The accelerator mode works with any model, but performance decreases if a model contains blocks that do not support acceleration. The accelerator mode supports the Simulink debugger and profiler. These tools help with debugging and determining relative performance of various parts of your model. For more information, see “Run Accelerator Mode with the Simulink Debugger” on page 32-33 and “How Profiler Captures Performance Data” on page 28-5.

The rapid accelerator mode works with only those models containing blocks that support code generation of a standalone executable. For this reason, rapid accelerator mode does not support the debugger or profiler. However, this mode generally results in faster execution than the accelerator mode. When used with dual-core processors, the rapid accelerator mode runs Simulink and the MATLAB technical computing environment from one core while the rapid accelerator target runs as a separate process on a second core.

For more information about the performance characteristics of the Accelerator and rapid accelerator modes, and how to measure the difference in performance, see “Comparing Performance” on page 32-35.

To optimize your model and achieve faster simulation automatically using Performance Advisor, see “Automated Performance Optimization”.

To employ modeling techniques that help achieve faster simulation, see “Manual Performance Optimization”.

How Acceleration Modes Work

In this section...
“Overview” on page 32-4
“Normal Mode” on page 32-4
“Accelerator Mode” on page 32-5
“Rapid Accelerator Mode” on page 32-7

Overview

The Accelerator and rapid accelerator modes use portions of the Simulink Coder product to create an executable.

The Accelerator and rapid accelerator modes replace the interpreted code normally used in Simulink simulations, shortening model run time.

Although the acceleration modes use some Simulink Coder code generation technology, you do not need the Simulink Coder software installed to accelerate your model.

Note: The code generated by the accelerator and rapid accelerator modes is suitable only for speeding the simulation of your model. Use Simulink Coder to generate code for other purposes.

Normal Mode

In normal mode, the MATLAB technical computing environment is the foundation on which the Simulink software is built. Simulink controls the solver and model methods used during simulation. Model methods on page 3-16 include such things as computation of model outputs. Normal mode runs in one process.

One Process

Accelerator Mode

By default, the accelerator mode uses Just-in-Time (JIT) acceleration to generate an execution engine in memory instead of generating C code or MEX files. You can also have your model fall back to the classic accelerator mode, in which Simulink generates and links code into a C-MEX S-function.

In the accelerator mode, the model methods are separate from the Simulink software and are part of the *acceleration target code*, which is used in later simulations.

Simulink checks that the acceleration target code is up to date before reusing it. For more information, see “Code Regeneration in Accelerated Models” on page 32-9.

There are two modes of operation in accelerator mode.

Just-In-Time Accelerator Mode

In this default mode, Simulink generates an execution engine in memory for the top-level model only and not for referenced models. As a result, a C compiler is not required during simulation.

Because the acceleration target code is in memory, it is available for reuse as long as the model is open. Simulink also serializes the acceleration target code so that the model does not need rebuilding when it is opened.

Classic Accelerator Mode

If you want to simulate your model using the classic, C-code generating, accelerator mode, run the following command:

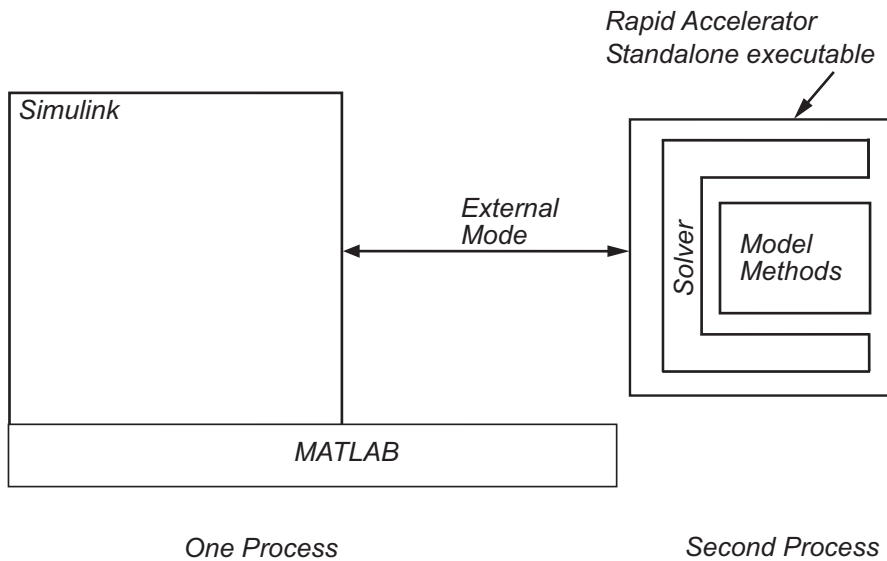

```
set_param(0, 'GlobalUseClassicAccelMode', 'on');
```

In this mode, Simulink generates and links code into a shared library, which communicates with the Simulink software. The target code executes in the same process as MATLAB and Simulink.

Rapid Accelerator Mode

The rapid accelerator mode creates a *Rapid Accelerator standalone executable* from your model. This executable includes the solver and model methods, but it resides outside of MATLAB and Simulink. It uses external mode (see “External Mode Communication”) to communicate with Simulink.

MATLAB and Simulink run in one process, and if a second processing core is available, the standalone executable runs there.

Code Regeneration in Accelerated Models

In this section...

“Determine If the Simulation Will Rebuild” on page 32-9

“Parameter Tuning in Rapid Accelerator Mode” on page 32-9

Changing the structure of your model causes the Rapid Accelerator mode to regenerate the standalone executable, and for the Accelerator mode to regenerate the target code and update (overwrite) the existing MEX-file. Changing the value of a tunable parameter does not trigger a rebuild.

Determine If the Simulation Will Rebuild

The Accelerator and Rapid Accelerator modes use a checksum to determine if the model has changed, indicating that the code should be regenerated. The checksum is an array of four integers computed using an MD5 checksum algorithm based on attributes of the model and the blocks it contains.

- 1 Use the `Simulink.BlockDiagram.getChecksum` command to obtain the checksum for your model. For example:

```
cs1 = Simulink.BlockDiagram.getChecksum('myModel');
```
- 2 Obtain a second checksum after you have altered your model. The code regenerates if the new checksum does not match the previous checksum.
- 3 Use the information in the checksum to determine why the simulation target rebuilt.

For a detailed explanation of this procedure, see the example model `slAcce1DemoWhyRebuild`.

Parameter Tuning in Rapid Accelerator Mode

In model rebuilds, Rapid Accelerator Mode handles block diagram and runtime parameters differently from other parameters.

Tuning Block Diagram Parameters

You can change some block diagram parameters during simulation without causing a rebuild. Tune these parameters using the `set_param` command or using the **Model Configuration Parameters** dialog box. These block diagram parameters include:

Solver Parameters		
AbsTol	MaxNumMinSteps	RelTol
ConsecutiveZCsStepRelTol	MaxOrder	StartTime
ExtrapolationOrder	MaxStep	StopTime
InitialStep	MinStep	ZCDetectionTol
MaxConsecutiveMinStep	OutputTimes	
MaxConsecutiveZCs	Refine	

Loading and Logging Parameters		
ConsistencyChecking	MinStepSizeMsg	SaveTime
Decimation	OutputOption	StateSaveName
FinalStateName	OutputSaveName	TimeSaveName
LimitDataPoints	SaveFinalState	
LoadExternalInput	SaveFormat	
MaxConsecutiveZCsMsg	SaveOutput	
MaxDataPoints	SaveState	

Tuning Runtime Parameters

To tune runtime parameters for maximum acceleration in Rapid Accelerator mode, follow this procedure which yields better results than using `set_param` for the same purpose:

- 1 Collect the runtime parameters in a runtime parameter structure while building a rapid accelerator target executable using the `Simulink.BlockDiagram.buildRapidAcceleratorTarget` function.
- 2 To change the parameters, use the `Simulink.BlockDiagram.modifyTunableParameters` function.
- 3 To specify the modified parameters to the `sim` command, use the `RapidAcceleratorParameterSets` and `RapidAcceleratorUpToDateCheck` parameters.

For more information, see “sim in parfor with Rapid Accelerator Mode” on page 24-21.

All other parameter changes can necessitate a rebuild of the model.

Parameter Changes:	Passed Directly to <code>sim</code> command	Passed Graphically via Block Diagram or via <code>set_param</code> command
Runtime	Does not require rebuild	Can require rebuild
Block diagram (logging parameters)	Does not require rebuild	Does not require rebuild

Choosing a Simulation Mode

In this section...

“Simulation Mode Tradeoffs” on page 32-12

“Comparing Modes” on page 32-13

“Decision Tree” on page 32-15

Simulation Mode Tradeoffs

In general, you must trade off simulation speed against flexibility when choosing either Accelerator mode or Rapid Accelerator mode instead of Normal mode.

Normal mode offers the greatest flexibility for making model adjustments and displaying results, but it runs the slowest.

Accelerator mode lies between Normal and Rapid Accelerator modes in performance and in interaction with your model. If your model has 3-D signals, use Normal or Accelerator mode. Accelerator mode does not support runtime diagnostics.

Rapid Accelerator mode runs the fastest, but this mode does not support the debugger or profiler, and works only with those models for which C code is available for all of the blocks in the model. In addition, Rapid Accelerator mode does not support 3-D parameters and sinks.

Note: An exception to this rule occurs when you run multiple simulations, each of which executes in less than one second in Normal mode. For example:

```
for i=1:100
sim(model); % executes in less than one second in Normal mode
end
```

For this set of conditions, you will typically obtain the best performance by simulating the model in Normal mode.

Tip To gain additional flexibility, consider using model referencing to componentize your model. If the top-level model uses Normal mode, then you can simulate a referenced model in a different simulation mode than you use for other portions of a model. During the model development process, you can choose different simulation modes for different portions of a model. For details, see “Simulate Model Referencing Models” on page 8-31.

Comparing Modes

The following table compares the characteristics of Normal mode, Accelerator mode, and Rapid Accelerator mode.

If you want to...	Then use this mode...		
	Normal	Accelerator	Rapid Accelerator
Performance			
Run your model in a separate address space			✓

If you want to...	Then use this mode...		
	Normal	Accelerator	Rapid Accelerator
Efficiently run batch and Monte Carlo simulations			✓
Model Adjustment			
Change model parameters such as solver, stop time without rebuilding	✓	✓	✓
Change block tunable parameters such as gain	✓	✓	✓
For more information on configuration set parameters which can be modified without requiring rebuild, see “Code Regeneration in Accelerated Models” on page 32-9			
Model Requirement			
Accelerate your model even if C code is not used for all blocks		✓	
Support Interpreted MATLAB Function blocks	✓	✓	
Support Non-Inlined MATLAB language or Fortran S-Functions	✓	✓	
Permit algebraic loops in your model	✓	✓	
Have your model work with the debugger or profiler	✓	✓	
Have your model include C++ code	✓	✓	
Data Display			
Use scopes and signal viewers	✓	✓	See “Behavior of Scopes and Viewers with Rapid Accelerator Mode” on page 32-20
Use scopes and signal viewers when running your model from the command line	✓	✓	

Note: Scopes and viewers do not update if you run your model from the command line in Rapid Accelerator mode.

Decision Tree

Use this decision tree to select between Normal, Accelerator, or Rapid Accelerator modes.

See “Comparing Performance” on page 32-35 to understand how effective the accelerator modes will be in improving the performance of your model.

“Accelerator and Rapid Accelerator Mode Data Type Considerations” on page 32-20

“Behavior of Scopes and Viewers with Rapid Accelerator Mode” on page 32-20

“Factors Inhibiting Acceleration” on page 32-21

Select Blocks for Accelerator Mode

The Accelerator simulation mode runs the following blocks as if you were running Normal mode because these blocks do not generate code for the accelerator build. Consequently, if your model contains a high percentage of these blocks, the Accelerator mode may not increase performance significantly. All of these Simulink blocks use interpreted code.

- Display
- From File
- From Workspace
- Inport (root level only)
- Interpreted MATLAB Function
- Outport (root level only)
- Scope
- To File
- To Workspace
- XY Graph

Note: In some instances, Normal mode output might not precisely match the output from Accelerator mode because of slight differences in the numerical precision between the interpreted and compiled versions of a model.

The following blocks can cause poor simulation runtime performance when run in the default JIT Accelerator mode.

- Transport Delay
- Variable Transport Delay

Select Blocks for Rapid Accelerator Mode

Blocks that do not support code generation (such as SimEvents) or blocks that generate code only for a specific target cannot be simulated in Rapid Accelerator mode.

Additionally, Rapid Accelerator mode does not work if your model contains any of the following blocks:

- Interpreted MATLAB Function
- Device driver S-functions, such as blocks from the Simulink Real-Time product, or those targeting Freescale™ MPC555

Note: In some instances, Normal mode output might not precisely match the output from Rapid Accelerator mode because of slight differences in the numerical precision between the interpreted and compiled versions of a model.

Control S-Function Execution

Note: In the default JIT Accelerator mode, inlining of user-written TLC S-Functions is not supported. If you run a model containing TLC S-Functions in the JIT Accelerator mode, there is a possibility of the execution speed reducing. The code generation speed, however, will be high due to JIT acceleration.

Inlining S-functions using the Target Language Compiler increases performance with the classic Accelerator mode by eliminating unnecessary calls to the Simulink API. By default, however, the classic Accelerator mode ignores an inlining TLC file for an S-function, even though the file exists. The Rapid Accelerator mode always uses the TLC file if one is available.

A device driver S-Function block written to access specific hardware registers on an I/O board is one example of why this behavior was chosen as the default. Because the

Simulink software runs on the host system rather than the target, it cannot access the targets I/O registers and so would fail when attempting to do so.

To direct the classic Accelerator mode to use the TLC file instead of the S-function MEX-file, specify `SS_OPTION_USE_TLC_WITH_ACCELERATOR` in the `mdlInitializeSizes` function of the S-function, as in this example:

```
static void mdlInitializeSizes(SimStruct *S)
{
/* Code deleted */
ssSetOptions(S, SS_OPTION_USE_TLC_WITH_ACCELERATOR);
}
```

Accelerator and Rapid Accelerator Mode Data Type Considerations

- Accelerator mode supports fixed-point signals and vectors up to 128 bits.
- Rapid Accelerator mode does not support fixed-point signals or vectors greater than 32 bits.
- Rapid Accelerator mode supports fixed-point parameters up to 128 bits.
- Rapid Accelerator mode supports fixed-point root inputs up to 32 bits
- Rapid Accelerator mode supports root inputs of Enumerated data type
- Rapid Accelerator mode does not support fixed-point data for the From Workspace block.
- Rapid Accelerator mode ignores the selection of the **Log fixed-point data as a fi object** (FixptAsFi) check box for the To Workspace block.
- Rapid Accelerator mode supports bus objects as parameters.
- The Accelerator mode and Rapid Accelerator mode store integers as compactly as possible.
- Fixed-Point Designer does not collect min, max, or overflow data in the Accelerator or Rapid Accelerator modes.
- Accelerator mode does not support runtime diagnostics.

Behavior of Scopes and Viewers with Rapid Accelerator Mode

Running the simulation from the command line or the menu determines the behavior of scopes and viewers in Rapid Accelerator mode.

Scope or Viewer Type	Simulation Run from Menu	Simulation Run from Command Line
Simulink Scope blocks	Same support as Normal mode	<ul style="list-style-type: none"> Logging is supported Scope window is not updated
Simulink signal viewer scopes	Graphics are updated, but logging is not supported	Not supported
Other signal viewer scopes	Support limited to that available in External mode	Not supported
Signal logging	Supported, with limitations listed in “Signal Logging in Rapid Accelerator Mode” on page 59-58	Supported, with limitations listed in “Signal Logging in Rapid Accelerator Mode” on page 59-58.
Multirate signal viewers	Not supported	Not supported
Stateflow Chart blocks	Same support for chart animation as Normal mode	Not supported

Rapid Accelerator mode does not support multirate signal viewers such as the DSP System Toolbox spectrum scope or the Communications System Toolbox™ scatterplot, signal trajectory, or eye diagram scopes.

Note: Although scopes and viewers do not update when you run Rapid Accelerator mode from the command line, they do update when you use the menu. “Run Acceleration Mode from the User Interface” on page 32-25 shows how to run Rapid Accelerator mode from the menu. “Interact with the Acceleration Modes Programmatically” on page 32-29 shows how to run the simulation from the command line.

Factors Inhibiting Acceleration

- You cannot use the Accelerator or Rapid Accelerator mode if your model:
 - Passes array parameters to MATLAB S-functions that are not numeric, logical, or character arrays, are sparse arrays, or that have more than two dimensions.
 - Uses Fcn blocks containing trigonometric functions having complex inputs.

- In some cases, changes associated with external or custom code do not cause Accelerator or Rapid Accelerator simulation results to change. These include:
 - TLC code
 - S-function source code, including `rtwmakecfg.m` files
 - Integrated custom code
 - S-Function Builder

In such cases, consider force regeneration of code for a top model. Alternatively, you can force regeneration of top model code by deleting code generation folders, such as `slprj` or the generated model code folder.

Note: With JIT acceleration, the acceleration target code is in memory. It is therefore available for reuse as long as the model is open, even if you delete the `slprj` folder.

Rapid Accelerator Mode Limitations

- Rapid Accelerator mode does not support:
 - Algebraic loops.
 - Targets written in C++.
 - Interpreted MATLAB Function blocks.
 - Noninlined MATLAB language or Fortran S-functions. You must write S-functions in C or inline them using the Target Language Compiler (TLC). For more information, see “Write Fully Inlined S-Functions”.
 - 3-D signals.
 - Debugger or Profiler.
 - Run time objects for `Simulink.RunTimeBlock` and `Simulink.BlockCompOutputPortData` blocks.
- Model parameters must be one of these data types:
 - `boolean`
 - `uint8` or `int8`
 - `uint16` or `int16`
 - `uint32` or `int32`
 - `single` or `double`

- Fixed-point
- Enumerated
- You cannot pause a simulation in Rapid Accelerator mode.
- For models that contain S-functions, ensure that the source files (.h, .c, and .cpp) for the S-function are in the same folder as the S-function MEX-file. See [Implicit Build Support](#) for more information. You can include additional files to an S-function or bypass the path limitation by using the `rtwmakecfg.m` file. For more information, see [Use rtwmakecfg.m API to Customize Generated Makefiles](#).
- If a Rapid Accelerator build includes referenced models (by using Model blocks), set up these models to use fixed-step solvers to generate code for them. The top model, however, can use a variable-step solver as long as the blocks in the referenced models are discrete.
- In certain cases, changing block parameters can result in structural changes to your model that change the model checksum. An example of such a change is changing the number of delays in a DSP simulation. In these cases, you must regenerate the code for the model. See “Code Regeneration in Accelerated Models” on page 32-9 for more information.
- For root inports, Rapid Accelerator mode supports only base as the `Srcworkspace`.
- For root inports, when you specify the minimum and maximum values that the block should output, Rapid Accelerator mode does not recognize these limits during simulation.
- In Rapid Accelerator mode, To File or To Workspace blocks inside function-call subsystems do not generate any logging files if the function-call port is grounded or unconnected.

Reserved Keywords

Certain words are reserved for use by the Simulink Coder code language and by Accelerator mode and Rapid Accelerator mode. These keywords must not appear as function or variable names on a subsystem, or as exported global signal names. Using the reserved keywords results in the Simulink software reporting an error, and the model cannot be compiled or run.

The keywords reserved for the Simulink Coder product are listed in “Construction of Generated Identifiers”. Additional keywords that apply only to the Accelerator and Rapid accelerator modes are:

`muDoubleScalarAbs`

`muDoubleScalarCos`

`muDoubleScalarMod`

<code>muDoubleScalarAcos</code>	<code>muDoubleScalarCosh</code>	<code>muDoubleScalarPower</code>
<code>muDoubleScalarAcosh</code>	<code>muDoubleScalarExp</code>	<code>muDoubleScalarRound</code>
<code>muDoubleScalarAsin</code>	<code>muDoubleScalarFloor</code>	<code>muDoubleScalarSign</code>
<code>muDoubleScalarAsinh</code>	<code>muDoubleScalarHypot</code>	<code>muDoubleScalarSin</code>
<code>muDoubleScalarAtan,</code>	<code>muDoubleScalarLog</code>	<code>muDoubleScalarSinh</code>
<code>muDoubleScalarAtan2</code>	<code>muDoubleScalarLog10</code>	<code>muDoubleScalarSqrt</code>
<code>muDoubleScalarAtanh</code>	<code>muDoubleScalarMax</code>	<code>muDoubleScalarTan</code>
<code>muDoubleScalarCeil</code>	<code>muDoubleScalarMin</code>	<code>muDoubleScalarTanh</code>

Perform Acceleration

In this section...

“Customize the Build Process” on page 32-25

“Run Acceleration Mode from the User Interface” on page 32-25

“Making Run-Time Changes” on page 32-27

Customize the Build Process

Compiler optimizations are off by default. This results in faster build times, but slower simulation times. You can optimize the build process toward a faster simulation.

- 1 From the **Simulation** menu, select **Model Configuration Parameters**.
- 2 In the Configuration Parameters dialog box, select the **All Parameters** tab, and then from the **Compiler optimization level** drop-down list, select **Optimizations on (faster runs)**.

Code generation takes longer with this option, but the model simulation runs faster.

- 3 Select **Verbose accelerator builds** to display progress information using code generation, and to see the compiler options in use.

Changing the Location of Generated Code

By default, the Accelerator mode places the generated code in a subfolder of the working folder called `slprj/accel/modelname` (for example, `slprj/accel/f14`). To change the name of the folder into which the Accelerator Mode writes generated code:

- 1 In the Simulink editor window, select **File > Simulink Preferences**.

The Simulink Preferences window appears.

- 2 In the Simulink Preferences window, navigate to the **Simulation cache folder** parameter.
- 3 Enter the absolute or relative path to your subfolder and click **Apply**.

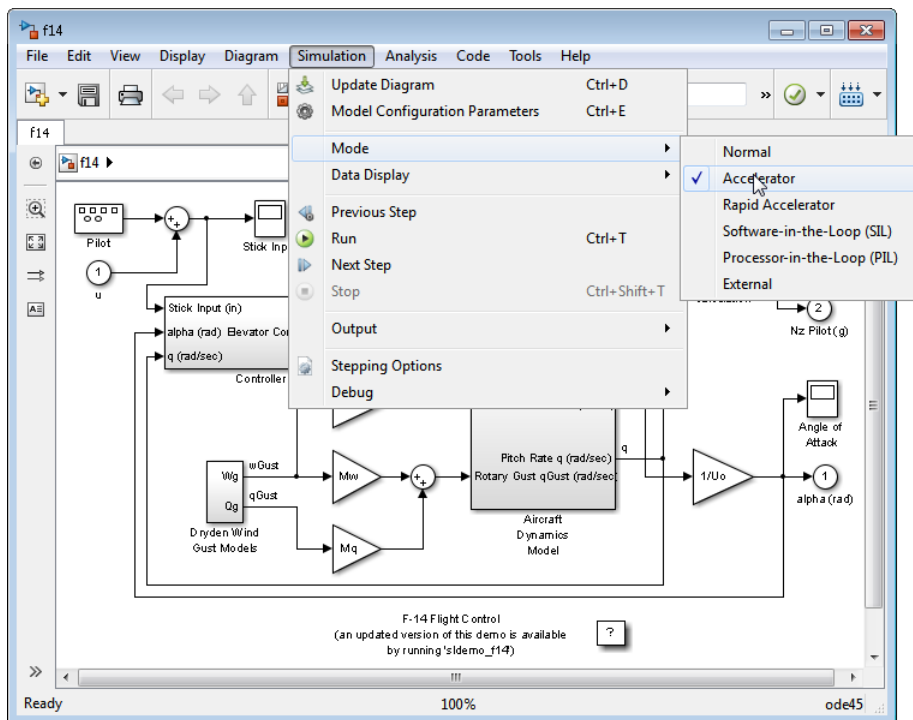

Run Acceleration Mode from the User Interface

To accelerate a model, first open it, and then from the **Simulation > Mode** menu, select either **Accelerator** or **Rapid Accelerator**. Then start the simulation.

The following example shows how to accelerate the already opened f14 model using the Accelerator mode:

- 1 From the **Simulation > Mode** menu, select **Accelerator**.

Alternatively, you can select **Accelerator** from the Simulink Editor toolbar.

- 2 From the **Simulation** menu, select **Run**.

The Accelerator and Rapid Accelerator modes first check to see if code was previously compiled for your model. If code was created previously, the Accelerator or Rapid Accelerator mode runs the model. If code was not previously built, they first generate and compile the C code, and then run the model.

For an explanation of why these modes rebuild your model, see “Code Regeneration in Accelerated Models” on page 32-9.

The Accelerator mode places the generated code in a subfolder of the working folder called `slprj/accel/modelname` (for example, `slprj/accel/f14`). If you want to change this path, see “Changing the Location of Generated Code” on page 32-25.

The Rapid Accelerator mode places the generated code in a subfolder of the working folder called `slprj/raccel/modelname` (for example, `slprj/raccel/f14`).

Note: The warnings that blocks generate during simulation (such as divide-by-zero and integer overflow) are not displayed when your model runs in Accelerator or Rapid Accelerator mode.

Making Run-Time Changes

A feature of the Accelerator and Rapid Accelerator modes is that simple adjustments (such as changing the value of a Gain or Constant block) can be made to the model while the simulation is still running. More complex changes (for example, changing from a `sin` to `tan` function) are not allowed during run time.

The Simulink software issues a warning if you attempt to make a change that is not permitted. The absence of a warning indicates that the change was accepted. The warning does not stop the current simulation, and the simulation continues with the previous values. If you wish to alter the model in ways that are not permitted during run time, you must first stop the simulation, make the change, and then restart the simulation.

In general, simple model changes are more likely to result in code regeneration when in Rapid Accelerator mode than when in Accelerator mode.

Interact with the Acceleration Modes Programmatically

In this section...

“Why Interact Programmatically?” on page 32-29

“Build JIT Accelerated Execution Engine” on page 32-29

“Control Simulation” on page 32-29

“Simulate Your Model” on page 32-30

“Customize the Acceleration Build Process” on page 32-31

Why Interact Programmatically?

You can build an accelerated model, select the simulation mode, and run the simulation from the command prompt or from MATLAB script. With this flexibility, you can create Accelerator mode MEX-files in batch mode, allowing you to build the C code and executable before running the simulations. When you use the Accelerator mode interactively at a later time, it will not be necessary to generate or compile MEX-files at the start of the accelerated simulations.

Build JIT Accelerated Execution Engine

With the `accelbuild` command, you can build a JIT accelerated execution engine without actually simulating the model. For example, to build an Accelerator mode simulation of `myModel`:

```
accelbuild myModel
```

Control Simulation

You can control the simulation mode from the command line prompt by using the `set_param` command:

```
set_param('modelName', 'SimulationMode', 'mode')
```

The simulation mode can be `normal`, `accelerator`, `rapid`, or `external`.

For example, to simulate your model with the Accelerator mode, you would use:

```
set_param('myModel', 'SimulationMode', 'accelerator')
```

However, a preferable method is to specify the simulation mode within the `sim` command:

```
simOut = sim('myModel', 'SimulationMode', 'accelerator');
```

You can use `bdroot` to set parameters for the currently active model (that is, the active model window) rather than *modelName* if you do not wish to explicitly specify the model name.

For example, to simulate the currently opened system in the Rapid Accelerator mode, you would use:

```
simOut = sim(bdroot, 'SimulationMode', 'rapid');
```

Simulate Your Model

You can use `set_param` to configure the model parameters (such as the simulation mode and the stop time), and use the `sim` command to start the simulation:

```
sim('modelName', 'ReturnWorkspaceOutputs', 'on');
```

However, the preferred method is to configure model parameters directly using the `sim` command, as shown in the previous section.

You can substitute `gcs` for *modelName* if you do not want to explicitly specify the model name.

Unless target code has already been generated, the `sim` command first builds the executable and then runs the simulation. However, if the target code has already been generated and no significant changes have been made to the model (see “Code Regeneration in Accelerated Models” on page 32-9 for a description), the `sim` command executes the generated code without regenerating the code. This process lets you run your model after making simple changes without having to wait for the model to rebuild.

Simulation Example

The following sequence shows how to programmatically simulate `myModel` in Rapid Accelerator mode for 10,000 seconds.

First open `myModel`, and then type the following in the Command Window:

```
simOut = sim('myModel', 'SimulationMode', 'rapid'...  
'StopTime', '10000');
```

Use the `sim` command again to resimulate after making a change to your model. If the change is minor (adjusting the gain of a gain block, for instance), the simulation runs without regenerating code.

Customize the Acceleration Build Process

You can programmatically control the Accelerator mode and Rapid Accelerator mode build process and the amount of information displayed during the build process. See “Customize the Build Process” on page 32-25 for details on why doing so might be advantageous.

Controlling the Build Process

Use `SimCompilerOptimization` to set the degree of optimization used by the compiler when generating code for acceleration. The permitted values are `on` or `off`. The default is `off`.

Enter the following at the command prompt to turn on compiler optimization:

```
set_param('myModel', 'SimCompilerOptimization', 'on')
```

When `SimCompilerOptimization` is set to `on` in JIT accelerated mode, the simulation time for some models improves, while the build time can become slower.

Controlling Verbosity During Code Generation

Use the `AccelVerboseBuild` parameter to display progress information during code generation. The permitted values are `on` or `off`. The default is `off`.

Enter the following at the command prompt to turn on verbose build:

```
set_param('myModel', 'AccelVerboseBuild', 'on')
```

Run Accelerator Mode with the Simulink Debugger

In this section...

“Advantages of Using Accelerator Mode with the Debugger” on page 32-33

“How to Run the Debugger” on page 32-33

“When to Switch Back to Normal Mode” on page 32-33

Advantages of Using Accelerator Mode with the Debugger

The Accelerator mode can shorten the length of your debugging sessions if you have large and complex models. For example, you can use the Accelerator mode to simulate a large model and quickly reach a distant breakpoint.

For more information, see “Accelerator Mode” on page 32-5.

Note: You cannot use the Rapid Accelerator mode with the debugger.

How to Run the Debugger

To run your model in the Accelerator mode with the debugger:

- 1 From the **Simulation > Mode** menu, select **Accelerator**.
- 2 At the command prompt, enter:

```
sldebug modelName
```
- 3 At the debugger prompt, set a time break:

```
tbreak 10000  
continue
```
- 4 Once you reach the breakpoint, use the debugger command **emode** (execution mode) to toggle between Accelerator and Normal mode.

When to Switch Back to Normal Mode

You must switch to Normal mode to step through the simulation by blocks, and when you want to use the following debug commands:

- trace
- break
- zcbreak
- nanbreak

Comparing Performance

In this section...
“Performance of the Simulation Modes” on page 32-35
“Measure Performance” on page 32-37

Performance of the Simulation Modes

The Accelerator and Rapid Accelerator modes give the best speed improvement compared to Normal mode when simulation execution time exceeds the time required for code generation. For this reason, the Accelerator and Rapid Accelerator modes generally perform better than Normal mode when simulation execution times are several minutes or more. However, models with a significant number of Stateflow or MATLAB Function blocks might show only a small speed improvement over Normal mode because in Normal mode these blocks also simulate through code generation.

Including tunable parameters in your model can also increase the simulation time.

The figure shows in general terms the performance of a hypothetical model simulated in Normal, Accelerator, and Rapid Accelerator modes.

Performance When the Target Must Be Rebuilt

The solid lines in the figure show performance when the target code must be rebuilt (“all targets out of date”). For this hypothetical model, the time scale is on the order of minutes, but it could be longer for more complex models.

As generalized in the figure, the time required to compile the model in Normal mode is less than the time required to build either the Accelerator target or Rapid Accelerator executable. It is evident from the figure that for small simulation stop times Normal mode results in quicker overall simulation times than either Accelerator mode or Rapid Accelerator mode.

The crossover point where Accelerator mode or Rapid Accelerator mode result in faster execution times depends on the complexity and content of your model. For instance, those models running in Accelerator mode containing large numbers of blocks using

interpreted code (see “Select Blocks for Accelerator Mode” on page 32-18) might not run much faster than they would in Normal mode unless the simulation stop time is very large. Similarly, models with a large number of Stateflow Chart blocks or MATLAB Function blocks might not show much speed improvement over Normal mode unless the simulation stop times are long.

For illustration purposes, the graphic represents a model with a large number of Stateflow Chart blocks or MATLAB Function blocks. The curve labeled “Normal” would have much smaller initial elapsed time than shown if the model did not contain these blocks.

Performance When the Targets Are Up to Date

As shown by the broken lines in the figure (“all targets up to date”) the time for the Simulink software to determine if the Accelerator target or the Rapid Accelerator executable are up to date is significantly less than the time required to generate code (“all targets out of date”). You can take advantage of this characteristic when you wish to test various design tradeoffs.

For instance, you can generate the Accelerator mode target code once and use it to simulate your model with a series of gain settings. This is an especially efficient way to use the Accelerator or Rapid Accelerator modes because this type of change does not result in the target code being regenerated. This means the target code is generated the first time the model runs, but on subsequent runs the Simulink code spends only the time necessary to verify that the target is up to date. This process is much faster than generating code, so subsequent runs can be significantly faster than the initial run.

Because checking the targets is quicker than code generation, the crossover point is smaller when the target is up to date than when code must be generated. This means subsequent runs of your model might simulate faster in Accelerator or Rapid Accelerator mode when compared to Normal mode, even for short stop times.

Measure Performance

You can use the `tic`, `toc`, and `sim` commands to compare Accelerator mode or Rapid Accelerator mode execution times to Normal mode.

- 1 Open your model.
- 2 From the **Simulation** > **Mode** menu, select **Normal**.
- 3 Use the `tic`, `toc`, and `sim` commands at the command line prompt to measure how long the model takes to simulate in Normal mode:

```
tic,[t,x,y]=sim('myModel',10000);toc
```

`tic` and `toc` work together to record and return the elapsed time and display a message such as the following:

```
Elapsed time is 17.789364 seconds.
```

- 4 Select either **Accelerator** or **Rapid Accelerator** from the **Simulation > Mode** menu, and build an executable for the model by clicking the **Run** button. The acceleration modes use this executable in subsequent simulations as long as the model remains structurally unchanged. “Code Regeneration in Accelerated Models” on page 32-9 discusses the things that cause your model to rebuild.

- 5 Rerun the compiled model at the command prompt:

```
tic,[t,x,y]=sim('myModel',10000);toc
```

- 6 The elapsed time displayed shows the run time for the accelerated model. For example:

```
Elapsed time is 12.419914 seconds.
```

The difference in elapsed times (5.369450 seconds in this example) shows the improvement obtained by accelerating your model.

How to Improve Performance in Acceleration Modes

In this section...

“Techniques” on page 32-39

“C Compilers” on page 32-39

Techniques

To get the best performance when accelerating your models:

- Verify that the Configuration Parameters dialog box settings are as follows:

On this pane...	Set...	To...
All Parameters tab	Solver data inconsistency	none
All Parameters tab	Array bounds exceeded	none
All Parameters tab	Signal storage reuse	selected

- Disable Stateflow debugging and animation.
- When logging large amounts of data (for instance, when using the Workspace I/O, To Workspace, To File, or Scope blocks), use decimation or limit the output to display only the last part of the simulation.
- Customize the code generation process to improve simulation speed. For details, see “Customize the Build Process” on page 32-25.

C Compilers

On computers running the Microsoft Windows operating system, the Accelerator and Rapid Accelerator modes use the default 64-bit C compiler supplied by MathWorks to compile your model. If you have a C compiler installed on your PC, you can configure the mex command to use it instead. You might choose to do this if your C compiler produces highly optimized code since this would further improve acceleration.

Note: For an up-to-date list of 32- and 64-bit C compilers that are compatible with MATLAB software for all supported computing platforms, see:

http://www.mathworks.com/support/compilers/current_release/

Nonvirtual and Virtual Blocks

When creating models, you need to be aware that Simulink blocks fall into two basic categories: nonvirtual blocks and virtual blocks. Nonvirtual blocks play an active role in the simulation of a system. If you add or remove a nonvirtual block, you change the model's behavior. Virtual blocks, by contrast, play no active role in the simulation; they help organize a model graphically. Some Simulink blocks are virtual in some circumstances and nonvirtual in others. Such blocks are called conditionally virtual blocks. The table lists Simulink virtual and conditionally virtual blocks.

Block Name	Condition Under Which Block Is Virtual
Bus Assignment	Virtual if input bus is virtual.
Bus Creator	Virtual if output bus is virtual.
Bus Selector	Virtual if input bus is virtual.
Demux	Always virtual.
Enable	Virtual unless connected directly to an Output block.
From	Always virtual.
Goto	Always virtual.
Goto Tag Visibility	Always virtual.
Ground	Always virtual.
Inport	Virtual <i>unless</i> the block resides in a conditionally executed or atomic subsystem <i>and</i> has a direct connection to an Output block.
Mux	Always virtual.
Output	Virtual when the block resides within any subsystem block (conditional or not), and does <i>not</i> reside in the root (top-level) Simulink window.
Selector	Virtual only when Number of input dimensions specifies 1 and Index Option specifies Select all , Index vector (dialog) , or Starting index (dialog) .
Signal Specification	Always virtual.
Subsystem	Virtual unless the block is conditionally executed or the Treat as atomic unit check box is selected.

Block Name	Condition Under Which Block Is Virtual
	You can check if a block is virtual with the <code>IsSubsystemVirtual</code> block property. See “Block-Specific Parameters”.
Terminator	Always virtual.
Trigger	Virtual when the output port is <i>not</i> present.

More About

- “Specify Block Properties” on page 33-4
- “Display Port Values for Debugging” on page 33-15
- “Control and Display the Sorted Order” on page 33-26
- “Access Block Data During Simulation” on page 33-45
- “Block Libraries”

Specify Block Properties

For each block in a model, you can set general block properties, such as:

- A description of the block
- The block execution order
- A block annotation
- Block callback functions

To set block properties, use the property inspector. You can set properties in the **Properties** and **Info** tabs of the property inspector when the block is selected. Alternatively, you can use the Block Properties dialog box. For more information on setting properties, see “Setting Properties and Parameters” on page 1-50.

Set Block Annotation Properties

In the property inspector, use the **Block Annotation** section to display the values of selected block parameters in an annotation. The annotation appears below the block icon.

Enter the text of the annotation in the text box. You can use a block property token in the annotation. The value for the property replaces the token in the annotation in the model. To display a list of tokens that you can use in an annotation, type % in the text box. The parameters that are valid for the selected block appear. See “Common Block Properties” and “Block-Specific Parameters”.

Suppose that you specify the following annotation text and tokens for a Product block:

```
Multiplication = %<Multiplication>
Sample time = %<SampleTime>
```

In the Simulink Editor, the block displays this annotation:

You can also create block annotations programmatically. See “Create Block Annotations Programmatically” on page 33-6.

Specify Block Callbacks

Use the **Callbacks** tab to specify block callbacks. Callbacks are MATLAB commands that you specify that execute when a specific model action occurs, such as when you select or delete a block. For more information on callbacks, see “Callbacks for Customized Model Behavior” on page 4-56.

- 1 Select the block whose callback you want to set.
- 2 In **Properties** tab of the property inspector, in the **Callbacks** section, select the function that you want to assign the callback to. For example, select `OpenFcn` to specify a behavior for double-clicking a block.
- 3 In the text box, enter the command that you want to execute when that block function occurs.

After you assign a callback to a function, the function displays an asterisk next to it in the list. The asterisks helps you to see the functions that have callbacks assigned to them.

Set a Block Callback Programmatically

This example shows how to use the `OpenFcn` callback to execute MATLAB scripts when you double-click a block. For example, in a MATLAB script you can define variables or open a plot of simulated data.

To create a callback programmatically, select the block to which you want to add this property. Then, at the MATLAB command prompt, enter a command in this form:

```
set_param(gcf, 'OpenFcn', 'myfunction')
```

In this example, `myfunction` represents a valid MATLAB command or a MATLAB script on your MATLAB search path.

Specify Block Execution Priority and Tag

In the **Advanced Properties** section of the block properties, you can specify the block priority and identify the block by assigning a value to the **Tag** property.

- **Priority** — Specify the execution priority of the block relative to other blocks in the model. For more information, see “Assign Block Priorities” on page 33-40.
- **Tag** — Specify an identifier for the block. Specify text to assign to the block Tag parameter. Setting this property is useful for finding the block in the model by searching or programmatically using `find_system`. See “Find Model Elements in Simulink Models” on page 12-57.

Use Block Description to Identify a Block

The **Info** tab displays information about the block type. The block author provides this description.

You can also enter a description in the **Description** box to provide information about the block instance.

- If you add a description, you can set up your model display so that the description appears in a tool tip when you hover over the block. Use **Display > Blocks > Tool Tip Options > Description** to enable this tool tip.
- The **Description** property can help you to find a block by searching. See “Find Model Elements in Simulink Models” on page 12-57.

Create Block Annotations Programmatically

You can use a block `AttributesFormatString` parameter to display specified block parameter values below the block. “Common Block Properties” and “Block-Specific Parameters” describe the parameters that a block can have. Use the Simulink `set_param` function to set this parameter to the attributes format that you want.

The attributes format can be any text that has embedded parameter names. An embedded parameter name is a parameter name preceded by `%<` and followed by `>`, for example, `%<priority>`. Simulink displays the attributes format text below the block icon, replacing each parameter name with the corresponding value. You can use line-feed characters (`\n`) to display each parameter on a separate line. For example, select a Gain block and enter this command at the MATLAB command prompt:

```
set_param(gcf, 'AttributesFormatString', 'pri=%<priority>\ngain=%<Gain>')
```

The Gain block displays this block annotation:

If a parameter value is not text or an integer, N/S (for not supported) appears in place of the value. If the parameter name is not valid, Simulink displays ??? in place of the value.

Adjust Visual Presentation to Improve Model Readability

As you build a model, you can adjust block positions, change block and background color, adjust fonts, and add elements that help to improve model readability. These changes can help to organize the model visually and help others understand the model when you share it.

You can make these types of changes to improve model readability:

- Flip or rotate blocks. These adjustments help blocks to fit in the model and connect with other blocks. See “Flip or Rotate a Block” on page 33-8.
- Reposition or hide block names. See “Move and Hide Block Names” on page 33-10.
- Add colors to blocks and to the background. See “Specify Model Colors” on page 33-10.
- Adjust aesthetics by changing fonts and deepening the intensity of drop shadows. See “Specify Fonts in Models” on page 33-11 and “Increase Drop Shadow Depth” on page 33-12.
- Surround groups of blocks with a box to show that the blocks are related. See “Box and Label Areas of a Model” on page 33-12.
- Document a model using text, image, and math annotations. See “Create an Annotation” on page 4-17.
- Annotate a block. See “Set Block Annotation Properties” on page 33-4.
- Change the block icon, for example, display a graphic on the block. Use a mask to achieve this effect. A mask also enables you to design a custom interface for a block. To learn about masks, see “Masking Fundamentals” on page 36-2.

Flip or Rotate a Block

You can change the orientation of a block by rotating it in 90-degree increments or by flipping it 180 degrees about its horizontal or vertical axis. Rotate or flip a block so that it fits better in the model, for example, in feedback loops. You might also need to rotate a block so that inports align with outports.

The figure shows a Gain block flipped to simplify a feedback loop diagram.

- To rotate or flip a block, select the block and select a command from the **Diagram > Rotate & Flip** menu. You can rotate clockwise (**Ctrl+R**) or counterclockwise.

The **Flip Block** command flips the block based on the orientation of its ports. For example, if the ports are on the sides, the block flips horizontally (about its vertical axis).

Port Location After Rotating or Flipping

Rotating moves block ports from the sides to top and bottom or the reverse, depending on the placement of the ports. The resulting positions of the block ports depend on the block *port rotation type*.

Rotating can reposition the ports on some blocks to maintain left-to-right or top-to-bottom port numbering order. A block whose ports are reordered after a rotation have the *default port rotation* type. This policy helps to maintain the left-right and top-down block diagram orientation convention used in control system modeling applications. Blocks by default use this rotation policy. The figure shows the effect of clockwise rotation on a block with the default port rotation policy.

A masked block can specify for ports to keep their order after rotation (see “Port rotation”). These blocks have a *physical port rotation* type. This policy helps when

designing blocks to use in mechanical and hydraulic systems modeling and other applications where diagrams do not have a preferred orientation. The figure shows the effect of clockwise rotation on a block with a physical port rotation type.

Flipping a block moves the ports to the opposite side of the block, creating a mirror image, regardless of port rotation type.

Move and Hide Block Names

By default, block names appear below blocks whose ports are on the sides and to the left of blocks whose ports are on the top and bottom. You can change the location of a block name, and you can hide block names.

To change the location of a block name, you can:

- Drag the block name to the opposite side of the block.
- Select the block and then select **Diagram > Rotate & Flip > Flip Block Name**.

To toggle the display of the block name, select **Diagram > Format > Show Block Name**.

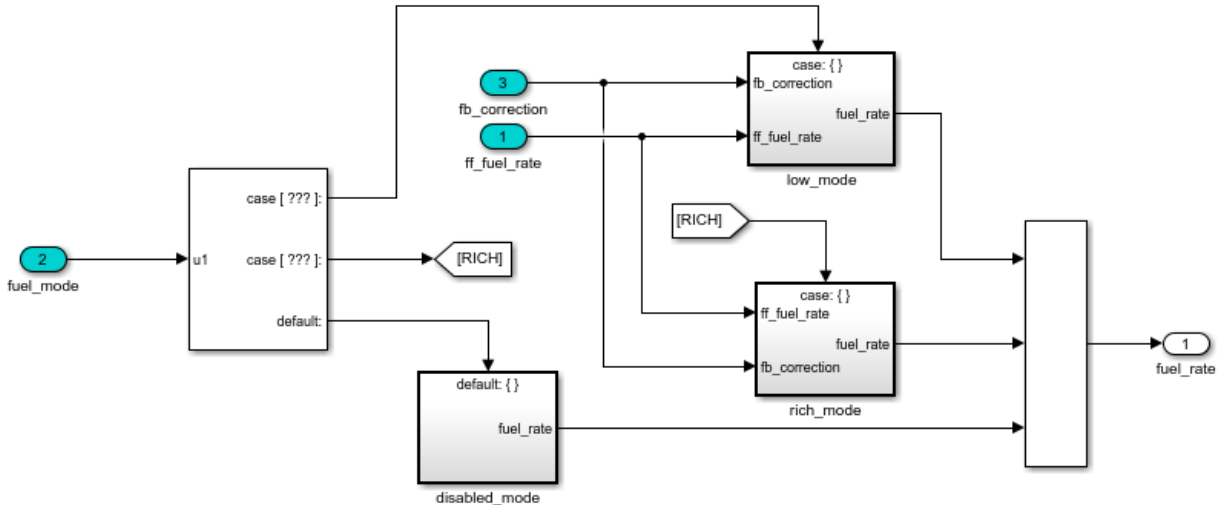

Specify Model Colors

You can specify the outline and interior colors of any block, and you can change the background color for any system in a model. You can also change text color and background color for annotations and fill color for areas.

This subsystem of the model `sldemo_fuelsys` uses color to identify the inports.

slidemo_fuelsys ▶ fuel_rate_control ▶ fuel_calc ▶ switchable_compensation ▶

Loop Compensation and Filtering

- To change outline color on a block, text color in an annotation, or interior color for an area, select the element, and then select **Diagram > Format > Foreground Color**.
- To change interior color on a block or background color in an annotation, select the element, and then select **Diagram > Format > Background Color**.
- To change a background color in a system, open the system, and then select **Diagram > Format > Canvas Color**.

You can select a color from the menu or select **Custom** to open the color picker and define your own color.

You can also use the property inspector to change color for an area or an annotation. To specify colors programmatically, see “Specify Colors Programmatically” on page 1-21

Specify Fonts in Models

Change font family, style, and size for any model element to make your model easier to read or to comply with company standards. You can modify the font for selected blocks,

signal labels, areas, and annotations. Changing a block's font changes the font for the name and for text that appears on the block.

You can also change the default font for the model. The default font affects any elements whose font you have not changed and any new elements you create. If you want to use the same default font in all new models, change the default model font in your default template. See “Use Customized Settings When Creating New Models” on page 1-8.

- To change the font of a block, signal label, area, or annotation, select the element, and then select **Diagram > Format > Font Style for Selection**. Use the dialog box to specify the font information.
- To change the default font for the model, with no selection, select **Diagram > Format > Font Style for Model**. Use the dialog box to specify the font information.

You can also use the property inspector to change font for an area or an annotation.

Increase Drop Shadow Depth

By default, blocks have a drop shadow. To make the block stand out more against the background, you can increase the depth of the drop shadow.

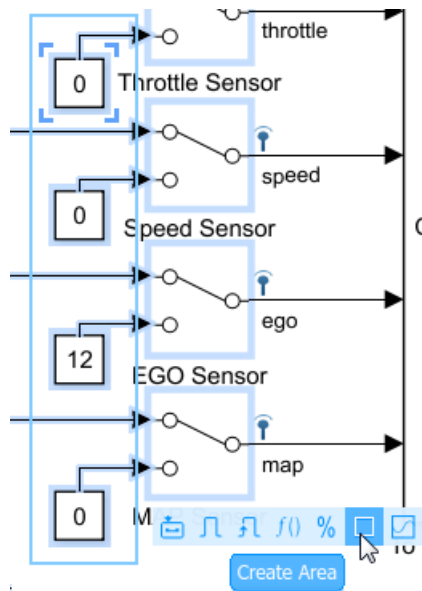

Select the blocks whose drop shadow depth you want to increase, and then select **Diagram > Format > Block Shadow**.

Tip To remove the default drop shadow for all blocks, select the Simulink Editor preference **Use classic theme**.

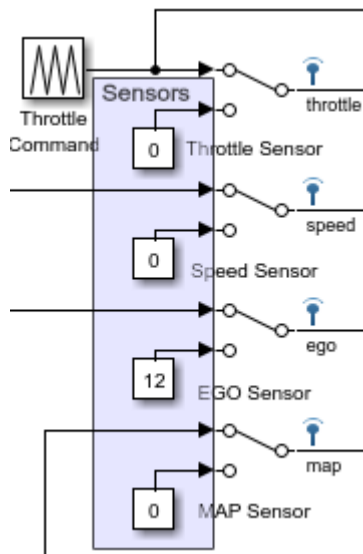

Box and Label Areas of a Model

Add an area to your model to visually group related model elements in a box. An area can move with the blocks it surrounds. You can add text to an area to briefly describe or label the area.

- 1 Drag a box around the area of interest in the model. For example, in the top level of the model `sldemo_fuelsys`, drag a box around the four Constant blocks that store the failure values of the sensors.
- 2 From the action bar, select **Create Area**.

- 3 Type the name of the area. The name appears in the upper-left corner of the area.

To enter the name later, select the area, click the **?**, and start typing, or use the **Name** property in the property inspector.

- 4 Optionally, add a description of the area contents using the property inspector.
- 5 To move the area and its contents, drag the area near the border.

Tip To move an area without moving its contents, hold **Alt** (**option** on a Mac) and drag.

Alternatively, you can drag an area box from the palette onto the canvas, resize the box, and move it to the desired location.

Convert Area to a Subsystem

An area is similar to a subsystem in that it is a way to group related blocks. However, a subsystem creates a hierarchy, replacing multiple blocks in a model with a single block. You can initially group related blocks in an area and later decide to put those blocks in a subsystem by converting the area. The resulting subsystem has the same name, blocks, description, and requirements traceability information as the area.

To convert an area to a subsystem, right-click the area and select **Create Subsystem from Area**.

Display Port Values for Debugging

In this section...

“Display Port Values for Easy Debugging” on page 33-15

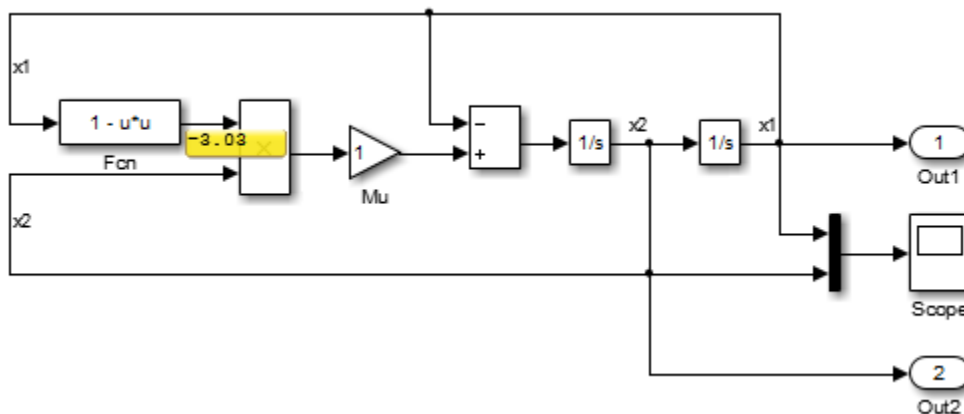

“Display Value for a Specific Port” on page 33-19

“Display Port Values for a Model” on page 33-22

“Port Value Display Limitations” on page 33-23

Display Port Values for Easy Debugging

For many blocks whose signals carry data, Simulink can display signal values (block output) as port value labels (similar to tool tips) on the block diagram during and after a simulation. Port value labels display block output values when Simulink runs block output methods. This model shows a port value label for the port on the Fcn block, an output value of -3.03 .

If the port value label appears empty, this means that no port value is currently available. For example, toggling a port value label on a continuous block when paused during simulation does not display any values in the label.

Port value labels are also empty when you have not yet simulated the model. This is because the block output methods do not run when the model does not simulate.

If you toggle or hover on a block that Simulink optimizes out of a simulation (such as a virtual subsystem block), while you simulate, the model displays the text `optimized`.

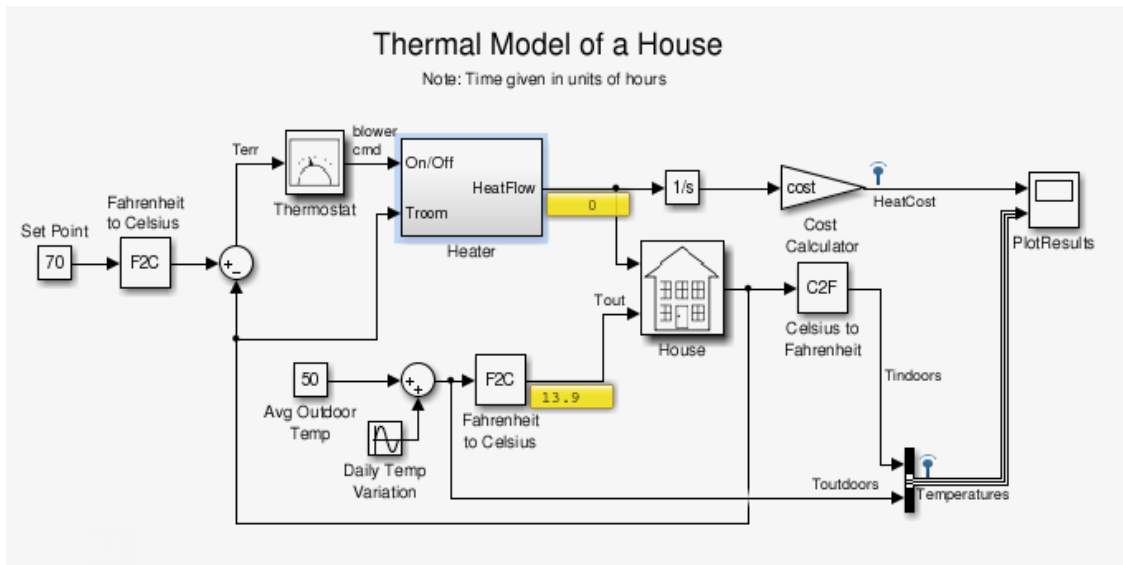

Displaying port value data tips can help during interactive debugging of a model. For example, the figure shows the output of a thermal model for a house.

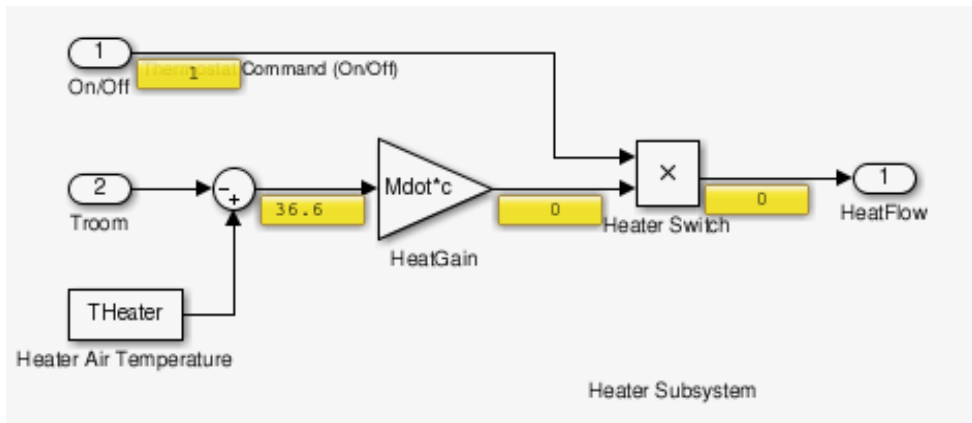

These results suggest a problem with the model because:

- The heating cost is 0 at all temperatures.
- The temperature inside the house matches ambient temperature almost exactly.

In such cases, debugging the blocks in the model interactively can help isolate the error. Port value labels provide information at the output of every block in the model. So in this example, if you step forward using Simulation Stepper, you can see that the output of the Heater subsystem is 0 at every time step.

To learn more, you can enable port value labels for blocks inside the Heater subsystem. Using Simulation Stepper, if you step forward again to display the values, you can see that there is an issue with the HeatGain block. The output is constant at 0.

This technique helps you isolate the issue.

To simplify debugging, you can turn on and off port value labels during simulation. Besides providing useful information for debugging, port value displays can help you

monitor a signal value during simulation. However, these labels are not saved with a model.

For nonnumeric data display, Simulink uses these values:

Message	Explanation
action	The signal executes action subsystems.
fcn-call	The signal is a function-call signal, e.g., Function Call Generator output.
ground	The signal is coming from a Ground block.
not a data signal	The signal does not contain valid data, e.g., the signal is from a block that is commented out.

In some cases:

- The port value display may not be able to acquire the value signal or
- The signal's value cannot be easily displayed

In such cases, Simulink uses these values.

Message	Explanation
...	The signal dimension exceeds the maximum number of elements Simulink can display. For more information, see “Display Port Values for a Model” on page 33-22.
(no message)	The simulation data available is insufficient. Step forward or press play to obtain more data.
click to add signals	You have enabled a port value label on a bus. However, you have not selected a signal to display. Click the label to select bus signals.
inaccessible	Simulink cannot obtain the port value. For an example, see “Signal Storage Reuse” on page 33-23.
[m*n]	This is a nonvector signal. Simulink cannot display the actual values of the matrix. It displays the matrix dimension instead.
no data yet	This message appears when: <ul style="list-style-type: none"> • The simulation data is not available. Start the simulation to see values.

Message	Explanation
	<ul style="list-style-type: none"> If the model contains subsystems (for example, an enabled subsystem) and model references and they are not executed during a simulation.
not used	Simulink cannot obtain the signal value due to optimization.
removed	Simulink cannot obtain the signal value due to block reduction.
optimized	Simulink cannot obtain the signal value due to optimization. In Normal mode, this message appears for blocks with Conditional input branch execution enabled. For more information, see “Conditional Execution Behavior” on page 10-56.
unavailable	The simulation data available is insufficient. For example, see “Simulation Stepper” on page 33-24.

Note: You can force a value label to display the signal value by designating the signal as a test point. Use the **Properties** dialog box to do this.

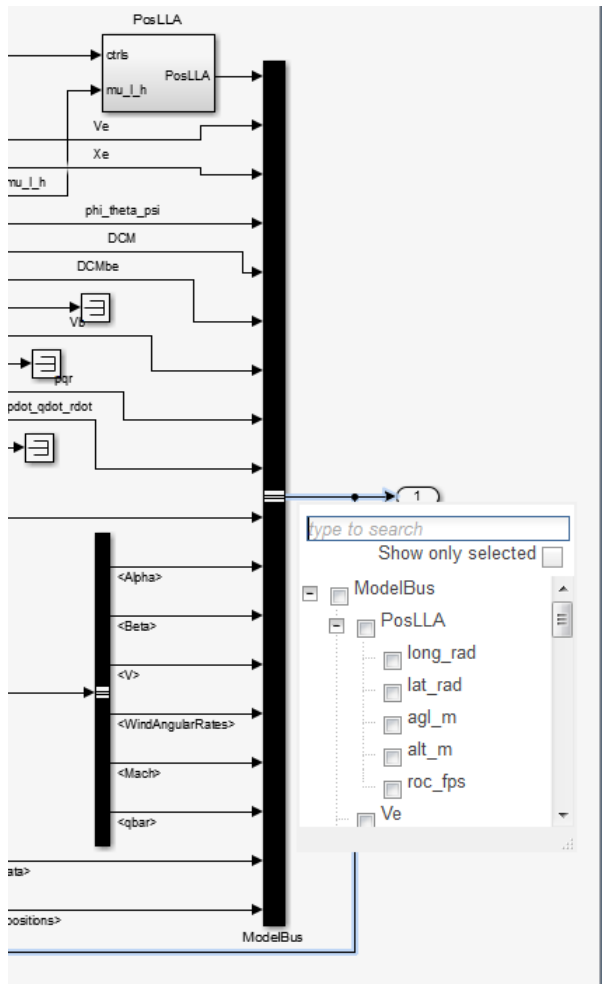

Display Value for a Specific Port

To display the value of a specific port or port values for a block before simulation, select one or more signals, right-click the selection, and select **Show Value Label of Selected Port**.

By default, Simulink displays the value of a signal when you click on it during simulation. You can control this behavior in **Display > Data Display in Simulation > Options > Display values > Enable by default during simulation**.

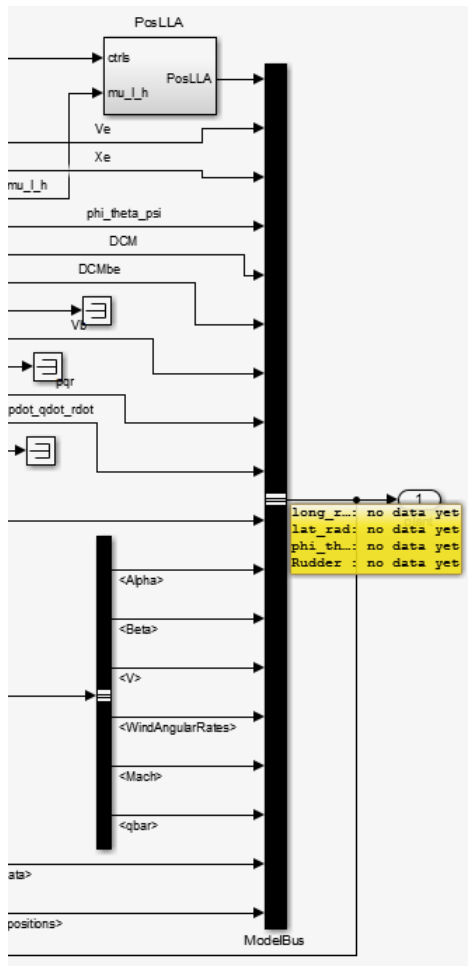

Note: To remove all data tips, select **Display > Data Display in Simulation > Remove All Value Labels**.

For bus signals, the **Show Value Label of Selected Port** option opens a dialog box where you can select from all signals in the bus. For example, in this model, you can see the dialog box for all signals that are contained in ModelBus.

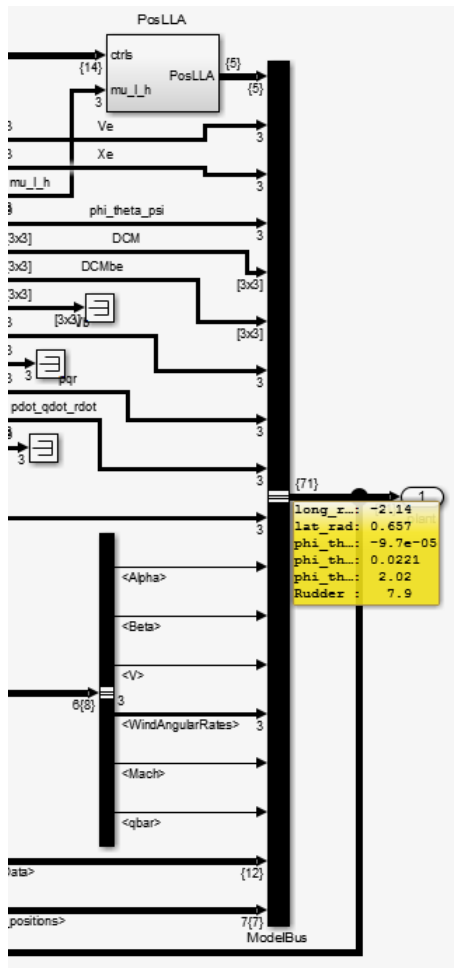

You can search for a signal by name or filter through the hierarchy. Select a parent signal to include all of the signals it contains. You can also filter the display to view only those signals you have selected.

Click anywhere outside the dialog box to close it. The port value label appears. The label has no data; it displays values when you simulate the model.

When you simulate the model, the port value label displays the names and values of the signals you chose. To change the signals to display, click on the port value label to reopen the dialog. You can also click on another signal to display its value.

Note: Simulink does not save the values of a signal when you remove the port value label.

Display Port Values for a Model

Specify port value display formatting and the frequency of updates. The Value Label Display Options dialog box controls these settings on the entire model.

- 1 In the model whose port values you want to display, select **Display > Data Display in Simulation > Options**.
- 2 In the Value Label Display Options dialog box, specify your preferences for:
 - The display options, including font size, the refresh frequency, and the number of elements displayed for vector signals with signal widths greater than 1
 - The display mode
 - Floating-point or fixed-point format

Port Value Display Limitations

Performance

Enabling the hovering option for a model or setting at least one block to **Toggle Value Labels When Clicked** slows down simulation.

Accelerated Modes

Port values work in Normal and Accelerator modes only. They do not work in Rapid Accelerator and External modes. The table shows how accelerator modes affect the display of port values.

Accelerated Mode	Port Values
Accelerator	<ul style="list-style-type: none"> • Signals not optimized in Accelerator mode display port values as in Normal mode. Signals optimized in Accelerator mode display port values as optimized. For more information, see “Display Port Values for Easy Debugging” on page 33-15. • Model reference blocks simulated in Accelerator mode do not get their port value displays updated.
Rapid Accelerator	Incompatible. The limitation exists whether the model or its parent specifies accelerated simulation. For more information, see “Accelerate, Refine, and Test Hybrid Dynamic System on Host Computer by Using RSim System Target File”.

Signal Storage Reuse

If the output port buffer of a block is shared with another block through the optimization of signal storage reuse, the port value displays as **inaccessible**. You can disable signal

storage reuse using the **Configuration Parameters > All Parameters > Signal storage reuse** check box. However, disabling signal storage reuse increases the memory used during simulation.

Signal Data Types

- Simulink displays the port value for ports connected to most kinds of signals, including signals with built-in data types (such as `double`, `int32`, or `Boolean`), `DYNAMICALLY_TYPED`, and several other data types.
- Simulink shows the floating format for only noncomplex signal value displays.
- Simulink displays the port value of fixed point data types based on the converted double value.
- Simulink does not display data for signals with some composite data types, such as bus signals.

Subsystems

- You cannot display port values for subsystems contained in a variant subsystem when there are no signal lines connecting to them. In such cases, during simulation, Simulink automatically determines block connectivity based on the active variant. However, you can display port values within the subsystems contained in the variant subsystem. You can also display values on signal lines outside of the variant subsystem.
- When you disable a conditionally executed subsystem, the port value display for a signal that goes into an Output block displays the value of the Output block, depending on the **Output when disabled** setting.
- Simulink does not display data for the ports of an enabled subsystem that is not enabled.

Simulation Stepper

If you do not enable port value display when stepping forward, the display will not be available when stepping back. When stepping back, if the port value is unavailable, the `unavailable` label is displayed.

Refine Factor

Port value displays do not honor refine factor values (**Configuration Parameters > Data Import/Export > Additional parameters > Refine factor**) because Simulink updates port value displays only during major time steps.

Signal Specification Block and Inport Block

When you display port values on Signal Specification and Inport blocks in a subsystem, the value that is driving the blocks displays instead of the block values.

Command-Line Simulations

For efficiency, Simulink does not support port value displays during a command-line simulation using the `sim` command.

Merge Block

Simulink does not display the output value of a merge block. To see this value, refer to the source block.

Command Line Interface

You cannot specify port value displays through the command line interface.

Non-Simulink signals

You cannot place port values on non-Simulink signals, such as Simscape or SimEvents signals. This limitation applies to conditional breakpoints as well.

What Is Sorted Order?

During the updating phase of simulation, Simulink determines the order in which to invoke the block methods during simulation. This block invocation ordering is the *sorted order*.

You cannot set this order, but you can assign priorities to nonvirtual blocks to indicate to Simulink their execution order relative to other blocks. Simulink tries to honor block priority settings, unless there is a conflict with data dependencies. To confirm the results of priorities that you have set, or to debug your model, display and review the sorted order of your nonvirtual blocks and subsystems.

Note: For more information about block methods and execution, see:

- “Block Methods” on page 3-15
 - “Conditional Execution Behavior” on page 10-56
-

Display the Sorted Order

To display the sorted order of the vdp model:

- 1 Open the van der Pol equation model:
vdp
- 2 In the model window, select **Display > Blocks > Sorted Execution Order**.

Simulink displays a notation in the top-right corner of each nonvirtual block and each nonvirtual subsystem. These numbers indicate the order in which the blocks execute. The first block to execute has a sorted order of 0.

For example, in the van der Pol equation model, the Integrator block with the sorted order 0:0 executes first. The Out1 block, with the sorted order 0:1, executes second. Similarly, the remaining blocks execute in numeric order from 0:2 to 0:8.

You can save the sorted order setting with your model. To display the sorted order when you reopen the model, select **Simulation > Update diagram**.

Sorted Order Notation

The sorted order notation varies depending on the type of block. The following table summarizes the different formats of sorted order notation. Each format is described in detail in the sections that follows the table.

Block Type	Sorted Order Notation	Description
“Nonvirtual Blocks” on page 33-30	$s:b$	<ul style="list-style-type: none"> s is the system index of the model or subsystem the block resides in. For root-level models, s is always 0. b specifies the block position within the sorted order for the designated execution context.
	$s:b \{x, y\}$	

Block Type	Sorted Order Notation	Description
		<ul style="list-style-type: none"> x,y are the system indices of the subsystems whose execution is controlled by this block.
“Nonvirtual Subsystems” on page 33-31 (not including function-call and action subsystems)	$s:b$	<ul style="list-style-type: none"> s is the system index of the model or subsystem. b specifies the block position within the sorted order for the designated execution context.
“Virtual Blocks and Subsystems” on page 33-33	Not applicable	Virtual blocks do not execute.
Action Subsystems	$s:b'$	<ul style="list-style-type: none"> s is the system index of the model or subsystem the block resides in. For root-level models, s is always 0. b' is the block index of the action block (but not of the action subsystem).
“Function-Call Subsystems” on page 33-34 and Function-Call models	One non-grounded initiator: $s:b^i$	<ul style="list-style-type: none"> s is the system index of the model or subsystem the block resides in. For root-level models, s is always 0. b^i is the block index of the root initiator in the subsystem’s hierarchy.
	Two or more initiators: <ul style="list-style-type: none"> $s:b^{i1}, s:b^{i2}, \dots, s:b^{in}$ where n is the number of non-grounded initiators. 	<ul style="list-style-type: none"> s is the system index of the model or subsystem the block resides in. For root-level models, s is always 0. b^{in} is the block index of the n-th root initiator in the subsystem’s hierarchy.
	Initiators are either Ground blocks or are unconnected: <ul style="list-style-type: none"> $s:G$ 	<ul style="list-style-type: none"> s is the system index of the model or subsystem the block resides in. For root-level models, s is always 0. G indicates that all function-call initiators are grounded.

Block Type	Sorted Order Notation	Description
“Branched Function-Call Signals” on page 33-36	$s : b^i [B_k]$	<ul style="list-style-type: none"> • s is the system index of the model or subsystem the block resides in. For root-level models, s is always 0. • b^i is the block index of the root initiator in the subsystem’s hierarchy. • B_k indicates that it is a branched function-call subsystem with branch index k.
Function-Call Feedback Latch Blocks	$s : b^i [B_m]$	<ul style="list-style-type: none"> • s is the system index of the model or subsystem the block resides in. For root-level models, s is always 0. • b^i is the block index of the root initiator in the subsystem’s hierarchy. • B_m indicates that it is a branched subsystem with branch index m.
Blocks in a model with asynchronous function-call inputs	Function-call root-level Inport and Outport blocks: F_i	<ul style="list-style-type: none"> • F indicates that it is executed in a function-call context. • i is the function-call index.
	Root-level data Inport blocks: If they drive a function-call subsystem, it is the function-call index of the subsystem. If they are part of the model that is not driven by asynchronous function-call inputs, then no function-call index is displayed.	
	Root-level function-call blocks: F_i Root-level branched function-call blocks: $F_i [B_k]$	<ul style="list-style-type: none"> • F indicates that it is executed in a function-call context. • i is the function-call index.

Block Type	Sorted Order Notation	Description
Blocks inside Export Function Models (See “Execution Order for Function-Call Root-level Inport Blocks” on page 10-10)	Function-call root-level Inport and Outport blocks: F_i	<ul style="list-style-type: none"> • F indicates that it is a function-call block. • i is the execution order for the function-call root-level Inport or Outport block in normal simulation mode.
	Root-level function-call subsystems: F_i Root-level branched function-call subsystems: $F_i[B_k]$	<ul style="list-style-type: none"> • F indicates that it is a function-call block. • i is the execution order for the function-call root-level Inport block in normal simulation mode. • B_k indicates a branched function-call subsystem with index k.
	Merge and Data Store Memory blocks: F_i, F_j, \dots	<ul style="list-style-type: none"> • F indicates that it is a function-call block. • i is the block execution index.
	Root-level data Inport and Outport blocks: Same execution order as the function-call subsystems they are connected to.	
“Bus-Capable Blocks” on page 33-37	$S : B$	<ul style="list-style-type: none"> • S is the system index of the model or subsystem the block resides in. For root-level models, S is always 0. • B indicates a bus-capable block.

Nonvirtual Blocks

In the van der Pol equation model, all the nonvirtual blocks in the model have a sorted order. The system index for the top-level model is 0, and the block execution order ranges from 0 to 8.

Nonvirtual Subsystems

The following model contains an atomic, nonvirtual subsystem named Discrete Cruise Controller.

When you enable the sorted order display for the root-level system, Simulink displays the sorted order of the blocks.

The Scope block in this model has the lowest sorted order, but its input depends on the output of the Car Dynamics subsystem. The Car Dynamics subsystem is virtual, so it does not have a sorted order and does not execute as an atomic unit. However, the blocks within the subsystem execute at the root level, so the Integrator block in the Car Dynamics subsystem executes first. The Integrator block sends its output to the Scope block in the root-level model, which executes second.

The Discrete Cruise Controller subsystem has a sorted order of 0:5:

- 0 indicates that this atomic subsystem is part of the root level of the hierarchical system comprised of the primary system and the two subsystems.
- 5 indicates that the atomic subsystem is the sixth block that Simulink executes relative to the blocks within the root level.

The sorted order of each block inside the Discrete Cruise Controller subsystem has the form 1:b, where:

- 1 is the system index for that subsystem.
- *b* is the block position in the execution order. In the Discrete Cruise Controller subsystem, the sorted order ranges from 0 to 8.

Note: Depending on your model configuration, Simulink can insert hidden, nonvirtual subsystems in your model. As a result, the visible blocks inside the hidden subsystem block can have a system index that is different from the current system index. For example, if you select **Model Configuration Parameters > All Parameters > Conditional input branch execution**, Simulink creates hidden, nonvirtual subsystems, which can affect the sorted execution order.

Virtual Blocks and Subsystems

Virtual blocks, such as the Mux block, exist only graphically and do not execute. Consequently, they are not part of the sorted order and do not display any sorted order notation.

Virtual subsystems do not execute as a unit, and like a virtual block, are not part of the sorted order. The blocks inside the virtual subsystem are part of the root-level system sorted order, and therefore share the system index.

In the model in “Nonvirtual Subsystems” on page 33-31, the virtual subsystem Car Dynamics does not have a sorted order. However, the blocks inside the subsystem have a sorted order in the execution context of the root-level model. The blocks have the same

system index as the root-level model. The Integrator block inside the Car Dynamics subsystem has a sorted order of $0:0$, indicating that the Integrator block is the first block executed in the context of the top-level model.

Function-Call Subsystems

Single Initiator

A function-call subsystem (or model) executes when the initiator invokes the function-call subsystem (or model) and, therefore, does not have a sorted order independent of its initiator. Specifically, for a subsystem that connects to one initiator, Simulink uses the notation $s:b^i$, where s is the index of the system that contains the initiator and b^i is the block index of the root initiator in the subsystems hierarchy.

For example, the sorted order for the subsystems f and g is $0:0$, since the sorted order of their root initiator, $Chart$, is $0:0$.

Multiple Initiators

For a function-call subsystem that connects to more than one initiator, the sorted order notation is $s:b^{i1}, s:b^{i2}, \dots, s:b^{in}$ where n is the number of non-grounded initiators, s is the system index of the model or subsystem the block resides in, and b^{in} is the block index of the n -th root initiator in the subsystem's hierarchy.

For example, open the `s1_subsys_fcncall16` model. The `f` subsystem has three initiators from the same level in the subsystem's hierarchy. Two are from the Stateflow chart, `Chart1`, and one from the Stateflow chart, `Chart`.

Because `Chart1` has a sorted order `0:2` and `Chart` has a sorted order of `0:4`, the function-call subsystem `f` has a sorted order notation of `0:2,0:4`.

Branched Function-Call Signals

When a function-call signal is branched using a Function-Call Split block, Simulink displays the order in which subsystems (or models) that connect to the branches execute when the initiator invokes the function call. Simulink uses the notation $s:b^i[B_k]$ to indicate this order. s is the system index of the model or subsystem the block resides in, b^i is the block index of the root initiator in the subsystem's hierarchy, and B_k indicates that it is a branched function-call subsystem with branch index k .

For example, open the `s1_subsys_fcncall111` model and display the sorted order. The sorted order indicates that the subsystem f (B0) executes before the subsystem g (B1).

Bus-Capable Blocks

A bus-capable block does not execute as a unit and therefore does not have a unique sorted order. Such a block displays its sorted order as $s : B$ where B stands for bus.

For example, open the `sldemo_bus_arrays` model and display the sorted order. Open the For Each Subsystem to see that the sorted order for the Bus Assignment block appears as $1 : B$.

For more information, see “Bus-Capable Blocks” on page 63-28.

How Simulink Determines the Sorted Order

Direct-Feedthrough Ports Impact on Sorted Order

To ensure that the sorted order reflects data dependencies among blocks, Simulink categorizes block input ports according to the dependency of the block outputs on the

block input ports. An input port whose current value determines the current value of one of the block outputs is a *direct-feedthrough* port. Examples of blocks that have direct-feedthrough ports include:

- Gain
- Product
- Sum

Examples of blocks that have non-direct-feedthrough inputs:

- Integrator — Output is a function of its state.
- Constant — Does not have an input.
- Memory — Output depends on its input from the previous time step.

Rules for Sorting Blocks

To sort blocks, Simulink uses the following rules:

- If a block drives the direct-feedthrough port of another block, the block must appear in the sorted order ahead of the block that it drives.

This rule ensures that the direct-feedthrough inputs to blocks are valid when Simulink invokes block methods that require current inputs.

- Blocks that do not have direct-feedthrough inputs can appear anywhere in the sorted order as long as they precede any direct-feedthrough blocks that they drive.

Placing all blocks that do not have direct-feedthrough ports at the beginning of the sorted order satisfies this rule. This arrangement allows Simulink to ignore these blocks during the sorting process.

Applying these rules results in the sorted order. Blocks without direct-feedthrough ports appear at the beginning of the list in no particular order. These blocks are followed by blocks with direct-feedthrough ports arranged such that they can supply valid inputs to the blocks which they drive.

The following model, from “Nonvirtual Subsystems” on page 33-31, illustrates this result. The following blocks do not have direct-feedthrough and therefore appear at the beginning of the sorted order of the root-level system:

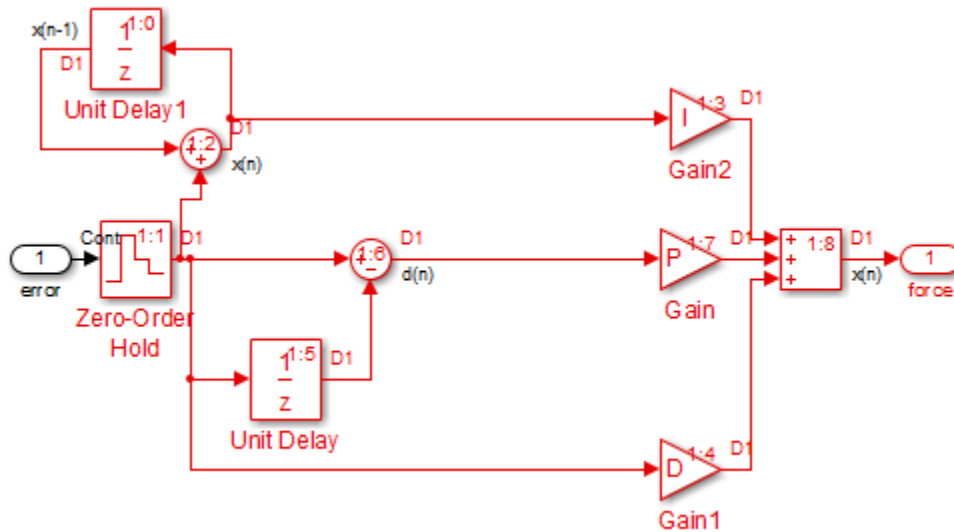

- Integrator block in the Car Dynamics virtual subsystem

- Speed block in the root-level model

Inside the Discrete Cruise Controller subsystem, all the Gain blocks, which have direct-feedthrough ports, run before the Sum block that they drive.

Assign Block Priorities

You can assign a priority to a nonvirtual block or to an entire subsystem. Higher priority blocks appear before lower priority blocks in the sorted order. The lower the number, the higher the priority. Set the block priority in the block properties in the **Advanced** section.

Rules for Block Priorities

Simulink honors the block priorities that you specify unless they violate data dependencies. (“Block Priority Violations” on page 33-43 describes situations that cause block property violations.)

In assessing priority assignments, Simulink attempts to create a sorted order such that the priorities for the individual blocks within the root-level system or within a nonvirtual subsystem are honored relative to one another.

Three rules pertain to priorities:

- “Priorities Are Relative” on page 33-41

- “Priorities Are Hierarchical” on page 33-42
- “Lack of Priority May Not Result in Low Priority” on page 33-43

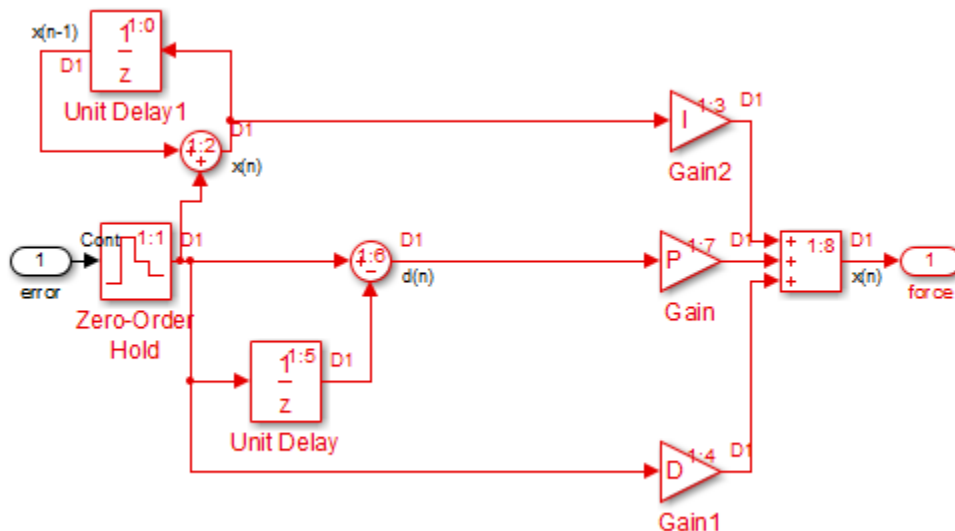

Priorities Are Relative

Priorities are relative; the priority of a block is relative to the priority of the blocks within the same system or subsystem.

For example, suppose you set the following priorities in the Discrete Cruise Controller subsystem in the model in “Nonvirtual Subsystems” on page 33-31.

Block	Priority
Gain	3
Gain1	2
Gain2	1

After updating the diagram, the sorted order for the Gain blocks is as follows.

The sorted order values of the Gain, Gain1, and Gain2 blocks reflect the respective priorities assigned: Gain2 has highest priority and executes before Gain1 and Gain;

Gain1 has second priority and executes after Gain2; and Gain executes after Gain1. Simulink takes into account the assigned priorities relative to the other blocks in that subsystem.

The Gain blocks are not the first, second, and third blocks to execute. Nor do they have consecutive sorted orders. The sorted order values do not necessarily correspond to the priority values. Simulink arranges the blocks so that their priorities are honored relative to each other.

Priorities Are Hierarchical

In the Car Dynamics virtual subsystem, suppose you set the priorities of the Gain blocks as follows.

Block	Priority
Gain	2
Gain1	1

After updating the diagram, the sorted order for the Gain blocks is as illustrated. With these priorities, Gain1 always executes before Gain.

You can set a priority of 1 to one block in each of the two subsystems because of the hierarchical nature of the subsystems within a model. Simulink never compares the priorities of the blocks in one subsystem to the priorities of blocks in any other subsystem.

For example, consider this model again.

The blocks within the Car Dynamics virtual subsystem are part of the root-level system hierarchy and are part of the root-level sorted order. The Discrete Cruise Controller subsystem has an independent sorted order with the blocks arranged consecutively from 1:0 to 1:7.

Lack of Priority May Not Result in Low Priority

A lack of priority does not necessarily result in a low priority (higher sorting order) for a given block. Blocks that do not have direct-feedthrough ports execute before blocks that have direct-feedthrough ports, regardless of their priority.

If a model has two atomic subsystems, A and B, you can assign priorities of 1 and 2 respectively to A and B. This priority causes all the blocks in A to execute before any of the blocks in B. The blocks within an atomic subsystem execute as a single unit, so the subsystem has its own system index and its own sorted order.

Block Priority Violations

Simulink software honors the block priorities that you specify unless they violate data dependencies. If Simulink is unable to honor a block priority, it displays a **Block Priority Violation** diagnostic message.

As an example:

- 1 Open the `sldemo_bounce` model.

Notice that the output of the Memory block provides the input to the Coefficient of Restitution Gain block.

- 2 Set the priority of the Coefficient of Restitution block to 1, and set the priority of the Memory block to 2.

Setting these priorities specifies that the Coefficient of Restitution block execute before the Memory block. However, the Coefficient of Restitution block depends on the output of the Memory block, so the priorities you just set violate the data dependencies.

- 3** In the model window, enable sorted order by selecting **Format > Block displays > Sorted Order**.
- 4** Select **Simulation > Update Diagram**.

The block priority violation warning appears in the **Diagnostic Viewer**. To open the **Diagnostic Viewer** window, click **View > Diagnostic Viewer**. The warning includes the priority for the respective blocks:

```
Warning: Unable to honor user-specified priorities.  
'sldemo_bounce/Memory' (pri=[2]) has to execute  
before 'sldemo_bounce/Coefficient of Restitution'  
(pri=[1]) to satisfy data dependencies
```

- 5** Remove the priorities from the Coefficient of Restitution and Memory blocks and update the diagram again to see the correct sorted order.

Access Block Data During Simulation

In this section...

“About Block Run-Time Objects” on page 33-45

“Access a Run-Time Object” on page 33-45

“Listen for Method Execution Events” on page 33-46

“Synchronizing Run-Time Objects and Simulink Execution” on page 33-47

About Block Run-Time Objects

Simulink provides an application programming interface, called the block run-time interface, that enables programmatic access to block data, such as block inputs and outputs, parameters, states, and work vectors, while a simulation is running. You can use this interface to access block run-time data from the MATLAB command line, the Simulink Debugger, and from Level-2 MATLAB S-functions (see “Write Level-2 MATLAB S-Functions” in the online Simulink documentation).

Note You can use this interface even when the model is paused or is running or paused in the debugger.

The block run-time interface consists of a set of Simulink data object classes (see “Data Objects” on page 57-54) whose instances provide data about the blocks in a running model. In particular, the interface associates an instance of `Simulink.RunTimeBlock`, called the block's run-time object, with each nonvirtual block in the running model. A run-time object's methods and properties provide access to run-time data about the block's I/O ports, parameters, sample times, and states.

Access a Run-Time Object

Every nonvirtual block in a running model has a `RuntimeObject` parameter whose value, while the simulation is running, is a handle for the blocks' run-time object. This allows you to use `get_param` to obtain a block's run-time object. For example, the following statement

```
rto = get_param(gcb, 'RuntimeObject');
```

returns the run-time object of the currently selected block. Run-time object data is read-only. You cannot use run-time objects to change a block's parameters, input, output, and state data.

Note Virtual blocks (see “Nonvirtual and Virtual Blocks” on page 33-2) do not have run-time objects. Blocks eliminated during model compilation as an optimization also do not have run-time objects (see “Block reduction”). A run-time object exists only while the model containing the block is running or paused. If the model is stopped, `get_param` returns an empty handle. When you stop a model, all existing handles for run-time objects become empty.

Listen for Method Execution Events

One application for the block run-time API is to collect diagnostic data at key points during simulation, such as the value of block states before or after blocks compute their outputs or derivatives. The block run-time API provides an event-listener mechanism that facilitates such applications. For more information, see the documentation for the `add_exec_event_listener` command. For an example of using method execution events, enter

```
sldemo_msfcn_lms
```

at the MATLAB command line. This Simulink model contains the S-function `adapt_lms.m`, which performs a system identification to determine the coefficients of an FIR filter. The S-function's `PostPropagationSetup` method initializes the block run-time object's `DWork` vector such that the second vector stores the filter coefficients calculated at each time step.

In the Simulink model, double-clicking on the annotation below the S-function block executes its `OpenFcn`. This function first opens a figure for plotting the FIR filter coefficients. It then executes the function `add_adapt_coef_plot.m` to add a `PostOutputs` method execution event to the S-function's block run-time object using the following lines of code.

```
% Add a callback for PostOutputs event
blk = 'sldemo_msfcn_lms/LMS Adaptive';

h    = add_exec_event_listener(blk, ...
    'PostOutputs', @plot_adapt_coefs);
```

The function `plot_adapt_coefs.m` is registered as an event listener that is executed after every call to the S-function's `Outputs` method. The function accesses the block run-time object's `DWork` vector and plots the filter coefficients calculated in the `Outputs` method. The calling syntax used in `plot_adapt_coefs.m` follows the standard needed for any listener. The first input argument is the S-function's block run-time object, and the second argument is a structure of event data, as shown below.

```
function plot_adapt_coefs(block, ei) %#ok<INUSD>
%
% Callback function for plotting the current adaptive filtering
% coefficients.

stemPlot = get_param(block.BlockHandle, 'UserData');

est = block.Dwork(2).Data;
set(stemPlot(2), 'YData', est);
drawnow('expose');
```

Synchronizing Run-Time Objects and Simulink Execution

You can use run-time objects to obtain the value of a block output and display in the MATLAB Command Window by entering the following commands.

```
rto = get_param(gcf, 'RuntimeObject')
rto.OutputPort(1).Data
```

However, the displayed data may not be the true block output if the run-time object is not synchronized with the Simulink execution. Simulink only ensures the run-time object and Simulink execution are synchronized when the run-time object is used either within a Level-2 MATLAB S-function or in an event listener callback. When called from the MATLAB Command Window, the run-time object can return incorrect output data if other blocks in the model are allowed to share memory.

To ensure the `Data` field contains the correct block output, open the Configuration Parameters dialog box, and then clear the **Signal storage reuse** check box on the **All Parameters** tab (see “Signal storage reuse”).

Set Block Parameter Values

Blocks have numeric parameters that determine how they calculate output values. To control the calculations that blocks perform, you can specify parameter values. For example, a Gain block has a **Gain** parameter, and a Transfer Fcn block has multiple parameters that represent the transfer function coefficients.

You can use numbers, variables, and expressions to set block parameter values. Choose a technique based on your modeling goals. For example, you can:

- Share parameter values between blocks and models by creating variables.
- Control parameter characteristics such as data type and dimensions by creating parameter objects.
- Model an algorithm as code by using mathematical expressions.

Set block parameters using the property inspector or the block dialog box. For more information, see “Block Parameters and Properties in Simulink” on page 1-54. To set block sample times, see “Specify Sample Time” on page 7-3.

Tip You can use the Model Explorer to make batch changes to many block parameter values at once. For more information, see “Model Explorer Overview” on page 12-2.

Programmatically Access Parameter Values

To programmatically access block parameter values, use the `get_param` and `set_param` functions. You can use this technique to adjust parameter values between simulation runs, or during a simulation, when you simulate a model programmatically.

Suppose you create a model named `myModel` that contains a Constant block named `My Constant`. Next, you use the block dialog box to set the **Constant value** parameter to `15`. To programmatically return the parameter value, use the function `get_param`. You specify the block path and the equivalent programmatic parameter name, `Value`.

```
paramValue = get_param('myModel/My Constant', 'Value')
```

```
paramValue =
```

```
15
```

To programmatically change the value, for example to 25, use the function `set_param`. Use the character vector `'25'` as the input to the function.

```
set_param('myModel/My Constant', 'Value', '25')
```

For a list of programmatic names of block parameters, see “Block-Specific Parameters”.

For more information about programmatic simulation, see “Run Simulations Programmatically” on page 24-2.

To avoid using the `get_param` and `set_param` functions, use the name of a MATLAB variable or `Simulink.Parameter` object as the parameter value, and change the value of the variable or object at the command prompt. See “Share and Reuse Block Parameter Values by Creating Variables” on page 34-11.

Specify Parameter Values

Goal	Block Parameter Value	Description
Store the parameter value in the model file.	2.3 [1.2 2.3 4.5; 7.9 8.7 6.5] 2 + 3i	Literal numeric value. Specify a scalar, vector, matrix, or multidimensional array. Use <code>i</code> to specify complex values.
<ul style="list-style-type: none"> Access the parameter value without having to locate the block in the model. Change the parameter value without having to modify the model file. Share the parameter value between blocks or between models. Identify the parameter by a specific name when sweeping or tuning the value. 	myVar	MATLAB variable that exists in a workspace. For more information, see “Share and Reuse Block Parameter Values by Creating Variables” on page 34-11.

Goal	Block Parameter Value	Description
<ul style="list-style-type: none"> • Avoid name clashes between workspace variables. • Organize parameter values using hierarchies and meaningful names. • Reduce the number of workspace variables that a model uses. 	<code>myParam.a.SpeedVect</code>	<p>Field of parameter structure.</p> <p>For more information, see “Organize Related Block Parameter Definitions in Structures” on page 34-22.</p>
<p>Use a portion of a matrix or array variable. For example, set the parameters of a n-D Lookup Table block.</p>	<code>myMatrixParam(:,2)</code>	<p>Index operation.</p>
<ul style="list-style-type: none"> • Define parameter characteristics, such as data type, complexity, units, allowed value range, and dimensions, separately from the parameter value. • Define a system constant with custom documentation. • Create a tunable parameter in the generated code. 	<code>myParam</code>	<p>Parameter object.</p> <p>For more information, see “Use Parameter Objects” on page 34-5.</p>

Goal	Block Parameter Value	Description
<ul style="list-style-type: none"> Model a complicated algorithm or subroutine by using code instead of blocks. Reduce block population in a model. Use MATLAB operators and functions to perform calculations in a model. Write a custom MATLAB function that calculates parameter values. 	$5^{3.2} - 1/3$ <code>myParam * myOtherparam + sin(0.78*pi)</code> <code>myFun(15.23)</code>	<p>Expression or custom function.</p> <p>For more information, see “Use MATLAB Functions and Custom Functions” on page 34-6.</p>
Specify a block parameter value by using a data type other than <code>double</code> .	<code>15.23</code> <code>single(15.23)</code> <code>myParam</code>	<p>Typed or untyped expression, numeric MATLAB variable, or parameter object.</p> <p>For more information about controlling parameter data types, see “Control Block Parameter Data Types” on page 34-54.</p>

Use Parameter Objects

Parameter objects are `Simulink.Parameter` objects and objects of the subclasses that you create. The parameter object exists in a workspace such as the base workspace or a data dictionary.

You can use parameter objects to define system constants. For example, use a parameter object to represent the radius of the Earth. Use the properties of the object to specify the physical units and to document the purpose of the value.

Create parameter objects to prepare your model for code generation. You can configure parameter objects to appear as tunable global variables in the generated code. You can also control the parameter data type through the object.

To create and use parameter objects in models, see “Data Objects” on page 57-54. For information about using variables to set block parameter values, see “Share and Reuse Block Parameter Values by Creating Variables” on page 34-11.

Use MATLAB Functions and Custom Functions

You can set a block parameter value to an expression that calls MATLAB functions and operators such as `sin` and `max`. You can also call your own custom functions that you write on the MATLAB path.

Suppose that a section of your block algorithm uses variables to calculate a single constant number used by the rest of the algorithm. You can perform the calculation by creating multiple blocks.

Instead, create a single Constant block that uses an expression written in MATLAB code. This technique reduces the size of the block algorithm and improves readability.

You can model a complicated portion of an algorithm by using an expression instead of many blocks. To operate on an existing signal, use a mathematical expression as the value of a parameter in an algorithmic block, such as the **Gain** parameter of a Gain block.

With expressions, you can also call your custom functions to set block parameter values. Suppose that you write a MATLAB function that calculates optimal P, I, and D parameters for a control algorithm by accepting a single input number.

```

paramFcn.m x +
1  function paramValue = paramFcn(performance,parameter)
2  %PARAMVALUE = paramFcn(PERFORMANCE,PARAMETER) returns the P, I, or D
3  %value PARAMVALUE that you request using PARAMETER. Specify performance
4  %criteria using PERFORMANCE.
5
6  % Initialize output.
7  paramValue = [];
8
9  % Calculate parameter value.
10 switch parameter
11     case 'P'
12         paramValue = performance*3;
13     case 'I'
14         paramValue = sqrt(performance)/0.175;
15     case 'D'
16         paramValue = performance^0.25;
17
18 % Validation

```

You can parameterize a PID Controller block by using the function to set the parameter values.

Controller parameters

Source:	internal
Proportional (P):	paramFcn(perf,'P')
Integral (I):	paramFcn(perf,'I')
Derivative (D):	paramFcn(perf,'D')

Considerations for Other Modeling Goals

Choose a technique to set block parameter values based on your modeling goals.

Goal	Features or Products	Best Practice
Run multiple simulations quickly.	Rapid accelerator simulations when you set 'RapidAccelerator' to 'off'.	Use variables or parameter objects to set block parameter values. This technique helps you to identify tunable parameters in the structure that <code>Simulink.BlockDiagram.buildRapidAcceleratorTarget</code> generates. See “Parallel Simulations Using Parfor: Parameter Sweep in Rapid Accelerator Mode” and <code>Simulink.BlockDiagram.buildRapidAcceleratorTarget</code> .
Override parameter values during testing.	Simulink Test™	Use variables or parameter objects to set block parameter values. See “Parameter Overrides”.
Estimate and optimize parameter values.	Simulink Design Optimization™	<p>Use variables or parameter objects to set block parameter values.</p> <p>To estimate or optimize a parameter that uses a data type other than <code>double</code>, use a parameter object to separate the value from the data type.</p> <p>For parameter estimation, see “Parameter Estimation”. For response optimization, see “Optimize Model Response”.</p>
Generate code from a model. Simulate an external program through SIL/PIL or External mode simulations.	Simulink Coder	<p>Use parameter objects to set block parameter values. This technique helps you to declare and identify tunable parameters in the generated code and to control parameter data types. See “Block Parameter Representation in the Generated Code”.</p> <p>When you use expressions to set block parameter values, avoid using operators and functions that result in loss of tunability in the generated code. See “Tunable Expression Limitations”.</p>

Share and Reuse Block Parameter Values by Creating Variables

To set a block parameter value, such as the **Gain** parameter of a Gain block, you can use numeric variables that you create and store in workspaces such as the base workspace, a model workspace, or a Simulink data dictionary. You can use the variable to set multiple parameter values in multiple blocks, including blocks in different models. To change the values of the block parameters, you change the value of the variable in the workspace.

Using a variable to set a block parameter value also enables you to:

- Access the parameter value without having to locate the block in the model.
- Change the parameter value without having to modify the model file (if you store the variable outside the model workspace).
- Identify the parameter by a specific, meaningful name when sweeping or tuning the value.

For basic information about setting block parameter values, see “Set Block Parameter Values” on page 34-2.

Reuse Parameter Values in Multiple Blocks and Models

You can create a numeric MATLAB variable in a workspace, such as the base workspace or a data dictionary, and use it to specify one or more block parameter values.

- 1 At the command prompt, create a numeric variable in the base workspace. For example, create a variable `myParam` whose value is `15.23`.

```
myParam = 15.23;
```

- 2 Open a block dialog box. Set the value of the target parameter to `myParam`.
- 3 Set the values of parameters in the same block or in other blocks to `myParam`.

If you store the variable in the base workspace, you can use the variable in all open models. For example, if you use model referencing to segment a model into components, you can use the variable in multiple models in a model reference hierarchy.

If you store the variable in a data dictionary, you can use the variable in all of the models that are linked to the dictionary or to other dictionaries that reference the dictionary. If you link multiple models to different data dictionaries, to use a variable in more than one of the models, consider storing the variable in a single separate dictionary to which

no models are linked. Then, use dictionary referencing to share the variable between the target models. Models that you link to a data dictionary cannot use variables that are in the base workspace.

Define a System Constant

To define a system constant, such as a variable that represents the radius of the Earth, consider creating a `Simulink.Parameter` object instead of a numeric MATLAB variable. Parameter objects allow you to specify physical units and custom documentation as well as other characteristics.

To create and use parameter objects in models, see “Data Objects” on page 57-54.

Control Scope of Parameter Values

The *scope* of a variable is the set of models and blocks that can use the variable. For example, variables that you create in the base workspace have global scope because all blocks in all open models can use the variables. Variables that you store in a model workspace have limited scope because only the blocks in the host model can use the variables.

You cannot create two variables that have the same name in the same scope. Controlling the scope of a variable helps you to avoid name conflicts and establish clear ownership of the variable.

The table describes the different ways that you can control the scope of a reusable parameter value.

Scope	Technique
All open models	Create a variable in the base workspace.
One or more targeted models	Create a variable in a data dictionary. To reuse the variable in multiple models, create a referenced dictionary. See “What Is a Data Dictionary?” on page 61-2
One model, including all subsystems in the model	Create a variable in the model workspace. See “Model Workspaces” on page 4-71.
Multiple blocks inside a subsystem, including blocks in nested subsystems	Mask the subsystem and create a mask parameter instead of a workspace variable.

Scope	Technique
	<p>To prevent blocks inside a subsystem from using workspace variables, in the subsystem block dialog box, set Permit Hierarchical Resolution to None. This technique allows you to use the same name to create both a variable in a workspace and a mask parameter in the subsystem mask. The blocks in the subsystem can use only the mask parameter.</p> <p>For information about subsystems, see Subsystem. For information about masking, see “Masking Fundamentals” on page 36-2.</p>

To avoid name conflicts when you have a large model with many variables in the same scope, consider packaging the variables into a single structure. For more information, see “Organize Related Block Parameter Definitions in Structures” on page 34-22.

For basic information about how blocks use the variable names that you specify, see “Symbol Resolution” on page 4-82.

Permanently Store Workspace Variables

Variables that you create in the base workspace variables do not persist between MATLAB sessions. However, you can store the variables in a MAT-file or script file, and load the file whenever you open the model using a model callback. A model *callback* is a set of commands that Simulink executes when you interact with a model in a particular way, such as opening the model. You can use a callback to load variables when you open the model. Use this technique to store variables while you learn about Simulink and experiment with models.

- 1 In a model that contains a Gain block, set the value of the **Gain** parameter to K.
- 2 At the command prompt, create a variable K in the base workspace.

```
K = 27;
```

- 3 In the Workspace browser, right-click the variable and select **Save As**.

To save multiple variables in one file, select all of the target variables in the Workspace browser, and then right-click any of the selected variables.

- 4 In the dialog box, set **Save as type** to **MATLAB Script**. Set **File name** to `loadvar` and click **Save**.

The script file `loadvar.m` appears in your current folder. You can open the file to view the command that creates the variable `K`.

- 5 In the model, select **File > Model Properties > Model Properties**.
- 6 In the **Callbacks** tab of the Model Properties dialog box, select `PreLoadFcn` as the callback that you want to define. In the **Model pre-load function** pane, enter `loadvar` and click **OK**.
- 7 Save the model.

The next time that you open the model, the `PreloadFcn` callback loads the variable `K` into the base workspace. You can also save the variable to a MAT-file, for example `loadvar.mat`, and set the model callback to `load loadvar`.

To learn about callbacks, see “Callbacks for Customized Model Behavior” on page 4-56 and “Callbacks for Customized Model Behavior” on page 4-56. To programmatically define a callback for loading variables, see “Programmatically Store Workspace Variables for a Model” on page 34-14.

When you save variables to a file, you must save the changes that you make to the variables during your MATLAB session. To permanently store variables for a model, consider using a model workspace or a data dictionary instead of a MAT-file or script file. For more information about permanently storing variables, see “Determine Where to Store Variables and Objects for Simulink Models” on page 57-81.

Programmatically Store Workspace Variables for a Model

In the example above, you define a model callback that creates variables when you open a model. You can programmatically save the variable and set the model callback.

- 1 At the command prompt, create the variable `K` in the base workspace.

```
K = 27;
```

- 2 Save the variable to a new script file named `loadvar.m`.

```
matlab.io.saveVariablesToScript('loadvar.m','K')
```

- 3 Set the model callback to load the script file.

```
set_param('myModel', 'PreloadFcn', 'loadvar')
```

- 4 Save the model.

```
save_system('myModel')
```

The function `matlab.io.saveVariablesToScript` saves variables to a script file. To save variables to a MAT-file, use the function `save`. To programmatically set model properties such as callbacks, use the function `set_param`.

Manage and Edit Workspace Variables

When you use variables to set block parameter values, you store the variables in a workspace or data dictionary. You can use the command prompt or the Model Explorer to create, move, copy, and edit variables. You can also determine where a variable is used in a model, list all of the variables that a model uses, and list all of the variables that a model does not use.

The Model Explorer allows you to manage variables by using a graphical interface. You can view and edit the contents of any workspace, including data dictionaries, and transfer variables from one workspace to another. To view and modify a variable whose value is a structure or array, you can launch the Variable Editor from the Model Explorer. For more information, see “Model Explorer Overview” on page 12-2 and “Edit and Manage Workspace Variables Used by Models” on page 57-88.

You can also create and edit variables directly through block dialog boxes or the property inspector. Use this technique to determine where a variable is stored. See “Manage Variables from Block Parameter” on page 34-45.

To view tunable block parameter values in a list that you can search, sort, and filter, use the **Parameters** tab in the Model Data Editor. You can also create and navigate to variables that the block parameters use. To use the Model Data Editor, see “Configure Data Properties by Using a Table” on page 57-103.

At the command prompt, you can create variables in the base workspace by entering commands such as `myVar = 15;`. To programmatically create and store variables in a different workspace, such as a model workspace, use the programmatic interface for the target workspace. The table shows the interfaces and techniques that you can use to programmatically manage variables.

Target Workspace	Technique or Interface
Base workspace	Enter commands at the command prompt.
Model workspace	See <code>Simulink.ModelWorkspace</code> .
Data dictionary	See “Store Data in Dictionary Programmatically” on page 61-52.

To programmatically list the variables that a model uses or does not use, see `Simulink.findVars`.

Package Shared Breakpoint and Table Data for Lookup Tables

To share breakpoint vectors or table data between multiple n-D Lookup Table, Prelookup, and Interpolation Using Prelookup blocks, consider storing the data in `Simulink.LookupTable` and `Simulink.Breakpoint` objects instead of MATLAB variables or `Simulink.Parameter` objects. This technique improves model readability by clearly identifying the data as parts of a lookup table and explicitly associating breakpoint data with table data.

Store Standalone Lookup Table in `Simulink.LookupTable` Object

A standalone lookup table consists of a set of table data and one or more breakpoint vectors. You do not share the table data or any of the breakpoint vectors with other lookup tables.

When you share a standalone lookup table, you use all of the table and breakpoint data together in multiple n-D Lookup Table blocks. To store this data in a `Simulink.LookupTable` object:

- 1 Create the object in a workspace or data dictionary. For example, at the command prompt, enter:
`myLUTObj = Simulink.LookupTable;`
- 2 Use the properties of the object to store the values of the table and breakpoint data.
- 3 Use the properties of the object to configure a unique name for the structure type in the generated code. In the property dialog box, under **Struct Type definition**, specify **Name**.
- 4 In the n-D Lookup Table blocks, set **Data specification** to `Lookup table object`.
- 5 To the right of **Data specification**, set **Name** to the name of the `Simulink.LookupTable` object.

For ways to create and configure `Simulink.LookupTable` objects, see `Simulink.LookupTable`

Store Shared Data in `Simulink.LookupTable` and `Simulink.Breakpoint` Objects

When you use Prelookup and Interpolation Using Prelookup blocks to more finely control the lookup algorithm, you can share breakpoint vectors and sets of table data. For example, you can share a breakpoint vector between two separate sets of table data. With this separation of the breakpoint data from the table data, you can share individual parts of a lookup table instead of sharing the entire lookup table.

To store breakpoint and table data:

- 1 Create a `Simulink.LookupTable` object for each unique set of table data. Create a `Simulink.Breakpoint` object for each unique breakpoint vector, including breakpoint vectors that you do not intend to share.
- 2 Use the properties of the objects to store the values of the table and breakpoint data.
- 3 Configure the `Simulink.LookupTable` objects to refer to the `Simulink.Breakpoint` objects for breakpoint data. In the `Simulink.LookupTable` objects, set **Specification** to `Reference`. Specify the names of the `Simulink.Breakpoint` objects.
- 4 In the Interpolation Using Prelookup blocks, set **Specification** to `Lookup table object`. Set **Name** to the name of a `Simulink.LookupTable` object.

In the Prelookup blocks, set **Specification** to `Breakpoint object`. Set **Name** to the name of a `Simulink.Breakpoint` object.

The example model `fxpdemo_lookup_shared_param` contains two Prelookup and two Interpolation Using Prelookup blocks. Configure the blocks so that each combination of a Prelookup and an Interpolation Using Prelookup block represents a unique lookup table. Share the breakpoint vector between the two lookup tables. In this case, each lookup table has unique table data but shared breakpoint data.

- 1 Open the example model.
- 2 In the Prelookup block dialog box, set **Specification** to `Breakpoint object`. Set **Name** to `sharedBkpts`.
- 3 Right-click `sharedBkpts` and select **Create Variable**.
- 4 In the **Create New Data** dialog box, set **Value** to `Simulink.Breakpoint` and click **Create**.

A `Simulink.Breakpoint` object appears in the base workspace.

- 5 In the property dialog box for `sharedBkpts`, specify **Value** as a vector, such as [1 2 3 4 5 6 7 8 9 10]. Click **OK**.
- 6 In the Prelookup block dialog box, click **OK**.
- 7 In the Prelookup1 block dialog box, set **Specification** to `Breakpoint` object. Set **Name** to `sharedBkpts`.
- 8 In the Interpolation Using Prelookup block dialog box, set **Specification** to `Lookup table` object. Set **Name** to `dataForFirstTable`.
- 9 Right-click `dataForFirstTable` and select **Create Variable**.
- 10 In the **Create New Data** dialog box, set **Value** to `Simulink.LookupTable` and click **Create**.

A `Simulink.LookupTable` object appears in the base workspace.

- 11 In the property dialog box for `dataForFirstTable`, specify **Value** as a vector, such as [10 9 8 7 6 5 4 3 2 1].
- 12 Set **Specification** to `Reference`.
- 13 In the table under **Specification**, set **Name** to `sharedBkpts` and click **OK**.
- 14 In the Interpolation Using Prelookup block dialog box, click **OK**.
- 15 Configure the Interpolation Using Prelookup1 block to use a `Simulink.LookupTable` object named `dataForSecondTable`. In the object property dialog box, specify **Value** as a vector, such as [0 0.5 1 1.5 2 2.5 3 3.5 4 4.5]. Configure the object to refer to `sharedBkpts` for the breakpoint data.

The model now represents two unique lookup tables:

- A combination of `sharedBkpts` and `dataForFirstTable`.
- A combination of `sharedBkpts` and `dataForSecondTable`.

These lookup tables share the same breakpoint data through `sharedBkpts`.

Parameter Interfaces for Reusable Components

You can use subsystems, referenced models, and custom library blocks as reusable components in other models. For guidelines to help you decide how to componentize a system, see “Componentization Guidelines” on page 15-29.

Typically, a reusable algorithm requires that numeric block parameters, such as the **Gain** parameter of a Gain block, either:

- Use the same value in all instances of the component.
- Use a different value in each instance of the component. Each value is instance specific.

By default, if you use a literal number or expression to set the value of a block parameter, the parameter uses the same value in all instances of the component. If you set multiple block parameter values by using a MATLAB variable, `Simulink.Parameter` object, or other parameter object in a workspace or data dictionary, these parameters also use the same value in all instances of the component.

Referenced Models

If you use model referencing to create a reusable component, to set parameter values that are specific to each instance, configure model arguments for the referenced model. When you instantiate the model by adding a Model block to a different model, you set the values of the arguments in the Model block. When you add another Model block to the same parent model or to a different model, you can set different values for the same arguments. Optionally, if you create more than two instances, you can set the same value for some of the instances and different values for the other instances.

If a model has many model arguments, consider packaging the arguments into a single structure. Instead of configuring many arguments, configure the structure as a single argument. Without changing the mathematical functionality of the component, this technique helps you to reduce the number of model argument values that you must set in each instance of the component.

For more information about model arguments, see “Parameterize Instances of a Reusable Referenced Model” on page 8-61.

