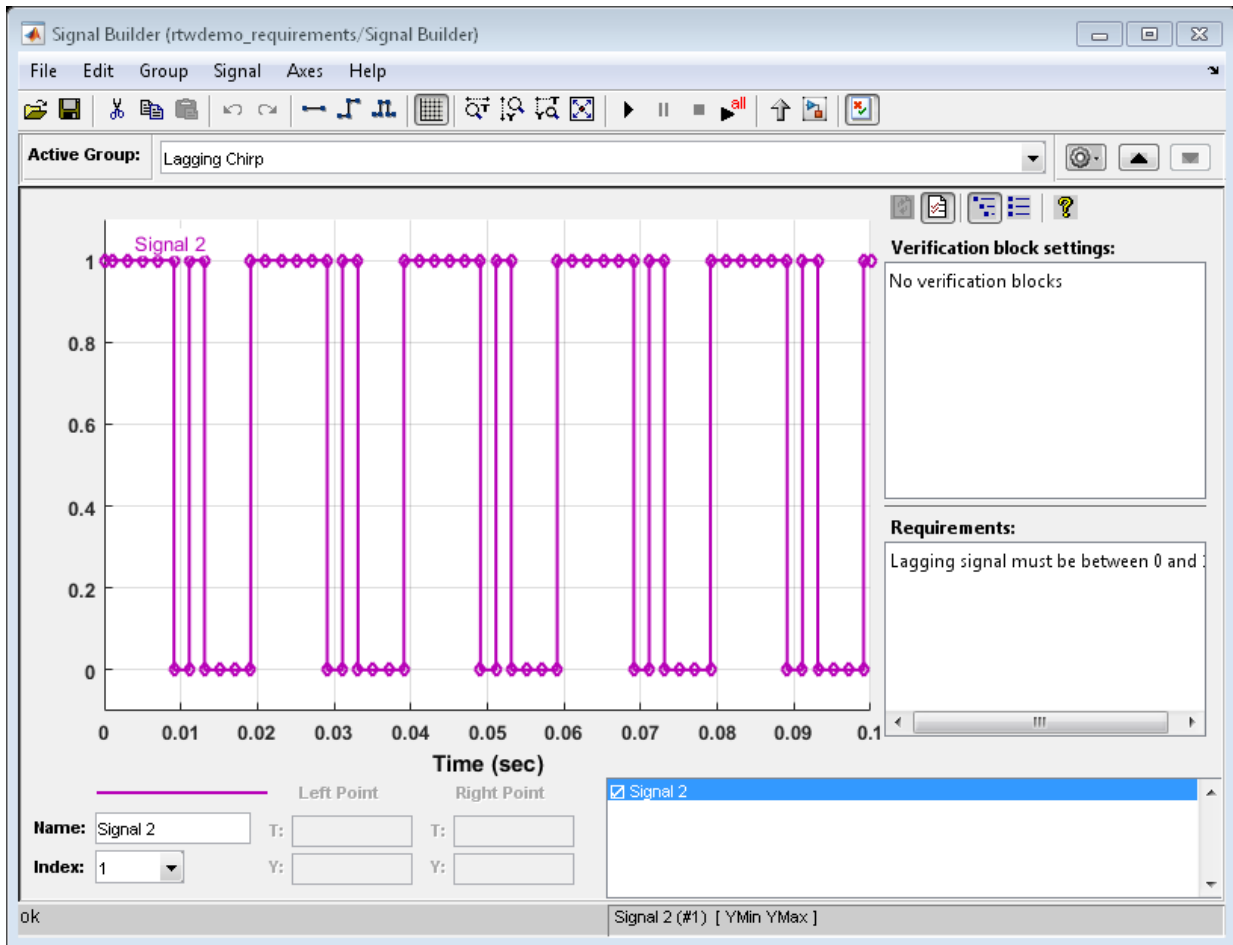

You can view requirements to model objects by using the object context menu. Right-click an object and select **Requirements Traceability**. To view the requirements, use these commands:

1. To view the requirements for the **DiscretePulseGenerator** block, open the Link Editor.

```
clockblock='rtwdemo_requirements/clock';
clockblockh=get_param(clockblock,'handle');
rmi('edit',clockblockh);
```

2. To view the requirements, open the **Signal Builder** block.

```
sigbblock='rtwdemo_requirements/Signal Builder';
open_system(sigbblock)
```

3. To view the requirements for the Stateflow® state, open the Link Editor.

```
state=find(sfroot, '-isa', 'Stateflow.State', '-and', 'Tag', 'req_state');
rmi('edit',state.id);
```

4. To view the requirements for the Stateflow transition, open the Link Editor.

```
trans=find(sfroot, '-isa', 'Stateflow.Transition', '-and', 'Tag', 'req_trans');
rmi('edit',trans.id);
```

5. To view the requirements for the Stateflow function, open the Link Editor.

```
func=find(sfroot, '-isa', 'Stateflow.Function', '-and', 'Tag', 'req_function');
rmi('edit', func.id);
```

Close the open windows.

```
close_system(sigblock);
```

### Set Configuration Parameters

Open the Configuration Parameters dialog box **Code Generation > Comments** pane. View the configuration parameter settings.

```
model = bdroot;
slCfgPrmDlg(model, 'Open');
slCfgPrmDlg(bdroot, 'TurnToPage', 'Comments');
```

### Generate Code

Generate code for the model.

```
rtwbuild('rtwdemo_requirements')

Starting build procedure for model: rtwdemo_requirements
Successful completion of build procedure for model: rtwdemo_requirements
```

In the generated code, view the comments containing the requirements.

```
rtwdemodbtype('rtwdemo_requirements_ert_rtw/rtwdemo_requirements.c', ...
 /* Function for Chart:', 'return result;', 1, 0);

/* Function for Chart: '<Root>/rebound_elimination' */
static real_T rebound_fcn(real_T prev_in, real_T prev_out, real_T curr_in)
{
 real_T result;

 /* Graphical Function 'rebound_fcn': '<S2>:2':
 * 1. Result Computation
 */
 /* Transition: '<S2>:4' */
 if (prev_in == curr_in) {
 /* Transition: '<S2>:5' */
 result = curr_in;
 } else {
 /* Transition: '<S2>:6' */
 /* Transition: '<S2>:7' */
```

```
 result = prev_out;
}
```

**See Also**

- For requirement traceability, see [Overview of the Requirements Management Interface](#)

**Close Model**

```
rtwdemoclean;
close_system('rtwdemo_requirements',0);
```

## Reload Existing Traceability Information

To reload existing traceability information for a model:

- 1 In the Configuration Parameters dialog box, on the **All Parameters** tab, under Model-to-code, click **Configure**.
- 2 In the Model-to-code navigation dialog box, in the **Build folder** field, type or browse to the build folder that contains the existing traceability information.

If you close and reopen a model, the **Navigate to Code** context menu option might not be available because Embedded Coder cannot find a build folder for your model in the current working folder. Without having to reset the current working folder or rebuild the model, do the following:

- 1 To open the Model-to-code navigation dialog box, click **Configure**.
- 2 In the Model-to-code navigation dialog box, click **Browse**.
- 3 Browse to the build folder for your model, and select the folder. The build folder path is displayed in the **Build folder** field.
- 4 If you selected **Model-to-code** for the build, clicking **Apply** or **OK** loads traceability information from the earlier build into your Simulink session.
- 5 To open the context menu and trace a model object to corresponding code, right-click a model object and select **C/C++ Code > Navigate to C/C++ Code**.

## Customize Traceability Reports

In the Configuration Parameters dialog box, the **Code Generation** section lists parameters that you can select and clear to customize the content of your traceability reports.

Select or clear any combination of the following parameters, which are on by default:

- **Eliminated / virtual blocks** (account for blocks that are untraceable)
- **Traceable Simulink blocks**
- **Traceable Stateflow objects**
- **Traceable MATLAB functions**

If you select all parameters, you get a complete mapping between model elements and the generated code.

The following figure shows the top section of the traceability report that is generated when you select all traceability content parameters for model `rtwdemo_hyperlinks`.

# Traceability Report for rtwdemo\_hyperlinks

Generate  
Traceability Matrix

## Table of Contents

1. [Eliminated / Virtual Blocks](#)
2. [Traceable Simulink Blocks / Stateflow Objects / MATLAB Functions](#)
  - o [rtwdemo\\_hyperlinks](#)

<a href="#">&lt;Root&gt;/Constant</a>	<a href="#">rtwdemo_hyperlinks.c:144</a>

## Generate a Traceability Matrix

If you have DO Qualification Kit software or IEC Certification Kit software and are using a Windows host, you can generate a traceability matrix into Microsoft Excel<sup>®</sup> format directly from the traceability report. See “Customize Traceability Reports” on page 61-29.

Go to the **Traceability Report** section of the HTML code generation report and click **Generate Traceability Matrix**.

To select an existing matrix file to update or specify a new matrix file to create, use the options in the Generate Traceability Matrix dialog box. Optionally, you can select and order the columns that appear in the generated matrix. For more information, see “Generating a Traceability Matrix” in either the DO Qualification Kit documentation or the IEC Certification Kit documentation.

## Traceability Limitations

These limitations apply to reports generated by Embedded Coder software.

- Under the following conditions, model-to-code traceability is disabled for a block if the block name contains:
  - A single quote (').
  - An asterisk (\*), that causes a name-mangling ambiguity relative to other names in the model. This name-mangling ambiguity occurs if in a block name or at the end of a block name, an asterisk precedes or follows a slash (/).
  - The character ÿ (char(255)).
- If a block name contains a newline character (\n), in the generated code comments, the block path name hyperlink replaces the newline character with a space for readability.
- You cannot trace blocks representing these types of subsystems to generated code:
  - Virtual subsystems
  - Masked subsystems
  - Nonvirtual subsystems for which code has been optimized away

If you cannot trace a subsystem at subsystem level, you might be able to trace individual blocks within the subsystem.

- If you open a model on a platform that is different from the platform used to generate code, you cannot use model-to-code and code-to-model traceability features.

# Component Verification in Embedded Coder

---

- “Component Verification in the Target Environment” on page 62-2
- “Goals of Component Verification” on page 62-3
- “Maximizing Code Portability and Configurability” on page 62-4
- “Simplifying Code Integration and Maximizing Code Efficiency” on page 62-5
- “Running Component Tests” on page 62-6

## Component Verification in the Target Environment

After you generate production code for a component design, you need to integrate, compile, link, and deploy the code as a complete application on the embedded system. One approach is to manually integrate the code into an existing software framework that consists of an operating system, device drivers, and support utilities. The algorithm can include externally written legacy or custom code.

An easier approach to verifying a component in a target environment is to use processor-in-the-loop (PIL) simulation. For information about PIL simulations, see “SIL and PIL Simulations” on page 64-2.

## Goals of Component Verification

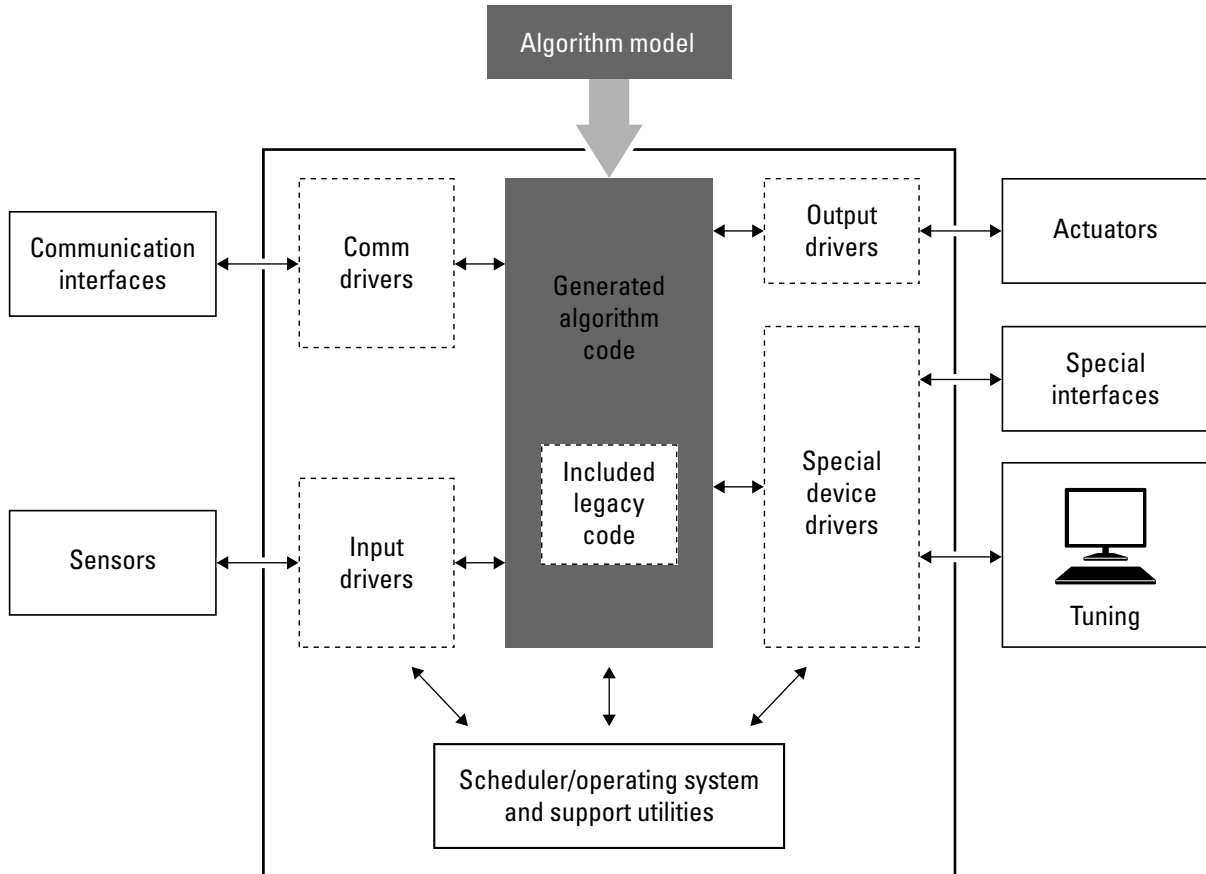

Assuming that you have generated production source code and integrated required externally written code, such as drivers and a scheduler, you can verify that the integrated software operates as expected by testing it in the target environment. During testing, you can achieve either of the following goals, depending on whether you export code that is strictly ANSI C/C++ or mixes ANSI C/C++ with code optimized for a target environment.

Goal	Type of Code Export
Maximize code portability and configurability	ANSI C/C++
Simplify integration and maximize use of processor resources and code efficiency	Mixed code

Regardless of your goal, you must integrate required external drivers and scheduling software. To achieve real-time execution, you must integrate the real-time scheduling software.

## Maximizing Code Portability and Configurability

To maximize code portability and configurability, limit the application code to ANSI/ISO C or C++ code only, as the following figure shows.

## Simplifying Code Integration and Maximizing Code Efficiency

To simplify code integration and maximize code efficiency for a target environment, use Embedded Coder features for:

- Controlling code interfaces
- Exporting subsystems
- Including target-specific code, including compiler optimizations

The following figure shows a mix of ANSI C/C++ code with code that is optimized for a target environment.

## Running Component Tests

The workflow for running software component tests in the target environment is:

- 1 Integrate external code, for example, for device drivers and a scheduler, with the generated C or C++ code for your component model. For more information, see “S-Functions and Code Generation” in the Simulink Coder documentation. For more specific references that depend on your verification goals, see the following table.

For	See
ANSI C/C++ code integration	“Integrate C Functions Using Legacy Code Tool” in the Simulink documentation. Also, open <code>rtwdemos</code> and navigate to the <b>Custom Code</b> folder.
Mixed code integration	<ul style="list-style-type: none"> <li>• “Export Function-Call Subsystems” on page 50-2 and example <code>rtwdemo_exporting_functions</code></li> <li>• “Control Generation of Function Prototypes” on page 25-2, “Control Generation of C++ Class Interfaces” on page 25-23, and example <code>rtwdemo_fcnprotoctrl</code></li> <li>• “What Is Code Replacement?” on page 38-2, “What Is Code Replacement Customization?” on page 51-3, and example <code>rtwdemo_crl_script</code></li> </ul>

- 2 Simulate the integrated component model.
- 3 Generate code for the integrated component model.
- 4 Connect to data interfaces for the generated C code data structures. See “Exchange Data Between Generated and External Code Using C API” and “Export ASAP2 File for Data Measurement and Calibration” in the Simulink Coder documentation. Also see examples `rtwdemo_capi` and `rtwdemo_asap2`.
- 5 Customize and control the build process, if required. See “Customize Post-Code-Generation Build Processing” in the Simulink Coder documentation, and example `rtwdemo_buildinfo`.
- 6 Create a zip file that contains generated code files, static files, and dependent data to build the generated code in an environment other than your host computer. See

“Relocate Code to Another Development Environment”, in the Simulink Coder documentation, and example `rtwdemo_buildinfo`.

# Component Verification With a Real-Time Target Environment in Embedded Coder

---

- “About Real-Time Software Component Verification” on page 63-2
- “Real-Time Software Component Testing” on page 63-4

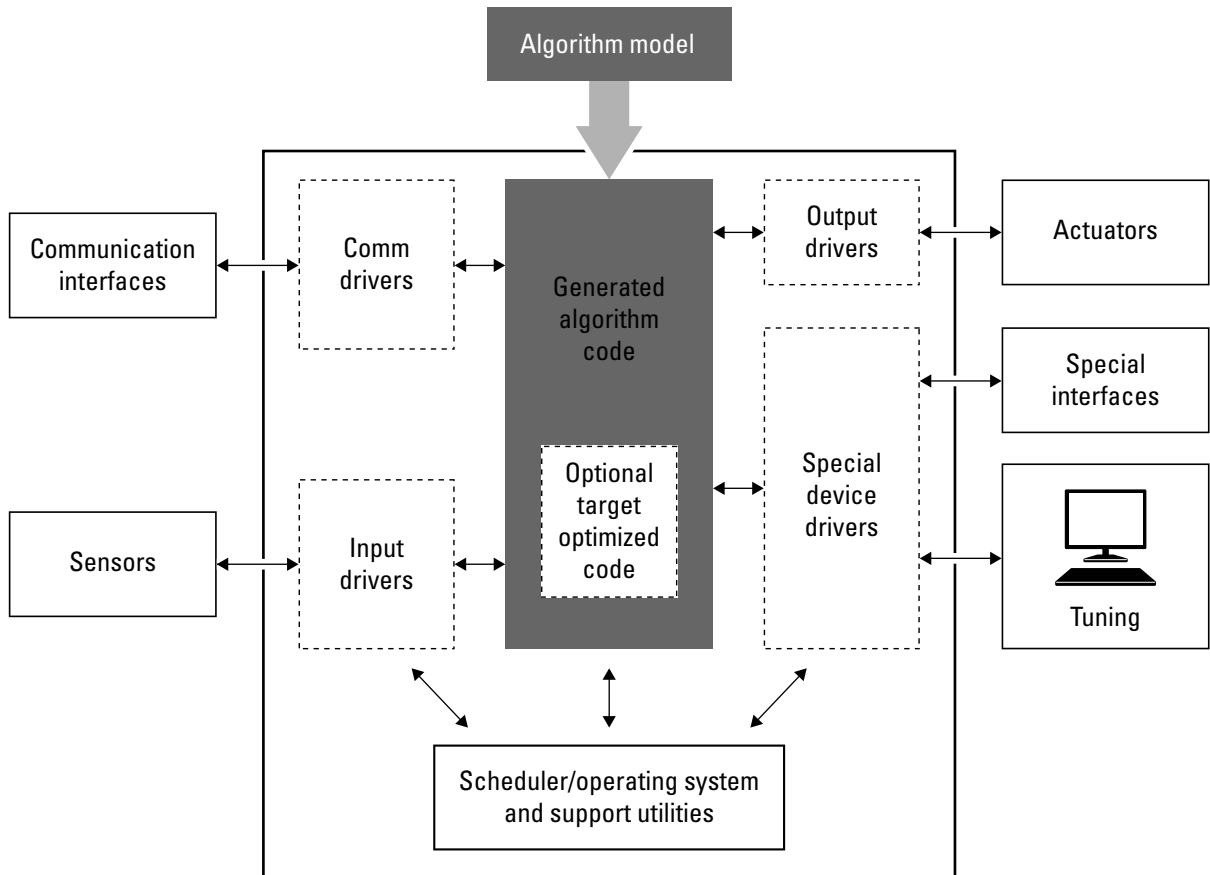

## About Real-Time Software Component Verification

One approach to verifying a software component is to build the component into a complete software system that can execute in real time in the target environment. A complete software system includes:

- Algorithm for the software component
- Scheduling algorithms
- Calls to drivers for board-specific devices

This single build approach is more time consuming to set up, but makes it easier to get the complete application running in the target environment.

The following figure shows code generated for an algorithm being built into a complete system executable for the target environment.

## Real-Time Software Component Testing

The workflow for testing component software as part of a complete real-time target environment is:

- 1 Develop a component model and generate source code for production.

For information on building in scheduling and real-time system support, see:

- “Time-Based Scheduling and Code Generation” and “Modeling for Multitasking Execution” in the Simulink Coder documentation. For an example, open `rtwdemos` and navigate to the **Multirate Support** folder.
  - “Asynchronous Events” in the Simulink Coder documentation and example `rtwdemo_async`
  - “Deploy Generated Standalone Executables To Target Hardware” on page 49-2
  - “Workflows for AUTOSAR” and examples “Generate Code That Is Compliant with the AUTOSAR Standard” and “Generate AUTOSAR-Compliant Code for Multiple Runnable Entities”.
- 2 Optimize generated code for a specific run-time environment, using specialized function libraries. For more information, see “What Is Code Replacement?” on page 38-2, “What Is Code Replacement Customization?” on page 51-3, and “Optimize Generated Code By Developing and Using Code Replacement Libraries - Simulink®”.
  - 3 Customize post code generation build processing to accommodate third-party tools and processes, as required. See “Customize Post-Code-Generation Build Processing” in the Simulink Coder documentation and example `rtwdemo_buildinfo`.
  - 4 Integrate external code, for example, for device drivers and a scheduler, with the generated C or C++ code for your component model. For more information, see “S-Functions and Code Generation” in the Simulink Coder documentation. For more specific references depending on your verification goals, see the following table.

“Scheduling Considerations” on page 64-7

“Imported Data and Function Definitions” on page 64-9

### What Are SIL and PIL Simulations?

With Embedded Coder, you can run software-in-the-loop (SIL) and processor-in-the-loop (PIL) simulations of your model. These simulations generate source code for either the top model or part of the model. A SIL simulation compiles and runs the generated code on your development computer. A PIL simulation cross-compiles source code on your development computer, and then downloads and runs the object code on a target processor or an equivalent instruction set simulator.

With SIL and PIL simulations, you can:

- Test whether your model and generated code are numerically equivalent.
- Observe code coverage.
- Perform code execution profiling.

### Why Use SIL and PIL

Through SIL and PIL, you can early on test and fix defects. For example, you can model and test a system component in normal mode. Then, you can reuse your test suites in a SIL or PIL simulation that runs compiled generated code. To check numerical equivalence, you compare normal and SIL or PIL simulation results. You thereby avoid leaving the Simulink environment to test generated code on a separate infrastructure.

This table describes situations where you can use SIL and PIL.

Situation	Use
Reuse test vectors developed for normal mode simulation to verify numerical output of generated (or legacy) code. For example, reusing test cases generated by Simulink Design Verifier™. See “What Is Test Case Generation?” in Simulink Design Verifier documentation.	SIL and PIL
Collect metrics for generated code: <ul style="list-style-type: none"> <li>• Code coverage. See “Configure Code Coverage with Third-Party Tools” on page 67-10.</li> <li>• Execution profiling. See “Code Execution Profiling with SIL and PIL” on page 58-2</li> <li>• Stack profiling. See “Perform Stack Profiling with IDE and Toolchain Targets” on page 73-28.</li> </ul>	SIL and PIL
Achieve IEC 61508, IEC 62304, ISO 26262, or DO-178 certification. See “Embedded Coder Reference Workflow Overview” in the IEC Certification Kit documentation and Testing of Outputs of Integration Process in the DO Qualification Kit documentation.	SIL and PIL
Without target hardware, get a convenient alternative to PIL.	SIL

Situation	Use
<p>With target hardware, for example, an evaluation board or instruction set simulator:</p> <ul style="list-style-type: none"> <li>• Verify behavior of target-specific code, for example, code replacement optimizations, and legacy code. See “What Is Code Replacement?” on page 38-2 and “What Is Code Replacement Customization?” on page 51-3.</li> <li>• Optimize the execution speed and memory footprint of your code. In this table, see the information about collecting execution profiling and stack profiling metrics.</li> <li>• Investigate effects of compiler settings and optimizations, for example, deviation from ANSI C overflow behavior.</li> </ul> <p>Normal simulation techniques do not account for restrictions and requirements that the hardware imposes, such as limited memory resources or behavior of target-specific optimized code.</p> <p>For information about running PIL simulations on specific targets, see “Sample Custom Targets” in the Simulink Coder documentation.</p>	PIL

---

**Note:** The SIL and PIL simulation modes are not designed for the reduction of model simulation times. If you want to speed up the simulation of your model, use the rapid accelerator mode. For an example, see “Rapid Accelerator Simulations Using PARFOR”.

---

## How SIL and PIL Simulations Work

In a SIL or PIL simulation, code is generated for either the top model or part of the model. With SIL, this code is compiled for and executed on your development computer. With PIL, the code is cross-compiled for the target hardware and runs on the target processor.

Through a communication channel, Simulink sends stimulus signals to the code on your computer or target processor for each sample interval of the simulation.

- For a top model, Simulink uses stimulus signals from the base or model workspace.

- If you have designated only part of the model to simulate in SIL or PIL mode, then a part of the model remains in Simulink and code is not generated for this part of the model. Typically, you configure this part of the model to provide test vectors for the software executing on the hardware. This part of the model can represent other parts of the algorithm or the environment in which the algorithm operates.

When your computer or target processor receives signals from Simulink, the processor executes the SIL or PIL algorithm for one sample step. The SIL or PIL algorithm returns output signals calculated during this step to Simulink through a communication channel. One sample cycle of the simulation is complete, and Simulink proceeds to the next sample interval. The process keeps repeating itself and the simulation progresses. SIL and PIL simulations do not run in real time. In each sample period, Simulink and the object code exchange I/O data.

## Comparison of SIL and PIL Simulations

Type of SIL or PIL Simulation	What Happens in SIL Simulation	What Happens in PIL Simulation
Specify through: <ul style="list-style-type: none"> <li>• Top-model simulation mode</li> <li>• Model block <b>Simulation mode</b> parameter</li> </ul>	<ul style="list-style-type: none"> <li>• Test behavior of generated source code on development computer. Simulation does not test code compiled for target hardware because code is compiled for the development computer (different compiler and different processor architecture than the target).</li> <li>• Generated production code compiled and executed on development computer as separate process, independent of MATLAB process.</li> <li>• Execution is host/host and nonreal time.</li> </ul>	<ul style="list-style-type: none"> <li>• Test object code that you intend to deploy in production on either real target hardware or an instruction set simulator.</li> <li>• On development computer, generated production code cross-compiled for target. Object code downloaded and executed on target processor or instruction set simulator.</li> <li>• Execution is host/target and nonreal time.</li> </ul>

Type of SIL or PIL Simulation	What Happens in SIL Simulation	What Happens in PIL Simulation
Use SIL or PIL block created from subsystem.	<ul style="list-style-type: none"> <li>Simulation runs compiled object code through S-function. S-function communicates with object code executing as standalone application on development computer. SIL block execution is independent of the MATLAB process.</li> <li>Execution is host/host and nonreal time.</li> </ul>	<ul style="list-style-type: none"> <li>Simulation runs cross-compiled object code through S-function on development computer. S-function communicates with object code executing as standalone application on target processor or instruction set simulator.</li> <li>Execution is host/target and nonreal time.</li> </ul>

## Code Interfaces for SIL and PIL

You generate standalone code when you perform, for example, a top-model or right-click subsystem build for a single deployable component. You can compile and link standalone code into a standalone executable or integrate it with other code. For more information on the standalone code interface, see “Entry-Point Functions and Scheduling”.

When you generate code for a referenced model hierarchy, the software generates standalone executable code for the top model and a library module called a *model reference target* for each referenced model. When the code executes, the standalone executable invokes the applicable model reference targets to compute the referenced model outputs. For more information, see “Build Model Reference Targets”.

To integrate generated code with legacy code, use standalone code because the standalone code interface is documented.

---

**Note:** SIL and PIL simulations do not provide direct support for custom code interfaces. You can incorporate these interfaces into Simulink as an S-function, for example, using the Legacy Code Tool, S-Function Builder, or handwritten code. Then, you can verify the custom code by using SIL and PIL simulations.

---

This table provides the interfaces that SIL and PIL simulations generate.

SIL/PIL Simulation	Code Interface
Top-model	SIL/PIL simulation generates the standalone code interface. If code exists, simulation calls standalone code for the model . If code does not exist, simulation generates standalone code.
Model block	<p>If you set <b>Code interface</b> block parameter to <b>Top model</b>, SIL/PIL simulation generates standalone code interface. Simulation calls standalone code for the model if it exists. Otherwise, simulation generates standalone code by using <code>slbuild('model')</code> command.</p> <p>If you set <b>Code interface</b> block parameter to <b>Model reference</b>, SIL/PIL simulation generates model reference code interface. Simulation calls model reference target for Model block if it exists. Otherwise, simulation generates model reference target by using <code>slbuild('model', 'ModelReferenceRTWTarget')</code> command.</p>
SIL or PIL block	Block uses standalone code interface.

## Scheduling Considerations

Item	Information
Algebraic loops	<p>There are algebraic loops that occur in SIL and PIL simulations but not in normal mode simulations:</p> <ul style="list-style-type: none"> <li>• <b>Single output/update function</b> in code generation optimization can introduce algebraic loops because the option introduces direct feedthrough via a combined output and update function.</li> </ul> <p><b>Single output/update function</b> is not compatible with <b>Minimize algebraic loop occurrences</b> (in the Subsystem Parameters dialog box and <b>Configuration Parameters &gt; Model Referencing</b> pane). <b>Minimize algebraic loop occurrences</b> allows code generation to remove algebraic loops by partitioning generated code between output and update functions to avoid direct feedthrough.</p> <ul style="list-style-type: none"> <li>• If you generate code for a virtual subsystem, code generation treats the subsystem as atomic and generates the code accordingly. The resulting code can change the execution behavior of your model, for</li> </ul>

Item	Information
	<p>example, by applying algebraic loops, and introduce inconsistencies to the simulation behavior.</p> <p>To enable consistent simulation and execution behavior for your model, declare virtual subsystems as atomic subsystems.</p> <p>For more information, see:</p> <ul style="list-style-type: none"> <li>• “Algebraic Loops”</li> <li>• “Algebraic Loops”</li> <li>• “Code Generation of Subsystems”</li> </ul>
Exported functions in feedback loops	<p>If your model has function-call subsystems and you export a subsystem that has context-dependent inputs (for example, feedback signals), the results of a SIL/PIL simulation with the generated code and the results of the normal mode simulation of your model can differ. One approach to make SIL/PIL and normal mode simulations yield identical results is to use Function-Call Feedback Latch blocks in your model. You can make context-dependent inputs become context-independent.</p> <p>Embedded Coder generates a warning identifying context-dependent inputs of exported function-call subsystems if you set <b>Configuration Parameters &gt; Diagnostics &gt; Connectivity &gt; Context-dependent inputs</b> to one of the following:</p> <ul style="list-style-type: none"> <li>• Enable all as warnings</li> <li>• Use local settings</li> <li>• Disable all</li> </ul> <p>For more information, see:</p> <ul style="list-style-type: none"> <li>• “Code Generation of Subsystems”</li> <li>• Function-Call Feedback Latch</li> <li>• “Context-dependent inputs”</li> </ul>

## Imported Data and Function Definitions

Item	Information
Imported data	<p>In SIL and PIL simulations, you can use signals, parameters, and data stores that specify storage classes with imported data definitions. The simulations define storage for imported data associated with:</p> <ul style="list-style-type: none"> <li>• Signals at the root level of the component (on the I/O boundary)</li> <li>• Parameters</li> <li>• Global data stores</li> </ul> <p>SIL and PIL simulations do not define storage for other imported data. For example, the simulations do not define storage for imported data associated with:</p> <ul style="list-style-type: none"> <li>• Internal signals (not on the I/O boundary)</li> <li>• Local data stores</li> </ul> <p>In these cases, define the storage through custom code included by the component under test or through the PIL <code>rtw.pil.RtIOStreamApplicationFramework</code> API.</p> <p>See also “Tunable Parameters and SIL/PIL” on page 64-62.</p>
GetSet custom storage class	<p>SIL and PIL simulations support the <code>GetSet</code> custom storage class. The SIL/PIL test harness provides C definitions of the <code>Get</code> and <code>Set</code> functions that are used during simulations. For more information, see “Access Data Through Functions with Custom Storage Class <code>GetSet</code>” on page 22-78.</p>
AUTOSAR Runtime Environment (RTE)	<p>You can use top-model and Model block SIL/PIL and SIL/PIL block simulations to perform model-based testing of an AUTOSAR software component. The generated code for the AUTOSAR software component is linked with a basic component-specific AUTOSAR Runtime Environment (RTE) to create a test application. This application tests AUTOSAR API calls made by the AUTOSAR software component.</p> <hr/> <p><b>Note:</b> For Model block SIL/PIL, to test the AUTOSAR interface, set the <b>Code interface</b> block parameter to <code>Top_model</code>.</p>

<b>Item</b>	<b>Information</b>
	For more information, see “Verify AUTOSAR C Code with SIL and PIL”.

### **Related Examples**

- “Test Generated Code with SIL and PIL Simulations”

## Choose a SIL or PIL Approach

### In this section...

“Test Top-Model Code” on page 64-12

“Test Referenced Model Code” on page 64-13

“Test Subsystem Code” on page 64-13

“Summary” on page 64-13

Consider a top model that consists of components A, B, C, and D:

- A and B are existing components for which code has previously been generated and tested.
- C, a referenced model, and D, a subsystem, are new components.

With software-in-the-loop (SIL) and processor-in-the-loop (PIL) simulations, you can use the following approaches to numerical equivalence testing:

- Test code from all components together. See “Test Top-Model Code” on page 64-12.
- Test new components separately (before testing code from all components). See “Test Referenced Model Code” on page 64-13 and “Test Subsystem Code” on page 64-13.

For some forms of testing, you require a test harness model. The test harness model:

- Generates test vectors or stimulus inputs that feed the block under test.
- Makes it possible for you to observe or capture output from the block.

The following example shows a simple test harness model.

The block under test is a Model block. The Sine Wave block generates the input for the Model block. Through the Scope block, you can observe the output from the Model block.

## Test Top-Model Code

To test code generated from the top-model components together (A, B, C, and D), you can use top-model SIL/PIL or Model block SIL/PIL.

- Top-model SIL/PIL:
  - 1 Create test vectors or stimulus inputs in the MATLAB workspace.
  - 2 Run the top model in normal, SIL, and PIL simulation modes. The software loads the test vectors or stimulus inputs from the MATLAB workspace.
  - 3 For each simulation mode, observe or capture outputs.
  - 4 Verify numerical equivalence by comparing normal outputs against SIL and PIL outputs.
- Model block SIL/PIL:
  - 1 Create a Model block that contains the top-model components.
  - 2 Insert the Model block in a simulation model, for example, your test harness model.
  - 3 Run simulations, switching the Model block between normal, SIL, and PIL modes. For the SIL and PIL simulation modes, set the **Code interface** Model block parameter to `Top model`.
  - 4 Verify numerical equivalence by comparing normal outputs against SIL and PIL outputs.

## Test Referenced Model Code

To test code generated from the component **C** as part of a model reference hierarchy, use the Model block SIL/PIL approach:

- Insert the Model block **C** in a simulation model, for example, your test harness model.
- Run simulations, switching the Model block between normal, SIL, and PIL modes. For the SIL and PIL simulation modes, set the **Code interface** Model block parameter to **Model reference**.
- Verify numerical equivalence by comparing normal outputs against SIL and PIL outputs.

## Test Subsystem Code

To test code generated from the subsystem **D**, use the SIL or PIL block approach:

- 1 Insert the subsystem in a simulation model, for example, your test harness model.
- 2 Run a normal mode simulation, capturing the outputs.
- 3 Create a SIL or PIL block from the subsystem.
- 4 In the model, replace the subsystem with the SIL or PIL block.
- 5 Run a simulation of the model, capturing the outputs.
- 6 Verify numerical equivalence by comparing normal mode subsystem outputs against SIL or PIL block outputs.

## Summary

Simulation Type	Component From Which Code Is Generated	Mode Selection Method	Generated Code Interface	Test Signal Source
Top-model SIL/PIL	Top model	Menu item on Simulink Editor toolbar	Standalone	MATLAB workspace
Model block SIL/PIL	Model referenced by Model block	Model block parameter <b>Simulation mode</b>	Determined by Model block parameter <b>Code interface</b> : standalone or model reference.	Simulation model, for example, test harness model

<b>Simulation Type</b>	<b>Component From Which Code Is Generated</b>	<b>Mode Selection Method</b>	<b>Generated Code Interface</b>	<b>Test Signal Source</b>
SIL or PIL block	Subsystem	Manual block substitution	Standalone	Simulation model, for example, test harness model.

# Configure and Run SIL Simulation

## In this section...

- “Simulation with Top Model” on page 64-15
- “Simulation with Model Blocks” on page 64-17
- “Simulation with Blocks From Subsystems” on page 64-18
- “Configure Hardware Implementation Settings” on page 64-19
- “Log Internal Signals of a Component” on page 64-22
- “Prevent Code Changes in Multiple Simulations” on page 64-23
- “Speed Up Testing” on page 64-24

There are three ways of running SIL and PIL simulations. You can use:

- The top model.
- Model blocks.
- SIL and PIL blocks that you create from subsystems.

## Simulation with Top Model

To configure and run a top-model SIL or PIL simulation:

- 1 Open your model.
- 2 Select either **Simulation > Mode > Software-in-the-Loop (SIL)** or **Simulation > Mode > Processor-in-the-Loop (PIL)**. This option is available only if the model is configured for an ERT or AUTOSAR target. See “Model Configuration Parameters: Code Generation” and “Export AUTOSAR Component XML and C Code” for configuration information.
- 3 If you have not already done so, in the Configuration Parameters dialog box, on the **Data Import/Export** pane:
  - In the **Input** check box and field, specify stimulus signals (or test vectors) for your top model.
  - Configure logging for model outputs, with either *output logging* or *signal logging*:
    - In the **Output** check box and field, specify *output logging*.

- In the **Signal logging** check box and field, specify *signal logging*.
  - Disable logging of Data Store Memory variables. The software does not support this option for this simulation mode. If you do not clear the **Data stores** check box, the software produces a warning when you run the simulation.
- 4 If you are configuring a SIL simulation, specify the portable word sizes option. You can then switch seamlessly between the SIL and PIL modes. Select **Code Generation > Verification > Enable portable word sizes**.
  - 5 If required, configure:
    - Code coverage.
    - Code execution profiling.
    - Creation of code generation report and static code metrics.
  - 6 Start the simulation.

---

**Note:** On a Windows operating system, the Windows Firewall can potentially block your SIL simulation. To allow the SIL simulation, use the Windows Security Alert dialog box. For example, in Windows 7, click **Allow access**.

---

You cannot:

- Close the model while the simulation is running. To interrupt the simulation, in the Command Window, press **Ctrl+C**.
- Alter the model during the simulation. You can move blocks and lines as long as it does not alter the behavior of the model.

You can run a top-model SIL or PIL simulation with the command `sim(model)`. The software supports the `sim` command option `SrcWorkspace` for the value `'base'`.

For a PIL simulation, you control the way code compiles and executes in the target environment through connectivity configurations.

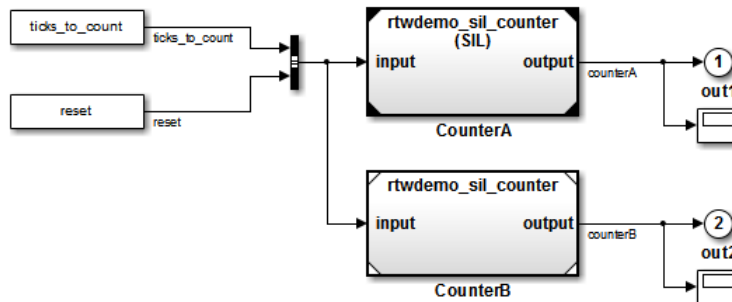

With a top-model SIL or PIL simulation, Simulink creates a hidden model, `modelName_wrapper`. The simulation generates code for the model and uses the hidden model to call this code at each time step. As a result, in some circumstances, logged signals can have a `_wrapper` suffix. The simulation can also generate warnings that refer to the hidden model. For example:

Warning: The model 'modelName\_wrapper' has the 'Configuration Parameters' ...

## Simulation with Model Blocks

To configure a Model block for a SIL or PIL simulation:

- 1 Open your model, for example, `rtwdemo_sil_modelblock`.
- 2 Right-click your Model block, for example, **Counter A**. In the context menu, select **Block Parameters (ModelReference)**, which opens the Function Block Parameters dialog box.
- 3 From the **Simulation Mode** drop-down list, select the required mode, for example, **Software-in-the-loop (SIL)**.
- 4 From the **Code interface** drop-down list, specify the code that you want to test, for example, **Model reference**.
- 5 Click **OK**. The software displays the simulation mode as a block label.

If you select **Top model**, the software displays the block label (**SIL: Top**).

- 6 If you are configuring a SIL simulation, specify the portable word sizes option. You can then switch seamlessly between the SIL and PIL modes. Select **Code Generation > Verification > Enable portable word sizes**.
- 7 If required, configure:
  - Code coverage.
  - Code execution profiling for your Model block, by configuring execution profiling for the top model.
  - Creation of code generation report and static code metrics.

- 8 Start the simulation.

---

**Note:** On a Windows operating system, the Windows Firewall can potentially block your SIL simulation. To allow the SIL simulation, use the Windows Security Alert dialog box. For example, in Windows 7, click **Allow access**.

---

For a PIL simulation, you control the way code compiles and executes in the target environment through connectivity configurations.

## Simulation with Blocks From Subsystems

To create a SIL or PIL block from a subsystem and use this block to test the code generated from the subsystem:

- 1 In the Configuration Parameters dialog box, click the **All Parameters** tab.
- 2 From the **Create block** drop-down list, select either **SIL** or **PIL**.
- 3 If required, configure code execution profiling.
- 4 Click **OK**.
- 5 In your model window, right-click the subsystem that you want to simulate.
- 6 Select **C/C++ Code > Build This Subsystem**.
- 7 Click **Build**, which starts the subsystem build process that creates a SIL or PIL block for the generated subsystem code.
- 8 Add the generated block to an environment or test harness model that supplies test vectors or stimulus input.
- 9 Run simulations with the environment or test harness model.

---

**Note:** On a Windows operating system, the Windows Firewall can potentially block your SIL simulation. To allow the SIL simulation, use the Windows Security Alert dialog box. For example, in Windows 7, click **Allow access**.

---

You cannot create a SIL or PIL block if you do one of the following:

- Disable the `CreateSILPILBlock` property.
- Select a code coverage tool.

**Create block** appears dimmed.

For a PIL simulation, you control the way code compiles and executes in the target environment through connectivity configurations.

## Configure Hardware Implementation Settings

For a SIL simulation, you must configure hardware implementation settings, which enables generated code compilation for your development computer. These settings can differ from the hardware implementation settings that you use when building the model for your production hardware. Use one of these approaches.

Approach	Details
Portable word sizes	<p>Switch between SIL and PIL modes without regenerating code. You use the same generated source code files for the SIL simulation on your development computer and for the production deployment on the target platform.</p> <p>To configure a model to use portable word sizes, in <b>Configuration Parameters &gt; All Parameters</b>, set:</p> <ul style="list-style-type: none"> <li>• <code>ProdEqTarget</code> to on.</li> <li>• <code>PortableWordSizes</code> to on.</li> </ul> <p>When you generate code for a model with portable word sizes specified, the code generator conditionalizes data type definitions in <code>rtwtypes.h</code>:</p> <pre>#ifdef PORTABLE_WORDSIZES           /* PORTABLE_WORDSIZES defined */ ... #else                                 /* PORTABLE_WORDSIZES not defined */ ... #endif                               /* PORTABLE_WORDSIZES */</pre> <p>If you use the template makefile approach to build code for your development computer, the template makefile that you select controls the passing of the <code>PORTABLE_WORDSIZES</code> definition to the compiler. For example, <code>ert_unix.tmf</code> has the following lines:</p>

Approach	Details
	<pre data-bbox="418 298 983 378"> ifeq (\$(PORTABLE_WORDSIZES),1) CPP_REQ_DEFINES += -DPORTABLE_WORDSIZES endif </pre> <hr/> <p data-bbox="418 440 1285 499"><b>Note:</b> The template makefile that you use to build code for your target must not contain the <code>PORTABLE_WORDSIZES</code> definition.</p> <hr/> <p data-bbox="418 562 1255 621">With the toolchain approach, the software specifies <code>-DPORTABLE_WORDSIZES</code> for the compiler only for host-based builds.</p> <p data-bbox="418 656 1322 715">For information about the template makefile and toolchain approaches to building code, see “Configure Build Process”.</p> <hr/> <p data-bbox="418 732 1329 982">Consider the case where your target uses code that your development computer cannot compile. When you switch from the PIL mode to the SIL mode and try to simulate the model, you see compilation errors. You can try to work around this problem by adding the source code files to the <code>SkipForSil</code> group in the build information object <code>RTW.BuildInfo</code>. The SIL build on the host platform does not compile source files present in the <code>SkipForSil</code> group. For information about how you add source code files to a group in the build information object, see:</p> <ul data-bbox="418 1013 1302 1112" style="list-style-type: none"> <li>• <code>addSourceFiles</code> in the Simulink Coder documentation</li> <li>• “Customize Post-Code-Generation Build Processing” in the Simulink Coder documentation</li> </ul>

Approach	Details
	<p>Numerical results can differ between generated code executing in a SIL simulation and generated code executing on the production hardware under one of these conditions:</p> <ul style="list-style-type: none"> <li>• Your model contains blocks implemented in TLC, for which C integral promotion in expressions can behave differently between the MATLAB host and the production hardware target. Normal and PIL simulation results match, but SIL simulation results can differ.</li> <li>• Your production hardware implements rounding to <b>Floor</b> for signed integer division, and divisions in your model use rounding mode <b>Ceiling</b>, <b>Floor</b>, <b>Simplest</b>, or <b>Zero</b>. Normal and PIL simulation results match, but SIL simulation results can differ.</li> <li>• You use custom code with the Stateflow product. In this case, type conversion statements are not inserted into the custom code, which target overflow behavior on the host can require. Normal and PIL simulation results match, but SIL simulation results can differ.</li> </ul>
Test hardware	<p>Only when you want to work around a limitation of portable word sizes.</p> <p>To configure a model for test hardware, in <b>Configuration Parameters &gt; All Parameters</b>, set:</p> <ul style="list-style-type: none"> <li>• <code>PortableWordSizes</code> to off.</li> <li>• <code>ProdEqTarget</code> to off.</li> <li>• <code>TargetHWDeviceType</code> to Custom Processor -&gt; MATLAB Host Processor.</li> </ul>
Production hardware	<p>Only when the production hardware settings match your development computer architecture.</p> <p>In <b>Configuration Parameters &gt; All Parameters</b>, set:</p> <ul style="list-style-type: none"> <li>• <code>PortableWordSizes</code> to off.</li> <li>• <code>ProdEqTarget</code> to on.</li> <li>• <code>ProdHWDeviceType</code> to match your development computer architecture. For example, you can select <code>Intel -&gt; x86-64 (Windows64)</code> and set <code>ProdLongLongMode</code> to on.</li> </ul>

For information about test and production targets, see “Platform Options for Development and Deployment” in the Simulink Coder documentation.

For an example of how to configure a model to maintain bit-true agreement between host simulation and target deployment, and generate code that is portable between the host and target systems, see “Configure Hardware Settings for Software-in-the-Loop (SIL) Simulation” on page 64-83.

## Log Internal Signals of a Component

SIL and PIL component outputs are available for observation and comparison with other simulation mode outputs. If you want to examine an internal signal, you can enable internal signal logging for top-model or Model block SIL or PIL. With signal logging, you can:

- Collect signal logging outputs during SIL/PIL simulations, for example, `logout`.
- Log the internal signals and the root-level outputs of a SIL/PIL component.
- Manage the SIL/PIL signal logging settings with the Simulink Signal Logging Selector.
- Use the Simulation Data Inspector to:
  - Observe streamed signals during the simulation
  - Compare logged signals from normal, SIL, and PIL simulations.

For SIL and PIL signal logging:

- Set **Configuration Parameters > All Parameters > Format** to **Dataset**.
- Select the **Configuration Parameters > Code Generation > Interface > Generate C API for: signals** check box.

The C API determines the addresses of the internal signals that require logging.

You can use other methods to examine internal signals of the SIL or PIL component:

- Manually route the signal to the top level.
- Use global data stores to access internal signals:
  - 1 Inside the component, connect a Data Store Write block to the required signal.

**2** Outside the component, use a Data Store Read block to access the signal value.

- Use MAT-file logging. Note that:
  - MAT-file logging does not support signal logging. If signal logging is enabled, `logout` is generated but not stored in the MAT-file.
  - For PIL, the target environment must support MAT-file logging.

For more information, see:

- “Test Points”
- “Export Signal Data Using Signal Logging”
- “Local and Global Data Stores”
- “Global Data Store Example”
- “Log Program Execution Results”

## Prevent Code Changes in Multiple Simulations

Use Model block SIL/PIL or the SIL/PIL block with fast restart when you want to run multiple SIL or PIL simulations with:

- Varying test vectors (parameter sets and input data).
- Unchanged generated code, that is, none of the simulations regenerate or rebuild code after the initial build. For example, you want to avoid the incremental code generation that an initial value change can trigger.

For Model block SIL/PIL, you can also use one of these methods:

- In your test harness model, set **Configuration Parameters** > **Model Referencing** > **Rebuild** to **Never**. If the Model block **Code interface** parameter is **Model reference**, the software does not rebuild the referenced model code. (If the **Code interface** parameter is **Top model**, the software ignores the **Rebuild** setting.)
- Create a protected model and generate source or binary code. Then, insert the protected model in your test harness model. With this method, you can verify top-model code (with the standalone code interface) or model reference code.

For the alternative methods of running Model block SIL/PIL, the following table summarizes code generation behavior after the initial build.

SIL and PIL Approach		Code Generation Behavior After Initial Build
Model block	<b>Configuration Parameters &gt; Model Referencing &gt; Rebuild</b> of test harness model set to <b>Never</b> .	<ol style="list-style-type: none"> <li><b>1</b> Component (algorithm) code from initial build is not regenerated.</li> <li><b>2</b> Component code makefile is not called.</li> <li><b>3</b> SIL/PIL application files from initial build are not regenerated.</li> <li><b>4</b> SIL/PIL application makefile is called.</li> </ol>
Model block (protected model)	Source code from protected model.	You observe the same behavior except for feature 2. In this case, the component code makefile is run. The component code is recompiled and linked to produce new object code.
	Binary code from protected model.	You observe features 1–4.

For more information, see:

- “Model Configuration Parameters: Model Referencing”
- “Create a Protected Model”

## Speed Up Testing

If your model has SIL/PIL blocks or Model blocks in SIL/PIL mode, you can speed up SIL/PIL testing by:

- Running the top-model simulation in accelerator mode. This mode accelerates the simulation of model components that are not in SIL or PIL mode.
- Turning on fast restart with the **Fast restart** button on the Simulink Editor toolbar. After the first simulation, you can tune parameters and rerun simulations without model recompilation.

**Note:** The SIL and PIL simulation modes are not designed for the reduction of model simulation times. If you want to speed up the simulation of your model, use the rapid accelerator mode. For an example, see “Rapid Accelerator Simulations Using PARFOR”.

## Configure and Run PIL Simulation

### In this section...

- “Simulation with Top Model” on page 64-15
- “Simulation with Model Blocks” on page 64-17
- “Simulation with Blocks From Subsystems” on page 64-18
- “Log Internal Signals of a Component” on page 64-22
- “Prevent Code Changes in Multiple Simulations” on page 64-23
- “Speed Up Testing” on page 64-24

There are three ways of running SIL and PIL simulations. You can use:

- The top model.
- Model blocks.
- SIL and PIL blocks that you create from subsystems.

### Simulation with Top Model

To configure and run a top-model SIL or PIL simulation:

- 1 Open your model.
- 2 Select either **Simulation > Mode > Software-in-the-Loop (SIL)** or **Simulation > Mode > Processor-in-the-Loop (PIL)**. This option is available only if the model is configured for an ERT or AUTOSAR target. See “Model Configuration Parameters: Code Generation” and “Export AUTOSAR Component XML and C Code” for configuration information.
- 3 If you have not already done so, in the Configuration Parameters dialog box, on the **Data Import/Export** pane:
  - In the **Input** check box and field, specify stimulus signals (or test vectors) for your top model.
  - Configure logging for model outputs, with either *output logging* or *signal logging*:
    - In the **Output** check box and field, specify *output logging*.
    - In the **Signal logging** check box and field, specify *signal logging*.

- Disable logging of Data Store Memory variables. The software does not support this option for this simulation mode. If you do not clear the **Data stores** check box, the software produces a warning when you run the simulation.
- 4 If you are configuring a SIL simulation, specify the portable word sizes option. You can then switch seamlessly between the SIL and PIL modes. Select **Code Generation > Verification > Enable portable word sizes**.
  - 5 If required, configure:
    - Code coverage.
    - Code execution profiling.
    - Creation of code generation report and static code metrics.
  - 6 Start the simulation.

---

**Note:** On a Windows operating system, the Windows Firewall can potentially block your SIL simulation. To allow the SIL simulation, use the Windows Security Alert dialog box. For example, in Windows 7, click **Allow access**.

---

You cannot:

- Close the model while the simulation is running. To interrupt the simulation, in the Command Window, press **Ctrl+C**.
- Alter the model during the simulation. You can move blocks and lines as long as it does not alter the behavior of the model.

You can run a top-model SIL or PIL simulation with the command `sim(model)`. The software supports the `sim` command option `SrcWorkspace` for the value `'base'`.

For a PIL simulation, you control the way code compiles and executes in the target environment through connectivity configurations.

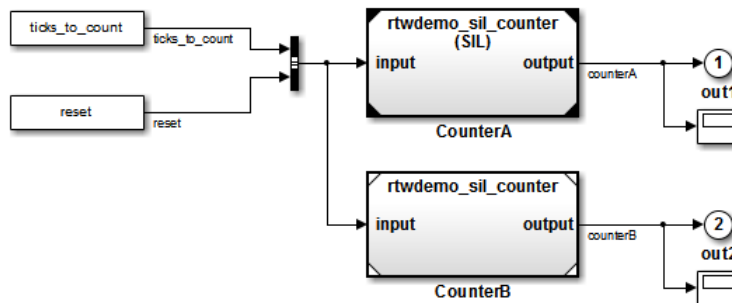

With a top-model SIL or PIL simulation, Simulink creates a hidden model, `modelName_wrapper`. The simulation generates code for the model and uses the hidden model to call this code at each time step. As a result, in some circumstances, logged signals can have a `_wrapper` suffix. The simulation can also generate warnings that refer to the hidden model. For example:

```
Warning: The model 'modelName_wrapper' has the 'Configuration Parameters' ...
```

## Simulation with Model Blocks

To configure a Model block for a SIL or PIL simulation:

- 1 Open your model, for example, `rtwdemo_sil_modelblock`.
- 2 Right-click your Model block, for example, `Counter A`. In the context menu, select **Block Parameters (ModelReference)**, which opens the Function Block Parameters dialog box.
- 3 From the **Simulation Mode** drop-down list, select the required mode, for example, `Software-in-the-loop (SIL)`.
- 4 From the **Code interface** drop-down list, specify the code that you want to test, for example, `Model reference`.
- 5 Click **OK**. The software displays the simulation mode as a block label.

If you select `Top model`, the software displays the block label (`SIL: Top`).

- 6 If you are configuring a SIL simulation, specify the portable word sizes option. You can then switch seamlessly between the SIL and PIL modes. Select **Code Generation > Verification > Enable portable word sizes**.
- 7 If required, configure:
  - Code coverage.
  - Code execution profiling for your Model block, by configuring execution profiling for the top model.
  - Creation of code generation report and static code metrics.
- 8 Start the simulation.

---

**Note:** On a Windows operating system, the Windows Firewall can potentially block your SIL simulation. To allow the SIL simulation, use the Windows Security Alert dialog box. For example, in Windows 7, click **Allow access**.

---

For a PIL simulation, you control the way code compiles and executes in the target environment through connectivity configurations.

## Simulation with Blocks From Subsystems

To create a SIL or PIL block from a subsystem and use this block to test the code generated from the subsystem:

- 1 In the Configuration Parameters dialog box, click the **All Parameters** tab.
- 2 From the **Create block** drop-down list, select either **SIL** or **PIL**.
- 3 If required, configure code execution profiling.
- 4 Click **OK**.
- 5 In your model window, right-click the subsystem that you want to simulate.
- 6 Select **C/C++ Code > Build This Subsystem**.
- 7 Click **Build**, which starts the subsystem build process that creates a SIL or PIL block for the generated subsystem code.
- 8 Add the generated block to an environment or test harness model that supplies test vectors or stimulus input.
- 9 Run simulations with the environment or test harness model.

---

**Note:** On a Windows operating system, the Windows Firewall can potentially block your SIL simulation. To allow the SIL simulation, use the Windows Security Alert dialog box. For example, in Windows 7, click **Allow access**.

---

You cannot create a SIL or PIL block if you do one of the following:

- Disable the `CreateSILPILBlock` property.
- Select a code coverage tool.

**Create block** appears dimmed.

For a PIL simulation, you control the way code compiles and executes in the target environment through connectivity configurations.

## Log Internal Signals of a Component

SIL and PIL component outputs are available for observation and comparison with other simulation mode outputs. If you want to examine an internal signal, you can enable internal signal logging for top-model or Model block SIL or PIL. With signal logging, you can:

- Collect signal logging outputs during SIL/PIL simulations, for example, `logout`.
- Log the internal signals and the root-level outputs of a SIL/PIL component.
- Manage the SIL/PIL signal logging settings with the Simulink Signal Logging Selector.
- Use the Simulation Data Inspector to:
  - Observe streamed signals during the simulation
  - Compare logged signals from normal, SIL, and PIL simulations.

For SIL and PIL signal logging:

- Set **Configuration Parameters** > **All Parameters** > **Format** to **Dataset**.
- Select the **Configuration Parameters** > **Code Generation** > **Interface** > **Generate C API for: signals** check box.

The C API determines the addresses of the internal signals that require logging.

You can use other methods to examine internal signals of the SIL or PIL component:

- Manually route the signal to the top level.
- Use global data stores to access internal signals:
  - 1 Inside the component, connect a Data Store Write block to the required signal.
  - 2 Outside the component, use a Data Store Read block to access the signal value.
- Use MAT-file logging. Note that:
  - MAT-file logging does not support signal logging. If signal logging is enabled, `logout` is generated but not stored in the MAT-file.
  - For PIL, the target environment must support MAT-file logging.

For more information, see:

- “Test Points”
- “Export Signal Data Using Signal Logging”
- “Local and Global Data Stores”
- “Global Data Store Example”
- “Log Program Execution Results”

## Prevent Code Changes in Multiple Simulations

Use Model block SIL/PIL or the SIL/PIL block with fast restart when you want to run multiple SIL or PIL simulations with:

- Varying test vectors (parameter sets and input data).
- Unchanged generated code, that is, none of the simulations regenerate or rebuild code after the initial build. For example, you want to avoid the incremental code generation that an initial value change can trigger.

For Model block SIL/PIL, you can also use one of these methods:

- In your test harness model, set **Configuration Parameters > Model Referencing > Rebuild** to **Never**. If the Model block **Code interface** parameter is **Model reference**, the software does not rebuild the referenced model code. (If the **Code interface** parameter is **Top model**, the software ignores the **Rebuild** setting.)
- Create a protected model and generate source or binary code. Then, insert the protected model in your test harness model. With this method, you can verify top-model code (with the standalone code interface) or model reference code.

For the alternative methods of running Model block SIL/PIL, the following table summarizes code generation behavior after the initial build.

SIL and PIL Approach		Code Generation Behavior After Initial Build
Model block	<b>Configuration Parameters &gt; Model Referencing &gt; Rebuild</b> of test harness model set to <b>Never</b> .	<b>1</b> Component (algorithm) code from initial build is not regenerated. <b>2</b> Component code makefile is not called.

SIL and PIL Approach		Code Generation Behavior After Initial Build
		<p><b>3</b> SIL/PIL application files from initial build are not regenerated.</p> <p><b>4</b> SIL/PIL application makefile is called.</p>
Model block (protected model)	Source code from protected model.	You observe the same behavior except for feature 2. In this case, the component code makefile is run. The component code is recompiled and linked to produce new object code.
	Binary code from protected model.	You observe features 1–4.

For more information, see:

- “Model Configuration Parameters: Model Referencing”
- “Create a Protected Model”

## Speed Up Testing

If your model has SIL/PIL blocks or Model blocks in SIL/PIL mode, you can speed up SIL/PIL testing by:

- Running the top-model simulation in accelerator mode. This mode accelerates the simulation of model components that are not in SIL or PIL mode.
- Turning on fast restart with the **Fast restart** button on the Simulink Editor toolbar. After the first simulation, you can tune parameters and rerun simulations without model recompilation.

---

**Note:** The SIL and PIL simulation modes are not designed for the reduction of model simulation times. If you want to speed up the simulation of your model, use the rapid accelerator mode. For an example, see “Rapid Accelerator Simulations Using PARFOR”.

---

- “SIL and PIL Limitations” on page 64-60

## Simulation Mode Override Behavior in Model Reference Hierarchy

When the top model contains a Model block, the simulation mode of the top model can override the simulation mode of the Model block. The Model block itself can be a parent block containing child Model blocks at lower levels of its reference hierarchy. The simulation mode of the parent block can override the simulation mode of the child block.

You can specify the simulation mode of a top model to be normal, accelerator, rapid accelerator, SIL, or PIL. With a Model block, you can specify all modes *except* rapid accelerator. This table shows how the software determines the effective simulation mode of a Model block in a reference hierarchy.

Mode of Top Model or Parent Block	Mode of Parent or Child Block in Reference Hierarchy			
	Normal	Accelerator	SIL	PIL
<b>Normal</b>	Equivalent	Compatible	Compatible	Compatible
<b>Accelerator</b>	Override	Equivalent	Compatible if top model mode is accelerator. Error if parent block mode is accelerator.	Compatible if top model mode is accelerator. Error if parent block mode is accelerator.
<b>Rapid accelerator</b>	Override	Override	Error	Error
<b>SIL</b>	Override	Override	Equivalent	Error
<b>PIL</b>	Override	Override	Error	Equivalent

The different types of behavior are:

- **Equivalent** — Both parent and child Model block run in the same simulation mode.
- **Compatible** — The software simulates the child block in the mode specified for the child block, for example, when the simulation mode of the top model is normal or accelerator.
- **Error** — The simulation produces an error. For example, if a top model has simulation mode rapid accelerator but contains a child block in SIL or PIL mode, then running a simulation produces an error: the rapid accelerator mode cannot override the SIL and PIL mode of child blocks. This behavior avoids the risk of “false positives”, that is, the simulation of a model in rapid accelerator mode does not lead to the conclusion that generated source or object code of child Model blocks is tested or verified.

- **Override** — The simulation mode of the top model or parent Model block overrides the simulation mode of the child block. For example, if a top model or parent Model block that you configured for a SIL simulation contains a child Model block with normal or accelerator simulation mode, then the software simulates the child block in SIL mode. The override behavior:
  - Allows a Model block in the reference hierarchy to have the SIL or PIL mode.
  - Makes lower-level referenced models execute in SIL or PIL mode if you simulate the top model or parent Model block in SIL or PIL mode. You do not have to switch the simulation mode of every model component in the hierarchy.

For a model reference hierarchy that consists of multiple subhierarchies, if the top-model simulation mode is normal or accelerator, the software can run only one subhierarchy in PIL mode. For example, if your normal mode top model contains multiple Model blocks, you can specify the PIL mode for only one of the Model blocks.

---

**Note:** You can view your model hierarchy in the Model Dependency Viewer. In the Referenced Model Instances view, the software displays Model blocks differently to indicate their simulation modes, for example, normal, accelerator, SIL, and PIL. In this view, the software does not indicate the simulation mode of the top model.

---

- “What Is Acceleration?”
- “SIL and PIL Simulations” on page 64-2

## Debug Generated Code During SIL Simulation

If a software-in-the-loop (SIL) simulation fails or you notice differences between the outputs of your original functions and the generated code, you can rerun the SIL simulation with a debugger enabled. By inserting breakpoints, you can observe the behavior of code sections, which can help you to understand the cause of the issue.

For a SIL simulation failure, you can also view information from the standard output and standard error streams in the Diagnostic Viewer. For example:

- Output from `printf` statements in your code.
- Error messages sent to `stderr`.
- Some low-level system messages.

During a SIL simulation, the SIL application redirects the `stdout` and `stderr` streams. When the application terminates, the Diagnostic Viewer displays the information from the redirected streams. The SIL application also provides a basic signal handler, which captures the POSIX<sup>®</sup> signals `SIGFPE`, `SIGILL`, `SIGABRT`, and `SIGSEV`. For this signal handler, the SIL application includes the file `signal.h`.

A SIL simulation supports these debuggers;

- On Windows, Microsoft Visual Studio debugger.
- On Linux, GNU Data Display Debugger (DDD).

---

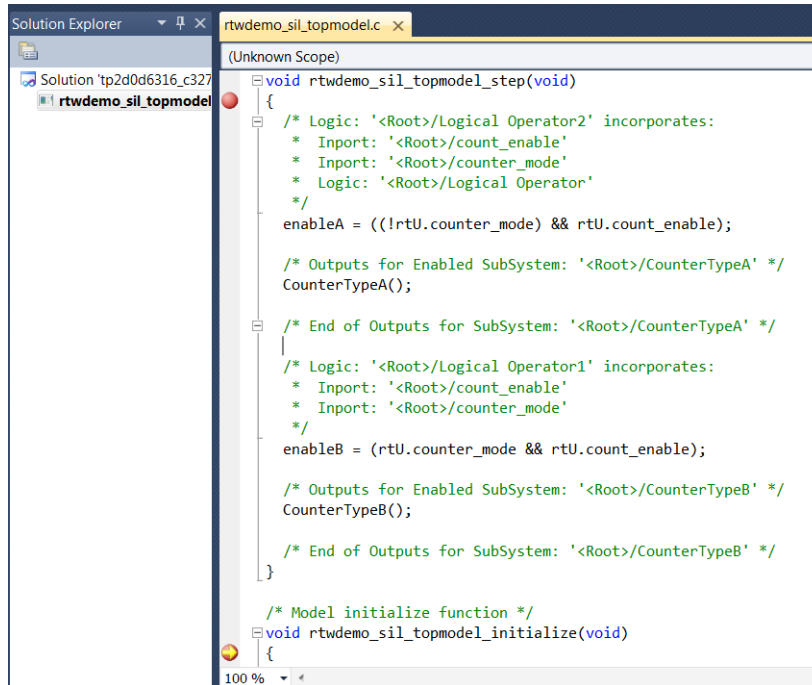

**Note:** You can perform SIL debugging only if the Simulink product family supports your Microsoft Visual C++ or GNU GCC compiler. For more information, see supported compilers.

---

To enable your debugger for a SIL simulation, on the **Configuration Parameters > Code Generation > Verification** pane, select the **Enable source-level debugging for SIL** check box.

If your top model has Model blocks where the **Code interface** block parameter is set to `Top model`, then the **Enable source-level debugging for SIL** parameters for the top model and referenced models must have the same settings. Otherwise, the software produces an error.

When you run the SIL simulation, for example on a Windows computer, your *model.c* or *model.cpp* file opens in the Microsoft Visual Studio IDE with debugger breakpoints at the start of the *model\_initialize* and *model\_step* functions.

```

Solution 'tp2d0d6316_c327'
 rtwdemo_sil_topmodel

rtwdemo_sil_topmodel.c
(Unknown Scope)
void rtwdemo_sil_topmodel_step(void)
{
 /* Logic: '<Root>/Logical Operator2' incorporates:
 * Inport: '<Root>/count_enable'
 * Inport: '<Root>/counter_mode'
 * Logic: '<Root>/Logical Operator'
 */
 enableA = ((!rtU.counter_mode) && rtU.count_enable);

 /* Outputs for Enabled SubSystem: '<Root>/CounterTypeA' */
 CounterTypeA();

 /* End of Outputs for SubSystem: '<Root>/CounterTypeA' */
 /* Logic: '<Root>/Logical Operator1' incorporates:
 * Inport: '<Root>/count_enable'
 * Inport: '<Root>/counter_mode'
 */
 enableB = (rtU.counter_mode && rtU.count_enable);

 /* Outputs for Enabled SubSystem: '<Root>/CounterTypeB' */
 CounterTypeB();

 /* End of Outputs for SubSystem: '<Root>/CounterTypeB' */
}

/* Model initialize function */
void rtwdemo_sil_topmodel_initialize(void)
{
}
100%

```

You can now use the debugger features to observe code behavior. For example, you can step through code and examine variables.

To end the debugging session:

- 1 Remove all breakpoints.
- 2 Click the **Continue** button (**F5**).

The SIL simulation runs to completion and the Microsoft Visual Studio IDE closes.

**Note:** In the Microsoft Visual Studio IDE, if you select **Debug > Stop Debugging**, the SIL simulation times out with the following error message:

```
The timeout of 1 seconds for receiving data from the rtiostream
```

interface has been exceeded. There are multiple possible causes for this failure.

...

## Create PIL Target Connectivity Configuration

### In this section...

“Target Connectivity Configurations for PIL” on page 64-39

“Create a Target Connectivity API Implementation” on page 64-40

“Register a Connectivity API Implementation” on page 64-42

“Verify Target Connectivity Configuration” on page 64-42

“Target Connectivity API Examples” on page 64-42

### Target Connectivity Configurations for PIL

Use target connectivity configurations and the target connectivity API to customize processor-in-the-loop (PIL) simulation for your target environments.

Through a target connectivity configuration, you specify:

- A configuration name for a target connectivity API implementation.
- Settings that define the set of compatible Simulink models. For example, the set of models that have a particular system target file, template makefile, and hardware implementation.

A PIL simulation requires a target connectivity API implementation that integrates third-party tools for:

- Cross-compiling generated code, creating the PIL application that runs on the target hardware.
- Downloading, starting, and stopping the application on the target.
- Communicating between Simulink and the target.

You can have many different target connectivity configurations for PIL simulation. Register a connectivity configuration with Simulink by creating an `sl_customization.m` file and placing it on the MATLAB search path.

When you run a PIL simulation, the software determines which of the available connectivity configurations to use. The software looks for a connectivity configuration that is compatible with the model under test. If the software finds multiple or no compatible connectivity configurations, the software generates an error message with information about resolving the problem.

## Create a Target Connectivity API Implementation

This diagram shows the components of the PIL target connectivity API.

You must provide implementations of the three API components:

- **Build API** — Specify the Simulink Coder toolchain or template makefile approach for building generated code.
- **Launcher API** — Control how Simulink starts and stops the PIL executable.
- **Communications API** — Customize connectivity between Simulink and the PIL target. Embedded Coder provides host-side support for TCP/IP and serial communications, which you can adapt for other protocols.

These steps outline how you create a target connectivity API implementation. The example code shown in the steps is taken from `ConnectivityConfig.m` in “Configure Processor-In-The-Loop (PIL) for a Custom Target”.

**1** Create a subclass of `rtw.connectivity.Config`.

```
ConnectivityConfig < rtw.connectivity.Config
```

**2** In the subclass:

- Instantiate `rtw.connectivity.MakefileBuilder`, which configures the build process.

```
builder = rtw.connectivity.MakefileBuilder(componentArgs, ...
 targetApplicationFramework, ...
 exeExtension);
```

- Create a subclass of `rtw.connectivity.Launcher`, which downloads and executes the application using a third-party tool.

```
launcher = mypil.Launcher(componentArgs, builder);
```

**3** Configure your `rtiostream` API implementation of the host-target communications on page 64-45 channel.

- For the target side, you must provide the driver code for communications, for example, TCP/IP or serial communications. To integrate this code into the build process, create a subclass of `rtw.pil.RtIOStreamApplicationFramework`.
- For the host side, you can use a supplied library for TCP/IP or serial communications. Instantiate `rtw.connectivity.RtIOStreamHostCommunicator`, which loads and initializes the library that you specify.

```
hostCommunicator = rtw.connectivity.RtIOStreamHostCommunicator(componentArgs, ...
 launcher, ...
 rtiostreamLib);
```

**4** If you require execution-time profiling of generated code, create a timer object that provides details of the hardware-specific timer and associated source files. See “Specify Hardware Timer” on page 64-51.

---

**Note:** Each time you modify a connectivity implementation, close and reopen the models to refresh them.

---

## Register a Connectivity API Implementation

To register a target connectivity API implementation as a target connectivity configuration in Simulink:

- 1 Create or update an `sl_customization.m` file. In this file:
  - Create a target connectivity configuration object that specifies, for example, the configuration name for a target connectivity API implementation and compatible models.
  - Invoke `registerTargetInfo`.
- 2 Add the folder containing `sl_customization.m` to the search path and refresh your customizations.

```
addpath(sl_customization_path);
sl_refresh_customizations;
```

For more information, see `rtw.connectivity.ConfigRegistry`.

## Verify Target Connectivity Configuration

Use the supplied `piltest` function to verify your target connectivity configuration early and independently of your model development and code generation. The function can run a suite of four tests. In each test, the function runs a normal and PIL mode simulation and compares the results. With the first three tests, the function runs a different PIL simulation for each test: top model, Model block, and PIL block. If the function detects differences between the normal and PIL mode results, it produces an error. In the fourth test, the function runs a Model block PIL simulation and introduces a deliberate mismatch. If the function does not detect the mismatch when comparing normal and PIL mode results, it produces an error.

## Target Connectivity API Examples

For step-by-step examples, see:

- “Configure Processor-In-The-Loop (PIL) for a Custom Target”

This example shows you how to create a custom PIL implementation using the target connectivity APIs. You can examine the code that configures the build process

to support PIL, a downloading and execution tool, and a communication channel between host and target. To activate a full host-based PIL configuration, follow the steps in the example.

- “Create a Target Communication Channel for Processor-In-The-Loop (PIL) Simulation”

This example shows you how to implement a communication channel for use with the Embedded Coder product and your embedded target. This communication channel enables exchange of data between different processes. PIL simulation requires exchange of data between the Simulink software running on your development computer and deployed code executing on target hardware.

The `rtiostream` interface provides a generic communication channel that you can implement in the form of target connectivity drivers for a range of connection types. The example shows how to configure your own target-side driver for TCP/IP, to operate with the default host-side TCP/IP driver. The default TCP/IP communications allow high-bandwidth communication between host and target, which you can use for transferring data such as video.

---

**Note:** If you customize the `rtiostream` TCP/IP implementation for your PIL simulations, you must turn off Nagle's algorithm for the server side of the connection. If Nagle's algorithm is not turned off, your PIL simulations can run at a significantly slower speed. The `matlabroot/rtw/c/src/rtiostream/rtiostreamtcpip/rtiostream_tcpip.c` file shows how you can turn off Nagle's algorithm:

```
/* Disable Nagle's Algorithm*/
option = 1;
sockStatus = setsockopt(1Fd, IPPROTO_TCP, TCP_NODELAY, (char*)&option, sizeof(option));
```

The code for your custom TCP/IP implementation can require modification.

---

The example also shows how to implement custom target connectivity drivers, for example, using serial, CAN, or USB for both host and target sides of the communication channel.

## Host-Target Communication for PIL

### In this section...

“Communications `rtiostream` API” on page 64-45

“Synchronize Host and Target” on page 64-46

“Test an `rtiostream` Driver” on page 64-47

### Communications `rtiostream` API

The `rtiostream` API supports communications for the target connectivity API. Use the `rtiostream` API to implement a communication channel that enables data exchange between different processes.

PIL simulation requires a host-target communications channel. This communications channel comprises driver code that runs on the host and target. The `rtiostream` API defines the signature of target-side and host-side functions that this driver code must implement.

The API is independent of the physical layer that sends the data. Possible physical layers include RS232, Ethernet, or Controller Area Network (CAN).

A full `rtiostream` implementation requires both host-side and target-side drivers. Code generation software includes host-side drivers for the default TCP/IP implementation and a version for serial communications. To use:

- The TCP/IP `rtiostream` communications channel, you must provide, or obtain from a third party, target-specific TCP/IP device drivers.
- The serial communications channel, you must provide, or obtain from a third party, target-specific serial device drivers.

For other communication channels and platforms, the code generation software does not provide default implementations. You must provide both the host-side and the target-side drivers.

The `rtiostream` API comprises the following functions:

- `rtIOStreamOpen`

- `rtIOStreamSend`
- `rtIOStreamRecv`
- `rtIOStreamClose`

For information about:

- Using `rtiostream` functions in a connectivity implementation, see “Create a Target Connectivity API Implementation” on page 64-40.
- Testing the `rtiostream` shared library methods from MATLAB code, see `rtiostream_wrapper`.
- Debugging and verifying the behavior of custom `rtiostream` interface implementations, see “Test an `rtiostream` Driver” on page 64-47.

## Synchronize Host and Target

If you use the `rtiostream` API to implement the communications channel, the host and target must be synchronized, which prevents Simulink from transmitting and receiving data before the target application is fully initialized.

To synchronize the host and target for TCP/IP `rtiostream` implementations, use the `setInitCommsTimeout` method from `rtw.connectivity.RtIOStreamHostCommunicator`. This approach works well for connection-oriented TCP/IP `rtiostream` implementations because Simulink automatically waits until the target server is running.

With other `rtiostream` implementations, for example, serial, the Simulink side of the `rtiostream` connection opens without waiting for the target to be fully initialized. In this case, you must make your `Launcher` implementation wait until the target application is fully initialized. Use one of the following approaches to synchronize your host and target:

- Add a pause at the end of the `Launcher` implementation that makes the `Launcher` wait until target initialization is complete.
- In the `Launcher` implementation, use third-party downloader or debugger APIs that wait until target initialization is complete.
- Implement a handshaking mechanism in the `Launcher / rtiostream` implementation that confirms completion of target initialization.

## Test an `rtiostream` Driver

Use a test suite to debug and verify the behavior of custom `rtiostream` interface implementations.

The test suite has the following advantages:

- Reduces time for integrating custom hardware that does not have built-in `rtiostream` support.
- Reduces time for testing custom `rtiostream` drivers.
- Helps analyze the performance of custom `rtiostream` drivers.

The test suite has two parts. One part of the test suite runs on the target.

---

**Note:** After building the target application, download it to the target and run it.

---

To start this part, compile and link the following files, which are in the folder `matlabroot/toolbox/coder/rtiostream/src/rtiostreamtest` (open).

- `rtiostreamtest.c`
- `rtiostreamtest.h`
- `rtiostream.h`, located in the folder `matlabroot/rtw/c/src` (open)
- `rtiostream` implementation under investigation (for example, `rtiostream_tcpip.c`)
- `main.c`

To run the MATLAB part of the test suite, invoke `rtiostreamtest`. The syntax is as follows:

```
rtiostreamtest(connection,param1,param2)
```

- `connection` is a character vector indicating the communication method. It can have values `'tcp'` or `'serial'`.
- `param1` and `param2` have different values depending on the value of `connection`.
  - If `connection` is `'tcp'`, then `param1` and `param2` are hostname and port, respectively. For example, `rtiostreamtest('tcp', 'localhost', 2345)`.

- If connection is 'serial', then param1 and param2 are COM port and baud rate, respectively. For example, `rtiostreamtest('serial', 'COM1', 9600)`.