Subsystems

If you use subsystems or custom libraries to create reusable components, to set parameter values that are specific to each instance, use masks, mask parameters, and parameter promotion. When you instantiate the component in a model, you set the values of the mask parameters in the Subsystem block. When you instantiate the component again in the same model or a different model, you can set different values for the same mask parameters. Optionally, if you create more than two instances, you can set the same value for some of the instances and different values for the other instances.

If the subsystem has many mask parameters, consider packaging the parameters into a single structure. Instead of configuring many mask parameters, configure the structure as a single parameter. Without changing the mathematical functionality of the component, this technique helps you to reduce the number of mask parameter values that you must set in each instance of the component.

For more information about subsystems, see **Subsystem**. For more information about custom block libraries, see “Create a Custom Block” on page 37-19. For more information about masks, see “Masking Fundamentals” on page 36-2. For more information about structures, see “Organize Related Block Parameter Definitions in Structures” on page 34-22.

Organize Related Block Parameter Definitions in Structures

When you use numeric MATLAB variables to set block parameter values in a model, large models can accumulate many variables, increasing the effort of maintenance and causing the variable names to grow in length.

Instead, you can organize these parameter values into structures. Each structure is a single variable and each field of the structure stores a numeric parameter value. You can assign meaningful names to the structures, substructures, and fields to indicate the purpose of each value.

Use structures to:

- Reduce the number of workspace variables that you must maintain.
- Avoid name conflicts between workspace variables.

You cannot create two variables that have the same name in the same scope, such as in the base workspace. When you create structures, you must provide each field a name, but multiple structures can each contain a field that uses the same name. Therefore, you can use each structure and substructure as a *namespace* that prevents the field names from conflicting with each other and with other variable names in the same scope.

- Logically group sets of block parameter values. For example, use nested structures to clearly identify the parameter values that each subsystem or referenced model uses.

If you use mask parameters or model arguments to pass parameter values to the components of a system, you can use structures to reduce the number of individual mask parameters or model arguments that you must maintain. Instead of passing multiple variables, you can pass a single structure variable.

For basic information about creating and manipulating MATLAB structures, see Structures. For basic information about setting block parameter values in a model, see “Set Block Parameter Values” on page 34-2.

To use structures to initialize bus signals, see “Specify Initial Conditions for Bus Signals” on page 63-80.

Create and Use Parameter Structure

This example shows how to create and use a parameter structure in a model.

The example model `f14` uses multiple variables from the base workspace to set block parameter values. For example, when you open the model, it creates the variables `Zw`, `Mw`, and `Mq` in the base workspace. To organize these variables into a single structure variable:

- 1 At the command prompt, open the example model.

```
f14
```

- 2 At the command prompt, create the parameter structure `myGains`. Set the field values by using the values of the target variables.

```
myGains.Zw = Zw;
myGains.Mw = Mw;
myGains.Mq = Mq;
```

- 3 In the Model Explorer, on the **Model Hierarchy** pane, click **Base Workspace**. In the **Contents** pane, right-click the variable `Mq` and select **Find Where Used**.
- 4 In the **Select a system** dialog box, click the node `f14` and click **OK**. Click **OK** when asked about updating the diagram.
- 5 In the **Contents** pane, right-click the row corresponding to the block labeled `Gain1` and select **Properties**. The `Gain1` block dialog box opens.
- 6 Change the value of the **Gain** parameter from `Mq` to `myGains.Mq` and click **OK**.
- 7 In the **Contents** pane, right-click the row corresponding to the `Transfer Fcn.1` block and select **Properties**.
- 8 Change the value of the **Denominator coefficients** parameter from `[1, -Mq]` to `[1, -myGains.Mq]` and click **OK**.
- 9 In the **Model Hierarchy** pane, click **Base Workspace**. Use **Find Where Used** to locate the blocks that use the variables `Mw` and `Zw`. In the block dialog boxes, replace the references to the variable names according to the table.

Variable Name	Replacement Name
<code>Mw</code>	<code>myGains.Mw</code>
<code>Zw</code>	<code>myGains.Zw</code>

- 10 Clear the old variables.

```
clear Zw Mw Mq
```

Each of the modified block parameters now uses a field of the `myGains` structure. The numeric value of each structure field is equal to the value of the corresponding variable that you cleared.

You can use the functions `Simulink.BlockDiagram.createVarStruct` and `Simulink.BlockDiagram.applyVarStruct` to migrate a model to use a single parameter structure instead of multiple workspace variables. For an example, see “Migration to Structure Parameters”.

Manage Structure Variables

To create, modify, and view a variable whose value is a structure, you can use the Model Explorer whether you store the variable in the base workspace, a model workspace, or a data dictionary. To view and modify the field values in the structure, open the Variable Editor. For more information, see “Edit and Manage Workspace Variables Used by Models” on page 57-88.

Define Parameter Hierarchy by Creating Nested Structures

To further organize block parameter values, create a hierarchy of nested structures.

For example, suppose that you create subsystems named `SubsystemA` and `SubsystemB` in your model. You use variables such as `Offset_SubsystemA` and `Offset_SubsystemB` to set block parameter values in the subsystems.

```
Gain_SubsystemA = 15.23;
Offset_SubsystemA = 89;
Init_SubsystemA = 0.59;

Coeffs_SubsystemB = [5.32 7.99];
Offset_SubsystemB = 57;
Init1_SubsystemB = 1.76;
Init2_SubsystemB = 2.76;
```

Create a parameter structure that contains a substructure for each subsystem. Use the values of the existing variables to set the field values.

```
myParams = struct(...
    'SubsystemA', struct(...
        'Gain', Gain_SubsystemA, ...
        'Offset', Offset_SubsystemA, ...
        'Init', Init_SubsystemA), ...
```

```

    'SubsystemB', struct(...
        'Coeffs', Coeffs_SubsystemB, ...
        'Offset', Offset_SubsystemB, ...
        'Init1', Init1_SubsystemB, ...
        'Init2', Init2_SubsystemB) ...
);

```

The single structure variable `myParams` contains all of the parameter information for the blocks in the subsystems. Because each substructure acts as a namespace, you can define the `Offset` field more than once.

To use the `Offset` field from the substructure `SubsystemB` as the value of a block parameter, specify the parameter value in the block dialog box as the expression `myParams.SubsystemB.Offset`.

Group Multiple Parameter Structures into an Array

To organize parameter structures that have similar characteristics, you can create a single variable whose value is an array of structures. This technique helps you to parameterize a model that contains multiple instances of an algorithm, such as a library subsystem or a referenced model that uses model arguments.

Suppose that you create two identical subsystems in a model.

Suppose that the blocks in each subsystem require three numeric values to set parameter values. Create an array of two structures to store the values.

```
myParams(1).Gain = 15.23;  
myParams(1).Offset = 89;  
myParams(1).Init = 0.59;  
  
myParams(2).Gain = 11.93;  
myParams(2).Offset = 57;  
myParams(2).Init = 2.76;
```

Each structure in the array stores the three parameter values for one of the subsystems.

To set the value of a block parameter in one of the subsystems, specify an expression that references a field of one of the structures in the array. For example, use the expression `myParams(2).Init`.

Organize Parameter Values for Reusable Components and Iterative Algorithms

You can also partition an array of structures in a For Each Subsystem block. This technique helps you to organize workspace variables when a model executes an algorithm repeatedly, for example by iterating the algorithm over a vector signal. For an example, see “Repeat an Algorithm Using a For Each Subsystem” on page 63-112.

If you use model arguments to specify different parameter values across multiple instances of a referenced model, you can use arrays of structures to organize the model argument values. In the referenced model workspace, create a structure variable and configure the model to use the structure as a model argument. Use the fields of the structure to set block parameter values in the model. Then, create an array of structures in the base workspace or a data dictionary to which the parent model or models are linked. In the parent model or models, use each of the structures in the array as the value of the model argument in a Model block. Each structure in the array stores the parameter values for one instance of the referenced model.

The example model `sldemo_md1ref_datamngt` contains three instances (masked Model blocks) of the referenced model `sldemo_md1ref_counter_datamngt`. The base workspace variables `IC1`, `IC2`, `Param1`, and `Param2` are `Simulink.Parameter` objects whose values are structures. The parent model uses these variables to set the values of mask parameters on the Model blocks. Since `IC1` is structurally identical to `IC2`, and `Param1` to `Param2`, you can combine these four structures into two arrays of structures.

- 1 Open the example parent model.

```
sldemo_md1ref_datamngt
```

The model creates the four `Simulink.Parameter` objects in the base workspace.

- 2 Open the example referenced model.

```
sldemo_mdhref_counter_datamngt
```

The model workspace defines two model arguments, `CounterICs` and `CounterParams`, whose values are structures. The blocks in the model use the fields of these structures to set parameter values.

- 3 In the model `sldemo_mdhref_datamngt`, double-click each of the Model blocks, which opens the mask dialog boxes. Each mask uses a different combination of the four parameter objects from the base workspace to set the model argument values in the Model blocks.
- 4 At the command prompt, view the values of the parameter objects from the base workspace.

```
Param1.Value
IC1.Value
```

```
ans =
```

```
    Increment: 1
 LowerLimit: -20
 UpperLimit: 20
```

```
ans =
```

```
    Count: 0
 OverflowState: InRange
```

The value of each parameter object is a structure. The structures in `Param2` and `IC2` have the same fields as the structures in `Param1` and `IC1` but different field values.

- 5 Combine the four parameter objects into two parameter objects whose values are arrays of structures.

```
% Create a new parameter object by copying Param1.
Param = Param1.copy;
```

```
% Use the structure in Param2 as the second structure in the new object.
Param.Value(2) = Param2.Value;
% The value of Param is now an array of two structures.
```

```
% Delete the old objects Param1 and Param2.
clear Param1 Param2
```

```
% Create a new parameter object by copying IC1.
% Use the structure in IC2 as the second structure in the new object.
IC = IC1.copy;
IC.Value(2) = IC2.Value;
clear IC1 IC2
```

- 6 In the parent model, double-click each of the Model blocks. In the mask dialog boxes, replace the parameter values according to the table.

Previous Value	New Value
Param1	Param(1)
IC1	IC(1)
Param2	Param(2)
IC2	IC(2)

Each Model block sets the value of the model argument CounterICs by using one of the structures in the array IC. Similarly, each block sets the value of CounterParams by using one of the structures in Param.

Explicitly Specify Field Data Types

To use a structure or array of structures to organize parameter values that use a data type other than `double`, you can explicitly specify the type when you create the structure. When you create the structure, use typed expressions such as `single(15.23)` to specify the field values.

```
myParams.Gain = single(15.23);
```

If you want to change the field value later, you must remember to explicitly specify the type again. If you do not specify the type, the field value uses the data type `double` instead:

```
myParams.Gain = 15.23;
% The field 'Gain' now uses the data type 'double' instead of 'single'.
```

To preserve the type specification, you can use subscripted assignment to assign a new value to the field:

```
% Assign value of type 'single'.
myParams.Gain = single(15.23);
```

```
% Assign new value while retaining type 'single'.
myParams.Gain(:) = 11.79;
```

To match a fixed-point data type, set the field value by using an `fi` object.

Control Field Data Types and Characteristics by Creating Parameter Object

A `Simulink.Parameter` object allows you to separate the value of a block parameter from its data type. If you use a parameter object to store a structure or array of structures, you can create a `Simulink.Bus` object to use as the data type of the entire structure.

You can use the bus object and the parameter object to explicitly control:

- The data type of each field. When you use this technique, you do not have to remember to use typed expressions or subscripted assignment to set the field values.
- The complexity, dimensions, and units of each field.
- The minimum and maximum value of each field if the field represents a tunable parameter value.
- The shape of the entire structure. The *shape* of the structure is the number, names, and hierarchy of fields.
- The tunability of the structure in the code that you generate from the model.

- 1 Create a parameter structure `myParams`.

```
myParams = struct(...
    'SubsystemA', struct(...
        'Gain', 15.23, ...
        'Offset', 89, ...
        'Init', 0.59), ...
    'SubsystemB', struct(...
        'Coeffs', [5.32 7.99], ...
        'Offset', 57, ...
        'Init1', 1.76, ...
        'Init2', 2.76) ...
);
```

- 2 Use the function `Simulink.Bus.createObject` to create `Simulink.Bus` objects that represent the structure and substructures.

```
Simulink.Bus.createObject(myParams)
```

Because `myParams` contains two unique substructures, the function creates three `Simulink.Bus` objects: one named `s1Bus1` to represent the parent structure `myParams`, one named `SubsystemA` for the substructure `SubsystemA`, and one named `SubsystemB` for the substructure `SubsystemB`.

- 3 Rename the bus object `s1Bus1` as `myParamsType`.

```
myParamsType = s1Bus1;
clear s1Bus1
```

- 4 Store the structure `myParams` in a `Simulink.Parameter` object.

```
myParams = Simulink.Parameter(myParams);
```

The `Value` property of the parameter object contains the structure.

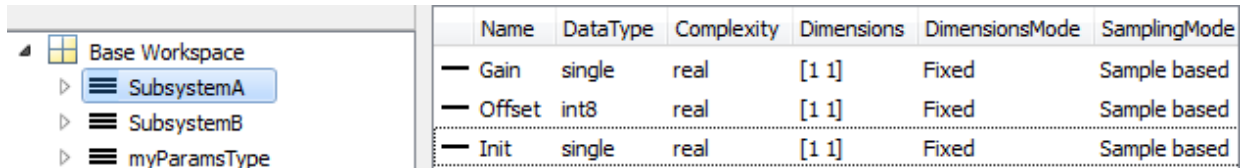

- 5 Set the data type of the parameter object to the bus object `myParamsType`.

```
myParams.DataType = 'Bus: myParamsType';
```

- 6 Open the Bus Editor to view the bus objects.

```
buseditor
```

- 7 In the **Model Hierarchy** pane, click the node `SubsystemA`. In the **Contents** pane, set the field data types according to the figure.

Name	DataType	Complexity	Dimensions	DimensionsMode	SamplingMode
Gain	single	real	[1 1]	Fixed	Sample based
Offset	int8	real	[1 1]	Fixed	Sample based
Init	single	real	[1 1]	Fixed	Sample based

- 8 Optionally, set the field data types for the substructure `SubsystemB`.

The parameter object `myParams` stores the parameter structure. The data type of the parameter object is the bus object `myParamsType`. Prior to simulation and code generation, the parameter object casts the field values to the data types that you specified in the bus object.

To use one of the fields to set a block parameter value, specify an expression such as `myParams.SubsystemB.Init1`.

To access the field values at the command prompt, use the `Value` property of the parameter object. Because the bus object controls the field data types, you do not need to use a typed expression to set the field value.

```
myParams.Value.SubsystemA.Gain = 12.79;
```

The bus object strictly controls the field characteristics and the shape of the structure. For example, if you set the value of the two-element field `myParams.SubsystemB.Coeffs` to a three-element array, the model generates an error when you set a block parameter value. To change the dimensions of the field, modify the element `Coeffs` in the bus object `SubsystemB`.

To manipulate bus objects after you create them, see “Modify Bus Objects” on page 63-57 and “Save and Import Bus Objects” on page 63-63.

Match Field Data Type with Signal Data Type

Suppose that you use the field `myParams.SubsystemA.Gain` to set the value of the **Gain** parameter in a Gain block. If you want the data type of the field to match the data type of the output signal of the block, consider using a `Simulink.AliasType` or a `Simulink.NumericType` object to set the data type of the field and the signal. If you do not use a data type object, you must remember to change the data type of the field whenever you change the data type of the signal.

- 1 At the command prompt, create a `Simulink.AliasType` object that represents the data type `single`.

```
myType = Simulink.AliasType;  
myType.BaseType = 'single';
```

- 2 In the Gain block dialog box, on the **Signal Attributes** tab, set **Output data type** to `myType`.
- 3 At the command prompt, open the Bus Editor.

```
buseditor
```

- 4 In the **Model Hierarchy** pane, select the bus object `SubsystemA`. In the **Contents** pane, set the data type of the field `Gain` to `myType`.

Now, both the output signal of the Gain block and the structure field `myParams.SubsystemA.Gain` use the data type that you specify by using the `BaseType` property of `myType`.

For more information about data type objects, see `Simulink.AliasType` and `Simulink.NumericType`.

Enforce Uniformity in an Array of Structures

All of the structures in an array of structures must have the same hierarchy of fields. Each field in the hierarchy must have the same characteristics throughout the array. You can use a parameter object and a bus object to enforce this uniformity among the structures.

To use a parameter object to represent an array of parameter structures, set the value of the object to the array of structures:

```
% Create array of structures.
myParams(1).Gain = 15.23;
myParams(1).Offset = 89;
myParams(1).Init = 0.59;
myParams(2).Gain = 11.93;
myParams(2).Offset = 57;
myParams(2).Init = 2.76;

% Create bus object.
Simulink.Bus.createObject(myParams);
myParamsType = slBus1;
clear slBus1

% Create parameter object and set data type.
myParams = Simulink.Parameter(myParams);
myParams.DataType = 'Bus: myParamsType';
```

To use one of the fields to set a block parameter value, specify an expression such as `myParams(2).Offset`.

To access the field values at the command prompt, use the `Value` property of the parameter object.

```
myParams.Value(2).Offset = 129;
```

Create a Structure of Constant-Valued Signals

You can use a structure in a Constant block to create a single bus signal that transmits multiple numeric constants. For more information, see `Constant`. For information about bus signals, see “Buses” on page 63-3.

Considerations Before Migrating to Parameter Structures

Before you migrate a model to use parameter structures, discover all of the blocks in the target model and in other models that use the variables that you intend to replace.

For example, suppose two blocks in a model use the workspace variable `myVar`. If you create a structure `myParams` with a field `myVar`, and set the parameter value in only one of the blocks to `myParams.myVar`, the other block continues to use the variable `myVar`. If you delete `myVar`, the model generates an error because the remaining block requires the deleted variable.

To discover all of the blocks that use a variable:

- 1 Open all models that might use the variable. If the models are in a model reference hierarchy, you can open only the top model.
- 2 Right-click the variable in the Model Explorer **Contents** pane and select **Find Where Used**. The Model Explorer displays all of the blocks that use the variable.

You can discover variable usage only in models that are open. Before you migrate to parameter structures, open all models that might use the target variables. For more information about determining variable usage in a model, see “Finding Blocks That Use a Specific Variable” on page 57-91.

Alternatively, you can refrain from deleting `myVar`. However, if you change the value of the `myParams.myVar` structure field, you must remember to change the value of `myVar` to match.

Parameter Structures in the Generated Code

You can configure parameter structures to appear in the generated code as structures and arrays of structures. For information about generating code with structure parameters, see “Organize Block Parameter Values into Structures in the Generated Code”.

Parameter Structure Limitations

- The value of a field that you use to set a block parameter must be numeric or of an enumerated type. The value of a field can be a real or complex scalar, vector, or multidimensional array.

- If the value of any of the fields of a structure is a multidimensional array, you cannot tune any of the field values during simulation.
- All of the structures in an array of structures must have the same hierarchy of fields. Each field in the hierarchy must have the same characteristics throughout the array:
 - Field name
 - Numeric data type, such as `single` or `int32`
 - Complexity
 - Dimensions

Suppose that you define an array of two structures.

```
paramStructArray = ...  
[struct('sensor1',int16(7),'sensor2',single(9.23)) ...  
 struct('sensor1',int32(9),'sensor2',single(11.71))];
```

You cannot use any of the fields in a block parameter because the field `sensor1` uses a different data type in each structure.

- Parameter structures do not support context-sensitive data typing in the generated code. If the parameter structure is tunable in the code, the fields of the structure use the numeric data types that you specify by using either typed expressions or a `Simulink.Bus` object. If you do not use typed expressions or a `Simulink.Bus` object, the fields of the structure use the `double` data type.

Package Shared Breakpoint and Table Data for Lookup Tables

When you share data between lookup table blocks, consider using `Simulink.LookupTable` and `Simulink.Breakpoint` objects instead of structures to store and group the data. This technique improves model readability by clearly identifying the data as parts of a lookup table and explicitly associating breakpoint data with table data. See “Package Shared Breakpoint and Table Data for Lookup Tables” on page 34-16.

on page 34-67

Tune and Experiment with Block Parameter Values

As you construct a model you can experiment with block parameters, such as the coefficients of a Transfer Fcn block, to help you decide which blocks to use. You can simulate the model with different parameter values, and capture and observe the simulation output.

You can change the values of most numeric block parameters during a simulation. To observe the effects, you can visualize the simulation output in real time. This technique allows you to quickly test parameter values while you develop an algorithm. You can visually:

- Tune and optimize control parameters.
- Calibrate model parameters.
- Test control robustness under different conditions.

When you begin a simulation, Simulink first updates the model diagram. This operation can take time for larger models. To test parameter values without repeatedly updating the model diagram, you can tune the parameter values during a single simulation run.

Alternatively, to avoid updating the model diagram, use Fast Restart. For more information about Fast Restart, see “Get Started with Fast Restart” on page 68-6.

If you cannot visually analyze the simulation output in real time, or if you must run many simulations, consider using a programmatic approach to sweeping parameter values. You can capture the simulation output data and perform analysis later. For more information, see “Optimize, Estimate, and Sweep Block Parameter Values” on page 34-48.

For basic information about accessing and setting block parameter values, see “Set Block Parameter Values” on page 34-2.

Iteratively Adjust Block Parameter Value Between Simulation Runs

This example shows how to rapidly prototype a model by changing block parameter values between simulation runs. You can experiment with parameter values and observe simulation results to help you decide which blocks to use and how to build your model.

The example model `sldemo_fuelsys` represents the fueling system of a gasoline engine. A subsystem in the model, `feedforward_fuel_rate`, calculates the fuel demand of the engine by using the constant number `14.6`, which represents the ideal (stoichiometric)

ratio of air to fuel that the engine consumes. Two blocks in the subsystem use the number to set the values of parameters.

Suppose that you want to change the design value of the ideal air-to-fuel ratio from 14.6 to 17.5 to observe the effect on the fuel demand. To store the design value in the model, you can modify the value in the block dialog boxes. Alternatively, you can store the value in a variable with a meaningful name, which allows you to reuse the value in the two blocks.

To observe the change in simulation outputs by changing the value in the block dialog boxes:

- 1 Open the example model.
`sldemo_fuelsys`
- 2 Set the model simulation time from 2000 to 50 for a faster simulation.
- 3 In the model, open the Scope block dialog box.

- 4 Simulate the model. Resize the window in the Scope block dialog box to see all of the simulation results.

The scope display shows that throughout the simulation, the `fuel` signal oscillates between approximately 0.9 and 1.6. The `air_fuel_ratio` signal quickly climbs to 15 without overshoot.

- 5 Navigate to the target subsystem.
`open_system('sldemo_fuelsys/fuel_rate_control/fuel_calc/feedforward_fuel_rate')`
- 6 Open the block parameter dialog box for the Constant block labeled `rich`.
- 7 Change the **Constant value** parameter from $1/(14.6 \cdot 0.8)$ to $1/(17.5 \cdot 0.8)$.
- 8 Similarly, change the **Constant value** parameter of the block labeled `normal` from $1/14.6$ to $1/17.5$.
- 9 Simulate the model.

The scope display shows that the signals now respond differently.

To replace the literal values in the block dialog boxes with a numeric variable:

- 1 In the block dialog box for the block labeled `normal`, set **Constant value** to $1 / \text{mixture}$ and click **OK**.
- 2 In the block dialog box for the block labeled `rich`, set **Constant value** to $1 / (\text{mixture} * 0.8)$ and click **Apply**.
- 3 Right-click the expression $1 / (\text{mixture} * 0.8)$ and select **Create Variable > mixture**.
- 4 In the **Create New Data** dialog box, set **Value** to `17.5` and click **Create**. In the **Data properties** dialog box, click **OK**.

The numeric variable `mixture` appears in the base workspace with value `17.5`. Between simulation runs, you can change the value of `mixture` in the base workspace instead of changing the parameter values in the block dialog boxes.

Tune Block Parameter Value During Simulation

This example shows how to observe the effect of changing a block parameter value during a simulation. This technique allows you to avoid updating the model diagram between simulation runs and to interactively test and debug your model.

The example model `sldemo_fuelsys` contains a Constant block, **Throttle Command**, that represents the throttle command. To observe the effect of increasing the magnitude of the command during simulation:

- 1 Open the example model.
`sldemo_fuelsys`
- 2 In the model, open the Scope block dialog box.

- 3 Begin a simulation.

The model is configured to simulate 2000 seconds. During the simulation, the values of the `fuel` and `air_fuel_ratio` signals appear on the scope graph in real time.

- 4 In the model, when the status bar indicates approximately 1000 (1000 seconds), click the Pause button  to pause the simulation.
- 5 In the scope display, the **fuel** graph plots the simulation output prior to the pause time.
- 6 Open the block dialog box for the block labeled **Throttle Command**. Change the value of the **Output values** parameter from [10 20 10] to [10 30 10] and click **OK**.
- 7 Click the Step Forward button  to advance the simulation step by step. Click the button about 15 times or until you see a change in the **fuel** graph in the scope display.

The plot of the signal **fuel** indicates a sharp increase in fuel demand that corresponds to the increased throttle command.

- 8 In the model, resume the simulation by clicking the Continue button .

The scope display shows the significant periodic increase in fuel demand, and the periodic reduction in the air-to-fuel ratio, throughout the rest of the simulation.

During the simulation, you must update the model diagram after:

- You change the value of a workspace variable.
- You use the function `set_param` to change the value of a block parameter.

For more information about updating the model diagram, see “Update Diagram and Run Simulation” on page 1-64.

Prepare for Parameter Tuning and Experimentation

- Consider using workspace variables to set block parameter values.

To access the value of a block parameter, such as the **Constant value** parameter of a Constant block, you must navigate to the block in the model and open the block dialog box, search for the block by using the Model Explorer, or use the function `set_param` at the command prompt.

Alternatively, if you set the block parameter value by creating a workspace variable, you can change the value of the variable by using the command prompt, the MATLAB Workspace browser, or the Model Explorer. You can also create a variable to set the same value for multiple block parameters. When you change the variable value, all of

the target block parameters use the new value. For more information about accessing and setting block parameter values, see “Set Block Parameter Values” on page 34-2.

- Learn how to visualize simulation output.

To observe simulation output in real time while you tune block parameter values, you can use blocks in a model such as the Scope block. You can also capture simulation output at the end of a simulation run, and view the data in the Simulation Data Inspector. For more information, see “Decide How to Visualize Simulation Data” on page 27-2.

- Consider specifying value ranges for block parameters that you expect to tune during simulation.

If you expect another person to use your model and tune the parameter, you can control the allowed tuning values by specifying a range. Also, it is a best practice to specify value ranges for all fixed-point block parameters that you expect to tune. To specify block parameter value ranges, see “Specify Minimum and Maximum Values for Block Parameters” on page 34-63.

- Learn how to control simulation duration and pace.

A simulation run can execute so quickly that you cannot tune block parameter values. Also, if you want to change a parameter value at a specific simulation time, you must learn to control the simulation pace. You can configure the simulation to run for a specific duration or to run forever, and pause and advance the simulation when you want to. For more information about controlling simulation execution, see “Simulate a Model Interactively” on page 23-2. To programmatically control simulations, see “Control Simulations Programmatically” on page 24-10.

Interactively Tune Using Dashboard Blocks

You can tune block parameter values by adding blocks from the Dashboard library to your model. Dashboard blocks allow you to adjust the parameter values of other blocks, and to observe simulation output in real time, by interacting with knobs, switches, and readouts that mimic the appearance of industrial controls. You can interact with the Dashboard blocks without having to locate the target block parameters in the model. For more information, see “Tune and Visualize Your Model with Dashboard Blocks” on page 26-73.

Which Block Parameters Are Tunable During Simulation?

Nontunable block parameters are parameters whose values you cannot change during simulation. For example, you cannot tune the **Sample time** block parameter. If a parameter is nontunable, you cannot change its value during simulation by changing the value in the block dialog box or by changing the value of a workspace variable.

Nontunable block parameters include:

- Sample times.
- Parameters that control the appearance or structure of a block such as the number of inputs of a Sum block.
- Priority, which allows you to control block execution order.
- Parameters that control the block algorithm, such as the **Integrator method** parameter of a Discrete-Time Integrator block.

To determine whether a block parameter is tunable during simulation, use one of these techniques:

- Begin a simulation and open the block dialog box. If the value of the target block parameter is gray during simulation, you cannot tune the parameter.
- At the command prompt, determine whether the flags `read-write` and `read-only-if-compiled` describe the parameter.

1 Select the block in the model.

2 At the command prompt, use the function `get_param` to return information about the block dialog box parameters. The function returns a structure that has a field for each parameter in the block dialog box.

```
paramInfo = get_param(gcf, 'DialogParameters');
```

Alternatively, rather than locating and selecting the block in the model, you can replace `gcb` with the block path, such as `'myModel/mySubsystem/myBlock'`.

3 View the information about the target block parameter. For example, to view the information about the **Sample time** parameter of a block, view the value of the field `SampleTime`, which is also a structure.

```
paramInfo.SampleTime
```

```
ans =
```

```
Prompt: 'Sample time:'  
Type: 'string'  
Enum: {}  
Attributes: {'read-write' 'read-only-if-compiled' 'dont-eval'}
```

- 4 Inspect the structure's `Attributes` field, whose value is a cell array of character vectors. If the flag `read-write` appears in the cell array, you can modify the parameter value. However, if the flag `read-only-if-compiled` also appears in the cell array, you cannot modify the parameter value during simulation.

If you use masks to create custom interfaces for blocks and subsystems, you can control the tunability of individual mask parameters. If you use model arguments to parameterize referenced models, you can tune the value of each model argument in each Model block.

Why Did the Simulation Output Stay the Same?

If the output of your simulation does not change after you change a parameter value, use these troubleshooting techniques:

- Locate the definition of a workspace variable.

If you use a workspace variable to set block parameter values, determine where the variable definition resides. For example, if you define a variable `myVar` in a model workspace and use it to set a block parameter value in the model, you cannot change the parameter value by changing the value of a variable named `myVar` in the base workspace. You must access the variable definition in the model workspace.

To locate the definition of a variable, open a block dialog box that uses the variable. Right-click the block parameter value and select **Explore Variable**. A dialog box opens, such as the Model Explorer, which displays the definition of the variable in the appropriate workspace. For more information about how models use variables, see “Symbol Resolution” on page 4-82.

- Specify value ranges for fixed-point parameters that you want to tune during simulation.

If the block parameter you want to tune uses a fixed-point data type with best-precision scaling, specify a minimum and maximum value for the parameter so that Simulink can calculate and apply an appropriate scaling. If you do not specify a value range, Simulink might apply a scaling that excludes the tuning values that you want to use. To specify value ranges, see “Specify Minimum and Maximum Values for Block Parameters” on page 34-63.

- Update the model diagram during a simulation run.

After you tune a block parameter value during a simulation run, you must update the model diagram if you use:

- A workspace variable to set the value of one or more block parameters. After you change the value of the variable, update the model diagram.
- The `set_param` function to change the parameter value.

To learn how to update a model diagram, see “Update Diagram and Run Simulation” on page 1-64.

Tunability Considerations for Other Modeling Goals

Rapid Accelerator Simulations

If a block parameter value references workspace variables, you cannot change the block parameter value during rapid accelerator simulation, such as by using the function `set_param`. Instead, you can tune the values of the referenced variables.

Alternatively, use parameter sets to tune runtime parameters in between rapid accelerator simulations. For more information, see “Tuning Runtime Parameters” on page 32-10.

Code Generation and Simulation of External Programs

Parameters that are tunable during simulation can appear as nontunable inlined parameters in the generated code. If you simulate an external program by using SIL, PIL, or External mode simulation, parameter tunability during the simulation can depend on your code generation settings.

To control parameter tunability in the generated code, you can adjust the code generation settings for a model by using the configuration parameter **Default parameter behavior**. You can also adjust settings for individual MATLAB variables, `Simulink.Parameter` objects, and other parameter objects. For more information, see “Configure Block Parameter Tunability for Rapid Prototyping” in the Simulink Coder documentation.

Stateflow Charts

To debug a Stateflow chart by changing data during simulation, see “Change Data Values During Simulation”.

- “Switch Between Sets of Parameter Values During Simulation and Code Execution” on page 34-67

Manage Variables from Block Parameter

To set the value of a block parameter, such as the **Gain** parameter of a Gain block, you can create a MATLAB variable, `Simulink.Parameter` object, or other parameter object in a workspace. See “Share and Reuse Block Parameter Values by Creating Variables” on page 34-11.

To create and edit variables from a block dialog box or the property inspector, right-click the name of the variable. Use this technique to configure the variable without having to find its definition or open additional dialog boxes such as Model Explorer manually.

Rename Variable

This example shows how to rename a variable by navigating to Model Explorer from a parameter in a block dialog box.

- 1 Open the model `f14`. The model loads data to the MATLAB base workspace.
- 2 Open the block dialog box for the Gain block that uses variable `Mw`.
- 3 Right-click the expression `Mw` in the **Gain** box and select **Explore Variable**.

Model Explorer opens with `Mw` as the selected variable in the base workspace.

- 4 In Model Explorer, right-click the variable `Mw` and select **Rename All**.
- 5 In the **Select a system** dialog box, click the name of the model `f14` to select it as the context for renaming the variable `Mw`.
- 6 Clear the **Search in referenced models** check box, since `f14` does not reference any models, and click **OK**.

With **Search in referenced models** selected, you can rename the target variable everywhere it is used in a model reference hierarchy. However, renaming the target variable in an entire hierarchy can take more time.

The **Update diagram to include recent changes** check box is cleared by default to save time by avoiding unnecessary model diagram updates. Select the check box to incorporate recent changes you made to the model by forcing a diagram update.

- 7 Click **OK** when asked to update the model diagram.

Since you just opened the model, you must update the model diagram at least once before renaming a variable. You could have selected **Update diagram to include**

recent changes in the **Select a system** dialog box to force an initial diagram update, though you typically use that option when you make changes to the model while performing multiple variable renaming operations.

- 8 In the **Rename All** dialog box, type the new name for the variable in the **New name** box and click **OK**.
- 9 In the block dialog, click **OK** to accept the change to the block parameter.

Edit Variable Value or Property

This example shows how to edit a variable from a parameter in a block dialog box. You can use this procedure to edit a variable made from a built-in or custom data type or from a class such as Simulink.Parameter.

- 1 Open the model f14. The model loads data to the MATLAB base workspace.
- 2 Open the block dialog box for the Gain block that uses the variable Mw.
- 3 Right-click the expression Mw in the **Gain** box and select **Open Variable**.
- 4 In the **Data properties** dialog box, type a new value for the variable in the **Value** box and click **OK**.

Navigate to Mask Parameter

This example shows how to navigate to a mask parameter from a parameter in a block dialog box. When you explore a model that contains multiple masked subsystems and masked blocks, you can find the mask that defines a particular parameter.

- 1 Open the model masking_example.
- 2 Open the block dialog box for the Gain block that uses the mask parameter m.
- 3 Right-click the expression m in the **Gain** box and select **Open Variable**.

The mask dialog box that contains the mask parameter m appears.

Create Variable

This example shows how to create a variable from a parameter in a block dialog box.

- 1 Open the model sldemo_fuelsys.
- 2 Open the block dialog box for the Constant block that has value 300.

- 3** In the **Constant value** box, replace the expression 300 with myVar.
- 4** Right-click the expression myVar and select **Create Variable**.
- 5** In the **Create New Data** dialog box, type 300 in the **Value** box and click **Create**.

In the **Create New Data** dialog box you can choose the workspace to define the new variable. If a model is linked to a data dictionary, you can choose to create a variable in the dictionary.

- 6** In the **Data properties** dialog box, click **OK**.

- “Tune and Experiment with Block Parameter Values” on page 34-36

Optimize, Estimate, and Sweep Block Parameter Values

When you *sweep* one or more parameters, you change their values between simulation runs, and compare and analyze the output signal data from each run. Use parameter sweeping to tune control parameters, estimate unknown model parameters, and test the robustness of a control algorithm by taking into consideration uncertainty in the real-world system.

You can sweep block parameter values or the values of workspace variables that you use to set the parameter values. Use block dialog boxes, the Model Explorer, the command prompt, or scripts to change parameter values and execute simulations.

If you want to repeatedly change the value of a block parameter, consider setting the parameter value by creating a variable in a workspace. You can use the Model Explorer or the command prompt to change the value of the variable instead of locating the block in the model. Also, several features and products that facilitate parameter optimization, estimation, and sweeping require that you set block parameter values by creating workspace variables.

To learn how to manipulate parameter values during the iterative process of creating a model, see “Tune and Experiment with Block Parameter Values” on page 34-36.

For basic information about accessing and setting block parameter values, see “Set Block Parameter Values” on page 34-2. For basic information about programmatically simulating a model, such as by using a script, see “Run Simulations Programmatically” on page 24-2.

Sweep Parameter Value and Inspect Simulation Results

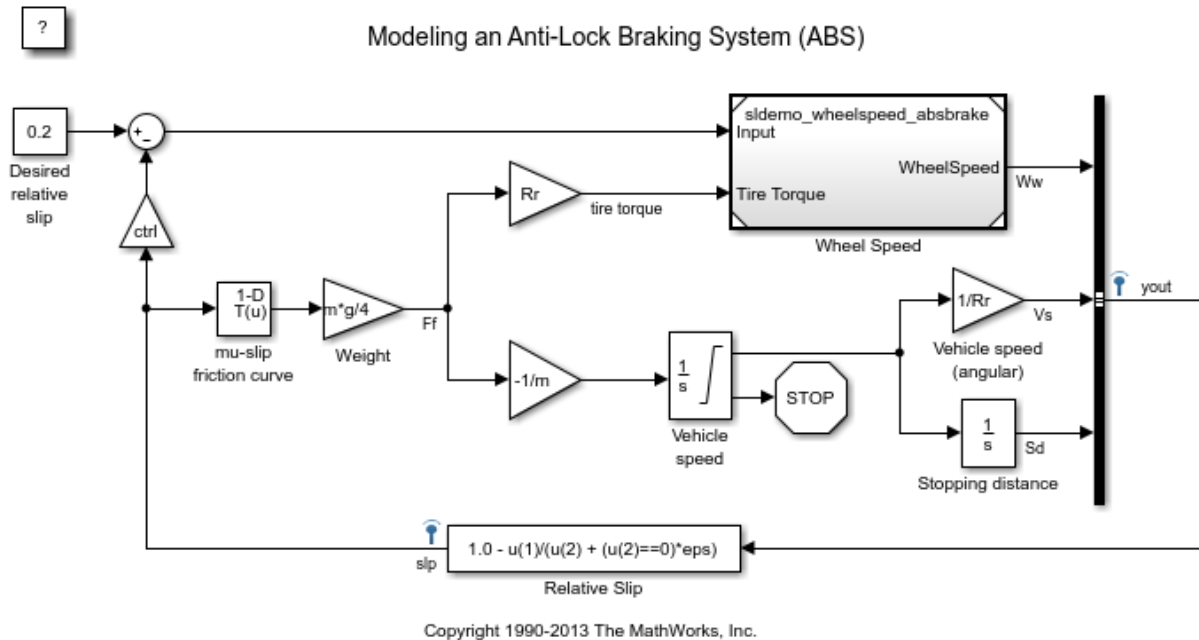

This example shows how to change a block parameter value between multiple programmatic simulation runs. Use this technique to determine an optimal parameter value by comparing the output signal data of each run.

The example model `sldemo_absbrake` uses a Constant block to specify a slip setpoint for an anti-lock braking system. Simulate the model with two different slip setpoint values, 0.24 and 0.25, and compare the output wheel speed of each simulation run.

To store the setpoint value, create a `Simulink.Parameter` object in the base workspace. This technique enables you to change the value with fewer lines of more readable code.

Open the example model.

```
open_system('sldemo_absbrake');
```

The signals `yout` (which is a virtual bus) and `slp` are configured for logging. When you simulate the model, you can collect and later inspect the values of these signals by using the Simulation Data Inspector.

In the block dialog box of the Constant block labeled `Desired relative slip`, set **Constant value** to `relSlip` and click **Apply**.

Right-click `relSlip` and select **Create Variable**.

In the Create New Data dialog box, set **Value** to `Simulink.Parameter(0.2)` and click **Create**. A `Simulink.Parameter` object, which stores the parameter value 0.2, appears in the base workspace.

You can use these commands at the command prompt to create the object and configure the block:

```
relSlip = Simulink.Parameter(0.2);  
set_param('sldemo_absbrake/Desired relative slip', 'Value', 'relSlip')
```

In the `relSlip` property dialog box, click **OK**.

At the command prompt, configure the model to stream the logged signals to the Simulation Data Inspector.

```
Simulink.sdi.changeLoggedToStreamed('sldemo_absbrake');
```

Create an array to store the two experimentation values for the relative slip setpoint, 0.24 and 0.25.

```
relSlip_vals = [0.24 0.25];
```

Loop through the experimentation values by setting the value of `relSlip` to each of the values stored in `relSlip_vals`. Use the `sim` function to simulate the model after setting the value of `relSlip`.

```
for i = 1:length(relSlip_vals)  
    relSlip.Value = relSlip_vals(i);  
    sim('sldemo_absbrake')  
end
```

The model streams the logged signals, `yout` and `slp`, to the Simulation Data Inspector. You can view the signal data in the Simulation Data Inspector.

Compare the output data of the two latest simulation runs.

```
runIDs = Simulink.sdi.getAllRunIDs();  
runResult = Simulink.sdi.compareRuns(runIDs(end-1), runIDs(end));
```

Plot the difference between the values of the `Ww` signal (which is an element of the virtual bus signal `yout`) by specifying the result index 1.

```
signalResult = getResultByIndex(runResult,1);  
plot(signalResult.Diff);
```

Capture and Visualize Simulation Results

Each simulation run during a parameter sweep produces outputs, such as signal values from Outport blocks and from logged signals.

You can capture these outputs in variables and objects for later analysis. For more information, see “Export Simulation Data” on page 59-3.

To visualize simulation output data so you can compare the effect of each parameter value, see “Decide How to Visualize Simulation Data” on page 27-2.

Improve Simulation Speed

To perform many simulations that each use different parameter values, you can use accelerated simulation modes. For larger models, accelerated simulations take less time to execute than normal simulations. If you also have Parallel Computing Toolbox, you can use the multiple cores of your processor to simultaneously execute simulations.

To improve the simulation speed of your model by using accelerated simulations and other techniques, see “Performance”. For information about parallel simulations, see “Run Parallel Simulations” on page 24-13.

For greatly increased simulation speed, you can use the command prompt or a script to execute simulations in rapid accelerator mode and set `RapidAcceleratorUpToDateCheck` to `off` (required for parallel rapid accelerator simulations). When you set `RapidAcceleratorUpToDateCheck` to `off`, to set the sweep values for each block parameter, you cannot use conventional techniques, for example, the block dialog box, the `set_param` function, or the values of MATLAB variables. Instead, you pass sets of parameter values to the `sim` function by using the `RapidAcceleratorParameterSets` name-value pair. When you use this approach, consider creating variables in workspaces and data dictionaries to set block parameter values. This technique enables you to more easily identify the parameter value in the structure that the `Simulink.BlockDiagram.buildRapidAcceleratorTarget` function generates.

For more information about `RapidAcceleratorUpToDateCheck`, and `RapidAcceleratorParameterSets`, see `sim`.

Sweep Parameter Values to Analyze System Robustness

You can sweep parameters through a range of values to analyze the robustness of a control algorithm. For example, use the Monte Carlo method to test the efficacy of a wind turbine control algorithm. You can perform many simulation runs, each of which uses a wind speed parameter that you randomly select from a distribution of possible speeds. Analysis of the simulation outputs can indicate the likelihood that the algorithm fails to control the system to your requirements.

For an example that shows how to sweep parameter values by using parallel simulation, see “Parallel Simulations Using `Parfor`: Parameter Sweep in Normal Mode”. This approach enables you to use conventional techniques to set parameter values.

For more information about sweeping parameter values by using acceleration and parallel simulation together, see “sim in parfor with Rapid Accelerator Mode” on page 24-21. For an example, see “Parallel Simulations Using Parfor: Parameter Sweep in Rapid Accelerator Mode”.

Sweep Parameter Values to Test and Verify System

If you have Simulink Test, you can confirm that your model still meets requirements when you use different parameter values. Parameter overrides enable you to set different parameter values for each test case. For more information, see “Parameter Overrides”.

Estimate and Calibrate Model Parameters

If you have Simulink Design Optimization, you can estimate model parameter values so that simulation outputs closely fit the data that you measure in the real world. Use this technique to estimate the real-world values of parameters in a *plant model*, which represents the dynamics of a real-world system, when you cannot directly measure the values. This estimation improves the accuracy of the plant model. For more information, see “Estimate Parameters from Measured Data”.

Tune and Optimize PID and Controller Parameters

If you have Simulink Control Design, you can use PID Tuner to tune the parameters of a PID Controller block. For more information, see “PID Controller Tuning in Simulink”.

If you have Simulink Design Optimization, you can optimize control parameter values so that simulation outputs meet response requirements that you specify. For more information, see “Design Optimization to Meet Step Response Requirements (GUI)”.

Control Block Parameter Data Types

A block parameter, such as the **Gain** parameter of a Gain block, has a data type in the same way that a signal has a data type (see “Control Signal Data Types” on page 57-7). MATLAB variables, `Simulink.Parameter` objects, and other parameter objects that you use to set block parameter values also have data types. Control block parameter data types to:

- Accurately simulate the execution of your control algorithm on hardware.
- Generate efficient code.
- Integrate the generated code with your custom code.
- Avoid using data types that your target hardware does not support.

Reduce Maintenance Effort with Data Type Inheritance

By default, block parameters, numeric MATLAB variables that use the data type `double`, and `Simulink.Parameter` objects acquire a data type through inherited and context-sensitive data typing. For example, if the input and output signals of a Gain block use the data type `single`, the **Gain** parameter typically uses the same data type. If you use a `Simulink.Parameter` object to set the value of the block parameter, by default, the object uses the same data type as the parameter. You can take advantage of this inheritance to avoid explicitly specifying data types for parameters.

Some inheritance rules choose a parameter data type other than the data type that the corresponding signals use. For example, suppose that:

- The input and output signals of a Gain block use fixed-point data types with binary-point-only scaling.
- On the **Parameter Attributes** tab, **Parameter data type** is set to `Inherit: Inherit via internal rule` (the default).
- On the **Parameter Attributes** tab, you specify a minimum and maximum value for the parameter by using **Parameter minimum** and **Parameter maximum**.

The data type setting `Inherit: Inherit via internal rule` can cause the block to choose a different data type, with a different word length or scaling, than the data type that the signals use. The minimum and maximum values that you specified for the parameter influence the scaling that the block chooses.

When you select internal rules (`Inherit: Inherit via internal rule`) to enable Simulink to choose data types, before simulating or generating code, configure the

characteristics of your target hardware. The internal rules can use these settings to choose data types that yield efficient generated code. To configure your hardware characteristics, see “Run on Target Hardware Pane”.

Context-Sensitive Data Typing

When you use a MATLAB variable or `Simulink.Parameter` object to set the value of a block parameter, you can configure the variable or parameter object to use *context-sensitive* data typing. When you simulate or generate code, the variable or parameter object uses the same data type as the block parameter. With this technique, you can match the data type of the variable or parameter object with the data type of the block parameter. To control the data type of the block parameter and the variable or object, you specify only the data type of the block parameter.

To use context-sensitive data typing, set the value of a MATLAB variable to a `double` value. For a `Simulink.Parameter` object, set the `Value` property by using a `double` value and set the `DataType` property to `auto` (the default).

Techniques to Explicitly Specify Parameter Data Types

Many blocks supported for discrete-time simulation and code generation (such as those in the built-in Discrete library) enable you to explicitly specify parameter data types. For example, in an **n-D Lookup Table** block dialog box, on the **Data Types** tab, you can specify a data type for the lookup table data by using the **Table data** parameter. In a Gain block dialog box, use the **Parameter Attributes** tab to set **Parameter data type**, which controls the data type of the **Gain** parameter.

Some blocks, such as those in the Continuous library, do not enable you to specify parameter data types. These block parameters use internal rules to choose a data type. To indirectly control the data type of such a parameter, apply the data type to a `Simulink.Parameter` object instead.

When you use a `Simulink.Parameter` object or other parameter object to set the value of a block parameter, you can use the `DataType` property of the object to specify a data type.

If you use model arguments, you can specify a data type:

- For the model argument that you store in the model workspace.
- With some blocks (such as those in the Discrete library), for the block parameter that uses the model argument.

- For the argument value that you specify in a Model block.

The default settings for these data types typically use inheritance and context-sensitive data typing. For example, the default value of the `DataType` property of a `Simulink.Parameter` object is `auto`, which causes the parameter object to acquire a data type from the block parameter or parameters that use the object.

To explicitly specify a data type, you can use the Data Type Assistant in block dialog boxes and property dialog boxes. For information about the Data Type Assistant, see “Specify Data Types Using Data Type Assistant” on page 57-40.

Calculate Best-Precision Fixed-Point Scaling for Tunable Block Parameters

When you apply fixed-point data types to a model, you can use the Data Type Assistant and the Fixed-Point Tool to calculate best-precision scaling for tunable block parameters. A block parameter, `Simulink.Parameter` object, or other parameter object is *tunable* if it appears in the generated code as a variable stored in memory.

The chosen scaling must accommodate the range of values that you expect to assign to the parameter. To enable the tools to calculate an appropriate scaling, specify the range information in the block or in a parameter object. Then, use one of these techniques to calculate the scaling:

- Use the Fixed-Point Tool to autoscale the entire model or subsystem. The tool can propose and apply fixed-point data types for data items including block parameters, `Simulink.Parameter` objects, signals, and states.
- Configure individual block parameters or parameter objects to calculate their own scaling.

When you later change value ranges for parameters, this technique enables you or the model to recalculate the scaling without having to autoscale the entire model. However, if changing the value range of the parameter also changes the value range of an associated signal, you must manually calculate and apply a new scaling for the signal or use the Fixed-Point Tool to autoscale the model or subsystem.

For basic information about fixed-point data types, block parameters, and other tools and concepts, use the information in the table.

- “Calculate Best-Precision Scaling for Individual Parameters” on page 34-58

Autoscale Entire Model by Using the Fixed-Point Tool

You can use the Fixed-Point Tool to autoscale data items in your model, including tunable parameters and signals whose values depend on those parameters. If you use this technique:

- To configure parameters as tunable, use parameter objects (for example, `Simulink.Parameter`) instead of the Model Parameter Configuration dialog box. The Fixed-Point Tool can autoscale parameter objects, but cannot autoscale numeric variables that you select through the Model Parameter Configuration dialog box.

If your model already uses the Model Parameter Configuration dialog box, use the `tunablevars2parameterobjects` function to create parameter objects instead.

- When you use `Simulink.Parameter` objects to set block parameter values, specify the value range information in the objects instead of the blocks. The Fixed-Point Tool uses the range information in each object to propose a data type for that object.
- To enable the tool to autoscale parameter values that you store as fields of a structure, use a `Simulink.Bus` object as the data type of the entire structure. Specify the range information for each field by using the `Min` and `Max` properties of the corresponding element in the bus object. The tool can then apply a data type to each element by using the `DataType` property.

To use a bus object as the data type of a parameter structure, see “Control Field Data Types and Characteristics by Creating Parameter Object” on page 34-29.

- Before you apply the data types that the Fixed-Point Tool proposes, clear the proposals for parameters and parameter objects whose data types you do not want the tool to change. For example, clear the proposals for these entities:

- Parameter objects that you import into the generated code from your own handwritten code by applying a storage class such as `ImportedExtern`.
- `Simulink.Parameter` model arguments in a model workspace.

Alternatively, before autoscaling the model, consider replacing these parameter objects with numeric MATLAB variables to prevent the Fixed-Point Tool from autoscaling them.

Allowing the tool to autoscale model arguments can increase the risk of unintentional data type mismatches between the model argument values (which you specify in Model blocks in a parent model), the model arguments in the model workspace, and the client block parameters in the model.

- Parameter objects whose `DataType` property is set to `auto` (context-sensitive). Clear the proposals if you want the parameter objects to continue to use context-sensitive data typing.

For more information about using the Fixed-Point Tool to autoscale `Simulink.Parameter` objects, see “Autoscale `Simulink.Parameter` Objects”.

Calculate Best-Precision Scaling for Individual Parameters

You can configure a block parameter or `Simulink.Parameter` object to calculate its own best-precision scaling. First, specify value range information for the target parameter or parameter object. Then, use the Data Type Assistant or the function `fixdt` to apply a data type to the parameter or object. Use these techniques when you do not want to use the Fixed-Point Tool to autoscale the model.

Enable Block Parameter to Automatically Calculate Best-Precision Scaling

You can enable the parameters of some blocks (typically blocks in the Discrete library) to automatically calculate best-precision fixed-point scaling. Use this technique to store the range and data type information in the model instead of a parameter object. When you use this technique, if you later change the range information, the block parameter automatically recalculates best-precision scaling.

In the block dialog box, use the function `fixdt` to specify a fixed-point data type with unspecified scaling. For example, use best-precision scaling for lookup table data, and store the data in a 16-bit word:

- 1 On the **Data Types** tab of an n-D Lookup Table block, under the **Minimum** and **Maximum** columns, specify a value range for the elements of the table data.

- 2 Under the **Data Type** column, set the table data type to `fixdt(1,16)`.
- 3 If you use a tunable `Simulink.Parameter` object to set the value of the table data parameter, set the `DataType` property of the object to `auto`. In the generated code, the parameter object uses the same scaling as the block parameter.

When you simulate or generate code, the lookup table data uses a signed 16-bit fixed-point data type whose binary-point scaling depends on the range information that you specify. The calculated scaling allows the fixed-point type to represent values that lie within the range. If you later change the minimum or maximum values, the block recalculates the scaling when you simulate or generate code.

Calculate Scaling for Parameter Object

If you use a `Simulink.Parameter` object to set the values of multiple block parameters, and if the block parameters use different data types (including different fixed-point scaling), you cannot set the `DataType` property of the object to `auto` (the default). Instead, you can calculate best-precision fixed-point scaling for the parameter object by specifying range and data type information in the object. You can also use this technique to store range and data type information in a parameter object instead of a block dialog box. When you use this technique, if you later change the range information, you must recalculate the best-precision scaling by using the Data Type Assistant.

Suppose that you create a parameter object to represent the value `15.25`, and that the design range of the value is between `0.00` and `32.00`. To calculate best-precision scaling, use the Data Type Assistant.

- 1 At the command prompt, create a parameter object in the base workspace whose value is `15.25`.

```
myParam = Simulink.Parameter(15.25);
```
- 2 In the MATLAB Workspace browser, double-click the object `myParam`. The property dialog box opens.
- 3 Specify range information in the object. For example, set **Minimum** to `0.00` and **Maximum** to `32.00`.
- 4 Set **Data type** to `fixdt(0,16,0)`.
- 5 Expand the Data Type Assistant and click **Calculate Best-Precision Scaling**.

The data type changes from `fixdt(0,16,0)` to `fixdt(0,16,10)`.

The calculated scaling (a fraction length of 10 bits) enables the fixed-point data type to represent parameter values that lie within the range that you specified.

If you specify range and data type information in a parameter object, consider removing the range and data type information from the blocks that use the object. Some tools, such as the Fixed-Point Tool, ignore the range information that you specify in the block and use only the information in the parameter object. Removing the information from the block prevents confusion and user errors.

For example, on the **Parameter Attributes** tab of a Gain block dialog box, set **Parameter minimum** and **Parameter maximum** to []. Set **Parameter data type** to an inherited data type such as **Inherit: Inherit from 'Gain'** so that the block parameter uses the same data type as the parameter object.

Detect Numerical Accuracy Issues Due to Quantization and Overflow

When the data type of a block parameter, MATLAB variable, or parameter object cannot represent the value that you specify, the data type quantizes the value, compromising numerical accuracy. For example, the 32-bit floating-point data type `single` (float in C code) cannot exactly represent the parameter value `1.73`. When the real-world value of a data item lies outside the range of values that the data type can represent, overflow can cause loss of information.

To detect these issues, use the diagnostic configuration parameters under **Configuration Parameters > Diagnostics > Data Validity > Parameters**. Set the values of these diagnostic configuration parameters to `warning` or `error`:

- **Detect downcast**
- **Detect precision loss**
- **Detect underflow**
- **Detect overflow**

Data Types of Mathematical Expressions

If you specify a block parameter using a mathematical expression, the block determines the final parameter data type using a combination of MATLAB and Simulink data typing rules.

Suppose that you define two parameter objects `int8Param` and `doubleParam`, and use the objects to specify the **Constant value** parameter in a Constant block.

```
int8Param = Simulink.Parameter(3);
```

```
int8Param.DataType = 'int8';

doubleParam = Simulink.Parameter(9.36);
doubleParam.DataType = 'double';
```

The Constant block determines the data type of the **Constant value** parameter using these steps:

- 1 Each parameter object casts the specified numeric value to the specified data type.

Parameter object	Data type	Numeric value	Result
int8Param	int8	3	int8(3)
doubleParam	double	9.36	double(9.36)

- 2 The block evaluates the specified expression, `int8Param * doubleParam`, using MATLAB rules.

An expression that involves a **double** data type and a different type returns a result of the different type. Therefore, the result of the expression `int8(3) * double(9.36)` is `int8(28)`.

Block Parameter Data Types in the Generated Code

For more information about controlling parameter data types in the generated code, see “Parameter Data Types in the Generated Code”.

- “Specify Minimum and Maximum Values for Block Parameters” on page 34-63
- “Tune and Experiment with Block Parameter Values” on page 34-36
- “Data Validity Diagnostics Overview”

Specify Minimum and Maximum Values for Block Parameters

You can protect your model design by preventing block parameters from using values outside of a range. For example, if the value of a parameter that represents the angle of an aircraft aileron cannot feasibly exceed a known magnitude, you can specify a design maximum for the parameter in the model.

Fixed-Point Designer enables Simulink to use your range information to calculate best-precision fixed-point scaling for:

- Tunable parameters.
- Signals, by taking into consideration the range of values that you intend to assign to tunable parameters.

For basic information about block parameters, see “Set Block Parameter Values” on page 34-2.

Specify Block Parameter Value Ranges

To specify a value range for a block parameter, choose a technique based on your modeling goals.

- You can specify value ranges for some block parameters by using other parameters of the same block. For example, you can control the value range of the **Gain** parameter of a Gain block by using the **Parameter minimum** and **Parameter maximum** parameters in the **Parameter Attributes** tab in the block dialog box. For other blocks, such as n-D Lookup Table and PID Controller, use the **Data Types** tab.

Use this technique to:

- Store the range information in the model file.
- Store the range information when you store fixed-point data type information in the block (for example, by setting the **Parameter data type** parameter of a Gain block to a fixed-point type, including best-precision scaling). This technique more clearly associates the range information with the data type information.
- To specify value ranges for the parameters of any block, consider using parameter objects (for example, `Simulink.Parameter`) to set the parameter values. You can specify the range information in the object, instead of the block, by using the **Min** and **Max** properties.

Use this technique to:

- Specify range information for blocks that cannot store minimum or maximum information, for example, many blocks in the Continuous library.
- Specify range information for a single value that you share between multiple block parameters (see “Share and Reuse Block Parameter Values by Creating Variables” on page 34-11). Instead of using a numeric MATLAB variable, use a parameter object so that you can specify the `Min` and `Max` properties.
- Store the range information when you store fixed-point data type information in a parameter object (by setting the `DataType` property to a fixed-point type instead of `auto`). This technique more clearly associates the range information with the data type information.

If you specify the range information in a parameter object, consider removing the range information from the block. For example, on the **Parameter Attributes** tab of a Gain block dialog box, set **Parameter minimum** and **Parameter maximum** to `[]`. Some tools, such as the Fixed-Point Tool, use the range information that you specify in the block only if you do not specify the range information in the parameter object. If you specify the range information in the parameter object, the tools ignore the range information that you specify in the block.

For basic information about creating and using data objects, see “Data Objects” on page 57-54.

Specify Valid Range Information

The minimum and maximum values that you specify for a parameter must evaluate to a finite, scalar, real number that uses the data type `double`. For example, you can set the **Parameter minimum** parameter of a Gain block to a literal number such as `15.23`, or to the name of a workspace variable whose value is `15.23`. Use a workspace variable to apply the same minimum or maximum to multiple block parameters. However, you cannot use variables to set the `Min` or `Max` properties of a parameter object.

To leave the minimum or maximum of a block parameter or parameter object unspecified, use an empty matrix `[]`, which is the default value.

Specify Range Information for Nonscalar Parameters

If the value of a block parameter is a vector or matrix, the range information that you specify applies to each element of the vector or matrix. If the value of any of the elements is outside the specified range, the model generates an error.

If the value of a block parameter is a structure or a field of a structure, specify range information for the structure fields by creating a `Simulink.Parameter` object whose data type is a `Simulink.Bus` object. Specify the range information by using the properties of the signal elements in the bus object. For more information, see “Control Field Data Types and Characteristics by Creating Parameter Object” on page 34-29.

Specify Range Information for Complex-Valued Parameters

If the value of a block parameter is complex (i), the range information that you specify applies separately to the real part and to the imaginary part of the complex number. If the value of either part of the number is outside the range, the model generates an error.

Restrict Allowed Values for Block Parameters

To protect your design by preventing block parameters from using values outside of a range, you can specify the minimum and maximum information by using other parameters of the same block. If you or your users set the value of the target parameter outside the range that you specify, the model generates an error.

Whether a block allows you to specify a value range for a parameter, consider using a parameter object (for example, `Simulink.Parameter`) to set the value of the target parameter. Use the properties of the object to specify the range information. This technique helps you to specify range information for a variable that you use to set multiple block parameter values.

Specify Range Information for Tunable Fixed-Point Parameters

When you use fixed-point data types in your model, you can enable Simulink to choose a best-precision scaling for block parameters and `Simulink.Parameter` objects. If you intend to tune such a parameter by changing its value during simulation or during execution of the generated code, the fixed-point scaling chosen by Simulink must accommodate the range of values that you expect to assign to the parameter.

Also, if you expect to change the value of a parameter, signal data types in the model must accommodate the corresponding expanded range of possible signal values. If you

use the Fixed-Point Tool to propose and apply fixed-point data types for a model, to allow the tool to accurately autoscale the signals, specify range information for tunable parameters.

To specify range information for tunable parameters, see “Calculate Best-Precision Fixed-Point Scaling for Tunable Block Parameters” on page 34-56. To learn how the Fixed-Point Tool autoscales signals by taking into account the value ranges of tunable parameters, see “Derive Ranges for Simulink.Parameter Objects”.

Switch Between Sets of Parameter Values During Simulation and Code Execution

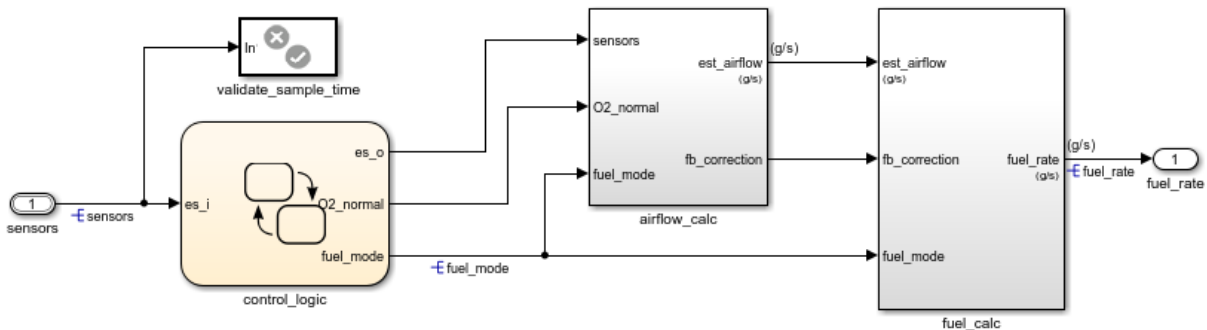

To store multiple independent sets of values for the same block parameters, you can use an array of structures. To switch between the parameter sets, create a variable that acts as an index into the array, and change the value of the variable. You can change the value of the variable during simulation and, if the variable is tunable, during execution of the generated code.

Explore Example Model

Open this example model:

```
open_system('sldemo_fuelsys_dd_controller')
```

Fuel Rate Controller

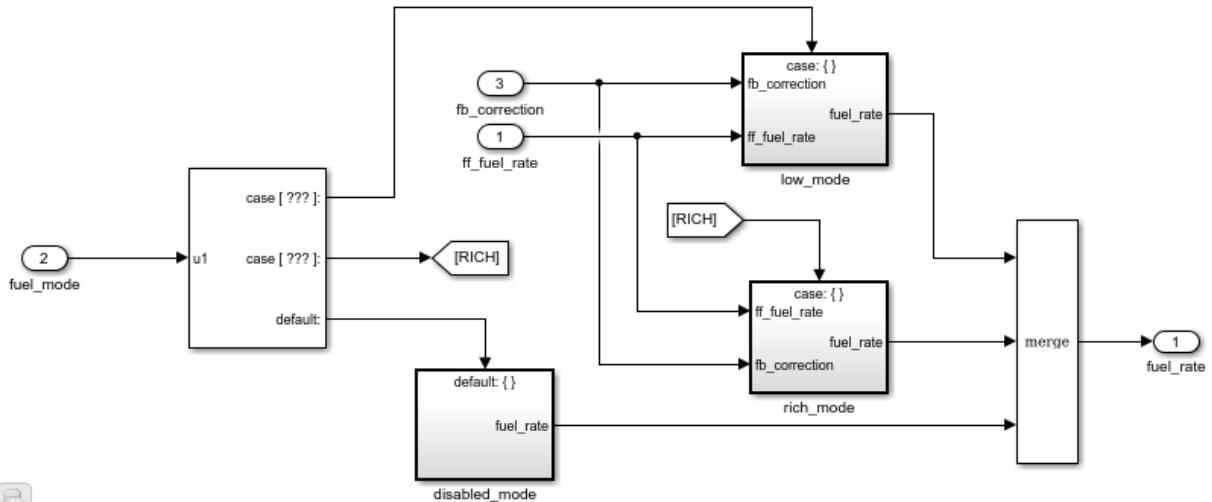

Copyright 1990-2015 The MathWorks, Inc.

This model represents the fueling system of a gasoline engine. The output of the model is the rate of fuel flow to the engine.

Navigate to the `switchable_compensation` nested subsystem.

```
open_system(['sldemo_fuelsys_dd_controller/fuel_calc/', ...
            'switchable_compensation'])
```

Loop Compensation and Filtering

This subsystem corrects and filters noise out of the fuel rate signal. The subsystem uses different filter coefficients based on the fueling mode, which the control logic changes based on sensor failures in the engine. For example, the control algorithm activates the `low_mode` subsystem during normal operation. It activates the `rich_mode` subsystem in response to sensor failure.

Open the `low_mode` subsystem.

```
open_system(['sldemo_fuelsys_dd_controller/fuel_calc/',...
            'switchable_compensation/low_mode'])
```

The Discrete Filter block filters the fuel rate signal. In the block dialog box, the **Numerator** parameter sets the numerator coefficients of the filter.

The sibling subsystem `rich_mode` also contains a Discrete Filter block, which uses different coefficients.

Update the model diagram to display the signal data types. The input and output signals of the block use the single-precision, floating-point data type `single`.

In the lower-left corner of the model, click the data dictionary badge. The data dictionary for this model, `sldemo_fuelsys_dd_controller.sldd`, opens in the Model Explorer.

In the **Contents** pane, view the properties of the `Simulink.NumericType` objects, such as `s16En15`. All of these objects currently represent the single-precision, floating-point data type `single`. The model uses these objects to set signal data types, including the input and output signals of the Discrete Filter blocks.

Suppose that during simulation and execution of the generated code, you want each of these subsystems to switch between different numerator coefficients based on a variable whose value you control.

Store Parameter Values in Array of Structures

Store the existing set of numerator coefficients in a `Simulink.Parameter` object whose value is a structure. Each field of the structure stores the coefficients for one of the Discrete Filter blocks.

```
lowBlock = ['sldemo_fuelsys_dd_controller/fuel_calc/'...
            'switchable_compensation/low_mode/Discrete Filter'];
```

```
richBlock = ['sldemo_fuelsys_dd_controller/fuel_calc/'...  
            'switchable_compensation/rich_mode/Discrete Filter'];  
params.lowNumerator = eval(get_param(lowBlock, 'Numerator'));  
params.richNumerator = eval(get_param(richBlock, 'Numerator'));  
params = Simulink.Parameter(params);
```

Copy the value of `params` into a temporary variable. Modify the field values in this temporary structure, and assign the modified structure as the second element of `params`.

```
temp = params.Value;  
temp.lowNumerator = params.Value.lowNumerator * 2;  
temp.richNumerator = params.Value.richNumerator * 2;  
params.Value(2) = temp;  
clear temp
```

The value of `params` is an array of two structures. Each structure stores one set of filter coefficients.

Create Variable to Switch Between Parameter Sets

Create a `Simulink.Parameter` object named `Ctrl`.

```
Ctrl = Simulink.Parameter(2);  
Ctrl.DataType = 'uint8';
```

In the `low_mode` subsystem, in the Discrete Filter block dialog box, set the **Numerator** parameter to the expression `params(Ctrl).lowNumerator`.

```
set_param(lowBlock, 'Numerator', 'params(Ctrl).lowNumerator');
```

In the Discrete Filter block in the `rich_mode` subsystem, set the value of the **Numerator** parameter to `params(Ctrl).richNumerator`.

```
set_param(richBlock, 'Numerator', 'params(Ctrl).richNumerator');
```

The expressions select one of the structures in `params` by using the variable `Ctrl`. The expressions then dereference one of the fields in the structure. The field value sets the values of the numerator coefficients.

To switch between the sets of coefficients, you change the value of `Ctrl` to the corresponding index in the array of structures.

Use Bus Object as Data Type of Array of Structures

Optionally, create a `Simulink.BUS` object to use as the data type of the array of structures. You can:

- Control the shape of the structures.
- For each field, control characteristics such as data type and physical units.
- Control the name of the `struct` type in the generated code.

Use the function `Simulink.Bus.createObject` to create the object and rename the object as `paramsType`.

```
Simulink.Bus.createObject(params.Value)
paramsType = slBus1;
clear slBus1
```

You can use the `Simulink.NumericType` objects from the data dictionary to control the data types of the structure fields. In the bus object, use the name of a data type object to set the `DataType` property of each element.

```
paramsType.Elements(1).DataType = 's16En15';
paramsType.Elements(2).DataType = 's16En7';
```

Use the bus object as the data type of the array of structures.

```
params.DataType = 'Bus: paramsType';
```

Use Enumerated Type for Switching Variable

Optionally, use an enumerated type as the data type of the switching variable. You can associate each of the parameter sets with a meaningful name and restrict the allowed values of the switching variable.

Create an enumerated type named `FilterCoeffs`. Create an enumeration member for each of the structures in `params`. Set the underlying integer value of each enumeration member to the corresponding index in `params`.

```
Simulink.defineIntEnumType('FilterCoeffs',{'Weak','Aggressive'},[1 2])
```

Use the enumerated type as the data type of the switching variable. Set the value of the variable to `Aggressive`, which corresponds to the index 2.

```
Ctrl.Value = FilterCoeffs.Aggressive;
```

Add New Objects to Data Dictionary

Add the objects that you created to the data dictionary
`sldemo_fuelsys_dd_controller.slidd`.

```
dictObj = Simulink.data.dictionary.open('sldemo_fuelsys_dd_controller.sldd');
sectObj = getSection(dictObj, 'Design Data');
addEntry(sectObj, 'Ctrl', Ctrl)
addEntry(sectObj, 'params', params)
addEntry(sectObj, 'paramsType', paramsType)
```

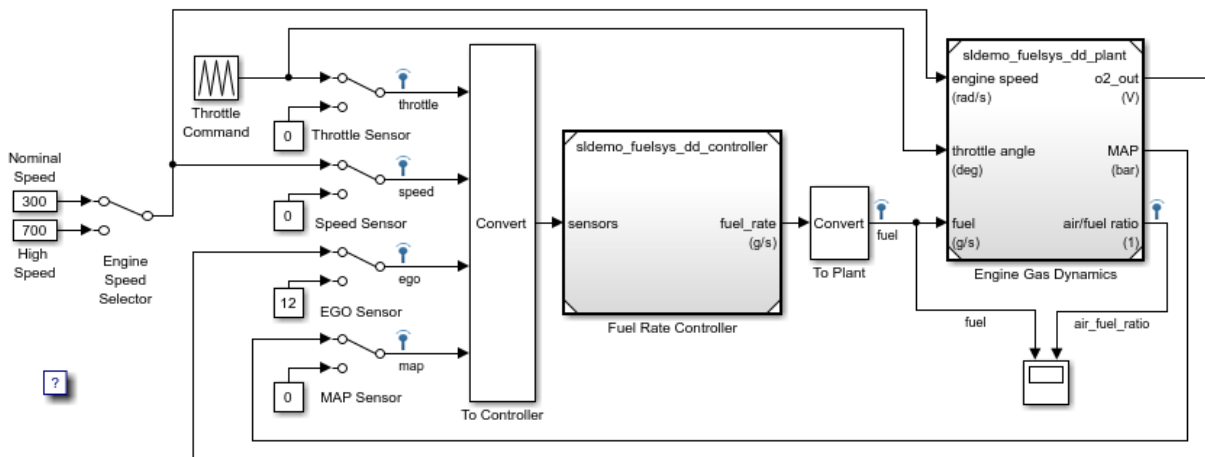

You can also store enumerated types in data dictionaries. However, you cannot import the enumerated type in this case because you cannot save changes to `sldemo_fuelsys_dd_controller.sldd`. For more information about storing enumerated types in data dictionaries, see “Enumerations in Data Dictionary”.

Switch Between Parameter Sets During Simulation

Open the example model `sldemo_fuelsys_dd`, which references the controller model `sldemo_fuelsys_dd_controller`.

```
open_system('sldemo_fuelsys_dd')
```

Fault-Tolerant Fuel Control System

The sensor switches simulate any combination of sensor failures.
The Engine Speed Selector switch simulates different engine speeds (rad/s).

Copyright 1990-2015 The MathWorks, Inc.

Set the simulation stop time to `Inf` so that you can interact with the model during simulation.

Begin a simulation run and open the Scope block dialog box. The scope shows that the fuel flow rate (the `fuel` signal) oscillates with significant amplitude during normal operation of the engine.

In the Model Explorer, view the contents of the data dictionary `sldemo_fuelsys_dd_controller.sldd`. Set the value of `Ctrl` to `FilterCoeffs.Weak`.

Update the `sldemo_fuelsys_dd` model diagram. The scope shows that the amplitude of the fuel rate oscillations decreases due to the less aggressive filter coefficients.

Stop the simulation.

Generate and Inspect Code

If you have Simulink Coder software, you can generate code that enables you to switch between the parameter sets during code execution.

In the Model Explorer, view the contents of the data dictionary `sldemo_fuelsys_dd_controller.sldd`. In the **Contents** pane, set **Column View** to **Storage Class**.

Use the **StorageClass** column to apply the storage class `ExportedGlobal` to `params` so that the array of structures appears as a tunable global variable in the generated code. Apply the same storage class to `Ctrl` so that you can change the value of the switching variable during code execution.

Alternatively, to configure the objects, use these commands:

```
tempEntryObj = getEntry(sectObj, 'params');
params = getValue(tempEntryObj);
params.StorageClass = 'ExportedGlobal';
setValue(tempEntryObj, params);

tempEntryObj = getEntry(sectObj, 'Ctrl');
Ctrl = getValue(tempEntryObj);
Ctrl.StorageClass = 'ExportedGlobal';
setValue(tempEntryObj, Ctrl);
```

Generate code from the controller model.

```
rtwbuild('sldemo_fuelsys_dd_controller')

### Starting build procedure for model: sldemo_fuelsys_dd_controller
```

```
### Successful completion of code generation for model: sldemo_fuelsys_dd_controller
```

In the code generation report, view the header file `sldemo_fuelsys_dd_controller_types.h`. The code defines the enumerated data type `FilterCoeffs`.

```
file = fullfile('sldemo_fuelsys_dd_controller_ert_rtw',...
    'sldemo_fuelsys_dd_controller_types.h');
rtwdemodbtype(file, '#ifndef DEFINED_TYPEDEF_FOR_FilterCoeffs_',...
    '/* Forward declaration for rtModel */',1,0)
```

```
#ifndef DEFINED_TYPEDEF_FOR_FilterCoeffs_
#define DEFINED_TYPEDEF_FOR_FilterCoeffs_

typedef enum {
    Weak = 1,                               /* Default value */
    Aggressive
} FilterCoeffs;

#endif
```

The code also defines the structure type `paramType`, which corresponds to the `Simulink.Bus` object. The fields use the single-precision, floating-point data type from the model.

```
rtwdemodbtype(file, '#ifndef DEFINED_TYPEDEF_FOR_paramType_',...
    '#ifndef DEFINED_TYPEDEF_FOR_FilterCoeffs_',1,0)
```

```
#ifndef DEFINED_TYPEDEF_FOR_paramType_
#define DEFINED_TYPEDEF_FOR_paramType_

typedef struct {
    real32_T lowNumerator[2];
    real32_T richNumerator[2];
} paramType;

#endif
```

View the source file `sldemo_fuelsys_dd_controller.c`. The code uses the enumerated type to define the switching variable `Ctrl`.

```
file = fullfile('sldemo_fuelsys_dd_controller_ert_rtw',...
    'sldemo_fuelsys_dd_controller.c');
```

```

rtwdemodbtype(file, 'FilterCoeffs Ctrl = Aggressive;', ...
    /* Block signals (auto storage) */ ,1,0)

FilterCoeffs Ctrl = Aggressive;          /* Variable: Ctrl
                                         * Referenced by:
                                         *   '<S12>/Discrete Filter'
                                         *   '<S13>/Discrete Filter'
                                         */

```

The code also defines the array of structures `params`.

```

rtwdemodbtype(file, /* Exported block parameters */ , ...
    /* Variable: params',1,1)

/* Exported block parameters */
paramsType params[2] = { {
    { 8.7696F, -8.5104F },

    { 0.0F, 0.2592F }
}, { { 17.5392F, -17.0208F },

    { 0.0F, 0.5184F }
} } ;                                     /* Variable: params

```

The code algorithm in the model `step` function uses the switching variable to index into the array of structures.

To switch between the parameter sets stored in the array of structures, change the value of `Ctrl` during code execution.

About Lookup Table Blocks

A *lookup table* block uses an array of data to map input values to output values, approximating a mathematical function. Given input values, Simulink performs a “lookup” operation to retrieve the corresponding output values from the table. If the lookup table does not define the input values, the block estimates the output values based on nearby table values.

The following example illustrates a one-dimensional lookup table that approximates the function $y = x^3$. The lookup table defines its output (y) data discretely over the input (x) range $[-3, 3]$. The following table and graph illustrate the input/output relationship:

x	-3	-2	-1	0	1	2	3
y	-27	-8	-1	0	1	8	27

An input of -2 enables the table to look up and retrieve the corresponding output value (-8). Likewise, the lookup table outputs 27 in response to an input of 3.

When the lookup table block encounters an input that does not match any of the table's x values, it can interpolate or extrapolate the answer. For instance, the lookup table does not define an input value of -1.5; however, the block can linearly interpolate the nearest data points (-2, -8) and (-1, -1) to estimate and return a value of -4.5.

Similarly, although the lookup table does not include data for x values beyond the range of $[-3, 3]$, the block can extrapolate values using a pair of data points at either end

of the table. Given an input value of 4, the lookup table block linearly extrapolates the nearest data points (2, 8) and (3, 27) to estimate an output value of 46.

Since table lookups and simple estimations can be faster than mathematical function evaluations, using lookup table blocks might result in speed gains when simulating a model. Consider using lookup tables in lieu of mathematical function evaluations when:

- An analytical expression is expensive to compute.
- No analytical expression exists, but the relationship has been determined empirically.

Simulink provides a broad assortment of lookup table blocks, each geared for a particular type of application. The sections that follow outline the different offerings, suggest how to choose the lookup table best suited to your application, and explain how to interact with the various lookup table blocks.

Anatomy of a Lookup Table

The following figure illustrates the anatomy of a two-dimensional lookup table. Vectors or *breakpoint data sets* and an array, referred to as *table data*, constitute the lookup table.

Each breakpoint data set is an index of input values for a particular dimension of the lookup table. The array of table data serves as a sampled representation of a function evaluated at the breakpoint values. Lookup table blocks use breakpoint data sets to relate a table's input values to the output values that it returns.

Lookup Tables Block Library

Several lookup table blocks appear in the Lookup Tables block library.

The following table summarizes the purpose of each block in the library.

Block Name	Description
1-D Lookup Table	Approximate a one-dimensional function.
2-D Lookup Table	Approximate a two-dimensional function.
n-D Lookup Table	Approximate an N-dimensional function.
Prelookup	Compute index and fraction for Interpolation Using Prelookup block.
Interpolation Using Prelookup	Use precalculated index and fraction values to accelerate approximation of N-dimensional function.
Direct Lookup Table (n-D)	Index into an N-dimensional table to retrieve the corresponding outputs.

Block Name	Description
Lookup Table Dynamic	Approximate a one-dimensional function using a dynamically specified table.
Sine	Use a fixed-point lookup table to approximate the sine wave function.
Cosine	Use a fixed-point lookup table to approximate the cosine wave function.

Guidelines for Choosing a Lookup Table

In this section...

- “Data Set Dimensionality” on page 35-8
- “Data Set Numeric and Data Types” on page 35-8
- “Data Accuracy and Smoothness” on page 35-8
- “Dynamics of Table Inputs” on page 35-9
- “Efficiency of Performance” on page 35-9
- “Summary of Lookup Table Block Features” on page 35-10

Data Set Dimensionality

In some cases, the dimensions of your data set dictate which of the lookup table blocks is right for your application. If you are approximating a one-dimensional function, consider using either the 1-D Lookup Table or Lookup Table Dynamic block. If you are approximating a two-dimensional function, consider the 2-D Lookup Table block. Blocks such as the n-D Lookup Table and Direct Lookup Table (n-D) allow you to approximate a function of N variables.

Data Set Numeric and Data Types

The numeric and data types of your data set influence the decision of which lookup table block is most appropriate. Although all lookup table blocks support real numbers, the Direct Lookup Table (n-D), 1-D Lookup Table, 2-D Lookup Table, and n-D Lookup Table blocks also support complex table data. All lookup table blocks support integer and fixed-point data in addition to `double` and `single` data types.

Note: For the Direct Lookup Table (n-D) block, fixed-point types are supported for the table data, output port, and optional table input port.

Data Accuracy and Smoothness

The desired accuracy and smoothness of the data returned by a lookup table determine which of the blocks you should use. Most blocks provide options to perform interpolation

and extrapolation, improving the accuracy of values that fall between or outside of the table data, respectively. For instance, the Lookup Table Dynamic block performs linear interpolation and extrapolation, while the n-D Lookup Table block performs either linear or cubic spline interpolation and extrapolation. In contrast, the Direct Lookup Table (n-D) block performs table lookups without any interpolation or extrapolation. You can achieve a mix of interpolation and extrapolation methods by using the Prelookup block with the Interpolation Using Prelookup block.

Dynamics of Table Inputs

The dynamics of the lookup table inputs impact which of the lookup table blocks is ideal for your application. The blocks use a variety of index search methods to relate the lookup table inputs to the table's breakpoint data sets. Most of the lookup table blocks offer a binary search algorithm, which performs well if the inputs change significantly from one time step to the next. The 1-D Lookup Table, 2-D Lookup Table, n-D Lookup Table, and Prelookup blocks offer a linear search algorithm. Using this algorithm with the option that resumes searching from the previous result performs well if the inputs change slowly. Some lookup table blocks also provide a search algorithm that works best for breakpoint data sets composed of evenly spaced breakpoints. You can achieve a mix of index search methods by using the Prelookup block with the Interpolation Using Prelookup block.

Efficiency of Performance

When the efficiency with which lookup tables operate is important, consider using the Prelookup block with the Interpolation Using Prelookup block. These blocks separate the table lookup process into two components — an index search that relates inputs to the table data, followed by an interpolation and extrapolation stage that computes outputs. These blocks enable you to perform a single index search and then reuse the results to look up data in multiple tables. Also, the Interpolation Using Prelookup block can perform sub-table selection, where the block interpolates a portion of the table data instead of the entire table. For example, if your 3-D table data constitutes a stack of 2-D tables to be interpolated, you can specify a selection port input to select one or more of the 2-D tables from the stack for interpolation. A full 3-D interpolation has 7 sub-interpolations but a 2-D interpolation requires only 3 sub-interpolations. As a result, significant speed improvements are possible when some dimensions of a table are used for data stacking and not intended for interpolation. These features make table lookup operations more efficient, reducing computational effort and simulation time.

Summary of Lookup Table Block Features

Use the following table to identify features that correspond to particular lookup table blocks, then select the block that best meets your requirements.

Enter Breakpoints and Table Data

In this section...

“Entering Data in a Block Parameter Dialog Box” on page 35-12

“Entering Data in the Lookup Table Editor” on page 35-12

“Entering Data Using Imports of the Lookup Table Dynamic Block” on page 35-14

Entering Data in a Block Parameter Dialog Box

This example shows how to populate a 1-D `Lookup Table` block using the parameter dialog box. The lookup table in this example approximates the function $y = x^3$ over the range $[-3, 3]$.

- 1 Copy a 1-D `Lookup Table` block from the `Lookup Tables` block library to a Simulink model.
- 2 In the 1-D `Lookup Table` block dialog box, enter the table dimensions and table data in the specified fields of the dialog box:
 - Set **Number of table dimensions** to 1.
 - Set **Table data** to `[-27 -8 -1 0 1 8 27]`.

Alternatively, to use an existing lookup table (`Simulink.LookupTable`) object, select **Data specification** > **Lookup table object**.

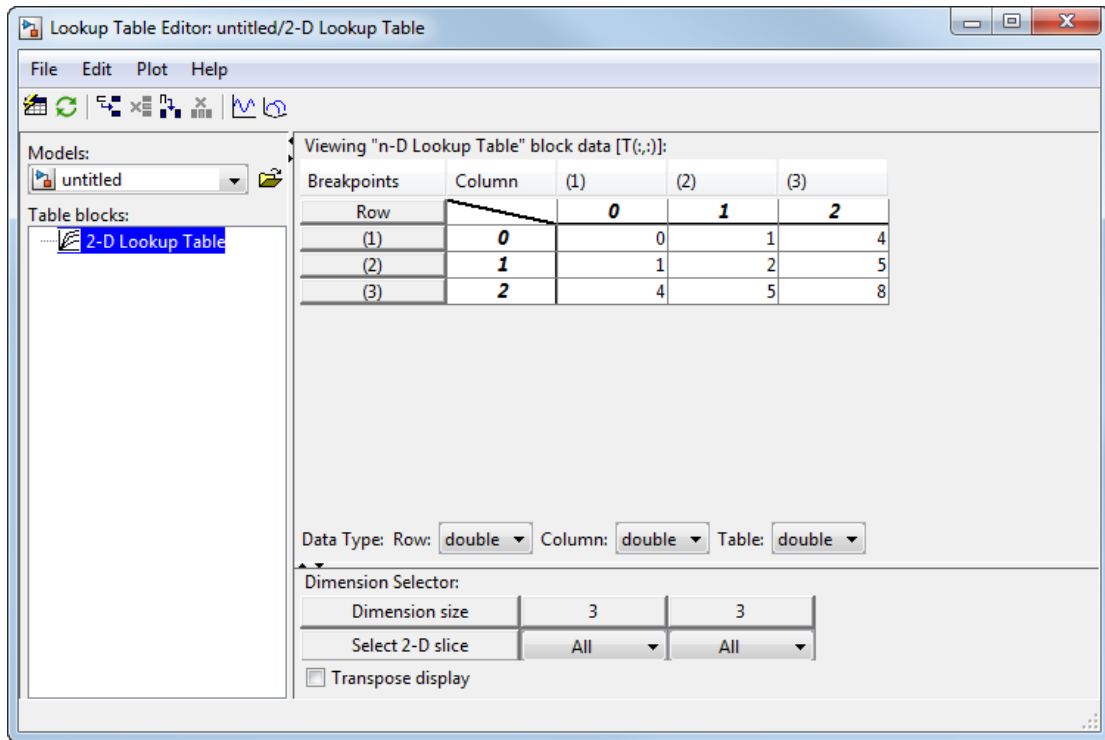

- 3 Enter the breakpoint data set using either of two methods:
 - To specify evenly spaced data points, set **Breakpoint specification** to **Even spacing**. Set **First point** to `-3` and **Spacing** to 1. The block calculates the number of evenly spaced breakpoints based on the table data.
 - To specify breakpoint data explicitly, set **Breakpoint specification** to **Explicit values** and set **Breakpoints 1** to `[-3:3]`.

Entering Data in the Lookup Table Editor

Use the following procedure to populate a 2-D `Lookup Table` block using the `Lookup Table Editor`. In this example, the lookup table approximates the function $z = x^2 + y^2$ over the input ranges $x = [0, 2]$ and $y = [0, 2]$.

- 1** Copy a 2-D Lookup Table block from the Lookup Tables block library to a Simulink model.
- 2** Open the Lookup Table Editor by selecting **Lookup Table Editor** from the Simulink **Edit** menu or by clicking **Edit table and breakpoints** on the dialog box of the 2-D Lookup Table block.
- 3** Under **Viewing "n-D Lookup Table" block data**, enter the breakpoint data sets and table data in the appropriate cells. To change data, click a cell, enter the new value, and press **Enter**.
 - In the cells associated with the **Row Breakpoints**, enter each of the values [0 1 2].
 - In the cells associated with the **Column Breakpoints**, enter each of the values [0 1 2].
 - In the table data cells, enter the values in the array [0 1 4; 1 2 5; 4 5 8].

The Lookup Table Editor looks like this:

- 4 In the Lookup Table Editor, select **File > Update Block Data** to update the data in the 2-D Lookup Table block.
- 5 Close the Lookup Table Editor.

Entering Data Using Inports of the Lookup Table Dynamic Block

Use the following procedure to populate a Lookup Table Dynamic block using that block's inports. In this example, the lookup table approximates the function $y = 3x^2$ over the range $[0, 10]$.

- 1 Copy a Lookup Table Dynamic block from the Lookup Tables block library to a Simulink model.
- 2 Copy the blocks needed to implement the equation $y = 3x^2$ to the Simulink model:
 - One Constant block to define the input range, from the Sources library

- One **Math Function** block to square the input range, from the Math Operations library
 - One **Gain** block to multiply the signal by 3, also from the Math Operations library
- 3 Assign the following parameter values to the Constant, Math Function, and Gain blocks using their dialog boxes:

Block	Parameter	Value
Constant	Constant value	0:10
Math Function	Function	square
Gain	Gain	3

- 4 Input the breakpoint data set to the Lookup Table Dynamic block by connecting the output of the Constant block to the input of the Lookup Table Dynamic block labeled **xdat**. This signal is the input breakpoint data set for x .
- 5 Input the table data to the Lookup Table Dynamic block by branching the output signal from the Constant block and connecting it to the Math Function block. Then connect the Math Function block to the Gain block. Finally, connect the Gain block to the input of the Lookup Table Dynamic block labeled **ydat**. This signal is the table data for y .

Characteristics of Lookup Table Data

In this section...

“Sizes of Breakpoint Data Sets and Table Data” on page 35-17

“Monotonicity of Breakpoint Data Sets” on page 35-18

“Representation of Discontinuities in Lookup Tables” on page 35-18

“Formulation of Evenly Spaced Breakpoints” on page 35-20

Sizes of Breakpoint Data Sets and Table Data

The following constraints apply to the sizes of breakpoint data sets and table data associated with lookup table blocks:

- The memory limitations of your system constrain the overall size of a lookup table.
- Lookup tables must use consistent dimensions so that the overall size of the table data reflects the size of each breakpoint data set.

To illustrate the second constraint, consider the following vectors of input and output values that create the relationship in the plot.

Vector of input values: [-3 -2 -1 0 1 2 3]

Vector of output values: [-3 -1 0 -1 0 1 3]

In this example, the input and output data are the same size (1-by-7), making the data consistently dimensioned for a 1-D lookup table.

The following input and output values define the 2-D lookup table that is graphically shown.

Row index input values: [1 2 3]
Column index input values: [1 2 3 4]
Table data: [11 12 13 14; 21 22 23 24; 31 32 33 34]

	1	2	3	4
1	11	12	13	14
2	21	22	23	24
3	31	32	33	34

In this example, the sizes of the vectors representing the row and column indices are 1-by-3 and 1-by-4, respectively. Consequently, the output table must be of size 3-by-4 for consistent dimensions.

Monotonicity of Breakpoint Data Sets

The first stage of a table lookup operation involves relating inputs to the breakpoint data sets. The search algorithm requires that input breakpoint sets be *strictly monotonically increasing*, that is, each successive element is greater than its preceding element. For example, the vector

$A = [0 \ 0.5 \ 1 \ 1.9 \ 2.1 \ 3]$

is a valid breakpoint data set as each element is larger than its predecessors.

Note: Although a breakpoint data set is strictly monotonic in `double` format, it might not be so after conversion to a fixed-point data type.

Representation of Discontinuities in Lookup Tables

You can represent discontinuities in lookup tables that have monotonically increasing breakpoint data sets. To create a discontinuity, repeat an input value in the breakpoint data set with different output values in the table data. For example, these vectors

of input (x) and output (y) values associated with a 1-D lookup table create the step transitions depicted in the plot that follows.

Vector of input values: `[-2 -1 -1 0 0 1 1 2]`

Vector of output values: `[-1 -1 -2 -2 2 2 1 1]`

This example has discontinuities at $x = -1$, 0 , and $+1$.

When there are two output values for a given input value, the block chooses the output according to these rules:

- If the input signal is less than zero, the block returns the output value associated with the last occurrence of the input value in the breakpoint data set. In this example, if the input is -1 , y is -2 , marked with a solid circle.
- If the input signal is greater than zero, the block returns the output value associated with the first occurrence of the input value in the breakpoint data set. In this example, if the input is 1 , y is 2 , marked with a solid circle.
- If the input signal is zero and there are two output values specified at the origin, the block returns the average of those output values. In this example, if the input is 0 , y is 0 , the average of the two output values -2 and 2 specified at $x = 0$.

When there are three points specified at the origin, the block generates the output associated with the middle point. The following example demonstrates this special rule.

Vector of input values: `[-2 -1 -1 0 0 0 1 1 2]`

Vector of output values: `[-1 -1 -2 -2 1 2 2 1 1]`

In this example, three points define the discontinuity at the origin. When the input is 0, y is 1, the value of the middle point.

You can apply this same method to create discontinuities in breakpoint data sets associated with multidimensional lookup tables.

Formulation of Evenly Spaced Breakpoints

You can represent evenly spaced breakpoints in a data set by using one of these methods.

Formulation	Example	When to Use This Formulation
<code>[first_value:spacing:last_value]</code>	<code>[10:10:200]</code>	The lookup table does <i>not</i> use <code>double</code> or <code>single</code> .
<code>first_value + spacing * [0:(last_value-first_value)/spacing]</code>	<code>1 + (0.02 * [0:450])</code>	The lookup table uses <code>double</code> or <code>single</code> .

Because floating-point data types cannot precisely represent some numbers, the second formulation works better for `double` and `single`. For example, use `1 + (0.02 * [0:450])` instead of `[1:0.02:10]`. For a list of lookup table blocks that support evenly spaced breakpoints, see “Summary of Lookup Table Block Features” on page 35-10.

Among other advantages, evenly spaced breakpoints can make the generated code division-free and reduce memory usage. For more information, see:

- `fixpt_evenspace_cleanup` in the Simulink documentation
- “Effects of Spacing on Speed, Error, and Memory Usage” in the Fixed-Point Designer documentation
- “Identify questionable fixed-point operations” in the Simulink Coder documentation

Tip Do not use the MATLAB `linspace` function to define evenly spaced breakpoints. Simulink uses a tighter tolerance to check whether a breakpoint set has even spacing. If you use `linspace` to define breakpoints for your lookup table, Simulink considers the breakpoints to be unevenly spaced.

Methods for Estimating Missing Points

In this section...

“About Estimating Missing Points” on page 35-22

“Interpolation Methods” on page 35-22

“Extrapolation Methods” on page 35-23

“Rounding Methods” on page 35-24

“Example Output for Lookup Methods” on page 35-25

About Estimating Missing Points

The second stage of a table lookup operation involves generating outputs that correspond to the supplied inputs. If the inputs match the values of indices specified in breakpoint data sets, the block outputs the corresponding values. However, if the inputs fail to match index values in the breakpoint data sets, Simulink estimates the output. In the block parameter dialog box, you can specify how to compute the output in this situation. The available lookup methods are described in the following sections.

Interpolation Methods

When an input falls between breakpoint values, the block interpolates the output value using neighboring breakpoints. Most lookup table blocks have the following interpolation methods available:

- **Flat** — Disables interpolation and uses the rounding operation titled **Use Input Below**. For more information, see “Rounding Methods” on page 35-24.
- **Nearest** — Disables interpolation and returns the table value corresponding to the breakpoint closest to the input. If the input is equidistant from two adjacent breakpoints, the breakpoint with the higher index is chosen.
- **Linear** — Fits a line between the adjacent breakpoints, and returns the point on that line corresponding to the input.
- **Cubic spline** — Fits a cubic spline to the adjacent breakpoints, and returns the point on that spline corresponding to the input.

Note: The Lookup Table Dynamic block does not let you select an interpolation method. The **Interpolation-Extrapolation** option in the **Lookup Method** field of the block parameter dialog box performs linear interpolation.

Each interpolation method includes a trade-off between computation time and the smoothness of the result. Although rounding is quickest, it is the least smooth. Linear interpolation is slower than rounding but generates smoother results, except at breakpoints where the slope changes. Cubic spline interpolation is the slowest method but produces the smoothest results.

Extrapolation Methods

When an input falls outside the range of a breakpoint data set, the block extrapolates the output value from a pair of values at the end of the breakpoint data set. Most lookup table blocks have the following extrapolation methods available:

- **Clip** — Disables extrapolation and returns the table data corresponding to the end of the breakpoint data set range. This does not provide protection against out-of-range values.
- **Linear** — If the interpolation method is **Linear**, this extrapolation method fits a line between the first or last pair of breakpoints, depending on whether the input is less than the first or greater than the last breakpoint. If the interpolation method is **Cubic spline**, this extrapolation method fits a linear surface using the slope of the interpolant at the first or last break point, depending on whether the input is less than the first or greater than the last breakpoint. The extrapolation method returns the point on the generated linear surface corresponding to the input.
- **Cubic spline** — Fits a cubic spline to the first or last pair of breakpoints, depending if the input is less than the first or greater than the last breakpoint, respectively. This method returns the point on that spline corresponding to the input.

Note: The Lookup Table Dynamic block does not let you select an extrapolation method. The **Interpolation-Extrapolation** option in the **Lookup Method** field of the block parameter dialog box performs linear extrapolation.

In addition to these methods, some lookup table blocks, such as the n-D Lookup Table block, allow you to select an action to perform when encountering situations that require extrapolation. For instance, you can specify that Simulink generate either a warning or

an error when the lookup table inputs are outside the ranges of the breakpoint data sets. To specify such an action, select it from the **Diagnostic for out-of-range input** list on the block parameter dialog box.

Rounding Methods

If an input falls between breakpoint values or outside the range of a breakpoint data set and you do not specify interpolation or extrapolation, the block rounds the value to an adjacent breakpoint and returns the corresponding output value. For example, the Lookup Table Dynamic block lets you select one of the following rounding methods:

- **Use Input Nearest** — Returns the output value corresponding to the nearest input value.
- **Use Input Below** — Returns the output value corresponding to the breakpoint value that is immediately less than the input value. If no breakpoint value exists below the input value, it returns the breakpoint value nearest the input value.
- **Use Input Above** — Returns the output value corresponding to the breakpoint value that is immediately greater than the input value. If no breakpoint value exists above the input value, it returns the breakpoint value nearest the input value.

Example Output for Lookup Methods

In the following model, the Lookup Table Dynamic block accepts a vector of breakpoint data given by $[-5:5]$ and a vector of table data given by $\sinh([-5:5])$.

The Lookup Table Dynamic block outputs the following values when using the specified lookup methods and inputs.

Lookup Method	Input	Output	Comment
Interpolation-Extrapolation	1.4	2.156	N/A
	5.2	83.59	N/A
Interpolation-Use End Values	1.4	2.156	N/A
	5.2	74.2	The block uses the value for $\sinh(5.0)$.
Use Input Above	1.4	3.627	The block uses the value for $\sinh(2.0)$.
	5.2	74.2	The block uses the value for $\sinh(5.0)$.
Use Input Below	1.4	1.175	The block uses the value for $\sinh(1.0)$.
	-5.2	-74.2	The block uses the value for $\sinh(-5.0)$.
Use Input Nearest	1.4	1.175	The block uses the value for $\sinh(1.0)$.

Edit Lookup Tables

In this section...
“Edit N-Dimensional Lookup Tables” on page 35-27
“Edit Custom Lookup Table Blocks” on page 35-29

You can edit a lookup table using:

- Lookup Table block dialog box
- Lookup Table Editor

To edit the lookup table in a block:

- 1 Open the subsystem that contains the lookup table block.
- 2 Open the lookup table block’s dialog box.
- 3 In the Table and Breakpoints tab, edit the **Table data** and relevant **Breakpoints** parameters as needed.

With the Lookup Table Editor, you can skip these steps and edit the desired lookup table without navigating to the block that uses it. However, you cannot use the Lookup Table Editor to change the dimensions of a lookup table. You must use the block parameter dialog box for this purpose.

Edit N-Dimensional Lookup Tables

If the lookup table of the block currently selected in the Lookup Table Editor tree view has more than two dimensions, the table view displays a two-dimensional slice of the lookup table.

The **Dimension Selector** specifies which slice currently appears and lets you select another slice. The selector consists of a 2-by-N array of controls, where N is the number of dimensions in the lookup table. Each column corresponds to a dimension of the lookup table. The first column corresponds to the first dimension of the table, the second column to the second dimension of the table, and so on. The **Dimension size** row of the selector array displays the size of each dimension. The **Select 2-D slice** row specifies which dimensions of the table correspond to the row and column axes of the slice and the indices that select the slice from the remaining dimensions.

To select another slice of the table, specify the row and column axes of the slice in the first two columns of the **Select 2-D slice** row. Then select the indices of the slice from the pop-up index lists in the remaining columns.

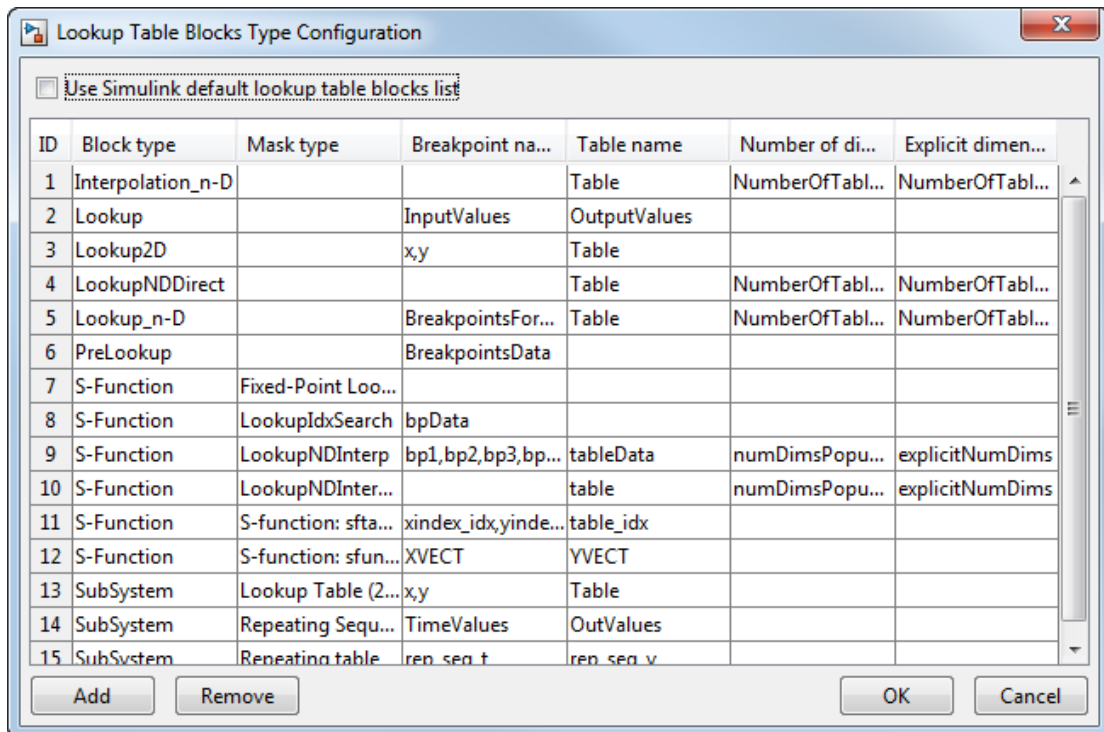

For example, the following selector displays slice (:,:,1) of a 3-D lookup table, as shown under Dimension Selector in the Lookup Table Editor.

To transpose the table display, select the **Transpose display** check box.

Edit Custom Lookup Table Blocks

You can use the Lookup Table Editor to edit custom lookup table blocks that you have created. To do this, you must first configure the Lookup Table Editor to recognize the custom lookup table blocks in your model.

- 1 Select **File > Configure**. The Lookup Table Blocks Type Configuration dialog box appears.

The dialog box displays a table of the lookup table block types that the Lookup Table Editor currently recognizes. This table includes the standard blocks. Each row of the table displays key attributes of a lookup table block type.

- 2 Click **Add** on the dialog box. A new row appears at the bottom of the block type table.
- 3 Enter information for the custom block in the new row under these headings.

Field Name	Description
Block type	Block type of the custom block. The block type is the value of the block's BlockType parameter.
Mask type	Mask type of the custom block. The mask type is the value of the block's MaskType parameter.
Breakpoint name	Names of the block parameters that store the breakpoints.
Table name	Name of the block parameter that stores the table data.
Number of dimensions	Leave empty.
Explicit dimensions	Leave empty.

4 Click **OK**.

To remove a custom lookup table block type from the list that the Lookup Table Editor recognizes, select the custom entry in the table of the Lookup Table Blocks Type Configuration dialog box and click **Remove**. To remove all custom lookup table block types, select the **Use Simulink default lookup table blocks list** check box at the top of the dialog box.

More About

- “About Lookup Table Blocks” on page 35-2
- “Lookup Table Glossary” on page 35-54

Import Lookup Table Data from MATLAB

In this section...

“Import Standard Format Lookup Table Data” on page 35-31

“Propagate Standard Format Lookup Table Data” on page 35-32

“Import Nonstandard Format Lookup Table Data” on page 35-33

“Propagate Nonstandard Format Lookup Table Data” on page 35-34

You can import table and breakpoint data from variables in the MATLAB workspace by referencing them in the **Table and Breakpoints** tab of the dialog box. The following examples show how to import and export standard format and non-standard format data from the MATLAB workspace.

Import Standard Format Lookup Table Data

Suppose you specify a 3-D lookup table in your n-D Lookup Table block.

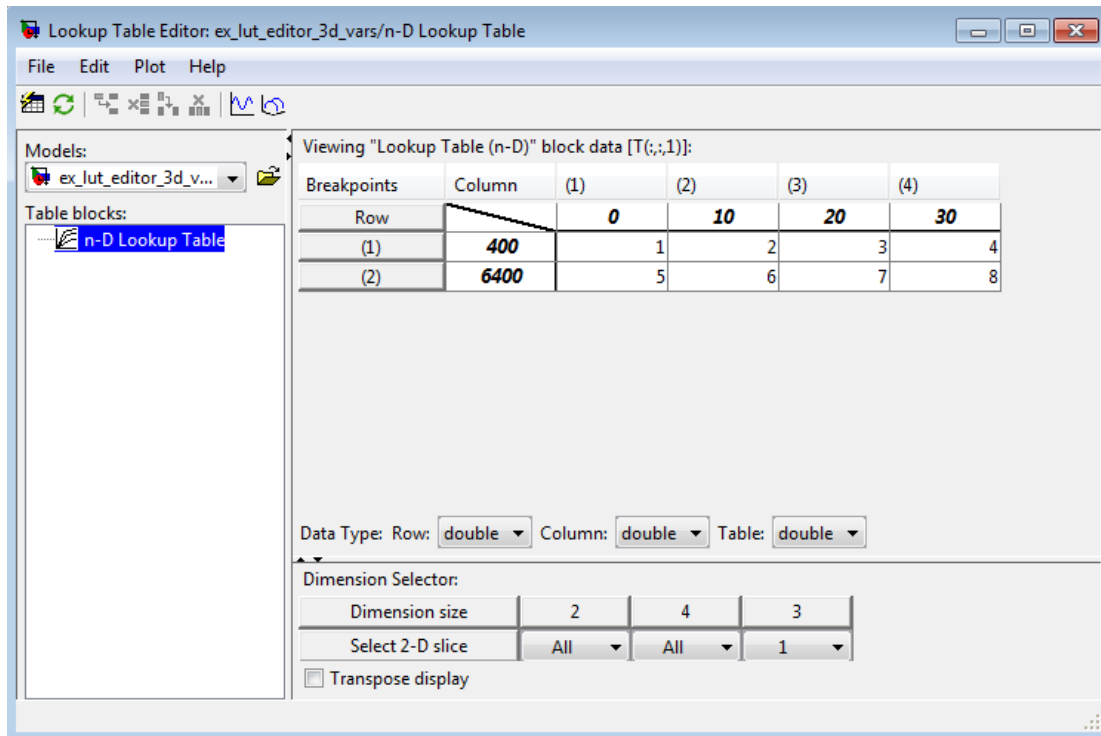

Create workspace variables to use as breakpoint and table data for the lookup table.

```
table3d_map = zeros(2,4,3);
table3d_map(:,:,1) = [ 1 2 3 4; 5 6 7 8];
table3d_map(:,:,2) = [ 11 12 13 14; 15 16 17 18];
table3d_map(:,:,3) = [ 111 112 113 114; 115 116 117 118];
bp3d_z = [ 0 10 20];
bp3d_x = [ 0 10 20 30];
bp3d_y = [ 400 6400];
```

Open the n-D Lookup Table block dialog box, and enter the following parameters in the Table and Breakpoints tab:

- Table data: table3d_map
- Breakpoints 1: bp3d_y
- Breakpoints 2: bp3d_x
- Breakpoints 3: bp3d_z

Click **Edit table and breakpoints** to open the Lookup Table Editor and show the data from the workspace variables.

Propagate Standard Format Lookup Table Data

When you make changes to your lookup table data, consider propagating the changes back to the MATLAB workspace variables the data was imported from using **File > Update Block Data**.

You can also use the Lookup Table Editor to edit the table data and breakpoint data set of `Simulink.LookupTable` and the breakpoint data set of `Simulink.Breakpoint` objects and propagate the changes back to the object.

Suppose you make a change to the lookup table variables imported from the MATLAB workspace variables in “Import Standard Format Lookup Table Data” on page 35-31. For example, change the value of the data in (1,1,1) from 1 to 33. To propagate this change back to `table3d_map` in the workspace, select **File > Update Block Data**. Click **Yes** to confirm that you want to overwrite `table3d_map`.

Import Nonstandard Format Lookup Table Data

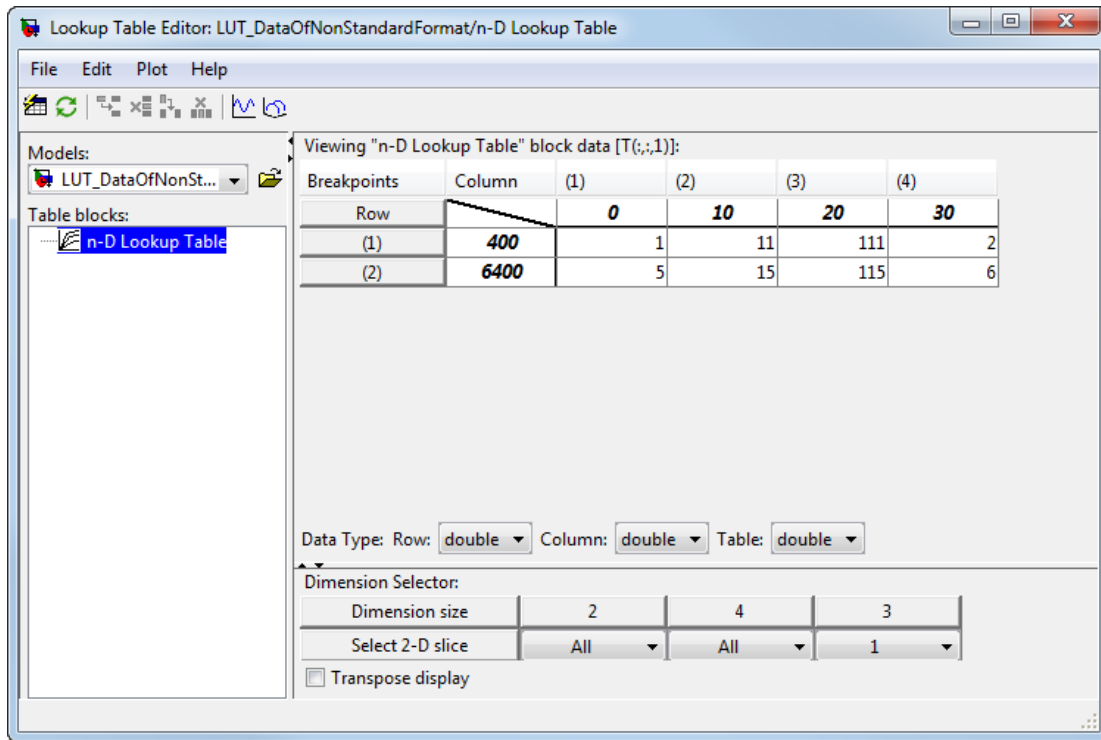

Suppose you specify a 3-D lookup table in your n-D Lookup Table block. Create workspace variables to use as breakpoint and table data for the lookup table. The variable for table data, `table3d_map_custom`, is a two-dimensional matrix.

```
table3d_map_custom = zeros(6,4);  
table3d_map_custom = [ 1 2 3 4; 5 6 7 8;  
11 12 13 14; 15 16 17 18;  
111 112 113 114; 115 116 117 118];  
bp3d_z =[ 0 10 20];  
bp3d_x =[ 0 10 20 30];  
bp3d_y =[ 400 6400];
```

Open the n-D Lookup Table block dialog box, and enter the following parameters in the Table and Breakpoints tab. Transform `table3d_map_custom` into a three-dimensional matrix for the table data input using the `reshape` command below.

- Table data: `reshape(table3d_map_custom,[2,4,3])`
- Breakpoints 1: `bp3d_y`
- Breakpoints 2: `bp3d_x`
- Breakpoints 3: `bp3d_z`

Click **Edit table and breakpoints** to open the Lookup Table Editor and show the data from the workspace variables.

Change 1 to 33 in the Lookup Table Editor. The Lookup Table Editor records your changes by maintaining a copy of the table. To restore the variable values from the MATLAB workspace, select **File > Reload Block Data**. To update the MATLAB workspace variables with the edited data, select **File > Update Block Data** in the Lookup Table Editor. You cannot propagate the change to `table3d_map_custom`, the workspace variable that contains the nonstandard table data for the n-D Lookup Table block. To propagate the change, you must register a customization function that resides on the MATLAB search path. For details, see “Propagate Nonstandard Format Lookup Table Data” on page 35-34.

Propagate Nonstandard Format Lookup Table Data

This example shows how to propagate changes from the Lookup Table Editor to workspace variables of nonstandard format. Suppose your Simulink model from “Import Nonstandard Format Lookup Table Data” on page 35-33 has a three-dimensional lookup table that gets its table data from the two-dimensional workspace variable

`table3d_map_custom`. Update the lookup table in the Lookup Table Editor and propagate these changes back to `table3d_map_custom` using a customization function.

- 1 Create a file named `s1_customization.m` with these contents.

```
function s1_customization(cm)
cm.LookupTableEditorCustomizer.getTableConvertToCustomInfoFcnHandle{end+1} = ...
@myGetTableConvertInfoFcn;
end
```

In this function:

- The argument `cm` is the handle to a customization manager object.
- The handle `@myGetTableConvertInfoFcn` is added to the list of function handles in the cell array for `cm.LookupTableEditorCustomizer.getTableConvertToCustomInfoFcnHandle`. You can use any alphanumeric name for the function whose handle you add to the cell array.

- 2 In the same file, define the `myGetTableConvertInfoFcn` function.

```
function blkInfo = myGetTableConvertInfoFcn(blk, tableStr)
    blkInfo.allowTableConvertLocal = true;
    blkInfo.tableWorkspaceVarName = 'table3d_map_custom';
    blkInfo.tableConvertFcnHandle = @myConvertTableFcn;
end
```

The `myGetTableConvertInfoFcn` function returns the `blkInfo` object containing three fields.

- `allowTableConvertLocal` — Allows table data conversion for a block.
- `tableWorkspaceVarName` — Specifies the name of the workspace variable that has a nonstandard table format.
- `tableConvertFcnHandle` — Specifies the handle for the conversion function.

When `allowTableConvertLocal` is set to `true`, the table data for that block is converted to the nonstandard format of the workspace variable whose name matches `tableWorkspaceVarName`. The conversion function corresponds to the handle that `tableConvertFcnHandle` specifies. You can use any alphanumeric name for the conversion function.

- 3 In the same file, define the `myConvertTableFcn` function. This function converts a three-dimensional lookup table of size *Rows* * *Columns* * *Height* to a two-dimensional variable of size *(Rows*Height)* * *Columns*.

```
% Converts 3-dimensional lookup table from Simulink format to
% nonstandard format used in workspace variable
function cMap = myConvertTableFcn(data)

% Determine the row and column number of the 3D table data
mapDim = size(data);
numCol = mapDim(2);
numRow = mapDim(1)*mapDim(3);
cMap = zeros(numRow, numCol);
% Transform data back to a 2-dimensional matrix
cMap = reshape(data,[numRow,numCol]);
end
```

- 4 Put `sl_customization.m` on the MATLAB search path. You can have multiple files named `sl_customization.m` on the search path. For more details, see “Behavior with Multiple Customization Functions” on page 35-37.
- 5 Refresh Simulink customizations at the MATLAB command prompt.
`sl_refresh_customizations`
- 6 Open the Lookup Table Editor for your lookup table block and select **File > Update Block Data**. Click **Yes** to overwrite the workspace variable `table3d_map_custom`.
- 7 Check the value of `table3d_map_custom` in the base workspace.

```
table3d_map_custom =

    33     2     3     4
     5     6     7     8
    11    12    13    14
    15    16    17    18
   111   112   113   114
   115   116   117   118
```

The change in the Lookup Table Editor has propagated to the workspace variable.

Note: If you do not overwrite the workspace variable `table3d_map_custom`, you are prompted to replace it with numeric data. Click **Yes** to replace the expression in the **Table data** field with numeric data. Click **No** if you do not want your Lookup Table Editor changes for the table data to appear in the block dialog box.

Behavior with Multiple Customization Functions

At the start of a MATLAB session, Simulink loads each `sl_customization.m` customization file on the path and executes the `sl_customization` function. Executing each function establishes the customizations for that session.

When you select **File > Update Block Data** in the Lookup Table Editor, the editor checks the list of function handles in the cell array for `cm.LookupTableEditorCustomizer.getTableConvertToCustomInfoFcnHandle`. If the cell array contains one or more function handles, the `allowTableConvertLocal` property determines whether changes in the Lookup Table Editor can be propagated.

- If the value is set to `true`, then the table data is converted to the nonstandard format in the workspace variable.
- If the value is set to `false`, then table data is not converted to the nonstandard format in the workspace variable.
- If the value is set to `true` and another customization function specifies it to be `false`, the Lookup Table Editor reports an error.

More About

- “Lookup Tables Block Library” on page 35-6
- “Edit Lookup Tables” on page 35-27
- “Guidelines for Choosing a Lookup Table” on page 35-8
- “Import Lookup Table Data from Excel” on page 35-38

Import Lookup Table Data from Excel

This example shows how to use the MATLAB `xlsread` function in a Simulink model to import data into a lookup table.

- 1 Save the Excel file in a folder on the MATLAB path.
- 2 Open the model containing the lookup table block and select **File > Model Properties > Model Properties**.
- 3 In the Model Properties dialog box, in the **Callbacks** tab, click **PostLoadFcn** callback in the model callbacks list.
- 4 Enter the code to import the Excel Spreadsheet data in the text box. Use the MATLAB `xlsread` function, as shown in this example for a 2-D lookup table.

```
% Import the data from Excel for a lookup table
data = xlsread('MySpreadsheet', 'Sheet1');
% Row indices for lookup table
breakpoints1 = data(2:end,1)';
% Column indices for lookup table
breakpoints2 = data(1,2:end);
% Output values for lookup table
table_data = data(2:end,2:end);
```

- 5 Click **OK**.

After you save your changes, the next time you open the model, Simulink invokes the callback and imports the data.

More About

- “Edit Lookup Tables” on page 35-27
- “Guidelines for Choosing a Lookup Table” on page 35-8
- “Import Lookup Table Data from MATLAB” on page 35-31

Create a Logarithm Lookup Table

Suppose you want to approximate the common logarithm (base 10) over the input range [1, 10] without performing an expensive computation. You can perform this approximation using a lookup table block as described in the following procedure.

- 1** Copy the following blocks to a Simulink model:
 - One **Constant** block to input the signal, from the Sources library
 - One **n-D Lookup Table** block to approximate the common logarithm, from the Lookup Tables library
 - One **Display** block to display the output, from the Sinks library
- 2** Assign the table data and breakpoint data set to the n-D Lookup Table block:
 - a** In the **Number of table dimensions** field, enter 1.
 - b** In the **Table data** field, enter
[0 .301 .477 .602 .699 .778 .845 .903 .954 1].
 - c** In the **Breakpoints 1** field, enter [1:10].
 - d** Click **Apply**.

The dialog box looks something like this:

- 3 Double-click the Constant block to open the parameter dialog box, and change the **Constant value** parameter to 5. Click **OK** to apply the changes and close the dialog box.
- 4 Connect the blocks as follows.

- 5 Start simulation.

The following behavior applies to the n-D Lookup Table block.

Value of the Constant Block	Action by the n-D Lookup Table Block	Example of Block Behavior	
		Input Value	Output Value
Equals a breakpoint	Returns the corresponding output value	5	0.699
Falls between breakpoints	Linearly interpolates the output value using neighboring breakpoints	7.5	0.874
Falls outside the range of the breakpoint data set	Linearly extrapolates the output value from a pair of values at the end of the breakpoint data set	10.5	1.023

For the n-D Lookup Table block, the default settings for **Interpolation method** and **Extrapolation method** are both **Linear**.

Prelookup and Interpolation Blocks

The following examples show the benefits of using Prelookup and Interpolation Using Prelookup blocks.

Action	Benefit	Example
Use an index search to relate inputs to table data, followed by an interpolation and extrapolation stage that computes outputs	Enables reuse of index search results to look up data in multiple tables, which reduces simulation time	To open the model, type <code>sldemo_bpcheck</code> at the command prompt.
Set breakpoint and table data types explicitly	Lowers memory required to store: <ul style="list-style-type: none"> • Breakpoint data that uses a smaller type than the input signal • Table data that uses a smaller type than the output signal 	To open the model, type <code>sldemo_interp_memory</code> at the command prompt.
	Provides easier sharing of: <ul style="list-style-type: none"> • Breakpoint data among Prelookup blocks • Table data among Interpolation Using Prelookup blocks 	To open the model, type <code>fxpdemo_lookup_shared_param</code> at the command prompt.
	Enables reuse of utility functions in the generated code	To open the model, type <code>fxpdemo_prelookup_utilfcn</code> at the command prompt.
Set the data type for intermediate results explicitly	Enables use of higher precision for internal computations than for table data or output data	To open the model, type <code>fxpdemo_interp_precision</code> at the command prompt.

Optimize Generated Code for Lookup Table Blocks

In this section...

“Remove Code That Checks for Out-of-Range Inputs” on page 35-44

“Optimize Breakpoint Spacing in Lookup Tables” on page 35-46

“Reduce Data Copies for Lookup Table Blocks” on page 35-47

Remove Code That Checks for Out-of-Range Inputs

By default, generated code for the following lookup table blocks include conditional statements that check for out-of-range breakpoint or index inputs:

- 1-D Lookup Table
- 2-D Lookup Table
- n-D Lookup Table
- Prelookup
- Interpolation Using Prelookup

To generate code that is more efficient, you can remove the conditional statements that protect against out-of-range input values.

Block	Check Box to Select
1-D Lookup Table	Remove protection against out-of-range input in generated code
2-D Lookup Table	
n-D Lookup Table	
Prelookup	
Interpolation Using Prelookup	Remove protection against out-of-range index in generated code

Selecting the check box on the block dialog box improves code efficiency because there are fewer statements to execute. However, if you are generating code for safety-critical applications, you should not remove the range-checking code.

To verify the usage of the check box, run the following Model Advisor checks and perform the recommended actions.

Model Advisor Check	When to Run the Check
By Product > Embedded Coder > Identify lookup table blocks that generate expensive out-of-range checking code	For code efficiency
By Product > Simulink Verification and Validation > Modeling Standards > DO-178C/DO-331 Checks > Check usage of lookup table blocks	For safety-critical applications

For more information about the Model Advisor, see “Consulting the Model Advisor” on page 5-2 in the Simulink documentation.

Optimize Breakpoint Spacing in Lookup Tables

When breakpoints in a lookup table are tunable, the spacing does not affect efficiency or memory usage of the generated code. When breakpoints are *not* tunable, the type of spacing can affect the following factors.

Factor	Even Power of 2 Spaced Data	Evenly Spaced Data	Unevenly Spaced Data
Execution speed	The execution speed is the fastest. The position search and interpolation are the same as for evenly-spaced data. However, to increase speed a bit more for fixed-point types, a bit shift replaces the position search, and a bit mask replaces the interpolation.	The execution speed is faster than that for unevenly-spaced data because the position search is faster and the interpolation uses a simple division.	The execution speed is the slowest of the different spacings because the position search is slower, and the interpolation requires more operations.
Error	The error can be larger than that for unevenly-spaced data because approximating a function with nonuniform curvature requires more points to achieve the same accuracy.	The error can be larger than that for unevenly-spaced data because approximating a function with nonuniform curvature requires more points to achieve the same accuracy.	The error can be smaller because approximating a function with nonuniform curvature requires fewer points to achieve the same accuracy.
ROM usage	Uses less command ROM, but more data ROM.	Uses less command ROM, but more data ROM.	Uses more command ROM, but less data ROM.
RAM usage	Not significant.	Not significant.	Not significant.

Follow these guidelines:

- For fixed-point data types, use breakpoints with even, power-of-2 spacing.
- For non-fixed-point data types, use breakpoints with even spacing.

To identify opportunities for improving code efficiency in lookup table blocks, run the following Model Advisor checks and perform the recommended actions:

- **By Product > Embedded Coder > Identify questionable fixed-point operations**
- **By Product > Embedded Coder > Identify blocks that generate expensive saturation and rounding code**

For more information about the Model Advisor, see “Consulting the Model Advisor” on page 5-2 in the Simulink documentation.

Reduce Data Copies for Lookup Table Blocks

When you use workspace variables to store table and breakpoint data for Lookup Table blocks, and then configure these variables for tunability, you can avoid data copies by using the same data type for the block parameter and variable. Workspace variables include numeric MATLAB variables and `Simulink.Parameter` objects that you store in a workspace, such as the base workspace, or in a data dictionary. If the data type of the variable is smaller than the data type of the block parameter, the generated code implicitly casts the data type of the variable to the data type of the block parameter. This implicit cast requires a data copy which can potentially significantly increase RAM consumption and slow down code execution speed for large vectors or matrices.

For more information, see “Parameter Data Types in the Generated Code” and “Block Parameter Representation in the Generated Code”.

Update Lookup Table Blocks to New Versions

In this section...

“Comparison of Blocks with Current Versions” on page 35-48

“Compatibility of Models with Older Versions of Lookup Table Blocks” on page 35-49

“How to Update Your Model” on page 35-50

“What to Expect from the Model Advisor Check” on page 35-50

Comparison of Blocks with Current Versions

In R2011a, the following lookup table blocks were replaced with newer versions in the Simulink library:

Block	Changes	Enhancements
Lookup Table	<ul style="list-style-type: none"> Block renamed as 1-D Lookup Table Icon changed 	<ul style="list-style-type: none"> Default integer rounding mode changed from Floor to Simplest Support for the following features: <ul style="list-style-type: none"> Specification of parameter data types different from input or output signal types Reduced memory use and faster code execution for nontunable breakpoints with even spacing Cubic-spline interpolation and extrapolation Table data with complex values Fixed-point data types with word lengths up to 128 bits Specification of data types for fraction and intermediate results Specification of index search method Specification of diagnostic for out-of-range inputs
Lookup Table (2-D)	<ul style="list-style-type: none"> Block renamed as 2-D Lookup Table Icon changed 	<ul style="list-style-type: none"> Default integer rounding mode changed from Floor to Simplest Support for the following features:

Block	Changes	Enhancements
		<ul style="list-style-type: none"> • Specification of parameter data types different from input or output signal types • Reduced memory use and faster code execution for nontunable breakpoints with even spacing • Cubic-spline interpolation and extrapolation • Table data with complex values • Fixed-point data types with word lengths up to 128 bits • Specification of data types for fraction and intermediate results • Specification of index search method • Specification of diagnostic for out-of-range inputs • Check box for Require all inputs to have the same data type now selected by default
Lookup Table (n-D)	<ul style="list-style-type: none"> • Block renamed as n-D Lookup Table • Icon changed 	<ul style="list-style-type: none"> • Default integer rounding mode changed from Floor to Simplest

Compatibility of Models with Older Versions of Lookup Table Blocks

When you load existing models that contain the Lookup Table, Lookup Table (2-D), and Lookup Table (n-D) blocks, those versions of the blocks appear. The current versions of the lookup table blocks appear only when you drag the blocks from the Simulink Library Browser into new models.

If you use the `add_block` function to add the Lookup Table, Lookup Table (2-D), or Lookup Table (n-D) blocks to a model, those versions of the blocks appear. If you want to add the *current* versions of the blocks to your model, change the source block path for `add_block`:

Block	Old Block Path	New Block Path
Lookup Table	simulink/Lookup Tables/Lookup Table	simulink/Lookup Tables/1-D Lookup Table

Block	Old Block Path	New Block Path
Lookup Table (2-D)	simulink/Lookup Tables/Lookup Table (2-D)	simulink/Lookup Tables/2-D Lookup Table
Lookup Table (n-D)	simulink/Lookup Tables/Lookup Table (n-D)	simulink/Lookup Tables/n-D Lookup Table

How to Update Your Model

To update your model to use current versions of the lookup table blocks, follow these steps:

Step	Action	Reason
1	Run the Upgrade Advisor.	Identify blocks that do not have compatible settings with the 1-D Lookup Table and 2-D Lookup Table blocks.
2	For each block that does not have compatible settings: <ul style="list-style-type: none"> Decide how to address each warning. Adjust block parameters as needed. 	Modify each Lookup Table or Lookup Table (2-D) block to ensure compatibility with the current versions.
3	Repeat steps 1 and 2 until you are satisfied with the results of the Upgrade Advisor check.	Ensure that block replacement works for the entire model.

After block replacement, the block names that appear in the model remain the same. However, the block icons match the ones for the 1-D Lookup Table and 2-D Lookup Table blocks. For more information about the Upgrade Advisor, see “Model Upgrades”.

What to Expect from the Model Advisor Check

The Model Advisor check groups all Lookup Table and Lookup Table (2-D) blocks into three categories:

- Blocks that have compatible settings with the 1-D Lookup Table and 2-D Lookup Table blocks
- Blocks that have incompatible settings with the 1-D Lookup Table and 2-D Lookup Table blocks

- Blocks that have repeated breakpoints

Blocks with Compatible Settings

When a block has compatible parameter settings, automatic block replacement can occur without backward incompatibilities.

Lookup Method in the Lookup Table or Lookup Table (2-D) Block	Parameter Settings After Automatic Block Replacement	
	Interpolation	Extrapolation
Interpolation-Extrapolation	Linear	Linear
Interpolation-Use End Values	Linear	Clip
Use Input Below	Flat	Not applicable

Depending on breakpoint spacing, one of two index search methods can apply.

Breakpoint Spacing in the Lookup Table or Lookup Table (2-D) Block	Index Search Method After Automatic Block Replacement
Not evenly spaced	Binary search
Evenly spaced and tunable	A prompt appears, asking you to select Binary search or Evenly spaced points.
Evenly spaced and not tunable	

Blocks with Incompatible Settings

When a block has incompatible parameter settings, the Model Advisor shows a warning and a recommended action, if applicable.

- If you perform the recommended action, you can avoid incompatibility during block replacement.
- If you use automatic block replacement without performing the recommended action, you might see numerical differences in your results.

Incompatibility Warning	Recommended Action	What Happens for Automatic Block Replacement
The Lookup Method is Use Input Nearest or Use Input	Change the lookup method to one of the following options:	The Lookup Method changes to Interpolation - Use End Values.

Incompatibility Warning	Recommended Action	What Happens for Automatic Block Replacement
Above. The replacement block does not support these lookup methods.	<ul style="list-style-type: none"> • Interpolation - Extrapolation • Interpolation - Use End Values • Use Input Below 	<p>In the replacement block, this setting corresponds to:</p> <ul style="list-style-type: none"> • Interpolation set to Linear • Extrapolation set to Clip
The Lookup Method is Interpolation - Extrapolation , but the input and output are not the same floating-point type. The replacement block supports linear extrapolation only when all inputs and outputs are the same floating-point type.	Change the extrapolation method or the port data types of the block.	You also see a message that explains possible numerical differences.
The block uses small fixed-point word lengths, so that interpolation uses only one rounding operation. The replacement block uses two rounding operations for interpolation.	None	You see a message that explains possible numerical differences.

Blocks with Repeated Breakpoints

When a block has repeated breakpoints, the Model Advisor recommends that you change the breakpoint data and rerun the check. You cannot perform automatic block replacement for blocks with repeated breakpoints.

Lookup Table Glossary

The following table summarizes the terminology used to describe lookup tables in the Simulink user interface and documentation.

Term	Meaning
breakpoint	A single element of a breakpoint data set. A breakpoint represents a particular input value to which a corresponding output value in the table data is mapped.
breakpoint data set	A vector of input values that indexes a particular dimension of a lookup table. A lookup table uses breakpoint data sets to relate its input values to the output values that it returns.
extrapolation	A process for estimating values that lie beyond the range of known data points.
interpolation	A process for estimating values that lie between known data points.
lookup table	An array of data that maps input values to output values, thereby approximating a mathematical function. Given a set of input values, a “lookup” operation retrieves the corresponding output values from the table. If the lookup table does not explicitly define the input values, Simulink can estimate an output value using interpolation, extrapolation, or rounding.
monotonically increasing	The elements of a set are ordered such that each successive element is greater than or equal to its preceding element.
rounding	A process for approximating a value by altering its digits according to a known rule.
strictly monotonically increasing	The elements of a set are ordered such that each successive element is greater than its preceding element.

Term	Meaning
table data	An array that serves as a sampled representation of a function evaluated at a lookup table's breakpoint values. A lookup table uses breakpoint data sets to index the table data, ultimately returning an output value.

Masking Fundamentals

A mask is a custom interface for a block that hides the block content, making it appear as an atomic block with its own icon and parameter dialog box. It encapsulates the block logic, provides controlled access to the block data, and simplifies the graphical appearance of a model.

When you mask a block, a mask definition is created and saved along with the block. A mask changes only the block interface, and not the underlying block characteristics. You can provide access to one or more underlying block parameters by defining corresponding mask parameters on the mask.

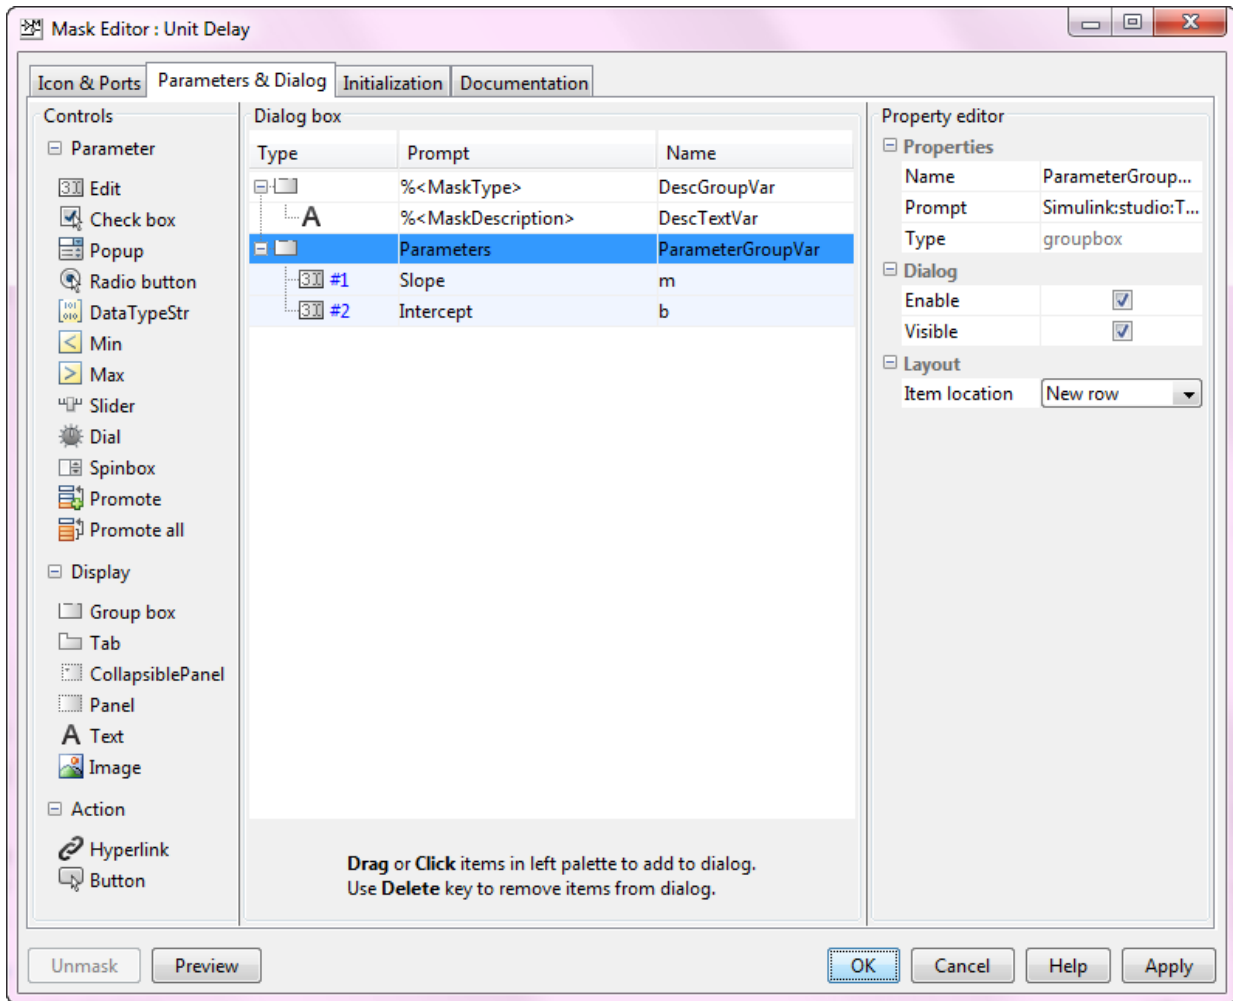

Mask a Simulink block to:

- Display a meaningful icon on a block
- Provide a customized dialog box for the block
- Provide a dialog box that enables you to access only select parameters of the underlying blocks
- Provide users customized description that is specific to the masked block
- Initialize parameters using MATLAB code

Consider the model `masking_example` that represents the equation of line $y = mx + b$.

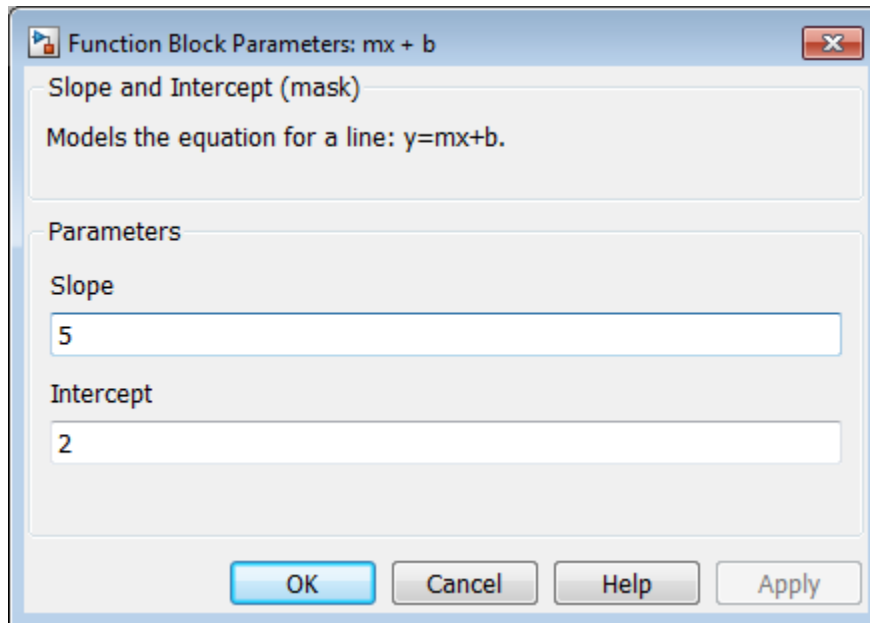

Each block has its own dialog box, making it complicated to specify the values for the line equation variables. To simplify the user interface, a mask is applied on the top-level subsystem block.

Here the variable m represents slope and the variable b represents the intercept for the line equation $y = mx + b$.

The mask dialog box displays the fields for **Slope** and **Intercept** that are internally mapped to variables m and b .

Masked blocks do not support content preview. To preview the contents of a subsystem, see “Preview Content of Hierarchical Items” on page 1-57.

Tip For masking examples, see Simulink Masking Examples. The examples are grouped by type. In an example model:

- To view the mask definition, double-click the View Mask block.
- To view the mask dialog box, double-click the block.

Masking Terminology

Term	Description
Mask icon	The masked block icon generated using drawing commands. Mask icon can

Term	Description
	be static or change dynamically with underlying block parameter values.
Mask parameters	The parameters that are defined in the Mask Editor and appear on the mask dialog box. Setting the value of a mask parameter on the mask dialog box sets the corresponding block parameter value.
Mask initialization code	MATLAB code that initializes a masked block or reflects current parameter values. Add mask initialization code in the Initialization pane of the Mask Editor dialog box. For example, add initialization code to set a parameter value automatically.
Mask dialog callback code	MATLAB code that runs in the base workspace when the value of a mask parameter changes. Use callback code to change the appearance of a mask dialog box dynamically and reflect current parameter values. For example, enable visible parameters on the dialog box.
Mask documentation	Description and usage information for a masked block defined in the Mask Editor.
Mask dialog box	A dialog box that contains fields for setting mask parameter values and provides mask description.
Mask workspace	Masks that define mask parameters or contain initialization code have a mask workspace. This workspace stores the evaluated values of the mask parameters and temporary values used by the mask.

More About

- “Block Masks”

- “Create a Simple Mask” on page 36-7
- “Mask Editor Overview”
- Set mask parameters
- Group parameters under tabs

Create a Simple Mask

You can mask a block interactively by using the Mask Editor or mask it programmatically. This example describes how to mask a block by using the **Mask Editor**. To mask a block programmatically, see “Control Masks Programmatically” on page 36-37.

For masking examples, see Simulink Masking Examples.

Step 1: Open Mask Editor

- 1 Open the model in which you want to mask a block. For example, open `subsystem_example`.

This model contains a Subsystem block that models the equation for a line: $y = mx + b$.

- 2 Right-click the Subsystem block and select **Mask > Create Mask**.

Step 2: Define the Mask

The **Mask Editor** contains four tabs that enable you to define the block mask and customize the dialog box for the mask.

For detailed information on each pane, see “Mask Editor Overview”.

Icon & Ports Tab

Use this tab to create an icon for the block mask. You can use the **Options** pane on the left to specify icon properties and icon visibility.

Add an image to the block mask.

- 1 In the **Block frame** drop-down box, select **Visible**.
- 2 In the **Icon transparency** drop-down box, select **Opaque**.
- 3 In the **Icon units** drop-down box, select **Autoscale**.
- 4 To restrict the icon rotation, select **Fixed** from the **Icon rotation** list.
- 5 In the **Icon drawing commands** text box, type `plot(y, x)`.

For more information on drawing command syntax, see “Icon drawing commands”.

- 6 To save the changes, click **Apply**. To preview the block mask icon without exiting the **Mask Editor**, click **Preview**

Note: For detailed information, see “Icon & Ports Pane”.

You can create static or dynamic block mask icons. For more information, see “Draw Mask Icon” on page 36-22 and `slexMaskDisplayAndInitializationExample`.

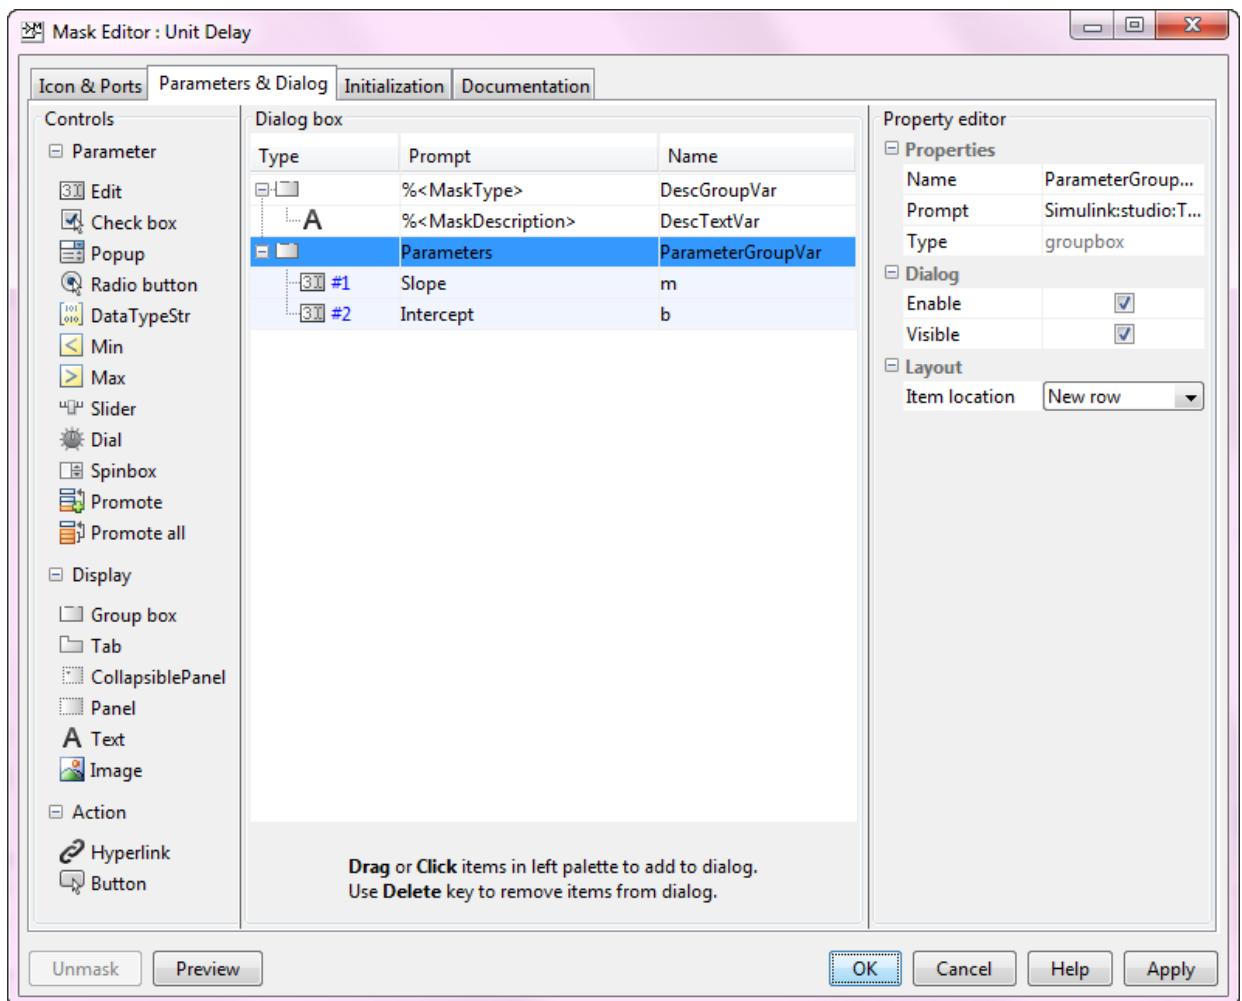

Parameters & Dialog Tab

Use this tab to add controls like parameters, displays, and action items to the mask dialog box.

To add **Edit** boxes to the block mask.

- 1 In the left pane, under **Parameter**, click **Edit** twice to add two new rows in the **Dialog box** pane.

- 2 Type **Slope** and **Intercept** in the **Prompt** and **Name** columns, respectively. The value that you enter in **Prompt** column appears on the mask dialog box. The value you enter in **Name** column is the mask parameter name. The mask parameter name must be a valid MATLAB name.
- 3 In the right pane, under **Property editor**, provide values in the **Properties**, **Dialog**, and **Layout** sections.
- 4 Click **Apply**.

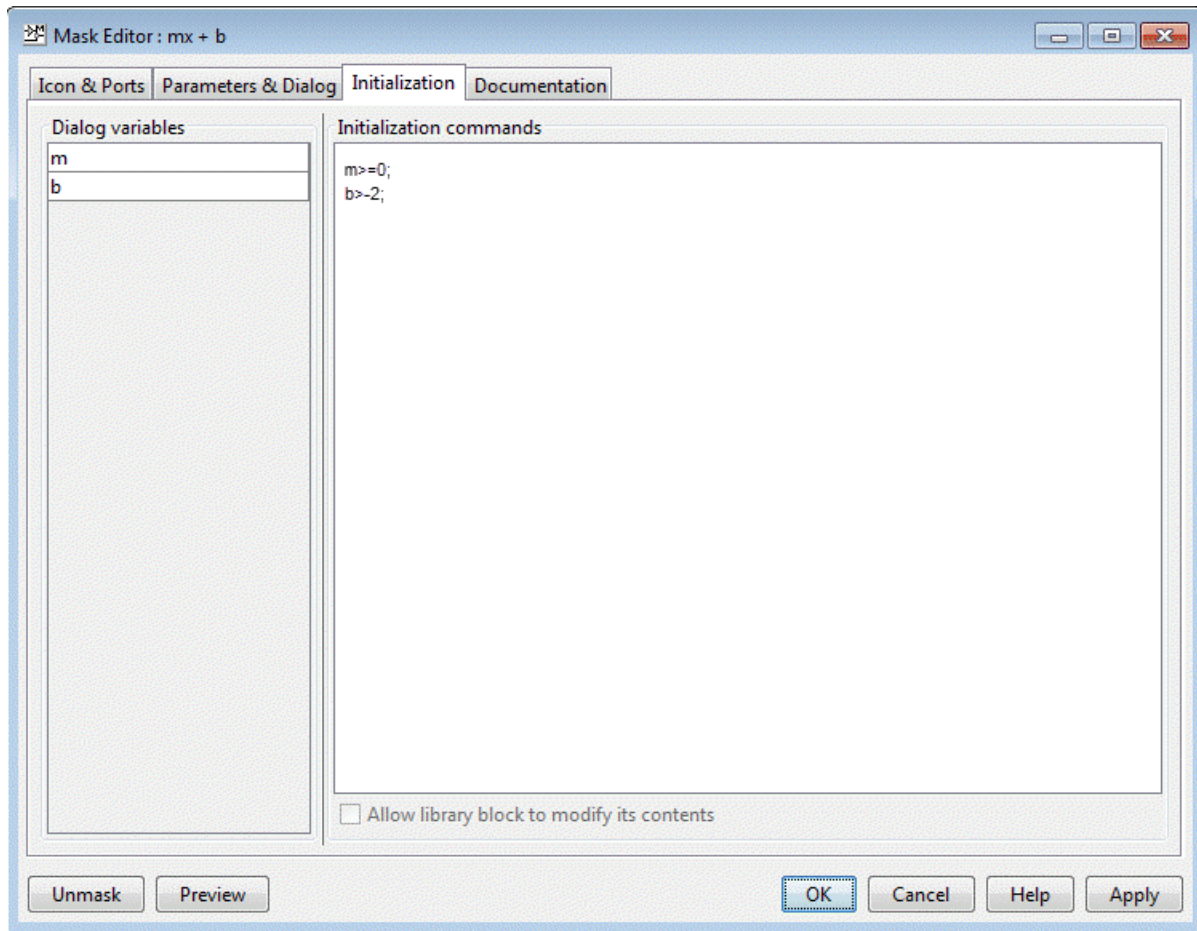

5 To preview the mask dialog box without exiting the Mask Editor, click **Preview**.

Note: For detailed information, see “Parameters & Dialog Pane”.

Initialization Tab

Use this pane to specify MATLAB code to control the mask parameters. You can add conditions for the user specified values, provide a predefined value for a mask parameter, and so on.

Consider the equation $y = mx + b$. To allow positive value for m , you can add MATLAB code in the initialization pane to specify the acceptable range for m as greater than zero.

Note: For detailed information, see “Initialization Pane”.

Documentation Tab

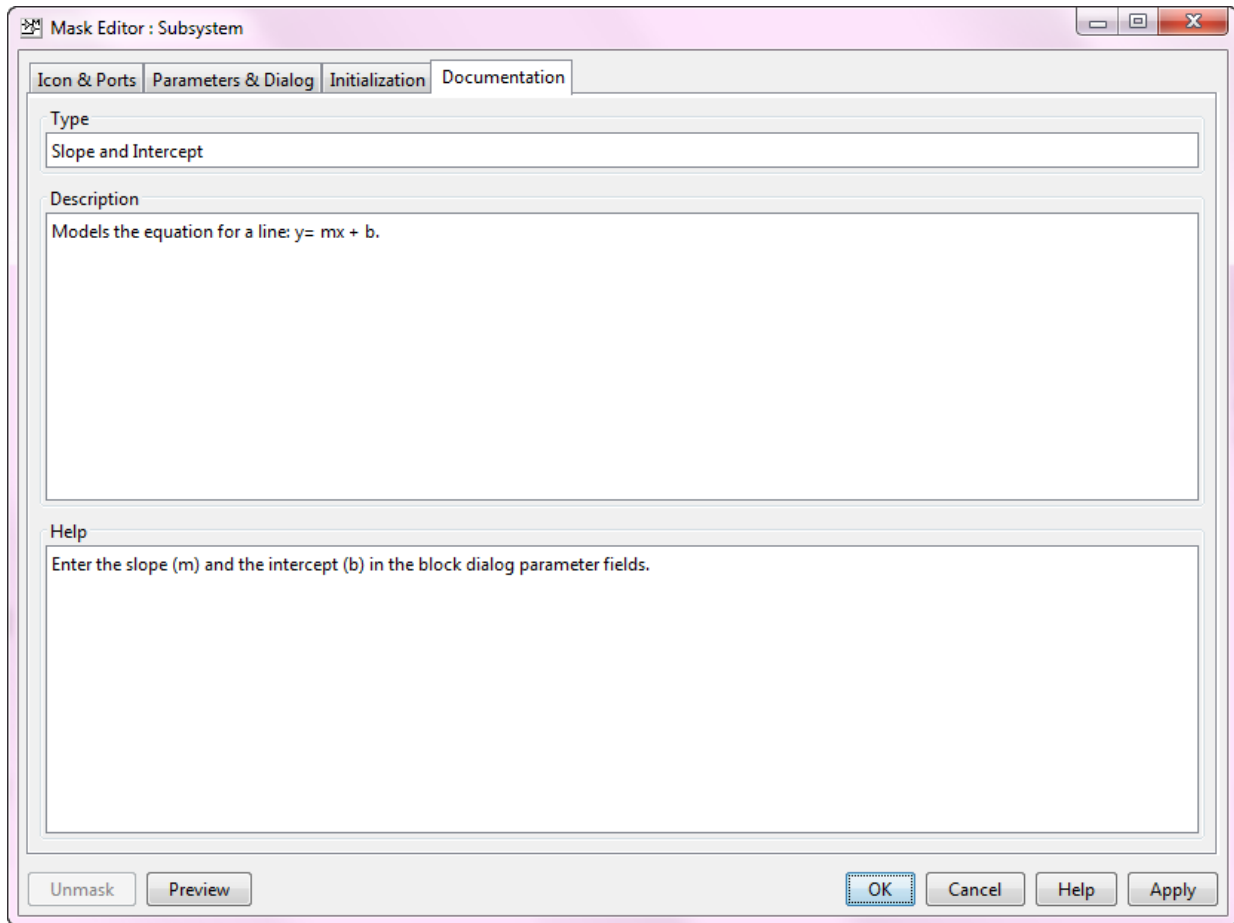

Use this tab to add a name, description, and additional information for the mask.

The **Documentation** tab contains these fields:

- 1 Type:** You can add a name for the block mask in this box. The mask name appears on top of the mask dialog box. You cannot add new lines.
- 2 Description:** You can add a description for the block mask in this box. By default, the description is displayed below the mask name, and it can contain new lines and spaces.
- 3 Help.** You can add additional information for the block mask in this box. You click **Help** on the mask dialog box, this information is displayed. You can use plain text, HTML and graphics, URLs, and web or eval commands to add information in the **Help** field.

After you have added information in the **Mask Editor**, click **Apply** or **OK**.

The block is now masked.

Note: For detailed information, see “Documentation Pane”.

Step 3: Operate on Mask

- 1 You can preview the mask and choose to unmask the block or edit the block mask.
- 2 Double-click the masked block.

The mask dialog box appears.

- 3 Type values in the **Slope** and **Intercept** boxes of the mask dialog box. To view the output, simulate the model.
- 4 Click **OK**.
- 5 To edit the mask definition, right-click the block and select **Mask > Edit Mask**. For more information, see “Manage Existing Masks” on page 36-16.
- 6 Right-click the masked block and select **Mask > Look Under Mask** to view:
 - The blocks inside the masked subsystem
 - The built-in block dialog box of a masked block
 - The base mask dialog box of a linked masked block

See Also

“Block Masks” | “Mask Editor Overview” | “Masking Fundamentals” on page 36-2

Manage Existing Masks

Change a Block Mask

You can change an existing mask by reopening the Mask Editor and using the same techniques that you used to create the mask:

- 1 Select the masked block.
- 2 Select **Mask > Edit Mask**.

The Mask Editor reopens, showing the existing mask definition. Change the mask as needed. After you change a mask, to preserve the changes.

View Mask Parameters

To display a mask dialog box, double-click the block. Alternatively, right-click the block and select **Mask > Mask Parameters** or click **Diagram > Mask > Mask Parameters**.

Tip Each block has a block parameter dialog box. To view the block parameters dialog box of a masked block, right-click the masked block and select **Block Parameters (BlockType)**.

Look Under Block Mask

To see the block diagram under a masked Subsystem block, built-in block, or the model referenced by a masked model block, right-click the block and select **Mask > Look Under Mask**.

Remove Mask

To remove a mask from a block,

- 1 Right-click the block.
- 2 Select **Mask > Edit Mask**.

The Mask Editor opens and displays the existing mask, for example:

- 3 Click **Unmask** in the lower left corner of the Mask Editor.

The Mask Editor removes the mask from the block.

Mask Callback Code

In this section...

“Add Mask Code” on page 36-18
 “Execute Drawing Command” on page 36-18
 “Execute Initialization Command” on page 36-19
 “Execute Callback Code” on page 36-20

Add Mask Code

You can use MATLAB code to initialize a mask and to draw mask icons. Since the location of code affects model performance, add your code to reflect the functionality you need.

Purpose	Add in Mask Editor	Programmatic Specification
Initialize the mask	Initialization pane	MaskInitialization parameter
Draw mask icon	Icon & Ports pane	MaskDisplay parameter
Callback code for mask parameters	Parameters & Dialog pane	MaskCallbacks parameter

Execute Drawing Command

Place MATLAB code for drawing mask icons in the **Icon Drawing Commands** section of the **Icon & Ports** pane. Simulink executes these commands sequentially to redraw the mask icon when:

- Block is rendered first on the Mask Editor canvas.
- Mask parameters and values that depend on drawing commands change.
- Block appearance is altered due to rotation or other changes.

Note: Placing MATLAB code for drawing mask icons in the **Initialization** pane affects model performance. This behavior is because Simulink redraws the icon each time the masked block is evaluated in the model.

Execute Initialization Command

Initialization commands for all masked blocks in a model run when you:

- Update the diagram
- Start simulation
- Start code generation
- Apply mask changes
- Change any of the parameters that define the mask, such as `MaskDisplay` and `MaskInitialization`, using the Mask Editor or `set_param`.
- Rotate or flip the masked block, if the icon depends on initialization commands.
- Cause the icon to be drawn or redrawn, and the icon drawing depends on initialization code.
- Change the value of a mask parameter by using the block dialog box or `set_param`.
- Copy the masked block within the same model or between different models.

When you open a model, Simulink locates visible masked blocks that reside at the top level of the model or in an open subsystem.

Simulink only executes the initialization commands for these visible masked blocks if they meet either of the following conditions:

- The masked block has icon drawing commands.

Note: Simulink does not initialize masked blocks that do not have icon drawing commands, even if they have initialization commands during model load.

- The masked subsystem belongs to a library and has the **Allow library block to modify its contents** parameter enabled.

When you load a model into memory without displaying it graphically, no initialization commands initially run for any masked blocks. See “Load a Model” on page 1-13 and `load_system` for information about loading a model without displaying it.

Note: The non-tunable parameters of a masked block are not evaluated if the model is already compiled (initialized).

Execute Callback Code

Simulink executes the callback commands when:

- You open the mask dialog box. Callback commands execute sequentially, starting with the top mask dialog box.
- You modify a parameter value in the mask dialog box and then change the cursor location. For example, you press the **Tab** key or click into another field in the dialog box after changing the parameter value.

Note: When you modify the parameter value by using the `set_param` command, the callback commands do not execute.

- You modify the parameter value, either in the mask dialog box or using `set_param`, and then apply the change by clicking **Apply** or **OK**. Mask initialization commands execute after callback commands. For more information, see “Initialization Pane”.
- You hover over a masked block to see the tool tip for the block, when the tool tip contains parameter names and values.

Note: Callback commands do not execute if the mask dialog box is open when the block tool tip appears.

- You update a diagram (for example, by pressing **Ctrl+D** or by selecting **Simulation > Update diagram** in the Simulink Editor).
- If you close a mask dialog box without saving the changes, the Callback command for parameters is executed sequentially.

Note: Buttons on mask dialog box are unavailable when the callback code associated with the button is being executed.

For related Simulink example models, see:

- Sequence mask callbacks
- Unsafe mask callbacks
- Unsafe nested mask callbacks

See Also

“Block Masks” | “Initialize Mask” on page 36-26

Draw Mask Icon

You can create icons that update when you change the mask parameters to reflect the purpose of the block. This example shows how to use drawing commands to create a mask icon.

In this section...
“Draw Static Icon” on page 36-22
“Draw Dynamic Icon” on page 36-24

Draw Static Icon

A static mask icon remains unchanged, independent of the value of the mask parameters.

- 1 Right-click the masked block that requires the icon and select **Mask > Edit Mask**.

- 2 In the **Icons & Ports** tab, enter this command in the **Icon Drawing commands** pane:

```
% Use specified image as mask icon
image('engine.jpg')
```

The image file must be on the MATLAB path.

For more examples of drawing command syntax, see “Icon drawing commands”.

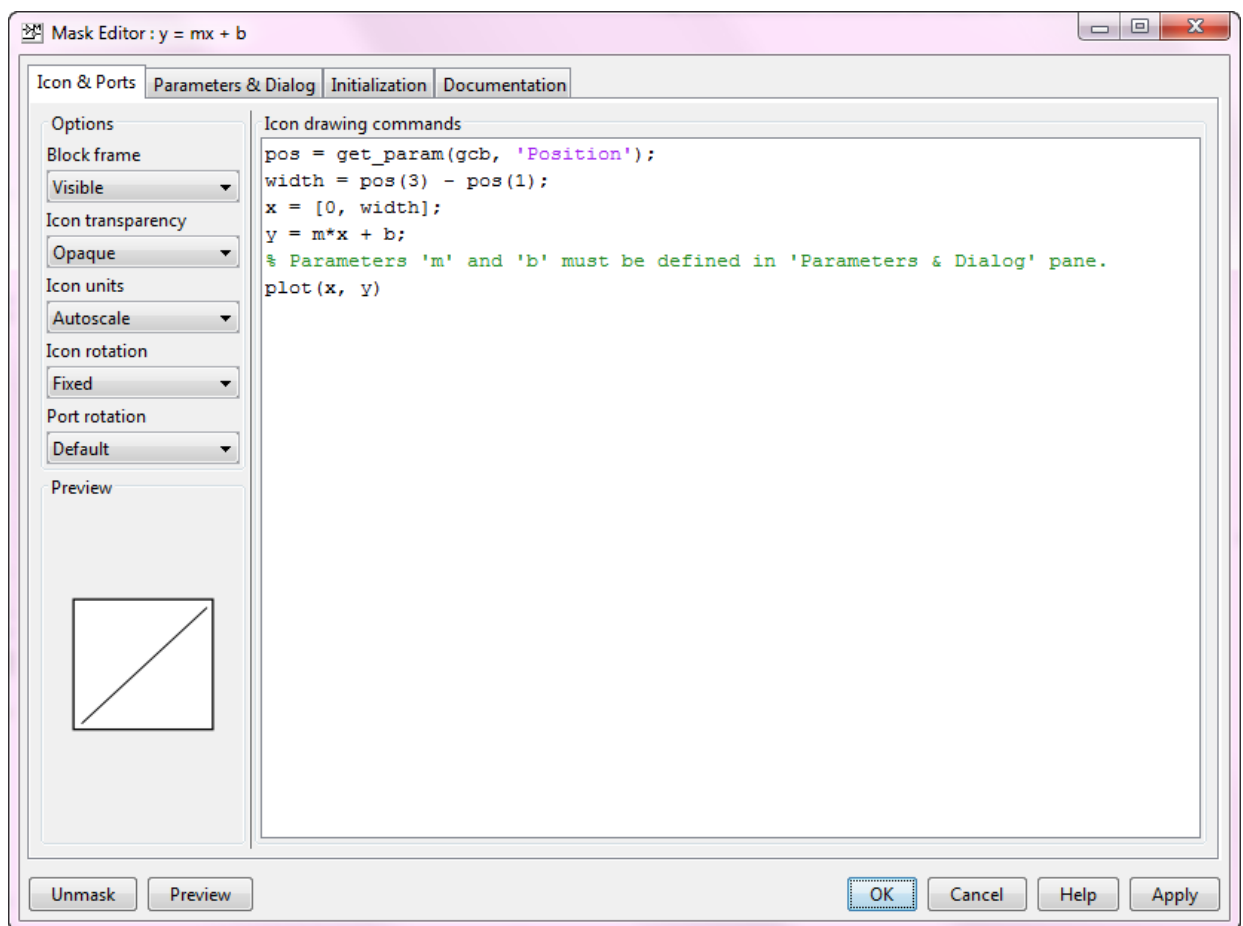

Images in formats `.cur`, `.hdf4`, `.ico`, `.pcx`, `.ras`, `.xwd`, `.svg` (full version) cannot be used as block mask images. However, you can use images in these formats if you wrap the file name in the `imread()` function and use the RGB triplet. Using the `imread()` function is not efficient. However, it is still supported for backward compatibility.

Draw Dynamic Icon

A dynamic icon changes with the values of the mask parameters. Use it to represent the purpose of the masked block.

- 1 Right-click the masked block that requires the icon and select **Mask > Edit Mask**.

The Mask Editor opens.

- 2 In the **Icons & Ports** tab, enter this command in the **Icon Drawing commands** pane:

```
pos = get_param(gcf, 'Position');
width = pos(3) - pos(1);
x = [0, width];
y = m*x + b;
% Parameters 'm' and 'b' must be defined in 'Parameters & Dialog' pane.
plot(x,y)
```

- 3 Under **Options**, set **Icon Units** to **Pixels**.

The drop-down lists under **Options** allow you to specify icon frame visibility, icon transparency, drawing context, icon rotation, and port rotation.

- 4 Click **Apply**. To view the icon generated, see `model_masking_example`.

Note: If Simulink cannot evaluate all commands in the **Icon Drawing commands** pane to generate an icon, three question marks (? ? ?) appear on the mask.

See `slexMaskDisplayAndInitializationExample` for more examples of icon drawing commands. This model shows how to draw:

- Static mask
- Dynamic shape mask
- Dynamic text mask
- Image mask

See Also

“Block Masks”

Initialize Mask

You can add MATLAB code in the Initialization pane of the Mask Editor to initialize a masked block. Simulink executes these initialization commands to initialize a masked subsystem at critical times, such as model loading and start of a simulation run. For more information, see “Execute Initialization Command” on page 36-19.

You can add mask initialization code for these cases:

- To specify the initial values of mask parameters. For example to specify an initial value of parameter **a**, type `a = 5` in the Initialization pane.
- To specify an acceptable range of inputs for mask parameter. For example, to specify the range between 0 and 10 as the acceptable values for parameter **a**, type `0 = a > = 10`.
- To specify the value of a child block. For example,

```
set_param('Child block Name','Parameter name','Parameter Value')
```

- To create a self-modifiable mask. For more information, see Self-Modifying Mask.

The initialization code of a masked subsystem can refer only to the variables in its local workspace.

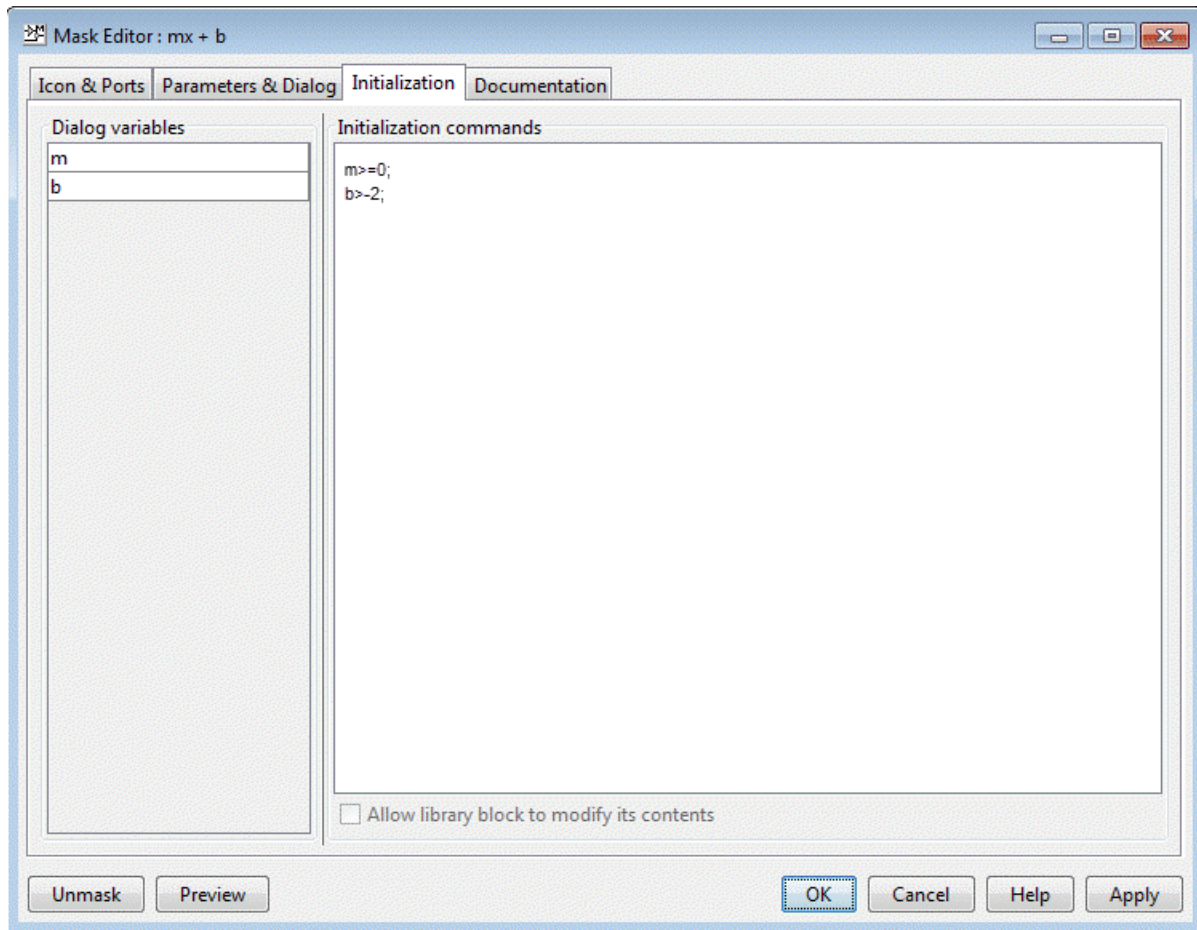

When you reference a block with, or copy a block into, a model, the mask dialog box displays the specified default values. You cannot use mask initialization code to change mask parameter default values in a library block or any other block.

Note: Blocks that contain initialization code do not work as expected when using model reference.

Use the Mask Editor **Initialization** pane to add MATLAB commands that initialize a masked block.

The **Initialization** pane contains these sections:

- **Dialog variables**
- **Initialization commands**

Dialog Variables

The **Dialog variables** section displays the names of the variables associated with the mask parameters of the masked block that are defined in the **Parameters** pane.

You can copy the name of a parameter from this list and paste it into the **Initialization commands** section.

You can change the name of the mask parameter variable in the list by double-clicking and editing the name.

Initialization Commands

You can add the initialization commands in this section. The initialization code must be a valid MATLAB expression, consisting of MATLAB functions and scripts, operators, and variables defined in the mask workspace. Initialization commands cannot access base workspace variables.

To avoid echoing results to the MATLAB Command Window, terminate initialization commands with a semicolon.

To view related examples, see

- Define mask display and initialization
- Use MATLAB graphics in masking

Mask Initialization Best Practices

Mask initialization commands must observe the following rules:

- Do not use initialization code to create dynamic mask dialog boxes (Dialog boxes whose appearance or control settings change depending on changes made to other control settings). Instead, use the mask callbacks that are intended for this purpose. For more information, see “Dynamic Mask Dialog Box” on page 36-51.
- Do not use `set_param` commands on blocks that reside in another masked subsystem that you are initializing. Trying to set parameters of blocks in lower-level masked subsystems can trigger unresolved symbol errors if lower-level masked subsystems reference symbols defined by higher-level masked subsystems.

Suppose, for example, a masked subsystem A contains a masked subsystem B which contains Gain block C, whose `Gain` parameter references a variable defined by B. Suppose also that subsystem A has initialization code that contains this command:

```
set_param([gcb '/B/C'], 'SampleTime', '-1');
```

Simulating or updating a model containing A causes an unresolved symbol error.

- You cannot use mask initialization code to create data objects. Data objects are objects of these classes:
 - `Simulink.Parameter` and subclasses
 - `Simulink.Signal` and subclasses

- Do not add initialization code to delete the same masked block.
- Use mask initialization code to control direct child blocks only.

“Block Masks” | “Masking Fundamentals” on page 36-2 | “Mask Callback Code” on page 36-18

Promote Parameter to Mask

In this section...
“Promote Underlying Parameters to Block Mask” on page 36-32
“Promote Underlying Parameters to Subsystem Mask” on page 36-34
“Best Practices” on page 36-36

Blocks and subsystems can have multiple parameters associated with them. Block masks allow you to expose one or more of these parameters while hiding others from view. Promoting specific parameters to the mask block simplifies the interface and enables you to specify the parameters the user of the block can view and set.

You can use the **Promote** button on the Mask Editor to promote any underlying parameter of a block either to a block mask or to a subsystem mask. The promoted block parameter gets associated with a parameter in the mask, enabling you to edit the parameter value from the mask dialog box.

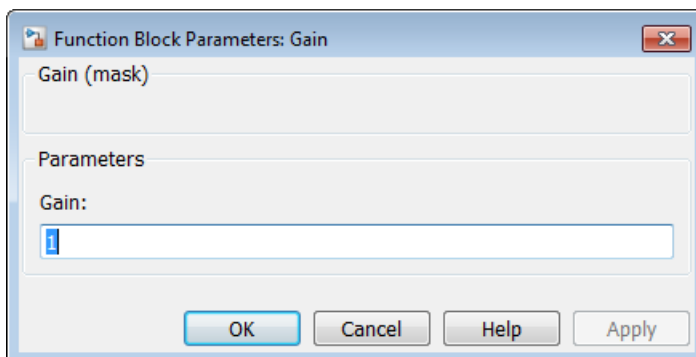

Promote parameters from the block dialog box to the mask:

- To customize the mask dialog box by moving the required parameters from the block dialog box to the mask dialog box.
- To reuse a library block at different instances of a model. For each instance of the library block, you can create individual mask dialog box by promoting parameters for each block.

Consider the block dialog box of the Gain block, which has parameters such as **Gain**, **Multiplication**.

To expose only the **Gain** parameter, mask the Gain block and promote the **Gain** parameter to the mask dialog box.

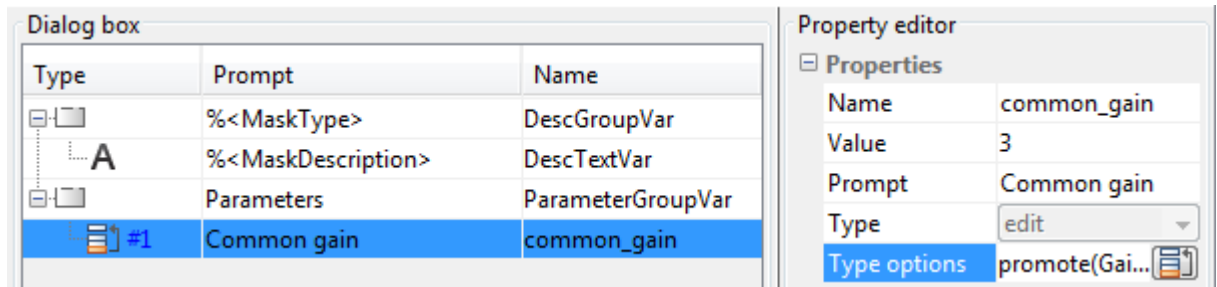

Similarly, you can mask a subsystem block and promote parameters to the mask from child blocks of the subsystem block. If the data type of subsystem child block parameters is the same, you can associate a single mask parameter with multiple promoted parameters. For example, you can promote multiple **Gain** parameters in a subsystem to a single dialog box on your mask.

If the parameter is of data type `popup` or `Data Type`, the options must also be the same for the parameters to be promoted together. The **Evaluate** attribute for all the parameters to be promoted must be similar.

For a related example, see Promote mask parameters.

Promote Underlying Parameters to Block Mask

- 1 Right-click the block whose parameter you want to promote and select **Mask > Create Mask**.
- 2 In the **Mask Editor** dialog box, click the **Parameters & Dialog** tab.
- 3 In the **Controls** pane, click **Promote**.
- 4 In the **Property editor** pane, next to **Type options**, click .

Use the **Promoted Parameter Selector** dialog box to select the parameters that you want to promote.

- To add a parameter to the **Promoted parameters** list, select a parameter from the **Promotable parameters** table and click the **Add to promoted parameter list** button .

To view the parameter properties such as **Type**, hover over the parameter name in the **Promotable parameter** pane.

Tip

- You can use the **Child blocks** list or the **Search** box to find underlying block parameters to promote.
- To prevent tuning of a property during simulation, you can disable the **Tunable** attribute while promoting a tunable parameter.

- Click **OK**.
- In the **Mask Editor** dialog box, edit the prompt names for the promoted parameters and click **OK**. You cannot edit the variable names.

- 8 Click **OK**. Look at the block mask. Only the parameters you promoted are available to set.

Note:

- You can use **Promote all**  to promote all parameters. **Promote all** is available for all block masks except for subsystem masks.
 - To remove a promoted parameter, select the parameter and press **Delete** key.
 - You cannot view or promote parameters of a nested masked or linked child block.
-

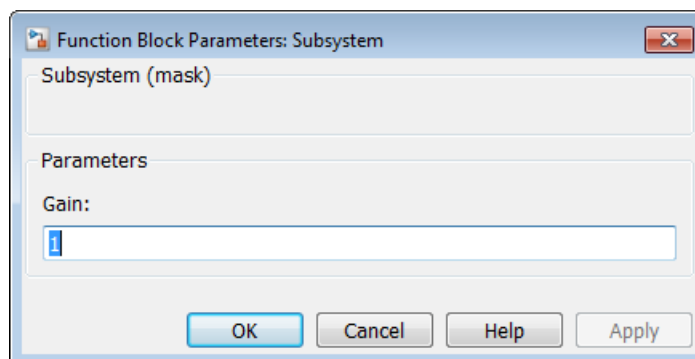

Promote Underlying Parameters to Subsystem Mask

- 1 Right-click the subsystem and select **Mask > Create Mask**.
- 2 In the **Mask Editor** dialog box, click the **Parameters & Dialog** tab.
- 3 In the **Controls** pane, click **Promote**.
- 4 In the **Property editor** pane, next to **Type options**, click .
- 5 In the **Promoted Parameter Selector** dialog box, select the parameters that you want to promote.
- 6 To add a parameter to the **Promoted parameters** list, select a parameter from the **Promotable parameters** table and click the **Add to promoted parameter list** button .

You can add parameters of the same data type from different child blocks to the **Promoted parameters** list. For example, the **Gain** parameter from a different child block can be added to the **Promoted parameters** list to promote to the single **Gain** parameter on the mask.

- 7 Click **OK**.
- 8 In the **Mask Editor** dialog box, edit the prompt names for the promoted parameters and click **OK**. You cannot edit the variable names.
- 9 Click **OK**. Look at the block mask. Only the parameters you promoted are available to set.

Best Practices

- Set the value of a promoted parameter only in the mask dialog box and not in the underlying block dialog box or from the command line.
- Parameters once promoted cannot be promoted again to any other mask.
- Do not edit the **Evaluate** attribute of the promoted parameter. This property is inherited from the block parameter.
- If you are promoting a nontunable parameter, do not edit the **Tunable** attribute.
- Parameters of a masked or linked child block cannot be viewed or promoted.
- Callbacks associated with a block parameter are promoted to the block mask and not to the subsystem mask. User-defined callbacks are sequentially executed after the dynamic dialog callback execute.

Control Masks Programmatically

In this section...

“Use `Simulink.Mask` and `Simulink.MaskParameter`” on page 36-37

“Use `get_param` and `set_param`” on page 36-38

“Programmatically Create Mask Parameters and Dialogs” on page 36-39

Simulink defines a set of parameters that help in setting and editing masks. To set and edit a mask from the MATLAB command line, you can use `Simulink.Mask` and `Simulink.MaskParameter` class methods. You can also use the `get_param` and `set_param` functions to set and edit masks. However, since these functions use delimiters that do not support Unicode (Non-English) characters it is recommended that you use methods of the `Simulink.Mask` and `Simulink.MaskParameter` class methods to control masks.

Use `Simulink.Mask` and `Simulink.MaskParameter`

Use methods of `Simulink.Mask` and `Simulink.MaskParameter` classes to perform the following mask operations:

- Create, copy, and delete masks
- Create, edit, and delete mask parameters
- Determine the block that owns the mask
- Get workspace variables defined for a mask

1 In this example the `Simulink.Mask.create` method is used to create a block mask:

```
maskObj = Simulink.Mask.create(gcb);
```

```
maskObj =
  Simulink.Mask handle
  Package: Simulink
  Properties:
      Type: ''
      Description: ''
      Help: ''
      Initialization: ''
      SelfModifiable: 'off'
```

```
        Display: ''
        IconFrame: 'on'
        IconOpaque: 'on'
    RunInitForIconRedraw: 'off'
        IconRotate: 'none'
        PortRotate: 'default'
        IconUnits: 'autoscale'
        Parameters: []
    Methods, Events, Superclasses
```

- 2 In this example the mask object is assigned to variable `maskObj` using the `Simulink.Mask.get` method:

```
maskObj = Simulink.Mask.get(gcb)

maskObj =
    Simulink.Mask handle
    Package: Simulink
    Properties:
        Type: ''
        Description: ''
        Help: ''
        Initialization: ''
        SelfModifiable: 'off'
        Display: ''
        IconFrame: 'on'
        IconOpaque: 'on'
    RunInitForIconRedraw: 'off'
        IconRotate: 'none'
        PortRotate: 'default'
        IconUnits: 'autoscale'
        Parameters: [1x1 Simulink.MaskParameter]
    Methods, Events, Superclasses
```

For examples of other mask operations, like creating and editing mask parameters and copying and deleting masks see `Simulink.Mask` and `Simulink.MaskParameter` .

Use `get_param` and `set_param`

The `set_param` and `get_param` functions have parameters for setting and controlling the mask. You can use these functions to set the mask of any block in the model or library based on a value passed from the MATLAB command line:

```
set_param(gcb, 'MaskStyleString', 'edit,edit', ..
```

```

'MaskVariables', 'maskparameter1=@1;maskparameter2=&2;',...
'MaskPromptString', 'Mask Parameter 1:|Mask Parameter 2:',...
'MaskValues', {'1', '2'});

get_param(gcb, 'MaskStyleString');

set_param(gcb, 'MaskStyles', {'edit', 'edit'}, 'MaskVariables',...
'maskparameter1=@1;maskparameter2=&2;', 'MaskPrompts',...
{'Mask Parameter 1:', 'Mask Parameter 2:'},...
'MaskValueString', '1|2');

get_param(gcb, 'MaskStyles');

```

where

- | separates individual character vector values for the mask parameters.
- @ indicates that the parameter field is evaluated.
- & indicates that the parameter field is not evaluated but assigned as a character vector.

Note: When you use `get_param` to get the Value of a mask parameter, Simulink returns the value that was last applied using the mask dialog. Values that you have entered into the mask dialog but not applied are not reflected when you use the `get_param` command.

To control the mask properties programmatically for a release before R2014a, see Mask Parameters.

Programmatically Create Mask Parameters and Dialogs

This example shows how to create this simple mask dialog, add controls to the dialog, and change the properties of the controls.

- 1 Create the mask for a block you selected in the model.

```
maskobj = Simulink.Mask.create(gcb);
```

- 2 Create parameters for the mask. You can change the location of these parameters on the dialog in a subsequent step.

```
maskobj.AddParameter('Type','checkbox','Prompt','Option 1',...  
'Name','option1');  
maskobj.AddParameter('Type','checkbox','Prompt','Option 2',...  
'Name','option2');
```

These commands create a mask dialog with the default layout. Simulink adds the two parameters to the **Parameters** group, which is internally named as `ParameterGroupVar` by default.

You can verify the group name programmatically.

```
dlg = maskobj.getDialogControls();
dlg(2)

ans =
  Group with properties:
    Name: 'ParameterGroupVar'
    Prompt: 'Simulink:studio:ToolBarParametersMenu'
    Row: 'new'
    Enabled: 'on'
    Visible: 'on'
    DialogControls: [1x1 Simulink.dialog.parameter.CheckBox]
```

- 3 To customize the dialog and to use tabs instead of the default group, remove the **Parameters** group box.

```
maskobj.removeDialogControl('ParameterGroupVar');
```

Simulink preserves the child dialog controls— the two check boxes in this example—even when you delete the `ParametersGroupVar` group surrounding them. These controls are parameters, that cannot be deleted using dialog control methods.

You can delete parameters using methods such as `Simulink.Mask.removeAllParameters`, which belongs to the `Simulink.Mask` class.

- 4 Create a tab container and get its handle.

```
tabgroup = maskobj.addDialogControl('tabcontainer', 'tabgroup');
```

- 5 Create tabs within this tab container.

```
tab1 = tabgroup.addDialogControl('tab', 'tab1');
tab1.Prompt = 'First';
tab2 = tabgroup.addDialogControl('tab', 'tab2');
tab2.Prompt = 'Second';
tab3 = tabgroup.addDialogControl('tab', 'tab3');
tab3.Prompt = 'Third (invisible)';
```

Make the third tab invisible.

```
tab3.Visible = 'off'
```

```
tab3 =
```

Tab with properties:

```
    Name: 'tab3'
    Prompt: 'Third (invisible)'
```

```
Enabled: 'on'  
Visible: 'on'  
DialogControls: []
```

For more information on dialog controls and their properties, type `help Simulink.dialog.Control` at the MATLAB command line.

“Block Masks” | “Masking Fundamentals” on page 36-2 | “Initialize Mask” on page 36-26

Pass Values to Blocks Under the Mask

The `masking_example` assigns the input values using the mask dialog box directly to block parameters underneath the mask, as described in “Masking Fundamentals” on page 36-2. The values are assigned, so the search that always occurs when a block parameter needs a value finds the mask parameter value automatically, as described in “Symbol Resolution” on page 4-82.

You can use the Mask Editor to insert any desired calculation between a value in the mask dialog box and an underlying block parameter

For more information, see the “Initialization Pane”.

To calculate a block parameter value, first break the link between the mask and block parameters by giving them different names. To facilitate such changes, **Dialog variables** lists all mask parameters.

You cannot use mask initialization code to change mask parameter default values in a library block or any other block.

You can use the initialization code for a masked block to link mask parameters indirectly to block parameters. In this approach, the initialization code creates variables in the mask workspace whose values are functions of the mask parameters and that appear in expressions that set the values of parameters of blocks concealed by the mask.

If you need both the character vector and the evaluated value, clear the **Evaluate** option. To get the value of a base workspace variable entered as the literal value of the mask

parameter, use the MATLAB `evalin` command in the mask initialization code. Suppose that the user types `'gain'` as the literal value of the mask parameter `k` where `gain` is the name of a base workspace variable. To obtain the value of the base workspace variable, use the following command in the initialization code for the mask:

```
value = evalin('base', k)
```

These values are stored in variables in the mask workspace. A masked block can access variables in its mask workspace. A workspace is associated with each masked subsystem that you create. The current values of the subsystem parameters are stored in the workspace and any variables created by the block initialization code and parameter callbacks.

To use a masked subsystem in a referenced model having model arguments, do not create in the mask workspace a variable that derives its value from a mask parameter. Instead, use blocks under the masked subsystem to perform the calculations for the mask workspace variable.

Mask Linked Blocks

In this section...

“Guidelines for Mask Parameters” on page 36-49

“Mask Behavior for Masked, Linked Blocks” on page 36-49

“Mask a Linked Block” on page 36-50

Simulink libraries can contain blocks that have masks. An example of this type of block is the Ramp block. These blocks become library links when copied to a model or another library. You can add a mask on this linked block. If this linked block is in a library and copied again, you can add another mask to this new linked block thus creating a stack of masks. Masking linked blocks allows you to add a custom interface to the link blocks similar to other Simulink blocks.

You can also apply a mask to a block, then include the block in a library. Masking a block that is later included in a library requires no special provisions. For more information, see “Create a Custom Library” on page 38-3.

The block mask that is present as part of the library is the base mask. A derived mask is the one created on top of the base mask.

For example, in the figure, Library A contains Block A, which has a Mask A. Block A is copied to Library B, and Mask B is added to it. When Block A is copied to Library B, a library link from Library B to Library A is created.

Block B is then copied to a model, and Mask C is added to it. This creates a library link from Block C to Library B. Block C now has Mask A, Mask B, and Mask C. Mask C is the derived mask and Mask B is the base mask.

For Block C:

- Mask parameter names are unique in the stack.
- You can set mask parameters for Mask B and Mask C.
- Mask B and Mask C inherit `MaskType` and `MaskSelfModifiable` parameters from Mask A.
- Mask initialization code for Mask C executes first, followed by Mask B and Mask A.
- Variables are resolved starting from the mask immediately above the current mask in the stack. If the current mask is the top mask, it follows the regular variable resolution rules.

Creating or changing a library block mask changes the block interface in all models that access the block using a library reference, but has no effect on instances of the block that exist as separate copies.

To view related example, see [Use self-modifying library masks](#).

Guidelines for Mask Parameters

- You cannot use same names for the mask parameters. The exception is the **Promote** type mask parameter, for which the name is inherited and is the same as that of the parameter promoted to it.
- You cannot set mask parameters for masks below the base mask. Mask parameters for masks below the base mask are inherited from the library.

Mask Behavior for Masked, Linked Blocks

The following are some of the behaviors that are important to understand about masked, linked blocks.

- The **MaskType** and the **MaskSelfModifiable** parameters are inherited from the base mask.
- The mask display code for the derived mask executes first, followed by the display code for the masks below it until we come across a mask whose **MaskIconFrame** parameter is set to **opaque**.
- The mask initialization code for the derived mask executes first, followed by the initialization code for the masks below it.
- Variables are resolved starting from the mask immediately above the current mask in the stack. If the current mask is the top mask, the regular variable resolution rules apply.
- When you save a Simulink model or library containing a block with multiple masks, using **File > Export Model to > Previous Version**, the **SourceBlock** parameter is modified to point to the library block having the bottom-most mask.
- The following occurs when you disable, break, or reestablish links to libraries:
 - If you disable the link to the library block, the entire mask hierarchy is saved to the model file so that the block can act as a standalone block.
 - If you break the link to the library block, the block becomes a standalone block.
 - If you reestablish the link after disabling by doing a restore, all changes to the mask are discarded. If you mask subsystems, you must reestablish the link after disabling by doing a push. When you do a push, subsystem changes are pushed to the library block and top mask changes are pushed to the immediate library.

Mask a Linked Block

Step 1: Create Custom Library with Masked Linked Block

- 1 In the **Simulink Library Browser**, click the arrow next to  and select **New Library**.
- 2 Open the Ramp block in the Library editor window.
- 3 Right-click the Ramp block and select **Mask > Create Mask**.
The **Mask Editor** opens.
- 4 In the **Icon drawing commands** section of the **Icons & Ports** pane, type:

```
plot ([0:10],[0,1:10])
```
- 5 In the **Parameter & Dialog** pane, select  **Promote** to promote the Slope and Initial Output parameters.
- 6 Click **OK**.
- 7 Rename the block to Derived Ramp block.

Step 2: Add a Mask to the Masked, Link Block

- 1 In the **Simulink Library Browser**, click the arrow next to  and select **New Model**. The Model editor window opens.
- 2 Drag the Derived Ramp block from the Library editor to the Model editor.

The Derived Ramp block in the model has multiple masks on it. You can set parameters of the derived mask.

Step 3: View Masks Below the Top Mask

- Right click the Derived Ramp block in the model and select **Mask > View Base Mask**. This opens the **Mask Editor** displaying the base mask definition.

Dynamic Mask Dialog Box

In this section...

“Show Parameter” on page 36-51

“Enable Parameter” on page 36-52

“Create Dynamic Mask Dialog Box” on page 36-52

“Set Up Nested Masked Block Parameters” on page 36-53

You can create dialogs for masked blocks whose appearance changes in response to user input. Features of masked dialog boxes that can change in this way include:

- Visibility of parameter controls — Changing a parameter can cause the control for another parameter to appear or disappear. The dialog expands or shrinks when a control appears or disappears, respectively.
- Enabled state of parameter controls — Changing a parameter can cause the control for another parameter to be enabled or disabled for input. A disabled control is grayed to indicate visually that it is disabled.
- Parameter values — Changing a mask dialog box parameter can cause related mask dialog box parameters to be set to appropriate values.

Creating a dynamic masked dialog box entails using the Mask Editor with the `set_param` command. Specifically, you use the Mask Editor to define parameters of the dialog box, both static and dynamic. For each dynamic parameter, you enter a callback function that defines how the dialog box responds to changes to that parameter (see “Execute Callback Code” on page 36-20). The callback function can in turn use the `set_param` command to set mask parameters that affect the appearance and settings of other controls on the dialog box (see “Create Dynamic Mask Dialog Box” on page 36-52). Finally, you save the model or library containing the masked subsystem to complete the creation of the dynamic masked dialog box.

To view related example, see [Create dynamic mask dialog boxes](#).

Show Parameter

The selected parameter appears on the mask dialog box only if this option is checked (the default).

Enable Parameter

Clearing this option grays the prompt of the selected parameter and disables the edit control of the prompt.

Create Dynamic Mask Dialog Box

This example shows how to create a mask dialog blocks whose appearance changes in response to your input.

You can set two parameters using this mask dialog box. The first parameter is a popup menu through which you select one of three gain values: **2**, **5**, or **User-defined**. Depending on the value that you select in this popup menu, an edit field for specifying the gain appears or disappears.

- 1** Mask a subsystem by right-clicking the block and selecting **Mask > Create Mask**.
- 2** Select the **Parameters & Dialog** pane on the Mask Editor.
- 3** Drag and drop a **Popup** parameter and select it in the **Dialog box** pane.
 - a** In the **Prompt** field, enter **Gain**.
 - b** In the **Name** field, enter **gainpopup**.
 - c** In the Property editor pane, clear **Evaluate** so that Simulink uses the literal values you specify for the popup.
 - d** In the **Type options** field, click the **Edit** button to enter these three values in the Popup Options dialog box:

```
2
5
User-defined
```

- 4** Enter this code in the **Dialog callback** field:

```
% Get the mask parameter values. This is a cell
% array of character vectors.
maskStr = get_param(gcb, 'gainpopup');

% The pop-up menu is the first mask parameter.
% Check the value selected in the pop-up
if strcmp(maskStr(1), 'U'),

    % Set the visibility of both parameters on when
```

```

    % User-defined is selected in the pop-up.
    set_param(gcf,'MaskVisibilities',{'on';'on'}),
else
    % Turn off the visibility of the Value field
    % when User-defined is not selected.
    set_param(gcf,'MaskVisibilities',{'on';'off'}),

    % Set the character vector in the Values field equal to the
    % character vector selected in the Gain pop-up menu.

    %maskStr{2}=maskStr{1};
    set_param(gcf,'editvalue',maskStr);
end

```

- 5 Drag and drop an **Edit** parameter and select it in the **Dialog box** pane.
 - a In the **Prompt** field, enter **Value**.
 - b In the **Name** field, enter **editvalue**.
 - c In the Property editor pane, clear **Visible** so that Simulink turns off the visibility of this property by default.
- 6 Click **Apply**.
- 7 To open the mask dialog box, double-click the masked subsystem .

If you select 2 or 5 as the **Gain**, Simulink hides the **Value**. If you select **User-defined** as the **Gain** the **Value** is visible.

Set Up Nested Masked Block Parameters

If lower-level masked subsystems reference symbols defined by higher-level masked subsystems and you try to set parameters of blocks in lower-level masked subsystems, unresolved symbol errors can occur. Therefore, avoid using `set_param` commands to set parameters of blocks residing in masked subsystems that reside in the masked subsystem being initialized. Trying if lower-level masked subsystems reference symbols defined by higher-level masked subsystems.

Suppose, for example, a masked subsystem A contains masked subsystem B, which contains Gain block C, whose Gain parameter references a variable defined by B. Suppose also that subsystem A's initialization code contains this command:

```
set_param([gcb '/B/C'], 'SampleTime', '-1');
```

Simulating or updating a model containing A causes an unresolved symbol error.

“Block Masks” | “Dynamic Masked Subsystem” on page 36-55

Dynamic Masked Subsystem

In this section...

“Allow Library Block to Modify Its Contents” on page 36-55

“Create Self-Modifying Masks for Library Blocks” on page 36-55

“Evaluate Blocks Under Self-Modifying Mask” on page 36-59

Allow Library Block to Modify Its Contents

This check box is enabled only if the masked subsystem resides in a library. Checking this option allows the block initialization code to modify the contents of the masked subsystem (that is, it lets the code add or delete blocks and set the parameters of those blocks). Otherwise, an error is generated when a masked library block tries to modify its contents in any way. To set this option at the MATLAB prompt, select the self-modifying block and enter the following command.

```
set_param(gcf, 'MaskSelfModifiable', 'on');
```

Then save the block.

Create Self-Modifying Masks for Library Blocks

You can create masked library blocks that can modify their structural contents. These self-modifying masks allow you to:

- Modify the contents of a masked subsystem based on parameters in the mask dialog box or when the subsystem is initially dragged from the library into a new model.
- Vary the number of ports on a multiport S-Function block that resides in a library.

Creating Self-Modifying Masks Using the Mask Editor

To create a self-modifying mask using the Mask Editor:

- 1 Unlock the library (see “Lock and Unlock Libraries” on page 38-7).
- 2 Right-click the block in the library.
- 3 Select **Mask > Edit Mask**. The Mask Editor opens.

- 4 In the Mask Editor **Initialization** pane, select the **Allow library block to modify its contents** option.
- 5 Enter the code that modifies the masked subsystem in the mask **Initialization** pane.

Do not enter code that structurally modifies the masked subsystem in a dialog parameter callback (see “Add Mask Code” on page 36-18). Doing so triggers an error when you edit the parameter.

- 6 Click **Apply** to apply the change or **OK** to apply the change and close the Mask Editor.
- 7 Lock the library.

Creating Self-Modifying Masks from the Command Line

To create a self-modifying mask from the command line:

- 1 Unlock the library using the following command:

```
set_param(gcs, 'Lock', 'off')
```

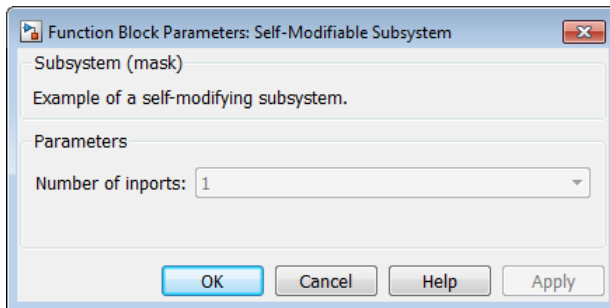

- 2 Specify that the block is self-modifying by using the following command:

```
set_param(block_name, 'MaskSelfModifiable', 'on')
```

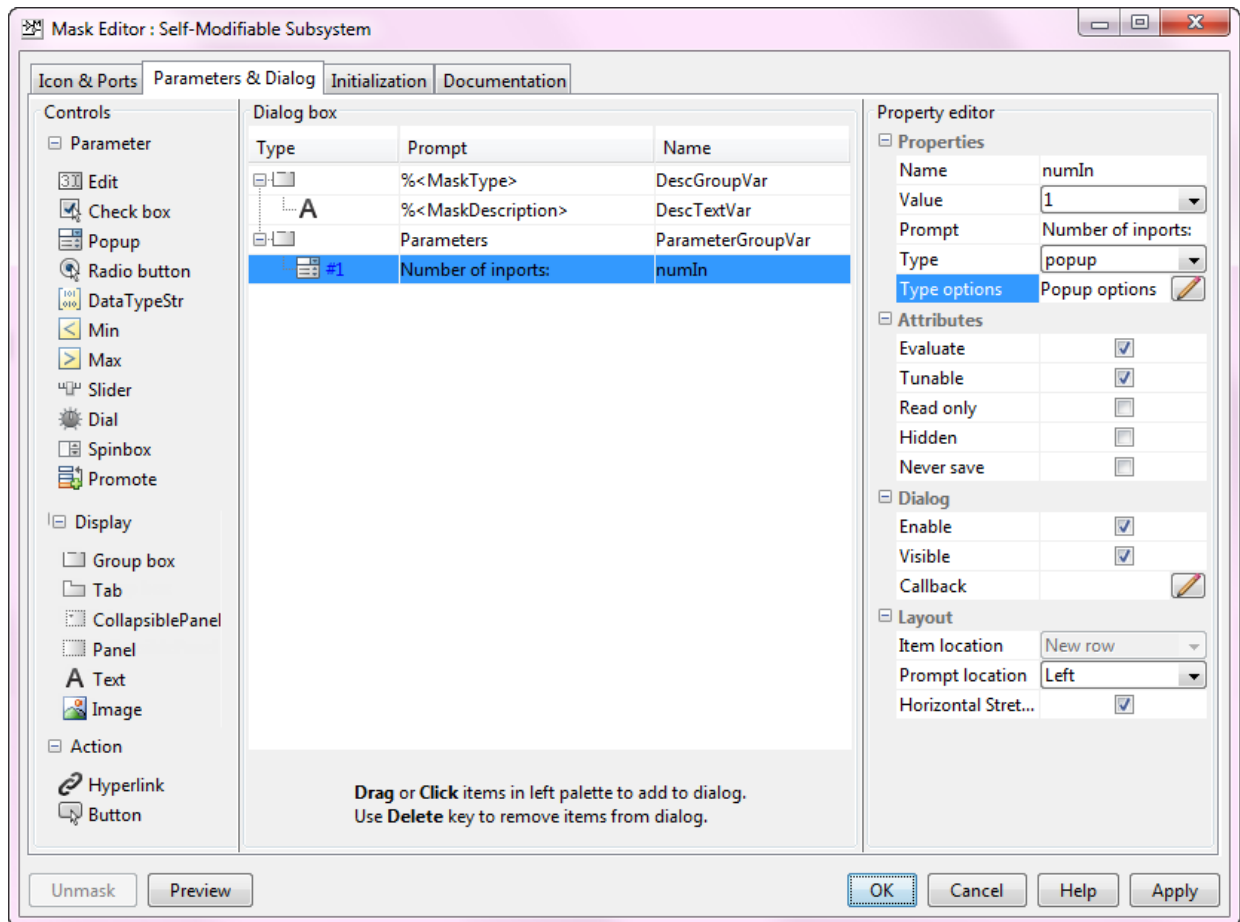

where `block_name` is the full path to the block in the library.

Create Self-Modifying Mask

The library `selfModifying_example` contains a masked subsystem that modifies its number of input ports based on a selection made in the subsystem mask dialog box.

- 1 Right-click the subsystem and select **Mask > Edit Mask**. The Mask Editor opens.
- 2 The Mask Editor **Parameters & Dialog** pane defines a parameter numIn that stores the value for the **Number of inports** option. This mask dialog box callback adds or removes Input ports inside the masked subsystem based on the selection made in the **Number of inports** list.

- To allow the dialog box callback to function properly, the **Allow library block to modify its contents** option on the Mask Editor **Initialization** pane is selected. If this option is not selected, copy of the library block could not modify their structural contents. Also, changing the selection in the **Number of inports** list would produce an error.

Evaluate Blocks Under Self-Modifying Mask

This example shows how to force Simulink to evaluate blocks inside self-modifying masks.

Simulink evaluates elements of models containing masks in the following order:

- 1 Mask dialog box
- 2 Mask initialization code

3 Blocks or masked subsystems under the mask

Suppose a block named `myBlock` inside subsystem `mySubsys` masked by a self-modifying mask depends on mask parameter `myParam` to update itself.

`myParam` is exposed to the user through the **Mask Parameters** dialog box. `mySubsys` is updated through MATLAB code written in the **Mask Initialization** pane.

In this model, the sequence of updates is as follows:

- 1 You modify `myParam` through the mask dialog box.
- 2 The mask initialization code receives this change and modifies `mySubsys` under the mask.
- 3 `myBlock`, which lies under `mySubsys`, modifies itself based on the change to `myParam`.

In this sequence, Simulink does not evaluate `myBlock`, which lies under `mySubsys`, when the mask initialization code executes. Instead, Simulink only evaluates and updates the masked subsystem `mySubsys`. Meanwhile, `myBlock` remains unmodified.

You can force Simulink to evaluate such blocks earlier by using the `Simulink.Block.eval` method in the initialization code of the masked subsystem.

```
Simulink.Block.eval('mySubsys/myBlock');
```

Debug Masks That Use MATLAB Code

In this section...

“Code Written in Mask Editor” on page 36-61

“Code Written Using MATLAB Editor/Debugger” on page 36-61

Code Written in Mask Editor

Debug initialization commands and parameter callbacks entered directly into the Mask Editor by:

- Removing the terminating semicolon from a command to echo its results to the MATLAB Command Window.
- Placing a keyboard command in the code to stop execution and give control to the keyboard.

Code Written Using MATLAB Editor/Debugger

Note: You cannot debug icon drawing commands using the MATLAB Editor/Debugger. For information on icon drawing commands syntax, see “Icon drawing commands”.

Debug initialization commands and parameter callbacks written in files using the MATLAB Editor/Debugger in the same way that you would with any other MATLAB program file.

When debugging initialization commands, you can view the contents of the mask workspace. However, when debugging parameter callbacks, you can only access the base workspace of the block. If you need the value of a mask parameter, use `get_param`.

More About

- “Initialize Mask” on page 36-26
- “Mask Callback Code” on page 36-18

Masking Example Models

The Simulink Masking Example models help you to understand and configure mask parameters, properties, and features. The examples are grouped by type. In an example model:

- To view the mask definition, double-click the View Mask block.
- To view the mask dialog box, double-click the block.

Types of Custom Blocks

In this section...

“MATLAB Function Blocks” on page 37-2

“MATLAB System Blocks” on page 37-2

“Subsystem Blocks” on page 37-3

“S-Function Blocks” on page 37-3

“Masked Blocks” on page 37-5

MATLAB Function Blocks

A MATLAB Function block allows you to use the MATLAB language to define custom functionality. These blocks are a good starting point for creating a custom block if:

- You have an existing MATLAB function that models the custom functionality.
- You find it easier to model custom functionality using a MATLAB function than using a Simulink block diagram.
- The custom functionality does not include continuous or discrete dynamic states.

You can create a custom block from a MATLAB function using one of the following types of MATLAB function blocks.

- The Fcn block allows you to use a MATLAB expression to define a single-input, single-output (SISO) block.
- The Interpreted MATLAB Function block allows you to use a MATLAB function to define a SISO block.
- The MATLAB Function block allows you to define a custom block with multiple inputs and outputs that you can deploy to an embedded processor.

Each of these blocks has advantages in particular modeling applications. For example, you can generate code from models containing MATLAB Function blocks, whereas you cannot generate code for models containing an Fcn block.

MATLAB System Blocks

A MATLAB System block allows you to use System objects written with the MATLAB language to define custom functionality. These blocks are a good starting point for creating a custom block if:

- You have an existing System object™ that models the custom functionality.
- You find it easier to model custom functionality using the MATLAB language than using a Simulink block diagram.
- The custom functionality includes discrete dynamic states.

Subsystem Blocks

Subsystem blocks allow you to build a Simulink diagram to define custom functionality. These blocks serve as a good starting point for creating a custom block if:

- You have an existing Simulink diagram that models custom functionality.
- You find it easier to model custom functionality using a graphical representation rather than using handwritten code.
- The custom functionality is a function of continuous or discrete system states.
- You can model the custom functionality using existing Simulink blocks.

Once you have a Simulink subsystem that models the required behavior, you can convert it into a custom block by:

- 1 Masking the block to hide the block contents and provide a custom block dialog box.
- 2 Placing the block in a library to prohibit modifications and allow for easily updating copies of the block.

For more information, see “Libraries” and “Block Masks”.

S-Function Blocks

S-function blocks allow you to write MATLAB, C, or C++ code to define custom functionality. These blocks serve as a good starting point for creating a custom block if:

- You have existing MATLAB, C, or C++ code that models custom functionality.
- You use continuous or discrete dynamic states or other system behaviors that require access to the S-function API.
- You cannot model the custom functionality using existing Simulink blocks.

You can create a custom block from an S-function using one of the following types of S-function blocks.

- The **Level-2 MATLAB S-Function** block allows you to write your S-function using the MATLAB language. (See “Write Level-2 MATLAB S-Functions”). You can debug a MATLAB S-function during a simulation using the MATLAB debugger.
- The **S-Function** block allows you to write your S-function in C or C++, or to incorporate existing code into your model using a C MEX wrapper. (See “C/C++ S-Functions”).
- The **S-Function Builder** block assists you in creating a C MEX S-function or a wrapper function to incorporate legacy C or C++ code. (See “C/C++ S-Functions”).
- The **Legacy Code Tool** transforms existing C or C++ functions into C MEX S-functions. (See “Integrate C Functions Using Legacy Code Tool”).

The S-function target in the Simulink Coder product automatically generates a C MEX S-function from a graphical subsystem. If you want to build your custom block in a Simulink subsystem, but implement the final version of the block in an S-function, you can use the S-function target to convert the subsystem to an S-function. See “Accelerate Simulation, Reuse Code, or Protect Intellectual Property by Using S-Function Target” in the Simulink Coder User's Guide for details and limitations on using the S-function target.

Comparing MATLAB S-Functions to MATLAB Functions for Code Generation

MATLAB S-functions and MATLAB functions for code generation have some fundamental differences.

- The Simulink Coder product can generate code for both MATLAB S-functions and MATLAB functions for code generation. However, MATLAB S-functions require a Target Language Compiler (TLC) file for code generation. MATLAB functions for code generation do not require a TLC-file.
- MATLAB S-functions can use any MATLAB function whereas MATLAB functions for code generation are a subset of the MATLAB language. For a list of supported functions for code generation, see “Functions and Objects Supported for C/C++ Code Generation — Alphabetical List” on page 44-2.
- MATLAB S-functions can model discrete and continuous state dynamics whereas MATLAB functions for code generation cannot model state dynamics.

Using S-Function Blocks to Incorporate Legacy Code

Each S-function block allows you to incorporate legacy code into your model, as follows.

- A MATLAB S-function accesses legacy code through its TLC-file. Therefore, the legacy code is available only in the generated code, not during simulation.

- A C MEX S-function directly calls legacy C or C++ code.
- The S-Function Builder generates a wrapper function that calls the legacy C or C++ code.
- The Legacy Code Tool generates a C MEX S-function to call the legacy C or C++ code, which is optimized for embedded systems. See “Integrate C Functions Using Legacy Code Tool” for more information.

See “About External Code Integration” in the Simulink Coder User’s Guide for more information.

See “S-Functions Incorporate Legacy C Code” in the Simulink Developing S-Functions for an example.

Masked Blocks

You can customize any block by adding a mask to it. A mask is a custom interface to the block. You can customize a block using a mask in many ways, such as:

- Change the block appearance.
- Hide some or all of the parameters from the user of the block.
- Customize block parameters.

To learn more about masked blocks, see “Block Masks”.

Comparison of Custom Block Functionality

In this section...

“Custom Block Considerations” on page 37-6

“Modeling Requirements” on page 37-10

“Speed and Code Generation Requirements” on page 37-13

Custom Block Considerations

When creating a custom block, consider the following.

- Does the custom block need multiple input and output ports?
- Does the block model continuous or discrete state behavior?
- Do the block inputs and outputs have various data attributes, such as data types or complexity?
- How important is the effect of the custom block on the speed of updating the Simulink diagram or simulating the Simulink model?
- Do you need to generate code for a model containing the custom block?

The following two tables provide an overview of how each custom block type addresses the previous questions. More detailed information for each consideration follows these two tables.

Modeling Requirements

Custom Block Type	Supports Multiple Inputs and Outputs	Models State Dynamics	Supports Various Data Attributes
Subsystem	Yes, including bus signals.	Yes.	Yes, including all data types, numeric types, and dimensions supported by the Simulink software. Also supports frame-based signals.
Fcn	No. Must have a single vector input and scalar output.	No.	Supports only real scalar signals with a data type of double or single.

Custom Block Type	Supports Multiple Inputs and Outputs	Models State Dynamics	Supports Various Data Attributes
Interpreted MATLAB Function	No. Must have a single vector input and output.	No.	Supports only n-D, real, or complex signals with a data type of double.
MATLAB Function	Yes, including bus signals.	No.	Yes, including all data types, numeric types, and dimensions supported by the Simulink software. Also supports frame-based signals.
MATLAB System	Yes, including bus signals.	Yes.	Yes, including all data types (except buses and enumerated), numeric types, and dimensions supported by the Simulink software. Also supports frame-based signals.
Level-2 MATLAB S-function	Yes, excluding bus signals	Yes, including limited access to other S-function APIs.	Yes, including all data types, numeric types, and dimensions supported by the Simulink software. Also supports frame-based signals.
C MEX S-function	Yes, including bus signals if using the Legacy Code Tool to generate the S-function.	Yes, including full access to all S-function APIs.	Yes, including all data types, numeric types, and dimensions supported by the Simulink software. Also supports frame-based signals.

Speed and Code Generation Requirements

Custom Block Type	Speed of Updating the Diagram	Simulation Overhead	Code Generation Support
Subsystem	Proportional to the complexity of the subsystem. For library blocks, can be slower the first time the library is loaded.	Proportional to the complexity of the subsystem. Library blocks introduce no additional overhead.	Natively supported.

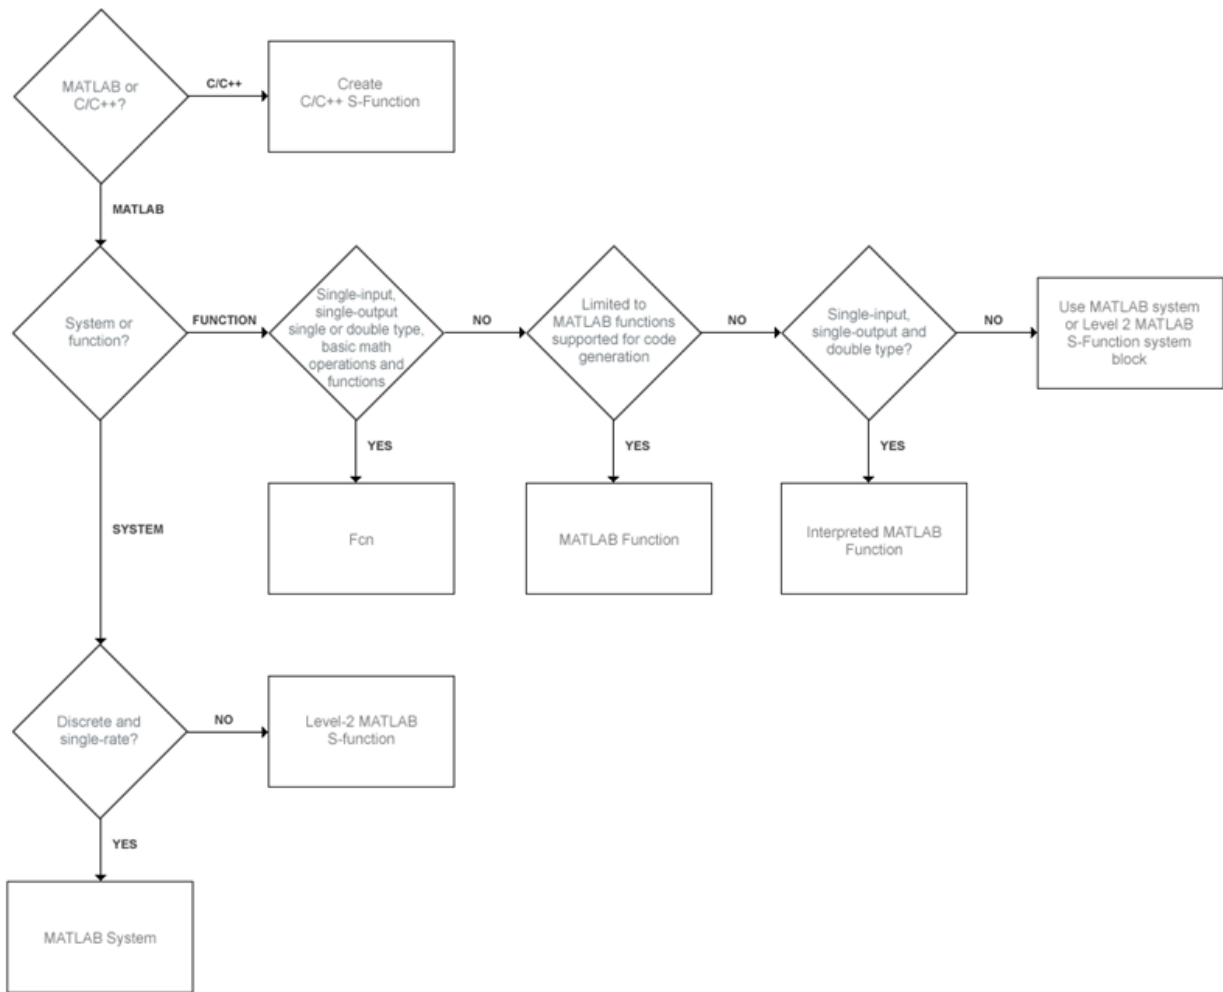

Custom Block Type	Speed of Updating the Diagram	Simulation Overhead	Code Generation Support
Fcn	Very fast.	Minimal, but these blocks also provide limited functionality.	Natively supported.
Interpreted MATLAB Function	Fast.	High and incurred when calling out to the MATLAB execution engine. Avoid these calls if simulation speed is a concern.	Not supported.
MATLAB Function	Can be slower if code must be generated to update the diagram.	Minimal if the MATLAB execution engine is not called. Simulation speed is equivalent to C MEX S-functions when the MATLAB execution engine is not called.	Natively supported, with exceptions. See “Code Generation” on page 37-16 for more information.
MATLAB System	Faster than MATLAB Function because code is not generated to update the diagram.	In interpreted execution mode, the simulation has the overhead of calling the MATLAB execution engine. In code generation mode, the first simulation incurs code generation overhead. However, in subsequent runs, the block simulation speed is equivalent to C MEX S-functions.	Natively supported, with exceptions.
Level-2 MATLAB S-function	Can be slower if the S-function overrides methods executed when updating the diagram.	Higher than for Interpreted MATLAB Function blocks because the MATLAB execution engine is called for every S-function method used.	MATLAB S-functions initialized as a <code>SimViewingDevice</code> do not generate code. Otherwise, MATLAB S-functions require a TLC-file for code generation.

Custom Block Type	Speed of Updating the Diagram	Simulation Overhead	Code Generation Support
		Very flexible, but very costly.	
C MEX S-function	Can be slower if the S-function overrides methods executed when updating the diagram.	Minimal, but proportional to the complexity of the algorithm and the efficiency of the code.	Might require a TLC-file.

Block Type Flowchart

The diagram shows how to decide which block to use. One deciding factor is whether you need the block for a function or a system. In this context:

- A function defines the relationship between a set of inputs and outputs.
- A system defines the relationship between a set of inputs and outputs. It can also define a set of states, parameters, and System object processing methods for initialization, output, update, termination, and so forth.

Modeling Requirements

Multiple Input and Output Ports

The following types of custom blocks support multiple input and output ports.

Custom Block Type	Multiple Input and Output Port Support
Subsystem	Supports multiple input and output ports, including bus signals. In addition, you can modify the number of input and output ports based on user-defined parameters. See “Self-Modifiable Linked Subsystems” on page 38-19 for more information.
Fcn, Interpreted MATLAB Function	Supports only a single input and a single output port. Use a Mux block to combine the inputs and a Demux block to separate the outputs if you pass multiple signals into or out of these blocks.
MATLAB Function	Supports multiple input and output ports, including bus signals. See “How Structure Inputs and Outputs Interface with Bus Signals” on page 39-78 for more information.
MATLAB System	Supports multiple input and output ports, including bus signals. See “Define System Objects” for more information.
S-function (MATLAB or C MEX)	Supports multiple input and output ports. In addition, you can modify the number of input and output ports based on user-defined parameters. S-functions generated using the Legacy Code Tool also accept Simulink bus signals. See “Integrate C Functions Using Legacy Code Tool” for more information.

State Behavior and the S-Function API

Simulink blocks communicate with the Simulink engine through the S-function API, a set of methods that fully specifies the behavior of blocks. Each custom block type accesses a different set of the S-function APIs, as follows.

Custom Block Type	S-Function API Support
Subsystem	Communicates directly with the engine. You can model state behaviors using appropriate blocks from the Continuous and Discrete Simulink block libraries.
Fcn, Interpreted MATLAB Function, MATLAB Function	All create a <code>mdlOutputs</code> method to calculate the value of the outputs given the value of the inputs. You cannot access any other S-function API methods using one of these blocks and, therefore, cannot model state behavior.
MATLAB System	Uses System object methods for S-function APIs: <code>mdlOutputs</code> (<code>stepImpl</code> , <code>outputImpl</code>), <code>mdlUpdate</code> (<code>updateImpl</code>),

Custom Block Type	S-Function API Support
	mdlInitializeConditions (resetImpl), mdlStart (setupImpl), mdlTerminate (releaseImpl).
MATLAB S-function	Accesses a larger subset of the S-function APIs, including methods you can use to model continuous and discrete states. For a list of supported methods, see “Level-2 MATLAB S-Function Callback Methods” in “Writing S-Functions”.
C MEX S-function	Accesses the complete set of S-function APIs.

Data Attribute Support

All custom block types support real scalar inputs and outputs with a data type of double.

Custom Block Type	Data Attribute Support
Subsystem	Supports any data type supported by the Simulink software, including fixed-point types. Also supports complex, 2-D, n-D, and frame-based signals.
Fcn	Supports only double or single data types. In addition, the input and output cannot be complex and the output must be a scalar signal. Does not support frame-based signals.
Interpreted MATLAB Function	Supports 2-D, n-D, and complex signals, but the signal must have a data type of double. Does not support frame-based signals.
MATLAB Function	Supports any data type supported by the Simulink software, including fixed-point types. Also supports complex, 2-D, n-D, and frame-based signals.
MATLAB System	Supports any data type supported by the Simulink software, including fixed-point types. Also supports complex, 2-D, n-D, and frame-based signals.
S-function (MATLAB or C MEX)	Supports any data type supported by the Simulink software, including fixed-point types. Also supports complex, 2-D, n-D, and frame-based signals.

Speed and Code Generation Requirements

Updating the Simulink Diagram

The Simulink software updates the diagram before every simulation and whenever requested by the user. Every block introduces some overhead into the “update diagram” process.

Custom Block Type	Speed of Updating the Diagram
Subsystem	The speed is proportional to the complexity of the algorithm implemented in the subsystem. If the subsystem is contained in a library, some cost is incurred when the Simulink software loads any unloaded libraries the first time the diagram is updated or readied for simulation. If all referenced library blocks remain unchanged, the Simulink software does not subsequently reload the library and compiling the model becomes faster than if the model did not use libraries.
Fcn, Interpreted MATLAB Function	Does not incur greater update cost than other Simulink blocks.
MATLAB Function	Performs simulation through code generation, so these blocks can take a significant amount of time when first updated. However, because code generation is incremental, Simulink does not repeatedly update the block if the block and the signals connected to it have not changed.
MATLAB System	Faster than MATLAB Function because code is not generated to update the diagram. However, because code generation is incremental, Simulink does not repeatedly update the block if the block and the signals connected to it have not changed.
S-function (MATLAB or C MEX)	Incurs greater costs than other Simulink blocks only if it overrides methods executed when updating the diagram. If these methods become complex, they can contribute significantly to the time it takes to update the diagram. For a list of methods executed when updating the diagram, see the process view in “Simulink Engine Interaction with C S-Functions”. When updating the diagram, the Simulink software invokes all relevant methods in the model initialization phase up to, but not including, mdlStart.

Simulation Overhead

For most applications, any of the custom block types provide acceptable simulation performance. Use the Simulink profiler to obtain an indication of the actual performance. See “How Profiler Captures Performance Data” on page 28-5 for more information.

You can break simulation performance into two categories. The interface cost is the time it takes to move data from the Simulink engine into the block. The algorithm cost is the time it takes to perform the algorithm that the block implements.

Custom Block Type	Simulation Overhead
Subsystem	If included in a library, introduces no interface or algorithm costs beyond what would normally be incurred if the block existed as a regular subsystem in the model.
Fcn	Has the least simulation overhead. The block is tightly integrated with the Simulink engine and implements a rudimentary expression language that is efficiently interpreted.
Interpreted MATLAB Function	Has a higher interface cost than most blocks and the same algorithm cost as a MATLAB function. When block data (such as inputs and outputs) is accessed or returned from an Interpreted MATLAB Function block, the Simulink engine packages this data into MATLAB arrays. This packaging takes additional time and causes a temporary increase in memory during communication. If you pass large amounts of data across this interface, such as, frames or arrays, this overhead can be substantial. Once the data has been converted, the MATLAB execution engine executes the algorithm. As a result, the algorithm cost is the same as for MATLAB function. Efficient code can be competitive with C code if MATLAB is able to optimize it, or if the code uses the highly optimized MATLAB library functions.
MATLAB Function	Performs simulation through code generation and so incurs the same interface cost as standard blocks. The algorithm cost of this block is harder to analyze because of the block's implementation. On average, a function for this block and a MATLAB function run at about the same speed. To reduce the algorithm cost, you can disable debugging for all the MATLAB Function blocks. If the MATLAB Function block uses simulation-only capabilities to call out to the MATLAB execution engine, it incurs all the costs

Custom Block Type	Simulation Overhead
	that a MATLAB S-function or Interpreted MATLAB Function block incur. Calling out to the MATLAB execution engine from a MATLAB Function block produces a warning to prevent you from doing so unintentionally.
MATLAB System	<p>Performs simulation through one of the following:</p> <ul style="list-style-type: none"> • Interpreted execution, the model simulates the block using the MATLAB execution engine. • Code generation, the model simulates the block using generated code. <p>For more information, see the MATLAB Function entry in this table.</p>
MATLAB S-function	Incurs the same algorithm costs as the Interpreted MATLAB Function block, but with a slightly higher interface cost. Because MATLAB S-functions can handle multiple inputs and outputs, the packaging is more complicated than for the Interpreted MATLAB Function block. In addition, the Simulink engine calls the MATLAB execution engine for each block method you implement whereas for the Interpreted MATLAB Function block, it calls the MATLAB execution engine only for the <code>mdlOutputs</code> method.
C MEX S-function	Simulates via the compiled code and so incurs the same interface cost as standard blocks. The algorithm cost depends on the complexity of the S-function.