You can run the MATLAB part of the test suite as follows:

```
rtiostreamtest('tcp', 'localhost', '2345')
```

An output in the following format appears in the MATLAB window:

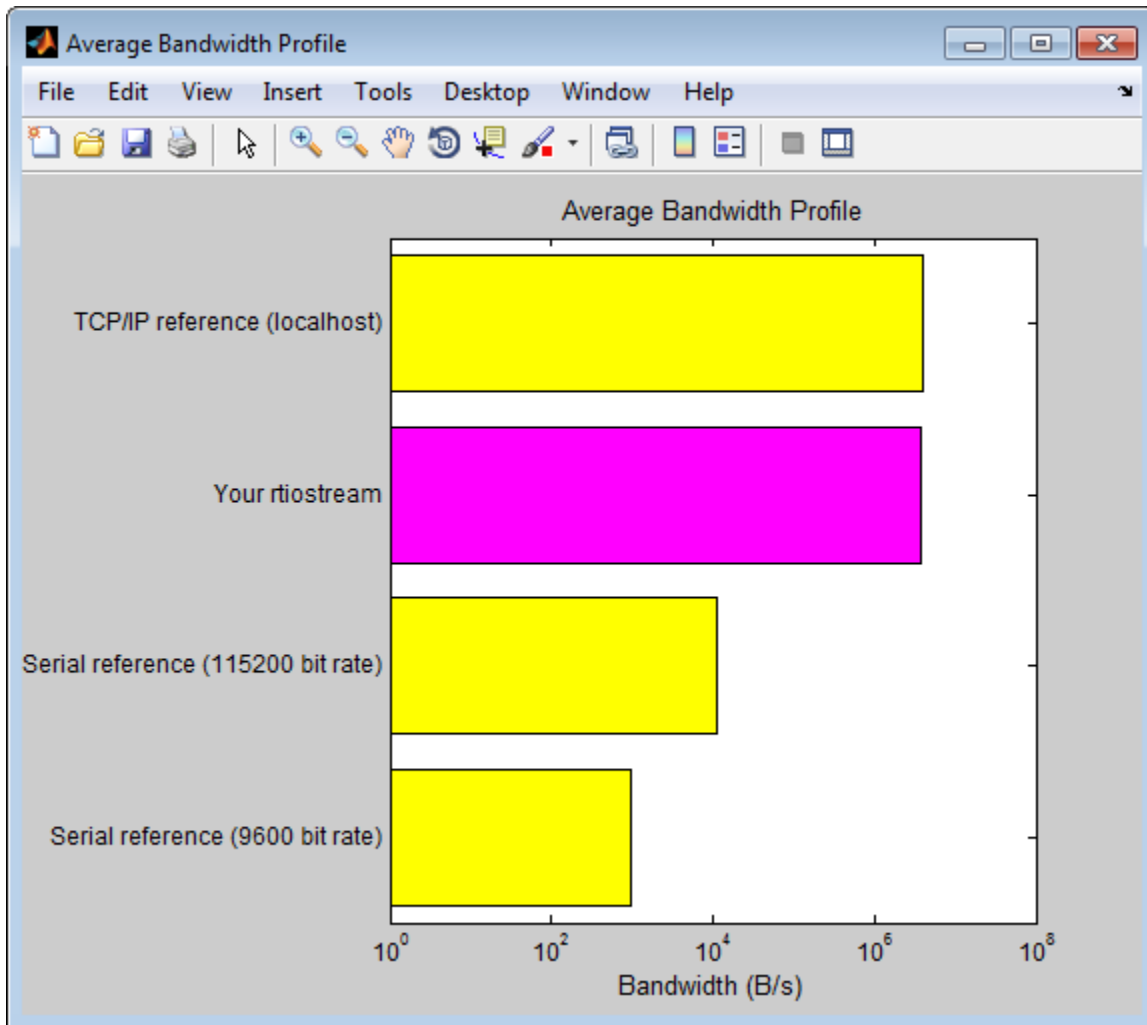

```
Test suite for rtiostream
Initializing connection with target...

Hardware characteristics discovered
Size of char : 8 bit

## Specify Hardware Timer

For processor-in-the-loop (PIL) code execution profiling, you must create a timer object that provides details of the hardware-specific timer and associated source files. You can use the Code Replacement Tool or the code replacement library API to specify this hardware-specific timer.

To specify the timer with the Code Replacement Tool:

- 1** Open the Code Replacement Tool. In the Command Window, enter `crtool`.
- 2** Create a new code replacement table. Select **File > New table**.
- 3** Create a new function entry. Under **Tables List**, right-click the new table. Then, from the context-menu, select **New entry > Function**.
- 4** In the middle view, select the new unnamed function.
- 5** On the **Mapping Information** pane:
  - a** From the **Function** drop-down list, select `code_profile_read_timer`.
  - b** Specify the count direction for your timer. For example, from the **Count direction** drop-down list, select **Up**.
  - c** In the **Ticks per second** field, specify the number of ticks per second for your timer, for example, `1e+09`.

The default value is 0. In this case, the software reports time measurements in terms of ticks, not seconds.

- d** In the **Name** field, specify a replacement function name, for example, `MyTimer`.
- e** Click **Apply**.

**f** To validate the function entry, click **Validate entry**.

- 6** On the **Build Information** pane, specify the required build information. See “Specify Build Information for Replacement Code” on page 51-59.
- 7** Save the table (**Ctrl+S**). When you save the table for the first time, use the Save As dialog box to specify the file name and location.

You must save the table in a location that is on the MATLAB search path. For example, you can save this file in the folder for your subclass of `rtw.connectivity.Config`.

The software stores your timer information as a code replacement library table.

- 8** Assuming you save the table as `MyCr1Table.m`, in your subclass of `rtw.connectivity.Config`, add the following line:

```
setTimer(this, MyCr1Table)
```

## PIL Simulation Sequence

A processor-in-the-loop (PIL) simulation cross-compiles production source code, and then downloads and runs object code on your target hardware. The connectivity configuration that you create controls the way code is compiled and executed on the target. This table describes the sequence of stages in a PIL simulation.

Stage		Description
1	Start	<p>For top-model PIL, on the Simulink Editor toolbar, you select the <b>Processor-in-the-Loop (PIL)</b> mode, and then click the Run button.</p> <p>For Model block PIL, you set the <b>Simulation mode</b> parameter of the Model block to <b>Processor-in-the-loop (PIL)</b>, and then run a simulation of the harness model that contains the Model block.</p> <p>For the PIL block, you run a simulation of the harness model that contains the PIL block.</p>
2	Validate target connectivity	The software verifies that a target connectivity configuration is registered for PIL. Otherwise, the software produces an error.
3	Generate production source code and build object code for target	<p>The generated source code is identical to the code that is produced when you run the <code>slbuild</code> command.</p> <ul style="list-style-type: none"> <li>For top-model PIL or Model block PIL with block parameter <b>Code interface</b> set to <code>Top model</code>, the generated code is identical to the code produced when you run <code>slbuild('model')</code>.</li> <li>For Model block PIL with block parameter <b>Code interface</b> set to <code>Model reference</code>, the generated code is identical to the code produced when you run <code>slbuild('model', 'ModelReferenceRTWTarget')</code>. The model reference simulation target is also produced.</li> </ul> <p>The software builds object code for the target by using the template makefile or toolchain that you specify.</p>
4	Create instances of PIL API components	The software instantiates your <code>rtw.connectivity.Config</code> class, which creates

Stage		Description
		instances of <code>rtw.connectivity.MakefileBuilder</code> , <code>rtw.connectivity.Launcher</code> , <code>rtw.pil.RtIOStreamApplicationFramework</code> , and <code>rtw.connectivity.RtIOStreamHostCommunicator</code> .
5	Generate PIL files	The generated PIL files are in the <code>pil</code> folder. At the end of the simulation, use the code generation report to view the files.
6	Build target application	<p>The software:</p> <ul style="list-style-type: none"> <li>• Uses your instance of <code>rtw.connectivity.MakefileBuilder</code> to build the target application.</li> <li>• Compiles the PIL interface file, <code>xil_interface.c</code>, and other PIL files into the target executable file. On a Windows system, for example, this file is called <code>modelName.exe</code>. The object code, including the executable file, is in the <code>pil</code> folder.</li> <li>• If configured, produces the code generation report.</li> </ul>
7	Start target application	The software uses <code>rtw.connectivity.Launcher</code> to start the application on the target.
8	Simulink engine interacts with PIL S-function	<p>The Simulink engine interacts with the PIL S-function in the same way that it interacts with a C S-function.</p> <p>From the host-side, the PIL S-function communicates with the target executable code through <code>rtIOStream</code> commands. On the target side, <code>xil_interface</code> executes generated code.</p>
9	Stop target application	The software uses <code>rtw.connectivity.Launcher</code> to stop the application on the target.

Stage		Description
10	End PIL simulation	<p>For top-model PIL, at the end of the simulation, the software destroys the <code>rtw.connectivity.Config</code> instance.</p> <p>For Model block PIL and PIL block, the block creates and owns the <code>rtw.connectivity.Config</code> instance, which is not destroyed at the end of the simulation. You can rerun the simulation, which now does not require the creation of another <code>rtw.connectivity.Config</code> instance. If you want to destroy the instance, close the parent model.</p>

## Verification of Code Generation Assumptions

The settings on the **Configuration Parameters > Hardware Implementation** pane specify target behavior, which result in the implementation of implicit assumptions in the generated code. Incorrect settings can lead to:

- Suboptimal code
- Code execution failure, incorrect code output, and nondeterministic code behavior

At the start of a processor-in-the-loop (PIL) simulation, the software verifies the **Hardware Implementation** pane settings with reference to the target hardware. The software checks:

- The correctness of settings. For example, the integer bit length in the **Number of bits: int** field.
- Whether the settings are optimized. For example, the rounding of signed integer division in the **Signed integer division rounds to** field.

If required, the software generates warnings and errors.

- “SIL and PIL Simulations” on page 64-2

## View SIL and PIL Files in Code Generation Report

With top-model and Model block SIL and PIL simulations, you can produce a code generation report and static code metrics that cover SIL and PIL files. The information helps you to:

- Understand and review the SIL and PIL testing process.
- See how your registered custom target connectivity files fit into the target application that runs during a SIL or PIL simulation.

This capability is not supported for simulations that you run with the PIL block.

To configure the creation of a code generation report and static code metrics, on the **Configuration Parameters > Code Generation > Report** pane, select the **Create code generation report**, **Open report automatically**, and **Static code metrics** check boxes. Then click **OK**.

At the end of the simulation, in the Code Generation Report window:

- To review code metrics, in the **Contents** view, click **Static Code Metrics Report**.
- To review SIL and PIL files, in the **Generated Code** view, expand the **SIL/PIL files** node. For example:
  - To review the S-function that runs on the host, click `modelName_sbs.c` or `modelName_pbs.c`.
  - To view the SIL or PIL interface that runs on the target, click `xil_interface.c`.

The screenshot shows the 'Code Generation Report' window. On the left, there is a 'Contents' pane with links to 'Summary', 'Subsystem Report', 'Code Interface Report', 'Traceability Report', 'Static Code Metrics Report' (highlighted), and 'Code Replacements Report'. Below that is a 'Generated Code' section with a tree view showing 'Main file' (ert\_main.c), 'Model files' (rtwdemo\_sil\_topmodel.c, rtwdemo\_sil\_topmodel.h), 'Shared files (1)', and 'SIL/PIL files' (codeinstr\_data\_stream.c, codeinstr\_data\_stream.h, codeinstrservice.h, coder\_assumptions.h, coder\_assumptions\_app.c, coder\_assumptions\_app.h, coder\_assumptions\_hwimpl.c, coder\_assumptions\_hwimpl.h, coderassumptionsapp.h, comms\_interface.h).

The main area displays a table of function metrics:

Function Name	Accumulated Stack Size (bytes)	Self Stack Size (bytes)	Lines of Code	Lines	Complexity
fid	2	6	6		
xilWriteDataAvail	2	6	4		
pwsEnabled	1	4	3		
enableA	1	2	1		
enableB	1	2	1		
<b>Total</b>	<b>102,483</b>	<b>304</b>			

\* The global variable is not directly used in any function.

**3. Function Information** [hide]

View function metrics in a call tree format or table format. Accumulated stack numbers include the estimated stack size of the function plus the maximum of the accumulated stack size of the subroutines that the function calls.

View: Call Tree | Table

Function Name	Accumulated Stack Size (bytes)	Self Stack Size (bytes)	Lines of Code	Lines	Complexity
[ - ] .main	1,556	12	22	32	6
[ + ] xilInit	1,544	0	20	33	6
[ + ] xilTerminateComms	532	0	9	18	1
[ + ] xilRun	446	8	14	20	3
[ - ] xilCommandDispatchAndResponse	447	1	20	34	4
[ + ] xilRun	446	8	14	20	3
[ + ] _processTargetToHostData	407	4	22	36	8
[ + ] finalizeCommandResponse	404	1	19	30	6
saveProcessMsgContext	0	0	5	9	1
restoreProcessMsgContext	0	0	4	6	1
[ + ] targetPrintf	417	14	32	54	3
[ + ] targetPrintf	415	12	29	41	3
[ + ] targetFopen	406	3	23	44	2

**Note:** Do not use the SIL or PIL files in code development as these files can change over releases. Use supplied APIs for code development.

## SIL and PIL Limitations

In this section...
“About SIL and PIL Limitations” on page 64-61
“General SIL and PIL Limitations” on page 64-62
“Top-Model SIL/PIL Limitations” on page 64-69
“Model Block SIL/PIL Limitations” on page 64-71
“SIL/PIL Block Limitations” on page 64-72

## About SIL and PIL Limitations

With Embedded Coder, you can run software-in-the-loop (SIL) and processor-in-the-loop (PIL) simulations in three ways:

- Top-model SIL/PIL — Set the top-model simulation mode to **Software-in-the-Loop (SIL)** or **Processor-in-the-Loop (PIL)**.
- Model block SIL/PIL — Set the Model block parameter **Simulation mode** to **Software-in-the-loop (SIL)** or **Processor-in-the-loop (PIL)**.
- SIL/PIL block — Use SIL or PIL blocks in the model.

The following sections describe modeling and code generation features that are either unsupported or partially supported by SIL and PIL simulations.

## General SIL and PIL Limitations

### Tunable Parameters and SIL/PIL

For Model block SIL/PIL and SIL/PIL block simulations, you can tune tunable *workspace* parameters but not tunable *dialog box* parameters. For information about tuning parameters, see “Block Parameter Representation in the Generated Code” on page 18-43.

For a top model with tunable parameters, you can run a SIL/PIL simulation but you cannot tune the parameters during the simulation.

The software cannot define, initialize, or tune the following types of tunable workspace parameters.

Parameter description	Software response		
	Top-Model SIL/PIL	Model Block SIL/PIL	SIL/PIL Block
Parameters with storage class that applies "static" scope or "const" keyword. For example, Custom, Const, or ConstVolatile	Warning	Warning	Warning
Parameters with multiword, fixed-point data types	Warning	Error	Warning
Parameters with data types that have different sizes on host and target	Warning	Error	Warning

For C++ class code, SIL/PIL you can tune tunable workspace parameters when **Parameter visibility** is `public`. If **Parameter visibility** is `private` or `protected`, tuning is supported only if **Parameter access** is `Method` or `Inlined method`.

For top-model SIL/PIL and the SIL/PIL block, consider the case where all of the following conditions apply:

- **Code Generation > Interface > Code interface packaging** is `Reusable function`.
- **All Parameters > Use dynamic memory allocation for model initialization** is not selected.

- **Optimization > Signals and Parameters > Default parameter behavior is Tunable.**
- The model contains parameters with storage class `Auto` or `SimulinkGlobal`.

If the SIL/PIL component cannot dynamically initialize tunable parameters in the `rtP` model parameter structure, you see an error message like the following:

```
Parameter Dialog:InitialOutput in 'rtwdemo_sil_topmodel/CounterTypeA/count'
is part of the imported "rtP" structure in the generated code but cannot be
initialized by SIL or PIL. To avoid this error, make sure the parameter
corresponds to a tunable base workspace variable with a storage class such
as SimulinkGlobal and is supported for dynamic parameter initialization /
tuning with SIL/PIL. Alternatively, select Configuration Parameters >
Code Generation > Interface and set 'Code interface packaging' to
'Nonreusable function', or select 'Use dynamic memory allocation for model
initialization'.
```

If you select **All Parameters > Use dynamic memory allocation for model initialization**, this limitation does not apply.

For Model block SIL/PIL, if you specify the code under test to be `Top model`, you can tune parameters while a simulation runs. If you tune parameters between successive runs of the simulation, the software generates new code for the later run. The new code uses your latest settings as initial parameter values.

### Global and Local Data Stores

SIL/PIL supports global data stores. For components that are not export-function models, top-model SIL/PIL and SIL/PIL block simulations that access global data stores must be single rate. Otherwise, the software produces an error.

SIL/PIL does not support local data stores.

### SIL/PIL Does Not Check Simulink Coder Error Status

SIL/PIL does not check the Simulink Coder error status of the generated code under test. This error status flags exceptional conditions during execution of the generated code.

Blocks in the model can also set the Simulink Coder error status, for example, custom blocks that you create. SIL/PIL does not check this error status and report errors.

### Missing Code Interface Description File Errors

SIL/PIL requires a code interface description file, which is created during code generation for the component under test. If the code interface description file is missing, the SIL/PIL

simulation cannot proceed. You see an error reporting that the file does not exist. If you select the unsupported option **Classic call interface**, this error can occur. Therefore, do not select the option.

### **To Workspace Block**

If you enable MAT-file logging, top-model SIL/PIL and SIL/PIL blocks support To Workspace blocks.

Model block SIL/PIL does not support To Workspace blocks.

### **Cannot Connect SIL/PIL Outputs to Merge Block**

If you connect Model block SIL/PIL or SIL/PIL block outputs to a Merge block, you see an error because S-function memory is not reusable.

### **Variant Condition Propagation with Variant Source and Variant Sink Blocks**

Top-model SIL/PIL and SIL/PIL block simulations do not support the propagation of variant conditions across component boundaries.

### **Initialize, Reset, and Terminate Function Blocks**

Top-model SIL/PIL supports the Initialize Function, Reset Function, and Terminate Function blocks only in export-function models. Model block SIL/PIL and the SIL/PIL block do not support the blocks.

### **Unsupported Blocks**

SIL/PIL does not support the following blocks:

- Scope blocks, and all types of run-time display. For example, display of port values and signal values.
- Stop blocks. SIL/PIL ignores the Stop Simulation block and continues simulating.

### **Multiword Fixed-Point I/O**

You cannot run SIL and PIL simulations of models that have multiword, fixed-point signals across component boundaries.

### **Fixed-Point Data Types Wider Than 32 Bits**

SIL/PIL supports fixed-point data types that are wider than 32 bits. For example:

- 64-bit `long` and `long long`
- 64-bit execution profiling timer data type
- `int64` and `uint64` in MATLAB Coder SIL execution.

The following constraints apply:

- For 64-bit data type support, the data type must be representable as `long` or `long long` on the MATLAB host *and* the target. Otherwise, the software uses the multiword, fixed-point approach, which SIL/PIL does not support.
- The software does not support the 40-bit `long` data type of the TI's C6000™ target.

Through the **Configuration > Hardware Implementation** pane, you can enable support for the 64-bit `long long` data type. For data types with widths between 33 and 40 bits (inclusive), the software implements the data types using the 40-bit `long` data type, which SIL/PIL does not support.

### Data Type Replacement

The software does not support replacement data type names that you define for the built-in data type `boolean` if these names map to the `int` or `uint` built-in data type.

### Continuous Sample Times

Top-model SIL/PIL and SIL/PIL block do not support continuous sample times at the SIL or PIL component boundary. However, they support continuous sample times within the component.

Model block SIL/PIL does not support continuous sample times.

### Variable-Size Signals

Model block SIL/PIL simulations support variable-size signals only if **All Parameters > Propagate sizes of variable-size signals** is `During execution`.

Top-model SIL/PIL and SIL/PIL block simulations treat variable-size signals at the I/O boundary of the SIL/PIL component as fixed-size signals, which can lead to errors during propagation of signal sizes. To avoid such errors, use only fixed-size signals at the I/O boundary of the SIL/PIL component.

There can be cases where no error occurs during propagation of signal sizes. In these cases, the software treats variable-size input signals as zero-size signals.

## Internal Signal Logging

SIL/PIL blocks do not support signal logging. For a workaround, see “Log Internal Signals of a Component” on page 64-22.

The following internal signal logging limitations apply to top-model and Model block SIL/PIL simulations.

Limitation	Applies To	
	Top-Model SIL/PIL	Model Block SIL/PIL
Only signals that are included in the C API are logged during SIL/PIL simulation. To observe the signals in the generated code, you can configure the signals as test points. For each signal, select the <b>Signal Properties &gt; Test point</b> check box.	Yes	Yes
Signals feeding merge blocks are not supported for logging in normal simulation but are logged in SIL/PIL mode. The logged values during SIL/PIL are the same as the logged values for the output of the merge block.	Yes	No
Top-model normal simulation logs data at a periodic rate but top-model SIL/PIL simulation logs data at a constant rate under these circumstances: <ul style="list-style-type: none"> <li>• <b>Default parameter behavior</b> is Tunable.</li> <li>• A constant sample time signal from a Model block is logged in the top model.</li> <li>• The logged signal is not directly connected to a root-level output port.</li> </ul> To avoid this behavior and log at the constant rate in all simulation modes, set <b>Default parameter behavior</b> to <b>Inlined</b> .	Yes	No
Features not supported: <ul style="list-style-type: none"> <li>• Signal logging in models referenced by the SIL/PIL component.</li> <li>• Virtual signals, for example, mux.</li> </ul>	Yes	Yes

Limitation	Applies To	
	Top-Model SIL/PIL	Model Block SIL/PIL
<ul style="list-style-type: none"> <li>• Buses.</li> <li>• Custom storage classes.</li> <li>• Continuous, asynchronous, and triggered sample times.</li> <li>• Logging of Stateflow states and local data.</li> <li>• Units.</li> </ul>		
Variable-size, function-call, and Action signals are not supported. A normal simulation produces an error. A SIL/PIL simulation produces a warning.	Yes	No
State port signals are not supported. A normal simulation produces an error. A SIL/PIL simulation does not produce a warning.	Yes	No

### Unsupported Implementation Errors

If you use a custom storage class (CSC) with a **Type** property that is **Other** or if you use a data store, signal, or parameter implementation that SIL/PIL does not support, you can see errors like the following:

The following *data interfaces* have implementations that are not supported by SIL or PIL.

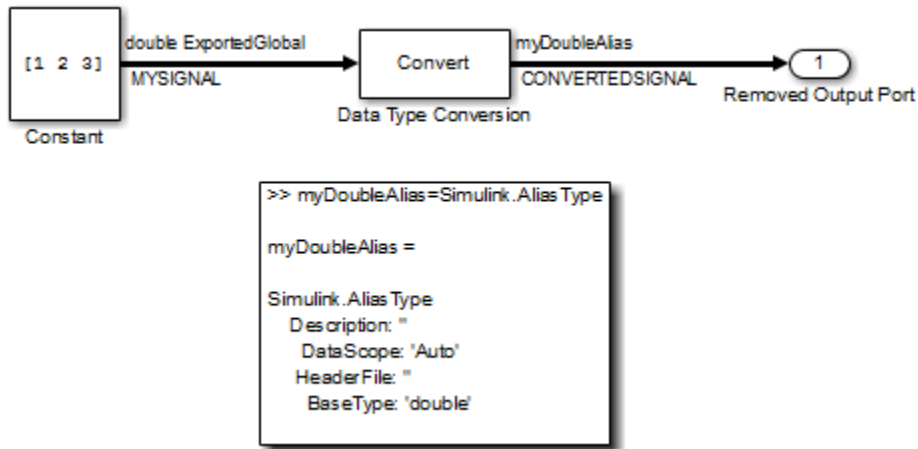

*data interfaces* can be global data stores, inports, outports, or parameters.

The model output port has been optimized through virtual output port optimization. See “Virtualized Output Ports Optimization” on page 55-16. The error occurs because the properties (for example, data type, dimensions) of the signal or signals entering the virtual root output port have been modified by routing the signals in one of the following ways:

- Through a Mux block.
- Through a block that changes the signal data type. To check the consistency of data types in the model, display Port Data Types by selecting **Display > Signals & Ports > Port Data Types**.
- Through a block that changes the signal dimensions. To check the consistency of data types in the model, display dimensions by selecting **Display > Signal & Ports > Signal Dimensions**.

Dimension changes from scalar (1) to matrix [1x1], and, matrix [1x1] to scalar (1), can lead to this error. It is difficult to inspect the model for such changes because **Display > Signal & Ports > Signal Dimensions** does not distinguish between (1) and [1x1] dimensions. Both signals are displayed as scalar signals. Check your model and workspace objects carefully. Make sure that you specify scalar dimensions consistently.

The following model causes this error by changing the output port signal data type.

### Hardware Implementation

PIL does not support multiword data types where the word order differs from the target byte order. The PIL simulation fails, displaying undefined behavior.

PIL requires that you configure the correct **Hardware Implementation** settings for the target environment, including byte ordering for targets. If you do not specify the correct byte ordering, the PIL simulation fails, displaying undefined behavior.

### Non-ASCII Characters in Folder Name

If the name of the current working folder contains non-ASCII characters, you cannot run a SIL simulation.

### State Logging

SIL/PIL does not support state logging.

## Top-Model SIL/PIL Limitations

### Top-Model Root-Level Logging

Top-model SIL/PIL supports signal logging for signals connected to root-level inports and outports. The C API is not required. Root-level logging has the following limitations:

- The characteristics of the logged data such as data type, sample time, and dimensions must match the characteristics of the root-level inports and outports (rather than the characteristics of the connected signal).

In some cases, there can be differences in data type and dimensions between the signal being logged and the root inport or outport that the signal is connected to. Consider the following examples.

- If a signal being logged has matrix dimensions [ 1x5 ] but the outport connected to the signal has vector dimensions (5), then the data logged during a SIL or PIL simulation has vector dimensions (5).
- If a signal being logged has scalar dimensions but the outport connected to the signal has matrix dimensions [ 1x1 ], then the data logged during a SIL or PIL simulation has matrix dimensions [ 1x1 ].
- Signals connected to duplicated inports are not logged during SIL/PIL simulation. No warning is issued.

During normal simulation, signals connected directly to duplicated inports are logged.

- The Signal Logging Selector / `DataLoggingOverride` override mechanism is not supported.
- Normal and SIL/PIL simulations log bus signals with names that are different when all of the following conditions apply:
  - The `SaveOutput` or `SignalLogging` configuration parameter is on.
  - The names of the elements in the bus signal are different from the corresponding names in the bus object. For example, when the `InheritFromInputs` parameter for a Bus Creator block is set to 'on'.
- The software inserts the suffix, `_wrapper` for *output logging*, if the save format is `Structure`, `Structure with time`, or `Dataset` and you run the `sim` command without specifying the single-output format. The software adds `_wrapper` to the block name for signals in `yout`. If the save format is `Array`, the software does not add the suffix. For example:

```
>> yout.signals

ans =
 values: [11x1 double]
 dimensions: 1
 label: 'SignalLogging'
 blockName: 'sillogging_wrapper/OutputLogging'
```

To avoid this behavior, run command-line simulations with the `sim` command specifying the single-output format. See “Run Simulations Programmatically”.

### Model in Compiled State During Top-Model SIL/PIL

During a top-model SIL/PIL simulation, the software places the model in a compiled state – see `model`. This action can result in a conflict over global resources between the model and the generated SIL/PIL code. In this case, differences between normal mode and SIL/PIL simulation outputs can result.

For example, consider a model that uses UDP blocks from the DSP System Toolbox. These blocks open UDP sockets, which can lead to resource contention between the model and the generated SIL/PIL code.

### Callback Support

SIL/PIL does not support the callbacks (model or block) `StartFcn` and `StopFcn`.

---

**Note:** Top-model SIL/PIL supports the callback `InitFcn`.

---

### Incremental Build

When you start a top-model SIL/PIL simulation, the software regenerates code if it detects changes to your model. The software detects changes by using a checksum for the model. The software does not detect changes that you make to:

- The `HeaderFile` property of a `Simulink.AliasType` object
- Legacy S-functions

If you make these changes, build (**Ctrl-B**) your model again before starting the next PIL simulation.

## Model Block SIL/PIL Limitations

### Top-Model Code Testing

The following limitations apply:

- The **Model Variants** block does not support the block parameter **CodeInterface**. The software behaves as if **CodeInterface** is set to 'Model reference'. To work around this limitation, use the **Variant Subsystem** block. Through this block, you can incorporate **Model** blocks for which **CodeInterface** is set to 'Top model'.
- Because model arguments do not apply to a top model, when the **Code interface** block parameter is set to **Top model**, the software does not support the **Model arguments** block parameter.
- Conditional execution does not apply to a top model. If a **Model** block is set up to execute conditionally and the **Code interface** block parameter is set to 'Top model', the software produces an error when you run a SIL or PIL simulation.
- For sample time independent models, you must set **Configuration Parameters > Solver > Periodic sample time constraint** to **Ensure sample time independent**.
- Simulation results from top-model code and model reference code can differ when a root-level Inport is connected to a root-level Outport by a signal that has a signal object with an initial value.

For top-model code, the software associates the signal object with the Inport. The software can apply the initial value for the signal object to the Inport. See “Initialization Behavior Summary for Signal Objects”.

For model reference code, the software associates the signal object with the Outport. The software does not apply the initial value for the signal object to the Inport.

### Conditionally Executed Subsystem

You see an error if:

- You place your **Model** block, in either SIL or PIL simulation mode, in a conditionally executed subsystem and the referenced model is multirate (that is, has multiple sample times). Single-rate, referenced models (with only a single sample time) are not affected.
- Your **Model** block, in either SIL or PIL simulation mode, has blocks that depend on absolute time **and** is conditionally executed.

### Outputs with Constant Sample Time

If the block parameter **Code interface** is `Top model`, Model block SIL/PIL supports outputs with constant sample time.

### Noninlined S-Functions

Model-block SIL/PIL simulations do not support noninlined S-functions.

## SIL/PIL Block Limitations

### PIL Block Mux

The PIL block supports mux signals, except mixed data-type mux signals that expand into individual signals during a right-click subsystem build.

### Code Coverage

SIL block simulations do not support the generation of code coverage results. PIL block support for code coverage depends on your target connectivity configuration and third-party product support.

### Subsystem with Inherited Sample Time Blocks

When you create a SIL/PIL block from a subsystem that has blocks with inherited sample times, the generated code and SIL/PIL wrapper acquire the sample time of the original parent model. If you use the SIL/PIL block in a context that does not allow explicit sample times, for example, within a triggered subsystem, you see an error.

Try one of these workarounds:

- Before you create the SIL/PIL block, in the parent model, set **Configuration Parameters > Solver > Periodic sample time constraint** to `Ensure sample time independent`.
- Using the subsystem, create a Model block that is independent of sample time. With this block, run Model block SIL/PIL simulations.

## Related Examples

- “SIL and PIL Simulations” on page 64-2
- “Choose a SIL or PIL Approach” on page 64-11

## Check Configuration

Use the `cgv.Config` class to check model settings for a SIL or PIL simulation. You can review your model configuration and determine the settings that you must change. By default, `cgv.Config` changes configuration parameter values to the value that it recommends, but does not save the model. Alternatively, you can:

- Change configuration parameter values to the values that `cgv.Config` recommends, and save the model. Specify this approach using the `SaveModel` property.
- List the values that `cgv.Config` recommends for the configuration parameters, but not change the configuration parameters or the model. Specify this approach using the `ReportOnly` property.

---

**Note:**

- Execution in the target environment can require additional modifications to configuration parameter values or the model.
  - Do not use referenced configuration sets in models that you are changing using `cgv.Config`. If the model uses a referenced configuration set, update the model with a copy of the configuration set. Use the `Simulink.ConfigSetRef.getRefConfigSet` method. For more information, see `Simulink.ConfigSetRef` in the Simulink documentation.
  - If you use `cgv.Config` on a model that executes a callback function, the callback function can change configuration parameter values each time the model loads. The callback function can revert changes that `cgv.Config`. For more information, see “Callbacks for Customized Model Behavior”.
- 

To verify that your model is configured for SIL or PIL:

- 1 Construct a `cgv.Config` object that changes the configuration parameter values without saving the model. For example, to configure your model for SIL:

```
c = cgv.Config('vdp', 'connectivity', 'sil');
```

---

**Tip**

- You can obtain a list of changes without changing the configuration parameter values. When you construct the object, include the 'ReportOnly', 'on' property name and value pair.
  - You can change the configuration parameter values and save the model. When you construct the object, include the 'SaveModel', 'on' property name and value pair.
- 

**2** Determine and change the configuration parameter values that the object recommends using the `configModel` method. For example:

```
c.configModel();
```

**3** Display a report of the changes that `configModel` makes. For example:

```
c.displayReport();
```

**4** Review the changes.

**5** To apply the changes to your model, save the model.

## Related Examples

- “Configure and Run SIL Simulation” on page 64-15
- “Verify Numerical Equivalence with CGV” on page 64-75
- “Verify Numerical Equivalence Between Two Modes of Execution of a Model” on page 64-76

## Verify Numerical Equivalence with CGV

Before verifying numerical equivalence:

- Configure your model for SIL or PIL simulation.
- Use the `cgv.Config` class of the CGV API to verify the model configuration for SIL or PIL simulation.
- Configure your model for code generation. For more information, see “Configure Model for Code Generation Objectives Using Code Generation Advisor” on page 28-2.
- Save your model. If you modify a model without saving it, CGV can issue an error.

To verify numerical equivalence:

- Set up the tests for the first execution environment. For example, simulation.
- Use `run(cgv.CGV)` to run the tests for the first execution environment.
- Set up the tests for the second execution environment. For example, top-model PIL.
- Use `cgv.CGV.run` to run the tests for the second execution environment.
- Use `getOutputData(cgv.CGV)` to get the output data for each execution environment.
- Use `getSavedSignals(cgv.CGV)` to display the signal names in the output data. (optional)
- Build a list of signal names for input to other `cgv.CGV` methods. (optional)
- Use `createToleranceFile(cgv.CGV)` to create a file correlating tolerance information with output signal names. (optional)
- Use `compare(cgv.CGV)` to compare the output signals of the first and second execution environments for numerical equivalence.

---

**Note:** Simulink Test™ is a separate product that provides additional capabilities for SIL and PIL testing, for example, test sequence construction and test management.

---

## Verify Numerical Equivalence Between Two Modes of Execution of a Model

### In this section...

“Configure the Model” on page 64-76

“Execute the Model” on page 64-77

“Compare All Output Signals” on page 64-78

“Compare Individual Output Signals” on page 64-80

“Plot Output Signals” on page 64-81

The following example describes configuring, executing, and comparing the results of the `rtwdemo_cgv` model in normal and software-in-the-loop (SIL) simulation modes.

### Configure the Model

The first task for verifying numerical equivalence is to check the configuration of your model.

- 1 Open the `rtwdemo_cgv` model.

```
cgvModel = 'rtwdemo_cgv';
load_system(cgvModel);
```

- 2 Save the model to a working directory.

```
save_system(cgvModel, fullfile(pwd, cgvModel));
close_system(cgvModel); % avoid original model shadowing saved model
```

- 3 Use the `cgv.Config` class to create a `cgv.Config` object. Specify parameters that check and modify configuration parameter values and save the model for top-model SIL mode of execution.

```
cgvCfg = cgv.Config('rtwdemo_cgv', 'connectivity', 'sil', 'SaveModel', 'on');
```

- 4 Use the `configModel` (`cgv.Config`) method to review your model configuration and to change the settings to configure your model for SIL. When `'connectivity'` is set to `'sil'`, the system target file is automatically set to `'ert.tlc'`. If you specified the parameter/value pair, (`'SaveModel', 'on'`) when you created the `cgvCfg` object, the `cgv.Config.configModel` method saves the model.

---

**Note:** CGV runs on models that are open. If you modify a model without saving it, CGV can issue an error.

---

```
cgvCfg.configModel(); % Evaluate, change, and save your model for SIL
```

- 5 Display a report of the changes that `cgv.Config.configModel` makes to the model.

```
cgvCfg.displayReport(); % In this example, this reports no changes
```

## Execute the Model

Use the CGV API to execute the model in two modes. The two modes in this example are normal mode simulation and SIL mode. In each execution of the model, the CGV object for each mode captures the output data and writes the data to a file.

- 1 If you have not already done so, follow the steps described in “Configure the Model” on page 64-76.
- 2 Create a `cgv.CGV` object that specifies the `rtwdemo_cgv` model in normal mode simulation.

```
cgvSim = cgv.CGV(cgvModel, 'connectivity', 'sim');
```

---

**Note:** When the top model is set to normal simulation mode, the CGV API sets referenced models in PIL mode to accelerator mode.

---

- 3 Provide the input file to the `cgvSim` object.

```
cgvSim.addInputData(1, [cgvModel '_data']);
```

- 4 Before execution of the model, specify the MATLAB files to execute or MAT-files to load. This step is optional.

```
cgvSim.addPostLoadFiles({[cgvModel '_init.m']});
```

- 5 Specify a location where the object writes all output data and metadata files for execution. This step is optional.

```
cgvSim.setOutputDir('cgv_output');
```

- 6 Execute the model.

```
result1 = cgvSim.run();
```

```
*** handling PostLoad file rtwdemo_cgv_init.m
Start CGV execution of model rtwdemo_cgv, ComponentType topmodel, ...
 connectivity sim, InputData rtwdemo_cgv_data.mat
End CGV execution: status completed
```

- 7 Get the output data associated with the input data.

```
outputDataSim = cgvSim.getOutputData(1);
```

- 8 For the next mode of execution, SIL, repeat steps 2–7.

```
cgvSil = cgv.CGV(cgvModel, 'Connectivity', 'sil');
cgvSil.addInputData(1, [cgvModel '_data']);
cgvSil.addPostLoadFiles({[cgvModel '_init.m']});
cgvSil.setOutputDir('cgv_output');
result2 = cgvSil.run();
```

At the MATLAB command line, the result is:

```
*** handling PostLoad file rtwdemo_cgv_init.m
Start CGV execution of model rtwdemo_cgv, ComponentType topmodel, ...
 connectivity sil, InputData rtwdemo_cgv_data.mat

Starting build procedure for model: rtwdemo_cgv
Successful completion of build procedure for ...
 model: rtwdemo_cgv
Preparing to start SIL simulation ...
Starting SIL simulation for model: rtwdemo_cgv
Stopping SIL simulation for model: rtwdemo_cgv
End CGV execution: status completed
```

## Compare All Output Signals

After setting up and running the test, compare the outputs by doing the following:

- 1 If you have not already done so, configure and test the model, as described in “Configure the Model” on page 64-76 and “Execute the Model” on page 64-77.
- 2 Test that the execution result of the model:

```
if ~result1 || ~result2
 error('Execution of model failed.');
```

```
end
```

- 3 Use the `getOutputData` (`cgv.CGV`) method to get the output data from the `cgv.CGV` objects.

```
simData = cgvSim.getOutputData(1);
silData = cgvSil.getOutputData(1);
```

- 4 Display a list of signals by name using the `getSavedSignals` (`cgv.CGV`) method.

```
cgvSim.getSavedSignals(simData);
```

At the MATLAB command line, the result is:

```
simData.hi0.Data(:,1)
simData.hi0.Data(:,2)
simData.Vector.Data(:,1)
simData.Vector.Data(:,2)
simData.Vector.Data(:,3)
simData.Vector.Data(:,4)
simData.BusOutputs.hi0.Data(:,1)
simData.BusOutputs.hi0.Data(:,2)
simData.BusOutputs.hi1.mid0.lo0.Data(1,1,:)
simData.BusOutputs.hi1.mid0.lo0.Data(1,2,:)
simData.BusOutputs.hi1.mid0.lo0.Data(2,1,:)
simData.BusOutputs.hi1.mid0.lo0.Data(2,2,:)
simData.BusOutputs.hi1.mid0.lo1.Data
simData.BusOutputs.hi1.mid0.lo2.Data
simData.BusOutputs.hi1.mid1.Data(:,1)
simData.BusOutputs.hi1.mid1.Data(:,2)
simData.ErrorsInjected.Data
```

- Using the list of signals, build a list of signals in a cell array of character vectors. The signal list can contain a number of signals.

```
signalList = {'simData.ErrorsInjected.Data'};
```

- Use the `createToleranceFile` (`cgv.CGV`) method to create a file, in this example, `'localtol'`, correlating tolerance information with output signal names.

```
toleranceList = {'absolute', 0.5}};
cgv.CGV.createToleranceFile('localtol', signalList, toleranceList);
```

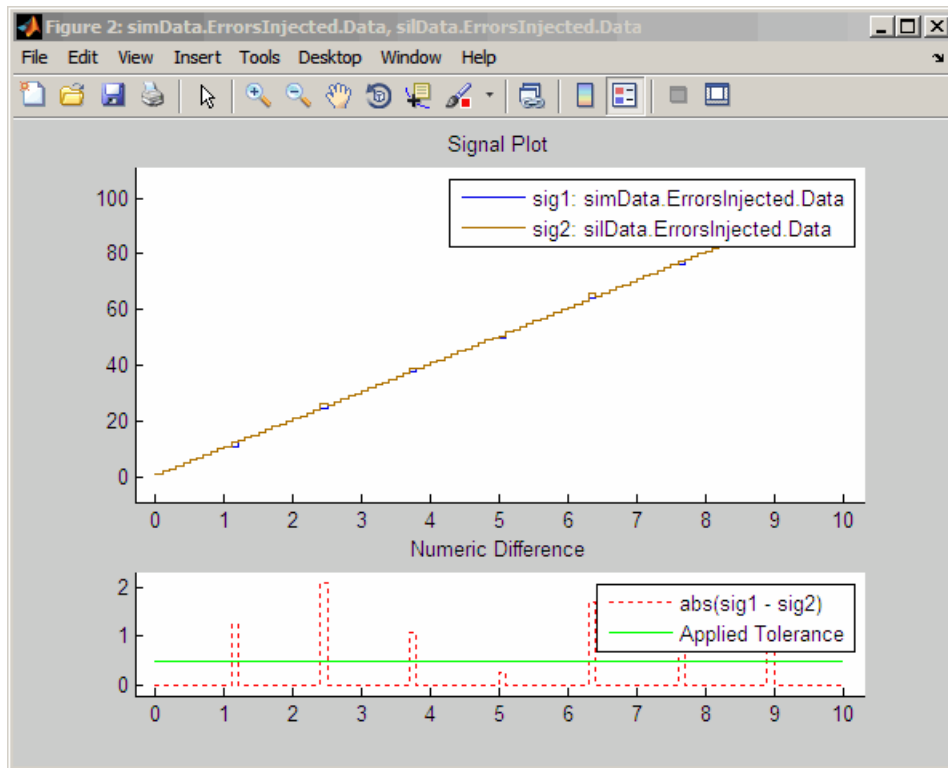

- Compare the output data signals. By default, the `compare` (`cgv.CGV`) method looks at all signals which have a common name between both executions. If a tolerance file is present, `cgv.CGV.compare` uses the associated tolerance for a specific signal during comparison; otherwise the tolerance is zero. In this example, the `'Plot'` parameter is set to `'mismatch'`. Therefore, only mismatched signals produce a plot.

```
[matchNames, ~, mismatchNames, ~] = ...
 cgv.CGV.compare(simData, silData, 'Plot', 'mismatch', ...
 'Tolerancefile', 'localtol');
fprintf('%d Signals match, %d Signals mismatch\n', ...
 length(matchNames), length(mismatchNames));
disp('Mismatched Signal Names:');
disp(mismatchNames);
```

At the MATLAB command line, the result is:

```
14 Signals match, 1 Signals mismatch
Mismatched Signal Names:
 'simData.ErrorsInjected.Data'
```

A plot results from the mismatch on signal `simData.ErrorsInjected.Data`.

The lower plot displays the numeric difference between the results.

## Compare Individual Output Signals

After setting up and running the test, compare the outputs of individual signals by doing the following:

- 1 If you have not already done so, configure and test the model, as described in “Configure the Model” on page 64-76 and “Execute the Model” on page 64-77.
- 2 Use the `getOutputData(cgv.CGV)` method to get the output data from the `cgv.CGV` objects.

```
simData = cgvSim.getOutputData(1);
silData = cgvSil.getOutputData(1);
```

- 3 Use the `getSavedSignals` (`cgv.CGV`) method to display the output data signal names. Build a list of specific signal names in a cell array of character vectors. The signal list can contain number of signals.

```
cgv.CGV.getSavedSignals(simData);
signalList = {'simData.BusOutputs.hi1.mid0.lo1.Data', ...
'simData.BusOutputs.hi1.mid0.lo2.Data', 'simData.Vector.Data(:,3)'};
```

- 4 Use the specified signals as input to the `compare` (`cgv.CGV`) method to compare the signals from separate runs.

```
[matchNames, ~, mismatchNames, ~] = ...
 cgv.CGV.compare(simData, silData, 'Plot', 'mismatch', ...
 'signals', signalList);
fprintf('%d Signals match, %d Signals mismatch\n', ...
 length(matchNames), length(mismatchNames));
if ~isempty(mismatchNames)
 disp('Mismatched Signal Names:');
 disp(mismatchNames);
end
```

At the MATLAB command line, the result is:

```
3 Signals match, 0 Signals mismatch
```

## Plot Output Signals

After setting up and running the test, use the `plot` (`cgv.CGV`) method to plot output signals.

- 1 If you have not already done so, configure and test the model, as described in “Configure the Model” on page 64-76 and “Execute the Model” on page 64-77.
- 2 Use the `getOutputData` (`cgv.CGV`) method to get the output data from the `cgv.CGV` objects.

```
simData = cgvSim.getOutputData(1);
```

- 3 Use the `getSavedSignals` (`cgv.CGV`) method to display the output data signal names. Build a list of specific signal names in a cell array of character vectors. The signal list can contain number of signals.

```
cgv.CGV.getSavedSignals(simData);
signalList = {'simData.Vector.Data(:,1)'};
```

- 4 Use the specified signal list as input to the `plot` (`cgv.CGV`) method to compare the signals from separate runs.

```
[signalNames, signalFigures] = cgv.CGV.plot(simData, ...
 'Signals', signalList);
```

## Configure Hardware Settings for Software-in-the-Loop (SIL) Simulation

This example shows how to configure a model to simulate target behavior with SIL when the target is different from the host computer.

```
open_system('rtwdemo_sil_hardware_config')
```

### Description

Embedded Coder provides several approaches for software-in-the-loop (SIL) code verification. One of these, for subsystem code verification, is the SIL block. When the target hardware is different from the simulation platform, you can configure the model to simulate the target behavior with SIL. Use one of the following methods:

- Select the "Enable portable word sizes" check box.
- Specify an appropriate setting for the "Test device vendor and type" parameter.

The above model is a closed-loop control system comprising a continuous-time plant and a discrete-time controller to be deployed on a generic 16-bit microcontroller.

The Controller subsystem employs fixed-point arithmetic. An overflow effect is intentionally added to help compare simulation results. To read more about each option, click the above grey buttons. Click the yellow buttons to view the configuration panels.

### Instructions

1. Click either of the blue buttons above to configure the model automatically.
2. Right-click the Controller subsystem and select C/C++ Code > Build This Subsystem.
3. In the dialog box, click "Build". The SIL block is created in an untitled model.  
This SIL block is an S-function wrapper for the generated subsystem code, and can be used to verify that the code provides the same result as the original subsystem.
4. Replace the original system with the S-function effect block and rerun the simulation to verify that the output is correct. Observe the overflow effect at around 10.8 seconds.

# Numerical Consistency between Model and Generated Code

---

## Numerical Consistency of Model and Generated Code Simulation Results

### In this section...

“Numerical Consistency” on page 65-2

“Numerical Consistency in Complex Systems” on page 65-3

“Reasons for Block-Level Numerical Differences” on page 65-5

### Numerical Consistency

In the Model-Based Design workflow, you use MathWorks products to generate code for numerical applications that employ fixed-point and floating-point arithmetic.

- To develop models, you use MATLAB, Simulink, and Stateflow.
- To generate source code, you use Simulink Coder and Embedded Coder.
- To test numerical equivalence between your model and generated code, you compare model and generated code simulation results. For example, normal mode simulation results compared with software-in-the-loop (SIL) simulation results.

The results from the model and generated code simulations are numerically consistent if:

- In fixed-point applications, the results agree in a bit-wise comparison.
- In floating-point applications, the results agree with an error tolerance that you specify.

Use the Simulation Data Inspector to compare results. To determine whether discrepancies exist or are significant, you can specify absolute and relative tolerance values:

- For fixed-point applications, you can specify an absolute tolerance of zero.
- For floating-point applications, you can specify tolerance with respect to a reference value or signal. The choice of reference depends on your application. Consider these examples:
  - An algorithm that solves a linear algebraic equation by iterative, feed-forward error calculations. You can specify tolerance with respect to `eps`.

- A Proportional-Integral-Derivative (PID) controller for a closed-loop system. For transient behavior, you can specify tolerance with criteria from a standard. For steady-state behavior, you can specify tolerance with reference to the PID controller characteristics.

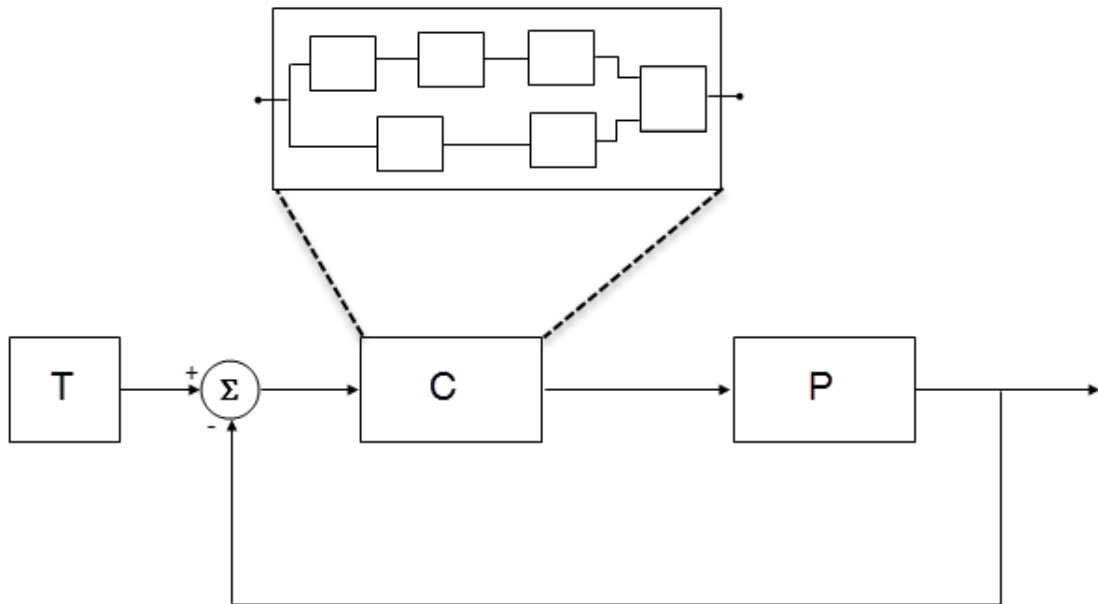

Programmatically, you can specify absolute and relative tolerance values through the `absTol` and `relTol` properties of the `Simulink.sdi.Signal` object.

## Numerical Consistency in Complex Systems

For complex systems, numerical differences between model and generated code simulations can be a result of block-level differences propagating through the system. If you observe numerical differences at the system level:

- 1 Identify blocks for which block-level numerical differences exceed the error tolerance.
- 2 Investigate each identified block.

Consider the following plant-controller model.

- T produces reference or test signals.
- C is the controller component. The controller output is the plant input. C can be a Model block that comprises multiple Model blocks.
- P is the plant component. The plant output is subtracted from the reference signal to produce the controller input.

To test numerical equivalence between the model controller and the generated code version:

- 1 Run the model in normal mode, and, using the Simulation Data Inspector, record the output of C.
- 2 Specify SIL mode for C. Rerun the simulation, recording the output of C.
- 3 Using the Simulation Data Inspector, compare normal and SIL mode outputs with reference to your specified error tolerance.

If the Simulation Data Inspector comparison indicates a match, the model and generated code results are numerically consistent.

If the normal and SIL mode outputs do not match:

- 1 Within C, enable signal logging for block outputs.
- 2 Run the model in normal mode.
- 3 Rerun the simulation with C in SIL mode.
- 4 Using the Simulation Data Inspector, compare the logged output signals with reference to your specified error tolerance. See “Compare Signal Data from Multiple Simulations”.
- 5 Identify blocks for which normal and SIL mode output differences exceed the error tolerance.
- 6 Analyze each identified block and look for the cause. For example, the generated code might use a different math library than MATLAB.

---

**Note:** If the comparison of a large number of signals is required, you can automate the workflow with Simulink Test. See “Code Generation Verification Workflow with Simulink Test”.

---

## Reasons for Block-Level Numerical Differences

In fixed-point and floating-point application development, there are factors that can affect numerical agreement between block-level results from model and generated code simulations.

Some factors can affect both fixed-point and floating-point applications. For example, the use of:

- Code generation optimization.
- Custom code.
- Code replacement library entries whose results differ from MATLAB results.
- Code replacement libraries that implement different algorithms.

Other factors affect only floating-point applications. For example:

- Numerical soundness of algorithm.

- Algorithm sensitivity to input.
- Closed loop and open loop behavior.

## Code Verification Through Software-in-the-Loop and Processor-in-the-Loop Execution

MATLAB Coder supports software-in-the-loop (SIL) and processor-in-the-loop (PIL) execution, which enables you to verify production-ready source code and compiled object code. With these execution modes, you can reuse test vectors developed for your MATLAB functions to verify the numerical behavior of library code.

In SIL execution, through a MATLAB SIL interface, the software compiles and runs library code on your development computer. In PIL execution, through a MATLAB PIL interface, the software cross-compiles and runs production object code on a target processor or an equivalent instruction set simulator. Before you run a PIL execution, you must set up a PIL connectivity configuration for your target.

The workflow for generating and verifying code is:

- 1 Set up MATLAB Coder.
- 2 Fix errors detected at design time.
- 3 Generate MEX function.
- 4 Test MEX function.
- 5 Generate C/C++ library code.
- 6 Verify generated C/C++ code through SIL or PIL execution — requires Embedded Coder license.

In step 4, you verify code that is generated for execution within MATLAB. However, this code is different from the standalone code generated for libraries. In step 6, with an Embedded Coder license, you use SIL or PIL execution to verify the standalone code.

For more information, use the following table.

Feature	See
SIL execution	<ul style="list-style-type: none"> <li>• “Software-in-the-Loop Execution with the MATLAB Coder App” on page 66-4</li> <li>• “Software-in-the-Loop Execution From Command Line” on page 66-6</li> </ul>

## Software-in-the-Loop Execution with the MATLAB Coder App

Use software-in-the-loop (SIL) execution to verify the numerical behavior of the generated C/C++ code with reference to your original MATLAB functions.

- 1 To open the MATLAB Coder app, on the MATLAB Toolstrip **Apps** tab, under **Code Generation**, click the app icon.
- 2 To open your project, click , and then click **Open existing project**. Select the project. For example, `kalman_filter01.prj`.
- 3 On the **Generate Code** page, click the **Generate** arrow .
- 4 In the **Generate** dialog box:
  - a Set **Build type** to **Static Library** or **Dynamic Library**.
  - b In the **Output file name** field, use the default value. For example, `kalman01`.
  - c Specify **Language**.
  - d Clear the **Generate code only** check box.
  - e In the **Hardware Board** field, use the default value (MATLAB Host Computer).

You do not have to specify the **Toolchain** setting. By default, the MATLAB Coder app locates an installed toolchain.

- 5 To generate the C or C++ code, click **Generate**.
- 6 Click **Verify Code**.
- 7 In the command field, specify the test file that calls the original MATLAB functions, for example, `test01_ui.m`.
- 8 If required, select the **Enable source-level debugging for SIL** check box.
- 9 To start the SIL execution, click **Run Generated Code**.

The MATLAB Coder app:

- Generates a standalone library, for example, `codegen\lib\kalman01`.
- Generates SIL interface code, for example, `codegen\lib\kalman01\sil`.
- Runs the test file, replacing calls to the MATLAB function with calls to the generated code in the library.

- Displays messages from the SIL execution in the **Test Output** tab.
- 10** Verify that the results from the SIL execution match the results from the original MATLAB functions.
  - 11** To terminate the SIL execution process, click **Stop SIL Verification**. Alternatively, on the **Test Output** tab, click the link that follows **To terminate execution**.

---

**Note:** On a Windows operating system, the Windows Firewall can potentially block the SIL execution. To allow the SIL execution, use the Windows Security Alert dialog box. For example, in Windows 7, click **Allow access**.

---

- “Generate Execution Time Profile” on page 59-3

## More About

- “Code Verification Through Software-in-the-Loop and Processor-in-the-Loop Execution” on page 66-2

## Software-in-the-Loop Execution From Command Line

Use software-in-the-loop (SIL) execution to verify the numerical behavior of the generated C/C++ code with reference to your original MATLAB functions.

To set up and start a SIL execution from the command line:

- 1 Create a `coder.EmbeddedCodeConfig` object.
- 2 Configure the object for SIL.
- 3 Use the `codegen` function to generate library code for your MATLAB function and the SIL interface.
- 4 Use the `coder.runTest` function to run the test file for your original MATLAB function.

To terminate the SIL execution, use the `clear function_sil` or `clear mex` command.

The following example shows how you can set up and run a SIL execution from the command line.

### SIL Execution of Code Generated for a Kalman Estimator

#### 1 Copy MATLAB code for Kalman estimator

From `docroot\toolbox\coder\examples\kalman`, copy the following files to your working folder:

- `kalman01.m` — MATLAB function for the Kalman estimator
- `test01_ui.m` — MATLAB file to test `kalman01.m`
- `plot_trajectory.m` — File that plots actual target trajectory and Kalman estimator output
- `position.mat` — Input data

```
src_dir = ...
 fullfile(docroot, 'toolbox', 'coder', 'examples', 'kalman');

copyfile(fullfile(src_dir, 'kalman01.m'), '.')
copyfile(fullfile(src_dir, 'test01_ui.m'), '.')
```

```
copyfile(fullfile(src_dir, 'plot_trajectory.m'), '.')
copyfile(fullfile(src_dir, 'position.mat'), '.')
```

For a description of the Kalman estimator in this example, see “C Code Generation at the Command Line”.

## 2 Configure SIL execution

- a** From your working folder, create a `coder.EmbeddedCodeConfig` object.

```
config = coder.config('lib');
config.GenerateReport = true; % Optional, documents code in HTML report
```

- b** Configure the object for SIL.

```
config.VerificationMode = 'SIL';

% Check that production hardware setting is the default
% i.e. 'Generic->MATLAB Host Computer'
disp(config.HardwareImplementation.ProdHWDeviceType);
```

- c** If required, enable the Microsoft Visual Studio debugger for SIL execution:

```
config.SILDebugging = true;
```

## 3 Generate code and run SIL execution

- a** Generate library code for the `kalman01` MATLAB function and the SIL interface.

```
codegen('-config', config, '-args', {zeros(2,1)}, 'kalman01');
```

The software creates the following output folders:

- `codegen\lib\kalman01` — Standalone code for `kalman01`.
- `codegen\lib\kalman01\sil` — SIL interface code for `kalman01`.

- b** Run the MATLAB test file `test01_ui` with `kalman01_sil`. `kalman01_sil` is the SIL interface for `kalman01`.

```
coder.runTest('test01_ui', ['kalman01_sil.' mexext]);
```

Verify that the output of this run matches the output from the original `kalman01.m` function.

**Note:** On a Windows operating system, the Windows Firewall can potentially block the SIL execution. To allow the SIL execution, use the Windows Security Alert dialog box. For example, in Windows 7, click **Allow access**.

---

#### 4 Debug code during SIL execution

If you enable the Microsoft Visual Studio debugger, then running the test file opens the Microsoft Visual Studio IDE with debugger breakpoints at the start of the `kalman01_initialize` and `kalman01` functions.

You can use the debugger features to observe code behavior. For example, you can step through code and examine variables.

To end the debugging session:

- a Remove all breakpoints.
- b Click the Continue button (F5).

The SIL execution runs to completion.

#### 5 Terminate SIL execution

Terminate the SIL execution process.

```
clear kalman01_sil;
```

You can also use the command `clear mex`, which clears MEX functions from memory.

### Related Examples

- “C Code Generation Using the MATLAB Coder App”
- “Software-in-the-Loop Execution with the MATLAB Coder App” on page 66-4
- “Debug Generated Code During SIL Execution” on page 66-9
- “Generate Execution Time Profile” on page 59-3

### More About

- “Code Verification Through Software-in-the-Loop and Processor-in-the-Loop Execution” on page 66-2

## Debug Generated Code During SIL Execution

If a SIL execution fails or you notice differences between the outputs of your original functions and the generated code, you can rerun the SIL execution with a debugger enabled. By inserting breakpoints, you can observe the behavior of code sections, which might help you to understand the cause of the problem.

For a SIL execution failure, you can also view information from the standard output and standard error streams in the MATLAB Command Window. For example:

- Output from `printf` statements in your code.
- If you enable run-time error detection, messages sent to `stderr`.
- Some low-level system messages.

---

**Note:** During a SIL execution, the SIL application redirects the `stdout` and `stderr` streams. When the application terminates, the MATLAB Command Window displays the information from the redirected streams. The SIL application also provides a basic signal handler, which captures the POSIX signals `SIGFPE`, `SIGILL`, `SIGABRT`, and `SIGSEV`. For this signal handler, the SIL application includes the file `signal.h`.

---

A SIL execution supports the following debuggers:

- On Windows, Microsoft Visual Studio debugger.
- On Linux, GNU Data Display Debugger (DDD).

---

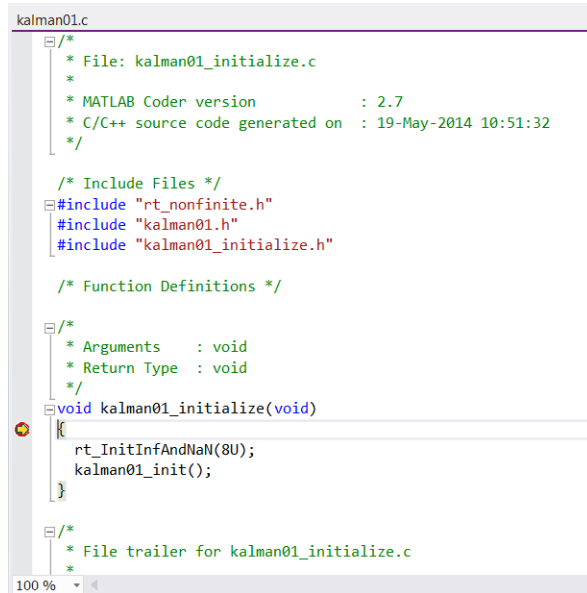

**Note:** You can perform SIL debugging only if your Microsoft Visual C++ or GNU GCC compiler is supported by the MATLAB product family. For more information, see supported compilers.

---

To run a SIL execution with debugging enabled:

- 1 On the **Generate Code** page, click **Verify Code**.
- 2 Select the **Enable source-level debugging for SIL** check box.
- 3 Click **Run Generated Code**.

On a Windows computer, your `user_fn.c` or `user_fn.cpp` file opens in the Microsoft Visual Studio IDE with debugger breakpoints at the start of the `user_fn_initialize` and `user_fn` functions.

```

kalman01.c
/*
 * File: kalman01_initialize.c
 *
 * MATLAB Coder version : 2.7
 * C/C++ source code generated on : 19-May-2014 10:51:32
 */

/* Include Files */
#include "rt_nonfinite.h"
#include "kalman01.h"
#include "kalman01_initialize.h"

/* Function Definitions */

/*
 * Arguments : void
 * Return Type : void
 */
void kalman01_initialize(void)
{
 rt_InitInfAndNaN(8U);
 kalman01_init();
}

/*
 * File trailer for kalman01_initialize.c
 */

```

You can now use the debugger features to observe code behavior. For example, you can step through code and examine variables.

To end the debugging session:

- 1 Remove all breakpoints.
- 2 Click the **Continue** button (**F5**).

The SIL execution runs to completion.

- 3 To terminate the SIL execution process, on the **Test Output** tab, click the link that follows **To terminate execution**, for example, `clear kalman01_sil`.

The Microsoft Visual Studio IDE closes automatically.

---

**Note:** If you select **Debug > Stop Debugging**, the SIL execution times out with the following error message:

Communications error: failed to send data to the target. There might be multiple reasons for this failure.

...  
...

---

## Create PIL Target Connectivity Configuration

### In this section...

“Target Connectivity Configurations for PIL” on page 66-12

“Create a Target Connectivity API Implementation” on page 66-13

“Register Target Connectivity Configuration” on page 66-14

“Verify Target Connectivity Configuration” on page 66-15

### Target Connectivity Configurations for PIL

Use target connectivity configurations and the target connectivity API to customize processor-in-the-loop (PIL) execution for your target environments.

Through a target connectivity configuration, you specify:

- A target connectivity configuration name for a target connectivity API implementation.
- Settings that define compatible MATLAB code. For example, the code that is generated for a particular hardware implementation.

A PIL execution requires a target connectivity PIL API implementation that integrates third-party tools for:

- Building the PIL application that runs on the target hardware
- Downloading, starting, and stopping the application on the target
- Communicating between MATLAB and the target

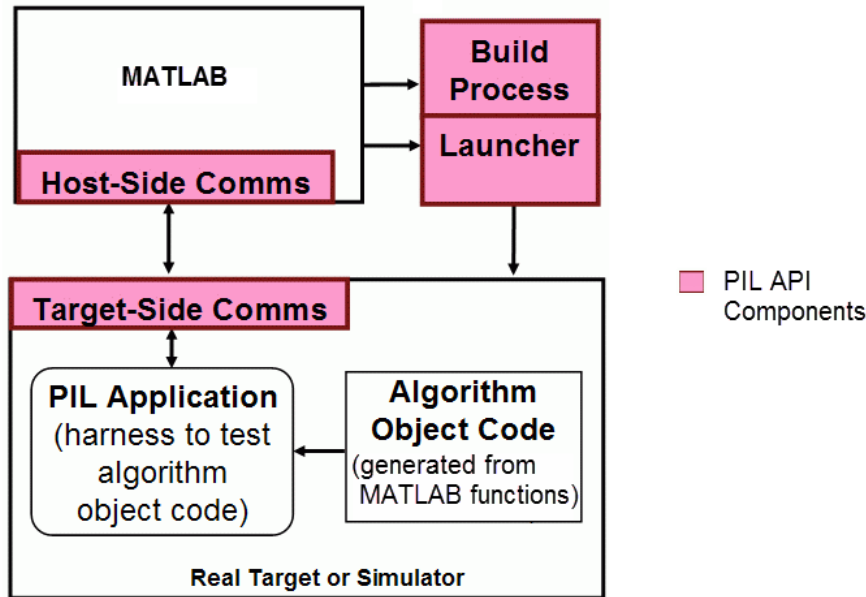

You can have many different connectivity configurations for PIL execution. Register a connectivity configuration with MATLAB by creating an `rtwTargetInfo.m` file and placing it on the MATLAB search path.

In a PIL execution, the software determines which of the available connectivity configurations to use. The software looks for a connectivity configuration that is compatible with the MATLAB code under test. If the software finds multiple or no compatible connectivity configurations, the software generates an error message with information about resolving the problem.

## Create a Target Connectivity API Implementation

This diagram shows the components of the PIL target connectivity API.

You must provide implementations of the three API components:

- Build API — Specify a toolchain approach for building generated code.
- Launcher API — Control how MATLAB starts and stops the PIL executable.
- Communications API — Customize connectivity between MATLAB and the PIL target. Embedded Coder provides host-side support for TCP/IP and serial communications, which you can adapt for other protocols.

These steps outline how you create a target connectivity API implementation. The example code shown in the steps is taken from the `ConnectivityConfig.m` file used in “Processor-in-the-Loop Execution From Command Line” on page 66-27.

- 1 Create a subclass of `rtw.connectivity.Config`.

```
ConnectivityConfig < rtw.connectivity.Config
```

- 2 In the subclass:

- Instantiate `rtw.connectivity.MakefileBuilder`, which configures the build process.

```
builder = rtw.connectivity.MakefileBuilder(componentArgs, ...
 targetApplicationFramework, ...
 exeExtension);
```

- Create a subclass of `rtw.connectivity.Launcher`, which downloads and executes the application using a third-party tool.

```
launcher = mypil.Launcher(componentArgs, builder);
```

### 3 Configure your `rtiostream` API implementation of the host-target communications on page 66-16 channel.

- For the target side, you must provide the driver code for communications, for example, code for TCP/IP or serial communications. To integrate this code into the build process, create a subclass of `rtw.pil.RtIOStreamApplicationFramework`.
- For the host side, you can use a supplied library for TCP/IP or serial communications. Instantiate `rtw.connectivity.RtIOStreamHostCommunicator`, which loads and initializes the library that you specify.

```
hostCommunicator = rtw.connectivity.RtIOStreamHostCommunicator(...
 componentArgs, ...
 launcher, ...
 rtiostreamLib);
```

### 4 If you require execution-time profiling of generated code, create a timer object that provides details of the hardware-specific timer and associated source files. See “Specify Hardware Timer” on page 66-22.

## Register Target Connectivity Configuration

To register a target connectivity API implementation as a target connectivity configuration in MATLAB:

### 1 Create or update an `rtwTargetInfo.m` file. In this file:

- Create a target connectivity configuration object that specifies, for example, the configuration name for a target connectivity API implementation and compatible MATLAB code.
- Invoke `registerTargetInfo`.

- 2 Add the folder containing `rtwTargetInfo.m` to the search path and refresh the MATLAB Coder library registration information.

For more information, see `rtw.connectivity.ConfigRegistry`.

## Verify Target Connectivity Configuration

Use the `piltest` function to verify your target connectivity configuration early and independently of your algorithm development and code generation. The function:

- Runs a MATLAB function on your development computer.
- Performs a PIL execution of generated MATLAB code on your target hardware.
- Compares results from the MATLAB function and the PIL execution. If the function detects differences, it produces an error.

For an example, see “PIL Execution of Code Generated for a Kalman Estimator” on page 66-27.

## Host-Target Communication for PIL

### In this section...

“Communications `rtiostream` API” on page 66-16

“Synchronize Host and Target” on page 66-17

“Test an `rtiostream` Driver” on page 66-18

### Communications `rtiostream` API

The `rtiostream` API supports communications for the target connectivity API. Use the `rtiostream` API to implement a communication channel that enables data exchange between different processes.

PIL verification requires a host-target communications channel. This communications channel comprises driver code that runs on the host and target. The `rtiostream` API defines the signature of target-side and host-side functions that must be implemented by this driver code.

The API is independent of the physical layer that sends the data. Possible physical layers include RS232, Ethernet, or Controller Area Network (CAN).

A full `rtiostream` implementation requires both host-side and target-side drivers. Code generation software includes host-side drivers for the default TCP/IP implementation as well as a version for serial communications. To use:

- The TCP/IP `rtiostream` communications channel, you must provide, or obtain from a third party, target-specific TCP/IP device drivers.
- The serial communications channel, you must provide, or obtain from a third party, target-specific serial device drivers.

For other communication channels and platforms, the code generation software does not provide default implementations. You must provide both the host-side and the target-side drivers.

The `rtiostream` API comprises the following functions:

- `rtIOStreamOpen`

- `rtIOStreamSend`
- `rtIOStreamRecv`
- `rtIOStreamClose`

For information about:

- Using `rtiostream` functions in a connectivity implementation, see “Create a Target Connectivity API Implementation” on page 66-13.
- Testing the `rtiostream` shared library methods from MATLAB code, see `rtiostream_wrapper`.
- Debugging and verifying the behavior of custom `rtiostream` interface implementations, see “Test an `rtiostream` Driver” on page 66-18.

## Synchronize Host and Target

If you use the `rtiostream` API to implement the communications channel, the host and target must be synchronized, which prevents MATLAB from transmitting and receiving data before the target application is fully initialized.

To synchronize the host and target for TCP/IP `rtiostream` implementations, use the `setInitCommsTimeout` method from `rtw.connectivity.RtIOStreamHostCommunicator`. This approach works well for connection-oriented TCP/IP `rtiostream` implementations because MATLAB automatically waits until the target server is running.

With other `rtiostream` implementations, for example, serial, the MATLAB side of the `rtiostream` connection opens without waiting for the target to be fully initialized. In this case, you must make your `Launcher` implementation wait until the target application is fully initialized. Use one of the following approaches to synchronize your host and target:

- Add a pause at the end of the `Launcher` implementation that makes the `Launcher` wait until target initialization is complete.
- In the `Launcher` implementation, use third-party downloader or debugger APIs that wait until target initialization is complete.
- Implement a handshaking mechanism in the `Launcher / rtiostream` implementation that confirms completion of target initialization.

## Test an `rtiostream` Driver

Use a test suite to debug and verify the behavior of custom `rtiostream` interface implementations.

The test suite has the following advantages:

- Reduces time for integrating custom hardware that does not have built-in `rtiostream` support.
- Reduces time for testing custom `rtiostream` drivers.
- Helps analyze the performance of custom `rtiostream` drivers.

The test suite has two parts. One part of the test suite runs on the target.

---

**Note:** After building the target application, download it to the target and run it.

---

To start this part, compile and link the following files, which are in the folder `matlabroot/toolbox/coder/rtiostream/src/rtiostreamtest` (open).

- `rtiostreamtest.c`
- `rtiostreamtest.h`
- `rtiostream.h`, located in the folder `matlabroot/rtw/c/src` (open)
- `rtiostream` implementation under investigation (for example, `rtiostream_tcpip.c`)
- `main.c`

To run the MATLAB part of the test suite, invoke `rtiostreamtest`. The syntax is as follows:

```
rtiostreamtest(connection,param1,param2)
```

- `connection` is a character vector indicating the communication method. It can have values `'tcp'` or `'serial'`.
- `param1` and `param2` have different values depending on the value of `connection`.
  - If `connection` is `'tcp'`, then `param1` and `param2` are hostname and port, respectively. For example, `rtiostreamtest('tcp', 'localhost', 2345)`.

- If connection is 'serial', then param1 and param2 are COM port and baud rate, respectively. For example, `rtiostreamtest('serial', 'COM1', 9600)`.

You can run the MATLAB part of the test suite as follows:

```
rtiostreamtest('tcp', 'localhost', '2345')
```

An output in the following format appears in the MATLAB window:

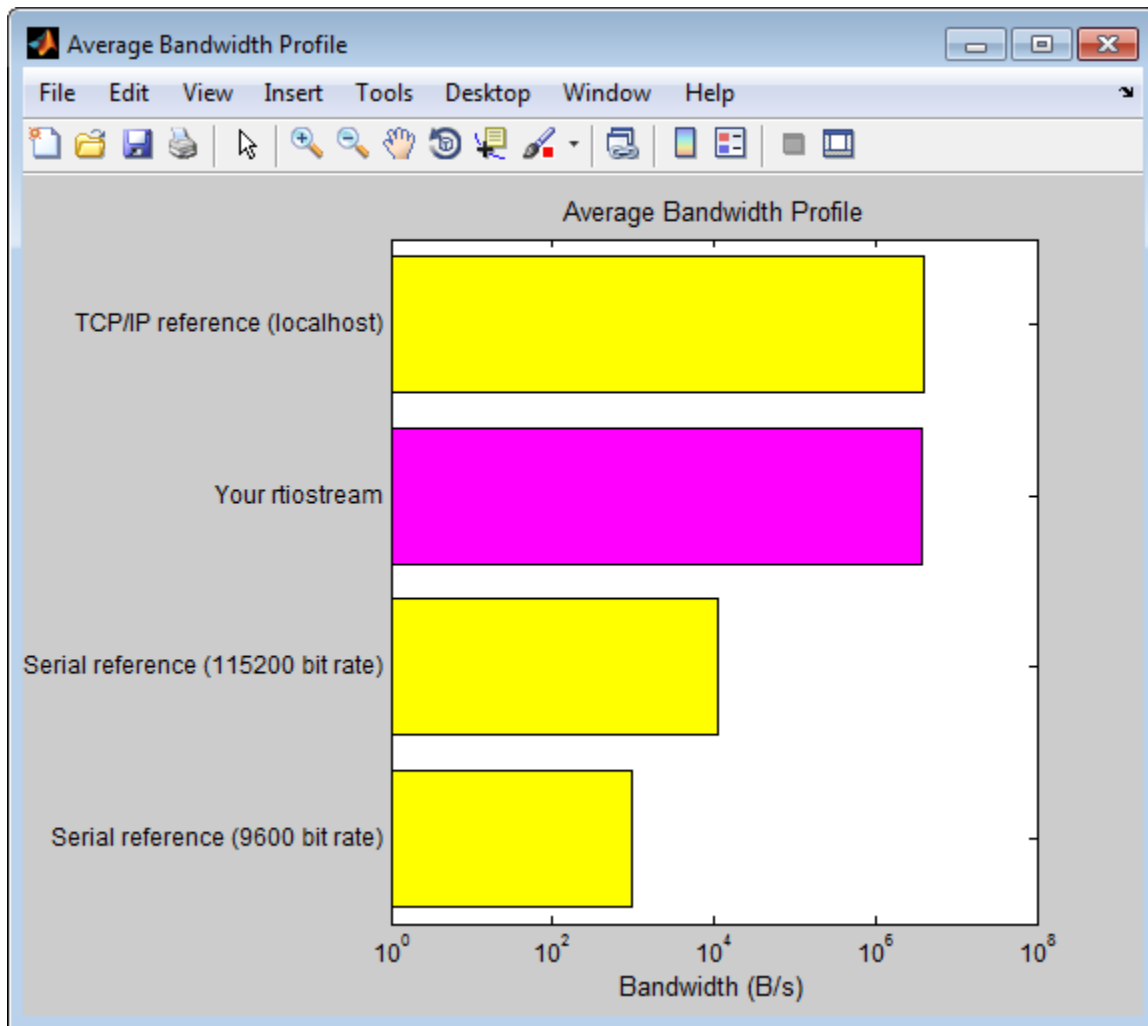

```
Test suite for rtiostream
Initializing connection with target...

Hardware characteristics discovered
Size of char : 8 bit
Size of short : 16 bit
Size of int : 32 bit
Size of long : 32 bit
Size of float : 32 bit
Size of double : 64 bit
Size of pointer : 64 bit
Byte ordering : Little Endian

rtiostream characteristics discovered
Round trip time : 0.96689 ms
rtIOStreamRecv behavior : non-blocking

Test results
Test 1 (fixed size data exchange): PASS
Test 2 (varying size data exchange): PASS

Test suite for rtiostream finished successfully
Furthermore, the following profile appears.
```

## **Related Examples**

- “Create PIL Target Connectivity Configuration” on page 66-12

## Specify Hardware Timer

For processor-in-the-loop (PIL) code execution profiling, you must create a timer object that provides details of the hardware-specific timer and associated source files. You can use the Code Replacement Tool or the code replacement library API to specify this hardware-specific timer.

To specify the timer with the Code Replacement Tool:

- 1 Open the Code Replacement Tool. In the Command Window, enter `crtool`.
- 2 Create a new code replacement table. Select **File > New table**.
- 3 Create a new function entry. Under **Tables List**, right-click the new table. Then, from the context-menu, select **New entry > Function**.
- 4 In the middle view, select the new unnamed function.
- 5 On the **Mapping Information** pane:
  - a From the **Function** drop-down list, select `code_profile_read_timer`.
  - b Specify the count direction for your timer. For example, from the **Count direction** drop-down list, select **Up**.
  - c In the **Ticks per second** field, specify the number of ticks per second for your timer, for example, `1e+09`.

The default value is 0. In this case, the software reports time measurements in terms of ticks, not seconds.

- d In the **Name** field, specify a replacement function name, for example, `MyTimer`.
- e Click **Apply**.

**f** To validate the function entry, click **Validate entry**.

- 6** On the **Build Information** pane, specify the required build information. See “Specify Build Information for Replacement Code” on page 51-59.
- 7** Save the table (**Ctrl+S**). When you save the table for the first time, use the Save As dialog box to specify the file name and location.

You must save the table in a location that is on the MATLAB search path. For example, you can save this file in the folder for your subclass of `rtw.connectivity.Config`.

The software stores your timer information as a code replacement library table.

- 8** Assuming you save the table as `MyCr1Table.m`, in your subclass of `rtw.connectivity.Config`, add the following line:

```
setTimer(this, MyCr1Table)
```

## Processor-in-the-Loop Execution with the MATLAB Coder App

Use processor-in-the-loop (PIL) execution to verify the numerical behavior of cross-compiled object code with reference to your original MATLAB functions.

Before you run a PIL execution, you must define a target connectivity configuration. In “Processor-in-the-Loop Execution From Command Line” on page 66-27, steps 1 and 2 of the example PIL Execution of Code Generated for a Kalman Estimator show how you can set up and register a connectivity configuration for host-based PIL.

- 1 To open the MATLAB Coder app, on the MATLAB Toolstrip **Apps** tab, under **Code Generation**, click the app icon.
- 2 To open your project, click , and then click **Open existing project**. Select the project. For example, `kalman_filter.prj`.
- 3 On the **Generate Code** page, click the **Generate** arrow .
- 4 In the **Generate** dialog box:
  - a Set **Build type** to **Static Library** or **Dynamic Library**.
  - b In the **Output file name** field, use the default value. For example, `kalman01`.
  - c Clear the **Generate code only** check box.
  - d From the **Hardware Board** drop-down list, select **None - Select device below**.
  - e In the **Device** fields, specify vendor and type. These settings must match the target hardware settings in the `rtwTargetInfo.m` file of your target connectivity configuration. For host-based PIL, select settings that match your host computer. For example:
    - For a Windows 64-bit system, set **Device vendor** to **Intel** and **Device type** to **x86-64 (Windows64)**. In addition, set **Enable long long** to **Yes**.
    - For a Linux 64-bit system, set **Device vendor** to **Intel** and **Device type** to **x86-64 (Linux 64)**.
    - For a Mac OS X system, set **Device vendor** to **Intel** and **Device type** to **x86-64 (Mac OS X)**.

You do not have to specify the **Toolchain** setting. By default, the MATLAB Coder app locates an installed toolchain.

- 5 To generate the C or C++ code, click **Generate**.
- 6 Click **Verify Code**.
- 7 In the command field, specify the test file that calls the original MATLAB functions, for example, `test01_ui.m`.
- 8 To start the PIL execution, click **Run Generated Code**.

The MATLAB Coder app:

- Generates a standalone library, for example, `codegen\lib\kalman01`.
  - Generates PIL interface code, for example, `codegen\lib\kalman01\pil`.
  - Runs the test file, replacing calls to the MATLAB function with calls to the generated code in the library.
  - Displays messages from the PIL execution in the **Test Output** tab.
- 9 Verify that the results from the PIL execution match the results from the original MATLAB functions.
  - 10 To terminate the PIL execution process, click **Stop PIL Verification**. Alternatively, on the **Test Output** tab, click the link that follows `To terminate execution`.

## Related Examples

## More About

- “Code Verification Through Software-in-the-Loop and Processor-in-the-Loop Execution” on page 66-2

## Processor-in-the-Loop Execution From Command Line

Use processor-in-the-loop (PIL) execution to verify code that you intend to deploy in production.

To set up and start a PIL execution from the command line:

- 1 Create and verify your target connectivity configuration.
- 2 Create a `coder.EmbeddedCodeConfig` object.
- 3 Configure the object for PIL.
- 4 Use the `codegen` function to generate library code for your MATLAB function and the PIL interface.
- 5 Use the `coder.runTest` function to run the test file for your original MATLAB function.

To terminate the PIL execution, use the `clear function_pil` or `clear mex` command.

The following example shows how you can use line commands to set up and run a PIL execution on your development computer.

### PIL Execution of Code Generated for a Kalman Estimator

#### 1 Create a target connectivity API implementation

- a In your current working folder, make a local copy of the connectivity classes.

```
src_dir = ...
 fullfile(matlabroot, 'toolbox', 'coder', 'simulinkcoder', '+coder', '+mypil');
if exist(fullfile('.', '+mypil'), 'dir')
 rmdir('+mypil', 's')
end
mkdir +mypil
copyfile(fullfile(src_dir, 'Launcher.m'), '+mypil');
copyfile(fullfile(src_dir, 'TargetApplicationFramework.m'), '+mypil');
copyfile(fullfile(src_dir, 'ConnectivityConfig.m'), '+mypil');
```

- b Make the copied files writable.

```
fileattrib(fullfile('+mypil', '*'), '+w');
```

- c Update the package name to reflect the new location of the files.

```
coder.mypil.Utils.UpdateClassName(...
 './+mypil/ConnectivityConfig.m',...
 'coder.mypil',...
 'mypil');
```

- d** Check that you now have a folder `+mypil` in the current folder, which includes three files, `Launcher.m`, `TargetApplicationFramework.m`, and `ConnectivityConfig.m`.

```
dir './+mypil'
```

- e** Review the code that starts the PIL application. The `mypil.Launcher` class configures a tool for starting the PIL executable. Open this class in the editor.

```
edit(which('mypil.Launcher'))
```

Review the content of this file. For example, consider the `setArgString` method. This method allows additional command line parameters to be supplied to the application. These parameters can include a TCP/IP port number. For an embedded processor implementation, you might have to hard code these settings.

- f** The class `mypil.ConnectivityConfig` configures target connectivity.

```
edit(which('mypil.ConnectivityConfig'))
```

Review the content of this file. For example:

- The creation of an instance of `rtw.connectivity.RtIOStreamHostCommunicator` that configures the host side of the TCP/IP communications channel.
- A call to the `setArgString` method of `Launcher` that configures the target side of the TCP/IP communications channel.
- A call to `setTimer` that configures a timer for execution time measurement. To define your own target-specific timer for execution time profiling, you must use the Code Replacement Library to specify a replacement for the function `code_profile_read_timer`.

- g** Review the target-side communication drivers.

```
rtiostreamtcpip_dir=fullfile(matlabroot,'rtw','c','src','rtiostream',...
 'rtiostreamtcpip');
```

```
edit(fullfile(rtiostreamtcpip_dir,'rtiostream_tcpip.c'))
```

Scroll down to the end of this file. The file contains a TCP/IP implementation of the functions `rtIOStreamOpen`, `rtIOStreamSend`, and `rtIOStreamRecv`.

These functions are required for target communication with the host. For each of these functions, you must provide an implementation that is specific to your target hardware and communication channel.

The `myPil.TargetApplicationFramework` class adds target-side communication drivers to the connectivity configuration.

```
edit(which('myPil.TargetApplicationFramework'))
```

The file specifies additional files to include in the build.

## 2 Register a target connectivity configuration

Use an `rtwTargetInfo.m` file to:

- Create a target connectivity configuration object.
- Invoke `registerTargetInfo`, which registers the target connectivity configuration.

The target connectivity configuration object specifies, for example:

- The configuration name and associated API implementation. See `rtw.connectivity.ConfigRegistry`
  - A toolchain for your target hardware. This example assumes that the target hardware is your host computer, and uses the toolchain supplied for host-based PIL verification. For information about toolchains, see “Custom Toolchain Registration”.
- Insert the following code into your `rtwTargetInfo.m` file, and save the file in the current working folder or in a folder that is on the MATLAB search path:

```
function rtwTargetInfo(tr)
% Register PIL connectivity config: myPil.ConnectivityConfig

tr.registerTargetInfo(@loc_createConfig);

% local function
function config = loc_createConfig

% Create object for connectivity configuration
config = rtw.connectivity.ConfigRegistry;
% Assign connectivity configuration name
config.ConfigName = 'My PIL Example';
% Associate the connectivity configuration with the connectivity
```

```

% API implementation
config.ConfigClass = 'mypil.ConnectivityConfig';

% Specify toolchains for host-based PIL
config.Toolchain = rtw.connectivity.Utils.getHostToolchainNames;

% Through the TargetHWDeviceType property, define compatible code for the
% target connectivity configuration
config.TargetHWDeviceType = {'Generic->32-bit x86 compatible' ...
 'Generic->Custom' ...
 'Intel->x86-64 (Windows64)', ...
 'Intel->x86-64 (Mac OS X)', ...
 'Intel->x86-64 (Linux 64)'};

```

- b** Refresh the MATLAB Coder library registration information.

```
RTW.TargetRegistry.getInstance('reset');
```

### 3 Verify Target Connectivity Configuration

Use the supplied `piltest` function to verify your target connectivity configuration.

- a** Create a `coder.EmbeddedCodeConfig` object for verifying the target connectivity configuration.

```
configVerify = coder.config('lib');
```

- b** Specify the manufacturer and test hardware type. For example, PIL execution on a 64-bit Windows development computer requires:

```
configVerify.HardwareImplementation.TargetHWDeviceType = ...
 'Intel->x86-64 (Windows64)';
configVerify.HardwareImplementation.ProdLongLongMode = true;
```

- c** Run `piltest`.

```
piltest(configVerify, 'ConfigParam', {'ProdLongLongMode'})
```

### 4 Copy MATLAB code for Kalman estimator

Copy the MATLAB code to your working folder.

```
src_dir = ...
 fullfile(docroot, 'toolbox', 'coder', 'examples', 'kalman');

copyfile(fullfile(src_dir, 'kalman01.m'), '.')
```

```
copyfile(fullfile(src_dir, 'test01_ui.m'), '.')
copyfile(fullfile(src_dir, 'plot_trajectory.m'), '.')
copyfile(fullfile(src_dir, 'position.mat'), '.')
```

For a description of the Kalman estimator in this example, see “C Code Generation at the Command Line”.

## 5 Configure the PIL execution

- a Create a `coder.EmbeddedCodeConfig` object.

```
config = coder.config('lib');
```

- b Configure the object for PIL.

```
config.VerificationMode = 'PIL';
```

- c Specify production hardware, which must match one of the test hardware settings in `rtwTargetInfo.m`. For PIL execution on your development computer, specify settings that match the computer. For example, if your computer is a Windows 64-bit system, specify:

```
config.HardwareImplementation.ProdHWDeviceType = ...
 'Intel->x86-64 (Windows64)';
config.HardwareImplementation.ProdLongLongMode = true;
```

For a Linux 64-bit system, set `ProdHWDeviceType` to `'Intel->x86-64 (Linux 64)'`.

For a Mac OS X system, set `ProdHWDeviceType` to `'Intel->x86-64 (Mac OS X)'`.

## 6 Generate code and run PIL execution

- a Generate library code for the `kalman01` MATLAB function and the PIL interface.

```
codegen('-config', config, '-args', {zeros(2,1)}, 'kalman01');
```

The software creates the following output folders:

- `codegen\lib\kalman01` — Standalone code for `kalman01`.
- `codegen\lib\kalman01\pil` — PIL interface code for `kalman01`.

- b Run the MATLAB test file `test01_ui` with `kalman01_pil`. `kalman01_pil` is the PIL interface for `kalman01`.

```
coder.runTest('test01_ui', ['kalman01_pil.' mexext]);
```

Verify that the output of this run matches the output from the original `kalman01.m` function.

### **7 Terminate PIL execution**

Terminate the PIL execution process.

```
clear kalman01_pil;
```

### **More About**

- “Code Verification Through Software-in-the-Loop and Processor-in-the-Loop Execution” on page 66-2

## Verification of Code Generation Assumptions

The settings on the **More Settings > Hardware** tab specify target behavior, which result in the implementation of implicit assumptions in the generated code. Incorrect settings can lead to:

- Suboptimal code
- Code execution failure, incorrect code output, and nondeterministic code behavior

At the start of a processor-in-the-loop (PIL) execution, the software verifies the **Hardware** tab settings with reference to the target hardware. The software checks:

- The correctness of settings. For example, the integer bit length in the **Sizes > int** field.
- Whether the settings are optimized. For example, the rounding of signed integer division in the **Signed integer division rounds to** field.

If required, the software generates warnings and errors.

## SIL/PIL Execution Support and Limitations

Feature		Supported
Output types	Static library	Yes
	Dynamic library	Yes
	Executable	No
Languages	C	Yes
	C++	Yes
Interface types	Inputs	Yes
	Outputs	Yes
	Constant inputs	Yes
	Global data	No
	Constant global data	Yes
	Reentrant code	Yes
	Multiple entry points	Yes
Data types	Basic types	Yes
	Enumerated types	Yes
	Structures	Yes
	Complex data	Yes
	Fixed-point data	Yes
	Multiword fixed-point data	SIL only
	char arrays	Yes
	Empty values	Yes
	Cell arrays	Yes
Size	Scalars	Yes
	Fixed-size arrays	Yes

Feature		Supported
	Static variable-size arrays	Yes
	Dynamic variable-size size arrays	No

## Simulink Code Coverage Metrics

### In this section...

“Statement Coverage for Code Coverage” on page 67-2

“Condition Coverage for Code Coverage” on page 67-3

“Decision Coverage for Code Coverage” on page 67-3

“Modified Condition/Decision Coverage (MCDC) for Code Coverage” on page 67-4

“Cyclomatic Complexity for Code Coverage” on page 67-4

“Relational Boundary for Code Coverage” on page 67-5

If you have a Simulink Verification and Validation license, you can run a SIL or PIL simulation that produces code coverage metrics for generated model code. The simulation performs several types of code coverage analysis.

### Statement Coverage for Code Coverage

Statement coverage determines the number of source code statements that execute when the code runs. Use this type of coverage to determine whether every statement in the program has been invoked at least once.

Statement coverage = (Number of executed statements / Total number of statements) \* 100

#### Statement Coverage Example

This code snippet contains five statements. To achieve 100% statement coverage, you need at least three test cases. Specifically, tests with positive  $x$  values, negative  $x$  values, and  $x$  values of zero.

```
if (x > 0)
 printf("x is positive");
else if (x < 0)
 printf("x is negative");
else
 printf("x is 0");
```

## Condition Coverage for Code Coverage

Condition coverage analyzes statements that include conditions in source code. Conditions are C/C++ Boolean expressions that contain relation operators (<, >, <=, or >=), equation operators (!= or ==), or logical negation operators (!), but that do not contain logical operators (&& or | |). This type of coverage determines whether every condition has been evaluated to all possible outcomes at least once.

Condition coverage = (Number of executed condition outcomes / Total number of condition outcomes) \*100

### Condition Coverage Example

In this expression:

```
y = x<=5 && x!=7;
```

there are these conditions:

```
x<=5
```

```
x!=7
```

## Decision Coverage for Code Coverage

Decision coverage analyzes statements that represent decisions in source code. Decisions are Boolean expressions composed of conditions and one or more of the logical C/C++ operators && or | |. Conditions within branching constructs (if/else, while, do-while) are decisions. Decision coverage determines the percentage of the total number of decision outcomes the code exercises during execution. Use this type of coverage to determine whether all decisions, including branches, in your code are tested.

Decision coverage = (Number of executed decision outcomes / Total number of decision outcomes) \*100

### Decision Coverage Example

This code snippet contains three decisions:

```
y = x<=5 && x!=7; // decision #1

if(x > 0) // decision #2
 printf("decision #2 is true");
else if(x < 0 && y) // decision #3
```

```

 printf("decision #3 is true");
else
 printf("decisions #2 and #3 are false");

```

## Modified Condition/Decision Coverage (MCDC) for Code Coverage

Modified condition/decision coverage (MCDC) is the extent to which the conditions within decisions are independently exercised during code execution.

- All conditions within decisions have been evaluated to all possible outcomes at least once.
- Every condition within a decision independently affects the outcome of the decision.

MCDC coverage = (Number of conditions evaluated to all possible outcomes affecting the outcome of the decision / Total number of conditions within the decisions) \*100

### Modified Condition/Decision Coverage Example

For this decision:

```
X || (Y && Z)
```

the following set of test cases delivers 100% MCDC coverage.

	X	Y	Z
Test case #1	0	0	1
Test case #2	0	1	0
Test case #3	0	1	1
Test case #4	1	0	1

## Cyclomatic Complexity for Code Coverage

Cyclomatic complexity is a measure of the structural complexity of code that uses the McCabe complexity measure. To compute the cyclomatic complexity of code, code coverage uses this formula:

$$c = \sum_{1}^{N} (o_n - 1)$$

$N$  is the number of decisions in the code.  $o_n$  is the number of outcomes for the  $n^{\text{th}}$  decision point. Code coverage adds 1 to the complexity number for each C/C++ function.

### Coverage Example

For this code snippet:

```
void evalNum(int x){
 if (x > 0)
 printf("x is positive");
 else if (x < 0)
 printf("x is negative");
 else
 printf("x is 0");
}
```

the cyclomatic complexity is 3.

## Relational Boundary for Code Coverage

Relational boundary code coverage examines code that has relational operations. Relational boundary code coverage metrics align with those for model coverage, as described in “Relational Boundary Coverage”. Fixed-point values in your model are integers during code coverage.

## Related Examples

- “Code Coverage for Models in Software-in-the-Loop (SIL) Mode and Processor-in-the-Loop (PIL) Mode” on page 67-6

## Code Coverage for Models in Software-in-the-Loop (SIL) Mode and Processor-in-the-Loop (PIL) Mode

In this section...
“Requirements to Enable SIL or PIL Code Coverage for a Model” on page 67-6
“Conditions for Simulink Verification and Validation Code Coverage Measurement” on page 67-7
“Reviewing the Coverage Results for Models in SIL or PIL Mode” on page 67-7
“Limitations” on page 67-9

### Requirements to Enable SIL or PIL Code Coverage for a Model

If you have both an Embedded Coder license and a Simulink Verification and Validation license, you can measure coverage for code generated from models in software-in-the-loop (SIL) mode or processor-in-the-loop (PIL) mode. The following configurations must apply for the parameters in **Code Generation Verification**:

- Under **Code profiling**, clear **Measure function execution times**.
- Under **Code coverage for SIL or PIL**, the selected **Code coverage tool** must be **None**.

## Conditions for Simulink Verification and Validation Code Coverage Measurement

There are two workflows for measuring code coverage:

- The top model is in SIL mode or PIL mode. Measures code coverage for the top model depending on `RecordCoverage`. Also measures code coverage for referenced models, depending on `CovModelRefEnable`.
- The top model is in Normal mode and contains at least one reference model in SIL or PIL mode. Measures code coverage for the referenced model if `CovModelRefEnable` is 'on', 'all', or 'filtered' and `RecordCoverage` is 'off'.

## Reviewing the Coverage Results for Models in SIL or PIL Mode

In the code coverage report, each hyperlink opens a report with more details on the coverage analysis for the model. The code coverage results in these reports are similar

to the coverage results for C/C++ code in S-function blocks, as described in “View Coverage Results for C/C++ Code in S-Function Blocks”. You can navigate from code coverage results to the associated model blocks by using the links within the detailed code coverage reports.

Link to model element

Logic block "[And](#)"

Metric	Coverage
Condition (C1)	100% (4/4) condition outcomes
MCDC (C1)	100% (2/2) conditions reversed the outcome

Code coverage summary

Covered expressions: [\(\\*rtu\\_upper >= rtb\\_input\) && rtb\\_inputGElower](#) (line 39) ← Link to code

Each detailed code coverage report also contains syntax highlighted code with coverage information.

Link to model element

```

34 /* Switch: '<Root>/Switch' incorporates:
35 * Logic: '<Root>/And'
36 * RelationalOperator: '<Root>/upper GE input'
37 * Switch: '<Root>/limit'
38 */
39 if ((*rtu_upper >= rtb_input) && rtb_inputGElower) {
40 *rty_output = rtb_input;
41 } else if (rtb_inputGElower) {

```

Link to code coverage result details

**Decisions analyzed:**

rtb_inputGElower	50%
false	5/5
true	0/5

Tooltip with code coverage results

```

 *limit' */
 per;
 wer;
 t>/Switch' */
 : '<Root>/Previous Output' */
51 localIDW->previousoutput_DSTATE = *rty_output;
52 }

```

## Limitations

Coverage for models in SIL and PIL mode has these limitations:

- The model must meet the requirements listed in “Requirements to Enable SIL or PIL Code Coverage for a Model” on page 67-6.
- Code coverage results must not include external C/C++ files in read-only folders.

## Related Examples

- “Software-in-the-Loop Code Coverage”

## Configure Code Coverage with Third-Party Tools

During a top-model or Model block SIL or PIL simulation, you can collect code coverage metrics for generated code using a third-party tool. Embedded Coder supports the following tools:

- LDRA Testbed from LDRA Software Technology. For information about installing and using this tool, go to [www.ldra.com](http://www.ldra.com).

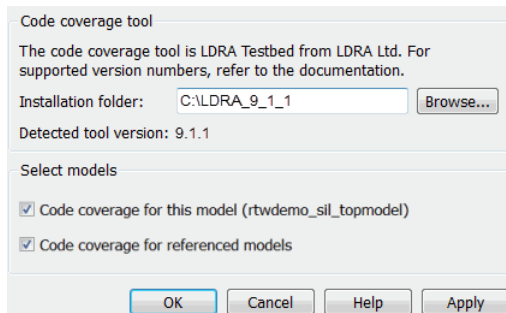

The software supports LDRA Testbed code coverage for SIL and PIL.

- BullseyeCoverage from Bullseye Testing Technology. For information about installing and using this tool, go to [www.bullseye.com/cgi-bin/mwEval](http://www.bullseye.com/cgi-bin/mwEval).

The software supports BullseyeCoverage code coverage for SIL and, in certain cases, PIL.

To configure a code coverage tool for a top-model or Model block SIL or PIL simulation:

- 1 Select **Simulation > Model Configuration Parameters > Code Generation > Verification**.
- 2 From the **Code coverage tool** drop-down list, select a tool, for example, **BullseyeCoverage** or **LDRA Testbed**.
- 3 Click **Configure Coverage** to open the Code Coverage Settings dialog box.
- 4 In the **Installation folder** field, specify the location where your coverage tool is installed. If you click **Browse**, the Select Installation Folder dialog box opens, which allows you to navigate to the folder where your coverage tool is installed. The software detects and displays the tool version.

By default, the software selects the following check boxes:

- **Code coverage for this model** — Generate coverage data for the current (top) model.
- **Code coverage for referenced models** — Generate data for models referenced by the current (top) model.

If your top model has Model blocks where the **Code interface** block parameter is set to `Top model`, then the top model and referenced models must have the same settings for these parameters. Otherwise, the software produces an error.

- 5 Click **OK**. You return to the **Verification** pane.
- 6 To view cumulative code coverage results within a code generation report, in the **Configuration Parameters > Code Generation > Report** pane, select the following check boxes:
  - **Create code generation report**
  - **Launch report automatically**
- 7 Click **OK**. You return to the model window.

With LDRA Testbed:

- The evaluation of cumulative code coverage begins from the point when you last added a new file to the existing set of source files. For example, existing code coverage results are deleted when you:
  - Run a simulation with a new model using the existing code generation folder.
  - Run a simulation that results in additional source code files being instrumented.
- If you switch between SIL and PIL simulations of a model, the software generates separate cumulative code coverage results for the SIL and PIL simulations.

For a model in a reference hierarchy, the software does not support simultaneous function execution time measurement and code coverage.

## View Code Coverage Information at the End of SIL or PIL Simulations

### In this section...

“View LDRA Testbed Results” on page 67-13

“View BullseyeCoverage Results” on page 67-15

If you configure third-party code coverage for a SIL or PIL simulation, when the simulation is complete, the code generation report opens automatically and you see hyperlinks in the Command Window.

### View LDRA Testbed Results

If you specified the LDRA Testbed, you see three links in the Command Window:

```
Starting SIL simulation for component: rtwdemo_sil_topmodel
Stopping SIL simulation for component: rtwdemo_sil_topmodel
Starting analysis of coverage data
Use the following links to view code coverage results:
 LDRA Testbed GUI
 LDRA Testbed Code Coverage Overview Report
 HTML code generation report with code coverage annotations
Completed code coverage analysis
>>
```

To go to the LDRA Testbed GUI, click the [LDRA Testbed GUI](#) link.

To open the LDRA Testbed Report with your Web browser, click the [LDRA Testbed Code Coverage Overview Report](#) link.

# LDRA Testbed<sup>®</sup> Dynamic Overview Report

Set : work3\_3afef0b64dc51060

Report Production	Report Configuration
<ul style="list-style-type: none"> <li>C/C++ LDRA Testbed Version: 8.5.1</li> </ul>	<ul style="list-style-type: none"> <li>DO-178B Level: 'a'</li> <li>Report Format: Procedure Listing</li> <li>Procedure Sort Method: Source File order</li> <li>Reporting Scope: Source file and associated header</li> </ul>

## Contents

### Combined Coverage for Selected Metrics

- Statement
- Branch/Decision
- Modified Condition/ Decision

[Table of Coverage Metric Pass Levels](#)

[Key to Terms](#)

For information about using this report, refer to the LDRA Testbed documentation.

LDRA Testbed analysis results for all code in the current code generation folder belong to a set. In this set, you can find analysis results for models that share the same code generation folder. The [LDRA Testbed Code Coverage Overview Report](#) link identifies the location of the LDRA Testbed analysis results, which is determined by:

- The LDRA Testbed configuration.
- The name of the LDRA Testbed set associated with the current code generation folder.

To view summary data and code annotations with coverage information in the code generation report, click the [HTML code generation report with code coverage annotations](#) link.

## View BullseyeCoverage Results

If you specified the BullseyeCoverage tool, you see two links in the Command Window:

```
Starting SIL simulation for component: rtwdemo_sil_topmodel
Stopping SIL simulation for component: rtwdemo_sil_topmodel
Processing code coverage data
Use the following links to view code coverage results:
 BullseyeCoverage browser (coverage for last run)
 HTML code generation report (cumulative coverage)
Completed code coverage analysis
>>
```

To view the coverage report using the BullseyeCoverage Browser, click the BullseyeCoverage browser (coverage for last run) link.

The BullseyeCoverage Browser shows coverage data for instrumented files associated with your latest top-model simulation. The coverage data shown in the browser is not cumulative and pertains only to the most recent simulation. For information about the BullseyeCoverage Browser, go to [www.bullseye.com](http://www.bullseye.com).

To view summary data and code annotations with coverage information in the code generation report, click the HTML code generation report (cumulative coverage) link.

## Related Examples

- “Configure Code Coverage with Third-Party Tools” on page 67-10
- “Collect Code Coverage Metrics with a Third-Party Tool”
- “Code Coverage Summary and Annotations” on page 67-18

## Configure Code Coverage Programmatically

You can configure code coverage for your model using command-line APIs. A typical workflow with BullseyeCoverage is:

- 1 Using `get_param`, retrieve the object containing coverage settings for the current model, for example, `gcs`.

```
>> covSettings = get_param(gcs, 'CodeCoverageSettings')

covSettings =

CodeCoverageSettings with properties:

 TopModelCoverage: 'on'
 ReferencedModelCoverage: 'off'
 CoverageTool: 'BullseyeCoverage'
```

The property `TopModelCoverage` determines whether the software generates code coverage data for just the top model, while `ReferencedModelCoverage` determines whether the software generates coverage data for models referenced by the top model. If neither property is 'on', then no code coverage data is generated during a SIL simulation.

If LDRA Testbed is the specified code coverage tool, then the property `CoverageTool` is 'LDRA Testbed'.

When you save your model, the properties `TopModelCoverage`, `ReferencedModelCoverage`, and `CoverageTool` are also saved.

- 2 Check the class of `covSettings`.

```
>> class(covSettings)

ans =

coder.coverage.CodeCoverageSettings
```

- 3 Turn on coverage for referenced models.

```
>> covSettings.ReferencedModelCoverage='on';
```

- 4 Using `set_param`, apply the new coverage settings to the model.

```
>>set_param(gcs,'CodeCoverageSettings', covSettings);
```

- 5 Assuming you have installed the BullseyeCoverage tool, specify the installation path.

```
>>coder.coverage.BullseyeCoverage.setPath('C:\Program Files\BullseyeCoverage')
```

For LDRA Testbed, use `coder.coverage.LDRA.setPath('C:\...')`.

- 6 Check that the path is saved as a preference.

```
>> coder.coverage.BullseyeCoverage.getPath
```

For LDRA Testbed, use `coder.coverage.LDRA.getPath`.

## Related Examples

- “Collect Code Coverage Metrics with a Third-Party Tool”
- “Configure Code Coverage with Third-Party Tools” on page 67-10

## Code Coverage Summary and Annotations

### In this section...

“LDRA Testbed Coverage” on page 67-18

“BullseyeCoverage Information” on page 67-20

If you specify a code coverage tool for a SIL or PIL simulation, the software produces a code generation report that provides summary data and code annotations with coverage information. Each code annotation is associated with a code feature and indicates the nature of the feature coverage during code execution.

The code generation report also allows you to navigate easily between blocks in your model and the corresponding sections in the source code.

### LDRA Testbed Coverage

The cumulative coverage data in a code generation report is derived from instrumented files associated with your latest top-model simulation **and** coverage data collected from simulations with other top models that share referenced models with your current top model.

The screenshot displays a code generation report for the file `rtwdemo_sil_topmodel.c`. The report includes a navigation pane on the left with sections for Contents, Generated Files, and Interface files. The main content area shows the LDRA Testbed code coverage enabled status and summary statistics:

Metric	Value
Function exit points	100%
Statement	87%
Branch/condition	37%
Branch/decision	57%
MC/DC	0%

The source code annotations include:

```

1 /*
2 * File: rtwdemo_sil_topmodel.c
3 *
4 * Code generated for Simulink model 'rtwdemo_sil_topmodel'.
5 *
6 * Model Version : 1.206
7 * Simulink Coder version : 8.2 (R2012a) 07-Oct-2011
8 * TLC version : 8.2 (Oct 7 2011)
9 * C/C++ source code generated on : Wed Oct 19 12:29:12 2011
10 *
11 * Target selection: ert.tlc
12 * Embedded hardware selection: Specified
13 * Code generation objectives: Unspecified
14 * Validation result: Not run
15 */
16
17 #include "rtwdemo_sil_topmodel.h"
18
19 /* Block signals and states (auto storage) */
20 D_Work rtUWork;
21

```

The software provides LDRA Testbed annotations in the code generation report to help you to review code coverage.

**Note:** Do not use the code generation report alone to verify that you have achieved your coverage goals. You must refer to the LDRA Testbed Report.

This example shows three kinds of annotations. On lines 134, 139, 140, and 141, the annotation `•` indicates that statement coverage for each of these lines of code is not complete.

```

• 134 if (rtWork.bitsForTID0.LogicalOperator1) (
=>b ^
135 /* Switch: 'cS2p/Switch1' incorporates:
136 * Constant: 'cS2p/CI'
137 * Inport: 'cRootp/reset'
138 */
• 139 if (rtU.reset) (
=> ^
140 rtWork.PreviousOutput_DSTATE = 0U;
• 141 }

```

Placing the cursor over the annotation `=>b` produces a tooltip.

```

• 134 if (rtWork.bitsForTID0.LogicalOperator1) (
=>b ^
Branch destinations
covered
<line>:<column>:158-3:
branch-destinations not
covered:134c45
 Switch: 'cS2p/Switch1' incorporates:
 Constant: 'cS2p/CI'
 Inport: 'cRootp/reset'
 rtU.reset) (

```

This tooltip indicates that only one branch destination is covered. The code within the curly brackets, which starts at column 45 of line 134, is not executed. As the `if` statement on line 139 lies within this code, the corresponding annotation `=>` states that the branch is not covered.

The following table describes the LDRA Testbed code annotations that you might see in a code generation report produced by a SIL and PIL simulations.

Code feature	Annotation symbol	What happened during simulation
Function	Fcn	Function <i>name</i> returned through this exit point.
	=>	Function <i>name</i> never returned through this exit point.
Branch/condition	=>	Condition not encountered.
	=>t	Condition evaluated true only.
	=>f	Condition evaluated false only.

Code feature	Annotation symbol	What happened during simulation
	tf	Condition evaluated both true and false.
Branch/decision	=>	Branch never encountered.
	=>b	Branch to at least one destination covered and branch to at least one other destination not covered.
	b	Branch fully exercised.
Modified Condition/ Decision Coverage (MC/DC)	=>mc	Condition did not independently affect outcome of decision.
	mc	Condition independently affected outcome of decision.
Statement	▪	Statements associated with line covered.
	•	Not all statements associated with line covered.
Code that is reformatted by LDRA Testbed and does not match the original source code. For example, source code with <code>#include</code> statements to include other files, and source code with <code>#define</code> statements for macros.  For detailed coverage information, refer to the LDRA Testbed report.	=> $\Sigma$	Zero coverage — probes within source code line or files included by source code line not exercised.
	=> $\Sigma$	Coverage probes within source code line or any included file partially exercised.
	$\Sigma$	Coverage probes within source code line or included files fully exercised.

## BullseyeCoverage Information

The cumulative coverage data in a code generation report is derived from instrumented files associated with your latest top-model simulation **and** coverage data collected from

simulations with other top models that share referenced models with your current top model.

```

File: rtwdemo_sil_topmodel.c
BullseyeCoverage code coverage enabled
Function: 100% Condition/decision: 50%
1 /*
2 * File: rtwdemo_sil_topmodel.c
3 *
4 * Code generated for Simulink model 'rtwdemo_sil_topmodel'.
5 *
6 * Model version : 1.208
7 * Simulink Coder version : 8.2 (R2012a)
8 * TLC version : 8.2 (Oct 7 2011)
9 * C/C++ source code generated on : Tue Oct 18 11:33:01 2011
10 *
11 * Target selection: ert.tlc
12 * Embedded hardware selection: Specified
13 * Code generation objectives: Unspecified
14 * Validation result: Not run
15 */
16
17 #include "rtwdemo_sil_topmodel.h"
18
19 /* Block signals and states (auto storage) */
20 rtWork rtWork;
21
22 /* External inputs (root inport signals with auto storage) */

```

The software provides BullseyeCoverage annotations in the code generation report to help you to review code coverage.

This example shows two kinds of annotations. At line 41, TF indicates that the `if` decision had both true and false outcomes during the simulation. At line 52, `=>F` indicates that the `if` decision was false only during the simulation.

```

TF 41 if (rtU.reset) {
42 rtDWork.PreviousOutput_DSTATE = 20U;
43 }
44
45 /* Switch: '<Root>/Switch' incorporates:
46 * Constant: '<Root>/C1'
47 * Constant: '<Root>/C5'
48 * Inport: '<Root>/ticks_to_count'
49 * RelationalOperator: '<Root>/upper_GE_input'
50 * Sum: '<Root>/Add'
51 */
=>F 52 if ((uint8_T)((uint32_T)rtU.ticks_to_count + (uint32
53 rtDWork.PreviousOutput_DSTATE) == 40)

```

The following table describes the BullseyeCoverage code annotations that you might see in a code generation report produced by a SIL simulation.

Code feature	Annotation symbol	What happened during simulation
Decision	=>	Decision not executed.
	TF	Decision evaluated both true and false.

Code feature	Annotation symbol	What happened during simulation
	=>T	Decision evaluated true only.
	=>F	Decision evaluated false only.
Function	=>	Function not called.
	Fcn	Function called.
Switch label	=>	Switch command not used.
	Sw	Switch command used.
Constant	k	Decision or condition was constant, which did not allow any variation in coverage.
Condition	=>	Condition not encountered.
	tf	Condition evaluated both true and false.
	=>t	Condition evaluated true only.
	=>f	Condition evaluated false only.
Try	=>	Try block never completed.
	Try	Try block covered.
Catch	=>	Catch block not covered.
	Cat	Catch block covered.

## Code Coverage Tool Support

Embedded Coder code coverage provides the following support for the BullseyeCoverage and LDRA Testbed tools.

Operating system	BullseyeCoverage		LDRA Testbed	
	Version supported	Compiler supported	Version supported	Compiler supported
Windows	8.9.37	Microsoft Visual C++ (MSVC)	9.4.6	<ul style="list-style-type: none"> <li>• Microsoft Visual C++ (MSVC)</li> <li>• LCC</li> <li>• MinGW</li> </ul>
Linux	8.9.37	gcc	9.4.6	gcc
Mac	Not supported		Not supported	

### Related Examples

- “Configure Code Coverage with Third-Party Tools” on page 67-10
- “Select and Configure Compiler or IDE”

## Tips and Limitations

### Right-Click Subsystem Build Unsupported for Code Coverage

The software does not support right-click builds for subsystems if a code coverage tool is specified.

### BullseyeCoverage License Wait

When you build your model, you might have to wait for a BullseyeCoverage license. If you want to see information about the wait, before you build your model, select **Configuration Parameters > All Parameters > Verbose build**.

### Current Working Folder Cannot be UNC Path

If your MATLAB current working folder is a Universal Naming Convention (UNC) path, code coverage fails.

### Characters in matlabroot and File Path

If `matlabroot` or the path to your generated files contains a space or the `.` (period) character, code coverage might fail.

### Header Files with Identical Names

Consider a model that is configured for LDRA Testbed code coverage. During the build process, if the software detects two header files with the same name in the folder for generated code, the software generates an error.

### Code Coverage for Source Files in Shared Utility Folders

The software supports code coverage for source files generated in shared utility folders. If you configure code coverage for a model that uses shared utility code generation, when you build the model, you also build all source files in the shared utilities folder with code coverage enabled.

Whenever you build a model, the code coverage settings of the model must be consistent with source files that you previously built in the shared utilities folder. Otherwise, the

software reports that code in the shared utilities folder is inconsistent with the current model configuration and must be rebuilt. For example, if you run a SIL simulation for a model with code coverage enabled and then run a SIL simulation for another model with code coverage disabled, the software must rebuild all source files in the shared utilities folder.

## BullseyeCoverage Behavior with Inline Macros

The BullseyeCoverage tool, by default, does not provide code coverage data for inline macros.

For example, if a model generates a file `slprj/ert/_sharedutils/rt_SATURATE.h` that contains the macro

```
#define rt_SATURATE(sig,ll,ul) (((sig) >= (ul)) ? (ul) : (((sig) <= (ll)) ? (ll) : (sig)))
```

and the macro is in `sat_ert_rtw/sat.c`, then the coverage report provides a measurement for `sat.c`, but no coverage data for the conditions within the macro `rt_SATURATE`.

To configure the BullseyeCoverage tool to provide code coverage data for inline macros:

- 1 Open the BullseyeCoverage Browser.
- 2 Select **Tools > Options** to open the Options dialog box.
- 3 On the **Build** tab, select the **Instrument macro expansions** check box.
- 4 Click **OK**.
- 5 Rerun your simulation.

Alternatively, you can add the text `-macro` to the BullseyeCoverage configuration file. For more information, go to [www.bullseye.com/help](http://www.bullseye.com/help).

## SIL and PIL Simulations with Open LDRA Testbed

If you enable code coverage with the LDRA Testbed tool, you must verify that the LDRA Testbed GUI is not open when you run your SIL or PIL simulation. If the set name in the LDRA Testbed GUI differs from the set name used by the SIL or PIL simulation, the SIL or PIL simulation fails.

## Minor SIL and PIL Differences for LDRA Testbed

The target connectivity API supports code coverage with LDRA Testbed for top-model and Model block PIL.

There are minor differences in the code coverage information collected during SIL and PIL simulations. In particular, with PIL, the software does not explicitly show function exit point coverage. However, you can infer the coverage of function exit points by examining statement coverage.

## PIL Zero Coverage LDRA Testbed Annotations

For a PIL simulation with LDRA Testbed code coverage specified, there might be some source files where the recorded coverage is zero. In this case, the software provides summary information indicating that:

- There is coverage to measure.
- The coverage is zero.

You do not see information for individual probes on each line. The displayed summary information has an associated annotation tooltip:

0 out of  $N$  coverage probes were exercised (detailed breakdown unavailable)

## PIL Support for BullseyeCoverage

Code coverage with BullseyeCoverage is available for top-model and Model block PIL provided your PIL application can write directly to the host file system. Your target for the PIL application must provide `fopen` and `fread` access to the host file system.

If code coverage is not available when you run the PIL application on your target hardware, you might be able to collect code coverage measurements by running the PIL application on an instruction set simulator that supports direct file I/O with the host file system.

## Modify Legacy Code

If you modify legacy code and rerun a SIL or PIL simulation, the legacy code is recompiled. However, the code from the model may be up-to-date. In this case, the code generation report is not updated and does not show the modified legacy code. Instead, the code coverage information for the modified legacy code is displayed with reference to the original legacy code. You must regenerate the report. For more information, see “Limitation”.

## IDE Link Does Not Support LDRA Testbed

When you generate code for IDE Link, you cannot use LDRA Testbed for SIL or PIL code coverage. Specifically, this limitation applies when you use the following settings together:

- **Configuration Parameters > Code Generation > System target file:**  
`idelink_ert.tlc`
- **Configuration Parameters > Code Generation > Verification > Code coverage tool:** LDRA Testbed.

## Customize Generated ASAP2 File

### In this section...

- “About ASAP2 File Customization” on page 69-2
- “ASAP2 File Structure on the MATLAB Path” on page 69-2
- “Customize the Contents of the ASAP2 File” on page 69-3
- “ASAP2 Templates” on page 69-4
- “Customize Computation Method Names” on page 69-6
- “Suppress Computation Methods for FIX\_AXIS” on page 69-7

### About ASAP2 File Customization

The Embedded Coder product provides a number of Target Language Compiler (TLC) files to enable you to customize the ASAP2 file generated from a Simulink model.

### ASAP2 File Structure on the MATLAB Path

The ASAP2 related files are organized within the folders identified below:

- TLC files for generating ASAP2 file

The *matlabroot/rtw/c/tlc/mw* (open) folder contains TLC files that generate ASAP2 files, *asamlib.tlc*, *asap2lib.tlc*, *asap2main.tlc*, and *asap2grouplib.tlc*. These files are included by the selected **System target file**. (See “Targets Supporting ASAP2” on page 44-3.)

- ASAP2 target files

The *matlabroot/toolbox/rtw/targets/asap2/asap2* (open) folder contains the ASAP2 system target file and other control files.

- Customizable TLC files

The *matlabroot/toolbox/rtw/targets/asap2/asap2/user* (open) folder contains files that you can modify to customize the content of your ASAP2 files.

- ASAP2 templates

The `matlabroot/toolbox/rtw/targets/asap2/asap2/user/templates` (open) folder contains templates that define each type of CHARACTERISTIC in the ASAP2 file.

## Customize the Contents of the ASAP2 File

The ASAP2 related TLC files enable you to customize the appearance of the ASAP2 file generated from a Simulink model. Most customization is done by modifying or adding to the files contained in the `matlabroot/toolbox/rtw/targets/asap2/asap2/user` (open) folder. This section refers to this folder as the `asap2/user` folder.

The user-customizable files provided are divided into two groups:

- The *static* files define the parts of the ASAP2 file that are related to the environment in which the generated code is used. They describe information specific to the user or project. The static files are not model dependent.
- The *dynamic* files define the parts of the ASAP2 file that are generated based on the structure of the source model.

The procedure for customizing the ASAP2 file is as follows:

- 1 Make a copy of the `asap2/user` folder before making modifications.
- 2 Remove the old `asap2/user` folder from the MATLAB path, or add the new `asap2/user` folder to the MATLAB path above the old folder. The MATLAB session uses the ASAP2 setup file, `asap2setup.tlc`, in the new folder.

`asap2setup.tlc` specifies the folders and files to include in the TLC path during the ASAP2 file generation process. Modify `asap2setup.tlc` to control the folders and folders included in the TLC path.

- 3 Modify the static parts of the ASAP2 file. These include
  - Project and header symbols, which are specified in `asap2setup.tlc`
  - Static sections of the file, such as file header and tail, A2ML, MOD\_COMMON, and so on. These are specified in `asap2userlib.tlc`.
  - Specify the appearance of the dynamic contents of the ASAP2 file by modifying the existing ASAP2 templates or by defining new ASAP2 templates. Sections of the ASAP2 file affected include

RECORD\_LAYOUT: modify parts of the ASAP2 template files.

**CHARACTERISTIC:** modify parts of the ASAP2 template files. For more information on modifying the appearance of **CHARACTERISTIC** records, see “ASAP2 Templates” on page 69-4.

- **MEASUREMENT:** These are specified in `asap2userlib.tlc`.
- **COMPU\_METHOD:** These are specified in `asap2userlib.tlc`.

## ASAP2 Templates

The appearance of **CHARACTERISTIC** records in the ASAP2 file is controlled using a different template for each type of **CHARACTERISTIC**. The `asap2/user` folder contains template definition files for scalars, 1-D Lookup Table blocks and 2-D Lookup Table blocks. You can modify these template definition files, or you can create additional templates as required.

The procedure for creating a new ASAP2 template is as follows:

- 1 Create a template definition file. See “Create Template Definition Files” on page 69-4.
- 2 Include the template definition file in the TLC path. The path is specified in the ASAP2 setup file, `asap2setup.tlc`.

### Create Template Definition Files

This section describes the components that make up an ASAP2 template definition file. This description is in the form of code examples from `asap2lookup1d.tlc`, the template definition file for the Lookup1D template. This template corresponds to the Lookup1D parameter group.

---

**Note** When creating a new template, use the corresponding parameter group name in place of `Lookup1D` in the code shown.

---

### Template Registration Function

The input argument is the name of the parameter group associated with this template:

```
%<LibASAP2RegisterTemplate("Lookup1D")>
```

### RECORD\_LAYOUT Name Definition Function

Record layout names (aliases) can be arbitrarily specified for each data type. This function is used by the other components of this file.

```
%function ASAP2UserFcnRecordLayoutAlias_Lookup1D(dtId) void
 %switch dtId
 %case tSS_UINT8
 %return "Lookup1D_UBYTE"
 ...
 %endswitch
%endfunction
```

### Function to Write RECORD\_LAYOUT Definitions

This function writes RECORD\_LAYOUT definitions associated with this template. The function is called by the built-in functions involved in the ASAP2 file generation process. The function name must be defined as shown, with the template name after the underscore:

```
%function ASAP2UserFcnWriteRecordLayout_Lookup1D() Output
 /begin RECORD_LAYOUT
 %<ASAP2UserFcnRecordLayoutAlias_Lookup1D(tSS_UINT8)>
 ...
 /end RECORD_LAYOUT
%endfunction
```

### Function to Write the CHARACTERISTIC

This function writes the CHARACTERISTIC associated with this template. The function is called by the built-in functions involved in the ASAP2 file generation process. The function name must be defined as shown, with the template name after the underscore.

The input argument to this function is a pointer to a parameter group record. The example shown is for a LOOKUP1D parameter group that has two members. The references to the associated x and y data records are obtained from the parameter group record as shown.

This function calls a number of built-in functions to obtain the required information. For example, LibASAP2GetSymbol returns the symbol (name) for the specified data record:

```
%function ASAP2UserFcnWriteCharacteristic_Lookup1D(paramGroup)
Output
```

```

%assign xParam = paramGroup.Member[0].Reference
%assign yParam = paramGroup.Member[1].Reference
%assign dtId = LibASAP2GetDataTypeId(xParam)
 /begin CHARACTERISTIC
 /* Name */ %<LibASAP2GetSymbol(xParam)>
 /* Long identifier */ %<LibASAP2GetLongID(xParam)>
 ...
 /end CHARACTERISTIC
%endfunction

```

## Customize Computation Method Names

In generated ASAP2 files, computation methods translate the electronic control unit (ECU) internal representation of measurement and calibration quantities into a physical model oriented representation. Simulink Coder software provides the ability to customize the names of computation methods. You can provide names that are more intuitive, enhancing ASAP2 file readability, or names that meet organizational requirements.

To customize computation method names, use the MATLAB function `getCompuMethodName`, which is defined in `matlabroot/toolbox/rtw/targets/asap2/asap2/user/getCompuMethodName.m`.

The `getCompuMethodName` function constructs a computation method name. The function prototype is

```
cmName = getCompuMethodName(dataTypeName, cmUnits)
```

where *dataTypeName* is the name of the data type associated with the computation method, *cmUnits* is the units as specified in the `Unit` property of a `Simulink.Parameter` or `Simulink.Signal` object (for example, rpm or m/s), and *cmName* returns the constructed computation method name.

The default constructed name returned by the function has the format

```
<localPrefix><datatype>_<cmUnits>
```

where

- `<local_Prefix>` is a local prefix, `CM_`, defined in `matlabroot/toolbox/rtw/targets/asap2/asap2/user/getCompuMethodName.m`.
- `<datatype>` and `<cmUnits>` are the arguments you specified to the `getCompuMethodName` function.

Additionally, in the generated ASAP2 file, the constructed name is prefixed with `<ASAP2CompuMethodName_Prefix>`, a model prefix defined in `matlabroot/toolbox/rtw/targets/asap2/asap2/user/asap2setup.tlc`.

For example, if you call the `getCompuMethodName` function with the `dataTypeName` argument `'int16'` and the `cmUnits` argument `'m/s'`, and generate an ASAP2 file for a model named `myModel`, the computation method name would appear in the generated file as follows:

```
/begin COMPU_METHOD
 /* Name of CompuMethod */ myModel_CM_int16_m_s
 /* Units */ "m/s"
 ...
/end COMPU_METHOD
```

## Suppress Computation Methods for FIX\_AXIS

Versions 1.51 and later of the ASAP2 specification state that for certain cases of lookup table axis descriptions (integer data type and no doc units), a computation method is not required and the Conversion Method parameter must be set to the value `NO_COMPU_METHOD`. You can control whether or not computation methods are suppressed when not required using the Target Language Compiler (TLC) option `ASAP2GenNoCompuMethod`. This TLC option is disabled by default. If you enable the option, ASAP2 file generation does not generate computation methods for lookup table axis descriptions when not required, and instead generates the value `NO_COMPU_METHOD`. For example:

```
/begin CHARACTERISTIC
/* Name */
lu1d_fix_axisTable_data
...
/begin AXIS_DESCR
 ...
 /* Conversion Method */
NO_COMPU_METHOD
 ...
/end CHARACTERISTIC
```

The `ASAP2GenNoCompuMethod` option is defined in `matlabroot/toolbox/rtw/targets/asap2/asap2/user/asap2setup.tlc`.

## Create a Transport Layer for External Communication

### In this section...

“About Creating a Transport Layer for External Communication” on page 69-8

“Design of External Mode” on page 69-8

“External Mode Communications Overview” on page 69-11

“External Mode Source Files” on page 69-12

“Implement a Custom Transport Layer” on page 69-16

### About Creating a Transport Layer for External Communication

This section helps you to connect your custom target by using external mode using your own low-level communications layer. The topics include:

- An overview of the design and operation of external mode
- A description of external mode source files
- Guidelines for modifying the external mode source files and building an executable to handle the tasks of the default `ext_comm` MEX-file

This section assumes that you are familiar with the execution of Simulink Coder programs, and with the basic operation of external mode.

### Design of External Mode

External mode communication between the Simulink engine and a target system is based on a client/server architecture. The client (the Simulink engine) transmits messages requesting the server (target) to accept parameter changes or to upload signal data. The server responds by executing the request.

A low-level *transport layer* handles physical transmission of messages. Both the Simulink engine and the model code are independent of this layer. Both the transport layer and code directly interfacing to the transport layer are isolated in separate modules that format, transmit, and receive messages and data packets.

This design makes it possible for different targets to use different transport layers. The GRT, ERT, and RSim targets support host/target communication by using TCP/IP and

RS-232 (serial) communication. The Simulink Desktop Real-Time target supports shared memory communication. The Wind River Systems Tornado® target supports TCP/IP only.

The Simulink Coder product provides full source code for both the client and server-side external mode modules, as used by the GRT, ERT, Rapid Simulation, and Tornado targets, and the Simulink Desktop Real-Time and Simulink Real-Time products. The main client-side module is `ext_comm.c`. The main server-side module is `ext_svr.c`.

These two modules call the specified transport layer through the following source files.

### Built-In Transport Layer Implementations

Protocol	Client or Server?	Source Files
TCP/IP	Client (host)	<ul style="list-style-type: none"> <li><code>matlabroot/toolbox/coder/simulinkcoder_core/ext_mode/host/common/rtiostream_interface.c</code></li> <li><code>matlabroot/rtw/c/src/rtiostream/rtiostreamtcpip/rtiostream_tcpip.c</code></li> </ul>
	Server (target)	<ul style="list-style-type: none"> <li><code>matlabroot/rtw/c/src/ext_mode/common/rtiostream_interface.c</code></li> <li><code>matlabroot/rtw/c/src/rtiostream/rtiostreamtcpip/rtiostream_tcpip.c</code></li> </ul>
Serial	Client (host)	<ul style="list-style-type: none"> <li><code>matlabroot/toolbox/coder/simulinkcoder_core/ext_mode/host/serial/ext_serial_transport.c</code></li> <li><code>matlabroot/rtw/c/src/rtiostream/rtiostreamserial/rtiostream_serial.c</code></li> </ul>
	Server (target)	<ul style="list-style-type: none"> <li><code>matlabroot/rtw/c/src/ext_mode/serial/ext_svr_serial_transport.c</code></li> <li><code>matlabroot/rtw/c/src/rtiostream/rtiostreamserial/rtiostream_serial.c</code></li> </ul>

For serial communication, the modules `ext_serial_transport.c` and `rtiostream_serial.c` implement the client-side transport functions and the modules `ext_svr_serial_transport.c` and `rtiostream_serial.c` implement the corresponding server-side functions. For TCP/IP communication, the modules `rtiostream_interface.c` and `rtiostream_tcpip.c` implement both client-side and server-side functions. You can edit copies of these files (but do not modify the originals).

You can support external mode using your own low-level communications layer by creating similar files using the following templates:

- Client (host) side: `matlabroot/rtw/c/src/rtiostream/rtiostreamtcpip/rtiostream_tcpip.c` (TCP/IP) or `matlabroot/rtw/c/src/rtiostream/rtiostreamserial/rtiostream_serial.c` (serial)
- Server (target) side: `matlabroot/rtw/c/src/rtiostream/rtiostreamtcpip/rtiostream_tcpip.c` (TCP/IP) or `matlabroot/rtw/c/src/rtiostream/rtiostreamserial/rtiostream_serial.c` (serial)

The file `rtiostream_interface.c` is an interface between the external mode protocol and an `rtiostream` communications channel. For more details on implementing an `rtiostream` communications channel, see “Communications `rtiostream` API” on page 64-45 in the Embedded Coder documentation. Implement your `rtiostream` communications channel by using the documented interface to avoid having to make changes to the file `rtiostream_interface.c` or other external mode related files.

---

**Note** Do not modify working source files. Use the templates provided in the `/custom` or `/rtiostream` folder as starting points, guided by the comments within them.

---

You need only provide code that implements low-level communications. You need not be concerned with issues such as data conversions between host and target, or with the formatting of messages. The Simulink Coder software handles these functions.

On the client (Simulink engine) side, communications are handled by `ext_comm` (for TCP/IP) and `ext_serial_win32_comm` (for serial) MEX-files.

On the server (target) side, external mode modules are linked into the target executable. This takes place automatically if the **External mode** code generation option is selected at code generation time, based on the **External mode transport** option selected in the target code generation options dialog box. These modules, called from the main program and the model execution engine, are independent of the generated model code.

The general procedure for implementing your own client-side low-level transport protocol is as follows:

- 1 Edit the template `rtiostream_tcpip.c` to replace low-level communication calls with your own communication calls.
- 2 Generate a MEX-file executable for your custom transport.

- 3 Register your new transport layer with the Simulink software, so that the transport can be selected for a model using the **Interface** pane of the Configuration Parameters dialog box.

For more details, see “Create a Custom Client (Host) Transport Protocol” on page 69-17.

The general procedure for implementing your own server-side low-level transport protocol is as follows:

- 1 Edit the template `rtiostream_tcpip.c` to replace low-level communication calls with your own communication calls. Typically this involves writing or integrating device drivers for your target hardware.
- 2 Modify template makefiles to support the new transport.

For more details, see “Create a Custom Server (Target) Transport Protocol” on page 69-21.

## External Mode Communications Overview

This section gives a high-level overview of how a Simulink Coder generated program communicates with Simulink external mode. This description is based on the TCP/IP version of external mode that ships with the Simulink Coder product.

For communication to take place,

- The server (target) program must have been built with the conditional `EXT_MODE` defined. `EXT_MODE` is defined in the `model.mk` file if the **External mode** code generation option was selected at code generation time.
- Both the server program and the Simulink software must be executing. This does not mean that the model code in the server system must be executing. The server can be waiting for the Simulink engine to issue a command to start model execution.

The client and server communicate by using bidirectional sockets carrying packets. Packets consist either of *messages* (commands, parameter downloads, and responses) or *data* (signal uploads).

If the target program was invoked with the `-w` command-line option, the program enters a wait state until it receives a message from the host. Otherwise, the program begins execution of the model. While the target program is in a wait state, the Simulink engine can download parameters to the target and configure data uploading.

When the user chooses the **Connect to Target** option from the **Simulation** menu, the host initiates a handshake by sending an `EXT_CONNECT` message. The server responds with information about itself. This information includes

- Checksums. The host uses model checksums to determine that the target code is an exact representation of the current Simulink model.
- Data format information. The host uses this information when formatting data to be downloaded, or interpreting data that has been uploaded.

At this point, host and server are connected. The server is either executing the model or in the wait state. (In the latter case, the user can begin model execution by selecting **Start Real-Time Code** from the **Simulation** menu.)

During model execution, the message server runs as a background task. This task receives and processes messages such as parameter downloads.

Data uploading comprises both foreground execution and background servicing of the signal packets. As the target computes model outputs, it also copies signal values into data upload buffers. This occurs as part of the task associated with each task identifier (`tid`). Therefore, data collection occurs in the foreground. Transmission of the collected data, however, occurs as a background task. The background task sends the data in the collection buffers to the Simulink engine by using data packets.

The host initiates most exchanges as messages. The target usually sends a response confirming that it has received and processed the message. Examples of messages and commands are:

- Connection message / connection response
- Start target simulation / start response
- Parameter download / parameter download response
- Arm trigger for data uploading / arm trigger response
- Terminate target simulation / target shutdown response

Model execution terminates when the model reaches its final time, when the host sends a terminate command, or when a Stop Simulation block terminates execution. On termination, the server informs the host that model execution has stopped, and shuts down its socket. The host also shuts down its socket, and exits external mode.

## External Mode Source Files

- “Client (Host) MEX-file Interface Source Files” on page 69-13

- “Server (Target) Source Files” on page 69-14
- “Other Files in the Server Folder” on page 69-16

### Client (Host) MEX-file Interface Source Files

The source files for the MEX-file interface component are located in the folder *matlabroot/toolbox/coder/simulinkcoder\_core/ext\_mode/host* (open), except as noted:

- `common/ext_comm.c`

This file is the core of external mode communication. It acts as a relay station between the target and the Simulink engine. `ext_comm.c` communicates to the Simulink engine by using a shared data structure, `ExternalSim`. It communicates to the target by using calls to the transport layer.

Tasks carried out by `ext_comm.c` include establishment of a connection with the target, downloading of parameters, and termination of the connection with the target.

- `common/rtiostream_interface.c`

This file is an interface between the external mode protocol and an `rtiostream` communications channel. For more details on implementing an `rtiostream` communications channel, see “Communications `rtiostream` API” on page 64-45 in the Embedded Coder documentation. Implement your `rtiostream` communications channel using the documented interface to avoid having to change the file `rtiostream_interface.c` or other external mode related files.

- `matlabroot/rtw/c/src/rtiostream/rtiostreamtcpip/rtiostream_tcpip.c`

This file implements required TCP/IP transport layer functions. The version of `rtiostream_tcpip.c` shipped with the Simulink Coder software uses TCP/IP functions including `recv()`, `send()`, and `socket()`.

- `matlabroot/rtw/c/src/rtiostream/rtiostreamserial/rtiostream_serial.c`

This file implements required serial transport layer functions. The version of `rtiostream_serial.c` shipped with the Simulink Coder software uses serial functions including `ReadFile()`, `WriteFile()`, and `CreateFile()`.

- `serial/ext_serial_transport.c`

This file implements required serial transport layer functions.

`ext_serial_transport.c` includes `ext_serial_utils.c`, which is located in `matlabroot/rtw/c/src/ext_mode/serial` (open) and contains functions common to client and server sides.

- `common/ext_main.c`

This file is a MEX-file wrapper for external mode. `ext_main.c` interfaces to the Simulink engine by using the standard `mexFunction` call. (See the `mexFunction` reference page and “MATLAB API for Other Languages” for more information.)

`ext_main.c` contains a function dispatcher, `esGetAction`, that sends requests from the Simulink engine to `ext_comm.c`.

- `common/ext_convert.c` and `ext_convert.h`

This file contains functions used for converting data from host to target formats (and vice versa). Functions include byte-swapping (big to little- endian), conversion from non-IEEE floats to IEEE doubles, and other conversions. These functions are called both by `ext_comm.c` and directly by the Simulink engine (by using function pointers).

---

**Note** You do not need to customize `ext_convert` to implement a custom transport layer. However, you might want to customize `ext_convert` for the intended target. For example, if the target represents the `float` data type in Texas Instruments format, `ext_convert` must be modified to perform a Texas Instruments to IEEE conversion.

---

- `common/extsim.h`

This file defines the `ExternalSim` data structure and access macros. This structure is used for communication between the Simulink engine and `ext_comm.c`.

- `common/extutil.h`

This file contains only conditionals for compilation of the `assert` macro.

- `common/ext_transport.h`

This file defines functions that must be implemented by the transport layer.

### Server (Target) Source Files

These files are linked into the `model.exe` executable. They are located within `matlabroot/rtw/c/src/ext_mode` (open) except as noted.

- `common/ext_svr.c`

`ext_svr.c` is analogous to `ext_comm.c` on the host, but generally is responsible for more tasks. It acts as a relay station between the host and the generated code. Like `ext_comm.c`, `ext_svr.c` carries out tasks such as establishing and terminating connection with the host. `ext_svr.c` also contains the background task functions that either write downloaded parameters to the target model, or extract data from the target data buffers and send it back to the host.

- `common/rtiostream_interface.c`

This file is an interface between the external mode protocol and an `rtiostream` communications channel. For more details on implementing an `rtiostream` communications channel, see “Communications `rtiostream` API” on page 64-45 in the Embedded Coder documentation. Implement your `rtiostream` communications channel by using the documented interface to avoid having to change the file `rtiostream_interface.c` or other external mode related files.

- `matlabroot/rtw/c/src/rtiostream/rtiostreamtcpip/rtiostream_tcpip.c`

This file implements required TCP/IP transport layer functions. The version of `rtiostream_tcpip.c` shipped with the Simulink Coder software uses TCP/IP functions including `recv()`, `send()`, and `socket()`.

- `matlabroot/rtw/c/src/rtiostream/rtiostreamserial/rtiostream_serial.c`

This file implements required serial transport layer functions. The version of `rtiostream_serial.c` shipped with the software uses serial functions including `ReadFile()`, `WriteFile()`, and `CreateFile()`.

- `matlabroot/rtw/c/src/rtiostream.h`

This file defines the `rtIOStream*` functions implemented in `rtiostream_tcpip.c`.

- `serial/ext_svr_serial_transport.c`

This file implements required serial transport layer functions. `ext_svr_serial_transport.c` includes `serial/ext_serial_utils.c`, which contains functions common to client and server sides.

- `common/updown.c`

`updown.c` handles the details of interacting with the target model. During parameter downloads, `updown.c` does the work of installing the new parameters into the

model's parameter vector. For data uploading, `updown.c` contains the functions that extract data from the model's `blockio` vector and write the data to the upload buffers. `updown.c` provides services both to `ext_svr.c` and to the model code (for example, `grt_main.c`). It contains code that is called by using the background tasks of `ext_svr.c` as well as code that is called as part of the higher priority model execution.

- `matlabroot/rtw/c/src/dt_info.h` (included by generated model build file `model.h`)

These files contain data type transition information that allows access to multi-data type structures across different computer architectures. This information is used in data conversions between host and target formats.

- `common/updown_util.h`

This file contains only conditionals for compilation of the `assert` macro.

- `common/ext_svr_transport.h`

This file defines the `Ext*` functions that must be implemented by the server (target) transport layer.

### Other Files in the Server Folder

- `common/ext_share.h`

Contains message code definitions and other definitions required by both the host and target modules.

- `serial/ext_serial_utils.c`

Contains functions and data structures for communication, MEX link, and generated code required by both the host and target modules of the transport layer for serial protocols.

- The serial transport implementation includes the additional files
  - `serial/ext_serial_pkt.c` and `ext_serial_pkt.h`
  - `serial/ext_serial_port.h`

### Implement a Custom Transport Layer

- “Requirements for Custom Transport Layers” on page 69-17

- “Create a Custom Client (Host) Transport Protocol” on page 69-17
- “MATLAB Commands to Rebuild ext\_comm and ext\_serial\_win32 MEX-Files” on page 69-18
- “Register a Custom Client (Host) Transport Protocol” on page 69-20
- “Create a Custom Server (Target) Transport Protocol” on page 69-21
- “Serial Receive Buffer Smaller than 64 Bytes” on page 69-23

### Requirements for Custom Transport Layers

- By default, `ext_svr.c` and `updown.c` use `malloc` to allocate buffers in target memory for messages, data collection, and other purposes, although there is also an option to preallocate static memory. If your target uses another memory allocation scheme, you must modify these modules.
- The target is assumed to support both `int32_T` and `uint32_T` data types.

### Create a Custom Client (Host) Transport Protocol

To implement the client (host) side of your low-level transport protocol,

- 1 Edit the template file `matlabroot/rtw/c/src/rtiostream/rtiostreamtcpip/rtiostream_tcpip.c` to replace low-level communication calls with your own communication calls.
  - a Copy and rename the file to `rtiostream_name.c` (replacing *name* with a name meaningful to you).
  - b Replace the functions `rtIOStreamOpen`, `rtIOStreamClose`, `rtIOStreamSend`, and `rtIOStreamRecv` with functions (of the same name) that call your low-level communication primitives. These functions are called from other external mode modules via `rtiostream_interface.c`. For more information, see “Communications `rtiostream` API” on page 64-45 in the Embedded Coder documentation.
  - c Build your `rtiostream` implementation into a shared library that exports the `rtIOStreamOpen`, `rtIOStreamClose`, `rtIOStreamRecv` and `rtIOStreamSend` functions.
- 2 Build the customized MEX-file executable using the MATLAB `mex` function. See “MATLAB Commands to Rebuild ext\_comm and ext\_serial\_win32 MEX-Files” on page 69-18 for examples of `mex` invocations.

Do not replace the existing `ext_comm` MEX-file if you want to preserve its existing function. Instead, use the `-output` option to name the resulting executable (for example, `mex -output ext_myrtiostream_comm ...` builds `ext_myrtiostream_comm.mexext`, on Windows platforms).

- 3 Register your new client transport layer with the Simulink software, so that the transport can be selected for a model using the **Interface** pane of the Configuration Parameters dialog box. For details, see “Register a Custom Client (Host) Transport Protocol” on page 69-20.

Sample commands for rebuilding external mode MEX-files are listed in “MATLAB Commands to Rebuild `ext_comm` and `ext_serial_win32` MEX-Files” on page 69-18.

### MATLAB Commands to Rebuild `ext_comm` and `ext_serial_win32` MEX-Files

The following table lists the commands for building the standard `ext_comm` and `ext_serial_win32` modules on PC and UNIX platforms.

Platform	Commands
Windows, TCP/IP	<pre>&gt;&gt; cd (matlabroot) &gt;&gt; mex toolbox\coder\simulinkcoder_core\ext_mode\host\common\ext_comm.c ... toolbox\coder\simulinkcoder_core\ext_mode\host\common\ext_convert.c ... toolbox\coder\simulinkcoder_core\ext_mode\host\common\rtiostream_interface.c ... toolbox\coder\simulinkcoder_core\ext_mode\host\common\ext_util.c ... -Irtw\c\src -Irtw\c\src\rtiostream\utils ... -Irtw\c\src\ext_mode\common ... -Ittoolbox\coder\simulinkcoder_core\ext_mode\host\common ... -Ittoolbox\coder\simulinkcoder_core\ext_mode\host\common\include ... -lmwruntimeutils -lsl_services ... -DEXTMODE_TCPIP_TRANSPORT ... -DSL_EXT_DLL -output toolbox\coder\simulinkcoder_core\ext_comm</pre> <p><b>Note:</b> The <code>rtiostream_interface.c</code> function defines <code>RTIOSTREAM_SHARED_LIB</code> as <code>libmwruntimeutils</code> and dynamically loads the MathWorks TCP/IP <code>rtiostream</code> shared library. Modify this file if you need to load a different <code>rtiostream</code> shared library.</p>
Linux, TCP/IP	<p>Use the Windows commands, with these changes:</p> <ul style="list-style-type: none"> <li>• Change <code>-DSL_EXT_DLL</code> to <code>-DSL_EXT_S0</code>.</li> <li>• Change <code>-lsl_services</code> to <code>-lmwsl_services</code>.</li> <li>• Replace back slashes with forward slashes.</li> </ul>

Platform	Commands
Mac, TCP/IP	<p>Use the Windows commands, with these changes:</p> <ul style="list-style-type: none"> <li>• Change <code>-DSL_EXT_DLL</code> to <code>-DSL_EXT_DYLIB</code>.</li> <li>• Change <code>-lsl_services</code> to <code>-lmwsl_services</code>.</li> <li>• Replace back slashes with forward slashes.</li> </ul>
Windows, serial	<pre data-bbox="348 489 1337 835">&gt;&gt; cd (matlabroot) &gt;&gt; mex toolbox\coder\simulinkcoder_core\ext_mode\host\common\ext_comm.c ... toolbox\coder\simulinkcoder_core\ext_mode\host\common\ext_convert.c ... toolbox\coder\simulinkcoder_core\ext_mode\host\serial\ext_serial_transport.c ... toolbox\coder\simulinkcoder_core\ext_mode\host\serial\ext_serial_pkt.c ... toolbox\coder\simulinkcoder_core\ext_mode\host\serial\rtiostream_serial_interface.c ... toolbox\coder\simulinkcoder_core\ext_mode\host\common\ext_util.c ... -Irtw\c\src -Irtw\c\src\rtiostream\utils ... -Irtw\c\src\ext_mode\common ... -Irtw\c\src\ext_mode\serial ... -Itoolbox\coder\simulinkcoder_core\ext_mode\host\common ... -Itoolbox\coder\simulinkcoder_core\ext_mode\host\common\include ... -lmwrtiostreamutils -lsl_services ... -DEXTMODE_SERIAL_TRANSPORT -DSL_EXT_DLL ... -output toolbox\coder\simulinkcoder_core\ext_serial_win32_comm</pre> <p data-bbox="348 892 1337 1020"><b>Note:</b> The <code>rtiostream_interface.c</code> function defines <code>RTIOSTREAM_SHARED_LIB</code> as <code>libmwrtiostreamserial</code> and dynamically loads the MathWorks serial <code>rtiostream</code> shared library. Modify this file if you need to load a different <code>rtiostream</code> shared library.</p>
Linux, serial	<p>Use the Windows commands, with these changes:</p> <ul style="list-style-type: none"> <li>• Change <code>-DSL_EXT_DLL</code> to <code>-DSL_EXT_S0</code>.</li> <li>• Change <code>-lsl_services</code> to <code>-lmwsl_services</code>.</li> <li>• Replace back slashes with forward slashes.</li> </ul>
Mac, serial	<p>Use the Windows commands, with these changes:</p> <ul style="list-style-type: none"> <li>• Change <code>-DSL_EXT_DLL</code> to <code>-DSL_EXT_DYLIB</code>.</li> <li>• Change <code>-lsl_services</code> to <code>-lmwsl_services</code>.</li> <li>• Replace back slashes with forward slashes.</li> </ul>

---

**Note:** `mex` requires a compiler supported by the MATLAB API. See the `mex` reference page and “MATLAB API for Other Languages” for more information about the `mex` function.

---

### Register a Custom Client (Host) Transport Protocol

To register a custom client transport protocol with the Simulink software, you must add an entry of the following form to an `sl_customization.m` file on the MATLAB path:

```
function sl_customization(cm)
 cm.ExtModeTransports.add('stf.tlc', 'transport', 'mexfile', 'Level1');
% -- end of sl_customization
```

where

- `stf.tlc` is the name of the system target file for which the transport will be registered (for example, 'grt.tlc')
- `transport` is the transport name to display in the **Transport layer** menu on the **Interface** pane of the Configuration Parameters dialog box (for example, 'mytcpip')
- `mexfile` is the name of the transport's associated external interface MEX-file (for example, 'ext\_mytcpip\_comm')

You can specify multiple targets and/or transports with additional `cm.ExtModeTransports.add` lines, for example:

```
function sl_customization(cm)
 cm.ExtModeTransports.add('grt.tlc', 'mytcpip', 'ext_mytcpip_comm', 'Level1');
 cm.ExtModeTransports.add('ert.tlc', 'mytcpip', 'ext_mytcpip_comm', 'Level1');
% -- end of sl_customization
```

If you place the `sl_customization.m` file containing the transport registration information on the MATLAB path, your custom client transport protocol will be registered with each subsequent Simulink session. The name of the transport will appear in the **Transport layer** menu on the **Interface** pane of the Configuration Parameters dialog box. When you select the transport for your model, the name of the associated external interface MEX-file will appear in the noneditable **MEX-file name** field, as shown in the following figure.

External mode

External mode configuration

Transport layer:  MEX-file name: ext\_mytcpip\_comm

MEX-file arguments:

Static memory allocation

### Create a Custom Server (Target) Transport Protocol

The `rtIOStream*` function prototypes in `matlabroot/rtw/c/src/rtiostream.h` define the calling interface for both the server (target) and client (host) side transport layer functions.

- The TCP/IP implementations are in `matlabroot/rtw/c/src/rtiostream/rtiostreamtcpip/rtiostream_tcpip.c`.
- The serial implementations are in `matlabroot/rtw/c/src/rtiostream/rtiostreamserial/rtiostream_serial.c`.

---

**Note:** The `Ext*` function prototypes in `matlabroot/rtw/c/src/ext_mode/common/ext_svr_transport.h` are implemented in `matlabroot/rtw/c/src/ext_mode/common/rtiostream_interface.c` or `matlabroot/rtw/c/src/ext_mode/serial/rtiostream_serial_interface.c`. In most cases you will not need to modify `rtiostream_interface.c` or `rtiostream_serial_interface.c` for your custom TCP/IP or serial transport layer.

---

To implement the server (target) side of your low-level TCP/IP or serial transport protocol:

- 1 Edit the template `matlabroot/rtw/c/src/rtiostream/rtiostreamtcpip/rtiostream_tcpip.c` or `matlabroot/rtw/c/src/rtiostream/rtiostreamserial/rtiostream_serial.c` to replace low-level communication calls with your own communication calls.
  - a Copy and rename the file to `rtiostream_name.c` (replacing *name* with a name meaningful to you).

- b** Replace the functions `rtIOStreamOpen`, `rtIOStreamClose`, `rtIOStreamSend`, and `rtIOStreamRecv` with functions (of the same name) that call your low-level communication drivers.

You must implement the functions defined in `rtiostream.h`, and your implementations must conform to the prototypes defined in that file. Refer to the original `rtiostream_tcpip.c` or `rtiostream_serial.c` for guidance.

- 2** Incorporate the external mode source files for your transport layer into the model build process, according to your target type:

- If your target uses toolchain controls to configure a build, use a build process mechanism such as a post code generation command or a `before_make` hook function to make the transport files available to the build process. (For more information on the build process mechanisms, see “Customize Post-Code-Generation Build Processing”, “Customize Build Process with `STF_make_rtw_hook` File”, and “Customize Build Process with `sl_customization.m`”.) For example:

- Add the file created in the previous step to the build information:

```
path/rtiostream_name.c
```

- For TCP/IP, add the following file to the build information:

```
matlabroot/rtw/c/src/ext_mode/common/rtiostream_interface.c
```

- For serial, add the following files to the build information:

```
matlabroot/rtw/c/src/ext_mode/serial/ext_serial_pkt.c
matlabroot/rtw/c/src/ext_mode/serial/rtiostream_serial_interface.c
matlabroot/rtw/c/src/ext_mode/serial/ext_svr_serial_transport.c
```

- If your target uses template makefile controls to configure a build, modify template makefiles to support the new transport. Be sure to include the file created in the previous step, `rtiostream_name.c`. If you are writing your own template makefile, make sure that the `EXT_MODE` code generation option is defined. The generated makefile will then link `rtiostream_name.c`, `rtiostream_interface.c` or `rtiostream_serial_interface.c`, and other server code into your executable.

---

**Note:** For external mode, check that `rtIOStreamRecv` is not a blocking implementation. Otherwise, it might cause the external mode server to block until the host sends data through the `comm` layer.

---

### Serial Receive Buffer Smaller than 64 Bytes

For serial communication, if the serial receive buffer of your target is smaller than 64 bytes:

- 1 Update the following macro with the actual target buffer size:

```
#define TARGET_SERIAL_RECEIVE_BUFFER_SIZE 64
```

Implement the change in the following files:

```
matlabroot/rtw/c/src/ext_mode/serial/ext_serial_utils.c
matlabroot/toolbox/coder/simulinkcoder_core/ext_mode/host/serial/ext_serial_utils.c
```

- 2 Run the command to rebuild the `ext_serial_win32` MEX-file. See “MATLAB Commands to Rebuild `ext_comm` and `ext_serial_win32` MEX-Files” on page 69-18.

## Control Build Process Compiling and Linking

After generating code for a model, the build process determines whether or not to compile and link an executable program. This decision is governed by the following:

- **Generate code only** option

When you select this option, the code generator produces code for the model, including a makefile.

- **Generate makefile** option

When you clear this option, the code generator does not produce a makefile for the model. You must specify post code generation processing, including compilation and linking, as a user-defined command, as explained in “Customize Post-Code-Generation Build Processing” on page 70-14.

- **Makefile-only target**

The Microsoft Visual C++ Project Makefile versions of the `grt` and Embedded Coder target configurations generate a Visual C++ project makefile (`model.mak`). To build an executable, you must open `model.mak` in the Visual C++ IDE and compile and link the model code.

- **HOST template makefile variable**

The template makefile variable `HOST` identifies the type of system upon which your executable is intended to run. The variable can be set to one of three possible values: `PC`, `UNIX`, or `ANY`.

By default, `HOST` is set to `UNIX` in template makefiles designed for use with The Open Group UNIX platforms (such as `grt_unix.tmf`), and to `PC` in the template makefiles designed for use with development systems for the PC (such as `grt_vc.tmf`).

If the Simulink software is running on the same type of system as that specified by the `HOST` variable, then the executable is built. Otherwise,

- If `HOST = ANY`, an executable is still built. This option is useful when you want to cross-compile a program for a system other than the one the Simulink software is running on.
- Otherwise, processing stops after generating the model code and the makefile; the following message is displayed on the MATLAB command line.

```
Make will not be invoked - template makefile is for a different host
```

- TGT\_FCN\_LIB template makefile variable

The template makefile variable TGT\_FCN\_LIB specifies compiler command line options. The line in the makefile is TGT\_FCN\_LIB = |>TGT\_FCN\_LIB<|. Use this token in a makefile conditional statement to specify a standard math library as a compiler option. Possible |>TGT\_FCN\_LIB<| token values are:

Value	Generates Calls To
Name of custom CRL	ISO®/IEC 9899:1990 C (ANSI_C) standard math library
ISO_C	ISO/IEC 9899:1999 C standard math library
ISO_C++	ISO/IEC 14882:2003 C++ standard math library
GNU	GNU extensions to the ISO/IEC 9899:1999 C standard math library

## Cross-Compile Code Generated on Microsoft Windows

If you need to generate code with the code generator on a Microsoft Windows system but compile the generated code on a different supported platform, you can do so by modifying your TMF and model configuration parameters. For example, you would need to do this if you develop applications with the MATLAB and Simulink products on a Windows system, but you run your generated code on a Linux system.

To set up a cross-compilation development environment, do the following (here a Linux system is the destination platform):

- 1 On your Windows system, copy the UNIX TMF for your target to a local folder. This will be your working folder for initiating code generation. For example, you might copy the file `matlabroot/rtw/c/grt/grt_unix.tmf` to `D:/work/my_grt_unix.tmf`.
- 2 Make the following changes to your copy of the TMF:
  - Add the following line near the `SYS_TARGET_FILE =` line:

```
MAKEFILE_FILESEP = /
```
  - Search for the line `'ifeq ($(OPT_OPTS),$(DEFAULT_OPT_OPTS))'` and, for each occurrence, remove the conditional logic and retain only the `'else'` code. That is, remove everything from the `'if'` to the `'else'`, inclusive, as well as the closing `'endif'`. Only the lines from the `'else'` portion should remain. This forces the run-time libraries to build for a Linux system.
- 3 Open your model and make the following changes in the **Code Generation** pane of the Configuration Parameters dialog:
  - Specify the name of your new TMF in the “Template makefile” text box (for example, `my_grt_unix.tmf`).
  - Select **Generate code only** and click **Apply**.
- 4 Generate the code.
- 5 If the build folder (folder from which the model was built) is not already Linux accessible, copy it to a Linux accessible path. For example, if your build folder for the generated code was `D:\work\mymodel_grt_rtw`, copy that entire folder tree to a path such as `/home/user/mymodel_grt_rtw`.
- 6 If the MATLAB folder tree on the Windows system is Linux accessible, skip this step. Otherwise, copy the include and source folders to a Linux accessible drive partition, for example, `/home/user/myinstall`. These folders appear in the makefile after

MATLAB\_INCLUDES = and ADD\_INCLUDES = and can be found by searching for \$(MATLAB\_ROOT). Paths that contain \$(MATLAB\_ROOT) must be copied. Here is an example list (your list will vary depending on your model):

```
$(MATLAB_ROOT)/rtw/c/grt
$(MATLAB_ROOT)/extern/include
$(MATLAB_ROOT)/simulink/include
$(MATLAB_ROOT)/rtw/c/src
$(MATLAB_ROOT)/rtw/c/tools
```

Additionally, paths containing \$(MATLAB\_ROOT) in the build rules (lines with %.o :) must be copied. For example, based on the build rule

```
%.o : $(MATLAB_ROOT)/rtw/c/src/ext_mode/tcpip/%.c
```

the following folder should be copied:

```
$(MATLAB_ROOT)/rtw/c/src/ext_mode/tcpip
```

---

**Note:** The path hierarchy relative to the MATLAB root must be maintained. For example, c:\MATLAB\rtw\c\tools\\* would be copied to /home/user/mlroot/rtw/c/tools/\*.

For some blocksets, it is easiest to copy a higher-level folder that includes the subfolders listed in the makefile. For example, the DSP System Toolbox product requires the following folders to be copied:

```
$(MATLAB_ROOT)/toolbox/dspblks
$(MATLAB_ROOT)/toolbox/rtw/dspblks
```

## 7 Make the following changes to the generated makefile:

- Set both MATLAB\_ROOT and ALT\_MATLAB\_ROOT equal to the Linux accessible path to *matlabroot* (for example, home/user/myinstall).
- Set COMPUTER to the computer value for your platform, such as GLNX86. Enter `help computer` in the MATLAB Command Window for a list of computer values.
- In the ADD\_INCLUDES list, change the build folder (designating the location of the generated code on the Windows system) and parent folders to Linux accessible include folders. For example, change D:\work\mymodel\_grt\_rtw\ to /home/user/mymodel\_grt\_rtw.

Additionally, if *matlabroot* is a UNC path, such as \\my-server\myapps\matlab, replace the hard-coded MATLAB root with \$(MATLAB\_ROOT).

- 8 From a Linux shell, compile the code you generated on the Windows system. You can do this by running the generated *model.bat* file or by typing the make command line as it appears in the *.bat* file.

---

**Note:** If errors occur during makefile execution, you may need to run the `dos2unix` utility on the makefile (for example, `dos2unix mymodel.mk`).

---

## Related Examples

- Use packNGo to Relocate Code to Another Development Environment

## Control Library Location and Naming During Build

Use the `TargetPreCompLibLocation` and `TargetLibSuffix` configuration parameters to control values in generated makefiles during model builds when you use the toolchain approach or the template makefile approach.

### In this section...

“Library Control Parameters” on page 70-7

“Specify the Location of Precompiled Libraries” on page 70-9

“Control the Location of Model Reference Libraries” on page 70-10

“Control the Suffix Applied to Library File Names” on page 70-11

### Library Control Parameters

Use the library control parameters to:

- Specify the location of precompiled libraries, such as blockset libraries or the Simulink Coder block library. Typically, a target has cross-compiled versions of these libraries and places them in a target-specific folder.
- Control the suffix applied to library file names (for example, `_target.a` or `_target.lib`).

Targets can set the parameters inside the system target file (STF) select callback. For example:

```
function mytarget_select_callback_handler(varargin)
 hDig=varargin{1};
 hSrc=varargin{2};
 slConfigUISetVal(hDig, hSrc, 'TargetPreCompLibLocation',...
 'c:\mytarget\precomplibs');
 slConfigUISetVal(hDig, hSrc, 'TargetLibSuffix',...
 '_target.library');
```

The TMF has corresponding expansion tokens:

```
|>EXPAND_LIBRARY_LOCATION<|
|>EXPAND_LIBRARY_SUFFIX<|
```

Alternatively, you can use a call to the `set_param` function. For example:

```
set_param(model, 'TargetPreCompLibLocation', ...
```

```
'c:\mytarget\precomplib');
```

---

**Note:** If your model contains referenced models, you can use the make option `USE_MDLREF_LIBPATHS` to control whether libraries used by the referenced models are copied to the parent model's build folder. For more information, see “Control the Location of Model Reference Libraries” on page 70-10.

---

### Using TargetLibSuffix with the Toolchain Approach

With `TargetLibSuffix`, you specify a suffix followed by an extension. For example:  
*suffix.extension*

However, when you use the toolchain approach, only the suffix provided by `TargetLibSuffix` is honored. The extension that the `TargetLibSuffix` provides is not honored because the toolchain approach provides a different extension.

For example, with the target makefile approach, the final binary name is composed of the *modelName*, the *suffix*, and the *extension* provided by `TargetLibSuffix`:

```
modelName+suffix.extension_from_TargetLibSuffix
```

With the toolchain approach, the final binary name is composed of the *modelName*, the *suffix*, and the *extension* provided by the toolchain approach:

```
model+suffix.extension_from_toolchain_approach
```

The extension that the toolchain approach uses comes from the file extension of the static library that the build tool creates. To get this information:

Create the toolchain object. For example, enter:

```
tc = ToolchainInfo used in the model
```

Get the build tool name. For example, enter:

```
tool = tc.getBuildTool('C Compiler');
or
```

```
tool = tc.getBuildTool('C++ Compiler');
```

Get the extension. For example, enter:

```
extension_from_ToolchainInfo = tool.getFileExtension('Static Library')
```

---

**Note:** Note: If you do not set the `TargetLibSuffix` parameter, template makefile and toolchain approaches behave identically. See “Customize Library File Suffix and File Type”.

---

## Specify the Location of Precompiled Libraries

Use the `TargetPreCompLibLocation` configuration parameter to:

- Override the precompiled library location specified in the `rtwmakecfg.m` file (see “Use `rtwmakecfg.m` API to Customize Generated Makefiles” on page 70-24 for details)
- Precompile and distribute target-specific versions of product libraries (for example, the DSP System Toolbox product)

For a precompiled library, such as a blockset library or the Simulink Coder block library, the location specified in `rtwmakecfg.m` is typically a location specific to the blockset or the Simulink Coder product. The code generator expects that the library exists in this location and links against the library during builds.

However, for some applications, such as custom targets, it is preferable to locate the precompiled libraries in a target-specific or other alternate location rather than in the location specified in `rtwmakecfg.m`. For a custom target, the code generator expects that the target-specific cross-compiler creates the library, and you place the library in the target-specific location. Libraries supported by the target should be compiled and placed in the target-specific location so they can be used during the build process.

You can set up the `TargetPreCompLibLocation` parameter in its select callback. The path that you specify for the parameter must be a fully qualified, absolute path to the library location. Relative paths are not supported. For example:

```
slConfigUISetVal(hDlg, hSrc, 'TargetPreCompLibLocation',...
'c:\mytarget\precomplibs');
```

Alternatively, you set the parameter with a call to the `set_param` function. For example:

```
set_param(model, 'TargetPreCompLibLocation',...
'c:\mytarget\precomplibs');
```

During makefile generation, the build process replaces the tokens with the location from the `rtwmakecfg.m` file. For example, if the library name in the `rtwmakecfg.m` file is `'rtwlib'`, the template makefile build approach expands the token from:

```
LIBS += |>EXPAND_LIBRARY_LOCATION<|\>EXPAND_LIBRARY_NAME<|\
```

```
_target.library
```

to:

```
LIBS += c:\mytarget\precomplibs\rtwlib_target.library
```

By default, `TargetPreCompLibLocation` is an empty character vector. The build process uses the location in `rtwmakecfg.m` for the token replacement.

## Control the Location of Model Reference Libraries

On platforms other than the Apple Macintosh platform, when building a model that uses referenced models, the default build process includes:

- Copy libraries that the referenced models uses to the parent model's build folder.
- Assign the file names of the libraries to `MODELREF_LINK_LIBS` in the generated makefile.

For example, if a model includes a referenced model `sub`, the build process assigns the library name `sub_rtwlib.lib` to `MODELREF_LINK_LIBS`. The build process copies the library file to the parent model's build folder. This definition is then used in the final link line, which links the library into the final product (usually an executable). This technique minimizes the length of the link line.

On the Macintosh platform, and optionally on other platforms, the build process includes:

- No copying of libraries that the referenced models uses to the parent model's build folder.
- Assign the relative paths and file names of the libraries to `MODELREF_LINK_LIBS` in the generated makefile.

When using this technique, the build process assigns a relative path such as `../slprj/grt/sub/sub_rtwlib.lib` to `MODELREF_LINK_LIBS`. The build process uses the path to gain access to the library file at link time.

To change to the nondefault behavior on platforms other than the Macintosh platform, select the **Configuration Parameters > Code Generation > Make command** field. Enter:

```
make_rtw USE_MDLREF_LIBPATHS=1
```

If you specify other Make command arguments, such as `OPTS=" -g "`, the order in which you specify the multiple arguments does not matter.

To return to the default behavior, set `USE_MDLREF_LIBPATHS` to 0, or remove it.

## Control the Suffix Applied to Library File Names

Use the `TargetLibSuffix` configuration parameter to control the suffix applied to library names (for example, `_target.lib` or `_target.a`). The specified suffix scheme must include a period (.). You can apply `TargetLibSuffix` to the following libraries:

- Libraries on which a target depends, as specified in the `rtwmakecfg.m` API. You can use `TargetLibSuffix` to change the suffix of both precompiled and non-precompiled libraries configured from the `rtwmakecfg` API. For details, see “Use `rtwmakecfg.m` API to Customize Generated Makefiles” on page 70-24.

In this case, a target can set the parameter in its select callback. For example:

```
s1ConfigUISetVal(hDlg, hSrc, 'TargetLibSuffix',...
'_target.library');
```

Alternatively, you can use a call to the `set_param` function. For example:

```
set_param(model, 'TargetLibSuffix', '_target.library');
```

During the TMF-to-makefile conversion, the build process replaces the token `|>EXPAND_LIBRARY_SUFFIX<|` with the specified suffix. For example, if the library name specified in the `rtwmakecfg.m` file is `'rtwlib'`, the TMF expands from:

```
LIBS += |>EXPAND_LIBRARY_LOCATION<|\ |>EXPAND_LIBRARY_NAME<|\
|>EXPAND_LIBRARY_SUFFIX<|
```

to:

```
LIBS += c:\mytarget\precomplibs\rtwlib_target.library
```

By default, `TargetLibSuffix` is set to an empty character vector. In this case, the build process replaces the token `|>EXPAND_LIBRARY_SUFFIX<|` with an empty character vector.

- Shared utility library and the model libraries created with model reference. For these cases, associated makefile variables do not require the `|>EXPAND_LIBRARY_SUFFIX<|` token. Instead, the build process includes `TargetLibSuffix` implicitly. For example, for a top model named `topmodel` with referenced models named `refmodel1` and `refmodel2`, the top model's TMF is expanded from:

```
SHARED_LIB = |>SHARED_LIB<|
```

```
MODELLIB = |>MODELLIB<|
MODELREF_LINK_LIBS = |>MODELREF_LINK_LIBS<|
```

to:

```
SHARED_LIB = \
..\slprj\ert_sharedutils\rtwshared_target.library
MODELLIB = topmodellib_target.library
MODELREF_LINK_LIBS = \
refmodel11_rtwlib_target.library refmodel12_rtwlib_target.library
```

By default, the `TargetLibSuffix` parameter is an empty character vector. In this case, the build process chooses a default suffix for these three tokens using a file extension of `.lib` on Windows hosts and `.a` on UNIX hosts. (For model reference libraries, the default suffix additionally includes `_rtwlib`.) For example, on a Windows host, the expanded makefile values are:

```
SHARED_LIB = ..\slprj\ert_sharedutils\rtwshared.lib
MODELLIB = topmodellib.lib
MODELREF_LINK_LIBS = refmodel11_rtwlib.lib refmodel12_rtwlib.lib
```

## Recompile Precompiled Libraries

You can recompile precompiled libraries included as part of the code generator, such as `rtwlib` or `dsplib`, by using a supplied MATLAB function, `rtw_precompile_libs`. You might consider doing this if you need to customize compiler settings for various platforms or environments. For details on using `rtw_precompile_libs`, see “Precompile S-Function Libraries” on page 39-162.

## Customize Post-Code-Generation Build Processing

The code generator provides a set of tools, including a build information object, you can use to customize build processing that occurs after code generation. You might use such customizations for target development or the integration of third-party tools into your application development environment.

In this section...
“Workflow for Setting Up Customizations” on page 70-14
“Build Information Object” on page 70-15
“Program a Post Code Generation Command” on page 70-16
“Define a Post Code Generation Command” on page 70-17
“Customize Build Process with PostCodeGenCommand and Relocate Generated Code to an External Environment” on page 70-18
“Suppress Makefile Generation” on page 70-20

### Workflow for Setting Up Customizations

The following figure and the steps that follow show the general workflow for setting up post-code-generation customizations.

- 1 Program the post code generation command.
- 2 Define the post code generation command.
- 3 Suppress makefile generation, if applicable.
- 4 Build the model.
- 5 Modify the command and rebuild the model until the build results are acceptable.

## Build Information Object

At the start of a model build, the build process logs the following build option and dependency information to a temporary build information object:

- Compiler options
- Preprocessor identifier definitions
- Linker options

- Source files and paths
- Include files and paths
- Precompiled external libraries

You can retrieve information from and add information to this object by using an extensive set of functions. For a list of available functions and detailed function descriptions, see “Build Process Customization”. “Program a Post Code Generation Command” on page 70-16 explains how to use the functions to control post code generation build processing.

## Program a Post Code Generation Command

For certain applications, you might want to control aspects of the build process after the code generation. For example, you might do this if you develop your own target, or you want to apply an analysis tool to the generated code before continuing with the build process. You can apply this level of control to the build process by programming and then defining a post code generation command.

A post code generation command is a MATLAB language file that typically calls functions that get data from or add data to the model's build information object. You can program the command as a script or function.

If You Program the Command as a...	Then the...
Script	Script can gain access to the model name and the build information directly
Function	Function can pass the model name and the build information as arguments

If your post code generation command calls user-defined functions, make sure the functions are on the MATLAB path. If the build process cannot find a function you use in your command, the build process errors out.

You can then call a combination of build information functions, as listed in “Build Process Customization”, to customize the model's post code generation build processing.

The following example shows a fragment of a post code generation command that gets the file names and paths of the source and include files generated for a model for analysis.

```

function analyzegeneratecode(buildInfo)
% Get the names and paths of source and include files
% generated for the model and then analyze them.

% buildInfo - build information for my model.

% Define cell array to hold data.
MyBuildInfo={};

% Get source file information.
MyBuildInfo.srcfiles=getSourceFiles(buildInfo, true, true);
MyBuildInfo.srcpaths=getSourcePaths(buildInfo, true);

% Get include (header) file information.
MyBuildInfo.incfiles=getIncludeFiles(buildInfo, true, true);
MyBuildInfo.incpaths=getIncludePaths(buildInfo, true);

% Analyze generated code.
.
.
.

```

## Define a Post Code Generation Command

After you program a post code generation command, you need to inform the build process that the command exists and to add it to the model's build processing. You do this by defining the command with the `PostCodeGenCommand` model configuration parameter. When you define a post code generation command, the build process evaluates the command after generating and writing the model's code to disk and before generating a makefile.

As the following syntax lines show, the arguments that you specify when setting the configuration parameter varies depending on whether you program the command as a script, function, or set of functions.

---

**Note:** When defining the command as a function, you can specify an arbitrary number of input arguments. To pass the model's name and build information to the function, specify identifiers `modelName` and `buildInfo` as arguments.

---

### Script

```

set_param(model, 'PostCodeGenCommand', ...
'pcgScriptName');

```

### Function

```
set_param(model, 'PostCodeGenCommand',...
 'pcgFunctionName(modelName)');
```

### Multiple Functions

```
pcgFunctions=...
'pcgFunction1Name(modelName);...
pcgFunction2Name(buildInfo)';
set_param(model, 'PostCodeGenCommand',...
 pcgFunctions);
```

The following call to `set_param` defines `PostCodGenCommand` to evaluate the function `analyzezencode`.

```
set_param(model, 'PostCodeGenCommand',...
 'analyzezencode(buildInfo)');
```

## Customize Build Process with PostCodeGenCommand and Relocate Generated Code to an External Environment

This example shows how to use the Build Information API and the **Post Code Generation Command** parameter, `PostCodeGenCommand`.

The `PostCodeGenCommand` parameter value is `rtwdemo_buildinfo_data`. This value directs the build process to invoke the function after code generation.

The example also demonstrates how to use the `rtwmakecfg.m` API.

For more information, click on the documentation links in the model.

### Open Example Model

Open the example model `rtwdemo_buildinfo`.

```
open_system('rtwdemo_buildinfo');
```

**Generate Code Using Simulink Coder (double-click)**

**Generate Code Using Embedded Coder (double-click)**

[Open rtwmakecfg.m](#)  
[Open rtwdemo\\_buildinfo\\_data.m](#)

**Open BuildInfo.html**

**Description**  
 This example shows how to use the Build Information API as well as the Post Code Generation Command parameter, PostCodeGenCommand. For more information, click on the documentation links below.  
 The function rtwdemo\_buildinfo\_data is invoked during the build process. Additionally, the rtwmakecfg.m API is shown.

**Instructions**

1. Generate code by double-clicking one of the blue buttons above. An HTML file named BuildInfo.html is created.
2. Select **Open BuildInfo.html** to view the file in a Web browser. Follow the hyperlinks to open the source files listed.

**Notes**

1. Use `get_param('rtwdemo_buildinfo', 'PostCodeGenCommand')` to see the function executed in the Post Code Gen Command stage.
2. Select **Open rtwdemo\_buildinfo\_data.m** to study the API for the Build Info object.
3. Select **Open rtwmakecfg.m** to study the use of rtwmakecfg API.
4. The buildInfo object is saved out to the following location `rtwdemo_<target>_rtw/buildInfo.mat`
5. The `packNGo` feature of the buildInfo object is invoked at the end of the post code generation function `rtwdemo_buildinfo_data.m`

## Generate Code from Model

Double-click on the **Generate Code Using Simulink Coder** button to generate code for the GRT target.

Or, if Embedded Coder is installed, double-click on the **Generate Code Using Embedded Coder** button to generate code for the ERT target.

The build process generates a `BuildInfo.html` file to document the build information object.

## Examine the Build Process Customizations and Output

Use the links in the model to examine the build process customizations and the post code generation query of the the build information object.

To view the `BuildInfo.html` file in a Web browser, click on **Open BuildInfo.html**.

The example uses the `PostCodeGenCommand` parameter of the model to generate the html file from the build information object. The file provides hyperlinks to open the source files (generated code) from the model. To view the `PostCodeGenCommand` parameter value, type:

```
get_param('rtwdemo_buildinfo','PostCodeGenCommand');
```

This value indicates a function to execute in the **Post Code Gen Command** stage.

```
rtwdemo_buildinfo_data(buildInfo);
```

To study how the example uses the `rtwmakecfg` API, click on **Open rtwmakecfg.m** or type:

```
edit rtwmakecfg.m;
```

To study the API for the `buildInfo.mat` object, click on **Open rtwdemo\_buildinfo\_data.m** or type:

```
edit rtwdemo_buildinfo_data.m;
```

The `buildInfo.mat` object is available at:

```
rtwdemo_<target>_rtw\buildInfo.mat
```

At the end of the `rtwdemo_buildinfo_data.m` post code generation function, the function invokes `packNGO` to package the source and objects identified in the `buildInfo` object for relocation.

### Further Study Topics

- “Build Process Customization”
- “Customize Post-Code-Generation Build Processing”
- “Use `rtwmakecfg.m` API to Customize Generated Makefiles”
- “Relocate Code to Another Development Environment”

### Suppress Makefile Generation

The code generator provides the ability to suppress makefile generation during the build process. For example, you might do this to integrate tools into the build process that are not driven by makefiles.

To instruct the code generator to not produce a makefile, do one of the following:

- Clear the **Generate makefile** option on the **Code Generation** pane of the Configuration Parameters dialog box.
- Set the value of the configuration parameter `GenerateMakefile` to off.

When you suppress makefile generation,

- You cannot explicitly specify a make command or template makefile.
- You must specify your own instructions for a post code generation processing, including compilation and linking, in a post code generation command as explained in “Program a Post Code Generation Command” on page 70-16 and “Define a Post Code Generation Command” on page 70-17.

## Configure Generated Code with TLC

### In this section...

“About Configuring Generated Code with TLC” on page 70-22

“Assigning Target Language Compiler Variables” on page 70-22

“Set Target Language Compiler Options” on page 70-23

### About Configuring Generated Code with TLC

You can use the Target Language Compiler (TLC) to fine tune your generated code. TLC supports extended code generation variables and options in addition to parameters available on the **Code Generation** pane on the Configuration Parameters dialog box. There are two ways to set TLC variables and options, as described in this section.

---

**Note:** You should not customize TLC files in the folder *matlabroot/rtw/c/tlc* even though the capability exists to do so. Such TLC customizations might not be applied during the code generation process and can lead to unpredictable results.

---

### Assigning Target Language Compiler Variables

The `%assign` statement lets you assign a value to a TLC variable, as in

```
%assign MaxStackSize = 4096
```

This is also known as creating a *parameter name/parameter value pair*.

For a description of the `%assign` statement see “Target Language Compiler Directives”. You should write your `%assign` statements in the **Configure RTW code generation settings** section of the system target file.

The following table lists the code generation variables you can set with the `%assign` statement.

#### Target Language Compiler Optional Variables

Variable	Description
MaxStackSize=N	When the <b>Enable local block outputs</b> check box is selected, the total allocation size of local variables that

Variable	Description
	<p>are declared by block outputs in the model cannot exceed <code>MaxStackSize</code> (in bytes). <code>MaxStackSize</code> can be a positive integer. If the total size of local block output variables exceeds this maximum, the remaining block output variables are allocated in global, rather than local, memory. The default value for <code>MaxStackSize</code> is <code>rtInf</code>, that is, unlimited stack size.</p> <p><b>Note:</b> Local variables in the generated code from sources other than local block outputs, such as from a Stateflow diagram or MATLAB Function block, and stack usage from sources such as function calls and context switching are not included in the <code>MaxStackSize</code> calculation. For overall executable stack usage metrics, do a target-specific measurement by using run-time (empirical) analysis or static (code path) analysis with object code.</p>
<code>MaxStackVariableSize=N</code>	<p>When the <b>Enable local block outputs</b> check box is selected, this limits the size of a local block output variable declared in the code to N bytes, where <math>N &gt; 0</math>. A variable whose size exceeds <code>MaxStackVariableSize</code> is allocated in global, rather than local, memory. The default is 4096.</p>
<code>WarnNonSaturatedBlocks=value</code>	<p>Flag to control display of overflow warnings for blocks that have saturation capability, but have it turned off (unchecked) in their dialog. These are the options:</p> <ul style="list-style-type: none"> <li>• 0 — Warning is not displayed.</li> <li>• 1 — Displays one warning for the model during code generation</li> <li>• 2 — Displays one warning that contains a list of offending blocks</li> </ul>

## Set Target Language Compiler Options

You can specify TLC command line options for code generation using the model parameter `TLCOptions` in a `set_param` function call. For information about these options, see “Specify TLC Options” and “Configure TLC”.

## Use `rtwmakecfg.m` API to Customize Generated Makefiles

Both the toolchain approach and the template makefile approach for builds let you add the following items to generated makefiles:

- Source folders
- Include folders
- Library names
- Module objects

### In this section...

“About the `rtwmakecfg` Function” on page 70-24

“Create the `rtwmakecfg` Function” on page 70-25

“Modify the Template Makefile for `rtwmakecfg`” on page 70-27

### About the `rtwmakecfg` Function

Using an `rtwmakecfg` function, you add this information to the makefile during the build operation for S-functions. The `rtwmakecfg` function is particularly useful when specifying added sources and libraries to build a model that contains one or more of your S-function blocks.

To add information pertaining to an S-function to the makefile:

- 1 Create the MATLAB language `rtwmakecfg` function in the `rtwmakecfg.m` file. The code generator associates this file with your S-function based on its folder location. “Create the `rtwmakecfg` Function” on page 70-25 describes the requirements for the `rtwmakecfg` function and the data it returns.
- 2 If you are using the template makefile approach, modify your target's TMF such that it supports macro expansion for the information that the `rtwmakecfg` function returns. “Modify the Template Makefile for `rtwmakecfg`” on page 70-27 describes the required modifications. If you are using the toolchain approach, the information that the `rtwmakecfg` function returns is used by the generated makefile; no further configuration is required.

After the TLC phase of the build process, when generating a makefile, the code generator searches for an `rtwmakecfg.m` file in the folder that contains the S-function MEX file. If it finds the file, the build process calls the `rtwmakecfg` function.

## Create the `rtwmakecfg` Function

Create the `rtwmakecfg.m` file containing the `rtwmakecfg` function in the same folder as your S-function component (a MEX-file with a platform-dependent extension, such as `.mexext` on Microsoft Windows systems). The function must return a structured array that contains these fields.

Field	Description
<code>makeInfo.includePath</code>	A cell array that specifies additional include folder names, organized as a row vector. The build process expands the folder names into include instructions in the generated makefile.
<code>makeInfo.sourcePath</code>	A cell array that specifies additional source folder names, organized as a row vector. You must include the folder names of files entered into the <b>S-function modules</b> field on the S-Function Block Parameters dialog box or into the block's <code>SFunctionModules</code> parameter if they are not in the same folder as the S-function. The build process expands the folder names into make rules in the generated makefile.
<code>makeInfo.sources</code>	A cell array that specifies additional source file names (C or C++), organized as a row vector. Do not include the name of the S-function or any files entered into the <b>S-function modules</b> field on the S-Function Block Parameters dialog box or into the block's <code>SFunctionModules</code> parameter. The build process expands the file names into make variables that contain the source files. Specify only file names (with extension). Specify path information with the <code>sourcePath</code> field.
<code>makeInfo.linkLibsObjs</code>	A cell array that specifies additional, fully qualified paths to object or library files against which the generated code links. The build process does not compile the specified objects and libraries. However, it includes them when linking the final executable. This inclusion can be useful for incorporating libraries that you do not want the build process to recompile or for which the source files are not available. You can also use this element to incorporate source files from languages other than C and C++. This is possible if you first create a C compatible object file or library outside of the build process.

Field	Description
<code>makeInfo.precompile</code>	A Boolean flag that indicates whether the libraries specified in the <code>rtwmakecfg.m</code> file exist in a specified location ( <code>precompile==1</code> ) or if you must create the libraries in the build folder during the build process ( <code>precompile==0</code> ).
<code>makeInfo.library</code>	A structure array that specifies additional run-time libraries and module objects, organized as a row vector. The build process expands the information into make rules in the generated makefile. For a list of the library fields, see the next table.

The `makeInfo.library` field consists of the following elements.

Element	Description
<code>makeInfo.library(n).Name</code>	A character array that specifies the name of the library (without an extension).
<code>makeInfo.library(n).Location</code>	A character array that specifies the folder in which the library is located when precompiled. For more information, see the description of <code>makeInfo.precompile</code> in the preceding table. A target can use the <code>TargetPreCompLibLocation</code> parameter to override this value. See “Specify the Location of Precompiled Libraries”.
<code>makeInfo.library(n).Modules</code>	A cell array that specifies the C or C++ source file base names (without an extension) that comprise the library. Do not include the file extension. The makefile appends the object extension.

**Note:** The `makeInfo.library` field must fully specify each library and how to build it. The modules list in the `makeInfo.library(n).Modules` element cannot be empty. If you need to specify a link-only library, use the `makeInfo.linkLibsObjs` field instead.

### Example:

```
disp(['Running rtwmakecfg from folder: ',pwd]);
makeInfo.includePath = { fullfile(pwd, 'somedir2') };
makeInfo.sourcePath = { fullfile(pwd, 'somedir2'), fullfile(pwd, 'somedir3') };
makeInfo.sources = { 'src1.c', 'src2.cpp' };
```

```

makeInfo.linkLibsObjs = { fullfile(pwd, 'somedir3', 'src3.object'),...
 fullfile(pwd, 'somedir4', 'mylib.library')};
makeInfo.precompile = 1;
makeInfo.library(1).Name = 'myprecompiledlib';
makeInfo.library(1).Location = fullfile(pwd, 'somedir2', 'lib');
makeInfo.library(1).Modules = {'srcfile1' 'srcfile2' 'srcfile3' };

```

---

**Note:** If a path that you specify in the `rtwmakecfg.m` API contains spaces, the build process does not convert the path to its nonspace equivalent. If the build environments you intend to support do not support spaces in paths, refer to “Enable Build Process When Folder Names Have Spaces”.

---

## Modify the Template Makefile for `rtwmakecfg`

To expand the information that an `rtwmakecfg` function generates, modify the following sections of your target's TMF:

- Include Path
- C Flags and/or Additional Libraries
- Rules

It is possible that these TMF code examples do not apply to your make utility. For additional examples, see the GRT or ERT TMFs located in *matlabroot/rtw/c/grt* (open) or *matlabroot/rtw/c/ert* (open).

### Add Folder Names to the Makefile Include Path

The following TMF code example adds folder names to the include path in the generated makefile:

```

ADD_INCLUDES = \
|>START_EXPAND_INCLUDES<| -I|>EXPAND_DIR_NAME<| \
|>END_EXPAND_INCLUDES<|

```

Additionally, the `ADD_INCLUDES` macro must be added to the `INCLUDES` line.

```
INCLUDES = -I. -I.. $(MATLAB_INCLUDES) $(ADD_INCLUDES) $(USER_INCLUDES)
```

### Add Library Names to the Makefile

The following TMF code example adds library names to the generated makefile.

```
LIBS =
```

```
|>START_PRECOMP_LIBRARIES<|
LIBS += |>EXPAND_LIBRARY_NAME<|.a |>END_PRECOMP_LIBRARIES<|
|>START_EXPAND_LIBRARIES<|
LIBS += |>EXPAND_LIBRARY_NAME<|.a |>END_EXPAND_LIBRARIES<|
```

For more information, see “Control Library Location and Naming During Build” on page 70-7.

## Add Rules to the Makefile

The TMF code example adds rules to the generated makefile.

```
|>START_EXPAND_RULES<|
$(BLD)/%.o: |>EXPAND_DIR_NAME<|/%.c $(SRC)/$(MAKEFILE) rtw_proj.tmw
 @$(BLANK)
 @echo ### "|>EXPAND_DIR_NAME<|\\"$*.c"
 $(CC) $(CFLAGS) $(APP_CFLAGS) -o $(BLD)/$(DIRCHAR)$*.o \
 |>EXPAND_DIR_NAME<|$(DIRCHAR)$*.c > $(BLD)/$(DIRCHAR)$*.lst
|>END_EXPAND_RULES<|

|>START_EXPAND_LIBRARIES<|MODULES_|>EXPAND_LIBRARY_NAME<| = \
|>START_EXPAND_MODULES<| |>EXPAND_MODULE_NAME<|.o \
|>END_EXPAND_MODULES<|

|>EXPAND_LIBRARY_NAME<|.a : $(MAKEFILE) rtw_proj.tmw
$(MODULES_|>EXPAND_LIBRARY_NAME<|:%.o=$(BLD)/%.o)
 @$(BLANK)
 @echo ### Creating $@
 $(AR) -r $@ $(MODULES_|>EXPAND_LIBRARY_NAME<|:%.o=$(BLD)/%.o)
|>END_EXPAND_LIBRARIES<|

|>START_PRECOMP_LIBRARIES<|MODULES_|>EXPAND_LIBRARY_NAME<| = \
|>START_EXPAND_MODULES<| |>EXPAND_MODULE_NAME<|.o \
|>END_EXPAND_MODULES<|

|>EXPAND_LIBRARY_NAME<|.a : $(MAKEFILE) rtw_proj.tmw
$(MODULES_|>EXPAND_LIBRARY_NAME<|:%.o=$(BLD)/%.o)
 @$(BLANK)
 @echo ### Creating $@
 $(AR) -r $@ $(MODULES_|>EXPAND_LIBRARY_NAME<|:%.o=$(BLD)/%.o)
|>END_PRECOMP_LIBRARIES<|
```

## Customize Build Process with `STF_make_rtw_hook` File

The build process lets you supply optional custom code in hook methods that are executed at specified points in the code generation and make process. You can use hook methods to add target-specific actions to the build process.

### In this section...

“The `STF_make_rtw_hook` File” on page 70-29

“Conventions for Using the `STF_make_rtw_hook` File” on page 70-29

“`STF_make_rtw_hook.m` Function Prototype and Arguments” on page 70-30

“Applications for `STF_make_rtw_hook.m`” on page 70-33

“Control Code Regeneration Using `STF_make_rtw_hook.m`” on page 70-34

“Use `STF_make_rtw_hook.m` for Your Build Procedure” on page 70-35

### The `STF_make_rtw_hook` File

You can modify hook methods in a file generically referred to as `STF_make_rtw_hook.m`, where *STF* is the name of a system target file, such as `ert` or `mytarget`. This file implements a function, `STF_make_rtw_hook`, that dispatches to a specific action, depending on the `hookMethod` argument passed in.

The build process calls `STF_make_rtw_hook`, passing in the `hookMethod` argument and other arguments. You implement only those hook methods that your build process requires.

If your model contains reference models, you can implement an `STF_make_rtw_hook.m` for each reference model as required. The build process calls each `STF_make_rtw_hook` for reference models, processing these files recursively (in dependency order).

### Conventions for Using the `STF_make_rtw_hook` File

For the build process to call the `STF_make_rtw_hook`, check that the following conditions are met:

- The `STF_make_rtw_hook.m` file is on the MATLAB path.

- The file name is the name of your system target file (STF), appended to the text `_make_rtw_hook.m`. For example, if you generate code with a custom system target file `mytarget.tlc`, name your hook file `mytarget_make_rtw_hook.m`, and name the hook function implemented within the file `mytarget_make_rtw_hook`.
- The hook function implemented in the file uses the function prototype described in “STF\_make\_rtw\_hook.m Function Prototype and Arguments” on page 70-30.

## **STF\_make\_rtw\_hook.m Function Prototype and Arguments**

The function prototype for `STF_make_rtw_hook` is:

```
function STF_make_rtw_hook(hookMethod, modelName, rtwRoot, templateMakefile,
buildOpts, buildArgs, buildInfo)
```

The arguments are defined as:

- `hookMethod`: Character vector specifying the stage of build process from which the `STF_make_rtw_hook` function is called. The following flowchart summarizes the build process, highlighting the hook points. Valid values for `hookMethod` are `'entry'`, `'before_tlc'`, `'after_tlc'`, `'before_make'`, `'after_make'`, `'exit'`, and `'error'`. The `STF_make_rtw_hook` function dispatches to the relevant code with a `switch` statement.

- **modelName**: Character vector specifying the name of the model. Valid at all stages of the build process.
- **rtwRoot**: Reserved.
- **templateMakefile**: Name of template makefile.
- **buildOpts**: A MATLAB structure containing the fields described in the following list. Valid for the 'before\_make', 'after\_make', and 'exit' stages only. The buildOpts fields include:
  - **modules**: Character vector specifying a list of additional files to compile.

- **codeFormat**: Character vector specifying the value of the **CodeFormat** TLC variable for the target. (ERT-based targets must use the 'Embedded-C' value for the **CodeFormat** TLC variable and use the corresponding 'ert.tlc' value in the `rtwgensettings.DerivedFrom` field.)
- **noninlinedSFcns**: Cell array specifying a list of noninlined S-functions in the model.
- **compilerEnvVal**: Character vector specifying the compiler environment variable value (for example, `C:\Applications\Microsoft Visual`).
- **buildArgs**: Character vector containing the argument to `make_rtw`. When you invoke the build process, **buildArgs** is copied from the argument following "make\_rtw" in the **Configuration Parameters+Code Generation+Make command** field.

For example, the following make arguments from the **Make command** field

```
make_rtw VAR1=0 VAR2=4
```

generate the following:

```
% make -f untitled.mk VAR1=0 VAR2=4
```

The **buildArgs** argument does not apply for toolchain approach builds because these builds do not allow adding make arguments to the `make_rtw` call. To provide custom definitions (for example, `VAR1=0 VAR2=4`) on the compiler command line that apply for both TMF approach and toolchain approach builds, use the **Configuration Parameters > Code Generation > Custom Code > Defines** field.

- **buildInfo**: The MATLAB structure that contains the model build information fields. Valid for the 'after\_tlc', 'before\_make', 'after\_make', and 'exit' stages only. For information about these fields and functions to access them, see "Build Process Customization".

## Applications for `STF_make_rtw_hook.m`

Here are some examples of how you might apply the `STF_make_rtw_hook.m` hook methods.

In general, you can use the `'entry'` hook to initialize the build process, for example, to change or validate settings before code is generated. One application for the `'entry'` hook is to rerun the auto-configuration script that initially ran at target selection time to compare model parameters before and after the script executes, for validation purposes.

The other hook points, `'before_tlc'`, `'after_tlc'`, `'before_make'`, `'after_make'`, `'exit'`, and `'error'` are useful for interfacing with external tool chains, source control tools, and other environment tools.

For example, you could use the `STF_make_rtw_hook.m` file at a stage after `'entry'` to obtain the path to the build folder. At the `'exit'` stage, you could then locate generated code files within the build folder and check them into your version control system. You might use `'error'` to clean up static or global data used by the hook function when an error occurs during code generation or the build process.

---

**Note:** The build process temporarily changes the MATLAB working folder to the build folder for stages `'before_make'`, `'after_make'`, `'exit'`, and `'error'`. Your `STF_make_rtw_hook.m` file must not make incorrect assumptions about the location of the build folder. At a point after the `'entry'` stage, you can obtain the path to the build folder. In the following MATLAB code example, the build folder path is returned as a character vector to the variable `buildDirPath`.