Code Generation

Not all custom block types support code generation with Simulink Coder.

Custom Block Type	Code Generation Support
Subsystem	Supports code generation.
Fcn	Supports code generation.
Interpreted MATLAB Function	Does not support code generation.
MATLAB Function	Supports code generation. However, if your MATLAB Function block calls out to the MATLAB execution engine, it will build with the Simulink Coder product only if the calls to the MATLAB execution engine do not affect the block outputs. Under this condition, the Simulink Coder product omits these calls from the generated C code. This feature allows you to leave visualization code in place, even when generating embedded code.
MATLAB System	Supports code generation. However, if your MATLAB System block calls out to the MATLAB execution engine, it will build with the Simulink Coder product only if the calls to the MATLAB execution engine do not affect the block outputs. Under this condition, the Simulink Coder product omits these calls from the generated C code. This feature allows you to leave visualization code in place, even when generating embedded code.
MATLAB S-function	Generates code only if you implement the algorithm using a Target Language Compiler (TLC) function. In accelerated and external mode simulations, you can choose to execute the S-function in interpretive mode by calling back to the MATLAB execution engine without implementing the algorithm in TLC. If the MATLAB S-function is a <code>SimViewingDevice</code> , the Simulink Coder product automatically omits the block during code generation.
C MEX S-function	Supports code generation. For noninlined S-functions, the Simulink Coder product uses the C MEX function during code generation. However, you must write a TLC-file for the S-function if you need to either inline the S-function or create a wrapper for hand-written code. See “S-Functions and Code Generation” in the Simulink Coder User's Guide for more information.

Expanding Custom Block Functionality

You can expand the functionality of any custom block using callbacks and MATLAB graphics.

Block callbacks perform user-defined actions at specific points in the simulation. For example, the callback can load data into the MATLAB workspace before the simulation or generate a graph of simulation data at the end of the simulation. You can assign block callbacks to any of the custom block types. For a list of available callbacks and more information on how to use them, see “Specify Block Callbacks” on page 4-62.

GUIDE, the MATLAB graphical user interface development environment, provides tools for easily creating custom user interfaces. See “App Building” for more information on using GUIDE.

How to Design a Custom Block

In general, use the following process to design a custom block:

- 1 “Defining Custom Block Behavior” on page 37-21
- 2 “Deciding on a Custom Block Type” on page 37-22
- 3 “Placing Custom Blocks in a Library” on page 37-26
- 4 “Adding a User Interface to a Custom Block” on page 37-29

Suppose you want to create a customized saturation block that limits the upper and lower bounds of a signal based on either a block parameter or the value of an input signal. In a second version of the block, you want the option to plot the saturation limits after the simulation is finished. The following tutorial steps you through designing these blocks. The library `ex_customsat_lib` contains the two versions of the customized saturation block.

The example model `sldemo_customsat` uses the basic version of the block.

Defining Custom Block Behavior

Begin by defining the features and limitations of your custom block. In this example, the block supports the following features:

- Turning on and off the upper or lower saturation limit.
- Setting the upper and/or lower limits via a block parameters.

- Setting the upper and/or lower limits using an input signal.

It also has the following restrictions:

- The input signal under saturation must be a scalar.
- The input signal and saturation limits must all have a data type of double.
- Code generation is not required.

Deciding on a Custom Block Type

Based on the custom block features, the implementation needs to support the following:

- Multiple input ports
- A relatively simple algorithm
- No continuous or discrete system states

Therefore, this tutorial implements the custom block using a Level-2 MATLAB S-function. MATLAB S-functions support multiple inputs and, because the algorithm is simple, do not have significant overhead when updating the diagram or simulating the model. See “Comparison of Custom Block Functionality” on page 37-6 for a description of the different functionality provided by MATLAB S-functions as compared to other types of custom blocks.

Parameterizing the MATLAB S-Function

Begin by defining the S-function parameters. This example requires four parameters:

- The first parameter indicates how the upper saturation limit is set. The limit can be off, set via a block parameter, or set via an input signal.
- The second parameter is the value of the upper saturation limit. This value is used only if the upper saturation limit is set via a block parameter. In the event this parameter is used, you should be able to change the parameter value during the simulation, i.e., the parameter is tunable.
- The third parameter indicates how the lower saturation limit is set. The limit can be off, set via a block parameter, or set via an input signal.
- The fourth parameter is the value of the lower saturation limit. This value is used only if the lower saturation limit is set via a block parameter. As with the upper saturation limit, this parameter is tunable when in use.

The first and third S-function parameters represent modes that must be translated into values the S-function can recognize. Therefore, define the following values for the upper and lower saturation limit modes:

- 1 indicates that the saturation limit is off.
- 2 indicates that the saturation limit is set via a block parameter.
- 3 indicates that the saturation limit is set via an input signal.

Writing the MATLAB S-Function

After you define the S-function parameters and functionality, write the S-function. The template `msfuntmpl.m` provides a starting point for writing a Level-2 MATLAB S-function. You can find a completed version of the custom saturation block in the file `custom_sat.m`. Save this file to your working folder before continuing with this tutorial.

This S-function modifies the S-function template as follows:

- The `setup` function initializes the number of input ports based on the values entered for the upper and lower saturation limit modes. If the limits are set via input signals, the method adds input ports to the block. The `setup` method then indicates there are four S-function parameters and sets the parameter tunability. Finally, the method registers the S-function methods used during simulation.

```
function setup(block)

% The Simulink engine passes an instance of the Simulink.MSFcnRunTimeBlock
% class to the setup method in the input argument "block". This is known as
% the S-function block's run-time object.

% Register original number of input ports based on the S-function
% parameter values

try % Wrap in a try/catch, in case no S-function parameters are entered
    lowMode    = block.DialogPrm(1).Data;
    upMode     = block.DialogPrm(3).Data;
    numInPorts = 1 + isequal(lowMode,3) + isequal(upMode,3);
catch
    numInPorts=1;
end % try/catch
block.NumInputPorts = numInPorts;
block.NumOutputPorts = 1;

% Setup port properties to be inherited or dynamic
block.SetPreCompInpPortInfoToDynamic;
block.SetPreCompOutPortInfoToDynamic;

% Override input port properties
block.InputPort(1).DatatypeID = 0; % double
```

```

block.InputPort(1).Complexity = 'Real';

% Override output port properties
block.OutputPort(1).DatatypeID = 0; % double
block.OutputPort(1).Complexity = 'Real';

% Register parameters. In order:
% -- If the upper bound is off (1) or on and set via a block parameter (2)
%    or input signal (3)
% -- The upper limit value. Should be empty if the upper limit is off or
%    set via an input signal
% -- If the lower bound is off (1) or on and set via a block parameter (2)
%    or input signal (3)
% -- The lower limit value. Should be empty if the lower limit is off or
%    set via an input signal
block.NumDialogPrms = 4;
block.DialogPrmsTunable = {'Nontunable','Tunable','Nontunable', ...
    'Tunable'};

% Register continuous sample times [0 offset]
block.SampleTimes = [0 0];

%% -----
%% Options
%% -----
% Specify if Accelerator should use TLC or call back into
% MATLAB script
block.SetAcce1RunOnTLC(false);

%% -----
%% Register methods called during update diagram/compilation
%% -----

block.RegBlockMethod('CheckParameters', @CheckPrms);
block.RegBlockMethod('ProcessParameters', @ProcessPrms);
block.RegBlockMethod('PostPropagationSetup', @DoPostPropSetup);
block.RegBlockMethod('Outputs', @Outputs);
block.RegBlockMethod('Terminate', @Terminate);
%end setup function

```

- The **CheckParameters** method verifies the values entered into the Level-2 MATLAB S-Function block.

```

function CheckPrms(block)

lowMode = block.DialogPrm(1).Data;
lowVal = block.DialogPrm(2).Data;
upMode = block.DialogPrm(3).Data;
upVal = block.DialogPrm(4).Data;

% The first and third dialog parameters must have values of 1-3
if ~any(upMode == [1 2 3]);
    error('The first dialog parameter must be a value of 1, 2, or 3');
end

```

```

if ~any(lowMode == [1 2 3]);
    error('The first dialog parameter must be a value of 1, 2, or 3');
end

% If the upper or lower bound is specified via a dialog, make sure there
% is a specified bound. Also, check that the value is of type double
if isequal(upMode,2),
    if isempty(upVal),
        error('Enter a value for the upper saturation limit.');
```

```

    end
    if ~strcmp(class(upVal), 'double')
        error('The upper saturation limit must be of type double.');
```

```

    end
end

if isequal(lowMode,2),
    if isempty(lowVal),
        error('Enter a value for the lower saturation limit.');
```

```

    end
    if ~strcmp(class(lowVal), 'double')
        error('The lower saturation limit must be of type double.');
```

```

    end
end

% If a lower and upper limit are specified, make sure the specified
% limits are compatible.
if isequal(upMode,2) && isequal(lowMode,2),
    if lowVal >= upVal,
        error('The lower bound must be less than the upper bound.');
```

```

    end
end

%end CheckPrms function

```

- The `ProcessParameters` and `PostPropagationSetup` methods handle the S-function parameter tuning.

```

function ProcessPrms(block)

%% Update run time parameters
block.AutoUpdateRuntimePrms;

%end ProcessPrms function

function DoPostPropSetup(block)

%% Register all tunable parameters as runtime parameters.
block.AutoRegRuntimePrms;

%end DoPostPropSetup function

```

- The `Outputs` method calculates the block's output based on the S-function parameter settings and any input signals.

```
function Outputs(block)

lowMode    = block.DialogPrm(1).Data;
upMode     = block.DialogPrm(3).Data;
sigVal     = block.InputPort(1).Data;
lowPortNum = 2; % Initialize potential input number for lower saturation limit

% Check upper saturation limit
if isequal(upMode,2), % Set via a block parameter
    upVal = block.RuntimePrm(2).Data;
elseif isequal(upMode,3), % Set via an input port
    upVal = block.InputPort(2).Data;
    lowPortNum = 3; % Move lower boundary down one port number
else
    upVal = inf;
end

% Check lower saturation limit
if isequal(lowMode,2), % Set via a block parameter
    lowVal = block.RuntimePrm(1).Data;
elseif isequal(lowMode,3), % Set via an input port
    lowVal = block.InputPort(lowPortNum).Data;
else
    lowVal = -inf;
end

% Assign new value to signal
if sigVal > upVal,
    sigVal = upVal;
elseif sigVal < lowVal,
    sigVal=lowVal;
end

block.OutputPort(1).Data = sigVal;

%end Outputs function
```

Placing Custom Blocks in a Library

Libraries allow you to share your custom blocks with other users, easily update the functionality of copies of the custom block, and collect blocks for a particular project into a single location. This example places the custom saturation block into a library.

- 1 In the Simulink Library Browser, select **File > New > Library**.
- 2 From the User-Defined Functions library, drag a Level-2 MATLAB S-Function block into your new library.

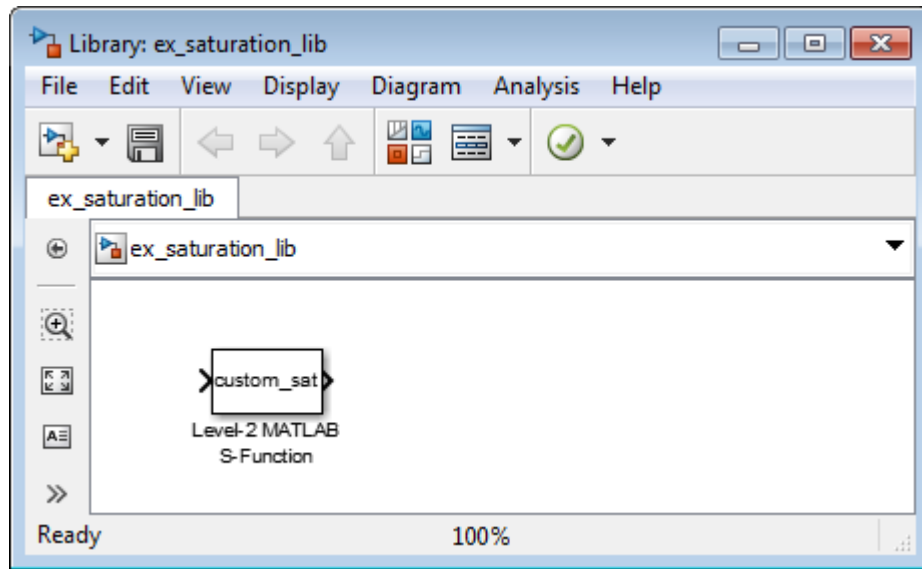

- 3 Save your library with the filename `saturation_lib`.
- 4 Double-click the block to open its Function Block Parameters dialog box.
- 5 In the **S-function name** field, enter the name of the S-function. For example, enter `custom_sat`. In the **Parameters** field enter `2, -1, 2, 1`.

- 6 Click **OK**.

You have created a custom saturation block that you can share with other users.

You can make the block easier to use by adding a customized user interface.

Adding a User Interface to a Custom Block

You can create a block dialog box for a custom block using the masking features of Simulink. Masking the block also allows you to add port labels to indicate which ports corresponds to the input signal and the saturation limits.

- 1 Open the library `saturation_lib` that contains the custom block you created,
- 2 Right-click the Level-2 MATLAB S-Function block and select **Mask > Create Mask**.
- 3 On the **Icon & Ports** pane in the **Icons drawing commands** box, enter `port_label('input', 1, 'uSig')`, and then click **Apply**.

This command labels the default port as the input signal under saturation.

- 4 In the **Parameters & Dialog** pane, add four parameters corresponding to the four S-Function parameters. For each new parameter, drag a popup or edit control to the **Dialog box** section, as shown in the table. Drag each parameter into the Parameters group.

Type	Prompt	Name	Evaluate	Tunable	Popup options	Callback
popup	Upper boundary	upMode	✓		No limit Enter limit as parameter Limit using input signal	customsat_callback('upperbound_callback')
edit	Upper limit:	upVal	✓	✓	N/A	customsat_callback('upperparam_callback')

Type	Prompt	Name	Evaluate	Tunable	Popup options	Callback
popup	Lower boundary	lowMode	✓		No limit	customsat_callback('lowerbound_callback')

Type	Prompt	Name	Evaluate	Tunable	Popup options	Callback
					Enter limit as parameter	
					Limit using input signal	
edit	Lower limit:	lowVal	✓	✓	N/A	customsat_callback('lowerparam_callback')

The MATLAB S-Function script `custom_sat_final.m` contains the mask parameter callbacks. Save `custom_sat_final.m` to your working folder to define the callbacks in this example. This MATLAB script has two input arguments. The first input argument is a character vector indicating which mask parameter invoked the callback. The second input argument is the handle to the associated Level-2 MATLAB S-Function block.

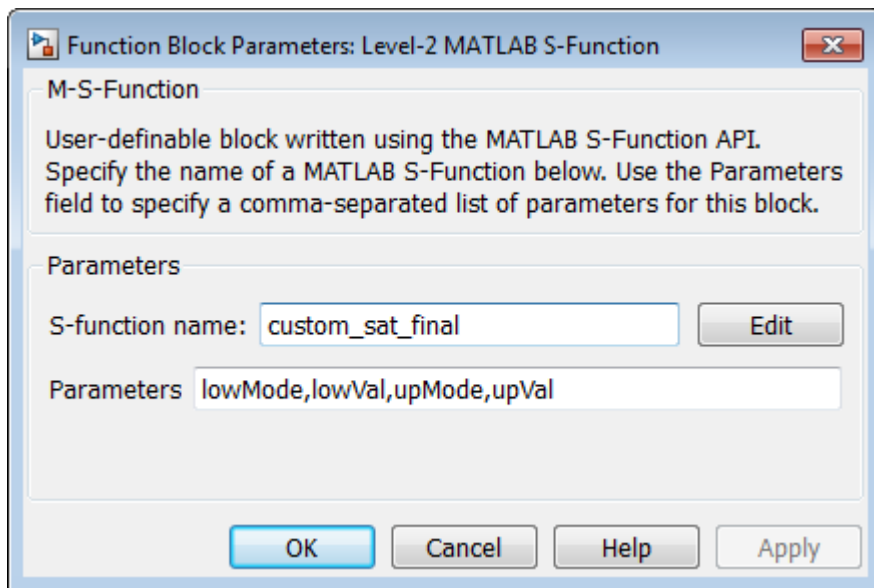

The figure shows the completed **Parameters & Dialog** pane in the Mask Editor.

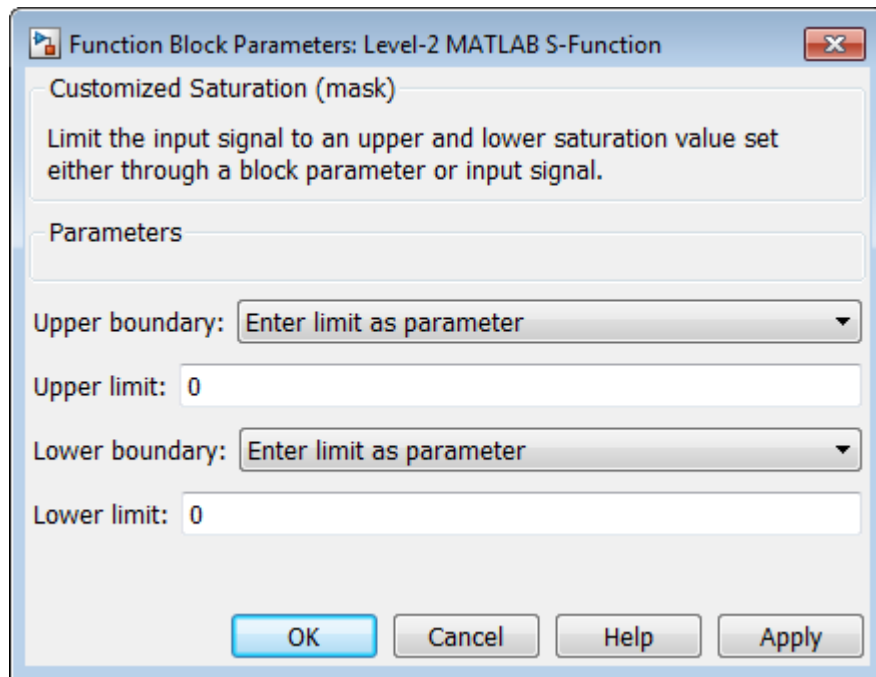

- 5 In the **Initialization** pane, select the **Allow library block to modify its contents** check box. This setting allows the S-function to change the number of ports on the block.
- 6 In the **Documentation** pane:
 - In the **Mask type** field, enter
Customized Saturation
 - In the **Mask description** field, enter
Limit the input signal to an upper and lower saturation value set either through a block parameter or input signal.

- 7 Click **OK**.
- 8 To map the S-function parameters to the mask parameters, right-click the Level-2 MATLAB S-Function block and select **Mask > Look Under Mask**.
- 9 Change the **S-function name** field to `custom_sat_final` and the **Parameters** field to `lowMode,lowVal,upMode,upVal`.

The figure shows the Function Block Parameters dialog box after the changes.

- 10 Click **OK**. Save and close the library to exit the edit mode.
- 11 Reopen the library and double-click the customized saturation block to open the masked parameter dialog box.

To create a more complicated user interface, place a MATLAB graphics user interface on top of the masked block. The block `OpenFcn` invokes the MATLAB graphics user interface, which uses calls to `set_param` to modify the S-function block parameters based on settings in the user interface.

Writing the Mask Callback

The function `customsat_callback.m` contains the mask callback code for the custom saturation block mask parameter dialog box. This function invokes local functions corresponding to each mask parameter through a call to `feval`.

The following local function controls the visibility of the upper saturation limit's field based on the selection for the upper saturation limit's mode. The callback begins by obtaining values for all mask parameters using a call to `get_param` with the property name `MaskValues`. If the callback needed the value of only one mask parameter, it could call `get_param` with the specific mask parameter name, for example, `get_param(block, 'upMode')`. Because this example needs two of the mask parameter values, it uses the `MaskValues` property to reduce the calls to `get_param`.

The callback then obtains the visibilities of the mask parameters using a call to `get_param` with the property name `MaskVisibilities`. This call returns a cell array of character vectors indicating the visibility of each mask parameter. The callback alters the values for the mask visibilities based on the selection for the upper saturation limit's mode and then updates the port label text.

The callback finally uses the `set_param` command to update the block's `MaskDisplay` property to label the block's input ports.

```
function customsat_callback(action,block)
% CUSTOMSAT_CALLBACK contains callbacks for custom saturation block

% Copyright 2003-2007 The MathWorks, Inc.

%% Use function handle to call appropriate callback
feval(action,block)

%% Upper bound callback
function upperbound_callback(block)

vals = get_param(block,'MaskValues');
vis = get_param(block,'MaskVisibilities');
portStr = {'port_label(''input'',1,'uSig')'};
switch vals{1}
    case 'No limit'
        set_param(block,'MaskVisibilities',[vis(1);{'off'};vis(3:4)]);
    case 'Enter limit as parameter'
        set_param(block,'MaskVisibilities',[vis(1);{'on'};vis(3:4)]);
    case 'Limit using input signal'
        set_param(block,'MaskVisibilities',[vis(1);{'off'};vis(3:4)]);
        portStr = [portStr;{'port_label(''input'',2,'up')'}];
end
if strcmp(vals{3},'Limit using input signal'),
    portStr = [portStr;{'port_label(''input'',',num2str(length(portStr)+1), ...
        ','low')'}]];
end
set_param(block,'MaskDisplay',char(portStr));
```

The final call to `set_param` invokes the `setup` function in the MATLAB S-function `custom_sat.m`. Therefore, the `setup` function can be modified to set the number of input ports based on the mask parameter values instead of on the S-function parameter values. This change to the `setup` function keeps the number of ports on the Level-2 MATLAB S-Function block consistent with the values shown in the mask parameter dialog box.

The modified MATLAB S-function `custom_sat_final.m` contains the following new `setup` function. If you are stepping through this tutorial, open the file and save it to your working folder.

```
%% Function: setup =====
```

```

function setup(block)

% Register original number of ports based on settings in Mask Dialog
ud = getPortVisibility(block);
numInPorts = 1 + isequal(ud(1),3) + isequal(ud(2),3);

block.NumInputPorts = numInPorts;
block.NumOutputPorts = 1;

% Setup port properties to be inherited or dynamic
block.SetPreCompInpPortInfoToDynamic;
block.SetPreCompOutPortInfoToDynamic;

% Override input port properties
block.InputPort(1).DatatypeID = 0; % double
block.InputPort(1).Complexity = 'Real';

% Override output port properties
block.OutputPort(1).DatatypeID = 0; % double
block.OutputPort(1).Complexity = 'Real';

% Register parameters. In order:
% -- If the upper bound is off (1) or on and set via a block parameter (2)
%    or input signal (3)
% -- The upper limit value. Should be empty if the upper limit is off or
%    set via an input signal
% -- If the lower bound is off (1) or on and set via a block parameter (2)
%    or input signal (3)
% -- The lower limit value. Should be empty if the lower limit is off or
%    set via an input signal
block.NumDialogPrms = 4;
block.DialogPrmsTunable = {'Nontunable','Tunable','Nontunable','Tunable'};

% Register continuous sample times [0 offset]
block.SampleTimes = [0 0];

%% -----
%% Options
%% -----
% Specify if Accelerator should use TLC or call back into
% MATLAB script
block.SetAccelRunOnTLC(false);

%% -----
%% Register methods called during update diagram/compilation
%% -----

block.RegBlockMethod('CheckParameters', @CheckPrms);
block.RegBlockMethod('ProcessParameters', @ProcessPrms);
block.RegBlockMethod('PostPropagationSetup', @DoPostPropSetup);
block.RegBlockMethod('Outputs', @Outputs);
block.RegBlockMethod('Terminate', @Terminate);
%endfunction

```

The `getPortVisibility` local function in `custom_sat_final.m` uses the saturation limit modes to construct a flag that is passed back to the `setup` function. The `setup` function uses this flag to determine the necessary number of input ports.

```
%% Function: Get Port Visibilities =====
function ud = getPortVisibility(block)

ud = [0 0];

vals = get_param(block.BlockHandle, 'MaskValues');
switch vals{1}
    case 'No limit'
        ud(2) = 1;
    case 'Enter limit as parameter'
        ud(2) = 2;
    case 'Limit using input signal'
        ud(2) = 3;
end

switch vals{3}
    case 'No limit'
        ud(1) = 1;
    case 'Enter limit as parameter'
        ud(1) = 2;
    case 'Limit using input signal'
        ud(1) = 3;
end
```

Adding Block Functionality Using Block Callbacks

The User-Defined Saturation with Plotting block in `customsat_lib` uses block callbacks to add functionality to the original custom saturation block. This block provides an option to plot the saturation limits when the simulation ends. The following steps show how to modify the original custom saturation block to create this new block.

- 1 Add a check box to the mask parameter dialog box to toggle the plotting option on and off.
 - a Right-click the Level-2 MATLAB S-Function block in `saturation_lib` and select **Mask+Create Mask**.
 - b On the Mask Editor **Parameters** pane, add a fifth mask parameter with the following properties.

Prompt	Name	Type	Tunable	Type options	Callback
Plot saturation limits	plotche	checkbox	No	NA	customsat_callback('plotsaturation

- c Click **OK**.

- 2 Write a callback for the new check box. The callback initializes a structure to store the saturation limit values during simulation in the Level-2 MATLAB S-Function block `UserData`. The MATLAB script `customsat_plotcallback.m` contains this new callback, as well as modified versions of the previous callbacks to handle the new mask parameter. If you are following through this example, open `customsat_plotcallback.m` and copy its local functions over the previous local functions in `customsat_callback.m`.

```

%% Plotting checkbox callback
function plotsaturation(block)

% Reinitialize the block's userdata
vals = get_param(block, 'MaskValues');
ud = struct('time', [], 'upBound', [], 'upVal', [], 'lowBound', [], 'lowVal', []);

if strcmp(vals{1}, 'No limit'),
    ud.upBound = 'off';
else
    ud.upBound = 'on';
end

if strcmp(vals{3}, 'No limit'),
    ud.lowBound = 'off';
else
    ud.lowBound = 'on';
end

set_param(gcb, 'UserData', ud);

```

- 3** Update the MATLAB S-function `Outputs` method to store the saturation limits, if applicable, as done in the new MATLAB S-function `custom_sat_plot.m`. If you are following through this example, copy the `Outputs` method in `custom_sat_plot.m` over the original `Outputs` method in `custom_sat_final.m`

```

%% Function: Outputs =====
function Outputs(block)

lowMode    = block.DialogPrm(1).Data;
upMode     = block.DialogPrm(3).Data;
sigVal     = block.InputPort(1).Data;
vals = get_param(block.BlockHandle, 'MaskValues');
plotFlag = vals{5};
lowPortNum = 2;

% Check upper saturation limit
if isequal(upMode, 2)
    upVal = block.RuntimePrm(2).Data;
elseif isequal(upMode, 3)
    upVal = block.InputPort(2).Data;
    lowPortNum = 3; % Move lower boundary down one port number
else
    upVal = inf;
end

% Check lower saturation limit
if isequal(lowMode, 2),
    lowVal = block.RuntimePrm(1).Data;
elseif isequal(lowMode, 3)
    lowVal = block.InputPort(lowPortNum).Data;
else
    lowVal = -inf;
end

```

```

% Use userdata to store limits, if plotFlag is on
if strcmp(plotFlag,'on');
    ud = get_param(block.BlockHandle,'UserData');
    ud.lowVal = [ud.lowVal;lowVal];
    ud.upVal = [ud.upVal;upVal];
    ud.time = [ud.time;block.CurrentTime];
    set_param(block.BlockHandle,'UserData',ud)
end

% Assign new value to signal
if sigVal > upVal,
    sigVal = upVal;
elseif sigVal < lowVal,
    sigVal=lowVal;
end

block.OutputPort(1).Data = sigVal;

%endfunction

```

- 4** Write the function `plotsat.m` to plot the saturation limits. This function takes the handle to the Level-2 MATLAB S-Function block and uses this handle to retrieve the block's `UserData`. If you are following through this tutorial, save `plotsat.m` to your working folder.

```

function plotSat(block)

% PLOTSAT contains the plotting routine for custom_sat_plot
% This routine is called by the S-function block's StopFcn.

ud = get_param(block,'UserData');
fig=[];
if ~isempty(ud.time)
    if strcmp(ud.upBound,'on')
        fig = figure;
        plot(ud.time,ud.upVal,'r');
        hold on
    end
    if strcmp(ud.lowBound,'on')
        if isempty(fig),
            fig = figure;
        end
        plot(ud.time,ud.lowVal,'b');
    end
    if ~isempty(fig)
        title('Upper bound in red. Lower bound in blue.')
    end

% Reinitialize userdata
ud.upVal=[];
ud.lowVal=[];
ud.time = [];
set_param(block,'UserData',ud);
end

```

- 5 Right-click the Level-2 MATLAB S-Function block and select **Properties**. The Block Properties dialog box opens. On the **Callbacks** pane, modify the **StopFcn** to call the plotting callback as shown in the following figure, then click **OK**.

Creating Custom Blocks from Masked Library Blocks

The Additional Math and Discrete Simulink library is a group of custom blocks created by extending the functionality of built-in Simulink blocks. The Additional Discrete library contains a number of masked blocks that extend the functionality of the standard Unit Delay block. See “Libraries” for more general information on Simulink libraries.

Creating Custom Blocks from MATLAB Functions

The Simulink product provides a number of examples that show how to incorporate MATLAB functions into a custom block.

- The Single Hydraulic Cylinder Simulation, `sldemo_hydcyl`, uses a Fcn block to model the control valve flow. In addition, the Control Valve Flow block is a library link to one of a number of custom blocks in the library `hydlib`.
- The Radar Tracking Model, `sldemo_radar`, uses an Interpreted MATLAB Function block to model an extended Kalman filter. The MATLAB function `aero_extkalman.m` implements the Kalman filter found inside the Radar Kalman Filter subsystem. In this example, the MATLAB function requires three inputs, which are bundled together using a Mux block in the Simulink model.
- The Spiral Galaxy Formation example, `sldemo_eml_galaxy`, uses several MATLAB Function blocks to construct two galaxies and calculate the effects of gravity as these two galaxies nearly collide. The example also uses MATLAB Function blocks to plot the simulation results using a subset of MATLAB functions not supported for code generation. However, because these MATLAB Function blocks have no outputs, the Simulink Coder product optimizes them away during code generation.

Creating Custom Blocks from System Objects

The Simulink product provides a number of examples that show how to incorporate System objects into a custom block. Access the MATLAB source code for each System object by clicking the **Source code** link from the block dialog box. For more information on using MATLAB System blocks and System objects, see “System Object Integration”).

- System Identification for an FIR System Using MATLAB System Blocks, `slexSysIdentMATLABSystemExample`, uses the MATLAB System block to implement Simulink blocks using a System object. It highlights two MATLAB System blocks.
- MATLAB System Block with Variable-Size Input and Output Signals, `slexVarSizeMATLABSystemExample`, uses the MATLAB System block to implement Simulink blocks with variable-size input and output signals. Due to the use of variable-size signals, the example uses System object propagation methods.
- Illustration of Law of Large Numbers Using MATLAB System Blocks, `slexLawOfLargeNumbersExample`, uses MATLAB System blocks to illustrate the law of large numbers. Due to the use of MATLAB functions not supported for code generation, the example uses System object propagation methods and interpreted execution.

Creating Custom Blocks from S-Functions

The Simulink model `sfundemos` contains various examples of MATLAB and C MEX S-functions. For more information on writing MATLAB S-functions, see “Write Level-2 MATLAB S-Functions”. For more information on writing C MEX S-functions, see “C/C++ S-Functions”. For a list of available S-function examples, see “S-Function Examples” in Writing S-Functions.

Custom Libraries and Linked Blocks

Why Create Custom Libraries?

A *block library* is a collection of blocks that you can use to create instances of those blocks in a Simulink model. You can create instances of blocks from installed Simulink libraries, and you can create custom libraries to create and maintain instances of your own blocks in models.

You can access the installed libraries from the Simulink Library Browser. You cannot modify the installed libraries. Instead, if you want others to be able to create customized blocks, you can create your own library of your blocks and add it to the Library Browser. Otherwise, you can make your library accessible to the models that use it.

Creating your own libraries is a useful componentization technique for:

- Providing frequently used, and seldom changed, modeling utilities
- Reusing components in a model or in multiple models

To learn how using custom libraries compares to other Simulink componentization techniques, see “Componentization Guidelines” on page 15-29.

How Block Instances Connect to Libraries

When you add masked blocks, subsystems, or charts from a custom library to a model, the block you add becomes a *linked block*. A linked block connects to the library block by way of a *library link*. The library block is the *prototype block*, and the linked block in the model is an *instance* of the library block.

The linked block looks and acts like the library block. However, if you change the library block, you need to update the link on the instances. Making changes to an instance can also require additional steps. To learn about how linked blocks work, see “Linked Blocks” on page 38-14.

Create a Custom Library

In this section...

- “Create a Library” on page 38-3
- “Blocks for Custom Libraries” on page 38-4
- “Annotations in Custom Libraries” on page 38-6
- “Lock and Unlock Libraries” on page 38-7
- “Prevent Disabling of Library Links” on page 38-7

Create a Library

You can create your own library and, optionally, add it to the Simulink Library Browser. You save a library as a .SLX file as you do a model. However, you cannot simulate in a library, and a library becomes locked for editing each time you close it. You must unlock a library before you make changes to it. See “Lock and Unlock Libraries” on page 38-7.

- 1 From the Simulink start page, select **Blank Library** and click **Create Library**.
- 2 Add blocks from models or libraries to the new library. Make the changes you want to the blocks, such as changing block parameters, adding masks, or adding blocks to subsystems.

Subsystem names in a library hierarchy must be unique. For example, do not create a hierarchy such as `Subsystem_Name1/Subsystem_Name2/Subsystem_Name1`.

- 3 Add annotations or images. Right-click the ones you want to appear in the library in the Library Browser and select **Show in Library Browser**.
- 4 If you plan to add the library to the Library Browser, you can order the blocks and annotations in your library model. By default, they appear alphabetically in the Library Browser, with subsystems first, then blocks, and then annotations. The user of your library can use the Library Browser context menu to choose between viewing them in alphabetical order or the order you specified. When the user selects this option, the order in which they appear in your library model determines the order they appear on the grid in the library in the Library Browser.
- 5 If you want the library to appear in the Library Browser, enable the model property `EnableLBRepository` before you save the library.

```
set_param(gcs, 'EnableLBRepository', 'on');
```

6 Save the library.

Where you save the library depends on how you plan to use it. If you want to add it to the Library Browser, save it to a folder on the MATLAB path or add the location to the MATLAB path. Otherwise, save it to a location where the models that use the blocks can access it.

If you want the library to appear in the Library Browser, you must also create a function `slblocks` on your MATLAB path that adds the library to the browser. For an example that shows complete steps for adding a library to the browser, see “Add Libraries to the Library Browser” on page 38-9.

Blocks for Custom Libraries

Your library can contain the blocks you need, configured for your purposes. Subsystems, masked blocks, and charts in your library become linked blocks as instances in the model and stay updated if you change them in your library. Knowing about custom blocks is also useful when you create a library. See “Types of Custom Blocks” on page 37-2.

You can create blocks in custom libraries with settings for specific purposes.

Create a Sublibrary

If your library contains many blocks, you can group the blocks into subsystems or separate sublibraries. To create a sublibrary, you create a library of the sublibrary blocks and reference the library from a Subsystem block in the parent library.

- 1 In the library you want to add a sublibrary to, add a Subsystem block.
- 2 Inside the Subsystem block, delete the default input and output ports.
- 3 If you want, create a mask for the subsystem that displays text or an image that conveys the sublibrary’s purpose.
- 4 In the subsystem’s block properties, set the `OpenFcn` callback to the name of the library you want to reference.

To learn more about masks, see “Create a Simple Mask” on page 36-7.

Prevent Library Block from Linking to Instance

You can configure a library block so the instances created from it are not linked blocks and are instead copies. Set the block’s `CopyFcn` callback.

```
set_param(gcbh, 'LinkStatus', 'none');
```

Include Block Description in Linked Block

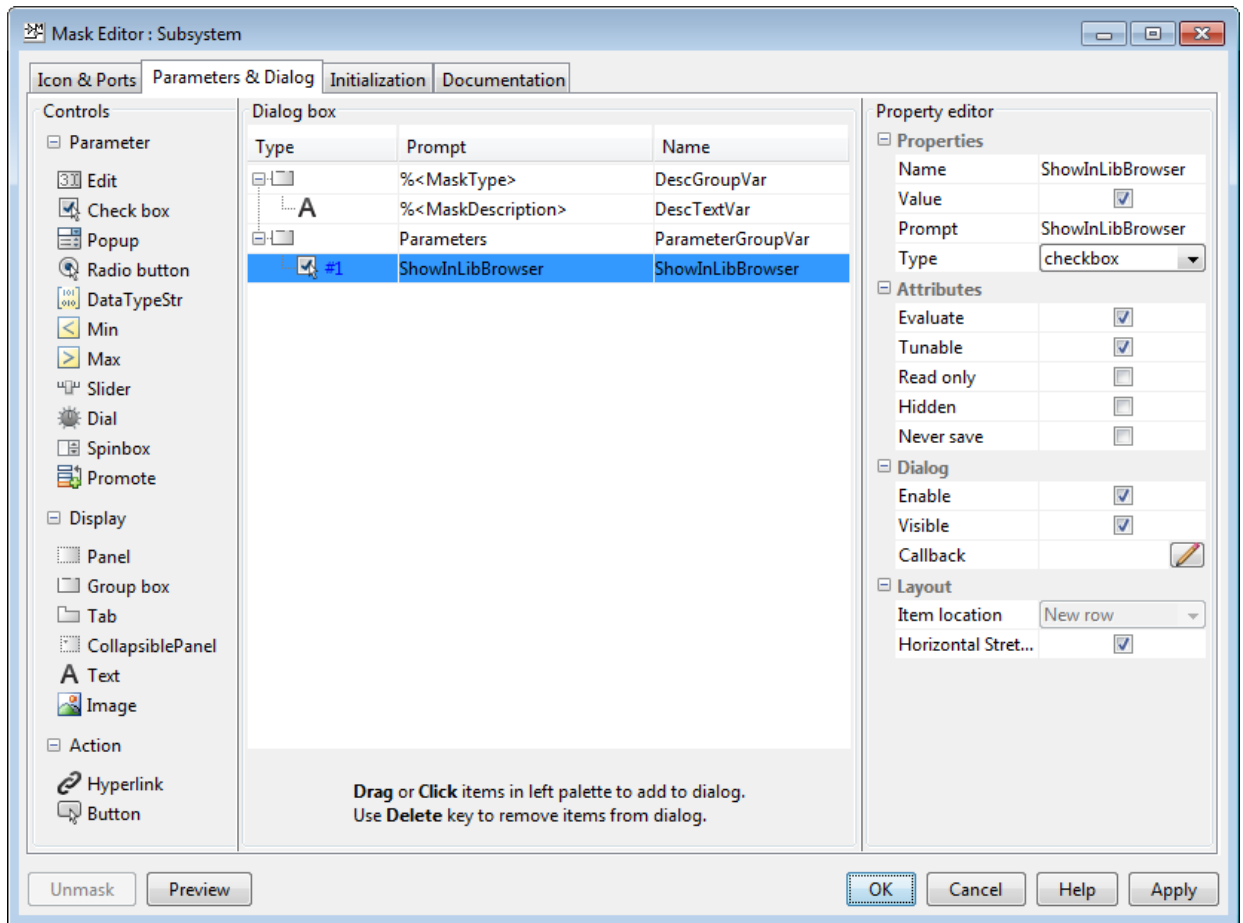

To add a description that appears in the linked block, mask the library block and add the description in the **Documentation** pane of the mask. Descriptions added to the library block through the block's properties do not appear on the linked block.

Configure Subsystems with OpenFcn Callback for Library Browser

A common use of a Subsystem block in a custom library is to set the **OpenFcn** callback property to open a library, creating a library hierarchy. However, you can use the **OpenFcn** callback property of a Subsystem block for other purposes, for example to run MATLAB code or to open a link.

If your subsystem block in a library is empty and its **OpenFcn** callback contains code that performs an action other than point to a library or model, then you need to add a `'ShowInLibBrowser'` mask parameter to the subsystem to have it appear in the Library Browser.

- 1** Right-click the subsystem and select **Mask > Create Mask**. If the block already has a mask, select **Edit Mask** instead.
- 2** In the Mask Editor **Parameters & Dialog** tab, on the **Controls** pane, click **Check box**.
- 3** In the **Dialog box** pane, set the prompt and name for the new check box to `ShowInLibBrowser` and click **OK**.

Annotations in Custom Libraries

You can add annotations in your custom library and optionally have them appear in the Library Browser. For example, you can add an annotation that documents the library. You can also add annotations that the user of your library can add to their model from the Library Browser. Annotations can contain text and images or display an equation. Annotations can also perform an action when clicked. Learn more about annotations in “Describe Models Using Annotations” on page 4-13.

You can add callout lines from annotations to blocks in your library. However, the callouts do not appear in the Library Browser.

If you want the annotation to appear in the Library Browser, after you add it to your library, right-click it and select **Show in Library Browser**. If you want a description to appear in a tooltip when the user hovers over the annotation in the Library Browser, add the description to the annotation programmatically. At the MATLAB command prompt, enter:

```
set_param(annotationHandle,'Description','descriptionText')
```

To get the annotation handle, use `find_system`. This example gets all the annotations in the library `mylib`:

```
ann = find_system('mylib','FindAll','on','Type','annotation');
```

To get a specific annotation, turn on regular expression search and specify part of the annotation text with the `'Name'` argument:

```
ann = find_system('mylib2','FindAll','on','RegExp','on','Type','annotation',...
'Name','matchingText');
```

“Add Libraries to the Library Browser” on page 38-9 includes instructions for adding an annotation that appears in the Library Browser.

Lock and Unlock Libraries

When you close a library, it becomes locked for editing. When you next open it, unlock it if you want to make changes to it. Click the lock badge in the lower-left corner of the library to unlock it. Additionally, if you try to modify a locked library, a message prompts you to unlock it.

You can unlock a library programmatically. At the MATLAB command prompt, enter:

```
set_param('library_name','Lock','off');
```

To lock the library programmatically, enter:

```
set_param('library_name','Lock','on');
```

Prevent Disabling of Library Links

By default, a user of the blocks in your library can disable the link to library blocks. If you want to control editing of linked blocks and prevent the block user from disabling

links, you can lock links to your library. Locking library links prevents the user from making any changes to the block instances.

- In your library, select **Diagram > Lock Links To Library**.

To understand how the block user interacts with blocks from locked libraries, see “Lock Links to Blocks in a Library” on page 38-24.

- “Linked Blocks” on page 38-14
- “Customize Library Browser Appearance” on page 65-23

Add Libraries to the Library Browser

This example shows how to create a block library and add it to the Simulink Library Browser. You also add an annotation to the library that appears in the Library Browser.

You create a function `sliblocks` to specify information about your library. You can save the function as a `.m` or `.mlx` file. You cannot save it as a P-code file.

- 1 From the Simulink start page, select **Blank Library** and click **Create Library**.
- 2 Add a Gain block and two Subsystem blocks to the library. Name the Subsystem blocks Subsystem1 and Subsystem2. In the Subsystem2 properties, set the `OpenFcn` callback to `mylib2`.

- 3 At the MATLAB command prompt, enter this command to enable the model property `EnableLBRepository`. Your library can appear in the browser only if this property is on when you save your library.

```
set_param(gcs, 'EnableLBRepository', 'on');
```

- 4 Save the library in a folder on the MATLAB path. For this example, name the library `mylib`.
- 5 Create another library `mylib2` and add some blocks and an annotation that contains the text `My annotation`. Right-click the annotation and select **Show in Library Browser**.
- 6 Add a description for the annotation. The description appears in the Library Browser when you hover over the annotation. You can do this programmatically using `set_param`. Use `find_system` to get the annotation handle. Use part of your annotation text with the `'Name'` argument. The `'RegExp'` argument enables partial matches.

```
ann = find_system('mylib2', 'findall', 'on', 'RegExp', 'on', 'Type', 'annotation', ...  
'Name', 'annotation');  
set_param(ann, 'Description', 'Use this annotation to label the model.');
```

- 7 Save `mylib2` to the same folder you saved `mylib` to.

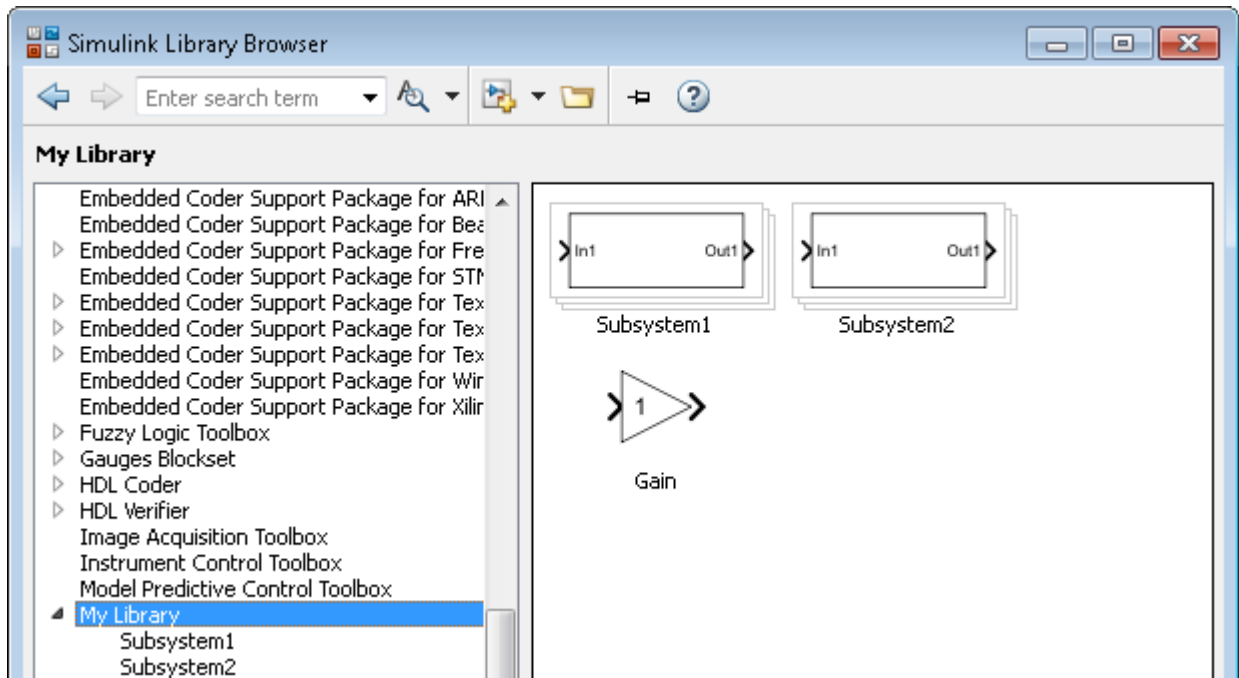

You can close both libraries if you want.

- 8 In MATLAB, right-click the folder you saved the library to and select **New File > Script**. Name the file `slblocks.m`.
- 9 Open `slblocks.m`. Add this function to it and save.

```
function blkStruct = slblocks  
    % This function specifies that the library should appear  
    % in the Library Browser  
    % and be cached in the browser repository  
  
    Browser.Library = 'mylib';  
    % 'mylib' is the name of the library  
  
    Browser.Name = 'My Library';  
    % 'My Library' is the library name that appears in the Library Browser  
  
    blkStruct.Browser = Browser;
```

- 10 In the Library Browser, refresh to see the new library. Right-click the library list and select **Refresh Library Browser**.

The figure shows the example library `mylib` with the Library Browser name **My Library**.

Because of the callback you created, clicking Subsystem2 displays the contents of the `mylib2` library. Hovering over the annotation in the Library Browser displays the description.

Note: If you saved your library without setting 'EnableLBRepository' to 'on', a message appears at the top of the Library Browser.

Click **Fix** and respond to the prompt as appropriate.

Specify Library Order in the Library List

You can specify the order of your library relative to the other libraries in the list by adding a `sl_customization.m` file to the MATLAB path and setting the sort priority of your library. For example, to see your library at the top of the list, you can set the sort priority to `-2`. By default, the sort priority of the Simulink library is `-1`. The other libraries have a sort priority of `0` by default, and these libraries appear below the Simulink library. Libraries with the same sort priority appear in alphabetical order.

This sample content of the `sl_customization.m` file places the new library at the top of the list of libraries.

```
function sl_customization(cm)
% Change the order of libraries in the Simulink Library Browser.
cm.LibraryBrowserCustomizer.applyOrder({'My Library',-2});
end
```

To make the customization take effect immediately, at the command prompt, enter:

```
sl_refresh_customizations
```

Linked Blocks

In this section...

- “Rules for Linked Blocks” on page 38-15
- “Parameterized Links” on page 38-16
- “Self-Modifiable Linked Subsystems” on page 38-19

A linked block is a referenced instance of a library block. A linked block contains a link (or path) to the corresponding library block. The link allows the block to update when the corresponding library block is updated.

You create a linked block by adding a library block with any of these conditions to a Simulink model:

- The reference library block is masked.
- The referenced library block is an unmasked Subsystem block that contains child blocks within itself.

To create a linked block, you can use the library blocks available in the Simulink Library Browser or from a user-defined library.

To locate the parent library block of a linked block, right-click the linked block and select **Library Link > Go To Library Link**.

Note:

- The **Go To Library Link** option is available only for the library blocks that are linked blocks and not for the Simulink built-in library blocks.
- The tooltip for a linked block shows the name of the referenced masked library block.

When you edit a library block (either in Simulink Editor or at the command line), the outdated links on the linked blocks are grayed out. Simulink refreshes or updates any outdated links to edited blocks when you activate the Simulink Editor windows, even if you do not save the library.

Simulink updates the outdated linked blocks in a model or library when you:

- Load the model or library.
- Simulate or update the model.
- Use the `find_system` command.
- Use `get_param` to query the link status of the block (see “Control Linked Block Programmatically” on page 38-31).

Note: The `LinkStatus` parameter updates the linked block while the `StaticLinkStatus` parameter returns the link status without updating the linked block.

To update the links manually, you can use these commands:

- **Simulation > Update Diagram (or press Ctrl+D)**
- **Diagram > Refresh Blocks (or press Ctrl+K)**

Rules for Linked Blocks

- You can change the values of a linked block parameter (including the existing mask).

Note: The **Allow library block to modify its contents** check box in the **Initialization** pane of the library block must be selected.

- You cannot set callback parameters for a linked block.
- If the reference library block of a linked block is a subsystem, you can make nonstructural changes such as changing the parameter value of the linked subsystem. To make structural changes to a linked block, disable the link of the linked block from its library block (See “Disable or Break Links to Library Blocks” on page 38-22).

Parameterized Links

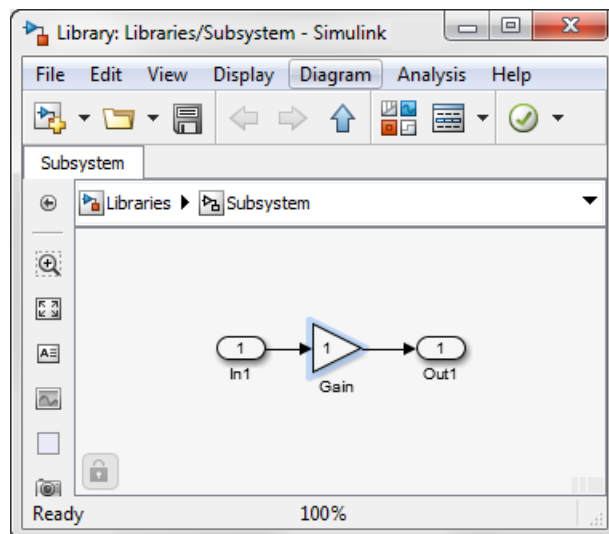

A parameterized link is created when you change the parameter values of the child blocks of a masked subsystem linked block. Such parameter value changes can only be applied through the MATLAB command prompt.

A parameterized link in a linked block allows you to have a parameter value that is different from the parent library block and yet retain the links to its parent library block.

Note: Changing the mask value of a parent library block does not create a parameterized link.

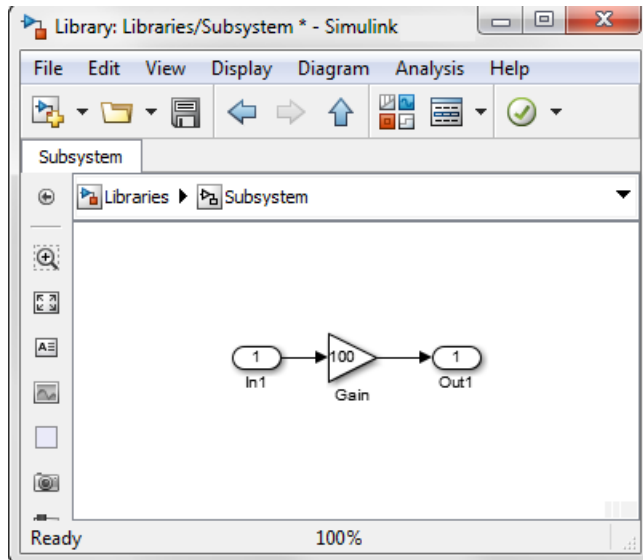

For example, you can use the `set_param` command to set a parameter value in the child blocks of a linked subsystem block. The `set_param` command overrides the parameter values of the child blocks of the subsystem linked link and thus creating a parameterized link.

Consider a masked subsystem linked block (see, Simple Linked Block) that contains a Gain block with its parameter value as 1.

Simple Linked Block

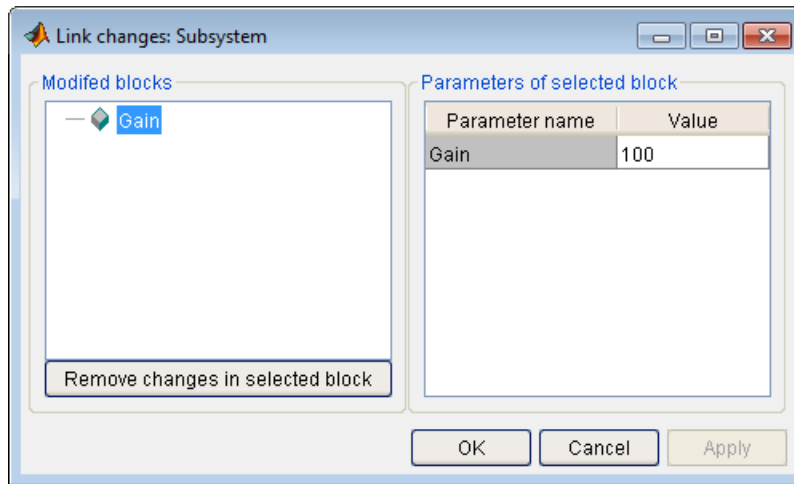

To change the Gain parameter value of this block to 100, type `set_param(ModelName, 'Gain', '100')` at the MATLAB command prompt. A parameterized link is now created, overriding the parameter value (see, Parameterized Linked Block).

Parameterized Linked Block

When you save a model containing a parameterized link, Simulink saves the changes to a local copy of the subsystem with the path to the parent library. When you reopen the model, Simulink copies the library block into the loaded model and applies the saved changes.

Note: To view the parameterized changes on a block, right-click the block, and on the context menu, select **View Changes**. The **Link changes** dialog box opens displaying the list of modified blocks. You can also use this dialog box to remove parameterized changes from a block.

Identifying Parameterized Links

A parameterized link displays these identifications:

- The link badge of a parameterized link contains a black link with a red star icon, . For more information, “Display Library Links” on page 38-20.
- The tooltip of a parameterized linked block displays **Modified parameter in link**.

- Block dialog box of a linked Subsystem block contains parameterized link.

Self-Modifiable Linked Subsystems

Tip We recommend using variant blocks over self-modifiable linked subsystems.

A self-modifiable linked subsystem is a linked block with the ability to have structural changes in the subsystem without disabling the link. A self-modifiable linked subsystem when you use a library block containing a self-modifiable mask as a linked block.

Self-modifiable linked subsystem allows you to create masked subsystems that modify their structural contents based on mask parameter dialog box values. It uses the mask initialization code to change the structural contents.

For more information, see “Dynamic Masked Subsystem” on page 36-55 and Self-Modifiable Mask.

More About

- “Display Library Links” on page 38-20
- “Control Linked Block Programmatically” on page 38-31
- “Custom Libraries and Linked Blocks” on page 38-2

Display Library Links

Each linked block has a link badge associated with it. The badge makes it easier to identify the linked block in a model and also displays its link status.

To control the display of library link badges in a Simulink model, click **Display > Library Links** and use these options:

- **None** — displays no links.
- **Disabled** — displays only disabled links (the default for new models).
- **User Defined** — displays only links to user libraries.
- **All** — displays all links.

If activated, link badges are displayed at the bottom left corner of a linked block. You can right-click the link badge to access link menu options.

The color and icon of the link badge indicates the status of the link.

Link Badge	Status
Black links 	Active link
Gray separated links 	Inactive link
Black links with a red star icon 	Active and modified (parameterized link)

Link Badge	Status
White links, black background 	Locked link

Note: If you have a variant subsystem block inside a linked block, modifying the parameters on the variant subsystem creates instance data on the topmost linked block. If the link badge is visible, the presence of instance data is indicated by the red star on the link badge.

“Linked Blocks” on page 38-14 | “Disable or Break Links to Library Blocks” on page 38-22 | “Restore Disabled or Parameterized Links” on page 38-26

Disable or Break Links to Library Blocks

Structural changes in a model include addition or deletion of blocks or adding ports while nonstructural changes are changes in parameter value.

A linked block does not allow structural changes to it. You can disable the link of a linked block from its parent library block and perform required modifications. A disabled linked block behaves like a local instance of a block and allows you to make structural and nonstructural changes.

To disable a link from the Model Editor, right-click the linked block and, on the context menu, click **Library Link > Disable Link**. Alternatively, select the linked block and click **Diagram > Library Link > Disable Link**

To prevent unintentional disabling of a linked block, you can lock its links to the library. To lock a link, on the library window, click **Diagram > Lock Links To Library**. You can later choose to unlock the locked link by selecting **Diagram > Unlock Links To Library** on the library window.

Note: Simulink offers to disable the library links (unless the link is locked) when you try to make structural changes to a block that contains active library links.

Do not use `set_param` to make structural changes to an active link. The result of this type of change is undefined.

A disabled link of a linked block can be restored. For more information, see “Restore Disabled or Parameterized Links” on page 38-26.

To break the link permanently, right-click the block that contains a disabled link, then select **Library Link > Break Link**. When you break a link, the linked block is converted to a standalone block.

To copy and break links to multiple blocks simultaneously, select multiple blocks and then drag. The locked links are ignored and not broken.

When you save the model, you can break links by supplying arguments to the `save_system` command. For more information, see `save_system`.

Some models can contain blocks from third-party libraries or optional Simulink blocksets. Breaking the link for such models does not guarantee that you can run the model

standalone. It is possible that a library block invokes functions supplied with the library and hence can run only if the library is installed on the system running the model.

Breaking a link can cause a model to fail when you install a new version of the library on a system. For example, if a model block invokes a function that is supplied from a library. If you break the link for such a block, the function can no longer be invoked from the model, causing simulation to fail. To avoid such problems, avoid breaking links to libraries.

“Linked Blocks” on page 38-14 | “Restore Disabled or Parameterized Links” on page 38-26

Lock Links to Blocks in a Library

You can lock links to a library. Lockable library links prevent unintentional disabling of these links. Lockable libraries ensure robust usage of mature stable libraries.

To lock links to a library, in the library window, click **Diagram > Lock Links To Library**. The linked block links to its parent library is now locked. When you refresh the Model Explorer, you see a change in the link badge. The locked link badges have a black background.

Locked linked block links cannot be disabled from the parent library block. Such links can only be disabled from the command line by changing the `LinkStatus` to `inactive`. For more information, see “Control Linked Block Programmatically” on page 38-31.

The context menu of a locked linked block displays **Locked Library Link** and not **Library Link**. Also notice that the only enabled option on this menu is **Go To Library Block**.

If you open a locked linked block, the window title displays **Locked Link: *blockname***. The bottom left corner shows a lock icon and a link badge.

To unlock links from the library window, select **Diagram > Unlock Links To Library**.

Rules for Locked Links

- Locked links cannot be edited. If you try to make a structural change to a locked link (such as editing the diagram), you see a message that you cannot modify the link because it is either locked or inside another locked link.
- The mask and block parameter dialogs are disabled for blocks inside locked links. For a resolved linked block with a mask, its parameter dialog is always disabled.
- You cannot parameterize locked links in the Model Editor.
- When you copy a block, the library status determines the status of a link (locked or not). If you copy a block from a library with locked links, the link is locked. If you later unlock the library links, any existing linked blocks do not change to unlocked links until you refresh the links.
- If you use sublibraries, when you lock links to a library, lock links to the sublibraries.

See Also

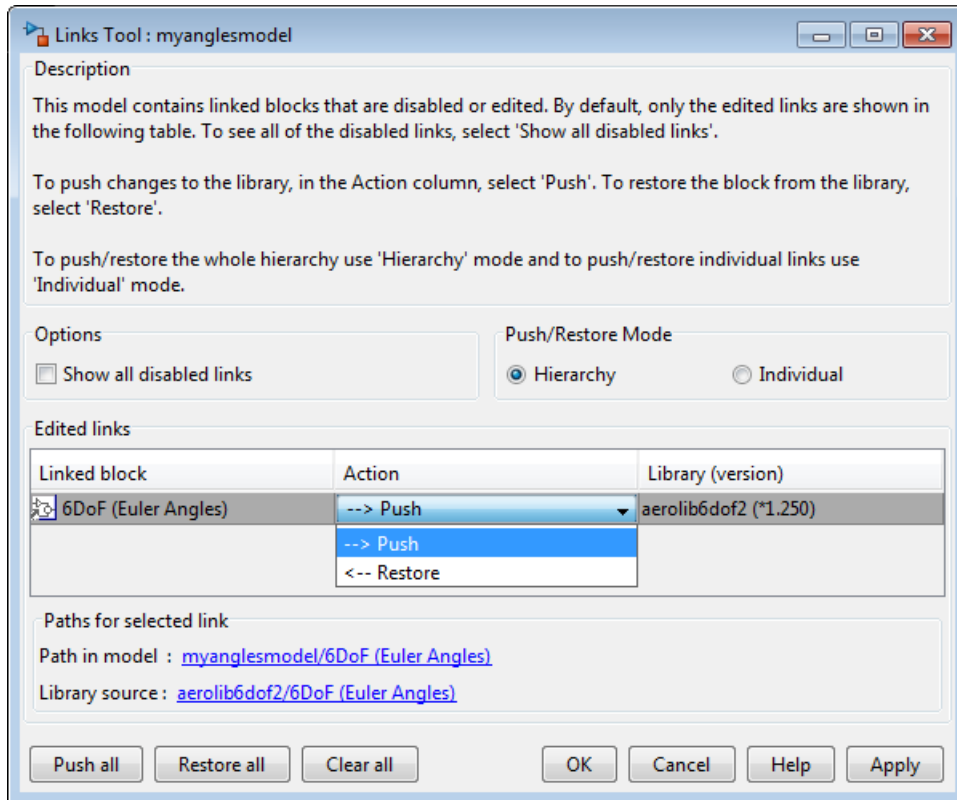

“Linked Blocks” on page 38-14 | “Restore Disabled or Parameterized Links” on page 38-26

Restore Disabled or Parameterized Links

You can restore disabled library links and resolve any differences between the linked block and its parent library block.

- 1 In the Model Editor window, right-click a disabled linked block, and on the context menu, select **Library Link > Resolve Link**.

The Links Tool window opens.

- 2 To view disabled links and the parameterized links, select **Show all disabled links** in the **Options** section.

- 3 To restore the links for an individual block or the whole hierarchy, select **Individual** or **Hierarchy** in the **Push/Restore Mode** section. For more information, see “Pushing or Restoring Link Hierarchies” on page 38-28.
- 4 The **Edited links** table has these columns:
 - **Linked block** — Displays the list of linked blocks that have disabled or parameterized links. Select a block to restore its links.
 - **Action** — Allows you to either push the linked block changes to the library or restore the linked block from the library.

Action Choice	Links Tool Action
Push	Replaces the version of the block in the library with the version in the model (linked block).
Restore	Replaces the version of the linked block in the model with the version in the library.
Push Individual	In the Individual mode, the disabled or edited block is pushed to the library, preserving the changes inside it without acting on the hierarchy. All other links are unaffected.
Restore Individual	In the Individual mode, the disabled or edited block is restored from the library, and all other links are unaffected.

To select the same action for all linked blocks, click **Push all**, **Restore all**, or **Clear all**.

- **Library** — Displays the library name and version number.
- 5 Click **OK** or **Apply** to complete the push or restore action. The version in the library and the linked block now match.

Note: Changes that you push to the library are not saved until you actively save the library.

If a linked block name has a cautionary icon , the model has other instances of this block linked from the same library block, and they have different changes. Choose one of the instances to push changes to the library block and restore links to the other blocks, or choose to restore all them with the library version.

Pushing or Restoring Link Hierarchies

Caution If you are using Push or Restore in the Hierarchy mode and you have a large hierarchy of edited and disabled links, ensure that you want to push or restore the whole hierarchy of links.

Pushing a hierarchy of disabled links affects the disabled links inside and outside the hierarchy for a given link. If you push changes from a disabled link in the middle of a hierarchy, the inside links are pushed and the outside links are restored if unchanged. This operation does not affect outer (parent) links with changes unless you also explicitly selected them for push. The Links Tool starts to push from the lowest inside links and then moves up in the hierarchy.

For examples:

- 1 Link A contains link B and both have changes.
 - Push A. The Links Tool pushes both A and B.
 - Push B. The Links Tool pushes B and not A.
- 2 Link A contains link B. A has no changes, and B has changes.
 - Push B. The Links Tool pushes B and restores A. When parent links are unmodified, they are restored.

If you have a hierarchy of parameterized links, the Links Tool can manipulate only the top level.

Tip To compare files and view structural changes, use **Analysis > Compare Simulink XML Files**.

Fix Unresolved Library Links

If Simulink is unable to find either the library block or the source library on your MATLAB path during linked block update, the link becomes unresolved. Simulink changes the appearance of these blocks.

If you double-click the unresolved block, the parameter dialog box displays an error similar to the following:

```
Failed to find 'source-block-name'  
in library 'source-library-name'  
referenced by  
"linked-block-path".
```

To fix an unresolved link, you can:

- Delete the unresolved block and copy the library block back into your model.
- Add the folder that contains the required library to the MATLAB path and select either **Simulation > Update Diagram** or **Diagram > Refresh Blocks**.
- Double-click the unresolved block to open its dialog box (see the **Unresolved Link** block reference page). On the dialog box that appears, correct the path name in the **Source block** field and click **OK**.

Control Linked Block Programmatically

Linked Block Information

Use the `libinfo` command to get information about the linked blocks in the model. `libinfo` also provides information about the parent library blocks of a linked block.

An example is as follows:

```
Block: 'tempModel/Subsystem1'%Linked block
      Library: 'temp'%Parent library block
ReferenceBlock: 'temp/Subsystem1'
LinkStatus: 'resolved' %Link status
```

The `ReferenceBlock` property gives the path of the library block to which a block links.

Lock Linked Blocks

Use the `LockLinksToLibrary` command to lock or unlock a linked block in a library from the command line. When you set the value of `LockLinksToLibrary` to `on`, the linked block links to the library are locked.

```
set_param('MyModelName', 'LockLinksToLibrary', 'on') %Lock links
set_param('MyModelName', 'LockLinksToLibrary', 'off') %Unlock links
```

Link Status

All blocks have a `LinkStatus` parameter and a `StaticLinkStatus` parameter that indicate whether the block is a linked block.

Use `get_param(gcb, 'StaticLinkStatus')` to query the link status without updating the linked blocks. You can use `StaticLinkStatus` to query the status of a linked block that either active or outdated.

Use `get_param` and `set_param` to query and set the `LinkStatus`, which can have these values.

Get LinkStatus Value	Description
none	Block is not a linked block.

Get LinkStatus Value	Description
resolved	Resolved link.
unresolved	Unresolved link.
implicit	Block resides in library block and is itself not a link to a library block. Suppose that A is a link to a subsystem in a library that contains the Gain block. If you open A and select the Gain block, <code>get_param(gcb, 'LinkStatus')</code> returns <code>implicit</code> .
inactive	Disabled link.

Set LinkStatus Value	Description
none	Breaks link. Use <code>none</code> to break a link, for example, <code>set_param(gcb, 'LinkStatus', 'none')</code> .
inactive	Disables link. Use <code>inactive</code> to disable a link, for example, <code>set_param(gcb, 'LinkStatus', 'inactive')</code> .
restore	Restores an inactive or disabled link to a library block and discards any changes made to the local copy of the library block. For example, <code>set_param(gcb, 'LinkStatus', 'restore')</code> replaces the selected block with a link to a library block of the same type. It discards any changes in the local copy of the library block. <code>restore</code> is equivalent to Restore Individual in the Links Tool.
propagate	Pushes any changes made to the disabled link to the library block and re-establishes its link. <code>propagate</code> is equivalent to Push Individual in the Links Tool.
restoreHierarchy	Restores all disabled links in the hierarchy with their corresponding library blocks. <code>restoreHierarchy</code> is equivalent to Restore in hierarchy mode in the Links Tool.
propagateHierarchy	Pushes all links with changes in the hierarchy to their libraries. <code>propagateHierarchy</code> is equivalent to Push in the Hierarchy mode of the Links Tool. See “Restore Disabled or Parameterized Links” on page 38-26.

Note:

- When you use `get_param` to query the link status of a block, the outdated block links also resolve.
 - Using the `StaticLinkStatus` command to query the link status when `get_param` is being used in the callback code of a child block, is efficient. `StaticLinkStatus` command, does not resolve any outdated links.
-

If you call `get_param` on a block inside a library link, Simulink resolves the link wherever necessary. Executing `get_param` can involve loading part of the library and executing callbacks.

Forwarding Tables

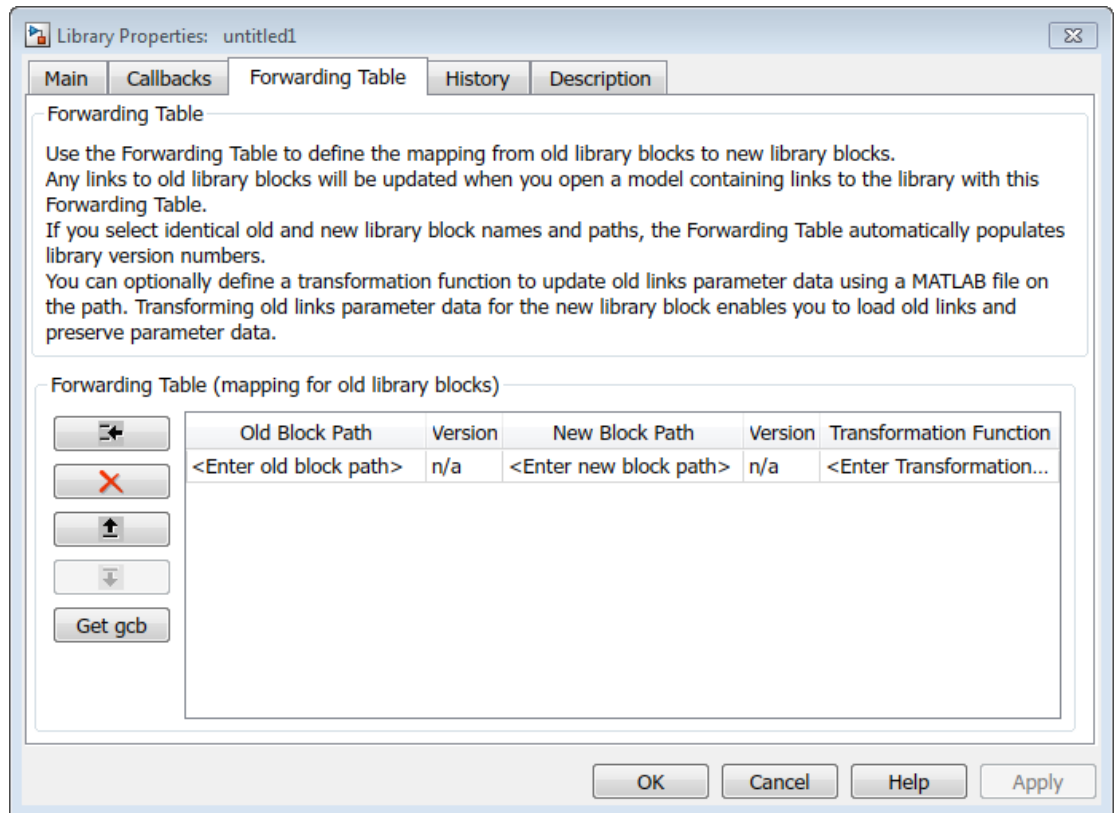

If you edit an existing library block, you would want to ensure that the changes do not break the model when the model is saved with an older version of the library block. The type of edits in the library block can include, library path change, library block name change, or addition, removal, or rename of parameters.

The Forwarding Table helps you to maintain compatibility of library blocks and thus ensures that the models continue to work. You can use the Forwarding table to create a map between the old and the new library blocks without any loss of data or functionality. After the mapping of old library blocks to new library blocks is specified in the forwarding table, links to the old library blocks update automatically during model load. For example, if you rename or move a block in a library, you can use a forwarding table to update the models that have link to the old library block.

Create Forwarding Table

Note: Models that have broken or disabled links cannot be updated using the forwarding tables.

- 1 Open the library model.
- 2 Click **Diagram > Unlock Library**. The library is now unlocked for editing.
- 3 Click **File > Library Properties > Library Properties**. The **Library Properties** dialog box opens.
- 4 Click the **Forwarding Table** tab.
- 5 Click  (Add New Entry) button. A new row is added in the Forwarding Table.

- 6 Specify values in the **Old Block Path** and **New Block Path** columns. To get the path of a block, select the block in the model and click .
- 7 In the **Version** column, you can choose to specify a version number for the library block.

If the old block name and the new block name are the same, the forwarding table populates the version number automatically. The initial value of the library version (`LibraryVersion`) is derived from the model version (`ModelVersion`) of the library at the time the library link is created. Any subsequent updated to the library block would update the library version to match the model version of the library.

Note:

- Version number must be a numeric value.
 - When the old and the new block paths are the same, the version number must be of the format `<major_version>.<minor_version>`. For example, while renaming a library block.
 - The version number cannot have more than one dot notation. For example, a version number of `1.3` is acceptable whereas, version number `1.3.1` is not acceptable.
 - When you use forwarding table to move a library block from one library to another, the version number format is not critical.
-

- 8** In the **Transformation Function** column, you can specify a MATLAB file that corrects the mismatch of parameter data between the old and the new link. Transforming old link parameter data for the new library block enables you to load old links and preserve parameter data. For more information, see “Transformation Functions” on page 38-38.

If no transformation function is specified, the Transformation Function column displays `No Transformation` when you save the library.

- 9** To apply the changes and close the dialog box, click **OK**. The mapping of old path to new path is created in the Forwarding Table. The links to the old library blocks are updated automatically when you open a model containing links to the library.

An example of user-defined forwarding table is as shown:

When you specify identical library block name and path for the older and the newer blocks, the Forwarding Table populates the version number automatically. For the first entry with identical names and path, the version number of the old block starts with 0, and the new version of the block is set as the model version of the library. You can view the model version of the library under the **History** tab of the Forwarding Table.

A transformation function must be specified when the instance-specific parameters (**InstanceData**) have changed in the old and the new library block.

In this example,

- Block path for **Block A** changes from **LibA** to **LibB**.
- Block name for **Block X** changes to **Block Y** while the library path remains the same.

- Block name for **Block M** changed to **Block N**. A transformation function is specified to take care of the instance-specific changes.
- Block version and instance-specific parameter changed for **Block L**.

Create Forwarding Table Programmatically

At the command line, you can create a simple forwarding table specifying the old locations and new locations of blocks that have moved within the library or to another library. You associate a forwarding table with a library by setting its `ForwardingTable` parameter to a cell array of two-element cell arrays, each of which specifies the old and new path of a block that has moved. For example, the syntax to create a forwarding table and assign it to a library named `Lib1` is,

```
set_param('Lib1', 'ForwardingTable', {{'Lib1/A', 'Lib2/A'}  
{'Lib1/B', 'Lib1/C'}});
```

Here,

- `Lib1` is the library associated to the forwarding table.
- Block A is transferred from `Lib1` to `Lib2`.
- Block B is renamed to Block C in the same library.

Transformation Functions

A linked block instance is associated with instance-specific parameters called `InstanceData`. When you create versions of a library block, parameter sets can get added or removed from the `InstanceData`.

A transformation function corrects the mismatch of parameters in the `InstanceData` of the new and old library links thus ensuring that the library links continue to work.

You can define a transformation function using a MATLAB file on the path, then specify the function in the **Transformation Function** column of the **Forwarding Table**.

The new block path defined in the forwarding table overrides the values defined in the transformation function. If the new block path is a dynamic value that changes based on certain conditions, then the new block path must be only defined using the transformation function.

The syntax for transformation function must be;

```
function outData = TransformationFcn(inData)
```

Here,

- `inData` is a structure with fields `ForwardingTableEntry` and `InstanceData`, and `ForwardingTableEntry` is also a structure.
- `outData` is a structure with fields `NewInstanceData` and `NewBlockPath`.

A general transformation function can have many local functions defined in it. The function calls the appropriate local functions based on old block names and versions. You can use this to combine multiple local functions into a single transformation function, to avoid having many transformation functions on the MATLAB path.

Consider the Compare to Const block in Simulink Library. Versions of this block are created without changing the name and the block path but parameters are added to the newer library block.

The table displays the parameter difference in two versions of the Compare to Const block. The instance data in each version has been highlighted.

Old Version	New Version
Block {	Block {
BlockType Reference	BlockType Reference
Name "Compare\nTo Constant"	Name "Compare\nTo Constant"
Ports [1, 1]	SID "15"
Position [210, 60, 250, 100]	Ports [1, 1]
SourceBlock "fixpt_lib_4/Logic & Com	Position [125, 50, 155, 80]
SourceType "Fixed-Point Compare To	ZOrder -5
relop "=="	LibraryVersion "1.271"
const "3.0"	SourceBlock "simulink/Logic and Bit\nOpen
}	SourceType "Compare To Constant"
	relop "<="
	const "3.0"
	OutDataTypeStr "boolean"
	ZeroCross on
	}

The New Version of the Compare to Const block has additional parameters (`OutDataTypeStr` and `ZeroCross`) associated with it. For such cases, the

transformation function must ensure that the additional parameters in the InstanceData are set so that the old library links work.

An example of transformation function for the Compare to Const block to add the OutDataTypeStr parameter with a value of uint8 is as follows,

```
function [outData] = TransformationCompConstBlk(inData)
outData.NewBlockPath = ''; % No change in the library block path
outData.NewInstanceData = [];
instanceData = inData.InstanceData;
% Get the field type 'Name' from instanceData
[ParameterNames{1:length(instanceData)}] = instanceData.Name;

if (~ismember('OutDataTypeStr',ParameterNames))
    % OutDataTypeStr parameter is not present in old link. Add it and set value uint8
    instanceData(end+1).Name = 'OutDataTypeStr';
    instanceData(end).Value = 'uint8';
end

outData.NewInstanceData = instanceData;
```

Create Mask Parameter Aliases

If a mask parameter is renamed, you must ensure that the existing MATLAB scripts that use the old parameter names, continues to work. To ensure the compatibility, you can create alias (alternate names) for a mask parameter name. Alias allows you to change the name of a mask parameter in a library block without having to recreate links to the block in existing models.

Consider a masked block that contains an **Edit** parameter. The mask parameter name for this **Edit** parameter is p1.

```
MaskObj=
% MaskParameter with properties:
```

```
    Type: 'edit'
TypeOptions: {0x1 cell}
    Name: 'p1'
    Prompt: 'p1'
    Value: '0'
    Evaluate: 'on'
    Tunable: 'on'
    NeverSave: 'off'
    Hidden: 'off'
    Enabled: 'on'
    Visible: 'on'
    ToolTip: 'on'
```

```
Callback: ''  
Alias: ''
```

Notice that the **Edit** mask parameter does not have any alias name. To add an alias name for the mask parameter, you can set a value for the **Alias** mask parameter property.

```
MaskObj.Alias = 'pa'
```

You can either use the mask parameter name or the alias to do a function call on the mask parameter. For example, in this case you can either use `set_param(gcb, 'p1, '10)` (mask parameter name) `set_param(gcb, 'pa, '10)` (mask parameter alias) to set a value for the **Edit** mask parameter.

Integrate MATLAB Algorithm in Model

Here is an example of a Simulink model that contains a MATLAB Function block:

The MATLAB Function block contains the following algorithm:

```
function [mean,stdev] = stats(vals)

% calculates a statistical mean and a standard
% deviation for the values in vals.

len = length(vals);
mean = avg(vals,len);
stdev = sqrt(sum(((vals-avg(vals,len)).^2))/len);
plot(vals,'-+');

function mean = avg(array,size)
mean = sum(array)/size;
```

You build this model in “Create Model That Uses MATLAB Function Block” on page 39-9.

Defining Local Variables for Code Generation

If you intend to generate code from the MATLAB algorithm in a MATLAB Function block, you must explicitly assign the class, size, and complexity of local variables before using them in operations or returning them as outputs (see “Data Definition for Code Generation” on page 47-2. In the example function `stats`, the local variable `len` is defined before being used to calculate mean and standard deviation:

```
len = length(vals);
```

Generally, once you assign properties to a variable, you cannot redefine its class, size, or complexity elsewhere in the function body, but there are exceptions (see “Reassignment of Variable Properties” on page 46-9).

More About

- “What Is a MATLAB Function Block?” on page 39-5

What Is a MATLAB Function Block?

The MATLAB Function block allows you to add MATLAB functions to Simulink models for deployment to desktop and embedded processors. This capability is useful for coding algorithms that are better stated in the textual language of MATLAB than in the graphical language of Simulink. From the MATLAB Function block, you can generate readable, efficient, and compact C/C++ code for deployment to desktop and embedded applications.

Calling Functions in MATLAB Function Blocks

MATLAB Function blocks can call any of the following types of functions:

- **Local functions**

Local functions are defined in the body of the MATLAB Function block. See “Call Local Functions” on page 54-9.

- **MATLAB toolbox functions that support code generation**

From MATLAB Function blocks, you can call toolbox functions that support code generation. When you build your model with Simulink Coder, these functions generate C code that is optimized to meet the memory and performance requirements of desktop and embedded environments. In the example shown in “Call Local Functions” on page 54-9, `length`, `sqrt`, and `sum` are examples of toolbox functions that support code generation. For a complete list of supported functions, see “Functions and Objects Supported for C/C++ Code Generation — Alphabetical List” on page 44-2.

- **MATLAB functions that do not support code generation**

From MATLAB Function blocks, you can also call *extrinsic* functions. These are functions on the MATLAB path that the compiler dispatches to MATLAB software for execution because the target language does not support them. These functions do not generate code; they execute only in the MATLAB workspace during simulation of the model. The Simulink Coder software attempts to compile all MATLAB functions unless you explicitly declare them to be extrinsic by using `coder.extrinsic`. See “Declaring MATLAB Functions as Extrinsic Functions” on page 54-12.

The code generation software detects calls to many common visualization functions, such as `plot`, `disp`, and `figure`. For MEX code generation, it automatically calls out to MATLAB for these functions. For standalone code generation, it does not generate

code for these visualization functions. This capability removes the requirement to declare these functions extrinsic using the `coder.extrinsic` function.

See “Resolution of Function Calls for Code Generation” on page 54-2.

- **Functions from Simulink Function blocks and Stateflow blocks**

From MATLAB Function blocks, you can also call functions defined in a Simulink Function block. You can call Stateflow functions with **Export Chart Level Functions (Make Global)** and **Allow exported functions to be called by Simulink** checked in the chart Properties dialog box.

More About

- “Why Use MATLAB Function Blocks?” on page 39-7

Why Use MATLAB Function Blocks?

MATLAB Function blocks provide the following capabilities:

- **Allow you to build MATLAB functions into embeddable applications** — MATLAB Function blocks support a subset of MATLAB toolbox functions that generate efficient C/C++ code. For information see “Functions and Objects Supported for C/C++ Code Generation — Alphabetical List” on page 44-2.. With this support, you can use Simulink Coder to generate embeddable C code from MATLAB Function blocks that implement a variety of sophisticated mathematical applications. In this way, you can build executables that harness MATLAB functionality, but run outside the MATLAB environment.
- **Inherit properties from Simulink input and output signals** — By default, both the size and type of input and output signals to a MATLAB Function block are inherited from Simulink signals. You can also choose to specify the size and type of inputs and outputs explicitly in the Ports and Data Manager (see “Ports and Data Manager” on page 39-36) or in the Model Explorer (see “Model Explorer Overview” on page 12-2).

More About

- “What Is a MATLAB Function Block?” on page 39-5

Use Nondirect Feedthrough in a MATLAB Function Block

By default, MATLAB Function blocks have direct feedthrough enabled. To disable, in the Ports and Data Manager, clear the **Allow direct feedthrough** check box. Nondirect feedthrough enables semantics to ensure that outputs rely only on current state.

To use nondirect feedthrough, do not program outputs to rely on inputs or updated persistent variables. For example, do not use the following code in a nondirect feedthrough block:

```
counter = counter + 1; % update state
output = counter;     % compute output based on updated state
```

Instead, use code such as:

```
output = counter;     % compute output based on current state
counter = counter + 1; % update state
```

Also, nondirect feedthrough semantics require function inlining. Do not disable inlining.

Using nondirect feedthrough enables you to use MATLAB Function blocks in a feedback loop and prevent algebraic loops.

Create Model That Uses MATLAB Function Block

In this section...

“Adding a MATLAB Function Block to a Model” on page 39-9

“Programming the MATLAB Function Block” on page 39-10

“Building the Function and Checking for Errors” on page 39-11

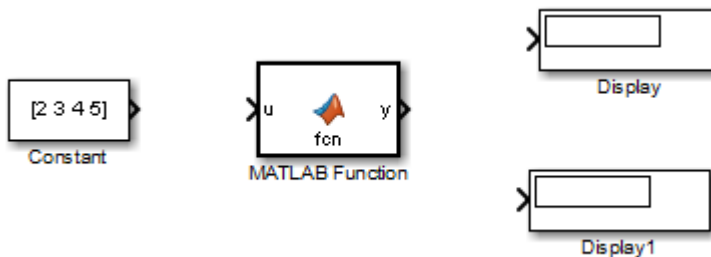

“Defining Inputs and Outputs” on page 39-13

Adding a MATLAB Function Block to a Model

- 1 Create a new Simulink model and add a MATLAB Function block to the model from the User-Defined Functions library:

- 2 Add the following Source and Sink blocks to the model:
 - From the Sources library, add a Constant block to the left of the MATLAB Function block and set its value to the vector $[2 \ 3 \ 4 \ 5]$.
 - From the Sinks library, add two Display blocks to the right of the MATLAB Function block.

- 3 In the Simulink Editor, select **File > Save As** and save the model as `call_stats_block1`.

Programming the MATLAB Function Block

The following exercise demonstrates programming the block to calculate the mean and standard deviation for a vector of values:

- 1 Open the `call_stats_block1` model that you saved at the end of “Adding a MATLAB Function Block to a Model” on page 39-9. Double-click the MATLAB Function block `fcn` to open it for editing.

A default function signature appears.

- 2 Edit the function header line:

```
function [mean,stdev] = stats(vals)
```

The function `stats` calculates a statistical mean and standard deviation for the values in the vector `vals`. The function header declares `vals` as an argument to the `stats` function, with `mean` and `stdev` as return values.

- 3 Save the model as `call_stats_block2`.
- 4 Complete the connections to the MATLAB Function block as shown.

- 5 In the MATLAB Function Block Editor, enter a line space after the function header and add the following code:

```
% calculates a statistical mean and a standard
% deviation for the values in vals.

len = length(vals);
mean = avg(vals,len);
stdev = sqrt(sum(((vals-avg(vals,len)).^2))/len);
```

```
plot(vals, '-+');  
  
function mean = avg(array,size)  
mean = sum(array)/size;
```

More about length

The function `length` is an example of a toolbox function that supports code generation. When you simulate this model, C code is generated for this function in the simulation application.

More about len

The class, size, and complexity of local variable `len` matches the output of the toolbox function `length`, which returns a real scalar of type `double`.

By default, implicitly declared local variables like `len` are temporary. They come into existence only when the function is called and cease to exist when the function is exited. To make implicitly declared variables persist between function calls, see `persistent`.

More about plot

The function `plot` is not supported for code generation. The code generation software detects calls to many common visualization functions, such as `plot`, `disp`, and `figure`. For MEX code generation, it automatically calls out to MATLAB for these functions. For standalone code generation, it does not generate code for these visualization functions.

- 6 Save the model as `call_stats_block2`.

Building the Function and Checking for Errors

After programming a MATLAB Function block in a Simulink model, you can build the function and test for errors. This section describes the steps:

- 1 Set up your compiler.
- 2 Build the function.
- 3 Locate and fix errors.

Setting Up Your Compiler

Building your MATLAB Function block requires a supported compiler. MATLAB automatically selects one as the default compiler. If you have multiple MATLAB-supported compilers installed on your system, you can change the default using the `mex -setup` command. See “Change Default Compiler”.

Supported Compilers for Simulation Builds

To view a list of compilers for building models containing MATLAB Function blocks for simulation:

- 1 Navigate to the Supported and Compatible Compilers Web page.
- 2 Select your platform.
- 3 In the table for Simulink and related products, find the compilers checked in the column titled Simulink for MATLAB Function blocks.

Supported Compilers for Code Generation

To generate code for models that contain MATLAB Function blocks, you can use any of the C compilers supported by Simulink software for code generation with Simulink Coder. For a list of these compilers:

- 1 Navigate to the Supported and Compatible Compilers Web page.
- 2 Select your platform.
- 3 In the table for Simulink and related products, find the compilers checked in the column titled Simulink Coder.

How to Generate Code for the MATLAB Function Block

- 1 Open the `call_stats_block2` model that you saved at the end of “Programming the MATLAB Function Block” on page 39-10.
- 2 Double-click its MATLAB Function block `stats` to open it for editing.
- 3 In the MATLAB Function Block Editor, select **Build Model** > **Build** to compile and build the example model.

If no errors occur, the **Simulation Diagnostics** window displays a message indicating success. Otherwise, this window helps you locate errors, as described in “How to Locate and Fix Errors” on page 39-13.

How to Locate and Fix Errors

If errors occur during the build process, the **Simulation Diagnostics** window lists the errors with links to the offending code.

The following exercise shows how to locate and fix an error in a MATLAB Function block.

- 1 In the `stats` function, change the local function `avg` to a fictitious local function `aug` and then compile again to see the following messages in window:

The **Simulation Diagnostics** window displays each detected error with a red button.

- 2 Click the first error line to display its diagnostic message in the bottom error window.

The message also links to a report about compile-time type information for variables and expressions in your MATLAB functions. This information helps you diagnose error messages and understand type propagation rules. For more information about the report, see “MATLAB Function Reports” on page 39-48.

- 3 In the diagnostic message for the selected error, click the blue link after the function name to display the offending code.

The offending line appears highlighted in the MATLAB Function Block Editor:

- 4 Correct the error by changing `aug` back to `avg` and recompile.

Defining Inputs and Outputs

In the `stats` function header for the MATLAB Function block you defined in “Programming the MATLAB Function Block” on page 39-10, the function argument `vals` is an input, and `mean` and `stdev` are outputs. By default, function inputs and outputs inherit their data type and size from the signals attached to their ports. In this topic, you examine input and output data for the MATLAB Function block to verify that it inherits the correct type and size.

- 1 Open the `call_stats_block2` model that you saved at the end of “Programming the MATLAB Function Block” on page 39-10. Double-click the MATLAB Function block `stats` to open it for editing.
- 2 In the MATLAB Function Block Editor, select **Edit Data**.

The Ports and Data Manager opens to help you define arguments for MATLAB Function blocks.

The left pane displays the argument `vals` and the return values `mean` and `stdev` that you have already created for the MATLAB Function block. Notice that `vals` is assigned a **Scope** of **Input**, which is short for **Input from Simulink**. `mean` and `stdev` are assigned the **Scope** of **Output**, which is short for **Output to Simulink**.

- 3 In the left pane of the Ports and Data Manager, click anywhere in the row for `vals` to highlight it.

The right pane displays the **Data** properties dialog box for `vals`. By default, the class, size, units, and complexity of input and output arguments are inherited from the signals attached to each input or output port. Inheritance is specified by setting **Size** to `-1`, **Complexity** to **Inherited**, and **Type** to **Inherit: Same as Simulink**.

The actual inherited values for size and type are set during compilation of the model, and are reported in the **Compiled Type** and **Compiled Size** columns of the left pane.

You can specify the type of an input or output argument by selecting a type in the **Type** field of the **Data** properties dialog box, for example, `double`. You can also specify the size of an input or output argument by entering an expression in the **Size** field. For example, you can enter `[2 3]` in the **Size** field to specify `vals` as a 2-by-3 matrix. See “Type Function Arguments” on page 39-61 and “Size Function Arguments” on page 39-68 for more information on the expressions that you can enter for type and size.

Note: The default first index for any arrays that you add to a MATLAB Function block function is 1, just as it would be in MATLAB.

Code Generation Readiness Tool

Information That the Code Generation Readiness Tool Provides

The code generation readiness tool screens MATLAB code for features and functions that code generation does not support. The tool provides a report that lists the source files that contain unsupported features and functions. The report also indicates the amount of work required to make the MATLAB code suitable for code generation. It is possible that the tool does not detect all code generation issues. Under certain circumstances, it is possible that the tool can report false errors. Therefore, before you generate C code, verify that your code is suitable for code generation by generating a MEX function.

Summary Tab

Code Generation Readiness - call_myfun.m

Summary | Code Structure

Code Generation Readiness Score:  3

Requires some significant changes

Code generation tools might fail unless the issues listed below are fixed.

Unsupported MATLAB function calls - 3 invocations

-  myfun.m →  categorical 1
-  myfun.m →  table 1
-  myfun.m →  sparse 1

Nested functions - 1 occurrence

Nested functions, used in myfun.m, are currently unsupported for code generation.

The **Summary** tab provides a **Code Generation Readiness Score**, which ranges from 1 to 5. A score of 1 indicates that the tool detects issues that require extensive changes to the MATLAB code to make it suitable for code generation. A score of 5 indicates that

the tool does not detect code generation issues; the code is ready to use with minimal or no changes.

On this tab, the tool also displays information about:

- MATLAB syntax issues. These issues are reported in the MATLAB editor. To learn more about the issues and how to fix them, use the Code Analyzer.
- Unsupported MATLAB function calls.
- Unsupported MATLAB language features, such as nested functions.
- Unsupported data types.

Code Structure Tab

If the code that you are checking calls other MATLAB functions, or you are checking multiple entry-point functions, the tool displays the **Code Structure Tab**.

This tab displays information about the relative size of each file and how suitable each file is for code generation.

Code Distribution

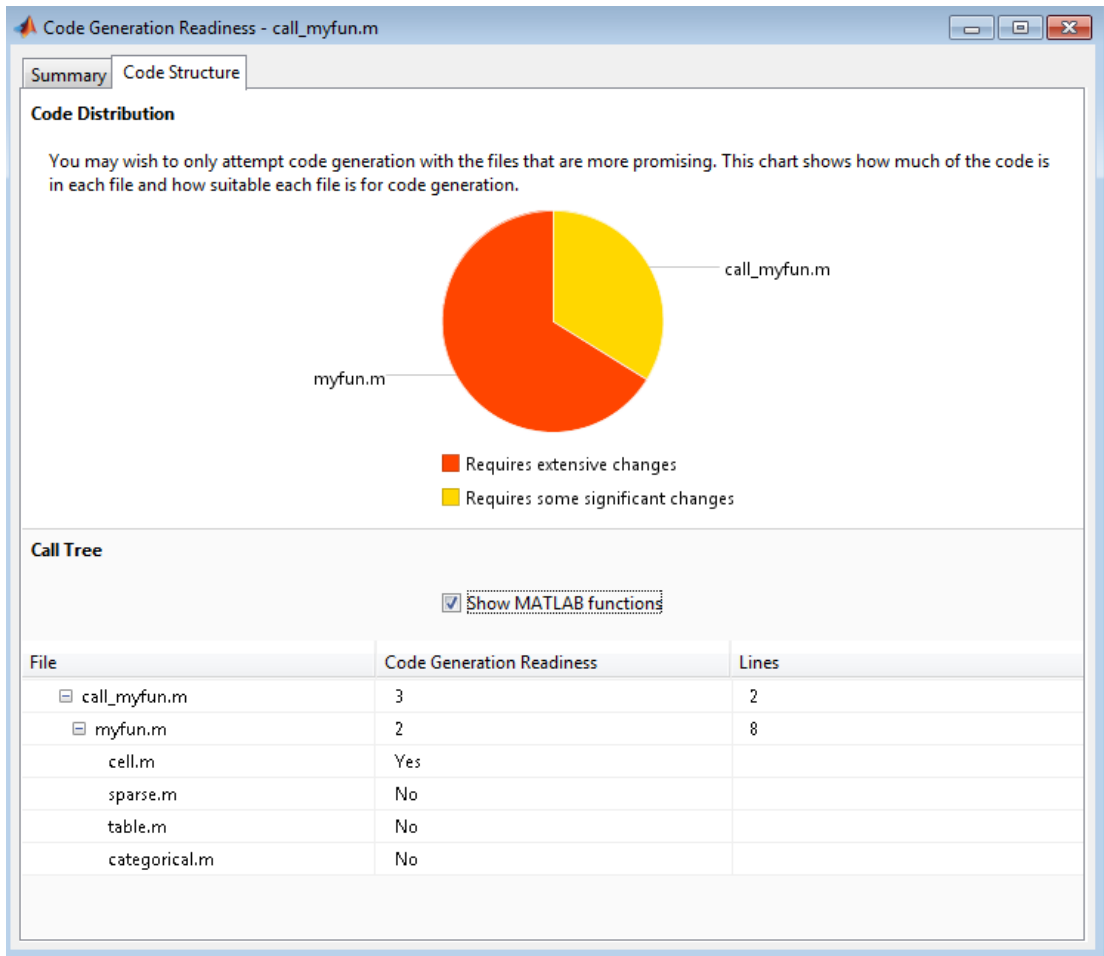

The **Code Distribution** pane displays a pie chart that shows the relative sizes of the files and how suitable each file is for code generation. During the planning phase of a project, you can use this information for estimation and scheduling. If the report indicates that multiple files are not suitable for code generation, consider fixing files that require minor changes before addressing files with significant issues.

Call Tree

The **Call Tree** pane displays information about the nesting of function calls. For each called function, the report provides a **Code Generation Readiness** score, which ranges from 1 to 5. A score of 1 indicates that the tool detects issues that require extensive changes to the MATLAB code to make it suitable for code generation. A score of 5 indicates that the tool does not detect code generation issues. The code is ready to use with minimal or no changes. The report also lists the number of lines of code in each file.

Show MATLAB Functions

If you select **Show MATLAB Functions**, the report also lists the MATLAB functions that your function calls. For each of these MATLAB functions, if code generation supports the function, the report sets **Code Generation Readiness** to **Yes**.

Check Code Using the Code Generation Readiness Tool

In this section...

“Run Code Generation Readiness Tool at the Command Line” on page 39-21

“Run the Code Generation Readiness Tool From the Current Folder Browser” on page 39-21

Run Code Generation Readiness Tool at the Command Line

- 1 Navigate to the folder that contains the file that you want to check for code generation readiness.
- 2 At the MATLAB command prompt, enter:

```
coder.screener('filename')
```

The **Code Generation Readiness** tool opens for the file named `filename`, provides a code generation readiness score, and lists issues that must be fixed prior to code generation.

Run the Code Generation Readiness Tool From the Current Folder Browser

- 1 In the current folder browser, right-click the file that you want to check for code generation readiness.
- 2 From the context menu, select **Check Code Generation Readiness**.

The **Code Generation Readiness** tool opens for the selected file and provides a code generation readiness score and lists issues that must be fixed prior to code generation.

Debugging a MATLAB Function Block

In this section...

“Debugging the Function in Simulation” on page 39-22

“Set Conditions on Breakpoints” on page 39-25

“Watching Function Variables During Simulation” on page 39-26

“Checking for Data Range Violations” on page 39-28

“Debugging Tools” on page 39-28

Debugging the Function in Simulation

In “Create Model That Uses MATLAB Function Block” on page 39-9, you created an example model with a MATLAB Function block that calculates the mean and standard deviation for a set of input values. The software enables debugging for a MATLAB Function when you set a breakpoint.

To debug the MATLAB Function in this model:

- 1 Open the `call_stats_block2` model and double-click the MATLAB Function block `stats` to open the editor.
- 2 In the MATLAB Function Block Editor, click the dash (-) in the left margin of the line:

```
len = length(vals);
```

A red dot appears in the line margin, indicating the breakpoint.

```

1  function [mean, stdev] = stats(vals)
2  %#codegen
3
4  % Calculates a statistical mean and a standard deviation
5  % for the values in vals
6
7  - coder.extrinsic('plot');
8
9  ● len = length(vals);
10 - mean = avg(vals,len);
11 - stdev = sqrt(sum(((vals-avg(vals,len)).^2)/len);
12 - plot(vals,'-+');
13
14  function mean = avg(array,size)
15 - mean = sum(array)/size;

```

- 3 Simulate the model.

Simulation pauses when execution reaches the breakpoint. This is indicated by a green arrow in the margin.

```

1  function [mean, stdev] = stats(vals)
2  %#codegen
3
4  % Calculates a statistical mean and a standard deviation
5  % for the values in vals
6
7  - coder.extrinsic('plot');
8
9  ● → len = length(vals);
10 - mean = avg(vals,len);
11 - stdev = sqrt(sum(((vals-avg(vals,len)).^2)/len);
12 - plot(vals,'-+');
13
14  function mean = avg(array,size)
15 - mean = sum(array)/size;

```

- 4 In the toolbar, click **Step** to advance execution.

The execution arrow advances to the next line of `stats`, which calls the local function `avg`.

- 5 In the toolbar, click **Step In**.

Execution advances to enter the local function `avg`. Once you are in a local function, you can use the **Step** or **Step In** commands to advance execution. If the local function calls another local function, use **Step In** to enter it. If you want to execute the remaining lines of the local function, use **Step Out**.

- 6** Click **Step** to execute the only line in the local function `avg`. When the local function `avg` finishes executing, a green arrow, pointing down, appears under the last line of the function.
- 7** Click **Step** to return to the function `stats`.

Execution advances to the line after the call to the local function `avg`.

- 8** Click **Step** twice to calculate the `stdev` and to execute the `plot` function.

The `plot` function executes in MATLAB:

In the MATLAB Function Block Editor, a green arrow points down under the last line of code, indicating the completion of the function `stats`.

- 9 Click **Continue** to continue execution of the model.

The computed values of `mean` and `stdev` appear in the Display blocks.

- 10 In the MATLAB Function Block Editor, click **Quit Debugging** to stop simulation.

Set Conditions on Breakpoints

To help you debug code, you can enter a MATLAB expression as a condition on a breakpoint inside a MATLAB Function block. Simulation then pauses on that breakpoint only when the condition is true. To set a conditional breakpoint, in the MATLAB

Function block editor, right-click beside the line of code and select **Set Conditional Breakpoint**. Type the condition in the pop-up window. You can use any valid MATLAB expression as a condition. This condition expression can include numerical values and any data that is in scope at the breakpoint.

To add or modify a condition on an existing breakpoint, right-click the breakpoint and select **Set/Modify the condition**. You can also perform these actions from the **Breakpoints** menu.

Watching Function Variables During Simulation

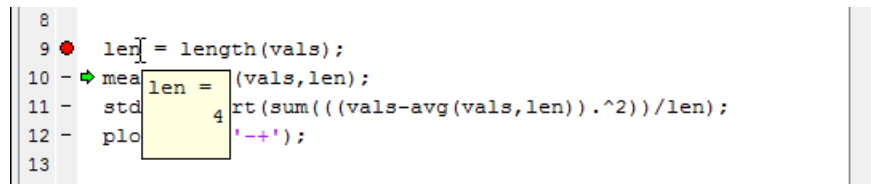

While you simulate a MATLAB Function block, you can use several tools to keep track of variable values in the function.

Watching with the Interactive Display

To display the value of a variable in the function of a MATLAB Function block during simulation:

- 1 In the MATLAB Function Block Editor, place the mouse cursor over the variable text and observe the pop-up display.

For example, to watch the variable `len` during simulation, place the mouse cursor over the text `len` in the code. The value of `len` appears adjacent to the cursor, as shown:

```

8
9 ● len = length(vals);
10 - → mea len = (vals, len);
11 - std 4 rt (sum((vals-avg(vals, len)).^2))/len);
12 - plo '-+');
13

```

Watching with the Command Line Debugger

You can report the values for a function variable with the Command Line Debugger utility in the MATLAB window during simulation. When you reach a breakpoint, the Command Line Debugger prompt, `debug>>`, appears. At this prompt, you can see the value of a variable defined for the MATLAB Function block by entering its name:

```
debug>> stdev
```

1.1180

debug>>

The Command Line Debugger also provides the following commands during simulation:

Command	Description
ctrl-c	Quit debugging and terminate simulation.
dbcont	Continue execution to next breakpoint.
dbquit	Quit debugging and terminate simulation.
dbstep [in out]	Advance to next program step after a breakpoint is encountered. Step over or step into/out of a MATLAB local function.
help	Display help for command line debugging.
print <var>	Display the value of the variable <code>var</code> in the current scope. If <code>var</code> is a vector or matrix, you can also index into <code>var</code> . For example, <code>var(1,2)</code> .
save	Saves all variables in the current scope to the specified file. Follows the syntax of the MATLAB <code>save</code> command. To retrieve variables to the MATLAB base workspace, use <code>load</code> command after simulation has been ended.
<var>	Equivalent to "print <var>" if variable is in the current scope.
who	Display the variables in the current scope.
whos	Display the size and class (type) of all variables in the current scope.

You can issue any other MATLAB command at the `debug>>` prompt, but the results are executed in the workspace of the MATLAB Function block. To issue a command in the MATLAB base workspace at the `debug>>` prompt, use the `evalin` command with the first argument 'base' followed by the second argument command, for example, `evalin('base','whos')`. To return to the MATLAB base workspace, use the `dbquit` command.

Watching with MATLAB

You can display the execution result of a MATLAB Function block line by omitting the terminating semicolon. If you do, execution results for the line are echoed to the MATLAB window during simulation.

Display Size Limits

The MATLAB Function Block Editor does not display the contents of matrices that have more than two dimensions or more than 200 elements. For matrices that exceed these limits, the MATLAB Function Block Editor displays the shape and base type only.

Checking for Data Range Violations

MATLAB Function blocks check inputs and outputs for data range violations when the input or output values enter or leave the blocks. To enable data range violation checking, set **Simulation range checking** in the **Diagnostics: Data Validity** pane of the Configuration Parameters dialog box to **error**.

Specifying a Range

To specify a range for input and output data, follow these steps:

- 1 In the Ports and Data Manager, select the input or output of interest.

The data properties dialog box opens.

- 2 In the data properties dialog box, select the General tab and enter a limit range, as described in “Setting General Properties” on page 39-41.

Debugging Tools

Use the following tools during a MATLAB Function block debugging session:

Tool Button	Description	Shortcut Key
 Build	Access this tool from the Editor tab by selecting Build Model > Build . Check for errors and build a simulation application (if no errors are found) for the model containing this MATLAB Function block.	Ctrl+B
 Update Diagram	Access this tool from the Editor tab by selecting Build Model > Update Diagram . Check for errors based on the latest changes you make to the MATLAB Function block.	Ctrl+D

Tool Button	Description	Shortcut Key
 Update Ports	<p>Access this tool from the Editor tab by selecting Build Model > Update Ports.</p> <p>Updates the ports of the MATLAB Function block with the latest changes made to the function argument and return values without closing the MATLAB Function Block Editor.</p>	Ctrl+Shift+A
 Run Model	<p>Start simulation of the model containing the MATLAB Function block. If execution is paused at a breakpoint, continues debugging.</p>	F5
 Stop Model	<p>Stop simulation of the model containing the MATLAB Function block. Alternatively, from the Editor tab, select Quit Debugging if execution is paused at a breakpoint.</p>	Shift+F5
 Set/Clear	<p>Access this tool by selecting Breakpoints > Set/Clear.</p> <p>Set a new breakpoint or clear an existing breakpoint for the selected line of code in the MATLAB Function block. The presence of the text cursor or highlighted text selects the line. A breakpoint indicator  appears on the selected line.</p> <p>Alternatively, click the hyphen character (-) next to the line number. A breakpoint indicator appears in place of the hyphen. Click the breakpoint indicator to clear the breakpoint.</p>	F12
 Enable/Disable	<p>Access this tool by selecting Breakpoints > Enable/Disable.</p> <p>Enable or disable an existing breakpoint for the selected line of code in the MATLAB Function block. If the breakpoint is disabled, an indicator  appears on the selected line.</p>	None

Tool Button	Description	Shortcut Key
 Set Condition	<p>Access this tool by selecting Breakpoints > Set Condition.</p> <p>Set a condition on the breakpoint for the selected line of code in the MATLAB Function block. If the breakpoint has a condition associated with it, an indicator  appears on the selected line.</p>	
 Clear All	<p>Access this tool by selecting Breakpoints > Clear All.</p> <p>Clear all existing breakpoints in the MATLAB Function block code.</p>	None
 Step	<p>Step through the execution of the next line of code in the MATLAB Function block. This tool steps past function calls and does not enter called functions for line-by-line execution. You can use this tool only after execution has stopped at a breakpoint.</p>	F10
 Step In	<p>Step through the execution of the next line of code in the MATLAB Function block. If the line calls a local function, step into the first line of the local function. You can use this tool only after execution has stopped at a breakpoint.</p>	F11
 Step Out	<p>Step out of line-by-line execution of the current function or local function. If in a local function, the debugger continues to the line following the call to this local function. You can use this tool only after execution has stopped at a breakpoint.</p>	Shift+F11
 Continue	<p>Continue debugging after a pause, such as stopping at a breakpoint. You can use this tool only after execution has stopped at a breakpoint.</p>	F5
 Quit Debugging	<p>Exit debug mode. You can use this tool only after execution has stopped at a breakpoint.</p>	Shift+F5

Prevent Algebraic Loop Errors in MATLAB Function and Stateflow Blocks

You can use Stateflow charts, MATLAB Function blocks, and Stateflow Truth Tables in feedback loops in your model. You can also use these blocks with synchronous subsystems enabled by the State Control block. To prevent algebraic loop or synchronous semantic errors, apply these restrictions.

Simulink Block	Restrictions
Stateflow Chart	Use Moore charts to prevent an algebraic loop. In the Property Inspector, set the State Machine Type to Moore . Moore charts prevent algebraic loops by ensuring that outputs depend only on current state.
MATLAB Function block	<p>Nondirect feedthrough semantics prevent algebraic loop errors by ensuring that outputs depend only on current state. To enable these semantics, clear the Allow direct feedthrough property check box.</p> <p>If your block uses direct feedthrough, do not:</p> <ul style="list-style-type: none"> • Call imported functions. • Define output function-call events. • Define or use persistent variables. <p>When you apply these restrictions, you allow the Simulink solver to try to solve the algebraic loop.</p>
Truth Table	<p>Do not:</p> <ul style="list-style-type: none"> • Call imported functions. • Define local or output function-call events. • Define local or data store memory data. • Define or use persistent variables.

Simulink Block	Restrictions
	<ul style="list-style-type: none"><li data-bbox="798 302 1302 328">• Use machine-parented data or events. <p data-bbox="798 354 1332 446">When you apply these restrictions, you allow the Simulink solver to try to solve the algebraic loop.</p>

MATLAB Function Block Editor

In this section...

“Customizing the MATLAB Function Block Editor” on page 39-34

“MATLAB Function Block Editor Tools” on page 39-34

“Editing and Debugging MATLAB Function Block Code” on page 39-35

“Ports and Data Manager” on page 39-36

Customizing the MATLAB Function Block Editor

Use the toolbar icons to customize the appearance of the MATLAB Function Block Editor in the same manner as the MATLAB editor. See “Basic Settings”.

MATLAB Function Block Editor Tools

Use the following tools to work with the MATLAB Function block:

Tool Button	Description
 Edit Data	Opens the Ports and Data Manager dialog to add or modify arguments for the current MATLAB Function block (see “Ports and Data Manager” on page 39-36).
 View Report	Opens the MATLAB Function report for the MATLAB Function block. For more information, see “MATLAB Function Reports” on page 39-48.
 Simulation Target	Opens the Simulation Target pane in the Configuration Parameters dialog to include custom code.
 Go To Diagram	Displays the MATLAB function in its native diagram without closing the editor.

See “Defining Inputs and Outputs” on page 39-13 for an example of defining an input argument for a MATLAB Function block.

Editing and Debugging MATLAB Function Block Code

Manual Indenting

To indent a block of code manually:

- 1 Highlight the text that you would like to indent.
- 2 Select one of the Indent tools on the Editor tab:

Tool	Description
	Applies smart indenting to selected text.
	Move selected text right one indent level.
	Move selected text left one indent level.

Opening a Selection

You can open a local function, function, file, or variable from within a file in the MATLAB Function Block Editor.

To open a selection:

- 1 Position the cursor in the name of the item you would like to open.
- 2 Right-click and select **Open <selection>** from the context menu.

The Editor chooses the appropriate tool to open the selection. For more information, refer to “Manage Files and Folders”.