```
buildDirPath = rtwprivate('get_makertwsettings',gcs,'BuildDirectory');
```

---

## Control Code Regeneration Using `STF_make_rtw_hook.m`

When you rebuild a model, by default, the build process performs checks to determine whether changes to the model or relevant settings require regeneration of the top model code. (For details on the criteria, see “Control Regeneration of Top Model Code” on page 40-43.) If the checks determine that top model code generation is required, the build process fully regenerates and compiles the model code. If the checks indicate that the top model generated code is current with respect to the model, and model settings do not require full regeneration, the build process omits regeneration of the top model code.

Regardless of whether the top model code is regenerated, the build process subsequently calls the build process hooks, including `STF_make_rtw_hook` functions and the post code generation command. The following mechanisms allow you to perform actions related to code regeneration in the `STF_make_rtw_hook` functions:

- To force code regeneration, use the following function call from the 'entry' hook:  

```
rtw.targetNeedsCodeGen('set', true);
```
- In hooks from 'before\_tlc' through 'exit', the `buildOpts` structure passed to the hook has a Boolean field `codeWasUpToDate`. The field is set to `true` if model code was up to date and code was not regenerated, or `false` if code was not up to date and code was regenerated. You can customize hook actions based on the value of this field. For example:

```
...
case 'before_tlc'
 if buildOpts.codeWasUpToDate
 %Perform hook actions for up to date model
 else
 %Perform hook actions for full code generation
 end
...

```

## Use STF\_make\_rtw\_hook.m for Your Build Procedure

To create a custom *STF\_make\_rtw\_hook* hook file for your build procedure, copy and edit the example `ert_make_rtw_hook.m` file, which is located in the folder `matlabroot/toolbox/coder/embeddedcoder` (open), as follows:

- 1** Copy `ert_make_rtw_hook.m` to a folder in the MATLAB path. Rename it in accordance with the naming conventions described in “Conventions for Using the STF\_make\_rtw\_hook File” on page 70-29. For example, to use it with the GRT target `grt.tlc`, rename it to `grt_make_rtw_hook.m`.
- 2** Rename the `ert_make_rtw_hook` function within the file to match the file name.
- 3** Implement the hooks that you require by adding code to case statements within the `switch hookMethod` statement.

## Customize Build Process with `sl_customization.m`

The Simulink customization file `sl_customization.m` is a mechanism that allows you to use MATLAB to customize the standard Simulink user interface. The Simulink software reads the `sl_customization.m` file, if present on the MATLAB path, when it starts and the customizations specified in the file are applied to the Simulink session. For more information on the `sl_customization.m` customization file, see “Registering Customizations”.

### In this section...

“The `sl_customization.m` File” on page 70-36

“Register Build Process Hook Functions Using `sl_customization.m`” on page 70-38

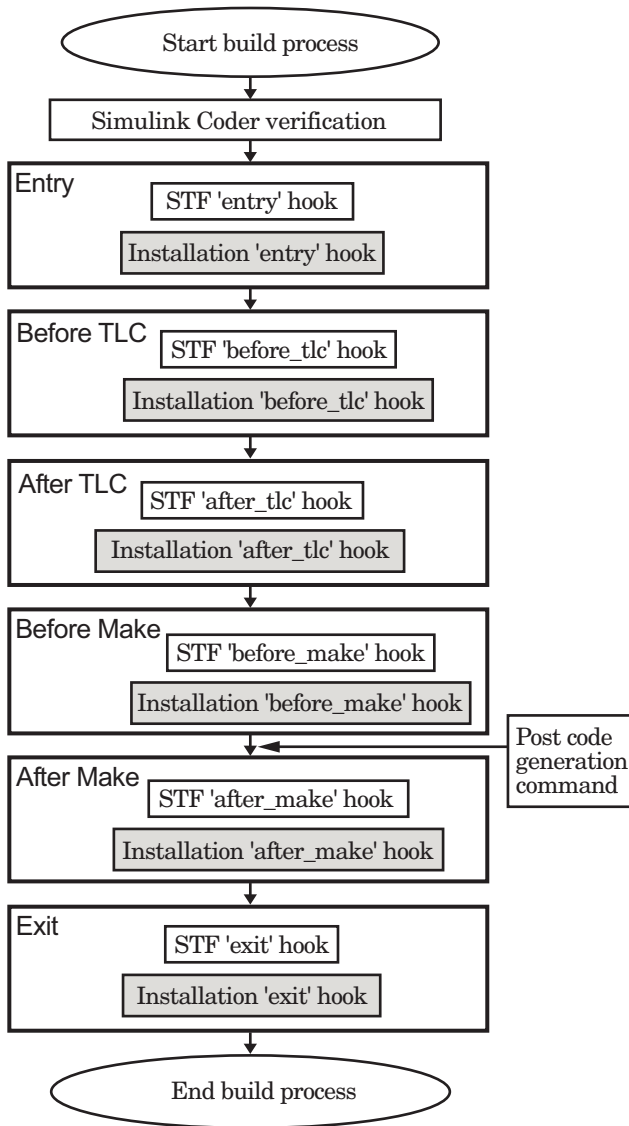

“Variables Available for `sl_customization.m` Hook Functions” on page 70-38

“Example Build Process Customization Using `sl_customization.m`” on page 70-39

## The `sl_customization.m` File

The `sl_customization.m` file can be used to register installation-specific hook functions to be invoked during the build process. The hook functions that you register through `sl_customization.m` complement System Target File (STF) hooks (described in “Customize Build Process with `STF_make_rtw_hook` File” on page 70-29) and post-code generation commands (described in “Customize Post-Code-Generation Build Processing” on page 70-14).

The following figure shows the relationship between installation-level hooks and the other available mechanisms for customizing the build process.

## Register Build Process Hook Functions Using `sl_customization.m`

To register installation-level hook functions that will be invoked during the build process, you create a MATLAB function called `sl_customization.m` and include it on the MATLAB path of the Simulink installation that you want to customize. The `sl_customization` function accepts one argument: a handle to a customization manager object. For example,

```
function sl_customization(cm)
```

As a starting point for your customizations, the `sl_customization` function must first get the default (factory) customizations, using the following assignment statement:

```
hObj = cm.RTWBuildCustomizer;
```

You then invoke methods to register your customizations. The customization manager object includes the following method for registering build process hook customizations:

- `addUserHook(hObj, hookType, hook)`

Registers the MATLAB hook script or function specified by `hook` for the build process stage represented by `hookType`. The valid values for `hookType` are `'entry'`, `'before_tlc'`, `'after_tlc'`, `'before_make'`, `'after_make'`, and `'exit'`.

Your instance of the `sl_customization` function should use this method to register installation-specific hook functions.

The Simulink software reads the `sl_customization.m` file when it starts. If you subsequently change the file, you must restart the Simulink session or enter the following command in the Command Window to enable the changes:

```
sl_refresh_customizations
```

## Variables Available for `sl_customization.m` Hook Functions

The following variables are available for `sl_customization.m` hook functions to use:

- `modelName` — The name of the Simulink model (valid for all stages)
- `dependencyObject` — An object containing the dependencies of the generated code (valid only for the `'after_make'` stage)

A hook script can directly access the valid variables. A hook function can pass the valid variables as arguments to the function. For example:

```
hObj.addUserHook('after_make', 'afterMakeFunction(modelName,dependencyObject);');
```

## Example Build Process Customization Using `sl_customization.m`

The `sl_customization.m` file shown in Example 1: `sl_customization.m` for Build Process Customizations uses the `addUserHook` method to specify installation-specific build process hooks to be invoked at the `'entry'` and `'after_tlc'` stages of the build process. For the hook function source code, see Example 2: `CustomRTWEntryHook.m` and Example 3: `CustomRTWPostProcessHook.m`.

### Example 1: `sl_customization.m` for Build Process Customizations

```
function sl_customization(cm)
% Register user customizations

% Get default (factory) customizations
hObj = cm.RTWBuildCustomizer;

% Register build process hooks
hObj.addUserHook('entry', 'CustomRTWEntryHook(modelName);');
hObj.addUserHook('after_tlc', 'CustomRTWPostProcessHook(modelName);');

end
```

### Example 2: `CustomRTWEntryHook.m`

```
function [str, status] = CustomRTWEntryHook(modelName)
str =sprintf('Custom entry hook for model '%s.',modelName);
disp(str)
status =1;
```

### Example 3: `CustomRTWPostProcessHook.m`

```
function [str, status] = CustomRTWPostProcessHook(modelName)
str =sprintf('Custom post process hook for model '%s.',modelName);
disp(str)
status =1;
```

If you include the above three files on the MATLAB path of the Simulink installation that you want to customize, the coded hook function messages will appear in the displayed output for builds. For example, if you open the ERT-based model `rtwdemo_udt`, open the **Code Generation** pane of the Configuration Parameters dialog box, and press **Ctrl+B** to initiate a build, the following messages are displayed:

```
>> rtwdemo_udt

Starting build procedure for model: rtwdemo_udt
Custom entry hook for model 'rtwdemo_udt.'
Custom post process hook for model 'rtwdemo_udt.'
```

```
Successful completion of build procedure for model: rtwdemo_uvt
>>
```

## Replace STF\_rtw\_info\_hook Supplied Target Data

Prior to MATLAB Release 14, custom targets supplied target-specific information with a hook file (referred to as *STF\_rtw\_info\_hook.m*). The *STF\_rtw\_info\_hook* specified properties such as word sizes for integer data types (for example, `char`, `short`, `int`, and `long`), and C implementation-specific properties of the custom target.

The *STF\_rtw\_info\_hook* mechanism has been replaced by the **Hardware Implementation** pane of the Configuration Parameters dialog box. Using this dialog box, you can specify properties that were formerly specified in your *STF\_rtw\_info\_hook* file.

For backward compatibility, existing *STF\_rtw\_info\_hook* files are available. However, you should convert your target and models to use of the **Hardware Implementation** pane. See “Configure Target Hardware”.

## Customize Build to Use Shared Utility Code

The shared utility folders (`slprj/target/_sharedutils`) typically store generated utility code that is common to a top model and the models it references. You can also force the build process to use a shared utilities folder for a standalone model. See “Specify Target Interfaces” for details.

If you want your target to support compilation of code generated in the shared utilities folder, you must modify your template makefile (TMF). The shared utilities folder is required to support model reference builds. See “Support Model Referencing” on page 71-83 to learn about additional updates for supporting model reference builds.

The exact syntax of the changes can vary due to differences in the `make` utility and compiler/archive tools used by your target. The examples below are based on the Free Software Foundation's GNU `make` utility. You can find the following updated TMF examples for GNU and Microsoft Visual C++ `make` utilities in the GRT and ERT target folders:

- GRT: `matlabroot/rtw/c/grt` (open)
  - `grt_lcc.tmf`
  - `grt_vc.tmf`
  - `grt_unix.tmf`
- ERT: `matlabroot/rtw/c/ert` (open)
  - `ert_lcc.tmf`
  - `ert_vc.tmf`
  - `ert_unix.tmf`

Use the GRT or ERT examples as a guide to the location, within the TMF, of the changes and additions described below.

---

**Note** The ERT-based TMFs contain extra code to handle generation of ERT S-functions and model reference simulation targets. Your target does not need to handle these cases.

---

## Modify Template Makefiles to Support Shared Utilities

Make the following changes to your TMF to support the shared utilities folder:

- 1 Add the following make variables and tokens to be expanded when the makefile is generated:

```

SHARED_SRC = |>SHARED_SRC<|
SHARED_SRC_DIR = |>SHARED_SRC_DIR<|
SHARED_BIN_DIR = |>SHARED_BIN_DIR<|
SHARED_LIB = |>SHARED_LIB<|

```

**SHARED\_SRC** specifies the shared utilities folder location and the source files in it. A typical expansion in a makefile is

```
SHARED_SRC = ../slprj/ert/_sharedutils/*.c
```

**SHARED\_LIB** specifies the library file built from the shared source files, as in the following expansion.

```
SHARED_LIB = ../slprj/ert/_sharedutils/rtwshared.lib
```

**SHARED\_SRC\_DIR** and **SHARED\_BIN\_DIR** allow specification of separate folders for shared source files and the library compiled from the source files. In the current release, TMFs use the same path, as in the following expansions.

```
SHARED_SRC_DIR = ../slprj/ert/_sharedutils
SHARED_BIN_DIR = ../slprj/ert/_sharedutils

```

- 2 Set the **SHARED\_INCLUDES** variable according to whether shared utilities are in use. Then append it to the overall **INCLUDES** variable.

```

SHARED_INCLUDES =
ifneq ($(SHARED_SRC_DIR),)
SHARED_INCLUDES = -I$(SHARED_SRC_DIR)
endif

INCLUDES = -I. $(MATLAB_INCLUDES) $(ADD_INCLUDES) \
 $(USER_INCLUDES) $(SHARED_INCLUDES)

```

- 3 Update the **SHARED\_SRC** variable to list shared files explicitly.

```
SHARED_SRC := $(wildcard $(SHARED_SRC))
```

- 4 Create a **SHARED\_OBJS** variable based on **SHARED\_SRC**.

```
SHARED_OBJS = $(addsuffix .o, $(basename $(SHARED_SRC)))
```

- 5 Create an **OPTS** (options) variable for compilation of shared utilities.

```
SHARED_OUTPUT_OPTS = -o $@
```

- 6 Provide a rule to compile the shared utility source files.

```

$(SHARED_OBJS) : $(SHARED_BIN_DIR)/%.o : $(SHARED_SRC_DIR)/%.c
$(CC) -c $(CFLAGS) $(SHARED_OUTPUT_OPTS) $<

```

- 7 Provide a rule to create a library of the shared utilities. The following example is based on The Open Group UNIX platforms.

```
$(SHARED_LIB) : $(SHARED_OBJS)
 @echo "### Creating $@"
 ar r $@ $(SHARED_OBJS)
 @echo "### Created $@"
```

- 8 Add `SHARED_LIB` to the rule that creates the final executable.

```
$(PROGRAM) : $(OBJS) $(LIBS) $(SHARED_LIB)
$(LD) $(LDFLAGS) -o $@ $(LINK_OBJS) $(LIBS) $(SHARED_LIB) \
 $(SYSLIBS)
@echo "### Created executable: $(MODEL)"
```

- 9 Remove explicit reference to `rt_nonfinite.c` or `rt_nonfinite.cpp` from your TMF. For example, change

```
ADD_SRCS = $(RTWLOG) rt_nonfinite.c
```

to

```
ADD_SRCS = $(RTWLOG)
```

# Custom Target Development in Simulink Coder

## About Embedded Target Development

The system target files bundled with the code generator are suitable for many different applications and development environments. Third-party targets provide additional versatility. If necessary, you can implement a custom target.

To implement a target based on the ARM Cortex<sup>®</sup>-A or ARM Cortex-M processor, install the corresponding support package and see the Target SDK: Embedded Coder Support Package for ARM Cortex-A Processors, “Develop a Target” or Embedded Coder Support Package for ARM Cortex-M Processors, “Develop a Target”. Otherwise, use these functions and topics.

### Custom Targets

You might want to implement a custom target for one of the following reasons:

- To enable end users to generate executable production code for a specific CPU or development board, using a specific development environment (compiler/linker/debugger).
- To support I/O devices on the target hardware by incorporating custom device driver blocks into your models.
- To configure the build process for a special compiler (such as a cross-compiler for an embedded microcontroller or DSP board) or development/debugging environment.

The code generator provides a point of departure for the creation of custom embedded targets, for the basic purposes above. This manual covers the tasks and techniques you need to implement a custom embedded target.

### Types of Targets

The following sections describe several types of targets intended for different use cases

- “About Target Types” on page 71-3
- “Rapid Prototyping Targets” on page 71-3
- “Turnkey Production Targets” on page 71-3
- “Verifying Targets With SIL and PIL Testing” on page 71-4
- “HIL Simulation Targets” on page 71-4

## About Target Types

There is a progression of capabilities from the first (baseline or rapid prototyping) to second (production) target types; you may want to implement an initial rapid prototyping target and a following, more full-featured turnkey version of a target. You might want to use software-in-the-loop (SIL) or processor-in-the-loop (PIL) testing at a particular stage to verify your embedded target. The target types are not mutually exclusive. An embedded target can support more than one of these use cases, or additional uses not outlined here.

The discussion of target types is followed by “Recommended Features for Embedded Targets” on page 71-4, which contains a suggested list of target features and general guidelines for embedded target development.

## Rapid Prototyping Targets

A *rapid prototyping target* or baseline target offers a starting point for targeting a production processor. A rapid prototyping target integrates coded generator software with one or more popular cross-development environments (compiler/linker/debugger tool chains). A rapid prototyping target provides a starting point from which you can customize the target for application needs.

Target files provided for this type of target should be readable, easy to understand, and fully commented and documented. Specific attention should be paid to the interface to the intended cross-development environment. This interface should be implemented using the preferred approach for that particular development system. For example, some development environments use traditional make utilities, while others are based on project-file builds that can be automated under control of the code generator.

When you use a rapid prototyping target, you need to include your own device driver and legacy code and modify linker memory maps to suit your needs. You should be familiar with the targeted development system.

## Turnkey Production Targets

A *turnkey production target* also targets a production processor, but includes the capability to create target executables that interact immediately with the external world. In general, ease of use is more important than simplicity or readability of the target files, because it is assumed that you do not want or need to modify these files.

Desirable features for a turnkey production target include

- Significant I/O driver support provided out of the box
- Easy downloading of generated standalone executables with third-party debuggers
- User-controlled placement of an executable in FLASH or RAM memory
- Support for target visibility and tuning

### **Verifying Targets With SIL and PIL Testing**

You can use software-in-the-loop (SIL) or processor-in-the-loop (PIL) to verify your generated code and validate the target compiler/processor environment.

You can use SIL and PIL simulation mode to verify automatically generated code by comparing the results with a normal mode simulation. With SIL, you can easily verify the behavior of production-intent source code on your host computer; however, it is generally not possible to verify exactly the same code that will subsequently be compiled for your target hardware because the code must be compiled for your host platform (i.e. a different compiler and different processor architecture than the target). With PIL simulation, you can verify exactly the same code that you intend to deploy in production, and you can run the code either on real target hardware or on an instruction set simulator.

For examples describing how to run processor-in-the-loop testing to verify a custom target, see “Sample Custom Targets” on page 71-9.

For more information on SIL and PIL, see “SIL and PIL Simulations” on page 64-2.

### **HIL Simulation Targets**

A specialized use case is the generation of executables intended for use in *hardware-in-the-loop* (HIL) simulations. In a HIL simulation, parts of a pure simulation are gradually replaced with hardware components as components are refined and fabricated. HIL simulation offers an efficient design process that eliminates costly iterations of part fabrication.

### **Recommended Features for Embedded Targets**

- “Basic Target Features” on page 71-5
- “Integration with Target Development Environments” on page 71-6
- “Observing Execution of Target Code” on page 71-6
- “Deployment and Hardware Issues” on page 71-7

## Basic Target Features

- You can base targets on the generic real-time (GRT) target or the Embedded Real-Time (ERT) target that is included in the Embedded Coder product.

If your target is based on the ERT target, it should use ‘Embedded-C’ value for the `CodeFormat` TLC variable, and it should inherit the options defined in the ERT target's system target file with the following lines in the TLC file:

```
%% Assign code format
%assign CodeFormat = "Embedded-C"
%%-----
/%
 BEGIN_RTW_OPTIONS
 rtwgensettings.DerivedFrom = 'ert.tlc';
 END_RTW_OPTIONS
%/
%%-----
```

By following these recommendations, your target has the production code generation capabilities of the ERT target.

See “Customize System Target Files” on page 71-29 for further details on the inheritance mechanism, setting the `CodeFormat`, and other details.

- The most fundamental requirement for an embedded target is that it generate a real-time executable from a model or subsystem. Typically, an embedded target generates a timer interrupt-based, bareboard executable (although targets can be developed for an operating system environment as well).

Your target should support code generator concepts of single-tasking and multitasking solver modes for model execution. Tasking support is available with the ERT target, but you should thoroughly understand how it works before implementing an ERT-based target.

For information on timer interrupt-based execution, see “Absolute and Elapsed Time Computation” and “Asynchronous Events”.

- You should generate the target executable's main program module, rather than using a static main module (such as the static `rt_main.c` or `rt_cppclass_main.cpp` module provided with the software). A generated `main.c` or `.cpp` can be made much more readable and more efficient, since it omits preprocessor checks and other extra code.

See “Deploy Generated Standalone Executables To Target Hardware” on page 49-2 for information on generated and static main program modules.

- Follow the guidelines in “Folder and File Naming Conventions” on page 71-11.

### **Integration with Target Development Environments**

- Most cross-development systems run under a Microsoft Windows PC host. Your target should support the Windows operating system as the host environment.

Some cross-development systems support one or more versions of The Open Group UNIX platforms, allowing for UNIX host support as well.

- Your embedded target must support at least one embedded development environment. The interface to a development environment can take one of several forms. The toolchain approach and template makefile approach generate standard makefiles to work with your development environment. For general information about these build approaches, see “Configure Build Process”. For detailed information about the structure of template makefiles, see “Customize Template Makefiles” on page 71-62.

Another approach with IDE-based tools is to create a Microsoft Visual Studio Solution from your target for integration within a Visual Studio project.

It is important to consider the license requirements and restrictions of the development environment vendor. You may need to modify files provided by the vendor and ship them as part of the embedded target.

See “Interface to Development Tools” on page 71-104 for further information.

### **Observing Execution of Target Code**

- Your target should support a mechanism you can use to observe the target code as it runs in real time (outside of a debugger).

You can use the `rtiostream` API to implement a communication channel to enable exchange of data between different processes. For an example of creating a communication channel for target connectivity, see “Create a Target Communication Channel for Processor-In-The-Loop (PIL) Simulation”. This `rtiostream` communication channel is required to enable processor-in-the-loop (PIL) on a new target. See “Communications `rtiostream` API” on page 64-45 in the Embedded Coder documentation.

One industry-standard approach is to use the CAN bus, with an ASAP2 file and CAN Calibration Protocol (CCP). There are several host-based graphical front-end tools available that connect to a CCP-enabled target and provide data viewing and parameter tuning. Supporting these tools requires implementation of CAN hardware drivers and CCP protocol for the target, as well as ASAP2 file generation. Your target can leverage the ASAP2 support provided with the code generator.

Another option is to support Simulink external mode over a serial interface (RS-232). See the “What You Can Do With a Host/Target Communication Channel” for information on using the external mode API.

### Deployment and Hardware Issues

- Device driver support is an important issue in the design of an embedded target. Device drivers are Simulink blocks that support either hardware I/O capabilities of the target CPU, or I/O features of the development board.

If you are developing a rapid prototyping target, consider providing minimal driver support, on the assumption that end users develop their own drivers. If you are developing a turnkey production target, you should provide full driver support.

See “Device Drivers”.

- Automatic download of generated code to the target hardware makes a target easier to use. Typically a debugger utility is used; if the chosen debugger supports command script files, this can be straightforward to implement. “STF\_make\_rtw\_hook.m” on page 71-21 describes a mechanism to execute code from the build process. You can use this mechanism to make `system()` calls to invoke utilities such as a debugger. You can invoke other simple downloading utilities in a similar fashion.

If your development system supports COM automation, you can control the download process by that mechanism. Using COM automation is discussed in “Interface to Development Tools” on page 71-104.

- Executables that are mapped to RAM memory are typical. You can provide optional support for FLASH or RAM placement of the executable by using your target's code generation options. To support this capability, you might need multiple linker command files, multiple debugger scripts, and possibly multiple makefiles or project files. Also include the ability to automatically switch between these files, depending on the RAM/FLASH option value.

- Select a popular, widely available evaluation or prototype board for your target processor. Consider enclosed and ruggedized versions of the target board. Also consider board level support for the various on-chip I/O capabilities of the target CPU, and the availability of development systems that support the selected board.

## **More About**

- “Sample Custom Targets”

- “Support C++ Class Interface Control”
- “Support Concurrent Execution of Multiple Tasks”
- “Interface to Development Tools”
- “Device Drivers”

## Sample Custom Targets

There are technical solutions on the MathWorks Web site that you can use as a starting point to create your own target solution. The solutions provide guides to the following tasks for creating custom targets:

- Methods of embedding code onto a custom processor
- Creating a system target file
- Customizing the makefile and main file
- Adding compiler, chip, and board specific information
- Integrating legacy code and device drivers
- Creating blocks and libraries
- Implementing processor-in-the-loop (PIL) testing.

- 1 Start by downloading the embedded targets development guide zip file from this web page:

Is there an example guide on developing an embedded target...?

The zip file provides example files and a guide to developing a custom embedded target. The guide is divided into two parts, one on creating a generic custom target and another on creating a target for the Freescale™ S12X processor using the Cosmic Compiler.

Read the example guide along with this document to understand the tasks for developing embedded targets.

- 2 For more detailed example files for specific processors, see:

- Is there an example Freescale S12X target... using the Cosmic Compiler?
- Is there an example Freescale S12X target... using the CodeWarrior Compiler?

These example kits contain example models, code generation files, and instruction guides on generating and testing code for the processor. The Cosmic example illustrates the use of the target connectivity API for processor-in-the-loop (PIL) testing. The CodeWarrior example does not have PIL but shows CAN Calibration Protocol (CCP) and Simulink external mode.

The intent of the example kits is to provide working examples that you can use as a base to create your own target solution. The intent is not to provide a full featured

and maintained Embedded Target product like those provided by MathWorks or third-party products, as listed on the Embedded Coder Hardware Support Web page.

**3** You can watch videos showing overviews of both the example kits at the following links:

- [www.mathworks.com/videos/programming-the-freescale-s12x-target-68811.html](http://www.mathworks.com/videos/programming-the-freescale-s12x-target-68811.html)
- [www.mathworks.com/videos/programming-arm9-using-the-hitex-str9-comstick-68812.html](http://www.mathworks.com/videos/programming-arm9-using-the-hitex-str9-comstick-68812.html)

For another example target for the ARM9 (STR9) processor, see [Is there an example ARM9 \(STR9\) target... using the GNU ARM Compiler and Hitex STR9-comStick?](#).

If you have questions on specific targets, please email [mytarget@mathworks.com](mailto:mytarget@mathworks.com).

The example kits and this document describe Embedded Coder features such as customized ert system target files and processor-in-the-loop testing, but you can study the examples as a starting point for use with Simulink Coder targets.

## Target Development Folders, Files, and Builds

Target development mechanics work with a number of folder and file types. The following topics provide the information needed to develop custom targets, configure folder usage, and use custom targets in the build process.

### In this section...

“Folder and File Naming Conventions” on page 71-11

“Components of a Custom Target” on page 71-12

“Key Folders Under Target Root (mytarget)” on page 71-17

“Key Files in Target Folder (mytarget/mytarget)” on page 71-19

“Additional Files for Externally Developed Targets” on page 71-22

“Target Development and the Build Process” on page 71-23

### Folder and File Naming Conventions

You can use a single folder for your custom target files, or if desired you can use subfolders, for example containing files associated with specific development environments or tools.

For a custom target implementation, the recommended folder and file naming conventions are

- Use *only* lowercase in folder names, filenames, and extensions.
- Do not embed spaces in folder names. Spaces in folder names cause errors with many third-party development environments.
- Include desired folders in the MATLAB path
- Do *not* place your custom target folder anywhere in the MATLAB folder tree (that is, in or under the *matlabroot* folder). If you place your folder under *matlabroot* you risk losing your work if you install a new MATLAB version (or reinstall the current version).

The following sections explain how to organize your target folders and files and add them to the your MATLAB path. They also provide high-level descriptions of the files.

In this document, *mytarget* is a placeholder name that represents folders and files that use the target's name. The names *dev\_tool1*, *dev\_tool2*, and so on represent

subfolders containing files associated with development environments or tools. This document describes an example structure where the folder `mytarget` contains subfolders for `mytarget`, `blocks`, `dev_tool1`, `dev_tool2`. The top level folder `mytarget` is the *target root folder*.

## Components of a Custom Target

- “Overview” on page 71-12
- “Code Components” on page 71-13
- “Control Files” on page 71-14

### Overview

The components of a custom target are files located in a hierarchy of folders. The top-level folder in this structure is called the *target root folder*. The target root folder and its contents are named, organized, and located on the MATLAB path according to conventions described in “Folder and File Naming Conventions” on page 71-11.

The components of a custom target include

- Code components: C source code that supervises and supports execution of generated model code.
- Control files:
  - A system target file (STF) to control the code generation process.
  - File(s) to control the building of an executable from the generated code. In a traditional make-based environment, a template makefile (TMF) generates a makefile for this purpose. Another approach is to generate project files in support of a modern integrated development environment (IDE) such as the Freescale Semiconductor CodeWarrior IDE.
  - Hook files: Optional TLC and MATLAB program files that can be invoked at well-defined stages of the build process. Hook files let you customize the build process and communicate information between various phases of the process.
- Other target files: Files that let you integrate your target into the MATLAB environment. For example, you can provide an `info.xml` file to make your target block libraries and examples available from a MATLAB session.

The next sections introduce key concepts and terminology you need to know to develop each component. References to more detailed information sources are provided.

## Code Components

An executable program containing code generated from a Simulink model consists of a number of code modules and data structures. These fall into two categories.

### Application Components

Application components are those which are specific to a particular model; they implement the functions represented by the blocks in the model. Application components are not specific to the target. Application components include

- Modules generated from the model
- User-written blocks (S-functions)
- Parameters of the model that are visible, and can be interfaced to, external code

### Execution Support Files

A number of code modules and data structures, referred to collectively as the *execution support files*, are responsible for managing and supporting the execution of the generated program. The execution support files modules are not automatically generated. Depending on the requirements of your target, you must implement certain parts of the execution support files. Execution Support Files summarizes the execution support files.

### Execution Support Files

You Provide...	The Code Generator Provides...
Customized main program	Generic main program
Timer interrupt handler to run model	Execution engine and integration solver (called by timer interrupt handler)
Other interrupt handlers	Example interrupt handlers (Asynchronous Interrupt blocks)
Device drivers	Example device drivers
Data logging, parameter tuning, signal monitoring, and external mode support	Data logging, parameter tuning, signal monitoring, and external mode APIs

### User-Written Execution Support Files

The code generator provides most of the execution support files. Depending on the requirements of your target, you must implement some or all of the following elements:

- A timer *interrupt service routine* (ISR). The timer runs at the program's base sample rate. The timer ISR is responsible for operations that must be completed within a single clock period, such as computing the current output sample. The timer ISR usually calls the `rt_OneStep` function.

If you are targeting a real-time operating system (RTOS), your generated code usually executes under control of the timing and task management mechanisms provided by the RTOS. In this case, you may not have to implement a timer ISR.

- The *main program*. Your main program initializes the blocks in the model, installs the timer ISR, and executes a background task or loop. The timer periodically interrupts the main loop. If the main program is designed to run for a finite amount of time, it is also responsible for cleanup operations — such as memory deallocation and masking the timer interrupt — before terminating the program.

If you are targeting a real-time operating system (RTOS), your main program most likely spawns tasks (corresponding to the sample rates used in the model) whose execution is timed and controlled by the RTOS.

Your main program typically is based on a generated or static main program. “Deploy Generated Standalone Executables To Target Hardware” on page 49-2 details the structure of the execution support files and the execution of code, and provides guidelines for customizing main programs.

- *Device drivers*. Drivers communicate with I/O devices on your target hardware. In production code, device drivers are normally implemented as inlined S-functions.
- *Other interrupt handlers*. If your models need to support asynchronous events, such as hardware generated interrupts and asynchronous read and write operations, you must supply interrupt handlers. The Interrupt Templates library provides examples.
- *Data logging, parameter tuning, signal monitoring, and external mode support*. It is atypical to implement rapid prototyping features such as external mode support in an embedded target. However, it is possible to support these features by using standard code generator APIs. See “Data Exchange Interfaces” for details.

## Control Files

The code generation and build process is directed by a number of TLC and MATLAB files collectively called *control files*. This section introduces and summarizes the main control files.

### Top-Level Control File (`make_rtw`)

The build process is initiated when you press **Ctrl+B**. At this point, the build process parses the **Make command** field of the **Code Generation** pane of the Configuration Parameters dialog box, expecting to find the name of a MATLAB command that controls the build process (as well as optional arguments to that command). The default command is `make_rtw`, and the default top-level control file for the build process is `make_rtw.m`.

---

**Note:** `make_rtw` is an internal MATLAB command used by the build process. Normally, target developers do not need detailed knowledge of how `make_rtw` works. (The details for target developers are described in “Target Development and the Build Process” on page 71-23.) You should not invoke `make_rtw` directly from MATLAB code, and you should not customize `make_rtw.m`.

---

The `make_rtw.m` file contains the logic required to execute your target-specific control files, including a number of hook points for execution of your custom code. `make_rtw` does the following:

- Passes optional arguments in to the build process
- Performs required preprocessing before code generation
- Executes the STF to perform code generation (and optional HTML report generation)
- Processes the TMF to generate a makefile
- Invokes a make utility to execute the makefile and build an executable
- Performs required post-processing (such as generating calibration data files or downloading the generated executable to the target)

### System Target File (STF)

The Target Language Compiler (TLC) generates target-specific C or C++ code from an partial description of your Simulink block diagram (`model.rtw`). The Target Language Compiler reads `model.rtw` and executes a program consisting of several target files (`.tlc` files.) The STF, at the top level of this program, controls the code generation process. The output of this process is a number of source files, which are fed to your development system's make utility.

You need to create a customized STF to set code generation parameters for your target. You should copy, rename, and modify the standard ERT system target file (`matlabroot/rtw/c/ert/ert.tlc`).

The detailed structure of the STF is described in “Customize System Target Files” on page 71-29.

---

**Note:** The STF selects whether the target supports the toolchain approach or template makefile approach for code generation. See “Customize System Target Files” on page 71-29.

---

### Template Makefile (TMF)

A TMF provides information about your model and your development system. The build process uses this information to create a makefile (.mk file) that builds an executable program.

Some targets implement more than one TMF, in order to support multiple development environments (for example, two or more cross-compilers) or multiple modes of code generation (for example, generating a binary executable versus generating a project file for your compiler).

The Embedded Coder software provides a large number of TMFs suitable for different types of development computer systems. These TMFs are located in *matlabroot*/rtw/c/ert (open). The standard TMFs are described in “Template Makefiles and Make Options”.

The detailed structure of the TMF is described in “Customize Template Makefiles” on page 71-62.

---

**Note:** The STF selects whether the target supports the toolchain approach or template makefile approach for code generation. See “Customize System Target Files” on page 71-29.

---

### Hook Files

The build process allows you to supply optional *hook files* that are executed at specified points in the code generation and make process. You can use hook files to add target-specific actions to the build process.

The hook files must follow well-defined naming and location requirements. “Folder and File Naming Conventions” on page 71-11 describes these requirements.

## Key Folders Under Target Root (mytarget)

- “Target Root Folder (mytarget)” on page 71-17
- “Target Folder (mytarget/mytarget)” on page 71-17
- “Target Block Folder (mytarget/blocks)” on page 71-17
- “Development Tools Folder (mytarget/dev\_tool1, mytarget/dev\_tool2)” on page 71-19
- “Target Source Code Folder (mytarget/src)” on page 71-19

### Target Root Folder (mytarget)

This folder contains the key subfolders for the target (see “Folder and File Naming Conventions” on page 71-11). You can also locate miscellaneous files (such as a `readme` file) in the target root folder. The following sections describe required and optional subfolders and their contents.

### Target Folder (mytarget/mytarget)

This folder contains files that are central to the target, such as the system target file (STF) and template makefile (TMF). “Key Files in Target Folder (mytarget/mytarget)” on page 71-19 summarizes the files that should be stored in `mytarget/mytarget`, and provides pointers to detailed information about these files.

---

**Note** `mytarget/mytarget` should be on the MATLAB path.

---

### Target Block Folder (mytarget/blocks)

If your target includes device drivers or other blocks, locate the block implementation files in this folder. `mytarget/blocks` contains

- Compiled block MEX-files
- Source code for the blocks
- TLC inlining files for the blocks
- Library models for the blocks (if you provide your blocks in one or more libraries)

---

**Note** `mytarget/blocks` should be on the MATLAB path.

---

You can also store example models and supporting files in `mytarget/blocks`. Alternatively, you can create a `mytarget/mytargetdemos` folder, which should also be on the MATLAB path.

To display your blocks in the standard Simulink Library Browser and/or integrate your example models into the MATLAB session environment, you can create the files described below and store them in `mytarget/blocks`.

### **mytarget/blocks/siblocks.m**

This file allows a group of blocks to be integrated into the Simulink Library and Simulink Library Browser.

#### **Example siblocks.m File**

```
function blkStruct = siblocks
% Information for "Blocksets and Toolboxes" subsystem
blkStruct.Name = sprintf('Embedded Target\n for MYTARGET');
blkStruct.OpenFcn = 'mytargetlib';
blkStruct.MaskDisplay = 'disp(''MYTARGET'')';

% Information for Simulink Library Browser
Browser(1).Library = 'mytargetlib';
Browser(1).Name = 'Embedded Target for MYTARGET';
Browser(1).IsFlat = 1;% Is this library "flat" (i.e. no subsystems)?

blkStruct.Browser = Browser;
```

### **mytarget/blocks/demos.xml**

This file provides information about the components, organization, and location of example models. MATLAB software uses this information to place the example in the MATLAB session environment.

#### **Example demos.xml File**

```
<?xml version="1.0" encoding="utf-8"?>
<demos>
 <name>Embedded Target for MYTARGET</name>
 <type>simulink</type>
 <icon>$toolbox/matlab/icons/boardicon.gif</icon>
 <description source = "file">mytarget_overview.html</description>

 <demosession>
 <label>Multirate model</label>
 <demositem>
 <label>MYTARGET demo</label>
 <file>mytarget_overview.html</file>
 <callback>mytarget_model</callback>
```

```
</demoitem>
</demosession>

</demos>
```

### **Development Tools Folder (`mytarget/dev_tool1`, `mytarget/dev_tool2`)**

These folders contain files associated with specific development environments or tools (`dev_tool1`, `dev_tool2`, etc.). Normally, your target supports at least one such development environment and invokes its compiler, linker, and other utilities during the build process. `mytarget/dev_tool1` includes linker command files, startup code, hook functions, and other files required to support this process.

For each development environment, you should provide a separate folder.

### **Target Source Code Folder (`mytarget/src`)**

This folder is optional. If the complexity of your target requires it, you can use `mytarget/src` to store common source code and configuration code (such as boot and startup code).

## **Key Files in Target Folder (`mytarget/mytarget`)**

- “Introduction” on page 71-19
- “`mytarget.tlc`” on page 71-20
- “`mytarget.tmf`” on page 71-20
- “`mytarget_genfiles.tlc`” on page 71-20
- “`mytarget_main.c`” on page 71-20
- “`STF_make_rtw_hook.m`” on page 71-21
- “`STF_rtw_info_hook.m` (obsolete)” on page 71-21
- “`info.xml`” on page 71-21
- “`mytarget_overview.html`” on page 71-21

### **Introduction**

The target folder `mytarget/mytarget` contains key files in your target implementation. These include the system target file, template makefile, main program module, and optional M and TLC hook files that let you add target-specific actions to the build process. The following sections describe the key target folder files.

**mytarget.tlc**

`mytarget.tlc` is the system target file (STF). Functions of the STF include

- Making the target visible in the System Target File Browser
- Definition of code generation options for the target (inherited and target-specific)
- Providing an entry point for the top-level control of the TLC code generation process

You should base your STF on `ert.tlc`, the STF provided by Embedded Coder software.

“Customize System Target Files” on page 71-29 gives detailed information on the structure of the STF, and also gives instructions on how to customize an STF to

- Display your target in the System Target File Browser
- Add your own target options to the Configuration Parameters dialog box
- Tailor the code generation and build process to the requirements of your target

**mytarget.tmf**

`mytarget.tmf` is the template makefile for building an executable for your target.

For basic information on the structure and operation of template makefiles, see “Customize Template Makefiles” on page 71-62.

If your target development environment requires automation of a modern integrated development environment (IDE) rather than use of a traditional make utility, see “Interface to Development Tools” on page 71-104.

**mytarget\_genfiles.tlc**

This file is optional. `mytarget_genfiles.tlc` is useful as a central file from which to invoke target-specific TLC files that generate additional files as part of your target build process. For example, your target may create sub-makefiles or project files for a development environment, or command scripts for a debugger to do automatic downloads. See “Using `mytarget_genfiles.tlc`” on page 71-45 for details.

**mytarget\_main.c**

A main program module is required for your target. To provide a main module, you can either

- Modify the `rt_main.c` or `rt_cppclass_main.cpp` module provided by the software
- Generate `mytarget_main.c` or `.cpp` during the build process

“Deploy Generated Standalone Executables To Target Hardware” on page 49-2 contains a detailed description of the operation of main programs. The section also contains guidelines for generating and modifying a main program module.

### **STF\_make\_rtw\_hook.m**

`STF_make_rtw_hook.m` is an optional hook file that you can use to invoke target-specific functions or executables at specified points in the build process. `STF_make_rtw_hook.m` implements a function that dispatches to a specific action depending on the `method` argument that is passed into it.

“Customize Build Process with STF\_make\_rtw\_hook File” describes the operation of the `STF_make_rtw_hook.m` hook file in detail.

### **STF\_rtw\_info\_hook.m (obsolete)**

Prior to Release 14, custom targets supplied target-specific information with a hook file (referred to as `STF_rtw_info_hook.m`). The `STF_rtw_info_hook` specified properties such as word sizes for integer data types (for example, `char`, `short`, `int`, and `long`), and C implementation-specific properties of the custom target.

The `STF_rtw_info_hook` mechanism has been replaced by the **Hardware Implementation** pane of the Configuration Parameters dialog box. Using this dialog box, you can specify the properties that were formerly specified in your `STF_rtw_info_hook` file.

For backward compatibility, existing `STF_rtw_info_hook` files are still available. However, you should convert your target and models to use the **Hardware Implementation** pane. See “Platform Options for Development and Deployment”.

### **info.xml**

This file provides information to MATLAB software that specifies where to display the target toolbox in the MATLAB session environment. For more information, see “Display Custom Documentation” in the MATLAB documentation.

### **mytarget\_overview.html**

By convention, this file serves as home page for the target examples.

The `<description>` field in `demos.xml` should point to `mytarget_overview.html` (see “`mytarget/blocks/demos.xml`” on page 71-18).

#### Example `mytarget_overview.html` File

```
<html>
<head><title>Embedded Target for MYTARGET</title></head><body>
<p style="color:#990000; font-weight:bold; font-size:x-large">Embedded Target
for MYTARGET Example Model</p>

<p>This example provides a simple model that allows you to generate an executable
for a supported target board. You can then download and run the executable and
set breakpoints to study and monitor the execution behavior.</p>

</body>
</html>
```

## Additional Files for Externally Developed Targets

- “Introduction” on page 71-22
- “`mytarget/mytarget/mytarget_setup.m`” on page 71-22
- “`mytarget/mytarget/doc`” on page 71-23

### Introduction

If you are developing an embedded target that is not installed into the MATLAB tree, you should provide a target setup script and target documentation within `mytarget/mytarget`, for the convenience of your users. The following sections describe the required materials and where to place them.

#### `mytarget/mytarget/mytarget_setup.m`

This file script adds paths for your target to the MATLAB path. Your documentation should instruct users to run the script when installing the target.

You should include a call to the MATLAB function `savepath` in your `mytarget_setup.m` script. This function saves the added paths, so users need to run `mytarget_setup.m` only once.

The following code is an example `mytarget_setup.m` file.

```
function mytarget_setup()
curpath = pwd;
tgtpath = curpath(1:end-length('\mytarget'));
```

```
addpath(fullfile(tgtpath, 'mytarget'));
addpath(fullfile(tgtpath, 'dev_tool1'));
addpath(fullfile(tgtpath, 'blocks'));
addpath(fullfile(tgtpath, 'mytargetdemos'));
savepath;
disp('MYTARGET Target Path Setup Complete.');
```

### **mytarget/mytarget/doc**

You should put the documentation related to your target in the folder `mytarget/mytarget/doc`.

## **Target Development and the Build Process**

- “About the Build Process” on page 71-23
- “Build Process Phases and Information Passing” on page 71-23
- “Additional Information Passing Techniques” on page 71-26

### **About the Build Process**

To develop an embedded target, you need a thorough understanding of the build process. Your embedded target uses the build process and may require you to modify or customize the process. A general overview of code generation and the build process is given in “Code Generation” and “Build Process”.

This section supplements that overview with a description of the build process as customized by the Embedded Coder software. The emphasis is on points in the process where customization hooks are available and on passing information between different phases of the process.

This section concludes with “Additional Information Passing Techniques” on page 71-26, describing assorted tips and tricks for passing information during the build process.

### **Build Process Phases and Information Passing**

It is important to understand where (and when) the build process obtains required information. Sources of information include

- The `model.rtw` file, which provides information about the generating model. The information in `model.rtw` is available to target TLC files.

- The code generation panes of the Configuration Parameters dialog box. Options (both general and target-specific) are provided through check boxes, menus, and edit fields. You can associate options with TLC variables in the `rtwoptions` data structure. Use the **Configuration Parameters > Code Generation > Custom Code > Additional build information > Defines** field to define makefile tokens .
- The selected toolchain (for toolchain approach builds) or selected template makefile `.tmf` (for template makefile approach builds); these generate the model-specific makefile.
- Environment variables on the host computer. Environment variables provide additional information about installed development tools.
- Other target-specific files such as target-related TLC files, linker command files, or project files.

It is also important to understand the several phases of the build process and how to pass information between the phases. The build process comprises several high-level phases:

- Execution of the top-level file (`slbuild.m` or `rtwbuild.m`) to sequence through the build process for a target
- Conversion of the model into the TLC input file (`model.rtw`)
- Generation of the target code by the TLC compiler
- Compilation of the generated code with `make` or other utilities
- Transmission of the final generated executable to the target hardware with a debugger or download utility

It is helpful to think of each phase of the process as a different “environment” that maintains its own data. These environments include

- MATLAB code execution environment (MATLAB)
- Simulink
- Target Language Compiler execution environment
- makefile
- Development environments such as and IDE or debugger

In each environment, you might get information from the various sources mentioned above. For example, during the TLC phase, execute MATLAB file might execute to obtain information from the MATLAB environment. Also, a given phase may generate information for a subsequent phase.

See “Key Files in Target Folder (mytarget/mytarget)” on page 71-19 for details on the available MATLAB file and TLC hooks for information passing, with code examples.

## Additional Information Passing Techniques

This section describes a number of useful techniques for passing information among different phases of the build process.

### **tlcvariable Field in rtwoptions Structure**

Parameters on the code generation panes of the Configuration Parameters dialog box can be associated with a TLC variable, and specified in the `tlcvariable` field of the option's entry in the `rtwoptions` structure. The variable value is passed on the command line when TLC is invoked. This provides a way to make code generation parameters and their values available in the TLC phase.

See “System Target File Structure” on page 71-30 for further information.

### **makevariable Field in rtwoptions Structure**

You can associate code generation parameters with a template makefile token, that you specify in the `makevariable` field of the option's entry in the `rtwoptions` structure. If a token of the same name as the `makevariable` name exists in the TMF, the token is updated with the option value when the final makefile is created. If the token does not exist in the TMF, the `makevariable` is passed in on the command line when `make` is invoked. Thus, in either case, the `makevariable` is available to the makefile.

See “System Target File Structure” on page 71-30 for further information.

### **Accessing Host Environment Variables**

You can access host shell environment variables at the MATLAB command line by entering the `getenv` command. For example:

```
getenv ('MSDEVDIR')
```

```
ans =
```

```
D:\Applications\Microsoft Visual Studio\Common\MSDev98
```

To access the same information from TLC, use the `FEVAL` directive to invoke `getenv`.

```
%assign eVar = FEVAL("getenv", "<varname>")
```

### **Supplying Development Environment Information to Your Template Makefile**

An embedded target must tie the build process to target-specific development tools installed on a host computer. For the make process to run these tools, the TMF must

be able to determine the name of the tools, the path to the compiler, linker, and other utilities, and possibly the host operating system environment variable settings.

Require the end user to modify the target TMF. The user enters path information (such as the location of a compiler executable), and possibly host operating system environment variables, as make variables. This allows the TMF to be tailored to specific needs.

### Using MATLAB Application Data

Application data provides a way for applications to save and retrieve data stored with the GUI. This technique enables you to create what is essentially a user-defined property for an object, and use this property to store data for use in the build process. If you are unfamiliar with this technique, see the “Store Data as Application Data” section of the MATLAB documentation of creating graphical user interfaces.

The following code examples illustrates the use of application data to pass information to TLC.

This file, `tlc2appdata.m`, stores the data passed in as application data under the name passed in (`appDataName`).

```
function k = tlc2appdata(appDataName,data)
 disp([mfilename,': ',appDataName,' ', data]);
 setappdata(0,appDataName,data);
 k = 0; % TLC expects a return value for FEVAL.
```

The following sample TLC file uses the FEVAL directive to invoke `tlc2appdata.m` to store arbitrary application data, under the name `z80`.

```
%% test.tlc
%%
%assign myApp = "z80"
%assign myData = "314159"
%assign dummy = FEVAL("tlc2appdata",myApp,myData)
```

To test this technique:

- 1 Create the `tlc2appdata.m` file as shown. Check that `tlc2appdata.m` is stored in a folder on the MATLAB path.
- 2 Create the TLC file as shown. Save it as `test.tlc`.
- 3 Enter the following command at the MATLAB prompt to execute the TLC file:

```
tlc test.tlc
```

- 4 Get the application data at the MATLAB prompt:

```
k = getappdata(0, 'z80')
```

The function returns the value 314159.

- 5 Enter the following command.

```
who
```

Note that application data is not stored in the MATLAB workspace. Also observe that the z80 data is not visible. Using application data in this way has the advantage that it does not clutter the MATLAB workspace. Also, it helps prevent you from accidentally deleting your data, since it is not stored directly in the your workspace.

A real-world use of application data might be to collect information from the *model.rtw* file and store it for use later in the build process.

### **Adding Block-Specific Information to the Makefile**

The `rtwmakecfg` mechanism provides a method for inlined S-functions such as driver blocks to add information to the makefile. This mechanism is described in “Use `rtwmakecfg.m` API to Customize Generated Makefiles”.

## **More About**

- “About Embedded Target Development”

## Customize System Target Files

This section provides information on the structure of the STF, guidelines for customizing an STF, and a basic tutorial that helps you get a skeletal STF up and running.

### In this section...

“Control Code Generation With the System Target File” on page 71-29

“System Target File Naming and Location Conventions” on page 71-30

“System Target File Structure” on page 71-30

“Define and Display Custom Target Options” on page 71-37

“Tips and Techniques for Customizing Your STF” on page 71-44

“Create a Custom Target Configuration” on page 71-48

### Control Code Generation With the System Target File

The system target file (STF) exerts overall control of the code generation stage of the build process. The STF also lets you control the presentation of your target to the end user. The STF provides

- Definitions of variables that are fundamental to the build process, such as the value for the `CodeFormat` TLC variable
- The main entry point to the top-level TLC program that generates code
- Target information for display in the System Target File Browser
- A mechanism for defining target-specific code generation options (and other parameters related to the build process) and for displaying them in the Configuration Parameters dialog box
- A mechanism for inheriting options from another target (such as the Embedded Real-Time (ERT) target)

Note that, although the STF is a Target Language Compiler (TLC) file, it contains embedded MATLAB code. Before creating or modifying an STF, you should acquire a working knowledge of TLC and of the MATLAB language. “Target Language Compiler” and “Scripts vs. Functions” describe the features and syntax of both the TLC and MATLAB languages.

While reading this section, you may want to refer to the STFs provided with the code generator. Most of these files are stored in the target-specific folders under `matlabroot/`

rtw/c (open). Additional STF files are stored under *matlabroot/toolbox/rtw/targets* (open).

## System Target File Naming and Location Conventions

An STF must be located in a folder on the MATLAB path for the target to be displayed in the System Target File Browser and invoked in the build process. Follow the location and naming conventions for STFs and related target files given in “Folder and File Naming Conventions” on page 71-11.

## System Target File Structure

- “Overview” on page 71-30
- “Header Comments” on page 71-32
- “TLC Configuration Variables” on page 71-33
- “TLC Program Entry Point and Related %includes” on page 71-34
- “RTW\_OPTIONS Section” on page 71-35
- “rtwgensettings Structure” on page 71-35
- “Additional Code Generation Options” on page 71-37
- “Model Reference Considerations” on page 71-37

### Overview

This section is a guide to the structure and contents of an STF. The following listing shows the general structure of an STF. Note that this is not a complete code listing of an STF. The listing consists of excerpts from each of the sections that make up an STF.

```
%%-----
%% Header Comments Section
%%-----
%% SYSTLC: Example Real-Time Target
%% TMF: my_target.tmf MAKE: make_rtw EXTMODE: ext_comm
%% Initial comments contain directives for STF Browser.
%% Documentation, date, copyright, and other info may follow.
 ...
%selectfile NULL_FILE
 ...
%%-----
%% TLC Configuration Variables Section
%%-----
%% Assign code format, language, target type.
%%
%assign CodeFormat = "Embedded-C"
```

```

%assign TargetType = "RT"
%assign Language = "C"
%%
%%-----
%% TLC Program Entry Point
%%-----
%% Call entry point function.
%include "codegenentry.tlc"
%%
%%-----
%% (OPTIONAL) Generate Files for Build Process
%%-----
%include "mytarget_genfiles.tlc"
%%-----
%% RTW_OPTIONS Section
%%-----
/%
BEGIN_RTW_OPTIONS
%% Define rtwoptions structure array. This array defines target-specific
%% code generation variables, and controls how they are displayed.
rtwoptions(1).prompt = 'example code generation options';
...
rtwoptions(6).prompt = 'Show eliminated blocks';
rtwoptions(6).type = 'Checkbox';
...
%------%
% Configure RTW code generation settings %
%------%
...
%-----
%% rtwgensettings Structure
%%-----
%% Define suffix text for naming build folder here.
rtwgensettings.BuildDirSuffix = '_mytarget_rtw'
%% Callback compatibility declaration
rtwgensettings.Version = '1';

%% (OPTIONAL) target inheritance declaration
rtwgensettings.DerivedFrom = 'ert.tlc';
%% (OPTIONAL) other rtwGenSettings fields...
...
END_RTW_OPTIONS
%/
%%-----
%% targetComponentClass - MATHWORKS INTERNAL USE ONLY
%% REMOVE NEXT SECTION FROM USER_DEFINED CUSTOM TARGETS
%%-----
/%
BEGIN_CONFIGSET_TARGET_COMPONENT
targetComponentClass = 'Simulink.ERTTargetCC';
END_CONFIGSET_TARGET_COMPONENT
%/

```

If you are creating a custom target based on an existing STF, you must remove the `targetComponentClass` section (bounded by the directives

BEGIN\_CONFIGSET\_TARGET\_COMPONENT and END\_CONFIGSET\_TARGET\_COMPONENT). This section is reserved for the use of targets developed internally by MathWorks.

### Header Comments

These lines at the head of the file are formatted as TLC comments. They provide required information to the System Target File Browser and to the build process. Note that you must place the browser comments at the head of the file, before other comments or TLC statements.

The presence of the comments enables the code generator to detect STFs. When the System Target File Browser is opened, the code generator scans the MATLAB path for TLC files that have formatted header comments. The comments contain the following directives:

- **SYSTLC**: The descriptor that appears in the browser.
- **TMF**: Name of the template makefile (TMF) to use during build process. When the target is selected, this filename is displayed in the “Template makefile” field of the **Code Generation** pane of the Configuration Parameters dialog box.
- **MAKE**: `make` command to use during build process. When the target is selected, this command is displayed in the **Make command** field of the **Code Generation** pane of the Configuration Parameters dialog box.
- **EXTMODE**: Name of external mode interface file (if any) associated with your target. If your target does not support external mode, use `no_ext_comm`.

The following header comments are from `matlabroot/rtw/c/ert/ert.tlc`.

```
%% SYSTLC: Embedded Coder TMF: ert_default_tmf MAKE: make_rtw \
%% EXTMODE: ext_comm
%% SYSTLC: Create Visual C/C++ Solution File for Embedded Coder\
%% TMF: RTW.MSVBuild MAKE: make_rtw EXTMODE: ext_comm
.
.
.
```

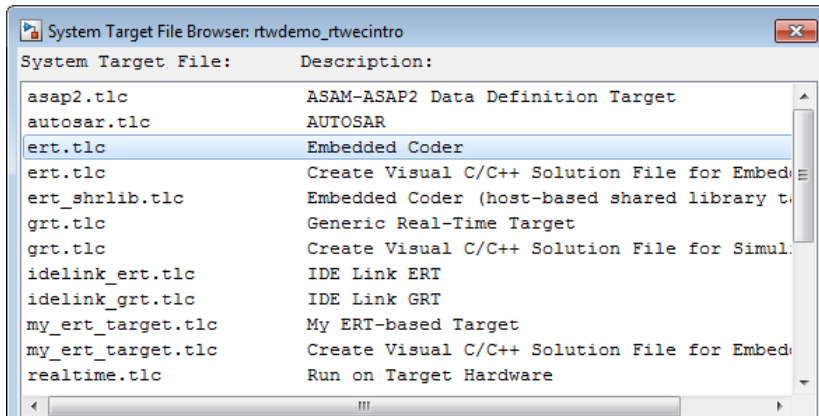

---

**Note:** Limitation: Each comment can only contain a maximum of two lines, as shown in the preceding example.

---

Note that you can specify more than one group of directives in the header comments. Each such group is displayed as a different target configuration in the System Target File Browser. In the above example, the first two lines of code specify the default configuration of the ERT target. The next two lines specify a configuration that creates

and builds a Microsoft Visual C++ Solution (.sln) file. The figure below shows how these configurations appear in the System Target File Browser.

See “Create a Custom Target Configuration” on page 71-48 for an example of customized header comments.

### TLC Configuration Variables

This section of the STF assigns global TLC variables that relate to the overall code generation process.

For an embedded target, in most cases you should simply use the global TLC variable settings used by the ERT target (`ert.tlc`). It is especially important that your STF use the ‘Embedded-C’ value for the `CodeFormat` TLC variable and uses the corresponding `rtwgensettings.DerivedFrom = 'ert.tlc'` in the `RTW_OPTIONS` section of the TLC file. Verify that values are assigned to the following variables:

- **CodeFormat:** The `CodeFormat` TLC variable selects generated code features. The ‘Embedded-C’ value for this variable is used by the ERT target. Your ERT-based target should specify ‘Embedded-C’ as the value for `CodeFormat`. This selection is designed for production code, minimal memory usage, static memory allocation, and a simplified interface to generated code.

For information on other values for the `CodeFormat` TLC variable, see “System Target Files and Code Generation Features”.

- **Language:** The only valid value is `C`, which enables support for C or C++ code generation as specified by the configuration parameter `TargetLang`.

- **TargetType**: The code generator defines the preprocessor symbols RT and NRT to distinguish simulation code from real-time code. These symbols are used in conditional compilation. The **TargetType** variable determines whether RT or NRT is defined.

Most targets are intended to generate real-time code. They assign **TargetType** as follows.

```
%assign TargetType = "RT"
```

Some targets, such as the model reference simulation target, accelerated simulation target, RSim target, and S-function target, generate code for use in nonreal time only. Such targets assign **TargetType** as follows.

```
%assign TargetType = "NRT"
```

### TLC Program Entry Point and Related %includes

The code generation process normally begins with `codegenentry.tlc`. The STF invokes `codegenentry.tlc` as follows.

```
%include "codegenentry.tlc"
```

---

**Note** `codegenentry.tlc` and the lower-level TLC files assume that `CodeFormat`, `TargetType`, and `Language` have been assigned. Set these variables before including `codegenentry.tlc`.

---

If you need to implement target-specific code generation features, you should include the TLC file `mytarget_genfiles.tlc` in your STF. This file provides a mechanism for executing custom TLC code before and after invoking `codegenentry.tlc`. For information on this mechanism, see

- “Using `mytarget_genfiles.tlc`” on page 71-45 for an example of custom TLC code for execution after the main code generation entry point.
- “Target Development and the Build Process” on page 71-23 for general information on the build process, and for information on other build process customization hooks.

Another way to customize the code generation process is to call lower-level functions (normally invoked by `codegenentry.tlc`) directly, and include your own TLC functions at each stage of the process. This approach should be taken with caution. See “TLC Files” for more information.

The lower-level functions called by `codegenentry.tlc` are

- `genmap.tlc`: maps block names to corresponding language-specific block target files.
- `commonsetup.tlc`: sets up global variables.
- `commonentry.tlc`: starts the process of generating code.

### RTW\_OPTIONS Section

The `RTW_OPTIONS` section is bounded by the directives:

```
/%
 BEGIN_RTW_OPTIONS
 .
 .
 .
 END_RTW_OPTIONS
%/
```

The first part of the `RTW_OPTIONS` section defines an array of `rtwoptions` structures. This structure is discussed in “Using `rtwoptions` to Display Custom Target Options” on page 71-38.

The second part of the `RTW_OPTIONS` section defines `rtwgensettings`, a structure defining the build folder name and other settings for the code generation process. See “`rtwgensettings` Structure” on page 71-35 for information about `rtwgensettings`.

### rtwgensettings Structure

The final part of the STF defines the `rtwgensettings` structure. This structure stores information that is written to the `model.rtw` file and used by the build process. The `rtwgensettings` fields of most interest to target developers are

- `rtwgensettings.Version`: Use this property to enable `rtwoptions` callbacks and to use the Callback API in `rtwgensettings.SelectCallback`.

---

**Note:** To use callbacks, you *must* set:

```
rtwgensettings.Version = '1';
```

---

Add the statement above to the **Configure RTW code generation settings** section of the system target file.

- `rtwgensettings.DerivedFrom`: This structure field defines the system target file from which options are to be inherited. See “Inheriting Target Options” on page 71-43.
- `rtwgensettings.SelectCallback`: This structure field specifies a `SelectCallback` function. You must set `rtwgensettings.Version = '1'`; or your callback will be ignored. `SelectCallback` is associated with the target rather than with any of its individual options. The `SelectCallback` function is triggered when the user selects a target with the System Target File browser.

The `SelectCallback` function is useful for setting up (or disabling) configuration parameters specific to the target.

The following code installs a `SelectCallback` function:

```
rtwgensettings.SelectCallback = 'my_select_callback_handler(hDlg,hSrc)';
```

The arguments to the `SelectCallback` function (`hDlg`, `hSrc`) are handles to private data used by the callback API functions.

---

**Note** If you have developed a custom target and you want it to be compatible with model referencing, you must implement a `SelectCallback` function to declare model reference compatibility. See “Support Model Referencing” on page 71-83.

---

- `rtwgensettings.ActivateCallback`: this property specifies an `ActivateCallback` function. The `ActivateCallback` function is triggered when the active configuration set of the model changes. This could happen during model loading, and also when the user changes the active configuration set.

The following code installs an `ActivateCallback` function:

```
rtwgensettings.ActivateCallback = 'my_activate_callback_handler(hDlg,hSrc)';
```

The arguments to the `ActivateCallback` function (`hDlg`, `hSrc`) are handles to private data used by the callback API functions.

- `rtwgensettings.PostApplyCallback`: this property specifies a `PostApplyCallback` function. The `PostApplyCallback` function is triggered when the user clicks the **Apply** or **OK** button after editing options in the Configuration Parameters dialog box. The `PostApplyCallback` function is called after the changes have been applied to the configuration set.

The following code installs an `PostApplyCallback` function:

```
rtwgensettings.PostApplyCallback = 'my_postapply_callback_handler(hDlg,hSrc)';
```

The arguments to the `PostApplyCallback` function (`hDlg`, `hSrc`) are handles to private data used by the callback API functions.

- `rtwgensettings.BuildDirSuffix`: Most targets define a folder name suffix that identifies build folders created by the target. The build process appends the suffix defined in the `rtwgensettings.BuildDirSuffix` field to the model name to form the name of the build folder. For example, if you define `rtwgensettings.BuildDirSuffix` as follows

```
rtwgensettings.BuildDirSuffix = '_mytarget_rtw'
```

the build folders are named `model_mytarget_rtw`.

### Additional Code Generation Options

“Configure Generated Code with TLC” describes additional TLC code generation variables. End users of a target can assign these variables by entering a MATLAB command of the form

```
set_param(modelName,'TLCOptions','-aVariable=val');
```

(For more information, see “Specify TLC Options”.)

However, the preferred approach is to assign these variables in the STF using statements of the form:

```
%assign Variable = val
```

For readability, we recommend that you add such assignments in the section of the STF after the comment **Configure RTW code generation settings**.

### Model Reference Considerations

See “Support Model Referencing” on page 71-83 for important information on STF and other modifications you may need to make to support the code generator model referencing features.

### Define and Display Custom Target Options

- “Using `rtwoptions` to Display Custom Target Options” on page 71-38
- “Example System Target File With Customized `rtwoptions`” on page 71-42

- “Inheriting Target Options” on page 71-43

### Using `rtwoptions` to Display Custom Target Options

You control the options to display in the **Code Generation** pane of the Configuration Parameters dialog box by customizing the `rtwoptions` structure in your system target file.

The fields of the `rtwoptions` structure define variables and associated user interface elements to be displayed in the Configuration Parameters dialog box. Using the `rtwoptions` structure array, you can define target-specific options displayed in the dialog box and organize options into categories. You can also write callback functions to specify how these options are processed.

When the **Code Generation** pane opens, the `rtwoptions` structure array is scanned and the listed options are displayed. Each option is represented by an assigned user interface element (check box, edit field, menu, or push button), which displays the current option value.

The user interface elements can be in an enabled or disabled (grayed-out) state. If an option is enabled, the user can change the option value.

You can also use the `rtwoptions` structure array to define special NonUI elements that cause callback functions to be executed, but that are not displayed in the **Code Generation** pane. See “NonUI Elements” on page 71-42 for details.

The elements of the `rtwoptions` structure array are organized into groups. Each group of items begins with a header element of type **Category**. The default field of a **Category** header must contain a count of the remaining elements in the category.

The **Category** header is followed by options to be displayed on the **Code Generation** pane. The header in each category is followed by one or more option definition elements.

Each category of target options corresponds to options listed under **Code Generation** in the Configuration Parameters dialog box.

The table `rtwoptions` Structure Fields Summary summarizes the fields of the `rtwoptions` structure.

#### Example `rtwoptions` Structure

The following `rtwoptions` structure is excerpted from an example system target file, `matlabroot/toolbox/rtw/rtwdemos/rtwoptions_demo/usertarget.tlc`. The

code defines an `rtwoptions` structure array. The default field of the first (header) element is set to 4, indicating the number of elements that follow the header.

```

rtwoptions(1).prompt = 'userPreferred target options (I)';
rtwoptions(1).type = 'Category';
rtwoptions(1).enable = 'on';
rtwoptions(1).default = 4; % number of items under this category
 % excluding this one.
rtwoptions(1).popupstrings = ''; % At the first item, user has to
rtwoptions(1).tlcvariable = ''; % initialize all supported fields
rtwoptions(1).tooltip = '';
rtwoptions(1).callback = '';
rtwoptions(1).makevariable = '';

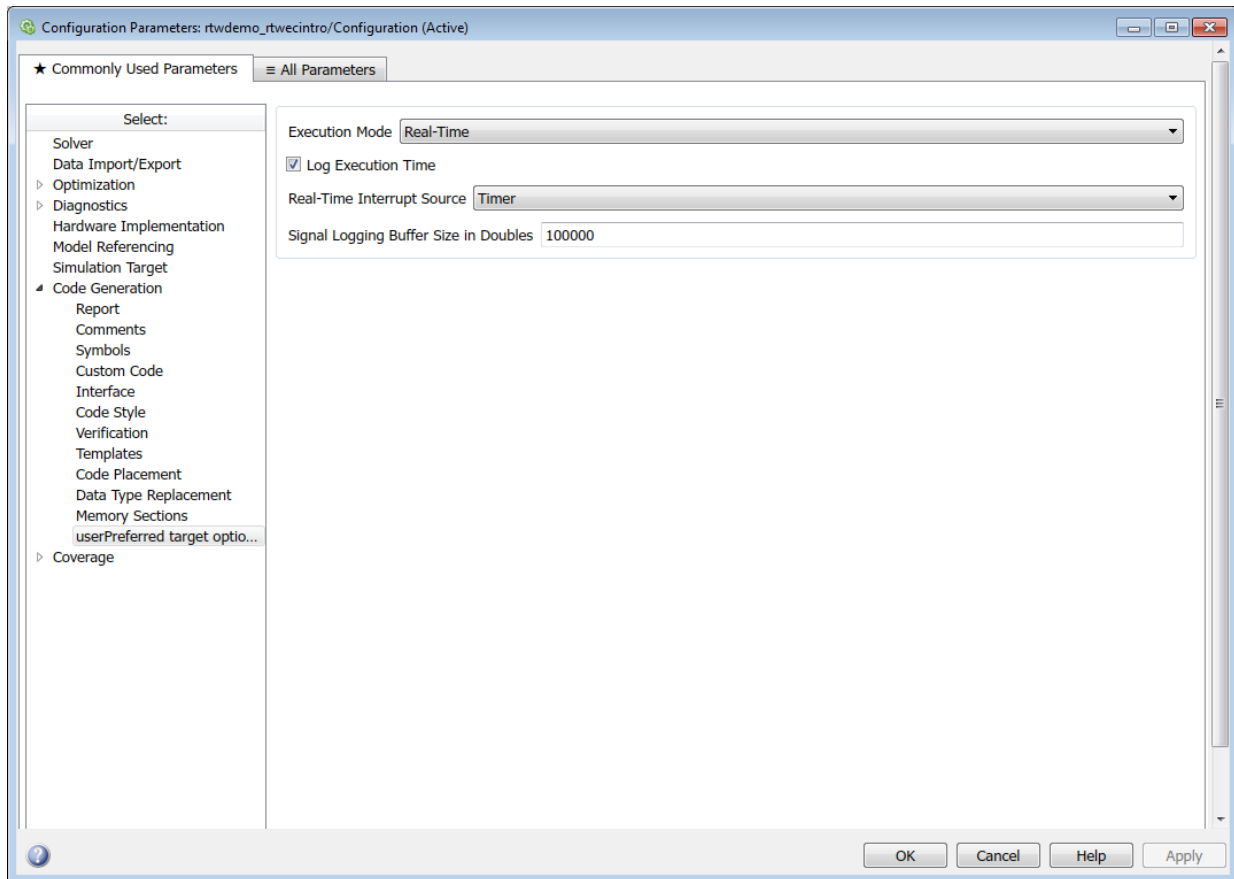

rtwoptions(2).prompt = 'Execution Mode';
rtwoptions(2).type = 'Popup';
rtwoptions(2).default = 'Real-Time';
rtwoptions(2).popupstrings = 'Real-Time|UserDefined';
rtwoptions(2).tlcvariable = 'tlcvariable1';
rtwoptions(2).tooltip = ['See this text as tooltip'];

rtwoptions(3).prompt = 'Log Execution Time';
rtwoptions(3).type = 'Checkbox';
rtwoptions(3).default = 'on';
rtwoptions(3).tlcvariable = 'RL32LogTETModifier';
rtwoptions(3).tooltip = ['']; % no tooltip

rtwoptions(4).prompt = 'Real-Time Interrupt Source';
rtwoptions(4).type = 'Popup';
rtwoptions(4).default = 'Timer';
rtwoptions(4).popupstrings = 'Timer|5|6|7|8|9|10|11|12|13|14|15';
rtwoptions(4).tlcvariable = 'tlcvariable3';
rtwoptions(4).callback = 'usertargetcallback(hDlg, hSrc, 'tlcvariable3')';
rtwoptions(4).tooltip = [''];
rtwoptions(4).tooltip = ['See TLC file for how to use reserved '...
 ' keyword ''hDlg'', and ''hSrc''.'];
...
rtwoptions(5).prompt = 'Signal Logging Buffer Size in Doubles';
rtwoptions(5).type = 'Edit';
rtwoptions(5).default = '100000';
rtwoptions(5).tlcvariable = 'tlcvariable2';
rtwoptions(5).tooltip = [''];

```

The first element adds a **userPreferred target options (I)** pane under **Code Generation** in the Configuration Parameters dialog box. The pane displays the options defined in `rtwoptions(2)`, `rtwoptions(3)`, `rtwoptions(4)`, and `rtwoptions(5)`.

If you want to define a large number of options, you can define multiple **Category** groups within a single system target file.

Note the `rtwoptions` structure and callbacks are written in MATLAB code, although they are embedded in a TLC file. To verify the syntax of your `rtwoptions` structure definitions and code, you can execute the commands at the MATLAB prompt by copying and pasting them to the MATLAB Command Window.

To learn more about `usertarget.tlc` and the example callback files provided with it, see “Example System Target File With Customized `rtwoptions`” on page 71-42. For more examples of target-specific `rtwoptions` definitions, see the `target.tlc` files under `matlabroot/rtw/c` (open).

rtwoptions Structure Fields Summary lists the fields of the `rtwoptions` structure.

### rtwoptions Structure Fields Summary

Field Name	Description
<code>callback</code>	For examples of callback usage, see “Example System Target File With Customized <code>rtwoptions</code> ” on page 71-42.
<code>closecallback</code> (obsolete)	Do not use <code>closecallback</code> . Use <code>rtwgensettings.PostApplyCallback</code> instead (see “ <code>rtwgensettings</code> Structure” on page 71-35).  <code>closecallback</code> is ignored.  For examples of callback usage, see “Example System Target File With Customized <code>rtwoptions</code> ” on page 71-42.
<code>default</code>	Default value of the option (empty if the <code>type</code> is <code>Pushbutton</code> ).
<code>enable</code>	Must be 'on' or 'off'. If 'on', the option is displayed as an enabled item; otherwise, as a disabled item.
<code>makevariable</code>	Template makefile token (if any) associated with the option. The <code>makevariable</code> is expanded during processing of the template makefile. See “Template Makefile Tokens” on page 71-62.
<code>modelReferenceParameter-Check</code>	Specifies whether the option must have the same value in a referenced model and its parent model. If this field is unspecified or has the value 'on' the option values must be same. If the field is specified and has the value 'off' the option values can differ. See “Controlling Configuration Option Value Agreement” on page 71-88.
<code>NonUI</code>	Element that is not displayed, but is used to invoke a close or open callback. See “NonUI Elements” on page 71-42.
<code>opencallback</code> (obsolete)	Do not use <code>opencallback</code> . Use <code>rtwgensettings.SelectCallback</code> instead (see “ <code>rtwgensettings</code> Structure” on page 71-35).  For examples of callback usage, see “Example System Target File With Customized <code>rtwoptions</code> ” on page 71-42.
<code>popupstrings</code>	If <code>type</code> is <code>Popup</code> , <code>popupstrings</code> defines the items in the menu. Items are delimited by the " " (vertical bar) character. The

Field Name	Description
	following example defines the items of the <b>MAT-file variable name modifier</b> menu used by the GRT target.  'rt_ _rt none'
prompt	Label for the option.
tlcvariable	Name of TLC variable associated with the option.
tooltip	Help text displayed when mouse is over the item.
type	Type of element: Checkbox, Edit, NonUI, Popup, Pushbutton, or Category.

### NonUI Elements

Elements of the `rtwoptions` array that have type `NonUI` exist solely to invoke callbacks. A `NonUI` element is not displayed in the Configuration Parameters dialog box. You can use a `NonUI` element if you want to execute a callback that is not associated with a user interface element, when the dialog box opens or closes. See the next section, “Example System Target File With Customized `rtwoptions`” on page 71-42 for an example.

---

**Note:** The default value of a `NonUI` element determines the set of values allowed for that element.

- If the default value is '0' or '1', the element stores a Boolean value.
  - If the default value contains an integer other than '0' or '1', the element stores a value of type `int32`.
  - If the default value does not contain an integer, the element is evaluated as a character vector.
- 

### Example System Target File With Customized `rtwoptions`

A working system target file, with MATLAB file callback functions, has been provided as an example of how to use the `rtwoptions` structure to display and process custom options on the **Code Generation** pane. The examples are compatible with the callback API.

The example target files are in the folder (open):

`matlabroot/toolbox/rtw/rtwdemos/rtwoptions_demo`

The example target files include:

- `usertarget.tlc`: The example system target file. This file illustrates how to define custom menus, check boxes, and edit fields. The file also illustrates the use of callbacks.
- `usertargetcallback.m`: A MATLAB file callback invoked by a menu.

Refer to the example files while reading this section. The example system target file, `usertarget.tlc`, illustrates the use of `rtoptions` to display the following custom target options:

- The **Execution Mode** menu.
- The **Log Execution Time** check box.
- The **Real-Time Interrupt Source** menu. The menu executes a callback defined in an external file, `usertargetcallback.m`. The TLC variable associated with the menu is passed in to the callback, which displays the menu's current value.
- The edit field **Signal Logging Buffer Size in Doubles**.

Try studying the example code while interacting with the example target options in the Configuration Parameters dialog box. To interact with the example target file,

- 1 Make `matlabroot/toolbox/rtw/rtwdemos/rtwoptions_demo` (open) your working folder.
- 2 Open a model of your choice.
- 3 Open the Configuration Parameters dialog box and select the **Code Generation** pane.
- 4 Click **Browse**. The System Target File Browser opens. Select `usertarget.tlc`. Then click **OK**.
- 5 Observe that the **Code Generation** pane contains a custom sub-tab: **userPreferred target options (I)**.
- 6 As you interact with the options in this category and open and close the Configuration Parameters dialog box, observe the messages displayed in the MATLAB Command Window. These messages are printed from code in the STF, or from callbacks invoked from the STF.

### Inheriting Target Options

`ert.tlc` provides a basic set of Embedded Coder code generation options. If your target is based on `ert.tlc`, your STF should normally inherit the options defined in ERT.

Use the `rtwgensettings.DerivedFrom` field in the `rtwgensettings` structure to define the system target file from which options are to be inherited. You should convert your custom target to use this mechanism as follows.

Set the `rtwgensettings.DerivedFrom` field value as in the following example:

```
rtwgensettings.DerivedFrom = 'stf.tlc';
```

where `stf` is the name of the system target file from which options are to be inherited. For example:

```
rtwgensettings.DerivedFrom = 'ert.tlc';
```

When the Configuration Parameters dialog box executes this line of code, it includes the options from `stf.tlc` automatically. If `stf.tlc` is a MathWorks internal system target file that has been converted to a new layout, the dialog box displays the inherited options using the new layout.

### Handling Unsupported Options

If your target does not support all of the options inherited from `ert.tlc`, you should detect unsupported option settings and display a warning or error message. In some cases, if a user has selected an option your target does not support, you may need to abort the build process. For example, if your target does not support the **Generate an example main program** option, the build process should not be allowed to proceed if that option is selected.

Even though your target may not support all inherited ERT options, it is required that the ERT options are retained in the **Code Generation** pane of the Configuration Parameters dialog box. Do not simply remove unsupported options from the `rtwoptions` structure in the STF. Options must be in the dialog box to be scanned by the code generator when it performs optimizations.

For example, you may want to prevent users from turning off the **Single output/update function** option. It may seem reasonable to remove this option from the dialog box and simply assign the TLC variable `CombineOutputUpdateFcns` to `on`. However, if the option is not included in the dialog box, the code generator assumes that output and update functions are *not* to be combined. Less efficient code is generated as a result.

## Tips and Techniques for Customizing Your STF

- “Introduction” on page 71-45
- “Required and Recommended %includes” on page 71-45

- “Handling Aliases for Target Option Values” on page 71-46
- “Supporting Multiple Development Environments” on page 71-48

## Introduction

The following sections include information on techniques for customizing your STF, including

- How to invoke custom TLC code from your STF
- Approaches to supporting multiple development environments

## Required and Recommended %includes

If you need to implement target-specific code generation features, we recommend that your STF include the TLC file `mytarget_genfiles.tlc`.

Once your STF has set up the required TLC environment, you must include `codegenentry.tlc` to start the standard code generation process.

`mytarget_genfiles.tlc` provides a mechanism for executing custom TLC code after the main code generation entry point. See “Using `mytarget_genfiles.tlc`” on page 71-45.

## Using `mytarget_genfiles.tlc`

`mytarget_genfiles.tlc` (optional) is useful as a central file from which to invoke target-specific TLC files that generate additional files as part of your target build process. For example, your target may create sub-makefiles or project files for a development environment, or command scripts for a debugger to do automatic downloads.

The build process can then invoke these generated files either directly from the make process, or after the executable is created. This is done with the `STF_make_rtw_hook.m` mechanism, as described in “Customize Build Process with `STF_make_rtw_hook` File”.

The following TLC code shows an example `mytarget_genfiles.tlc` file.

```
%selectfile NULL_FILE

%assign ModelName = CompiledModel.Name

%% Create Debugger script
%assign model_script_file = "%<ModelName>.cfg"
%assign script_file = "debugger_script_template.tlc"
```

```
%if RTWVerbose
 %selectfile STDOUT
 ### Creating %<model_script_file>
 %selectfile NULL_FILE
%endif

#include "%<script_file>"
%openfile bld_file = "%<model_script_file>"
%<CreateDebuggerScript()>
%closefile bld_file
```

### Handling Aliases for Target Option Values

This section describes utility functions that can be used to detect and resolve alias values or legacy values when testing user-specified values for the target device type (`ProdHWDeviceType`) and the code replacement library (`CodeReplacementLibrary`).

#### **RTW.isHWDeviceTypeEq**

To test if two target device type values represent the same hardware device, invoke the following function:

```
result = RTW.isHWDeviceTypeEq(type1, type2)
```

where *type1* and *type2* are character vectors containing target device type values or aliases.

The `RTW.isHWDeviceTypeEq` function returns true if *type1* and *type2* are character vectors representing the same hardware device. For example, the following call returns true:

```
RTW.isHWDeviceTypeEq('Specified', 'Generic->Custom')
```

For a description of the target device type option `ProdHWDeviceType`, see the command-line information for the **Hardware Implementation** pane parameters “Device vendor” and “Device type” in the Simulink reference documentation.

#### **RTW.resolveHWDeviceType**

To return the device type value for a hardware device, given a value that might be an alias or legacy value, invoke the following function:

```
result = RTW.resolveHWDeviceType(type)
```

where *type* is a character vector containing a target device type value or alias.

The `RTW.resolveHWDeviceType` function returns the device type value of the device. For example, the following calls both return `'Generic->Custom'`:

```
RTW.resolveHWDeviceType('Specified')
RTW.resolveHWDeviceType('Generic->Custom')
```

For a description of the target device type option `ProdHWDeviceType`, see the command-line information for the **Hardware Implementation** pane parameters “Device vendor” and “Device type” in the Simulink reference documentation.

### **RTW.isTf1Eq**

To test if two code replacement library (CRL) names represent the same CRL, invoke the following function:

```
result = RTW.isTf1Eq(name1,name2)
```

where *name1* and *name2* are character vectors containing CRL values or aliases.

The `RTW.isTf1Eq` function returns true if *name1* and *name2* are character vectors representing the same code replacement library. For example, the following call returns true:

```
RTW.isTf1Eq('GNU','GNU C99 extensions')
```

For a description of the `CodeReplacementLibrary` parameter, see “Code replacement library”.

### **RTW.resolveTf1Name**

To return the CRL value for a code replacement library, given a value that might be an alias or legacy value, invoke the following function:

```
result = RTW.resolveTf1Name(name)
```

where *name* is a character vector containing a CRL value or alias.

The `RTW.resolveTf1Name` function returns the value of the referenced code replacement library. For example, the following calls both return `'GNU C99 extensions'`:

```
RTW.resolveTf1Name('GNU')
RTW.resolveTf1Name('GNU C99 extensions')
```

For a description of the `CodeReplacementLibrary` parameter, see “Code replacement library”.

## Supporting Multiple Development Environments

Your target may require support for multiple development environments (for example, two or more cross-compilers) or multiple modes of code generation (for example, generating a binary executable versus generating a project file for your compiler).

One approach to this requirement is to implement multiple STFs. Each STF invokes a template makefile for the development environment. This amounts to providing two separate targets.

## Create a Custom Target Configuration

- “Introduction” on page 71-48
- “my\_ert\_target Overview” on page 71-49
- “Creating Target Folders” on page 71-50
- “Create ERT-Based, Toolchain Compliant STF” on page 71-51
- “Create ERT-Based TMF” on page 71-58
- “Create Test Model and S-Function” on page 71-58
- “Verify Target Operation” on page 71-60

### Introduction

This tutorial can supplement the example target guides described in “Sample Custom Targets” on page 71-9. For an introduction and example files, try the example targets first.

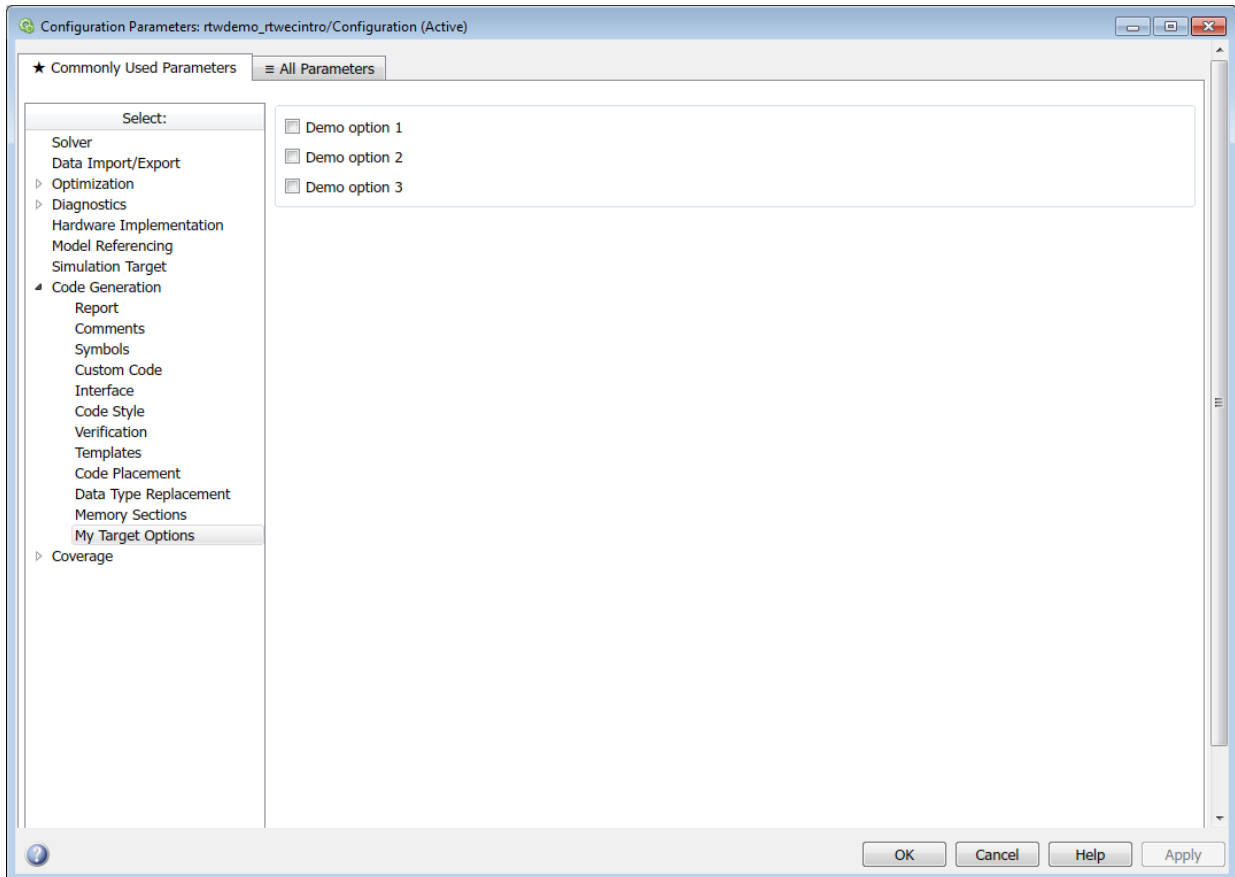

This tutorial guided you through the process of creating an ERT-based target, `my_ert_target`. This exercise illustrates several tasks, which are typical for creating a custom target:

- Setting up target folders and modifying the MATLAB path.
- Making modifications to a standard STF and TMF such that the custom target is visible in the System Target File Browser, inherits ERT options, displays target-specific options, and generates code with the default host-based compiler.
- Testing the build process with the custom target, using a simple model that incorporates an inlined S-function.

During this exercise, you implement an operational, but skeletal, ERT-based target. This target can be useful as a starting point in a complete implementation of a custom embedded target.

## my\_ert\_target Overview

In the following sections, you create a skeletal target, `my_ert_target`. The target inherits and supports the standard options of the ERT target and displays additional target-specific options in the Configuration Parameters dialog box (see Target-Specific Options for `my_ert_target`).

## Target-Specific Options for my\_ert\_target

`my_ert_target` supports a toolchain-based build, generating code and executables that run on the host system. `my_ert_target` uses the `lcc` compiler on a Microsoft Windows platform. The chosen compiler is readily available and is distributed with the

code generator. On a Microsoft Windows platform, if you use a different compiler, you can set up `lcc` temporarily as your default compiler through the following MATLAB command:

```
mex -setup
```

The software displays links for supported compilers that are installed on your computer. Click the `lcc` link.

---

**Note** On Linux systems, make sure that you have an installed C compiler. If so, you can use Linux folder syntax to complete this exercise.

`my_ert_target` can also support template makefile-based builds. For more information about using this target with the template makefile approach, see “Create ERT-Based TMF” on page 71-58.

---

You can test `my_ert_target` with a model that is compatible with the ERT target (see “Select an ERT System Target File” on page 30-3). Generated programs operate identically to ERT generated programs.

To simplify the testing of your target, test with `targetmodel`, a very simple fixed-step model (see “Create Test Model and S-Function” on page 71-58). The S-Function block in `targetmodel` uses the source code from the `timestwo` example, and generates fully inlined code. See “S-Function Examples” and “Inline S-Functions with TLC” for further discussion of the `timestwo` example S-function.

### Creating Target Folders

Create folders to store the target files and add them to the MATLAB path, following the recommended conventions (see “Folder and File Naming Conventions” on page 71-11). You also create a folder to store the test model, S-function, and generated code.

This example assumes that your target and model folders are located within the folder `c:/work`. Do not place your target and model folders within the MATLAB folder tree (that is, in or under the `matlabroot` folder).

To create the folders and make them accessible:

- 1 Create a target root folder, `my_ert_target`. From the MATLAB Command Window on a Windows platform, enter:

```
cd c:/work
```

```
mkdir my_ert_target
```

- 2 Within the target root folder, create a subfolder to store your target files.

```
mkdir my_ert_target/my_ert_target
```

- 3 Add these folders to your MATLAB path.

```
addpath c:/work/my_ert_target
addpath c:/work/my_ert_target/my_ert_target
```

- 4 Create a folder, `my_targetmodel`, to store the test model, S-function, and generated code.

```
mkdir my_targetmodel
```

### Create ERT-Based, Toolchain Compliant STF

Create an STF for your target by copying and modifying the standard STF for the ERT target. Then, validate the STF by viewing the new target in the System Target File Browser and in the Configuration Parameters dialog box.

#### Editing the STF

To edit the STF, use these steps:

- 1 Change your working folder to the folder you created in “Creating Target Folders” on page 71-50.

```
cd c:/work/my_ert_target/my_ert_target
```

- 2 Place a copy of `matlabroot/rtw/c/ert/ert.tlc` in `c:/work/my_ert_target/my_ert_target` and rename it to `my_ert_target.tlc`. The file `ert.tlc` is the STF for the ERT target.

- 3 Open `my_ert_target.tlc` in a text editor of your choice.

- 4 Customize the STF, replacing the header comment lines with directives that make your STF visible in the System Target File Browser and define the associated TMF, `make` command, and external mode interface file (if any). For more information about these directives, see “Header Comments” on page 71-32 .

Replace the header comments in `my_ert_target.tlc` with the following header comments.

```
%% SYSTLC: My ERT-based Target TMF: my_ert_target_lcc.tmf MAKE: make_rtw \
%% EXTMODE: no_ext_comm
```

- 5 The file `my_ert_target.tlc` inherits the standard ERT options, using the mechanism described in “Inheriting Target Options” on page 71-43.

Therefore, the existing `rtwoptions` structure definition is superfluous. Edit the `RTW_OPTIONS` section such that it includes only the following code.

```
/%
BEGIN_RTW_OPTIONS

%-----%
% Configure RTW code generation settings %
%-----%

rtwgenSettings.BuildDirSuffix = '_ert_rtw';

END_RTW_OPTIONS
%/
```

- 6 Delete the code after the end of the `RTW_OPTIONS` section, which is delimited by the directives `BEGIN_CONFIGSET_TARGET_COMPONENT` and `END_CONFIGSET_TARGET_COMPONENT`. This code is for use only by internal MathWorks developers.
- 7 Modify the build folder suffix in the `rtwgenSettings` structure in accordance with the conventions described in “`rtwgenSettings` Structure” on page 71-35.

To set the suffix to a character vector for the `_my_ert_target` custom target, change the line

```
rtwgenSettings.BuildDirSuffix = '_ert_rtw'
```

to

```
rtwgenSettings.BuildDirSuffix = '_my_ert_target_rtw'
```

- 8 Modify the `rtwgenSettings` structure to inherit options from the ERT target and declare Release 14 or later compatibility as described in “`rtwgenSettings` Structure” on page 71-35. Add the following code to the `rtwgenSettings` definition:

```
rtwgenSettings.DerivedFrom = 'ert.tlc';
rtwgenSettings.Version = '1';
```

- 9 Add an `rtwoptions` structure that defines a target-specific options category with three check boxes just after the `BEGIN_RTW_OPTIONS` directive. The following code shows the complete `RTW_OPTIONS` section, including the previous `rtwgenSettings` changes.

```
/%
BEGIN_RTW_OPTIONS

rtwoptions(1).prompt = 'My Target Options';
rtwoptions(1).type = 'Category';
rtwoptions(1).enable = 'on';
rtwoptions(1).default = 3; % number of items under this category
```

```

 % excluding this one.
rtwoptions(1).popupstrings = '';
rtwoptions(1).tlcvariable = '';
rtwoptions(1).tooltip = '';
rtwoptions(1).callback = '';
rtwoptions(1).makevariable = '';

rtwoptions(2).prompt = 'Demo option 1';
rtwoptions(2).type = 'Checkbox';
rtwoptions(2).default = 'off';
rtwoptions(2).tlcvariable = 'DummyOpt1';
rtwoptions(2).makevariable = '';
rtwoptions(2).tooltip = ['Demo option1 (non-functional)'];
rtwoptions(2).callback = '';

rtwoptions(3).prompt = 'Demo option 2';
rtwoptions(3).type = 'Checkbox';
rtwoptions(3).default = 'off';
rtwoptions(3).tlcvariable = 'DummyOpt2';
rtwoptions(3).makevariable = '';
rtwoptions(3).tooltip = ['Demo option2 (non-functional)'];
rtwoptions(3).callback = '';

rtwoptions(4).prompt = 'Demo option 3';
rtwoptions(4).type = 'Checkbox';
rtwoptions(4).default = 'off';
rtwoptions(4).tlcvariable = 'DummyOpt3';
rtwoptions(4).makevariable = '';
rtwoptions(4).tooltip = ['Demo option3 (non-functional)'];
rtwoptions(4).callback = '';

%-----%
% Configure RTW code generation settings %
%-----%

rtwgensettings.BuildDirSuffix = '_my_ert_target_rtw';
rtwgensettings.DerivedFrom = 'ert.tlc';
rtwgensettings.Version = '1';
rtwgensettings.SelectCallback = 'enableToolchainCompliant(hSrc, hDlg)';
%SelectCallback provides toolchain approach support, but requires custom function
%Omit this SelectCallback if using the template makefile approach

END_RTW_OPTIONS
%/

```

**10** Save your changes to `my_ert_target.tlc` and close the file.

### Create ToolchainCompliant Function

To enable builds using the toolchain approach, you create a function that corresponds to the `SelectCallback` near the end of the custom STF. This function sets properties for toolchain compliance.

```
function enableToolchainCompliant(hSrc, hDlg)
```

```
hCS = hSrc.getConfigSet();

% The following parameters enable toolchain compliance.
slConfigUISetVal(hDlg, hSrc, 'UseToolchainInfoCompliant', 'on');
hCS.setProp('GenerateMakefile', 'on');

% The following parameters are not required for toolchain compliance.
% But, it is recommended practice to set these default values and
% disable the parameters (as shown).
hCS.setProp('RTWCompilerOptimization', 'off');
hCS.setProp('MakeCommand', 'make_rtw');
hCS.setPropEnabled('RTWCompilerOptimization', false);
hCS.setPropEnabled('MakeCommand', false);
end
```

---

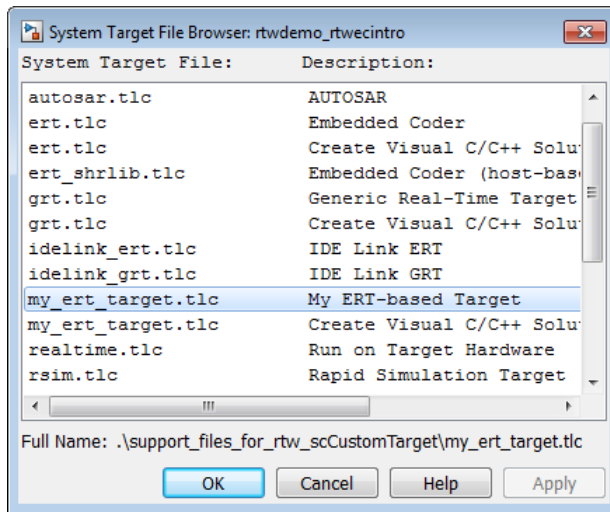

**Note:** If you are using the template makefile approach, omit calling the function enabling toolchain-compliance from your STF file. Instead, use the information in “Create ERT-Based TMF” on page 71-58.

---

### Viewing the STF

At this point, you can verify that the target inherits and displays ERT options as follows:

- 1 Create a new model.
- 2 Open the Model Explorer or the Configuration Parameters dialog box.
- 3 Select the **Code Generation** pane.
- 4 Click **Browse** to open the System Target File browser.
- 5 In the file browser, scroll through the list of targets to find the new target, `my_ert_target.tlc`. (This step assumes that your MATLAB path contains `c:/work/my_ert_target/my_ert_target`, as previously set in “Creating Target Folders” on page 71-50.)
- 6 Select My ERT-based Target and click **OK**.

- 7 The **Code Generation** pane now shows that the model is configured for the `my_ert_target.tlc` target. The **System target file**, **Language**, **Toolchain**, and **Build configuration** fields should appear:

- 8 Select the **My Target Options** pane. The target displays the three check box options defined in the `rtwoptions` structure.

- 9 Select the **Code Generation** pane and reopen the System Target File Browser.
- 10 Select the Embedded Coder target (`ert.tlc`). The target displays the standard ERT options.
- 11 Close the model. You do not need to save it.

The STF for the skeletal target is complete. If you are using the toolchain approach, you are ready to invoke the build process for your target.

If you prefer to use the template makefile approach, the reference to a TMF, `my_ert_target_lcc.tmf`, in the STF header comments prevents you from invoking

the build process for your target until the TMF file is in place. First, you must create a `my_ert_target_lcc.tmf` file.

### Create ERT-Based TMF

If you are using the toolchain makefile approach with a toolchain compliant custom target, omit the steps that apply to the template makefile approach. (Skip this section.)

If you are using the templated makefile approach, follow the steps applying to TMF and omit calling the function enabling toolchain-compliance from your STF file, which is described in “Create ERT-Based, Toolchain Compliant STF” on page 71-51.

Create a TMF for your target by copying and modifying the standard ERT TMF for the LCC compiler:

- 1 Make sure that your working folder is still set to the target file folder you created previously in “Creating Target Folders” on page 71-50.

```
c:/work/my_ert_target/my_ert_target
```

- 2 Place a copy of `matlabroot/rtw/c/ert/ert_lcc.tmf` in `c:/work/my_ert_target/my_ert_target` and rename it `my_ert_target_lcc.tmf`. The file `ert_lcc.tmf` is the ERT compiler-specific template makefile for the LCC compiler.

- 3 Open `my_ert_target_lcc.tmf` in a text editor.

- 4 Change the `SYS_TARGET_FILE` parameter so that the file reference for your `.tlc` file is generated in the make file. Change the line

```
SYS_TARGET_FILE = any
```

to

```
SYS_TARGET_FILE = my_ert_target.tlc
```

- 5 Save changes to `my_ert_target_lcc.tmf` and close the file.

Your target can now generate code and build a host-based executable. In the next sections, you create a test model and test the build process using `my_ert_target`.

### Create Test Model and S-Function

In this section, you build a simple test model for later use in code generation:

- 1 Set your working folder to `c:/work/my_targetmodel`.

```
cd c:/work/my_targetmodel
```

For the remainder of this tutorial, `my_targetmodel` is assumed to be the working folder. Your target writes the output files of the code generation process into a build folder within the working folder. When inlined code is generated for the `timestwo` S-function, the build process looks for the TLC implementation of the S-function in the working folder.

- 2 Copy the following C and TLC files for the `timestwo` S-function to your working folder:

- `matlabroot/toolbox/simulink/simdemos/simfeatures/src/timestwo.c`
- `matlabroot/toolbox/simulink/simdemos/simfeatures/tlc_c/timestwo.tlc`

- 3 Build the `timestwo` MEX-file in `c:/work/my_targetmodel`.

```
mex timestwo.c
```

- 4 Create the following model, using an S-Function block from the Simulink User-Defined Functions library. Save the model in your working folder as `targetmodel`.

- 5 Double-click the S-Function block to open the Block Parameters dialog box. Enter the S-function name `timestwo`. Click **OK**. The block is now bound to the `timestwo` MEX-file.
- 6 Open Model Explorer or the Configuration Parameters dialog box and select the **Solver** pane.
- 7 Set the solver **Type** to `fixed-step` and click **Apply**.
- 8 Save the model.
- 9 Open the scope and run a simulation. Verify that the `timestwo` S-function multiplies its input by 2.0.

Keep the `targetmodel` model open for use in the next section, in which you generate code using the test model.

## Verify Target Operation

In this section you configure `targetmodel` for the `my_ert_target` custom target, and use the target to generate code and build an executable:

- 1 Open the Configuration Parameters dialog box and select the **Code Generation** pane.
- 2 Click **Browse** to open the System Target File Browser.
- 3 In the Browser, select **My ERT-based Target** and click **OK**.
- 4 The Configuration Parameters dialog box now displays the **Code Generation** pane for `my_ert_target`.
- 5 Select the **Code Generation > Report** pane and select the **Create code generation report** option.
- 6 Click **Apply** and save the model. The model is configured for `my_ert_target`.
- 7 Build the model. If the build succeeds, the MATLAB Command Window displays the message below.

```
Created executable: ../targetmodel.exe
Successful completion of build procedure for model:
targetmodel
```

Your working folder contains the `targetmodel.exe` file and the build folder, `targetmodel_my_ert_target_rtw`, which contains generated code and other files. The working folder also contains an `slprj` folder, used internally by the build process.

The code generator also creates and displays a code generation report.

- 8 To view the generated model code, go to the code generation report window. In the **Contents** pane, click the `targetmodel.c` link.
- 9 In `targetmodel.c`, locate the model step function, `targetmodel_step`. Observe the following code.

```
/* S-Function Block: <Root>/S-Function */
/* Multiply input by two */
targetmodel_B.SFunction = targetmodel_B.SineWave * 2.0;
```

The presence of this code confirms that the `my_ert_target` custom target has generated an inlined output computation for the S-Function block in the model.

## Customize Template Makefiles

To configure or customize a template makefile (TMF), you should be familiar with how the `make` command works and how it processes makefiles. You should also understand makefile build rules. For information on these topics, refer to the documentation provided with the `make` utility you use.

### In this section...

“Template Makefiles and Tokens” on page 71-62

“Invoke the `make` Utility” on page 71-68

“Structure of the Template Makefile” on page 71-69

“Customize and Create Template Makefiles” on page 71-73

## Template Makefiles and Tokens

TMFs are made up of statements containing tokens. The build process expands tokens and creates a makefile, `model.mk`. TMFs are designed to generate makefiles for specific compilers on specific platforms. The generated `model.mk` file is tailored to compile and link code generated from your model, using commands specific to your development system.

### Creation of `model.mk`

### Template Makefile Tokens

The `make_rtw` command (or a different command provided with some targets) directs the process of generating `model.mk`. The `make_rtw` command processes the TMF specified

on the **Code Generation** pane of the Configuration Parameters dialog box. `make_rtw` copies the TMF, line by line, expanding each token encountered. Template Makefile Tokens Expanded by `make_rtw` lists the tokens and their expansions.

These tokens are used in several ways by the expanded makefile:

- To control the conditional behavior in the makefile. The conditionals are used to control the source file lists, library names, target to be built, and other build-related information.
- To provide the macro definitions for compiling the files, for example, `-DINTEGER_CODE=1`.

### Template Makefile Tokens Expanded by `make_rtw`

Token	Expansion
<b>General purpose</b>	
>ADDITIONAL_LDFLAGS<	Linker flags automatically added by blocks.
>ALT_MATLAB_BIN<	Alternate full pathname for the MATLAB executable; value is different than value for MATLAB_BIN token when the full pathname contains spaces.
>ALT_MATLAB_ROOT<	Alternate full pathname for the MATLAB installation; value is different than value for MATLAB_ROOT token when the full pathname contains spaces.
>BUILDARGS<	Options passed to <code>make_rtw</code> . This token is provided so that the contents of your <i>model.mk</i> file changes when you change the build arguments, thus forcing an update of modules when your build options change.
>COMBINE_OUTPUT_UPDATE_FCNS<	True (1) when <b>Single output/update function</b> is selected, otherwise False (0). Used for the macro definition <code>-DNESTEPFCN=1</code> .
>COMPUTER<	Computer type. See the MATLAB <code>computer</code> command.
>EXPAND_LIBRARY_LOCATION<	Location of precompiled library file. The <code>TargetPreCompLibLocation</code> configuration parameter can override this setting. For examples, see “Control Library Location and Naming During Build”.

Token	Expansion
>EXPAND_LIBRARY_NAME<	Library name. For examples, see “Control Library Location and Naming During Build” and “Modify the Template Makefile for rtwmakecfg”.
>EXPAND_LIBRARY_SUFFIX<	Library suffix. The <code>TargetLibSuffix</code> configuration parameter can override this setting. For examples, see “Control Library Location and Naming During Build”.
>EXT_MODE<	True (1) to enable generation of external mode support code, otherwise False (0).
>EXTMODE_TRANSPORT<	Index of transport mechanism (for example, <code>tcpip</code> , <code>serial</code> ) for external mode.
>EXTMODE_STATIC<	True (1) if static memory allocation is selected for external mode. False (0) if dynamic memory allocation is selected.
>EXTMODE_STATIC_SIZE<	Size of static memory allocation buffer (if any) for external mode.
>GENERATE_ERT_S_FUNCTION<	True (1) when <b>Create SIL block</b> is selected, otherwise False (0). Used for control of the makefile target of the build.
>INCLUDE_MDL_TERMINATE_FCN<	True (1) when <b>Terminate function required</b> is selected, otherwise False (0). Used for the macro definition <code>-DTERMFCN==1</code> .
>INTEGER_CODE<	True (1) when <b>Support floating-point numbers</b> is not selected, otherwise False (0). <code>INTEGER_CODE</code> is a required macro definition when compiling the source code and is used when selecting precompiled libraries to link against.
>MAKEFILE_NAME<	<code>model.mk</code> — The name of the makefile that was created from the TMF.
>MAT_FILE<	True (1) when <b>MAT-file logging</b> is selected, otherwise False (0). <code>MAT_FILE</code> is a required macro definition when compiling the source code and also is used to include logging code in the build process.
>MATLAB_BIN<	Location of the MATLAB executable.

Token	Expansion
>MATLAB_ROOT<	Path to where MATLAB is installed.
>MEM_ALLOC<	Either RT_MALLOC or RT_STATIC. Indicates how memory is to be allocated.
>MEXEXT<	MEX-file extension. See the MATLAB <code>mexext</code> command.
>MODEL_MODULES<	Additional generated source modules. For example, you can split a large model into two files, <code>model.c</code> and <code>model1.c</code> . In this case, this token expands to <code>model1.c</code> .
>MODEL_MODULES_OBJ<	Object filenames (.obj) corresponding to additional generated source modules.
>MODEL_NAME<	Name of the Simulink block diagram currently being built.
>MULTITASKING<	True (1) if solver mode is multitasking, otherwise False (0).
>NCSTATES<	Number of continuous states.
>NUMST<	Number of sample times in the model.
>PORTABLE_WORDSIZES<	True (1) when <b>Enable portable word sizes</b> is selected, otherwise False (0).
>RELEASE_VERSION<	The MATLAB release version.
>S_FUNCTIONS<	List of noninlined S-function sources.
>S_FUNCTIONS_LIB<	List of S-function libraries available for linking.
>S_FUNCTIONS_OBJ<	Object (.obj) file list corresponding to noninlined S-function sources.
>SOLVER<	Solver source filename, for example, <code>ode3.c</code> .
>SOLVER_OBJ<	Solver object (.obj) filename, for example, <code>ode3.obj</code> .
>TARGET_LANG_EXT<	<code>c</code> when the <b>Language</b> selection is C, <code>cpp</code> when the <b>Language</b> selection is C++. Used in the makefile to control the extension on generated source files.
>TGT_FCN_LIB<	Specifies compiler command line options. The line in the makefile is <code>TGT_FCN_LIB =  &gt;TGT_FCN_LIB&lt; </code> . Use this token in a makefile conditional statement to

Token	Expansion										
	<p>specify a standard math library as a compiler option. Possible <code>&gt;TGT_FCN_LIB&lt;</code> token values are:</p> <table border="1" data-bbox="655 388 1332 802"> <thead> <tr> <th data-bbox="655 388 991 427">Value</th> <th data-bbox="997 388 1332 427">Generates Calls To</th> </tr> </thead> <tbody> <tr> <td data-bbox="655 434 991 538">Name of custom CRL</td> <td data-bbox="997 434 1332 538">ISO®/IEC 9899:1990 C (ANSI_C) standard math library</td> </tr> <tr> <td data-bbox="655 545 991 614">ISO_C</td> <td data-bbox="997 545 1332 614">ISO/IEC 9899:1999 C standard math library</td> </tr> <tr> <td data-bbox="655 621 991 690">ISO_C++</td> <td data-bbox="997 621 1332 690">ISO/IEC 14882:2003 C++ standard math library</td> </tr> <tr> <td data-bbox="655 697 991 802">GNU</td> <td data-bbox="997 697 1332 802">GNU extensions to the ISO/IEC 9899:1999 C standard math library</td> </tr> </tbody> </table>	Value	Generates Calls To	Name of custom CRL	ISO®/IEC 9899:1990 C (ANSI_C) standard math library	ISO_C	ISO/IEC 9899:1999 C standard math library	ISO_C++	ISO/IEC 14882:2003 C++ standard math library	GNU	GNU extensions to the ISO/IEC 9899:1999 C standard math library

Name of custom CRL	ISO®/IEC 9899:1990 C (ANSI_C) standard math library										
ISO_C	ISO/IEC 9899:1999 C standard math library										
ISO_C++	ISO/IEC 14882:2003 C++ standard math library										
GNU	GNU extensions to the ISO/IEC 9899:1999 C standard math library										
<code>&gt;TID01EQ&lt;</code>	True (1) if sampling rates of the continuous task and the first discrete task are equal, otherwise False (0).										
<b>S-function and build information support</b>											
<b>Note:</b> For examples of the tokens in this section, see “Modify the Template Makefile for <code>rtwmakecfg</code> ”.											
<code>&gt;START_EXPAND_INCLUDES&lt;</code> <code>&gt;EXPAND_DIR_NAME&lt;</code> <code>&gt;END_EXPAND_INCLUDES&lt;</code>	List of folder names to add to the include path. Additionally, the <code>ADD_INCLUDES</code> macro must be added to the <code>INCLUDES</code> line.										
<code>&gt;START_EXPAND_LIBRARIES&lt;</code> <code>&gt;EXPAND_LIBRARY_NAME&lt;</code> <code>&gt;END_EXPAND_LIBRARIES&lt;</code>	List of library names.										
<code>&gt;START_EXPAND_MODULES&lt;</code> <code>&gt;EXPAND_MODULE_NAME&lt;</code> <code>&gt;END_EXPAND_MODULES&lt;</code>	Library module names within <code>&gt;START_EXPAND_LIBRARIES&lt;</code> and <code>&gt;START_PRECOMP_LIBRARIES&lt;</code> library lists.										
<code>&gt;START_EXPAND_RULES&lt;</code> <code>&gt;EXPAND_DIR_NAME&lt;</code> <code>&gt;END_EXPAND_RULES&lt;</code>	Makefile rules.										
<code>&gt;START_PRECOMP_LIBRARIES&lt;</code>	List of precompiled library names.										

Token	Expansion
>EXPAND_LIBRARY_NAME<   >END_PRECOMP_LIBRARIES<	
<b>Model reference support</b>	
<b>Note:</b> For examples of the tokens in this section, see “Providing Model Referencing Support in the TMF” on page 71-85.	
>MASTER_ANCHOR_DIR<	For parallel builds, current work folder ( <code>pwd</code> ) at the time the build started.
>MODELLIB<	Name of the library file generated for the current model.
>MODELREFS<	List of models referenced by the top model.
>MODELREF_LINK_LIBS<	List of referenced model libraries against which the top model links.
>MODELREF_LINK_RSPFILE_NAME<	Name of a response file against which the top model links. This token is valid only for build environments that support linker response files. For an example of its use, see <code>matlabroot/rtw/c/grt/grt_vc.tmf</code> .
>MODELREF_TARGET_TYPE<	Type of target being built. Possible values are <ul style="list-style-type: none"> <li>• <b>NONE:</b> Standalone model or top model referencing other models</li> <li>• <b>RTW:</b> Model reference target build</li> <li>• <b>SIM:</b> Model reference simulation target build</li> </ul>
>RELATIVE_PATH_TO_ANCHOR<	Relative path, from the location of the generated makefile, to the MATLAB working folder.
>START_DIR<	Current work folder ( <code>pwd</code> ) at the time the build started. This token is required for parallel builds.
>START_MDLREFINC_EXPAND_INCLUDES<   >MODELREF_INC_PATH<   >END_MDLREFINC_EXPAND_INCLUDES<	List of include paths for models referenced by the top model.
>SHARED_BIN_DIR<	Folder for the library file built from the shared source files.

Token	Expansion
>SHARED_LIB<	Library file built from the shared source files, including the path to the library folder.
>SHARED_SRC<	Shared source files specification, including the path to the shared utilities folder.
>SHARED_SRC_DIR<	Folder for shared source files.

These tokens are expanded by substitution of parameter values known to the build process. For example, if the source model contains blocks with two different sample times, the TMF statement

```
NUMST = |>NUMST<|
```

expands to the following in *model.mk*.

```
NUMST = 2
```

In addition to the above, `make_rtw` expands tokens from other sources:

- Target-specific tokens defined in the target options of the Configuration Parameters dialog box
- Structures in the `rtwoptions` section of the system target file. Structures in the `rtwoptions` structure array that contain the field `makevariable` are expanded.

The following example is extracted from *matlabroot/rtw/c/grt/grt.tlc*. The section starting with `BEGIN_RTW_OPTIONS` contains MATLAB code that sets up `rtwoptions`. The following directive causes the `|>EXT_MODE<|` token to be expanded to 1 (on) or 0 (off), depending on how you set the external mode options.

```
rtwoptions(2).makevariable = 'EXT_MODE'
```

## Invoke the make Utility

- “make Command” on page 71-68
- “make Utility Versions” on page 71-69

### make Command

After creating *model.mk* from your TMF, the build process invokes a `make` command. To invoke `make`, the build process issues this command.

```
makecommand -f model.mk
```

*makecommand* is defined by the MAKECMD macro in your target's TMF (see “Structure of the Template Makefile” on page 71-69). You can specify additional options to **make** in the **Make command** field of the **Code Generation** pane. (See the sections “Specify a Make Command” and “Template Makefiles and Make Options”.)

For example, specifying OPT\_OPTS=-O2 in the **Make command** field causes `make_rtw` to generate the following **make** command.

```
makecommand -f model.mk OPT_OPTS=-O2
```

A comment at the top of the TMF specifies the available **make** command options. If these options do not provide you with enough flexibility, you can configure your own TMF.

### make Utility Versions

The **make** utility lets you control nearly every aspect of building your real-time program. There are several different versions of **make** available. The code generator provides the Free Software Foundation GNU **make** for both UNIX<sup>12</sup> and PC platforms in platform-specific subfolders under

```
matlabroot/bin
```

It is possible to use other versions of **make** with the code generator, although GNU **Make** is recommended. To be compatible with the code generator, verify that your version of **make** supports the following command format.

```
makecommand -f model.mk
```

## Structure of the Template Makefile

A TMF has multiple sections, including the following:

- **Abstract** — Describes what the makefile targets. Here is a representative abstract from the GRT TMFs in *matlabroot/rtw/c/grt* (open):

```
File : grt_lcc.tmf
#
Abstract:
Template makefile for building a PC-based stand-alone generic real-time
version of Simulink model using generated C code and LCC compiler
Version 2.4.
#
```

12. UNIX is a registered trademark of The Open Group in the United States and other countries.

```

This makefile attempts to conform to the guidelines specified in the
IEEE Std 1003.2-1992 (POSIX) standard. It is designed to be used
with GNU Make (gmake) which is located in matlabroot/bin/win32.
#
Note that this template is automatically customized by the build
procedure to create "<model>.mk"
#
The following defines can be used to modify the behavior of the
build:
OPT_OPTS - Optimization options. Default is none. To enable
debugging specify as OPT_OPTS=-g4.
OPTS - User specific compile options.
USER_SRCS - Additional user sources, such as files needed by
S-functions.
USER_INCLUDES - Additional include paths
(i.e. USER_INCLUDES="-Iwhere-ever -Iwhere-ever2")
(For Lcc, have a '/' as file separator before the
file name instead of a '\' .
i.e., d:\work\proj1\myfile.c - reqd for 'gmake')
#
This template makefile is designed to be used with a system target
file that contains 'rtwgensettings.BuildDirSuffix'. See grt.tlc.

```

- **Macros read by make\_rtw section** — Defines macros that tell `make_rtw` how to process the TMF. Here is a representative **Macros read by make\_rtw** section from the GRT TMFs in `matlabroot/rtw/c/grt` (open):

```

#----- Macros read by make_rtw -----
#
The following macros are read by the build procedure:
#
MAKECMD - The command that invokes the make utility
HOST - The platform (for example, PC) for which this TMF is written
SHELL - An operating system shell command (for example, cmd) for the platform
BUILD - The flag that indicates whether to invoke make from the build procedure
SYS_TARGET_FILE - Name of system target file.

MAKECMD = "%MATLAB%\bin\win32\gmake"
HOST = PC
SHELL = cmd
BUILD = yes
SYS_TARGET_FILE = grt.tlc
BUILD_SUCCESS = *** Created
COMPILER_TOOL_CHAIN = lcc

MAKEFILE_FILESEP = /

```

The macros in this section might include:

- **MAKECMD** — Specifies the command used to invoke the make utility. For example, if `MAKECMD = mymake`, then the make command invoked is

```
mymake -f model.mk
```

- **HOST** — Specifies the platform targeted by this TMF. This can be PC, UNIX, *computer\_name* (see the MATLAB `computer` command), or ANY.
- **SHELL** — Specifies an operating system shell command for the platform. For Windows, this can be `cmd`.
- **BUILD** — Instructs `make_rtw` whether or not it should invoke `make` from the build procedure. Specify `yes` or `no`.
- **SYS\_TARGET\_FILE** — Specifies the name of the system target file or the value `any`. This is used for consistency checking by `make_rtw` to verify the system target file specified in the **Target selection** panel of the **Code Generation** pane of the Configuration Parameters dialog box. If you specify `any`, you can use the TMF with any system target file.
- **BUILD\_SUCCESS** — Optional macro that specifies the build success message to be displayed for `make` completion on the PC. For example,

```
BUILD_SUCCESS = ### Successful creation of
```

The **BUILD\_SUCCESS** macro, if used, replaces the standard build success message found in the TMFs distributed with the bundled code generator targets (such as GRT):

```
@echo ### Created executable $(MODEL).exe
```

Your TMF must include either the standard build success message, or use the **BUILD\_SUCCESS** macro. For an example of the use of **BUILD\_SUCCESS**, see *matlabroot/rtw/c/grt/grt\_lcc.tmf* or the code example above this list of macros.

- **BUILD\_ERROR** — Optional macro that specifies the build error message to be displayed when an error is encountered during the `make` procedure. For example,

```
BUILD_ERROR = ['Error while building ', modelName]
```

- **VERBOSE\_BUILD\_OFF\_TREATMENT = PRINT\_OUTPUT\_ALWAYS** — Optional macro to include if you want the makefile output to be displayed regardless of the setting of the **Verbose build** option in the **Code Generation > Debug** pane.
- **COMPILER\_TOOL\_CHAIN** — For builds on Windows systems, specifies which compiler setup file — located in *matlabroot/toolbox/rtw/rtw* (open) — to use:
  - `lcc` selects `setup_for_lcc.m`
  - `vc` selects `setup_for_visual.m`

- `vcx64` selects `setup_for_visual_x64.m`
- `default` selects `setup_for_default.m`

For builds on UNIX systems, specify `unix`. Other values are flagged as unknown and `make_rtw` uses `setup_for_default.m`.

---

**Note:** Do not omit `COMPILER_TOOL_CHAIN` or leave it unspecified in your TMF. If your compiler is not the host compiler, specify `COMPILER_TOOL_CHAIN = default`.

---

- **DOWNLOAD** — An optional macro that you can specify as yes or no. If specified as yes (and `BUILD=yes`), then `make` is invoked a second time with the download target.

```
make -f model.mk download
```

- **DOWNLOAD\_SUCCESS** — An optional macro that you can use to specify the download success message to be used when looking for a completed download. For example,

```
DOWNLOAD_SUCCESS = ### Downloaded
```

- **DOWNLOAD\_ERROR** — An optional macro that you can use to specify the download error message to be displayed when an error is encountered during the download. For example,

```
DOWNLOAD_ERROR = ['Error while downloading ', modelName]
```

- **Tokens expanded by `make_rtw` section** — Defines the tokens that `make_rtw` expands. Here is a brief excerpt from a representative **Tokens expanded by `make_rtw` section** from the GRT TMFs in `matlabroot/rtw/c/grt` (open):

```
#----- Tokens expanded by make_rtw -----
#
The following tokens, when wrapped with ">" and "<" are expanded by the
build procedure.
#
MODEL_NAME - Name of the Simulink block diagram
MODEL_MODULES - Any additional generated source modules
MAKEFILE_NAME - Name of makefile created from template makefile <model>.mk
MATLAB_ROOT - Path to where MATLAB is installed.
...

MODEL = >MODEL_NAME<|
MODULES = >MODEL_MODULES<|
MAKEFILE = >MAKEFILE_NAME<|
```

```
MATLAB_ROOT = |>MATLAB_ROOT<|
...
```

For more information about TMF tokens, see [Template Makefile Tokens Expanded by make\\_rtw](#).

- Subsequent sections vary based on compiler, host, and target. Some common sections include `Model` and reference models, `External mode`, `Tool Specifications` or `Tool Definitions`, `Include Path`, `C Flags`, `Additional Libraries`, and `Source Files`.
- `Rules` section — Contains the make rules used in building an executable from the generated source code. The build rules are typically specific to your version of make. The `Rules` section might be followed by related sections such as `Dependencies`.

## Customize and Create Template Makefiles

- “Introduction” on page 71-73
- “Setting Up a Template Makefile” on page 71-73
- “Using Macros and Pattern Matching Expressions in a Template Makefile” on page 71-74
- “Customizing Generated Makefiles with `rtwmakecfg`” on page 71-76
- “Supporting Continuous Time in Custom Targets” on page 71-76
- “Model Reference Considerations” on page 71-77

### Introduction

This section describes the mechanics of setting up a custom template makefile (TMF) and incorporating it into the build process. It also discusses techniques for modifying a TMF and MATLAB file mechanisms associated with the TMF.

Before creating a custom TMF, you should read “Folder and File Naming Conventions” on page 71-11 to understand the folder structure and MATLAB path requirements for custom targets.

### Setting Up a Template Makefile

To customize or create a new TMF, you should copy an existing GRT or ERT TMF from one of the following locations:

```
matlabroot/rtw/c/grt (open)
matlabroot/rtw/c/ert (open)
```

Place the copy in the same folder as the associated system target file (STF). Usually, this is the `mytarget/mytarget` folder within the target folder structure. Then, rename your TMF (for example, `mytarget.tmf`) and modify it.

To allow the build process to locate and select your TMF, you must provide information in the STF file header (see “System Target File Structure” on page 71-30). For a target that implements a single TMF, the standard way to specify the TMF to be used in the build process is to use the TMF directive of the STF file header.

```
TMF: mytarget.tmf
```

### Using Macros and Pattern Matching Expressions in a Template Makefile

This section shows, through an example, how to use macros and file-pattern-matching expressions in a TMF to generate commands in the `model.mk` file.

The make utility processes the `model.mk` makefile and generates a set of commands based upon dependency rules defined in `model.mk`. After `make` generates the set of commands for building or rebuilding `test`, `make` executes them.

For example, to build a program called `test`, `make` must link the object files. However, if the object files don't exist or are out of date, `make` must compile the source code. Thus there is a dependency between source and object files.

Each version of `make` differs slightly in its features and how rules are defined. For example, consider a program called `test` that gets created from two sources, `file1.c` and `file2.c`. Using most versions of `make`, the dependency rules would be

```
test: file1.o file2.o
 cc -o test file1.o file2.o

file1.o: file1.c
 cc -c file1.c

file2.o: file2.c
 cc -c file2.c
```

In this example, a UNIX<sup>13</sup> environment is assumed. In a PC environment the file extensions and compile and link commands are different.

In processing the first rule

---

13. UNIX is a registered trademark of The Open Group in the United States and other countries.

```
test: file1.o file2.o
```

make sees that to build `test`, it needs to build `file1.o` and `file2.o`. To build `file1.o`, make processes the rule

```
file1.o: file1.c
```

If `file1.o` doesn't exist, or if `file1.o` is older than `file1.c`, make compiles `file1.c`.

The format of TMFs follows the above example. Our TMFs use additional features of make such as macros and file-pattern-matching expressions. In most versions of make, a macro is defined with

```
MACRO_NAME = value
```

References to macros are made with `$(MACRO_NAME)`. When make sees this form of expression, it substitutes `value` for `$(MACRO_NAME)`.

You can use pattern matching expressions to make the dependency rules more general. For example, using GNU<sup>14</sup> Make, you could replace the two “`file1.o: file1.c`” and “`file2.o: file2.c`” rules with the single rule

```
%.o : %.c
 cc -c $<
```

Note that `$<` in the previous example is a special macro that equates to the dependency file (that is, `file1.c` or `file2.c`). Thus, using macros and the “%” pattern matching character, the previous example can be reduced to

```
SRCS = file1.c file2.c
OBJS = $(SRCS:.c=.o)
```

```
test: $(OBJS)
 cc -o $@ $(OBJS)
```

```
%.o : %.c
 cc -c $<
```

Note that the `$@` macro above is another special macro that equates to the name of the current dependency target, in this case `test`.

This example generates the list of objects (`OBJS`) from the list of sources (`SRCS`) by using the text substitution feature for macro expansion. It replaces the source file extension

---

14. GNU is a registered trademark of the Free Software Foundation.

(for example, `.c`) with the object file extension (`.o`). This example also generalized the build rule for the program, `test`, to use the special "\$@" macro.

### Customizing Generated Makefiles with `rtwmakecfg`

TMFs provide tokens that let you add the following items to generated makefiles:

- Source folders
- Include folders
- Run-time library names
- Run-time module objects

S-functions can add this information to the makefile by using an `rtwmakecfg.m` file function. This function is particularly useful when building a model that contains one or more of your S-Function blocks, such as device driver blocks.

To add information pertaining to an S-function to the makefile,

- 1 Create the function `rtwmakecfg` in file `rtwmakecfg.m`. The code generator associates this file with your S-function based on its folder location.
- 2 Modify your target's TMF such that it supports macro expansion for the information returned by `rtwmakecfg` functions.

After the TLC phase of the build process, when generating a makefile from the TMF, the build process searches for an `rtwmakecfg.m` file in the folder that contains the S-function component. If it finds the file, the build process calls the `rtwmakecfg` function. For more information, see “Use `rtwmakecfg.m` API to Customize Generated Makefiles”.

### Supporting Continuous Time in Custom Targets

If you want your custom ERT-based target to support continuous time, you must update your template makefile (TMF) and the static main program module (for example, `mytarget_main.c`) for your target.

#### Template Makefile Modifications

Add the `NCSTATES` token expansion after the `NUMST` token expansion, as follows:

```
NUMST = |>NUMST<|
NCSTATES = |>NCSTATES<|
```

In addition, add `NCSTATES` to the `CPP_REQ_DEFINES` macro, as in the following example:

```
CPP_REQ_DEFINES = -DMODEL=$(MODEL) -DNUMST=$(NUMST) -DNCSTATES=$(NCSTATES) \
-DMAT_FILE=$(MAT_FILE) \
-DINTEGER_CODE=$(INTEGER_CODE) \
-DONESTEPFCN=$(ONESTEPFCN) -DTERMFCN=$(TERMFCN) \
-DHAVESTDIO \
-DMULTI_INSTANCE_CODE=$(MULTI_INSTANCE_CODE) \
```

### Modifications to Main Program Module

The main program module defines a static main function that manages task scheduling for the supported tasking modes of single- and multiple-rate models. `NUMST` (the number of sample times in the model) determines whether the main function calls multirate or single-rate code. However, when a model uses continuous time, do not rely on `NUMST` directly.

When the model has continuous time and the flag `TID01EQ` is true, both continuous time and the fastest discrete time are treated as one rate in generated code. The code associated with the fastest discrete rate is guarded by a major time step check. When the model has only two rates, and `TID01EQ` is true, the generated code has a single-rate call interface.

To support models that have continuous time, update the static main module to take `TID01EQ` into account, as follows:

- 1 Before `NUMST` is referenced in the file, add the following code:

```
#if defined(TID01EQ) && TID01EQ == 1 && NCSTATES == 0
#define DISC_NUMST (NUMST - 1)
#else
#define DISC_NUMST NUMST
#endif
```

- 2 Replace instances of `NUMST` in the file by `DISC_NUMST`.

### Model Reference Considerations

See “Support Model Referencing” on page 71-83 for important information on TMF modifications you may need to make to support the code generator model referencing features.

---

**Note:** If you are using a TMF without the variables `SHARED_SRC` or `MODELREFS`, the file might have been used with a previous release of Simulink software. If you want your

TMF to support model referencing, add either variable `SHARED_SRC` or `MODELREFS` to the make file.

---

### **More About**

- “About Embedded Target Development”
- “Sample Custom Targets”
- “Customize System Target Files”
- “Custom Target Optional Features”
- “Support Toolchain Approach with Custom Target”

## Custom Target Optional Features

This section describes how to configure a custom embedded target to support these optional features.

To ...	Use Target Configuration Parameters ...	For more information, see ...
Indicate a custom target is toolchain-compliant	<code>UseToolchainInfoCompliantGenerateMakefile</code>	“Support Toolchain Approach with Custom Target”
Build a model that includes referenced models and uses a custom target	<code>ModelReferenceCompliantParMdlRefBuildCompliant</code> (parallel build support)	“Support Model Referencing”
Control the compiler optimization level building generated code for a custom target	<code>CompOptLevelCompliant</code>	“Support Compiler Optimization Level Control”
Control C function prototypes of initialize and step functions that are generated for a model that uses a custom target	<code>ModelStepFunctionPrototCompliant</code> (ERT only)	“Support C Function Prototype Control”
Control C++ class interfaces that are generated for a model that uses a custom target	<code>CPPClassGenCompliant</code> (ERT only)	“Support C++ Class Interface Control”
Enable concurrent execution of multiple tasks on a multicore platform for a model that uses a custom target	<code>ConcurrentExecutionComp</code>	“Support Concurrent Execution of Multiple Tasks”

The required configuration changes are modifications to your system target file (STF), and in some cases also modifications to your template makefile (TMF) or your custom static main program.

The API for STF callbacks provides a function `SelectCallback` for use in STFs. `SelectCallback` is associated with the target rather than with its individual options.

If you implement a `SelectCallback` function for a target, it is triggered whenever the user selects the target in the System Target File Browser.

The API provides the functions `slConfigUIGetVal`, `slConfigUISetEnabled`, and `slConfigUISetVal` for controlling custom target configuration options from a user-written `SelectCallback` function. (For function descriptions and examples, see the function reference pages.)

The general requirements for supporting one of the optional features include:

- To support model referencing or compiler optimization level control, the target must be derived from the GRT or the ERT target. To support C function prototype control or C++ class interface control, the target must be derived from the ERT target.
- The system target file (STF) must declare feature compliance by including one of the target configuration parameters listed above in a `SelectCallback` function call.
- Additional changes such as TMF modifications or static main program modifications may be required, depending on the feature. See the detailed steps in the subsections for individual features.

For an example that shows how to configure custom target optional features, see “Customize System Target Files”.

## Support Toolchain Approach with Custom Target

This section describes how to configure a custom system target file to support builds with the toolchain approach.

In the Configuration Parameters dialog box, on the Code Generation pane of, you can present either the build controls for the toolchain approach or the template makefile approach. The model parameters that contribute to determining which build controls appear include these parameters.

Model Parameter	Value	Notes
UseToolchainInfoCompliant	on	For toolchain approach, set this parameter to 'on'. For TMF approach, set this parameter to 'off'.
GenerateMakefile	on	For toolchain approach, set this parameter to 'on'.

When the dialog box detects that the selected target has these properties, the dialog box recognizes the target as toolchain-compliant and displays the build controls for the toolchain approach.

Because the custom target file cannot set these properties directly, use a `SelectCallback` function in the custom target file to set the properties. The `SelectCallback` function call in the `RTW_OPTION` section of the TLC file can take the form:

```
rtwgensettings.SelectCallback = 'enableToolchainCompliant(hSrc, hDlg)';
```

A corresponding callback function can contain:

```
function enableToolchainCompliant(hSrc, hDlg)
 hCS = hSrc.getConfigSet();

 % The following parameters enable toolchain compliance.
 slConfigUISetVal(hDlg, hSrc, 'UseToolchainInfoCompliant', 'on');
 hCS.setProp('GenerateMakefile', 'on');

 % The following parameters are not required for toolchain compliance.
 % But, it is recommended practice to set these default values and
 % disable the parameters (as shown).
 hCS.setProp('RTWCompilerOptimization', 'off');
 hCS.setProp('MakeCommand', 'make_rtw');
 hCS.setPropEnabled('RTWCompilerOptimization', false);
```

```
hCS.setPropEnabled('MakeCommand',false);
end
```

When you select your custom target, the configuration parameters dialog box displays the toolchain approach build controls. For an example, see “Create a Custom Target Configuration” on page 71-48.

For an example that shows how to configure custom target optional features, see “Customize System Target Files”.

## Support Model Referencing

This section describes how to configure a custom embedded target to support model referencing. Without the described modifications, you will not be able to use the custom target when building a model that includes referenced models. If you do not intend to use referenced models with your target, you can skip this section. If you later find that you need to use referenced models, you can upgrade your target then.

### In this section...

“About Model Referencing with a Custom Target” on page 71-83

“Declaring Model Referencing Compliance” on page 71-84

“Providing Model Referencing Support in the TMF” on page 71-85

“Controlling Configuration Option Value Agreement” on page 71-88

“Supporting the Shared Utilities Folder” on page 71-88

“Verifying Worker Configuration for Parallel Builds of Model Reference Hierarchies (Optional)” on page 71-92

“Preventing Resource Conflicts (Optional)” on page 71-94

### About Model Referencing with a Custom Target

The requirements for supporting model referencing are as follows:

- The target must be derived from the GRT target or the ERT target.
- The system target file (STF) must declare model reference compliance, as described in “Declaring Model Referencing Compliance” on page 71-84.
- The template makefile (TMF) must define some entities that support model referencing, as described in “Providing Model Referencing Support in the TMF” on page 71-85.
- The TMF must support using the Shared Utilities folder, as described in “Supporting the Shared Utilities Folder” on page 71-88.

Optionally, you can provide additional capabilities that support model referencing:

- You can configure a target to support parallel builds for large model reference hierarchies (see “Reduce Build Time for Referenced Models”). To do this, you must

modify the STF and TMF for parallel builds as described in “Declaring Model Referencing Compliance” on page 71-84 and “Providing Model Referencing Support in the TMF” on page 71-85.

- If your target supports parallel builds for large model reference hierarchies, you can additionally set up automatic verification of MATLAB Distributed Computing Server workers, as described in “Verifying Worker Configuration for Parallel Builds of Model Reference Hierarchies (Optional)” on page 71-92.
- You can modify hook files to handle referenced models differently than top models to prevent resource conflicts, as described in “Preventing Resource Conflicts (Optional)” on page 71-94.

See “Overview of Model Referencing” for information about model referencing in Simulink models, and “Generate Code for Referenced Models” for information about model referencing in generated code.

For an example that shows how to configure custom target optional features, see “Customize System Target Files”.

## Declaring Model Referencing Compliance

To declare model reference compliance for your target, you must implement a callback function that sets the `ModelReferenceCompliant` flag, and then install the callback function in the `SelectCallback` field of the `rtwgensettings` structure in your STF. The callback function is triggered whenever the user selects the target in the System Target File Browser. For example, the following STF code installs a `SelectCallback` function named `custom_select_callback_handler`:

```
rtwgensettings.SelectCallback = 'custom_select_callback_handler(hDlg,hSrc)';
```

The arguments to the `SelectCallback` function (`hDlg`, `hSrc`) are handles to private data used by the callback API functions. These handles are restricted to use in STF callback functions. They should be passed in without alteration.

Your callback function should set the `ModelReferenceCompliant` flag as follows:

```
slConfigUISetVal(hDlg,hSrc,'ModelReferenceCompliant','on');
slConfigUISetEnabled(hDlg,hSrc,'ModelReferenceCompliant',false);
```

If you might use the target to build models containing large model reference hierarchies, consider configuring the target to support parallel builds, as discussed in “Reduce Build Time for Referenced Models”.

To configure a target for parallel builds, your callback function must also set the `ParMdlRefBuildCompliant` flag as follows:

```
sIConfigUISetVal(hDlG,hSrc,'ParMdlRefBuildCompliant','on');
sIConfigUISetEnabled(hDlG,hSrc,'ParMdlRefBuildCompliant',false);
```

For more information about the STF callback API, see the `sIConfigUISetVal`, `sIConfigUISetEnabled`, and `sIConfigUISetVal` function reference pages.

## Providing Model Referencing Support in the TMF

Do the following to configure the template makefile (TMF) to support model referencing:

- 1 Add the following make variables and tokens to be expanded when the makefile is generated:

```
MODELREFS = |>MODELREFS<|
MODELLIB = |>MODELLIB<|
MODELREF_LINK_LIBS = |>MODELREF_LINK_LIBS<|
MODELREF_LINK_RSPFILE = |>MODELREF_LINK_RSPFILE_NAME<|
MODELREF_INC_PATH = |>START_MDLREFINC_EXPAND_INCLUDES<|\
 -I|>MODELREF_INC_PATH<| |>END_MDLREFINC_EXPAND_INCLUDES<|
RELATIVE_PATH_TO_ANCHOR = |>RELATIVE_PATH_TO_ANCHOR<|
MODELREF_TARGET_TYPE = |>MODELREF_TARGET_TYPE<|
```

The following code excerpt shows how makefile tokens are expanded for a referenced model.

```
MODELREFS =
MODELLIB = engine3200cc_rtwlib.a
MODELREF_LINK_LIBS =
MODELREF_LINK_RSPFILE =
MODELREF_INC_PATH =
RELATIVE_PATH_TO_ANCHOR = ../../..
MODELREF_TARGET_TYPE = RTW
```

The following code excerpt shows how makefile tokens are expanded for the top model that references the referenced model.

```
MODELREFS = engine3200cc transmission
MODELLIB = archlib.a
MODELREF_LINK_LIBS = engine3200cc_rtwlib.a transmission_rtwlib.a
MODELREF_LINK_RSPFILE =
MODELREF_INC_PATH = -I../slprj/ert/engine3200cc -I../slprj/ert/transmission
RELATIVE_PATH_TO_ANCHOR = ..
MODELREF_TARGET_TYPE = NONE
```

Token	Expands to
MODELREFS for the top model	List of referenced model names.

Token	Expands to
MODELLIB	Name of the library generated for the model.
MODELREF_LINK_LIBS token for the top model	List of referenced model libraries that the top model links against.
MODELREF_LINK_RSPFILE token for the top model	Name of a response file that the top model links against. This token is valid only for build environments that support linker response files. For an example of its use, see <i>matlabroot/rtw/c/grt/grt_vc.tmf</i> .
MODELREF_INC_PATH token for the top model	Include path to the referenced models.
RELATIVE_PATH_TO_ANCHOR	Relative path, from the location of the generated makefile, to the MATLAB working folder.
MODELREF_TARGET_TYPE	Signifies the type of target being built. Possible values are <ul style="list-style-type: none"> <li>• NONE: Standalone model or top model referencing other models</li> <li>• RTW: Model reference target build</li> <li>• SIM: Model reference simulation target build</li> </ul>

If you are configuring your target to support parallel builds, as discussed in “Reduce Build Time for Referenced Models”, you must also add the following token definitions to your TMF:

```
START_DIR = |>START_DIR<|
MASTER_ANCHOR_DIR = |>MASTER_ANCHOR_DIR<|
```

Token	Expands to
START_DIR	Current work folder (pwd) at the time the build started.
MASTER_ANCHOR_DIR	Current work folder (pwd) at the time the build started.

- 2 Add `RELATIVE_PATH_TO_ANCHOR` and `MODELREF_INC_PATH` include paths to the overall `INCLUDES` variable.

```
INCLUDES = -I. -I$(RELATIVE_PATH_TO_ANCHOR) $(MATLAB_INCLUDES) $(ADD_INCLUDES) \
$(USER_INCLUDES) $(MODELREF_INC_PATH) $(SHARED_INCLUDES)
```

- 3 Change the `SRCS` variable in your `TMF` so that it initially lists only common modules. Additional modules are then appended conditionally, as described in the next step. For example, change

```
SRCS = $(MODEL).c $(MODULES) ert_main.c $(ADD_SRCS) $(EXT_SRC)
```

to

```
SRCS = $(MODULES) $(S_FUNCTIONS)
```

- 4 Create variables to define the final target of the makefile. You can remove variables that may have existed for defining the final target. For example, remove

```
PROGRAM = ../$(MODEL)
```

and replace it with

```
ifeq ($(MODELREF_TARGET_TYPE), NONE)
Top model for RTW
PRODUCT = $(RELATIVE_PATH_TO_ANCHOR)/$(MODEL)
BIN_SETTING = $(LD) $(LDFLAGS) -o $(PRODUCT) $(SYSLIBS)
BUILD_PRODUCT_TYPE = "executable"
ERT based targets
SRCS += $(MODEL).c ert_main.c $(EXT_SRC)
GRT based targets
SRCS += $(MODEL).c grt_main.c rt_sim.c $(EXT_SRC) $(SOLVER)
else
sub-model for RTW
PRODUCT = $(MODELLIB)
BUILD_PRODUCT_TYPE = "library"
endif
```

- 5 Create rules for the final target of the makefile (replace existing final target rules). For example:

```
ifeq ($(MODELREF_TARGET_TYPE), NONE)
Top model for RTW
$(PRODUCT) : $(OBJS) $(SHARED_LIB) $(LIBS) $(MODELREF_LINK_LIBS)
 $(BIN_SETTING) $(LINK_OBJS) $(MODELREF_LINK_LIBS)
 $(SHARED_LIB) $(LIBS)
 @echo "### Created $(BUILD_PRODUCT_TYPE): $@"
else
sub-model for RTW
$(PRODUCT) : $(OBJS) $(SHARED_LIB) $(LIBS)
 @rm -f $(MODELLIB)
 $(ar) ruvs $(MODELLIB) $(LINK_OBJS)
```

```

 @echo "### Created $(MODELLIB)"
 @echo "### Created $(BUILD_PRODUCT_TYPE): $@"
endif

```

- 6 Create a rule to allow referenced models to compile files that reside in the MATLAB working folder (pwd).

```

%.o : $(RELATIVE_PATH_TO_ANCHOR) /%.c
$(CC) -c $(CFLAGS) $<

```

---

**Note:** If you are using a TMF without the variables `SHARED_SRC` or `MODELREFS`, the file might have been used with a previous release of Simulink software. If you want your TMF to support model referencing, add either variable `SHARED_SRC` or `MODELREFS` to the make file.

---

## Controlling Configuration Option Value Agreement

By default, the value of a configuration option defined in the system target file for a TLC-based custom target must be the same in any referenced model and its parent model. To relax this requirement, include the `modelReferenceParameterCheck` field in the `rtwoptions` structure element that defines the configuration option, and set the value of the field to `'off'`. For example:

```

rtwoptions(2).prompt = 'My Custom Parameter';
rtwoptions(2).type = 'Checkbox';
rtwoptions(2).default = 'on';
rtwoptions(2).modelReferenceParameterCheck = 'on';
rtwoptions(2).tlcvariable = 'mytlcvariable';
...

```

The configuration option **My Custom Parameter** can differ in a referenced model and its parent model. See “Customize System Target Files” on page 71-29 for information about TLC-based system target files, and `rtwoptions` Structure Fields Summary for a list of `rtwoptions` fields.

## Supporting the Shared Utilities Folder

- “Overview” on page 71-89
- “Implementing Shared Utilities Folder Support” on page 71-90

## Overview

The makefile used by the build process must support compiling and creating libraries, and so on, from the locations in which the code is generated. Therefore, you need to update your makefile and the model reference build process to support the shared utilities location. The **Shared code placement** options have the following requirements:

- **Auto**
  - Standalone model build — Build files go to the build folder; makefile is not updated.
  - Referenced model or top model build — Use shared utilities folder; makefile requires full model reference support.
- **Shared location**
  - Standalone model build — Use shared utilities folder; makefile requires shared location support.
  - Referenced model or top model build — Use shared utilities folder; makefile requires full model reference support.

The shared utilities folder (`slprj/target/_sharedutils`) typically stores generated utility code that is common between a top model and the models it references. You can also force the build process to use a shared utilities folder for a standalone model. See “Code Generation Folder Structure for Model Reference Targets” for details.

If you want your target to support compilation of code generated in the shared utilities folder, several updates to your template makefile (TMF) are required. Support for Model Reference builds requires the shared utilities folder. See the preceding sections to learn about additional updates for supporting Model Reference builds.

The exact syntax of the changes can vary due to differences in the make utility and compiler/archiver tools used by your target. The examples below are based on the GNU<sup>15</sup> make utility. You can find the following updated TMF examples for GNU and Microsoft Visual C++ make utilities in the GRT and ERT target folders:

- GRT: `matlabroot/rtw/c/grt` (open)
  - `grt_lcc.tmf`
  - `grt_vc.tmf`

15. GNU is a registered trademark of the Free Software Foundation.

- grt\_unix.tmf
- ERT: *matlabroot*/rtw/c/ert (open)
  - ert\_lcc.tmf
  - ert\_vc.tmf
  - ert\_unix.tmf

Use the GRT or ERT examples as a guide to the location, within the TMF, of the changes and additions described below.

---

**Note** The ERT-based TMFs contain extra code to handle generation of ERT S-functions and Model Reference simulation targets. Your target does not need to handle these cases.

---

### Implementing Shared Utilities Folder Support

Make the following changes to your TMF to support the shared utilities folder:

- 1 Add the following make variables and tokens to be expanded when the makefile is generated:

```
SHARED_SRC = |>SHARED_SRC<|
SHARED_SRC_DIR = |>SHARED_SRC_DIR<|
SHARED_BIN_DIR = |>SHARED_BIN_DIR<|
SHARED_LIB = |>SHARED_LIB<|
```

SHARED\_SRC specifies the shared utilities folder location and the source files in it. A typical expansion in a makefile is

```
SHARED_SRC = ../slprj/ert/_sharedutils/*.c
```

SHARED\_LIB specifies the library file built from the shared source files, as in the following expansion.

```
SHARED_LIB = ../slprj/ert/_sharedutils/rtwshared.lib
```

SHARED\_SRC\_DIR and SHARED\_BIN\_DIR allow specification of separate folders for shared source files and the library compiled from the source files. In the current release, the TMFs use the same path, as in the following expansions.

```
SHARED_SRC_DIR = ../slprj/ert/_sharedutils
```

```
SHARED_BIN_DIR = ../slprj/ert/_sharedutils
```

- 2 Set the `SHARED_INCLUDES` variable according to whether shared utilities are in use. Then append it to the overall `INCLUDES` variable.

```
SHARED_INCLUDES =
ifneq ($(SHARED_SRC_DIR),)
SHARED_INCLUDES = -I$(SHARED_SRC_DIR)
endif
```

```
INCLUDES = -I. $(MATLAB_INCLUDES) $(ADD_INCLUDES) \
$(USER_INCLUDES) $(SHARED_INCLUDES)
```

- 3 Update the `SHARED_SRC` variable to list shared files explicitly.

```
SHARED_SRC := $(wildcard $(SHARED_SRC))
```

- 4 Create a `SHARED_OBJS` variable based on `SHARED_SRC`.

```
SHARED_OBJS = $(addsuffix .o, $(basename $(SHARED_SRC)))
```

- 5 Create an `OPTS` (options) variable for compilation of shared utilities.

```
SHARED_OUTPUT_OPTS = -o $@
```

- 6 Provide a rule to compile the shared utility source files.

```
$(SHARED_OBJS) : $(SHARED_BIN_DIR)/%.o : $(SHARED_SRC_DIR)/%.c
$(CC) -c $(CFLAGS) $(SHARED_OUTPUT_OPTS) $<
```

- 7 Provide a rule to create a library of the shared utilities. The following example is based on UNIX<sup>16</sup>.

```
$(SHARED_LIB) : $(SHARED_OBJS)
@echo "### Creating $@"
ar r $@ $(SHARED_OBJS)
@echo "### Created $@"
```

---

**Note:** Depending on your make utility, you may be able to combine Steps 6 and 7 into one rule. For example, `gmake` (used with `ert_unix.tmf`) uses:

```
$(SHARED_LIB) : $(SHARED_SRC)
@echo "### Creating $@"
cd $(SHARED_BIN_DIR); $(CC) -c $(CFLAGS) $(GCC_WALL_FLAG_MAX) $(notdir $?)
ar ruvs $@ $(SHARED_OBJS)
@echo "### $@ Created "
```

---

16. UNIX is a registered trademark of The Open Group in the United States and other countries.

See this and other examples in the files `ert_vc.tmf`, `ert_lcc.tmf`, and `ert_unix.tmf` located at `matlabroot/rtw/c/ert` (open).

---

- 8 Add `SHARED_LIB` to the rule that creates the final executable.

```
$(PROGRAM) : $(OBJS) $(LIBS) $(SHARED_LIB)
$(LD) $(LDFLAGS) -o $$@ $(LINK_OBJS) $(LIBS)
$(SHARED_LIB) $(SYSLIBS)
@echo "### Created executable: $(MODEL)"
```

- 9 Remove explicit references to `rt_nonfinite.c` from your TMF. For example, change

```
ADD_SRCS = $(RTWLOG) rt_nonfinite.c
```

to

```
ADD_SRCS = $(RTWLOG)
```

---

**Note** If your target interfaces to a development environment that is not makefile based, you must make equivalent changes to provide information to your target compilation environment.

---

## Verifying Worker Configuration for Parallel Builds of Model Reference Hierarchies (Optional)

If your target supports parallel builds for large model reference hierarchies, you can additionally set up automatic verification of MATLAB Distributed Computing Server workers. This addresses the possibility that parallel workers might have different configurations, some of which might not be compatible with a specific target build. For example, the required compiler might not be installed on a worker system.

The code generator provides a programming interface that you can use to automatically check the configuration of parallel workers. If parallel workers are not set up as expected, take action, such as reverting to sequential builds or throwing an error.

To set up automatic verification of workers, you must define a parallel configuration check function named `STF_par_cfg_chk`, where `STF` designates your system target file name. For example, the parallel configuration check function for `ert.tlc` is `ert_par_cfg_chk`.

The general syntax for the function is:

```
function varargout = STF_par_cfg_chk(action,varargin)
```

The number of output and input arguments vary according to the *action* specified, and according to the types of information you choose to coordinate between the client and the workers. The function should support the following general sequence of parallel configuration setup calls, differentiated by the first argument passed in:

Call Syntax	Called on:	Action
<code>cfg = STF_par_cfg_chk('getPreferredCfg');</code>	Client	Return a structure representing the preferred configuration for MATLAB Distributed Computing Server workers.
<code>[tf, cfg] = STF_par_cfg_chk('getWorkerCfg', cfg);</code>	Workers	Each worker is passed the MATLAB Distributed Computing Server client's preferred configuration. Return true if the worker can support the preferred configuration; otherwise return false along with a structure representing a configuration the worker can support. Information returned by each worker is added to a cell array of configurations.
<code>[tf, cfg] = STF_par_cfg_chk('getCommonCfg', cfgs);</code>	Client	The client is passed the cell array of worker configurations. If a usable common configuration exists, return true, and return the common configuration to set for all systems. If a common configuration cannot be established, return false or take some action, such as reverting to sequential builds or throwing an error.
<code>tf = STF_par_cfg_chk('setCommonCfg', cfg);</code>	Workers and client	Each system is passed the common configuration to use. Set up the common configuration and, if successful, return true. If errors or issues occur, return false or take some action, such as reverting to sequential builds or throwing an error.
<code>STF_par_cfg_chk('clearCfg');</code>	Workers and client	Clean up after completion of the parallel build.

The parallel configuration check functions for MathWorks provided targets are implemented as wrapper functions that call a function named `parallelMdlRefHostConfigCheckFcn`. For example, see the ERT parallel configuration check function in the file `matlabroot/toolbox/rtw/rtw/`

`ert_par_cfg_chk.m`, and the function it calls in the file `matlabroot/toolbox/simulink/simulink/+Simulink/parallelMdlRefHostConfigCheckFcn.m`. The `parallelMdlRefHostConfigCheckFcn` function tries to establish a common compiler across the MATLAB Distributed Computing Server client and workers.

For more information about parallel builds, see “Reduce Build Time for Referenced Models”.

## Preventing Resource Conflicts (Optional)

Hook files are optional TLC and MATLAB program files that are invoked at well-defined stages of the build process. Hook files let you customize the build process and communicate information between various phases of the process.

If you are adapting your custom target for code generation compatibility with model reference features, consider adding checks to your hook files for handling referenced models differently than top models to prevent resource conflicts.

For example, consider adding the following check to your `STF_make_rtw_hook.m` file:

```
% Check if this is a referenced model
mdlRefTargetType = get_param(codeGenModelName, 'ModelReferenceTargetType');
isNotModelRefTarget = strcmp(mdlRefTargetType, 'NONE'); % NONE, SIM, or RTW
if isNotModelRefTarget
 % code that is specific to the top model
else
 % code that is specific to the referenced model
end
```

You may need to do a similar check in your TLC code.

```
%if !IsModelReferenceTarget()
 %% code that is specific to the top model
%else
 %% code that is specific to the referenced model
%endif
```

## More About

- “About Embedded Target Development”
- “Sample Custom Targets”

## Support Compiler Optimization Level Control

This section describes how to configure a custom embedded target to support compiler optimization level control. Without the described modifications, you will not be able to use the **Compiler optimization level** parameter on the **All Parameters** tab of the Configuration Parameters dialog box to control the compiler optimization level for building generated code. (For more information about compiler optimization level control, see “Compiler optimization level”.)

### In this section...

“About Compiler Optimization Level Control and Custom Targets” on page 71-95

“Declaring Compiler Optimization Level Control Compliance” on page 71-95

“Providing Compiler Optimization Level Control Support in the Target Makefile” on page 71-96

## About Compiler Optimization Level Control and Custom Targets

The requirements for supporting compiler optimization level control are as follows:

- The target must be derived from the GRT target or the ERT target.
- The system target file (STF) must declare compiler optimization level control compliance, as described in “Declaring Compiler Optimization Level Control Compliance” on page 71-95.
- The target makefile must honor the setting for **Compiler optimization level**, as described in “Providing Compiler Optimization Level Control Support in the Target Makefile” on page 71-96.

For an example that shows how to configure custom target optional features, see “Customize System Target Files”.

## Declaring Compiler Optimization Level Control Compliance

To declare compiler optimization level control compliance for your target, you must implement a callback function that sets the `CompOptLevelCompliant` flag, and then install the callback function in the `SelectCallback` field of the `rtwgensettings` structure in your STF. The callback function is triggered whenever the user selects the target in the System Target File Browser. For example, the following STF code installs a `SelectCallback` function named `custom_select_callback_handler`:

```
rtwgensettings.SelectCallback = 'custom_select_callback_handler(hDlg,hSrc)';
```

The arguments to the `SelectCallback` function (`hDlg`, `hSrc`) are handles to private data used by the callback API functions. These handles are restricted to use in STF callback functions. They should be passed in without alteration.

Your callback function should set the `CompOptLevelCompliant` flag as follows:

```
slConfigUISetVal(hDlg,hSrc,'CompOptLevelCompliant','on');
slConfigUISetEnabled(hDlg,hSrc,'CompOptLevelCompliant',false);
```

For more information about the STF callback API, see the `slConfigUIGetVal`, `slConfigUISetEnabled`, and `slConfigUISetVal` function reference pages.

When the `CompOptLevelCompliant` target configuration parameter is set to `on`, the **Compiler optimization level** parameter is displayed in the **Code Generation** pane of the Configuration Parameters dialog box for your model.

## Providing Compiler Optimization Level Control Support in the Target Makefile

As part of supporting compiler optimization level control for your target, you must modify the target makefile to honor the setting for **Compiler optimization level**. Use a GRT or ERT target provided by MathWorks as a model for making the modifications.

## Support C Function Prototype Control

This section describes how to configure a custom embedded target to support C function prototype control. Without the described modifications, you will not be able to use the **Configure Model Functions** button on the **Interface** pane of the Configuration Parameters dialog box to control the function prototypes of initialize and step functions that are generated for your model. (For more information about C function prototype control, see “Control Generation of Function Prototypes” on page 25-2 in the Embedded Coder documentation.)

### In this section...

“About C Function Prototype Control and Custom Targets” on page 71-97

“Declaring C Function Prototype Control Compliance” on page 71-97

“Providing C Function Prototype Control Support in the Custom Static Main Program” on page 71-98

## About C Function Prototype Control and Custom Targets

The requirements for supporting C function prototype control are as follows:

- The target must be derived from the ERT target.
- The system target file (STF) must declare C function prototype control compliance, as described in “Declaring C Function Prototype Control Compliance” on page 71-97.
- If your target uses a custom static main program, and if a nondefault function prototype control configuration is associated with a model, the static main program must call the function prototype controlled initialize and step functions, as described in “Providing C Function Prototype Control Support in the Custom Static Main Program” on page 71-98.

For an example that shows how to configure custom target optional features, see “Customize System Target Files”.

## Declaring C Function Prototype Control Compliance

To declare C function prototype control compliance for your target, you must implement a callback function that sets the `ModelStepFunctionPrototypeControlCompliant` flag, and then install the callback function in the `SelectCallback` field of the `rtwgensettings` structure in your STF. The callback function is triggered

whenever the user selects the target in the System Target File Browser. For example, the following STF code installs a `SelectCallback` function named `custom_select_callback_handler`:

```
rtwgensettings.SelectCallback = 'custom_select_callback_handler(hDlg,hSrc)';
```

The arguments to the `SelectCallback` function (`hDlg`, `hSrc`) are handles to private data used by the callback API functions. These handles are restricted to use in STF callback functions. They should be passed in without alteration.

Your callback function should set the `ModelStepFunctionPrototypeControlCompliant` flag as follows:

```
slConfigUISetVal(hDlg,hSrc,'ModelStepFunctionPrototypeControlCompliant','on');
slConfigUISetEnabled(hDlg,hSrc,'ModelStepFunctionPrototypeControlCompliant',false);
```

For more information about the STF callback API, see the `slConfigUIGetVal`, `slConfigUISetEnabled`, and `slConfigUISetVal` function reference pages.

When the `ModelStepFunctionPrototypeControlCompliant` target configuration parameter is set to `on`, you can use the **Configure Model Functions** button on the **Interface** pane of the Configuration Parameters dialog box to control the function prototypes of initialize and step functions that are generated for your model.

## Providing C Function Prototype Control Support in the Custom Static Main Program

If your target uses a custom static main program, and if a nondefault function prototype control configuration is associated with a model, you must update the static main program to call the function prototype controlled initialize and step functions. You can do this in either of the following ways:

- 1 Manually adapt your static main program to declare model data and call the function prototype controlled initialize and step functions.
- 2 Generate your main program using **Generate an example main program** on the **Templates** pane of the Configuration Parameters dialog box. The generated main program declares model data and calls the function prototype controlled initialize and step function.

## Support C++ Class Interface Control

This section describes how to configure a custom embedded target to support C++ class interface control. Without the described modifications, you will not be able to use C++ class code interface packaging and the **Configure C++ Class Interface** button on the **Interface** pane of the Configuration Parameters dialog box to generate and configure C++ class interfaces to model code. (For more information about C++ class interface control, see “Control Generation of C++ Class Interfaces” on page 25-23 in the Embedded Coder documentation.)

### In this section...

“About C++ Class Interface Control and Custom Targets” on page 71-100

“Declaring C++ Class Interface Control Compliance” on page 71-100

“Providing C++ Class Interface Control Support in the Custom Static Main Program” on page 71-101

## About C++ Class Interface Control and Custom Targets

The requirements for supporting C++ class interface control are as follows:

- The target must be derived from the ERT target.
- The system target file (STF) must declare C++ class interface control compliance, as described in “Declaring C++ Class Interface Control Compliance” on page 71-100.

For an example that shows how to configure custom target optional features, see “Customize System Target Files”.

## Declaring C++ Class Interface Control Compliance

To declare C++ class interface control compliance for your target, you must implement a callback function that sets the `CPPClassGenCompliant` flag, and then install the callback function in the `SelectCallback` field of the `rtwgensettings` structure in your STF. The callback function is triggered whenever the user selects the target in the System Target File Browser. For example, the following STF code installs a `SelectCallback` function named `custom_select_callback_handler`:

```
rtwgensettings.SelectCallback = 'custom_select_callback_handler(hDlg,hSrc)';
```

The arguments to the `SelectCallback` function (`hDlg`, `hSrc`) are handles to private data used by the callback API functions. These handles are restricted to use in STF callback functions. They should be passed in without alteration.

Your callback function should set the `CPPClassGenCompliant` flag as follows:

```
sIConfigUISetVal(hDlg,hSrc,'CPPClassGenCompliant','on');
sIConfigUISetEnabled(hDlg,hSrc,'CPPClassGenCompliant',false);
```

For more information about the STF callback API, see the `sIConfigUIGetVal`, `sIConfigUISetEnabled`, and `sIConfigUISetVal` function reference pages.

When the `CPPClassGenCompliant` target configuration parameter is set to `on`, you can use the `C++ class` code interface packaging and the **Configure C++ Class Interface** button on the **Interface** pane of the Configuration Parameters dialog box to generate and configure C++ class interfaces to model code.

## Providing C++ Class Interface Control Support in the Custom Static Main Program

Selecting `C++ class` code interface packaging for your model turns on the model option **Generate an example main program**. With this option on, code generation generates an example main program, `ert_main.cpp`. The generated example main program declares model data and calls the C++ class interface configured model step method, and illustrates how the generated code can be deployed.

To customize the build process and disable generation and inclusion of an example main program, see the `setTargetProvidesMain` function. Disabling example main generation permits including a custom main program.

- “About Embedded Target Development”
- “Sample Custom Targets”
- “Customize System Target Files”

## Support Concurrent Execution of Multiple Tasks

If a custom embedded target must support concurrent execution of multiple tasks on a multicore platform, the target must declare support for concurrent execution by setting the target configuration option `ConcurrentExecutionCompliant`. Otherwise, you will not be able to configure a multicore target model for concurrent execution.

If `ConcurrentExecutionCompliant` is not already configured for your custom target, you can set the option in the following ways:

- Include the following code directly in your system target file (*mytarget.tlc*):

```
rtwgensettings.SelectCallback = 'slConfigUISetVal(hDlg,hSrc,...
'ConcurrentExecutionCompliant','on');';
rtwgensettings.ActivateCallback = 'slConfigUISetVal(hDlg,hSrc,...
'ConcurrentExecutionCompliant','on');';
```

- Implement a callback function that sets the `ConcurrentExecutionCompliant` option, and then install the callback function in the `SelectCallback` field of the `rtwgensettings` structure in your STF. The callback function is triggered whenever the user selects the target in the System Target File Browser. For example, the following STF code installs a `SelectCallback` function named `custom_select_callback_handler`:

```
rtwgensettings.SelectCallback = 'custom_select_callback_handler(hDlg,hSrc)';
```

The arguments to the `SelectCallback` function (`hDlg`, `hSrc`) are handles to private data used by the callback API functions. These handles are restricted to use in STF callback functions. They should be passed in without alteration.

Your callback function should set the `ConcurrentExecutionCompliant` option as follows:

```
slConfigUISetVal(hDlg,hSrc,'ConcurrentExecutionCompliant','on');
slConfigUISetEnabled(hDlg,hSrc,'ConcurrentExecutionCompliant',false);
```

For more information about the STF callback API, see the `slConfigUIGetVal`, `slConfigUISetEnabled`, and `slConfigUISetVal` function reference pages.

When the `ConcurrentExecutionCompliant` target configuration option is set to 'on', you can select the custom target and configure your multicore target model for concurrent execution.

For an example that shows how to configure custom target optional features, see “Customize System Target Files”.

## **More About**

- “About Embedded Target Development”
- “Sample Custom Targets”
- “Customize System Target Files”

## Interface to Development Tools

Unless you are developing a target purely for code generation purposes, you will want your embedded target to support a complete build process. A full post-code generation build process includes

- Compilation of generated code
- Linking of compiled code and runtime libraries into an executable program module (or some intermediate representation of the executable code, such as S-Rec format)
- Downloading the executable to target hardware with a debugger or other utility
- Initiating execution of the downloaded program

Supporting a complete build process is inherently a complex task, because it involves interfacing to cross-development tools and utilities that are external to the code generator.

If your development tools can be controlled with traditional makefiles and a make utility such as `gmake`, it may be relatively simple for you to adapt existing target files (such as the `ert.tlc` and `ert.tmf` files provided by the Embedded Coder software) to your requirements. This approach is discussed in “Template Makefile Approach” on page 71-105.

In this section...
“About Interfacing to Development Tools” on page 71-104
“Template Makefile Approach” on page 71-105
“Interface to an Integrated Development Environment” on page 71-105

### About Interfacing to Development Tools

Automating your build process through a modern integrated development environment (IDE) presents a different set of challenges. Each IDE has its own way of representing the set of source files and libraries for a project and for specifying build arguments. Interfacing to an IDE may require generation of specialized file formats required by the IDE (for example, project files) and, and also may require the use of inter-application communication (IAC) techniques to run the IDE. One such approach to build automation is discussed in “Interface to an Integrated Development Environment” on page 71-105.

## Template Makefile Approach

A template makefile provides information about your model and your development system. The build process uses this information to create a makefile (.mk file) to build an executable program. The code generator provides a number of template makefiles suitable for development computer compilers, such as LCC (`ert_lcc.tmf`) and Microsoft Visual C++ (`ert_vc.tmf`).

Adapting one of the existing template makefiles to your cross-compiler's make utility may require little more than copying and renaming the template makefile in accordance with the conventions of your project.

If you need to make more extensive modifications, you need to understand template makefiles in detail. For a detailed description of the structure of template makefiles and of the tokens used in template makefiles, see “Customize Template Makefiles” on page 71-62.

The following topics supplement the basic template makefile information:

- “Supporting Multiple Development Environments” on page 71-48
- “Supplying Development Environment Information to Your Template Makefile” on page 71-26

## Interface to an Integrated Development Environment

This section describes techniques that have been used to integrate embedded targets with integrated development environment (IDEs), including

- How to generate a header file containing directives to define variables (and their values) required by a non-makefile based build.
- Some problems and solutions specific to interfacing embedded targets with the Freescale Semiconductor CodeWarrior IDE. The examples provided should help you to deal with similar interfacing problems with your particular IDE.
- “Generating a CPP\_REQ\_DEFINES Header File” on page 71-105
- “Interfacing to the Freescale CodeWarrior IDE” on page 71-107

### Generating a CPP\_REQ\_DEFINES Header File

In template makefiles, the token `CPP_REQ_DEFINES` is expanded and replaced with a list of parameter settings entered with various dialog boxes. This variable often contains

information such as `MODEL` (name of generating model), `NUMST` (number of sample times in the model), `MT` (model is multitasking or not), and numerous other parameters (see “Template Makefiles and Tokens” on page 71-62).

The makefile mechanism handles the `CPP_REQ_DEFINES` token automatically. If your target requires use of a project file, rather than the traditional makefile approach, you can generate a header file containing directives to define these variables and provide their values.

The following TLC file, `gen_rtw_req_defines.tlc`, provides an example. The code generates a C header file, `cpp_req_defines.h`. The information required to generate each `#define` directive is derived either from information in the `model.rtw` file (e.g., `CompiledModel.NumSynchronousSampleTimes`), or from make variables from the `rtwoptions` structure (for example, `PurelyIntegerCode`).

```
%% File: gen_rtw_req_defines_h.tlc
%openfile CPP_DEFINES = "cpp_req_defines.h"
#ifdef _CPP_REQ_DEFINES_
#define _CPP_REQ_DEFINES_
#define MODEL %<CompiledModel.Name>
#define ERT 1
#define NUMST %<CompiledModel.NumSynchronousSampleTimes>
#define TID01EQ %<CompiledModel.FixedStepOpts.TID01EQ>
%%
%if CompiledModel.FixedStepOpts.SolverMode == "MultiTasking"
#define MT 1
#define MULTITASKING 1
%else
#define MT 0
#define MULTITASKING 0
#endif
%%
#define MAT_FILE 0
#define INTEGER_CODE %<PurelyIntegerCode>
#define ONESTEPFCN %<CombineOutputUpdateFcns>
#define TERMFCN %<IncludeMdlTerminateFcn>
%%
#define MULTI_INSTANCE_CODE 0
#define HAVESTDIO 0
#endif
%closefile CPP_DEFINES
```

## Interfacing to the Freescale CodeWarrior IDE

Interfacing an embedded target's build process to the CodeWarrior IDE requires that two problems must be dealt with:

- The build process must generate a CodeWarrior compatible project file. This problem, and a solution, is discussed in “XML Project Import” on page 71-107. The solution described is applicable to ASCII project file formats.
- During code generation, the target must automate a CodeWarrior session that opens a project file and builds an executable. This task is described in “Build Process Automation” on page 71-112. The solution described is applicable to IDEs that can be controlled with Microsoft Component Object Model (COM) automation.

### XML Project Import

This section illustrates how to use the Target Language Compiler (TLC) to generate an eXtensible Markup Language (XML) file, suitable for import into the CodeWarrior IDE, that contains information about the source code generated by an embedded target.

The choice of XML format is dictated by the fact that the CodeWarrior IDE supports project export and import with XML files. As of this writing, native CodeWarrior project files are in a proprietary binary format.

Note that if your target needs to support some other compiler's project file format, you can apply the techniques shown here to other ASCII file formats (see “Generating a CPP\_REQ\_DEFINES Header File” on page 71-105).

To illustrate the basic concept, consider a hypothetical XML file exported from a CodeWarrior stationery project. The following is a partial listing:

```
<target>
 <settings>
 ...
 <\settings>
 <file><name>foo.c<\name>
 <\file>
 ...
 <file><name>foobar.c<\name>
 <\file>
 <fileref><name>foo.c<\name>
 <\fileref>
 ...
 <fileref><name>foobar.c<\name>
```

```
<\fileref>
<\target>
```

Insert this XML code into an `%openfile/%closefile` block within a TLC file, `test.tlc`, as shown below.

```
% test.tlc
%% This code will generate a file model_project.xml,
%% where model is the generating model name specified in
%% the CompiledModel.Name field of the model.rtw file.
%openfile XMLFileContents = %<CompiledModel.Name>_project.xml
<target>
 <settings>
 ...
 <\settings>
 <file><name>%<CompiledModel.Name>.c<\name>
 <\file>
 ...
 <file><name>foobar.c<\name>
 <\file>
 <fileref><name>%<CompiledModel.Name>.c<\name>
 <\fileref>
 ...
 <fileref><name>foobar.c<\name>
 <\fileref>
<\target>
%closefile XMLFileContents
%selectfile NULL_FILE
```

Note the use of the TLC token `CompiledModel.Name`. The token is resolved and the resulting filename is included in the output stream. You can specify other information, such as paths and libraries, in the output stream by specifying other tokens defined in `model.rtw`. For example, `System.Name` may be defined as `<Root>/Subsystem1`.

Now suppose that `test.tlc` is invoked during a target's build process, where the generating model is `mymodel`. This should be done after the `codegenentry` statement. For example, `test.tlc` could be included directly in the system target file:

```
%include "codegenentry.tlc"
%include "test.tlc"
```

Alternatively, the `%include "test.tlc"` directive could be inserted into the `mytarget_genfiles.tlc` hook file, if present.

TLC tokens such as

```
<file><name>%<CompiledModel.Name>.c<\name>
```

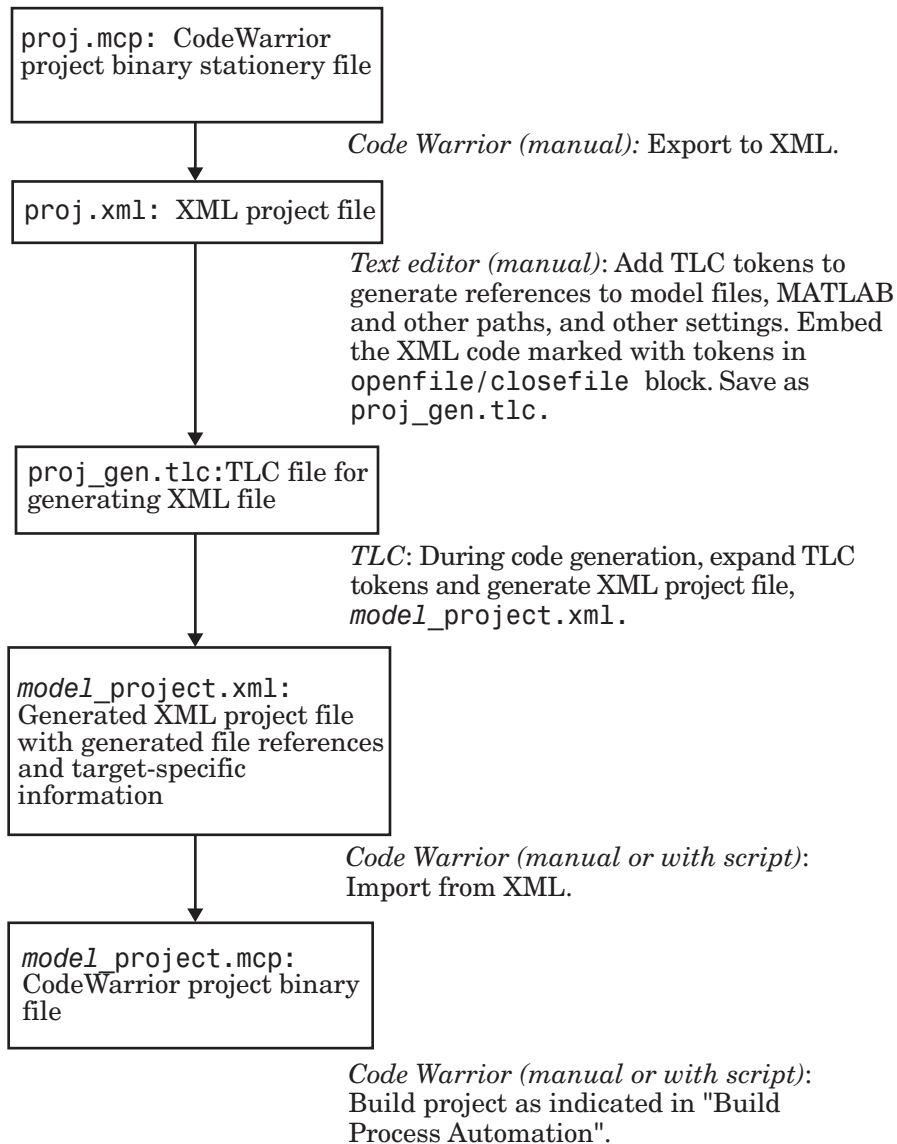

are expanded, with the `CompiledModel` record in the `mymodel.rtw` file, as in

```
<file><name>mymodel.c<\name>
```

`test.tlc` generates an XML file, file `model_project.xml`, from a model.

`model_project.xml` contains references to generated code files. `model_project.xml` can be imported into the CodeWarrior IDE as a project.

The following flowchart summarizes this process.

**Note** This process has drawbacks. First, manually editing an XML file exported from a CodeWarrior stationery project can be a laborious task, involving modification of a few

dozen lines embedded within several thousand lines of XML code. Second, if you make changes to the CodeWarrior project after importing the generated XML file, the XML file must be exported and manually edited once again.

---

### **Build Process Automation**

An application that supports COM automation can control other applications that include a COM interface. Using MATLAB COM automation functions, a MATLAB file can command a COM-compatible development system to execute tasks required by the build process.

The MATLAB COM automation functions described in this section are documented in “Call COM Objects”.

For information about automation commands supported by the CodeWarrior IDE, see your CodeWarrior documentation.

COM automation is used by some embedded targets to automate the CodeWarrior IDE to execute tasks such as:

- Opening a new CodeWarrior session
- Configure a project
- Loading a CodeWarrior project file
- Removing object code from the project
- Building or rebuilding the project
- Debug an application

COM technology automates certain repetitive tasks and allows the user to interact directly with the external application. For example, when the end user of the embedded targets capability initiates a build, the target quickly invokes CodeWarrior actions and leaves a project built and ready to run with the IDE.

### **Example COM Automation Functions**

The functions below use the MATLAB `actxserver` command to invoke COM functions for controlling the CodeWarrior IDE from a MATLAB file:

- `CreateCWComObject`: Create a COM connection to the CodeWarrior IDE.
- `OpenCW`: Open the CodeWarrior IDE without opening a project.

- **OpenMCP**: Open the CodeWarrior project file (.mcp file) specified by the input argument.
- **BuildCW**: Open the specified .mcp file, remove object code, and build project.

These functions are examples; they do not constitute a full implementation of a COM automation interface. If your target creates the project file during code generation, the top-level **BuildCW** function should be called after the code generation process is completed. Normally **BuildCW** would be called from the **exit** method of your *STF\_make\_rtw\_hook.m* file (see “STF\_make\_rtw\_hook.m” on page 71-21).

In the code examples, the variable **in\_qualifiedMCP** is assumed to store a fully qualified path to a CodeWarrior project file (for example, path, filename, and extension). For example:

```
in_qualifiedMCP = 'd:\work\myproject.mcp';
```

In actual practice, your code is responsible for determining the conventions used for the project filename and location. One simple convention would be to default to a project file *model.mcp*, located in your target's build folder.