Note: If you open a MATLAB Function block input or output parameter, the Ports and Data Manager opens with the selected parameter highlighted. You can use the Ports and Data Manager to modify parameter attributes. For more information, refer to “Ports and Data Manager” on page 39-36.

Evaluating a Selection

You can use the **Evaluate a Selection** menu option to report the value for a MATLAB function variable or equation in the MATLAB window during simulation.

To evaluate a selection:

- 1 Highlight the variable or equation that you would like to evaluate.
- 2 Hold the mouse over the highlighted text and then right-click and select **Evaluate Selection** from the context menu. (Alternatively, select **Evaluate Selection** from the **Text** menu).

When you reach a breakpoint, the MATLAB command Window displays the value of the variable or equation at the Command Line Debugger prompt.

```
debug>> stdev
```

```
1.1180
```

```
debug>>
```

Note: You cannot evaluate a selection while MATLAB is busy, for example, running a MATLAB file.

Setting Data Scope

To set the data scope of a MATLAB Function block input parameter:

- 1 Highlight the input parameter that you would like to modify.
- 2 Hold the mouse over the highlighted text and then right-click and select **Data Scope for <selection>** from the context menu.
- 3 Select:
 - **Input** if your input data is provided by the Simulink model via an input port to the MATLAB Function block.
 - **Parameter** if your input is a variable of the same name in the MATLAB or model workspace or in the workspace of a masked subsystem containing this block.

For more information, refer to “Setting General Properties” on page 39-41.

Ports and Data Manager

The Ports and Data Manager provides a convenient method for defining objects and modifying their properties in a MATLAB Function block.

The Ports and Data Manager provides the same data definition capabilities for individual MATLAB Function blocks as the Model Explorer provides across the model hierarchy (see “Model Explorer Overview” on page 12-2).

Ports and Data Manager Dialog Box

The Ports and Data Manager dialog box allows you to add and define data arguments, input triggers, and function call outputs for MATLAB Function blocks. Using this dialog, you can also modify properties for the MATLAB Function block and the objects it contains.

The dialog box consists of two panes:

- The **Contents** (left) pane lists the objects that have been defined for the MATLAB Function block.
- The **Dialog** (right) pane displays fields for modifying the properties of the selected object.

Properties vary according to the scope and type of the object. Therefore, the Ports and Data Manager properties dialogs are dynamic, displaying only the property fields that are relevant for the object you add or modify.

When you first open the dialog box, it displays the properties of the MATLAB Function block.

Opening the Ports and Data Manager

To open the Ports and Data Manager from the MATLAB Function Block Editor, select **Edit Data** on the Editor tab. The Ports and Data Manager appears for the MATLAB Function block that is open and has focus.

Ports and Data Manager Tools

The following tools are specific to the Ports and Data Manager:

Tool Button	Description
 Go to Block Editor	Displays the MATLAB function in the MATLAB Function Block Editor.

Tool Button	Description
 Show Block Dialog	Displays the default MATLAB function properties (see “MATLAB Function Block Properties” on page 39-38). Use this button to return to the settings used by the block after viewing data associated with the block arguments.

MATLAB Function Block Properties

This section describes each property of a MATLAB Function block.

Name

Name of the MATLAB Function block.

Update method

Method for activating the MATLAB Function block. You can choose from the following update methods:

Update Method	Description
Inherited (default)	Input from the Simulink model activates the MATLAB Function block. If you define an input trigger, the MATLAB Function block executes in response to a Simulink signal or function-call event on the trigger port. If you do not define an input trigger, the MATLAB Function block implicitly inherits triggers from the model. These implicit events are the sample times (discrete or continuous) of the signals that provide inputs to the chart. If you define data inputs, the MATLAB Function block samples at the rate of the fastest data input. If you do not define data inputs, the MATLAB Function block samples as defined by its parent subsystem's execution behavior.
Discrete	The MATLAB Function block is sampled at the rate you specify as the block's Sample Time property. An implicit event is generated at regular time intervals corresponding to the specified rate. The sample time is in the same units as the Simulink simulation time. Note that other blocks in the model can have different sample times.
Continuous	The Simulink software wakes up (samples) the MATLAB Function block at each step in the simulation, as well as at intermediate time points that can be requested by the solver. This method is consistent with the continuous method.

Saturate on integer overflow

Option that determines how the MATLAB Function block handles overflow conditions during integer operations:

Setting	Action When Overflow Occurs
Enabled (default)	Saturates an integer by setting it to the maximum positive or negative value allowed by the word size. Matches MATLAB behavior.
Disabled	In simulation mode, generates a run-time error. For Simulink Coder code generation, the behavior depends on your C language compiler.

Note: The **Saturate on integer overflow** option is relevant only for integer arithmetic. It has no effect on fixed-point or double-precision arithmetic.

When you enable **Saturate on integer overflow**, MATLAB adds additional checks during simulation to detect integer overflow or underflow. Therefore, it is more efficient to disable this option if you are sure that integer overflow and underflow will not occur in your MATLAB Function block code.

Note that the code generated by Simulink Coder does *not* check for integer overflow or underflow and, therefore, may produce unpredictable results when **Saturate on integer overflow** is disabled. In this situation, it is recommended that you simulate first to test for overflow and underflow before generating code.

Lock Editor

Option for locking the MATLAB Function Block Editor. When enabled, this option prevents users from making changes to the MATLAB Function block.

Treat these inherited Simulink signal types as fi objects

Setting that determines whether to treat inherited fixed-point and integer signals as Fixed-Point Designer `fi` objects (“Ways to Construct `fi` Objects”).

- When you select **Fixed-point**, the MATLAB Function block treats all fixed-point inputs as Fixed-Point Designer `fi` objects.
- When you select **Fixed-point & Integer**, the MATLAB Function block treats all fixed-point and integer inputs as Fixed-Point Designer `fi` objects.

MATLAB Function block fimath

Setting that defines `fimath` properties for the MATLAB Function block. The block associates the `fimath` properties you specify with the following objects:

- All fixed-point and integer input signals to the MATLAB Function block that you choose to treat as `fi` objects.
- All `fi` and `fimath` objects constructed in the MATLAB Function block.

You can select one of the following options for the **MATLAB Function block fimath**.

Setting	Description
Same as MATLAB	When you select this option, the block uses the same <code>fimath</code> properties as the current default <code>fimath</code> . The edit box appears dimmed and displays the current global <code>fimath</code> in read-only form.
Specify other	When you select this option, you can specify your own <code>fimath</code> object in the edit box. You can do so in one of two ways: <ul style="list-style-type: none"> • Constructing the <code>fimath</code> object inside the edit box. • Constructing the <code>fimath</code> object in the MATLAB or model workspace and then entering its variable name in the edit box. If you use this option and plan to share your model with others, make sure you define the variable in the model workspace. See “Sharing Models with Fixed-Point MATLAB Function Blocks”. <p>For more information on <code>fimath</code> objects, see “<code>fimath</code> Object Construction”.</p>

Description

Description of the MATLAB Function block.

Document link

Link to documentation for the MATLAB Function block. To document a MATLAB Function block, set the **Document link** property to a Web URL address or MATLAB expression that displays documentation in a suitable format (for example, an HTML file or text in the MATLAB Command Window). The MATLAB Function block evaluates the expression when you click the blue **Document link** text.

Adding Data to a MATLAB Function Block

You can define data arguments for MATLAB Function blocks using the following methods:

Method	For Defining	Reference
Define data directly in the MATLAB Function block code	Input and output data	See “Defining Inputs and Outputs” on page 39-13.
Use the Ports and Data Manager	Input, output, and parameter data in the MATLAB Function block that is open and has focus	See “Defining Data in the Ports and Data Manager” on page 39-41.
Use the Model Explorer	Input, output, and parameter data in MATLAB Function blocks at all levels of the model hierarchy	See “Model Explorer Overview” on page 12-2

Defining Data in the Ports and Data Manager

To add a data argument, in the Ports and Data Manager, select **Add > Data** and modify the data properties.

Setting General Properties

You can set the following properties in the General tab:

Property	Description
Name	Name of the data argument, following the same naming conventions used in MATLAB.
Scope	<p>Where data resides in memory, relative to its parent. Scope determines the range of functionality of the data argument. You can set scope to one of the following values:</p> <ul style="list-style-type: none"> • Parameter— Specifies that the source for this data is a variable of the same name in the MATLAB or model workspace or in the workspace of a masked subsystem containing this block. If a variable of the same name exists in more than one of the workspaces visible to the block, the variable closest to the block in the workspace hierarchy is used (see “Model Workspaces” on page 4-71). • Input— Data provided by the model via an input port to the MATLAB Function block. • Output— Data provided by the MATLAB Function block via an output port to the model.

Property	Description
	<ul style="list-style-type: none"> • Data Store Memory— Data provided by a Data Store Memory block in the model. <p>For more information, see “Defining Inputs and Outputs” on page 39-13 and “Add Parameter Arguments” on page 39-72.</p>
Port	Index of the port associated with the data argument. This property applies only to input and output data.
Tunable	Indicates whether the parameter used as the source of this data item is tunable (see “Tunable Parameters” on page 3-8). This property applies only to parameter data. Clear this option if the parameter must be a constant expression, such as for MATLAB toolbox functions supported for code generation (see “Functions and Objects Supported for C/C++ Code Generation — Alphabetical List” on page 44-2).
Data must resolve to Simulink signal object	Specifies that the data argument must resolve to a Simulink signal object. This property applies only to output data. This property appears only if you set the model configuration parameter Signal resolution to a value other than None . See “Symbol Resolution” on page 4-82 for more information.
Size	Size of the data argument. Size can be a scalar value or a MATLAB vector of values. Size defaults to -1 , which means that it is inherited, as described in “Inheriting Argument Sizes from Simulink” on page 39-68. This property does not apply to Data Store Memory data. For more details, see “Size Function Arguments” on page 39-68.
Variable Size	Indicates whether the size of this data item is variable. This property does not apply to Data Store Memory data.
Complexity	Indicates real or complex data arguments. You can set complexity to one of the following values: <ul style="list-style-type: none"> • Off— Data argument is a real number • On— Data argument is a complex number • Inherited— Data argument inherits complexity based on its scope. Input and output data inherit complexity from the Simulink signals connected to them; parameter data inherits complexity from the parameter to which it is bound.

Property	Description
Type	<p>Type of data object. You can specify the data type by:</p> <ul style="list-style-type: none"> • Selecting a built-in type from the Type drop down list. • Entering an expression in the Type field that evaluates to a data type (see “About Data Types in Simulink” on page 57-2). • Using the Data Type Assistant to specify a data Mode, then specifying the data type based on that mode. <hr/> <p>Note: To display the Data Type Assistant, click the Show data type assistant button:</p> <div style="text-align: center;">  </div> <hr/> <p>For more information, see “Specifying Argument Types” on page 39-61.</p>
Unit (e.g., m, m/s², N*m)	Specify physical units for input and output data. By default, the property is set to inherit the unit from the Simulink signal on the corresponding input or output port. See “Units in MATLAB Function Blocks” on page 39-71.
Limit range	<p>Specify the range of acceptable values for input or output data. The MATLAB Function block uses this range to validate the input or output as it enters or leaves the block. You can enter an expression or parameter that evaluates to a numeric scalar value.</p> <ul style="list-style-type: none"> • Minimum — The smallest value allowed for the data item during simulation. The default value is <code>-inf</code>. • Maximum — The largest value allowed for the data item during simulation. The default value is <code>inf</code>.

Setting Description Properties

You can set the following properties on the Description tab:

Property	Description
Save final value to base workspace	The MATLAB Function block assigns the value of the data argument to a variable of the same name in the MATLAB base workspace at the end of simulation.

Property	Description
Description	Description of the data argument.
Document link	Link to documentation for the data argument. You can enter a Web URL address or a MATLAB command that displays documentation in a suitable format, such as an HTML file or text in the MATLAB Command Window. When you click the blue text, Document link , displayed at the bottom of the Data properties dialog, the MATLAB Function block evaluates the link and displays the documentation.

Adding Input Triggers to a MATLAB Function Block

An input trigger is an event on the input port that causes the MATLAB Function block to execute. See “Create a Triggered Subsystem” on page 10-40.

You can define the following types of triggers in MATLAB Function blocks:

- Rising
- Falling
- Either (rising or falling)
- Function call

For a description of each trigger type, see “Setting Input Trigger Properties” on page 39-45.

Use the Ports and Data Manager to add input triggers to a MATLAB Function block that is open and has focus. To add an input trigger and modify its properties, follow these steps:

- 1 In the Ports and Data Manager, select **Add > Input Trigger**.

The Ports and Data Manager adds a default definition of the new input trigger to the MATLAB Function block and displays the Trigger properties dialog.

- 2 Modify trigger properties.
- 3 Return to the MATLAB Function block properties at any time by selecting **Tools > Block Dialog**.

The Trigger Properties Dialog

The Trigger properties dialog in the Ports and Data Manager allows you to set and modify the properties of input triggers in MATLAB Function blocks.

To open the Trigger properties dialog, select an input trigger in the Contents pane.

Setting Input Trigger Properties

You can set the following properties in the Trigger properties dialog:

Property	Description
Name	Name of the input trigger, following the same naming conventions used in MATLAB.
Port	Index of the port associated with the input trigger. The default value is 1.
Trigger	Type of event that triggers execution of the MATLAB Function block. You can select one of the following types of triggers: <ul style="list-style-type: none"> • Rising (default) — Triggers execution of the MATLAB Function block when the control signal rises from a negative or zero value to a positive value (or zero if the initial value is negative). • Falling— Triggers execution of the MATLAB Function block when the control signal falls from a positive or zero value to a negative value (or zero if the initial value is positive). • Either— Triggers execution of the MATLAB Function block when the control signal is either rising or falling. • Function call— Triggers execution of the MATLAB Function block from a block that outputs function-call events, or from an S-function
Description	Description of the input trigger.
Document link	Link to documentation for the input trigger. You can enter a Web URL address or a MATLAB command that displays documentation in a suitable format, such as an HTML file or text in the MATLAB Command Window. When you click the blue text that reads Document link displayed at the bottom of the Trigger properties dialog, the MATLAB Function block evaluates the link and displays the documentation.

Adding Function Call Outputs to a MATLAB Function Block

A function call output is an event on the output port of a MATLAB Function block that causes a Function-Call Subsystem block in the Simulink model to execute. Another

block can invoke a function-call subsystem directly during a simulation. See “Create a Function-Call Subsystem” on page 10-54.

Use the Ports and Data Manager to add and modify function call outputs to a MATLAB Function block that is open and has focus. To add a function call output and modify its properties, follow these steps:

- 1 In the Ports and Data Manager, select **Add > Function Call Output**.

The Ports and Data Manager adds a default definition of the new function call output to the MATLAB Function block and displays the Function Call properties dialog.

- 2 Modify function call output properties.
- 3 Return to the MATLAB Function block properties at any time by selecting **Tools > Block Dialog**.

Considerations when Supplying Output to the Function-Call Subsystem

If a MATLAB Function block triggers a function-call subsystem, and supplies an output signal to the same function-call subsystem, the signal to the function-call subsystem can effectively be delayed by one time step compared to the function call. At the moment of the function call, the function-call subsystem sees the previous MATLAB Function block output value even if the output data has been updated within the block MATLAB code.

The Function Call Properties Dialog

The Function Call properties dialog in the Ports and Data Manager allows you to edit the properties of function call outputs in MATLAB Function blocks.

To open the Function Call properties dialog, select a function call output in the Contents pane.

Setting Function Call Output Properties

You can set the following properties in the Function Call properties dialog:

Property	Description
Name	Name of the function call output, following the same naming conventions used in MATLAB.
Port	Index of the port associated with the function call output. Function call output ports are numbered sequentially after input and output ports.

Property	Description
Description	Description of the function call output.
Document link	Link to documentation for the function call output. You can enter a Web URL address or a MATLAB command that displays documentation in a suitable format, such as an HTML file or text in the MATLAB Command Window. When you click Document link displayed at the bottom of the Function Call properties dialog, the MATLAB Function block evaluates the link and displays the documentation.

About MATLAB Function Reports

When you build a Simulink model that contains MATLAB Function blocks, Simulink generates a report in HTML format for each MATLAB Function block in your model. You can use the report to debug your MATLAB functions and verify that they are suitable for code generation. The report provides links to your MATLAB functions and compile-time type information for the variables and expressions in these functions. If your model fails to build, this information simplifies finding sources of error messages and aids understanding of type propagation rules.

Note: If you have a Stateflow license, there is one report for each Stateflow chart, regardless of the number of MATLAB functions it contains.

Note: If you have identical MATLAB Function blocks in your model, for example, one in a library and one in the model, a single report is generated for the identical blocks.

Opening MATLAB Function Reports

Use one of the following methods:

- In the MATLAB Function Block Editor, select **View Report**.
- If compilation errors occur, in the **Diagnostic Viewer** window, select the `report` link.

Description of MATLAB Function Reports

When you build the MATLAB function, the code generation software generates an HTML report. The report provides the following information, as applicable:

- MATLAB code information, including a list of all functions and their compilation status
- Call stack information, providing information on the nesting of function calls
- Summary of compilation results, including type of target and number of warnings or errors
- List of error and warning messages
- List of variables in your MATLAB function

Viewing Your MATLAB Function Code

To view your MATLAB function code, click the **MATLAB code** tab. The report displays the MATLAB code for the function highlighted in the list on this tab.

The **MATLAB code** tab provides:

- A list of the MATLAB functions that have been compiled. The report displays icons next to each function name to indicate whether compilation was successful:
 -  Errors in function.
 -  Warnings in function.
 -  Successful compilation, no errors or warnings.
- A filter control that you can use to sort your functions by:

- Size
- Complexity
- Class

Viewing Local Functions

The report annotates the local function with the name of the parent function in the list of functions on the **MATLAB code** tab.

For example, if the MATLAB function `fcn1` contains the local function `subfcn` and `fcn2` contains the local function `subfcn2`, the report displays:

```
fcn1 > subfcn1  
fcn2 > subfcn2
```

Viewing Specializations

If your MATLAB function calls the same function with different types of inputs, the report numbers each of these **specializations** in the list of functions on the **MATLAB code** tab.

For example, if the function `fcn` calls the function `subfcn` with different types of inputs:

```
function y = fcn(u)  
% Specializations  
y = y + subfcn(single(u));  
y = y + subfcn(double(u));
```

The report numbers the specializations in the list of functions.

```
fcn > subfcn > 1  
fcn > subfcn > 2
```

Viewing Call Stack Information

The report provides call stack information:

- On the **Call stack** tab.
- In the list of **Callers**.

If a function is called from more than one function, this list provides details of each call site. Otherwise, the list is disabled.

Viewing Call Stack Information on the Call Stack Tab

To view call stack information, click the **Call stack** tab. The call stack lists the functions in the order that the top-level function calls them. It also lists the local functions that each function calls.

Viewing Function Call Sites in the Callers List

If a function is called from more than one function, this list provides details of each call site. To navigate between call sites, select a call site from the **Callers** list. If the function is not called more than once, this list is disabled.

Viewing the Compilation Summary Information

To view a summary of the compilation results, including type of target and number of errors or warnings, click the **Summary** tab.

Viewing Error and Warning Messages

The report provides information about errors and warnings. If errors occur during simulation of a Simulink model, simulation stops. If warnings occur, but no errors, simulation of the model continues.

The report provides information about warnings and errors by listing all errors and warnings in chronological order in the **All Messages** tab.

Viewing Errors and Warnings in the All Messages Tab

If errors or warnings occurred during compilation, click the **All Messages** tab to view a complete list of these messages. The report lists the messages in the order that the compiler detects them. It is best practice to address the first message in the list, because often subsequent errors and warnings are related to the first message.

To locate the offending line of code for an error or warning in the list, click the message in the list. The report highlights errors in the list and MATLAB code in red and warnings in orange. Click the blue line number next to the offending line of code in the MATLAB code pane to go to the error in the source file.

Note: You can fix errors only in the source file.

Function: stats Callers: Select a function call site:

```

1 function [mean, stdev] = stats(vals)
2 %#codegen
3
4 % Calculates a statistical mean and a standard deviation
5 % for the values in vals
6
7 coder.extrinsic('plot');
8
9 len = length(vals);
10 mean = avg(vals, len);
11 stdev = sqrt(sum((vals-avg(vals, len)).^2)/len);
12 plot(vals, '-+');
13

```

Summary		All Messages (2)	Variables	
Order	Type	Function	Line	Description
1		stats	10	Undefined function or variable 'avg'.
2		stats	11	Undefined function or variable 'avg'.

Viewing Error and Warning Information in Your MATLAB Code

If errors or warnings occurred during compilation, the report underlines them in your MATLAB code. The report underlines errors in red and warnings in orange. To learn more about a particular error or warning, place your pointer over the underlined text.

MATLAB Code Variables in a Report

The report provides compile-time type information for the variables and expressions in your MATLAB code, including name, type, size, complexity, and class. It also provides type information for fixed-point data types, including word length and fraction length. You can use this type information to find the sources of error messages and to understand type propagation rules.

You can view information about the variables in your MATLAB code:

- On the **Variables** tab, view the list.

- In your MATLAB code, place your cursor over the variable name.

In the MATLAB code, an orange variable name indicates a compile-time constant argument to a specialized function. The information for a constant argument includes the value. This information helps you to see when code generation created function specializations for different constant argument values.

Variables on the Variables Tab

To view a list of the variables in your MATLAB function, click the **Variables** tab. The report displays a complete list of variables in the order that they appear in the function that you selected on the **MATLAB code** tab. Clicking a variable in the list highlights instances of that variable, and scrolls the MATLAB code pane so that you can view the first instance.

As applicable, the report provides the following information about each variable:

- Order
- Name
- Type
- Size
- Complexity
- Class
- DataTypeMode (DT mode) — for fixed-point data types only. For more information, see “Data Type and Scaling Properties”.
- Signed — sign information for built-in data types, signedness information for fixed-point data types.
- Word length (WL) — for fixed-point data types only.
- Fraction length (FL) — for fixed-point data types only.

Note: For more information on viewing fixed-point data types, see “Use Fixed-Point Code Generation Reports”.

The report displays a column only if at least one variable in the code has information in that column. For example, if the code does not contain fixed-point data types, the report does not display the **DT mode**, **WL**, or **FL** columns.

Sorting Variables on the Variables Tab

By default, the report lists the variables in the order that they appear in the selected function.

To sort the variables, click the column headings on the **Variables** tab. To sort the variables by multiple columns, hold down the **Shift** key when you click the column headings.

To restore the list to the original order, click the **Order** column heading.

Structures on the Variables Tab

To display structure field properties, expand the structure on the **Variables** tab.

Summary	All Messages (0)	Variables	Target Build Log		
Order	Variable	Type	Size	Class	Complex
1	s	Output	1 x 1	struct	-
1.1	s.a	Field	1 x 1	double	No
1.2	s.b	Field	1 x 1	double	No

If you sort the variables by type, size, complexity, or class, it is possible that a structure and its fields do not appear sequentially in the list. To restore the list to the original order, click the **Order** column heading.

Variable-Size Arrays in the Variables Tab

For variable-size arrays, the **Size** field includes information about the computed maximum size of the array. The size of each array dimension that varies is prefixed with a colon **:**. The size of an unbounded dimension is **:?**.

In the following report, variables **A** and **B** are variable-size. The second dimension of **A** has a maximum size of 100. The size of the second dimension of **B** is **:?**.

Summary	All Messages (0)	Variables	Target Build Log		
Order	Variable	Type	Size	Class	Complex
1	C	Output	1 x :100	double	No
2	A	Input	1 x :100	double	No
3	B	Input	1 x :?	double	No

If you declare a variable-size array, and then fix the dimensions of this array in the code, the report appends * to the size of the variable. In the generated C code, this variable appears as a variable-size array, but the sizes of its dimensions do not change during execution.

Summary	All Messages (0)	Variables	Target Build Log		
Order	Variable	Type	Size	Class	Complex
1	y	Output	1 x 1 *	double	No

For information about how to use the size information for variable-size arrays, see “Variable-Size Data Definition for Code Generation”.

Renamed Variables in the Variables Tab

If your MATLAB function reuses a variable with a different size, type, or complexity, the code generator attempts to create separate, uniquely named variables. For more information, see “Reuse the Same Variable with Different Properties”. The report numbers the renamed variables in the list on the **Variables** tab. When you place your cursor over a renamed variable, the report highlights only the instances of this variable that share data type, size, and complexity.

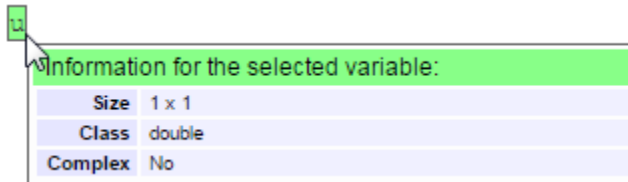

For example, suppose that your code uses the variable `t` to hold a scalar double, and reuses it outside the for-loop to hold a vector of doubles. In the list on the **Variables** tab, the report displays two variables, `t>1` and `t>2`,

Summary	All Messages (0)	Variables	Target Build Log		
Order	Variable	Type	Size	Class	Complex
1	y	Output	1 x 1	double	No
2	u	Input	5 x 5	double	No
3	t > 1	Local	1 x 1	double	No
4	t > 2	Local	:25 x 1	double	No

Viewing Information About Variables and Expressions in Your MATLAB Function Code

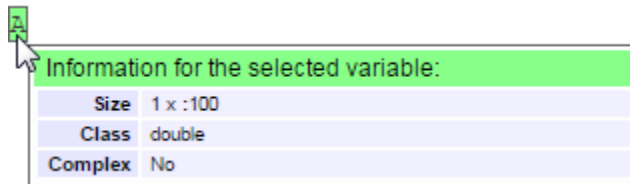

To view information about a particular variable or expression in your MATLAB function code, on the MATLAB code pane, place your cursor over the variable name or expression. The report highlights variables and expressions in different colors:

Green, when the variable has data type information at this location in the code

Information for the selected variable:	
Size	1 x 1
Class	double
Complex	No

For variable-size arrays, the **Size** field includes information on the computed maximum size of the array. The size of each array dimension that varies is prefixed with a colon **:**.

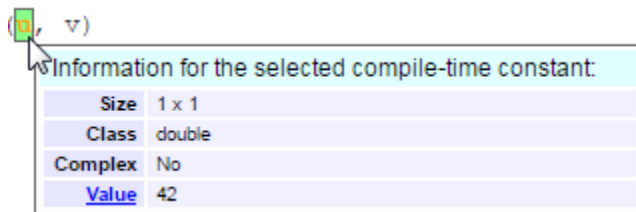

Information for the selected variable:	
Size	1 x :100
Class	double
Complex	No

Green with orange text, when a constant argument has data type and value information

When the variable is a compile-time constant argument to a specialized function:

- The variable name is orange.
- The information for the variable includes the value.

Information for the selected compile-time constant:	
Size	1 x 1
Class	double
Complex	No
Value	42

If you export the value as a variable to the base workspace, you can use the Workspace browser to view detailed information about the variable.

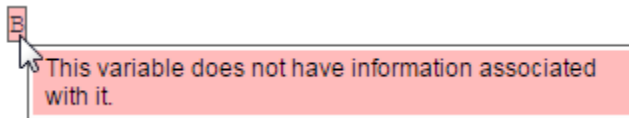

To export the value to the base workspace:

- 1 Click the **Value** link.

- 2 In the Export Constant Value dialog box, specify the **Variable name**.
- 3 Click **OK**.

The variable and its value appear in the Workspace browser.

Pink, when the variable has no data type information

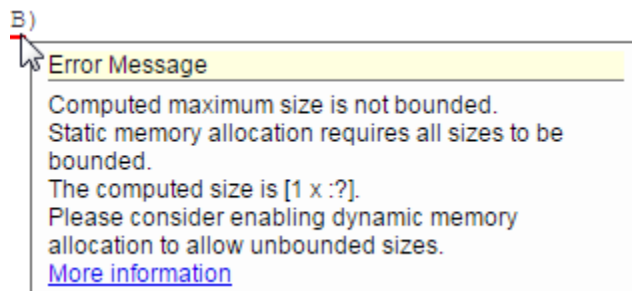

Purple, information about expressions

You can also view information about expressions in your MATLAB code. On the MATLAB code pane, place your cursor over an expression. The report highlights expressions in purple and provides more detailed information.

Red, when there is error information

Keyboard Shortcuts for the MATLAB Function Report

You can use keyboard shortcuts settings to perform actions in the report.

This table lists actions that you can associate with a keyboard shortcut. The keyboard shortcuts are defined in your MATLAB preferences. See “Define Keyboard Shortcuts”.

Action	Default Keyboard Shortcut for a Windows Platform
Zoom in	Ctrl+Plus
Zoom out	Ctrl+Minus
Evaluate selected MATLAB code	F9
Open help for selected MATLAB code	F1
Open selected MATLAB code	Ctrl+D
Step backward through files that you opened in the code pane	Alt+Left
Step forward through files that you opened in the code pane	Alt+Right
Refresh	F5
Search	Ctrl+F

Alternatively, you can select these actions from a context menu. To open the context menu, right-click anywhere in the report.

Zoom In	Ctrl+Plus
Zoom Out	Ctrl+Minus
Evaluate Selection	F9
Help on Selection	F1
Open Selection	Ctrl+D
Back	Alt+ Left
Forward	Alt+ Right
Refresh	F5
Find...	Ctrl+F
Page Source	

This table lists keyboard shortcuts that help you navigate between panes and tabs in the code generation report. To advance through data in the selected pane, use the **Tab** key. These keyboard shortcuts override the keyboard shortcut settings in your MATLAB preferences. See “Define Keyboard Shortcuts”.

To select	Use
MATLAB code tab	Ctrl+M
Call stack tab	Ctrl+K
Code Pane	Ctrl+W
Summary Tab	Ctrl+S
All Messages Tab	Ctrl+A
Variables Tab	Ctrl+V

Searching in the MATLAB Function Report

Use the keyboard shortcut associated with **F**ind in your MATLAB preferences. The default keyboard shortcut for **F**ind on a Windows platform is **Ctrl+F**.

Report Limitations

The report displays information about the variables and expressions in your MATLAB code with the following limitations:

varargin and **varargout**

The report does not support `varargin` and `varargout` arrays.

Loop Unrolling

The report does not display full information for unrolled loops. It displays data types of one arbitrary iteration.

Dead Code

The report does not display information about dead code.

Structures

The report does not provide complete information about structures.

- The report does not provide information about all structure fields in the `struct()` constructor.
- If a structure has a nonscalar field, and an expression accesses an element of this field, the report does not provide information for the field.

Column Headings on the Variables Tab

If you scroll through the list of variables, the report does not display the column headings on the **Variables** tab.

Multiline Matrices

On the **MATLAB code** pane, the report does not support selection of multiline matrices. It supports only selection of individual lines at a time. For example, if you place your cursor over the following matrix, you cannot select the entire matrix.

```
out1 = [1 2 3;  
        4 5 6];
```

The report does support selection of single line matrices.

```
out1 = [1 2 3; 4 5 6];
```

“Inheriting Argument Data Types” on page 39-63

“Built-In Data Types for Arguments” on page 39-63

“Specifying Argument Types with Expressions” on page 39-64

“Specifying Fixed-Point Designer Data Properties” on page 39-64

About Function Arguments

You create function arguments for a MATLAB Function block by entering them in its function header in the MATLAB Function Block Editor. When you define arguments, the Simulink software creates corresponding ports on the MATLAB Function block that you can attach to signals. You can select a *data type mode* for each argument that you define for a MATLAB Function block. Each data type mode presents its own set of options for selecting a *data type*.

By default, the data type mode for MATLAB Function block function arguments is **Inherited**. This means that the function argument inherits its data type from the incoming or outgoing signal. To override the default type, you first choose a data type mode and then select a data type based on the mode.

Specifying Argument Types

To specify the type of a MATLAB Function block function argument:

- 1 From the MATLAB Function Block Editor, select **Edit Data** to open the Ports and Data Manager.
- 2 In the left pane, select the argument of interest.
- 3 In the **Data** properties dialog box (right pane), click the Show data type assistant button  to display the Data Type Assistant. Then, choose an option from the **Mode** drop-down menu.

The **Data** properties dialog box changes dynamically to display additional fields for specifying the data type associated with the mode.

- 4 Based on the mode you select, specify a desired data type:

Mode	What to Specify
Inherit (default)	<p>You cannot specify a value. The data type is inherited from previously-defined data, based on the scope you selected for the MATLAB Function block function argument:</p> <ul style="list-style-type: none"> • If scope is Input, data type is inherited from the input signal on the designated port. • If scope is Output, data type is inherited from the output signal on the designated port. • If scope is Parameter, data type is inherited from the associated parameter, which can be defined in the Simulink masked subsystem or the MATLAB workspace. <p>See “Inheriting Argument Data Types” on page 39-63.</p>
Built in	<p>Select from the drop-down list of supported data types, as described in “Built-In Data Types for Arguments” on page 39-63.</p>
Fixed point	<p>Specify the fixed-point data properties as described in “Specifying Fixed-Point Designer Data Properties” on page 39-64.</p>
Expression	<p>Enter an expression that evaluates to a data type, as described in “Specifying Argument Types with Expressions” on page 39-64.</p>
Bus Object	<p>In the Bus object field, enter the name of a <code>Simulink.Bus</code> object to define the properties of a MATLAB structure. You must define the bus object in the base workspace. See “How Structure Inputs and Outputs Interface with Bus Signals” on page 39-78.</p> <hr/> <p>Note: You can click the Edit button to create or modify <code>Simulink.Bus</code> objects using the Simulink Bus Editor (see “Attach Bus Signals to MATLAB Function Blocks” on page 39-76).</p>
Enumerated	<p>In the Enumerated field, enter the name of a <code>Simulink.IntEnumType</code> object that you define in the base workspace. See “Code Generation for Enumerations” on page 39-103.</p>

Inheriting Argument Data Types

MATLAB Function block function arguments can inherit their data types, including fixed point types, from the signals to which they are connected. , and set data type mode using one of these methods:

- 1 Select the argument of interest in the Ports and Data Manager
- 2 In the **Data** properties dialog, select **Inherit: Same as Simulink** from the **Type** drop-down menu.

See “Built-In Data Types for Arguments” on page 39-63 for a list of supported data types.

Note An argument can also inherit its complexity (whether its value is a real or complex number) from the signal that is connected to it. To inherit complexity, set the **Complexity** field on the **Data** properties dialog to **Inherited**.

After you build the model, the **Compiled Type** column of the Ports and Data Manager gives the actual type inherited from Simulink in the compiled simulation application.

The inherited type of output data is inferred from diagram actions that store values in the specified output. In the preceding example, the variables `mean` and `stdev` are computed from operations with double operands, which yield results of type `double`. If the expected type matches the inferred type, inheritance is successful. In all other cases, a mismatch occurs during build time.

Note Library MATLAB Function blocks can have inherited data types, sizes, and complexities like ordinary MATLAB Function blocks. However, all instances of the library block in a given model must have inputs with the same properties.

Built-In Data Types for Arguments

When you select **Built-in** for **Data type mode**, the **Data** properties dialog displays a **Data type** field that provides a drop-down list of supported data types. You can also choose a data type from the **Data Type** column in the Ports and Data Manager. The supported data types are:

Data Type	Description
double	64-bit double-precision floating point
single	32-bit single-precision floating point
int32	32-bit signed integer
int16	16-bit signed integer
int8	8-bit signed integer
uint32	32-bit unsigned integer
uint16	16-bit unsigned integer
uint8	8-bit unsigned integer
boolean	Boolean (1 = true; 0 = false)

Specifying Argument Types with Expressions

You can specify the types of MATLAB Function block function arguments as expressions in the Ports and Data Manager.

- 1 Select `<data type expression>` from the **Type** drop-down menu of the Data properties dialog.
- 2 In the **Type** field, replace “`<data type expression>`” with an expression that evaluates to a data type. The following expressions are allowed:
 - Alias type from the MATLAB workspace, as described in “Creating a Data Type Alias”.
 - `fixdt` function to create a `Simulink.NumericType` object describing a fixed-point or floating-point data type
 - `type` operator, to base the type on previously defined data

Specifying Fixed-Point Designer Data Properties

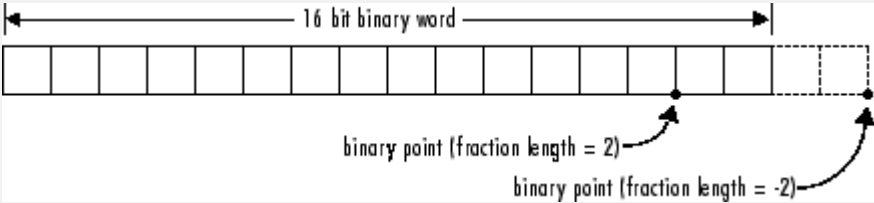

MATLAB Function blocks can represent signals and parameter values as fixed-point numbers. To simulate models that use fixed-point data in MATLAB Function blocks, you must install the Fixed-Point Designer product on your system.

You can set the following fixed-point properties:

Signedness. Select whether you want the fixed-point data to be **Signed** or **Unsigned**. Signed data can represent positive and negative quantities. Unsigned data represents positive values only. The default is **Signed**.

Word length. Specify the size (in bits) of the word that will hold the quantized integer. Large word sizes represent large quantities with greater precision than small word sizes. Word length can be any integer between 0 and 128 bits. The default is 16.

Scaling. Specify the method for scaling your fixed point data to avoid overflow conditions and minimize quantization errors. You can select the following scaling modes:

Scaling Mode	Description
Binary point (default)	<p>If you select this mode, the Data Type Assistant displays the Fraction Length field, specifying the binary point location.</p> <p>Binary points can be positive or negative integers. A positive integer moves the binary point left of the rightmost bit by that amount. For example, an entry of 2 sets the binary point in front of the second bit from the right. A negative integer moves the binary point further right of the rightmost bit by that amount, as in this example:</p>  <p>The diagram shows a horizontal row of 16 small squares representing bits. Above the squares, a double-headed arrow spans the entire row and is labeled "16 bit binary word". Below the squares, two dots are marked. The first dot is located between the 14th and 15th squares from the left. An arrow points from the text "binary point (fraction length = 2)" to this dot. The second dot is located to the right of the 16th square, between the 16th and 17th squares. An arrow points from the text "binary point (fraction length = -2)" to this dot. A dashed line extends from the 16th square to the right, ending at the second dot.</p> <p>The default is 0.</p>
Slope and bias	<p>If you select this mode, the Data Type Assistant displays fields for entering the Slope and Bias.</p> <ul style="list-style-type: none"> • Slope can be any <i>positive</i> real number. The default is 1.0. • Bias can be any real number. The default value is 0.0. <p>You can enter slope and bias as expressions that contain parameters defined in the MATLAB workspace.</p>

Note: You should use binary-point scaling whenever possible to simplify the implementation of fixed-point data in generated code. Operations with fixed-point data using binary-point scaling are performed with simple bit shifts and eliminate the expensive code implementations required for separate slope and bias values.

Data type override. Specify whether the data type override setting is **Inherit** (default) or **Off**.

Calculate Best-Precision Scaling. The Simulink software can automatically calculate “best-precision” values for both **Binary point** and **Slope and bias** scaling, based on the **Limit range** properties you specify.

To automatically calculate best precision scaling values:

- 1 Specify **Minimum**, **Maximum**, or both **Limit range** properties.
- 2 Click **Calculate Best-Precision Scaling**.

The Simulink software calculates the scaling values, then displays them in either the **Fraction Length**, or **Slope** and **Bias** fields.

Note: The **Limit range** properties do not apply to **Constant** or **Parameter** scopes. Therefore, Simulink cannot calculate best-precision scaling for these scopes.

Fixed-point Details. You can view the following Fixed-point details:

Fixed-point Detail	Description
Representable maximum	The maximum number that can be represented by the chosen data type, sign, word length and fraction length (or data type, sign, slope and bias).
Maximum	The maximum value specified.
Minimum	The minimum value specified.
Representable minimum	The minimum number that can be represented by the chosen data type, sign, word length and fraction length (or data type, sign, slope and bias).

Fixed-point Detail	Description
Precision	The precision for the given word length and fraction length (or slope and bias).

Using Data Type Override with the MATLAB Function Block

If you set the Data Type Override mode to **Double** or **Single** in Simulink, the MATLAB Function block sets the type of all inherited input signals and parameters to `fi_double` or `fi_single` objects respectively (see “MATLAB Function Block with Data Type Override” for more information). You must check the data types of your inherited input signals and parameters and use the Ports and Data Manager (see “Ports and Data Manager” on page 39-36) to set explicit types for any inputs that should not be fixed-point. Some operations, such as `sin`, are not applicable to fixed-point objects.

Note: If you do not set the correct input types explicitly, you may encounter compilation problems after setting Data Type Override.

How Do I Set Data Type Override?

To set Data Type Override, follow these steps:

- 1 From the Simulink **Analysis** menu, select **Fixed-Point Tool**.
- 2 Set the value of the **Data type override** parameter to **Double** or **Single**.

Size Function Arguments

In this section...

“Specifying Argument Size” on page 39-68

“Inheriting Argument Sizes from Simulink” on page 39-68

“Specifying Argument Sizes with Expressions” on page 39-69

Specifying Argument Size

To examine or specify the size of an argument, follow these steps:

- 1 From the MATLAB Function Block Editor, select **Edit Data**.
- 2 Enter the size of the argument in the **Size** field of the Data properties dialog, located in the **General** pane.

Note: The default value is -1, indicating that size is inherited, as described in “Inheriting Argument Sizes from Simulink” on page 39-68.

Inheriting Argument Sizes from Simulink

Size defaults to -1, which means that the data argument inherits its size from Simulink based on its scope:

For Scope	Inherits Size
Input	From the Simulink input signal connected to the argument.
Output	From the Simulink output signal connected to the argument.
Parameter	From the Simulink or MATLAB parameter to which it is bound. See “Add Parameter Arguments” on page 39-72.

After you compile the model, the **Compiled Size** column in the **Contents** pane displays the actual size used in the compiled simulation application.

The size of an output argument is the size of the value that is assigned to it. If the expected size in the Simulink model does not match, a mismatch error occurs during compilation of the model.

Note: No arguments with inherited sizes are allowed for MATLAB Function blocks in a library.

Specifying Argument Sizes with Expressions

The size of a data argument can be a scalar value or a MATLAB vector of values.

To specify size as a scalar, set the **Size** field to 1 or leave it blank. To specify **Size** as a vector, enter an array of up to two dimensions in [row column] format where

- Number of dimensions equals the length of the vector.
- Size of each dimension corresponds to the value of each element of the vector.

For example, a value of [2 4] defines a 2-by-4 matrix. To define a row vector of size 5, set the **Size** field to [1 5]. To define a column vector of size 6, set the **Size** field to [6 1] or just 6. You can enter a MATLAB expression for each [row column] element in the **Size** field. Each expression can use one or more of the following elements:

- Numeric constants
- Arithmetic operators, restricted to +, -, *, and /
- Parameters
- Calls to the MATLAB functions `min`, `max`, and `size`

The following examples are valid expressions for **Size**:

```
k+1
size(x)
min(size(y),k)
```

In these examples, `k`, `x`, and `y` are variables of scope `Parameter`.

Once you build the model, the **Compiled Size** column displays the actual size used in the compiled simulation application.

Units in MATLAB Function Blocks

In this section...

“Units for Input and Output Data” on page 39-71

“Consistency Checking” on page 39-71

“Units for Stateflow Limitations” on page 39-71

Units for Input and Output Data

MATLAB Function blocks support the specification of physical units as properties for data inputs and outputs. Specify units by using the **Unit (e.g., m, m/s², N*m)** parameter. When you start typing in the unit field, this parameter provides matching suggestions for units that Simulink supports. By default, the property is set to inherit the unit from the Simulink signal on the corresponding input or output port. If you select the **Data must resolve to Simulink signal object** property for output data, you cannot specify units. In this case, output data is assigned the same unit type as the Simulink signal connected to the output port.

To display the units on the Simulink lines in the model, select **Display > Signals and Ports > Port Units**.

Consistency Checking

MATLAB Function blocks check the consistency of the signal line unit from Simulink with the unit setting for the corresponding input or output data in the block. If the units do not match, Simulink displays a warning during model update.

Units for Stateflow Limitations

The unit property settings do not affect the execution of the MATLAB Function block. Simulink checks only consistency with the corresponding Simulink signal line connected to the input or output. It does not check consistency of assignments inside the MATLAB Function blocks. For example, Simulink does not warn against an assignment of an input with unit set to `ft` to an output with unit set to `m`. A MATLAB Function block does not perform unit conversions.

More About

- “Unit Specification in Simulink Models” on page 9-2

Add Parameter Arguments

Parameter arguments for MATLAB Function blocks do not take their values from signals in the Simulink model. Instead, Simulink searches up the workspace hierarchy. Simulink first looks in a masked workspace if the MATLAB Function block or a parent subsystem is masked. If the value is not found, it next looks in the model workspace and then the MATLAB base workspace.

You can provide a custom interface for parameters by masking the MATLAB Function block. Creating a mask for a block allows you to define the access for each parameter.

- 1 In the MATLAB Function Block Editor, add an argument to the function header of the MATLAB Function block. The name of the argument must match the name of the masked parameter or MATLAB variable that you want to pass to the MATLAB Function block.

The new argument appears as an input port on the MATLAB Function block in the model.

- 2 In the MATLAB Function Block Editor, click **Edit Data**.
- 3 Select the new argument.
- 4 Set **Scope** to **Parameter** and click **Apply**.

The input port for the parameter argument no longer appears in the MATLAB Function block.

Note: Parameter arguments appear as arguments in the function header of the MATLAB Function block to maintain MATLAB consistency. As a result, you can test functions in a MATLAB Function block by copying and pasting them to MATLAB.

Resolve Signal Objects for Output Data

In this section...

“Implicit Signal Resolution” on page 39-73

“Eliminating Warnings for Implicit Signal Resolution in the Model” on page 39-73

“Disabling Implicit Signal Resolution for a MATLAB Function Block” on page 39-73

“Forcing Explicit Signal Resolution for an Output Data Signal” on page 39-74

Implicit Signal Resolution

MATLAB Function blocks participate in signal resolution with Simulink signal objects. By default, output data from MATLAB Function blocks become associated with Simulink signal objects of the same name during a process called *implicit signal resolution*.

By default, implicit signal resolution generates a warning when you update the chart in the Simulink model. The following sections show you how to manage implicit signal resolution at various levels of the model hierarchy. See “Symbol Resolution” on page 4-82 and “Explicit and Implicit Symbol Resolution” on page 4-85 for more information.

Eliminating Warnings for Implicit Signal Resolution in the Model

To enable implicit signal resolution for all signals in a model, but eliminate the attendant warnings, follow these steps:

- 1 In the Simulink Editor, select **Simulation > Model Configuration Parameters**.

The Configuration Parameters dialog appears.

- 2 In the left pane of the Configuration Parameters dialog, under Diagnostics, select **Data Validity**.

Data Validity configuration parameters appear in the right pane.

- 3 In the Signal resolution field, select **Explicit and implicit**.

Disabling Implicit Signal Resolution for a MATLAB Function Block

To disable implicit signal resolution for a MATLAB Function block in your model, follow these steps:

- 1 Right-click the MATLAB Function block and select **Block Parameters (Subsystem)** in the context menu.

The Block Parameters dialog opens.

- 2 In the Permit hierarchical resolution field, select **ExplicitOnly** or **None**, and click **OK**.

Forcing Explicit Signal Resolution for an Output Data Signal

To force signal resolution for an output signal in a MATLAB Function block, follow these steps:

- 1 In the Simulink model, right-click the signal line connected to the output that you want to resolve and select **Properties** from the context menu.
- 2 In the Signal Properties dialog, enter a name for the signal that corresponds to the signal object.
- 3 Select the **Signal name must resolve to Simulink signal object** check box and click **OK**.

- “Symbol Resolution” on page 4-82

Types of Structures in MATLAB Function Blocks

In MATLAB Function blocks, you can define structure data as inputs or outputs that interact with bus signals. MATLAB Function blocks also support arrays of buses. You can also define structures inside MATLAB functions that are not part of MATLAB Function blocks.

The following table summarizes how to create different types of structures in MATLAB Function blocks:

Scope	How to Create	Details
Input	Create structure data with scope of Input.	You can create structure data as inputs or outputs in the top-level MATLAB function for interfacing to other environments. See “Create Structures in MATLAB Function Blocks” on page 39-82.
Output	Create structure data with scope of Output.	
Local	Create a local variable implicitly in a MATLAB function.	See “Define Scalar Structures for Code Generation” on page 49-4.
Persistent	Declare a variable to be persistent in a MATLAB function.	See persistent .
Parameter	Create structure data with scope of Parameter.	See “Define and Use Structure Parameters” on page 39-89.

Structures in MATLAB Function blocks can contain fields of any type and size, including muxed signals, buses, and arrays of structures.

Related Examples

- “Combine Buses into an Array of Buses” on page 63-91

More About

- “What Is a MATLAB Function Block?” on page 39-5
- “Structure Definition for Code Generation” on page 49-2

Attach Bus Signals to MATLAB Function Blocks

For an example of how to use structures in a MATLAB Function block, open the model `emldemo_bus_struct`.

In this model, a MATLAB Function block receives a bus signal using the structure `inbus` at input port 1 and outputs two bus signals from the structures `outbus` at output port 1 and `outbus1` at output port 2. The input signal comes from the Bus Creator block `MainBusCreator`, which bundles signals `ele1`, `ele2`, and `ele3`. The signal `ele3` is the output of another Bus Creator block `SubBusCreator`, which bundles the signals `a1` and `a2`. The structure `outbus` connects to a Bus Selector block `BusSelector1`; the structure `outbus1` connects to another Bus Selector block `BusSelector3`.

To explore the MATLAB function `fcn`, double-click the MATLAB Function block. Notice that the code implicitly defines a local structure variable `mystruct` using the `struct` function, and uses this local structure variable to initialize the value of the first output `outbus`. It initializes the second output `outbus1` to the value of field `ele3` of structure `inbus`.

Structure Definitions in Example

Here are the definitions of the structures in the MATLAB Function block in the example, as they appear in the Ports and Data Manager:

	Name	Scope	Port	Resolve Signal	Data Type	Size
	<code>inbus</code>	Input	1		Inherit: Same as Simulink	-1
	<code>outbus</code>	Output	1	<input type="checkbox"/>	Bus: MainBus	1
	<code>outbus1</code>	Output	2	<input type="checkbox"/>	Bus: SubBus	1

Bus Objects Define Structure Inputs and Outputs

Each structure input and output must be defined by a `Simulink.Bus` object in the base workspace (see “Create Structures in MATLAB Function Blocks” on page 39-82). This means that the structure shares the same properties as the bus object, including number, name, type, and sequence of fields. In this example, the following bus objects define the structure inputs and outputs:

Name	Data Type	Complexity	Dimensions	Dimensionality
ele1	double	real	1	Fixed
ele2	single	real	1	Fixed
ele3(SubBus)	SubBus	real	1	Fixed

The `Simulink.Bus` object `MainBus` defines structure input `inbus` and structure output `outbus`. The `Simulink.Bus` object `SubBus` defines structure output `outbus1`. Based on these definitions, `inbus` and `outbus` have the same properties as `MainBus` and, therefore, reference their fields by the same names as the fields in `MainBus`, using dot notation (see “Index Substructures and Fields” on page 39-80). Similarly, `outbus1` references its fields by the same names as the fields in `SubBus`. Here are the field references for each structure in this example:

Structure	First Field	Second Field	Third Field
<code>inbus</code>	<code>inbus.ele1</code>	<code>inbus.ele2</code>	<code>inbus.ele3</code>
<code>outbus</code>	<code>outbus.ele1</code>	<code>outbus.ele2</code>	<code>outbus.ele3</code>
<code>outbus1</code>	<code>outbus1.a1</code>	<code>outbus1.a2</code>	—

How Structure Inputs and Outputs Interface with Bus Signals

Buses in a Simulink model appear inside the MATLAB Function block as structures; structure outputs from the MATLAB Function block appear as buses in Simulink models. When you create structure inputs, the MATLAB Function block determines the type, size, and complexity of the structure from the input signal. When you create structure outputs, you must define their type, size, and complexity in the MATLAB function.

You connect structure inputs and outputs from MATLAB Function blocks to any bus signal, including:

- Blocks that output bus signals — such as Bus Creator blocks
- Blocks that accept bus signals as input — such as Bus Selector and Gain blocks
- S-Function blocks
- Other MATLAB Function blocks

You can use global bus type data in Data Store Memory blocks with MATLAB Function blocks. For more information on using buses and Data Store Memory, see “Data Stores with Buses and Arrays of Buses” on page 60-30.

Working with Virtual and Nonvirtual Buses

MATLAB Function blocks supports nonvirtual buses only (see “Virtual and Nonvirtual Buses” on page 63-4). For MATLAB Function block bus inputs, incoming virtual bus signals are converted to nonvirtual buses.

Rules for Defining Structures in MATLAB Function Blocks

Follow these rules when defining structures in MATLAB Function blocks:

- For each structure input or output in a MATLAB Function block, you must define a `Simulink.Bus` object in the base workspace to specify its type.
- MATLAB Function blocks support nonvirtual buses only.

See Also

`Simulink.Bus`

Index Substructures and Fields

As in MATLAB, you index substructures and fields structures in MATLAB Function blocks by using dot notation. However, for code generation from MATLAB, you must reference field values individually (see “Structure Definition for Code Generation” on page 49-2).

For example, in the `emldemo_bus_struct` model described in “Attach Bus Signals to MATLAB Function Blocks” on page 39-76, the MATLAB function uses dot notation to index fields and substructures:

```
function [outbus, outbus1] = fcn(inbus)
%#codegen
substruct.a1 = inbus.ele3.a1;
substruct.a2 = int8([1 2;3 4]);

mystruct = struct('ele1',20.5,'ele2',single(100),
                 'ele3',substruct);

outbus = mystruct;
outbus.ele3.a2 = 2*(substruct.a2);

outbus1 = inbus.ele3;
```

The following table shows how the code generation software resolves symbols in dot notation for indexing elements of the structures in this example:

Dot Notation	Symbol Resolution
<code>substruct.a1</code>	Field <code>a1</code> of local structure <code>substruct</code>
<code>inbus.ele3.a1</code>	Value of field <code>a1</code> of field <code>ele3</code> , a substructure of structure <code>inputinbus</code>
<code>inbus.ele3.a2(1,1)</code>	Value in row 1, column 1 of field <code>a2</code> of field <code>ele3</code> , a substructure of structure <code>input inbus</code>

Create Structures in MATLAB Function Blocks

Here is the workflow for creating a structure in a MATLAB Function block:

- 1 Decide on the type (or scope) of the structure (see “Types of Structures in MATLAB Function Blocks” on page 39-75).
- 2 Based on the scope, follow these guidelines for creating the structure:

For Structure Scope:	Follow These Steps:
Input	<p>a Create a <code>Simulink.Bus</code> object in the base workspace to define the structure input.</p> <p>b Add data to the MATLAB Function block, as described in “Adding Data to a MATLAB Function Block” on page 39-40. The data should have the following properties</p> <ul style="list-style-type: none"> • Scope = Input • Type = Bus: <object name> <p>For <object name>, enter the name of the <code>Simulink.Bus</code> object that defines the structure input</p> <p>See “Rules for Defining Structures in MATLAB Function Blocks” on page 39-79.</p>
Output	<p>a Create a <code>Simulink.Bus</code> object in the base workspace to define the structure output.</p> <p>b Add data to the MATLAB Function block with the following properties:</p> <ul style="list-style-type: none"> • Scope = Output • Type = Bus: <object name> <p>For <object name>, enter the name of the <code>Simulink.Bus</code> object that defines the structure output</p> <p>c Define and initialize the output structure implicitly as a variable in the MATLAB function, as described in “Structure Definition for Code Generation” on page 49-2.</p> <p>d Make sure the number, type, and size of fields in the output structure variable definition match the properties of the <code>Simulink.Bus</code> object.</p>

For Structure Scope:	Follow These Steps:
Local	Define the structure implicitly as a local variable in the MATLAB function, as described in “Structure Definition for Code Generation” on page 49-2. By default, local variables in MATLAB Function blocks are temporary.
Persistent	Define the structure implicitly as a persistent variable in the MATLAB function.
Parameter	<p>a Create a structure variable in the base workspace.</p> <p>b Add data to the MATLAB Function block with the following properties:</p> <ul style="list-style-type: none">• Name = same name as the structure variable you created in step 1.• Scope = Parameter <p>See “Define and Use Structure Parameters” on page 39-89.</p>

Assign Values to Structures and Fields

You can assign values to any structure, substructure, or field in a MATLAB Function block. Here are the guidelines:

Operation	Conditions
Assign one structure to another structure	You must define each structure with the same number, type, and size of fields, either as <code>Simulink.Bus</code> objects in the base workspace or locally as implicit structure declarations (see “Create Structures in MATLAB Function Blocks” on page 39-82).
Assign one structure to a substructure of a different structure and vice versa	You must define the structure with the same number, type, and size of fields as the substructure, either as <code>Simulink.Bus</code> objects in the base workspace or locally as implicit structure declarations.
Assign an element of one structure to an element of another structure	The elements must have the same type and size.

For example, the following table presents valid and invalid structure assignments based on the specifications for the model described in “Attach Bus Signals to MATLAB Function Blocks” on page 39-76:

Assignment	Valid or Invalid?	Rationale
<code>outbus = mystruct;</code>	Valid	Both <code>outbus</code> and <code>mystruct</code> have the same number, type, and size of fields. The structure <code>outbus</code> is defined by the <code>Simulink.Bus</code> object <code>MainBus</code> and <code>mystruct</code> is defined locally to match the field properties of <code>MainBus</code> .
<code>outbus = inbus;</code>	Valid	Both <code>outbus</code> and <code>inbus</code> are defined by the same <code>Simulink.Bus</code> object, <code>MainBus</code> .
<code>outbus1 = inbus.ele3;</code>	Valid	Both <code>outbus1</code> and <code>inbus.ele3</code> have the same type and size because each is defined by the <code>Simulink.Bus</code> object <code>SubBus</code> .

Assignment	Valid or Invalid?	Rationale
<code>outbus1 = inbus;</code>	Invalid	The structure <code>outbus1</code> is defined by a different <code>Simulink.Bus</code> object than the structure <code>inbus</code> .

Initialize a Matrix Using a Nontunable Structure Parameter

The following simple example uses a nontunable structure parameter input to initialize a matrix output. The model looks like this:

This model defines a structure variable `p` in its pre-load callback function, as follows:

The structure `p` has two fields, `rows` and `cols`, which specify the dimensions of a matrix. The MATLAB Function block uses a constant input `u` to initialize the matrix output `y`. Here is the code:

```
function y = fcn(u, p)
y = zeros(p.rows,p.cols) + u;
```

Running the model initializes each element of the 2-by-3 matrix `y` to 99, the value of `u`:

Define and Use Structure Parameters

In this section...

“Defining Structure Parameters” on page 39-89

“FIMATH Properties of Nontunable Structure Parameters” on page 39-89

Defining Structure Parameters

To define structure parameters in MATLAB Function blocks, follow these steps:

- 1 Define and initialize a structure variable

A common method is to create a structure in the base workspace.

- 2 In the Ports and Data Manager, add data in the MATLAB Function block with the following properties:

Property	What to Specify
Name	Enter same name as the structure variable you defined in the base workspace
Scope	Select Parameter
Tunable	Leave checked if you want to change (tune) the value of the parameter during simulation; otherwise, clear to make the parameter nontunable and preserve the initial value during simulation
Type	Select Inherit: Same as Simulink

- 3 Click **Apply**.

FIMATH Properties of Nontunable Structure Parameters

FIMATH properties for nontunable structure parameters containing fixed-point values are based on the initial values of the structure. They do *not* come from the FIMATH properties specified for fixed-point input signals to the parent MATLAB Function block. (These FIMATH properties appear in the properties dialog box for MATLAB Function blocks.)

Declare Variable-Size Inputs and Outputs

- 1 In the MATLAB Function Block Editor, select **Edit Data**.
- 2 Select **Add > Data**
- 3 Select the **Variable size** check box.
- 4 Set **Scope** as either Input or Output.
- 5 Enter size:

For:	What to Specify
Input	Enter -1 to inherit size from Simulink or specify the explicit size and upper bound. For example, enter [2 4] to specify a 2-D matrix where the upper bounds are 2 for the first dimension and 4 for the second.
Output	Specify the explicit size and upper bound.

Filter a Variable-Size Signal

In this section...

“About the Example” on page 39-95
 “Simulink Model” on page 39-95
 “Source Signal” on page 39-96
 “MATLAB Function Block: uniquify” on page 39-96
 “MATLAB Function Block: avg” on page 39-98
 “Variable-Size Results” on page 39-99

About the Example

The following example appears throughout this section to illustrate how MATLAB Function blocks exchange variable-size data with other Simulink blocks. The model uses a variable-size vector to store the values of a white noise signal. The size of the vector may vary at run time as the signal values get pruned by functions that:

- Filter out signal values that are not unique within a specified tolerance of each other
- Average every two signal values and output only the resulting means

Simulink Model

Open the example model by typing `emldemo_process_signal` at the MATLAB command prompt. The model contains the following blocks:

Simulink Block	Description
Band-Limited White Noise	Generates a set of normally distributed random values as the source of the white noise signal.
MATLAB Function <code>uniquify</code>	Filters out signal values that are not unique to within a specified tolerance of each other.
MATLAB Function <code>avg</code>	Outputs the average of a specified number of unique signal values.
Unique values	Scope that displays the unique signal values output from the <code>uniquify</code> function.

Simulink Block	Description
Average values	Scope that displays the average signal values output from the <code>avg</code> function.

Source Signal

The band-limited white noise signal has these properties:

Parameters

Noise power:

Sample time:

Seed:

Interpret vector parameters as 1-D

The size of the noise power value defines the size of the matrix that holds the signal values — in this case, a 1-by-9 vector of double values.

MATLAB Function Block: `uniquify`

This block filters out signal values that are not within a tolerance of 0.2 of each other. Here is the code:

```
function y = uniquify(u) %#codegen
y = emldemo_uniquetol(u,0.2);
```

The `uniquify` function calls an external MATLAB function `emldemo_uniquetol` to filter the signal values. `uniquify` passes the 1-by-9 vector of white noise signal values as the first argument and the tolerance value as the second argument. Here is the code for `emldemo_uniquetol`:

```
function B = emldemo_uniquetol(A,tol) %#codegen
```

```

A = sort(A);
coder.varsize('B',[1 100]);
B = A(1);
k = 1;
for i = 2:length(A)
    if abs(A(k) - A(i)) > tol
        B = [B A(i)];
        k = i;
    end
end
end

```

`emldemo_uniquetol` returns the filtered values of `A` in an output vector `B` so that $\text{abs}(B(i) - B(j)) > \text{tol}$ for all `i` and `j`. Every time Simulink samples the Band-Limited White Noise block, it generates a different set of random values for `A`. As a result, `emldemo_uniquetol` may produce a different number of output signals in `B` each time it is called. To allow `B` to accommodate a variable number of elements, `emldemo_uniquetol` declares it as variable-size data with an explicit upper bound:

```
coder.varsize('B',[1 100]);
```

In this statement, `coder.varsize` declares `B` as a vector whose first dimension is fixed at 1 and whose second dimension can grow to a maximum size of 100. Accordingly, output `y` of the `uniquify` block must also be variable sized so it can pass the values returned from `emldemo_uniquetol` to the **Unique values** scope. Here are the properties of `y`:

Data y

General Description

Name:

Scope: Port:

Data must resolve to Simulink signal object

Size: Variable size

Complexity:

Sampling mode:

Type:

For variable-size outputs, you must specify an explicit size and upper bound, shown here as [1 9].

MATLAB Function Block: avg

This block averages signal values filtered by the `uniquify` block as follows:

If number of signal values:	The MATLAB Function block:
> 1 and divisible by 2	Averages every consecutive pair of values
> 1 but <i>not</i> divisible by 2	Drops the first (smallest) value and average the remaining consecutive pairs
= 1	Returns the value unchanged

The `avg` function outputs the results to the **Average values** scope. Here is the code:

```
function y = avg(u) %#codegen

if numel(u) == 1
    y = u;
else
    k = numel(u)/2;
    if k ~= floor(k)
        u = u(2:numel(u));
    end
    y = emldemo_navg(u,2);
end
```

Both input `u` and output `y` of `avg` are declared as variable-size vectors because the number of elements varies depending on how the `uniquify` function block filters the signal values. Input `u` inherits its size from the output of `uniquify`.

Data u

General Description

Name:

Scope: Port:

Size: Variable size

Complexity:

Type:

The `avg` function calls an external MATLAB function `emldemo_navg` to calculate the average of every two consecutive signal values. Here is the code for `emldemo_navg`:

```
function B = emldemo_navg(A,n) %#codegen
assert(n>=1 && n<=numel(A));

B = zeros(1,numel(A)/n);
k = 1;
for i = 1 : numel(A)/n
    B(i) = mean(A(k + (0:n-1)));
    k = k + n;
end
```

Variable-Size Results

Simulating the model produces the following results:

- The `uniquify` block outputs a variable number of signal values each time it executes:

- The avg block outputs a variable number of signal values each time it executes — approximately half the number of the unique values:

Code Generation for Enumerations

Enumerations represent a fixed set of named values. Enumerations help make your MATLAB code and generated C/C++ code more readable. For example, the generated code can test equality with code such as `if (x == Red)` instead of using `strcmp`. To generate C/C++ code, you must have Simulink Coder.

When you use enumerations in a MATLAB Function block, adhere to these restrictions:

- “Define Enumerations for MATLAB Function Blocks” on page 39-103
- “Use Allowed Operations on Enumerations” on page 39-105
- “Use MATLAB Toolbox Functions That Support Enumerations” on page 39-105

Define Enumerations for MATLAB Function Blocks

You can define enumerations for MATLAB Function blocks in two ways:

- To import an externally defined enumeration, use the `Simulink.defineIntEnumType` function. See “Import Enumerations Defined Externally to MATLAB” on page 58-12.
- In a class definition file, define an enumerated type. For example:

```
classdef PrimaryColors < Simulink.IntEnumType
    enumeration
        Red(1),
        Blue(2),
        Yellow(4)
    end
end
```

If you define an enumerated type in a class definition file, the class must derive from one of these base types: `Simulink.IntEnumType`, `int8`, `uint8`, `int16`, `uint16`, or `int32`. Then, you can exchange enumerated data between MATLAB Function blocks and other Simulink blocks in a model.

If you use Simulink Coder to generate C/C++ code, you can use the enumeration class base type to control the size of an enumerated type in generated C/C++ code. You can:

- Represent an enumerated type as a fixed-size integer that is portable to different targets.

- Reduce memory usage.
- Interface with legacy code.
- Match company standards.

The base type determines the representation of the enumerated type in generated C/C++ code.

If the base type is `Simulink.IntEnumType`, the code generator produces a C enumeration type. Consider the following MATLAB enumerated type definition:

```
classdef LEDcolor < Simulink.IntEnumType
    enumeration
        GREEN(1),
        RED(2)
    end
end
```

This enumerated type definition results in the following C code:

```
typedef enum {
    GREEN = 1,
    RED
} LEDcolor;
```

For built-in integer base types, the code generator produces a `typedef` statement for the enumerated type and `#define` statements for the enumerated values. Consider the following MATLAB enumerated type definition:

```
classdef LEDcolor < int16
    enumeration
        GREEN(1),
        RED(2)
    end
end
```

This enumerated type definition results in the following C code:

```
typedef int16_T LEDcolor;

#define GREEN ((LEDcolor)1)
#define RED ((LEDcolor)2)
```

To customize the code generated for an enumerated type, see “Customize Simulink Enumeration” on page 58-9.

Use Allowed Operations on Enumerations

For code generation, you are restricted to the operations on enumerations listed in this table.

Operation	Example
assignment operator, =	<code>xon = LEDcolor.GREEN</code> <code>xoff = LEDcolor.RED</code>
relational operators, < > <= >= == ~= You cannot use == or ~= to test equality between an enumeration member and a character array or cell array of character arrays.	<code>xon == xoff</code>
cast operation	<code>double(LEDcolor.RED)</code>
indexing operation	<code>m = [1 2]</code> <code>n = LEDcolor(m)</code> <code>p = n(LEDcolor.GREEN)</code>
control flow statements: if, switch, while	<code>if state == sysMode.ON</code> <code>led = LEDcolor.GREEN;</code> <code>else</code> <code>led = LEDcolor.RED;</code> <code>end</code>

Use MATLAB Toolbox Functions That Support Enumerations

For code generation, you can use enumerations with these MATLAB toolbox functions:

- `cast`
- `cat`
- `circshift`
- `fliplr`
- `flipud`
- `histc`
- `intersect`
- `ipermute`

- `isequal`
- `isequaln`
- `isfinite`
- `isinf`
- `ismember`
- `isnan`
- `issorted`
- `length`
- `permute`
- `repmat`
- `reshape`
- `rot90`
- `setdiff`
- `setxor`
- `shiftdim`
- `sort`
- `sortrows`
- `squeeze`
- `union`
- `unique`

More About

- “What Is a MATLAB Function Block?” on page 39-5
- “Add Enumerated Inputs, Outputs, and Parameters to a MATLAB Function Block” on page 39-107
- “Use Enumerations to Control an LED Display” on page 39-108

Add Enumerated Inputs, Outputs, and Parameters to a MATLAB Function Block

When you add enumerated inputs, outputs, or parameters to a MATLAB Function block, follow these guidelines:

- For inputs, inherit the type from the enumerated type of the connected Simulink signal or specify the enumeration explicitly.
- For outputs, specify the enumerated type explicitly.
- For tunable parameters, specify the enumerated type explicitly. For nontunable parameters, derive properties from an enumerated parameter in a parent Simulink masked subsystem or enumerated variable defined in the MATLAB base workspace.

To add enumerated data to a MATLAB Function block:

- 1 In the MATLAB Function Block Editor, select **Edit Data**.
- 2 In the Ports and Data Manager, select **Add > Data**.
- 3 In the **Name** field, enter a name for the enumerated data.

For parameters, the name must match the enumerated masked parameter or workspace variable name.

- 4 In the **Type** field, specify an enumerated type.
 - For an explicit enumerated type, set **Type** to `Enum:<class name>`. Replace `<class name>` with the name of an enumerated data type that you defined in a MATLAB file on the MATLAB path.

The **Complexity** field is not visible because enumerated data types do not support complex values.

- To inherit the enumerated type from a connected Simulink signal (for inputs only), set **Type** to `Inherit:Same as Simulink`.

Use Enumerations to Control an LED Display

In this section...

“Simulink Model” on page 39-108

“Enumeration Class Definitions” on page 39-109

“MATLAB Function Block Function” on page 39-109

“Simulation” on page 39-110

This example shows how to use enumerations in a MATLAB Function block. The example shows how MATLAB Function blocks exchange enumerated data with other Simulink blocks.

The `emldemo_led_switch` model uses enumerations to represent the modes of a device that controls the colors of an LED display. The MATLAB Function block receives an enumerated input signal that represents the mode. The enumerated output signal represents the color that the LED displays.

Simulink Model

To open the model, at the command prompt, enter:

```
emldemo_led_switch
```

The model contains the blocks listed in this table.

Simulink Block	Description
Step	Provides source of the on/off signal. Outputs an initial value of 0 (off) and at 10 seconds steps up to a value of 1 (on).
Data Type Conversion from <code>double</code> to <code>int32</code>	Converts the <code>Step</code> signal of type <code>double</code> to type <code>int32</code> .
Data Type Conversion from <code>int32</code> to enumerated type <code>switchmode</code>	Converts the value of type <code>int32</code> to the enumerated type <code>switchmode</code> . TheData Type Conversion block parameters have these settings: <ul style="list-style-type: none"> • Output minimum: []

Simulink Block	Description
	<ul style="list-style-type: none"> • Output maximum: [] • Output data type: Enum:switchmode
MATLAB Function block checkState	Evaluates the enumerated input state to determine the value of the enumerated output ledval. state inherits its enumerated type switchmode from the Simulink step signal. ledval has the type Enum:led.
Display	Displays the value of ledval.

Enumeration Class Definitions

The `switchmode` enumeration represents the allowed modes for the input to the `checkstate` block.

```
classdef switchmode < Simulink.IntEnumType
    enumeration
        OFF(0)
        ON(1)
    end
end
```

The `led` enumeration represents the colors that the `checkstate` block can output.

```
classdef led < Simulink.IntEnumType
    enumeration
        GREEN(1),
        RED(8)
    end
end
```

Both enumeration classes inherit from the built-in type `Simulink.IntEnumType` and reside on the MATLAB path.

MATLAB Function Block Function

The function `checkState` uses enumerations to activate an LED display, based on the state of a device. It lights a green LED display to indicate the ON state. It lights a red LED display to indicate the OFF state.

```
function ledval = checkState(state)
%#codegen

if state == switchmode.ON
    ledval = led.GREEN;
else
    ledval = led.RED;
end
```

Simulation

When you simulate the model, the Display block displays the state of the LED display. If you simulate the model for less than 10 seconds, the state is off. The Display block displays **RED**. If you simulate the model for more than 10 seconds, the state is on. The Display block displays **GREEN**.

Share Data Globally

In this section...

“When Do You Need to Use Global Data?” on page 39-111

“Using Global Data with the MATLAB Function Block” on page 39-111

“Choosing How to Store Global Data” on page 39-112

“How to Use Data Store Memory Blocks” on page 39-113

“How to Use Simulink.Signal Objects” on page 39-115

“Using Data Store Diagnostics to Detect Memory Access Issues” on page 39-117

“Limitations of Using Shared Data in MATLAB Function Blocks” on page 39-117

When Do You Need to Use Global Data?

You might need to use global data with a MATLAB Function block if:

- You have multiple MATLAB functions that use global variables and you want to call these functions from MATLAB Function blocks.
- You have an existing model that uses a large amount of global data and you are adding a MATLAB Function block to this model, and you want to avoid cluttering your model with additional inputs and outputs.
- You want to scope the visibility of data to parts of the model.

Using Global Data with the MATLAB Function Block

In Simulink, you store global data using data store memory. You implement data store memory using either **Data Store Memory** blocks or **Simulink.Signal** objects. How you store global data depends on the number and scope of your global variables. For more information, see “Local and Global Data Stores” on page 60-3 and “Choosing How to Store Global Data” on page 39-112.

How MATLAB Globals Relate to Data Store Memory

In MATLAB functions in Simulink, global declarations are not mapped to the MATLAB global workspace. Instead, you register global data with the MATLAB Function block to map the data to data store memory. This difference allows global data in MATLAB functions to inter-operate with the Simulink solver and to provide diagnostics if they are misused.

A global variable resolves hierarchically to the closest data store memory with the same name in the model. The same global variable occurring in two different MATLAB Function blocks might resolve to different data store memory depending on the hierarchy of your model. You can use this ability to scope the visibility of data to a subsystem.

How to Use Globals with the MATLAB Function Block

To use global data in your MATLAB Function block, or in any code that this block calls, you must:

- 1 Declare a global variable in your MATLAB Function block, or in any code that is called by the MATLAB Function block.
- 2 Register a Data Store Memory block or `Simulink.Signal` object that has the same name as the global variable with the MATLAB Function block.

For more information, see “How to Use Data Store Memory Blocks” on page 39-113 and “How to Use Simulink.Signal Objects” on page 39-115.

Choosing How to Store Global Data

The following table summarizes whether to use Data Store Memory blocks or `Simulink.Signal` objects.

If you want to:	Use:	For more information:
Use a small number of global variables in a single model that does not use model reference.	Data Store Memory blocks. Note: Using Data Store Memory blocks scopes the data to the model.	“How to Use Data Store Memory Blocks” on page 39-113
Use a large number of global variables in a single model that does not use model reference.	<code>Simulink.Signal</code> objects defined in the model workspace. <code>Simulink.Signal</code> objects offer these advantages: <ul style="list-style-type: none"> • You do not have to add numerous Data Store Memory blocks to your model. 	“How to Use Simulink.Signal Objects” on page 39-115

If you want to:	Use:	For more information:
	<ul style="list-style-type: none"> You can load the <code>Simulink.Signal</code> objects in from a MAT-file. 	
Share data between multiple models (including referenced models).	<p><code>Simulink.Signal</code> objects defined in the base workspace</p> <hr/> <p>Note: If you use Data Store Memory blocks as well as <code>Simulink.Signal</code>, note that using Data Store Memory blocks scopes the data to the model.</p>	“How to Use <code>Simulink.Signal</code> Objects” on page 39-115

How to Use Data Store Memory Blocks

- 1 Add a MATLAB Function block to your model.
- 2 Double-click the MATLAB Function block to open its editor.
- 3 Declare a global variable in the MATLAB Function block code, or in any MATLAB file that the MATLAB Function block code calls. For example:

```
global A;
```

- 4 Add a Data Store Memory block to your model and set the following:
 - a Set the **Data store name** to match the name of the global variable in your MATLAB Function block code.
 - b Set **Data type** to an explicit data type.

The data type cannot be `auto`.
 - c Set the **Signal type**.
 - d Specify an **Initial value**.

The initial value of the Data Store Memory block cannot be unspecified.

- 5 Register the variable to the MATLAB Function block.

- a In the Ports and Data Manager, add data with the same name as the global variable.
- b Set the **Scope** of the data to **Data Store Memory**.

For more information on using the Ports and Data Manager, see “Ports and Data Manager” on page 39-36.

Example: Using Data Store Memory with the MATLAB Function Block

This simple model demonstrates how a MATLAB Function block uses the global data stored in Data Store Memory block A.

- 1 Open the `dsm_demo` model. At the MATLAB command line, enter:

```
run(docpath(fullfile(docroot, 'toolbox', 'simulink', 'examples', 'dsm_demo.mdl')))
```
- 2 Double-click the MATLAB Function block to open the MATLAB Function Block Editor.

The MATLAB Function block modifies the value of global data A each time it executes.

```
function y = fcn
%#codegen
global A;
A = A+1;
y = A;
```

- 3 In the MATLAB Function Block Editor, select **Edit Data**.
- 4 In the Ports and Data Manager, select the data A in the left pane.

The Ports and Data Manager displays the data attributes in the right pane. Note that A has a scope of **Data Store Memory**.

- 5 In the model, double-click the Data Store Memory block A.

The Block Parameters dialog box opens. Note that **A** has an initial value of 25.

- 6 Simulate the model.

The MATLAB Function block reads the initial value of global data stored in **A** and updates the value of **A** each time it executes.

How to Use Simulink.Signal Objects

- 1 Create a `Simulink.Signal` object in the model workspace.

Tip Create a `Simulink.Signal` object in the base workspace to use the global data with multiple models.

- a In the Model Explorer, navigate to *model_name* > **Model Workspace** in the **Model Hierarchy** pane.

- b Select **Add > Simulink Signal**.

- c Ensure that these settings apply to the `Simulink.Signal` object:

- i Set **Data type** to an explicit data type.

The data type cannot be `auto`.

- ii Set **Dimensions** to be fully specified.

The signal dimensions cannot be `-1` or `inherited`.

- iii Set the **Complexity**.

- iv Specify an **Initial value**.

The initial value of the signal cannot be unspecified.

- 2 Register the `Simulink.Signal` object to the MATLAB Function block.

- a In the Ports and Data Manager, add data with the same name as the `Simulink.Signal` object you created in the model (or base) workspace.

- b Set the **Scope** of the data to `Data Store Memory`.

- 3 Declare a global variable with the same name in the code for your MATLAB Function block.

```
global Sig;
```

For more information on using the Ports and Data Manager, see “Ports and Data Manager” on page 39-36.

Example: Using a Simulink.Signal Object with a MATLAB Function Block

- 1 Open the `simulink_signal_local` model. At the MATLAB command line, enter:

```
addpath(fullfile(docroot, 'toolbox', 'simulink', 'examples'))
simulink_signal_local
```

- 2 Double-click the MATLAB Function block to open its editor.

The MATLAB Function block modifies the value of global data `A` each time it executes.

```
function y = fcn
%#codegen
global A;
A = A+1;
y = A;
```

- 3 From the MATLAB Function Block Editor menu, select **Edit Data**.
- 4 In the Ports and Data Manager, select the data `A` in the left pane.

The Ports and Data Manager displays the data attributes in the right pane. Note that `A` has a scope of **Data Store Memory**.

- 5 From the model menu, select **View > Model Explorer**.
- 6 In the left pane of the Model Explorer, select the model workspace for the `simulink_signal_local` model.

The **Contents** pane displays the data in the model workspace.

- 7 Click the `Simulink.Signal` object `A`.

The right pane displays attributes for A, including.

Attribute	Value
Data type	double
Complexity	real
Dimensions	1
Initial value	5

8 Simulate the model.

The MATLAB Function block reads the initial value of global data stored in A and updates the value of A each time it executes.

Using Data Store Diagnostics to Detect Memory Access Issues

You can configure your model to provide run-time and compile-time diagnostics for avoiding problems with data stores. Diagnostics are available in the Configuration Parameters dialog box and the parameters dialog box for the Data Store Memory block. These diagnostics are available for Data Store Memory blocks only, not for `Simulink.Signal` objects. For more information on using data store diagnostics, see “Data Store Diagnostics” on page 60-3.

Note: If you pass data store memory arrays to functions, optimizations such as `A=foo(A)` might result in the code generation software marking the entire contents of the array as read or written even though only some elements were accessed.

Limitations of Using Shared Data in MATLAB Function Blocks

There is no Data Store Memory support for:

- MATLAB structures
- Variable-sized data

“Debugging MATLAB Function Library Blocks” on page 39-137

“Properties You Can Specialize Across Instances of Library Blocks” on page 39-137

When to Use MATLAB Function Block Libraries

In Simulink, you can create your own block libraries as a way to reuse the functionality of blocks or subsystems in one or more models. If you want to reuse a set of MATLAB algorithms in Simulink models, you can encapsulate your MATLAB code in a MATLAB Function block library.

As with other Simulink block libraries, you can specialize each instance of MATLAB Function library blocks in your model to use different data types, sample times, and other properties. Library instances that inherit the same properties can reuse generated code

How to Create Custom MATLAB Function Block Libraries

Here is a basic workflow for creating custom block libraries with MATLAB Function blocks. To work through these steps with an example, see “Example: Creating a Custom Signal Processing Filter Block Library” on page 39-120.

- 1 Add polymorphic MATLAB code to MATLAB Function blocks in a Simulink model.

Polymorphic code is code that can process data with different properties, such as type, size, and complexity.

- 2 Configure the blocks to inherit the properties you want to specialize.

For a list of properties you can specialize, see “Properties You Can Specialize Across Instances of Library Blocks” on page 39-137.

- 3 Optionally, customize your library code using masking.
- 4 Add instances of MATLAB Function library blocks to a Simulink model.

Note: If your MATLAB Function block library is masked, you cannot modify contents of the block with mask initialization code. The **Allow library block to modify its contents** option in the Mask dialog box is not support for MATLAB Function block libraries.

Example: Creating a Custom Signal Processing Filter Block Library

- “What You Will Learn” on page 39-120
- “About the Filter Algorithms” on page 39-120
- “Step 1: Add the Filter Algorithms to MATLAB Function Library Blocks” on page 39-121
- “Step 2: Configure Blocks to Inherit Properties You Want to Specialize” on page 39-122
- “Step 3: Customize Your Library Using Masking” on page 39-123
- “Step 4: Add Instances of MATLAB Library Blocks to a Simulink Model” on page 39-127

What You Will Learn

This simple example takes you through the workflow described in “How to Create Custom MATLAB Function Block Libraries” on page 39-119 to show you how to:

- Create a library of signal processing filter algorithms using MATLAB Function blocks
- Customize one of the library blocks using mask parameters
- Convert one of the filter algorithms to source-protected P-code that you can call from a MATLAB Function library block

About the Filter Algorithms

The MATLAB filter algorithms are:

my_fft

Performs a discrete Fourier transform on an input signal. The input can be a vector, matrix, or multidimensional array whose length is a power of 2.

my_conv

Convolve two input vector signals. Outputs a subsection of the convolution with a size specified by a mask parameter, **Shape**.

my_sobel

Convolve a 2D input matrix with a Sobel edge detection filter.

Step 1: Add the Filter Algorithms to MATLAB Function Library Blocks

- 1** In Simulink, create a library model by selecting **File > New > Library**
- 2** Drag three MATLAB Function blocks into the model from the User-Defined Functions section of the Simulink Library Browser and name them:
 - my_fft_filter
 - my_conv_filter
 - my_sobel_filter
- 3** Save the library model as `my_filter_lib`.
- 4** Open the MATLAB Function block named `my_fft_filter`, replace the template code with the following code, and save the block:

```
function y = my_fft(x)
```

```
y = fft(x);
```

- 5** Replace the template code in `my_conv_filter` block with the following code and save the block:

```
function c = my_conv(a, b)
```

```
c = conv(a, b);
```

- 6** Replace the template code in `my_sobel_filter` block with the following code and save the block:

```
function y = my_sobel(u)
```

```
%% "my_sobel_filter" is a MATLAB function
```

```
%% on the MATLAB path.
```

```
y = my_sobel_filter(u);
```

The `my_sobel` function acts as a wrapper that calls a MATLAB function, `my_sobel_filter`, on the code generation path. `my_sobel_filter` implements

the algorithm that convolves a 2D input matrix with a Sobel edge detection filter. By calling the function rather than inlining the code directly in the MATLAB Function block, you can reuse the algorithm both as MATLAB code and in a Simulink model. You will create `my_sobel_filter` next.

- 7 In the same folder where you created `my_filter_lib`, create a new MATLAB function `my_sobel_filter` with the following code:

```
function y = my_sobel_filter(u)

% Sobel edge detection filter
h = [1  2  1;...
     0  0  0;...
    -1 -2 -1];

y = abs(conv2(u, h));
```

Save the file as `my_sobel_filter.m`.

Step 2: Configure Blocks to Inherit Properties You Want to Specialize

In this example, the data in the signal processing filter algorithms must inherit size, type, and complexity from the Simulink model. By default, data in MATLAB Function blocks inherit these properties. To explicitly configure data to inherit properties:

- 1 Open a MATLAB Function block and select **Edit Data**.
- 2 In the left pane of the Ports and Data Manager, select the data of interest.
- 3 In the right pane, configure the data to inherit properties from Simulink:

To Inherit	What to Specify
Size	Enter -1 in Size field
Complexity	Select Inherited from the Complexity menu
Type	Select Inherit: Same as Simulink from the Type menu

For example, if you open the MATLAB Function block `my_fft_filter` and look at the properties of input `x` in the Ports and Data Manager, you see that size, type, and complexity are inherited by default.

Note: If your design has specific requirements or constraints, you can enter values for any of these properties, rather than inherit them from Simulink. For example, if your algorithm is not supposed to work with complex inputs, set **Complexity** to **Off**.

Step 3: Customize Your Library Using Masking

In this exercise you will modify the convolution filter `my_conv` to use a custom parameter `shape` that specifies what subsection of the convolution to output. To customize this algorithm for your library, place the `my_conv_filter` block under a masked subsystem and define `shape` as a mask parameter.

1 Convert the block to a masked subsystem:

- a Right-click the `my_conv_filter` block and select **Subsystem & Model Reference > Create Subsystem from Selection**.

The `my_conv_filter` block changes to a subsystem block.

- b Change the name of the subsystem to `my_conv_filter`.
- c Right-click the `my_conv_filter` subsystem and select **Mask > Create Mask** from the context menu.

The Mask Editor appears with the **Icon & Ports** tab open.

- d Enter in the **Icon drawing commands** text box:

```
disp('my_conv');
port_label('output', 1, 'c');
port_label('input', 1, 'a');
port_label('input', 2, 'b');
```

- e Select the **Parameters & Dialog** tab.
- f Highlight the **Parameters** line item in the Dialog box pane.
- g Add a popup-type parameter by clicking **Popup** under the **Parameter** list in the **Controls** pane.

A new parameter will appear in the Dialog box pane.

- h In the **Property editor** pane, set the **Properties**:

Property	Value
Name	shape
Value	full
Prompt	shape
Type	popup
Type options	Open the Type Options Editor and enter: full same valid

- i Set the **Attributes**, **Dialog**, and **Layout** properties in the **Property editor** pane:

Attributes, Dialog, and Layout Items	Value
Attributes	<ul style="list-style-type: none"> • Evaluate: Checked • Tunable: Cleared • Read only: Cleared • Hidden: Cleared • Never save: Cleared
Dialog	<ul style="list-style-type: none"> • Enable: Checked • Visible: Checked • Callback: no entry
Layout	<ul style="list-style-type: none"> • Item location: Grayed out • Prompt location: Left

- i Click **OK**.

Your subsystem should now look like this:

2 Set subsystem properties for code reuse:

- a Right-click the `my_conv_filter` subsystem and select **Block Parameters (Subsystem)** from the context menu.
- b In the subsystem parameters dialog box, select the **Treat as atomic unit** check box.

The dialog box expands to display new fields.

- c To generate a reusable function, select the Code Generation tab and in the **Function packaging** field, select **Reusable function** from the drop-down menu.

Note: This is an optional step, required for this example. If you leave the default setting of **Auto**, the code generation software uses an internal rule to determine whether to inline the function or not.

- d Click **OK**.

3 Define the `shape` parameter in the MATLAB Function `my_conv`:

- a Right-click the `my_conv_filter` subsystem and select **Mask > Look Under Mask** from the context menu.

The block diagram under the masked subsystem opens, containing the `my_conv_filter` block:

- b Change the names of the port blocks to match the data names as follows:

Change:	To:
In1	a
In2	b
Out1	c

- c Double-click the my_conv_filter block to open the MATLAB Function Block Editor.
- d In the MATLAB Function Block Editor, select **Edit Data**.
- e In the Ports and Data Manager, select **Add > Data**.

A new data element appears selected, along with its properties dialog.

- f Enter the following properties:

Property	What To Specify
Name	Enter shape .
Scope	Select Parameter .
Tunable	Clear the box.

- g Leave **Size**, **Complexity**, and **Type** as inherited (the defaults), as described in “Step 2: Configure Blocks to Inherit Properties You Want to Specialize” on page 39-122.
 - h Click **Apply**, close the Ports and Data Manager, and return to the MATLAB Function Block Editor.
- 4 Use the **shape** parameter to determine the size of the convolution to output:

- a** In the MATLAB Function Block Editor, modify the `my_conv` function to call `conv` with the right shape:

```
function c = my_conv(a, b, shape)
if shape == 1
    c = conv(a, b, 'full');
elseif shape == 2
    c = conv(a, b, 'same');
else
    c = conv(a, b, 'valid');
end
```

- b** Save your changes and close the MATLAB Function Block Editor.

Step 4: Add Instances of MATLAB Library Blocks to a Simulink Model

In this exercise, you will add specialized instances of the `my_conv_filter` library block to a simple test model.

- 1** Open a new Simulink model.

For purposes of this exercise, set the following configuration parameters for simulation:

Pane	Section	What to Specify
Solver	Solver options	<ul style="list-style-type: none"> • Select Fixed-Step for Type • Select discrete (no continuous states) for Solver • Enter 1 for Fixed-step size
Data Import/Export	Save options	Structure for Format

- 2** Drag two instances of the `my_conv_filter` block from the `my_filter_lib` library into the model.
- 3** Add Constant, Outport, and Display blocks. Your model should look something like this:

Both library instances share the same size, type, and complexity for inputs **a** and **b** respectively.

- 4 Double-click each library instance.

The **shape** parameter defaults to **full** for both instances.

- 5 Simulate the model.

Each library instance outputs the same result, the full 2D convolution:

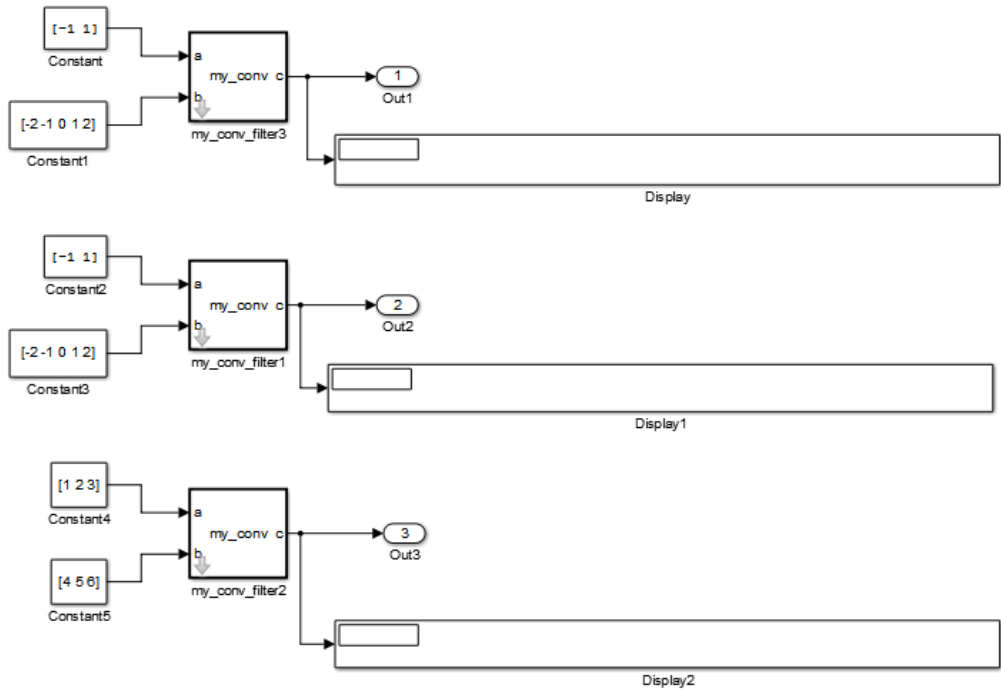

- 6 Specialize the second instance, `my_conv_filter1` by setting the value of its `shape` parameter to **same**.
- 7 Now simulate the model again.

This time, the outputs have different sizes: `my_conv_filter3` outputs the full 2D convolution, while `my_conv_filter1` displays the central part of the convolution as a 1-by-2 vector, the same size as `a`:

- 8 Now, add a third instance by copying my_conv_filter1. Specialize the new instance, my_conv_filter2, so that it does not inherit the same size inputs as the first two instances:

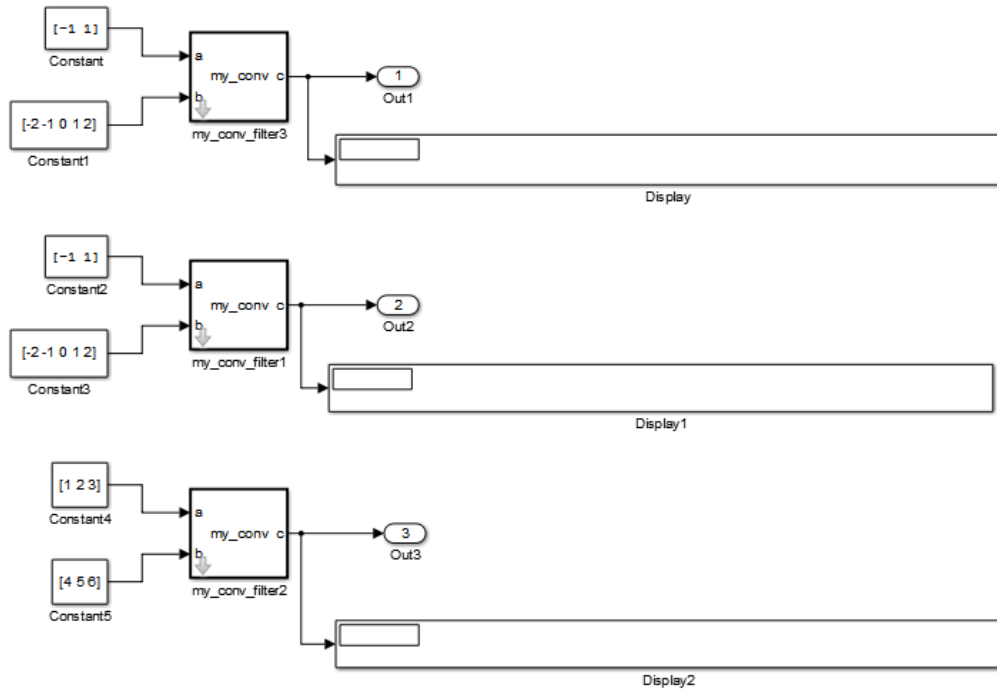

9 Simulate the model again.

This time, `my_conv_filter1` and `my_conv_filter2` each display the central part of the convolution, but the output sizes are different because each matches a different sized input `a`.

Code Reuse with Library Blocks

When instances of MATLAB Function library blocks inherit the same properties, they can reuse generated code, as illustrated by an example based on “Step 4: Add Instances of MATLAB Library Blocks to a Simulink Model” on page 39-127:

In this model, the library instances `my_conv_filter` and `my_conv_filter1` inherit the same size, type, and complexity for each respective input. For each instance, input `a` is a 1-by-2 vector and input `b` is a 1-by-5 vector. By comparison, the inputs of `my_conv_filter2` inherit different respective sizes; both are 1-by-3 vectors.

In addition, each library instance has a mask parameter called `shape` that determines what subsection of the convolution to output. Assume that the value of `shape` is the same for each instance.

To generate code for this example, follow these steps:

- 1 Enable code reuse for the library block:
 - a In the library, right-click the MATLAB Function block `my_conv_filter` and select **Block Parameters (Subsystem)** from the context menu.
 - b In the Function Block Parameters dialog box, set these parameters:

- Select the **Treat as atomic unit** check box.
 - In the **Function packaging** field, select **Reusable** function from the drop-down menu.
- 2 Configure the model for code generation.

For purposes of this exercise, set the following configuration parameters:

Pane	Section	What to Specify
Code Generation	Target selection	Enter ert.tlc for System target file
Code Generation > Report		Select Create code generation report check box.

- 3 Build the model.

If you build this model, the generated C code reuses logic for the `my_conv_filter` and `my_conv_filter1` library instances because they inherit the same input properties:

```

/*
 * Output and update for atomic system:
 *   '<Root>/my_conv_filter'
 *   '<Root>/my_conv_filter1'
 */
void sp_algorithm_tes_my_conv_filter(const real32_T rtu_a[2], const real32_T
    rtu_b[5], rtB_my_conv_filter_sp_algorithm *localB)
{
    int32_T jA;
    int32_T jA_0;
    real32_T s;
    int32_T jC;

    /* MATLAB Function Block: '<S1>/my_conv_filter' */
    /* MATLAB Function 'my_conv_filter/my_conv_filter': '<S4>:1' */
    /* '<S4>:1:4' */
    for (jC = 0; jC < 6; jC++) {
        if (5 < jC + 2) {
            jA = jC - 4;
        } else {
            jA = 0;
        }
    }
}

```

```
    }  
  
    if (2 < jC + 1) {  
        jA_0 = 2;  
    } else {  
        jA_0 = jC + 1;  
    }  
  
    s = 0.0F;  
    while (jA + 1 <= jA_0) {  
        s += rtu_b[jC - jA] * rtu_a[jA];  
        jA++;  
    }  
  
    localB->c[jC] = s;  
}  
  
/* end of MATLAB Function Block: '<S1>/my_conv_filter' */  
}
```

However, a separate function is generated for my_conv_filter2:

```
/* Output and update for atomic system: '<Root>/my_conv_filter2' */
void sp_algorithm_te_my_conv_filter2(const real_T rtu_a[3], const real_T rtu_b[3],
    rtB_my_conv_filter_sp_algorit_h *localB)
{
    int32_T jA;
    int32_T jA_0;
    real_T s;
    int32_T jC;

    /* MATLAB Function Block: '<S3>/my_conv_filter' */
    /* MATLAB Function 'my_conv_filter/my_conv_filter': '<S6>:1' */
    /* '<S6>:1:4' */
    for (jC = 0; jC < 5; jC++) {
        if (3 < jC + 2) {
            jA = jC - 2;
        } else {
            jA = 0;
        }

        if (3 < jC + 1) {
            jA_0 = 3;
        } else {
            jA_0 = jC + 1;
        }

        s = 0.0;
        while (jA + 1 <= jA_0) {
            s += rtu_b[jC - jA] * rtu_a[jA];
            jA++;
        }

        localB->c[jC] = s;
    }

    /* end of MATLAB Function Block: '<S3>/my_conv_filter' */
}
```

Note: Generating C code for this model requires a Simulink Coder or Embedded Coder license.

Debugging MATLAB Function Library Blocks

You debug MATLAB Function library blocks the same way you debug any MATLAB Function block. However, when you add a breakpoint in a library block, the breakpoint is shared by all instances. As you continue execution, the debugger stops at the breakpoint in each instance.

Properties You Can Specialize Across Instances of Library Blocks

You can specialize instances of MATLAB Function library blocks by allowing them to inherit any of the following properties from Simulink:

Property	Inherits by Default?	How to Specify Inheritance
Type	Yes	Set data type property to Inherit: Same as Simulink .
Size	Yes	Set data size property to -1 .
Complexity	Yes	Set data complexity property to Inherited .
Limit range	No	Specify minimum and maximum values as Simulink parameters. For example, if minimum value = <code>aParam</code> and maximum value = <code>aParam + 3</code> , different instances of a MATLAB Function library block can resolve to different <code>aParam</code> parameters defined in their parent mask subsystems.
Sampling mode (input)	Yes	MATLAB Function block input ports always inherit sampling mode
Data type override mode for fixed-point data	Yes	Set data type override property to Inherit .
Sample time (block)	Yes	Set block sample time property to -1 .

Use Traceability in MATLAB Function Blocks

In this section...

“Extent of Traceability in MATLAB Function Blocks” on page 39-139

“Traceability Requirements” on page 39-139

“Basic Workflow for Using Traceability” on page 39-139

“Tutorial: Using Traceability in a MATLAB Function Block” on page 39-140

Extent of Traceability in MATLAB Function Blocks

Like other Simulink blocks, MATLAB Function blocks support bidirectional traceability, but extend navigation to lines of source code. That is, you can navigate between a line of generated code and its corresponding line of source code. In other Simulink blocks, you can navigate between a line of generated code and its corresponding object.

In addition, you can select to include the source code as comments in the generated code. When you select this option, the MATLAB source code appears immediately after the associated traceability tag. For more information, see “Include MATLAB Code as Comments in Generated Code” on page 39-143.

For information about how traceability works in Simulink blocks, see “What Is Code Tracing?”.

Traceability Requirements

To enable traceability comments in your code, you must have a license for Embedded Coder software. These comments appear only in code that you generate for an Embedded Real-Time (ERT) target.

Note: Traceability is not supported for MATLAB files that you call from a MATLAB Function block.

Basic Workflow for Using Traceability

The workflow for using traceability is described in “Trace Model Objects to Generated Code”. Here are the basic steps:

- 1 Open the MATLAB Function block in your Simulink model.
- 2 Define your system target file to be an Embedded Real-Time (ERT) target.
 - a In the model, select **Simulation > Model Configuration Parameters**.
 - b In the **Code Generation** pane, enter `ert.tlc` for the system target file.
- 3 Enable traceability options.
 - a In the **Code Generation > Report** pane, select **Create code generation report**.

This action automatically selects the **Open report automatically** and **Code-to-model** options.

- b Select **Model-to-code**.

This action automatically selects all options in the **Traceability report contents** section.

- 4 Generate the source code and header files for your model.
- 5 Trace a line of code:

To Trace:	Do This:
Line of source code to lines of generated code	Right-click in a line in your source code and select Code Generation > Navigate to Code from the context menu
Line of generated code to lines of source code	Click a hyperlink in the traceability comment in your generated code
Hyperlinked line number in generated code to lines of source code	Click a line number hyperlink in the source code

Tutorial: Using Traceability in a MATLAB Function Block

This example shows how to trace between source code and generated code in a MATLAB Function block in the `eml_fire` model. Follow these steps:

- 1 Type `eml_fire` at the MATLAB prompt.
- 2 In the Simulink model window, double-click the `flame` block to open the MATLAB Function Block Editor.

- 3 In the Simulink model window, select **Simulation > Model Configuration Parameters**.
- 4 In the **Code Generation** pane, go to the **Target selection** section and enter `ert.tlc` for the system target file. Then click **Apply**.

Note: Traceability comments appear hyperlinked in generated code only for embedded real-time (`ert`) targets.

- 5 In the **Code Generation > Report** pane, select the **Create code generation report** option.

This action automatically selects the **Open report automatically** and **Code-to-model** options.

- 6 Select the **Model-to-code** option in the **Navigation** section. Then click **Apply**.

This action automatically selects all options in the **Traceability report contents** section.

- 7 Go to the **Code Generation > Interface** pane. In the **Software environment** section, select the **continuous time** option. Then click **Apply**.

Note: Because this example model contains a block with a continuous sample time, you must perform this step before generating code.

- 8 In the model window, press **Ctrl+B**.

This action generates source code and header files for the `eml_fire` model that contains the `flame` block. After the code generation process is complete, the code generation report appears automatically.

- 9 Click the `eml_fire.c` hyperlink in the report.
- 10 Scroll down through the code to see the traceability comments, which appear as links inside `/*...*/` brackets, as in this example.

```
for (b_x = 0; b_x < 256; b_x++) {
    /* '<S2>:1:19' */
    /* '<S2>:1:21' */
    yb = loopVar_i + 2;

    /* '<S2>:1:22' */
    xb = b_x - 1;
```

- 11** Click the `<S2>:1:19` hyperlink in this traceability comment:

```
/* '<S2>:1:19' */
```

Line 19 of the function appears highlighted in the MATLAB Function Block Editor.

- 12** You can trace a line in a MATLAB function to lines of generated code. For example, right-click in line 21 of your function and select **Code Generation > Navigate to Code** from the context menu.

The code location for line 21 appears highlighted in `eml_fire.c`.

- 13** You can trace a line of generated code to a line of source code in a MATLAB function using the line number hyperlinks in the generated code.

- “What Is Code Tracing?”

Include MATLAB Code as Comments in Generated Code

If you have a Simulink Coder license, you can include MATLAB source code as comments in the code generated for a MATLAB Function block. Including this information in the generated code enables you to:

- Correlate the generated code with your source code.
- Understand how the generated code implements your algorithm.
- Evaluate the quality of the generated code.

When you select this option, the generated code includes:

- The source code as a comment immediately after the traceability tag. When you enable traceability and generate code for ERT targets (requires an Embedded Coder license), the traceability tags are hyperlinks to the source code. For more information on traceability for the MATLAB Function block, see “Use Traceability in MATLAB Function Blocks” on page 39-139.

For examples and information on the location of the comments in the generated code, see “Location of Comments in Generated Code” on page 39-144.

- The function help text in the function body in the generated code. The function help text is the first comment after the MATLAB function signature. It provides information about the capabilities of the function and how to use it.

Note: With an Embedded Coder license, you can also include the function help text in the function banner of the generated code. For more information, see “Including MATLAB Function Help Text in the Function Banner” on page 39-146.

How to Include MATLAB Code as Comments in the Generated Code

To include MATLAB source code as comments in the code generated for a MATLAB Function block:

- 1 In the model, select **Simulation > Model Configuration Parameters**.
- 2 In the **Code Generation > Comments** pane, select **MATLAB source code as comments** and click **Apply**.

Location of Comments in Generated Code

The automatically generated comments containing the source code appear after the traceability tag in the generated code as follows.

Straight-Line Source Code

The comment containing the source code precedes the generated code that implements the source code statement. This comment appears after any comments that you add that precede the generated code. The comments are separated from the generated code because the statements are assigned to function outputs.

MATLAB Code

```
function [x y] = straightline(r,theta)
%#codegen
% Convert polar to Cartesian
x = r * cos(theta);
y = r * sin(theta);
```

Commented C Code

```
/* MATLAB Function 'straightline': '<S1>:1' */
/* Convert polar to Cartesian */
/* '<S1>:1:4' x = r * cos(theta); */
/* '<S1>:1:5' y = r * sin(theta); */
straightline0_Y.x = straightline0_U.r * cos(straightline0_U.theta);

/* Output: '<Root>/y' incorporates:
 * Inport: '<Root>/r'
 * Inport: '<Root>/theta'
 * MATLAB Function Block: '<Root>/straightline'
 */
straightline0_Y.y = straightline0_U.r * sin(straightline0_U.theta);
```

If Statements

The comment for the `if` statement immediately precedes the code that implements the statement. This comment appears after any comments that you add that precede the generated code. The comments for the `elseif` and `else` clauses appear immediately after the code that implements the clause, and before the code generated for statements in the clause.

MATLAB Code

```
function y = ifstmt(u,v)
```

```

%#codegen
if u > v
    y = v + 10;
elseif u == v
    y = u * 2;
else
    y = v - 10;
end

```

Commented C Code

```

/* MATLAB Function 'MLFcn': '<S1>:1' */
/* '<S1>:1:3' if u > v */
if (MLFcn_U.u > MLFcn_U.v) {
    /* Output: '<Root>/y' */
    /* '<S1>:1:4' y = v + 10; */
    MLFcn_Y.y = MLFcn_U.v + 10.0;
} else if (MLFcn_U.u == MLFcn_U.v) {
    /* Output: '<Root>/y' */
    /* '<S1>:1:5' elseif u == v */
    /* '<S1>:1:6' y = u * 2; */
    MLFcn_Y.y = MLFcn_U.u * 2.0;
} else {
    /* Output: '<Root>/y' */
    /* '<S1>:1:7' else */
    /* '<S1>:1:8' y = v - 10; */
    MLFcn_Y.y = MLFcn_U.v - 10.0;
}

```

For Statements

The comment for the `for` statement header immediately precedes the generated code that implements the header. This comment appears after any comments that you add that precede the generated code.

MATLAB Code

```

function y = forstmt(u)
%#codegen
y = 0;
for i=1:u
    y = y + 1;
end

```

Commented C Code

```

/* MATLAB Function 'MLFcn': '<S1>:1' */
/* '<S1>:1:3' y = 0; */

```

```
rtb_y = 0.0;

/* '<S1>:1:5' for i=1:u */
for (i = 1.0; i <= MLFcn_U.u; i++) {
    /* '<S1>:1:6' y = y + 1; */
    rtb_y++;
}
```

While Statements

The comment for the `while` statement header immediately precedes the generated code that implements the statement header. This comment appears after any comments that you add that precede the generated code.

Switch Statements

The comment for the `switch` statement header immediately precedes the generated code that implements the statement header. This comment appears after any comments that you add that precede the generated code. The comments for the `case` and `otherwise` clauses appear immediately after the generated code that implements the clause, and before the code generated for statements in the clause.

Including MATLAB Function Help Text in the Function Banner

You can include the function help text in the function banner of the code generated for a MATLAB Function block. The function help text is the first comment after the MATLAB function signature. It provides information about the capabilities of the function and how to use it.

- 1 In the model, select **Simulation > Model Configuration Parameters**.
- 2 In the **Code Generation > Comments** pane, select **MATLAB function help text** and click **Apply**.

Note: If the function is inlined, the function help text is also inlined. Therefore, the help text for inlined functions appears in the function body in the generated code even when this option is selected.

Limitations of MATLAB Source Code as Comments

The MATLAB Function block has the following limitations for including MATLAB source code as comments.

- You cannot include MATLAB source code as comments for:
 - MathWorks toolbox functions
 - P-code
 - Simulation targets
 - Stateflow Truth Table blocks
- The appearance or location of comments can vary depending on the following conditions:
 - Comments might still appear in the generated code even if the implementation code is eliminated, for example, due to constant folding.
 - Comments might be eliminated from the generated code if a complete function or code block is eliminated.
 - For certain optimizations, the comments might be separated from the generated code.
 - The generated code always includes legally required comments from the MATLAB source code, even if you do not choose to include source code comments in the generated code.

Integrate C Code Using the MATLAB Function Block

In this section...

“Call C Code from a Simulink model” on page 39-148

“Control Imported Bus and Enumeration Type Definitions” on page 39-150

Call C Code from a Simulink model

You can call external C code from a Simulink model using a MATLAB Function block and the `coder.ceval` command. Follow these high-level steps:

- 1 Start with existing C code consisting of the source (.c) and header (.h) files.
- 2 In the MATLAB Function block, enter the MATLAB code that calls the C code. Use the command `coder.ceval`.
- 3 Specify the C source and header files for simulation in the **Simulation Target** pane of the Configuration Parameters dialog box.

Include the header file using double quotations, such as `#include "program.h"`.

- 4 If you need to access C source and header files outside your working folder, list the path in the **Simulation Target** pane of the Configuration Parameters dialog box, in the **Include Directories** text box.
- 5 Test your Simulink model and ensure it functions correctly.
- 6 To use the same source and header files for code generation, click **Use the same custom code settings as Simulation Target** in the **Code Generation > Custom Code** pane.

You can also specify different source and header files.

If you have a Simulink Coder license, you can generate code for targets using this method.

Call the `doubleIt` Program Using a MATLAB Function Block

This example shows how to call the simple C program `doubleIt` from a MATLAB Function block.

- 1 Create the source file `doubleIt.c` in your current working folder.

```

/* doubleIt, a simple program that returns double the input */
#include "doubleIt.h"

double doubleIt(double u)
{
    return(u*2.0);
}

```

- 2 Create the header file `doubleIt.h` in your current working folder.

```
double doubleIt(double u);
```

- 3 Create a new Simulink model.
- 4 Add a MATLAB Function block to the model and double-click the block to open the editor.
- 5 Enter code that calls the `doubleIt` program:

```

function y = callingDoubleIt(u)

y = 0.0;
y = coder.ceval('doubleIt',u);

```

- 6 Connect a Constant block having a value of 3.5 to the input port of the MATLAB Function block.
- 7 Connect a Display block to the output port.

- 8 In the Configuration Parameters dialog box, open the **Simulation Target** pane.
- 9 In the **Insert custom C code in generated** section, select **Header file** from the list, and enter `#include "doubleIt.h"` in the **Header file** text box.
- 10 In the **Include list of additional** section, select **Source files** from the list, enter `doubleIt.c` in the **Source files** text box, and click **OK**.

11 Simulate the model.

The value 7 appears in the Display block.

Control Imported Bus and Enumeration Type Definitions

This procedure applies to simulation only.

Simulink generates code for MATLAB Function blocks and Stateflow to simulate the model. When you call external C code using MATLAB Function blocks or Stateflow, you can control the type definitions for imported buses and enumerations in model simulation.

Simulink can generate type definitions, or you can supply a header file containing the type definitions. You control this behavior using the **Generate typedefs for imported bus and enumeration types** check box in the **All Parameters** pane of the Configuration Parameters dialog box.

To include a custom header file defining the enumeration and bus types:

- 1 Clear the **Generate typedefs for imported bus and enumeration types** check box.
- 2 List the header file in the **Simulation Target** pane, in the **Header file** text box.