```
%=====
% Function: CreateCWComObject
% Abstract: Creates the COM connection to CodeWarrior
%
function ICodeWarriorApp = CreateCWComObject
 vprint([mfilename ' : creating CW com object']);
 try
 ICodeWarriorApp = actxserver('CodeWarrior.CodeWarriorApp');
 catch
 error(['Error creating COM connection to ' ComObj ...
 '. Verify that CodeWarrior is installed. Verify COM access to
CodeWarrior outside of MATLAB.']);
 end
 return;

%=====
% Function: OpenCW
% Abstract: Opens CodeWarrior without opening a project. Returns the
 handle ICodeWarriorApp.
%
function ICodeWarriorApp = OpenCW()
 ICodeWarriorApp = CreateCWComObject;
 CloseAll;
 OpenMCP(in_qualifiedMCP);

%=====
% Function: OpenMCP
```

```

% Abstract: open an MCP project file
%
function OpenMCP(in_qualifiedMCP)
% Argument checking. This method requires valid project file.
if ~exist(in_qualifiedMCP)
 error(['filename ': Missing or empty project file argument']);
end
if isempty(in_qualifiedMCP)
 error(['filename ': Missing or empty project file argument']);
end
ICodeWarriorApp = CreateCWComObject;
vprint(['filename ': Importing]);
try
 ICodeWarriorProject = ...
 invoke(ICodeWarriorApp.Application,...
 'OpenProject', in_qualifiedMCP,...
 1,0,0);
catch
 error(['Error using COM connection to import project. ' ...
 'Verify that CodeWarrior is installed. Verify COM access to
CodeWarrior outside of MATLAB.']);
end

%=====
% Function: BuildCW
% Abstract: Opens CodeWarrior.
% Opens the specified CodeWarrior project.
% Deletes objects.
% Builds.
%
function ICodeWarriorApp = BuildCW(in_qualifiedMCP)
% ICodeWarriorApp = BuildCW;
ICodeWarriorApp = CreateCWComObject;
CloseAll;
OpenMCP(in_qualifiedMCP);
try
 invoke(ICodeWarriorApp.DefaultProject,'RemoveObjectCode', 0, 1);
catch
 error(['Error using COM connection to remove objects of current project. ' ...
 'Verify that CodeWarrior is installed. Verify COM access to
CodeWarrior outside of MATLAB.']);
end
try
 invoke(ICodeWarriorApp.DefaultProject,'BuildAndWaitToComplete');
catch
 error(['Error using COM connection to build current project. ' ...
 'Verify that CodeWarrior is installed. Verify COM access to
CodeWarrior outside of MATLAB.']);
end
end

```

## More About

- “About Embedded Target Development”

- “Sample Custom Targets”
- “Customize System Target Files”

## Device Drivers

Device drivers that communicate with target hardware are essential to many real-time development projects.

You can integrate existing C (or C++) device driver functions into Simulink models by using the Legacy Code Tool. When you use the code generator to generate code from a model, the Legacy Code Tool can insert a call to your C function into the generated code. For details, see “Build S-Function With Legacy Code Tool” and “Integrate C Functions into Simulink Models with Legacy Code Tool”.

# Project and Build Configurations for Embedded Targets in Embedded Coder

---

- “Model Setup” on page 72-2
- “IDE Projects” on page 72-12
- “XMakefiles for Software Build Tool Chains” on page 72-14

## Model Setup

### In this section...

“Block Selection” on page 72-2

“Configure Target Hardware Resources” on page 72-3

“Configuration Parameters” on page 72-5

“Model Reference” on page 72-11

### Block Selection

You can create models for targeting the same way you create other Simulink models—by combining standard blocks and C-MEX S-functions.

You can use blocks from the following sources:

- The Embedded Coder Support Packages.
- The Embedded Targets library (`embeddedtargetslib`) in the Embedded Coder product.
- Blocks from the System Toolboxes products
- Custom blocks

Avoid using blocks that do not generate code, including the following blocks.

Block Name/Category	Library	Description
Scope	Simulink, DSP System Toolbox software	Provides oscilloscope view of your output. Do not use the <b>Save data to workspace</b> option on the <b>Data history</b> pane in the Scope Parameters dialog.
To Workspace	Simulink	Return data to your MATLAB workspace.
From Workspace	Simulink	Send data to your model from your MATLAB workspace.
Spectrum Scope	DSP System Toolbox	Compute and display the short-time FFT of a signal. It has internal

Block Name/Category	Library	Description
		buffering that can slow your process without adding value.
To File	Simulink	Send data to a file on your host machine.
From File	Simulink	Get data from a file on your host machine.
Triggered to Workspace	DSP System Toolbox	Send data to your MATLAB workspace.
Signal To Workspace	DSP System Toolbox	Send a signal to your MATLAB workspace.
Signal From Workspace	DSP System Toolbox	Get a signal from your MATLAB workspace.
Triggered Signal From Workspace	DSP System Toolbox	Get a signal from your MATLAB workspace.
To Wave device	DSP System Toolbox	Send data to a .wav device.
From Wave device	DSP System Toolbox	Get data from a .wav device.

## Configure Target Hardware Resources

This topic contains the following subtopics:

- “About Supported IDEs” on page 72-3
- “Configure Parameters Under the Target Hardware Resources Tab” on page 72-4

### About Supported IDEs

This “Configure Target Hardware Resources” on page 72-3 section applies to the following IDEs:

- Analog Devices VisualDSP++®
- Texas Instruments Code Composer Studio™ 3.3
- Texas Instruments Code Composer Studio 4 (makefile generation only)
- Texas Instruments Code Composer Studio 5 (makefile generation only)
- Wind River Diab/GCC (makefile generation only)

### Configure Parameters Under the Target Hardware Resources Tab

Configure the parameters under the Target Hardware Resources tab of your Simulink model for a specific tool chain and target hardware. Doing so updates other parameters in the Configuration Parameters dialog to the default values for the software build tool chain and target hardware you are using.

---

**Note:** The Target Preferences (Removed) block has been removed from the Simulink block libraries for the Embedded Coder and Simulink Coder products.

Parameters in the Target Preferences block have been moved to the Target Hardware Resources tab.

---

To configure your Simulink model for a specific tool chain and target hardware:

- 1 In a Simulink model, open the model Configuration Parameters by:
  - Clicking the gear icon,  

  - Pressing **Ctrl+E** on your keyboard
  - Selecting the **Simulation > Model Configuration Parameters** menu items
- 2 In the Configuration Parameters dialog, click **Code Generation**, and then click “+” next to Code Generation. This action displays the sub-panes under Code Generation.
- 3 On the Code Generation pane, change **System target file** to `idmlink_ert.tlc` or `idmlink_grt.tlc`.

The dialog displays a **Coder Target** pane under the Code Generation pane.

- 4 Select the **Coder Target** pane.
- 5 Select the **Target Hardware Resources** tab.
- 6 Set the following parameters to match the tool chain and target hardware you are using:
  - **IDE/Tool Chain**
  - **Board**
  - **Processor**

- 7 Review the other parameters under the **Target Hardware Resources** tab.
- 8 Click **Apply**, and save the changes to your model.

## Configuration Parameters

- “What are Configuration Parameters?” on page 72-5
- “Setting Model Configuration Parameters” on page 72-5

### What are Configuration Parameters?

To see the model Configuration Parameters, open the **Configuration Parameters** dialog. You can do this in the model editor by selecting **Simulation > Model Configuration Parameters**, or by pressing **Ctrl+E** on your keyboard.

The **Configuration Parameters** dialog specifies the values for a model's active *configuration set*. These parameters determine the type of solver used, the import and export settings, and other values that determine how the model runs.

### Setting Model Configuration Parameters

To set the Configuration Parameters to the right values for you to generate code from your model, see “Configure Parameters Under the Target Hardware Resources Tab” on page 72-4. This action initializes the model Configuration Parameters to the right default values for you to generate code. You can then use the Configuration Parameters dialog to make further modifications to the values. You can generate buildable code using these default values.

The following subsections provide a quick overview of the panes and parameters with which you are most likely to interact.

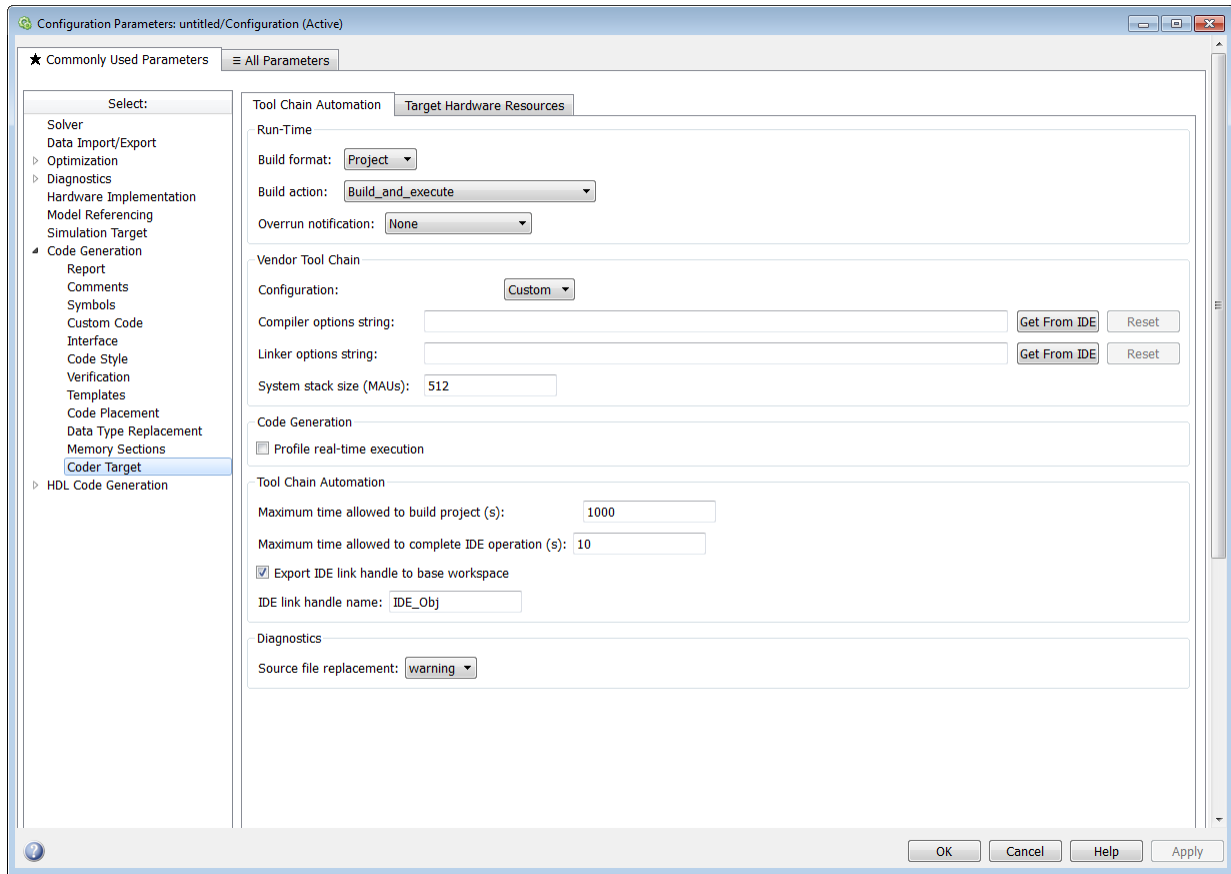

#### Code Generation Pane

When you set **System target file** to `idmlink_ert.tlc` or `idmlink_grt.tlc`, the dialog adds an **Coder Target** pane to the list of panes under **Code Generation**.

Leave **Language** set to **C**. The `idmlink_ert.tlc` and `idmlink_grt.tlc` system target files do not support C++ code generation.

For more information, see “Model Configuration Parameters: Code Generation”.

## Coder Target Pane Parameters

The Coder Target entry provides options in these areas:

- **Run-Time** — Set options for run-time operations, like the build action
- **Vendor Tool Chain** — Set compiler, linker, and system stack size options
- **Code Generation** — Configure your code generation requirements
- **Link Automation** — Export an IDE link handle object, such as `IDE_Obj`, to your MATLAB workspace
- **Diagnostics** — Determine how the code generation process responds when you use source code replacement in the **Custom Code** pane.

For more information, see Code Generation Pane: Coder Target.

### **Build format**

Select **Project** to create an IDE project, or select **Makefile** to create a makefile build script.

### **Build action**

Your selection for **Build action** determines what happens when you press **Ctrl+B**. Your selection tells Simulink Coder software when to stop the code generation and build process.

To run your model on the processor, select **Build\_and\_execute**. This selection is the default build action.

The actions are cumulative—each action performs an additional step relative to the preceding action on the list.

If you set **Build format** to **Project**, select one of the following options:

- **Create\_project** — Directs Simulink Coder software to start the IDE and populate a new project with the files from the build process. This option offers a convenient way to build projects in the IDE.
- **Archive\_library** — Directs Simulink Coder software to create an archive library for this model. Use this option when you plan to use the model in a model reference application. Model reference requires that you archive your the IDE projects for models that you use in model referencing.
- **Build** — Builds the executable file, but does not download the file to the target hardware.
- **Build\_and\_execute** — Directs Simulink Coder software to build, download, and run your generated code as an executable on your target hardware.
- **Create\_processor\_in\_the\_loop\_project** — Directs code generation process to create PIL algorithm object code as part of the project build. This option requires an Embedded Coder license.

If you set **Build format** to **Makefile**, select one of the following options:

- **Create\_makefile** — Creates a makefile.
- **Archive\_library** — Creates a makefile and the generated output will be an archive library.

- **Build** — Creates a makefile and an executable.
- **Build\_and\_execute** — Creates a makefile and an executable. Then it evaluates the `execute` instruction in the current configuration.

### Overrun notification

To enable the overrun indicator, choose one of three ways for the target to respond to an overrun condition in your model:

- **None** — Ignore overruns encountered while running the model.
- **Print\_message** — When the target encounters an overrun condition, it prints a message to the standard output device, `stdout`.
- **Call\_custom\_function** — Respond to overrun conditions by calling the custom function you identify in **Function name**.

### Function name

When you select `Call_custom_function` from the **Overrun notification** list, you enable this option. Enter the name of the function the target should use to notify you that an overrun condition occurred. The function must exist in your code on the target hardware.

### Configuration

The **Configuration** parameter defines sets of build options that apply to the files generated from your model.

The **Release** and **Debug** option apply build settings that are defined by your compiler. For more information, refer to your compiler documentation.

**Custom** has the same default values as **Release**, but:

- Leaves **Compiler options string** empty.

### Compiler options string

To determine the degree of optimization provided by the optimizing compiler, enter the optimization level to apply to files in your project. For details about the compiler options, refer to your IDE documentation. When you create new projects, the code generator does not set optimization flags.

With Texas Instruments Code Composer Studio 3.3 and Analog Devices VisualDSP++, the user interface displays **Get From IDE** and **Reset** buttons next to this parameter. If

you have an active project open in the IDE, you can click **Get From IDE** to import the compiler option setting from the current project in the IDE. To reset the compiler option to the default value, click **Reset**.

### **Linker options string**

To specify the options provided by the linker during link time, you enter the linker options as text. For details about the linker options, refer to your IDE documentation. When you create new projects, the code generator does not set linker options.

With Texas Instruments Code Composer Studio 3.3 and Analog Devices VisualDSP++, the user interface displays **Get From IDE** and **Reset** buttons next to this parameter. If you have an active project open in the IDE, you can click **Get From IDE** to import the linker options text from the current project in the IDE. To clear the linker options, click **Reset**.

### **System stack size (MAUs)**

Enter the amount of memory that is available for allocating stack data, measured in minimum addressable units (MAU). Block output buffers are placed on the stack until the stack memory is fully allocated. After that, the output buffers go in global memory. An MAU is typically 1 byte, but its size can vary by target hardware.

This parameter is used in targets to allocate the stack size for the generated application. For example, with embedded processors that are not running an operating system, this parameter determines the total stack space that can be used for the application. For operating systems, this value specifies the stack space allocated per thread.

This parameter also applies to the “Maximum stack size (bytes)” parameter, located in the Optimization > Signals and Parameters pane.

### **System heap size (MAUs)**

Set the default heap size that the target hardware reserves for dynamic memory allocation.

The target hardware uses this heap for functions like printf() and system services code.

The following IDEs use this parameter:

- Analog Devices VisualDSP++
- Wind River Diab/GCC (makefile generation only)

**Profile real-time execution**

To enable the real-time execution profile capability, select **Profile real-time execution**. With this selected, the build process instruments your code to provide performance profiling at the task level or for atomic subsystems. When you run your code, the executed code reports the profiling information in an HTML report.

**Link Automation**

When you build a model for a system target file, the code generator automatically creates or uses an existing *IDE link handle object* (named `IDE_Obj`, by default) to connect to your IDE.

Although `IDE_Obj` is a handle for a specific instance of the IDE, it also contains information about the IDE instance to which it refers, such as the target the IDE accesses. In this pane, the **Export IDE link handle to base workspace** option lets you instruct the code generator to export the object to your MATLAB workspace, giving it the name you assign in **IDE link handle name**.

You can also use the IDE link handle object to interact with the IDE using IDE Automation Interface commands.

**Maximum time allowed to build project (s)**

Specifies how long the software waits for the IDE to build the software.

**Maximum time allowed to complete IDE operation (s)**

Specifies how long the software waits for IDE functions, such as `read` or `write`, to return completion messages. If you do not specify a timeout, the default value is 10 seconds.

**Export IDE link handle to base workspace**

Directs the software to export the `IDE_Obj` object to your MATLAB workspace.

**IDE link handle name**

Specifies the name of the `IDE_Obj` object that the build process creates.

**Source file replacement**

Selects the diagnostic action to take if the software detects conflicts when you replace source code with custom code. The diagnostic message responds to both source file replacement in the Configuration Parameters under Code Generation > Coder Target parameters and under Code Generation > Custom Code.

The following settings define the messages you see and how the code generation process responds:

- **none** — Does not generate warnings or errors when it finds conflicts.
- **warning** — Displays a warning. `warn` is the default value.
- **error** — Terminates the build process and displays an error message that identifies which file has the problem and suggests how to resolve it.

The build operation continues if you select **warning** and the software detects custom code replacement problems. You see warning messages as the build progresses.

Select **error** the first time you build your project after you specify custom code to use. The error messages can help you diagnose problems with your custom code replacement files. Use **none** when the replacement process works and you do not want to see multiple messages during your build.

## Model Reference

The `idelink_ert.tlc` and `idelink_grt.tlc` system target files provide support for generating code from models that use Model Reference. A referenced model will generate an archive library.

To enable Model Reference builds:

- 1 Open your referenced model.
- 2 Select Simulation > Model Configuration Parameters from the model menus.
- 3 From the list of panes under **Code Generation**, choose **Coder Target**.
- 4 In the right pane, under Run-Time, select `Archive_library` from the **Build action** list.

If your top-model uses a reference model that does not have the **Build action** set to `Archive_library`, the build process automatically changes the **Build action** to `Archive_library` and issues a warning about the change.

### Configuration Parameters in Reference Models

Use the same Coder Target pane settings in Configuration Parameters for the models in the model hierarchy.

## IDE Projects

### In this section...

“Support for Third Party Products” on page 72-12

“Code Generation and Build” on page 72-12

### Support for Third Party Products

For more information about support for third-party IDEs and targets, see:

- Supported and Compatible Compilers
- Hardware Support

### Code Generation and Build

#### Building Your Model

In your model, click **Build Model**. The software performs the actions you selected for **Build action** in the model Configuration Parameters, under Code Generation > Coder Target.

#### IDE Project Generator Features

The *IDE Project Generator* component provides or supports the following features for developing IDE projects and generating code:

- Automatically create IDE projects for your generated code during the code generation process.
- Customize code generation using options in the model Configuration Parameters.
- Configure the automatic project build process.
- Automatically download and run your generated projects on your target hardware.

#### IDE Link Handle Objects

IDE Project Generator automatically creates and uses an IDE link handle object to communicate with your IDE and target hardware.

To create the IDE link handle object, IDE Project Generator use the following constructor function:

- `ticcs` for Texas Instruments Code Composer Studio

For a command line example of how to use a constructor function, see the corresponding reference page for each function.

## XMakefiles for Software Build Tool Chains

In this section...
“What is the XMakefile Feature” on page 72-14
“Using Makefiles to Generate and Build Software” on page 72-16
“Making an XMakefile Configuration Operational” on page 72-19
“Creating a New XMakefile Configuration” on page 72-19
“XMakefile User Configuration dialog” on page 72-25

### What is the XMakefile Feature

- “Overview” on page 72-14
- “Available XMakefile Configurations” on page 72-14
- “Feature Support” on page 72-16

#### Overview

You can use makefiles instead of IDE projects during the automated software build process. This approach is described in “Using Makefiles to Generate and Build Software” on page 72-16.

The XMakefile feature lets you choose the *configuration* of a specific software build tool chain to use during the automated build process. The configuration contains paths and settings for your make utility, compiler, linker, archiver, pre-build, post-build, and execute tools.

You can also create a new configuration for a new tool chain, as described in “Creating a New XMakefile Configuration” on page 72-19.

Your requirements for specific features may determine whether you choose makefiles or IDE projects. See “Feature Support” on page 72-16.

#### Available XMakefile Configurations

The following list describes the configurations in the XMakefile dialog that this product supports:

- `adivdsp_blackfin`: Analog Devices VisualDSP++ & Analog Devices Blackfin®

- `adivdsp_sharc`: Analog Devices VisualDSP++ & Analog Devices SHARC®
- `adivdsp_tigersharc`: Analog Devices VisualDSP++ & Analog Devices TigerSHARC®
- `gcc_target`: GNU Compiler Collection & Host Operating System or Embedded Operating System
- `ticcs_c2000_ccsv3`: Texas Instruments Code Composer Studio 3 & Texas Instruments C2000
- `ticcs_c2000_ccsv4`: Texas Instruments Code Composer Studio 4 & Texas Instruments C2000
- `ticcs_c2000_ccsv5`: Texas Instruments Code Composer Studio 5.1 & Texas Instruments C2000
- `ticcs_c5500_ccsv3`: Texas Instruments Code Composer Studio 3 & Texas Instruments C5500
- `ticcs_c5500_ccsv4`: Texas Instruments Code Composer Studio 4 & Texas Instruments C5500
- `ticcs_c5500_ccsv5`: Texas Instruments Code Composer Studio 5.1 & Texas Instruments C5500
- `ticcs_c6000_ccsv3`: Texas Instruments Code Composer Studio 3 & Texas Instruments C6000
- `ticcs_c6000_ccsv4`: Texas Instruments Code Composer Studio 4 & Texas Instruments C6000
- `ticcs_c6000_ccsv5`: Texas Instruments Code Composer Studio 5.1 & Texas Instruments C6000
- `ticcs_c6000_dspbios_ccsv3`: Texas Instruments Code Composer Studio 3 & Texas Instruments DSP/BIOS on C6000
- `ticcs_c6000_dspbios_ccsv4`: Texas Instruments Code Composer Studio 4 & Texas Instruments DSP/BIOS on C6000
- `ticcs_c6000_dspbios_ccsv5`: Texas Instruments Code Composer Studio 5.1 & Texas Instruments DSP/BIOS on C6000
- `wrsdiab_arm9_vxworks67_rtp`: Wind River Systems DIAB Compiler & ARM 9 & VxWorks 6.7 & real-time process applications
- `wrsdiab_arm9_vxworks67_rtp_so`: Wind River Systems DIAB Compiler & ARM 9 & VxWorks 6.7 & real-time process applications with shared object
- `wrsdiab_hostsim_vxworks67_rtp`: Wind River Systems DIAB Compiler & VxWorks Host Simulator & VxWorks 6.7 & real-time process applications

- `wrsdiab_hostsim_vxworks67_rtp_so`: Wind River Systems DIAB Compiler & VxWorks Host Simulator & VxWorks 6.7 & real-time process applications with shared object
- `wrsdiab_hostsim_vxworks68_rtp`: Wind River Systems DIAB Compiler & VxWorks Host Simulator & VxWorks 6.8 & real-time process applications
- `wrsdiab_hostsim_vxworks68_rtp_so`: Wind River Systems DIAB Compiler & VxWorks Host Simulator & VxWorks 6.8 & real-time process applications with shared object
- `wrsgnu_arm9_vxworks67_rtp`: Wind River Systems GNU Compiler & VxWorks Host Simulator & VxWorks 6.7 & real-time process applications
- `wrsgnu_hostsim_vxworks67_rtp`: Wind River Systems GNU Compiler & VxWorks Host Simulator & VxWorks 6.7 & real-time process applications with shared object
- `wrsgnu_hostsim_vxworks68_rtp`: Wind River Systems GNU Compiler & VxWorks Host Simulator & VxWorks 6.8 & real-time process applications with shared object
- `xilinx_ise_14_x`: Xilinx ISE Design Suite & ARM Cortex-A9 running Linux on Xilinx Zynq<sup>®</sup>-7000 platform

For more information about supported versions of third-party software, see “Support for Third Party Products” on page 72-12

### **Feature Support**

With makefiles, you cannot use features that rely on direct communications between your MathWorks software and third-party IDEs.

You cannot use the following features with makefiles:

- IDE Project Generation
- IDE Automation Interface
- IDE debugger communications during Processor-in-the-loop (PIL) simulation

## **Using Makefiles to Generate and Build Software**

### **Configuring Your Model to Use Makefiles**

Update your model Configuration Parameters to use a makefile instead of an IDE when you build software from the model:

- 1 Configure your model for your IDE, tool chain, and target hardware, as described in “Configure Target Hardware Resources” on page 72-3.

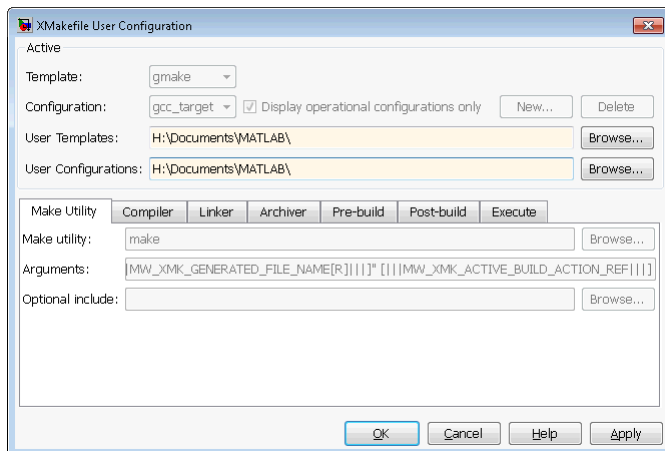

- 2 In the Configuration Parameters dialog, under the **Code Generation** tab, select **Coder Target**.
- 3 Set **Build format** to **Makefile**. For more information, see “Build format” on page 72-7.
- 4 Set **Build action** to **Build\_and\_execute**. For more information, see “Build action” on page 72-7.

### Choosing an XMakefile Configuration

Configure how to generate makefiles:

- 1 Enter `xmakefilesetup` on the MATLAB Command Window. The software opens an XMakefile User Configuration dialog.

- 2 Set the **Template** parameter to the option that matches the **Configuration** parameter.

---

**Note:** In most cases, the only option for **Template** is **gmake**. However, if you have installed a Support Package, **Template** can have multiple options.

---

- 3 For **Configuration**, select the option that describes your software build toolchain and target platform. Click **Apply**.

---

**Note:** Changing some elements of the XMakefile dialog disables other elements until you apply the changes. Click **Apply** or **OK** after changing:

- **Template**
  - **Configurations**
  - **User Templates**
  - **User Configurations**
  - **Tool Directories**
- 

**Note:** With the XMakefile User Configuration dialog, if you have an Embedded Coder license and do not have a Simulink Coder license, the **Configuration** list includes two unsupported options: `gcc_target` or `msvs_host`. Disregard those two configurations. Choose one of the other configurations.

---

Things to consider while setting **Configuration**:

- Selecting **Display operational configurations only** hides configurations that contain incomplete or invalid information. For a configuration to be operational, the vendor tool chain must be installed, and the configuration must have the valid paths for each component of the vendor tool chain. For more information, see “Making an XMakefile Configuration Operational” on page 72-19.
- To display the configurations, including non-operational configurations, clear **Display operational configurations only**.
- The list of configurations can include non-editable configurations defined in the software and editable configurations defined by you.
- To create a new editable configuration, use the **New** button.
- For more information, see “XMakefile User Configuration dialog” on page 72-25.

### Building Your Model

In your model, click **Build Model**.

This action creates a makefile and performs the other actions you specified in **Build action**.

By default, this process outputs files in the <builddir>/<buildconfiguration> folder. For example, in `model_name/CustomMW`.

## Making an XMakefile Configuration Operational

When the XMakefile utility starts, it checks each configuration file to verify that the specified paths for the vendor tool chain are valid. If the paths are not valid, the configuration is non-operational. Typically, the cause of this problem is a difference between the path in the configuration and the actual path of the vendor toolchain.

To make a configuration operational:

- 1 Clear **Display operational configurations only** to display non-operational configurations.
- 2 Select the non-operational configuration from the **Configuration** options.
- 3 When you click **Apply**, a new dialog prompts you for the folder path of the missing resources the configuration requires.

Use mapped network drives instead of UNC paths to specify directory locations. Using UNC paths with compilers that do not support them causes build errors.

## Creating a New XMakefile Configuration

- “Overview” on page 72-19
- “Create a Configuration” on page 72-20
- “Modify the Configuration” on page 72-21
- “Test the Configuration” on page 72-23

### Overview

This example shows you how to add support for a software development toolchain to the XMakefile utility. This example uses the Intel Compiler and an IDE.

---

**Note:** To specify directory locations, use mapped network drives instead of UNC paths. UNC paths cause build errors with compilers that do not support them.

---

## Create a Configuration

When you click **New**, the new configuration inherits values and behavior from the current configuration. To create a configuration for the Intel Compiler, clone a configuration from one of these configurations: `montavista_arm` and `gcc_target`.

Open the XMakefile User Configuration UI by typing `xmakefilesetup` at the MATLAB prompt. This action displays the following dialog.

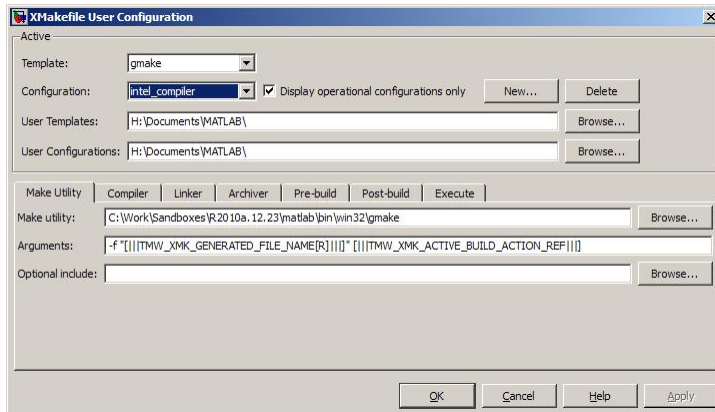

Select an existing configuration, such as `montavista_arm` or `gcc_target`. Click the **New** button.

A pop-up dialog prompts you for the name of the new configuration. Enter `intel_compiler` and click **OK**.

The dialog displays a new configuration called `intel_compiler`, based on the previous configuration.

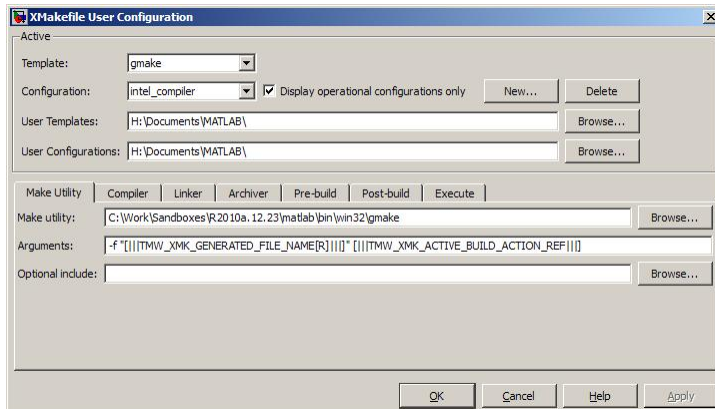

## Modify the Configuration

Adjust the compiler, linker, and archiver settings of the newly created configuration. This example assumes the location of the Intel compiler is `C:\Program Files\Intel\Compiler\`.

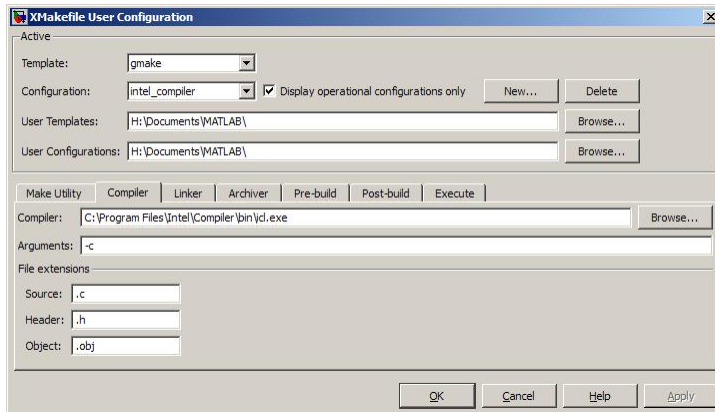

## Make Utility

You do not need to make changes. This configuration uses the gmake tool that ships with MATLAB.

## Compiler

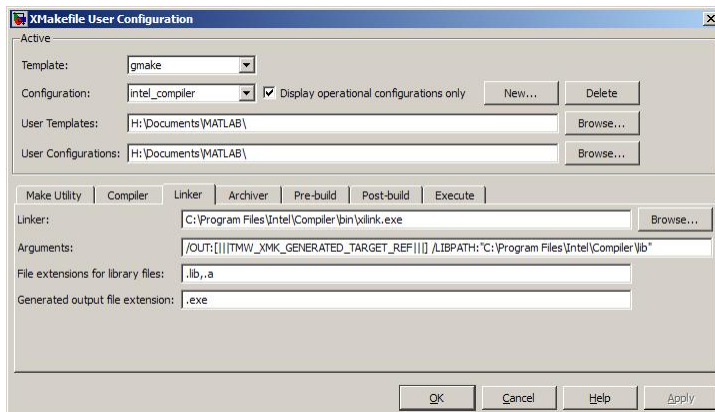

For **Compiler**, enter the location of `icl.exe` in the Intel installation.

## Linker

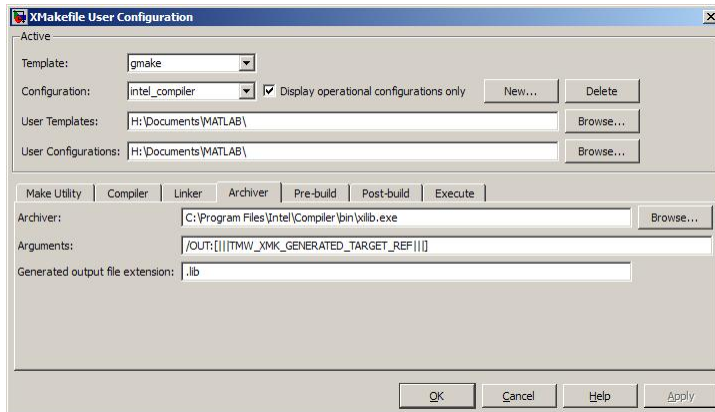

For **Linker**, enter the location of the linker executable, xilink.exe.

For **Arguments**, add the /LIBPATH path to the Intel libraries.

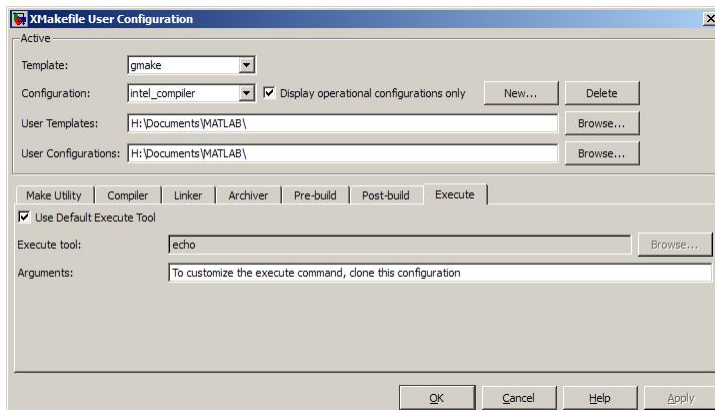

## Archiver

For **Archiver**, enter the location of the archiver, xilib.exe. Confirm that **File extensions for library files** includes **.lib**.

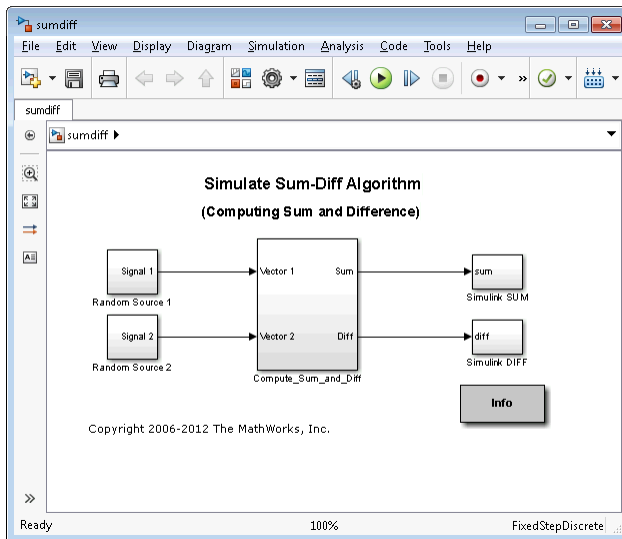

### Other tabs

For this example, ignore the remaining tabs. In other circumstances, you can use them to configure additional build actions. In a later step of this example, you will configure the software to automatically build and run the generated code.

### Test the Configuration

Open the “sumdiff” model by entering `sumdiff` on the MATLAB prompt.

Configure the `sumdiff` model for use with an IDE. Follow the steps in “Configure Target Hardware Resources” on page 72-3, set the **IDE/Tool Chain** parameter, set **Board** to **Custom**, and **Processor** to **Intel x86/Pentium**.

On the Tool Chain Automation page, set **Operating System** to **None** or select **Windows**. Click **OK**.

Open the Configuration Parameters for the `sumdiff` model by pressing **Ctrl+E**. Set **Build format** to **Makefile** and **Build action** to **Build\_and\_execute**.

Save the model to a temporary location, such as `C:\Temp\IntelTest\`.

Set that location as a Current Folder by typing `cd C:\temp\IntelTest\` at the MATLAB prompt.

Build the model by pressing **Ctrl+B**. The MATLAB Command Window displays something like:

```
TLC code generation complete.
Creating HTML report file sumdiff_codegen_rpt.html
Creating project: c:\temp\IntelTest\sumdiff_idenameide\sumdiff.mk
Project creation done.
Building project...
Build done.
Downloading program: c:\temp\IntelTest\sumdiff_idenameide\sumdiff
Download done.
```

A command window comes up showing the running model. Terminate the generated executable by pressing **Ctrl+C**.

## XMakefile User Configuration dialog

- “Active” on page 72-25
- “Make Utility” on page 72-27
- “Compiler” on page 72-27
- “Linker” on page 72-28
- “Archiver” on page 72-29
- “Pre-build” on page 72-29
- “Post-build” on page 72-30
- “Execute” on page 72-30
- “Tool Directories” on page 72-31

### Active

### Template

Set the **Template** parameter to the option that matches the **Configuration** parameter.

---

**Note:** In most cases, the only option for **Template** is **gmake**. However, if you have installed a Support Package, **Template** can have multiple options.

---

The template defines the syntax rules for writing the contents of the makefile or buildfile. The default template is `gmake`, which works with the GNU make utility.

To add templates to this parameter, save them as `.mkt` files to the location specified by the **User Templates** parameter. For more information, see “User Templates” on page 72-27.

### **Configuration**

Select the configuration that best describes your toolchain and target hardware.

You cannot edit or delete the configurations provided by MathWorks. You can, however, edit and delete the configurations that you create.

Use the **New** button to create an editable copy of the currently selected configuration.

Use the **Delete** button to delete a configuration you created.

---

**Note:** You cannot edit or delete the configurations provided by MathWorks.

---

---

**Note:** Use mapped network drives instead of UNC paths to specify directory locations. Using UNC paths with compilers that do not support them causes build errors.

---

### **Display operational configurations only**

When you open the XMakefile User Configuration dialog, the software verifies that each configuration provided by MathWorks contains valid paths to the executable files it uses. If the paths are valid, the configuration is operational. If the paths are not valid, the configuration is not operational.

This setting only applies to configurations provided by MathWorks, not configurations you create.

To display valid configurations, select **Display operational configurations only**.

To display the configurations, including non-operational configurations, clear **Display operational configurations only**.

For more information, see “Making an XMakefile Configuration Operational” on page 72-19.

## User Templates

Set the path of the folder to which you can add template files. Saving templates files with the `.mkt` extension to this folder adds them to the **Templates** options.

## User Configurations

Set the location of configuration files you create with the **New** button.

## Make Utility

### Make utility

Set the path and filename of the make utility executable.

### Arguments

Define the command-line arguments to pass to the make utility. For more information, consult the third-party documentation for your make utility.

### Optional include

Set the path and file name of an optional makefile to include.

## Compiler

### Compiler

Set the path and file name of the compiler executable.

### Arguments

Define the command-line arguments to pass to the compiler. For more information, consult the third-party documentation for your compiler.

### Source

Define the file name extension for the source files. Use commas to separate multiple file extensions.

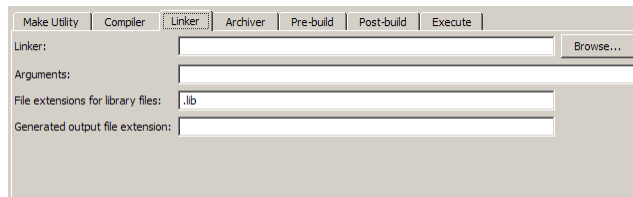

### Header

Define the file name extension for the header files. Use commas to separate multiple file extensions.

### Object

Define the file name extension for the object files.

### Linker

The screenshot shows a dialog box titled "Linker" with several tabs: "Make Utility", "Compiler", "Linker", "Archiver", "Pre-build", "Post-build", and "Execute". The "Linker" tab is active. It contains four input fields: "Linker:" with a "Browse..." button, "Arguments:", "File extensions for library files:" (containing ".lib"), and "Generated output file extension:".

### Linker

Set the path and file name of the linker executable.

### Arguments

Define the command-line arguments to pass to the linker. For more information, consult the third-party documentation for your linker.

### File extensions for library files

Define the file name extension for the file library files. Use commas to separate multiple file extensions.

### Generated output file extension

Define the file name extension for the generated libraries or executables.

## Archiver

The screenshot shows a dialog box with tabs for 'Make Utility', 'Compiler', 'Linker', 'Archiver', 'Pre-build', 'Post-build', and 'Execute'. The 'Archiver' tab is active. It features three text input fields: 'Archiver:' (with a 'Browse...' button), 'Arguments:', and 'Generated output file extension:'.

### Archiver

Set the path and file name of the archiver executable.

### Arguments

Define the command-line arguments to pass to the archiver. For more information, consult the third-party documentation for your archiver.

### Generated output file extension

Define the file name extension for the generated libraries.

## Pre-build

The screenshot shows a dialog box with tabs for 'Make Utility', 'Compiler', 'Linker', 'Archiver', 'Pre-build', 'Post-build', and 'Execute'. The 'Pre-build' tab is active. It features a checkbox labeled 'Enable Pre-build Step', a 'Pre-build tool:' input field (with a 'Browse...' button), and an 'Arguments:' input field.

### Enable Prebuild Step

Select this check box to define a prebuild tool that runs before the compiler.

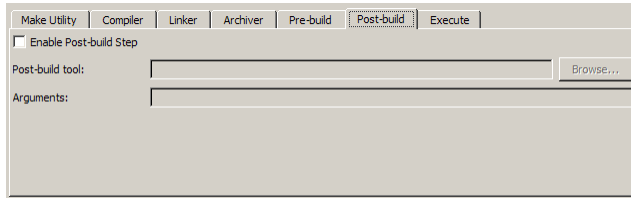

### Prebuild tool

Set the path and file name of the prebuild tool executable.

### Arguments

Define the command-line arguments to pass to the prebuild tool. For more information, consult the third-party documentation for your prebuild tool.

## Post-build

The screenshot shows a dialog box with tabs for 'Make Utility', 'Compiler', 'Linker', 'Archiver', 'Pre-build', 'Post-build', and 'Execute'. The 'Post-build' tab is active. It contains a checkbox labeled 'Enable Post-build Step'. Below it is a text field for 'Post-build tool:' with a 'Browse...' button to its right. At the bottom is a text area for 'Arguments:'.

### Enable Postbuild Step

Select this check box to define a postbuild tool that runs after the compiler or linker.

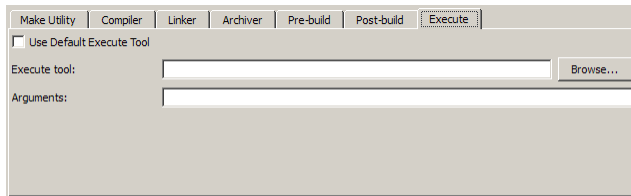

### Postbuild tool

Set the path and file name of the postbuild tool executable.

### Arguments

Define the command-line arguments to pass to the postbuild tool. For more information, consult the third-party documentation for your postbuild tool.

## Execute

The screenshot shows a dialog box with tabs for 'Make Utility', 'Compiler', 'Linker', 'Archiver', 'Pre-build', 'Post-build', and 'Execute'. The 'Execute' tab is active. It contains a checkbox labeled 'Use Default Execute Tool'. Below it is a text field for 'Execute tool:' with a 'Browse...' button to its right. At the bottom is a text area for 'Arguments:'.

### Use Default Execute Tool

Select this check box to use the generated derivative as the execute tool when the build process is complete. Uncheck it to specify a different tool. The default value, `echo`, simply displays a message that the build process is complete.

---

**Note:** On the Linux operating system, multirate multitasking executables require root privileges to schedule POSIX threads with real-time priority. If you are using makefiles to build multirate multitasking executables on your Linux development system, you

cannot use **Execute tool** to run the executable. Instead, use the Linux command, `sudo`, to run the executable.

---

### Execute tool

Set the path and file name of the execute tool executable or built-in command.

### Arguments

Define the command-line arguments to pass to the execute tool. For more information, consult the third-party documentation for your execute tool.

### Tool Directories

### Installation

Use the Tool Directories tab to change the toolchain path of an operational configuration.

For example, if you installed two versions of a vendor build tool in separate folders, you can use the **Installation** path to change which one the configuration uses.

# Verification and Profiling Generated Code in Embedded Coder

---

- “PIL Simulation for IDE and Toolchain Targets” on page 73-2
- “Code Execution Profiling for IDE and Toolchain Targets” on page 73-19
- “Perform Execution-Time Profiling for IDE and Toolchain Targets” on page 73-22
- “Perform Stack Profiling with IDE and Toolchain Targets” on page 73-28

## PIL Simulation for IDE and Toolchain Targets

### In this section...

“Overview” on page 73-2

“PIL Approaches” on page 73-3

“Communications” on page 73-7

“Running Your PIL Application to Perform Simulation and Verification” on page 73-13

“Performing a Model Block PIL Simulation via SCI Using Makefiles” on page 73-13

“Definitions” on page 73-17

“PIL Issues and Limitations” on page 73-17

### Overview

Verification consists broadly of running generated code on a processor and verifying that the code does what you intend. Embedded Coder provides processor-in-the-loop (PIL) simulation to meet this need. PIL compares the numeric output of your model under simulation with the numeric output of your model running as an executable on a target hardware.

With PIL, you run your generated code on a target hardware or instruction set simulator. To verify your generated code, you compare the output of model simulation modes, such as Normal or Accelerator, with the output of the generated code running on the processor. You can switch between simulation and PIL modes. This flexibility allows you to verify the generated code by executing the model as compiled code in the target environment. You can model and test your embedded software component in Simulink and then reuse your regression test suites across simulation and compiled object code. This process avoids the time-consuming process of leaving the Simulink software environment to run tests again on object code compiled for the production hardware.

Embedded Coder supports the following PIL approaches:

- Model block PIL
- Top-model PIL
- PIL block

When you use makefiles with PIL, use the “model block PIL” approach. With makefiles, the other two approaches, “top-model PIL” and “PIL block”, and are not supported.

## PIL Approaches

- “Model Block PIL” on page 73-3
- “Top-Model PIL” on page 73-4
- “PIL Block” on page 73-5

### Model Block PIL

Use model block PIL to:

- Verify code generated for referenced models (model reference code interface).
- Provide a test harness model (or a system model) to generate test vector or stimulus inputs.
- Switch a model block between normal, SIL, or PIL simulation modes.

To perform a model block PIL simulation, start with a top-model that contains a model block. The top-model serves as a test harness, providing inputs and outputs for the model block. The model block references the model you plan to run on target hardware. During PIL simulation, the referenced model runs on the target hardware.

For more information about using the model block, see [Model](#), [Model Variants](#) and [“Model Referencing”](#).

By default, your MathWorks software uses the IDE debugger for PIL communications with the target hardware. To achieve faster communications, consider using one of the alternatives presented in [“Communications”](#) on page 73-7.

To use model block PIL:

- 1 Create and share a configuration reference between the top model and the referenced model, as described in [“Share a Configuration for Multiple Models”](#).
- 2 Right-click the Model block, and select **ModelReference Parameters**.
- 3 When the software displays the **Function Block Parameters: Model** dialog box, set **Simulation mode** to **Processor-in-the-loop (PIL)** and click **OK**.
- 4 Open the model block.

- 5 In the referenced model (model block) Configuration Parameters (**Ctrl+E**), under **Code Generation > Coder Target**, set **Build action** set to `Archive_library`. This action avoids a warning when you start the simulation.
- 6 Save the changes to both models.
- 7 In the top-model menu bar, select **Simulation > Run**. This action builds the referenced model in the model block, downloads it to your target hardware, and runs the PIL simulation.

---

**Note:** In the top-model Configuration Parameters (**Ctrl+E**), under **Code Generation > Coder Target**, leave **Build action** set to `Build_and_execute`. Do not change **Build action** to `Create_Processor_In_the_Loop_Project`.

---

### Top-Model PIL

Use top-model PIL to:

- Verify code generated for a top-model (standalone code interface).
- Load test vectors or stimulus inputs from the MATLAB workspace.
- Switch the entire model between normal and SIL or PIL simulation modes.

### Setting Model Configuration Parameters to Generate the PIL Application

Configure your model to generate the PIL executable from your model:

- 1 Configure your model to run on target hardware, as described in “Configure Target Hardware Resources” on page 72-3.
- 2 From the model toolstrip, select **Simulation > Model Configuration Parameters**.
- 3 In Configuration Parameters, select **Code Generation**.
- 4 Set **System Target File** to `idmlink_ert.tlc`.
- 5 From the list of panes under **Code Generation**, choose **Coder Target**.
- 6 Set **Build format** to `Project`.
- 7 Set **Build action** to `Create_processor_in_the_loop_project`.
- 8 Click **OK** to close the Configuration Parameters dialog box.

For more information, see “Code Generation: Coder Target Pane”.

### Running the Top-Model PIL Application

To create a PIL block, perform the following steps:

- 1 In the model toolstrip, set the Simulation mode to Processor-in-the-loop.

- 2 In the model toolstrip, click Run.

A new Simulink Editor opens with the new PIL model block in it. The third-party IDE compiles and links the PIL executable file. Follow the progress of the build process in the MATLAB Command Window.

### PIL Block

Use the PIL block to:

- Verify code generated for a top-model (standalone code interface) or subsystem (right-click build standalone code interface).
- Represent a component running in SIL or PIL mode. The test harness model or a system model provides test vector or stimulus inputs.

### Preparing Your Model to Generate a PIL Block

Start with a model that contains the algorithm blocks you want to verify on the processor as compiled object code. To create a PIL application and PIL block from your algorithm subsystem, follow these steps:

- 1 Identify the algorithm blocks to cosimulate.
- 2 Convert those blocks into an unmasked subsystem in your model.

For information about how to convert your process to a subsystem, refer to *Creating Subsystems* in *Using Simulink* or in the online Help system.

- 3 Open the newly created subsystem.
- 4 Configure your subsystem to run on target hardware, as described in “Configure Target Hardware Resources” on page 72-3.

### Setting Model Configuration Parameters to Generate the PIL Application

After you create your subsystem, set the Configuration Parameters for your model to enable the model to generate a PIL block.

Configure your model to enable it to generate PIL algorithm code and a PIL block from your subsystem:

- 1 From the model menu bar, select **Simulation > Model Configuration Parameters**. This action opens the Configuration Parameters dialog box.
- 2 In the Configuration Parameters dialog box, select **Code Generation**.
- 3 Set **System Target File** to `idlink_ert.tlc`.
- 4 From the list of panes under **Code Generation**, choose **Coder Target**.
- 5 Set **Build format** to **Project**.
- 6 Set **Build action** to `Create_processor_in_the_loop_project`.
- 7 Click **OK** to close the Configuration Parameters dialog box.

For more information, see “Code Generation: Coder Target Pane”.

### Creating the PIL Block from a Subsystem

To create a PIL block, perform the following steps:

- 1 Right-click the masked subsystem in your model and select **C/C++ Code > Build This Subsystem** from the context menu.

A new Simulink Editor opens and the new PIL block appears in it. The third-party IDE compiles and links the PIL executable file.

This step builds the PIL algorithm object code and a PIL block that corresponds to the subsystem, with the same inputs and outputs. Follow the progress of the build process in the MATLAB Command Window.

- 2 Copy the new PIL block from the new model to your model. To simulate the subsystem processes concurrently, place it parallel to your masked subsystem. Otherwise, replace the subsystem with the PIL block.

To see a PIL block in a parallel masked subsystem, search the product help for *Getting Started with Application Development* and select the example that matches your IDE.

---

**Note:** Models can have multiple PIL blocks for different subsystems. They cannot have more than one PIL block for the same subsystem. Including multiple PIL blocks for the same subsystem causes errors and inaccurate results.

---

## Communications

- “TCP/IP” on page 73-8
- “Additional Steps for TI C6000 Processors” on page 73-9
- “Serial Communication Interface (SCI) for Texas Instruments C2000” on page 73-10
- “IDE Debugger” on page 73-11

Choose one of the following communication methods for transferring code and data during PIL simulations:

Method	Speed	Comments
IDE Debugger	Slow	<ul style="list-style-type: none"> <li>• Supports PIL communications with an executable running an embedded target hardware.</li> <li>• Supports the largest number of targets.</li> <li>• Requires a physical connection between host and target hardware.</li> <li>• Only works with builds from IDE projects. Does not work with builds from makefiles.</li> </ul>
TCP/IP	Fast	<ul style="list-style-type: none"> <li>• Supports PIL communications with an executable running on a Linux or Windows host.</li> <li>• Supports embedded targets running Linux, TI DSP/BIOS, and Wind River VxWorks.</li> <li>• Requires network connection between host and target hardware.</li> </ul>

Method	Speed	Comments
		<ul style="list-style-type: none"> <li>• Works with builds from IDE projects and from makefiles.</li> </ul>
Serial Communication Interface (SCI)	Fast	<ul style="list-style-type: none"> <li>• Supports PIL communications with an executable running an embedded target hardware.</li> <li>• Supports TI C2802x, C2803x, 2806x, c280x, C281x, C2834x, C28x3x microcontrollers.</li> <li>• Requires an SCI connection between host and target hardware.</li> <li>• Works with builds from IDE projects and from makefiles.</li> </ul>

### TCP/IP

You can use TCP/IP for PIL communications with target hardware running:

- Linux
- Texas Instruments DSP/BIOS
- Wind River VxWorks

Using TCP/IP for PIL communications is typically faster than using a debugger, particularly for large data sets, such as with video and audio applications.

It also works well when you build an application on a remote Linux target using the `remoteBuild` function.

You can use TCP/IP with the following PIL approaches:

- Top-model PIL
- Model block PIL

TCP/IP does not work with the Subsystem PIL approach.

To enable and configure TCP/IP with PIL:

- 1 Set up a PIL simulation according to the PIL approach you have chosen.
- 2 In the MATLAB Command Window, use `setpref` to specify the IP address of the PIL server (`servername`).

If you are running the PIL server on a remote target, specify the IP address of the target hardware. For example:

```
setpref('MathWorks_Embedded_IDE_Link_PIL_Preferences','servername','144.212.109.114');
```

If you are running PIL server locally, on your host Windows or Linux system, enter 'localhost' instead of an IP address:

```
setpref('MathWorks_Embedded_IDE_Link_PIL_Preferences','servername','localhost');
```

- 3 Specify the TCP/IP port number to use for PIL data communication. Use one of the free ports in your system. For example:

```
setpref('MathWorks_Embedded_IDE_Link_PIL_Preferences','portnum', 17025);
```

- 4 Enable PIL communications over TCP/IP:

```
setpref('MathWorks_Embedded_IDE_Link_PIL_Preferences','enabletcpip', true);
```

To disable PIL communications over TCP/IP, change the value to **false**. This action automatically enables PIL communications over an IDE debugger, if an IDE is available.

- 5 Open the Configuration Parameters in your model. On the Coder Target pane, set the **Operating System** parameter to the operating system your target hardware is running.

---

**Note:** You cannot use TCP/IP for PIL when the value of **Operating System** is **None**.

---

- 6 Regenerate the code or PIL block.

To disable PIL communications over TCP/IP, enter:

```
setpref('MathWorks_Embedded_IDE_Link_PIL_Preferences','enabletcpip', false);
```

### Additional Steps for TI C6000 Processors

Add an IP Config block to the following location in your model:

- For top-model PIL, add it at the top level of your model.
- For model block PIL, add it to the referenced model to which you are pointing.
- For Subsystem PIL, place it in the subsystem.

Configure the IP Config block settings.

To determine the IP address assigned to the PIL server on the C6000 target:

- 1 Enter an arbitrary IP address the first time you specify the IP address.
- 2 Build and run the code for your model.
- 3 In the CCS command window, observe the actual IP address assigned to the C6000 processor by the DHCP server.
- 4 Enter the actual IP address the second time you specify the IP address.

### Serial Communication Interface (SCI) for Texas Instruments C2000

You can use SCI for processor-in-the-loop (PIL) simulations with Texas Instruments C2000 processors that support Serial Communications Interface (SCI). For other targets, configure PIL to communicate through TCP/IP or an IDE debugger.

SCI typically provides faster communications than an IDE debugger, particularly for large data sets.

To enable and configure SCI with PIL:

- 1 Set up a PIL simulation according to the PIL approach you have chosen. For more information, see “PIL Approaches” on page 73-3.
- 2 In the MATLAB Command Window, use `setpref` to specify the Configuration Parameters:
  - a Select the SCI port on your host computer for communicating with the target hardware. For example, to use COM1, enter the following command:

```
setpref('MathWorks_Embedded_IDE_Link_PIL_Preferences', 'COMPort', 'COM1');
```
  - b Set the baud rate of the SCI port. For example, if both the host computer and the target support 11,5200 baud, enter:

```
setpref('MathWorks_Embedded_IDE_Link_PIL_Preferences', 'BaudRate', 115200);
```
  - c Enable PIL communications over SCI:

```
setpref('MathWorks_Embedded_IDE_Link_PIL_Preferences', 'enableserial', true);
```
- 3 Configure the serial communications settings on your host computer to match the preceding values. For example, in Windows 7:
  - a Open the Windows Device Manager. (Press the Windows key on your keyboard and search for “Device Manager”.)
  - b Expand **Ports (COM & LPT1)**.
  - c Right-click the communications port you previously specified in MATLAB, such as **Communications Port (COM1)**, and select **Properties**.

- d** Go to the **Port Settings** tab, and match the value of **Bits per second** with the baud rate you previously specified in MATLAB. This value should match the baud rate you set in MATLAB. For example, 'BaudRate' , 115200.
- 4** Regenerate the code or PIL block.

Note: In serial PIL simulation, the changes that you make to the BaudRate or COMPort parameters in MathWorks\_Embedded\_IDE\_Link\_PIL\_Preferences are not detected, if the following conditions are met:

- You have already built your PIL application.
- You have set the **Configuration Parameters >Model Referencing >Rebuild** option to a value other than **Always**.
- You have not made changes to the model.

To apply your COM port or baudrate changes, either change the value in the **Configuration Parameters >Model Referencing >Rebuild** option to **Always**, or resave the model to force a new build of the PIL application.

To disable PIL communications over SCI, enter:

```
setpref('MathWorks_Embedded_IDE_Link_PIL_Preferences','enableserial',false);
```

---

**Note:** If you change the following parameters while using TCP/IP or serial communication for PIL, the software does not regenerate the PIL and communication code.

- TCP/IP Communication Parameters: **IP Address** and **Port number**
- Serial Communication Parameters: **COM Port** and **BaudRate**

To work around this issue, remove the `slprj` folder, generated code, and the generated MEX file. Then, regenerate the PIL code.

---

See “Performing a Model Block PIL Simulation via SCI Using Makefiles” on page 73-13

## IDE Debugger

To enable PIL communications over an IDE debugger, disable PIL communications over TCP/IP and SCI by entering the following commands:

```
setpref('MathWorks_Embedded_IDE_Link_PIL_Preferences','enabletcpip',false);
setpref('MathWorks_Embedded_IDE_Link_PIL_Preferences','enableserial',false);
```

Then regenerate the code or PIL block.

Using IDE debugger for PIL communication only works when you build your code from IDE projects. Using IDE debugger for PIL communication does not work with builds from makefiles.

### Configuring Breakpoints

You can use the `setStartApplicationPause` API to set breakpoints in the PIL application on the *first* PIL block simulation. If you do not use the `setStartApplicationPause` API, you can configure breakpoints after the initial run. The breakpoints remain active for subsequent runs.

You can enter the following static API method to pause after loading the application and manually configure breakpoints:

```
rtw.connectivity.Launcher.setStartApplicationPause(pauseAmount)
```

About this method:

- This method tells the MATLAB session to pause immediately after the PIL launcher starts the PIL application.
- `pauseAmount` is a pause time in seconds. To disable the pause, enter 0.

When you do not specify a pause, the software displays the following message:

```
To pause during PIL application start, run: >> rtw.connectivity.Launcher.
setStartApplicationPause(120)
```

The default pause is 120 sec. You can change this value.

When you specify a pause, a Start PIL Application Pause message box appears and displays following message:

```
Pausing during PIL application start for 120s (click OK to continue).
To disable this pause, see the hyperlink in the MATLAB command window.
```

- The MATLAB Command Window shows the following text:

```
To remove the pause during PIL application start,
run: >> rtw.connectivity.Launcher.setStartApplicationPause(0)
```

where `rtw.connectivity.Launcher.setStartApplicationPause(0)` is a hyperlink.

- The pause times out, or you can clear it early by closing the message box.
- During the pause, you cannot access MATLAB and thus cannot configure breakpoints programmatically via the IDE Automation Interface API.
- For the PIL block, the debugger stays open between simulation runs. When you perform an initial simulation run, you can automatically configure breakpoints via the IDE Automation Interface API before starting the second simulation.

## Running Your PIL Application to Perform Simulation and Verification

After you add PIL block to your model, add the required pause in seconds, using the following command in the MATLAB command prompt:

```
rtw.connectivity.Launcher.setStartApplicationPause(120)
```

Then click **Simulation > Run** or press **Ctrl+T** to run the PIL simulation and view the results.

---

**Note** The pause command is to make sure that the automatic download of PIL completes, before the model starts executing.

---

## Performing a Model Block PIL Simulation via SCI Using Makefiles

This example shows you the complete workflow for performing a processor-in-the loop (PIL) simulation that uses Serial Communications Interface (SCI) for communications.

### Prerequisites

Follow the board vendor's instructions for setting up a Texas Instruments C2000-based board that supports SCI. Connect the board to your host computer using a serial cable.

### Configure Your Model for Target Hardware

- 1 Enter `fuelsys_pil` in MATLAB. This action opens the `fuelsys_pil` model with the title, "Verifying the Fixed-Point Fuel Control System".
- 2 Configure `fuelsys_pil`. Follow the steps in "Configure Target Hardware Resources" on page 72-3 setting:

- **IDE/Tool Chain** to the version of CCS you are using.
- **Board** to a board that supports using SCI, such as SD F28335 eZdsp.

**3** Click **Yes**.

If you are working with CCSv3, configure `fuelsys_pil` to use makefiles:

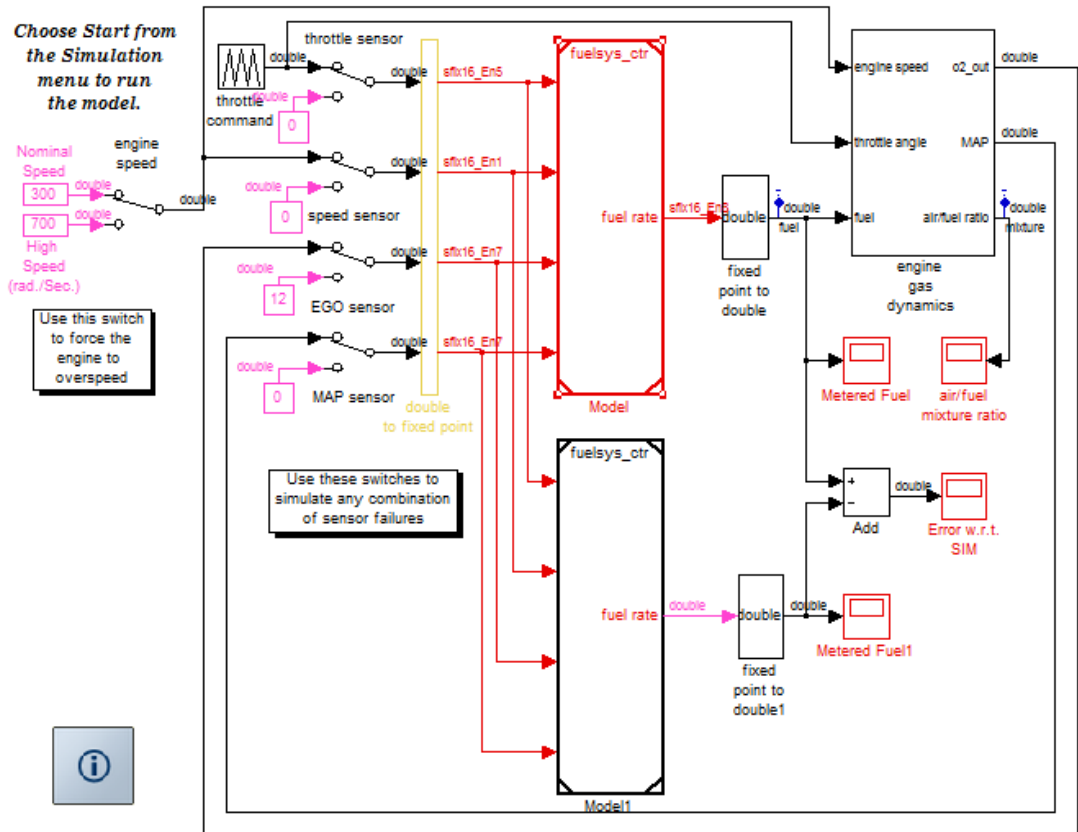

- 1** Select **Simulation > Model Configuration Parameters**.
- 2** In the Configuration Parameters dialog box, expand **Code Generation** and select **Coder Target**.
- 3** On the Coder Target pane, set **Build format** to **Makefile**.

If you are working with CCSv4/5, you do not need to configure the model to use makefiles. Initializing the configuration parameters for CCSv4/5 automatically sets **Build format** to **Makefile**.

### **Configure Your Model for the Model Block PIL Approach**

- 1** In the `fuelsys_pil`, copy the `fuelsys_ctr` model and paste it into the vacant space below. Connect it to the input/output signals provided.

## Verifying the Fixed-Point Fuel Control System

Copyright 2005-2011 The MathWorks, Inc.

- 2 Right-click the upper **fuelsys\_ctr** model, labeled “Model”, and select **ModelReference Parameters**.
- 3 In the **Function Block Parameters: Model** dialog box, set the **Simulation mode** parameter to **Processor-in-the-loop (PIL)**. Click the **OK** button.
- 4 Open the upper **fuelsys\_ctr** model, labeled “Model”.
- 5 From the menu in the open **fuelsys\_ctr** model, select **Simulation > Model Configuration Parameters** (or press **Ctrl+E**).

- 6 In the Configuration Parameters dialog box, in the **Solver** pane, set the **Type** parameter to **Fixed-step**, and set **Solver** to **ode3 (Bogacki-Shampine)**.
- 7 In the MATLAB Command Window, enter:

```
set_param('fuelsys_ctr', 'ModelReferenceSymbolNameMessage', 'none')
```
- 8 In the **Code Generation > Interface** pane, clear the Software environment **absolute time** check box.
- 9 In the **Code Generation > Coder Target** pane, set the Run time **Build action** parameter to **Archive library**.
- 10 Save the changes to your model, and leave the model open.
- 11 Open the top model, `fuelsys_pil`. Open the Configuration Parameters dialog box, in the **Solver** pane, verify that the **Type** parameter is set to **Fixed-step**, and reset **Solver** to **ode3 (Bogacki-Shampine)**.

---

**Note:** For information other PIL approaches, see “PIL Approaches” on page 73-3.

---

### Enable and configure SCI

- 1 Use `setpref` to specify the Configuration Parameters in MATLAB :

```
setpref('MathWorks_Embedded_IDE_Link_PIL_Preferences', 'COMPort', 'COM1');
setpref('MathWorks_Embedded_IDE_Link_PIL_Preferences', 'BaudRate', 115200);
setpref('MathWorks_Embedded_IDE_Link_PIL_Preferences', 'enableserial', true);
```
- 2 Configure the serial communications settings on your host computer to match the preceding values. For example, in Windows 7:
  - a Open the Windows Device Manager. (Press the Windows key on your keyboard and search for “Device Manager”.)
  - b Expand **Ports (COM & LPT1)**.
  - c Right-click the communications port you previously specified in MATLAB, such as **Communications Port (COM1)**, and select **Properties**.
  - d Go to the **Port Settings** tab, and match the value of **Bits per second** with the baud rate you previously specified in MATLAB. This value should match the baud rate you set in MATLAB. For example, `'BaudRate', 115200`.

### Configure the Software to Use Makefiles

Set up the `xmakefile` for CCSv4/5 as described in the section “Using Makefiles with Code Composer Studio 4/5” on page 76-5.

## Run the PIL Simulation

- 1 Make sure the SD F28335 eZdsp board is connected to your host computer via serial and USB cables and powered up.
- 2 Add the required pause in seconds, using the following command in the MATLAB command prompt:  

```
run: >> rtw.connectivity.Launcher.setStartApplicationPause(120)
```
- 3 Simulate the `fuelsys_pil` model (press **Ctrl+T**).

## Definitions

### PIL Algorithm

The algorithmic code, which corresponds to a subsystem or portion of a model, to test during the PIL simulation. The PIL algorithm is in compiled object form to enable verification at the object level.

### PIL Application

The executable application that runs on the processor platform. The code generator produces code for a PIL application by augmenting your algorithmic code with the PIL execution framework. The PIL execution framework code compiles as part of your embedded application.

The PIL execution framework code includes the `string.h` header file so that the PIL application can use the `memcpy` function. The PIL application uses `memcpy` to exchange data between the Simulink model and the simulation processor.

### PIL Block

When you build a subsystem from a model for PIL, the process creates a PIL block optimized for PIL simulation. When you run the simulation, the PIL block acts as the interface between the model and the PIL application running on the processor. The PIL block inherits the signal names and shape from the source subsystem in your model. Inheritance is convenient for copying the PIL block into the model to replace the original subsystem for simulation.

## PIL Issues and Limitations

Consider the following issues when you work with PIL blocks.

### Constraints

When using PIL in your models, keep in mind the following constraints:

- Models can have multiple PIL blocks for different subsystems. They cannot have more than one PIL block for the same subsystem. Including multiple PIL blocks for the same subsystem causes errors and inaccurate results.
- A model can contain a single model block running PIL mode.
- A model can contain a subsystem PIL block or a model block in PIL mode, but not both.

### Generic PIL Issues

Refer to PIL Feature Support and Limitations on page 64-60 for general information about using the PIL block with embedded link products.

### With Texas Instruments CCS, PIL with DSP/BIOS Enabled Does Not Support System Stack Profiling

Enabling DSP/BIOS™ for Texas Instruments processors disables the stack profiling option. To use stack profiling with PIL, open the **Target Hardware Resources** pane in model Configuration Parameters, and set the **Operating System** parameter to **None**. For help opening the Target Hardware Resources pane, see “Configure Target Hardware Resources” on page 72-3.

### Simulink Coder grt.tlc-Based Targets Not Supported

PIL does not support `grt.tlc` system target files.

To use PIL, set **System target file** in the Configuration Parameters > Code Generation pane to `idelink_ert.tlc`.

## Code Execution Profiling for IDE and Toolchain Targets

### In this section...

“Execution-Time Profiling” on page 73-19

“Stack Profiling” on page 73-19

### Execution-Time Profiling

You can measure the execution times during a standalone execution or processor-in-the-loop (PIL) simulation. You can generate execution time profiles for synchronous tasks, asynchronous tasks, and atomic subsystems. Use this feature to check whether your code runs in real time on your target hardware. For details, see “Perform Execution-Time Profiling for IDE and Toolchain Targets” on page 73-22.

You can use this profiling for generated code in the following cases:

- **Code Generation > System target file** is `ert.tlc` and **Code Generation > Target hardware** is not None, for example, ARM Cortex-A9 (QEMU) or ARM Cortex-M3 (QEMU).
- **Code Generation > System target file** is `idelink_ert.tlc`

The following table provides execution time profiling support information.

Mode	Coder Target > Tool Chain Automation > Build format parameter value
Standalone execution or PIL simulation	Project
PIL simulation	Makefile

### Stack Profiling

With stack profiling, you can determine how generated code uses the processor system stack. Using the `profile` method, you can initialize and test the size and usage of the stack. See “Perform Stack Profiling with IDE and Toolchain Targets” on page 73-28. This information can help you optimize both the size of the stack and how your code uses the stack.

You can use this profiling for generated code in the following cases:

- **Code Generation > System target file** is `ert.tlc` and **Code Generation > Target hardware** is not None, for example, ARM Cortex-A9 (QEMU) or ARM Cortex-M3 (QEMU).
- **Code Generation > System target file** is `idelink_ert.tlc`

---

**Note:** Stack profiling is not supported on embedded targets that run an operating system or RTOS.

---

To provide stack profiling, `profile` writes a known pattern to the addresses in the stack. After you run your application for a while, and then stop your application, `profile` examines the contents of the stack addresses. `profile` counts each address that does not contain the known pattern. The total number of addresses that have been used, compared to the total number of addresses that you allocated, becomes the stack usage profile. This profile process does not determine how often your application changes an address.

You can profile the stack with the manually written code in a project and the code that you generate from a model.

When you use `profile` to initialize and test the stack operation, the software returns a report that contains information about stack size, usage, addresses, and direction. With this information, you can modify your code to use the stack efficiently. The following program listing shows the stack usage results from running an application on a simulator.

```
profile(IDE_Obj, 'stack', 'report')
```

```
Maximum stack usage:
```

```
System Stack: 532/1024 (51.95%) MAUs used.
```

```
 name: System Stack
startAddress: [512 0]
endAddress: [1535 0]
 stackSize: 1024 MAUs
growthDirection: ascending
```

The following table describes the entries in the report.

Report Entry	Units	Description
System Stack	Minimum Addressable Unit (MAU)	Maximum number of MAUs used and the total MAUs allocated for the stack.
name	Character vector for the stack name	Lists the name assigned to the stack.
startAddress	Decimal address and page	Lists the address of the stack start and the memory page.
endAddress	Decimal address and page	Lists the address of the end of the stack and the memory page.
stackSize	Addresses	Reports number of address locations, in MAUs, allocated for the stack.
growthDirection	Not applicable	Reports whether the stack grows from the lower address to the higher address (ascending) or from higher to lower (descending).

## Related Examples

- “Perform Stack Profiling with IDE and Toolchain Targets” on page 73-28

## Perform Execution-Time Profiling for IDE and Toolchain Targets

### In this section...

“Execution-Time Profiling During Standalone Execution” on page 73-22

“Execution-Time Profiling During PIL Simulation” on page 73-25

### Execution-Time Profiling During Standalone Execution

During standalone execution, instrumentation in the generated code collects execution-time samples, which are stored in target hardware memory. After halting target hardware execution, you can use the `profile` function to transfer the execution data from target hardware memory to the MATLAB workspace for viewing and analysis.

You can perform profiling by task or subsystem. A profiling sample represents a task or subsystem execution instance. Each sample requires two memory locations, one for the start time and one for the end time. Therefore, you must specify a buffer size that is twice the number of required profiling samples. Sample collection begins with the start of code execution and ends when the buffer is full.

#### Task Profiling

To configure a model for task execution profiling:

- 1 In your model, select **Simulation > Model Configuration Parameters**.
- 2 Select the **Code Generation > Coder Target** pane.
- 3 Set **Build format** to `Project` and set **Build action** to `Build_and_execute`.
- 4 Select **Profile real-time execution**.
- 5 In the **Profile by** list, select **Tasks**.
- 6 Specify **Number of profiling samples to collect**, the size of the buffer that stores execution data. Enter a value that is twice the number of profiling samples you require.
- 7 Click **OK**.

To view the execution profile for your model:

1

Click **Build Model** on the model toolstrip. This action builds, loads, and runs your code on the processor.

- 2 To stop the running program, select **Debug > Halt** in the IDE or use `IDE_obj.halt` from the MATLAB command line. Gathering profiling data from a running program can yield inaccurate results.
- 3 At the MATLAB command prompt, enter

```
profile(IDE_Obj, 'execution', 'report')
```

to view the MATLAB software graphic of the execution report and the HTML execution report.

For more information about other reporting options, see the product help for the `profile` function.

The following profiling plot is from an application that runs with three rates — the base rate and two slower rates. Gaps in the **Sub-Rate 2** task bars indicate preempted operations.

## Subsystem Profiling

To configure a model for subsystem execution profiling:

- 1 Configure your model for your IDE, tool chain, and target hardware, as described in “Configure Target Hardware Resources” on page 72-3.

- 2 On the **Coder Target** pane, set **Build format** to **Project** and set **Build action** to **Build\_and\_execute**.
- 3 Select **Profile real-time execution**.
- 4 In the **Profile by** list, select **Atomic subsystems**.
- 5 Specify **Number of profiling samples to collect**, the size of the buffer that stores execution data. Enter a value that is twice the number of profiling samples you require.
- 6 Click **OK**.

To view the execution profile for your model:

1

Click **Build Model** on the model toolstrip. This action builds, loads, and runs your code on the processor.

- 2 To stop the running program, select **Debug > Halt** in the IDE or use `IDE_obj.halt` from the MATLAB command line. Gathering profiling data from a running program can yield inaccurate results.
- 3 At the MATLAB command prompt, enter:

```
profile(IDE_Obj, 'execution', 'report')
```

to view the MATLAB software graphic of the execution report and the HTML execution report.

The following profiling plot is from an application with three subsystems — **For Iterator Subsystem**, **For Iterator Subsystem1**, and **Idle Task Subsystem**.

## Execution-Time Profiling During PIL Simulation

During a processor-in-the-loop (PIL) simulation, you can profile execution times of synchronous tasks. The software stores the profile data in a `coder.profile.ExecutionTime` object, located in the MATLAB workspace. After halting the PIL simulation, you can view and analyze the data.

### Gathering Execution Profile Data

- 1 Configure a model for PIL simulation, as described in “PIL Simulation for IDE and Toolchain Targets” on page 73-2.
- 2 In your model, select **Simulation > Model Configuration Parameters**.
- 3 In the Configuration Parameters dialog box, select **Code Generation**, and then **Verification**.
- 4 Select the **Measure task execution time** check box.
- 5 Provide a valid MATLAB variable name in the **Workspace** edit box. The software uses this name when it creates the `coder.profile.ExecutionTime` object.
- 6 Click **OK** to close the Configuration Parameters dialog box.

- 7 Run the PIL simulation, as described in “PIL Simulation for IDE and Toolchain Targets” on page 73-2.

The software creates the `coder.profile.ExecutionTime` object and stores the execution profile data in it.

- 8 Halt the PIL simulation.

### Analyzing the Execution Profile Data

After halting the PIL simulation, you can view or analyze the data in the `coder.profile.ExecutionTime` object. For more information, see:

- “View and Compare Code Execution Times” on page 58-7
- “Analyze Code Execution Data” on page 58-18

Depending on the target, the execution profile data is measured in seconds or timer ticks.

Targets	Units
Texas Instruments C2000, C5000, and C6000 processors with Code Composer Studio IDE	Seconds
Texas Instruments C6000 processors running DSP/BIOS with Code Composer Studio IDE	Timer Ticks
Analog Devices Blackfin, SHARC, and TigerSHARC processors with VisualDSP++ IDE	Timer Ticks
ARM processors running Wind River VxWorks	Timer Ticks

The `coder.profile.ExecutionTime` class has property `TimerTicksPerSecond` for getting and setting the data units. You can use this property on the execution profile data object after halting the PIL simulation. When the data unit is timer ticks, using the `TimerTicksPerSecond` property converts the data units to seconds.

### See Also

`profile` | `TimerTicksPerSecond`

### Related Examples

- “Configure Target Hardware Resources” on page 72-3

- “View and Compare Code Execution Times” on page 58-7
- “Analyze Code Execution Data” on page 58-18

## Perform Stack Profiling with IDE and Toolchain Targets

To profile the system stack operation:

- 1 Load an application.
- 2 Set up the stack to enable profiling.
- 3 Run your application.
- 4 Request the stack profile information.

Follow these steps to profile the stack as your application interacts with it. This particular example uses Texas Instruments Code Composer Studio 3.3. However, you can generalize from this example to another supported IDE.

- 1 Load the application to profile.
- 2 Use the `profile` method with the **setup** input keyword to initialize the stack to a known state.

```
profile(IDE_Obj, 'stack', 'setup')
```

With the **setup** input argument, `profile` writes a known pattern into the addresses that compose the stack.

- 3 Run your application.
- 4 Stop your running application. Stack use results gathered from an application that is running may be inaccurate.
- 5 Use the `profile` method to capture and view the results of profiling the stack.

```
profile(IDE_Obj, 'stack', 'report')
```

The following example shows how to set up and profile the stack. The IDE link handle object, `IDE_Obj`, must exist in your MATLAB workspace and your application must be loaded on your processor. This example comes from a TI C6713 simulator.

```
profile(IDE_Obj, 'stack', 'setup') % Set up processor stack
%by write A5 to the stack addresses.
```

Maximum stack usage:

System Stack: 0/1024 (0%) MAUs used.

```
 name: System Stack
startAddress: [512 0]
endAddress: [1535 0]
 stackSize: 1024 MAUs
```

```
growthDirection: ascending
```

```
run(IDE_Obj)
halt(IDE_Obj)
profile(IDE_Obj, 'stack', 'report') % Request stack use report.
```

```
Maximum stack usage:
```

```
System Stack: 356/1024 (34.77%) MAUs used.
```

```
 name: System Stack
startAddress: [512 0]
endAddress: [1535 0]
 stackSize: 1024 MAUs
growthDirection: ascending
```

# Processor-Specific Optimizations for Embedded Targets in Embedded Coder

---

## Replace Code for Embedded Targets

### In this section...

“Using a Processor-Specific Code Replacement Library to Optimize Code” on page 74-2

“Process of Determining Optimization Effects Using Real-Time Profiling Capability” on page 74-2

### Using a Processor-Specific Code Replacement Library to Optimize Code

You can optimize the code the code generator produces for a specific processor by configuring the code generator to use a code replacement library (CRL) during code generation. If you have an Embedded Coder license, you can develop and apply custom code replacement libraries.

For more information about replacing code, using code replacement libraries that MathWorks provides, see “What Is Code Replacement?” on page 38-2 and “Replace Code Generated from Simulink Models” on page 38-10. For information about developing code replacement libraries, see “What Is Code Replacement Customization?” on page 51-3 and “Develop a Code Replacement Library” on page 51-27.

### Process of Determining Optimization Effects Using Real-Time Profiling Capability

You can use the real-time profiling capability to examine the results of applying the processor-specific library functions and operators to your generated code. After you select a processor-specific code replacement library, use the real-time execution profiling capability to examine the change in program execution time.

Use the following process to evaluate the effects of applying a processor-specific code replacement library when you generate code:

- 1 Enable real-time profiling in your model. Refer to “Code Execution Profiling”.
- 2 Generate code for your project without specifying a code replacement library (the default **Code replacement library** setting is **NONE**).
- 3 Profile the code, and save the report.
- 4 Rebuild your project using a processor-specific code replacement library.

- 5** Profile the code, and save the second report.
- 6** Compare the profile report from running your application with the processor-specific library selected to the profile results in the first report with no code replacement library selected.

For an example of verifying the code optimization, search help for "Optimizing Embedded Code via Code Replacement Library" and select the example that matches your IDE.

# Working with Texas Instruments Code Composer Studio 3.3 IDE in Embedded Coder

- “Setting Up Code Composer Studio (ert.tlc System Target File)” on page 75-88
- “IDE Link Frequently Asked Question: Why do I get an error when I invoke TICCS?” on page 75-90

## Set Up

Before you use Embedded Coder with Code Composer Studio (CCS IDE) for the first time, use the `checkEnvSetup` function to check for third-party tools and set environment variables. Run `checkEnvSetup` again whenever you configure CCS IDE to interact with a new board or processor, or upgrade the related third-party tools.

To verify that CCSv3 is installed on your machine and has at least one board configured, enter

```
ccsboardinfo
```

in the MATLAB Command Window. With CCS installed and configured, MATLAB software returns information about the boards that CCS recognizes on your machine, in a form similar to the following listing.

Board Num	Board Name	Proc Num	Processor Name	Processor Type
1	C6xxx Simulator (Texas Instrum	.0	6701	TMS320C6701
0	C6x13 DSK (Texas Instruments)	0	CPU	TMS320C6x1x

If MATLAB software does not return information about the boards, open your CCS installation and use the Setup Utility in CCS to configure at least one board.

As a final test, start CCS to verify that it runs. For Embedded Coder to operate with CCS, the CCS IDE must be able to run on its own.

# Code Composer Studio

**In this section...**

“Using Code Composer Studio with Embedded Coder Software” on page 75-3

“Default Project Configuration” on page 75-3

## Using Code Composer Studio with Embedded Coder Software

Texas Instruments (TI) facilitates development of software for TI DSPs by offering Code Composer Studio (CCS) Integrated Development Environment (IDE). Used in combination with Embedded Coder software and Simulink Coder software, CCS provides an integrated environment that, once installed, does not require coding.

Executing code generated from Simulink Coder software on a particular target requires that you tailor the code to the specific hardware target. Target-specific code includes I/O device drivers and interrupt service routines (ISRs). The software must use CCS to compile and link the generated source code in order to load and execute on a TI DSP. To help you to build an executable, Embedded Coder software uses Embedded Coder software to start the code building process within CCS. After you download your executable to your target and run it, the code runs wholly on the target hardware. You can access the running process only from the CCS debugging tools or across a link using Embedded Coder software. A wide range of Texas Instruments DSPs are supported:

- TI's C2000™
- TI's C5000™
- TI's C6000

## Default Project Configuration

CCS offers two standard project configurations, **Release** and **Debug**. Project configurations define sets of project build options. When you specify the build options at the project level, the options apply to the files in your project. For more information about the build options, refer to your TI documentation. The models you build with Embedded Coder software use a custom configuration that provides a third combination of build and optimization settings — **CustomMW**.

### **Default Build Options in the CustomMW Configuration**

The default settings for **CustomMW** are the same as the **Release** project configuration in **CCS**, except for the compiler options.

Your **CCS** documentation provides complete details on the compiler build options. You can change the individual settings or the build configuration within **CCS**.

# Getting Started

**In this section...**

“Overview” on page 75-5

“Verifying Your Code Composer Studio Installation” on page 75-8

## Overview

- “IDE Automation Interface” on page 75-6
- “IDE Project Generator” on page 75-7
- “Verification” on page 75-7

Embedded Coder software enables you to use MATLAB functions to communicate with Code Composer Studio software and with information stored in memory and registers on a processor. With the `ticcs` objects, you can transfer information to and from Code Composer Studio software and with the embedded objects you get information about data and functions stored in your signal processor memory and registers, as well as information about functions in your project.

Embedded Coder lets you build, test, and verify automatically generated code using MATLAB, Simulink, Simulink Coder, and the Code Composer Studio integrated development environment. You can use Embedded Coder to verify code executing within the Code Composer Studio software environment using a model in Simulink software. This processor-in-the-loop testing environment uses code automatically generated from Simulink models by Embedded Coder software. A range of Texas Instruments targets are supported:

- TI’s C2000
- TI’s C5000
- TI’s C6000

With Embedded Coder , you can use MATLAB software and Simulink software to interactively analyze, profile and debug processor-specific code execution behavior within CCS. In this way, Embedded Coder automates deployment of the complete embedded software application and makes it easy for you to assess possible differences between the model simulation and processor code execution results.

Embedded Coder consists of these components:

- IDE Project Generator—add embedded framework code to the C code generated from Simulink models, and package as a complete IDE project
- IDE Automation Interface—use functions in the MATLAB command window to access and manipulate data and files in the IDE and on the processor
- Verification—verify how your programs run on your processor

With Embedded Coder, you create objects that connect MATLAB software to Code Composer Studio software.

---

**Note** Embedded Coder uses objects. You work with them the way you use other MATLAB objects. You can set and get their properties, and use their methods to change them or manipulate them and the IDE to which they refer.

---

The next sections describe briefly the components of Embedded Coder software.

### **IDE Automation Interface**

The IDE Automation Interface component is a collection of methods that use the Code Composer Studio API to communicate between MATLAB software and Code Composer Studio. With the interface, you can do the following:

- Automate complex tasks in the development environment by writing MATLAB software scripts to communicate with the IDE, or debug and analyze interactively in a live MATLAB software session.
- Automate debugging by executing commands from the powerful Code Composer Studio software command language.
- Exchange data between MATLAB software and the processor running in Code Composer Studio software.
- Set breakpoints, step through code, set parameters and retrieve profiling reports.
- Automate project creation, including adding source files, include paths, and preprocessor defines.
- Configure batch building of projects.
- Debug projects and code.
- Execute API Library commands.

The IDE Automation Interface provides an application program interface (API) between MATLAB software and Code Composer Studio. Using the API, you can create new

projects, open projects, transfer data to and from memory on the processor, add files to projects, and debug your code.

### **IDE Project Generator**

The IDE Project Generator component is a collection of methods that use the Code Composer Studio API to create projects in Code Composer Studio and generate code with Embedded Coder. With the interface, you can do the following:

- Automated project-based build process

Automatically create and build projects for code generated by Embedded Coder.

- Customize code generation

Use Embedded Coder with a Embedded Coder system target file (STF) to generate processor-specific and optimized code.

- Customize the build process
- Automate code download and debugging

Rapidly and effortlessly debug generated code in the Code Composer Studio software debugger, using either the instruction set simulator or real hardware.

- Create and build CCS projects from Simulink software models. IDE Project Generator uses Simulink Coder software or Embedded Coder software to build projects that work with C2000 software, C5000™ software, and C6000™ software processors.
- Highly customized code generation with the system target file `idelink_ert.tlc` and `idelink_grt.tlc` that enable you to use the Configuration Parameters in your model to customize your generated code.
- Automate the process of building and downloading your code to the processor, and running the process on your hardware.

### **Verification**

Verifying your processes and algorithms is an essential part of developing applications. The components of Embedded Coder combine to provide the following verification tools for you to apply as you develop your code:

- Processor-in-the-loop simulation (PIL)
- Execution profiling
- Stack profiling

## Verifying Your Code Composer Studio Installation

To verify that CCS is installed on your machine and has at least one board configured, enter

```
ccsboardinfo
```

in the MATLAB Command Window. With CCS installed and configured, MATLAB software returns information about the boards that CCS recognizes on your machine, in a form similar to the following listing.

Board Num	Board Name	Proc Num	Processor Name	Processor Type
1	C6xxx Simulator (Texas Instrum	.0	6701	TMS320C6701
0	C6x13 DSK (Texas Instruments)	0	CPU	TMS320C6x1x

If MATLAB software does not return information about boards, open your CCS installation and use the Setup Utility in CCS to configure at least one board.

As a final test, start CCS to verify that it runs. For Embedded Coder to operate with CCS, the CCS IDE must be able to run on its own.

Embedded Coder uses objects to create:

- Connections to the Code Composer Studio Integrated Development Environment (CCS IDE)
- Connections to the RTDX™ (RTDX) interface. This object is a subset of the object that refers to the CCS IDE.

Concepts to know about the objects in this toolbox are covered in these sections:

- “Constructing ticcs Objects” on page 75-42
- “ticcs Properties and Property Values” on page 75-43
- “Overloaded Functions for ticcs Objects” on page 75-43

Refer to MATLAB Classes and Objects in your MATLAB documentation for more details on object-oriented programming in MATLAB software.

Many of the objects use COM server features to create handles for working with the objects. Refer to your MATLAB documentation for more information about COM as used by MATLAB software.

- “Closing the Links or Cleaning Up CCS IDE” on page 75-24

## Introducing the IDE Automation Interface

Embedded Coder provides a connection between MATLAB software and a processor in CCS. You can use objects to control and manipulate a signal processing application using the computational power of MATLAB software. This approach can help you debug and develop your application. Another possible use for automation is creating MATLAB scripts that verify and test algorithms that run in their final implementation on your production processor.

Before using the functions available with the objects, you must select a processor because objects you create are specific to a designated processor and a designated instance of CCS IDE. For multiprocessor boards or multiple board configurations of CCS, select the specific processor.

When you have one board with a single processor, the object defaults to the existing processor. For the objects, the simulator counts as a board; if you have both a board and a simulator that CCS recognizes, you must specify the processor explicitly.

To get you started using objects for CCS software, Embedded Coder includes a tutorial that introduces you to working with data and files. As you work through this tutorial, you perform the following tasks that step you through creating and using objects for CCS IDE:

- 1 Select your processor.
- 2 Create and query objects to CCS IDE.
- 3 Use MATLAB software to load files into CCS IDE.
- 4 Work with your CCS IDE project from MATLAB software.
- 5 Close the connections you opened to CCS IDE.

The tutorial provides a working process (a *workflow*) for using Embedded Coder and your signal processing programs to develop programs for a range of Texas Instruments processors.

During this tutorial, you load and run a digital signal processing application on a processor you select. The tutorial shows both writing to memory and reading from memory in the “Working with Projects and Data” on page 75-18” portion of the tutorial.

You can use the `read` and `write` methods, as described in this tutorial, to read and write data to and from your processor.

The tutorial covers the object methods and functions for Embedded Coder. The functions listed in the first table apply to CCS IDE independent of the objects — you do not need an object to use these functions. The methods listed in the second and third table requires a `ticcs` object that you use in the method syntax:

#### Functions for Working With Embedded Coder

The following functions do not require a `ticcs` object as an input argument:

Function	Description
<code>ccsboardinfo</code>	Return information about the boards that CCS IDE recognizes as installed on your PC.
<code>ticcs</code>	Construct an object to communicate with CCS IDE. When you construct the object you specify the processor board and processor.

### Methods for Working with ticcs Objects

The methods in the following table require a `ticcs` object as an input argument:

Method	Description
<code>add</code>	Add files to active project in IDE.
<code>address</code>	Memory address and page value of symbol in IDE.
<code>build</code>	Build or rebuild current project.
<code>display (IDE Object)</code>	Display the properties of an object to CCS IDE and RTDX.
<code>halt</code>	Terminate execution of a process running on the processor.
<code>info</code>	Return information about the processor or information about open RTDX channels.
<code>insert</code>	Insert debug point in file.
<code>isrtdxcapable</code>	Test whether your processor supports RTDX communications.
<code>isvisible</code>	Determine whether IDE appears on desktop.
<code>isrunning</code>	Test whether the processor is executing a process.
<code>list</code>	Return various information listings from Code Composer Studio software.
<code>load</code>	Load program file onto processor.
<code>read</code>	Retrieve data from memory on the processor.
<code>regread</code>	Read values from processor registers.
<code>regwrite</code>	Write data values to registers on processor.
<code>remove</code>	Remove file, project, or breakpoint.
<code>restart</code>	Restore the program counter (PC) to the entry point for the current program.

Method	Description
<code>run</code>	Execute the program loaded on the processor.
<code>visible</code>	Set whether CCS IDE window is visible on the desktop while CCS IDE is running.
<code>write</code>	Write data to memory on the processor.

### Running Code Composer Studio Software on Your Desktop — Visibility

When you create a `ticcs` object, Embedded Coder starts CCS in the background.

When CCS IDE is running in the background, it does not appear on your desktop, in your task bar, or on the **Applications** page in the Task Manager. It does appear as a process, `cc_app.exe`, on the **Processes** tab in Microsoft Windows Task Manager.

You can make the CCS IDE visible with the function `visible`. The function `isvisible` returns the status of the IDE—whether it is visible on your desktop. To close the IDE when it is not visible and MATLAB software is not running, use the **Processes** tab in Microsoft Windows Task Manager and look for `cc_app.exe`.

If a link to CCS IDE exists when you close CCS, the application does not close. Microsoft Windows software moves it to the background (it becomes invisible). Only after you clear links to CCS IDE, or close MATLAB software, does closing CCS IDE unload the application. You can see if CCS IDE is running in the background by checking in the Microsoft Windows Task Manager. When CCS IDE is running, the entry `cc_app.exe` appears in the **Image Name** list on the **Processes** tab.

When you close MATLAB software while CCS IDE is not visible, MATLAB software closes CCS if it started the IDE. This happens because the operating system treats CCS as a subprocess in MATLAB software when CCS is not visible. Having MATLAB software close the invisible IDE when you close MATLAB software prevents CCS from remaining open. You do not need to close it using Microsoft Windows Task Manager.

If CCS IDE is not visible when you open MATLAB software, closing MATLAB software leaves CCS IDE running in an invisible state. MATLAB software leaves CCS IDE in the visibility and operating state in which it finds it.

### Interactive Learning

You have the option of running this tutorial from the MATLAB Command Window or entering the functions as described in the following tutorial sections.

To run the tutorial in MATLAB software, click `run ccstutorial`. This command opens the tutorial in an interactive mode where the tutorial program provides prompts and text descriptions to which you respond to move to the next portion of the lesson. The interactive tutorial covers the same information provided by the following tutorial sections. You can view the tutorial file by clicking `ccstutorial.m`.

### Selecting Your Processor

Links for CCS IDE provides two tools for selecting a board and processor in multiprocessor configurations. One is a command line tool called `ccsboardinfo` which prints a list of the available boards and processors. So that you can use this function in a script, `ccsboardinfo` can return a MATLAB software structure that you use when you want your script to select a board without your help.

---

**Note** The board and processor you select is used throughout the tutorial.

---

- 1 To see a list of the boards and processors installed on your PC, enter the following command at the MATLAB software prompt:

```
ccsboardinfo
```

MATLAB software returns a list that shows you the boards and processors that CCS IDE recognizes as installed on your system.

- 2 To use the Selection Utility, `boardprocsel`, to select a board, enter

```
[boardnum,procnum] = boardprocsel
```

When you use `boardprocsel`, you see a dialog similar to the following. Note that some entries vary depending on your board set.

- 3 Select a board name and processor name from the lists.

You are selecting a board and processor number that identifies your particular processor. When you create the object for CCS IDE in the next section of this tutorial, the selected board and processor become the processor of the object.

- 4 Click **Done** to accept your board and processor selection and close the dialog.

boardnum and procnum now represent the **Board name** and **Processor name** you selected — boardnum = 1 and procnum = 0

### Creating and Querying Objects for CCS IDE

In this tutorial section, you create the connection between MATLAB software and CCS IDE. This connection, or object, is a MATLAB software object that you save as variable `IDE_Obj`.

You use function `ticcs` to create objects. When you create objects, `ticcs` input arguments let you define other object property values, such as the global timeout. Refer to the `ticcs` reference documentation for more information on these input arguments.

Use the generated object `IDE_Obj` to direct actions to your processor. In the following tasks, `IDE_Obj` appears in function syntax that interacts with CCS IDE and the processor:

- 1 Create an object that refers to your selected board and processor. Enter the following command at the prompt.

```
IDE_Obj=ticcs('boardnum',boardnum,'procnum',procnum)
```

If you were to watch closely, and your machine is not too fast, you see Code Composer Studio software appear briefly when you call `ticcs`. If CCS IDE was not running before you created the new object, CCS starts and runs in the background.

- 2 Enter `visible(IDE_Obj, 1)` to force CCS IDE to be visible on your desktop.

Usually, you need to interact with Code Composer Studio software while you develop your application. The first function in this tutorial, `visible`, controls the state of CCS on your desktop. `visible` accepts Boolean inputs that make CCS either visible on your desktop (input to `visible = 1`) or invisible on your desktop (input to `visible = 0`). For this tutorial, use `visible` to set the CCS IDE visibility to 1.

- 3 Next, enter `display(IDE_Obj)` at the prompt to see the status information.

```
TICCS Object:
 Processor type : Cxx
 Processor name : CPU
 Running? : No
 Board number : 0
 Processor number : 0
 Default timeout : 10.00 secs

 RTDX channels : 0
```

Embedded Coder provides methods to read the status of a board and processor:

- `info` — Return a structure of testable board conditions.
- `display` — Print information about the processor.
- `isrunning` — Return the state (running or halted) of the processor.
- `isrtdxcapable` — Return whether the hardware supports RTDX.

- 4 Type `linkinfo = info(IDE_Obj)`.

The `IDE_Obj` link status information provides information about the hardware as follows:

```
linkinfo =
 procname: 'CPU_1'
 isbigendian: 0
 isrtdxcapable: 0
 family: 320
```

```
 subfamily: 103
 revfamily: 11
 targettype: 'simulator'
 siliconrev: 0
 timeout: 10
 boardname: 'Cxxxx Device Simulator'
```

- 5 Check whether the processor is running by entering

```
runstatus = isrunning(IDE_Obj)
```

MATLAB software responds, indicating that the processor is stopped, as follows:

```
runstatus =
```

```
 0
```

- 6 At last, verify that the processor supports RTDX communications by entering

```
usesrtdx = isrtdxcapable(IDE_Obj)
usesrtdx =
```

```
 1
```

### Loading Files into CCS

You have established the connection to a processor and board and have created and queried objects. Next, the processor needs something to do.

In this part of the tutorial, you load the executable code for the processor CPU in CCS IDE. Embedded Coder includes a CCS project file. Through the next tasks in the tutorial, you locate the tutorial project file and load it into CCS IDE. The `open` method directs CCS to load a project file or workspace file.

---

**Note** CCS has workspace and workspace files that are different from the MATLAB workspace files and workspace. Remember to monitor both workspaces.

---

After you have executable code running on your processor, you can exchange data blocks with it. Exchanging data is the purpose of the objects provided by Embedded Coder software.

- 1 To load the project file to your processor, enter the following command at the MATLAB software prompt. `getdemoproject` is a specialized function for loading

Embedded Coder example files. It is not supported as a standard Embedded Coder function.