To configure Simulink to automatically generate type definitions:

- 1 Select the **Generate typedefs for imported bus and enumeration types** check box.
- 2 Do not list a header file that corresponds to the buses or enumerations.

Enhance Code Readability for MATLAB Function Blocks

In this section...

“Requirements for Using Readability Optimizations” on page 39-152

“Converting If-Elseif-Else Code to Switch-Case Statements” on page 39-152

“Example of Converting Code for If-Elseif-Else Decision Logic to Switch-Case Statements” on page 39-154

Requirements for Using Readability Optimizations

To use readability optimizations in your code, you must have an Embedded Coder license. These optimizations appear only in code that you generate for an embedded real-time (ert) target.

Note: These optimizations do not apply to MATLAB files that you call from the MATLAB Function block.

For more information, see “Select an ERT System Target File” and “Control Code Style” in the Embedded Coder documentation.

Converting If-Elseif-Else Code to Switch-Case Statements

When you generate code for embedded real-time targets, you can choose to convert `if-elseif-else` decision logic to `switch-case` statements. This conversion can enhance readability of the code.

For example, when a MATLAB Function block contains a long list of conditions, the `switch-case` structure:

- Reduces the use of parentheses and braces
- Minimizes repetition in the generated code

How to Convert If-Elseif-Else Code to Switch-Case Statements

The following procedure describes how to convert generated code for the MATLAB Function block from `if-elseif-else` to `switch-case` statements.

Step	Task	Reference
1	Verify that your block follows the rules for conversion.	“Verifying the Contents of the Block” on page 39-156
2	Enable the conversion.	“Enabling the Conversion” on page 39-157
3	Generate code for your model.	“Generating Code for Your Model” on page 39-158

Rules for Conversion

For the conversion to occur, the following rules must hold. LHS and RHS refer to the left-hand side and right-hand side of a condition, respectively.

Construct	Rules to Follow
MATLAB Function block	<p>Must have two or more <i>unique</i> conditions, in addition to a default.</p> <p>For more information, see “How the Conversion Handles Duplicate Conditions” on page 39-154.</p>
Each condition	Must test equality only.
	Must use the same variable or expression for the LHS.
Note: You can reverse the LHS and RHS.	
Each LHS	Must be a single variable or expression, not a compound statement.
	Cannot be a constant.
	Must have an integer or enumerated data type.
	Cannot have any side effects on simulation.
For example, the LHS can read from but not write to global variables.	
Each RHS	Must be a constant.
	Must have an integer or enumerated data type.

How the Conversion Handles Duplicate Conditions

If a MATLAB Function block has duplicate conditions, the conversion preserves only the first condition. The generated code discards all other instances of duplicate conditions.

After removal of duplicates, two or more unique conditions must exist. Otherwise, no conversion occurs and the generated code contains all instances of duplicate conditions.

The following examples show how the conversion handles duplicate conditions.

Example of Generated Code	Code After Conversion
<pre>if (x == 1) { block1 } else if (x == 2) { block2 } else if (x == 1) { // duplicate block3 } else if (x == 3) { block4 } else if (x == 1) { // duplicate block5 } else { block6 }</pre>	<pre>switch (x) { case 1: block1; break; case 2: block2; break; case 3: block4; break; default: block6; break; }</pre>
<pre>if (x == 1) { block1 } else if (x == 1) { // duplicate block2 } else { block3 }</pre>	<p>No change, because only one unique condition exists</p>

Example of Converting Code for If-Elseif-Else Decision Logic to Switch-Case Statements

Suppose that you have the following model with a MATLAB Function block. Assume that the output data type is `double` and the input data type is `Controller`, an enumerated type that you define. (For more information, see “Code Generation for Enumerations” on page 39-103.)

The block contains the following code:

```
function system = fcn(type)
%#codegen

if (type == Controller.P)
    system = 0;
elseif (type == Controller.I)
    system = 1;
elseif (type == Controller.PD)
    system = 2;
elseif (type == Controller.PI)
    system = 3;
elseif (type == Controller.PID)
    system = 4;
else
    system = 10;
end
```

The enumerated type definition in `Controller.m` is:

```
classdef Controller < Simulink.IntEnumType
    enumeration
        P(0)
        I(1)
        PD(2)
        PI(3)
        PID(4)
        UNKNOWN(10)
    end
end
```

If you generate code for an embedded real-time target using default settings, you see something like this:

```
if (if_to_switch_em1_blocks_U.In1 == P) {
```

```

/* '<S1>:1:4' */
/* '<S1>:1:5' */
if_to_switch_eml_blocks_Y.Out1 = 0.0;
} else if (if_to_switch_eml_blocks_U.In1 == I) {
/* '<S1>:1:6' */
/* '<S1>:1:7' */
if_to_switch_eml_blocks_Y.Out1 = 1.0;
} else if (if_to_switch_eml_blocks_U.In1 == PD) {
/* '<S1>:1:8' */
/* '<S1>:1:9' */
if_to_switch_eml_blocks_Y.Out1 = 2.0;
} else if (if_to_switch_eml_blocks_U.In1 == PI) {
/* '<S1>:1:10' */
/* '<S1>:1:11' */
if_to_switch_eml_blocks_Y.Out1 = 3.0;
} else if (if_to_switch_eml_blocks_U.In1 == PID) {
/* '<S1>:1:12' */
/* '<S1>:1:13' */
if_to_switch_eml_blocks_Y.Out1 = 4.0;
} else {
/* '<S1>:1:15' */
if_to_switch_eml_blocks_Y.Out1 = 10.0;
}

```

The LHS variable `if_to_switch_eml_blocks_U.In1` appears multiple times in the generated code.

Note: By default, variables that appear in the block do not retain their names in the generated code. Modified identifiers guarantee that no naming conflicts occur.

Traceability comments appear between each set of `/*` and `*/` markers. To learn more about traceability, see “Use Traceability in MATLAB Function Blocks” on page 39-139.

Verifying the Contents of the Block

Check that the block follows all the rules in “Rules for Conversion” on page 39-153.

Construct	How the Construct Follows the Rules
MATLAB Function block	Five unique conditions exist, in addition to the default: <ul style="list-style-type: none"> (type == Controller.P)

Construct	How the Construct Follows the Rules
	<ul style="list-style-type: none"> • (type == Controller.I) • (type == Controller.PD) • (type == Controller.PI) • (type == Controller.PID)
Each condition	Each condition: <ul style="list-style-type: none"> • Tests equality • Uses the same input for the LHS
Each LHS	Each LHS: <ul style="list-style-type: none"> • Contains a single variable • Is the input to the block and therefore not a constant • Is of enumerated type <code>Controller</code>, which you define in <code>Controller.m</code> on the MATLAB path • Has no side effects on simulation
Each RHS	Each RHS: <ul style="list-style-type: none"> • Is an enumerated value and therefore a constant • Is of enumerated type <code>Controller</code>

Enabling the Conversion

- 1 Open the Configuration Parameters dialog box.
- 2 In the **Code Generation** pane, select `ert.tlc` for the **System target file**.

This step specifies an embedded real-time target for your model.

- 3 In the **Code Generation > Code Style** pane, select the **Convert if-elseif-else patterns to switch-case statements** check box.

Tip This conversion works on a per-model basis. If you select this check box, the conversion applies to:

- All MATLAB Function blocks in a model
- MATLAB functions in all Stateflow charts of that model

- Flow charts in all Stateflow charts of that model

For more information, see “Enhance Readability of Code for Flow Charts” in the Embedded Coder documentation.

Generating Code for Your Model

In the model window, press **Ctrl+B**.

The code for the MATLAB Function block uses `switch-case` statements instead of `if-elseif-else` code:

```
switch (if_to_switch_eml_blocks_U.In1) {
  case P:
    /* '<S1>:1:4' */
    /* '<S1>:1:5' */
    if_to_switch_eml_blocks_Y.Out1 = 0.0;
    break;

  case I:
    /* '<S1>:1:6' */
    /* '<S1>:1:7' */
    if_to_switch_eml_blocks_Y.Out1 = 1.0;
    break;

  case PD:
    /* '<S1>:1:8' */
    /* '<S1>:1:9' */
    if_to_switch_eml_blocks_Y.Out1 = 2.0;
    break;

  case PI:
    /* '<S1>:1:10' */
    /* '<S1>:1:11' */
    if_to_switch_eml_blocks_Y.Out1 = 3.0;
    break;

  case PID:
    /* '<S1>:1:12' */
    /* '<S1>:1:13' */
    if_to_switch_eml_blocks_Y.Out1 = 4.0;
    break;

  default:
```

```
/* '<S1>:1:15' */  
if_to_switch_eml_blocks_Y.Out1 = 10.0;  
break;  
}
```

The `switch-case` statements provide the following benefits to enhance readability:

- The code reduces the use of parentheses and braces.
- The LHS variable `if_to_switch_eml_blocks_U.In1` appears only once, minimizing repetition in the code.

Control Run-Time Checks

In this section...

“Types of Run-Time Checks” on page 39-160

“When to Disable Run-Time Checks” on page 39-160

“How to Disable Run-Time Checks” on page 39-161

Types of Run-Time Checks

In simulation, the code generated for your MATLAB Function block includes the following run-time checks:

- Memory integrity checks

These checks detect violations of memory integrity in code generated for MATLAB Function blocks and stop execution with a diagnostic message.

Caution For safety, these checks are enabled by default. Without memory integrity checks, violations result in unpredictable behavior.

- Responsiveness checks in code generated for MATLAB Function blocks

These checks enable periodic checks for Ctrl+C breaks in the generated code. Enabling responsiveness checks also enables graphics refreshing.

Caution For safety, these checks are enabled by default. Without these checks, the only way to end a long-running execution might be to terminate MATLAB.

When to Disable Run-Time Checks

Generally, generating code with run-time checks enabled results in more lines of generated code and slower simulation than generating code with the checks disabled. Disabling run-time checks usually results in streamlined generated code and faster simulation, with these caveats:

Consider disabling:	Only if:
Memory integrity checks	You are sure that your code is safe and that all array bounds and dimension checking is unnecessary.
Responsiveness checks	You are sure that you will not need to stop execution of your application using Ctrl+C.

How to Disable Run-Time Checks

MATLAB Function blocks enable run-time checks by default, but you can disable them explicitly for all MATLAB Function blocks in your Simulink model. Follow these steps:

- 1 Open your MATLAB Function block.
- 2 In the MATLAB Function Block Editor, select **Simulation Target**.
- 3 In the **All Parameters** tab of the Configuration Parameters dialog box, clear the **Ensure memory integrity** or **Ensure responsiveness** check boxes, as applicable, and click **Apply**.

Track Object Using MATLAB Code

In this section...

“Learning Objectives” on page 39-162

“Tutorial Prerequisites” on page 39-162

“Example: The Kalman Filter” on page 39-163

“Files for the Tutorial” on page 39-166

“Tutorial Steps” on page 39-167

“Best Practices Used in This Tutorial” on page 39-184

“Key Points to Remember” on page 39-184

Learning Objectives

In this tutorial, you will learn how to:

- Use the MATLAB Function block to add MATLAB functions to Simulink models for modeling, simulation, and deployment to embedded processors.

This capability is useful for coding algorithms that are better stated in the textual language of MATLAB than in the graphical language of Simulink.

- Use `coder.extrinsic` to call MATLAB code from a MATLAB Function block.

This capability allows you to do rapid prototyping. You can call existing MATLAB code from Simulink without having to make this code suitable for code generation.

- Check that existing MATLAB code is suitable for code generation before generating code.

You must prepare your code before generating code.

- Specify variable-size inputs when generating code.

Tutorial Prerequisites

- “What You Need to Know” on page 39-163
- “Required Products” on page 39-163

What You Need to Know

To complete this tutorial, you should have basic familiarity with MATLAB software. You should also understand how to create and simulate a basic Simulink model.

Required Products

To complete this tutorial, you must install the following products:

- MATLAB
- MATLAB Coder
- Simulink
- Simulink Coder
- C compiler

For a list of supported compilers, see http://www.mathworks.com/support/compilers/current_release/.

You must set up the C compiler before generating C code. See “Setting Up Your C Compiler” on page 39-168.

For instructions on installing MathWorks products, see the MATLAB installation documentation for your platform. If you have installed MATLAB and want to check which other MathWorks products are installed, enter `ver` in the MATLAB Command Window.

Example: The Kalman Filter

- “Description” on page 39-163
- “Algorithm” on page 39-164
- “Filtering Process” on page 39-165
- “Reference” on page 39-166

Description

This section describes the example used by the tutorial. You do not have to be familiar with the algorithm to complete the tutorial.

The example for this tutorial uses a Kalman filter to estimate the position of an object moving in a two-dimensional space from a series of noisy inputs based on past positions.

The position vector has two components, x and y , indicating its horizontal and vertical coordinates.

Kalman filters have a wide range of applications, including control, signal and image processing; radar and sonar; and financial modeling. They are recursive filters that estimate the state of a linear dynamic system from a series of incomplete or noisy measurements. The Kalman filter algorithm relies on the state-space representation of filters and uses a set of variables stored in the state vector to characterize completely the behavior of the system. It updates the state vector linearly and recursively using a state transition matrix and a process noise estimate.

Algorithm

This section describes the algorithm of the Kalman filter and is implemented in the MATLAB version of the filter supplied with this tutorial.

The algorithm predicts the position of a moving object based on its past positions using a Kalman filter estimator. It estimates the present position by updating the Kalman state vector, which includes the position (x and y), velocity (Vx and Vy), and acceleration (Ax and Ay) of the moving object. The Kalman state vector, `x_est`, is a persistent variable.

```
% Initial conditions
persistent x_est p_est
if isempty(x_est)
    x_est = zeros(6, 1);
    p_est = zeros(6, 6);
end
```

`x_est` is initialized to an empty 6x1 column vector and updated each time the filter is used.

The Kalman filter uses the laws of motion to estimate the new state:

$$X = X_0 + Vx.dt$$

$$Y = Y_0 + Vy.dt$$

$$Vx = Vx_0 + Ax.dt$$

$$Vy = Vy_0 + Ay.dt$$

These laws of motion are captured in the state transition matrix A , which is a matrix that contains the coefficient values of x , y , Vx , Vy , Ax , and Ay .

```
% Initialize state transition matrix
dt=1;
A=[ 1 0 dt 0 0 0;...
    0 1 0 dt 0 0;...
    0 0 1 0 dt 0;...
    0 0 0 1 0 dt;...
    0 0 0 0 1 0 ;...
    0 0 0 0 0 1 ];
```

Filtering Process

The filtering process has two phases:

- Predicted state and covariance

The Kalman filter uses the previously estimated state, x_{est} , to predict the current state, x_{prd} . The predicted state and covariance are calculated in:

```
% Predicted state and covariance
x_prd = A * x_est;
p_prd = A * p_est * A' + Q;
```

- Estimation

The filter also uses the current measurement, z , and the predicted state, x_{prd} , to estimate a more accurate approximation of the current state. The estimated state and covariance are calculated in:

```
% Measurement matrix
H = [ 1 0 0 0 0 0; 0 1 0 0 0 0 ];
Q = eye(6);
R = 1000 * eye(2);

% Estimation
S = H * p_prd' * H' + R;
B = H * p_prd';
klm_gain = (S \ B)';

% Estimated state and covariance
x_est = x_prd + klm_gain * (z - H * x_prd);
p_est = p_prd - klm_gain * H * p_prd;

% Compute the estimated measurements
y = H * x_est;
```

Files for the Tutorial

- “About the Tutorial Files” on page 39-166
- “Location of Files” on page 39-166
- “Names and Descriptions of Files” on page 39-166

About the Tutorial Files

The tutorial uses the following files:

- Simulink model files for each step of the tutorial.
- Example MATLAB code files for each step of the tutorial.

Throughout this tutorial, you work with Simulink models that call MATLAB files containing a Kalman filter algorithm.

- A MAT-file that contains example input data.
- A MATLAB file for plotting.

Location of Files

The tutorial files are available in the following folder: `docroot\toolbox\simulink\examples\kalman`. To run the tutorial, you must copy these files to a local folder. For instructions, see “Copying Files Locally” on page 39-167.

Names and Descriptions of Files

Type	Name	Description
MATLAB function files	ex_kalman01	Baseline MATLAB implementation of a scalar Kalman filter.
	ex_kalman02	Version of the original algorithm suitable for code generation.
	ex_kalman03	Version of Kalman filter suitable for code generation and for use with frame-based and packet-based inputs.

Type	Name	Description
	ex_kalman04	Disabled inlining for code generation.
Simulink model files	ex_kalman00	Simulink model without a MATLAB Function block.
	ex_kalman11	Complete Simulink model with a MATLAB Function block for scalar Kalman filter.
	ex_kalman22	Simulink model with a MATLAB Function block for a Kalman filter that accepts fixed-size (frame-based) inputs.
	ex_kalman33	Simulink model with a MATLAB Function block for a Kalman filter that accepts variable-size (packet-based) inputs.
	ex_kalman44	Simulink model to call ex_kalman04.m, which has inlining disabled.
MATLAB data file	position	Contains the input data used by the algorithm.
Plot files	plot_trajectory	Plots the trajectory of the object and the Kalman filter estimated position.

Tutorial Steps

- “Copying Files Locally” on page 39-167
- “Setting Up Your C Compiler” on page 39-168
- “About the ex_kalman00 Model” on page 39-168
- “Adding a MATLAB Function Block to Your Model” on page 39-170
- “Simulating the ex_kalman11 Model” on page 39-172
- “Modifying the Filter to Accept a Fixed-Size Input” on page 39-174
- “Using the Filter to Accept a Variable-Size Input” on page 39-178
- “Debugging the MATLAB Function Block” on page 39-181
- “Generating C Code” on page 39-182

Copying Files Locally

Copy the tutorial files to a local working folder:

- 1 Create a local *solutions* folder, for example, `c:\simulink\kalman\solutions`.
- 2 Change to the `docroot\toolbox\simulink\examples` folder. At the MATLAB command line, enter:

```
cd(fullfile(docroot, 'toolbox', 'simulink', 'examples'))
```

- 3 Copy the contents of the `kalman` subfolder to your local *solutions* folder, specifying the full path name of the *solutions* folder:

```
copyfile('kalman', 'solutions')
```

For example:

```
copyfile('kalman', 'c:\simulink\kalman\solutions')
```

Your *solutions* folder now contains a complete set of solutions for the tutorial. If you do not want to perform the steps for each task in the tutorial, you can view the solutions to see how the code should look.

- 4 Create a local *work* folder, for example, `c:\simulink\kalman\work`.
- 5 Copy the following files from your *solutions* folder to your *work* folder.

- `ex_kalman01`
- `ex_kalman00`
- `position`
- `plot_trajectory`

Your *work* folder now contains all the files that you need to get started with the tutorial.

Setting Up Your C Compiler

Building your MATLAB Function block requires a supported compiler. MATLAB automatically selects one as the default compiler. If you have multiple MATLAB-supported compilers installed on your system, you can change the default using the `mex -setup` command. See “Change Default Compiler”.

About the `ex_kalman00` Model

First, examine the `ex_kalman00` model supplied with the tutorial to understand the problem that you are trying to solve using the Kalman filter.

- 1 Open the `ex_kalman00` model in Simulink:

- a Set your MATLAB current folder to the folder that contains your working files for this tutorial. At the MATLAB command line, enter:

```
cd work
```

where *work* is the full path name of the folder containing your files.

- b At the MATLAB command line, enter:

```
ex_kalman00
```

This model is an incomplete model to demonstrate how to integrate MATLAB code with Simulink. The complete model is `ex_kalman11`, which is also supplied with this tutorial.

InitFcn Model Callback Function

The model uses this callback function to:

- Load position data from a MAT-file.
- Set up data used by the Index generator block, which provides the second input to the Selector block.

To view this callback:

- 1 Select **File > Model Properties > Model Properties**.
- 2 Select the **Callbacks** tab.
- 3 Select `InitFcn` in the **Model callbacks** pane.

The callback appears.

```
load position.mat;  
[R,C]=size(position);  
idx=(1:C)';  
t=idx-1;
```

Source Blocks

The model uses two Source blocks to provide position data and a scalar index to a Selector block.

Selector Block

The model uses a Selector block that selects elements of its input signal and generates an output signal based on its index input and its **Index Option** settings. By changing the configuration of this block, you can generate different size signals.

To view the Selector block settings, double-click the Selector block to view the function block parameters.

In this model, the **Index Option** for the first port is `Select all` and for the second port is `Index vector (port)`. Because the input is a 2×310 position matrix, and the index data increments from 1 to 310, the Selector block simply outputs one 2×1 output at each sample time.

MATLAB Function Block

The model uses a MATLAB Function block to plot the trajectory of the object and the Kalman filter estimated position. This function:

- First declares the `figure`, `hold`, and `plot_trajectory` functions as extrinsic because these MATLAB visualization functions are not supported for code generation. When you call an unsupported MATLAB function, you must declare it to be extrinsic so MATLAB can execute it, but does not try to generate code for it.
- Creates a figure window and holds it for the duration of the simulation. Otherwise a new figure window appears for each sample time.
- Calls the `plot_trajectory` function, which plots the trajectory of the object and the Kalman filter estimated position.

Simulation Stop Time

The simulation stop time is 309, because the input to the filter is a vector containing 310 elements and Simulink uses zero-based indexing.

Adding a MATLAB Function Block to Your Model

To modify the model and code yourself, work through the exercises in this section. Otherwise, open the supplied model `ex_kalman11` in your *solutions* subfolder to see the modified model.

For the purposes of this tutorial, you add the MATLAB Function block to the `ex_kalman00.mdl` model supplied with the tutorial. You would have to develop your own test bench starting with an empty Simulink model.

Adding the MATLAB Function Block

To add a MATLAB Function block to the `ex_kalman00` model:

- 1 Open `ex_kalman00` in Simulink.
`ex_kalman00`
- 2 Add a MATLAB Function block to the model:
 - a At the MATLAB command line, type `slLibraryBrowser` to open the Simulink Library Browser.
 - b From the list of Simulink libraries, select the **User-Defined Functions** library.
 - c Click the MATLAB Function block and drag it into the `ex_kalman00` model. Place the block just above the red text annotation that reads **Place MATLAB Function Block here**.
 - d Delete the red text annotations from the model.
 - e Save the model in the current folder as `ex_kalman11`.

Calling Your MATLAB Code from the MATLAB Function Block

To call your MATLAB code from the MATLAB Function block:

- 1 Double-click the MATLAB Function block to open the MATLAB Function Block Editor.
- 2 Delete the default code displayed in the editor.
- 3 Copy the following code to the MATLAB Function block.

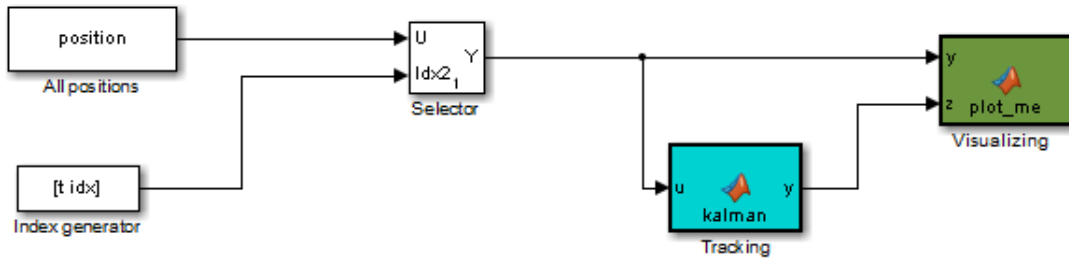

```
function y = kalman(u)
%#codegen

y = ex_kalman01(u);
```

- 4 Save the model.

Connecting the MATLAB Function Block Input and Output

- 1 Connect the MATLAB Function block input and output so that your model looks like this.

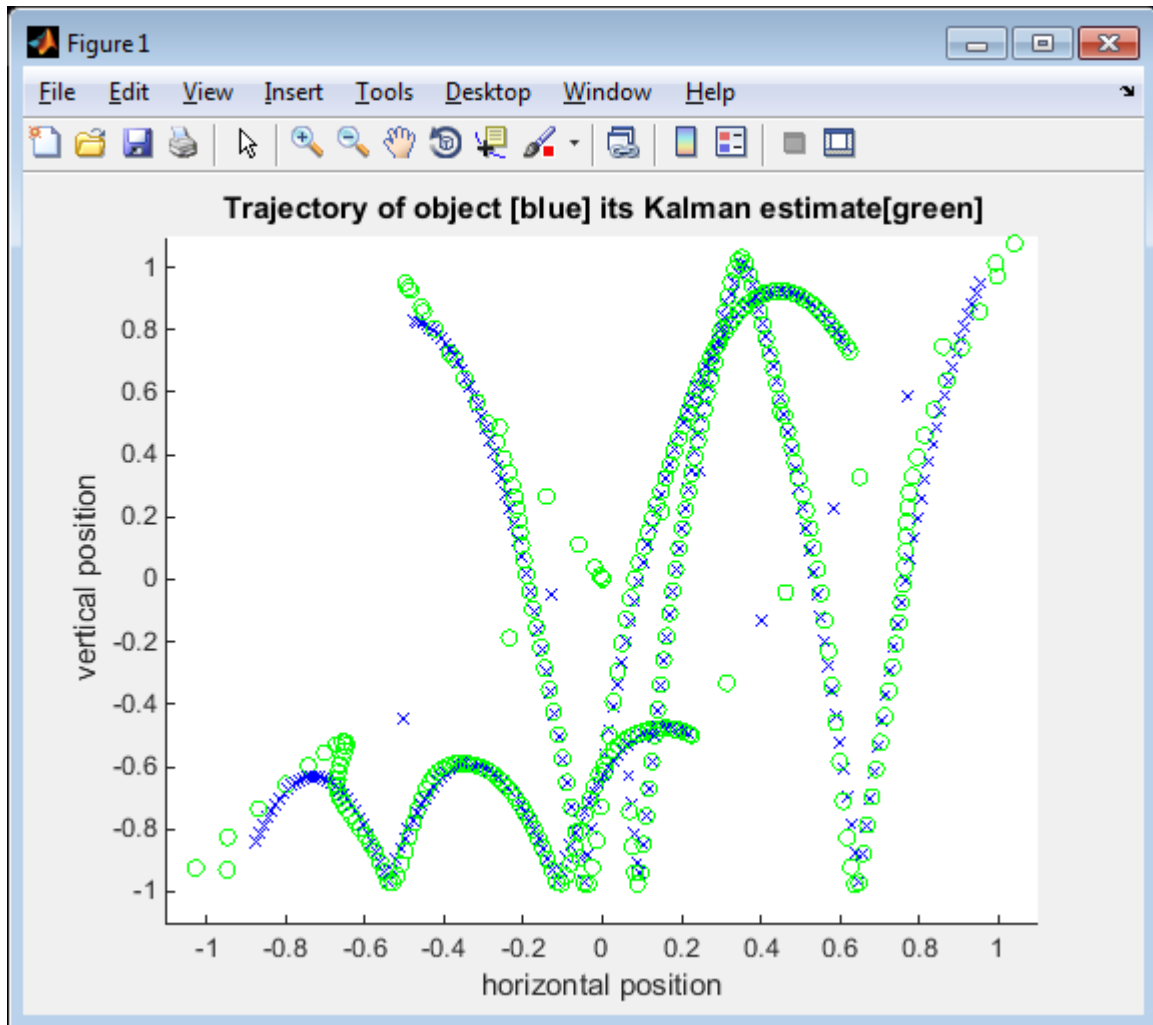

2 Save the model.

Simulating the ex_kalman11 Model

To simulate the model:

1 In the Simulink model window, select **Simulation > Run**.

As Simulink runs the model, it plots the trajectory of the object in blue and the Kalman filter estimated position in green. Initially, you see that it takes a short time for the estimated position to converge with the actual position of the object. Then three sudden shifts in position occur—each time the Kalman filter readjusts and tracks the object after a few iterations.

2 The simulation stops.

You have proved that your MATLAB algorithm works in Simulink. You are now ready to modify the filter to accept a fixed-size input, as described in “Modifying the Filter to Accept a Fixed-Size Input” on page 39-174.

Modifying the Filter to Accept a Fixed-Size Input

The filter you have worked on so far in this tutorial uses a simple batch process that accepts one input at a time, so you must call the function repeatedly for each input. In this part of the tutorial, you learn how to modify the algorithm to accept a fixed-sized input, which makes the algorithm suitable for frame-based processing. You then modify the model to provide the input as fixed-size frames of data and call the filter passing in the data one frame at a time.

Modifying Your MATLAB Code

To modify the code yourself, work through the exercises in this section. Otherwise, open the supplied file `ex_kalman03.m` in your *solutions* subfolder to see the modified algorithm.

You can now modify the algorithm to process a vector containing more than one input. You need to find the length of the vector and call the filter code for each element in the vector in turn. You do this by calling the filter algorithm in a `for` loop.

- 1 Open `ex_kalman02.m` in the MATLAB Editor. At the MATLAB command line, enter:

```
edit ex_kalman02.m
```

- 2 Add a `for` loop around the filter code.

- a Before the comment:

```
% Predicted state and covariance  
insert:
```

```
for i=1:size(z,2)
```

- b After:

```
% Compute the estimated measurements  
y = H * x_est;  
insert:
```

```
end
```

- c Select the code between the `for` statement and the `end` statement, right-click to open the context menu and select **Smart Indent** to indent the code.

Your filter code should now look like this:

```

for i=1:size(z,2)
    % Predicted state and covariance
    x_prd = A * x_est;
    p_prd = A * p_est * A' + Q;

    % Estimation
    S = H * p_prd' * H' + R;
    B = H * p_prd';
    klm_gain = (S \ B)';

    % Estimated state and covariance
    x_est = x_prd + klm_gain * (z - H * x_prd);
    p_est = p_prd - klm_gain * H * p_prd;

    % Compute the estimated measurements
    y = H * x_est;
end

```

- 3** Modify the line that calculates the estimated state and covariance to use the i^{th} element of input z .

Change:

```

x_est = x_prd + klm_gain * (z - H * x_prd);
to:

```

```

x_est = x_prd + klm_gain * (z(1:2,i) - H * x_prd);

```

- 4** Modify the line that computes the estimated measurements to append the result to the i^{th} element of the output y .

Change:

```

y = H * x_est;
to:

```

```

y(:,i) = H * x_est;

```

The code analyzer message indicator in the top right turns orange to indicate that the code analyzer has detected warnings. The code analyzer underlines the offending code in orange and places a orange marker to the right.

- 5** Move your pointer over the orange marker to view the error information.

The code analyzer detects that `y` must be fully defined before sub-scripting it and that you cannot grow variables through indexing in generated code.

- 6 To address this warning, preallocate memory for the output `y`, which is the same size as the input `z`. Add this code before the `for` loop.

```
% Pre-allocate output signal:  
y=zeros(size(z));
```

The orange marker disappears and the code analyzer message indicator in the top right edge of the code turns green, which indicates that you have fixed all the errors and warnings detected by the code analyzer.

Why Preallocate the Outputs?

You must preallocate outputs here because the code generation does not support increasing the size of an array over time. Repeatedly expanding the size of an array over time can adversely affect the performance of your program. See “Preallocating Memory”.

- 7 Change the function name to `ex_kalman03` and save the file as `ex_kalman03.m` in the current folder.

You are ready to begin the next task in the tutorial, “Modifying Your Model to Call the Updated Algorithm” on page 39-176.

Modifying Your Model to Call the Updated Algorithm

To modify the model yourself, work through the exercises in this section. Otherwise, open the supplied model `ex_kalman22.mdl` in your *solutions* subfolder to see the modified model.

Next, update your model to provide the input as fixed-size frames of data and call `ex_kalman03` passing in the data one frame at a time.

- 1 Open `ex_kalman11` model in Simulink.

```
ex_kalman11
```

- 2 Double-click the MATLAB Function block to open the MATLAB Function Block Editor.

- 3 Replace the code that calls `ex_kalman02` with a call to `ex_kalman03`.

```
function y = kalman(u)
```

```
##codegen
```

```
y = ex_kalman03(u);
```

4 Close the editor.

5 Modify the InitFcn callback:

a Select **File > Model Properties > Model Properties**.

The Model Properties dialog box opens.

b In this dialog box, select the **Callbacks** tab.

c Select InitFcn in the **Model callbacks** pane.

d Replace the existing callback with:

```
load position.mat;
[R,C]=size(position);
FRAME_SIZE=5;
idx=(1:FRAME_SIZE:C)';
LEN=length(idx);
t=(1:LEN)' - 1;
```

This callback sets the frame size to 5, and the index to increment by 5.

e Click **Apply** and close the Model Properties dialog box.

6 Update the Selector block to use the correct indices.

a Double-click the Selector block to view the function block parameters.

The Function Block Parameters dialog box opens.

b Set the second **Index Option** to **Starting index (port)**.

c Set the **Output Size** for the second input to `FRAME_SIZE`, click **Apply** and close the dialog box.

Now, the **Index Option** for the first port is **Select all** and for the second port is **Starting index (port)**. Because the index increments by 5 each sample time, and the output size is 5, the Selector block outputs a 2×5 output at each sample time.

7 Change the model simulation stop time to 61. Now the frame size is 5, so the simulation completes in a fifth of the sample times.

a In the Simulink model window, select **Simulation > Model Configuration Parameters**.

- b** In the left pane of the Configuration Parameters dialog box, select **Solver**.
 - c** In the right pane, set **Stop time** to **61**.
 - d** Click **Apply** and close the dialog box.
- 8** Save the model as `ex_kalman22.mdl`.

Testing Your Modified Algorithm

To simulate the model:

- 1** In the Simulink model window, select **Simulation > Run**.

As Simulink runs the model, it plots the trajectory of the object in blue and the Kalman filter estimated position in green as before when you used the batch filter.

- 2** The simulation stops.

You have proved that your algorithm accepts a fixed-size signal. You are now ready for the next task, “Using the Filter to Accept a Variable-Size Input” on page 39-178.

Using the Filter to Accept a Variable-Size Input

In this part of the tutorial, you learn how to specify variable-size data in your Simulink model. Then you test your Kalman filter algorithm with variable-size inputs and see that the algorithm is suitable for processing packets of data of varying size. For more information on using variable-size data in Simulink, see “Variable-Size Signal Basics” on page 64-2.

Updating the Model to Use Variable-Size Inputs

To modify the model yourself, work through the exercises in this section. Otherwise, open the supplied model `ex_kalman33.mdl` in your *solutions* subfolder to see the modified model.

- 1** Open `ex_kalman22.mdl` in Simulink.
`ex_kalman22`
- 2** Modify the `InitFcn` callback:
 - a** Select **File > Model Properties > Model Properties**.

The Model Properties dialog box opens.

- b** Select the **Callbacks** tab.
- c** Select **InitFcn** in the **Model callbacks** pane.
- d** Replace the existing callback with:

```
load position.mat;
idx=[ 1 1 ;2 3 ;4 6 ;7 10 ;11 15 ;16 30 ;
      31 70 ;71 100 ;101 200 ;201 250 ;251 310];
LEN=length(idx);
t=(0:1:LEN-1)';
```

This callback sets up indexing to generate eleven different size inputs. It specifies the start and end indices for each sample time. The first sample time uses only the first element, the second sample time uses the second and third elements, and so on. The largest sample, 101 to 200, contains 100 elements.

- e** Click **Apply** and close the **Model Properties** dialog box.
- 3** Update the Selector block to use the correct indices.
- a** Double-click the Selector block to view the function block parameters.
The Function Block Parameters dialog box opens.
 - b** Set the second **Index Option** to **Starting and ending indices (port)**, then click **Apply** and close the dialog box.

This setting means that the input to the index port specifies the start and end indices for the input at each sample time. Because the index input specifies different starting and ending indices at each sample time, the Selector block outputs a variable-size signal as the simulation progresses.
- 4** Use the Ports and Data Manager to set the MATLAB Function input **x** and output **y** as variable-size data.
- a** Double-click the MATLAB Function block to open the MATLAB Function Block Editor.
 - b** From the editor menu, select **Edit Data**.
 - c** In the Ports and Data Manager left pane, select the input **u**.

The Ports and Data Manager displays information about **u** in the right pane.
 - d** On the **General** tab, select the **Variable size** check box and click **Apply**.
 - e** In the left pane, select the output **y**.
 - f** On the **General** tab:

- i Set the **Size** of *y* to [2 100] to specify a 2-D matrix where the upper bounds are 2 for the first dimension and 100 for the second, which is the maximum size input specified in the InitFcn callback.
 - ii Select the **Variable size** check box.
 - iii Click **Apply**.
- g Close the Ports and Data Manager.
- 5 Now do the same for the other MATLAB Function block. Use the Ports and Data Manager to set the Visualizing block inputs *y* and *z* as variable-size data.
 - a Double-click the Visualizing block to open the MATLAB Function Block Editor.
 - b From the editor menu, select **Edit Data**.
 - c In the Ports and Data Manager left pane, select the input *y*.
 - d On the **General** tab, select the **Variable size** check box and click **Apply**.
 - e In the left pane, select the input *z*.
 - f On the **General** tab, select the **Variable size** check box and click **Apply**.
 - g Close the Ports and Data Manager.
 - 6 Change the model simulation stop time to 10. This time, the filter processes one of the eleven different size inputs each sample time.
 - 7 Save the model as `ex_kalman33.mdl`.

Testing Your Modified Model

To simulate the model:

- 1 In the Simulink model window, select **Simulation > Run**.

As Simulink runs the model, it plots the trajectory of the object in blue and the Kalman filter estimated position in green as before.

Note that the signal lines between the Selector block and the Tracking and Visualization blocks change to show that these signals are variable-size.

- 2 The simulation stops.

You have successfully created an algorithm that accepts variable-size inputs. Next, you learn how to debug your MATLAB Function block, as described in “Debugging the MATLAB Function Block” on page 39-181.

Debugging the MATLAB Function Block

You can debug your MATLAB Function block just like you can debug a function in MATLAB.

- 1 Double-click the MATLAB Function block that calls the Kalman filter to open the MATLAB Function Block Editor.

- 2 In the editor, click the dash (-) character in the left margin of the line:

```
y = kalman03(u);
```

A small red ball appears in the margin of this line, indicating that you have set a breakpoint.

- 3 In the Simulink model window, select **Simulation > Run**.

The simulation pauses when execution reaches the breakpoint and a small green arrow appears in the left margin.

- 4 Place the pointer over the variable `u`.

The value of `u` appears adjacent to the pointer.

- 5 From the MATLAB Function Block Editor menu, select **Step In**.

The `kalman03.m` file opens in the editor and you can now step through this code using **Step**, **Step In**, and **Step Out**.

- 6 Select **Step Out**.

The `kalman03.m` file closes and the MATLAB Function block code reappears in the editor.

- 7 Place the pointer over the output variable `y`.

You can now see the value of `y`.

- 8 Click the red ball to remove the breakpoint.

- 9 From the MATLAB Function Block Editor menu, select **Quit Debugging**.

- 10 Close the editor.

- 11 Close the figure window.

Now you are ready for the next task, “Generating C Code” on page 39-182.

Generating C Code

You have proved that your algorithm works in Simulink. Next you generate code for your model.

Note: Before generating code, you must check that your MATLAB code is suitable for code generation. If you call your MATLAB code as an extrinsic function, you must remove extrinsic calls before generating code.

- 1 Rename the MATLAB Function block to **Tracking**. To rename the block, double-click the annotation **MATLAB Function** below the MATLAB Function block and replace the text with **Tracking**.

When you generate code for the MATLAB Function block, Simulink Coder uses the name of the block in the generated code. It is good practice to use a meaningful name.

- 2 Before generating code, ensure that Simulink Coder creates a code generation report. This HTML report provides easy access to the list of generated files with a summary of the configuration settings used to generate the code.

- a In the Simulink model window, select **Simulation > Model Configuration Parameters**.

The Configuration Parameters dialog box opens.

- b In the left pane of the Configuration Parameters dialog box, select **Report** under **Code Generation**.

- c In the right pane, select **Create code generation report**.

The **Open report automatically** option is also selected.

- d Click **Apply** and close the Configuration Parameters dialog box.

- e Save your model.

- 3 To generate code for the Tracking block:

- a In your model, select the Tracking block.

- b In the Simulink model window, select **Code > C/C++ Code > Build Selected Subsystem**.

- 4 The Simulink software generates an error informing you that it cannot log variable-size signals as arrays. You need to change the format of data saved to the MATLAB workspace. To change this format:

- In the Simulink model window, select **Simulation > Model Configuration Parameters**.

The Configuration Parameters dialog box opens.

- In the left pane of the Configuration Parameters dialog box, select **Data Import/Export** and set the **Format** to **Structure with time**.

The logged data is now a structure that has two fields: a time field and a signals field, enabling Simulink to log variable-size signals.

- Click **Apply** and close the Configuration Parameters dialog box.
- Save your model.

- 5 Repeat step 3 to generate code for the Tracking block.

The Simulink Coder software generates C code for the block and launches the code generation report.

For more information on using the code generation report, see “Reports for Code Generation”.

- 6 In the left pane of the code generation report, click the **Tracking.c** link to view the generated C code. Note that in the code generated for the MATLAB Function block, **Tracking**, there is no code for the **ex_kalman03** function because inlining is enabled by default.
- 7 Modify your filter algorithm to disable inlining:

- a In **ex_kalman03.m**, after the function declaration, add:

```
coder.inline('never');
```

- b Change the function name to **ex_kalman04** and save the file as **ex_kalman04.m** in the current folder.
- c In your **ex_kalman33** model, double-click the Tracking block.

The MATLAB Function Block Editor opens.

- d Modify the call to the filter algorithm to call **ex_kalman04**.

```
function y = kalman(u)
```

```
    %#codegen
```

```
    y = ex_kalman04(u);
```

- e Save the model as `ex_kalman44.mdl`.
- 8 Generate code for the updated model.
 - a Select the Tracking block.
 - b In the model window, select **Code > C/C++Code > Build Selected Subsystem**.

The **Build code for Subsystem** dialog box appears.

- c Click the **Build** button.

The Simulink Coder software generates C code for the block and launches the code generation report.

- d In the left pane of the code generation report, click the `Tracking.c` link to view the generated C code.

This time the `ex_kalman04` function has code because you disabled inlining.

```
/* Forward declaration for local functions */
static void Tracking_ex_kalman04(const real_T z_data[620], const int32_T
    z_sizes[2], real_T y_data[620], int32_T y_sizes[2]);

/* Function for MATLAB Function Block: '<Root>/Tracking' */
static void Tracking_ex_kalman04(const real_T z_data[620], const int32_T    48
    z_sizes[2], real_T y_data[620], int32_T y_sizes[2])
```

Best Practices Used in This Tutorial

Best Practice — Saving Incremental Code Updates

Save your code before making modifications. This practice provides a fallback in case of error and a baseline for testing and validation. Use a consistent file naming convention. For example, add a two-digit suffix to the file name for each file in a sequence.

Key Points to Remember

- Back up your MATLAB code before you modify it.

- Decide on a naming convention for your files and save interim versions frequently. For example, this tutorial uses a two-digit suffix to differentiate the various versions of the filter algorithm.
- For simulation purposes, before generating code, call your MATLAB code using `coder.extrinsic` to check that your algorithm is suitable for use in Simulink. This practice provides these benefits:
 - You do not have to make the MATLAB code suitable for code generation.
 - You can debug your MATLAB code in MATLAB while calling it from Simulink.
- Create a Simulink Coder code generation report. This HTML report provides easy access to the list of generated files with a summary of the configuration settings used to generate the code.

Filter Audio Signal Using MATLAB Code

In this section...

- “Learning Objectives” on page 39-186
- “Tutorial Prerequisites” on page 39-186
- “Example: The LMS Filter” on page 39-187
- “Files for the Tutorial” on page 39-189
- “Tutorial Steps” on page 39-191

Learning Objectives

In this tutorial, you will learn how to:

- Use the MATLAB Function block to add MATLAB functions to Simulink models for modeling, simulation, and deployment to embedded processors.

This capability is useful for coding algorithms that are better stated in the textual language of MATLAB than in the graphical language of Simulink.

- Use `coder.extrinsic` to call MATLAB code from a MATLAB Function block.

This capability allows you to call existing MATLAB code from Simulink without first having to make this code suitable for code generation, allowing for rapid prototyping.

- Check that existing MATLAB code is suitable for code generation.
- Convert a MATLAB algorithm from batch processing to streaming.
- Use persistent variables in code that is suitable for code generation.

You need to make the filter weights persistent so that the filter algorithm does not reset their values each time it runs.

Tutorial Prerequisites

- “What You Need to Know” on page 39-187
- “Required Products” on page 39-187

What You Need to Know

To work through this tutorial, you should have basic familiarity with MATLAB software. You should also understand how to create a basic Simulink model and how to simulate that model. For more information, see “Create Simple Model”.

Required Products

To complete this tutorial, you must install the following products:

- MATLAB
- MATLAB Coder
- Simulink
- Simulink Coder
- DSP System Toolbox
- C compiler

For a list of supported compilers, see http://www.mathworks.com/support/compilers/current_release/.

For instructions on installing MathWorks products, refer to the installation documentation. If you have installed MATLAB and want to check which other MathWorks products are installed, enter `ver` in the MATLAB Command Window. For instructions on installing and setting up a C compiler, see “Setting Up the C or C++ Compiler”.

Example: The LMS Filter

- “Description” on page 39-187
- “Algorithm” on page 39-188
- “Filtering Process” on page 39-189
- “Reference” on page 39-189

Description

A least mean squares (LMS) filter is an adaptive filter that adjusts its transfer function according to an optimizing algorithm. You provide the filter with an example of the desired signal together with the input signal. The filter then calculates the filter weights, or coefficients, that produce the least mean squares of the error between the output signal and the desired signal.

This example uses an LMS filter to remove the noise in a music recording. There are two inputs. The first input is the distorted signal: the music recording plus the filtered noise. The second input is the desired signal: the unfiltered noise. The filter works to eliminate the difference between the output signal and the desired signal and outputs the difference, which, in this case, is the clean music recording. When you start the simulation, you hear both the noise and the music. Over time, the adaptive filter removes the noise so you hear only the music.

Algorithm

This example uses the least mean squares (LMS) algorithm to remove noise from an input signal. The LMS algorithm computes the filtered output, filter error, and filter weights given the distorted and desired signals.

At the start of the tutorial, the LMS algorithm uses a batch process to filter the audio input. This algorithm is suitable for MATLAB, where you are likely to load in the entire signal and process it all at once. However, a batch process is not suitable for processing a signal in real time. As you work through the tutorial, you refine the design of the filter to convert the algorithm from batch-based to stream-based processing.

The baseline function signature for the algorithm is:

```
function [ signal_out, err, weights ] = ...  
    lms_01(signal_in, desired)
```

The filtering is performed in the following loop:

```
for n = 1:SignalLength  
    % Compute the output sample using convolution:  
    signal_out(n,ch) = weights' * signal_in(n:n+FilterLength-1,ch);  
    % Update the filter coefficients:  
    err(n,ch) = desired(n,ch) - signal_out(n,ch) ;  
    weights = weights + mu*err(n,ch)*signal_in(n:n+FilterLength-1,ch);  
end
```

where `SignalLength` is the length of the input signal, `FilterLength` is the filter length, and `mu` is the adaptation step size.

What Is the Adaptation Step Size?

LMS algorithms have a step size that determines the amount of correction to apply as the filter adapts from one iteration to the next. Choosing the appropriate step size requires experience in adaptive filter design. A step size that is too small increases the time for the filter to converge. Filter convergence is the process where the error

signal (the difference between the output signal and the desired signal) approaches an equilibrium state over time. A step size that is too large might cause the adapting filter to overshoot the equilibrium and become unstable. Generally, smaller step sizes improve the stability of the filter at the expense of the time it takes to adapt.

Filtering Process

The filtering process has three phases:

- Convolution

The convolution for the filter is performed in:

```
signal_out(n,ch) = weights' * signal_in(n:n+FilterLength-1,ch);
```

What Is Convolution?

Convolution is the mathematical foundation of filtering. In signal processing, convolving two vectors or matrices is equivalent to filtering one of the inputs by the other. In this implementation of the LMS filter, the convolution operation is the vector dot product between the filter weights and a subset of the distorted input signal.

- Calculation of error

The error is the difference between the desired signal and the output signal:

```
err(n,ch) = desired(n,ch) - signal_out(n,ch);
```

- Adaptation

The new value of the filter weights is the old value of the filter weights plus a correction factor that is based on the error signal, the distorted signal, and the adaptation step size:

```
weights = weights + mu*err(n,ch)*signal_in(n:n+FilterLength-1,ch);
```

Files for the Tutorial

- “About the Tutorial Files” on page 39-190

- “Location of Files” on page 39-190
- “Names and Descriptions of Files” on page 39-190

About the Tutorial Files

The tutorial uses the following files:

- Simulink model files for each step of the tutorial.
- MATLAB code files for each step of the example.

Throughout this tutorial, you work with Simulink models that call MATLAB files that contain a simple least mean squares (LMS) filter algorithm.

Location of Files

The tutorial files are available in the following folder: `docroot\toolbox\simulink\examples\lms`. To run the tutorial, you must copy these files to a local folder. For instructions, see “Copying Files Locally” on page 39-191.

Names and Descriptions of Files

Type	Name	Description
MATLAB files	<code>lms_01</code>	Baseline MATLAB implementation of batch filter. Not suitable for code generation.
	<code>lms_02</code>	Filter modified from batch to streaming.
	<code>lms_03</code>	Frame-based streaming filter with Reset and Adapt controls.
	<code>lms_04</code>	Frame-based streaming filter with Reset and Adapt controls. Suitable for code generation.
	<code>lms_05</code>	Disabled inlining for code generation.
	<code>lms_06</code>	Demonstrates use of <code>coder.nullcopy</code> .
Simulink model files	<code>acoustic_environment</code>	Simulink model that provides an overview of the acoustic environment.
	<code>noise_cancel_00</code>	Simulink model without a MATLAB Function block.
	<code>noise_cancel_01</code>	Complete <code>noise_cancel_00</code> model including a MATLAB Function block.

Type	Name	Description
	noise_cancel_02	Simulink model for use with lms_02.m.
	noise_cancel_03	Simulink model for use with lms_03.m.
	noise_cancel_04	Simulink model for use with lms_04.m.
	noise_cancel_05	Simulink model for use with lms_05.m.
	noise_cancel_06	Simulink model for use with lms_06.m.
	design_templates	Simulink model containing Adapt and Reset controls.

Tutorial Steps

- “Copying Files Locally” on page 39-191
- “Setting Up Your C Compiler” on page 39-192
- “Running the acoustic_environment Model” on page 39-192
- “Adding a MATLAB Function Block to Your Model” on page 39-193
- “Calling Your MATLAB Code As an Extrinsic Function for Rapid Prototyping” on page 39-194
- “Simulating the noise_cancel_01 Model” on page 39-196
- “Modifying the Filter to Use Streaming” on page 39-198
- “Adding Adapt and Reset Controls” on page 39-203
- “Generating Code” on page 39-207
- “Optimizing the LMS Filter Algorithm” on page 39-211

Copying Files Locally

Copy the tutorial files to a local folder:

- 1 Create a local *solutions* folder, for example, `c:\test\lms\solutions`.
- 2 Change to the `docroot\toolbox\simulink\examples` folder. At the MATLAB command line, enter:

```
cd(fullfile(docroot, 'toolbox', 'simulink', 'examples'))
```
- 3 Copy the contents of the `lms` subfolder to your *solutions* folder, specifying the full path name of the *solutions* folder:

```
copyfile('lms', 'solutions')
```

Your *solutions* folder now contains a complete set of solutions for the tutorial. If you do not want to perform the steps for each task, you can view the supplied solution to see how the code should look.

- 4 Create a local *work* folder, for example, `c:\test\lms\work`.
- 5 Copy the following files from your *solutions* folder to your *work* folder.
 - `lms_01`
 - `lms_02`
 - `noise_cancel_00`
 - `acoustic_environment`
 - `design_templates`

Your *work* folder now contains all the files that you need to get started.

You are now ready to set up your C compiler.

Setting Up Your C Compiler

Building your MATLAB Function block requires a supported compiler. MATLAB automatically selects one as the default compiler. If you have multiple MATLAB-supported compilers installed on your system, you can change the default using the `mex -setup` command. See “Change Default Compiler” and the list of .

Running the `acoustic_environment` Model

Run the `acoustic_environment` model supplied with the tutorial to understand the problem that you are trying to solve using the LMS filter. This model adds band-limited white noise to an audio signal and outputs the resulting signal to a speaker.

To simulate the model:

- 1 Open the `acoustic_environment` model in Simulink:
 - a Set your MATLAB current folder to the folder that contains your working files for this tutorial. At the MATLAB command line, enter:

```
cd work
```

where *work* is the full path name of the folder containing your files. See “Find Files and Folders” for more information.
 - b At the MATLAB command line, enter:

```
acoustic_environment
```

- 2 Ensure that your speakers are on.
- 3 To simulate the model, from the Simulink model window, select **Simulation > Run**.
As Simulink runs the model, you hear the audio signal distorted by noise.
- 4 While the simulation is running, double-click the Manual Switch to select the audio source.

Now you hear the desired audio input without any noise.

The goal of this tutorial is to use a MATLAB LMS filter algorithm to remove the noise from the noisy audio signal. You do this by adding a MATLAB Function block to the model and calling the MATLAB code from this block.

Adding a MATLAB Function Block to Your Model

To modify the model and code yourself, work through the exercises in this section. Otherwise, open the supplied model `noise_cancel_01` in your *solutions* subfolder to see the modified model.

For the purposes of this tutorial, you add the MATLAB Function block to the `noise_cancel_00` model supplied with the tutorial. In practice, you would have to develop your own test bench starting with an empty Simulink model.

To add a MATLAB Function block to the `noise_cancel_00` model:

- 1 Open `noise_cancel_00` in Simulink.
`noise_cancel_00`
- 2 Add a MATLAB Function block to the model:
 - a At the MATLAB command line, type `slLibraryBrowser` to open the Simulink Library Browser.
 - b From the list of Simulink libraries, select the **User-Defined Functions** library.
 - c Click the MATLAB Function block and drag it into the `noise_cancel_00` model. Place the block just above the red text annotation **Place MATLAB Function Block here**.
 - d Delete the red text annotations from the model.
 - e Save the model in the current folder as `noise_cancel_01`.

Calling Your MATLAB Code As an Extrinsic Function for Rapid Prototyping

In this part of the tutorial, you use the `coder.extrinsic` function to call your MATLAB code from the MATLAB Function block for rapid prototyping.

Why Call MATLAB Code As an Extrinsic Function?

Calling MATLAB code as an extrinsic function provides these benefits:

- For rapid prototyping, you do not have to make the MATLAB code suitable for code generation.
- Using `coder.extrinsic` enables you to debug your MATLAB code in MATLAB. You can add one or more breakpoints in the `lms_01.m` file, and then start the simulation in Simulink. When the MATLAB execution engine encounters a breakpoint, it temporarily halts execution so that you can inspect the MATLAB workspace and view the current values of all variables in memory. For more information about debugging MATLAB code, see “Debug a MATLAB Program”.

How to Call MATLAB Code As an Extrinsic Function

To call your MATLAB code from the MATLAB Function block:

- 1 Double-click the MATLAB Function block to open the MATLAB Function Block Editor.
- 2 Delete the default code displayed in the MATLAB Function Block Editor.
- 3 Copy the following code to the MATLAB Function block.

```
function [ Signal_Out, Weights ] = LMS(Noise_In, Signal_In) %#codegen
    % Extrinsic:
    coder.extrinsic('lms_01');

    % Compute LMS:
    [ ~, Signal_Out, Weights ] = lms_01(Noise_In, Signal_In);
end
```

Why Use the Tilde (~) Operator?

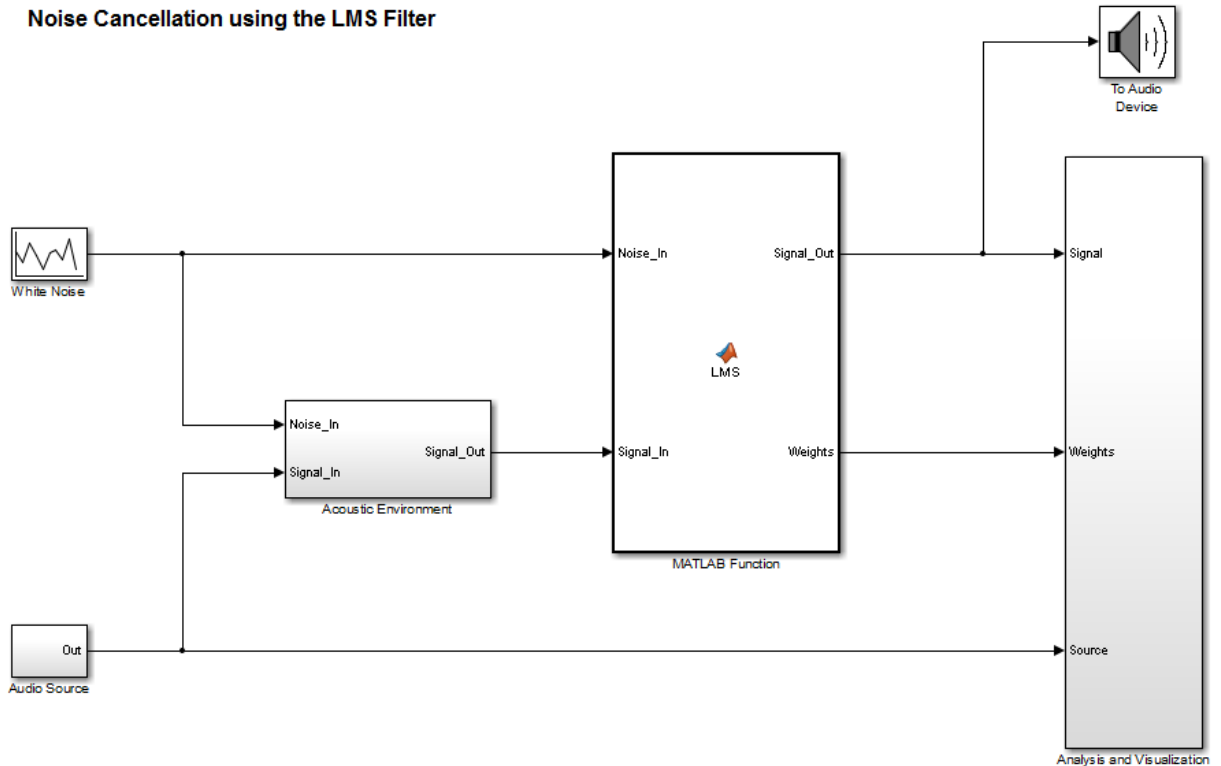

Because the LMS function does not use the first output from `lms_01`, replace this output with the MATLAB `~` operator. MATLAB ignores inputs and outputs specified by `~`. This syntax helps avoid confusion in your program code and unnecessary clutter in your workspace, and allows you to reuse existing algorithms without modification.

- 4 Save the model.

The `lms_01` function inputs `Noise_In` and `Signal_In` now appear as input ports to the block and the function outputs `Signal_Out` and `Weights` appear as output ports.

Connecting the MATLAB Function Block Inputs and Outputs

- 1 Connect the MATLAB Function block inputs and outputs so that your model looks like this.

See “Block and Signal Line Shortcuts and Actions” on page 1-91 for more information.

- 2 In the MATLAB Function block code, preallocate the outputs by adding the following code after the extrinsic call:

```
% Outputs:  
Signal_Out = zeros(size(Signal_In));  
Weights = zeros(32,1);  
The size of Weights is set to match the Numerator coefficients of the Digital Filter  
in the Acoustic Environment subsystem.
```

Why Preallocate the Outputs?

For code generation, you must assign variables explicitly to have a specific class, size, and complexity before using them in operations or returning them as outputs in MATLAB functions. For more information, see “Differences in Behavior After Compiling MATLAB Code” on page 43-8.

- 3 Save the model.

You are now ready to check your model for errors.

Simulating the noise_cancel_01 Model

To simulate the model:

- 1 Ensure that you can see the **Time Domain** plots.

To view the plots, in the `noise_cancel_01` model, open the Analysis and Visualization block and then open the Time Domain block.

- 2 In the Simulink model window, select **Simulation > Run**.

As Simulink runs the model, you see and hear outputs. Initially, you hear the audio signal distorted by noise. Then the filter attenuates the noise gradually, until you hear only the music playing with very little noise remaining. After two seconds, you hear the distorted noisy signal again and the filter attenuates the noise again. This cycle repeats continuously.

MATLAB displays the following plot showing this cycle.

3 Stop the simulation.

Why Does the Filter Reset Every 2 Seconds?

The filter resets every 2 seconds because the model uses 16384 samples per frame and a sampling rate of 8192, so the 16384 samples represent 2 seconds of audio.

To see the model configuration:

- 1 Double-click the White Noise subsystem and note that it uses a **Sample time** of $1/F_s$ and **Samples per frame** of `FrameSize`. The music in the Audio Source subsystem also uses these values.
- 2 `FrameSize` is set in the model `InitFcn` callback. To view this callback:
 - a Right-click inside the model window and select **Model Properties** from the context menu.
 - b Select the **Callbacks** tab.
 - c Select `InitFcn` in the **Model callbacks** pane.

Note that `FrameSize = 16*1024`, which is 16384.

- 3 `Fs` is set in the model `PostLoadFcn` callback. To view this callback, select `PostLoadFcn` in the **Model callbacks** pane:

The following MATLAB commands set up `Fs`:

```
data = load('handel.mat');  
music = data.y;  
Fs = data.Fs;
```

Modifying the Filter to Use Streaming

- “What Is Streaming?” on page 39-198
- “Why Use Streaming?” on page 39-198
- “Viewing the Modified MATLAB Code” on page 39-199
- “Summary of Changes to the Filter Algorithm” on page 39-199
- “Modifying Your Model to Call the Updated Algorithm” on page 39-200
- “Simulating the Streaming Algorithm” on page 39-201

What Is Streaming?

A streaming filter is called repeatedly to process fixed-size chunks of input data, or *frames*, until it has processed the entire input signal. The frame size can be as small as a single sample, in which case the filter would be operating in a sample-based mode, or up to a few thousand samples, for frame-based processing.

Why Use Streaming?

The design of the filter algorithm in `lms_01` has the following disadvantages:

- The algorithm does not use memory efficiently.

Preallocating a fixed amount of memory for each input signal for the lifetime of the program means more memory is allocated than is in use.

- You must know the size of the input signal at the time you call the function.

If the input signal is arriving in real time or as a stream of samples, you would have to wait to accumulate the entire signal before you could pass it, as a batch, to the filter.

- The signal size is limited to a maximum size.

In an embedded application, the filter is likely to be processing a continuous input stream. As a result, the input signal can be substantially longer than the maximum length that a filter working in batch mode could possibly handle. To make the filter work for any signal length, it must run in real time. One solution is to convert the filter from batch-based processing to stream-based processing.

Viewing the Modified MATLAB Code

The conversion to streaming involves:

- Introducing a first-in, first-out (FIFO) queue

The FIFO queue acts as a temporary storage buffer, which holds a small number of samples from the input data stream. The number of samples held by the FIFO queue must be exactly the same as the number of samples in the filter's impulse response, so that the function can perform the convolution operation between the filter coefficients and the input signal.

- Making the FIFO queue and the filter weights persistent

The filter is called repeatedly until it has processed the entire input signal. Therefore, the FIFO queue and filter weights need to persist so that the adaptation process does not have to start over again after each subsequent call to the function.

Open the supplied file `lms_02.m` in your *work* subfolder to see the modified algorithm.

Summary of Changes to the Filter Algorithm

Note the following important changes to the filter algorithm:

- The filter weights and the FIFO queue are declared as persistent:

```
persistent weights;  
persistent fifo;
```

- The FIFO queue is initialized:

```
fifo = zeros(FilterLength,ChannelCount);
```

- The FIFO queue is used in the filter update loop:

```
% For each channel:
for ch = 1:ChannelCount

    % For each sample time:
    for n = 1:FrameSize

        % Update the FIFO shift register:
        fifo(1:FilterLength-1,ch) = fifo(2:FilterLength,ch);
        fifo(FilterLength,ch) = signal_in(n,ch);

        % Compute the output sample using convolution:
        signal_out(n,ch) = weights' * fifo(:,ch);

        % Update the filter coefficients:
        err(n,ch) = desired(n,ch) - signal_out(n,ch) ;
        weights = weights + mu*err(n,ch)*fifo(:,ch);

    end
end
```

- You cannot output a persistent variable. Therefore, a new variable, `weights_out`, is used to output the filter weights:

```
function [ signal_out, err, weights_out ] = ...
    lms_02(distorted, desired)

weights_out = weights;
```

Modifying Your Model to Call the Updated Algorithm

To modify the model yourself, work through the exercises in this section. Otherwise, open the supplied model `noise_cancel_02` in your *solutions* subfolder to see the modified model.

- 1 In the `noise_cancel_01` model, double-click the MATLAB Function block to open the MATLAB Function Block Editor.
- 2 Modify the MATLAB Function block code to call `lms_02`.
 - a Modify the extrinsic call.

```
% Extrinsic:
coder.extrinsic('lms_02');
```

- b** Modify the call to the filter algorithm.

```
% Compute LMS:
[ ~, Signal_Out, Weights ] = lms_02(Noise_In, Signal_In);
```

Modified MATLAB Function Block Code

Your MATLAB Function block code should now look like this:

```
function [ Signal_Out, Weights ] = LMS(Noise_In, Signal_In)
% Extrinsic:
coder.extrinsic('lms_02');
% Outputs:
Signal_Out = zeros(size(Signal_In));
Weights = zeros(32,1);
% Compute LMS:
[ ~, Signal_Out, Weights ] = lms_02(Noise_In, Signal_In);
end
```

- 3** Change the frame size from 16384 to 64, which represents a more realistic value.
 - a** Right-click inside the model window and select **Model Properties** from the context menu.
 - b** Select the **Callbacks** tab.
 - c** In the **Model callbacks** list, select **InitFcn**.
 - d** Change the value of **FrameSize** to 64.
 - e** Click **Apply** and close the dialog box.
- 4** Save your model as `noise_cancel_02`.

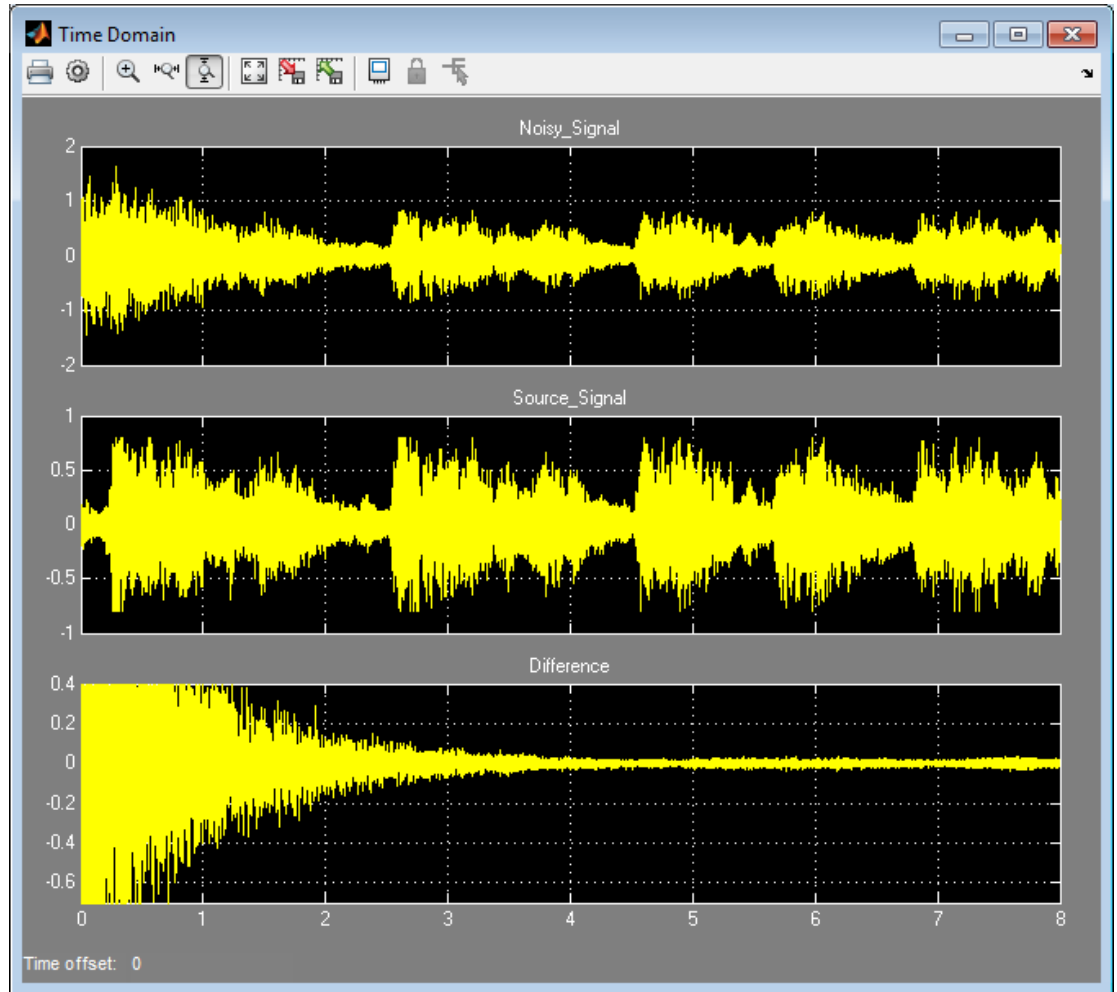

Simulating the Streaming Algorithm

To simulate the model:

- 1** Ensure that you can see the **Time Domain** plots.
- 2** Start the simulation.

As Simulink runs the model, you see and hear outputs. Initially, you hear the audio signal distorted by noise. Then, during the first few seconds, the filter attenuates the noise gradually, until you hear only the music playing with very little noise

remaining. MATLAB displays the following plot showing filter convergence after only a few seconds.

3 Stop the simulation.

The filter algorithm is now suitable for Simulink. You are ready to elaborate your model to use **Adapt** and **Reset** controls.

Adding Adapt and Reset Controls

- “Why Add Adapt and Reset Controls?” on page 39-203
- “Modifying Your MATLAB Code” on page 39-203
- “Modifying Your Model to Use Reset and Adapt Controls” on page 39-204
- “Simulating the Model with Adapt and Reset Controls” on page 39-206

Why Add Adapt and Reset Controls?

In this part of the tutorial, you add Adapt and Reset controls to your filter. Using these controls, you can turn the filtering on and off. When **Adapt** is enabled, the filter continuously updates the filter weights. When **Adapt** is disabled, the filter weights remain at their current values. If **Reset** is set, the filter resets the filter weights.

Modifying Your MATLAB Code

To modify the code yourself, work through the exercises in this section. Otherwise, open the supplied file `lms_03.m` in your *solutions* subfolder to see the modified algorithm.

To modify your filter code:

- 1 Open `lms_02.m`.
- 2 In the **Set up** section, replace

```
if ( isempty(weights) )
with
if ( reset || isempty(weights) )
```
- 3 In the filter loop, update the filter coefficients only if **Adapt** is **ON**.

```
if adapt
    weights = weights + mu*err(n,ch)*fifo(:,ch);
end
```
- 4 Change the function signature to use the **Adapt** and **Reset** inputs and change the function name to `lms_03`.

```
function [ signal_out, err, weights_out ] = ...
    lms_03(signal_in, desired, reset, adapt)
```
- 5 Save the file in the current folder as `lms_03.m`:

Summary of Changes to the Filter Algorithm

Note the following important changes to the filter algorithm:

- The new input parameter `reset` is used to determine if it is necessary to reset the filter coefficients:

```
if ( reset || isempty(weights) )
    % Filter coefficients:
    weights = zeros(L,1);
    % FIFO Shift Register:
    fifo = zeros(L,1);
end
```

- The new parameter `adapt` is used to control whether the filter coefficients are updated or not.

```
if adapt
    weights = weights + mu*err(n)*fifo;
end
```

Modifying Your Model to Use Reset and Adapt Controls

To modify the model yourself, work through the exercises in this section. Otherwise, open the supplied model `noise_cancel_03` in your *solutions* subfolder to see the modified model.

- 1 Open the `noise_cancel_02` model.
- 2 Double-click the MATLAB Function block to open the MATLAB Function Block Editor.
- 3 Modify the MATLAB Function block code:

- a Update the function declaration.

```
function [ Signal_Out, Weights ] = ...
    LMS(Adapt, Reset, Noise_In, Signal_In )
```

- b Update the extrinsic call.

```
coder.extrinsic('lms_03');
```

- c Update the call to the LMS algorithm.

```
% Compute LMS:
[ ~, Signal_Out, Weights ] = ...
    lms_03(Noise_In, Signal_In, Reset, Adapt);
```

- d Close the MATLAB Function Block Editor.

The `lms_03` function inputs `Reset` and `Adapt` now appear as input ports to the MATLAB Function block.

- 4 Open the `design_templates` model.

- 5 Copy the Settings block from this model to your `noise_cancel_02` model:
 - a From the `design_templates` model menu, select **Edit > Select All**.
 - b Select **Edit > Copy**.
 - c From the `noise_cancel_02` model menu, select **Edit > Paste**.
- 6 Connect the Adapt and Reset outputs of the Settings subsystem to the corresponding inputs on the MATLAB Function block. Your model should now appear as follows.

7 Save the model as `noise_cancel_03`.

Simulating the Model with Adapt and Reset Controls

To simulate the model and see the effect of the Adapt and Reset controls:

- 1 In the `noise_cancel_03` model, view the Convergence scope:
 - a Double-click the Analysis and Visualization subsystem.
 - b Double-click the Convergence scope.
- 2 In the Simulink model window, select **Simulation > Run**.

Simulink runs the model as before. While the model is running, toggle the Adapt and Reset controls and view the Convergence scope to see their effect on the filter.

The filter converges when **Adapt** is ON and **Reset** is OFF, then resets when you toggle **Reset**. The results might look something like this:

- 3 Stop the simulation.

Generating Code

You have proved that your algorithm works in Simulink. Next you generate code for your model. Before generating code, you must ensure that your MATLAB code is suitable for code generation. For code generation, you must remove the extrinsic call to your code.

Making Your Code Suitable for Code Generation

To modify the model and code yourself, work through the exercises in this section. Otherwise, open the supplied model `noise_cancel_04` and file `lms_04.m` in your *solutions* subfolder to see the modifications.

- 1 Rename the MATLAB Function block to `LMS_Filter`. Select the annotation `MATLAB Function` below the MATLAB Function block and replace the text with `LMS_Filter`.

When you generate code for the MATLAB Function block, Simulink Coder uses the name of the block in the generated code. It is good practice to use a meaningful name.

- 2 In your `noise_cancel_03` model, double-click the MATLAB Function block.

The MATLAB Function Block Editor opens.

- 3 Delete the extrinsic declaration.

```
% Extrinsic:
coder.extrinsic('lms_03');
```

- 4 Delete the preallocation of outputs.

```
% Outputs:
Signal_Out = zeros(size(Signal_In));
Weights = zeros(32,1);
```

- 5 Modify the call to the filter algorithm.

```
% Compute LMS:
[ ~, Signal_Out, Weights ] = ...
    lms_04(Noise_In, Signal_In, Reset, Adapt);
```

- 6 Save the model as `noise_cancel_04`.

- 7 Open `lms_03.m`

- a Modify the function name to `lms_04`.
- b Turn on error checking specific to code generation by adding the `%codegen` compilation directive after the function declaration.

```
function [ signal_out, err, weights_out ] = ...
    lms_04(signal_in, desired, reset, adapt) %codegen
```

The code analyzer message indicator in the top right turns red to indicate that the code analyzer has detected code generation issues. The code analyzer underlines the offending code in red and places a red marker to the right of it.

- 8 Move your pointer over the first red marker to view the error information.

The code analyzer detects that code generation requires `signal_out` to be fully defined before subscripting it and does not support growth of variable size data through indexing.

- 9 Move your pointer over the second red marker and note that the code analyzer detects the same errors for `err`.
- 10 To address these errors, preallocate the outputs `signal_out` and `err`. Add this code after the filter setup.

```
% Output Arguments:

% Pre-allocate output and error signals:
signal_out = zeros(FrameSize,ChannelCount);
err = zeros(FrameSize,ChannelCount);
```

Why Preallocate the Outputs?

You must preallocate outputs here because code generation does not support increasing the size of an array over time. Repeatedly expanding the size of an array over time can adversely affect the performance of your program. See “Preallocating Memory”.

The red error markers for the two lines of code disappear. The code analyzer message indicator in the top right edge of the code turns green, which indicates that you have fixed all the errors and warnings detected by the code analyzer.

- 11 Save the file as `lms_04.m`.

Generating Code for `noise_cancel_04`

- 1 Before generating code, ensure that Simulink Coder creates a code generation report. This HTML report provides easy access to the list of generated files with a summary of the configuration settings used to generate the code.
 - a In the Simulink model window, select **Simulation > Model Configuration Parameters**.
 - b In the left pane of the Configuration Parameters dialog box, select **Code Generation > Report**.
 - c In the right pane, select **Create code generation report**.
The **Launch report automatically** option is also selected.
 - d Click **Apply** and close the Configuration Parameters dialog box.
 - e Save your model.
- 2 To generate code for the LMS Filter subsystem:

- a In your model, select the LMS Filter subsystem.
- b From the Build Model tool menu, select **Build Selected Subsystem**.

The **Build code for subsystem** dialog box appears. Click the **Build** button.

The Simulink Coder software generates C code for the subsystem and launches the code generation report.

For more information on using the code generation report, see “Generate a Code Generation Report” in the Simulink Coder documentation.

- c In the left pane of the code generation report, click the `LMS_Filter.c` link to view the generated C code. Note that the `lms_04` function has no code because inlining is enabled by default.
- 3 Modify your filter algorithm to disable inlining:
- a In `lms_04.m`, after the function declaration, add:

```
coder.inline('never')
```
 - b Change the function name to `lms_05` and save the file as `lms_05.m` in the current folder.
 - c In your `noise_cancel_04` model, double-click the MATLAB Function block.

The MATLAB Function Block Editor opens.
 - d Modify the call to the filter algorithm to call `lms_05`.

```
% Compute LMS:
[ ~, Signal_Out, Weights ] = ...
    lms_05(Noise_In, Signal_In, Reset, Adapt);
```
 - e Save the model as `noise_cancel_05`.
- 4 Generate code for the updated model.
- a In the model, select the LMS Filter subsystem.

- b** From the Build Model tool menu, select **Build Selected Subsystem**.

The **Build code for subsystem** dialog box appears.

- c** Click the **Build** button.

The Simulink Coder software generates C code for the subsystem and launches the code generation report.

- d** In the left pane of the code generation report, click the `LMS_Filter.c` link to view the generated C code.

This time the `lms_05` function has code because you disabled inlining.

```
/* Forward declaration for local functions */
static void LMS_Filter_lms_05 ...
    (const real_T signal_in[64],const real_T ...
     desired[64], real_T reset, real_T adapt, ...
     real_T signal_out[64], ...
     real_T err[64], real_T weights_out[32]);

/* Function for MATLAB Function Block: 'root/LMS_Filter' */
static void LMS_Filter_lms_05 ...
    (const real_T signal_in[64], const real_T ...
     desired[64], real_T reset, real_T adapt, ...
     real_T signal_out[64], ...
     real_T err[64], real_T weights_out[32])
```

Optimizing the LMS Filter Algorithm

This part of the tutorial demonstrates when and how to preallocate memory for a variable without incurring the overhead of initializing memory in the generated code.

In `lms_05.m`, the MATLAB code not only declares `signal_out` and `err` to be a `FrameSize`-by-`ChannelCount` vector of real doubles, but also initializes each element of `signal_out` and `err` to zero. These signals are initialized to zero in the generated C code.

MATLAB Code	Generated C Code
<pre>% Pre-allocate output and error signals: signal_out = zeros(FrameSize,ChannelCount); err = zeros(FrameSize,ChannelCount);</pre>	<pre>/* Pre-allocate output and error signals: */ 79 for (i = 0; i < 64; i++) { 80 signal_out[i] = 0.0;</pre>

MATLAB Code	Generated C Code
	81 err[i] = 0.0; 82 }

This forced initialization is unnecessary because both `signal_out` and `err` are explicitly initialized in the MATLAB code before they are read.

Note: You should not use `coder.nullcopy` when declaring the variables `weights` and `fifo` because these variables need to be initialized in the generated code. Neither variable is explicitly initialized in the MATLAB code before they are read.

Use `coder.nullcopy` in the declaration of `signal_out` and `err` to eliminate the unnecessary initialization of memory in the generated code:

- 1 In `lms_05.m`, preallocate `signal_out` and `err` using `coder.nullcopy`:

```
% Pre-allocate output and error signals:
signal_out = coder.nullcopy(zeros(FrameSize, ChannelCount));
err = coder.nullcopy(zeros(FrameSize, ChannelCount));
```

Caution After declaring a variable with `coder.nullcopy`, you must explicitly initialize the variable in your MATLAB code before reading it. Otherwise, you might get unpredictable results.

- 2 Change the function name to `lms_06` and save the file as `lms_06.m` in the current folder.
- 3 In your `noise_cancel_05` model, double-click the MATLAB Function block.

The MATLAB Function Block Editor opens.

- 4 Modify the call to the filter algorithm.

```
% Compute LMS:
[~, Signal_Out, Weights] = ...
    lms_06(Noise_In, Signal_In, Reset, Adapt);
```

- 5 Save the model as `noise_cancel_06`.

Generate code for the updated model.

- 1 Select the LMS Filter subsystem.

- 2 From the Build Model tool menu, select **Build Selected Subsystem**.

The **Build code for subsystem** dialog box appears. Click the **Build** button.

The Simulink Coder software generates C code for the subsystem and launches the code generation report.

- 3 In the left pane of the code generation report, click the `LMS_Filter.c` link to view the generated C code.

In the generated C code, this time there is no initialization to zero of `signal_out` and `err`.

Encapsulating the Interface to External Code

Use the `coder.ExternalDependency` class to encapsulate the interface between external code and MATLAB code intended for code generation. With the encapsulation, you can separate the details of the interface from your MATLAB code. The methods of `coder.ExternalDependency`:

- specify the location of external files
- update build information
- define the programming interface for external functions

In your MATLAB code, you can call the external code without providing build information.

The workflow is:

- 1 Write a class definition file for a class that derives from `coder.ExternalDependency`.
- 2 Store the class definition file in a folder on the MATLAB path.
- 3 In your MATLAB code, use a method of the class to call an external function.
- 4 Generate code from your MATLAB code.

More About

- “Best Practices for Using `coder.ExternalDependency`” on page 39-218

Encapsulate Interface to an External C Library

Use `coder.ExternalDependency` to encapsulate the interface to an external C dynamic linked library .

Write a function `adder` that returns the sum of its inputs.

```
function c = adder(a,b)
    %#codegen
    c = a + b;
end
```

Generate a library that contains `adder`.

```
codegen('adder', '-args', {-2,5}, '-config:dll', '-report');
```

Write the class definition file `AdderAPI.m` to encapsulate the library interface.

```
%=====
% This class abstracts the API to an external Adder library.
% It implements static methods for updating the build information
% at compile time and build time.
%=====

classdef AdderAPI < coder.ExternalDependency
    %#codegen

    methods (Static)

        function bName = getDescriptiveName(~)
            bName = 'AdderAPI';
        end

        function tf = isSupportedContext(ctx)
            if ctx.isMatlabHostTarget()
                tf = true;
            else
                error('adder library not available for this target');
            end
        end

        function updateBuildInfo(buildInfo, ctx)
            [~, linkLibExt, execLibExt, ~] = ctx.getStdLibInfo();

            % Header files
```

```
hdrFilePath = fullfile(pwd, 'codegen', 'dll', 'adder');
buildInfo.addIncludePaths(hdrFilePath);

% Link files
linkFiles = strcat('adder', linkLibExt);
linkPath = hdrFilePath;
linkPriority = '';
linkPrecompiled = true;
linkLinkOnly = true;
group = '';
buildInfo.addLinkObjects(linkFiles, linkPath, ...
    linkPriority, linkPrecompiled, linkLinkOnly, group);

% Non-build files
nbFiles = 'adder';
nbFiles = strcat(nbFiles, execLibExt);
buildInfo.addNonBuildFiles(nbFiles, '', '');
end

%API for library function 'adder'
function c = adder(a, b)
    if coder.target('MATLAB')
        % running in MATLAB, use built-in addition
        c = a + b;
    else
        % running in generated code, call library function
        coder.cinclude('adder.h');

        % Because MATLAB Coder generated adder, use the
        % housekeeping functions before and after calling
        % adder with coder.ceval.
        % Call initialize function before calling adder for the
        % first time.

        coder.ceval('adder_initialize');
        c = 0;
        c = coder.ceval('adder', a, b);

        % Call the terminate function after
        % calling adder for the last time.

        coder.ceval('adder_terminate');
    end
end
```

```
        end
    end
end
```

Write a function `adder_main` that calls the external library function `adder`.

```
function y = adder_main(x1, x2)
%#codegen
    y = AdderAPI.adder(x1, x2);
end
```

Generate a MEX function for `adder_main`. The MEX Function exercises the `coder.ExternalDependency` methods.

```
codegen('adder_main', '-args', {7,9}, '-report')
```

Copy the library to the current folder using the file extension for your platform.

For Windows, use:

```
copyfile(fullfile(pwd, 'codegen', 'dll', 'adder', 'adder.dll'));
```

For Linux, use:

```
copyfile(fullfile(pwd, 'codegen', 'dll', 'adder', 'adder.so'));
```

For Mac, use:

```
copyfile(fullfile(pwd, 'codegen', 'dll', 'adder', 'adder.dylib'));
```

Run the MEX function and verify the result.

```
adder_main_mex(2,3)
```

`coder.BuildConfig` | `coder.ExternalDependency` | `error`

More About

- “Encapsulating the Interface to External Code” on page 39-214

Best Practices for Using `coder.ExternalDependency`

In this section...

“Terminate Code Generation for Unsupported External Dependency” on page 39-218

“Parameterize Methods for MATLAB and Generated Code” on page 39-218

“Parameterize `updateBuildInfo` for Multiple Platforms” on page 39-219

Terminate Code Generation for Unsupported External Dependency

The `isSupportedContext` method returns true if the external code interface is supported in the build context. If the external code interface is not supported, do not return false. Instead, use `error` to terminate code generation with an error message. For example:

```
function tf = isSupportedContext(ctx)
    if ctx.isMatlabHostTarget()
        tf = true;
    else
        error('MyLibrary is not available for this target');
    end
end
```

Parameterize Methods for MATLAB and Generated Code

Parameterize methods that call external functions so that the methods run in MATLAB. For example:

```
...
if coder.target('MATLAB')
    % running in MATLAB, use built-in addition
    c = a + b;
else
    % running in generated code, call library function
    coder.ceval('adder_initialize');
end
...
```

Parameterize `updateBuildInfo` for Multiple Platforms

Parameterize the `updateBuildInfo` method to support multiple platforms. For example, use `coder.BuildConfig.getStdLibInfo` to get the platform-specific library file extensions.

```
...
    [~, linkLibExt, execLibExt, ~] = ctx.getStdLibInfo()
% Link files
linkFiles = strcat('adder', linkLibExt);
buildInfo.addLinkObjects(linkFiles, linkPath, linkPriority, ...
    linkPrecompiled, linkLinkOnly, group);
...
```

Update Build Information from MATLAB code

You can control aspects of the build process that occur after code generation but before compilation. For example, you can specify compiler or linker options.

To customize the build from your MATLAB code:

- 1 In your MATLAB code, call `coder.updateBuildInfo` to update the build information object. You specify a build information object method and the input arguments for the method.
- 2 Generate code from your MATLAB code.

- “System Objects Methods That Support Code Generation” on page 40-11
- “System Objects in Simulink” on page 40-13
- “System Object Methods” on page 40-14
- “System Design in Simulink Using System Objects” on page 40-17

What Are System Objects?

A System object is a specialized kind of MATLAB object. System Toolboxes include System objects and most System Toolboxes also have MATLAB functions and Simulink blocks. System objects are designed specifically for implementing and simulating dynamic systems with inputs that change over time. Many signal processing, communications, and controls systems are dynamic. In a dynamic system, the values of the output signals depend on both the instantaneous values of the input signals and on the past behavior of the system. System objects use internal states to store that past behavior, which is used in the next computational step. As a result, System objects are optimized for iterative computations that process large streams of data in segments, such as video and audio processing systems. This ability to process streaming data provides the advantage of not having to hold large amounts of data in memory. Use of streaming data also allows you to use simplified programs that use loops efficiently.

For example, you could use System objects in a system that reads data from a file, filters that data and then writes the filtered output to another file. Typically, a specified amount of data is passed to the filter in each loop iteration. The file reader object uses a state to keep track of where in the file to begin the next data read. Likewise, the file writer object keeps tracks of where it last wrote data to the output file so that data is not overwritten. The filter object maintains its own internal states to ensure that the filtering is performed correctly. This diagram represents a single loop of the system.

These advantages make System objects particularly well suited for processing streaming data

Many System objects support:

- Fixed-point arithmetic (requires a Fixed-Point Designer license)
- C code generation (requires a MATLAB Coder or Simulink Coder license)
- HDL code generation (requires an HDL Coder license)
- Executable files or shared libraries generation (requires a MATLAB Compiler™ license)

Note: Check your product documentation to confirm fixed-point, code generation, and MATLAB Compiler support for the specific System objects you want to use.

System objects use a minimum of two commands to process data—a constructor to create the object (such as `fft256 = dsp.FFT`) and a function call (such as `fft256(x)`) to run data through the object. This separation of declaration from execution lets you create multiple, persistent, reusable objects, each with different settings. Using this approach avoids repeated input validation and verification, allows for easy use within a programming loop, and improves overall performance. In contrast, MATLAB functions must validate parameters every time you call the function.

In addition to the System objects provided with System Toolboxes, you can also create your own System objects. See “Define System Objects”.

System Design and Simulation in Simulink

You can use System objects in your model to simulate in Simulink.

- 1** Create a System object to be used in your model. See “Define New Kinds of System Objects for Use in Simulink” on page 40-17 for information.
- 2** Test your new System object in MATLAB. See “Test New System Objects in MATLAB” on page 40-22
- 3** Add the System object to your model using the **MATLAB System** block. See “Add System Objects to Your Simulink Model” on page 40-23 for information.
- 4** Add other Simulink blocks as needed and connect the blocks to construct your system.
- 5** Run the system

System Objects in MATLAB Code Generation

In this section...

“System Objects in Generated Code” on page 40-5

“System Objects in codegen” on page 40-9

“System Objects in the MATLAB Function Block” on page 40-9

“System Objects in the MATLAB System Block” on page 40-9

“System Objects and MATLAB Compiler Software” on page 40-10

System Objects in Generated Code

You can generate C/C++ code in MATLAB from your system that contains System objects by using MATLAB Coder. You can generate efficient and compact code for deployment in desktop and embedded systems and accelerate fixed-point algorithms.

System Objects Code with Persistent Objects for Code Generation

This example shows how to use System objects to make MATLAB code suitable for code generation. The example highlights key factors to consider, such as passing property values and using extrinsic functions. It also shows that by using persistent objects, the object states are maintained between calls.

```
function w = lmsystem(x, d)
% LMSSYSTEMIDENTIFICATION System identification using
% LMS adaptive filter
% #codegen

    % Declare System objects as persistent
    persistent hlms;

    % Initialize persistent System objects only once.
    % Do this with 'if isempty(persistent variable).'
    % This condition will be false after the first time.

    if isempty(hlms)
        % Create LMS adaptive filter used for system
        % identification. Pass property value arguments
        % as constructor arguments. Property values must
        % be constants during compile time.
```

```
        hlms = dsp.LMSFilter(11, 'StepSize', 0.01);  
    end  
  
    [~,~,w] = hlms(x,d);      % Filter weights  
end
```

This example shows how to compile the `lmssystem` function and produce a MEX file with the same name in the current directory.

```
% LMSSYSTEMIDENTIFICATION System identification using  
% LMS adaptive filter  
  
coefs = fir1(10,.25);  
hfilt = dsp.FIRFilter('Numerator', coefs);  
  
x = randn(1000,1);          % Input signal  
hSrc = dsp.SignalSource(x,100); % Use x as input-signal with  
                                     % 100 samples per frame  
  
% Generate code for lmssystem  
codegen lmssystem -args {ones(100,1),ones(100,1)}  
  
while ~isDone(hSrc)  
    in = hSrc();  
    d = hfilt(in) + 0.01*randn(100,1); % Desired signal  
    w = lmssystem_mex(in,d);          % Call generated mex file  
    stem([coefs.' ,w]);  
end
```

For another detailed code generation example, see “Generate Code for MATLAB Handle Classes and System Objects” in the MATLAB Coder product documentation.

Usage Rules and Limitations for System Objects for Generating Code

The following usage rules and limitations apply to using System objects in code generated from MATLAB.

Object Construction and Initialization

- If objects are stored in persistent variables, initialize System objects once by embedding the object handles in an `if` statement with a call to `isempty()`.
- Set arguments to System object constructors as compile-time constants.

- You cannot initialize System objects properties with other MATLAB class objects as default values in code generation. You must initialize these properties in the constructor.

Inputs and Outputs

- System objects accept a maximum of 1024 inputs. A maximum of 8 dimensions per input is supported.
- The data type of the inputs should not change.
- If you want the size of inputs to change, verify that variable-size is enabled. Code generation support for variable-size data also requires that the `Enable variable sizing` option is enabled, which is the default in MATLAB.

Note: Variable-size properties in MATLAB Function block in Simulink are not supported. System objects predefined in the software do not support variable-size if their data exceeds the `DynamicMemoryAllocationThreshold` value.

- Do not set System objects to become outputs from the MATLAB Function block.
- Do not use the Save and Restore Simulation State as SimState option for any System object in a MATLAB Function block.
- Do not pass a System object as an example input argument to a function being compiled with `codegen`.
- Do not pass a System object to functions declared as extrinsic (functions called in interpreted mode) using the `coder.extrinsic` function. System objects returned from extrinsic functions and scope System objects that automatically become extrinsic can be used as inputs to another extrinsic function, but do not generate code.

Tunable and Nontunable Properties

- The value assigned to a nontunable property must be a constant and there can be at most one assignment to that property (including the assignment in the constructor).
- For most System objects, the only time you can set their nontunable properties during code generation is when you construct the objects.
 - For System objects that are predefined in the software, you can set their tunable properties at construction time or using dot notation after the object is locked.
 - For System objects that you define, you can change their tunable properties at construction time or using dot notation during code generation. For `getNumInputsImpl` and `getNumOutputsImpl` methods, if you set the

return argument from an object property, that object property must have the `Nontunable` attribute.

- Objects cannot be used as default values for properties.

Global Variables

- Global variables are allowed in a System object, unless you will be using that System object in Simulink via the MATLAB System block. To avoid syncing global variables between a MEX file and the workspace, use a coder configuration object. For example:

```
f = coder.MEXConfig;  
f.GlobalSyncMethod = 'NoSync'  
Then, include '-config f' in your codegen command.
```

Methods

- Code generation support is available only for these System object methods:
 - `get`
 - `getNumInputs`
 - `getNumOutputs`
 - `isDone` (for sources only)
 - `isLocked`
 - `release`
 - `reset`
 - `set` (for tunable properties)
 - `step`
- For System objects that you define,

Code generation support is available only for these methods:

- `getDiscreteStateImpl`
- `getNumInputsImpl`
- `getNumOutputsImpl`
- `infoImpl`
- `isDoneImpl`
- `isInputDirectFeedThroughImpl`

- `outputImpl`
- `processTunedPropertiesImpl`
- `releaseImpl` — Code is not generated automatically for this method. To release an object, you must explicitly call the `release` method in your code.
- `resetImpl`
- `setupImpl`
- `stepImpl`
- `updateImpl`
- `validateInputsImpl`
- `validatePropertiesImpl`

System Objects in codegen

You can include System objects in MATLAB code in the same way you include any other elements. You can then compile a MEX file from your MATLAB code by using the `codegen` command, which is available if you have a MATLAB Coder license. This compilation process, which involves a number of optimizations, is useful for accelerating simulations. See “Getting Started with MATLAB Coder” and “MATLAB Classes” for more information.

Note: Most, but not all, System objects support code generation. Refer to the particular object’s reference page for information.

System Objects in the MATLAB Function Block

Using the MATLAB Function block, you can include any System object and any MATLAB language function in a Simulink model. This model can then generate embeddable code. System objects provide higher-level algorithms for code generation than do most associated blocks. For more information, see “What Is a MATLAB Function Block?” on page 39-5 in the Simulink documentation.

System Objects in the MATLAB System Block

Using the MATLAB System block, you can include in a Simulink model individual System objects that you create with a class definition file. The model can then generate

embeddable code. For more information, see “MATLAB System Block” on page 42-2 in the Simulink documentation.

System Objects and MATLAB Compiler Software

MATLAB Compiler software supports System objects for use inside MATLAB functions. The compiler product does not support System objects for use in MATLAB scripts.

System Objects Methods That Support Code Generation

In this section...

“Code Generation Supported System Objects Methods” on page 40-11

“Simulation-Only System Objects Methods” on page 40-11

Code Generation Supported System Objects Methods

Only the following methods are supported in code generation.

- `getDiscreteStateImpl`
- `getNumInputsImpl`
- `getNumOutputsImpl`
- `isDoneImpl`
- `infoImpl`
- `isInputDirectFeedthroughImpl`
- `outputImpl`
- `processTunedPropertiesImpl`
- `releaseImpl` — Code is not generated automatically for the this method. To release an object, you must explicitly call the `release` method in your code.
- `resetImpl`
- `setupImpl`
- `stepImpl`
- `updateImpl`
- `validateInputsImpl`
- `validatePropertiesImpl`

Simulation-Only System Objects Methods

The following methods are for simulation only and do not support code generation.

- `getDiscreteStateSpecificationImpl`
- `getHeaderImpl`

- `getInputNamesImpl`
- `getIconImpl`
- `getOutputDataTypeImpl`
- `getOutputNamesImpl`
- `getOutputSizeImpl`
- `getPropertyGroupsImpl`
- `isInactivePropertyImpl`
- `isOutputComplexImpl`
- `loadObjectImpl`
- `propagatedInputComplexity`
- `propagatedInputDataType`
- `propagatedInputFixedSize`
- `propagatedInputSize`
- `saveObjectImpl`
- `supportsMultipleInstanceImpl`

System Objects in Simulink

In this section...
“System Objects in the MATLAB Function Block” on page 40-13
“System Objects in the MATLAB System Block” on page 40-13

System Objects in the MATLAB Function Block

You can include System object code in Simulink models using the `MATLAB Function` block. Your function can include one or more System objects. Portions of your system may be easier to implement in the MATLAB environment than directly in Simulink. Many System objects have Simulink block counterparts with equivalent functionality. Before writing MATLAB code to include in a Simulink model, check for existing blocks that perform the desired operation.

System Objects in the MATLAB System Block

You can include individual System objects that you create with a class definition file into Simulink using the `MATLAB System` block. This provides one way to add your own algorithm blocks into your Simulink models. For information, see “System Object Integration” in the Simulink documentation.

System Object Methods

In this section...
“What Are System Object Methods?” on page 40-14
“Running a System Object” on page 40-14
“Common Methods” on page 40-15

What Are System Object Methods?

After you create a System object, you use various object methods to process data or obtain information from or about the object. The syntax for using methods is `<method>(<system object name>)`, plus possible extra input arguments. For example, for `txfourier = dsp.FFT`, where `txfourier` is a name you assign, you call the `reset` method using `reset(txfourier)`. For more information about methods, see the descriptions in “Common Methods” on page 40-15.

Running a System Object

To run a System object and perform the operation defined by its algorithm, you call the object as if it were a function. For example, to create an FFT object that uses the `dsp.FFT` System object, specifies a length of 1024, and names it `dft`, use

```
dft = dsp.FFT;
```

To run this object on input `x`, use

```
dft(x);
```

If you run a System object without any input arguments, you must include empty parentheses. For example, `asysobj()`.

When you run a System object, it also performs other important tasks related to data processing, such as initialization and handling object states.

Note: An alternative way to run a System object is to use the `step` method. For example, for an object created using `dft = dsp.FFT`, you can run it using `step(dft,x)`.

Common Methods

All System objects support the following methods, each of which is linked from each object's reference page. In cases where a method is not applicable to a particular object, calling that method has no effect on the object.

Method	Description
Run System object like a function, or step	<p>Run the object to process data using the algorithm defined by that object.</p> <p>Example: For <code>dft = dsp.FFT;</code>, the standard way to run the object is <code>y = dft(x)</code>. The alternative way is <code>y = step(dft,x)</code>.</p> <p>As part of this processing, the object initializes needed resources, returns outputs, and updates the object states. After you start running the object, you cannot change any input specifications (i.e., dimensions, data type, complexity). During execution, you can change only tunable properties. Both ways of running a System object return regular MATLAB variables.</p>
<code>release</code>	Releases any special resources allocated by the object, such as file handles and device drivers, and unlocks the object. For System objects, use the <code>release</code> method instead of a destructor.
<code>reset</code>	Resets the internal states of a locked object to the initial values for that object and leaves the object locked
<code>getNumInputs</code>	Returns the number of inputs (excluding the object itself) expected running the object. This number varies for an object depending on whether any properties enable additional inputs.
<code>getNumOutputs</code>	Returns the number of outputs expected from running the object. This number varies for an object depending on whether any properties enable additional outputs.
<code>getDiscreteState</code>	Returns the discrete states of the object in a structure. If the object is unlocked (when the object is first created and before you have run it or after you have released the object), the states are empty. If the object has no discrete states, <code>getDiscreteState</code> returns an empty structure.

Method	Description
<code>clone</code>	Creates another object of the same type with the same property values
<code>isLocked</code>	Returns a logical value indicating whether the object is locked.
<code>isDone</code>	Applies to source objects only. Returns a logical value indicating whether the end of the data file has been reached. If a particular object does not have end-of-data capability, this method value returns <code>false</code> .
<code>info</code>	Returns a structure containing characteristic information about the object. The fields of this structure vary depending on the object. If a particular object does not have characteristic information, the structure is empty.

For a complete list of methods for writing new System objects, see “System Objects Methods for Defining New Objects” on page 41-3.

System Design in Simulink Using System Objects

In this section...

“Define New Kinds of System Objects for Use in Simulink” on page 40-17

“Test New System Objects in MATLAB” on page 40-22

“Add System Objects to Your Simulink Model” on page 40-23

Define New Kinds of System Objects for Use in Simulink

- “Define System Object with Block Customizations” on page 40-17
- “Define System Object with Nondirect Feedthrough” on page 40-20

A System object is a component you can use to create your system in MATLAB. You can write the code in MATLAB and use that code to create a block in Simulink. To define your own System object, you write a class definition file, which is a text-based MATLAB file that contains the code defining your object. See “System Object Integration” in the Simulink documentation.

Define System Object with Block Customizations

This example shows how to create a System object for use in Simulink. The example performs system identification using a least mean squares (LMS) adaptive filter.

This example shows how to create a class definition text file to define your System object. The code in this example creates a least mean squares (LMS) filter and includes customizations to the block icon and dialog appearance. It is similar to the System Identification Using MATLAB System Blocks Simulink example.

Note: Instead of manually creating your class definition file, you can use the **New > System Object > Simulink Extension** menu option to open a template. This template includes customizations of the System object for use in the Simulink MATLAB System block. You edit the template file, using it as guideline, to create your own System object.

On the first line of the class definition file, specify the name of your System object and subclass from both `matlab.System` and `matlab.system.mixin.CustomIcon`. The `matlab.System` base class enables you to use all the basic System object methods and specify the block input and output names, title, and property groups. The `CustomIcon` mixin class enables the method that lets you specify the block icon.

Add the appropriate basic System object methods to set up, reset, set the number of inputs and outputs, and run your algorithm. See the reference pages for each method and the full class definition file below for the implementation of each of these methods.

- Use the `setupImpl` method to perform one-time calculations and initialize variables.
- Use the `stepImpl` method to implement the block's algorithm.
- Use the `resetImpl` method to reset the state properties or `DiscreteState` properties.
- Use the `getNumInputsImpl` and `getNumOutputsImpl` methods to specify the number of inputs and outputs, respectively.

Add the appropriate `CustomIcon` methods to define the appearance of the MATLAB System block in Simulink. See the reference pages for each method and the full class definition file below for the implementation of each of these methods.

- Use the `getHeaderImpl` method to specify the title and description to display on the block dialog.
- Use the `getPropertyGroupsImpl` method to specify groups of properties to display on the block dialog.
- Use the `getIconImpl` method to specify the text to display on the block icon.
- Use the `getInputNamesImpl` and `getOutputNamesImpl` methods to specify the labels to display for the block input and output ports.

The full class definition file for the least mean squares filter is:

```
classdef lmsSysObj < matlab.System &...
    matlab.system.mixin.CustomIcon
    % lmsSysObj Least mean squares (LMS) adaptive filtering.
    % #codegen

    properties
        % Mu Step size
        Mu = 0.005;
    end

    properties (Nontunable)
        % Weights Filter weights
        Weights = 0;
        % N Number of filter weights
        N = 32;
    end
end
```

```

properties (DiscreteState)
    X;
    H;
end

methods (Access = protected)
    function setupImpl(obj)
        obj.X = zeros(obj.N,1);
        obj.H = zeros(obj.N,1);
    end

    function [y, e_norm] = stepImpl(obj,d,u)
        tmp = obj.X(1:obj.N-1);
        obj.X(2:obj.N,1) = tmp;
        obj.X(1,1) = u;
        y = obj.X'*obj.H;
        e = d-y;
        obj.H = obj.H + obj.Mu*e*obj.X;
        e_norm = norm(obj.Weights'-obj.H);
    end

    function resetImpl(obj)
        obj.X = zeros(obj.N,1);
        obj.H = zeros(obj.N,1);
    end

end

% Block icon and dialog customizations
methods (Static, Access = protected)
    function header = getHeaderImpl
        header = matlab.system.display.Header(...
            'lmsSysObj', ...
            'Title', 'LMS Adaptive Filter');
    end

    function groups = getPropertyGroupsImpl
        upperGroup = matlab.system.display.SectionGroup(...
            'Title', 'General', ...
            'PropertyList', {'Mu'});

        lowerGroup = matlab.system.display.SectionGroup(...
            'Title', 'Coefficients', ...
            'PropertyList', {'Weights', 'N'});
    end
end

```

```
        groups = [upperGroup,lowerGroup];
    end
end

methods (Access = protected)
    function icon = getIconImpl(~)
        icon = sprintf('LMS Adaptive\nFilter');
    end
    function [in1name, in2name] = getInputNamesImpl(~)
        in1name = 'Desired';
        in2name = 'Actual';
    end
    function [out1name, out2name] = getOutputNamesImpl(~)
        out1name = 'Output';
        out2name = 'EstError';
    end
end
end
```

Define System Object with Nondirect Feedthrough

This example shows how to create a System object for use in Simulink. The example performs system identification using a least mean squares (LMS) adaptive filter and uses feedback loops.

This example shows how to create a class definition text file to define your System object. The code in this example creates an integer delay and includes feedback loops, and customizations to the block icon. For information on feedback loops, see “Use System Objects in Feedback Loops” on page 42-14. This example implements a System object that you can use for nondirect feedthrough. It is similar to the System Identification Using MATLAB System Blocks Simulink example.

On the first line of the class definition file, subclass from `matlab.System` and `matlab.system.mixin.CustomIcon`. The `matlab.System` base class enables you to use all the basic System object methods and specify the block input and output names, title, and property groups. The `CustomIcon` mixin class enables the method that lets you specify the block icon. The `Nondirect` mixin enables the methods that let you specify how the block is updated and what it outputs.

Add the appropriate basic System object methods to set up and reset the object and set and validate the properties. Since this object supports nondirect feedthrough, you do not implement the `stepImpl` method. You implement the `updateImpl` and `outputImpl`

methods instead. See the reference pages for each method and the full class definition file below for the implementation of each of these methods.

- Use the `setupImpl` method to initialize some of the object's properties.
- Use the `resetImpl` method to reset the property states.
- Use the `validatePropertiesImpl` method to check that the property values are valid.

Add the following `Nondirect` mixin class methods instead of the `stepImpl` method to specify how the block updates its state and its output. See the reference pages and the full class definition file below for the implementation of each of these methods.

- Use the `outputImpl` method to implement code to calculate the block output.
- Use the `updateImpl` method to implement code to update the block's internal states.
- Use the `isInputDirectFeedthroughImpl` method to specify that the block is not direct feedthrough. Its inputs do not directly affect its outputs.

Add the `getIconImpl` method to define the block icon when it is used in Simulink via the MATLAB System block. See the reference page and the full class definition file below for the implementation of this method.

The full class definition file for the delay is:

```
classdef intDelaySysObj < matlab.System &...
    matlab.system.mixin.Nondirect &...
    matlab.system.mixin.CustomIcon
    % intDelaySysObj Delay input by specified number of samples.
    % #codegen

    properties
        % InitialOutput Initial output
        InitialOutput = 0;
    end

    properties (Nontunable)
        % NumDelays Number of delays
        NumDelays = 1;
    end

    properties (DiscreteState)
        PreviousInput;
    end
end
```

```
methods (Access = protected)
function setupImpl(obj, ~)
    obj.PreviousInput = ones(1,obj.NumDelays)*obj.InitialOutput;
end

function [y] = outputImpl(obj, ~)
    % Output does not directly depend on input
    y = obj.PreviousInput(end);
end

function updateImpl(obj, u)
    obj.PreviousInput = [u obj.PreviousInput(1:end-1)];
end

function flag = isInputDirectFeedthroughImpl(~,~)
    flag = false;
end

function validatePropertiesImpl(obj)
    if ((numel(obj.NumDelays)>1) || (obj.NumDelays <= 0))
        error('Number of delays must be positive non-zero scalar value.');
```

```
    end
    if (numel(obj.InitialOutput)>1)
        error('Initial output must be scalar value.');
```

```
    end
end

function resetImpl(obj)
    obj.PreviousInput = ones(1,obj.NumDelays)*obj.InitialOutput;
end

function icon = getIconImpl(~)
    icon = sprintf('Integer\nDelay');
```

```
end
end
end
```

Test New System Objects in MATLAB

- 1 Create an instance of your new System object. For example, create an instance of the `lmsSysObj`.

```
s = lmsSysObj;
```

- 2 Run the object multiple times with different inputs. This tests for syntax errors and other possible issues before you add it to Simulink. For example,

```
desired = 0;  
actual = 0.2;  
s(desired,actual);
```

Add System Objects to Your Simulink Model

- 1 Add your System objects to your Simulink model by using the MATLAB System block as described in “Mapping System Objects to Block Dialog Box” on page 42-19.
- 2 Add other Simulink blocks, connect them, and configure any needed parameters to complete your model as described in the Simulink documentation. See the System Identification for an FIR System Using MATLAB System Blocks Simulink example.
- 3 Run your model in the same way you run any Simulink model.

- isInputSizeLockedImpl
- getPropertyGroupsImpl
- getSimulateUsingImpl
- isDoneImpl
- infoImpl
- isInactivePropertyImpl
- isInputDirectFeedthroughImpl
- isOutputComplexImpl
- isOutputFixedSizeImpl
- loadObjectImpl
- outputImpl
- processTunedPropertiesImpl
- propagatedInputComplexity
- propagatedInputDataType
- propagatedInputFixedSize
- propagatedInputSize

- `releaseImpl`
- `resetImpl`
- `saveObjectImpl`
- `setProperty`
- `setupImpl`
- `showFiSettingsImpl`
- `showSimulateUsingImpl`
- `stepImpl`
- `supportsMultipleInstanceImpl`
- `updateImpl`
- `validateInputsImpl`
- `validatePropertiesImpl`

Define Basic System Objects

This example shows how to create a basic System object that increments a number by one. The class definition file used in the example contains the minimum elements required to define a System object.

Create System Object

You can create and edit a MAT-file or use the MATLAB Editor to create your System object. This example describes how to use the **New** menu in the MATLAB Editor.

In MATLAB, on the Editor tab, select **New > System Object > Basic**. A simple System object template opens.

Subclass your object from `matlab.System`. Replace `Untitled` with `AddOne` in the first line of your file.

```
classdef AddOne < matlab.System
```

Save the file and name it `AddOne.m`.

Define Algorithm

The `stepImpl` method contains the algorithm to execute when you run your object. Define this method so that it contains the actions you want the System object to perform.

- 1 In the basic System object you created, inspect the `stepImpl` method template.

```
methods (Access = protected)
    function y = stepImpl(obj,u)
        % Implement algorithm. Calculate y as a function of input u and
        % discrete states.
        y = u;
    end
end
```

The `stepImpl` method access is always set to `protected` because it is an internal method that users do not directly call or run.

All methods, except static methods, expect the System object handle as the first input argument. The default value, inserted by MATLAB Editor, is `obj`. You can use any name for your System object handle.

By default, the number of inputs and outputs are both 1. Inputs and outputs can be added using **Inputs/Outputs**. If you use variable number of inputs or outputs, insert the appropriate `getNumInputsImpl` or `getNumOutputsImpl` method.

Alternatively, if you create your System object by editing a MAT-file, you can add the `stepImpl` method using **Insert Method > Implement algorithm**.

- 2 Change the computation in the `y` function to add 1 to the value of `u`.

```
methods (Access = protected)
```

```
function y = stepImpl(~,u)
    y = u + 1;
end
```

Note: Instead of passing in the object handle, you can use the tilde (~) to indicate that the object handle is not used in the function. Using the tilde instead of an object handle prevents warnings about unused variables.

- 3 Remove the additional, unused methods that are included by default in the basic template. Alternatively, you can modify these methods to add more System object actions and properties. You can also make no changes, and the System object still operates as intended.

The class definition file now has all the code necessary for this System object.

```
classdef AddOne < matlab.System
% ADDONE Compute an output value one greater than the input value

% All methods occur inside a methods declaration.
% The stepImpl method has protected access
methods (Access = protected)

    function y = stepImpl(~,u)
        y = u + 1;
    end
end
end
```

`matlab.System` | `getNumInputsImpl` | `getNumOutputsImpl` | `stepImpl`

Related Examples

- “Change Number of Inputs or Outputs” on page 41-8

Change Number of Inputs or Outputs

This example shows how to specify two inputs and two outputs to a System object .

If you specify the inputs and outputs to the `stepImpl` method, you do not need to specify the `getNumInputsImpl` and `getNumOutputsImpl` methods. If you have a variable number of inputs or outputs (using `varargin` or `varargout`), include the `getNumInputsImpl` or `getNumOutputsImpl` method, respectively, in your class definition file.

Note: You should only use `getNumInputsImpl` or `getNumOutputsImpl` methods to change the number of System object inputs or outputs. Do not use any other handle objects within a System object to change the number of inputs or outputs.