```
demopjt= getDemoProject(IDE_Obj,'ccstutorial')
demopjt.ProjectFile
ans =
C:\Temp\EmbIDELinkCCDemos_v4.1\ccstutorial\cxx\cxx\ccstut.pjt
demoPjt.DemoDir
ans =
```

```
C:\Temp\EmbIDELinkCCDemos_v4.1\ccstutorial\cxx\cxx
```

Your paths may be different if you use a different processor. Note where the software stored the example files on your machine. In general, Embedded Coder software stores the example project files in

```
EmbIDELinkCCDemos_v#. #
```

Embedded Coder creates this folder in a location where you have write permission. There are two locations where Embedded Coder software tries to create the example folder, in the following order:

- a** In a temporary folder on your C drive, such as `C:\temp\`.
  - b** If Embedded Coder software cannot use the `temp` folder, you see a dialog that asks you to select a location to store the examples.
- 2** Enter the following command at the MATLAB command prompt to build the processor executable file in CCS IDE.

```
build(IDE_Obj, 'all', 20)
```

You may get an error related to one or more missing `.lib` files. If you installed CCS IDE in a folder other than the default installation folder, browse in your installation folder to find the missing file or files. Refer to the path in the error message as an indicator of where to find the missing files.

- 3** Change your working folder to the example folder and enter `load(IDE_Obj, 'projectname.out')` to load the processor execution file, where *projectname* is the tutorial you chose, such as `ccstut_67x`.

You have a loaded program file and associated symbol table to the IDE and processor.

- 4** To determine the memory address of the global symbol `ddat`, enter the following command at the prompt:

```
ddata = address(IDE_Obj, 'ddat')
ddata =

 1.0e+009 *
 2.1475 0
```

Your values for `ddata` may be different depending on your processor.

---

**Note** The symbol table is available after you load the program file into the processor, not after you build a program file.

---

- 5 To convert `ddata` to a hexadecimal character vector that contains the memory address and memory page, enter the following command at the prompt:

```
dec2hex(ddata)
```

MATLAB software displays the following response, where the memory page is `0x00000000` and the address is `0x80000010`.

```
ans =

 80000010
 00000000
```

## Working with Projects and Data

After you load the processor code, you can use Embedded Coder functions to examine and modify data values in the processor.

When you look at the source file listing in the CCS IDE Project view window, there should be a file named `ccstut.c`. Embedded Coder ships this file with the tutorial and includes it in the project.

`ccstut.c` has two global data arrays — `ddat` and `idat` — that you declare and initialize in the source code. You use the functions `read` and `write` to access these processor memory arrays from MATLAB software.

Embedded Coder provides three functions to control processor execution — `run`, `halt`, and `restart`.

- 1 To see these commands, use the following function to add a breakpoint to line 68 of `ccstut.c`.

```
insert(IDE_Obj, 'ccstut.c', 68)
```

Line 68 is

```
printf("Embedded Coder: Tutorial - Memory Modified by Matlab!\n");
```

For information about adding breakpoints to a file, refer to `insert` in the online Help system. Then proceed with the tutorial.

- 2 To see the new functions, try the following functions.

```
halt(IDE_Obj) % Halt the processor.
restart(IDE_Obj) % Reset the PC to start of program.
run(IDE_Obj, 'runthalt', 30); % Wait for program execution to stop at
 % breakpoint (timeout = 30 seconds).
```

When you switch to viewing CCS IDE, you see that your program stopped at the breakpoint you inserted, and the program printed the following messages in the CCS IDE **Stdout** tab. Nothing prints in the MATLAB command window:

```
Embedded Coder: Tutorial - Initialized Memory
Double Data array = 16.3 -2.13 5.1 11.8
Integer Data array = -1-508-647-7000 (call me anytime!)
```

- 3 Before you restart your program (currently stopped at line 68), change some values in memory. Perform one of the following procedures based on your processor.

**C5xxx processor family** — Enter the following functions to see the `read` and `write` functions.

- a Enter `ddatv = read(IDE_Obj, address(IDE_Obj, 'ddat'), 'double', 4)`.

MATLAB software responds with

```
ddatv =
```

```
 16.3000 -2.1300 5.1000 11.8000
```

- b Enter `idatv = read(IDE_Obj, address(IDE_Obj, 'idat'), 'int16', 4)`.

Now MATLAB software responds

```
idatv =
```

```
-1 508 647 7000
```

If you used 8-bit integers (`int8`), the returned values would be incorrect.

```
idatv=read(IDE_Obj,address(IDE_Obj,'idat'),'int8',4)
```

```
idatv =
```

```
1 0 -4 1
```

- c** You can change the values stored in `ddat` by entering  

```
write(IDE_Obj,address(IDE_Obj,'ddat'),double([pi 12.3
exp(-1)...
sin(pi/4)]))
```

The `double` argument directs MATLAB software to write the values to the processor as double-precision data.

- d** To change `idat`, enter

```
write(IDE_Obj,address(IDE_Obj,'idat'),int32([1:4]))
```

Here you write the data to the processor as 32-bit integers (convenient for representing phone numbers, for example).

- e** Start the program running again by entering the following command:

```
run(IDE_Obj,'runtohalt',30);
```

The `Stdout` tab in CCS IDE reveals that `ddat` and `idat` contain new values. Next, read those new values back into MATLAB software.

- f** Enter `ddatv = read(IDE_Obj,address(IDE_Obj,'ddat'),'double',4)`.

```
ddatv =
```

```
3.1416 12.3000 0.3679 0.7071
```

`ddatv` contains the values you wrote in step **c**.

- g** Verify that the change to `idatv` occurred by entering the following command at the prompt:

```
idatv = read(IDE_Obj,address(IDE_Obj,'idat'),'int16',4)
```

MATLAB software returns the new values for `idatv`.

```
idatv =
```

```
1 2 3 4
```

- h** Use `restart` to reset the program counter for your program to the beginning. Enter the following command at the prompt:

```
restart(IDE_Obj);
```

**C6xxx processor family** — Enter the following commands to see the `read` and `write` functions.

- a** Enter `ddatv = read(IDE_Obj, address(IDE_Obj, 'ddat'), 'double', 4)`.

MATLAB software responds with

```
ddatv =
```

```
16.3000 -2.1300 5.1000 11.8000
```

- b** Enter `idatv = read(IDE_Obj, address(IDE_Obj, 'idat'), 'int16', 4)`.

MATLAB software responds

```
idatv =
```

```
-1 508 647 7000
```

If you used 8-bit integers (`int8`), the returned values would be incorrect.

```
idatv=read(IDE_Obj, address(IDE_Obj, 'idat'), 'int8', 4)
```

```
idatv =
```

```
1 0 -4 1
```

- c** Change the values stored in `ddat` by entering `write(IDE_Obj, address(IDE_Obj, 'ddat'), double([pi 12.3 exp(-1)... sin(pi/4)]))`

The `double` argument directs MATLAB software to write the values to the processor as double-precision data.

- d** To change `idat`, enter the following command:

```
write(IDE_Obj,address(IDE_Obj,'idat'),int32([1:4]))
```

In this command, you write the data to the processor as 32-bit integers (convenient for representing phone numbers, for example).

- e** Next, start the program running again by entering the following command:

```
run(IDE_Obj,'runtohalt',30);
```

The **Stdout** tab in CCS IDE reveals that `ddat` and `idat` contain new values. Read those new values back into MATLAB software.

- f** Enter `ddatv = read(IDE_Obj,address(IDE_Obj,'ddat'),'double',4)`.

```
ddatv =
```

```
3.1416 12.3000 0.3679 0.7071
```

Verify that `ddatv` contains the values you wrote in step c.

- g** Verify that the change to `idatv` occurred by entering the following command:

```
idatv = read(IDE_Obj,address(IDE_Obj,'idat'),'int32',4)
```

MATLAB software returns the new values for `idatv`.

```
idatv =
```

```
1 2 3 4
```

- h** Use `restart` to reset the program counter for your program to the beginning. Enter the following command at the prompt:

```
restart(IDE_Obj);
```

- 4** Embedded Coder offers more functions for reading and writing data to your processor. These functions let you read and write data to the processor registers: `regread` and `regwrite`. They let you change variable values on the processor in real time. The functions behave slightly differently depending on your processor.

Select one of the following procedures to see `regread` and `regwrite` used with your processor.

**C5xxx processor family** — Most registers are memory-mapped and available using `read` and `write`. However, the PC register is not memory mapped. To access this register, use the special functions — `regread` and `regwrite`. The following commands show how to use these functions to read and write to the PC register.

- a** To read the value stored in register PC, enter the following command at the prompt to indicate to MATLAB software the data type to read. The input character vector `binary` indicates that the PC register contains a value stored as an unsigned binary integer.

```
IDE_Obj.regread('PC','binary')
```

MATLAB software displays

```
ans =
```

```
33824
```

- b** To write a new value to the PC register, enter the following command. This time, the `binary` input argument tells MATLAB software to write the value to the processor as an unsigned binary integer. Notice that you used `hex2dec` to convert the hexadecimal character vector to decimal.

```
IDE_Obj.regwrite('PC',hex2dec('100'),'binary')
```

- c** Verify that the PC register contains the value you wrote.

```
IDE_Obj.regread('PC','binary')
```

**C6xxx processor family** — `regread` and `regwrite` let you access the processor registers directly. Enter the following commands to get data into and out of the A0 and B2 registers on your processor.

- a** To retrieve the value in register A0 and store it in a variable in your MATLAB workspace. Enter the following command:

```
treg = IDE_Obj.regread('A0','2scomp');
```

`treg` contains the two's complement representation of the value in A0.

- b To retrieve the value in register B2 as an unsigned binary integer, enter the following command:

```
IDE_Obj.regread('B2','binary');
```

- c Next, enter the following command to use `regwrite` to put the value in `treg` into register A2.

```
IDE_Obj.regwrite('A2',treg,'2scomp');
```

CCS IDE reports that A0, B2, and A2 have the values you expect. Select **View > CPU Registers > Core Registers** from the CCS IDE menu bar to list the processor registers.

### Closing the Links or Cleaning Up CCS IDE

Objects that you create in Embedded Coder software have COM handles to CCS. Until you delete these handles, the CCS process (`cc_app.exe` in the Microsoft Windows Task Manager) remains in memory. Closing MATLAB software removes these COM handles, but there may be times when you want to delete the handles without closing the application.

Use `clear` to remove objects from your MATLAB workspace and to delete handles they contain. `clear all` deletes everything in your workspace. To retain your MATLAB software data while deleting objects and handles, use `clear objname`. This applies to IDE link handle objects you created with `ticcs`. To remove the objects created during the tutorial, the tutorial program executes the following command at the prompt:

```
clear cvar cfield uintcvar
```

This tutorial also closes the project in CCS with the following command:

```
close(IDE_Obj,projfile,'project')
```

To delete your link to CCS, enter `clear IDE_Obj` at the prompt.

Your development tutorial using Code Composer Studio IDE is done.

During the tutorial you

- 1 Selected your processor.
- 2 Created and queried links to CCS IDE to get information about the link and the processor.

- 3 Used MATLAB software to load files into CCS IDE, and used MATLAB software to run that file.
- 4 Worked with your CCS IDE project from MATLAB software by reading and writing data to your processor, and changing the data from MATLAB software.
- 5 Created and used the embedded objects to manipulate data in a C-like way.
- 6 Closed the links you opened to CCS IDE.

## Getting Started with RTDX

- “Using RTDX” on page 75-26
- “Creating the ticcs Objects” on page 75-30
- “Configuring Communications Channels” on page 75-32
- “Running the Application” on page 75-33
- “Closing the Connections and Channels or Cleaning Up” on page 75-39
- “Listing Functions” on page 75-41

Texas Instruments Real-Time Data Exchange (RTDX) provides “real-time, continuous visibility into the way target applications operate in the real world. RTDX allows system developers to transfer data between target devices and a host without interfering with the target application.”

You can use RTDX with Embedded Coder software and Code Composer Studio to accelerate development and deployment to Texas Instruments C2000 processors. RTDX helps you test and analyze your processing algorithms in your MATLAB workspace. RTDX lets you interact with your process in real time while it's running on the processor. For example, you can:

- Send and retrieve data from memory on the processor
- Change the operating characteristics of the program
- Make changes to algorithms as required without stopping the program or setting breakpoints in the code

Enabling real-time interaction lets you more easily see your process or algorithm in action, the results as they develop, and the way the process runs.

This tutorial assumes you have Texas Instruments Code Composer Studio software and at least one target development board. You can use the hardware simulator in CCS IDE to run this tutorial.

After you complete the tutorial, you can start using RTDX with your applications and hardware.

---

**Note:** To use RTDX with the XDS100 USB JTAG Emulator and the C28027 chip, add the following line to the linker command file:

```
_RTDX_interrupt_mask = ~0x00000008;
```

---

## Using RTDX

Digital signal processing development efforts begin with an idea for processing data; an application area, such as audio or wireless communications or multimedia computing; and a platform or hardware to host the signal processing. Usually these processing efforts involve applying strategies like signal filtering, compression, and transformation to change data content; or isolate features in data; or transfer data from one form to another or one place to another.

Developers create algorithms they need to accomplish the desired result. After they have the algorithms, they use models and target hardware development tools to test their algorithms, to determine whether the processing achieves the goal, and whether the processing works on the proposed platform.

Embedded Coder and the links for RTDX and CCS IDE ease the job of taking algorithms from the model realm to the real world of the processor on which the algorithm runs.

RTDX and links for CCS IDE provide a communications pathway to manipulate data and processing programs on your processor. RTDX offers real-time data exchange in two directions between MATLAB software and your processor process. Data you send to the processor do little to alter running processes. Plotting data you retrieve from the processor lets you see how your algorithms are performing in real time.

To introduce the techniques and tools available in Embedded Coder for using RTDX, the following procedures use many of the methods in the link software to configure the processor, open and enable channels, send data to the processor, and clean up after you finish your testing. Among the functions covered are:

### Functions From Objects for CCS IDE

Function	Description
ticcs	Create connections to CCS IDE and RTDX.

Function	Description
cd	Change the CCS IDE working folder from MATLAB software.
open	Load program files in CCS IDE.
run	Run processes on the processor.

### Functions From the RTDX Class

Function	Description
close	Close the RTDX links between MATLAB software and your processor.
configure	Determine how many channel buffers to use and set the size of each buffer.
disable	Disable the RTDX links before you close them.
display	Return the properties of an object in formatted layout. When you omit the closing semicolon on a function, <code>disp</code> (a built-in function) provides the default display for the results of the operation.
enable	Enable open channels so you can use them to send and retrieve data from your processor.
isenabled	Determine whether channels are enabled for RTDX communications.
isreadable	Determine whether MATLAB software can read the specified memory location.
iswritable	Determine whether MATLAB software can write to the processor.
msgcount	Determine how many messages are waiting in a channel queue.
open	Open channels in RTDX.
readmat	Read data matrices from the processor into MATLAB software as an array.

Function	Description
readmsg	Read one or more messages from a channel.
writemsg	Write messages to the processor over a channel.

This tutorial provides the following workflow to show you how to use many of the functions in the links. By performing the steps provided, you work through many of the operations yourself. The tutorial follows the general task flow for developing digital signal processing programs through testing with the links for RTDX.

Within this set of tasks, numbers 1, 2, and 4 are fundamental to function syntax that interacts development projects. Whenever you work with MATLAB software and objects for RTDX, you perform the functions and tasks outlined and presented in this tutorial. The differences lie in Task 3. Task 3 is the most important for using Embedded Coder to develop your processing system.

- 1 Create an RTDX link to your desired processor and load the program to the processor.

The projects begin this way. Without the links you cannot load your executable to the processor.

- 2 Configure channels to communicate with the processor.

Creating the links in Task 1 did not open communications to the processor. With the links in place, you open as many channels as you need to support the data transfer for your development work. This task includes configuring channel buffers to hold data when the data rate from the processor exceeds the rate at which MATLAB software can capture the data.

- 3 Run your application on the processor. You use MATLAB software to investigate the results of your running process.
- 4 Close the links to the processor and clean up the links and associated debris left over from your work.

Closing channels and cleaning up the memory and links you created prepares CCS IDE, RTDX, and Embedded Coder for the next time you start development on a project.

This tutorial uses an executable program named `rtdxtutorial_6xevm.out` as your application. When you use the RTDX links and CCS IDE to develop your own

applications, replace `rtdxtutorial_6xevm.out` in Task 3 with the filename and path to your digital signal processing application.

You can view the tutorial file used here by clicking `rtdxtutorial`. To run this tutorial in MATLAB software, click `run rtdxtutorial`.

---

**Note** To be able to open and enable channels over a link to RTDX, the program loaded on your processor must include functions or code that define the channels.

Your C source code might look something like this to create two channels, one to write and one to read.

```
rtdx_CreateInputChannel(ichan); % processor reads from this.
rtdx_CreateOutputChannel(ochan); % processor writes to this.
```

These are the entries we use in `int16.c` (the source code that generates `rtdxtutorial_6xevm.out` to create the read and write channels.

If you are working with a model in Simulink software and using code generation, use the `To Rtdx` and `From Rtdx` blocks in your model to add the RTDX communications channels to your model and to the executable code on your processor.

---

One more note about this tutorial. Throughout the code we use both the dot notation (direct property referencing) to access functions and link properties and the function form.

For example, use the following command to open and configure `ichan` for write mode.

```
IDE_Obj.rtdx.open('ichan','w');
```

You could use an equivalent syntax, the function form, that does not use direct property referencing.

```
open(IDE_Obj.rtdx,'ichan','w');
```

Or, use

```
open(rx,'ichan','w');
```

if you created an alias `rx` to the RTDX portion of `IDE_Obj`, as shown by the following command:

```
rx = IDE_Obj.rtdx;
```

## Creating the ticcs Objects

With your processing model converted to an executable for your desired processor, you are ready to use the objects to test and run your model on your processor. Embedded Coder and the objects do not distinguish the source of the executable — whether you used Embedded Coder, CCS IDE, or some other development tool to program and compile your model to an executable does not alter the object connections. So long as your `.out` file is acceptable to the processor you select, Embedded Coder provides the connection to the processor.

Before continuing with this tutorial, you must load a valid GEL file to configure the EMIF registers of your processor and perform required processor initialization steps. Default GEL files provided by CCS are stored in `.. \IDE_Obj \gel` in the folder where you installed CCS software. Select **File > Load\_GEL** in CCS IDE to load the default GEL file that matches your processor family, such as `init6x0x.gel` for the Cxxxx processor family, and your configuration.

---

**Note:** If you are performing the steps in this tutorial, create `demoPjt` as described in “Loading Files into CCS” on page 75-16 before continuing.

---

Begin the process of getting your model onto the processor by creating a an object that refers to CCS IDE. Start by clearing function syntax that interacts existing handles and setting echo on so you see functions execute as the program runs:

```
1 clear all; echo on;
```

`clear all` removes debugging breakpoints and resets persistent variables because function breakpoints and persistent variables are cleared whenever the MATLAB file changes or is cleared. Breakpoints within your executable remain after `clear`. Clearing the MATLAB workspace does not alter your executable.

```
2 Now construct the link to your board and processor by entering
```

```
IDE_Obj=ticcs('boardnum',0);
```

`boardnum` defines which board the new link accesses. In this example, `boardnum` is 0. Embedded Coder connects the link to the first, and in this case only, processor on the board. To find the `boardnum` and `procnum` values for the boards and simulators on your system, use `ccsboardinfo`. When you enter the following command at the prompt

```
ccsboardinfo
```

- 3 To open and load the processor file, change the path for MATLAB software to be able to find the file.

```
projname = C:\Temp\EmbIDELinkCCDemos_v4.1\rtdxtutorial\cxx\cxxxp\rtdxtut_sim.pjt

outfile = C:\Temp\EmbIDELinkCCDemos_v4.1\rtdxtutorial\cxx\cxxxp\rtdxtut_sim.out

processor_dir = demoPjt.DemoDir

processor_dir = C:\Temp\EmbIDELinkCCDemos_v4.1\rtdxtutorial\cxx\cxxxp

cd(IDE_Obj,processor_dir); % Go to processor directory
cd(IDE_Obj,tgt_dir); % Or IDE_Obj.cd(tgt_dir)
dir(IDE_Obj); % Or IDE_Obj.dir
```

To load the project file to your processor, enter the following commands at the MATLAB software prompt. `getDemoProject` is a specialized function for loading Embedded Coder example files. It is not supported as a standard Embedded Coder function.

```
demoPjt = getDemoProject(IDE_Obj,'ccstutorial');

demoPjt.ProjectFile

ans = C:\Temp\EmbIDELinkCCDemos_v4.1\ccstutorial\cxx\cxxxp\ccstut.pjt

demoPjt.DemoDir

ans = C:\Temp\EmbIDELinkCCDemos_v4.1\ccstutorial\cxx\cxxxp
```

Notice where the example files are stored on your machine. In general, Embedded Coder software stores the example project files in

```
EmbIDELinkCCDemos_v#.#
```

For example, if you are using version 4.1 of Embedded Coder software, the project examples are stored in `EmbIDELinkCCDemos_v4.1\`. Embedded Coder software creates this folder in a location on your machine where you have write permission. Usually, there are two locations where Embedded Coder software tries to create the example folder, in the order shown.

- a In a temporary folder on the C drive, such as `C:\temp\`.
  - b If Embedded Coder software cannot use the `temp` folder, you see a dialog that asks you to select a location to store the examples.
- 4 You have reset the folder path to find the tutorial file. Now open the `.out` file that matches your processor type.

```
IDE_Obj.open('rtdxtutorial_xxx.out')
```

Because `open` is overloaded for the CCS IDE and RTDX links, this may seem a bit strange. In this syntax, `open` loads your executable file onto the processor identified by `IDE_Obj`. Later in this tutorial, you use `open` with a different syntax to open channels in RTDX.

In the next section, you use the new link to open and enable communications between MATLAB software and your processor.

### Configuring Communications Channels

Communications channels to the processor do not exist until you open and enable them through Embedded Coder and CCS IDE. Opening channels consists of opening and configuring each channel for reading or writing, and enabling the channels.

In the `open` function, you provide the channel names as character vectors for the channel name property. The channel name you use is not random. The channel name must match a channel defined in the executable file. If you specify a character vector that does not identify an existing channel in the executable, the `open` operation fails.

In this tutorial, two channels exist on the processor — `ichan` and `ochan`. Although the channels are named `ichan` for input channel and `ochan` for output channel, neither channel is configured for input or output until you configure them from MATLAB software or CCS IDE. You could configure `ichan` as the output channel and `ochan` as the input channel. The links would work just the same. For simplicity, the tutorial configures `ichan` for input and `ochan` for output. One more note—reading and writing are defined as seen by the processor. When you write data from MATLAB software, you write to the channel that the processor reads, `ichan` in this case. Conversely, when you read from the processor, you read from `ochan`, the channel that the processor writes to:

- 1 Configure buffers in RTDX to store the data until MATLAB software can read it into your workspace. Often, MATLAB software cannot read data as quickly as the processor can write it to the channel.

```
IDE_Obj.rtdx.configure(1024,4); % define 4 channels of 1024 bytes each
```

Channel buffers are optional. Adding them provides a measure of insurance that data gets from your processor to MATLAB software without getting lost.

- 2 Define one of the channels as a write channel. Use `'ichan'` for the channel name and `'w'` for the mode. Either `'w'` or `'r'` fits here, for write or read.

```
IDE_Obj.rtdx.open('ichan','w');
```

- 3 Now enable the channel you opened.

```
IDE_Obj.rtdx.enable('ichan');
```

- 4 Repeat steps 2 and 3 to prepare a read channel.

```
IDE_Obj.rtdx.open('ochan','r');
IDE_Obj.rtdx.enable('ochan');
```

- 5 To use the new channels, enable RTDX by entering

```
IDE_Obj.rtdx.enable;
```

You could do this step before you configure the channels — the order does not matter.

- 6 Reset the global time-out to 20s to provide a little room for error. `ticcs` applies a default timeout value of 10 s. In some cases this may not be enough.

```
IDE_Obj.rtdx.get('timeout')
ans =
 10
IDE_Obj.rtdx.set('timeout', 20); % Reset timeout = 20 seconds
```

- 7 Check that the `timeout` property value is now 20s and that your object has a valid configuration for the rest of the tutorial.

```
IDE_Obj.rtdx
```

```
RTDX Object:
 API version: 1.0
 Default timeout: 20.00 secs
 Open channels: 2
```

## Running the Application

To this point you have been doing common housekeeping functions. You load the processor, configure the communications, and set up other properties you need.

This tutorial shows you some of the Embedded Coder functions you can use to prototype and experiment with your application. To see the RTDX `readmat`, `readmsg`, and `writemsg` functions, you write data to your processor. Then, after the data has been processed, you read data from the processor.

- 1 Restart the program you loaded on the processor. `restart` sets the program counter (PC) to the beginning of the executable code on the processor.

```
IDE_Obj.restart
```

Restarting the processor does not start the program executing. You use `run` to start program execution.

**2** Type `IDE_Obj.run('run');`

Using 'run' for the run mode tells the processor to continue to execute the loaded program continuously until it receives a halt directive. In this mode, control returns to MATLAB software so you can work in MATLAB software while the program runs. Other options for the mode are

- 'runtohalt' — start to execute the program and wait to return control to MATLAB software until the process reaches a breakpoint or execution terminates.
- 'tohalt' — change the state of a running processor to 'runtohalt' and wait to return until the program halts. Use `tohalt` mode to stop the running processor cleanly.

**3** Type the following functions to enable the write channel and verify the change:

```
IDE_Obj.rtdx.enable('ichan');
IDE_Obj.rtdx.isenabled('ichan')
```

If MATLAB software responds `ans = 0` your channel is not enabled and you cannot proceed with the tutorial. Try to enable the channel again and verify the status.

**4** Write some data to the processor. Check that you can write to the processor, then use `writemsg` to send the data. You do not need to enter the if-test code shown.

```
if IDE_Obj.rtdx.iswritable('ichan'), % Used in a script application.
 disp('writing to processor...') % Optional to display progress.
 indata=1:10
 IDE_Obj.rtdx.writemsg('ichan', int16(indata))
end % Used in scripts for channel testing.
```

The `if` statement simulates writing the data from within a MATLAB software script. The script uses `iswritable` to check that the input channel is functioning. If `iswritable` returns `0` the script would skip the write and exit the program, or respond in some way. When you are writing or reading data to your processor in a script or MATLAB file, checking the status of the channels can help you avoid errors during execution.

As your application runs you may find it helpful to display progress messages. In this case, the program directed MATLAB software to print a message as it reads the data from the processor by adding the function

```
disp('writing to processor...')
```

Function `IDE_Obj.rtdx.writemsg('ichan', int16(indata))` results in 20 messages stored on the processor. Here's how.

When you write `indata` to the processor, the following code running on the processor takes your input data from `ichan`, adds one to the values and copies the data to memory:

```
while (!RTDX_isInputEnabled(&ichan))

{ /* wait for channel enable from MATLAB */
RTDX_read(&ichan, recvd, sizeof(recvd));
puts("\n\n Read Completed ");

for (j=1; j<=20; j++) {
 for (i=0; i<MAX; i++) {
 recvd[i] +=1;
 }
 while (!RTDX_isOutputEnabled(&ochan))
 { /* wait for channel enable from MATLAB */ }
 RTDX_write(&ochan, recvd, sizeof(recvd));
 while (RTDX_writing != NULL)
 { /* wait for data xfer INTERRUPT DRIVEN for Cxxxx */ }
}
```

Program `int16_rtdx.c` contains this source code. You can find the file in a folder in the `..\tidemos\rtdxtutorial` folder.

- 5 Type the following to check the number of available messages to read from the processor.

```
num_of_msgs = IDE_Obj.rtdx.msgcount('ochan');
```

`num_of_msgs` should be zero. Using this process to check the amount of data lets you or your program know how much data to expect.

- 6 Type the following to verify that your read channel `ochan` is enabled for communications.

```
IDE_Obj.rtdx.isenabled('ochan')
```

You should get back `ans = 0` — you have not enabled the channel yet.

- 7 Now enable and verify 'ochan'.

```
IDE_Obj.rtdx.enable('ochan');
IDE_Obj.rtdx.isenabled('ochan')
```

To show that `ochan` is ready, MATLAB software responds `ans = 1`. If not, try enabling `ochan` again.

**8** Type

```
pause(5);
```

The `pause` function gives the processor extra time to process the data in `indata` and transfer the data to the buffer you configured for `ochan`.

**9** Repeat the check for the number of messages in the queue. There should be 20 messages available in the buffer.

```
num_of_msgs = IDE_Obj.rtdx.msgcount('ochan')
```

With `num_of_msgs = 20`, you could use a looping structure to read the messages from the queue in to MATLAB software. In the next few steps of this tutorial you read data from the `ochan` queue to different data formats within MATLAB software.

**10** Read one message from the queue into variable `outdata`.

```
outdata = IDE_Obj.rtdx.readmsg('ochan','int16')
```

```
outdata =
 2 3 4 5 6 7 8 9 10 11
```

Notice the `'int16'` `represent` option. When you read data from your processor you need to tell MATLAB software the data type you are reading. You wrote the data in step 4 as 16-bit integers so you use the same data type here.

While performing reads and writes, your process continues to run. You did not need to stop the processor to get the data or send the data, unlike using most debuggers and breakpoints in your code. You placed your data in memory across an RTDX channel, the processor used the data, and you read the data from memory across an RTDX channel, without stopping the processor.

**11** You can read data into cell arrays, rather than into simple double-precision variables. Use the following function to read three messages to cell array `outdata`, an array of three, 1-by-10 vectors. Each message is a 1-by-10 vector stored on the processor.

```
outdata = IDE_Obj.rtdx.readmsg('ochan','int16',3)
```

```

outdata =
 [1x10 int16] [1x10 int16] [1x10 int16]

```

- 12** Cell array `outdata` contains three messages. Look at the second message, or matrix, in `outdata` by using dereferencing with the array.

```
outdata{1,2}
```

```

outdata =
 4 5 6 7 8 9 10 11 12 13

```

- 13** Read two messages from the processor into two 2-by-5 matrices in your MATLAB workspace.

```
outdata = IDE_Obj.rtdx.readmsg('ochan','int16',[2 5],2)
```

```

outdata =
 [2x5 int16] [2x5 int16]

```

To specify the number of messages to read and the data format in your workspace, you used the `siz` and `nummsgs` options set to `[2 5]` and `2`.

- 14** You can look at both matrices in `outdata` by dereferencing the cell array again.

```
outdata{1,:}
```

```

ans =
 6 8 10 12 14
 7 9 11 13 15
ans =
 7 9 11 13 15
 8 10 12 14 16

```

- 15** For a change, read a message from the queue into a column vector.

```
outdata = IDE_Obj.rtdx.readmsg('ochan','int16',[10 1])
```

```

outdata =
 8
 9
 10
 11
 12
 13
 14
 15
 16
 17

```

- 16** Embedded Coder provides a function for reading messages into matrices—`readmat`. Use `readmat` to read a message into a 5-by-2 matrix in MATLAB software.

```
outdata = readmat(IDE_Obj.rtdx,'ochan','int16',[5 2])
```

```
outdata =
```

```
9 14
10 15
11 16
12 17
13 18
```

Because a 5-by-2 matrix requires ten elements, MATLAB software reads one message into `outdata` to fill the matrix.

- 17** To check your progress, see how many messages remain in the queue. You have read eight messages from the queue so 12 should remain.

```
num_of_msgs = IDE_Obj.rtdx.msgcount('ochan')

num_of_msgs =
 12
```

- 18** To see the connection between messages and a matrix in MATLAB software, read data from 'ochan' to fill a 4-by-5 matrix in your workspace.

```
outdata = IDE_Obj.rtdx.readmat('ochan','int16',[4 5])

outdata =
 10 14 18 13 17
 11 15 19 14 18
 12 16 11 15 19
 13 17 12 16 20
```

Filling the matrix required two messages worth of data.

- 19** To verify that the last step used two messages, recheck the message count. You should find 10 messages waiting in the queue.

```
num_of_msgs = IDE_Obj.rtdx.msgcount('ochan')
```

- 20** Continuing with matrix reads, fill a 10-by-5 matrix (50 matrix elements or five messages).

```
outdata = IDE_Obj.rtdx.readmat('ochan','int16',[10 5])

outdata =
 12 13 14 15 16
 13 14 15 16 17
 14 15 16 17 18
 15 16 14 18 19
 16 17 18 19 20
 17 18 19 20 21
 18 19 20 21 22
 19 20 21 22 23
 20 21 22 23 24
 21 22 23 24 25
```

- 21** Recheck the number of messages in the queue to see that five remain.

- 22** `flush` lets you remove messages from the queue without reading them. Data in the message you remove is lost. Use `flush` to remove the next message in the read queue. Then check the waiting message count.

```
IDE_Obj.rtdx.flush('ochan',1)
num_of_msgs = IDE_Obj.rtdx.msgcount('ochan')

num_of_msgs =
 4
```

- 23** Empty the remaining messages from the queue and verify that the queue is empty.

```
IDE_Obj.rtdx.flush('ochan', 'all')
```

With the `all` option, `flush` discards the messages in the `ochan` queue.

### Closing the Connections and Channels or Cleaning Up

One of the most important programmatic processes you should do in every RTDX session is to clean up at the end. Cleaning up includes stopping your processor, disabling the RTDX channels you enabled, disabling RTDX and closing your open channels. Performing this series of tasks prevents trouble caused by unexpected interactions with remaining handles, channels, and links from earlier development work.

Best practices suggest that you include the following tasks (or an subset that meets your development needs) in your development scripts and programs.

We use several functions in this section; each has a purpose — the operational details in the following list explain how and why we use each one. They are

- **close** — close the specified RTDX channel. To use the channel again, you must open and enable the channel. Compare **close** to **disable**. `close('rtdx')` closes the communications provided by RTDX. After you close RTDX, you cannot communicate with your processor.
- **disable** — remove RTDX communications from the specified channel, but does not remove the channel, or link. Disabling channels may be useful when you do not want to see the data that is being fed to the channel, but you may want to read the channel later. By enabling the channel later, you have access to the data entering the channel buffer. Note that data that entered the channel while it was disabled is lost.
- **halt** — stop a running processor. You may still have one or more messages in the host buffer.

Use the following procedure to shut down communications between MATLAB software and the processor, and end your session:

- 1 Begin the process of shutting down the processor and RTDX by stopping the processor. Type the following functions at the prompt.

```
if (isrunning(IDE_Obj)) % Use this test in scripts.
 IDE_Obj.halt; % Halt the processor.
end % Done.
```

Your processor may already be stopped at this point. In a script, you might put the function in an `if`-statement as we have done here. When you direct a stopped processor to halt, the function returns immediately.

- 2 You have stopped the processor. Now disable the RTDX channels you opened to communicate with the processor.

```
IDE_Obj.rtdx.disable('all');
```

If required, using `disable` with channel name and processor identifier input arguments lets you disable only the channel you choose. When you have more than one board or processor, you may find disabling selected channels meets your needs.

When you finish your RTDX communications session, disable RTDX so that Embedded Coder releases your open channels before you close them.

```
IDE_Obj.rtdx.disable;
```

- 3 Use the following function syntaxes to close your open channels. Either close selected channels by using the channel name in the function, or use the `all` option to close the open channels.

- `IDE_Obj.rtdx.close('ichan')` to close your input channel in this tutorial.
- `IDE_Obj.rtdx.close('ochan')` to close your output channel in the tutorial.
- `IDE_Obj.rtdx.close('all')` to close your open RTDX channels, regardless of whether they are part of this tutorial.

Consider using the `all` option with the `close` function when you finish your RTDX work. Closing channels reduces unforeseen problems caused by channel objects that exist but do not get closed when you end your session.

- 4 When you created your RTDX object (`IDE_Obj = ticcs('boardnum',1)`) at the beginning of this tutorial, the `ticcs` function opened CCS IDE and set the visibility to 0. To avoid problems that occur when you close the interface to RTDX

with CCS visibility set to 0, make CCS IDE visible on your desktop. The following `if` statement checks the CCS IDE visibility and changes it if required.

```
if IDE_Obj.isvisible,
 IDE_Obj.visible(1);
end
```

Visibility can cause problems. When CCS IDE is running invisibly on your desktop, do not use `clear all` to remove your links for CCS IDE and RTDX. Without a `ticcs` object that references the CCS IDE you cannot access CCS IDE to change the visibility setting, or close the application. To close CCS IDE when you do not have an existing object, either create a new object to access the CCS IDE, or use Microsoft Windows Task Manager to end the process `cc_app.exe`, or close the MATLAB software.

- 5 You have finished the work in this tutorial. Enter the following commands to close your remaining references to CCS IDE and release the associated resources.

```
clear ('all'); % Calls the link destructors to remove all links.
echo off
```

`clear all` without the parentheses removes the variables from your MATLAB workspace.

You have completed the tutorial using RTDX. During the tutorial you

- 1 Opened connections to CCS IDE and RTDX and used those connections to load an executable program to your processor.
- 2 Configured a pair of channels so you could transfer data to and from your processor.
- 3 Ran the executable on the processor, sending data to the processor for processing and retrieving the results.
- 4 Stopped the executing program and closed the links to CCS IDE and RTDX.

This tutorial provides a working process for using Embedded Coder and your signal processing programs to develop programs for a range of Texas Instruments processors. While the processor may change, the essentials of the process remain the same.

### Listing Functions

To review a complete list of functions and methods that operate with `ticcs` objects, either CCS IDE or RTDX, enter either of the following commands at the prompt.

```
help ticcs
help rtdx
```

If you already have a `ticcs` object `IDE_Obj`, you can use dot notation to return the methods for CCS IDE or RTDX by entering one of the following commands at the prompt:

- `IDE_Obj.methods`
- `IDE_Obj.rtdx.methods`

In either instance MATLAB software returns a list of the available functions for the specified link type, including both public and private functions. For example, to see the functions (methods) for links to CCS IDE, enter:

```
help ticcs
```

## Constructing `ticcs` Objects

When you create a connection to CCS IDE using the `ticcs` command, you are creating a “`ticcs` object for accessing the CCS IDE and RTDX interface”. The `ticcs` object implementation relies on MATLAB software object-oriented programming capabilities.

The discussions in this section apply to the `ticcs` objects in Embedded Coder.

Like other MATLAB software structures, objects in Embedded Coder have predefined fields called object properties.

You specify object property values by one of the following methods:

- Setting the property values when you create the `ticcs` object
- Creating an object with default property values, and changing these property values later

For examples of setting `ticcs` object properties, refer to `ticcs`.

### Constructor for `ticcs` Objects

The easiest way to create an object is to use the function `ticcs` to create an object with the default properties. Create an object named `IDE_Obj` to refer to CCS IDE by entering

```
IDE_Obj = ticcs
```

MATLAB software responds with a list of the properties of the object `IDE_Obj` you created along with the associated default property values.

```
ticcs object:
```

```

API version : 1.0
Processor type : Cxx
Processor name : CPU
Running? : No
Board number : 0
Processor number : 0
Default timeout : 10.00 secs

RTDX channels : 0

```

Inspecting the output reveals two objects listed—a CCS IDE object and an RTDX object. CCS IDE and RTDX objects cannot be created separately. By design they maintain a member class relationship; the RTDX object is a class, a member of the CCS object class. In this example, `IDE_Obj` is an instance of the class `CCS`. If you enter

```
rx = IDE_Obj.rtdx
```

`rx` is a handle to the RTDX portion of the CCS object. As an alias, `rx` replaces `IDE_Obj.rtdx` in functions such as `readmat` or `writemsg` that use the RTDX communications features of the CCS link. Typing `rx` at the command line now produces

```
rx
```

```
RTDX channels : 0
```

The object properties are described in the function reference, and in more detail in `tics Object Properties`. These properties are set to default values when you construct objects.

## tics Properties and Property Values

Objects in Embedded Coder software have properties associated with them. Each property is assigned a value. You can set the values of most properties, either when you create the link or by changing the property value later. However, some properties have read-only values. And a few property values, such as the board number and the processor to which the link attaches, become read-only after you create the object. You cannot change those after you create your link.

## Overloaded Functions for tics Objects

Several functions in this Embedded Coder have the same name as functions in other MathWorks toolboxes or in MATLAB software. These behave similarly to their original counterparts, but you apply these functions directly to an object. This concept of having

functions with the same name operate on different types of objects (or on data) is called *overloading* of functions.

For example, the `set` command is overloaded for `ticcs` objects. After you specify your link by assigning values to its properties, you can apply the functions in this toolbox (such as `readmat` for using RTDX to read an array of data from the processor) directly to the variable name you assign to your object, without specifying your object parameters again.

## **ticcs Object Properties**

- “Quick Reference to `ticcs` Object Properties” on page 75-44
- “Details About `ticcs` Object Properties” on page 75-45

Embedded Coder provides an interface to your processor hardware so you can communicate with processors for which you are developing systems and algorithms. Each `ticcs` object comprises two objects—a CCS IDE object and an RTDX interface object. The objects are not separable; the RTDX object is a subclass of the CCS IDE object. Each of the objects has multiple properties. To configure the interface objects for CCS IDE and RTDX, you set parameters that define details such as the desired board, the processor, the timeout period applied for communications operations, and a number of other values. Because Embedded Coder uses objects to create the interface, the parameters you set are called properties and you treat them as properties when you set them, retrieve them, or modify them.

This section details the properties for the `ticcs` objects for CCS IDE and RTDX. First the section provides tables of the properties, for quick reference. Following the tables, the section offers in-depth descriptions of each property, its name and use, and whether you can set and get the property value associated with the property. Descriptions include a few examples of the property in use.

MATLAB software users may find much of this handling of objects familiar. Objects in Embedded Coder, behave like objects in MATLAB software and the other object-oriented toolboxes. For C++ programmers, discussion of object-oriented programming is likely to be a review.

### **Quick Reference to `ticcs` Object Properties**

The following table lists the properties for the `ticcs` objects in Embedded Coder. The second column tells you which object the property belongs to. Knowing which property belongs to each object in a `ticcs` object tells you how to access the property.

Property Name	Applies to Which Connection?	User Settable?	Description
apiversion	CCS IDE	No	Reports the version number of your CCS API.
boardnum	CCS IDE	Yes/initially	Specifies the index number of a board that CCS IDE recognizes.
ccsappexe	CCS IDE	No	Specifies the path to the CCS IDE executable. Read-only property.
numchannels	RTDX	No	Contains the number of open RTDX channels for a specific link.
page	CCS IDE	Yes/default	Stores the default memory page for reads and writes.
procnum	CCS IDE	Yes/at start only	Stores the number CCS Setup Utility assigns to the processor.
timeout	CCS IDE	Yes/default	Contains the global timeout setting for the link.
version	RTDX	No	Reports the version of your RTDX software.

Some properties are read only — you cannot set the property value. Other properties, you can change. If the entry in the User Settable column is “Yes/initially”, you can set the property value only when you create the link. Thereafter it is read only.

### Details About ticcs Object Properties

To use the links for CCS IDE and RTDX interface you set values for:

- **boardnum** — specify the board with which the link communicates.
- **procnum** — specify the processor on the board. If the board has multiple processors, **procnum** identifies the processor to use.
- **timeout** — specify the global timeout value. (Optional. Default is 10 s.)

Details of the properties associated with connections to CCS IDE and RTDX interface appear in the following sections, listed in alphabetical order by property name.

Many of these properties are object linking and embedding (OLE) handles. The MATLAB software COM server creates the handles when you create objects for CCS IDE and RTDX. You can manipulate the OLE handles using `get`, `set`, and `invoke` to work directly with the COM interface with which the handles interact.

### **apiversion**

Property `appversion` contains a character vector that reports the version of the application program interface (API) for CCS IDE that you are using when you create a link. You cannot change this character vector. When you upgrade the API, or CCS IDE, the text changes to match. Use `display` to see the `apiversion` property value for a link. This example shows the `appversion` value for link `IDE_Obj`.

```
display(IDE_Obj)

TICCS Object:
 API version : 1.0
 Processor type : Cxx
 Processor name : CPU
 Running? : No
 Board number : 0
 Processor number : 0
 Default timeout : 10.00 secs

 RTDX channels : 0
```

Note that the API version is not the same as the CCS IDE version.

### **boardnum**

Property `boardnum` identifies the board referenced by the IDE link handle object for CCS. When you create a link, you use `boardnum` to specify the board you are using. To get the value for `boardnum`, use `ccsboardinfo` or the CCS Setup utility from Texas Instruments software. The CCS Setup utility assigns the number for each board installed on your system.

### **ccsappexe**

Property `ccsappexe` contains the path to the CCS IDE executable file `cc_app.exe`. When you use `ticcs` to create a link, MATLAB software determines the path to the CCS IDE executable and stores the path in this property. This is a read-only property. You cannot set it.

**numchannels**

Property `numchannels` reports the number of open RTDX communications channels for an RTDX link. Each time you open a channel for a link, `numchannels` increments by one. For new links `numchannels` is zero until you open a channel for the link.

To see the value for `numchannels` create a link to CCS IDE. Then open a channel to RTDX. Use `display` to see the RTDX link properties.

```

IDE_Obj=ticcs

TICCS Object:
 API version : 1.0
 Processor type : Cxx
 Processor name : CPU
 Running? : No
 Board number : 0
 Processor number : 0
 Default timeout : 10.00 secs

 RTDX channels : 0

rx=IDE_Obj.rtdx

 RTDX channels : 0

open(rx,'ichan','r','ochan','w');

get(IDE_Obj.rtdx)

ans =

 numChannels: 2
 Rtdx: [1x1 COM]
 RtdxChannel: {'' '' ''}
 procType: 103
 timeout: 10

```

**page**

Property `page` contains the default value CCS IDE uses when the user does not specify the page input argument in the syntax for a function that access memory.

**procnum**

Property **procnum** identifies the processor referenced by the IDE link handle object for CCS. When you create an object, you use **procnum** to specify the processor you are using. The CCS Setup Utility assigns a number to each processor installed on each board. To determine the value of **procnum** for a processor, use `ccsboardinfo` or the CCS Setup utility from Texas Instruments software.

To identify a processor, you need both the **boardnum** and **procnum** values. For boards with one processor, **procnum** equals zero. CCS IDE numbers the processors on multiprocessor boards sequentially from 0 to the number of processors. For example, on a board with four processors, the processors are numbered 0, 1, 2, and 3.

**rtdx**

Property **rtdx** is a subclass of the **ticcs** link and represents the RTDX portion of the IDE link handle object for CCS. As shown in the example, **rtdx** has properties of its own that you can set, such as **timeout**, and that report various states of the link.

```
get(IDE_Obj.rtdx)

ans =

 version: 1
 numChannels: 0
 Rtdx: [1x1 COM]
 RtdxChannel: {'' [] ''}
 procType: 103
 timeout: 10
```

In addition, you can create an alias to the **rtdx** portion of a link, as shown in this code example.

```
rx=IDE_Obj.rtdx

RTDX channels : 0
```

Now you can use **rx** with the functions in Embedded Coder, such as **get** or **set**. If you have two open channels, the display looks like the following example:

```
get(rx)

ans =
```

```

numChannels: 2
 Rtdx: [1x1 COM]
RtdxChannel: {2x3 cell}
procType: 98
timeout: 10

```

### **rtdxchannel**

Property `rtdxchannel`, along with `numchannels` and `proctype`, is a read-only property for the RTDX portion of the IDE link handle object for CCS. To see the value of this property, use `get` with the link. Neither `set` nor `invoke` work with `rtdxchannel`.

`rtdxchannel` is a cell array that contains the channel name, handle, and mode for each open channel for the link. For each open channel, `rtdxchannel` contains three fields, as follows:

<code>.rtdxchannel{i,1}</code>	Channel name of the <i>i</i> th-channel, <i>i</i> from 1 to the number of open channels
<code>.rtdxchannel{i,2}</code>	Handle for the <i>i</i> th-channel
<code>.rtdxchannel{i,3}</code>	Mode of the <i>i</i> th-channel, either 'r' for read or 'w' for write

With four open channels, `rtdxchannel` contains four channel elements and three fields for each channel element.

### **timeout**

Property `timeout` specifies how long CCS IDE waits for a process to finish. Two `timeout` periods can exist — one global, one local. You set the global `timeout` when you create the IDE link handle object for CCS. The default global `timeout` value is 10 s. However, when you use functions to read or write data to CCS IDE or your processor, you can set a local `timeout` that overrides the global value. If you do not set a specific `timeout` value in a read or write process syntax, the global `timeout` value applies to the operation. Refer to the help for the read and write functions for the syntax to set the local `timeout` value for an operation.

### **version**

Property `version` reports the version number of your RTDX software. When you create a `ticcs` object, `version` contains a character vector that reports the version of the RTDX application that you are using. You cannot change this text. When you upgrade

the API, or CCS IDE, the text changes to match. Use `display` to see the `version` property value for a link. This example shows the `apiversion` value for object `rx`.

```
get(rx) % rx is an alias for IDE_Obj.rtdx.
```

```
ans =
```

```
 version: 1
 numChannels: 0
 Rtdx: [1x1 COM]
 RtdxChannel: {'' [] ''}
 procType: 103
 timeout: 10
```

## Function List

The following is a complete list of functions for working with CCS v.3.3. It includes Automation Interface and other types of functions.

- `activate`
- `add`
- `address`
- `animate`
- `build`
- `ccsboardinfo`
- `cd`
- `checkEnvSetup`
- `close`
- `configure`
- `dir`
- `disable`
- `display (IDE Object)`
- `enable`
- `flush`
- `getbuildopt`
- `halt`

- info
- insert
- xmakefilesetup
- isenabled
- isreadable
- isrtdxcapable
- isrunning
- isvisible
- iswritable
- list
- load
- msgcount
- new
- open
- profile
- read
- readmat
- readmsg
- regread
- regwrite
- reload
- remove
- reset
- restart
- run
- save
- setbuildopt
- symbol
- ticcs
- visible

- `write`
- `writemsg`

## IDE Project Generator

### In this section...

“Introducing IDE Project Generator” on page 75-53

“IDE Project Generator and Board Selection” on page 75-53

“Generate an IDE Project” on page 75-55

“Model Reference” on page 75-58

### Introducing IDE Project Generator

IDE Project Generator provides the following features for developing project and generating code:

- Support automated project building for Texas Instruments Code Composer Studio software that lets you create projects from code generated by Embedded Coder products. The project automatically populates CCS projects in the CCS development environment.
- Configure code generation using model Configuration Parameters and processor preferences block options
- Select from two system target files to generate code specific to your processor
- Configure project build process
- Automatically download and run your generated projects on your processor

---

**Note:** You cannot generate code for C6000 processors in big-endian mode. Code generation supports only little-endian processor data byte order.

---

### IDE Project Generator and Board Selection

IDE Project Generator uses `ticcs` objects to connect to the IDE. Each time you build a model to generate a project, the build process starts by issuing the `ticcs` method, as shown here:

```
IDE_Obj=ticcs('boardnum',boardnum,'procnum',procnum)
```

The software attempts to connect to the board (`boardnum`) and processor (`procnum`) associated with the **Board name** and **Processor number** parameters located on the Target Hardware Resources pane in the model Configuration Parameters.

The result of the `ticcs` method changes, depending on the boards you configured in CCS. The following table describes how the software selects the board to connect to in your board configuration.

CCS Board Configuration State	Response by Software
Code Composer Studio or Embedded Coder software not installed.	Returns an error message asking you to verify that you installed both Code Composer Studio and Embedded Coder.
Code Composer Studio software does not have configured boards.	Returns an error message that the software could not find boards in your configuration. Use <b>Setup Code Composer Studio</b> to configure at least one board.
Code Composer Studio software has one configured board.	Attaches to the board regardless of the value of the <b>Board</b> parameter. You see a warning message telling you which board the software selected.
Code Composer Studio software has one board configured that does not match the value of the <b>Board</b> parameter. <sup>(*)</sup>	Returns a warning message that the software could not find the board specified in the block and connected to the board listed in the warning message. The software connects to the first board in your CCS configuration.
Code Composer Studio has more than one board configured. The value of the <b>Board</b> parameter is one of the configured boards.	Connects to the specified board.
Code Composer Studio has more than one board configured. The value of the <b>Board</b> parameter is not one of the configured boards. <sup>(*)</sup>	Returns a message asking you to select a board from the list of configured boards. You have two choices: <ul style="list-style-type: none"> <li>• Select a board to use for project generation, and click <b>OK</b>. Your selection does not change the value of the <b>Board</b> parameter. The software connects to the selected board.</li> <li>• Click <b>Abort</b> to stop the project build and code generation process. The software does not connect to the IDE or board.</li> </ul>

(\*)You may encounter the situation where you do not have the valid board configured in CCS because of one of the following conditions:

- You changed your board configuration and saved the model. When you reopen the model, the board specified in **Board name** in the block is not in your configuration.
- You are working with a model from a source whose board configuration is not the same as yours.

Use `ccsboardinfo` at the MATLAB prompt to verify or review your configured boards.

## Generate an IDE Project

- “Creating the Model” on page 75-56
- “Specify Configuration Parameters for Your Model” on page 75-56

In this tutorial you will use the Embedded Coder software to:

- Build a model.
- Generate a project from the model.
- Build the project and run the binary on a processor.

---

**Note** The model shows project generation. You cannot not build and run the model on your processor without additional blocks.

---

To generate a project from a model, complete the following tasks:

- 1 Create a model application.
- 2 Configure your model for your IDE, tool chain, and target hardware, as described in “Configure Target Hardware Resources” on page 72-3.
- 3 In the Configuration Parameters, also set:
  - Solver parameters such as simulation start and solver options
  - Software options such as processor configuration and processor compiler selection
- 4 Generate your project.
- 5 Review your project in CCS.

## Creating the Model

To build a model, follow these steps:

- 1 Open the Simulink Library Browser.
- 2 Use Simulink blocks to create a model, or open one of the example models for Texas Instruments Code Composer Studio.
- 3 Name and save your model before continuing.

## Specify Configuration Parameters for Your Model

The following sections describe how to configure the build and run parameters for your model. Generating a project, or building and running a model on the processor, starts with configuring model options in the Configuration Parameters dialog in Simulink software.

### Setting Solver Parameters

After you have designed and implemented your digital signal processing model in Simulink software, complete the following steps to set the Configuration Parameters for the model:

- 1 Configure your model for your IDE, tool chain, and target hardware, as described in “Configure Target Hardware Resources” on page 72-3.
- 2 Select the Solver pane in the Configuration Parameters dialog.
- 3 Set **Start time** to **0.0** and **Stop time** to **inf** (model runs without stopping). If you set a stop time, your generated code does not honor the setting. Set this to **inf** for completeness.
- 4 Under **Solver options**, set **Type** to **fixed-step** and set **Solver** to **discrete (no continuous states)**. For PIL, set **Type** and **Solver** to any setting.
- 5 For **Fixed step size (fundamental sample time)**, enter **Auto**, and clear the checkbox for **Treat each discrete rate as a separate task**.

---

**Note** Generated code does not honor Simulink software stop time from the simulation. Stop time is interpreted as **inf**. To implement a stop in generated code, add a **Stop Simulation** block in your model.

---

When you use PIL, you can set the **Solver options** to any selection from the **Type** and **Solver** lists.

Ignore the **Data Import/Export**, **Diagnostics**, and **Optimization** panes in the Configuration Parameters dialog. The default settings are valid for your new model.

### Setting Code Generation Parameters

To configure your software to use the right processor files and to compile and run your model executable file, configure the **Code Generation** pane in the Configuration Parameters dialog.

- 1 In the Configuration Parameters dialog, select the **Code Generation** pane.
- 2 Use the **Browse** button to set **System target file** to `idmlink_grt.tlc`.

### Setting Coder Target Parameters

To configure code generation options and to compile and run your model executable file, configure the Coder Target pane in the Configuration Parameters dialog.

- 1 In the Configuration Parameters dialog, expand the node for the **Code Generation** pane and select the **Coder Target** pane.
- 2 Set the following options in the pane under **Vendor Tool Chain**:
  - **Configuration** should be Custom.
  - Set **Compiler options string** and **Linker options string** should be blank.
- 3 Under **Link Automation**, verify that **Export IDE link handle to base workspace** is selected and provide a name for the handle in **Coder Target handle name** (optional).
- 4 Set the following **Run-Time** options:
  - **Build action**: `Build_and_execute`.
  - **Interrupt overrun notification method**: `None`.

You have configured the your software options that let you generate a project for you processor. You may have noticed that you did not configure a few of the Configuration Parameters panes, such as **Comments**, **Symbols**, and **Optimization**.

For your new model, the default values for the options in these panes are right. For other models you develop, you may want to set the options in these panes to provide information during the build and to run TLC debugging when you generate code. Refer to your product documentation for more information about setting the Configuration Parameters.

### Building Your Project

After you set the Configuration Parameters and configure the code generator to create the files that you need, direct the build process to create your project:

- 1 Press **OK** to close the Configuration Parameters dialog.
- 2 Press **Ctrl+B** to generate your project into CCS IDE.

When you press **Ctrl+B** with **Create\_project** selected for **Build action**, the automatic build process starts CCS IDE, populates a new project in the development environment, builds the project, loads the binary on the processor, and runs it.

- 3 To stop processor execution, use the **Halt** option in CCS or enter `IDE_Obj.halt` at the MATLAB command prompt. (Where “IDE\_Obj” is the IDE link handle name you specified previously in **Configuration Parameters**.)

### Model Reference

Model reference lets your model include other models as modular components. This technique provides useful features because it:

- Simplifies working with large models by letting you build large models from smaller ones, or even large ones.
- Lets you generate code for the modules in the model, and later, regenerate code for modules that change.
- Lets you develop the modules independently.
- Lets you reuse modules and models by reference, rather than including the model or module multiple times in your model. Also, multiple models can refer to the same model or module.

Your product documentation provides much more information about model reference.

#### How Model Reference Works

Model reference behaves differently in simulation and in code generation. For this discussion, you need to know the following terms:

- Top-model — The root model block or model. It refers to other blocks or models. In the model hierarchy, this is the topmost model.
- Referenced models — Blocks or models that other models reference, such as models the top-model refers to. The models or blocks below the top-model in the hierarchy are reference models.

The following sections describe briefly how model reference works. More details are available in your product documentation in the online Help system.

### **Model Reference in Simulation**

When you simulate the top-model, the code generator detects that your model contains referenced models. Simulink software generates code for the referenced models and uses the generated code to build shared library files for updating the model diagram and simulation. It also creates an executable (a MEX file, `.mex`) for each reference model that is used to simulate the top-model.

When you rebuild reference models for simulations or when you run or update a simulation, Simulink software rebuilds the model reference files. Whether reference files or models are rebuilt depends on:

- Whether and how you change the models.
- The **Rebuild** parameter on the **Model Reference** pane in the Configuration Parameters dialog.

### **Model Reference in Code Generation**

Embedded Coder software requires executables to generate code from models. If you have not simulated your model at least once, the code generator creates a `.mex` file for simulation.

Next, for each referenced model, the code generation process calls `make_rtw` and builds each referenced model. This build process creates a library file for each of the referenced models in your model.

After building the referenced models, the code generator calls `make_rtw` on the top-model, linking to the library files it created for the associated referenced models.

### **Using Model Reference**

With few limitations or restrictions, Embedded Coder provides full support for generating code from models that use model reference.

#### **Build Action Setting**

The most important requirement for using model reference with the TI's processors is to set the **Build action** for the Model blocks in the simulation to `Archive_library`.

To set the build action

- 1 Open your model.
- 2 Select **Simulation > Model Configuration Parameters** from the model menus.  
The Configuration Parameters dialog opens.
- 3 Expand the node for the Code Generation pane. Then select the **Coder Target** pane.
- 4 In the right pane, under **Run-Time**, select **Archive\_library** from the **Build action** list.

If your top-model uses a reference model that does not have the build action set to `Archive_library`, the build process automatically changes the build action to `Archive_library` and issues a warning about the change.

As a result of selecting the `Archive_library` setting, other options are disabled:

- DSP/BIOS is disabled for the referenced models. Only the top-model supports DSP/BIOS operation.
- **Interrupt overrun notification method**, **Export IDE link handle to base workspace**, and **System stack size** are disabled for the referenced models.

#### Other Block Limitations

Model reference with Embedded Coder does not allow you to use the following blocks or S-functions in reference models:

- Blocks from the C62x DSP Library (in `c60001.lib`) (because these are noninlined S-functions)
- Blocks from the C64x DSP Library (in `c60001.lib`) (because these are noninlined S-functions)
- Noninlined S-functions
- Driver blocks, such as the ADC or DAC blocks from a Embedded Coder block library

#### Configuring Processors to Use Model Reference

Processors that you plan to use in Model Referencing must meet some general requirements.

- The **System target file** on the **Code Generation** pane of the **Configuration Parameters** dialog must match the target hardware.
- When you generate code from a model that references another model, you need to configure both the top-level model and the referenced models for the same code generation processor.

- The External mode option is not supported in model reference processor builds. Embedded Coder product does not support External mode. If you select this option, it is ignored during code generation.
- To support model reference builds, your TMF must support use of the shared utilities folder, as described in Supporting Shared Utility Directories in the Build Process in the Simulink Coder documentation.

To use an existing processor, or a new processor, with Model Reference, you set the `ModelReferenceCompliant` flag for the processor. For information on how to set this option, refer to `ModelReferenceCompliant` in the online Help system.

If you start with a model that was created prior to version 2.4 (R14SP3), to make your model compatible with the model reference processor, use the following command to set the `ModelReferenceCompliant` flag to On:

```
set_param(bdroot, 'ModelReferenceCompliant', 'on')
```

Models that you develop with versions 2.4 and later of Embedded Coder automatically include the model reference capability. You do not need to set the flag.

## Exporting Filter Coefficients from FDATool

### In this section...

“About FDATool” on page 75-62

“Preparing to Export Filter Coefficients to Code Composer Studio Projects” on page 75-63

“Exporting Filter Coefficients to Your Code Composer Studio Project” on page 75-66

“Preventing Memory Corruption When You Export Coefficients to Processor Memory” on page 75-71

### About FDATool

Signal Processing Toolbox™ software provides the Filter Design and Analysis tool (FDATool) that lets you design a filter and then export the filter coefficients to a matching filter implemented in a CCS project.

Using FDATool with CCS IDE enables you to:

- Design your filter in FDATool
- Use CCS to test your filter on a processor
- Redesign and optimize the filter in FDATool
- Test your redesigned filter on the processor

For instructions on using FDATool, refer to the section “Filter Design and Analysis Tool” in the Signal Processing Toolbox documentation.

Procedures in this chapter show how to use the FDATool export options to export filter coefficients to CCS. Using these procedures, you can perform the following tasks:

- Export filter coefficients from FDATool in a header file—“Exporting Filter Coefficients from FDATool to the CCS IDE Editor” on page 75-67
- Export filter coefficients from FDATool to processor memory—“Replacing Existing Coefficients in Memory with Updated Coefficients” on page 75-72

---

**Caution** For the best results, export coefficients in a header file. Exporting coefficients directly to processor memory can generate unexpected results or corrupt memory.

---

Also see the reference pages for the following functions. These primary functions allow you to use to access variables and write them to processor memory from the MATLAB Command window.

- `address` — Return the address of a symbol so you can read or write to it.
- `ticcs` — Create a connection between MATLAB software and CCS IDE so you can work with the project in CCS from the MATLAB Command window.
- `write` — Write data to memory on the processor.

## Preparing to Export Filter Coefficients to Code Composer Studio Projects

- “Features of a Filter” on page 75-63
- “Selecting the Export Mode” on page 75-64
- “Choosing the Export Data Type” on page 75-64

### Features of a Filter

When you create a filter in FDATool, the filter includes defining features identified in the following table.

Defining Feature	Description
Structure	Structure defines how the elements of a digital filter—gains, adders/subtractors, and delays—combine to form the filter. See the Signal Processing Toolbox documentation in the Online Help system for more information about filter structures.
Design Method	Defines the mathematical algorithm used to determine the filter response, length, and coefficients.
Response Type and Specifications	Defines the filter passband shape, such as lowpass or bandpass, and the specifications for the passband.
Coefficients	Defines how the filter structure responds at each stage of the filter process.
Data Type	Defines how to represent the filter coefficients and the resulting filtered output. Using a floating-point or fixed-point coefficient alters the filter response and output data values.

When you export your filter, FDATool exports only the number of and value of the filter coefficients and the data type used to define the coefficients.

## Selecting the Export Mode

You can export a filter by generating an ANSI C header file, or by writing the filter coefficients directly to processor memory. The following table summarizes when and how to use the export modes.

To...	Use Export Mode...	When to Use	Suggested Use
Add filter coefficients to a project in CCS	C header file	You implemented a filter algorithm in your program, but you did not allocate memory on your processor for the filter coefficients.	<ul style="list-style-type: none"> <li>Add the generated ANSI C header file to a project. Building and loading this project into your processor allocates static memory locations on the processor and writes your filter coefficients to those locations.</li> <li>Edit the file so the header file allocates extra processor memory and then add the header file to your project. Refer to “Allocating Extra Memory for Filter Coefficients” on page 75-71 in the next section.</li> </ul> <p>(For a sample generated header file, refer to “Reviewing ANSI C Header File Contents” on page 75-70.)</p>
Modify the filter coefficients in an embedded application loaded on a processor	Write directly to memory	You loaded a program on your processor. The program allocated space in your processor memory to store the filter coefficients.	<ul style="list-style-type: none"> <li>Optimize your filter design in FDATool. Then,</li> <li>Write the updated filter coefficients directly to the allocated processor memory. Refer to section “Preventing Memory Corruption When You Export Coefficients to Processor Memory” on page 75-71 for more information.</li> </ul>

## Choosing the Export Data Type

The export process provides two ways you can specify the data type to use to represent the filter coefficients. Select one of the options shown in the following table when you export your filter.

Specify Data Type for Export	Description
<b>Export suggested</b>	Uses the data type that FDATool suggests to preserve the fidelity of the filter coefficients and the performance of your filter in the project
<b>Export as</b>	Lets you specify the data type to use to export the filter coefficients

FDATool exports filter coefficients that use the following data types directly without modifications:

- Signed integer (8, 16, or 32 bits)
- Unsigned integer (8, 16, or 32 bits)
- Double-precision floating point (64 bits)
- Single-precision floating point (32 bits)

Filters in FDATool in the Signal Processing Toolbox software use double-precision floating point. You cannot change the data type.

If you have installed DSP System Toolbox software, you can use the filter quantization options in FDATool to set the word and fraction lengths that represent your filter coefficients. For information about using the quantization options, refer to Filter Design and Analysis Tool in the Filter Design Toolbox documentation in the Online help system.

If your filter uses one of the supported data types, **Export suggested** specifies that data type.

If your filter does not use one of the supported data types, FDATool converts the unsupported data type to one of the supported types and then suggests that data type. For more information about how FDATool determines the data type to suggest, refer to “How FDATool Determines the Export Suggested Data Type” on page 75-66.

Follow these best-practice guidelines when you implement your filter algorithm in source code and design your filter in FDATool:

- Implement your filter using one of the data types FDATool exports without modifications.
- Design your filter in FDATool using the data type you used to implement your filter.

### To Choose the Export Data Type

When you export your filter, follow this procedure to select the export data type so that the exported filter coefficients closely match the coefficients of your filter in FDATool.

- 1 In FDATool, select **Targets > Code Composer Studio IDE** to open the Export to Code Composer Studio IDE dialog.
- 2 Perform one of the following actions:
  - Select **Export suggested** to export the coefficients in the suggested data type.
  - Select **Export as** and choose the data type your filter requires from the list.

---

**Caution** If you select **Export as**, the exported filter coefficients can be very different from the filter coefficients in FDATool. As a result, your filter cutoff frequencies and performance may not match your design in FDATool.

---

### How FDATool Determines the Export Suggested Data Type

By default, FDATool represents filter coefficients as double-precision floating-point data. When you export your filter coefficients, FDATool suggests the same data type.

If you set custom word and fraction lengths to represent your filter coefficients, the export process suggests a data type to maintain the best fidelity for the filter.

The export process converts your custom word and fraction lengths to a suggested export data type, using the following rules:

- Round the word length up to the nearest larger supported data type. For example, round an 18-bit word length up to 32 bits.
- Set the fraction length to the maintain the same difference between the word and fraction length in the new data type as applies in the custom data type.

For example, if you specify a fixed-point data type with word length of 14 bits and fraction length of 11 bits, the export process suggests an integer data type with word length of 16 bits and fraction length of 13 bits, retaining the 3 bit difference.

## Exporting Filter Coefficients to Your Code Composer Studio Project

- “Exporting Filter Coefficients from FDATool to the CCS IDE Editor” on page 75-67

- “Reviewing ANSI C Header File Contents” on page 75-70

### Exporting Filter Coefficients from FDATool to the CCS IDE Editor

In this section, you export filter coefficients to a project by generating an ANSI C header file that contains the coefficients. The header file defines global arrays for the filter coefficients. When you compile and link the project to which you added the header file, the linker allocates the global arrays in static memory locations in processor memory.

Loading the executable file into your processor allocates enough memory to store the exported filter coefficients in processor memory and writes the coefficients to the allocated memory.

Use the following steps to export filter coefficients from FDATool to the CCS IDE text editor.

- 1 Start FDATool by entering `fdatool` at the MATLAB command prompt.

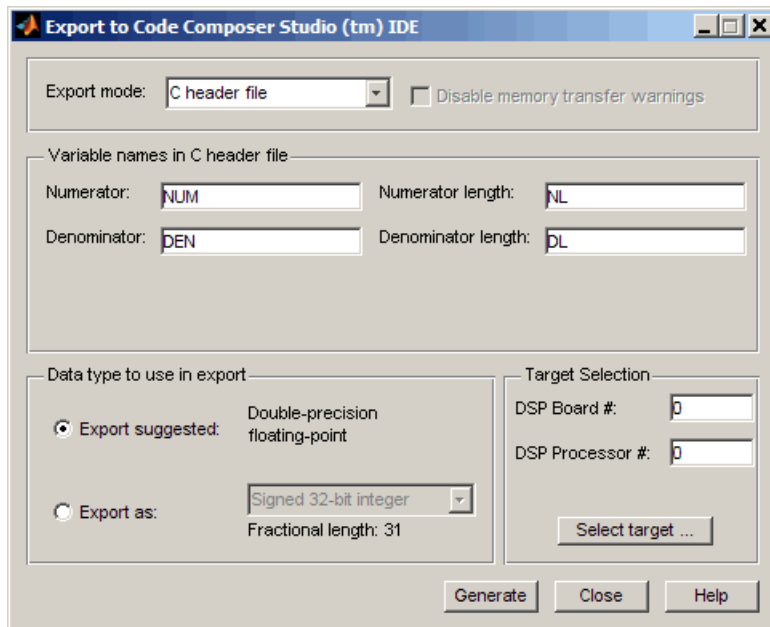

```
fdatool % Starts FDATool.
```

- 2 Design a filter with the same structure, length, design method, specifications, and data type you implemented in your source code filter algorithm.

The following figure shows a Direct-form II IIR filter example that uses second-order sections.

- 3 Click **Store Filter** to store your filter design. Storing the filter allows you to recall the design to modify it.
- 4 To export the filter coefficients, select **Targets > Code Composer Studio IDE** from the FDATool menu bar.

The Export to Code Composer Studio IDE dialog opens, as shown in the following figure.

- 5 Set **Export mode** to C header file.

- 6 In **Variable names in C header file**, enter variable names for the **Numerator**, **Denominator**, **Numerator length**, and **Denominator length** parameters where the coefficients will be stored.

The dialog shows only the variables you need to export to define your filter.

---

**Note:** You cannot use reserved ANSI C programming keywords, such as `if` or `int` as variable names, or include invalid characters such as spaces or semicolons (`;`).

---

- 7 In **Data type to use in export**, select **Export suggested** to accept the recommended export data type. FDATool suggests a data type that retains filter coefficient fidelity.

You may find it useful to select the **Export as** option and select an export data type other than the one suggested.

---

**Caution** If you deviate from the suggested data type, the exported filter coefficients can be very different from the filter coefficients in FDATool. As a result, your filter cutoff frequencies and performance may not match your design in FDATool.

---

For more information about how FDATool decides which data type to suggest, refer to “How FDATool Determines the Export Suggested Data Type” on page 75-66.

- 8 If you know the board number and processor number of your target, enter **DSP Board #** and **DSP Processor #** values to identify your board.

When you have only one board or simulator, Embedded Coder software sets **DSP Board #** and **DSP Processor #** values for your board automatically.

If you have more than one board defined in CCS Setup:

- Click **Select target** to open the Selection Utility dialog.
  - From the list of boards and list of processors, select the board name and processor name to use.
  - Click **Done** to set the **DSP Board #** and **DSP Processor #** values.
- 9 Click **Generate** to generate the ANSI header file. FDATool prompts you for a file name and location to save the generated header file.

The default location to save the file is your MATLAB working folder. The default file name is `fdacoeffs.h`.

- 10 Click **OK** to export the header file to the CCS editor.

If CCS IDE is not open, this step starts the IDE.

The export process does not add the file to your active project in the IDE.

- 11 Drag your generated header file into the project that implements the filter.
- 12 Add a `#include` statement to your project source code to include the new header file when you build your project.

- 13** Generate a `.out` file and load the file into your processor. Loading the file allocates locations in static memory on the processor and writes the filter coefficients to those locations.

To see an example header file, refer to “Reviewing ANSI C Header File Contents” on page 75-70.

### Reviewing ANSI C Header File Contents

The following program listing shows the exported header (`.h`) file that FDATool generates. This example shows a direct-form II filter that uses five second-order sections. The filter is stable and has linear phase.

Comments in the file describe the filter structure, number of sections, stability, and the phase of the filter. Source code shows the filter coefficients and variables associated with the filter design, such as the numerator length and the data type used to represent the coefficients.

```

/*
 * Filter Coefficients (C Source) generated by the Filter Design and Analysis Tool

## Preventing Memory Corruption When You Export Coefficients to Processor Memory

- “Allocating Extra Memory for Filter Coefficients” on page 75-71
- “Using the Exported Header File to Allocate Extra Processor Memory” on page 75-72
- “Replacing Existing Coefficients in Memory with Updated Coefficients” on page 75-72
- “Changing Filter Coefficients Stored on Your Processor” on page 75-73

### Allocating Extra Memory for Filter Coefficients

You can allocate extra memory by editing the generated ANSI C header file. You can then load the associated program file into your processor as described in “Using the Exported Header File to Allocate Extra Processor Memory” on page 75-72. Extra

memory lets you change filter coefficients and overwrite existing coefficients stored in processor memory more easily.

To prevent problems when you update filter coefficients in a project, , such as writing coefficients to unintended memory locations, use the **C header file** export mode option in FDATool to update filter coefficients in your program.

### Using the Exported Header File to Allocate Extra Processor Memory

You can edit the generated header file so the linked program file allocates extra processor memory. By allocating extra memory, you avoid the problem of insufficient memory when you export new coefficients directly to allocated memory.

For example, changing the following command in the header file:

```
const real64_T NUM[47] = {...}
to
```

```
real64_T NUM[256] = {...}
allocates enough memory for NUM to store up to 256 numerator filter coefficients rather
than 47.
```

Exporting the header file to CCS IDE does not add the filter to your project. To incorporate the filter coefficients from the header file, add a `#include` statement:

```
#include "headerfilename.h"
```

Refer to “Exporting Filter Coefficients to Your Code Composer Studio Project” on page 75-66 for information about generating a header file to export filter coefficients.

When you export filter coefficients directly to processor memory, the export process writes coefficients to as many memory locations as they need. The write process does not perform bounds checking. Plan memory allocation carefully, so that the software writes to the right locations and has enough memory for filter coefficients.

### Replacing Existing Coefficients in Memory with Updated Coefficients

When you redesign a filter and export new coefficients to replace existing coefficients in memory, verify the following conditions for your new design:

- Your redesign did not increase the memory required to store the coefficients beyond the allocated memory.

Changes that increase the memory required to store the filter coefficients include the following redesigns:

- Increasing the filter order
- Changing the number of sections in the filter
- Changing the numerical precision (changing the export data type)
- Your changes did not change the export data type.

---

**Caution** Identify changes that require additional memory to store the coefficients before you begin your export. Otherwise, exporting the new filter coefficients may overwrite data in memory locations you did not allocate for storing coefficients. Also, exporting filter coefficients to memory after you change the filter order, structure, design algorithm, or data type can yield unexpected results and corrupt memory.

---

Changing the filter design algorithm in FDATool, such as changing from Butterworth to Maximally Flat, often changes the number of filter coefficients (the filter order), the number of sections, or both. Also, the coefficients from the new design algorithm may not work with your source code filter implementation.

If you change the design algorithm, verify that your filter structure and length are the same after you redesign your filter, and that the coefficients will work with the filter you implemented.

If you change the number of sections or the filter order, your filter will not work well unless your filter algorithm implementation accommodates the changes.

### **Changing Filter Coefficients Stored on Your Processor**

This example writes filter coefficients to processor memory to replace the existing coefficients. To perform this process, you need the names of the variables in which your project stores the filter data.

Before you export coefficients directly to memory, verify that your project allocated enough memory for the new filter coefficients. If your project allocated enough memory, you can modify your filter in FDATool and then follow the steps in this example to export the updated filter coefficients to the allocated memory.

If your new filter requires additional memory space, use a C header file to allocate memory on the processor and export the new coefficients as described in “Exporting Filter Coefficients to Your Code Composer Studio Project” on page 75-66.

For important guidelines on writing directly to processor memory, refer to “Preventing Memory Corruption When You Export Coefficients to Processor Memory” on page 75-71.

Follow these steps to export filter coefficients from FDATool directly to memory on your processor.

- 1 Load the program file that contains your filter into CCS IDE to activate the program symbol table. The symbol must contain the global variables you use to store the filter coefficients and length parameters.
- 2 Start FDATool.
- 3 Click **Filter Manager** to open the Filter Manager dialog, shown in the following figure.

- 4 Highlight the filter to modify on the list of filters, and select **Edit current filter**. The highlighted filter appears in FDATool for you to change.

If you did not store your filter from a previous session, design the filter in FDATool and continue.

- 5 Click **Close** to dismiss the Filter Manager dialog.
- 6 Adjust the filter specifications in FDATool to modify its performance.
- 7 In FDATool, select **Targets > Code Composer Studio IDE** to open the Export to Code Composer Studio IDE dialog.

Keep the export dialog open while you work. When you do so, the contents update as you change the filter in FDATool.

---

**Tip** Click **Generate** to export coefficients to the same processor memory location multiple times without reentering variable names.

---

- 8 In the Export to Code Composer Studio dialog:
  - Set **Export mode** to **Write directly to memory**
  - Clear **Disable memory transfer warnings** to get a warning if your processor does not support the export data type.
- 9 In **Variable names in target symbol table**, enter the names of the variables in the processor symbol table that correspond to the memory allocated for the parameters, such as **Numerator** and **Denominator**. Your names must match the names of the filter coefficient variables in your program.

Variable names in target symbol table

Numerator:	<input type="text" value="NUM"/>	Numerator length:	<input type="text" value="NL"/>
Denominator:	<input type="text" value="DEN"/>	Denominator length:	<input type="text" value="DL"/>
Number of sections:	<input type="text" value="NS"/>		

- 10 Select **Export suggested** to accept the recommended export data type.

For more information about how FDATool determines the data type to suggest, refer to “How FDATool Determines the Export Suggested Data Type” on page 75-66.

- 11 If you know the board number and processor number of your target, enter **DSP Board #** and **DSP Processor #** values to identify your board.

---

**Note:** When you have only one board or simulator, Embedded Coder sets **DSP Board #** and **DSP Processor #** to your board automatically.

---

If you have more than one board defined in CCS Setup:

- Click **Select target** to open the Selection Utility dialog.
  - Select the board name and processor name to use from the list of boards.
- 12** Click **Generate** to export your filter. If your processor does not support the data type you export, you see a warning similar to the following message.

You can continue to export the filter, or cancel the export process. To prevent this warning dialog from appearing, select **Disable memory transfer warnings** in the Export to Code Composer Studio IDE dialog.

- 13** (Optional) Continue to optimize filter performance by modifying your filter in FDATool and then export the updated filter coefficients directly to processor memory.
- 14** When you finish testing your filter, return to FDATool, and click **Store filter** to save your changes.

# Using Makefiles with Code Composer Studio 3.x

**In this section...**

“Introduction” on page 75-77

“Set Up XMakefile for CCSv3” on page 75-77

“Prepare Your Model for CCSv3 and Makefiles” on page 75-78

“Create Target Configuration File in CCSv3” on page 75-79

“Load and Run the Embedded Software” on page 75-79

## Introduction

This tutorial shows you how to use the XMakefile feature in your MathWorks software to build and run embedded software with Code Composer Studio 3.3 (CCSv3). For more information about XMakefile, see “XMakefiles for Software Build Tool Chains” on page 72-14

---

**Note:** The Embedded Coder IDE Project Generator feature is not available for CCSv3 in the current release. For more information about IDE Project Generator, see “IDE Projects” on page 72-12

---

To build the target software, complete the process covered in this chapter:

- Set up XMakefile for CCSv3.
- Prepare your model for CCSv3.
- Create a Target Configuration File in CCSv3.
- Load and run the embedded software.

## Set Up XMakefile for CCSv3

The XMakefile feature tells your MathWorks software how to create makefiles for a *configuration*, which is a specific combination of tool chain and embedded target hardware. Some configurations require additional information before you can use them.

Select and complete a configuration for Code Composer Studio 3.3 (CCSv3):

- 1 Enter `xmakefilesetup` at the MATLAB command prompt. This action opens the XMakefile User Configuration dialog.
- 2 Clear **Display operational configurations only**. This displays the configuration files, including ones that need updated path information.
- 3 For **Configurations**, select a configuration that matches your target and ends with `ccsv3`. Then click **Apply**.
- 4 If the configuration is incomplete, the software displays a series of **Browse For Folder** dialog boxes that include instructions to provide missing information.
- 5 Examine the **Tool Directories** tab to see if the paths are right.
- 6 When you have supplied the missing information, and the configuration is complete, click **OK** to close the XMakefile User Configuration dialog.

For example, to generate code for CCSv3 and a C6000 processor with DSP/BIOS:

- 1 Enter `xmakefilesetup` on the command line.
- 2 In the XMakefile dialog, clear **Display operational configurations only**, set **Configurations** to `ticcs_c6000_dspbios_ccsv3`, and click **Apply**.
- 3 A **Browse For Folder** appears, stating “Select the C6000 Code Generation Tools root installation directory...”.

Browse and select a path such as `C:\Program Files\Texas Instruments\C6000 Code Generation Tools`.

- 4 Another **Browse For Folder** dialog appears, stating “Select the C6000 CSL root installation directory...”.

Browse and select a path such as `C:\Program Files\C6xCSL\`.

- 5 Examine the **Tool Directories** tab to see if the paths are right.
- 6 With the updated information, the `ticcs_c6000_dspbios_ccsv3` configuration is operational. Click **OK** to save the updated configuration, and close the dialog.

## Prepare Your Model for CCSv3 and Makefiles

- 1 Configure your model as described in “Configure Target Hardware Resources” on page 72-3
- 2 On the Coder Target pane, under the Tool Chain Automation tab, set **Build format** to **Makefile**.
- 3 Build your embedded software by pressing **CTRL+B**.

## Create Target Configuration File in CCSv3

Before loading and running your target software, use the CCSv3 IDE to create a “target configuration file”. The TI Debug Server uses this file while it works with CCSv3 to load and run your target software. The XML-based target configuration file describes the target board and processor. The file name ends with a \*.ccxml extension.

Create a target configuration file:

- 1 In the CCSv3, select **File > New > Target Configuration File** to display a **New Target Configuration** dialog:
  - For **File name**, update the file name that ends with **.ccxml** to describe your project and hardware.
  - Click **Finish**. This action displays a utility in the CCS editor pane for customizing the target configuration file.
- 2 Use the utility to select the **Connection** and **Device** type. Typing a partial string next to **Device** filters the list of devices.
- 3 Click **Save**.

---

**Note:** For more information about target configuration files, consult the Texas Instruments documentation for CCSv3.

---

## Load and Run the Embedded Software

First set the Windows system variable, Path, so you can call the TI Debug Server Scripting (DSS) API from a folder.

- 1 In Windows, right-click **My Computer**, and select **Properties**. This action opens the System Properties dialog.
- 2 In **System Properties**, select the **Advanced** tab, and click **Environment Variables**. This action opens the Environment Variables dialog.
- 3 In **Environment Variables**, under **System variables**, select the Path variable, and click **Edit**. This action opens the Edit System Variable dialog.
- 4 In Edit System Variable, for **Variable value**, append a semicolon and the full path of the \ccsv3\scripting\bin subdirectory. For example, append `;C:\ti\ccsv3\scripting\bin`.

---

**Note:** The path cannot contain spaces. Customize the installation directory when you install CCSv3 so it does not contain spaces.

---

For more information about using DSS, see [http://processors.wiki.ti.com/index.php/Debug\\_Server\\_Scripting](http://processors.wiki.ti.com/index.php/Debug_Server_Scripting).

MathWorks provides an example JavaScript file, `runProgram.js`, for you to use with DSS. This script loads and runs the specified program on the target specified in the target configuration file. You can create a copy of this script and modify it to suit your needs. The location of `runProgram.js` is:

```
[MATLABROOT]\toolbox\idelink\extensions\ticcs\ccsdemos
```

The specific syntax for running `dss.bat` with `runProgram.js` is:

```
> dss runProgram.js targetConfigurationFile programFile
```

Replace *targetConfigurationFile* and *programFile* with paths and file names. For example, if you are using a working directory called the CCSv3 workspace, and the model name is `myProgram`, enter:

```
> dss runProgram.js c:\workspace\myC6416dsk.ccxml myProgram.out
```

This command builds and loads your software on the target or simulator.

You have completed the process of loading and running embedded software using XMakefile and CCSv3.

## Reported Limitations and Tips

### In this section...

“Example Programs Do Not Run Well with Incorrect GEL Files” on page 75-81  
“Changing Values of Local Variables Does Not Work” on page 75-82  
“Code Composer Studio Cannot Find a File After You Halt a Program” on page 75-82  
“C54x XPC Register Can Be Modified Only Through the PC Register” on page 75-84  
“Working with More Than One Installed Version of Code Composer Studio” on page 75-84  
“Changing CCS Versions During a MATLAB Session” on page 75-85

“Uninstalling Code Composer Studio 3.3 Prevents Embedded Coder From Connecting” on page 75-86  
“PostCodeGenCommand Commands Do Not Apply to IDE Projects” on page 75-87

Some long-standing issues apply to the Embedded Coder product. When you are using `ticcs` objects and the software methods to work with Code Composer Studio and supported hardware or simulators, recall the information in this section.

The latest issues in the list appear at the bottom. HIL refers to “hardware in the loop,” also called processor in the loop (PIL) here and in other applications, and sometimes referred to as function calls.

### Example Programs Do Not Run Well with Incorrect GEL Files

To run the Embedded Coder examples, you must load the corresponding GEL files before you run the examples. For some boards, the examples run fine with the default CCS GEL file. Some boards need to run device-specific GEL files for the examples to work well.

Here are examples and boards which require specific GEL files.

- Board: C5416 DSK

Examples: `rtdxtutorial`, `rtdx1msdemo`

Emulator: XDS-510

GEL file to load: `c5416_dsk.gel`

In general, if a example does not run with the default GEL file, try using a device-specific GEL file by defining the file in the CCS Setup Utility.

## Changing Values of Local Variables Does Not Work

If you halt the execution of your program on your DSP and modify a local variable's value, the new value may not be acknowledged by the compiler. If you continue to run your program, the compiler uses the original value of the variable.

This problem happens only with local variables. When you write to the local variable via the Code Composer Studio Watch Window or via a MATLAB object, you are writing into the variable's absolute location (register or address in memory).

However, within the processor function, the compiler sometimes saves the local variable's values in an intermediate location, such as in another register or to the stack. That intermediate location cannot be determined or changed/updated with a new value during execution. Thus the compiler uses the old, unchanged variable value from the intermediate location.

## Code Composer Studio Cannot Find a File After You Halt a Program

When you halt a running program on your processor, Code Composer Studio may display a dialog that says it cannot find a source code file or a library file.

When you halt a program, CCS tries to display the source code associated with the current program counter. If the program stops in a system library like the runtime library, DSP/BIOS, or the board support library, it cannot find the source code for debug. You can either find the source code to debug it or select the **Don't show this message again** check box to ignore messages like this in the future.

For more information about how CCS responds to the halt, refer the online Help for CCS. In the online help system, use the search engine to search for the keywords "Troubleshooting" and "Support." The following information comes from the online help for CCS, starting with the error message:

## File Not Found

The debugger is unable to locate the source file required to enable source-level debugging for this program.

To specify the location of the source file

- 1 Click **Yes**. The *Open* dialog appears.
- 2 In the *Open* dialog, specify the location and name of the source file then click **Open**.

The next section provides more details about file paths.

## Defining a Search Path for Source Files

The *Directories* dialog enables you to specify the search path the debugger uses to find the source files included in a project.

### To Specify Search Path Directories

- 1 Select **Option > Customize**.
- 2 In the *Customize* dialog, select the **Directories** tab. Use the scroll arrows at the top of the dialog to locate the tab.

The *Directories* dialog offers the following options.

- **Directories**. The **Directories** list displays the defined search path. The debugger searches the listed folders in order from top to bottom.

If two files have the same name and are located in different folders, the file located in the folder that appears highest in the **Directories** list takes precedence.

- **New**. To add a new folder to the **Directories** list, click **New**. Enter the full path or click **browse [...]** to navigate to a folder. By default, the new folder is added to the bottom of the list.
- **Delete**. Select a folder in the **Directories** list, then click **Delete** to remove that folder from the list.
- **Up**. Select a folder in the **Directories** list, then click **Up** to move that folder higher in the list.
- **Down**. Select a folder in the **Directories** list, then click **Down** to move that folder lower in the list.

- 3 Click **OK** to close the *Customize* dialog and save your changes.

## C54x XPC Register Can Be Modified Only Through the PC Register

You cannot modify the XPC register value directly using `regwrite` to write into the register. When you are using extended program addressing in C54x, you can modify the XPC register by using `regwrite` to write a 23-bit data value in the PC register. Along with the 16-bit PC register, this operation also modifies the 7-bit XPC register that is used for extended program addressing. On the C54x, the PC register is 23 bits (7 bits in XPC + 16 bits in PC).

You can then read the XPC register value using `regread`.

## Working with More Than One Installed Version of Code Composer Studio

When you have more than one version of Code Composer Studio installed on your machine, you cannot select which CCS version MATLAB Embedded Coder attaches to when you create a `ticcs` object. If, for example, you have both CCS for C5000 and CCS for C6000 versions installed, you cannot choose to connect to the C6000 version rather than the C5000 version.

When you issue the command

```
IDE_obj = ticcs
```

Embedded Coder starts the CCS version you last used. If you last used your C5000 version, the `IDE_obj` object accesses the C5000 version.

### Workaround

To make your `ticcs` object access the right processor:

- 1 Start and close the CCS version you plan to use before you create the `ticcs` object in MATLAB.
- 2 Create the `ticcs` object using the `boardnum` and `procnum` properties to select your processor, if required.

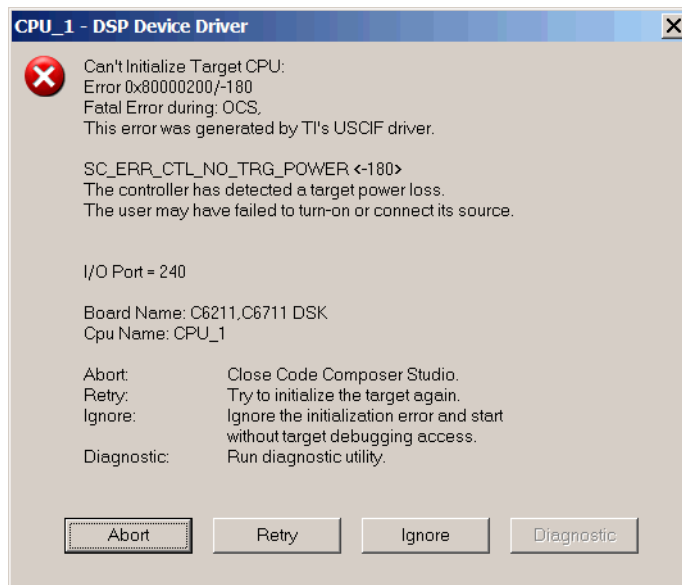

Recall that `ccsboardinfo` returns the `boardnum` and `procnum` values for the processors that CCS recognizes.

## Changing CCS Versions During a MATLAB Session

You can use only one version of CCS in a single MATLAB session. Embedded Coder does not support using multiple versions of CCS in a MATLAB session. To use another CCS version, exit MATLAB software and restart it. Then create your links to the new version of CCS.

## MATLAB Hangs When Code Composer Studio Cannot Find a Board

In MATLAB software, when you create a `ticcs` object, the construction process for the object automatically starts CCS. If CCS cannot find a processor that is connected to your PC, you see a message from CCS like the following DSP Device Driver dialog that indicates CCS could not initialize the processor.