You always set the `getNumInputsImpl` and `getNumOutputsImpl` methods access to `protected` because they are internal methods that users do not directly call or run.

Update the Algorithm for Multiple Inputs and Outputs

Update the `stepImpl` method to specify two inputs and two outputs. You do not need to implement associated `getNumInputsImpl` or `getNumOutputsImpl` methods.

```
methods (Access = protected)
    function [y1,y2] = stepImpl(~,x1,x2)
        y1 = x1 + 1;
        y2 = x2 + 1;
    end
end
```

Update the Algorithm and Associated Methods

Update the `stepImpl` method to use `varargin` and `varargout`. In this case, you must implement the associated `getNumInputsImpl` and `getNumOutputsImpl` methods to specify two or three inputs and outputs.

```
methods (Access = protected)
    function varargout = stepImpl(obj,varargin)
        varargout{1} = varargin{1}+1;
        varargout{2} = varargin{2}+1;
        if (obj.numInputsOutputs == 3)
            varargout{3} = varargin{3}+1;
        end
end
```

```

end

function validatePropertiesImpl(obj)
    if ~(obj.numInputsOutputs == 2) ||...
        (obj.numInputsOutputs == 3)
        error('Only 2 or 3 input and outputs allowed.');
```

```

    end
end

function numIn = getNumInputsImpl(obj)
    numIn = 3;
    if (obj.numInputsOutputs == 2)
        numIn = 2;
    end
end

function numOut = getNumOutputsImpl(obj)
    numOut = 3;
    if (obj.numInputsOutputs == 2)
        numOut = 2;
    end
end
end

```

Use this syntax to run the algorithm with two inputs and two outputs.

```

addit = AddOne;
x1 = 3;
x2 = 7;
[y1,y2] = addit(x1,x2);

```

To change the number of inputs or outputs, you must release the object before rerunning it.

```

release(addit)
x1 = 3;
x2 = 7;
x3 = 10
[y1,y2,y3] = addit(x1,x2,x3);

```

Complete Class Definition File with Multiple Inputs and Outputs

```

classdef AddOne < matlab.System
    % ADDONE Compute output values one greater than the input values

```

```
% This property is nontunable and cannot be changed
% after the setup method has been called or when
% the object is running.
properties (Nontunable)
    numInputsOutputs = 3;    % Default value
end

% All methods occur inside a methods declaration.
% The stepImpl method has protected access
methods (Access = protected)
    function varargout = stepImpl(obj,varargin)
        if (obj.numInputsOutputs == 2)
            varargout{1} = varargin{1}+1;
            varargout{2} = varargin{2}+1;
        else
            varargout{1} = varargin{1}+1;
            varargout{2} = varargin{2}+1;
            varargout{3} = varargin{3}+1;
        end
    end
end

function validatePropertiesImpl(obj)
    if ~((obj.numInputsOutputs == 2) || ...
        (obj.numInputsOutputs == 3))
        error('Only 2 or 3 input and outputs allowed.');
```

end

Specify System Block Input and Output Names

This example shows how to specify the names of the input and output ports of a System object-based block implemented using a MATLAB System block.

Define Input and Output Names

This example shows how to use `getInputNamesImpl` and `getOutputNamesImpl` to specify the names of the input port as “source data” and the output port as “count.”

If you do not specify the `getInputNamesImpl` and `getOutputNamesImpl` methods, the object uses the `stepImpl` method input and output variable names for the input and output port names, respectively. If the `stepImpl` method uses *varargin* and *varargout* instead of variable names, the port names default to empty character vectors.

```
methods (Access = protected)
    function inputName = getInputNamesImpl(~)
        inputName = 'source data';
    end

    function outputName = getOutputNamesImpl(~)
        outputName = 'count';
    end
end
```

Complete Class Definition File with Named Inputs and Outputs

```
classdef MyCounter < matlab.System

    % MyCounter Count values above a threshold

    properties
        Threshold = 1
    end
    properties (DiscreteState)
        Count
    end

    methods
        function obj = MyCounter(varargin)
            setProperties (obj,nargin,varargin{:});
        end
    end
end
```

```
methods (Access = protected)
    function setupImpl(obj)
        obj.Count = 0;
    end
    function resetImpl(obj)
        obj.Count = 0;
    end
    function y = stepImpl(obj,u)
        if (u > obj.Threshold)
            obj.Count = obj.Count + 1;
        end
        y = obj.Count;
    end
    function inputName = getInputNamesImpl(~)
        inputName = 'source data';
    end
    function outputName = getOutputNamesImpl(~)
        outputName = 'count';
    end
end
end
```

Validate Property and Input Values

This example shows how to verify that the user's inputs and property values are valid.

Validate Properties

This example shows how to validate the value of a single property using `set.PropertyName` syntax. In this case, the *PropertyName* is `Increment`.

```
methods
    % Validate the properties of the object
    function set.Increment(obj, val)
        if val >= 10
            error('The increment value must be less than 10');
        end
        obj.Increment = val;
    end
end
```

This example shows how to validate the value of two interdependent properties using the `validatePropertiesImpl` method. In this case, the `UseIncrement` property value must be `true` and the `WrapValue` property value must be less than the `Increment` property value.

```
methods (Access = protected)
    function validatePropertiesImpl(obj)
        if obj.UseIncrement && obj.WrapValue > obj.Increment
            error('Wrap value must be less than increment value');
        end
    end
end
```

Validate Inputs

This example shows how to validate that the first input is a numeric value.

```
methods (Access = protected)
    function validateInputsImpl(~, x)
        if ~isnumeric(x)
            error('Input must be numeric');
        end
    end
end
```

```
end
```

Complete Class Definition File with Property and Input Validation

```
classdef AddOne < matlab.System
% ADDONE Compute an output value by incrementing the input value

% All properties occur inside a properties declaration.
% These properties have public access (the default)
properties (Logical)
    UseIncrement = true
end

properties (PositiveInteger)
    Increment = 1
    WrapValue = 10
end

methods
% Validate the properties of the object
function set.Increment(obj,val)
    if val >= 10
        error('The increment value must be less than 10');
    end
    obj.Increment = val;
end
end

methods (Access = protected)
function validatePropertiesImpl(obj)
    if obj.UseIncrement && obj.WrapValue > obj.Increment
        error('Wrap value must be less than increment value');
    end
end

% Validate the inputs to the object
function validateInputsImpl(~,x)
    if ~isnumeric(x)
        error('Input must be numeric');
    end
end

function out = stepImpl(obj,in)
    if obj.UseIncrement
        out = in + obj.Increment;
    end
end
end
```

```
    else
      out = in + 1;
    end
  end
end
end
```

Related Examples

- “Define Basic System Objects” on page 41-5

More About

- “Methods Timing” on page 41-91
- “Property Set Methods”
- “System Object Input Arguments and ~ in Code Examples” on page 41-94

Initialize Properties and Setup One-Time Calculations

This example shows how to write code to initialize and set up a System object.

In this example, you allocate file resources by opening the file so the System object can write to that file. You do these initialization tasks one time during setup, rather than every time you run the object.

Define Public Properties to Initialize

In this example, you define the public `Filename` property and specify the value of that property as the nontunable character vector, `default.bin`. Users cannot change *nontunable* properties after the `setup` method has been called. Refer to the Methods Timing section for more information.

```
properties (Nontunable)
    Filename = 'default.bin'
end
```

Define Private Properties to Initialize

Users cannot access *private* properties directly, but only through methods of the System object. In this example, you define the `pFileID` property as a private property. You also define this property as *hidden* to indicate it is an internal property that never displays to the user.

```
properties (Hidden,Access = private)
    pFileID;
end
```

Define Setup

You use the `setupImpl` method to perform setup and initialization tasks. You should include code in the `setupImpl` method that you want to execute one time only. The `setupImpl` method is called once the first time you run the object. In this example, you allocate file resources by opening the file for writing binary data.

```
methods
    function setupImpl(obj)
        obj.pFileID = fopen(obj.Filename,'wb');
        if obj.pFileID < 0
            error('Opening the file failed');
        end
    end
```

```
end  
end
```

Although not part of setup, you should close files when your code is done using them. You use the `releaseImpl` method to release resources.

Complete Class Definition File with Initialization and Setup

```
classdef MyFile < matlab.System  
% MyFile write numbers to a file  
  
% These properties are nontunable. They cannot be changed  
% after the setup method has been called or the object  
% is running.  
properties (Nontunable)  
    Filename = 'default.bin' % the name of the file to create  
end  
  
% These properties are private. Customers can only access  
% these properties through methods on this object  
properties (Hidden,Access = private)  
    pFileID; % The identifier of the file to open  
end  
  
methods (Access = protected)  
    % In setup allocate any resources, which in this case  
    % means opening the file.  
    function setupImpl(obj)  
        obj.pFileID = fopen(obj.Filename,'wb');  
        if obj.pFileID < 0  
            error('Opening the file failed');  
        end  
    end  
end  
  
% This System object™ writes the input to the file.  
function stepImpl(obj,data)  
    fwrite(obj.pFileID,data);  
end  
  
% Use release to close the file to prevent the  
% file handle from being left open.  
function releaseImpl(obj)  
    fclose(obj.pFileID);  
end  
end
```

end

Set Property Values at Construction Time

This example shows how to define a System object constructor and allow it to accept name-value property pairs as input.

Set Properties to Use Name-Value Pair Input

Define the System object constructor, which is a method that has the same name as the class (MyFile in this example). Within that method, you use the `setProperties` method to make all public properties available for input when the user constructs the object. `nargin` is a MATLAB function that determines the number of input arguments. `varargin` indicates all of the object's public properties.

```
methods
    function obj = MyFile(varargin)
        setProperties(obj,nargin,varargin{:});
    end
end
```

Complete Class Definition File with Constructor Setup

```
classdef MyFile < matlab.System
% MyFile write numbers to a file

    % These properties are nontunable. They cannot be changed
    % after the setup method has been called or while the
    % object is running.
    properties (Nontunable)
        Filename = 'default.bin' % the name of the file to create
        Access = 'wb' % The file access character vector (write, binary)
    end

    % These properties are private. Customers can only access
    % these properties through methods on this object
    properties (Hidden,Access = private)
        pFileID; % The identifier of the file to open
    end

    methods
        % You call setProperties in the constructor to let
        % a user specify public properties of object as
        % name-value pairs.
        function obj = MyFile(varargin)
            setProperties(obj,nargin,varargin{:});
        end
    end
end
```

```
        end
    end

    methods (Access = protected)
        % In setup allocate any resources, which in this case is
        % opening the file.
        function setupImpl(obj)
            obj.pFileID = fopen(obj.Filename,obj.Access);
            if obj.pFileID < 0
                error('Opening the file failed');
            end
        end
    end

    % This System object™ writes the input to the file.
    function stepImpl(obj,data)
        fwrite(obj.pFileID,data);
    end

    % Use release to close the file to prevent the
    % file handle from being left open.
    function releaseImpl(obj)
        fclose(obj.pFileID);
    end
end
end
```

Reset Algorithm State

This example shows how to reset an object state.

Reset Counter to Zero

pCount is an internal counter property of the System object obj. The user calls the reset method on the locked object, which calls the resetImpl method. In this example, pCount resets to 0.

Note: When resetting an object's state, make sure you reset the size, complexity, and data type correctly.

```
methods (Access = protected)
    function resetImpl(obj)
        obj.pCount = 0;
    end
end
```

Complete Class Definition File with State Reset

```
classdef Counter < matlab.System
% Counter System object™ that increments a counter

    properties (Access = private)
        pCount
    end

    methods (Access = protected)
        % Increment the counter and return
        % its value as an output
        function c = stepImpl(obj)
            obj.pCount = obj.pCount + 1;
            c = obj.pCount;
        end

        % Reset the counter to zero.
        function resetImpl(obj)
            obj.pCount = 0;
        end
    end
end
```

end

Define Property Attributes

This example shows how to specify property attributes.

Property attributes, which add details to a property, provide a layer of control to your properties. In addition to the MATLAB property attributes, System objects can use these three additional attributes—`nontunable`, `logical`, and `positiveInteger`. To specify multiple attributes, separate them with commas.

Specify Property as Nontunable

Use the *nontunable* attribute for a property when the algorithm depends on the value being constant once data processing starts. Defining a property as nontunable may improve the efficiency of your algorithm by removing the need to check for or react to values that change. For code generation, defining a property as nontunable allows the memory associated with that property to be optimized. You should define all properties that affect the number of input or output ports as nontunable.

System object users cannot change nontunable properties after the `setup` method has been called or while the object is running. In this example, you define the `InitialValue` property, and set its value to 0.

```
properties (Nontunable)
    InitialValue = 0;
end
```

Specify Property as Logical

Logical properties have the value, `true` or `false`. System object users can enter 1 or 0 or any value that can be converted to a logical. The value, however, displays as `true` or `false`. You can use sparse logical values, but they must be scalar values. In this example, the `Increment` property indicates whether to increase the counter. By default, `Increment` is tunable property. The following restrictions apply to a property with the `Logical` attribute,

- Cannot also be `Dependent` or `PositiveInteger`
- Default value must be `true` or `false`. You cannot use 1 or 0 as a default value.

```
properties (Logical)
    Increment = true
end
```

Specify Property as Positive Integer

In this example, the private property `MaxValue` is constrained to accept only real, positive integers. You cannot use sparse values. The following restriction applies to a property with the `PositiveInteger` attribute,

- Cannot also be `Dependent` or `Logical`

```
properties (PositiveInteger)
    MaxValue
end
```

Specify Property as DiscreteState

If your algorithm uses properties that hold state, you can assign those properties the `DiscreteState` attribute. Properties with this attribute display their state values when users call `getDiscreteStateImpl` via the `getDiscreteState` method. The following restrictions apply to a property with the `DiscreteState` attribute,

- Numeric, logical, or `fi` value, but not a scaled double `fi` value
- Does not have any of these attributes: `Nontunable`, `Dependent`, `Abstract`, `Constant`, or `Transient`.
- No default value
- Not publicly settable
- `GetAccess` = `Public` by default
- Value set only using the `setupImpl` method or when the `System` object is locked during `resetImpl` or `stepImpl`

In this example, you define the `Count` property.

```
properties (DiscreteState)
    Count;
end
```

Complete Class Definition File with Property Attributes

```
classdef Counter < matlab.System
% Counter Increment a counter to a maximum value

    % These properties are nontunable. They cannot be changed
    % after the setup method has been called or while the
    % object is running.
```

```
properties (Nontunable)
    % The initial value of the counter
    InitialValue = 0
end
properties (Nontunable, PositiveInteger)
    % The maximum value of the counter
    MaxValue = 3
end

properties (Logical)
    % Whether to increment the counter
    Increment = true
end

properties (DiscreteState)
    % Count state variable
    Count
end

methods (Access = protected)
    % Increment the counter and return its value
    % as an output

    function c = stepImpl(obj)
        if obj.Increment && (obj.Count < obj.MaxValue)
            obj.Count = obj.Count + 1;
        else
            disp(['Max count, ' num2str(obj.MaxValue) ',reached'])
        end
        c = obj.Count;
    end

    % Setup the Count state variable
    function setupImpl(obj)
        obj.Count = 0;
    end

    % Reset the counter to one.
    function resetImpl(obj)
        obj.Count = obj.InitialValue;
    end
end
```

end

Hide Inactive Properties

This example shows how to hide the display of a property that is not active for a particular object configuration.

Hide an inactive property

You use the `isInactivePropertyImpl` method to hide a property from displaying. If the `isInactiveProperty` method returns `true` to the property you pass in, then that property does not display.

```
methods (Access = protected)
    function flag = isInactivePropertyImpl(obj,propertyName)
        if strcmp(propertyName,'InitialValue')
            flag = obj.UseRandomInitialValue;
        else
            flag = false;
        end
    end
end
```

Complete Class Definition File with Hidden Inactive Property

```
classdef Counter < matlab.System
    % Counter Increment a counter

    % These properties are nontunable. They cannot be changed
    % after the setup method has been called or when the
    % object is running.
    properties (Nontunable)
        % Allow the user to set the initial value
        UseRandomInitialValue = true
        InitialValue = 0
    end

    % The private count variable, which is tunable by default
    properties (Access = private)
        pCount
    end

    methods (Access = protected)
        % Increment the counter and return its value
        % as an output
        function c = stepImpl(obj)
```

```
    obj.pCount = obj.pCount + 1;
    c = obj.pCount;
end

% Reset the counter to either a random value or the initial
% value.
function resetImpl(obj)
    if obj.UseRandomInitialValue
        obj.pCount = rand();
    else
        obj.pCount = obj.InitialValue;
    end
end

% This method controls visibility of the object's properties
function flag = isInactivePropertyImpl(obj,propertyName)
    if strcmp(propertyName,'InitialValue')
        flag = obj.UseRandomInitialValue;
    else
        flag = false;
    end
end
end
end
```

Limit Property Values to Finite List

This example shows how to limit a property to accept only a finite set of character vector values.

Specify a Set of Valid Character Vector Values

String sets use two related properties. You first specify the user-visible property name and default character vector value. Then, you specify the associated hidden property by appending “Set” to the property name. You must use a capital “S” in “Set.”

In the “Set” property, you specify the valid character vector values as a cell array of the `matlab.system.StringSet` class. This example uses `Color` and `ColorSet` as the associated properties.

```
properties
    Color = 'blue'
end

properties (Hidden,Transient)
    ColorSet = matlab.system.StringSet({'red','blue','green'});
end
```

Complete Class Definition File with StringSet

```
classdef Whiteboard < matlab.System
% Whiteboard Draw lines on a figure window
%
% This System object™ illustrates the use of StringSets

    properties
        Color = 'blue'
    end

    properties (Hidden,Transient)
        % Let them choose a color
        ColorSet = matlab.system.StringSet({'red','blue','green'});
    end

    methods (Access = protected)
        function stepImpl(obj)
            h = Whiteboard.getWhiteboard();
            plot(h, ...
                randn([2,1]),randn([2,1]), ...
```

```

        'Color',obj.Color(1));
    end
    function releaseImpl(obj)
        cla(Whiteboard.getWhiteboard());
        hold on
    end
end

methods (Static)
    function a = getWhiteboard()
        h = findobj('tag','whiteboard');
        if isempty(h)
            h = figure('tag','whiteboard');
            hold on
        end
        a = gca;
    end
end
end
end

```

String Set System Object Example

```

%%
% Each time you run the object, it draws lines on a whiteboard

%% Construct the System object
hGreenInk = Whiteboard;
hBlueInk = Whiteboard;

% Change the color
% Note: Press tab after typing the first single quote to
% display all enumerated values.
hGreenInk.Color = 'green';
hBlueInk.Color = 'blue';

% Take a few steps
for i=1:3
    hGreenInk();
    hBlueInk();
end

%% Clear the whiteboard
hBlueInk.release();

```

```
%% Display System object used in this example  
type('Whiteboard.m');
```

Process Tuned Properties

This example shows how to specify the action to take when a tunable property value changes during simulation.

The `processTunedPropertiesImpl` method is useful for managing actions to prevent duplication. In many cases, changing one of multiple interdependent properties causes an action. With the `processTunedPropertiesImpl` method, you can control when that action is taken so it is not repeated unnecessarily.

Control When a Lookup Table Is Generated

This example of `processTunedPropertiesImpl` causes the `pLookupTable` to be regenerated when either the `NumNotes` or `MiddleC` property changes.

```
methods (Access = protected)
    function processTunedPropertiesImpl(obj)
        propChange = isChangedProperty(obj, 'NumNotes') || ...
            isChangedProperty(obj, 'MiddleC')
        if propChange
            obj.pLookupTable = obj.MiddleC * ...
                (1+log(1:obj.NumNotes)/log(12));
        end
    endend
```

Complete Class Definition File with Tuned Property Processing

```
classdef TuningFork < matlab.System
    % TuningFork Illustrate the processing of tuned parameters
    %

    properties
        MiddleC = 440
        NumNotes = 12
    end

    properties (Access = private)
        pLookupTable
    end

    methods (Access = protected)
        function resetImpl(obj)
            obj.MiddleC = 440;
            obj.pLookupTable = obj.MiddleC * ...
```

```
        (1+log(1:obj.NumNotes)/log(12));
end

function hz = stepImpl(obj,noteShift)
    % A noteShift value of 1 corresponds to obj.MiddleC
    hz = obj.pLookupTable(noteShift);
end

function processTunedPropertiesImpl(obj)
    propChange = isChangedProperty(obj,'NumNotes')||...
        isChangedProperty(obj,'MiddleC')
    if propChange
        obj.pLookupTable = obj.MiddleC *...
            (1+log(1:obj.NumNotes)/log(12));
    end
end
end
```

Release System Object Resources

This example shows how to release resources allocated and used by the System object. These resources include allocated memory, files used for reading or writing, etc.

Release Memory by Clearing the Object

This method allows you to clear the axes on the Whiteboard figure window while keeping the figure open.

```
methods
    function releaseImpl(obj)
        cla(Whiteboard.getWhiteboard());
        hold on
    end
end
```

Complete Class Definition File with Released Resources

```
classdef Whiteboard < matlab.System
% Whiteboard Draw lines on a figure window
%
% This System object™ shows the use of StringSets
%
    properties
        Color = 'blue'
    end

    properties (Hidden)
        % Let user choose a color
        ColorSet = matlab.system.StringSet({'red','blue','green'});
    end

    methods (Access = protected)
        function stepImpl(obj)
            h = Whiteboard.getWhiteboard();
            plot(h, ...
                randn([2,1]), randn([2,1]), ...
                'Color',obj.Color(1));
        end

        function releaseImpl(obj)
            cla(Whiteboard.getWhiteboard());
            hold on
        end
    end
end
```

```
        end
    end

    methods (Static)
        function a = getWhiteboard()
            h = findobj('tag','whiteboard');
            if isempty(h)
                h = figure('tag','whiteboard');
                hold on
            end
            a = gca;
        end
    end
end
```

Define Composite System Objects

This example shows how to define System objects that include other System objects.

This example defines a bandpass filter System object from separate highpass and lowpass filter System objects.

Store System Objects in Properties

To define a System object from other System objects, store those other objects in your class definition file as properties. In this example, the highpass and lowpass filters are the separate System objects defined in their own class-definition files.

```
properties (Access = private)
    % Properties that hold filter System objects
    pLowpass
    pHighpass
end
```

Complete Class Definition File of Bandpass Filter Composite System Object

```
classdef BandpassFIRFilter < matlab.System
    % Implements a bandpass filter using a cascade of eighth-order lowpass
    % and eighth-order highpass FIR filters.

    properties (Access = private)
        % Properties that hold filter System objects
        pLowpass
        pHighpass
    end

    methods (Access = protected)
        function setupImpl(obj)
            % Setup composite object from constituent objects
            obj.pLowpass = LowpassFIRFilter;
            obj.pHighpass = HighpassFIRFilter;
        end

        function yHigh = stepImpl(obj,u)
            yLow = obj.pLowpass(u);
            yHigh = obj.pHighpass(yLow);
        end

        function resetImpl(obj)
```

```
        reset(obj.pLowpass);
        reset(obj.pHighpass);
    end
end
end
```

Class Definition File for Lowpass FIR Component of Bandpass Filter

```
classdef LowpassFIRFilter < matlab.System
% Implements eighth-order lowpass FIR filter with 0.6pi cutoff

    properties (Nontunable)
        % Filter coefficients
        Numerator = [0.006, -0.0133, -0.05, 0.26, 0.6, 0.26, -0.05, -0.0133, 0.006];
    end

    properties (DiscreteState)
        State
    end

    methods (Access = protected)
        function setupImpl(obj)
            obj.State = zeros(length(obj.Numerator)-1,1);
        end
        function y = stepImpl(obj,u)
            [y,obj.State] = filter(obj.Numerator,1,u,obj.State);
        end
        function resetImpl(obj)
            obj.State = zeros(length(obj.Numerator)-1,1);
        end
    end
end
```

Class Definition File for Highpass FIR Component of Bandpass Filter

```
classdef HighpassFIRFilter < matlab.System
% Implements eighth-order highpass FIR filter with 0.4pi cutoff

    properties (Nontunable)
        % Filter coefficients
        Numerator = [0.006, 0.0133, -0.05, -0.26, 0.6, -0.26, -0.05, 0.0133, 0.006];
    end

    properties (DiscreteState)
        State
    end
end
```

```
end

methods (Access = protected)
    function setupImpl(obj)
        obj.State = zeros(length(obj.Numerator)-1,1);

Define Finite Source Objects

This example shows how to define a System object that performs a specific number of steps or specific number of reads from a file.

Use the FiniteSource Class and Specify End of the Source

- 1 Subclass from finite source class.

```
classdef RunTwice < matlab.System & ...  
    matlab.system.mixin.FiniteSource
```

- 2 Specify the end of the source with the `isDoneImpl` method. In this example, the source has two iterations.

```
methods (Access = protected)  
    function bDone = isDoneImpl(obj)  
        bDone = obj.NumSteps==2  
    end
```

Complete Class Definition File with Finite Source

```
classdef RunTwice < matlab.System & ...  
    matlab.system.mixin.FiniteSource  
    % RunTwice System object that runs exactly two times  
    %  
    properties (Access = private)  
        NumSteps  
    end  
  
    methods (Access = protected)  
        function resetImpl(obj)  
            obj.NumSteps = 0;  
        end  
  
        function y = stepImpl(obj)  
            if ~obj.isDone()  
                obj.NumSteps = obj.NumSteps + 1;  
                y = obj.NumSteps;  
            else  
                y = 0;  
            end  
        end  
  
        function bDone = isDoneImpl(obj)
```

```
        bDone = obj.NumSteps==2;
    end
end
end
```

Save System Object

This example shows how to save a System object.

Save System Object and Child Object

Define a `saveObjectImpl` method to specify that more than just public properties should be saved when the user saves a System object. Within this method, use the default `saveObjectImpl@matlab.System` to save public properties to the struct, `s`. Use the `saveObject` method to save child objects. Save protected and dependent properties, and finally, if the object is locked, save the object's state.

```
methods (Access = protected)
function s = saveObjectImpl(obj)
    s = saveObjectImpl@matlab.System(obj);
    s.child = matlab.System.saveObject(obj.child);
    s.protectedprop = obj.protectedprop;
    s.pdependentprop = obj.pdependentprop;
    if isLocked(obj)
        s.state = obj.state;
    end
end
end
```

Complete Class Definition Files with Save and Load

The `Counter` class definition file sets up an object with a count property. This counter is used in the `MySaveLoader` class definition file to count the number of child objects.

```
classdef Counter < matlab.System
    properties(DiscreteState)
        Count
    end
    methods (Access=protected)
        function setupImpl(obj, ~)
            obj.Count = 0;
        end
        function y = stepImpl(obj, u)
            if u > 0
                obj.Count = obj.Count + 1;
            end
            y = obj.Count;
        end
    end
end
```

```
end
end

classdef MySaveLoader < matlab.System

    properties (Access = private)
        child
        pdependentprop = 1
    end

    properties (Access = protected)
        protectedprop = rand;
    end

    properties (DiscreteState = true)
        state
    end

    properties (Dependent)
        dependentprop
    end

    methods
        function obj = MySaveLoader(varargin)
            obj@matlab.System();
            setProperties(obj,nargin,varargin{:});
        end

        function set.dependentprop(obj, value)
            obj.pdependentprop = min(value, 5);
        end

        function value = get.dependentprop(obj)
            value = obj.pdependentprop;
        end
    end

    methods (Access = protected)
        function setupImpl(obj)
            obj.state = 42;
            obj.child = Counter;
        end
        function out = stepImpl(obj,in)
            obj.state = in + obj.state + obj.protectedprop + obj.pdependentprop;
            out = obj.child(obj.state);
        end
    end
end
```

```
    end
end

% Serialization
methods (Access = protected)
function s = saveObjectImpl(obj)
    % Call the base class method
    s = saveObjectImpl@matlab.System(obj);

    % Save the child System objects
    s.child = matlab.System.saveObject(obj.child);

    % Save the protected & private properties
    s.protectedprop = obj.protectedprop;
    s.pdependentprop = obj.pdependentprop;

    % Save the state only if object locked
    if isLocked(obj)
        s.state = obj.state;
    end
end

function loadObjectImpl(obj,s,wasLocked)
    % Load child System objects
    obj.child = matlab.System.loadObject(s.child);

    % Load protected and private properties
    obj.protectedprop = s.protectedprop;
    obj.pdependentprop = s.pdependentprop;

    % Load the state only if object locked
    if wasLocked
        obj.state = s.state;
    end

    % Call base class method to load public properties
    loadObjectImpl@matlab.System(obj,s,wasLocked);
end
end
end
```

Load System Object

This example shows how to load and save a System object.

Load System Object and Child Object

Define a `loadObjectImpl` method to load a previously saved System object. Within this method, use the `matlab.System.loadObject` to load the child System object, load protected and private properties, load the state if the object is locked, and use `loadObjectImpl` from the base class to load public properties.

```
methods (Access = protected)
    function loadObjectImpl(obj,s,wasLocked)
        obj.child = matlab.System.loadObject(s.child);

        obj.protectedprop = s.protectedprop;
        obj.pdependentprop = s.pdependentprop;

        if wasLocked
            obj.state = s.state;
        end

        loadObjectImpl@matlab.System(obj,s,wasLocked);
    end
end
```

Complete Class Definition Files with Save and Load

The Counter class definition file sets up an object with a count property. This counter is used in the MySaveLoader class definition file to count the number of child objects.

```
classdef Counter < matlab.System
    properties (DiscreteState)
        Count
    end
    methods (Access=protected)
        function setupImpl(obj, ~)
            obj.Count = 0;
        end
        function y = stepImpl(obj, u)
            if u > 0
                obj.Count = obj.Count + 1;
            end
            y = obj.Count;
        end
    end
end
```

```
    end
  end
end

classdef MySaveLoader < matlab.System

  properties (Access = private)
    child
    pdependentprop = 1
  end

  properties (Access = protected)
    protectedprop = rand;
  end

  properties (DiscreteState = true)
    state
  end

  properties (Dependent)
    dependentprop
  end

  methods
    function obj = MySaveLoader(varargin)
      obj@matlab.System();
      setProperties(obj,nargin,varargin{:});
    end

    function set.dependentprop(obj, value)
      obj.pdependentprop = min(value, 5);
    end

    function value = get.dependentprop(obj)
      value = obj.pdependentprop;
    end
  end

  methods (Access = protected)
    function setupImpl(obj)
      obj.state = 42;
      obj.child = Counter;
    end
    function out = stepImpl(obj,in)
      obj.state = in + obj.state + obj.protectedprop + obj.pdependentprop;
    end
  end
end
```

```
        out = obj.child(obj.state);
    end
end

% Serialization
methods (Access = protected)
function s = saveObjectImpl(obj)
    % Call the base class method

Define System Object Information

This example shows how to define information to display for a System object.

Define System Object Info

You can define your own `info` method to display specific information for your System object. The default `infoImpl` method returns an empty struct. This `infoImpl` method returns detailed information when the `info` method is called using `info(x, 'details')` or only count information if it is called using `info(x)`.

```
methods (Access = protected)
    function s = infoImpl(obj,varargin)
        if nargin>1 && strcmp('details',varargin(1))
            s = struct('Name','Counter',...
                'Properties', struct('CurrentCount', ...
                    obj.Count,'Threshold',obj.Threshold));
        else
            s = struct('Count',obj.Count);
        end
    end
end
```

Complete Class Definition File with InfoImpl

```
classdef Counter < matlab.System
    % Counter Count values above a threshold

    properties
        Threshold = 1
    end

    properties (DiscreteState)
        Count
    end

    methods (Access = protected)
        function setupImpl(obj)
            obj.Count = 0;
        end

        function resetImpl(obj)
            obj.Count = 0;
        end
    end
end
```

```
function y = stepImpl(obj,u)
    if (u > obj.Threshold)
        obj.Count = obj.Count + 1;
    end
    y = obj.Count;
end

function s = infoImpl(obj,varargin)
    if nargin>1 && strcmp('details',varargin(1))
        s = struct('Name','Counter',...
            'Properties', struct('CurrentCount', ...
                obj.Count, 'Threshold',obj.Threshold));
    else
        s = struct('Count',obj.Count);
    end
end
end
end
end
```

Define Block Icon

This example shows how to define the block icon of a System object–based block implemented using a MATLAB System block.

Use the CustomIcon Class and Define the Icon

- 1 Subclass from custom icon class.

```
classdef MyCounter < matlab.System & ...  
    matlab.system.mixin.CustomIcon
```

- 2 Use `setIconImpl` to specify the block icon as `New Counter` with a line break (`\n`) between the two words.

```
methods (Access = protected)  
    function icon = getIconImpl(~)  
        icon = sprintf('New\nCounter');  
    end  
end
```

Complete Class Definition File with Defined Icon

```
classdef MyCounter < matlab.System & ...  
    matlab.system.mixin.CustomIcon  
  
    % MyCounter Count values above a threshold  
  
    properties  
        Threshold = 1  
    end  
    properties (DiscreteState)  
        Count  
    end  
  
    methods  
        function obj = MyCounter(varargin)  
            setProperties(obj,nargin,varargin{:});  
        end  
    end  
  
    methods (Access = protected)  
        function setupImpl(obj)  
            obj.Count = 0;  
        end
```

```
function resetImpl(obj)
    obj.Count = 0;
end
function y = stepImpl(obj,u)
    if (u > obj.Threshold)
        obj.Count = obj.Count + 1;
    end
    y = obj.Count;
end
function icon = getIconImpl(~)
    icon = sprintf('New\nCounter');
end
end
end
```

Add Header to MATLAB System Block

This example shows how to add a header panel to a System object–based block implemented using a MATLAB System block.

Define Header Title and Text

This example shows how to use `getHeaderImpl` to specify a panel title and text for the `MyCounter` System object.

If you do not specify the `getHeaderImpl`, the block does not display any title or text for the panel.

You always set the `getHeaderImpl` method access to `protected` because it is an internal method that end users do not directly call or run.

```
methods (Static, Access = protected)
    function header = getHeaderImpl
        header = matlab.system.display.Header('MyCounter',...
            'Title', 'My Enhanced Counter');
    end
end
```

Complete Class Definition File with Defined Header

```
classdef MyCounter < matlab.System

    % MyCounter Count values

    properties
        Threshold = 1
    end
    properties (DiscreteState)
        Count
    end

    methods (Static, Access = protected)
        function header = getHeaderImpl
            header = matlab.system.display.Header('MyCounter',...
                'Title', 'My Enhanced Counter',...
                'Text', 'This counter is an enhanced version.');
```

```
methods (Access = protected)
    function setupImpl(obj,u)
        obj.Count = 0;
    end
    function y = stepImpl(obj,u)
        if (u > obj.Threshold)
            obj.Count = obj.Count + 1;
        end
        y = obj.Count;
    end
    function resetImpl(obj)
        obj.Count = 0;
    end
end
end
```

Add Data Types Tab to MATLAB System Block

This example shows how to add a Data Types tab to the MATLAB System block dialog box. This tab includes fixed-point data type settings.

Display Data Types Tab

This example shows how to use `matlab.system.showFiSettingsImpl` to display the Data Types tab in the MATLAB System block dialog.

```
methods (Static, Access = protected)
    function showTab = showFiSettingsImpl
        showTab = true;
    end
end
```

Complete Class Definition File with Data Types Tab

Use `showFiSettingsImpl` to display the Data Types tab for a System object that adds an offset to a fixed-point input.

```
classdef FiTabAddOffset < matlab.System
% FiTabAddOffset Add an offset to input

    properties
        Offset = 1;
    end

    methods
        function obj = FiTabAddOffset(varargin)
            setProperties(obj,nargin,varargin{:});
        end
    end

    methods (Access = protected)
        function y = stepImpl(~,u)
            y = u + obj.Offset;
        end
    end

    methods(Static, Access=protected)
        function header = getHeaderImpl
            header = matlab.system.display.Header('Title',...
                'Add Offset','Text','Add an offset to the input');
```

```
end  
  
function isVisible = showFiSettingsImpl  
    isVisible = true;  
end  
end  
end  
end
```

Add Property Groups to System Object and MATLAB System Block

This example shows how to define property sections and section groups for System object display. The sections and section groups display as panels and tabs, respectively, in the MATLAB System block dialog.

Define Section of Properties

This example shows how to use `matlab.system.display.Section` and `getPropertyGroupsImpl` to define two property group sections by specifying their titles and property lists.

If you do not specify a property in `getPropertyGroupsImpl`, the block does not display that property.

```
methods (Static, Access = protected)
    function groups = getPropertyGroupsImpl
        valueGroup = matlab.system.display.Section(...
            'Title', 'Value parameters', ...
            'PropertyList', {'StartValue', 'EndValue'});

        thresholdGroup = matlab.system.display.Section(...
            'Title', 'Threshold parameters', ...
            'PropertyList', {'Threshold', 'UseThreshold'});
        groups = [valueGroup, thresholdGroup];
    end
end
```

Define Group of Sections

This example shows how to use `matlab.system.display.SectionGroup`, `matlab.system.display.Section`, and `getPropertyGroupsImpl` to define two tabs, each containing specific properties.

```
methods (Static, Access = protected)
    function groups = getPropertyGroupsImpl
        upperGroup = matlab.system.display.Section(...
            'Title', 'Upper threshold', ...
            'PropertyList', {'UpperThreshold'});
        lowerGroup = matlab.system.display.Section(...
            'Title', 'Lower threshold', ...
            'PropertyList', {'UseLowerThreshold', 'LowerThreshold'});

        thresholdGroup = matlab.system.display.SectionGroup(...
```

```

        'Title', 'Parameters', ...
        'Sections', [upperGroup,lowerGroup]);

    valuesGroup = matlab.system.display.SectionGroup(...
        'Title', 'Initial conditions', ...
        'PropertyList', {'StartValue'});

    groups = [thresholdGroup, valuesGroup];
end
end

```

Complete Class Definition File with Property Group and Separate Tab

```

classdef EnhancedCounter < matlab.System

Control Simulation Type in MATLAB System Block

This example shows how to specify a simulation type and whether the **Simulate using** parameter appears on the Simulink MATLAB System block dialog box. The simulation options are 'Code generation' and 'Interpreted mode'.

If you do not include the `getSimulateUsingImpl` method in your class definition file, the System object allows both simulation modes and defaults to 'Code generation'. If you do not include the `showSimulateUsingImpl` method, the **Simulate using** parameter appears on the block dialog box.

You must set the `getSimulateUsingImpl` and `showSimulateUsingImpl` methods to **static** and the access for these methods to **protected**.

Use `getSimulateUsingImpl` to specify that only interpreted execution is allowed for the System object.

```
methods(Static,Access = protected)
    function simMode = getSimulateUsingImpl
        simMode = 'Interpreted execution';
    end
end
```

View the method in the complete class definition file.

```
classdef PlotRamp < matlab.System
    % Display a button to launch a plot figure.

    properties (Nontunable)
        RampLimit = 10;
    end

    methods(Static, Access=protected)
        function group = getPropertyGroupsImpl
            group = matlab.system.display.Section(mfilename('class'));
            group.Actions = matlab.system.display.Action(@(~,obj)...
                visualize(obj),'Label','Visualize');
        end

        function simMode = getSimulateUsingImpl
            simMode = 'Interpreted execution';
        end
    end
end
```

```
methods
function obj = ActionDemo(varargin)
    setProperties(obj,nargin,varargin{:});
end

function visualize(obj)
    figure;
    d = 1:obj.RampLimit;
    plot(d);
end
methods(Static,Access = protected)
end
end
end
```

Add Button to MATLAB System Block

This example shows how to add a button to the MATLAB System block dialog box. This button launches a figure that plots a ramp function.

Define Action for Dialog Button

This example shows how to use `matlab.system.display.Action` to define the MATLAB function or code associated with a button in the MATLAB System block dialog. The example also shows how to set button options and use an `actionData` object input to store a figure handle. This part of the code example uses the same figure when the button is clicked multiple times, rather than opening a new figure for each button click.

```
methods(Static,Access = protected)
    function group = getPropertyGroupsImpl
        group = matlab.system.display.Section(mfilename('class'));
        group.Actions = matlab.system.display.Action(@(actionData,obj)...
            visualize(obj,actionData),'Label','Visualize');
    end
end

methods
    function obj = ActionDemo(varargin)
        setProperties(obj,nargin,varargin{:});
    end

    function visualize(obj,actionData)
        f = actionData.UserData;
        if isempty(f) || ~ishandle(f)
            f = figure;
            actionData.UserData = f;
        else
            figure(f); % Make figure current
        end

        d = 1:obj.RampLimit;
        plot(d);
    end
end
```

Complete Class Definition File for Dialog Button

Define a property group and a second tab in the class definition file.

```
classdef PlotRamp < matlab.System
    % Display a button to launch a plot figure.

    properties (Nontunable)
        RampLimit = 10;
    end

    methods(Static,Access = protected)
        function group = getPropertyGroupsImpl
            group = matlab.system.display.Section(mfilename('class'));
            group.Actions = matlab.system.display.Action(@(actionData,obj)...
                visualize(obj,actionData),'Label','Visualize');
        end
    end

    methods
        function obj = ActionDemo(varargin)
            setProperties(obj,nargin,varargin{:});
        end

        function visualize(obj,actionData)
            f = actionData.UserData;
            if isempty(f) || ~ishandle(f)
                f = figure;
                actionData.UserData = f;
            else
                figure(f); % Make figure current
            end

            d = 1:obj.RampLimit;
            plot(d);
        end
    end
end
```

Specify Locked Input Size

This example shows how to specify whether the size of a System object input is locked. The size of a locked input cannot change until the System object is unlocked. Run the object to lock it. Use `release` to unlock the object.

Use the `isInputSizeLockedImpl` method to specify that the input size is locked.

```
methods (Access = protected)
    function flag = isInputSizeLockedImpl(~,~)
        flag = true;
    end
end
```

View the method in the complete class definition file.

```
classdef Counter < matlab.System
    %Counter Count values above a threshold

    properties
        Threshold = 1
    end

    properties (DiscreteState)
        Count
    end

    methods
        function obj = Counter(varargin)
            setProperties(obj,nargin,varargin{:});
        end
    end

    methods (Access=protected)
        function resetImpl(obj)
            obj.Count = 0;
        end

        function y = stepImpl(obj, u1)
            if (any(u1 >= obj.Threshold))
                obj.Count = obj.Count + 1;
            end
            y = obj.Count;
        end
    end
end
```

```
function flag = isInputSizeLockedImpl(~,~)
    flag = true;
end
end
end
```

Set Output Size

This example shows how to specify the size of a System object output using the `getOutputSizeImpl` method. Use this method when Simulink cannot infer the output size from the inputs during model compilation.

Note: For variable-size inputs, the propagated input size from `propagatedInputSizeImpl` differs depending on the environment.

- MATLAB — When you first run an object, it uses the actual sizes of the inputs.
 - Simulink — The maximum of all the input sizes is set before the model runs and does not change during the run.
-

Subclass from both the `matlab.System` base class and the `Propagates` mixin class.

```
classdef CounterReset < matlab.System & ...  
    matlab.system.mixin.Propagates
```

Use the `getOutputSizeImpl` method to specify the output size.

```
methods (Access = protected)  
    function sizeout = getOutputSizeImpl(~)  
        sizeout = [1 1];  
    end  
end
```

View the method in the complete class definition file.

```
classdef CounterReset < matlab.System & matlab.system.mixin.Propagates  
    % CounterReset Count values above a threshold  
  
    properties  
        Threshold = 1  
    end  
  
    properties (DiscreteState)  
        Count  
    end  
  
    methods (Access = protected)  
        function setupImpl(obj)
```

```
    obj.Count = 0;
end

function y = stepImpl(obj,u1,u2)
    % Add to count if u1 is above threshold
    % Reset if u2 is true
    if (u2)
        obj.Count = 0;
    elseif (any(u1 > obj.Threshold))
        obj.Count = obj.Count + 1;
    end
    y = obj.Count;
end

function resetImpl(obj)
    obj.Count = 0;
end

function [sz,dt,cp] = getDiscreteStateSpecificationImpl(~,name)
    if strcmp(name,'Count')
        sz = [1 1];
        dt = 'double';
        cp = false;
    else
        error(['Error: Incorrect State Name: ', name.']);
    end
end

function dataout = getOutputDataTypeImpl(~)
    dataout = 'double';
end

function sizeout = getOutputSizeImpl(~)
    sizeout = [1 1];
end

function cplxout = isOutputComplexImpl(~)
    cplxout = false;
end

function fixedout = isOutputFixedSizeImpl(~)
    fixedout = true;
end

function inLocked = isInputSizeLockedImpl(~,idx)
    if idx == 1
        inLocked = false;
    else
        inLocked = true;
    end
end
```

```
end
end
end
end
```

Set Output Data Type

This example shows how to specify the data type of a System object output using the `getOutputDataTypeImpl` method. A second example shows how to specify a gain object with bus output. Use this method when Simulink cannot infer the data type from the inputs during model compilation or when you want bus output. To use bus output, you must define the bus data type in the base work space and you must include the `getOutputDataTypeImpl` method in your class definition file.

For both examples, subclass from both the `matlab.System` base class and the `matlab.system.mixin.Propagates` mixin class.

```
classdef CounterReset < matlab.System & ...
    matlab.system.mixin.Propagates
```

Use the `getOutputDataTypeImpl` method to specify the output data type as a double.

```
methods (Access = protected)
    function dataout = getOutputDataTypeImpl(~)
        dataout = 'double';
    end
end
```

View the method in the complete class definition file.

```
classdef CounterReset < matlab.System & matlab.system.mixin.Propagates
    % CounterReset Count values above a threshold

    properties
        Threshold = 1
    end

    properties (DiscreteState)
        Count
    end

    methods (Access = protected)
        function setupImpl(obj)
            obj.Count = 0;
        end

        function resetImpl(obj)
            obj.Count = 0;
        end
    end
end
```

```
function y = stepImpl(obj,u1,u2)
    % Add to count if u1 is above threshold
    % Reset if u2 is true
    if (u2)
        obj.Count = 0;
    elseif (u1 > obj.Threshold)
        obj.Count = obj.Count + 1;
    end
    y = obj.Count;
end

function [sz,dt,cp] = getDiscreteStateSpecificationImpl(~,name)
    if strcmp(name,'Count')
        sz = [1 1];
        dt = 'double';
        cp = false;
    else
        error(['Error: Incorrect State Name: ', name.']);
    end
end

function dataout = getOutputDataTypeImpl(~)
    dataout = 'double';
end

function sizeout = getOutputSizeImpl(~)
    sizeout = [1 1];
end

function cplxout = isOutputComplexImpl(~)
    cplxout = false;
end

function fixedout = isOutputFixedSizeImpl(~)
    fixedout = true;
end

end
end
```

Use the `getOutputDataTypeImpl` method to specify the output data type as a bus. Specify the bus name in a property.

```
properties(Nontunable)
    OutputBusName = 'bus_name';
end

methods (Access = protected)
    function out = getOutputDataTypeImpl(obj)
```

```

        out = obj.OutputBusName;
    end
end

```

View the method in the complete class definition file. This class definition file also includes code to implement a custom icon for this object in the MATLAB System block

```

classdef busGain < matlab.System & matlab.system.mixin.Propagates
% busGain Apply a gain of two to bus input.

```

```

    properties
        GainK = 2;
    end

    properties(Nontunable)
        OutputBusName = 'bus_name';
    end

    methods (Access=protected)
        function out = stepImpl(obj,in)
            out.a = obj.GainK * in.a;
            out.b = obj.GainK * in.b;
        end

        function out = getOutputSizeImpl(obj)
            out = propagatedInputSize(obj, 1);
        end

        function out = isOutputComplexImpl(obj)
            out = propagatedInputComplexity(obj, 1);
        end

        function out = getOutputDataTypeImpl(obj)
            out = obj.OutputBusName;
        end

        function out = isOutputFixedSizeImpl(obj)
            out = propagatedInputFixedSize(obj,1);
        end
    end
end

```

Set Output Complexity

This example shows how to specify whether a System object output is complex or real using the `isOutputComplexImpl` method. Use this method when Simulink cannot infer the output complexity from the inputs during model compilation.

Subclass from both the `matlab.System` base class and the `Propagates` mixin class.

```
classdef CounterReset < matlab.System & ...
    matlab.system.mixin.Propagates
```

Use the `isOutputComplexImpl` method to specify that the output is real.

```
methods (Access = protected)
    function cplxout = isOutputComplexImpl(~)
        cplxout = false;
    end
end
```

View the method in the complete class definition file.

```
classdef CounterReset < matlab.System & matlab.system.mixin.Propagates
    % CounterReset Count values above a threshold

    properties
        Threshold = 1
    end

    properties (DiscreteState)
        Count
    end

    methods (Access = protected)
        function setupImpl(obj)
            obj.Count = 0;
        end

        function resetImpl(obj)
            obj.Count = 0;
        end

        function y = stepImpl(obj,u1,u2)
            % Add to count if u1 is above threshold
            % Reset if u2 is true
        end
    end
end
```

```
    if (u2)
        obj.Count = 0;
    elseif (u1 > obj.Threshold)
        obj.Count = obj.Count + 1;
    end
    y = obj.Count;
end

function [sz,dt,cp] = getDiscreteStateSpecificationImpl(~,name)
    if strcmp(name,'Count')
        sz = [1 1];
        dt = 'double';
        cp = false;
    else
        error(['Error: Incorrect State Name: ', name.']);
    end
end
function dataout = getOutputDataTypeImpl(~)
    dataout = 'double';
end
function sizeout = getOutputSizeImpl(~)
    sizeout = [1 1];
end
function cplxout = isOutputComplexImpl(~)
    cplxout = false;
end
function fixedout = isOutputFixedSizeImpl(~)
    fixedout = true;
end
end
end
```

Specify Whether Output Is Fixed- or Variable-Size

This example shows how to specify that System object output is fixed- or variable-size.

This example shows how to specify that a System object output is fixed-size. Fixed-size output is always the same size, while variable-size output can be different size vectors. `isOutputSizeLockedImpl` accepts the port index and returns `true` if the input size is locked (variable sized vectors are disallowed) and `false` if the input size is not locked (variable sized vectors are allowed). Use the `isOutputFixedSizeImpl` method when Simulink cannot infer the output type from the inputs during model compilation.

Subclass from both the `matlab.System` base class and the `matlab.system.mixin.Propagates` mixin class.

```
classdef CounterReset < matlab.System & ...
    matlab.system.mixin.Propagates
```

Use the `isOutputFixedSizeImpl` method to specify that the output is fixed size.

```
methods (Access = protected)
    function fixedout = isOutputFixedSizeImpl(~)
        fixedout = true;
    end
end
```

View the method in the complete class definition file.

```
classdef CounterReset < matlab.System & matlab.system.mixin.Propagates
    % CounterReset Count values above a threshold

    properties
        Threshold = 1
    end

    properties (DiscreteState)
        Count
    end

    methods (Access = protected)
        function setupImpl(obj)
            obj.Count = 0;
        end

        function resetImpl(obj)
```

```
        obj.Count = 0;
    end

    function y = stepImpl(obj,u1,u2)
        % Add to count if u1 is above threshold
        % Reset if u2 is true
        if (u2)
            obj.Count = 0;
        elseif (u1 > obj.Threshold)
            obj.Count = obj.Count + 1;
        end
        y = obj.Count;
    end

    function [sz,dt,cp] = getDiscreteStateSpecificationImpl(~,name)
        if strcmp(name,'Count')
            sz = [1 1];
            dt = 'double';
            cp = false;
        else
            error(['Error: Incorrect State Name: ', name.']);
        end
    end

    function dataout = getOutputDataTypeImpl(~)
        dataout = 'double';
    end

    function sizeout = getOutputSizeImpl(~)
        sizeout = [1 1];
    end

    function cplxout = isOutputComplexImpl(~)
        cplxout = false;
    end

    function fixedout = isOutputFixedSizeImpl(~)
        fixedout = true;
    end
end
end
```

For a System object with variable-size output, you do not need to add any method to the class definition file because variable-size output is the default.

Specify Discrete State Output Specification

This example shows how to specify the size, data type, and complexity of a discrete state property using the `getDiscreteStateSpecificationImpl` method. Use this method when your System object has a property with the `DiscreteState` attribute and Simulink cannot infer the output specifications during model compilation.

Subclass from both the `matlab.System` base class and from the `Propagates` mixin class.

```
classdef CounterReset < matlab.System & ...  
    matlab.system.mixin.Propagates
```

Use the `getDiscreteStateSpecificationImpl` method to specify the size and data type. Also specify the complexity of a discrete state property, which is used in the counter reset example.

```
methods (Access = protected)  
    function [sz,dt,cp] = getDiscreteStateSpecificationImpl(~,name)  
        sz = [1 1];  
        dt = 'double';  
        cp = false;  
    end  
end
```

View the method in the complete class definition file.

```
classdef CounterReset < matlab.System & matlab.system.mixin.Propagates  
    % CounterReset Count values above a threshold  
  
    properties  
        Threshold = 1  
    end  
  
    properties (DiscreteState)  
        Count  
    end  
  
    methods (Access = protected)  
        function setupImpl(obj)  
            obj.Count = 0;  
        end  
  
        function resetImpl(obj)
```

```

        obj.Count = 0;
    end

    function y = stepImpl(obj,u1,u2)
        % Add to count if u1 is above threshold
        % Reset if u2 is true
        if (u2)
            obj.Count = 0;
        elseif (u1 > obj.Threshold)
            obj.Count = obj.Count + 1;
        end
        y = obj.Count;
    end

    function [sz,dt,cp] = getDiscreteStateSpecificationImpl(~,name)
        sz = [1 1];
        dt = 'double';
        cp = false;
    end
    function dataout = getOutputDataTypeImpl(~)
        dataout = 'double';
    end
    function sizeout = getOutputSizeImpl(~)
        sizeout = [1 1];
    end
    function cplxout = isOutputComplexImpl(~)
        cplxout = false;
    end
    function fixedout = isOutputFixedSizeImpl(~)
        fixedout = true;
    end
end
end
end

```

Set Model Reference Discrete Sample Time Inheritance

This example shows how to disallow model reference discrete sample time inheritance for a System object. The System object defined in this example has one input, so by default, it allows sample time inheritance. To override the default and disallow inheritance, the class definition file for this example includes the `allowModelReferenceDiscreteSampleTimeInheritanceImpl` method, with its output set to `false`.

```
methods (Access = protected)
    function flag = ...
        allowModelReferenceDiscreteSampleTimeInheritanceImpl(obj)
        flag = false;
    end
end
```

View the method in the complete class definition file.

```
classdef MyCounter < matlab.System

    % MyCounter Count values

    properties
        Threshold = 1;
    end

    properties (DiscreteState)
        Count
    end

    methods (Static, Access = protected)
        function header = getHeaderImpl
            header = matlab.system.display.Header('MyCounter',...
                'Title', 'My Enhanced Counter',...
                'Text', 'This counter is an enhanced version.');
```

```
        obj.Count = 0;
    end
    function y = stepImpl(obj,u)
        if (u > obj.Threshold)
            obj.Count = obj.Count + 1;
        end
        y = obj.Count;
    end
    function resetImpl(obj)
        obj.Count = 0;
    end
end
end
```

Use Update and Output for Nondirect Feedthrough

This example shows how to implement nondirect feedthrough for a System object using the `updateImpl`, `outputImpl` and `isInputDirectFeedthroughImpl` methods. In nondirect feedthrough, the object's outputs depend only on the internal states and properties of the object, rather than the input at that instant in time. You use these methods to separate the output calculation from the state updates of a System object. Implementing these two methods overrides the `stepImpl` method. This enables you to use the object in a feedback loop and prevent algebraic loops.

Subclass from the Nondirect Mixin Class

To use the `updateImpl`, `outputImpl`, and `isInputDirectFeedthroughImpl` methods, you must subclass from both the `matlab.System` base class and the Nondirect mixin class.

```
classdef IntegerDelaySysObj < matlab.System & ...  
    matlab.system.mixin.Nondirect
```

Implement Updates to the Object

Implement an `updateImpl` method to update the object with previous inputs.

```
methods (Access = protected)  
    function updateImpl(obj,u)  
        obj.PreviousInput = [u obj.PreviousInput(1:end-1)];  
    end  
end
```

Implement Outputs from Object

Implement an `outputImpl` method to output the previous, not the current input.

```
methods (Access = protected)  
    function [y] = outputImpl(obj,~)  
        y = obj.PreviousInput(end);  
    end  
end
```

Implement Whether Input Is Direct Feedthrough

Implement an `isInputDirectFeedthroughImpl` method to indicate that the input is nondirect feedthrough.

```

methods (Access = protected)
    function flag = isInputDirectFeedthroughImpl(~,~)
        flag = false;
    end
end

```

Complete Class Definition File with Update and Output

```

classdef intDelaySysObj < matlab.System &...
    matlab.system.mixin.Nondirect
    % intDelaySysObj Delay input by specified number of samples.

    properties
        InitialOutput = 0;
    end
    properties (Nontunable)
        NumDelays = 1;
    end
    properties (DiscreteState)
        PreviousInput;
    end

    methods (Access = protected)
        function validatePropertiesImpl(obj)
            if ((numel(obj.NumDelays)>1) || (obj.NumDelays <= 0))
                error('Number of delays must be positive non-zero scalar value.');
            end
            if (numel(obj.InitialOutput)>1)
                error('Initial Output must be scalar value.');
            end
        end

        function setupImpl(obj)
            obj.PreviousInput = ones(1,obj.NumDelays)*obj.InitialOutput;
        end

        function resetImpl(obj)
            obj.PreviousInput = ones(1,obj.NumDelays)*obj.InitialOutput;
        end

        function [y] = outputImpl(obj,~)
            y = obj.PreviousInput(end);
        end
        function updateImpl(obj, u)
            obj.PreviousInput = [u obj.PreviousInput(1:end-1)];
        end
    end
end

```

```
    end
    function flag = isInputDirectFeedthroughImpl(~,~)
        flag = false;
    end
end
end
```

Enable For Each Subsystem Support

This example shows how to enable using a System object in a Simulink For Each subsystem. Include the `supportsMultipleInstanceImpl` method in your class definition file. This method applies only when the System object is used in Simulink via the MATLAB System block.

Use the `supportsMultipleInstanceImpl` method and have it return `true` to indicate that the System object supports multiple calls in a Simulink For Each subsystem.

```
methods (Access = protected)
    function flag = supportsMultipleInstanceImpl(obj)
        flag = true;
    end
end
```

View the method in the complete class definition file.

```
classdef RandSeed < matlab.System
    % RANDSEED Random noise with seed for use in For Each subsystem

    properties (DiscreteState)
        count;
    end

    properties (Nontunable)
        seed = 20;
    end

    properties (Nontunable,Logical)
        useSeed = false;
    end

    methods (Access = protected)
        function y = stepImpl(obj,u1)
            % Initial use after reset/setup
            % and use the seed
            if (obj.useSeed && ~obj.count)
                rng(obj.seed);
            end
            obj.count = obj.count + 1;
            [m,n] = size(u1);
            % Uses default rng seed
            y = rand(m,n) + u1;
        end
    end
end
```

```
    end

    function setupImpl(obj)
        obj.count = 0;
    end
    function resetImpl(obj)
        obj.count = 0;
    end

    function flag = supportsMultipleInstanceImpl(obj)
        flag = obj.useSeed;
    end
end
end
```

System Object Input Arguments and ~ in Code Examples

All methods, except static methods, expect the System object handle as the first input argument. You can use any name for your System object handle. In many examples, instead of passing in the object handle, ~ is used to indicate that the object handle is not used in the function. Using ~ instead of an object handle prevents warnings about unused variables.

What Are Mixin Classes?

Mixin classes are partial classes that you can combine in various combinations to form desired behaviors using multiple inheritance. System objects are composed of a base class, `matlab.System` and may include one or more mixin classes. You specify the base class and mixin classes on the first line of your class definition file.

The following mixin classes are available for use with System objects.

- `matlab.system.mixin.CustomIcon` — Defines a block icon for System objects in the MATLAB System block
- `matlab.system.mixin.FiniteSource` — Adds the `isDone` method to System objects that are sources
- `matlab.system.mixin.Nondirect` — Allows the System object, when used in the MATLAB System block, to support nondirect feedthrough by making the runtime callback functions, `output` and `update` available
- `matlab.system.mixin.Propagates` — Enables System objects to operate in the MATLAB System block using the interpreted execution

Best Practices for Defining System Objects

A System object is a specialized kind of MATLAB object that is optimized for iterative processing. Use System objects when you need to run an object multiple times or process data in a loop. When defining your own System object, use the following suggestions to help your code run efficiently.

- Define all one-time calculations in the `setupImpl` method and cache the results in a private property. Use the `stepImpl` method for repeated calculations.
- If properties are accessed more than once in the `stepImpl` method, cache those properties as local variables inside the method. A typical example of multiple property access is a loop. Iterative calculations using cached local variables run faster than calculations that must access the properties of an object. When the calculations for the method complete, you can save the local cached results back to the properties of that System object. Copy frequently used tunable properties into private properties. This best practice also applies to the `updateImpl` and `outputImpl` methods.

In this example, `k` is accessed multiple times in each loop iteration, but is saved to the object property only once.

```
function y = stepImpl(obj,x)
    k = obj.MyProp;
    for p=1:100
        y = k * x;
        k = k + 0.1;
    end
    obj.MyProp = k;
end
```

- Property default values are shared across all instances of an object. Two instances of a class can access the same default value if that property has not been overwritten by either instance.
- Do not use character vector comparisons or character vector-based switch statements in the `stepImpl` method. Instead, create a method handle in `setupImpl`. This handle points to a method in the same class definition file. Use that handle in a loop in `stepImpl`.

This example shows how to use method handles and cached local variables in a loop to implement an efficient object. In `setupImpl`, choose `myMethod1` or `myMethod2` based on a character vector comparison and assign the method handle to the `pMethodHandle` property. Because there is a loop in `stepImpl`, assign the

`pMethodHandle` property to a local method handle, `myFun`, and then use `myFun` inside the loop.

```
classdef MyClass < matlab.System
    function setupImpl(obj)
        if strcmp(obj.Method, 'Method1')
            obj.pMethodHandle = @myMethod1;
        else
            obj.pMethodHandle = @myMethod2;
        end
    end
    function y = stepImpl(obj,x)
        myFun = obj.pMethodHandle;
        for p=1:1000
            y = myFun(obj,x)
        end
    end
    function y = myMethod1(x)
        y = x+1;
    end
    function y = myMethod2(x)
        y = x-1;
    end
end
```

- If the number of System object inputs does not change, do not implement the `getNumInputsImpl` method. Also do not implement the `getNumInputsImpl` method when you explicitly list the inputs in the `stepImpl` method instead of using `varargin`. The same caveats apply to the `getNumOutputsImpl` and `varargout` outputs.
- For the `getNumInputsImpl` and `getNumOutputsImpl` methods, if you set the return argument from an object property, that object property must have the `Nontunable` attribute.
- If the variables in a method do not need to retain their values between calls use local scope for those variables in that method.
- For properties that do not change, define them in as `Nontunable` properties. `Tunable` properties have slower access times than `Nontunable` properties
- Use the `protected` or `private` attribute instead of the `public` attribute for a property, whenever possible. Some `public` properties have slower access times than `protected` and `private` properties.
- Avoid using a customized `stepImpl`, `get`, or `set` methods, whenever possible.

- Avoid using character vector comparisons within a customized `stepImpl`, `get`, or `set` methods, whenever possible. Use `setupImpl` for character vector comparisons instead.
- Specify Boolean values using `true` or `false` instead of `1` or `0`, respectively.

Insert System Object Code Using MATLAB Editor

In this section...

“Define System Objects with Code Insertion” on page 41-99

“Create Fahrenheit Temperature String Set” on page 41-102

“Create Custom Property for Freezing Point” on page 41-103

“Define Input Size As Locked” on page 41-104

Define System Objects with Code Insertion

You can define System objects from the MATLAB Editor using code insertion options. When you select these options, the MATLAB Editor adds predefined properties, methods, states, inputs, or outputs to your System object. Use these tools to create and modify System objects faster, and to increase accuracy by reducing typing errors.

To access the System object editing options, create a new System object, or open an existing one.

To add predefined code to your System object, select the code from the appropriate menu. For example, when you click **Insert Property > Numeric**, the MATLAB Editor adds the following code:

```
properties(Nontunable)
    Property
end
```

The MATLAB Editor inserts the new property with the default name Property, which you can rename. If you have an existing properties group with the Nontunable

attribute, the MATLAB Editor inserts the new property into that group. If you do not have a property group, the MATLAB Editor creates one with the correct attribute.

Insert Options

Properties	Properties of the System object: Numeric, Logical, String Set, Positive Integer, Tunable Numeric, Private, Protected, and Custom. When you select String Set or Custom Properties, a separate dialog box opens to guide you in creating these properties.
Methods	<p>Methods commonly used in System object definitions. The MATLAB Editor creates only the method structure. You specify the actions of that method.</p> <p>The Insert Method menu organizes methods by categories, such as Algorithm, Inputs and Outputs, and Properties and States. When you select a method from the menu, the MATLAB Editor inserts the method template in your System object code. In this example, selecting Insert Method > Release resources inserts the following code:</p> <pre>function releaseImpl(obj) % Release resources, such as file handles end</pre> <p>If an method from the Insert Method menu is present in the System object code, that method is shown shaded on the Insert Method menu:</p>

	
States	Properties containing the <code>DiscreteState</code> attribute.
Inputs / Outputs	<p>Inputs, outputs, and related methods, such as Validate inputs and Lock input size.</p> <p>When you select an input or output, the MATLAB Editor inserts the specified code in the <code>stepImpl</code> method. In this example, selecting Insert > Input causes the MATLAB Editor to insert the required input variable <code>u2</code>. The MATLAB Editor determines the variable name, but you can change it after it is inserted.</p> <pre>function y = stepImpl(obj,u,u2) % Implement algorithm. Calculate y as a function of % input u and discrete states. y = u; end</pre>

Create Fahrenheit Temperature String Set

- 1 Open a new or existing System object.
- 2 In the MATLAB Editor, select **Insert Property > String Set**.
- 3 In the **String Set** dialog box, under **Name**, replace **COLOR** with **TemperatureUnit**.
- 4 Remove the existing **COLOR** property values with the - (minus) button.
- 5 Add a property value with the + (plus) button. Enter **Fahrenheit**.
- 6 Add another property value with +. Enter **Celsius**.
- 7 Add another property value with +. Enter **Kelvin**.
- 8 Select **Fahrenheit** as the default value by clicking **Default**.

The dialog box now looks as shown:

- 9 To create this string set and associated properties, with the default value selected, click **Insert**.

Examine the System object definition. The MATLAB Editor has added the following code:

```
properties (Nontunable)
```

```
    TemperatureUnit = 'Fahrenheit';  
end  
  
properties(Constant, Hidden)  
    TemperatureUnitSet = matlab.system.StringSet({'Fahrenheit', 'Celsius', 'Kelvin'});  
end
```

For more information on the `StringSet` class, see `matlab.System.StringSet`.

Create Custom Property for Freezing Point

- 1 Open a new or existing System object.
- 2 In the MATLAB Editor, select **Insert Property > Custom Property**.
- 3 In the Custom Property dialog box, under **System Object Attributes**, select **Nontunable**. Under **MATLAB Property Attributes**, select **Constant**. Leave **GetAccess** as **public**. **SetAccess** is grayed out because properties of type constant can not be set using System object methods.

The dialog box now looks as shown:

- 4 To insert the property into the System object code, click **Insert**.

```
properties(Nontunable, Constant)
    Property
end
```

- 5 Replace Property with your property.

```
properties(Nontunable, Constant)
    FreezingPointFahrenheit = 32;
end
```

Define Input Size As Locked

- 1 Open a new or existing System object.

- 2 In the MATLAB Editor, select **Insert Method > Lock input size**.

The MATLAB Editor inserts this code into the System object:

```
function flag = isInputSizeLockedImpl(obj,index)
    % Return true if input size is not allowed to change while
    % system is running
    flag = true;
end
```

Related Examples

Analyze System Object Code

In this section...
“View and Navigate System object Code” on page 41-106
“Example: Go to StepImpl Method Using Analyzer” on page 41-106

View and Navigate System object Code

View and navigate System object code using the Analyzer.

The Analyzer displays all elements in your System object code.

- Navigate to a specific input, output, property, state, or method by clicking the name of that element.
- Expand or collapse element sections with the arrow buttons.
- Identify access levels for properties and custom methods with the + (public), # (protected), and – (private) symbols.

Example: Go to StepImpl Method Using Analyzer

- 1 Open an existing System object.
- 2 Select **Analyze**.
- 3 Click stepImpl.

The cursor in the MATLAB Editor window jumps to the `stepImpl` method.

```
        d = 1:obj.Kamplimit;
        plot(d);
    end
end

methods(Access = protected, Static)
function group = getPropertyGroupsImpl
    % Define property section(s) for System block dialog
    group = matlab.system.display.Section(mfilename('class'));
    group.Actions = matlab.system.display.Action(@(~,obj)...
        visualize(obj), 'Label', 'Visualize');
end

function simMode = getSimulateUsingImpl
    % Return only allowed simulation mode in System block dialog
    simMode = 'Interpreted execution';
end

end

methods(Access = protected)
function y = stepImpl(~,u)
    % Implement algorithm. Calculate y as a function of input u and
    % discrete states.
    y = u;
end
```

Define System Object for Use in Simulink

In this section...
“Develop System Object for Use in System Block” on page 41-109
“Define Block Dialog Box for Plot Ramp” on page 41-110

Develop System Object for Use in System Block

You can develop a System object for use in a System block and interactively preview the block dialog box. This feature requires Simulink.

With the **System Block** editing options, the MATLAB Editor inserts predefined code into the System object. This coding technique helps you create and modify your System object faster and increases accuracy by reducing typing errors.

Using these options, you can also:

- View and interact with the block dialog design as you define the System object.
- Add dialog customization methods. If the block dialog box is open when you make changes, the block dialog design preview updates the display on saving the file.
- Add icon methods. However, these elements display only on the MATLAB System Block in Simulink, not in the Preview Dialog Box.

Define Block Dialog Box for Plot Ramp

- 1 Create a System object and name it `PlotRamp`. This name becomes the block dialog box title. Save the System object.
- 2 Add a comment that contains the block description.

```
% Display a button to launch a plot figure.
```

This comment becomes the block parameters dialog box description, under the block title.

- 3 Select **System Block > Preview Block Dialog**. The block dialog box displays as you develop the System object.

- 4 Add a ramp limit by selecting **Insert Property > Numeric**. Then change the property name and set the value to 10.

```
properties (Nontunable)
    RampLimit = 10;
end
```

- 5 Using the **System Block** menu, insert the `getPropertyGroupsImpl` method.

```
methods(Access = protected, Static)
    function group = getPropertyGroupsImpl
        % Define property section(s) for System block dialog
        group = matlab.system.display.Section(mfilename('class'));
    end
end
```

- 6 Add code to create the group for the visualize action..

```
methods(Access = protected, Static)
    function group = getPropertyGroupsImpl
        % Define property section(s) for System block dialog
        group = matlab.system.display.Section(mfilename('class'));
        group.Actions = matlab.system.display.Action(@(~, obj)...
            visualize(obj), 'Label', 'Visualize');
    end
end
```

- 7 Add a function that adds code to display the **Visualize** button on the dialog box.

```
methods
    function visualize(obj)
        figure;
```

```
        d = 1:obj.RampLimit;  
        plot(d);  
    end  
end
```

- 8 As you add elements to the System block definition, save your file. Observe the effects of your code additions to the System block definition.

The **System Block** menu also displays checks next to the methods you have implemented, which can help you track your development.

The class definition file now has all the code necessary for the PlotRamp System object.

```
classdef PlotRamp < matlab.System
    % Display a button to launch a plot figure.

    properties (Nontunable)
        RampLimit = 10;
    end

    methods(Static, Access=protected)
        function group = getPropertyGroupsImpl
            group = matlab.system.display.Section(mfilename('class'));
            group.Actions = matlab.system.display.Action(@(~,obj)...
                visualize(obj), 'Label', 'Visualize');
        end
    end

    methods
        function visualize(obj)
            figure;
            d = 1:obj.RampLimit;
            plot(d);
        end
    end
end
```

After you complete your System block definition, save it, and then load it into a MATLAB System block in Simulink.

Related Examples

- “Insert System Object Code Using MATLAB Editor” on page 41-99

Use Enumerations in System Objects

Enumerated data is data that is restricted to a finite set of values. To use enumerated data in a System object in MATLAB or Simulink, you refer to them in your System objectclass definition and define your enumerated class in a separate class definition file.

For a System object that will be used in MATLAB only, see “Enumerations”.

For a System object that will be used in a MATLAB System block in Simulink, see “Enumerated Data”

Enumerations can derive from any integer type smaller than or equal to an `int32`. For example,

```
classdef Bearing < uint8
    enumeration
        North (0)
        East (90)
        South (180)
        West (270)
    end
end
```

Enumerations can also derive from `Simulink.IntEnumType`. You use this type of enumeration to add attributes, such as custom headers, to the input or output of the MATLAB System block. See “Use Enumerated Data in Simulink Models” on page 58-7.

Use Global Variables in System Objects

Global variables are variables that you can access in other MATLAB functions or Simulink blocks.

System Object Global Variables in MATLAB

For System objects that are used only in MATLAB, you define global variables in System object class definition files in the same way that you define global variables in other MATLAB code (see “Global Variables”).

System Object Global Variables in Simulink

For System objects that are used in the MATLAB System block in Simulink, you also define global variables as you do in MATLAB. However, to use global variables in Simulink, you need to declare global variables in the `stepImpl`, `updateImpl`, or `outputImpl` method if you have declared them in methods called by `stepImpl`, `updateImpl`, or `outputImpl`, respectively.

You set up and use global variables for the MATLAB System block in the same way as you do for the MATLAB Function block (see “Data Stores” and “Share Data Globally” on page 39-111). Like the MATLAB Function block, you must also use variable name matching with a Data Store Memory block to use global variables in Simulink.

For example, this class definition file defines a System object that increments the first row of a matrix by 1 at each time step. You must include `getGlobalNamesImpl` if the class file is P-coded.

```
classdef GlobalSysObjMatrix < matlab.System
    methods (Access = protected)
        function y = stepImpl(obj)
            global B;
            B(1,:) = B(1, :)+1;
            y = B;
        end

        % Include getGlobalNamesImpl only if the class file is P-coded.
        function globalNames = getGlobalNamesImpl(~)
            globalNames = {'B'};
        end
end
```

```
end  
end
```

This model includes the `GlobalSysObjMatrix` object in a MATLAB System block and the associated Data Store Memory block.

MATLAB System Block

In this section...

“Why Use the MATLAB System Block?” on page 42-2

“Choosing the Right Block Type” on page 42-2

“System Objects” on page 42-3

“Interpreted Execution or Code Generation” on page 42-3

“MATLAB System Block Limitations” on page 42-4

“MATLAB System and System Objects Examples” on page 42-5

Why Use the MATLAB System Block?

System objects let you implement algorithms using the MATLAB language. The MATLAB System block enables you to use System objects in Simulink.

The MATLAB System block lets you:

- Share the same System object in MATLAB and Simulink
- Dedicate integration of System objects with Simulink
- Unit test your algorithm in MATLAB before using it in Simulink
- Customize dialog box customization
- Simulate efficiently with better initialization
- Handle states
- Customize block icons with port labels
- Access two simulation modes

Choosing the Right Block Type

There are several mechanisms for including MATLAB algorithms in Simulink, such as:

- MATLAB System block
- MATLAB Function block

- Interpreted MATLAB Function block
- Level-2 MATLAB S-Function block
- Fcn block

For help on choosing the right block, see “Types of Custom Blocks” on page 37-2 and “Comparison of Custom Block Functionality” on page 37-6.

System Objects

Before you use a MATLAB System block, you must have a System object to associate with the block. A System object is a specialized kind of MATLAB class. System objects are designed specifically for implementing and simulating dynamic systems with inputs that change over time.

For more information on creating System objects, see “Define System Objects”.

Note: To use your System object in the Simulink environment, it must have a constructor that you can call with no arguments. By default, the System object constructor has this capability and you do not need to define your own constructor. However, if you create your own System object constructor, you must be able to call it with no arguments.

System objects exist in other MATLAB products. MATLAB System block supports only the System objects written in the MATLAB language. In addition, if a System object has a corresponding Simulink block, you cannot implement a MATLAB System block for it.

Interpreted Execution or Code Generation

You can use MATLAB System blocks in Simulink models for simulation via interpreted execution or code generation.

- With interpreted execution, the model simulates the block using the MATLAB execution engine.
- With code generation, the model simulates the block using code generation (requires the use of the subset of MATLAB code supported for code generation). For a list of supported functions, see “Functions and Objects Supported for C/C++ Code Generation — Alphabetical List” on page 44-2.

MATLAB System Block Limitations

These capabilities are currently not supported.

Category	Limitation Description	Workaround
System Objects	Tunable logical and character vector properties of the System object are nontunable parameters in the MATLAB System block.	—
Data Types	<ul style="list-style-type: none"> • The MATLAB System block does not support virtual buses as input or output. • The MATLAB System block does not support nonvirtual buses that contain variable-size signals. • System objects cannot use fixed-point signals with nonbinary point scaling or nonzero bias. • System objects cannot use user-defined opaque data types. 	—
Sample Time	Cannot use MATLAB System blocks to model continuous time or multirate systems.	—
Linearizations	Cannot use Jacobian based linearization.	—
Global Variables	Global variables defined in the model Configuration Parameters Simulation Target > Custom Code pane and referenced by the System object are not shared with Stateflow and the MATLAB Function block.	—
Debugging	MATLAB debugging for code-generation-based simulation.	Set the MATLAB System block Simulate using parameter to Interpreted execution , and then debug. When you are done,

Category	Limitation Description	Workaround
		set Simulate using back to Code generation.
Fixed-Point Tool	The Fixed-Point Tool does not return design min/max, min/max logging, and autoscaling information for MATLAB System blocks.	—
Model coverage analysis (Simulink Verification and Validation software)	Simulink Verification and Validation cannot perform model analysis for MATLAB System block with Simulate using parameter set to Interpreted execution.	—
Check model compatibility (Simulink Design Verifier software)	Simulink Design Verifier cannot perform compatibility checks for a model or subsystem that contains a MATLAB System block.	—

MATLAB System and System Objects Examples

For examples of MATLAB System and System objects, see:

Example	Description
System Identification for an FIR System Using MATLAB System Blocks	This example shows how to use the MATLAB System block to implement Simulink blocks using a System object. It highlights two MATLAB System blocks. Access the MATLAB source code for each System object by clicking the Source code link from the block dialog box.
Variable-Size Input and Output Signals Using MATLAB System Blocks	This example shows how to use the MATLAB System block to implement Simulink blocks with variable-size input and output signals. Due to the use of variable-size signals, the example uses propagation methods.
Illustration of Law of Large Numbers Using MATLAB System Blocks	This example shows how to use MATLAB System blocks to illustrate the law of large numbers. Due to the use of MATLAB functions not supported for code generation, the example

Example	Description
	uses propagation methods and interpreted execution.
Using Buses with MATLAB System Blocks	This example shows how to use MATLAB System blocks with nonvirtual buses at input or output. Due to the use Simulink buses, the example uses propagation methods. The example defines the bus types in the MATLAB base workspace using model callbacks.

- “Comparison of Custom Block Functionality” on page 37-6

Implement a MATLAB System Block

Implement a block and assign a System object to it. You can then explore the block to see the effect.

- 1 Create a new model and add the MATLAB System block from the User-Defined Functions library.

- 2 In the block dialog box, from the **New** list, select **Basic**, **Advanced**, or **Simulink Extension** if you want to create a new System object from a template. Modify the template according to your needs and save the System object.
- 3 Enter the full path name for the System object in the **System object name**. Click the list arrow. If valid System objects exist in the current folder, the names appear in the list.

The MATLAB System block icon and port labels update to those of the corresponding System object. For example, suppose you selected a System object named `lmsSysObj` in your current folder. The block updates as shown in the figure:

Note: After you associate the block with a System object class name, you cannot assign a new System object using the same MATLAB System block dialog box. Instead, right-click the MATLAB System block, select **Block Parameters (MATLABSystem)** and enter a new class name in **System object name**.

Understanding the MATLAB System Block

- 1 Double-click the block. The MATLAB System dialog box reflects the System object parameters. The dialog box usually includes a **Source code** link that leads to the System object class file. For example:

The **Source code** link appears if the System object uses MATLAB language. It does not appear if you have:

- Converted the System object to P-code
 - Overridden the default behavior using the `getHeaderImpl` method
- 2 Click **Source code** and observe that the public and active properties in the System object appear in the MATLAB System block dialog box as block parameters.
 - 3 Select how you want the model to simulate the block using the **Simulate using** parameter. (This parameter appears at the bottom of each MATLAB System block if there is only one tab, or the bottom of the first of multiple tabs.)

You might want to add that note about not being able to get to the MATLAB System block dialog box the same way after you've associated the block with a System object. Look under mask is one way you can get to it.

Change Blocks Implemented with System Objects

To implement a block with another System object, right-click the MATLAB System block and select Block Parameters (MATLABSystem). Then, use the block dialog box to identify a new class name in **System object name**. For more information, see “Implement a MATLAB System Block” on page 42-7.

Related Examples

- “System Identification for an FIR System Using MATLAB System Blocks”

Change Block Icon and Port Labels

To change the icon appearance of your block, you must use the `matlab.system.mixin.CustomIcon` class. You can define port labels using `System` object methods.

- 1 Add the `matlab.system.mixin.CustomIcon` class name to the `System` object, after the `matlab.System` class. For example:

```
classdef lmsSysObj < matlab.System & matlab.system.mixin.CustomIcon
```

This code subclasses from the `matlab.system.mixin.CustomIcon` class in addition to the `matlab.System` base class.

- 2 To define the icon, implement the `getIconImpl` method.
- 3 To define the port labels, implement the following optional methods to change the input and output port labels. You do not need the `matlab.system.mixin.CustomIcon` class to use these methods.

```
getInputNamesImpl  
getOutputNamesImpl
```

If you do not implement these methods, the `System` object uses the input and output port names from the `stepImpl` method. If you are using the `matlab.system.mixin.Nondirect` class and do not implement these methods, the `System` object uses the input names from `updateImpl` and the output port names from `OutputImpl`.

Modify MATLAB System Block Dialog

To change the MATLAB System block dialog, implement the methods for the following classes:

Description	<code>matlab.system.display</code> Methods
Define header text for property group.	<code>matlab.system.display.Header</code>
Group properties together.	<code>matlab.system.display.Section</code>
Group properties into a separate tab.	<code>matlab.system.display.SectionGroup</code>

Nonvirtual Buses and MATLAB System Block

The MATLAB System block supports nonvirtual buses as input and output signals. The corresponding System object input or output must be a MATLAB structure whose fields match those defined by the nonvirtual bus. If the System object output is a MATLAB structure, it must define propagator methods. In addition, the `getOutputDataTypeImpl` method must return the name of the corresponding bus object. This bus object must exist in the base workspace or a data dictionary linked to the model.

Note: If the output is the same bus type as the input, do not use the `propagatedInputDataType` method to obtain the name of the bus object. Instead, you must return the name of the bus object directly.

Use System Objects in Feedback Loops

If your algorithm needs to process nondirect feedthrough data through the System object, use the `matlab.system.mixin.Nondirect` class. This class uses the `output` and `update` methods to process nondirect feedthrough data through a System object.

Most System objects use direct feedthrough, where the object's input is needed to generate the output. For these direct feedthrough objects, the `step` method calculates the output and updates the state values. For nondirect feedthrough, however, the object's output depends on internal states and not directly on the inputs. The inputs, or a subset of the inputs, are used to update the object states. For these objects, calculating the output is separated from updating the state values. This enables you to use an object as a feedback element in a feedback loop.

A delay object is an example of a nondirect feedthrough object.

- 1 Add the `matlab.system.mixin.Nondirect` class to the top of the parent class file for the System object, after the `matlab.System` class. For example:

```
IntegerDelaySysObj < matlab.System & matlab.system.mixin.Nondirect
```

This step subclasses from the `matlab.system.mixin.Nondirect` class in addition to the `matlab.System` base class.

- 2 Implement the following methods:

```
outputImpl  
updateImpl
```

When implementing the `outputImpl` method, do not access the System object inputs for which the direct feedthrough flag is false.

- 3 If the System object supports code generation and does not inherit from `matlab.system.mixin.Propagates`, Simulink can automatically infer the direct feedthrough settings from the System object MATLAB code. However, if the System object does not support code generation, the default `isInputDirectFeedthroughImpl` method returns false (no direct feedthrough). In this case, override this method if you want nondefault behavior.

The processing of the nondirect feedthrough changes the way that the software calls the System object methods within the context of the Simulink engine.

Simulation Modes

Interpreted Execution vs. Code Generation

You can use MATLAB System block in Simulink models for simulation via interpreted execution or code generation. Implementing a MATLAB System block with a valid System object class name enables the **Simulate using** parameter. This parameter appears at the bottom of each MATLAB System block if there is only one tab, or the bottom of the first of multiple tabs. Use the **Simulate using** parameter to control how the block simulates. The table describes how to choose the right value for your purpose.

- With interpreted execution, the model simulates the block using the MATLAB execution engine.

Note: With interpreted execution, if you set the **Optimization > Use division for fixed-point net slope computation** parameter to 'On' or 'Use division for reciprocals of integers only' in the Configuration Parameters dialog box, you might get unoptimized numeric results. This is because MATLAB code does not support this parameter.

- With code generation, the model simulates the block using code generation, using the subset of MATLAB code supported for code generation.

Action	Select	Pros	Cons
Upon first model run, simulate and generate code for MATLAB System using only the subset of MATLAB functions supported for code generation. Choosing this option causes the simulation to run the generated code.	Code generation (default)	Potentially better performance.	System object is limited to the subset of MATLAB functions supported for code generation. Simulation may start more slowly.
Simulate model using all supported MATLAB functions.	Interpreted execution	System object can contain any supported	Potentially slower performance. If the MATLAB functions in the System object do not

Action	Select	Pros	Cons
Choosing this option can slow simulation performance.		MATLAB function. Faster startup time.	support code generation, the System object must contain propagation methods.

To take advantage of faster performance, consider using propagation methods in your System object. For more information, see “Add and Implement Propagation Methods” on page 42-30.

Simulation Using Code Generation

While simulating and generating code for one or more simulation targets (in this case, System object blocks), the model displays status messages in the bottom left of the Simulink Editor window. A model can have multiple copies of the same block, where blocks are considered the same if they

- Use the same System object.
- Have inputs and tunable parameters that have identical signals, data types, and complexities.
- Have nontunable parameters that have the same value.

When the model has multiple copies of the same block, the software does not regenerate the code for each block. It reuses the code from the first time that code was generated for one of these blocks. The status messages reflect this and do not show status messages for each of these blocks.

When the code generation process is complete, Simulink creates a MEX-file for the generated code.

Mapping System Objects to Block Dialog Box

The System object source code controls the appearance of the block dialog box. This section describes System object to block dialog box mapping using the System Identification for an FIR System Using MATLAB System Blocks example. This example uses two System objects, one that uses default System object to block dialog box mapping, and one that uses a custom mapping.

In this section...
“System Object to Block Dialog Box Default Mapping” on page 42-19
“System Object to Block Dialog Box Custom Mapping” on page 42-21

System Object to Block Dialog Box Default Mapping

The following figure shows how the source code corresponds to the dialog box elements if you do not customize the dialog using the `getHeaderImpl` or `getPropertyGroupsImpl` methods. (The link to open the source code and the **Simulate using** parameter appear on all MATLAB System block dialog boxes.)

```

The Delay block from the System Identification for an FIR System Using MATLAB System Blocks is an example of a block that uses a System object that draws the dialog box using the default mapping. This block has one input and one output.

This block uses a System object that has direct feedthrough set to false (nondirect feedthrough). This setting means that the System object does not directly use the input to compute the output, enabling the model to use this block safely in a feedback system without introducing an algebraic loop. For more information on nondirect feedthrough, see “Use System Objects in Feedback Loops” on page 42-14.

For an example of a custom block dialog box, see “System Object to Block Dialog Box Custom Mapping” on page 42-21.

System Object to Block Dialog Box Custom Mapping

The LMS Adaptive block is an example of a block with a custom header and property groups. The System object code uses the `getHeaderImpl` and `getPropertyGroupsImpl` methods from `matlab.System` to customize these block dialog elements.

The LMS Adaptive Filter block estimates the coefficients of an unknown system (formed by the Unknown System and Delay blocks). Its inputs are the desired signal and the actual signal. Its outputs are the estimated signal and the vector norm of the error in the estimated coefficients. It uses the `lmsSysObj` System object.

```

classdef lmsSysObj < matlab.System & matlab.system.mixin.CustomIcon
%lmsSysObj Least mean squares (LMS) adaptive filtering.

methods(Static, Access=protected)

function header = getHeaderImpl
header = matlab.system.display.Header(...
'Title', 'LMS Adaptive Filter');
end

function groups = getPropertyGroupsImpl
firstGroup = matlab.system.display.SectionGroup(...
'Title', 'General', ...
'PropertyList', {'Mu'});

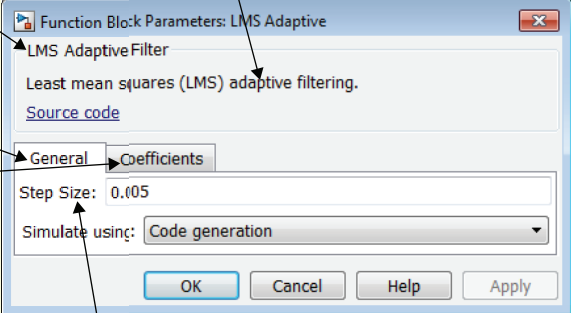

secondGroup = matlab.system.display.SectionGroup(...
'Title', 'Coefficients', ...
'PropertyList', {'TrueCoefficients', 'NumCoeff'});

groups = [firstGroup, secondGroup];
end
end

Considerations for Using System Objects in Simulink

In this section...

“System Objects in Simulink” on page 42-24

“System Objects in For Each Subsystems” on page 42-25

“Input Validation” on page 42-25

System Objects in Simulink

There are differences in how you can use System objects in a MATLAB System block in Simulink versus using the same object in MATLAB. You see these differences when working with variable-size signals and tunable parameters and when using System objects as properties.

Variable-Size Signals

To use variable-size signals in a System object, you must implement `matlab.system.mixin.Propagates` methods. In particular, use the `isOutputFixedSizeImpl` method to specify if an output is variable-size or fixed-size. This is true for interpreted execution and code generation simulation methods.

Tunable Parameters

Simulink registers public tunable properties of a System object as tunable parameters of the corresponding MATLAB System block. If a System object property is tunable, it is also tunable in the MATLAB System block. At runtime, you can change the parameter using one of the following approaches. The change applies at the top of the simulation loop.

- At the MATLAB command line, use the `set_param` to change the parameter value.
- In the Simulink editor, edit the MATLAB System block dialog box to change the parameter value, and then update the block diagram.

You cannot change public tunable properties from System object internal methods such as `stepImpl`.

During simulation, setting an invalid value on a tunable parameter causes an error message and stops simulation.

System Objects as Properties

The MATLAB System block allows a System object to have other System objects as public or private properties. However:

- System objects and other MATLAB objects stored as public properties are read only. As a result, you cannot set the value of the parameter, you can only get the value of a parameter.
- System objects stored as property values appear dimmed in the MATLAB System block dialog box.

Default Property Values

MATLAB does not require that objects assign default values to properties. However, in Simulink, if your System object has properties with no assigned default values, the associated dialog box parameter requires that the value data type be a built-in Simulink data type.

System Objects in For Each Subsystems

To use the MATLAB System block within a For Each Subsystem block, implement the `matlab.system.supportsMultipleInstanceImpl` method. This method should return `true`. The MATLAB System block clones the System object for each For Each Subsystem iteration.

Input Validation

In Simulink, use the `validateInputsImpl` method to validate only attributes (size, data type, and complexity) of the input. Do not use this method to validate the value of the input.

Simulink Engine Interaction with System Object Methods

Simulink Engine Phases Mapped to System Object Methods

This diagram shows a process view of the order in which the MATLAB System block invokes System object methods within the context of the Simulink engine.

Note the following:

- Simulink calls the `stepImpl`, `outputImpl`, and `updateImpl` methods multiple times during simulation at each time step. Simulink typically calls other methods once per simulation.

- The Simulink engine calls the `isOutputFixedSizeImpl`, `getDiscreteStateSpecificationImpl`, `isOutputComplexImpl`, `getOutputDataTypeImpl`, `getOutputSizeImpl` when using `matlab.system.mixin.Propagates`.
- Simulink calls `saveObjectImpl` and `loadObjectImpl` for saving and restoring `SimState`, the Simulation Stepper, and Fast Restart.
- Default implementations save and restore all properties with public access, including `DiscreteState`.

Add and Implement Propagation Methods

In this section...
“When to Use Propagation Methods” on page 42-30
“Add Propagation Methods to System Objects” on page 42-30
“Implement Propagation Methods” on page 42-31

When to Use Propagation Methods

Propagation methods define output specifications. Use them when the output specifications cannot be inferred directly from the inputs during Simulink model compilation.

Consider using propagation methods in your System object when:

- The System object requires access to all MATLAB functions that do not support code generation, which means that you cannot generate code for simulation. You must use propagation methods in this case. Use these methods to specify information for the outputs.
- You want to use variable-size signals.
- You do not care whether code is generated, but you want to improve startup performance. Use propagation methods to specify information for the inputs and outputs, enabling quicker startup time.

At startup, the Simulink software tries to evaluate the input and output ports of the model blocks for signal attribute propagation. In the case of MATLAB System blocks, if the software cannot perform this evaluation, it displays a message prompting you to add propagation methods to the System object.

Add Propagation Methods to System Objects

Propagation methods are in the class `matlab.system.mixin.Propagates`. To add these methods to the System object, add the `matlab.system.mixin.Propagates` class to the top of the parent class file for the System object, after the `matlab.System` class. For example:

```
classdef Counter < matlab.System & matlab.system.mixin.Propagates
```

Implement Propagation Methods

Simulink evaluates the uses of the propagation methods to evaluate the input and output ports of the MATLAB System block for startup.

Each method has a default implementation, listed in the **Default Implementation Should Suffice if** column. If your System object does not use the default implementation, you must implement a version of the propagation method for your System object.

Description	Propagation Method	Default Implementation Should Suffice if	Example
Gets dimensions of output ports. The associated method is <code>getOutputSize</code> .	<code>getOutputSizeImpl</code>	<ul style="list-style-type: none"> • Only one input • Only one output • An input size that is the same as the output size 	<ul style="list-style-type: none"> • <code>FindIfFixedInput</code> or <code>FindIfVarSizeInput</code> block in MATLAB System Block with Variable-Size Input and Output Signals • Analysis block in Illustration of Law of Large Numbers
Gets data types of output ports. Share Data with Other Blocks

In this section...

“Data Sharing with the MATLAB System Block” on page 42-33

“Choose How to Store Shared Data” on page 42-34

“How to Use Data Store Memory Blocks for the MATLAB System Block” on page 42-35

“How to Set Up Simulink.Signal Objects” on page 42-37

“Using Data Store Diagnostics to Detect Memory Access Issues” on page 42-40

“Limitations of Using Shared Data in MATLAB System Blocks” on page 42-40

“Use Shared Data with P-Coded System Objects” on page 42-40

Share data between MATLAB System and other blocks using the `global` keyword and the Data Store Memory block or `Simulink.Signal` object. You might need to use global data with a MATLAB System block if:

- You have an existing model that uses a large amount of global data, you are adding a MATLAB System block to this model, and you want to avoid cluttering your model with additional inputs and outputs.
- You want to scope the visibility of data to parts of the model.

Data Sharing with the MATLAB System Block

In Simulink, you store global data using data store memory. You implement data store memory using either Data Store Memory blocks or `Simulink.Signal` objects. How you store global data depends on the number and scope of your global variables.

Scoping Rules for Shared Data in MATLAB System Blocks

The MATLAB System block uses these scoping rules:

- If you use the same name for both Data Store Memory block and `Simulink.Signal` object, Data Store Memory block scopes the data to the model.
- A global variable resolves hierarchically to the closest Data Store Memory block with the same name in the model. The same global variable appearing in two different MATLAB System blocks might resolve to different Data Store Memory blocks depending on the hierarchy of the model. You can use this ability to scope the visibility of data to a subsystem.

Using Shared Data in MATLAB System Blocks

MATLAB System blocks support data store memory for:

- MATLAB structures (buses)
- Enumerated data types

How to Use Data Sharing with the MATLAB System Block

To use shared data in your MATLAB System block:

- 1 Declare a global variable in the System object that you associate with the MATLAB System block.

You can use the `global` keyword in these methods of the System object:

- `stepImpl`
 - `outputImpl`
 - `updateImpl`
- 2 Add a Data Store Memory block or `Simulink.Signal` object that has the same name as the global variable in the System object.

To share data between referenced models using the `Simulink.Signal` object, define the `Simulink.Signal` object in the base workspace and use the same global variable name as in the MATLAB System block.

Choose How to Store Shared Data

You can use Data Store Memory blocks or `Simulink.Signal` objects to store shared data.

Type of Data	Global Data Storage Method	Related Links
A small number of global variables in a single model that does not use model reference.	Data Store Memory blocks. Note: Using Data Store Memory blocks scopes the data to the model.	“How to Use Data Store Memory Blocks for the MATLAB System Block” on page 42-35
A large number of global variables in a single model	<code>Simulink.Signal</code> objects defined in the	“How to Set Up Simulink.Signal Objects” on page 42-37

Type of Data	Global Data Storage Method	Related Links
that does not use model reference.	model workspace. Simulink.Signal objects offer these advantages: <ul style="list-style-type: none"> • You do not have to add numerous Data Store Memory blocks to your model. • You can load the Simulink.Signal objects in from a MAT-file. 	
Data shared between multiple models (including referenced models).	Simulink.Signal objects defined in the base workspace Note: If you use Data Store Memory blocks as well as Simulink.Signal , note that using Data Store Memory blocks scopes the data to the model.	“How to Set Up Simulink.Signal Objects” on page 42-37

How to Use Data Store Memory Blocks for the MATLAB System Block

- 1 Declare a global keyword in the System object methods that support globals. For example:

```
global A;
```
- 2 Add a MATLAB System block to your model.
- 3 Double-click the MATLAB System block and associate the System object.
- 4 Add a Data Store Memory block to your model and set:
 - a **Data store name** to match the name of the global variable in your MATLAB System block code.
 - b **Data type** to an explicit data type.

The data type cannot be `auto`.

- c **Signal type.**
- d **Initial value.**

The initial value of the Data Store Memory block cannot be unspecified.

Use Data Store Memory with the MATLAB System Block

This model demonstrates how a MATLAB System block uses the global data stored in Data Store Memory block B. The MATLAB System block is associated with the `globalSysObjMatrix1` System object. To see the completed model, open the `ex_globalsys_objmatrix1` model.

- 1 Drag these blocks into a new model:
 - MATLAB System
 - Data Store Memory
 - Display
- 2 Create a System object to associate with the MATLAB System block. To start, from the MATLAB System block, create a Basic System object template file.
- 3 In MATLAB Editor, create a System object with code like the following. Save the System object as `globalSysObjMatrix1.m`. The System object modifies B each time it executes.

```
classdef globalSysObjMatrix1 < matlab.System
    % Global/DSM support scalar example

    methods(Access = protected)
        function setupImpl(obj)
```

```

        % Perform one-time calculations, such as computing constants
    end

    function y = stepImpl(obj)
        global B;
        B(:,1)= B(:,1)+100;
        y = B;
    end
end
end
end

```

- 4 Double-click the MATLAB System block and associate the `globalSysObjMatrix1` System object with the block.
- 5 In the model, double-click the Data Store Memory block `B`.
- 6 In the Signal Attributes tab, enter an initial value, for example:
`[74 75 5 1;22 23 24 32;33 44 55 22]`
- 7 Simulate the model.

The MATLAB System block reads the initial value of global data stored in `B` and updates the value of `B` each time it executes. This model executes for five time steps.

- 8 Save and close your model.

How to Set Up Simulink.Signal Objects

Create a `Simulink.Signal` object in the model workspace.

Tip Create a `Simulink.Signal` object in the base workspace to use the global data with multiple models.

- 1 In the Model Explorer, navigate to *model_name* > **Model Workspace** in the **Model Hierarchy** pane.

Select **Add > Simulink Signal**.

- 2 Ensure that these settings apply to the `Simulink.Signal` object:

- a Set **Data type** to an explicit data type.

The data type cannot be `auto`.

- b Set **Dimensions** to be fully specified.

The signal dimensions cannot be `-1` or `inherited`.

- c Set the **Complexity**.

- d Specify an **Initial value**.

The initial value of the signal cannot be unspecified.

- e Set **Name** to the name of the global variable.

Use a `Simulink.Signal` Object with a MATLAB System Block

This simple model demonstrates how a MATLAB System block uses a `Simulink.Signal` with signal `B`. The MATLAB System block is associated with the `globalSysObjScalar` System object. To see the completed model, open the `ex_globalsys_simulink_signal_share` model.

- 1 Drag these blocks into a new model:
 - MATLAB System
 - Display
- 2 Create a System object to associate with the MATLAB System block. To start, from the MATLAB System block, create a Basic System object template file.
- 3 In MATLAB Editor, create a System object. Save the System object as `globalSysObjScalar.m`. The System object modifies `B` each time it executes.