Four options let you decide how to respond to the failure:

- **Abort** — Closes CCS and suspends control for about 30 seconds. If you used MATLAB software functions to open CCS, such as when you create a `ticcs` object, the system returns control to MATLAB command window after a considerable delay, and issues this warning:

??? Unable to establish connection with Code Composer Studio.

- **Ignore** — Starts CCS without connecting to a processor. In the CCS IDE you see a status message that says EMULATOR DISCONNECTED in the status area of the IDE. If you used MATLAB to start CCS, you get control immediately and Embedded Coder creates the `ticcs` object. Because CCS is not connected to a processor, you cannot use the object to perform processor operations from MATLAB, such as loading or running programs.
- **Retry** — CCS tries again to initialize the processor. If CCS continues not to find your hardware processor, the same DSP Device Driver dialog reappears. This process continues until either CCS finds the processor or you choose one of the other options to respond to the warning.

One more option, **Diagnostic**, lets you enter diagnostic mode if it is enabled. Usually, **Diagnostic** is not available for you to use.

## Using Mapped Drives

Limitations in Code Composer Studio do not allow you to load programs after you set your CCS working folder to a read-only mapped drive. Load operations fail with an Application Error dialog.

The following combination of commands does not work:

- 1 `cd(IDE_obj, 'mapped_drive_letter')` % Change CCS working directory to read-only mapped drive.
- 2 `load(IDE_obj, 'program_file')` % Loading program fails.

## Uninstalling Code Composer Studio 3.3 Prevents Embedded Coder From Connecting

Description On a machine where CCS 3.3 and CCS 3.1 are installed, uninstalling 3.3 makes 3.1 unusable from MATLAB. This is because the CCS 3.3 uninstaller leaves stale registry entries in the Windows Registry that prevent MATLAB from connecting to CCS 3.1.

Texas Instruments has documented this uninstall problem and the solution on their Web site.

Updated information on this issue may also be available from the Bug Reports section of [www.mathworks.com](http://www.mathworks.com) at <http://www.mathworks.com/support/bugreports/379676>

## **PostCodeGenCommand Commands Do Not Apply to IDE Projects**

PostCodeGenCommand commands, such as the addCompileFlags and addLinkFlags functions in the BuildInfo API do not alter code generated by Embedded Coder while **System Target File** is set to `idelink_ert.tlc` or `idelink_grt.tlc`.

Use the 'Compiler options string' and 'Linker options string' parameters located in the Configuration Parameters dialog (**Ctrl+E**) on the Code Generation > Coder Target pane instead. You can also automate this process using a model callback to SET\_PARAM the 'CompilerOptionsStr' and 'LinkerOptionsStr' parameters.

## Setting Up Code Composer Studio (ert.tlc System Target File)

### In this section...

“Prepare Your Model for CCSv3.3” on page 75-88

“Prepare Your Model for CCSv4/5/6” on page 75-88

### Prepare Your Model for CCSv3.3

For Code Composer Studio 3.3, select Texas Instruments Code Composer Studio v3.3 (C2000) as the toolchain, and press Ctrl + B to build and generate the .out (executable) file. To download and run the executable, use Code Composer Studio.

### Prepare Your Model for CCSv4/5/6

- 1 Configure your model as described in “Hardware Implementation Pane”, setting **Toolchain** to Texas Instruments Code Composer Studio v4 (C2000), Texas Instruments Code Composer Studio v5 (C2000) or Texas Instruments Code Composer Studio v6 (C2000).
- 2 If you want to load and run the application automatically after the build, on the **Coder Target** pane, select **Build, load and run** value from **Build action** and specify the \*.ccxml file in **CCS hardware configuration file** that matches the selected target hardware.

Otherwise, you have to create your own .ccxml file that matches the target hardware and the connection. See “Create Target Configuration File in CCSv4/5/6” on page 75-88 to create your own .ccxml file (Target Configuration File) in CCSv4/5/6.

- 3 Build your embedded software by pressing **CTRL+B**.

### Create Target Configuration File in CCSv4/5/6

Before loading and running your target software, use the CCSv4/5/6 IDE to create a “target configuration file”. The TI Debug Server uses this file while it works with CCSv4/5 to load and run your target software.

Create a target configuration file:

- 1 In the CCSv4/5/6, select **File > New > Target Configuration File** to display a **New Target Configuration** dialog:

- For **File name**, update the file name that ends with `.ccxml` to describe your project and hardware.
  - Click **Finish**. This action displays a utility in the CCSv4/5/6 editor pane for customizing the target configuration file.
- 2** Use the utility to select the **Connection** and **Device** type. Typing a partial string next to **Device** filters the list of devices.
  - 3** Click **Save**.

## IDE Link Frequently Asked Question: Why do I get an error when I invoke TICCS?

### In this section...

“Why do I get an error when I invoke TICCS?” on page 75-90

“How can I fix this problem?” on page 75-90

“What happens if I click Deselect All when CCS prompts that 'New components were detected'?” on page 75-92

“How do I use CCS Component Manager to enable IDE Link Components?” on page 75-92

### Why do I get an error when I invoke TICCS?

IDE Link uses a plugin component that needs to be registered with CCS. If the plugin is not registered, you get the following error messages when you invoke TICCS.

Example 1:

```
cc = ticcs
```

```
Could not start the MATLAB(R) component in CCS.
Please use IDE Link FAQ to troubleshoot the problem.
```

Example 2:

```
cc = ticcs
```

```
Could not start the MATLAB component in CCS.
```

### How can I fix this problem?

To fix this problem, perform the following steps:

- 1 Register IDE Link components.
- 2 Enable IDE Link component.

#### Register IDE Link Components

The following instructions show you how to register the components required by IDE Link.

---

**Note:** Before you register the components, you must have write permission to modify the registry. If you do not have this permission, look for someone who has (e.g., system administrator) and have this person perform the registration.

---

- 1 Close Code Composer Studio IDE.
- 2 Close MATLAB.
- 3 Open a Microsoft Windows Command Prompt by clicking Start and then Programs > Accessories > Command Prompt.

- 4 Register the LinkCCS.dll component. In MATLAB Command Window, enter:

```
regsvr32 [MATLABROOT]\bin\win32\LinkCCS.dll
```

- 5 Verify that the preceding command displays the following message in a dialog box:

```
DllRegisterServer in [MATLABROOT]\bin\win32\LinkCCS.dll succeeded
```

- 6 Register the MWCCSStu.ocx component. In MATLAB Command Window, enter:

```
regsvr32 [MATLABROOT]\toolbox\idelink\extensions\ticcs\bin\win32\MWCCSStu.ocx
```

- 7 Verify that the preceding command displays the following message in a dialog box:

```
DllRegisterServer in [MATLABROOT]\toolbox\idelink\extensions\ticcs\bin\win32\MWCCSStu.ocx succeeded
```

After you register the components, enable the CCS component before using IDE Link.

### To enable IDE Link Component

- 1 Open MATLAB
- 2 Enter `cc = ticcs` at the MATLAB prompt. CCS starts and prompts that "New components were detected".
- 3 Click Yes to enable components for compatible CCS releases. The first time CCS is invoked (either through TICCS or directly), it detects new components and asks if you want enable them. You see the following dialog:

---

**Note:** Click OK to enable the new component. For more information on ticcs or to see this FAQ again, enter `help ticcs` at the MATLAB prompt. For your convenience these instructions are available [here](#).

---

## **What happens if I click Deselect All when CCS prompts that 'New components were detected'?**

You will not be able to use IDE Link. The New Components dialog box appears only once.

To enable the components after you click 'Deselect All', use the CCS Component Manager.

## **How do I use CCS Component Manager to enable IDE Link Components?**

- 1** To open the CCS Component Manager, select Start and then Programs > Texas Instruments > Code Composer Studio 3.x > Component Manager. The left pane of the Component Manager presents the CCS installations select tree.
- 2** On the select tree, double-click The MathWorks, Inc. to see the MathWorks components.
- 3** Select the checkbox for [MATLABROOT]\toolbox\idelink\extensions\tics\bin\win32 to enable the component.
- 4** Select File > Save from the menu bar to save the new settings and then close the Component Manager.

# Working with Texas Instruments Code Composer Studio 4 & 5 IDE in Embedded Coder

---

- “Set Up” on page 76-2
- “Code Composer Studio” on page 76-3
- “Getting Started” on page 76-4
- “Using Makefiles with Code Composer Studio 4/5” on page 76-5
- “Reported Limitations and Tips” on page 76-11

## Set Up

Before you use Embedded Coder with Code Composer Studio (CCS IDE) for the first time, use the `checkEnvSetup` function to check for third-party tools and set environment variables. Run `checkEnvSetup` again whenever you configure CCS IDE to interact with a new board or processor, or upgrade the related third-party tools.

To verify that CCSv3 is installed on your machine and has at least one board configured, enter

```
ccsboardinfo
```

in the MATLAB Command Window. With CCS installed and configured, MATLAB software returns information about the boards that CCS recognizes on your machine, in a form similar to the following listing.

Board Num	Board Name	Proc Num	Processor Name	Processor Type
0	F28335 XDS100 USB Emulator	0	TMS320C2800_0	TMS320C2800

If MATLAB software does not return information about the boards, open your CCS installation and use the Setup Utility in CCS to configure at least one board.

As a final test, start CCS to verify that it runs. For Embedded Coder to operate with CCS, the CCS IDE must be able to run on its own.

# Code Composer Studio

## Feature Support

When you use Code Composer Studio 4 or Code Composer Studio 5 with Embedded Coder software, you can use:

- Makefiles to automate building and deploying software to target hardware. For more information, see “XMakefiles for Software Build Tool Chains” on page 72-14 and “Using Makefiles with Code Composer Studio 4/5” on page 76-5.
- Processor-in-the-loop (PIL) simulations to verify your software running on target hardware. For more information, see “PIL Simulation for IDE and Toolchain Targets” on page 73-2.
- Execution profiling with PIL to measure the performance of synchronous tasks running on target hardware. For more information, see “Execution-Time Profiling During PIL Simulation” on page 73-25.

Features that require IDE projects (**Build format = Project**), such as IDE Project Generator and IDE Automation Interface, are not available for use with Code Composer Studio 4 & 5.

You can use CCSv4/5 with the Simulink Block Libraries for the following Texas Instruments processors:

- TI's C2000

## Getting Started

<b>In this section...</b>
“Verifying Your Code Composer Studio Installation” on page 76-4
“Learning About Makefiles” on page 76-4

### Verifying Your Code Composer Studio Installation

On your host computer, install CCSv4/5 and other third-party tools for your board and processor, and set the environment variables. Then use the `checkEnvSetup` function in MATLAB to verify that your setup includes the required software. For more information and examples, see `checkEnvSetup`.

### Learning About Makefiles

To learn about using makefiles, see “XMakefiles for Software Build Tool Chains” on page 72-14.

For an example of using CCSv4/5 with makefiles, model-block PIL, and the Serial Communications Interface (SCI), see “Performing a Model Block PIL Simulation via SCI Using Makefiles” on page 73-13.

## Using Makefiles with Code Composer Studio 4/5

### In this section...

“Introduction” on page 76-5

“Set Up XMakefile for CCSv4/5” on page 76-5

“Prepare Your Model for CCSv4/5 and Makefiles” on page 76-6

“Create Target Configuration File in CCSv4/5” on page 76-7

“Configure Windows Path for TI Debug Server Scripting (DSS)” on page 76-7

“Load and Run the Embedded Software Using DSS” on page 76-8

### Introduction

This tutorial shows you how to use the XMakefile feature in your MathWorks software to build and run embedded software with Code Composer Studio 4 or 5 (CCSv4/5). For more information about XMakefile, see “XMakefiles for Software Build Tool Chains” on page 72-14

---

**Note:** The Embedded Coder IDE Project Generator feature is not available for CCSv4/5 in the current release. For more information about IDE Project Generator, see “IDE Projects” on page 72-12

---

To build the target software, complete the process covered in this chapter:

- Set up XMakefile for CCSv4/5.
- Prepare your model for CCSv4/5.
- Create a Target Configuration File in CCSv4/5.
- Load and run the embedded software.

### Set Up XMakefile for CCSv4/5

The XMakefile feature tells your MathWorks software how to create makefiles for a *configuration*, which is a specific combination of tool chain and embedded target hardware. Some configurations require additional information before you can use them.

Select and complete a configuration for Code Composer Studio 4 & 5 (CCSv4/5):

- 1 Enter `xmakefilesetup` at the MATLAB command prompt. This action opens the XMakefile User Configuration dialog.
- 2 Clear **Display operational configurations only**. This displays the configuration files, including ones that need updated path information.
- 3 For **Configurations**, select a configuration that matches your target and ends with `ccsv4` or `ccsv5`. Then click **Apply**.
- 4 If the configuration is incomplete, the software displays a series of **Browse For Folder** dialog boxes that include instructions to provide missing information.
- 5 Examine the **Tool Directories** tab to see if the paths are right.
- 6 When you have supplied the missing information, and the configuration is complete, click **OK** to close the XMakefile User Configuration dialog.

For example, to generate code for CCSv4/5 and a C2000 processor:

- 1 Enter `xmakefilesetup` on the command line.
- 2 In the XMakefile dialog, clear **Display operational configurations only**, set **Configurations** to `ticcs_c2000_ccsv4` or `ticcs_c2000_ccsv5`, and click **Apply**.
- 3 A **Browse For Folder** appears, stating “Select the CCS installation directory...”.  
Browse and select a path such as `C:\ti\ccsv5`.
- 4 A **Browse For Folder** appears, stating “Select the C2000 Code Generation Tools root installation directory...”.  
Browse and select a path such as `C:\ti\ccsv5\tools\compiler\c2000_6.2.0`.
- 5 Examine the **Tool Directories** tab and verify the paths shown there.
- 6 With the updated information, the `ticcs_c2000_ccsv4` or `ticcs_c2000_ccsv5` configuration is operational. Click **OK** to save the updated configuration, and close the dialog.

## Prepare Your Model for CCSv4/5 and Makefiles

- 1 Configure your model as described in “Configure Target Hardware Resources” on page 72-3, setting **IDE/Tool Chain** to Texas Instruments Code Composer Studio v4 (makefile generation only) or Texas Instruments Code Composer Studio v5 (makefile generation only).

Choosing either of those options automatically sets **Build format** to **Makefile**.

- 2 Build your embedded software by pressing **CTRL+B**.

## Create Target Configuration File in CCSv4/5

Before loading and running your target software, use the CCSv4/5 IDE to create a “target configuration file”. The TI Debug Server uses this file while it works with CCSv4/5 to load and run your target software. The XML-based target configuration file describes the target board and processor. The file name ends with a **\*.ccxml** extension.

Create a target configuration file:

- 1 In the CCSv4/5, select **File > New > Target Configuration File** to display a **New Target Configuration** dialog:
  - For **File name**, update the file name that ends with **.ccxml** to describe your project and hardware.
  - Click **Finish**. This action displays a utility in the CCSv4/5 editor pane for customizing the target configuration file.
- 2 Use the utility to select the **Connection** and **Device** type. Typing a partial string next to **Device** filters the list of devices.
- 3 Click **Save**.

---

**Note:** For more information about target configuration files, consult the Texas Instruments documentation for CCSv4/5.

---

## Configure Windows Path for TI Debug Server Scripting (DSS)

Set the Windows system variable, Path, so you can call the TI Debug Server Scripting (DSS) API from a folder.

- 1 In Windows, right-click **My Computer**, and select **Properties**. This action opens the System Properties dialog.
- 2 In **System Properties**, select the **Advanced** tab, and click **Environment Variables**. This action opens the Environment Variables dialog.
- 3 In **Environment Variables**, under **System variables**, select the Path variable, and click **Edit**. This action opens the Edit System Variable dialog.

- 4 In Edit System Variable, for **Variable value**, append a semicolon and the full path of the `\ccsv4\scripting\bin` or `\ccsv5\scripting\bin` subdirectory. For example, append `;C:\ti\ccsv4\scripting\bin`.

---

**Note:** The path cannot contain spaces. Customize the installation directory when you install CCSv4/5 so it does not contain spaces.

---

## Load and Run the Embedded Software Using DSS

MathWorks provides an example JavaScript file, `runProgram.js`, for you to use with DSS. This script loads and runs the specified program on the target specified in the target configuration file. You can create a copy of this script and modify it to suit your needs. The location of `runProgram.js` is:

```
[MATLABROOT]\toolbox\idelink\extensions\ticcs\ccsdemos
```

### Load and Run Embedded Software Automatically Using XMakefile Configuration

The syntax for running `dss.bat` with `runProgram.js` using XMakefile Configuration is:

```
> dss runProgramFile targetConfigurationFile [|||MW_XMK_GENERATED_TARGET_REF[E]|||]
```

For example, to automate, load, and run an embedded software on C2000 processor with CCSv4/5 using xmakefile configuration, the steps are as follows:

- 1 Enter `xmakefilesetup` on the [MATLAB] command prompt.
- 2 In the **XMakefile User Configuration** dialog box, clear **Display operational configurations only** check box.
- 3 Select `ticcs_c2000_ccsv4` or `ticcs_c2000_ccsv5` in **Configuration** parameter.
- 4 Click **Apply**.
- 5 Create a new Configuration as explained in the section, “Creating a New XMakefile Configuration” on page 72-19.
- 6 Select **Execute** tab. In this tab, enter values for the syntax 

```
> dss runProgramFile targetConfigurationFile [|||MW_XMK_GENERATED_TARGET_REF[E]|||]
```

 in the **Execute tool** and **Arguments** parameters.

- In the **Execute tool** parameter, enter the executable name 'dss.bat'.
- In the **Arguments** parameter, replace runProgramFile and targetConfigurationFile with complete filepath.

When you enter the filepath, use double quotes or double back-slashes.

For example:

```
[MATLABROOT]\\toolbox\\idmlink\\extensions\\ticcs\\ccsdemos\\
\\runProgram.js
```

```
C:\\ccsv4\\CCSTargetConfigurations\\ezdsp28335.ccxml
```

```
[| | |MW_XMK_GENERATED_TARGET_REF[E] | | |]
```

or

```
"[MATLABROOT]\\toolbox\\idmlink\\extensions\\ticcs\\ccsdemos\\runProgram.js"
```

```
"C:\\ccsv4\\CCSTargetConfigurations\\ezdsp28335.ccxml"
```

```
[| | |MW_XMK_GENERATED_TARGET_REF[E] | | |]
```

You have completed the process of loading and running the embedded software using XMakefile on the target or simulator.

### Load and Run Embedded Software Using Windows Command Prompt

The syntax for running dss.bat with runProgram.js using Windows command prompt is:

```
> dss runProgramFile targetConfigurationFile programFile
```

Replace runProgramFile, targetConfigurationFile, and the programFile with complete file path and the file name. For example, if you are using a working directory called 'CCSv4/5 workspace', and the model name 'myProgram', enter,

```
> dss c:\\ccsv4\\runProgram.js c:\\workspace\\myC6416dsk.ccxml
c:\\test\\myProgram.out
```

This command loads and runs the embedded software on the target or simulator.

For more information about using DSS, see [http://processors.wiki.ti.com/index.php/Debug\\_Server\\_Scripting](http://processors.wiki.ti.com/index.php/Debug_Server_Scripting).

## Troubleshooting DSS

With Code Composer Studio 4 & 5, using `runProgram.js` to download and run the generated program file can produce an error message similar to:

```
SEVERE: Could not open session. Found 2 devices matching: .*
Spectrum Digital DSK-EVM-eZdsp onboard USB Emulator_0/C64XP_0
Spectrum Digital DSK-EVM-eZdsp onboard USB Emulator_0/IcePick_C_0
```

If this happens, specify one of the devices in line 65 in `runProgram.js`. For example:

```
debugSession = debugServer.openSession(".*C64XP.*");
```

Alternatively, to connect to the first board & CPU detected, use ("`*`", "`*`") in line 65. For example:

```
debugSession = debugServer.openSession("*", "*");
```

Remember to restore the original code to work with other devices.

## Advanced DSS Features

To use advanced DSS features, you can also use the CCSv4/5 example batch file, `loadti.bat`, as follows:

Change directories to the `loadti` subdirectory. For example:

```
> cd c:\ccs4_install\ccsv4\scripting\examples\loadti
```

Run `loadti.bat` using the following syntax:

```
> loadti -a -c=targetConfigurationFile programFile
```

Replace `targetConfigurationFile` with the complete path of the target configuration file.

Replace `programFile` with the name of the `.out` created using the XMakefile feature. For example:

```
> loadti -a -c=c:\workspace\myC6416dsk.ccxml myProgram.out
```

For more information about `loadti` and its options, type the following on your system command prompt

```
> loadti -help
```

## Reported Limitations and Tips

### In this section...

“Example Programs Do Not Run well with Incorrect GEL Files” on page 76-11

“PostCodeGenCommand Commands Do Not Apply to IDE Projects” on page 76-11

Some long-standing issues apply to the Embedded Coder product.

### Example Programs Do Not Run well with Incorrect GEL Files

To run the Embedded Coder examples, you must load the GEL files before you run the examples. For some boards, the examples run fine with the default CCSv4/5 GEL file. Some boards need to run device-specific GEL files for the examples to work.

In general, if a example does not run with the default GEL file, try using a device-specific GEL file by defining the file in the CCSv4/5 Setup Utility.

### PostCodeGenCommand Commands Do Not Apply to IDE Projects

PostCodeGenCommand commands, such as the `addCompileFlags` and `addLinkFlags` functions in the BuildInfo API do not alter code generated while **System Target File** is set to `idelink_ert.tlc` or `idelink_grt.tlc`.

Use the 'Compiler options string' and 'Linker options string' parameters located in the Configuration Parameters dialog (**Ctrl+E**) on the **Code Generation > Coder Target** pane instead. You can also automate this process using a model callback to `SET_PARAM` the 'CompilerOptionsStr' and 'LinkerOptionsStr' parameters.

## Specify Comment Style for C/C++ Code

### In this section...

“Specify Comment Style Using the MATLAB Coder App” on page 77-2

“Specify Comment Style Using the Command-Line Interface” on page 77-3

If you have an Embedded Coder, you can specify the comment style for C/C++ code generated from MATLAB code. Specify single-line style to generate single-line comments preceded by `//`. Specify multiline style to generate single-line or multiline comments delimited by `/*` and `*/`. Single-line style is the default for C++ code generation. Multiline style is the default for C code generation. For C code generation, select single-line comment style only if your compiler supports it.

### Specify Comment Style Using the MATLAB Coder App

- 1 On the **Generate Code** page, to open the **Generate** dialog box, click the **Generate** arrow .
- 2 Set **Build type** to one of the following:
  - Source Code
  - Static Library (.lib)
  - Dynamic Library (.dll)
  - Executable (.exe)
- 3 Click **More Settings**.
- 4 On the **Code Appearance** tab, select the **Include comments** check box if it is not already selected. By default, the **Include comments** check box is selected.
- 5 Set **Comment Style** to one of the following options.

Value	Description
Auto(Use standard comment style of the target language)	For C, generate multiline comments. For C++, generate single-line comments. (default)
Single-line (Use C++-style comments)	Generate single-line comments preceded by <code>//</code> .
Multi-line (Use C-style comments)	Generate single-line or multiline comments delimited by <code>/*</code> and <code>*/</code> .

## Specify Comment Style Using the Command-Line Interface

- 1 Create a code configuration object for C/C++ code generation. For example, create a configuration object for C/C++ static library generation:

```
cfg = coder.config('lib', 'ecoder', true);
```

- 2 Set the `CommentStyle` property to one of the following values:

Value	Description
'Auto'	For C, generate multiline comments. For C++, generate single-line comments. (default)
'Single-line'	Generate single-line comments preceded by <code>//</code> .
'Multi-line'	Generate single-line or multiline comments delimited by <code>/*</code> and <code>*/</code> .

For example, this code sets the comment style to single-line style:

```
cfg.CommentStyle='Single-line';
```

## Specify Indent Style for C/C++ Code

### In this section...

“Specify Indent Style Using the MATLAB Coder App” on page 77-5

“Specify Indent Style Using the Command-Line Interface” on page 77-5

If you have an Embedded Coder license, you can control the indent style and indent size in C/C++ code generated from MATLAB code. Indent style controls the placement of braces. Indent size controls the number of characters per indentation level.

You can specify the K&R indent style or the Allman indent style. Both styles:

- Place the function opening and closing braces on their own lines at the same indentation level as the function header.
- Indent code within the function according to the indent size.
- For blocks within a function, place closing braces on a new line at the same indentation level as the control statement.
- Indent code within a block according to the indent size.

The K&R style and the Allman style differ in their placement of the opening brace for a control statement. If you want the opening brace on the same line as its control statement, select the K&R style. Here is code that has the K&R indent style:

```
void addone(const double x[6], double z[6])
{
 int i0;
 for (i0 = 0; i0 < 6; i0++) {
 z[i0] = x[i0] + 1.0;
 }
}
```

If you want the opening brace on its own line, select the Allman style. Here is code that has the Allman indent style:

```
void addone(const double x[6], double z[6])
{
 int i0;
 for (i0 = 0; i0 < 6; i0++)
 {
 z[i0] = x[i0] + 1.0;
 }
}
```

```

}
}

```

## Specify Indent Style Using the MATLAB Coder App

- 1 On the **Generate Code** page, to open the **Generate** dialog box, click the **Generate** arrow .
- 2 Set **Build type** to one of the following:
  - Source Code
  - Static Library (.lib)
  - Dynamic Library (.dll)
  - Executable (.exe)
- 3 Click **More Settings**.
- 4 On the **All Settings** tab, under **Advanced**, set **Indent style** to K&R or Allman.
- 5 On the **All Settings** tab, under **Advanced**, set **Indent size** to an integer from 2 to 8.

## Specify Indent Style Using the Command-Line Interface

- 1 Create a code configuration object for 'lib', 'dll', or 'exe'. For example:

```
cfg = coder.config('lib','ecoder',true); % or dll or exe
```
- 2 Set the `IndentStyle` property to 'K&R' or 'Allman'. For example:

```
cfg.IndentStyle = 'Allman';
```
- 3 Set the `IndentSize` property to an integer from 2 to 8. For example:

```
cfg.IndentSize = 4;
```

- “Configure Build Settings”

## Generate Custom File and Function Banners for C/C++ Code

When you generate C and C++ code from MATLAB code, you can use a code generation template (CGT) file to specify custom:

- File banners
- Function Banners
- File trailers
- Comments before code sections

This example shows how you can create your own CGT file and customize it to generate your own file and function banners.

- 1 Create a local copy of the default CGT file for MATLAB Coder and rename it. The default CGT file is `matlabcoder_default_template.cgt` in the `matlabroot/toolbox/coder/matlabcoder/templates/` folder.
- 2 Store the copy in a folder that is outside of the MATLAB folder structure, but on the MATLAB path. If necessary, add the folder to the MATLAB path. If you intend to use the CGT file with a custom target, locate the CGT file in a folder under your target root folder. If the file is not on the MATLAB path, specify a full path to the file when adding the file to your configuration.
- 3 View the default template and generated output. For example, here is the default File Banner section:

```

%%
%% Custom File Banner section (optional)
%% Customize File banners by using either custom tokens or the following
%% predefined tokens:
%% %<FileName>, %<MATLABCoderVersion>, %<EmbeddedCoderVersion>
%% %<SourceGeneratedOn>, %<HardwareSelection>, %<OutputType>
%%
%% You can also use "custom tokens" in all of the sections below. See the
%% documentation center for more details.
%%
<FileBanner style="classic">
File: %<FileName>

MATLAB Coder version : %<MATLABCoderVersion>
C/C++ source code generated on : %<SourceGeneratedOn>
</FileBanner>

```

When you generate code using this default, the file banner looks similar to this file banner:

```

/*
 * File: coderand.c

```

```

*
* MATLAB Coder version : 2.7
* C/C++ source code generated on : 06-Apr-2014 14:34:15
*/

```

- 4** Edit your local copy of the CGT file. You can change the default values and add your own custom tokens. For example, here is the File Banner section with the style changed to `box` and a custom token `myCustomToken`:

```

%%
%% Custom File Banner section (optional)
%% Customize File banners by using either custom tokens or the following
%% predefined tokens:
%% %<FileName>, %<MATLABCoderVersion>, %<EmbeddedCoderVersion>
%% %<SourceGeneratedOn>, %<HardwareSelection>, %<OutputType>
%%
%% You can also use "custom tokens" in all of the sections below. See the
%% documentation center for more details.
%%
<FileBanner style="box">
File: %<FileName>

My custom token : %<myCustomToken>

MATLAB Coder version : %<MATLABCoderVersion>
C/C++ source code generated on : %<SourceGeneratedOn>
</FileBanner>

```

For more information, see “Code Generation Template Files for MATLAB Code” on page 77-9.

- 5** Create a configuration object for generation of a C static library for an embedded target.

```

% Create configuration object for an embedded target
cfgObj = coder.config('lib','ecoder',true);

```

- 6** Create a `MATLABCodeTemplate` object from your CGT file and add it to the configuration object.

```

% Specify the custom CGT file
CGTFile = 'myCGTFile.cgt';
% Use custom template
cfgObj.CodeTemplate = coder.MATLABCodeTemplate(CGTFile);

```

- 7** Assign values for custom tokens that you added to the template. For example, assign the value `'myValue'` to the `myCustomToken` token that you added in a previous step.

```

cfgObj.CodeTemplate.setTokenValue('myCustomToken','myValue');

```

- 8** Generate code using the configuration object that you created.

```
codegen -config cfgObj coderand
```

- 9 View the changes to the generated file banner. For example, here is the file banner for `coderand.c` using the customized CGT file:

```
/* File: coderand.c */
/*
/* My custom token : myValue
/*
/* MATLAB Code version : 2.7
/* C/C++ source code generated on : 06-Apr-2014 14:42:55
/*
```

Changes to a CGT file do not affect the generated code unless you create a `MATLABCodeTemplate` object from the modified CGT file, and then add it to the configuration object. If you modify the CGT File, `myCGTFile.cgt`, used in the previous example, you must repeat these steps:

- 1 Create a `MATLABCodeTemplate` object from `myCGTFile.cgt` and add it to the configuration object.

```
CGTFile = 'myCGTFile.cgt';
cfgObj.CodeTemplate = coder.MATLABCodeTemplate(CGTFile);
```

- 2 Assign the value `'myValue'` to the `myCustomToken` token.

```
cfgObj.CodeTemplate.setTokenValue('myCustomToken','myValue');
```

- 3 Generate code.

```
codegen -config cfgObj coderand
```

- “Code Generation Template Files for MATLAB Code” on page 77-9

## Code Generation Template Files for MATLAB Code

### In this section...

“Default CGT File” on page 77-9

“CGT File Structure” on page 77-9

“Components of the CGT File Sections” on page 77-11

A code generation template (CGT) file defines the sections in generated code that you can customize using comments and tokens. Using a code generation template (CGT) file for the generation of C and C++ code from MATLAB code, you can specify custom file banners and function banners for generated code. File banners are comment sections in the header and trailer sections of a generated file. Function banners are comment sections for each function in the generated code. You can also customize comments before code sections. Use these banners to:

- Add a company copyright statement.
- Specify a special version symbol for your configuration management system.
- Remove time stamps.
- Add other custom information to your generated files.

For information on creating, customizing, and using a CGT file, see “Generate Custom File and Function Banners for C/C++ Code” on page 77-6.

### Default CGT File

You can base your custom template on the default CGT file, `matlabcoder_default_template.cgt`, in the `matlabroot/toolbox/coder/matlabcoder/templates/` folder.

---

**Note:** If you choose not to customize banners for your generated code, the default template is used for code generation.

---

### CGT File Structure

A CGT file consists of 13 optional sections.

**File Banner Section**

Contains comments and tokens for use in generating a custom file banner.

**Function Banner Section**

Contains comments and tokens for use in generating a custom function banner.

**Shared Utility Function Banner**

Contains comments and tokens for use in generating custom banners for shared utility functions.

**File Trailer Section**

Contains comments for use in generating a custom trailer banner.

**Include Files Banner**

Contains comments for use in generating a custom banner for the include files section.

**Type Definitions**

Contains comments for use in generating a custom banner for the type definitions section.

**Named Constants**

Contains comments for use in generating a custom banner for the named constants section.

**Variable Declarations**

Contains comments for use in generating a custom banner for the variable declarations section.

**Variable Definitions**

Contains comments for use in generating a custom banner for the variable definitions section.

**Function Declarations**

Contains comments for use in generating a custom banner for the function declarations section.

**Function Definitions**

Contains comments for use in generating a custom banner for the function definitions section.

**Custom Source Code**

Contains comments for use in generating a custom banner for the custom source code section.

**Custom Header Code**

Contains comments for use in generating a custom banner for the custom header code section.

**Components of the CGT File Sections**

Each CGT file section is defined by open and close tags.

CGT File Section	Open Tag	Close Tag
“File Banner” on page 77-14	<FileBanner>	</FileBanner>
“Function Banner Section” on page 77-10	<FunctionBanner>	</FunctionBanner>
“Shared Utility Function Banner” on page 77-10	<SharedUtilityBanner>	</SharedUtilityBanner>
“File Trailer Section” on page 77-10	<FileTrailer>	</FileTrailer>
“Include Files Banner” on page 77-10	<IncludeFilesBanner>	</IncludeFilesBanner>
“Type Definitions” on page 77-10	<TypeDefinitionsBanner>	</TypeDefinitionsBanner>
“Named Constants” on page 77-10	<NamedConstantsBanner>	</NamedConstantsBanner>
“Variable Declarations” on page 77-10	<VariableDeclarationsBanner>	</VariableDeclarationsBanner>

CGT File Section	Open Tag	Close Tag
“Variable Definitions” on page 77-10	<VariableDefinitionsBanner>	</VariableDefinitionsBanner>
“Function Declarations” on page 77-10	<FunctionDeclarationsBanner>	</FunctionDeclarationsBanner>
“Function Definitions” on page 77-11	<FunctionDefinitionsBanner>	</FunctionDefinitionsBanner>
“Custom Source Code” on page 77-11	<CustomSourceCodeBanner>	</CustomSourceCodeBanner>
“Custom Header Code” on page 77-11	<CustomHeaderCodeBanner>	</CustomHeaderCodeBanner>

You can customize your banners by including tokens and comments between the open and close tags for each section. Tokens are replaced with values in the generated code. The following rules apply to tokens in your CGT file:

- You can have only one token per line.
- Token values must not contain a ‘\t’ for formatting.

---

**Note:** In the contents of your banner, C comment indicators, ‘/\*’ or ‘\*/’, can introduce an error in the generated code.

---

An open tag includes tag attributes. Enclose the value of the attribute in double quotes. The attributes available for an open tag are:

- **width:** specifies the width of the file or function banner comments in the generated code. The default value is 80.
- **style:** specifies the boundary for the file or function banner comments in the generated code.

The open tag syntax is:

```
<OpenTag style = "style_value" width = "num_width">
```

There are five options for the banner style. The `CommentStyle` and `TargetLang` configuration object properties determine the use of C or C++ comment style. The built-in style options for the `style` attribute are:

- classic

Using C style comments

```
/* single line comments */

/*
 * multiple line comments
 * second line
 */
```

Using C++ style comments

```
// single line comments

//
// multiple line comments
// second line
//
```

- box

Using C style comments

```

/* banner contents */

```

Using C++ style comments

```
////////////////////////////////////
// banner contents //
////////////////////////////////////
```

- open\_box

Using C style comments

```

 * banner contents

```

Using C++ style comments

```
////////////////////////////////////
// banner contents
```

```
//
```

- **doxygen**

Using C style comments

```
/** single line comments */
```

```
/**
 * multiple line comments
 * second line
 */
```

Using C++ style comments

```
///single line comments
```

```
///
/// multiple line comments
///second line
///
```

- **doxygen\_qt**

Using C style comments

```
/*! single line comments */
```

```
/*!
 * multiple line comments
 * second line
 */
```

Using C++ style comments

```
/*!single line comments
```

```
///
/*! multiple line comments
/*!second line
/*!
```

## **File Banner**

This section contains comments and tokens for use in generating a custom file banner that precedes the generated C and C++ code. If you omit the file banner section from the

CGT file, the code generator does not generate a file banner in the generated code. The file banner section provided in the default CGT file is:

```

%%
%% Custom File Banner section (optional)
%% Customize File banners by using either custom tokens or the following
%% predefined tokens:
%% %<FileName>, %<MATLABCoderVersion>, %<EmbeddedCoderVersion>
%% %<SourceGeneratedOn>, %<HardwareSelection>, %<OutputType>
%%
%% You can also use "custom tokens" in all of the sections below. See the
%% documentation center for more details.
%%
<FileBanner style="classic">
File: %<FileName>

MATLAB Coder version : %<MATLABCoderVersion>
C/C++ source code generated on : %<SourceGeneratedOn>
</FileBanner>

```

### Summary of Tokens for File Banner Generation

FileName	Name of the generated file (for example, "kalman.c")
SourceGeneratedOn	Time stamp of generated file
MATLABCoderVersion	Version of MATLAB Coder
EmbeddedCoderVersion	Version of Embedded Coder
HardwareSelection	Selected target
OutputType	Type of output (for example, lib, exe, or dll)

### Function Banner

This section contains comments and tokens for use in generating a custom function banner that precedes a generated C or C++ function. If you omit the function banner section from the CGT file, the code generator does not generate function banners. The function banner section provided in the default CGT file is:

```

%%
%% Custom function banner section (optional)
%% Customize function banners by using the following predefined tokens:
%% %<FunctionName>, %<FunctionDescription>
%% %<Arguments>, %<ReturnType>
%%
<FunctionBanner style="classic">
%<FunctionDescription>
Arguments : %<Arguments>
Return Type : %<ReturnType>
</FunctionBanner>

```

**Summary of Tokens for Function Banner Generation**

FunctionName	Name of function
FunctionDescription	Short abstract about the function
Arguments	List of function arguments
ReturnType	Return type of function

**Shared Utility Banner**

This section contains comments and tokens for use in generating a custom shared utility function banner that precedes a generated C or C++ shared utility function. If you omit the shared utility function banner section from the CGT file, the code generator does not generate shared utility function banners. The shared utility function banner section provided in the default CGT file is:

```

%%
%% Custom Shared Utility Function Banner section (optional)
%% Customize shared utility function banners by using the following
%% predefined tokens:
%% %<FunctionName>, %<FunctionDescription>
%% %<Arguments>, %<ReturnType>
%%
<SharedUtilityBanner style="classic">
Arguments : %<Arguments>
Return Type : %<ReturnType>
</SharedUtilityBanner>

```

**Summary of Tokens for Shared Utility Function Banner Generation**

FunctionName	Name of function
FunctionDescription	Short abstract about the function
Arguments	List of function arguments
ReturnType	Return type of function

**File Trailer**

The file trailer section contains comments for generating a custom file trailer that follows the generated C or C++ code. If you omit the file trailer section from the CGT file, the code generator does not generate a file trailer. The file trailer section provided in the default CGT file is:

```

%%
%% Custom file trailer section (optional)

```

```
%% You can use any of the predefined tokens used for File Banner
%%
<FileTrailer style="classic">
File trailer for %<FileName>

[EOF]
</FileTrailer>
```

Tokens for the file banner are available for the file trailer. See [Summary of Tokens for File Banner Generation](#).

### **Include Files Banner**

The include files banner section contains comments for generating a custom banner that precedes the include files section in the generated code. If you omit the include files banner section from the CGT file, the code generator does not generate a banner for this section. The include files banner section provided in the default CGT file is:

```
<IncludeFilesBanner style="classic">
Include Files
</IncludeFilesBanner>
```

### **Type Definitions Banner**

The type definitions banner section contains comments for generating a custom banner that precedes the type definitions section in the generated code. If you omit the type definitions banner section from the CGT file, the code generator does not generate a banner for this section. The type definitions banner section provided in the default CGT file is:

```
<TypeDefinitionsBanner style="classic">
Type Definitions
</TypeDefinitionsBanner>
```

### **Named Constants Banner**

The named constants banner section contains comments for generating a custom banner that precedes the named constants section in the generated code. If you omit the named constants banner section from the CGT file, the code generator does not generate a banner for this section. The named constants banner section provided in the default CGT file is:

```
<NamedConstantsBanner style="classic">
Named Constants
</NamedConstantsBanner>
```

### **Variable Declarations**

The variable declarations banner section contains comments for generating a custom banner that precedes the variable declarations section in the generated code. If you omit the variable declarations banner section from the CGT file, the code generator does not generate a banner for this section. The variable declarations banner section provided in the default CGT file is:

```
<VariableDeclarationsBanner style="classic">
Variable Declarations
</VariableDeclarationsBanner>
```

### **Variable Definitions**

The variable definitions banner section contains comments for generating a custom banner that precedes the variable definitions section in the generated code. If you omit the variable definitions banner section from the CGT file, the code generator does not generate a banner for this section. The variable definitions banner section provided in the default CGT file is:

```
<VariableDefinitionsBanner style="classic">
Variable Definitions
</VariableDefinitionsBanner>
```

### **Function Declarations**

The function declarations banner section contains comments for generating a custom banner that precedes the function declarations section in the generated code. If you omit the function declarations banner section from the CGT file, the code generator does not generate a banner for this section. The function declarations banner section provided in the default CGT file is:

```
<functionDeclarationsBanner style="classic">
Function Declarations
</FunctionDeclarationsBanner>
```

### **Function Definitions**

The function definitions banner section contains comments for generating a custom banner that precedes the function definitions section in the generated code. If you omit the function definitions banner section from the CGT file, the code generator does not generate a banner for this section. The function definitions banner section provided in the default CGT file is:

```
<FunctionDefinitionsBanner style="classic">
Function Definitions
</FunctionDefinitionsBanner>
```

### **Custom Source Code**

The custom source code banner section contains comments for generating a custom banner that precedes the custom source code section in the generated code. If you omit the custom source code banner section from the CGT file, the code generator does not generate a banner for this section. The custom source code banner section provided in the default CGT file is:

```
<CustomSourceCodeBanner style="classic">
Custom Source Code
</CustomSourceCodeBanner>
```

### **Custom Header Code**

The custom header code banner section contains comments for generating a custom banner that precedes the custom header code section in the generated code. If you omit the custom header code banner section from the CGT file, the code generator does not generate a banner for this section. The custom header code banner section provided in the default CGT file is:

```
<CustomHeaderCodeBanner style="classic">
Custom Header Code
</CustomHeaderCodeBanner>
```

## **See Also**

`coder.MATLABCodeTemplate`

## **More About**

- “Generate Custom File and Function Banners for C/C++ Code” on page 77-6

## Customize Generated Identifiers

### In this section...

“Customize Identifiers by Using the MATLAB Coder App” on page 77-20

“Customize Generated Identifiers by Using the Command-Line Interface” on page 77-21

If you have Embedded Coder, you can customize the identifiers in C/C++ code generated from MATLAB code. For each kind of identifier that you want to customize, set the appropriate identifier format parameter to a macro that specifies the format of the generated identifiers. The macro can include:

- Valid C or C++ language identifiers (a-z, A-Z, \_, 0–9).
- The tokens listed in the following table. \$M is required.

Token	Description
\$M	Code generator inserts name mangling text to avoid naming collisions.  Required.
\$N	Code generator inserts the name of the object (global variable, global type, local function, local temporary variable, or constant macro) for which the identifier is generated.  Improves readability of generated code.
\$R	Code generator inserts the root project name into identifier, replacing unsupported characters with the underscore ( _ ) character.

### Customize Identifiers by Using the MATLAB Coder App

- 1 On the **Generate Code** page, to open the **Generate** dialog box, click the **Generate** arrow .
- 2 Set **Build type** to one of the following:
  - Source Code
  - Static Library

- Dynamic Library
  - Executable
- 3 Click **More Settings**.
  - 4 On the **Code Appearance** tab, under **Identifier Format**, for each kind of identifier that you want to customize, enter the macro.

Parameter	Default Macro
<b>Global variables</b>	\$M\$N
<b>Global types</b>	\$M\$N
<b>Field name of global types</b>	\$M\$N
<b>Local functions</b>	\$M\$N
<b>Local temporary variables</b>	\$M\$N
<b>Constant macros</b>	\$M\$N
<b>EMX Array Types</b>	emxArray_ \$M\$N
<b>EMX Array Utility Functions</b>	emx\$M\$N

For example, suppose that **Global variables** has the value `glob_ $M$N`. For a global variable named `g`, when name mangling is not required, the generated identifier is `glob_g`. If name mangling is required, the generated identifier includes the name mangling text.

## Customize Generated Identifiers by Using the Command-Line Interface

- 1 Create a code configuration object for a library or executable program. For example:
 

```
cfg = coder.config('lib', 'ecoder', true);
```
- 2 For each kind of identifier that you want to customize, specify the macro as a character vector.

Parameter	Description	Default Macro
<code>CustomSymbolStrGlobalVar</code>	Global variables	' \$M\$N '
<code>CustomSymbolStrType</code>	Global types	' \$M\$N '
<code>CustomSymbolStrField</code>	Field name of global types	' \$M\$N '
<code>CustomSymbolStrFcn</code>	Local functions	' \$M\$N '

Parameter	Description	Default Macro
CustomSymbolStrTmpVar	Local temporary variables	'\$M\$N'
CustomSymbolStrMacro	Constant macros	'\$M\$N'
CustomSymbolStrEMXArray	EMX Array Types	'emxArray_ \$M\$N'
CustomSymbolStrEMXArrayFcn	EMX Array Utility Functions	'emx\$M\$N'

For example:

```
cfg.CustomSymbolStrGlobalVar = 'glob_ MN';
```

For a global variable named `g`, when name mangling is not required, the generated identifier is `glob_g`. If name mangling is required, the generated identifier includes the name mangling text.

## Control Signed Left Shifts in Generated Code

### In this section...

“Control Signed Left Shifts Using the MATLAB Coder App” on page 77-23

“Control Signed Left Shifts Using the Command-Line Interface” on page 77-23

If you have an Embedded Coder license, you can control whether MATLAB Coder replaces multiplications by powers of two with signed left bitwise shifts. Some coding standards, such as MISRA, do not allow bitwise operations on signed integers.

By default, MATLAB Coder replaces multiplication by powers of two with signed left shifts. Here is an example of generated C code that uses a signed left shift for multiplication by eight.

```
i <<= 3;
```

To increase the likelihood of generating MISRA C:2012 compliant code, disable the replacement of multiplication by powers of two with signed left shifts. Here is an example of generated C code that does not use a signed left shift for multiplication by eight:

```
i = i * 8;
```

### Control Signed Left Shifts Using the MATLAB Coder App

- 1 On the **Generate Code** page, to open the **Generate** dialog box, click the **Generate** arrow .
- 2 Set **Build type** to one of the following:
  - Source Code
  - Static Library (.lib)
  - Dynamic Library (.dll)
  - Executable (.exe)
- 3 Click **More Settings**.
- 4 On the **Code Appearance** tab, select or clear the **Use signed shift left for fixed-point operations and multiplication by powers of 2** check box.

### Control Signed Left Shifts Using the Command-Line Interface

- 1 Create a code configuration object for 'lib', 'dll', or 'exe'. For example:

- ```
cfg = coder.config('lib','ecoder',true); % or dll or exe
```
- 2 Set the `EnableSignedLeftShifts` property to `true` or `false`. For example:
- ```
cfg.EnableSignedLeftShifts = false;
```

## Control Data Type Casts in Generated Code

### In this section...

“Specify Casting Mode Using the MATLAB Coder App” on page 77-26

“Specify Casting Mode Using the Command-Line Interface” on page 77-27

If you have an Embedded Coder license, you can control data type casts in C/C++ code generated from MATLAB code. You can specify one of the following casting modes.

Casting Mode	Description
Nominal	<p>Nominal casting mode is the default casting mode. Generated C/C++ code uses the default C compiler data type casting. When you do not have special data type information requirements, choose this option. Here is an example of code generated using nominal casting mode:</p> <pre data-bbox="793 899 1095 1185"> short addone(short x) {     int i0;     i0 = x + 1;     if (i0 &gt; 32767) {         i0 = 32767;     }      return (short)i0; } </pre>
Standards Compliant	<p>Generated C/C++ code has data type casts that conform to MISRA standards. The MISRA data type casting eliminates common MISRA standard violations, including address arithmetic and assignment. It reduces 10.1, 10.2, 10.3, and 10.4 violations. Here is an example of code generated using standards-compliant casting mode:</p> <pre data-bbox="793 1515 1095 1539"> short addone(short x) </pre>

Casting Mode	Description
	<pre data-bbox="793 302 1144 552"> {   int i0;   i0 = (int)x + (int)1;   if (i0 &gt; (int)32767) {     i0 = (int)32767;   }    return (short)i0; } </pre>
Explicit	<p data-bbox="793 569 1299 791">Generated C/C++ code has explicit data type casts. Explicit data type casts provide information about the amount of memory that the variable uses and the level of precision for calculations using the variable. Here is an example of code generated using explicit casting mode:</p> <pre data-bbox="793 817 1095 1104"> short addone(short x) {   int i0;   i0 = (int)x + 1;   if (i0 &gt; 32767) {     i0 = 32767;   }    return (short)i0; } </pre>

## Specify Casting Mode Using the MATLAB Coder App

- 1 On the **Generate Code** page, to open the **Generate** dialog box, click the **Generate** arrow .
- 2 Set **Build type** to one of the following:
  - Source Code
  - Static Library (.lib)
  - Dynamic Library (.dll)
  - Executable (.exe)
- 3 Click **More Settings**.

- 4 On the **All Settings** tab, under **Advanced**, set **Casting mode** to one of the following values:
  - Nominal
  - Standards Compliant
  - Explicit

## Specify Casting Mode Using the Command-Line Interface

- 1 Create a code configuration object for 'lib', 'dll', or 'exe'. For example:

```
cfg = coder.config('lib','ecoder',true); % or dll or exe
```

- 2 Set the **CastingMode** property to one of the following values:

- 'Nominal'
- 'Standards'
- 'Explicit'

For example:

```
cfg.IndentStyle = 'Standards';
```

## Simplify Multiply Operations for Array Indexing in Loops

If you use Embedded Coder to generate C/C++ code from MATLAB code, you can enable an optimization that simplifies array indexing in loops in the generated code. When possible, for array indices in loops, this optimization replaces multiply operations with add operations. Multiply operations can be expensive. This optimization, referred to as strength reduction, is useful when the C/C++ compiler on the target platform does not optimize the array indexing.

Here is code generated without the optimization:

```
for (i = 0; i < 10; i++) {
 z[5 * (1 + i) - 1] = x[5 * (1 + i)];
}
```

Here is code generated with the optimization:

```
for (b_i = 0; b_i < 10; b_i++) {
 z[i + 4] = x[i + 5];
 i += 5;
}
```

By default, the strength reduction optimization is disabled. To enable it:

- At the command line, set the configuration object parameter `EnableStrengthReduction` to `true`.
- In the MATLAB Coder app, project build settings, on the **All Settings** tab, set **Simplify array indexing** to **Yes**.

Even when the optimization replaces the multiply operations in the generated code, it is possible that the C/C++ compiler can generate multiply instructions.

# Code Replacement for MATLAB Code

---

- “What Is Code Replacement?” on page 78-2
- “Choose a Code Replacement Library” on page 78-8
- “Replace Code Generated from MATLAB Code” on page 78-10

## What Is Code Replacement?

Code replacement is a technique to change the code that the code generator produces for functions and operators to meet application code requirements. For example, you can replace generated code to meet requirements such as:

- Optimization for a specific run-time environment, including, but not limited to, specific target hardware.
- Integration with existing application code.
- Compliance with a standard, such as AUTOSAR.
- Modification of code behavior, such as enabling or disabling nonfinite or inline support.
- Application- or project-specific code requirements, such as:
  - Elimination of `math.h`.
  - Elimination of system header files.
  - Elimination of calls to `memcpy` or `memset`.
  - Use of BLAS.
  - Use of a specific BLAS.

To apply this technique, configure the code generator to apply a code replacement library (CRL) during code generation. By default, the code generator does not apply a code replacement library. You can choose from the following libraries that MathWorks provides:

- GNU C99 extensions—GNU<sup>17</sup> gcc math library, which provides C99 extensions as defined by compiler option `-std=gnu99`.
- AUTOSAR 4.0—Produces code that more closely aligns with the AUTOSAR standard. Requires an Embedded Coder license.
- Intel IPP for x86-64 (Windows)—Generates calls to the Intel Performance Primitives (IPP) library for the x86-64 Windows platform.
- Intel IPP/SSE for x86-64 (Windows)—Generates calls to the IPP and Streaming SIMD Extensions (SSE) libraries for the x86-64 Windows platform.
- Intel IPP for x86-64 (Windows using MinGW compiler)—Generates calls to the IPP library for the x86-64 Windows platform and MinGW compiler.

---

17. GNU is a registered trademark of the Free Software Foundation.

- Intel IPP/SSE for x86-64 (Windows using MinGW compiler)—Generates calls to the IPP and SSE libraries for the x86-64 Windows platform and MinGW compiler.
- Intel IPP for x86/Pentium (Windows)—Generates calls to the IPP library for the x86/Pentium Windows platform.
- Intel IPP/SSE for x86/Pentium (Windows)—Generates calls to the Intel Performance IPP and SSE libraries for the x86/Pentium Windows platform.
- Intel IPP for x86-64 (Linux)—Generates calls to the IPP library for the x86-64 Linux platform.
- Intel IPP/SSE with GNU99 extensions for x86-64 (Linux)—Generates calls to the GNU libraries for IPP and SSE, with GNU C99 extensions, for the x86-64 Linux platform.

Libraries that include GNU99 extensions are intended for use with the GCC compiler. If use one of those libraries with another compiler, generated code might not compile.

Depending on the product licenses that you have, other libraries might be available. If you have an Embedded Coder license, you can view and choose from other libraries and you can create custom code replacement libraries.

## Code Replacement Libraries

A *code replacement library* consists of one or more code replacement tables that specify application-specific implementations of functions and operators. For example, a library for a specific embedded processor specifies function and operator replacements that optimize generated code for that processor.

A *code replacement table* contains one or more *code replacement entries*, with each entry representing a potential replacement for a function or operator. Each entry maps a *conceptual representation* of a function or operator to an *implementation representation* and priority.

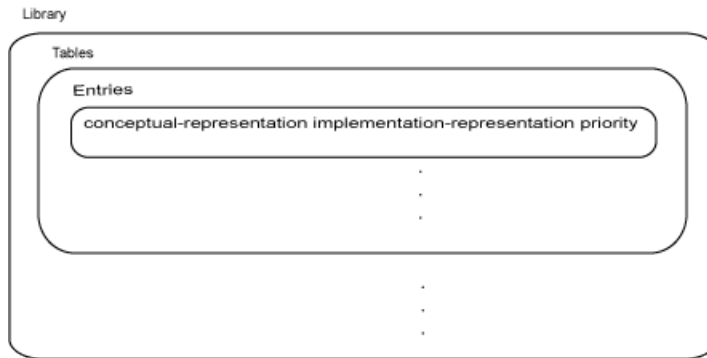

Table Entry Component	Description
Conceptual representation	<p>Identifies the table entry and contains match criteria for the code generator. Consists of:</p> <ul style="list-style-type: none"> <li>• Function name or a key. The function name identifies most functions. For operators and some functions, a series of characters, called a key identifies a function or operator. For example, function name 'COS' and operator key 'RTW_OP_ADD'.</li> <li>• Conceptual arguments that observe code generator naming ('y1', 'u1', 'u2', ...), with corresponding I/O types (output or input) and data types.</li> <li>• Other attributes, such as an algorithm, fixed-point saturation, and rounding modes, which identify matching criteria for the function or operator.</li> </ul>
Implementation representation	<p>Specifies replacement code. Consists of:</p> <ul style="list-style-type: none"> <li>• Function name. For example, 'cos_db1' or 'u8_add_u8_u8'.</li> <li>• Implementation arguments, with corresponding I/O types (output or input) and data types.</li> <li>• Parameters that provide additional implementation details, such as header and source file names and paths of build resources.</li> </ul>

Table Entry Component	Description
Priority	Defines the entry priority relative to other entries in the table. The value can range from 0 to 100, with 0 being the highest priority. If multiple entries have the same priority, the code generator uses the first match with that priority.

When the code generator looks for a match in a code replacement library, it creates and populates a *call site object* with the function or operator conceptual representation. If a match exists, the code generator uses the matched code replacement entry populated with the implementation representation and uses it to generate code.

The code generator searches the tables in a code replacement library for a match in the order that the tables appear in the library. If the code generator finds multiple matches within a table, the priority determines the match. The code generator uses a higher-priority entry over a similar entry with a lower priority.

## Code Replacement Terminology

Term	Definition
Cache hit	A code replacement entry for a function or operator, defined in the specified code replacement library, for which the code generator finds a match.
Cache miss	A conceptual representation of a function or operator for which the code generator does not find a match.
Call site object	Conceptual representation of a function or operator that the code generator uses when it encounters a call site for a function or operator. The code generator uses the object to query the code replacement library for a conceptual representation match. If a match exists, the code generator returns a code replacement object, fully populated with the conceptual representation, implementation representation, and priority, and uses that object to generate replacement code.
Code replacement library	One or more code replacement tables that specify application-specific implementations of functions

Term	Definition
	and operators. When configured to use a code replacement library, the code generator uses criteria defined in the library to search for matches. If a match is found, the code generator replaces code that it generates by default with application-specific code defined in the library.
Code replacement table	One or more code replacement table entries. Provides a way to group related or shared entries for use in different libraries.
Code replacement entry	Represents a potential replacement for a function or operator. Maps a conceptual representation of a function or operator to an implementation representation and priority.
Conceptual argument	Represents an input or output argument for a function or operator being replaced. Conceptual arguments observe naming conventions ('y1', 'u1', 'u2', ...) and data types familiar to the code generator.
Conceptual representation	Represents match criteria that the code generator uses to qualify functions and operators for replacement. Consists of: <ul style="list-style-type: none"> <li>• Function or operator name or key</li> <li>• Conceptual arguments with type, dimension, and complexity specification for inputs and output</li> <li>• Attributes, such as an algorithm and fixed-point saturation and rounding modes</li> </ul>
Implementation argument	Represents an input or output argument for a C or C++ replacement function. Implementation arguments observe C/C++ name and data type specifications.

Term	Definition
Implementation representation	<p>Specifies C or C++ replacement function prototype. Consists of:</p> <ul style="list-style-type: none"> <li>• Function name (for example, 'cos_dbl' or 'u8_add_u8_u8')</li> <li>• Implementation arguments specifying type, type qualifiers, and complexity for the function inputs and output</li> <li>• Parameters that provide build information, such as header and source file names and paths of build resources and compile and link flags</li> </ul>
Key	<p>Identifies a function or operator that is being replaced. A function name or key appears in the conceptual representation of a code replacement entry. The key RTW_OP_ADD identifies the addition operator.</p>
Priority	<p>Defines the match priority for a code replacement entry relative to other entries, which have the same name and conceptual argument list, within a code replacement library. The priority can range from 0 to 100, with 0 being the highest priority. The default is 100. If a library provides two implementations for a function or operator, the implementation with the higher priority shadows the one with the lower priority.</p>

## Code Replacement Limitations

Code replacement verification — It is possible that code replacement behaves differently than you expect. For example, data types that you observe in code generator input might not match what the code generator uses as intermediate data types during an operation. Verify code replacements by examining generated code.

## Related Examples

## Choose a Code Replacement Library

### In this section...

“About Choosing a Code Replacement Library” on page 78-8

“Explore Available Code Replacement Libraries” on page 78-8

“Explore Code Replacement Library Contents” on page 78-8

### About Choosing a Code Replacement Library

By default, the code generator does not use a code replacement library.

If you are considering using a code replacement library:

- 1 Explore available libraries. Identify one that best meets your application needs.
  - Consider the lists of application code replacement requirements and libraries that MathWorks provides in “What Is Code Replacement?” on page 78-2.
  - See “Explore Available Code Replacement Libraries” on page 78-8.
- 2 Explore the contents of the library. See “Explore Code Replacement Library Contents” on page 37-8.

If you do not find a suitable library and you have an Embedded Coder license, you can create a custom code replacement library.

### Explore Available Code Replacement Libraries

You can select the code replacement library to use for code generation in a project, on the **Custom Code** tab, by setting the **Code replacement library** parameter. Alternatively, in a code configuration object, set the `CodeReplacementLibrary` parameter.

### Explore Code Replacement Library Contents

Use the Code Replacement Viewer to explore the content of a code replacement library.

- 1 At the command prompt, type `crviewer`.

```
>> crviewer
```

The viewer opens. To view the content of a specific library, specify the name of the library as an argument in single quotes. For example:

```
>> crviewer('GNU C99 extensions')
```

- 2** In the left pane, select the name of a library. The viewer displays information about the library in the right pane.
- 3** In the left pane, expand the library, explore the list of tables it contains, and select a table from the list. In the middle pane, the viewer displays the function and operator entries that are in that table, along with abbreviated information for each entry.
- 4** In the middle pane, select a function or operator. The viewer displays information from the table entry in the right pane.

If you select an operator entry that specifies net slope fixed-point parameters (instantiated from entry class `RTW.Tf1COperationEntryGenerator` or `RTW.Tf1COperationEntryGenerator_NetSlope`), the viewer displays an additional tab that shows fixed-point settings.

See [Code Replacement Viewer](#) for details on what the viewer displays.

## Replace Code Generated from MATLAB Code

This example shows how to replace generated code using a code replacement library. Code replacement is a technique for changing the code that the code generator produces for functions and operators to meet application code requirements.

### Prepare for Code Replacement

- 1 Make sure that you have installed required software. Required software is:
  - MATLAB
  - MATLAB Coder
  - C compiler

Some code replacement libraries available in your development environment require Embedded Coder.

For instructions on installing MathWorks products, see the MATLAB installation documentation. If you have installed MATLAB and want to see which other MathWorks products are installed, in the MATLAB Command Window, enter `ver`.

- 2 Identify an existing MATLAB function or create a new MATLAB function for which you want the code generator to replace code.

### Choose a Code Replacement Library

If you are not sure which library to use, explore available libraries.

### Configure Code Generator To Use Code Replacement Library

- 1 Configure the code generator to apply a code replacement library during code generation for the MATLAB function. Do one of the following:
  - In a project, on the **Custom Code** tab, set the **Code replacement library** parameter.
  - In a code configuration object, set the `CodeReplacementLibrary` parameter.
- 2 Configure the code generator to produce only code. Before you build an executable, verify your code replacements. Do one of the following:
  - In a project, in the **Generate** dialog box, select the **Generate code only** check box.

- In a code configuration object, set the `GenCodeOnly` parameter.

### Include Code Replacement Information In Code Generation Report

If you have an Embedded Coder license, you can configure the code generator to include a code replacement section in the code generation report. The additional information helps you verify code replacements.

**1** Configure the code generator to generate a report.

- In a project, on the **Debugging** tab, set the **Always create a code generation report** parameter.
- In a code configuration object, set the `GenerateReport` parameter.

**2** Include the code replacement section in the report.

- In a project, on the **Debugging** tab, select the **Code replacements** check box.
- In a code configuration object, set the `GenerateCodeReplacementReport` parameter.

### Generate Replacement Code

Generate C/C++ code from the MATLAB code. If you configured the code generator to produce a report, generate a code generation report. For example, in the MATLAB Coder app, on the **Generate Code** page, click **Generate**. Or, at the command prompt, enter:

```
codegen -report myFunction -args {5} -config cfg
```

The code generator produces the code and displays the report.

### Verify Code Replacements

Verify code replacements by examining the generated code. Code replacement can sometimes behave differently than you expect. For example, data types that you observe in the code generator input might not match what the code generator uses as intermediate data types during an operation.

# Storage Classes for Code Generation from MATLAB Code

---

- “Storage Classes for Code Generation from MATLAB Code” on page 79-2
- “Control Declarations and Definitions of Global Variables in Code Generated from MATLAB Code” on page 79-5

## Storage Classes for Code Generation from MATLAB Code

If you have an Embedded Coder license, you can use storage classes to control the declaration and definition of a global variable in the generated C/C++ code.

In the context of code generation, a *storage class* is a specification that determines the declaration and definition of a variable in the generated code. For code generation, the term storage class is not the same as the C language term *storage class specifier*.

Storage classes help you to integrate generated code with external code. You can make a generated variable visible to external code. You can also make variables declared in the external code visible to the generated code. For code generation from MATLAB code, you can use storage classes with global variables only. The storage class determines:

- The file placement of a global variable declaration and definition.
- Whether the global variable is imported from external code or exported for use by external code.

To assign a storage class to a global variable, in your MATLAB code, use the `coder.storageClass` function. Only when you use an Embedded Coder project or configuration object for generation of C/C++ libraries or executables does the code generator recognize `coder.storageClass` calls.

The syntax for `coder.storageClass` is:

```
coder.storageClass(global_name, storage_class)
```

`global_name` is the name of a global variable, specified as a character vector. `global_name` must be a compile-time constant.

`storage_class` can be one of the following values.

Storage Class	Description
'ExportedGlobal'	<ul style="list-style-type: none"> <li>• Defines the variable in the <b>Variable Definitions</b> section of the C file <code>entry_point_name.c</code>.</li> <li>• Declares the variable as an <b>extern</b> in the <b>Variable Declarations</b> section of the header file <code>entry_point_name.h</code>.</li> </ul>

Storage Class	Description
	<ul style="list-style-type: none"> <li>Initializes the variable in the function <code>entry_point_name_initialize.h</code>.</li> </ul>
'ExportedDefine'	Declares the variable with a <code>#define</code> directive in the <code>Exported data define</code> section of the header file <code>entry_point_name.h</code> .
'ImportedExtern'	Declares the variable as an <code>extern</code> in the <code>Variable Declarations</code> section of the header file <code>entry_point_name_data.h</code> . The external code must supply the variable definition.
'ImportedExternPointer'	Declares the variable as an <code>extern pointer</code> in the <code>Variable Declarations</code> section of the header file <code>entry_point_name_data.h</code> . The external code must define a valid pointer variable.

Storage classes have these requirements and limitations:

- Assign the storage class to a global variable in a function that declares the global variable. You do not have to assign the storage class in more than one function.
- After you assign a storage class to a global variable, you cannot assign a different storage class to that global variable.
- You cannot assign a storage class to a constant global variable.
- A global variable with an `ExportedDefine` storage class must be a scalar but not a complex or multi-word scalar. The global variable must only be read and not written to in the code.

If you do not assign a storage class to a global variable, except for the declaration location, the variable behaves like it has an `'ExportedGlobal'` storage class. For an `'ExportedGlobal'` storage class, the global variable is declared in the file `entry_point_name.h`. When the global variable does not have a storage class, the variable is declared in the file `entry_point_name_data.h`.

## Control Declarations and Definitions of Global Variables in Code Generated from MATLAB Code

This example uses storage classes to control the declarations and definitions of global variables in C/C++ code generated from MATLAB code. Using storage classes helps you to interface generated code with external code.

This example requires an Embedded Coder license.

Write a function `addglobals` that adds four global variables. Declare the global variables in the function.

```
function y = addglobals
% Define the global variables.
global u;
global v;
global x;
global z;
% Assign the storage classes.
coder.storageClass('u','ExportedGlobal');
coder.storageClass('v','ImportedExtern');
coder.storageClass('x','ImportedExternPointer');
coder.storageClass('z','ExportedDefine');
y = u + v + x + z;
end
```

Create a file `c:\myfiles\myfile.c` that defines and initializes the imported global variables `u` and `v`.

```
#include <stdio.h>
/* Variable definitions for imported variables */
double v = 1.0;
double *x = &v;
```

Create a code configuration object. Configure the code generation parameters to include `myfile.c`. For output type `'lib'`, or if you generate source code only, you can generate code without providing this file. Otherwise, you must provide this file.

```
cfg = coder.config('dll','ecoder', true);
cfg.CustomSource = 'myfile.c';
cfg.CustomInclude = 'c:\myfiles';
```

Generate the code. This example uses the `-globals` argument to specify the types and initial values of the global variables `u`, `v`, `x`, and `z`. Alternatively, you can define global variables in the MATLAB global workspace. For the imported global variables `v` and `x`, the code generator uses the initial values only to determine the type.

```
codegen -config cfg -globals {'u', 1, 'v', 2, 'x', 3, 'z', 4} addglobals -report
```

From the initial values 1, 2, 3, and 4 `codegen` determines that `u`, `v`, `x` and `z` have type `double`. `codegen` defines and declares the exported global variables `u` and `z`. It generates code that initializes `u` to 1.0 and `z` to 4.0. `codegen` declares the imported global variables `v` and `x`. It does not define these variables or generate code that initializes them. `myfile.c` provides the code that defines and initializes `v` and `x`.

To view the code generated for the global variables, open the report. Click the [View report link](#).

View the definition for the exported global `z` in the `Exported data define` section in `addglobals.h`.

```
/* Definition for custom storage class: ExportedDefine */
#define z 4.0
```

View the definition and declaration for the exported global `u`.

- `u` is defined in the `Variable Definitions` section in `addglobals.c`.

```
/* Variable Definitions */
/* Definition for custom storage class: ExportedGlobal */
double u;
```

- `u` is declared as `extern` in the `Variable Declarations` section in `addglobals.h`.

```
/* Variable Declarations */
/* Declaration for custom storage class: ExportedGlobal */
extern double u;
```

- `u` is initialized in `addglobals_initialize.c`.

```
/* Include Files */
#include "rt_nonfinite.h"
#include "addglobals.h"
```

```
#include "addglobals_initialize.h"

/* Named Constants */
#define b_u (1.0)

/* Function Definitions */

/*
 * Arguments : void
 * Return Type : void
 */
void addglobals_initialize(void)
{
 rt_InitInfAndNaN(8U);
 u = b_u;
}
```

View the definition and declaration for the imported external global `v` and the imported external global pointer `x`.

`v` and `x` are declared as `extern` in the **Variable Declarations** section in `addglobals_data.h`.

```
/* Variable Declarations */
/* Declaration for custom storage class: ImportedExtern */
extern double v;

/* Declaration for custom storage class: ImportedExternPointer */
extern double *x;
```

- “Find Potential Data Type Issues in Generated Code” on page 80-5
- “PIL Execution with ARM Cortex-A at the Command Line” on page 80-13
- “PIL Execution with ARM Cortex-A by Using the MATLAB Coder App” on page 80-15

## Highlight Potential Data Type Issues in a Report

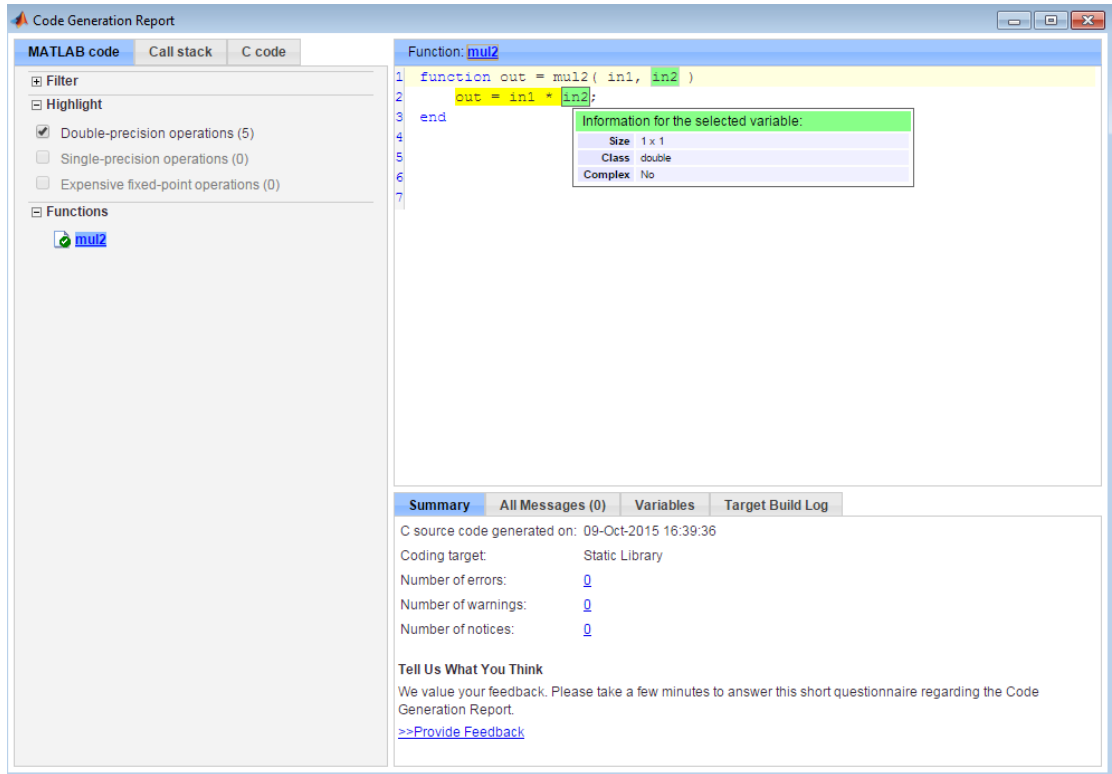

In this section...
“Enable Highlight Option Using the MATLAB Coder App” on page 80-3
“Enable Highlight Option Using the Command Line Interface” on page 80-4

If you have an Embedded Coder license, you have the option to highlight potential data types issues in the code generation report for standalone code generated from MATLAB code. If you enable this option, the **Highlight** section on the **MATLAB code** tab lists the number of single-precision and double-precision operations in the generated C/C++ code. If you have a Fixed-Point Designer license, it also lists the number of expensive fixed-point operations.

To highlight the MATLAB code that corresponds to the potential data type issues:

- 1 Select the check box for the type of operation that you want to highlight.
- 2 Select the function that you want to highlight.

The report highlights the operations in the selected function. The following example report highlights MATLAB code that results in double-precision operations in the generated code.

The option to highlight potential data type issues is disabled by default.

## Enable Highlight Option Using the MATLAB Coder App

- 1 On the **Generate Code** page, to open the **Generate** dialog box, click the **Generate** arrow .
- 2 Set **Build type** to one of the following:
  - Source Code
  - Static Library (.lib)
  - Dynamic Library (.dll)
  - Executable (.exe)

- 3 Click **More Settings**.
- 4 On the **Debugging** tab, select the **Always create a code generation report** and **Highlight potential data type issues** check boxes.

## Enable Highlight Option Using the Command Line Interface

- 1 Create an embedded code configuration object for 'lib', 'dll', or 'exe':

```
cfg = coder.config('lib','ecoder',true); % or dll or exe
```

- 2 Set the `GenerateReport` and `HighlightPotentialDataTypeIssues` configuration object properties to `true`:

```
cfg.GenerateReport = true;
cfg.HighlightPotentialDataTypeIssues = true;
```

### Data Type Issues Overview

When you generate C code from MATLAB code, you can highlight potential data type issues in the C code generation report. The report highlights MATLAB code that requires single-precision, double-precision, or expensive fixed-point operations. The expensive fixed-point operations checks require a Fixed-Point Designer license.

- The double-precision check highlights expressions that result in a double-precision operation. When trying to achieve a strict-single or fixed-point design, manual inspection of code can be time-consuming and error prone.

For a strict-single precision design, specify a standard math library that supports single-precision implementations. To change the library for a project, during the Generate Code step, in the project settings dialog box, on the **Custom Code** tab, set the **Standard math library** to **C99 (ISO)**.

- The single-precision check highlights expressions that result in a single operation.
- The expensive fixed-point operations check identifies optimization opportunities for fixed-point code. It highlights expressions in the MATLAB code that require cumbersome multiplication or division, expensive rounding, expensive comparison, or multiword operations. For more information on optimizing generated fixed-point code, see “Tips for Making Generated Code More Efficient”.

### Enable Highlighting of Potential Data Type Issues

**Procedure 80.1. Enable the highlight option using the MATLAB Coder app**

- 1 On the **Generate Code** page, to open the **Generate** dialog box, click the **Generate** arrow .
- 2 Set **Build type** to one of the following:
  - Source Code
  - Static Library (.lib)
  - Dynamic Library (.dll)
  - Executable (.exe)
- 3 Click **More Settings**.
- 4 On the **Debugging** tab, select the **Always create a code generation report** and **Highlight potential data type issues** check boxes.

#### Procedure 80.2. Enable the highlight option using the command-line interface

- 1 Create an embedded code configuration object for 'lib', 'dll', or 'exe':

```
cfg = coder.config('lib','ecoder',true); % or dll or exe
```
- 2 Set the `GenerateReport` and `HighlightPotentialDataTypeIssues` configuration object properties to true:

```
cfg.GenerateReport = true;
cfg.HighlightPotentialDataTypeIssues = true;
```

## Find and Address Cumbersome Operations

Cumbersome operations usually occur due to an insufficient range of output. Avoid inputs to a multiply or divide operation that have word lengths larger than the base integer type of your processor. Software can process operations with larger word lengths, but this approach requires more code and runs slower.

This example requires Embedded Coder and Fixed-Point Designer licenses to run. The target word length for the processor in this example is 64.

- 1 Create the function `myMul`.

```
function out = myMul(in1, in2)
 out = fi(in1*in2, 1, 64, 0);
end
```
- 2 Generate code for `myMul`.

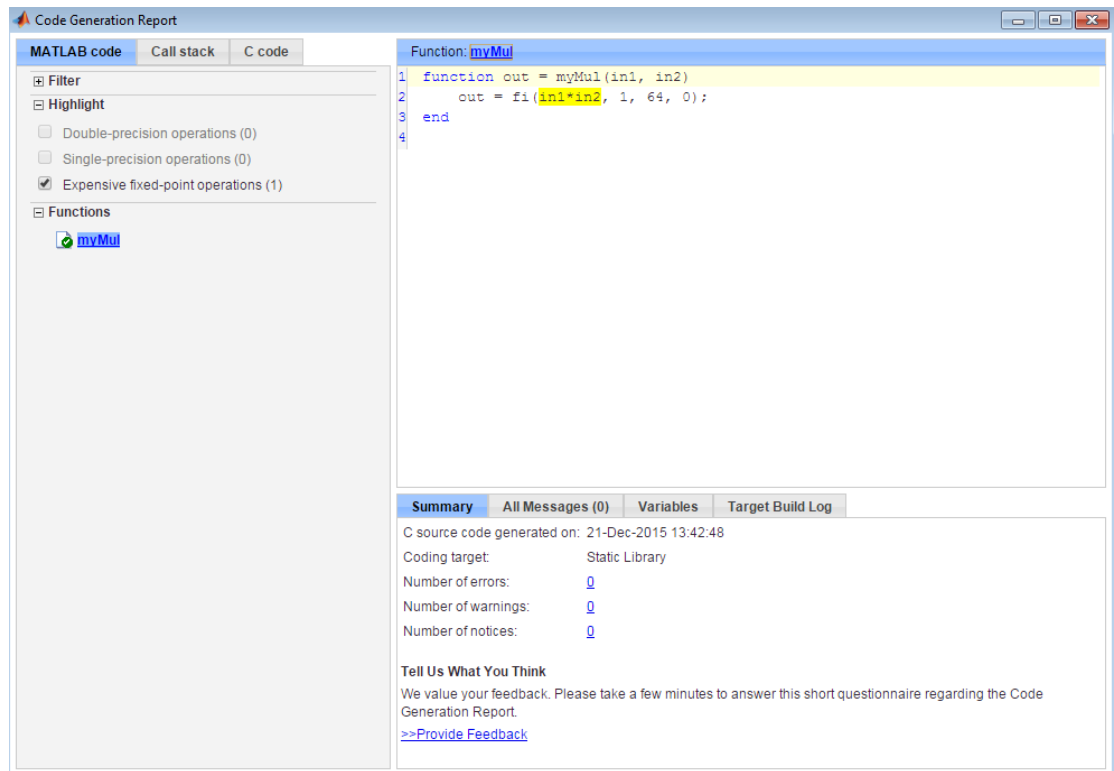

```
cfg = coder.config('lib');
```

```

cfg.GenerateReport = true;
cfg.HighlightPotentialDataTypeIssues = true;
fm = fimath('ProductMode', 'SpecifyPrecision', 'ProductWordLength', 64);
codegen -config cfg myMul -args {fi(1, 1, 64, 4, fm), fi(1, 1, 64, 4, fm)}

```

- 3 Click **View report**.
- 4 In the Code Generation Report, on the left pane, click the **MATLAB code** tab.
- 5 Expand the **Highlight** section and select the **Expensive fixed-point operations** check box.

To resolve this issue, modify the data types of `in1` and `in2` so that the word length of the product does not exceed the target word length of 64.

## Find and Address Expensive Rounding

Traditional handwritten code, especially for control applications, almost always uses "no effort" rounding. For example, for unsigned integers and two's complement signed integers, shifting right and dropping the bits is equivalent to rounding to floor. To get results comparable to, or better than, what you expect from traditional handwritten code, use the `floor` rounding method.

This example requires Embedded Coder and Fixed-Point Designer licenses to run.

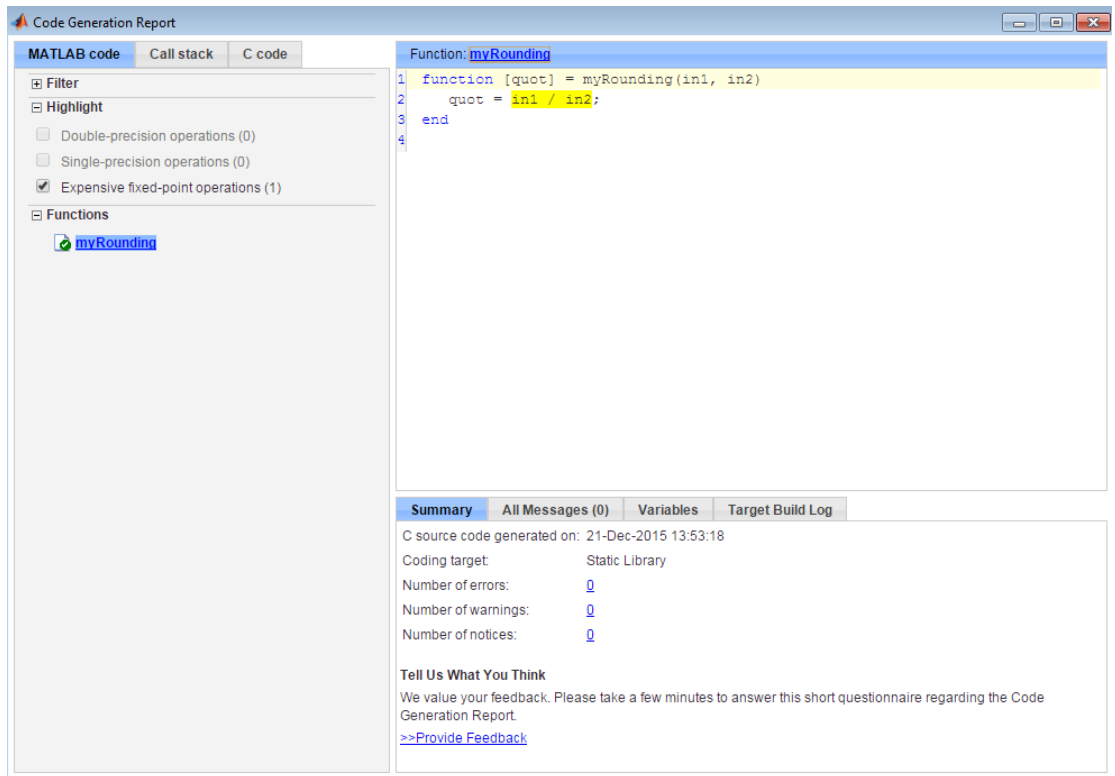

- 1 Create the function `myRounding`.

```
function [quot] = myRounding(in1, in2)
 quot = in1 / in2;
end
```

- 2 Generate code for `myRounding`.

```
cfg = coder.config('lib');
cfg.GenerateReport = true;
cfg.HighlightPotentialDataTypeIssues = true;
codegen -config cfg myRounding -args {fi(1, 1, 16, 2), fi(1, 1, 16, 4)}
```

- 3 Click **View report**.
- 4 In the Code Generation Report, on the left pane, click the **MATLAB code** tab.
- 5 Expand the **Highlight** section and select the **Expensive fixed-point operations** check box.

This division operation uses the default rounding method, `nearest`. Changing the rounding method to `FLOOR` provides a more efficient implementation.

## Find and Address Expensive Comparison Operations

Comparison operations generate extra code when a casting operation is required to do the comparison. For example, before comparing an unsigned integer to a signed integer, one of the inputs must be cast to the signedness of the other. Consider optimizing the data types of the input arguments so that a cast is not required in the generated code.

This example requires Embedded Coder and Fixed-Point Designer licenses to run.

- 1 Create the function `myRelop`.

```
function out = myRelop(in1, in2)
 out = in1 > in2;
end
```

- 2 Generate code for myRelop.

```
cfg = coder.config('lib');
cfg.GenerateReport = true;
cfg.HighlightPotentialDataTypeIssues = true;
codegen -config cfg myRelop -args {fi(1, 1, 14, 3, 1), fi(1, 0, 14, 3, 1)}
```

- 3 Click **View report**.
- 4 In the Code Generation Report, on the left pane, click the **MATLAB code** tab.
- 5 Expand the **Highlight** section and select the **Expensive fixed-point operations** check box.

The screenshot shows the 'Code Generation Report' window with the 'MATLAB code' tab selected. The left pane shows the 'Filter' section with 'Expensive fixed-point operations (1)' checked. The main pane displays the MATLAB code for the 'myRelop' function, with the line 'out = in1 > in2;' highlighted in yellow. The bottom pane shows a 'Summary' section with the following information:

Summary	All Messages (0)	Variables	Target Build Log
C source code generated on: 21-Dec-2015 13:56:30			
Coding target:	Static Library		
Number of errors:	<a href="#">0</a>		
Number of warnings:	<a href="#">0</a>		
Number of notices:	<a href="#">0</a>		

Below the summary, there is a section titled 'Tell Us What You Think' with the text: 'We value your feedback. Please take a few minutes to answer this short questionnaire regarding the Code Generation Report.' and a link: '>>Provide Feedback'.

The first input argument, `in1`, is signed, while `in2` is unsigned. Extra code is generated because a cast must occur before the two inputs can be compared.

Change the signedness and scaling of one of the inputs to generate more efficient code.

## Find and Address Multiword Operations

Multiword operations can be inefficient on hardware. When an operation has an input or output data type larger than the largest word size of your processor, the generated code contains multiword operations. You can avoid multiword operations in the generated code by specifying local `fimath` properties for variables. You can also manually specify input and output word lengths of operations that generate multiword code.

This example requires Embedded Coder and Fixed-Point Designer licenses to run. The target word length is 64 in this example.

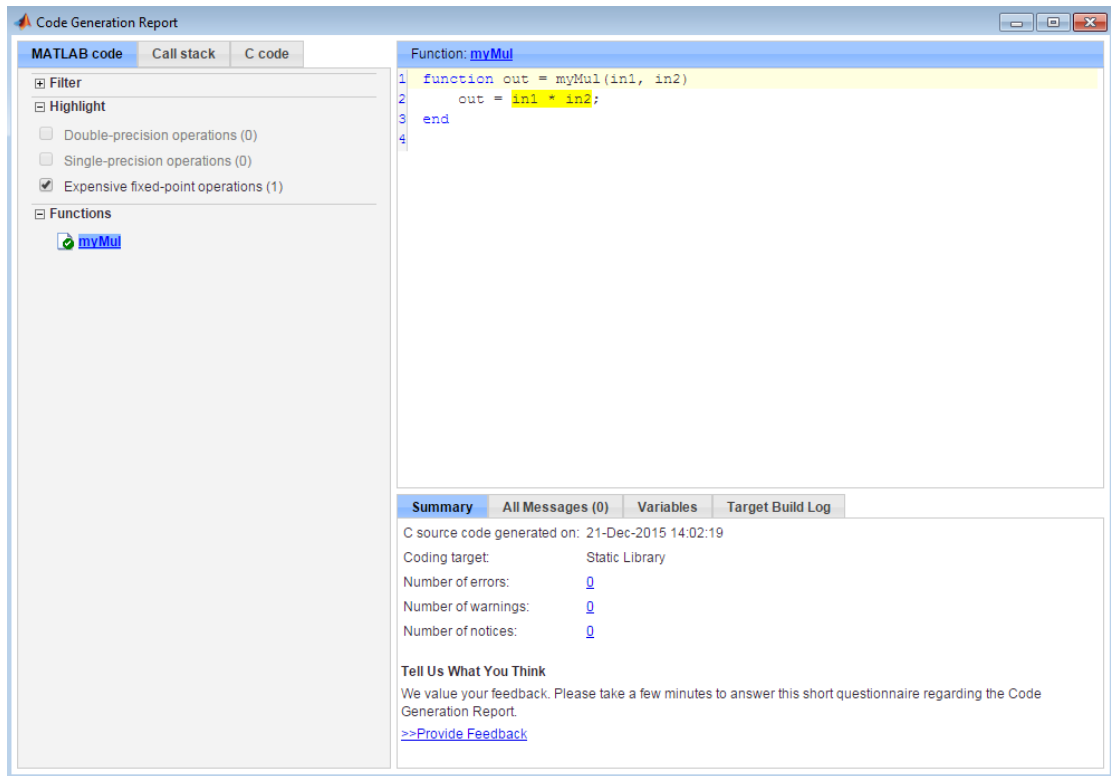

- 1 Create the function `myMul`.

```
function out = myMul(in1, in2)
 out = in1 * in2;
end
```

- 2 Generate code for `myMul`.

```
cfg = coder.config('lib');
cfg.GenerateReport = true;
cfg.HighlightPotentialDataTypeIssues = true;
codegen -config cfg myMul -args {fi(1, 1, 33, 4), fi(1, 1, 32, 4)}
```

- 3 Click **View report**.
- 4 In the Code Generation Report, on the left pane, click the **MATLAB code** tab.
- 5 Expand the **Highlight** section and select the **Expensive fixed-point operations** check box.

The `in1 * in2` operation is highlighted in the HTML report. On the bottom pane, click the **Variables** tab. The word length of `in1` is 33 bits, and the word length of `in2` is 32 bits. Hovering over the highlighted expression reveals that the product has a word length of 65, which is larger than the target word length of 64. Therefore, the software detects a multiword operation.

To resolve this issue, modify the data types of `in1` and `in2` so the word length of the product does not exceed the target word length, or specify the `ProductMode` property of the local `fimath` object.

## PIL Execution with ARM Cortex-A at the Command Line

This example shows how to set up a PIL execution to verify generated code at the command line.

You can use processor-in-the-loop (PIL) executions to verify generated code that you deploy to target hardware by using a MATLAB Coder procedure. You can profile algorithm performance and speed for your generated code. To verify generated code with the MATLAB Coder app, you must have an Embedded Coder license.

This PIL execution is available with these hardware support packages. To use the PIL execution, install one of these support packages.

- Embedded Coder Support Package for BeagleBone Black Hardware
- Embedded Coder Support Package for ARM Cortex-A Processors

In the Command Window, select the hardware for PIL execution.

```
hw = coder.hardware('ARM Cortex-A9 (QEMU)')
```

```
hw =
```

```
Hardware with properties:
```

```
 Name: 'ARM Cortex-A9 (QEMU)'
 CPUClockRate: 1000
```

When using the BeagleBone hardware, more hardware properties are supported (Username, Password, and DeviceAddress). Set these properties based on your specific hardware or application.

```
hw = coder.hardware('BeagleBone Black')
```

```
hw =
```

```
Hardware with properties:
```

```
 Name: 'BeagleBone Black'
 CPUClockRate: 1000
 Password: 'root'
 Username: 'admin'
 DeviceAddress: '192.168.1.10'
```

Add the hardware to the MATLAB Coder configuration object.

```
cfg = coder.config('lib','ecoder',true);
cfg.VerificationMode = 'PIL';
cfg.Hardware = hw;
```

Generate PIL code for a function, `computeFFT`.

```
codegen -config cfg computeFFT -args {zeros(1,16)}
```

For another example of PIL verification, see the "Processor-in-the-Loop Verification of MATLAB Functions" page in the documentation of the Embedded Coder Support Package for ARM Cortex-A Processors. Install the support package to view the documentation.

## PIL Execution with ARM Cortex-A by Using the MATLAB Coder App

You can use processor-in-the-loop (PIL) executions to verify generated code that you deploy to target hardware by using a MATLAB Coder procedure. You can profile algorithm performance and speed for your generated code. To verify generated code with the MATLAB Coder app, you must have an Embedded Coder license.

This PIL execution is available with these hardware support packages. To use the PIL execution, install one of these support packages.

- Embedded Coder Support Package for BeagleBone Black Hardware
- Embedded Coder Support Package for ARM Cortex-A Processors

You can set up PIL execution with the MATLAB Coder app.

To configure the build type and hardware board:

- 1** On the **Generate Code** page, in the **Generate** dialog box:
  - Set the **Build type** to **Static Library** or **Dynamic Library**.
  - Clear the **Generate code only** check box.
  - Set the **Hardware Board** to **BeagleBone Black** or **ARM Cortex-A9 (QEMU)**.
- 2** If necessary, modify the settings for your board. To modify the settings, click **More Settings**, and then click **Hardware**.
- 3** To generate the library, click **Generate**.
- 4** Set up your PIL execution. Click **Verify Code** to open the **Verify Code** dialog box.

Because the hardware board is not MATLAB Host Computer, the **Verify Code** dialog box is configured for PIL execution.

In the **Verify Code** dialog box:

- Enter the name of the test file to use for PIL execution.
  - Select **Generated code**.
- 5** To start the PIL execution, click **Run Generated Code**.
  - 6** To stop the PIL execution, click **Stop**.

For another example of PIL verification, see the "Processor-in-the-Loop Verification of MATLAB Functions" page in the documentation of the Embedded Coder Support Package for ARM Cortex-A Processors. Install the support package to view the documentation.