```

classdef globalSysObjScalar < matlab.System
    % Global/DSM support scalar example

    methods(Access = protected)
        function setupImpl(obj)
            % Perform one-time calculations, such as computing constants
            end

        function y = stepImpl(obj)
            global B;
            B= B+100;
            y = B;
        end
    end
end
end

```

- 4 Double-click the MATLAB System block and associate the `globalSysObjScalar` System object with the block.
- 5 From the model menu, select **View > Model Explorer**.
- 6 In the left pane of the Model Explorer, select the model workspace for this model.

The **Contents** pane displays the data in the model workspace.

- 7 In the Model Explorer, in the **Model Hierarchy** pane, navigate to *model_name* > **Model Workspace**. In the **Contents** pane, set **Name** to **B**.
- 8 Navigate back to *model_name* > **Model Workspace**.
 - Select **Add > Simulink Signal**.
 - Make these settings for the `Simulink.Signal` object:

Attribute	Value
Data type	double
Complexity	real
Dimensions	1
Initial value	25

- 9 Simulate the model.

The MATLAB System block reads the initial value of global data stored in **B** and updates the value of **B** each time it executes. The model runs for five time steps.

10 Save and close your model.

Using Data Store Diagnostics to Detect Memory Access Issues

You can configure your model to provide run-time and compile-time diagnostics to avoid problems with data stores. Diagnostics are available in the Configuration Parameters dialog box and the Parameters dialog box for the Data Store Memory block. These diagnostics are available for Data Store Memory blocks only, not for `Simulink.Signal` objects. For more information on using data store diagnostics, see “Data Store Diagnostics” on page 60-3.

Limitations of Using Shared Data in MATLAB System Blocks

The MATLAB System block does not support data store memory for variable-sized data

Use Shared Data with P-Coded System Objects

If the System object is P-code, you must implement the `getGlobalNamesImpl` method to provide the global variable names you use in the System object. For example:

```

classdef GlobalSysObjMatrix < matlab.System
    % Matrix DSM support: Increment first row by 1 at each time step
    methods (Access = protected)
        function y = stepImpl(obj)
            global B;
            B(1,:) = B(1, :)+1;
            y = B;
        end

        function globalNames = getGlobalNamesImpl(~)
            globalNames = {'B'};
        end
    end
end
  
```

Troubleshoot System Objects in Simulink

In this section...

“Class Not Found” on page 42-42

“Error Invoking Object Method” on page 42-42

“Performance” on page 42-43

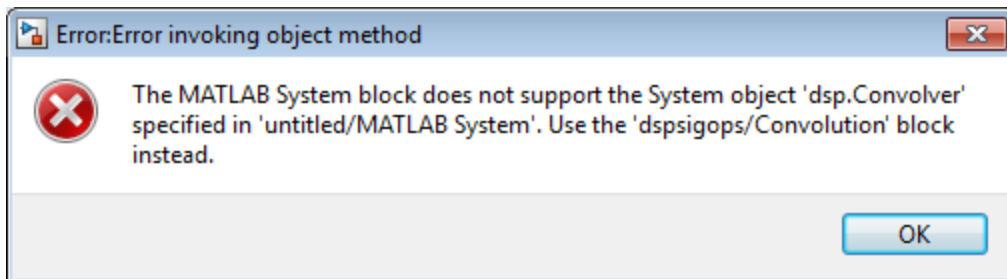

Class Not Found

The MATLAB System block **System object name** parameter requires that you enter the full path to the System object class. In addition:

- Check that the System object class is on your MATLAB path.
- Check capitalization to make sure it matches.
- Check that the class name is a supported System object.
- Do not include the file extension.

Error Invoking Object Method

The MATLAB System block supports only System objects written in the MATLAB language. If the software can identify an alternative block, it suggests that block in the error message, for example:

This message indicates that there is an existing dedicated and optimized block that you should use.

Performance

For fastest performance, set the block **Simulate using** parameter to **Code generation**. This setting allows the MATLAB System block to run as fast as it can. The parameter is set to this value by default.

This setting causes a slower startup time, as the software generates C code and creates a MEX-file from it. However, after code generation, later simulations have better performance. When the block uses generated code to simulate, performance is typically better than simulation without generated code.

In some cases, the implementation of your System object does not allow you to generate code, which requires you to set **Simulate using** to **Interpreted execution**. For example, your System object can require MATLAB functions beyond the subset supported for code generation. In this case, use propagation methods to specify the block input and output port information. The MATLAB System block then propagates this signal attribution information.

When to Generate Code from MATLAB Algorithms

Generating code from MATLAB algorithms for desktop and embedded systems allows you to perform your software design, implementation, and testing completely within the MATLAB workspace. You can:

- Verify that your algorithms are suitable for code generation
- Generate efficient, readable, and compact C/C++ code automatically, which eliminates the need to manually translate your MATLAB algorithms and minimizes the risk of introducing errors in the code.
- Modify your design in MATLAB code to take into account the specific requirements of desktop and embedded applications, such as data type management, memory use, and speed.
- Test the generated code and easily verify that your modified algorithms are functionally equivalent to your original MATLAB algorithms.
- Generate MEX functions to:
 - Accelerate MATLAB algorithms in certain applications.
 - Speed up fixed-point MATLAB code.
- Generate hardware description language (HDL) from MATLAB code.

When Not to Generate Code from MATLAB Algorithms

Do not generate code from MATLAB algorithms for the following applications. Use the recommended MathWorks product instead.

To:	Use:
Deploy an application that uses handle graphics	MATLAB Compiler
Use Java	MATLAB Compiler SDK™
Use toolbox functions that do not support code generation	Toolbox functions that you rewrite for desktop and embedded applications
Deploy MATLAB based GUI applications on a supported MATLAB host	MATLAB Compiler
Deploy web-based or Windows applications	MATLAB Compiler SDK

To:	Use:
Interface C code with MATLAB	MATLAB <code>mex</code> function

Prerequisites for C/C++ Code Generation from MATLAB

To generate C/C++ or MEX code from MATLAB algorithms, you must install the following software:

- MATLAB Coder product
- C/C++ compiler

MATLAB Code Design Considerations for Code Generation

When writing MATLAB code that you want to convert into efficient, standalone C/C++ code, you must consider the following:

- Data types

C and C++ use static typing. To determine the types of your variables before use, MATLAB Coder requires a complete assignment to each variable.

- Array sizing

Variable-size arrays and matrices are supported for code generation. You can define inputs, outputs, and local variables in MATLAB functions to represent data that varies in size at run time.

- Memory

You can choose whether the generated code uses static or dynamic memory allocation.

With dynamic memory allocation, you potentially use less memory at the expense of time to manage the memory. With static memory, you get better speed, but with higher memory usage. Most MATLAB code takes advantage of the dynamic sizing features in MATLAB, therefore dynamic memory allocation typically enables you to generate code from existing MATLAB code without modifying it much. Dynamic memory allocation also allows some programs to compile even when upper bounds cannot be found.

Static allocation reduces the memory footprint of the generated code, and therefore is suitable for applications where there is a limited amount of available memory, such as embedded applications.

- Speed

Because embedded applications must run in real time, the code must be fast enough to meet the required clock rate.

To improve the speed of the generated code:

- Choose a suitable C/C++ compiler. Do not use the default compiler that MathWorks supplies with MATLAB for Windows 64-bit platforms.
- Consider disabling run-time checks.

By default, for safety, the code generated for your MATLAB code contains memory integrity checks and responsiveness checks. Generally, these checks result in more generated code and slower simulation. Disabling run-time checks usually results in streamlined generated code and faster simulation. Disable these checks only if you have verified that array bounds and dimension checking is unnecessary.

Why Are There Differences?

To convert MATLAB code to C/C++ code that works efficiently, the code generation process introduces optimizations that intentionally cause the generated code to behave differently — and sometimes produce different results — from the original source code. This section describes these differences.

Character Size

MATLAB supports 16-bit characters, but the generated code represents characters in 8 bits, the standard size for most embedded languages like C. See “Code Generation for Character Arrays” on page 47-8.

Order of Evaluation in Expressions

Generated code does not enforce order of evaluation in expressions. For most expressions, order of evaluation is not significant. However, for expressions with side effects, the

generated code may produce the side effects in different order from the original MATLAB code. Expressions that produce side effects include those that:

- Modify persistent or global variables
- Display data to the screen
- Write data to files
- Modify the properties of handle class objects

In addition, the generated code does not enforce order of evaluation of logical operators that do not short circuit.

For more predictable results, it is good coding practice to split expressions that depend on the order of evaluation into multiple statements.

- Rewrite

```
A = f1() + f2();
```

as

```
A = f1();  
A = A + f2();
```

so that the generated code calls `f1` before `f2`.

- Assign the outputs of a multi-output function call to variables that do not depend on one another. For example, rewrite

```
[y, y.f, y.g] = foo;
```

as

```
[y, a, b] = foo;  
y.f = a;  
y.g = b;
```

- When you access the contents of multiple cells of a cell array, assign the results to variables that do not depend on one another. For example, rewrite

```
[y, y.f, y.g] = z{:};
```

as

```
[y, a, b] = z{:};  
y.f = a;
```

```
y.g = b;
```

Termination Behavior

Generated code does not match the termination behavior of MATLAB source code. For example, if infinite loops do not have side effects, optimizations remove them from generated code. As a result, the generated code can possibly terminate even though the corresponding MATLAB code does not.

Size of Variable-Size N-D Arrays

For variable-size N-D arrays, the `size` function might return a different result in generated code than in MATLAB source code. The `size` function sometimes returns trailing ones (singleton dimensions) in generated code, but always drops trailing ones in MATLAB. For example, for an N-D array `X` with dimensions `[4 2 1 1]`, `size(X)` might return `[4 2 1 1]` in generated code, but always returns `[4 2]` in MATLAB. See “Incompatibility with MATLAB in Determining Size of Variable-Size N-D Arrays” on page 48-23.

Size of Empty Arrays

The size of an empty array in generated code might be different from its size in MATLAB source code. See “Incompatibility with MATLAB in Determining Size of Empty Arrays” on page 48-24.

Size of Empty Array That Results from Deleting Elements of an Array

Deleting all elements of an array results in an empty array. The size of this empty array in generated code might differ from its size in MATLAB source code.

Case	Example Code	Size of Empty Array in MATLAB	Size of Empty Array in Generated Code
Delete all elements of an m-by-n array by using the colon operator (:).	<pre>coder.varsize('X',[4,4],[1,1]); X = zeros(2); X(:) = [];</pre>	0-by-0	1-by-0
Delete all elements of a row vector by	<pre>coder.varsize('X',[1,4],[0,1]); X = zeros(1,4); X(:) = [];</pre>	0-by-0	1-by-0

Case	Example Code	Size of Empty Array in MATLAB	Size of Empty Array in Generated Code
using the colon operator (:).			
Delete all elements of a column vector by using the colon operator (:).	<pre>coder.varsize('X',[4,1],[1,0]); X = zeros(4,1); X(:) = [];</pre>	0-by-0	0-by-1
Delete all elements of a column vector by deleting one element at a time.	<pre>coder.varsize('X',[4,1],[1,0]); X = zeros(4,1); for i = 1:4 X(i) = []; end</pre>	1-by-0	0-by-1

Floating-Point Numerical Results

The generated code might not produce the same floating-point numerical results as MATLAB in the following situations:

When computer hardware uses extended precision registers

Results vary depending on how the C/C++ compiler allocates extended precision floating-point registers. Computation results might not match MATLAB calculations because of different compiler optimization settings or different code surrounding the floating-point calculations.

For certain advanced library functions

The generated code might use different algorithms to implement certain advanced library functions, such as `fft`, `svd`, `eig`, `mldivide`, and `mrdivide`.

For example, the generated code uses a simpler algorithm to implement `svd` to accommodate a smaller footprint. Results might also vary according to matrix properties. For example, MATLAB might detect symmetric or Hermitian matrices at run time and switch to specialized algorithms that perform computations faster than implementations in the generated code.

For implementation of BLAS library functions

For implementations of BLAS library functions, generated C/C++ code uses reference implementations of BLAS functions. These reference implementations might produce different results from platform-specific BLAS implementations in MATLAB.

NaN and Infinity Patterns

The generated code might not produce exactly the same pattern of NaN and inf values as MATLAB code when these values are mathematically meaningless. For example, if MATLAB output contains a NaN, output from the generated code should also contain a NaN, but not necessarily in the same place.

Code Generation Target

The `coder.target` function returns different values in MATLAB than in the generated code. The intent is to help you determine whether your function is executing in MATLAB or has been compiled for a simulation or code generation target. See `coder.target`.

MATLAB Class Initial Values

Before code generation, at class loading time, MATLAB computes class initial values. The code generator uses the value that MATLAB computes. It does not recompute the initial value. If the initialization uses a function call to compute the initial value, the code generator does not execute this function. If the function modifies a global state, for example, a persistent variable, code generator might provide a different initial value than MATLAB. For more information, see “Defining Class Properties for Code Generation” on page 51-4.

Variable-Size Support for Code Generation

See “Incompatibilities with MATLAB in Variable-Size Support for Code Generation” on page 48-21.

Complex Numbers

See “Code Generation for Complex Data” on page 47-4.

MATLAB Language Features Supported for C/C++ Code Generation

MATLAB Features That Code Generation Supports

Code generation from MATLAB code supports the following language features:

- n-dimensional arrays (see “Array Size Restrictions for Code Generation” on page 47-9)
- matrix operations, including deletion of rows and columns
- variable-sized data (see “Variable-Size Data Definition for Code Generation” on page 48-3)
- subscripting (see “Incompatibility with MATLAB in Matrix Indexing Operations for Code Generation” on page 48-27)
- complex numbers (see “Code Generation for Complex Data” on page 47-4)
- numeric classes (see “Supported Variable Types” on page 46-16)
- double-precision, single-precision, and integer math
- fixed-point arithmetic
- program control statements `if`, `switch`, `for`, `while`, and `break`
- arithmetic, relational, and logical operators
- local functions
- persistent variables
- global variables
- structures (see “Structure Definition for Code Generation” on page 49-2)
- cell arrays (see “Cell Arrays”)
- characters (see “Code Generation for Character Arrays” on page 47-8)
- function handles (see “Function Handle Limitations for Code Generation” on page 52-2)
- anonymous functions (see “Code Generation for Anonymous Functions” on page 52-4)
- recursive functions
- variable length input and output argument lists

- subset of MATLAB toolbox functions (see “Functions and Objects Supported for C/C++ Code Generation — Alphabetical List” on page 44-2)
- subset of functions and System objects in Aerospace Toolbox, Audio System Toolbox™, Communications System Toolbox, Computer Vision System Toolbox, DSP System Toolbox, Fixed-Point Designer, Image Processing Toolbox™, Phased Array System Toolbox™, Robotics System Toolbox™, Signal Processing Toolbox™, Statistics and Machine Learning Toolbox™, System Identification Toolbox, Wavelet Toolbox™, WLAN System Toolbox™ (see “Functions and Objects Supported for C/C++ Code Generation — Category List” on page 44-186)
- MATLAB classes (see “MATLAB Classes Definition for Code Generation” on page 51-2)
- function calls (see “Resolution of Function Calls for Code Generation” on page 54-2)

MATLAB Language Features That Code Generation Does Not Support

Code generation from MATLAB does not support the following frequently used MATLAB constructs:

- string arrays
- categorical arrays
- date and time arrays
- Java
- Map containers
- nested functions
- sparse matrices
- tables
- time series objects
- try/catch statements

This list is not exhaustive. To see if a construct is supported for code generation, see “MATLAB Features That Code Generation Supports” on page 43-13.

Functions, Classes, and System Objects Supported for Code Generation

- “Functions and Objects Supported for C/C++ Code Generation — Alphabetical List” on page 44-2
- “Functions and Objects Supported for C/C++ Code Generation — Category List” on page 44-186

Functions and Objects Supported for C/C++ Code Generation — Alphabetical List

You can generate efficient C/C++ code for a subset of MATLAB built-in functions and toolbox functions, classes, and System objects that you call from MATLAB code. These function, classes, and System objects appear in alphabetical order in the following table.

To find supported functions, classes, and System objects by MATLAB category or toolbox, see “Functions and Objects Supported for C/C++ Code Generation — Category List” on page 44-186.

Note: For more information on code generation for fixed-point algorithms, refer to “Code Acceleration and Code Generation from MATLAB”.

bwareaopen	Image Processing Toolbox	<p>BW must be a 2-D binary image. N-D arrays are not supported. conn can only be one of the two-dimensional connectivities (4 or 8) or a 3-by-3 matrix. The 3-D connectivities (6, 18, and 26) are not supported. Matrices of size 3-by-3-by-...-by-3 are not supported. conn must be a compile-time constant.</p> <p>MATLAB Function Block support: No.</p>
bwboundaries	Image Processing Toolbox	<p>The conn and options arguments must be compile-time constants and the return value A can only be a full matrix, not a sparse matrix.</p> <p>If you choose the generic MATLAB Host Computer target platform, generated code uses a precompiled, platform-specific shared library.</p> <p>MATLAB Function Block support: No.</p>

Name	Product	Remarks and Limitations
bwconncomp	Image Processing Toolbox	<p>The input image must be 2-D.</p> <p>The <code>conn</code> argument must be a compile-time constant and the only connectivities supported are 4 or 8. You can specify connectivity as a 3-by-3 matrix, but it can only be <code>[0 1 0; 1 1 1; 0 1 0]</code> or <code>ones(3)</code>.</p> <p>The <code>CC</code> struct return value does not include the <code>PixelIdxList</code> field.</p> <p>MATLAB Function Block support: No.</p>
bwdist	Image Processing Toolbox	<p>The <code>method</code> argument must be a compile-time constant. Input images must have fewer than 2^{32} pixels.</p> <p>Generated code for this function uses a precompiled, platform-specific shared library.</p> <p>MATLAB Function Block support: Yes.</p>
bweuler	Image Processing Toolbox	<p>If you choose the generic <code>MATLAB Host Computer</code> target platform, generated code uses a precompiled, platform-specific shared library.</p> <p>MATLAB Function Block support: Yes.</p>
bwlabel	Image Processing Toolbox	<p>When generating code, the parameter <code>n</code> must be a compile-time constant.</p> <p>MATLAB Function Block support: No.</p>
bwlookup	Image Processing Toolbox	<p>For best results, specify an input image of class <code>logical</code>.</p> <p>If you choose the generic <code>MATLAB Host Computer</code> target platform, generated code uses a precompiled, platform-specific shared library.</p> <p>MATLAB Function Block support: Yes.</p>

Name	Product	Remarks and Limitations
bwmorph	Image Processing Toolbox	<p>The character vector specifying the operation must be a constant and, for best results, specify an input image of class <code>logical</code>.</p> <p>If you choose the generic MATLAB Host Computer target platform, generated code uses a precompiled, platform-specific shared library.</p> <p>MATLAB Function Block support: No.</p>
bwpack	Image Processing Toolbox	<p>Generated code for this function uses a precompiled platform-specific shared library.</p> <p>MATLAB Function Block support: Yes.</p>
bwperim	Image Processing Toolbox	<p>Supports only 2-D images. Does not support any no-output-argument syntaxes. The connectivity matrix input argument, <code>conn</code>, must be a compile-time constant.</p> <p>If you choose the generic MATLAB Host Computer target platform, generated code uses a precompiled, platform-specific shared library.</p> <p>MATLAB Function Block support: Yes.</p>
bwselect	Image Processing Toolbox	<p>Supports only the 3 and 4 input argument syntaxes: <code>BW2 = bwselect(BW,c,r)</code> and <code>BW2 = bwselect(BW,c,r,n)</code>. The optional fourth input argument, <code>n</code>, must be a compile-time constant. In addition, with code generation, <code>bwselect</code> only supports only the 1 and 2 output argument syntaxes: <code>BW2 = bwselect(____)</code> or <code>[BW2, idx] = bwselect(____)</code>.</p> <p>If you choose the generic MATLAB Host Computer target platform, generated code uses a precompiled, platform-specific shared library.</p> <p>MATLAB Function Block support: Yes.</p>

Name	Product	Remarks and Limitations
bwtraceboundary	Image Processing Toolbox	The <code>dir</code> , <code>fstep</code> , and <code>conn</code> arguments must be compile-time constants. MATLAB Function Block support: No.
bwunpack	Image Processing Toolbox	Generated code for this function uses a precompiled platform-specific shared library. MATLAB Function Block support: Yes. The input argument <code>M</code> must be a compile-time constant.
ca2tf	DSP System Toolbox	All inputs must be constant. Expressions or variables are allowed if their values do not change.
cameraMatrix	Computer Vision System Toolbox	Supports MATLAB Function block: No
cameraParameters	Computer Vision System Toolbox	Supports MATLAB Function block: No Use the <code>toStruct</code> method to pass a <code>cameraParameters</code> object into generated code. See the “Code Generation for Depth Estimation From Stereo Video” example.
cameraPose	Computer Vision System Toolbox	Supports MATLAB Function block: No
cameraPoseToExtrinsics	Computer Vision System Toolbox	Supports MATLAB Function block: No
cart2hom	Robotics System Toolbox	Supports MATLAB Function block: Yes

Functions and Objects Supported for C/C++ Code Generation — Category List

You can generate efficient C/C++ code for a subset of MATLAB built-in functions and toolbox functions, classes, and System objects that you call from MATLAB code. These functions, classes, and System objects are listed by MATLAB category or toolbox category in the following tables.

For an alphabetical list of supported functions, classes, and System objects, see “Functions and Objects Supported for C/C++ Code Generation — Alphabetical List” on page 44-2.

Note: For more information on code generation for fixed-point algorithms, refer to “Code Acceleration and Code Generation from MATLAB”.

Aerospace Toolbox

C and C++ code generation for the following Aerospace Toolbox quaternion functions requires the Aerospace Blockset software.

Function	Remarks and Limitations
quatconj	—
quatdivide	—
quatinv	—
quatmod	—
quatmultiply	—
quatnorm	—
quatnormalize	—

Arithmetic Operations in MATLAB

See “Array vs. Matrix Operations” for detailed descriptions of the following operator equivalent functions.

Function	Remarks and Limitations
ctranspose	—
idivide	<ul style="list-style-type: none"> For efficient generated code, MATLAB rules for divide by zero are supported only for the 'round' option.
isa	—
ldivide	—

Function	Remarks and Limitations
minus	—
mldivide	—
mpower	If A is a 2-by-2 or larger matrix and B is Inf or -Inf, mpower(A,B) returns a matrix of NaNs.
mrdivide	—
mtimes	<ul style="list-style-type: none"> • Multiplication of pure imaginary numbers by non-finite numbers might not match MATLAB. The code generator does not specialize multiplication by pure imaginary numbers—it does not eliminate calculations with the zero real part. For example, $(\text{Inf} + 1i) * 1i = (\text{Inf} * 0 - 1 * 1) + (\text{Inf} * 1 + 1 * 0)i = \text{NaN} + \text{Inf}i$. • “Variable-Sizing Restrictions for Code Generation of Toolbox Functions” on page 48-30
plus	—
power	<ul style="list-style-type: none"> • Generates an error during simulation. When both X and Y are real, but power(X,Y) is complex, returns NaN in the generated code. To get the complex result, make the input value X complex by passing in complex(X). For example, power(complex(X),Y). • Generates an error during simulation. When both X and Y are real, but X.^Y is complex, returns NaN in generated code. To get the complex result, make the input value X complex by using complex(X).^Y.
rdivide	—
times	Multiplication of pure imaginary numbers by non-finite numbers might not match MATLAB. The code generator does not specialize multiplication by pure imaginary numbers—it does not eliminate calculations with the zero real part. For example, $(\text{Inf} + 1i) * 1i = (\text{Inf} * 0 - 1 * 1) + (\text{Inf} * 1 + 1 * 0)i = \text{NaN} + \text{Inf}i$.

uminus	—
uplus	—

Audio System Toolbox

C and C++ code generation for the following functions and System objects requires the Audio System Toolbox software.

Name	Remarks and Limitations
Audio I/O and Waveform Generation	
audioDeviceReader	“System Objects in MATLAB Code Generation” Supports MATLAB Function block: Yes
audioDeviceWriter	“System Objects in MATLAB Code Generation” Supports MATLAB Function block: Yes
wavetableSynthesizer	“System Objects in MATLAB Code Generation” Supports MATLAB Function block: Yes
audioOscillator	“System Objects in MATLAB Code Generation” Supports MATLAB Function block: Yes
Audio Processing Algorithm Design	
designVarSlopeFilter	Supports MATLAB Function block: Yes
designParamEQ	Supports MATLAB Function block: Yes
designShelvingEQ	Supports MATLAB Function block: Yes
integratedLoudness	Supports MATLAB Function block: Yes
crossoverFilter	“System Objects in MATLAB Code Generation” Supports MATLAB Function block: Yes
compressor	“System Objects in MATLAB Code Generation” Supports MATLAB Function block: Yes
expander	“System Objects in MATLAB Code Generation” Supports MATLAB Function block: Yes
noiseGate	“System Objects in MATLAB Code Generation” Supports MATLAB Function block: Yes

Name	Remarks and Limitations
limiter	“System Objects in MATLAB Code Generation” Supports MATLAB Function block: Yes
multibandParametricEQ	“System Objects in MATLAB Code Generation” Supports MATLAB Function block: Yes
octaveFilter	“System Objects in MATLAB Code Generation” Supports MATLAB Function block: Yes
weightingFilter	“System Objects in MATLAB Code Generation” Supports MATLAB Function block: Yes
loudnessMeter	“System Objects in MATLAB Code Generation” Supports MATLAB Function block: No Dynamic Memory Allocation must not be turned off.
reverberator	“System Objects in MATLAB Code Generation” Supports MATLAB Function block: Yes
Audio Plugins	
audioPluginInterface	Supports MATLAB Function block: Yes
audioPluginParameter	Supports MATLAB Function block: Yes
audioPlugin	Supports MATLAB Function block: Yes
audioPluginSource	Supports MATLAB Function block: Yes

Bit-Wise Operations MATLAB

Function	Remarks and Limitations
flintmax	—
swapbytes	Inheritance of the class of the input to <code>swapbytes</code> in a MATLAB Function block is supported only when the class of the input is <code>double</code> . For non-double inputs, the input port data types must be specified, not inherited.

Casting in MATLAB

Function	Remarks and Limitations
cast	—
char	Does not support cell arrays.
class	—
double	—
int8, int16, int32, int64	—
logical	—
single	—
typecast	<ul style="list-style-type: none"> • Value of data type argument must be lowercase. • When you use <code>typecast</code> with inheritance of input port data types in MATLAB Function blocks, you can receive a size error. To avoid this error, specify the block input port data types explicitly. • Integer input or result classes must map directly to a C type on the target hardware. • The input must be a variable-length vector or a fixed-size vector. See “Variable-Sizing Restrictions for Code Generation of Toolbox Functions” on page 48-30 • The output vector always has the same orientation as the input vector.
uint8, uint16, uint32, uint64	—

Character Functions in MATLAB

Function	Remarks and Limitations
bin2dec	<ul style="list-style-type: none"> • Does not support cell arrays. • Does not match MATLAB when the input is empty.
blanks	—
char	Does not support cell arrays.
deblank	<ul style="list-style-type: none"> • Supports only inputs from the <code>char</code> class. Does not support cell arrays.

Function	Remarks and Limitations
	<ul style="list-style-type: none"> Input values must be in the range 0-127.
dec2bin	<ul style="list-style-type: none"> If input <code>d</code> is <code>double</code>, <code>d</code> must be less than 2^{52}. If input <code>d</code> is <code>single</code>, <code>d</code> must be less than 2^{23}. Unless you specify input <code>n</code> to be constant and <code>n</code> is large enough that the output has a fixed number of columns regardless of the input values, this function requires variable-sizing support. Without variable-sizing support, <code>n</code> must be at least 52 for <code>double</code>, 23 for <code>single</code>, 16 for <code>char</code>, 32 for <code>int32</code>, 16 for <code>int16</code>, and so on.
dec2hex	<ul style="list-style-type: none"> If input <code>d</code> is <code>double</code>, <code>d</code> must be less than 2^{52}. If input <code>d</code> is <code>single</code>, <code>d</code> must be less than 2^{23}. Unless you specify input <code>n</code> to be constant, and <code>n</code> is large enough that the output has a fixed number of columns regardless of the input values, this function requires variable-sizing support. Without variable-sizing support, <code>n</code> must be at least 13 for <code>double</code>, 6 for <code>single</code>, 4 for <code>char</code>, 8 for <code>int32</code>, 4 for <code>int16</code>, and so on.
hex2dec	Does not support cell arrays.
hex2num	<ul style="list-style-type: none"> Does not support cell arrays. For <code>n = hex2num(S)</code>, <code>size(S,2) <= length(num2hex(0))</code>
iscellstr	—
ischar	—
isletter	<ul style="list-style-type: none"> Input values from the <code>char</code> class must be in the range 0-127.
isspace	<ul style="list-style-type: none"> Input values from the <code>char</code> class must be in the range 0–127.
isstrprop	<ul style="list-style-type: none"> Supports only inputs from <code>char</code> and <code>integer</code> classes. Input values must be in the range 0-127.
lower	<ul style="list-style-type: none"> Supports only <code>char</code> inputs. Does not support cell arrays. Input values must be in the range 0-127.
num2hex	—
str2double	<ul style="list-style-type: none"> Does not support cell arrays. Always returns a complex result.

Function	Remarks and Limitations
strcmp	<ul style="list-style-type: none"> • Does not support enumeration inputs. • When one input is a cell array and the other input is a character array, the character array must be a compile-time row vector. • When both inputs are empty character arrays that have different sizes, returns true.
strcmpi	<ul style="list-style-type: none"> • Does not support enumeration inputs. • Input values from the <code>char</code> class must be in the range 0-127. • When one input is a cell array and the other input is a character array, the character array must be a compile-time row vector. • When both inputs are empty character arrays that have different sizes, returns true.
strfind	<ul style="list-style-type: none"> • Does not support cell arrays. • Inputs must be character row vectors. • Returns an empty output as a 1-by-0 character array.
strjoin	Returns an empty output as a 1-by-0 character array.
strjust	<ul style="list-style-type: none"> • Does not support a cell array of character vectors for the first argument. • Returns an empty output as a 1-by-0 character array.
strncmp	<ul style="list-style-type: none"> • Does not support enumeration inputs. • When one input is a cell array and the other input is a character array, the character array must be a compile-time row vector.
strncmpi	<ul style="list-style-type: none"> • Does not support enumeration inputs. • Input values from the <code>char</code> class must be in the range 0-127. • When one input is a cell array and the other input is a character array, the character array must be a compile-time row vector.
strrep	<ul style="list-style-type: none"> • Does not support cell arrays. • Inputs must be character row vectors. • Returns an empty output as a 1-by-0 character array.
strtok	<ul style="list-style-type: none"> • Does not support a cell array for the first argument. • Returns an empty output as a 1-by-0 character array.

Function	Remarks and Limitations
<code>strtrim</code>	<ul style="list-style-type: none"> • Supports only inputs from the <code>char</code> class. Does not support cell arrays. • Input values must be in the range 0-127. • Returns an empty output as a 1-by-0 character array.
<code>upper</code>	<ul style="list-style-type: none"> • Supports only inputs from the <code>char</code> class. Does not support cell arrays. • Input values must be in the range 0-127.

Communications System Toolbox

C and C++ code generation for the following functions and System objects requires the Communications System Toolbox software.

	<ul style="list-style-type: none"> Performs arithmetic in the output class. Hence, results might not match MATLAB due to different rounding errors

Computer Vision System Toolbox

C and C++ code generation for the following functions and System objects requires the Computer Vision System Toolbox software.

Name	Remarks and Limitations
Feature Detection, Extraction, and Matching	
BRISKPoints	Supports MATLAB Function block: No To index locations with this object, use the syntax: <code>points.Location(idx, :)</code> , for <code>points</code> object. See <code>visionRecoverformCodeGeneration_kernel.m</code> , which is used in the “Introduction to Code Generation with Feature Matching and Registration” example.
cornerPoints	Supports MATLAB Function block: No To index locations with this object, use the syntax: <code>points.Location(idx, :)</code> , for <code>points</code> object. See <code>visionRecoverformCodeGeneration_kernel.m</code> , which is used in the “Introduction to Code Generation with Feature Matching and Registration” example.
detectBRISKFeatures	Supports MATLAB Function block: No Generates portable C code using a C++ compiler that links to OpenCV (Version 2.4.9) libraries. “Portable C Code Generation for Functions That Use OpenCV Library”
detectFASTFeatures	Supports MATLAB Function block: No Generates portable C code using a C++ compiler that links to OpenCV (Version 2.4.9) libraries. “Portable C Code Generation for Functions That Use OpenCV Library”

Name	Remarks and Limitations
detectHarrisFeatures	Compile-time constant input: 'FilterSize' Supports MATLAB Function block: No Generated code for this function uses a precompiled platform-specific shared library.
detectMinEigenFeatures	Compile-time constant input: 'FilterSize' Supports MATLAB Function block: No Generated code for this function uses a precompiled platform-specific shared library.
detectMSERFeatures	Supports MATLAB Function block: No Generates portable C code using a C++ compiler that links to OpenCV (Version 2.4.9) libraries “Portable C Code Generation for Functions That Use OpenCV Library” For code generation, the function outputs <code>regions.PixelList</code> as an array. The region sizes are defined in <code>regions.Lengths</code> .
detectSURFFeatures	Supports MATLAB Function block: No Generates portable C code using a C++ compiler that links to OpenCV (Version 2.4.9) libraries. “Portable C Code Generation for Functions That Use OpenCV Library”
extractFeatures	Compile-time constant input restrictions: 'Method' Supports MATLAB Function block: Yes for Block method only. Generates portable C code using a C++ compiler that links to OpenCV (Version 2.4.9) libraries for BRISK, FREAK, and SURF Methods. “Portable C Code Generation for Functions That Use OpenCV Library”
extractHOGFeatures	Supports MATLAB Function block: No
extractLBPFeatures	Generates platform-dependent library: No Supports MATLAB Function block: Yes

Name	Remarks and Limitations
matchFeatures	Generates platform-dependent library: Yes for MATLAB host only when using the Exhaustive method. Generates portable C code for non-host target only when using the Exhaustive method. Generates portable C code using a C++ compiler that links to OpenCV (Version 2.4.9) libraries when not using the Exhaustive method. “Portable C Code Generation for Functions That Use OpenCV Library” Compile-time constant input: 'Method' and 'Metric'. Supports MATLAB Function block: No
MSERRegions	Supports MATLAB Function block: Yes For code generation, you must specify both the pixellist cell array and the length of each array, as the second input. The object outputs, regions.PixelList as an array. The region sizes are defined in regions.Lengths . Generated code for this function uses a precompiled platform-specific shared library.
SURFPoints	Supports MATLAB Function block: No To index locations with this object, use the syntax: points.Location(idx, :) , for points object. See visionRecovertransformCodeGeneration_kernel.m , which is used in the “Introduction to Code Generation with Feature Matching and Registration” example.
Image Registration and Geometric Transformations	
estimateGeometricTransform	Supports MATLAB Function block: No
vision.GeometricShearer	Supports MATLAB Function block: Yes “System Objects in MATLAB Code Generation”
Object Detection and Recognition	

Name	Remarks and Limitations
ocr	Compile-time constant input: 'TextLayout', 'Language', and 'CharacterSet'. Supports MATLAB Function block: No Generated code for this function uses a precompiled platform-specific shared library.
ocrText	Supports MATLAB Function block: No
vision.PeopleDetector	Supports MATLAB Function block: No Generates portable C code using a C++ compiler that links to OpenCV (Version 2.4.9) libraries. “Portable C Code Generation for Functions That Use OpenCV Library” “System Objects in MATLAB Code Generation”
vision.CascadeObjectDetector	Supports MATLAB Function block: No Generates portable C code using a C++ compiler that links to OpenCV (Version 2.4.9) libraries “Portable C Code Generation for Functions That Use OpenCV Library” “System Objects in MATLAB Code Generation”
Tracking and Motion Estimation	
assignDetectionsToTracks	Supports MATLAB Function block: Yes
opticalFlowFarneback	Supports MATLAB Function block: No Generates portable C code using a C++ compiler that links to OpenCV (Version 2.4.9) libraries. “Portable C Code Generation for Functions That Use OpenCV Library”
opticalFlowHS	Supports MATLAB Function block: No
opticalFlowLKDoG	Supports MATLAB Function block: No
opticalFlowLK	Supports MATLAB Function block: No
vision.ForegroundDetector	Supports MATLAB Function block: No For MATLAB host target: Generates platform-dependent library For nonMATLAB host target: Generates portable C code “System Objects in MATLAB Code Generation”

Name	Remarks and Limitations
vision.HistogramBasedTracker	Supports MATLAB Function block: Yes “System Objects in MATLAB Code Generation”
vision.KalmanFilter	Supports MATLAB Function block: Yes “System Objects in MATLAB Code Generation”
vision.PointTracker	Supports MATLAB Function block: No Generates portable C code using a C++ compiler that links to OpenCV (Version 2.4.9) libraries. “Portable C Code Generation for Functions That Use OpenCV Library” “System Objects in MATLAB Code Generation”
vision.TemplateMatcher	Supports MATLAB Function block: Yes “System Objects in MATLAB Code Generation”
Camera Calibration and Stereo Vision	
bboxOverlapRatio	Supports MATLAB Function block: No
bbox2points	Supports MATLAB® Function block: Yes
disparity	Compile-time constant input restriction: 'Method'. Supports MATLAB Function block: No Generates portable C code using a C++ compiler that links to OpenCV (Version 2.4.9) libraries. “Portable C Code Generation for Functions That Use OpenCV Library”
cameraPoseToExtrinsics	Supports MATLAB Function block: Yes
cameraMatrix	Supports MATLAB Function block: No
cameraPose	Supports MATLAB Function block: No
cameraParameters	Supports MATLAB Function block: No Use the toStruct method to pass a cameraParameters object into generated code. See the “Code Generation for Depth Estimation From Stereo Video” example.

Name	Remarks and Limitations
detectCheckerboardPoints	<p>Supports MATLAB Function block: No Code generation will not support specifying images as file names or cell arrays of file names. It supports only checkerboard detection in a single image or stereo pair of images. For example, these syntaxes are supported:</p> <ul style="list-style-type: none"> • detectCheckerboardPoints(I1) • detectCheckerboardPoints(I1,I2) <p>I1 and I2 are single grayscale or RGB images.</p>
epipolarline	Supports MATLAB Function block: Yes
estimateEssentialMatrix	Supports MATLAB Function block: No
estimateFundamentalMatrix	<p>Compile-time constant input restriction: 'Method', 'OutputClass', 'DistanceType', and 'ReportRuntimeError'. Supports MATLAB Function block: Yes</p>
estimateUncalibratedRectification	Supports MATLAB Function block: Yes
estimateWorldCameraPose	Supports MATLAB Function block: No
extrinsics	Supports MATLAB Function block: No
extrinsicsToCameraPose	Supports MATLAB Function block: Yes
generateCheckerboardPoints	Supports MATLAB Function block: No
isEpipoleInImage	Supports MATLAB Function block: Yes

Control Flow in MATLAB

Function	Remarks and Limitations
break	—
continue	—
end	—
for	—
if, elseif, else	—
parfor	Treated as a for-loop in a MATLAB Function block.
return	—
switch, case, otherwise	<ul style="list-style-type: none"> • If all case expressions are scalar integer values, generates a C <code>switch</code> statement. At run time, if the switch value is not an integer, generates an error. • When the case expressions contain noninteger or nonscalar values, the code generator produces C <code>if</code> statements in place of a C <code>switch</code> statement.
while	—

Control System Toolbox

C and C++ code generation for the following functions requires the Control System Toolbox software.

Name	Remarks and Limitations
extendedKalmanFilter	<p>For more information, see “Generate Code for Online State Estimation in MATLAB”.</p> <p>Supports MATLAB Function block: No</p>
unscentedKalmanFilter	<p>For more information, see “Generate Code for Online State Estimation in MATLAB”.</p> <p>Supports MATLAB Function block: No</p>

Data and File Management in MATLAB

Function	Remarks and Limitations
computer	<ul style="list-style-type: none"> Information about the computer on which the code generator is running. Use only when the code generation target is S-function (Simulation) or MEX-function.
fclose	—
feof	—
fopen	<ul style="list-style-type: none"> Does not support: <ul style="list-style-type: none"> machineformat, encoding, or fileID inputs message output fopen('all') Opening a file in text mode. (The file access type cannot be 'rt'.) If you disable extrinsic calls, you cannot return fileIDs created with fopen to MATLAB or extrinsic functions. You can use such fileIDs only internally. When generating C/C++ executables, static libraries, or dynamic libraries, you can open up to 20 files. The generated code does not report errors from invalid file identifiers. Write your own file open error handling in your MATLAB code. Test whether fopen returns -1, which indicates that the file open failed. For example: <pre> ... fid = fopen(filename, 'r'); if fid == -1 % fopen failed else % fopen successful, okay to call fread A = fread(fid); ... </pre> The behavior of the generated code for fread is compiler-dependent if you: <ol style="list-style-type: none"> Open a file using fopen with a permission of a+.

Function	Remarks and Limitations
	<p>2 Read the file using <code>fread</code> before calling an I/O function, such as <code>fseek</code> or <code>frewind</code>, that sets the file position indicator.</p>
<p><code>fprintf</code></p>	<ul style="list-style-type: none"> • Does not support: <ul style="list-style-type: none"> • <code>b</code> and <code>t</code> subtypes on <code>%u</code>, <code>%o</code> <code>%x</code>, and <code>%X</code> formats. • <code>\$</code> flag for reusing input arguments. • printing arrays. • There is no automatic casting. Input arguments must match their format types for predictable results. • Escaped characters are limited to the decimal range of 0–127. • A call to <code>fprintf</code> with <code>fileID</code> equal to 1 or 2 becomes <code>printf</code> in the generated C/C++ code in the following cases: <ul style="list-style-type: none"> • The <code>fprintf</code> call is inside a <code>parfor</code> loop. • Extrinsic calls are disabled. • When the MATLAB behavior differs from the C compiler behavior, <code>fprintf</code> matches the C compiler behavior in the following cases: <ul style="list-style-type: none"> • The format specifier has a corresponding C format specifier, for example, <code>%e</code> or <code>%E</code>. • The <code>fprintf</code> call is inside a <code>parfor</code> loop. • Extrinsic calls are disabled. • When you call <code>fprintf</code> with the format specifier <code>%s</code>, do not put a null character in the middle of the input character vector. Use <code>fprintf(fid, '%c', char(0))</code> to write a null character. • When you call <code>fprintf</code> with an integer format specifier, the type of the integer argument must be a type that the target hardware can represent as a native C type. For example, if you call <code>fprintf('%d', int64(n))</code>, the target hardware must have a native C type that supports a 64-bit integer.

Function	Remarks and Limitations
fread	<ul style="list-style-type: none"> • <code>precision</code> must be a constant. • The source and output that <code>precision</code> specifies cannot have values long, ulong, unsigned long, bitN, or ubitN. • You cannot use the <code>machineformat</code> input. • If the source or output that <code>precision</code> specifies is a C type, for example, <code>int</code>, the target and production sizes for that type must: <ul style="list-style-type: none"> • Match. • Map directly to a MATLAB type. • The source type that <code>precision</code> specifies must map directly to a C type on the target hardware. • If the <code>fread</code> call reads the entire file, all of the data must fit in the largest array available for code generation. • If <code>sizeA</code> is not constant or contains a nonfinite element, then dynamic memory allocation is required. • Treats a <code>char</code> value for <code>source</code> or <code>output</code> as a signed 8-bit integer. Use values between 0 and 127 only. • The generated code does not report file read errors. Write your own file read error handling in your MATLAB code. Test that the number of bytes read matches the number of bytes that you requested. For example: <pre style="margin-left: 20px;"> ... N = 100; [vals, numRead] = fread(fid, N, '*double'); if numRead ~= N % fewer elements read than expected end ... </pre>
frewind	—

Function	Remarks and Limitations
fseek	<ul style="list-style-type: none"> • When the MATLAB behavior differs from the C compiler behavior, the generated code matches the C compiler behavior. Examples include: <ul style="list-style-type: none"> • Seeking past the end of a file. • Seeking away from the end of a file opened with append access. • The offset is passed to the C run-time environment as a signed long data type. Therefore, the offset value must fit in the long data type on the target hardware.
ftell	<p>When the MATLAB behavior differs from the C compiler behavior, the generated code usually matches the C compiler behavior. For example, if you use <code>fseek</code> to seek past the end of a file, the behavior of <code>ftell</code> in the generated code matches the C compiler behavior.</p>
fwrite	<ul style="list-style-type: none"> • The precision argument must be a constant. • Does not support precision types 'long', 'ulong', 'unsigned long', 'bitn', and 'ubitn'. • Does not support the machine format (order for writing bytes) input argument. • If the precision is a C type such as <code>int</code>, the target and production sizes for that type must: <ul style="list-style-type: none"> • Match. • Map directly to a MATLAB integer type. • Treats a <code>char</code> type as a signed 8-bit integer. Use values from 0 through 127 only. • When appending to a file and using a skip argument, it must be possible for the C run-time <code>fseek</code> to seek beyond the end of the file and initialize unwritten bytes to 0. This behavior matches the behavior of POSIX and Windows.

Function	Remarks and Limitations
load	<ul style="list-style-type: none"> • Use only when generating MEX or code for Simulink simulation. To load compile-time constants, use <code>coder.load</code>. • Does not support use of the function without assignment to a structure or array. For example, use <code>S = load(filename)</code>, not <code>load(filename)</code>. • The output <code>S</code> must be the name of a structure or array without any subscripting. For example, <code>S(i) = load('myFile.mat')</code> is not allowed. • Arguments to <code>load</code> must be compile-time constant character vectors. • Does not support loading objects. • If the MAT-file contains unsupported constructs, use <code>load(filename, variables)</code> to load only the supported constructs. • You cannot use <code>save</code> in a function intended for code generation. The code generator does not support the <code>save</code> function. Furthermore, you cannot use <code>coder.extrinsic</code> with <code>save</code>. Prior to generating code, you can use <code>save</code> to save the workspace data to a MAT-file. <p>You must use <code>coder.ysize</code> to explicitly declare variable-size data loaded using the <code>load</code> function.</p>

Data Types in MATLAB

Function	Remarks and Limitations
cell	“Cell Array Limitations for Code Generation” on page 50-8
deal	—
fieldnames	Does not support objects. The input must be a structure.
iscell	—

Fixed-Point Designer

In addition to function-specific limitations listed in the table, the following general limitations apply to the use of Fixed-Point Designer functions in generated code, with `fiaccl`:

- `fipref` and `quantizer` objects are not supported.
- Word lengths greater than 128 bits are not supported.
- You cannot change the `fimath` or `numericType` of a given `fi` variable after that variable has been created.
- The `boolean` value of the `DataTypeMode` and `DataType` properties are not supported.
- For all `SumMode` property settings other than `FullPrecision`, the `CastBeforeSum` property must be set to `true`.
- You can use parallel `for` (`parfor`) loops in code compiled with `fiaccl`, but those loops are treated like regular `for` loops.
- When you compile code containing `fi` objects with nontrivial slope and bias scaling, you may see different results in generated code than you achieve by running the same code in MATLAB.
- The general limitations of C/C++ code generated from MATLAB apply. For more information, see “MATLAB Language Features Supported for C/C++ Code Generation”.

Function	Remarks/Limitations

Histograms in MATLAB

Function	Remarks and Limitations
hist	<ul style="list-style-type: none"> • Histogram bar plotting not supported. Call with at least one output argument. • If supplied, the second argument <code>x</code> must be a scalar constant. • Inputs must be real. <p>For the syntax <code>[nout, xout] = hist(y,x)</code>:</p> <ul style="list-style-type: none"> • When <code>y</code> is a fixed-size vector or variable-length vector: <ul style="list-style-type: none"> • <code>nout</code> is always a row vector. • If <code>x</code> is a vector, <code>xout</code> is a vector with the same orientation as <code>x</code>. • If <code>x</code> is a scalar (fixed-size), <code>xout</code> is a row vector. • <code>nout</code> and <code>xout</code> are column vectors when the following conditions are true: <ul style="list-style-type: none"> • <code>y</code> is a matrix • <code>size(y,1)</code> and <code>size(y,2)</code> do not have fixed length 1 • One of <code>size(y,1)</code> and <code>size(y,2)</code> has length 1 at run time • A variable-size <code>x</code> is interpreted as a vector input even if it is a scalar at run time. • If at least one of the inputs is empty, vector orientations in the output can differ from MATLAB.

Function	Remarks and Limitations
<code>histc</code>	<ul style="list-style-type: none"> • The output of a variable-size array that becomes a column vector at run time is a column-vector, not a row-vector. • If supplied, <code>dim</code> must be a constant. • “Variable-Sizing Restrictions for Code Generation of Toolbox Functions” on page 48-30

Image Acquisition Toolbox

If you install Image Acquisition Toolbox software, you can generate C and C++ code for the `VideoDevice` System object. See `imaq.VideoDevice` and “Code Generation with `VideoDevice` System Object”.

Image Processing in MATLAB

Function	Remarks and Limitations
<code>im2double</code>	—
<code>rgb2gray</code>	—

Image Processing Toolbox

The following table lists the Image Processing Toolbox functions that have been enabled for code generation. You must have the MATLAB Coder software installed to generate C code from MATLAB for these functions.

Image Processing Toolbox provides three types of code generation support:

- Functions that generate C code.
- Functions that generate C code that depends on a platform-specific shared library (`.dll`, `.so`, or `.dylib`). Use of a shared library preserves performance optimizations in these functions, but this limits the target platforms for which you can generate code. For more information, see “Code Generation for Image Processing”.
- Functions that generate C code or C code that depends on a shared library, depending on which target platform you specify in MATLAB Coder. If you specify the generic `MATLAB Host Computer` target platform, these functions generate C code that depends on a shared library. If you specify any other target platform, these functions generate C code.

In generated code, each supported toolbox function has the same name, arguments, and functionality as its Image Processing Toolbox counterpart. However, some functions have limitations. The following table includes information about code generation limitations that might exist for each function. In the following table, all the functions generate C code. The table identifies those functions that generate C code that depends on a shared library, and those functions that can do both, depending on which target platform you choose.

Function	Remarks/Limitations
<code>adaptthresh</code>	<p>The <code>ForegroundPolarity</code> and <code>Statistic</code> arguments must be compile-time constants.</p> <p>If you choose the generic <code>MATLAB Host Computer</code> target platform, generated code uses a precompiled, platform-specific shared library.</p> <p>MATLAB Function Block support: Yes. The <code>NeighborhoodSize</code> argument must be a compile-time constant.</p>
<code>affine2d</code>	<p>When generating code, you can only specify single objects—arrays of objects are not supported.</p> <p>MATLAB Function Block support: Yes.</p>
<code>boundarymask</code>	<p>The <code>conn</code> argument must be a compile-time constant.</p> <p>If you choose the generic <code>MATLAB Host Computer</code> target platform, generated code uses a precompiled, platform-specific shared library.</p> <p>MATLAB Function Block support: Yes.</p>
<code>bwareaopen</code>	<p><code>BW</code> must be a 2-D binary image. N-D arrays are not supported. <code>conn</code> can only be one of the two-dimensional connectivities (4 or 8) or a 3-by-3 matrix. The 3-D connectivities (6, 18, and 26) are not supported. Matrices of size 3-by-3-by-...-by-3 are not supported. <code>conn</code> must be a compile-time constant.</p> <p>MATLAB Function Block support: No.</p>
<code>bwboundaries</code>	<p>The <code>conn</code> and <code>options</code> arguments must be compile-time constants and the return value <code>A</code> can only be a full matrix, not a sparse matrix.</p> <p>If you choose the generic <code>MATLAB Host Computer</code> target platform, generated code uses a precompiled, platform-specific shared library.</p>

Function	Remarks/Limitations
	MATLAB Function Block support: No.
bwconncomp	<p>The input image must be 2-D.</p> <p>The <code>conn</code> argument must be a compile-time constant and the only connectivities supported are 4 or 8. You can specify connectivity as a 3-by-3 matrix, but it can only be <code>[0 1 0;1 1 1;0 1 0]</code> or <code>ones(3)</code>.</p> <p>The <code>CC</code> struct return value does not include the <code>PixelIdxList</code> field.</p> <p>MATLAB Function Block support: No.</p>
bwdist	<p>The <code>method</code> argument must be a compile-time constant. Input images must have fewer than 2^{32} pixels.</p> <p>Generated code for this function uses a precompiled, platform-specific shared library.</p> <p>MATLAB Function Block support: Yes.</p>
bweuler	<p>If you choose the generic <code>MATLAB Host Computer</code> target platform, generated code uses a precompiled, platform-specific shared library.</p> <p>MATLAB Function Block support: Yes.</p>
bwlabel	<p>When generating code, the parameter <code>n</code> must be a compile-time constant.</p> <p>MATLAB Function Block support: No.</p>
bwlookup	<p>For best results, specify an input image of class <code>logical</code>.</p> <p>If you choose the generic <code>MATLAB Host Computer</code> target platform, generated code uses a precompiled, platform-specific shared library.</p> <p>MATLAB Function Block support: Yes.</p>

Function	Remarks/Limitations
bwmorph	<p>The character vector specifying the operation must be a constant and, for best results, specify an input image of class <code>logical</code>.</p> <p>If you choose the generic <code>MATLAB Host Computer</code> target platform, generated code uses a precompiled, platform-specific shared library.</p> <p>MATLAB Function Block support: No.</p>
bwpack	<p>Generated code for this function uses a precompiled platform-specific shared library.</p> <p>MATLAB Function Block support: Yes.</p>
bwperim	<p>Supports only 2-D images. Does not support any no-output-argument syntaxes. The connectivity matrix input argument, <code>conn</code>, must be a compile-time constant.</p> <p>If you choose the generic <code>MATLAB Host Computer</code> target platform, generated code uses a precompiled, platform-specific shared library.</p> <p>MATLAB Function Block support: Yes.</p>
bwselect	<p>Supports only the 3 and 4 input argument syntaxes: <code>BW2 = bwselect(BW,c,r)</code> and <code>BW2 = bwselect(BW,c,r,n)</code>. The optional fourth input argument, <code>n</code>, must be a compile-time constant. In addition, with code generation, <code>bwselect</code> only supports only the 1 and 2 output argument syntaxes: <code>BW2 = bwselect(____)</code> or <code>[BW2, idx] = bwselect(____)</code>.</p> <p>If you choose the generic <code>MATLAB Host Computer</code> target platform, generated code uses a precompiled, platform-specific shared library.</p> <p>MATLAB Function Block support: Yes.</p>
bwtraceboundary	<p>The <code>dir</code>, <code>fstep</code>, and <code>conn</code> arguments must be compile-time constants.</p> <p>MATLAB Function Block support: No.</p>

Function	Remarks/Limitations
bwunpack	<p>Generated code for this function uses a precompiled platform-specific shared library.</p> <p>MATLAB Function Block support: Yes. The input argument M must be a compile-time constant.</p>
conndef	<p>Input arguments must be compile-time constants.</p> <p>MATLAB Function Block support: Yes.</p>
demosaic	<p>The sensorAlignment argument must be a compile-time constant.</p> <p>MATLAB Function Block support: Yes.</p>
edge	<p>The method, direction, and sigma arguments must be a compile-time constants. In addition, nonprogrammatic syntaxes are not supported. For example, the syntax edge(im), where edge does not return a value but displays an image instead, is not supported.</p> <p>If you choose the generic MATLAB Host Computer target platform, generated code uses a precompiled, platform-specific shared library.</p> <p>MATLAB Function Block support: Yes. The input arguments thresh and sigma must be compile-time constants.</p>
fitgeotrans	<p>The transformtype argument must be a compile-time constant. The function supports the following transformation types: 'nonreflectivesimilarity', 'similarity', 'affine', or 'projective'.</p> <p>MATLAB Function Block support: Yes.</p>
fspecial	<p>Inputs must be compile-time constants. Expressions or variables are allowed if their values do not change.</p> <p>MATLAB Function Block support: Yes. The input arguments hsize, radius, len, and theta must be compile-time constants.</p>
getrangefromclass	<p>MATLAB Function Block support: Yes.</p>

Function	Remarks/Limitations
grayconnected	<p>If you choose the generic MATLAB Host Computer target platform, generated code uses a precompiled, platform-specific shared library.</p> <p>MATLAB Function Block support: Yes.</p>
histeq	<p>All the syntaxes that include indexed images are not supported. This includes all syntaxes that accept <code>map</code> as input and return <code>newmap</code>.</p> <p>If you choose the generic MATLAB Host Computer target platform, generated code uses a precompiled, platform-specific shared library.</p> <p>MATLAB Function Block support: Yes. The input argument <code>N</code> must be a compile-time constant.</p>
hough	<p>The optional parameter names <code>'Theta'</code> and <code>'RhoResolution'</code> must be compile-time character vector constants. The optional <code>Theta</code> vector must have a bounded size.</p> <p>MATLAB Function Block support: Yes. The input argument <code>BW</code> must be fixed size, the <code>RhoResolution</code> parameter must be a compile-time constant, and the <code>Theta</code> vector must have a bounded size.</p>
houghlines	<p>The optional parameter names <code>'FillGap'</code> and <code>'MinLength'</code> must be compile-time character vector constants. Their associated values need not be compile-time constants.</p> <p>MATLAB Function Block support: No.</p>
houghpeaks	<p>The optional parameter names <code>'Threshold'</code> and <code>'NHoodSize'</code> must be compile-time character vector constants. Their associated values need not be compile-time constants.</p> <p>MATLAB Function Block support: Yes.</p>

iptcheckmap	<p>MATLAB Function Block support: Yes.</p>

Function	Remarks/Limitations
lab2rgb	Character vector input arguments must be compile-time constants. MATLAB Function Block support: Yes.
label2idx	MATLAB Function Block support: No.
label2rgb	Referring to the standard syntax: $\text{RGB} = \text{label2rgb}(\text{L}, \text{map}, \text{zerocolor}, \text{order})$ <ul style="list-style-type: none"> • Submit at least two input arguments: the label matrix, <code>L</code>, and the colormap matrix, <code>map</code>. • <code>map</code> must be an <code>n-by-3, double</code>, colormap matrix. You cannot use a character vector containing the name of a MATLAB colormap function or a function handle of a colormap function. • If you set the boundary color <code>zerocolor</code> to the same color as one of the regions, <code>label2rgb</code> will not issue a warning. • If you supply a value for <code>order</code>, it must be <code>'noshuffle'</code>. MATLAB Function Block support: Yes.
mean2	MATLAB Function Block support: Yes.
medfilt2	The <code>padopt</code> argument must be a compile-time constant. If you choose the generic MATLAB Host Computer target platform, generated code uses a precompiled, platform-specific shared library. MATLAB Function Block support: Yes. The neighborhood size input argument must be a compile-time constant.
multithresh	If you choose the generic MATLAB Host Computer target platform, generated code uses a precompiled, platform-specific shared library. MATLAB Function Block support: Yes. The input argument <code>N</code> must be compile-time constant.

Function	Remarks/Limitations
offsetstrel	<p>The 'ball' input argument and all other input arguments must be compile-time constants. None of the methods are supported for code generation. When generating code, you can only specify single objects—arrays of objects are not supported.</p> <p>MATLAB Function Block support: Yes.</p>
ordfilt2	<p>The <code>padopt</code> argument must be a compile-time constant.</p> <p>If you choose the generic MATLAB Host Computer target platform, generated code uses a precompiled, platform-specific shared library.</p> <p>MATLAB Function Block support: Yes.</p>
otsuthresh	<p>MATLAB Function Block support: Yes.</p>
padarray	<p>Support only up to 3-D inputs.</p> <p>Input arguments, <code>padval</code> and <code>direction</code> are expected to be compile-time constants.</p> <p>MATLAB Function Block support: Yes. The input argument <code>padsize</code> must be a compile-time constant.</p>
projective2d	<p>When generating code, you can only specify single objects—arrays of objects are not supported.</p> <p>MATLAB Function Block support: Yes.</p>
psnr	<p>MATLAB Function Block support: Yes.</p>
regionprops	<p>Supports only 2-D images. Does not support the table output type. Does not accept cell arrays as input—use a comma-separated list instead. Does not support the properties <code>ConvexArea</code>, <code>ConvexHull</code>, <code>ConvexImage</code>, <code>Solidity</code>, and <code>SubarrayIdx</code>.</p> <p>If you choose the generic MATLAB Host Computer target platform, generated code uses a precompiled, platform-specific shared library.</p> <p>MATLAB Function Block support: No.</p>
rgb2gray	<p>MATLAB Function Block support: Yes.</p>

Function	Remarks/Limitations
rgb2lab	Character vector input arguments must be compile-time constants. MATLAB Function Block support: Yes.
rgb2ycbcr	If you choose the generic MATLAB Host Computer target platform, generated code uses a precompiled, platform-specific shared library. MATLAB Function Block support: Yes.
strel	All of the input arguments must be compile-time constants. None of the methods are supported for code generation. When generating code, you can only specify single objects—arrays of objects are not supported. MATLAB Function Block support: Yes.
stretchlim	If you choose the generic MATLAB Host Computer target platform, generated code uses a precompiled, platform-specific shared library. MATLAB Function Block support: Yes.
superpixels	Character vector input arguments must be compile-time constants. The value of 'IsInputLabel' (true or false) must be a compile-time constant. MATLAB Function Block support: No.
watershed	Supports only 2-D images. Supports only 4- or 8-connectivity. Supports only up to 65,535 regions. The output type is always <code>uint16</code> . If you choose the generic MATLAB Host Computer target platform, generated code uses a precompiled, platform-specific shared library. MATLAB Function Block support: No.
ycbcr2rgb	If you choose the generic MATLAB Host Computer target platform, generated code uses a precompiled, platform-specific shared library. MATLAB Function Block support: Yes.

Input and Output Arguments in MATLAB

Function	Remarks and Limitations
nargin	—

Function	Remarks and Limitations
nargout	<ul style="list-style-type: none"> For a function with no output arguments, returns 1 if called without a terminating semicolon. <hr/> <p>Note: This behavior also affects extrinsic calls with no terminating semicolon. nargout is 1 for the called function in MATLAB.</p>

Interpolation and Computational Geometry in MATLAB

Function	Remarks and Limitations
cart2pol	—
cart2sph	—
inpolygon	Supports single-precision and double-precision inputs, but uses double-precision arithmetic even if all inputs are single-precision.
interp1	<ul style="list-style-type: none"> Does not support the 'cubic' method. Instead, use 'v5cubic' or 'spline'. The input argument <i>x</i> (sample points) must be strictly increasing or strictly decreasing. Indices are not reordered. If the input argument <i>v</i> (sample values) is a variable-length vector (1-by-: or :-by-1), the shape of the output <i>vq</i> matches the shape in MATLAB. <p>If the input argument <i>v</i> is variable-size, is not a variable-length vector, and becomes a row vector at run time, an error occurs.</p> <ul style="list-style-type: none"> If the input argument <i>xq</i> (query points) is variable-size, is not a variable-length vector, and becomes a row or column vector at run time, an error occurs. “Variable-Sizing Restrictions for Code Generation of Toolbox Functions” on page 48-30
interp1q	Might not match MATLAB when some <i>Y</i> values are Inf or NaN.
interp2	<ul style="list-style-type: none"> <i>Xq</i> and <i>Yq</i> must be the same size. Use <code>meshgrid</code> to evaluate on a grid. For best results, provide <i>X</i> and <i>Y</i> as vectors.

Function	Remarks and Limitations
	<ul style="list-style-type: none"> • For the 'cubic' method, reports an error if the grid does not have uniform spacing. In this case, use the 'spline' method. • For best results when you use the 'spline' method: <ul style="list-style-type: none"> • Use <code>meshgrid</code> to create the inputs <code>Xq</code> and <code>Yq</code>. • Use a small number of interpolation points relative to the dimensions of <code>V</code>. Interpolating over a large set of scattered points can be inefficient.
interp3	<ul style="list-style-type: none"> • <code>Xq</code>, <code>Yq</code>, and <code>Zq</code> must be the same size. Use <code>meshgrid</code> to evaluate on a grid. • For best results, provide <code>X</code>, <code>Y</code>, and <code>Z</code> as vectors. • For the 'cubic' method, reports an error if the grid does not have uniform spacing. In this case, use the 'spline' method. • For best results when you use the 'spline' method: <ul style="list-style-type: none"> • Use <code>meshgrid</code> to create the inputs <code>Xq</code>, <code>Yq</code>, and <code>Zq</code>. • Use a small number of interpolation points relative to the dimensions of <code>V</code>. Interpolating over a large set of scattered points can be inefficient.
interp _n	<ul style="list-style-type: none"> • For best results, provide <code>X1</code>, <code>X2</code>, . . . , <code>X_n</code> as vectors. • Does not support the 'cubic' or 'spline' methods for 2-D and higher interpolation. • The interpolation method must be a constant character vector.
meshgrid	—

Function	Remarks and Limitations
mkpp	<ul style="list-style-type: none"> • The output structure <code>pp</code> differs from the <code>pp</code> structure in MATLAB. In MATLAB, <code>ppval</code> cannot use the <code>pp</code> structure from the code generator. For code generation, <code>ppval</code> cannot use a <code>pp</code> structure created by MATLAB. <code>unmkpp</code> can use a MATLAB <code>pp</code> structure for code generation. <p>To create a MATLAB <code>pp</code> structure from a <code>pp</code> structure created by the code generator:</p> <ul style="list-style-type: none"> • In code generation, use <code>unmkpp</code> to return the piecewise polynomial details to MATLAB. • In MATLAB, use <code>mkpp</code> to create the <code>pp</code> structure. <ul style="list-style-type: none"> • If you do not provide <code>d</code>, then <code>coefs</code> must be two-dimensional and have a fixed number of columns. In this case, the number of columns is the order. • To define a piecewise constant polynomial, <code>coefs</code> must be a column vector or <code>d</code> must have at least two elements. • If you provide <code>d</code> and <code>d</code> is 1, <code>d</code> must be a constant. Otherwise, if the input to <code>ppval</code> is nonscalar, the shape of the output of <code>ppval</code> can differ from <code>ppval</code> in MATLAB. • If you provide <code>d</code>, it must have a fixed length. One of the following sets of statements must be true: <ol style="list-style-type: none"> 1 Suppose that <code>m = length(d)</code> and <code>npieces = length(breaks) - 1</code>. <pre style="margin-left: 40px;">size(coefs,j) = d(j) size(coefs,m+1) = npieces size(coefs,m+2) = order j = 1,2,...,m. The dimension m+2 must be fixed length.</pre> 2 Suppose that <code>m = length(d)</code> and <code>npieces = length(breaks) - 1</code>. <pre style="margin-left: 40px;">size(coefs,1) = prod(d)*npieces size(coefs,2) = order The second dimension must be fixed length.</pre> <ul style="list-style-type: none"> • If you do not provide <code>d</code>, the following statements must be true:

Function	Remarks and Limitations
	Suppose that $m = \text{length}(d)$ and $\text{npieces} = \text{length}(\text{breaks}) - 1$. $\text{size}(\text{coefs},1) = \text{prod}(d) * \text{npieces}$ $\text{size}(\text{coefs},2) = \text{order}$ The second dimension must be fixed length.
pchip	<ul style="list-style-type: none"> • Input x must be strictly increasing. • Does not remove y entries with NaN values. • If you generate code for the $\text{pp} = \text{pchip}(x,y)$ syntax, you cannot input pp to the ppval function in MATLAB. To create a MATLAB pp structure from a pp structure created by the code generator: <ul style="list-style-type: none"> • In code generation, use unmkpp to return the piecewise polynomial details to MATLAB. • In MATLAB, use mkpp to create the pp structure.
pol2cart	—
polyarea	—
ppval	The size of output v does not match MATLAB when both of the following statements are true: <ul style="list-style-type: none"> • The input x is a variable-size array that is not a variable-length vector. • x becomes a row vector at run time. The code generator does not remove the singleton dimensions. However, MATLAB might remove singleton dimensions. For example, suppose that x is a $:4\text{-by-}:5$ array (the first dimension is variable size with an upper bound of 4 and the second dimension is variable size with an upper bound of 5). Suppose that $\text{ppval}(\text{pp},0)$ returns a $2\text{-by-}3$ fixed-size array. v has size $2\text{-by-}3\text{-by-}:4\text{-by-}:5$. At run time, suppose that, $\text{size}(x,1) = 1$ and $\text{size}(x,2) = 5$. In the generated code, the $\text{size}(v)$ is $[2,3,1,5]$. In MATLAB, the size is $[2,3,5]$.
rectint	—
sph2cart	—

Function	Remarks and Limitations
spline	<ul style="list-style-type: none"> • Input <code>x</code> must be strictly increasing. • Does not remove <code>Y</code> entries with NaN values. • Does not report an error for infinite end slopes in <code>Y</code>. • If you generate code for the <code>pp = spline(x, Y)</code> syntax, you cannot input <code>pp</code> to the <code>ppval</code> function in MATLAB. To create a MATLAB <code>pp</code> structure from a <code>pp</code> structure created by the code generator: <ul style="list-style-type: none"> • In code generation, use <code>unmkpp</code> to return the piecewise polynomial details to MATLAB. • In MATLAB, use <code>mkpp</code> to create the <code>pp</code> structure.
unmkpp	<ul style="list-style-type: none"> • <code>pp</code> must be a valid piecewise polynomial structure created by <code>mkpp</code>, <code>spline</code>, or <code>pchip</code> in MATLAB or by the code generator. • Does not support <code>pp</code> structures created by <code>interp1</code> in MATLAB.

Function	Remarks and Limitations
eig	<ul style="list-style-type: none"> • V might represent a different basis of eigenvectors, and the eigenvalues in D might not be in the same order as in MATLAB. • For the generalized eigenvalue problem, $[V,D] = \text{eig}(A,B)$, the 'qz' option is always used. • For the standard eigenvalue problem, $[V,D] = \text{eig}(A)$, when A is Hermitian, <code>schur</code> is used to calculate V and D. Otherwise, the results of $[V,D] = \text{eig}(A)$ are similar to those obtained using $[V,D] = \text{eig}(A, \text{eye}(\text{size}(A)), 'qz')$ in MATLAB, except that the columns of V are normalized. • Options 'balance', and 'nobalance' are not supported for the standard eigenvalue problem. 'chol' is not supported for the symmetric generalized eigenvalue problem. • Outputs are of complex type. • Does not support the option to calculate left eigenvectors.
eye	<ul style="list-style-type: none"> • <code>classname</code> must be a built-in MATLAB numeric type. Does not invoke the static <code>eye</code> method for other classes. For example, <code>eye(m, n, 'myclass')</code> does not invoke <code>myclass.eye(m, n)</code>. • Size arguments must have a fixed size.
false	<ul style="list-style-type: none"> • Dimensions must be real, nonnegative, integers.
find	<ul style="list-style-type: none"> • Issues an error if a variable-size input becomes a row vector at run time. <hr/> <p>Note: This limitation does not apply when the input is scalar or a variable-length row vector.</p> <hr/> <ul style="list-style-type: none"> • For variable-size inputs, the shape of empty outputs, 0-by-0, 0-by-1, or 1-by-0, depends on the upper bounds of the size of the input. The output might not match MATLAB when the input array is a scalar or <code>[]</code> at run time. If the input is a variable-length row vector, the size of an empty output is 1-by-0, otherwise it is 0-by-1. • Always returns a variable-length vector. Even when you provide the output vector <code>k</code>, the output cannot be fixed-size because the output can contain fewer than <code>k</code> elements. For example, <code>find(x, 1)</code> returns a variable-length vector with 1 or 0 elements.

Function	Remarks and Limitations

filter	<ul style="list-style-type: none"> • If supplied, <code>dim</code> must be a constant. • <code>v</code>

Function	Remarks and Limitations
freqspace	—
ifft	<ul style="list-style-type: none"> • Output is complex. • Does not support the 'symmetric' option. • “Variable-Sizing Restrictions for Code Generation of Toolbox Functions” on page 48-30
ifft2	Does not support the 'symmetric' option.
ifftn	<ul style="list-style-type: none"> • Does not support the 'symmetric' option. • The <code>siz</code> argument must have a fixed size.
ifftshift	—
svd	Uses a different SVD implementation than MATLAB. Because the singular value decomposition is not unique, left and right singular vectors might differ from those computed by MATLAB.
zp2tf	—

Signal Processing Toolbox

C and C++ code generation for the following functions requires the Signal Processing Toolbox software. These functions do not support variable-size inputs, you must define the size and type of the function inputs. For more information, see “Specifying Inputs in Code Generation from MATLAB”.

Note: Many Signal Processing Toolbox functions require constant inputs in generated code. To specify a constant input for `codegen`, use `coder.Constant`.

Function	Remarks/Limitations
barthannwin	Window length must be a constant. Expressions or variables are allowed if their values do not change.
bartlett	Window length must be a constant. Expressions or variables are allowed if their values do not change.
besselap	Filter order must be a constant. Expressions or variables are allowed if their values do not change.

Function	Remarks/Limitations
bitrevorder	—
blackman	Window length must be a constant. Expressions or variables are allowed if their values do not change.
blackmanharris	Window length must be a constant. Expressions or variables are allowed if their values do not change.
bohmanwin	Window length must be a constant. Expressions or variables are allowed if their values do not change.
buttap	Filter order must be a constant. Expressions or variables are allowed if their values do not change.
butter	Filter coefficients must be constants. Expressions or variables are allowed if their values do not change.
buttord	All inputs must be constants. Expressions or variables are allowed if their values do not change.
cfirpm	All inputs must be constants. Expressions or variables are allowed if their values do not change.
cheb1ap	All inputs must be constants. Expressions or variables are allowed if their values do not change.
cheb2ap	All inputs must be constants. Expressions or variables are allowed if their values do not change.
cheb1ord	All inputs must be constants. Expressions or variables are allowed if their values do not change.
cheb2ord	All inputs must be constants. Expressions or variables are allowed if their values do not change.
chebwin	All inputs must be constants. Expressions or variables are allowed if their values do not change.
cheby1	All Inputs must be constants. Expressions or variables are allowed if their values do not change.
cheby2	All inputs must be constants. Expressions or variables are allowed if their values do not change.
db2pow	—

Function	Remarks/Limitations
dct	<p>C and C++ code generation for <code>dct</code> requires DSP System Toolbox software.</p> <p>Length of transform dimension must be a power of two. If specified, the pad or truncation value must be constant. Expressions or variables are allowed if their values do not change.</p>
downsample	—
dpss	All inputs must be constants. Expressions or variables are allowed if their values do not change.
ellip	Inputs must be constant. Expressions or variables are allowed if their values do not change.
ellipap	All inputs must be constants. Expressions or variables are allowed if their values do not change.
ellipord	All inputs must be constants. Expressions or variables are allowed if their values do not change.
filtfilt	<p>Filter coefficients must be constants. Expressions or variables are allowed if their values do not change.</p> <p>Code generation does not support second-order sections as input. You must use transfer functions.</p>
findpeaks	—
fir1	All inputs must be constants. Expressions or variables are allowed if their values do not change.
fir2	All inputs must be constants. Expressions or variables are allowed if their values do not change.
fircls	All inputs must be constants. Expressions or variables are allowed if their values do not change.
fircls1	All inputs must be constants. Expressions or variables are allowed if their values do not change.
firls	All inputs must be constants. Expressions or variables are allowed if their values do not change.
firpm	All inputs must be constants. Expressions or variables are allowed if their values do not change.

Function	Remarks/Limitations
firpmord	All inputs must be constants. Expressions or variables are allowed if their values do not change.
flattopwin	All inputs must be constants. Expressions or variables are allowed if their values do not change.
freqz	<ul style="list-style-type: none"> • Does not support variable-size inputs. • When called with no output arguments, and without a semicolon at the end, <code>freqz</code> returns the complex frequency response of the input filter, evaluated at 512 points. <p>If the semicolon is added, the function produces a plot of the magnitude and phase response of the filter.</p> <p>See “freqz With No Output Arguments”.</p>
gausswin	All inputs must be constant. Expressions or variables are allowed if their values do not change.
hamming	All inputs must be constant. Expressions or variables are allowed if their values do not change.
hann	All inputs must be constant. Expressions or variables are allowed if their values do not change.
idct	<p>C and C++ code generation for <code>idct</code> requires DSP System Toolbox software.</p> <p>Length of transform dimension must be a power of two. If specified, the <code>pad</code> or <code>truncation</code> value must be constant. Expressions or variables are allowed if their values do not change.</p>
intfilt	All inputs must be constant. Expressions or variables are allowed if their values do not change.
kaiser	All inputs must be constant. Expressions or variables are allowed if their values do not change.
kaiserord	—

Function	Remarks/Limitations
levinson	<p>C and C++ code generation for <code>levinson</code> requires DSP System Toolbox software.</p> <p>If specified, the order of recursion must be a constant. Expressions or variables are allowed if their values do not change.</p>
maxflat	All inputs must be constant. Expressions or variables are allowed if their values do not change.
nuttallwin	All inputs must be constant. Expressions or variables are allowed if their values do not change.
parzenwin	All inputs must be constant. Expressions or variables are allowed if their values do not change.

Function	Remarks and Limitations
ClassificationE or CompactClassif	<p>When you train one of these models using <code>fitcecoc</code> or Classification Learner:</p> <ul style="list-style-type: none"> • The predictor variables in the input argument <code>Tbl</code> cannot be sparse. The predictor data input argument value <code>X</code> must be a full, numeric matrix. • The class labels input argument value (<code>Y</code>) cannot be a categorical array. • The <code>ClassNames</code> name-value pair argument cannot be a categorical array. • You cannot use the <code>CategoricalPredictors</code> name-value pair argument or supply a table containing at least one categorical predictor. That is, code generation does not support categorical predictors. To dummy-code variables that you want treated as categorical, use <code>dummyvar</code>. • All binary learners must be support vector machines or logistic-regression, linear classification models. That is, for the <code>Learners</code> name-value pair argument, you can specify <ul style="list-style-type: none"> • <code>'svm'</code> • An SVM template object or a cell vector of such objects (see <code>templateSVM</code>). • A linear classification model template object or a cell vector of such objects (see <code>templateLinear</code>). • For limitations on <code>ClassificationSVM</code> or <code>ClassificationLinear</code> model objects, see their entries in this table. • You cannot specify to fit posterior probabilities by using the <code>FitPosterior</code> name-value pair argument.

Function	Remarks and Limitations
ClassificationLi	<p>When you train one of these models using <code>fitclinear</code>:</p> <ul style="list-style-type: none"> • The predictor data input argument value <code>X</code> must be a full, numeric matrix. • The class labels input argument value (<code>Y</code>) cannot be a categorical array. • The <code>ClassNames</code> name-value pair argument cannot be a categorical array. • Logistic regression learners are supported only. That is, you can specify <code>'logistic'</code> only for the <code>Learner</code> name-value pair argument. • You can specify one regularization strength only. That is, you can specify <code>'auto'</code> or a nonnegative scalar only for the <code>Lambda</code> name-value pair argument. • You cannot specify a score transformation function by using the <code>ScoreTransform</code> name-value pair argument or by assigning the <code>ScoreTransform</code> object property.
ClassificationS or CompactClassif	<p>When you train one of these models using <code>fitsvm</code> or <code>Classification Learner</code>:</p> <ul style="list-style-type: none"> • The class labels input argument value (<code>Y</code>) cannot be a categorical array. • The <code>ClassNames</code> name-value pair argument cannot be a categorical array. • You cannot use the <code>CategoricalPredictors</code> name-value pair argument or supply a table containing at least one categorical predictor. That is, code generation does not support categorical predictors. To dummy-code variables that you want treated as categorical, use <code>dummyvar</code>. • MATLAB does not support one-class learning. • You cannot specify a score transformation function by using the <code>ScoreTransform</code> name-value pair argument or by assigning the <code>ScoreTransform</code> object property. Consequently, <code>saveCompactModel</code> cannot accept compact SVM models equipped to estimate class posterior probabilities, that is, models returned by <code>fitPosterior</code> or <code>fitSVMPosterior</code>.

Function	Remarks and Limitations																				
predict method of <code>ClassificationCompactClass</code>	<ul style="list-style-type: none"> You must call <code>predict</code> within a function that you declare (that is, you cannot call <code>predict</code> at the top-level). System Objects Supported for Code Generation

Code Generation for System Objects

You can generate C and C++ code for a subset of System objects provided by the following toolboxes.

Toolbox Name	See
Communications System Toolbox	“System Objects in MATLAB Code Generation” in the DSP System Toolbox documentation.
Computer Vision System Toolbox	“System Objects in MATLAB Code Generation” in the Computer Vision System Toolbox documentation.
DSP System Toolbox	“System Objects in MATLAB Code Generation” in the DSP System Toolbox documentation.
Image Acquisition Toolbox	<ul style="list-style-type: none"> • <code>imaq.VideoDevice</code>. • “Code Generation with VideoDevice System Object” in the Image Acquisition Toolbox documentation.
Phased Array System Toolbox	“Code Generation” in the Phased Array System Toolbox documentation.
System Identification Toolbox	“Generate Code for Online Parameter Estimation in MATLAB” in the System Identification Toolbox documentation.
WLAN System Toolbox	“System Objects in MATLAB Code Generation” in the DSP System Toolbox documentation.

To use these System objects, you need to install the requisite toolbox. For a list of System objects supported for C and C++ code generation, see “Functions and Objects Supported for C/C++ Code Generation — Alphabetical List” on page 44-2 and “Functions and Objects Supported for C/C++ Code Generation — Category List” on page 44-186.

System objects are MATLAB object-oriented implementations of algorithms. They extend MATLAB by enabling you to model dynamic systems represented by time-varying algorithms. System objects are well integrated into the MATLAB language, regardless of

whether you are writing simple functions, working interactively in the command window, or creating large applications.

In contrast to MATLAB functions, System objects automatically manage state information, data indexing, and buffering, which is particularly useful for iterative computations or stream data processing. This enables efficient processing of long data sets. For general information about MATLAB objects, see “Object-Oriented Programming”.

Defining MATLAB Variables for C/C++ Code Generation

- “Variables Definition for Code Generation” on page 46-2
- “Best Practices for Defining Variables for C/C++ Code Generation” on page 46-3
- “Eliminate Redundant Copies of Variables in Generated Code” on page 46-7
- “Reassignment of Variable Properties” on page 46-9
- “Reuse the Same Variable with Different Properties” on page 46-10
- “Avoid Overflows in for-Loops” on page 46-14
- “Supported Variable Types” on page 46-16

Variables Definition for Code Generation

In the MATLAB language, variables can change their properties dynamically at run time so you can use the same variable to hold a value of any class, size, or complexity. For example, the following code works in MATLAB:

```
function x = foo(c) %#codegen
if(c>0)
    x = 0;
else
    x = [1 2 3];
end
disp(x);
end
```

However, statically-typed languages like C must be able to determine variable properties at compile time. Therefore, for C/C++ code generation, you must explicitly define the class, size, and complexity of variables in MATLAB source code before using them. For example, rewrite the above source code with a definition for *x*:

```
function x = foo(c) %#codegen
x = zeros(1,3);
if(c>0)
    x = 0;
else
    x = [1 2 3];
end
disp(x);
end
```

For more information, see “Best Practices for Defining Variables for C/C++ Code Generation” on page 46-3.

Best Practices for Defining Variables for C/C++ Code Generation

In this section...

“Define Variables By Assignment Before Using Them” on page 46-3

“Use Caution When Reassigning Variables” on page 46-5

“Use Type Cast Operators in Variable Definitions” on page 46-5

“Define Matrices Before Assigning Indexed Variables” on page 46-6

Define Variables By Assignment Before Using Them

For C/C++ code generation, you should explicitly and unambiguously define the class, size, and complexity of variables before using them in operations or returning them as outputs. Define variables by assignment, but note that the assignment copies not only the value, but also the size, class, and complexity represented by that value to the new variable. For example:

Assignment:	Defines:
<code>a = 14.7;</code>	a as a real double scalar.
<code>b = a;</code>	b with properties of a (real double scalar).
<code>c = zeros(5,2);</code>	c as a real 5-by-2 array of doubles.
<code>d = [1 2 3 4 5; 6 7 8 9 0];</code>	d as a real 5-by-2 array of doubles.
<code>y = int16(3);</code>	y as a real 16-bit integer scalar.

Define properties this way so that the variable is defined on the required execution paths during C/C++ code generation (see Defining a Variable for Multiple Execution Paths).

The data that you assign to a variable can be a scalar, matrix, or structure. If your variable is a structure, define the properties of each field explicitly (see Defining Fields in a Structure).

Initializing the new variable to the value of the assigned data sometimes results in redundant copies in the generated code. To avoid redundant copies, you can define variables without initializing their values by using the `coder.nullcopy` construct as described in “Eliminate Redundant Copies of Variables in Generated Code” on page 46-7.

When you define variables, they are local by default; they do not persist between function calls. To make variables persistent, see `persistent`.

Defining a Variable for Multiple Execution Paths

Consider the following MATLAB code:

```
...
if c > 0
    x = 11;
end
% Later in your code ...
if c > 0
    use(x);
end
...
```

Here, x is assigned only if $c > 0$ and used only when $c > 0$. This code works in MATLAB, but generates a compilation error during code generation because it detects that x is undefined on some execution paths (when $c \leq 0$),

To make this code suitable for code generation, define x before using it:

```
x = 0;
...
if c > 0
    x = 11;
end
% Later in your code ...
if c > 0
    use(x);
end
...
```

Defining Fields in a Structure

Consider the following MATLAB code:

```
...
if c > 0
    s.a = 11;
    disp(s);
else
    s.a = 12;
    s.b = 12;
end
```

```

end
% Try to use s
use(s);
...

```

Here, the first part of the `if` statement uses only the field `a`, and the `else` clause uses fields `a` and `b`. This code works in MATLAB, but generates a compilation error during C/C++ code generation because it detects a structure type mismatch. To prevent this error, do not add fields to a structure after you perform certain operations on the structure. For more information, see “Structure Definition for Code Generation” on page 49-2.

To make this code suitable for C/C++ code generation, define all fields of `s` before using it.

```

...
% Define all fields in structure s
s = struct('a',0, 'b', 0);
if c > 0
    s.a = 11;
    disp(s);
else
    s.a = 12;
    s.b = 12;
end
% Use s
use(s);
...

```

Use Caution When Reassigning Variables

In general, you should adhere to the "one variable/one type" rule for C/C++ code generation; that is, each variable must have a specific class, size and complexity. Generally, if you reassign variable properties after the initial assignment, you get a compilation error during code generation, but there are exceptions, as described in “Reassignment of Variable Properties” on page 46-9.

Use Type Cast Operators in Variable Definitions

By default, constants are of type `double`. To define variables of other types, you can use type cast operators in variable definitions. For example, the following code defines variable `y` as an integer:

```

...
x = 15; % x is of type double by default.

```

```
y = uint8(x); % y has the value of x, but cast to uint8.  
...
```

Define Matrices Before Assigning Indexed Variables

When generating C/C++ code from MATLAB, you cannot grow a variable by writing into an element beyond its current size. Such indexing operations produce run-time errors. You must define the matrix first before assigning values to its elements.

For example, the following initial assignment is not allowed for code generation:

```
g(3,2) = 14.6; % Not allowed for creating g  
           % OK for assigning value once created
```

For more information about indexing matrices, see “Incompatibility with MATLAB in Matrix Indexing Operations for Code Generation” on page 48-27.

Eliminate Redundant Copies of Variables in Generated Code

In this section...

“When Redundant Copies Occur” on page 46-7

“How to Eliminate Redundant Copies by Defining Uninitialized Variables” on page 46-7

“Defining Uninitialized Variables” on page 46-8

When Redundant Copies Occur

During C/C++ code generation, the code generator checks for statements that attempt to access uninitialized memory. If it detects execution paths where a variable is used but is potentially not defined, it generates a compile-time error. To prevent these errors, define variables by assignment before using them in operations or returning them as function outputs.

Note, however, that variable assignments not only copy the properties of the assigned data to the new variable, but also initialize the new variable to the assigned value. This forced initialization sometimes results in redundant copies in C/C++ code. To eliminate redundant copies, define uninitialized variables by using the `coder.nullcopy` function, as described in “How to Eliminate Redundant Copies by Defining Uninitialized Variables” on page 46-7.

How to Eliminate Redundant Copies by Defining Uninitialized Variables

- 1 Define the variable with `coder.nullcopy`.
- 2 Initialize the variable before reading it.

When the uninitialized variable is an array, you must initialize all of its elements before passing the array as an input to a function or operator — even if the function or operator does not read from the uninitialized portion of the array.

What happens if you access uninitialized data?

Uninitialized memory contains arbitrary values. Therefore, accessing uninitialized data may lead to segmentation violations or nondeterministic program behavior (different runs of the same program may yield inconsistent results).

Defining Uninitialized Variables

In the following code, the assignment statement `X = zeros(1,N)` not only defines `X` to be a 1-by-5 vector of real doubles, but also initializes each element of `X` to zero.

```
function X = fcn %#codegen

N = 5;
X = zeros(1,N);
for i = 1:N
    if mod(i,2) == 0
        X(i) = i;
    else
        X(i) = 0;
    end
end
```

This forced initialization creates an extra copy in the generated code. To eliminate this overhead, use `coder.nullcopy` in the definition of `X`:

```
function X = fcn2 %#codegen

N = 5;
X = coder.nullcopy(zeros(1,N));
for i = 1:N
    if mod(i,2) == 0
        X(i) = i;
    else
        X(i) = 0;
    end
end
```

Reassignment of Variable Properties

For C/C++ code generation, there are certain variables that you can reassign after the initial assignment with a value of different class, size, or complexity:

Dynamically sized variables

A variable can hold values that have the same class and complexity but different sizes. If the size of the initial assignment is not constant, the variable is dynamically sized in generated code. For more information, see “Variable-Size Data”.

Variables reused in the code for different purposes

You can reassign the type (class, size, and complexity) of a variable after the initial assignment if each occurrence of the variable can have only one type. In this case, the variable is renamed in the generated code to create multiple independent variables. For more information, see “Reuse the Same Variable with Different Properties” on page 46-10.

Reuse the Same Variable with Different Properties

In this section...

“When You Can Reuse the Same Variable with Different Properties” on page 46-10

“When You Cannot Reuse Variables” on page 46-10

“Limitations of Variable Reuse” on page 46-13

When You Can Reuse the Same Variable with Different Properties

You can reuse (reassign) an input, output, or local variable with different class, size, or complexity if the code generator can unambiguously determine the properties of each occurrence of this variable during C/C++ code generation. If so, MATLAB creates separate uniquely named local variables in the generated code. You can view these renamed variables in the code generation report (see “MATLAB Code Variables in a Report” on page 39-52).

A common example of variable reuse is in `if-elseif-else` or `switch-case` statements. For example, the following function `example1` first uses the variable `t` in an `if` statement, where it holds a scalar double, then reuses `t` outside the `if` statement to hold a vector of doubles.

```
function y = example1(u) %#codegen
if all(all(u>0))
    % First, t is used to hold a scalar double value
    t = mean(mean(u)) / numel(u);
    u = u - t;
end
% t is reused to hold a vector of doubles
t = find(u > 0);
y = sum(u(t(2:end-1)));
```

To compile this example and see how MATLAB renames the reused variable `t`, see Variable Reuse in an `if` Statement.

When You Cannot Reuse Variables

You cannot reuse (reassign) variables if it is not possible to determine the class, size, and complexity of an occurrence of a variable unambiguously during code generation. In this case, variables cannot be renamed and a compilation error occurs.

For example, the following `example2` function assigns a fixed-point value to `x` in the `if` statement and reuses `x` to store a matrix of doubles in the `else` clause. It then uses `x` after the `if-else` statement. This function generates a compilation error because after the `if-else` statement, variable `x` can have different properties depending on which `if-else` clause executes.

```
function y = example2(use_fixpoint, data) %#codegen
    if use_fixpoint
        % x is fixed-point
        x = fi(data, 1, 12, 3);
    else
        % x is a matrix of doubles
        x = data;
    end
    % When x is reused here, it is not possible to determine its
    % class, size, and complexity
    t = sum(sum(x));
    y = t > 0;
end
```

Variable Reuse in an if Statement

To see how MATLAB renames a reused variable `t`:

- 1 Create a MATLAB file `example1.m` containing the following code.

```
function y = example1(u) %#codegen
if all(all(u>0))
    % First, t is used to hold a scalar double value
    t = mean(mean(u)) / numel(u);
    u = u - t;
end
% t is reused to hold a vector of doubles
t = find(u > 0);
y = sum(u(t(2:end-1)));
end
```

- 2 Compile `example1`.

For example, to generate a MEX function, enter:

```
codegen -o example1x -report example1.m -args {ones(5,5)}
```

Note: `codegen` requires a MATLAB Coder license.

When the compilation is complete, `codegen` generates a MEX function, `example1x` in the current folder, and provides a link to the code generation report.

- 3 Open the code generation report.
- 4 In the MATLAB code pane of the code generation report, place your pointer over the variable `t` inside the `if` statement.

The code generation report highlights both instances of `t` in the `if` statement because they share the same class, size, and complexity. It displays the data type information for `t` at this point in the code. Here, `t` is a scalar double.

```
% First time t is used to hold a scalar double value.
t = mean(mean(u)) / numel(u);
u = u - t;
```

Information for the selected variable:	
Size	1 x 1
Complex	No
Class	double

- 5 In the MATLAB code pane of the report, place your pointer over the variable `t` outside the for-loop.

This time, the report highlights both instances of `t` outside the `if` statement. The report indicates that `t` might hold up to 25 doubles. The size of `t` is `:25`, that is, a column vector containing a maximum of 25 doubles.

```
t = find(u);
y = sum(u(t(2:end-1)));
```

Information for the selected variable:	
Size	:25
Complex	No
Class	double

- 6 Click the **Variables** tab to view the list of variables used in `example1`.

The report displays a list of the variables in `example1`. There are two uniquely named local variables `t>1` and `t>2`.

- 7 In the list of variables, place your pointer over `t>1`.

The code generation report highlights both instances of `t` in the `if` statement.

- 8 In the list of variables, place your pointer over `t>2`

The code generation report highlights both instances of `t` outside the `if` statement.

Limitations of Variable Reuse

The following variables cannot be renamed in generated code:

- Persistent variables.
- Global variables.
- Variables passed to C code using `coder.ref`, `coder.rref`, `coder.wref`.
- Variables whose size is set using `coder.ysize`.
- Variables whose names are controlled using `coder.cstructname`.
- The index variable of a `for`-loop when it is used inside the loop body.
- The block outputs of a MATLAB Function block in a Simulink model.
- Chart-owned variables of a MATLAB function in a Stateflow chart.

Avoid Overflows in for-Loops

When memory integrity checks are enabled, if the code generator detects that a loop variable might overflow on the last iteration of the `for`-loop, it reports an error.

To avoid this error, use the workarounds provided in the following table.

Loop conditions causing the error	Workaround
<ul style="list-style-type: none"> The loop counter increments by 1 The end value equals the maximum value of the integer type The loop is not covering the full range of the integer type 	<p>Rewrite the loop so that the end value is not equal to the maximum value of the integer type. For example, replace:</p> <pre>N=intmax('int16') for k=N-10:N</pre> <p>with:</p> <pre>for k=1:10</pre>
<ul style="list-style-type: none"> The loop counter decrements by 1 The end value equals the minimum value of the integer type The loop is not covering the full range of the integer type 	<p>Rewrite the loop so that the end value is not equal to the minimum value of the integer type. For example, replace:</p> <pre>N=intmin('int32') for k=N+10:-1:N</pre> <p>with:</p> <pre>for k=10:-1:1</pre>
<ul style="list-style-type: none"> The loop counter increments or decrements by 1 The start value equals the minimum or maximum value of the integer type The end value equals the maximum or minimum value of the integer type <p>The loop covers the full range of the integer type.</p>	<p>Rewrite the loop casting the type of the loop counter start, step, and end values to a bigger integer or to double. For example, rewrite:</p> <pre>M= intmin('int16'); N= intmax('int16'); for k=M:N % Loop body end to M= intmin('int16'); N= intmax('int16'); for k=int32(M):int32(N) % Loop body</pre>

Loop conditions causing the error	Workaround
<ul style="list-style-type: none">• The loop counter increments or decrements by a value not equal to 1• On last loop iteration, the loop variable value is not equal to the end value	end Rewrite the loop so that the loop variable on the last loop iteration is equal to the end value.
Note: The software error checking is conservative. It may incorrectly report a loop as being potentially infinite.	

Supported Variable Types

You can use the following data types for C/C++ code generation from MATLAB:

Type	Description
char	Character array
complex	Complex data. Cast function takes real and imaginary components
double	Double-precision floating point
int8, int16, int32, int64	Signed integer
logical	Boolean true or false
single	Single-precision floating point
struct	Structure
uint8, uint16, uint32, uint64	Unsigned integer
Fixed-point	See “Fixed-Point Data Types”.

Defining Data for Code Generation

- “Code Generation for Character Arrays” on page 47-8
- “Array Size Restrictions for Code Generation” on page 47-9
- “Code Generation for Constants in Structures and Arrays” on page 47-10

Data Definition for Code Generation

To generate efficient standalone code, you must define the following types and classes of data differently than you normally would when running your code in MATLAB.

Data	What's Different	More Information
Arrays	Maximum number of elements is restricted	“Array Size Restrictions for Code Generation” on page 47-9
Complex numbers	<ul style="list-style-type: none"> • Complexity of variables must be set at time of assignment and before first use • Expressions containing a complex number or variable evaluate to a complex result, even if the result is zero <hr/> <p>Note: Because MATLAB does not support complex integer arithmetic, you cannot generate code for functions that use complex integer arithmetic</p>	“Code Generation for Complex Data” on page 47-4
Characters	Restricted to 8 bits of precision	“Code Generation for Character Arrays” on page 47-8
Enumerated data	<ul style="list-style-type: none"> • Supports integer-based enumerated types only • Restricted use in <code>switch</code> statements and <code>for</code>-loops 	“Enumerations”
Function handles	<ul style="list-style-type: none"> • Using the same bound variable to reference different function 	“Function Handles”

Data	What's Different	More Information
	<p>handles can cause a compile-time error.</p> <ul style="list-style-type: none">• Cannot pass function handles to or from primary or extrinsic functions• Cannot view function handles from the debugger	

Code Generation for Complex Data

In this section...

“Restrictions When Defining Complex Variables” on page 47-4

“Code Generation for Complex Data with Zero-Valued Imaginary Parts” on page 47-4

“Results of Expressions That Have Complex Operands” on page 47-7

Restrictions When Defining Complex Variables

For code generation, you must set the complexity of variables at the time of assignment. Assign a complex constant to the variable or use the `complex` function. For example:

```
x = 5 + 6i; % x is a complex number by assignment.
y = complex(5,6); % y is the complex number 5 + 6i.
```

After assignment, you cannot change the complexity of a variable. Code generation for the following function fails because $x(k) = 3 + 4i$ changes the complexity of x .

```
function x = test1( )
x = zeros(3,3); % x is real
for k = 1:numel(x)
    x(k) = 3 + 4i;
end
end
```

To resolve this issue, assign a complex constant to x .

```
function x = test1( )
x = zeros(3,3)+ 0i; %x is complex
for k = 1:numel(x)
    x(k) = 3 + 4i;
end
end
```

Code Generation for Complex Data with Zero-Valued Imaginary Parts

For code generation, complex data that has all zero-valued imaginary parts remains complex. This data does not become real. This behavior has the following implications:

- In some cases, results from functions that sort complex data by absolute value can differ from the MATLAB results. See “Functions That Sort Complex Values by Absolute Value” on page 47-5.
- For functions that require that complex inputs are sorted by absolute value, complex inputs with zero-valued imaginary parts must be sorted by absolute value. These functions include `ismember`, `union`, `intersect`, `setdiff`, and `setxor`.

Functions That Sort Complex Values by Absolute Value

Functions that sort complex values by absolute value include `sort`, `issorted`, `sortrows`, `median`, `min`, and `max`. These functions sort complex numbers by absolute value even when the imaginary parts are zero. In general, sorting the absolute values produces a different result than sorting the real parts. Therefore, when inputs to these functions are complex with zero-valued imaginary parts in generated code, but real in MATLAB, the generated code can produce different results than MATLAB. In the following examples, the input to `sort` is real in MATLAB, but complex with zero-valued imaginary parts in the generated code:

- **You Pass Real Inputs to a Function Generated for Complex Inputs**

- 1 Write this function:

```
function myout = mysort(A)
myout = sort(A);
end
```

- 2 Call `mysort` in MATLAB.

```
A = -2:2;
mysort(A)

ans =

    -2    -1     0     1     2
```

- 3 Generate a MEX function for complex inputs.

```
A = -2:2;
codegen mysort -args {complex(A)} -report
```

- 4 Call the MEX Function with real inputs.

```
mysort_mex(A)

ans =
```

```
0    1    -1    2    -2
```

You generated the MEX function for complex inputs, therefore, it treats the real inputs as complex numbers with zero-valued imaginary parts. It sorts the numbers by the absolute values of the complex numbers. Because the imaginary parts are zero, the MEX function returns the results to the MATLAB workspace as real numbers.

- **Input to `sort` Is Output from a Function That Returns Complex in Generated Code**

- 1 Write this function:

```
function y = myfun(A)
x = eig(A);
y = sort(x, 'descend');
```

The output from `eig` is the input to `sort`. In generated code, `eig` returns a complex result. Therefore, in the generated code, `x` is complex.

- 2 Call `myfun` in MATLAB.

```
A = [2 3 5;0 5 5;6 7 4];
myfun(A)
```

```
ans =
```

```
12.5777
 2.0000
-3.5777
```

The result of `eig` is real. Therefore, the inputs to `sort` are real.

- 3 Generate a MEX function for complex inputs.

```
codegen myfun -args {complex(A)}
```

- 4 Call the MEX function.

```
myfun_mex(A)
```

```
ans =
```

```
12.5777
-3.5777
 2.0000
```

In the MEX function, `eig` returns a complex result. Therefore, the inputs to `sort` are complex. The MEX function sorts the inputs in descending order of the absolute values.

Results of Expressions That Have Complex Operands

In general, expressions that contain one or more complex operands produce a complex result in generated code, even if the value of the result is zero. Consider the following line of code:

```
z = x + y;
```

Suppose that at run time, `x` has the value $2 + 3i$ and `y` has the value $2 - 3i$. In MATLAB, this code produces the real result $z = 4$. During code generation, the types for `x` and `y` are known, but their values are not known. Because either or both operands in this expression are complex, `z` is defined as a complex variable requiring storage for a real and an imaginary part. `z` equals the complex result $4 + 0i$ in generated code, not 4 , as in MATLAB code.

Exceptions to this behavior are:

- Functions that take complex arguments but produce real results return real values.

```
y = real(x); % y is the real part of the complex number x.  
y = imag(x); % y is the real-valued imaginary part of x.  
y = isreal(x); % y is false (0) for a complex number x.
```

- Functions that take real arguments but produce complex results return complex values.

```
z = complex(x,y); % z is a complex number for a real x and y.
```

Code Generation for Character Arrays

The code generator translates the 16-bit Unicode encoding of a character in MATLAB to an 8-bit encoding that the locale setting determines. The code generator does not support characters that require more than 1 byte in MATLAB. This restriction applies to character arrays that are passed between MATLAB and the code generator. For example, the restriction applies to entry-point function inputs and to outputs from extrinsic calls. For code generation, some MATLAB functions accept only 7-bit ASCII characters. See “Functions and Objects Supported for C/C++ Code Generation — Alphabetical List” on page 44-2.

If a character is not in the 7-bit ASCII codeset, casting the character to a numeric type, such as double, produces a different result in the generated code than in MATLAB. A best practice for code generation is to avoid performing arithmetic with characters.

More About

- “Locale Settings for MATLAB Process”

Array Size Restrictions for Code Generation

For code generation, the maximum number of elements of an array is constrained by the code generator and the target hardware. The maximum number of elements is the smaller of:

- `intmax('int32')`.
- The largest integer that fits in the C `int` data type on the target hardware.

These restrictions apply even on a 64-bit platform.

For a fixed-size array, if the number of elements exceeds the maximum, the code generator reports an error at compile time. For a variable-size array, if the number of elements exceeds the maximum during simulation, the software reports an error. Generated standalone code cannot report array size violations.

See Also

- “Variable-Size Data”

Code Generation for Constants in Structures and Arrays

The code generator does not recognize constant structure fields or array elements in the following cases:

Fields or elements are assigned inside control constructs

In the following code, the code generator recognizes that the structure fields `s.a` and `s.b` are constants.

```
function y = mystruct()
s.a = 3;
s.b = 5;
y = zeros(s.a,s.b);
```

If any structure field is assigned inside a control construct, the code generator does not recognize the constant fields. This limitation also applies to arrays with constant elements. Consider the following code:

```
function y = mystruct(x)
s.a = 3;
if x > 1
    s.b = 4;
else
    s.b = 5;
end
y = zeros(s.a,s.b);
```

The code generator does not recognize that `s.a` and `s.b` are constant. If variable-sizing is enabled, `y` is treated as a variable-size array. If variable-sizing is disabled, the code generator reports an error.

Constants are assigned to array elements using non-scalar indexing

In the following code, the code generator recognizes that `a(1)` is constant.

```
function y = myarray()
a = zeros(1,3);
a(1) = 20;
y = coder.const(a(1));
```

In the following code, because `a(1)` is assigned using non-scalar indexing, the code generator does not recognize that `a(1)` is constant.

```
function y = myarray()  
a = zeros(1,3);  
a(1:2) = 20;  
y = coder.const(a(1));
```

A function returns a structure or array that has constant and nonconstant elements

For an output structure that has both constant and nonconstant fields, the code generator does not recognize the constant fields. This limitation also applies to arrays that have constant and nonconstant elements. Consider the following code:

```
function y = mystruct_out(x)  
s = create_structure(x);  
y = coder.const(s.a);  
  
function s = create_structure(x)  
s.a = 10;  
s.b = x;
```

Because `create_structure` returns a structure `s` that has one constant field and one nonconstant field, the code generator does not recognize that `s.a` is constant. The `coder.const` call fails because `s.a` is not constant.

Code Generation for Variable-Size Data

- “Variable-Sizing Restrictions for Code Generation of Toolbox Functions” on page 48-30

What Is Variable-Size Data?

Variable-size data is data whose size can change at run time. By contrast, fixed-size data is data whose size is known and locked at compile time and, therefore, cannot change at run time.

For example, in the following MATLAB function `nway`, `B` is a variable-size array; its length is not known at compile time.

```
function B = nway(A,n)
% Compute average of every N elements of A and put them in B.
if ((mod(numel(A),n) == 0) && (n >= 1 && n <= numel(A)))
    B = ones(1,numel(A)/n);
    k = 1;
    for i = 1 : numel(A)/n
        B(i) = mean(A(k + (0:n-1)));
        k = k + n;
    end
else
    error('n <= 0 or does not divide number of elements evenly');
end
```

Variable-Size Data Definition for Code Generation

In the MATLAB language, data can vary in size. By contrast, the semantics of generated code constrains the class, complexity, and shape of every expression, variable, and structure field. Therefore, for code generation, you must use each variable consistently. Each variable must:

- Be either complex or real (determined at first assignment)
- Have a consistent shape

For fixed-size data, the shape is the same as the size returned in MATLAB. For example, if `size(A) == [4 5]`, the shape of variable `A` is 4 x 5. For variable-size data, the shape can be abstract. That is, one or more dimensions can be unknown (such as `4x?` or `?x?`).

By default, the compiler detects code logic that attempts to change these fixed attributes after initial assignments, and flags these occurrences as errors during code generation. However, you can override this behavior by defining variables or structure fields as variable-size data.

For more information, see “Bounded Versus Unbounded Variable-Size Data” on page 48-4

Bounded Versus Unbounded Variable-Size Data

Bounded variable-size data has fixed upper bounds. *Unbounded variable-size data* does not have fixed upper bounds; this data *must* be allocated on the heap and requires dynamic memory allocation. You cannot use dynamic memory allocation for variable-size data in MATLAB Function blocks. Use bounded instead of unbounded variable-size data.

Specify Variable-Size Data Without Dynamic Memory Allocation

In this section...

“Fixing Upper Bounds Errors” on page 48-5

“Specifying Upper Bounds for Variable-Size Data” on page 48-5

Fixing Upper Bounds Errors

If the code generator cannot determine or compute the upper bound, you must specify an upper bound. See “Specifying Upper Bounds for Variable-Size Data” on page 48-5 and “Diagnosing and Fixing Errors in Detecting Upper Bounds” on page 48-19

Specifying Upper Bounds for Variable-Size Data

- “Using a Matrix Constructor with Nonconstant Dimensions” on page 48-6

When to Specify Upper Bounds for Variable-Size Data

When using static allocation on the stack during code generation, the code generator must be able to determine upper bounds for variable-size data. Specify the upper bounds explicitly for variable-size data from external sources, such as inputs and outputs.

Specifying Upper Bounds for Local Variable-Size Data

When using static allocation, MATLAB uses a sophisticated analysis to calculate the upper bounds of local data at compile time. However, when the analysis fails to detect an upper bound or calculates an upper bound that is not precise enough for your application, you need to specify upper bounds explicitly for local variables.

Constraining the Value of a Variable That Specifies Dimensions of Variable-Size Data

Use the `assert` function with relational operators to constrain the value of variables that specify the dimensions of variable-size data. For example:

```
function y = dim_need_bound(n) %#codegen
assert (n <= 5);
L = ones(n,n);
```

```
M = zeros(n,n);  
M = [L; M];  
y = M;
```

This `assert` statement constrains input `n` to a maximum size of 5, defining `L` and `M` as variable-sized matrices with upper bounds of 5 for each dimension.

Specifying the Upper Bounds for All Instances of a Local Variable

Use the `coder.versize` function to specify the upper bounds for all instances of a local variable in a function. For example:

```
function Y = example_bounds1(u) %#codegen  
Y = [1 2 3 4 5];  
coder.versize('Y',[1 10]);  
if (u > 0)  
    Y = [Y Y+u];  
else  
    Y = [Y Y*u];  
end
```

The second argument of `coder.versize` specifies the upper bound for each instance of the variable specified in the first argument. In this example, the argument `[1 10]` indicates that for every instance of `Y`:

- First dimension is fixed at size 1
- Second dimension can grow to an upper bound of 10

By default, `coder.versize` assumes dimensions of 1 are fixed size. For more information, see the `coder.versize` reference page.

Using a Matrix Constructor with Nonconstant Dimensions

You can define a variable-size matrix by using a constructor with nonconstant dimensions. For code in a MATLAB Function block, you must also add an `assert` statement to provide upper bounds for the dimensions. For example:

```
function y = var_by_assign(u) %#codegen  
assert (u < 20);  
if (u > 0)  
    y = ones(3,u);  
else  
    y = zeros(3,1);  
end
```

Variable-Size Data in Code Generation Reports

In this section...
“What Reports Tell You About Size” on page 48-7
“How Size Appears in Code Generation Reports” on page 48-8
“How to Generate a Code Generation Report” on page 48-8

What Reports Tell You About Size

Code generation reports:

- Differentiate fixed-size from variable-size data
- Identify variable-size data with unknown upper bounds
- Identify variable-size data with fixed dimensions

If you define a variable-size array and then subsequently fix the dimensions of this array in the code, the report appends * to the size of the variable. In the generated C code, this variable appears as a variable-size array, but the size of its dimensions does not change during execution.

- Provide guidance on how to fix size mismatch and upper bounds errors.

How Size Appears in Code Generation Reports

Variable	Type	Size
B	Output	1 x :?
A	Input	1 x :100
n	Input	1 x 1

:? means variable size, unknown upper bound
 No colon prefix (:) means fixed size
 :100 means variable size, upper bound = 100

Variable	Type	Size
y	Output	1 x 10*

* means that you declared y as variable size, but subsequently fixed its dimensions

How to Generate a Code Generation Report

When you build a Simulink model that contains MATLAB Function blocks, Simulink automatically generates a report in HTML format for each MATLAB Function block in your model. See “MATLAB Function Reports” on page 39-48

Define Variable-Size Data for Code Generation

In this section...

“When to Define Variable-Size Data Explicitly” on page 48-9

“Using a Matrix Constructor with Nonconstant Dimensions” on page 48-9

“Inferring Variable Size from Multiple Assignments” on page 48-10

“Defining Variable-Size Data Explicitly Using `coder. varsized`” on page 48-11

When to Define Variable-Size Data Explicitly

For code generation, you must assign variables to have a specific class, size, and complexity before using them in operations or returning them as outputs. Generally, you cannot reassign variable properties after the initial assignment. Therefore, attempts to grow a variable or structure field after assigning it a fixed size might cause a compilation error. In these cases, you must explicitly define the data as variable sized using one of these methods:

Method	See
Assign the data from a variable-size matrix constructor such as <ul style="list-style-type: none"> • <code>ones</code> • <code>zeros</code> • <code>repmat</code> 	“Using a Matrix Constructor with Nonconstant Dimensions” on page 48-9
Assign multiple, constant sizes to the same variable before using (reading) the variable.	“Inferring Variable Size from Multiple Assignments” on page 48-10
Define all instances of a variable to be variable sized	“Defining Variable-Size Data Explicitly Using <code>coder. varsized</code> ” on page 48-11

Using a Matrix Constructor with Nonconstant Dimensions

You can define a variable-size matrix by using a constructor with nonconstant dimensions. For code in a MATLAB Function block, you must also add an `assert` statement to provide upper bounds for the dimensions. For example:

```
function y = var_by_assign(u) %#codegen
assert (u < 20);
if (u > 0)
    y = ones(3,u);
else
    y = zeros(3,1);
end
```

Inferring Variable Size from Multiple Assignments

You can define variable-size data by assigning multiple, constant sizes to the same variable before you use (read) the variable in your code. When MATLAB uses static allocation on the stack for code generation, it infers the upper bounds from the largest size specified for each dimension. When you assign the same size to a given dimension across all assignments, MATLAB assumes that the dimension is fixed at that size. The assignments can specify different shapes as well as sizes.

Inferring Upper Bounds from Multiple Definitions with Different Shapes

```
function y = var_by_multiassign(u) %#codegen
if (u > 0)
    y = ones(3,4,5);
else
    y = zeros(3,1);
end
```

When static allocation is used, this function infers that `y` is a matrix with three dimensions, where:

- First dimension is fixed at size 3
- Second dimension is variable with an upper bound of 4
- Third dimension is variable with an upper bound of 5

The code generation report represents the size of matrix `y` like this:

Variable	Type	Size
y	Output	3 x :4 x :5

Defining Variable-Size Data Explicitly Using `coder.varsize`

Use the function `coder. varsize` to define one or more variables or structure fields as variable-size data. Optionally, you can also specify which dimensions vary along with their upper bounds (see “Specifying Which Dimensions Vary” on page 48-11). For example:

- Define **B** as a variable-size 2-by-2 matrix, where each dimension has an upper bound of 64:

```
coder. varsize('B', [64 64]);
```

- Define **B** as a variable-size matrix:

```
coder. varsize('B');
```

When you supply only the first argument, `coder. varsize` assumes all dimensions of **B** can vary and that the upper bound is `size(B)`.

For more information, see the `coder. varsize` reference page.

Specifying Which Dimensions Vary

You can use the function `coder. varsize` to specify which dimensions vary. For example, the following statement defines **B** as a row vector whose first dimension is fixed at 2, but whose second dimension can grow to an upper bound of 16:

```
coder. varsize('B',[2, 16],[0 1])
```

The third argument specifies which dimensions vary. This argument must be a logical vector or a double vector containing only zeros and ones. Dimensions that correspond to zeros or `false` have fixed size; dimensions that correspond to ones or `true` vary in size. `coder. varsize` usually treats dimensions of size 1 as fixed (see “Defining Variable-Size Matrices with Singleton Dimensions” on page 48-12).

For more information about the syntax, see the `coder. varsize` reference page.

Allowing a Variable to Grow After Defining Fixed Dimensions

Function `var_by_if` defines matrix **Y** with fixed 2-by-2 dimensions before first use (where the statement `Y = Y + u` reads from **Y**). However, `coder. varsize` defines **Y** as a variable-size matrix, allowing it to change size based on decision logic in the `else` clause:

```
function Y = var_by_if(u) %#codegen
```

```
if (u > 0)
    Y = zeros(2,2);
    coder.varsize('Y');
    if (u < 10)
        Y = Y + u;
    end
else
    Y = zeros(5,5);
end
```

Without `coder.varsize`, MATLAB infers `Y` to be a fixed-size, 2-by-2 matrix and generates a size mismatch error during code generation.

Defining Variable-Size Matrices with Singleton Dimensions

A singleton dimension is a dimension for which `size(A,dim) = 1`. Singleton dimensions are fixed in size when:

- You specify a dimension with an upper bound of 1 in `coder.varsize` expressions.

For example, in this function, `Y` behaves like a vector with one variable-size dimension:

```
function Y = dim_singleton(u) %#codegen
Y = [1 2];
coder.varsize('Y', [1 10]);
if (u > 0)
    Y = [Y 3];
else
    Y = [Y u];
end
```

- You initialize variable-size data with singleton dimensions using matrix constructor expressions or matrix functions.

For example, in this function, both `X` and `Y` behave like vectors where only their second dimensions are variable sized:

```
function [X,Y] = dim_singleton_vects(u) %#codegen
Y = ones(1,3);
X = [1 4];
coder.varsize('Y','X');
if (u > 0)
    Y = [Y u];
else
```

```

        X = [X u];
    end

```

You can override this behavior by using `coder.versize` to specify explicitly that singleton dimensions vary. For example:

```

function Y = dim_singleton_vary(u) %#codegen
Y = [1 2];
coder.versize('Y', [1 10], [1 1]);
if (u > 0)
    Y = [Y Y+u];
else
    Y = [Y Y*u];
end

```

In this example, the third argument of `coder.versize` is a vector of ones, indicating that each dimension of `Y` varies in size. For more information, see the `coder.versize` reference page.

Defining Variable-Size Structure Fields

To define structure fields as variable-size arrays, use colon (`:`) as the index expression. The colon (`:`) indicates that all elements of the array are variable sized. For example:

```

function y=struct_example() %#codegen

d = struct('values', zeros(1,0), 'color', 0);
data = repmat(d, [3 3]);
coder.versize('data(:).values');

for i = 1:numel(data)
    data(i).color = rand-0.5;
    data(i).values = 1:i;
end

y = 0;
for i = 1:numel(data)
    if data(i).color > 0
        y = y + sum(data(i).values);
    end;
end

```

The expression `coder.versize('data(:).values')` defines the field `values` inside each element of matrix `data` to be variable sized.

Here are other examples:

- `coder.ysize('data.A(:).B')`

In this example, `data` is a scalar variable that contains matrix `A`. Each element of matrix `A` contains a variable-size field `B`.

- `coder.ysize('data(:).A(:).B')`

This expression defines field `B` inside each element of matrix `A` inside each element of matrix `data` to be variable sized.

C Code Interface for Arrays

C Code Interface for Statically Allocated Arrays

For statically allocated arrays, the generated code contains the definition of the array and the size of the array.

For example, consider the MATLAB function `myunique_tol`.

```
function B = myunique_tol(A, tol) %#codegen
A = sort(A);
coder.varsize('B', [1 100], [0 1]);
B = A(1);
k = 1;
for i = 2:length(A)
    if abs(A(k) - A(i)) > tol
        B = [B A(i)];
        k = i;
    end
end
```

The statement `coder.varsize('B', [1 100], [0 1])` specifies that `B` is a variable-size array whose first dimension is fixed at 1 and second dimension can vary up to 100 elements. Without this statement, `B` is a dynamically allocated array.

Generate code for `myunique_tol` specifying that input `A` is a variable-size real double vector whose first dimension is fixed at 1 and second dimension can vary up to 100 elements.

```
codegen -config:lib -report myunique_tol -args {coder.typeof(0,[1 100],1),coder.typeof(0)}
```

In the generated code, the function declaration is:

```
extern void myunique_tol(const double A_data[], const int A_size[2], double tol,
    double B_data[], int B_size[2])
```

The function signature declares the input argument `A` and the output argument `B`. `A_size` contains the size of `A`. `B_size` contains the size of `B` after the call to `myunique_tol`. Use `B_size` to determine the number of elements of `B` that you can access after the call to `myunique_tol`. `B_size[0]` contains the size of the first dimension. `B_size[1]` contains the size of the second dimension. Therefore, the number of elements

of B is `B_size[0]*B_Size[1]`. Even though B has 100 elements in the C code, only `B_size[0]*B_Size[1]` elements contain valid data.

The following C main function shows how to call `myuniquetol`.

```
void main()
{
    double A[100], B[100];
    int A_size[2] = { 1, 100 };
    int B_size[2];
    int i;
    for (i = 0; i < 100; i++) {
        A[i] = (double)1/i;
    }
    myuniquetol(A, A_size, 0.1, B, B_size);
}
```

Diagnose and Fix Variable-Size Data Errors

In this section...

“Diagnosing and Fixing Size Mismatch Errors” on page 48-17

“Diagnosing and Fixing Errors in Detecting Upper Bounds” on page 48-19

Diagnosing and Fixing Size Mismatch Errors

Check your code for these issues:

Assigning Variable-Size Matrices to Fixed-Size Matrices

You cannot assign variable-size matrices to fixed-size matrices in generated code. Consider this example:

```
function Y = example_mismatch1(n) %#codegen
assert(n < 10);
B = ones(n,n);
A = magic(3);
A(1) = mean(A(:));
if (n == 3)
    A = B;
end
Y = A;
```

Compiling this function produces this error:

```
??? Dimension 1 is fixed on the left-hand side
but varies on the right ...
```

There are several ways to fix this error:

- Allow matrix A to grow by adding the `coder.varsize` construct:

```
function Y = example_mismatch1_fix1(n) %#codegen
coder.varsize('A');
assert(n < 10);
B = ones(n,n);
A = magic(3);
A(1) = mean(A(:));
if (n == 3)
    A = B;
end
Y = A;
```

```
Y = A;
```

- Explicitly restrict the size of matrix B to 3-by-3 by modifying the `assert` statement:

```
function Y = example_mismatch1_fix2(n) %#codegen
coder.varsize('A');
assert(n == 3)
B = ones(n,n);
A = magic(3);
A(1) = mean(A(:));
if (n == 3)
    A = B;
end
Y = A;
```

- Use explicit indexing to make B the same size as A:

```
function Y = example_mismatch1_fix3(n) %#codegen
assert(n < 10);
B = ones(n,n);
A = magic(3);
A(1) = mean(A(:));
if (n == 3)
    A = B(1:3, 1:3);
end
Y = A;
```

Empty Matrix Reshaped to Match Variable-Size Specification

If you assign an empty matrix `[]` to variable-size data, MATLAB might silently reshape the data in generated code to match a `coder.varsize` specification. For example:

```
function Y = test(u) %#codegen
Y = [];
coder.varsize('Y', [1 10]);
if u < 0
    Y = [Y u];
end
```

In this example, `coder.varsize` defines Y as a column vector of up to 10 elements, so its first dimension is fixed at size 1. The statement `Y = []` designates the first dimension of Y as 0, creating a mismatch. The right hand side of the assignment is an empty matrix and the left hand side is a variable-size vector. In this case, MATLAB reshapes the empty matrix `Y = []` in generated code to `Y = zeros(1,0)` so it matches the `coder.varsize` specification.

Performing Binary Operations on Fixed and Variable-Size Operands

You cannot perform binary operations on operands of different sizes. Operands have different sizes if one has fixed dimensions and the other has variable dimensions. For example:

```
function z = mismatch_operands(n) %#codegen
assert(n >= 3 && n < 10);
x = ones(n,n);
y = magic(3);
z = x + y;
```

When you compile this function, you get an error because `y` has fixed dimensions (3 x 3), but `x` has variable dimensions. Fix this problem by using explicit indexing to make `x` the same size as `y`:

```
function z = mismatch_operands_fix(n) %#codegen
assert(n >= 3 && n < 10);
x = ones(n,n);
y = magic(3);
z = x(1:3,1:3) + y;
```

Diagnosing and Fixing Errors in Detecting Upper Bounds

Check your code for these issues:

Using Nonconstant Dimensions in a Matrix Constructor

You can define variable-size data by assigning a variable to a matrix with nonconstant dimensions. For example:

```
function y = dims_vary(u) %#codegen
if (u > 0)
    y = ones(3,u);
else
    y = zeros(3,1);
end
```

However, compiling this function generates an error because you did not specify an upper bound for `u`.

To fix the problem, add an `assert` statement before the first use of `u`:

```
function y = dims_vary_fix(u) %#codegen
```

```
assert (u < 20);  
if (u > 0)  
    y = ones(3,u);  
else  
    y = zeros(3,1);  
end
```

Incompatibilities with MATLAB in Variable-Size Support for Code Generation

In this section...

“Differences When Curly-Brace Indexing of Variable-Size Cell Array Inside Concatenation Returns No Elements” on page 48-28

“Dynamic Memory Allocation Not Supported for MATLAB Function Blocks” on page 48-29

Incompatibility with MATLAB for Scalar Expansion

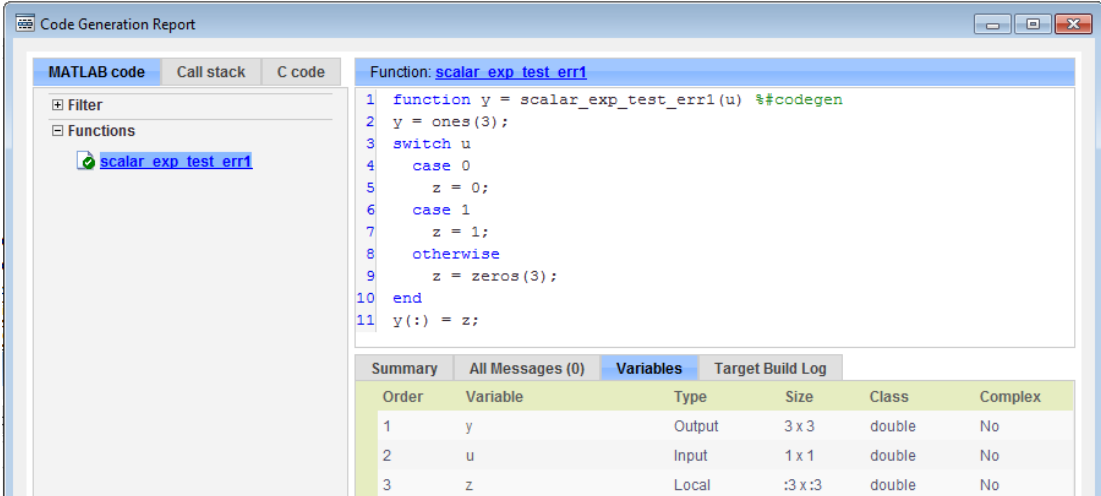

Scalar expansion is a method of converting scalar data to match the dimensions of vector or matrix data. Except for some matrix operators, MATLAB arithmetic operators work on corresponding elements of arrays with equal dimensions. For vectors and rectangular arrays, both operands must be the same size unless one is a scalar. If one operand is a scalar and the other is not, MATLAB applies the scalar to every element of the other operand—this property is known as *scalar expansion*.

During code generation, the standard MATLAB scalar expansion rules apply except when operating on two variable-size expressions. In this case, both operands must be the same size. The generated code does not perform scalar expansion even if one of the variable-size expressions turns out to be scalar at run time. Instead, it generates a size mismatch error at run time for MEX functions. Run-time error checking does not occur for non-MEX builds; the generated code will have unspecified behavior.

For example, in the following function, `z` is scalar for the `switch` statement `case 0` and `case 1`. MATLAB applies scalar expansion when evaluating `y(:) = z`; for these two cases.

```
function y = scalar_exp_test_err1(u) %#codegen
y = ones(3);
switch u
    case 0
        z = 0;
    case 1
        z = 1;
    otherwise
        z = zeros(3);
end
y(:) = z;
```

When you generate code for this function, the code generator determines that `z` is variable size with an upper bound of 3.

The screenshot shows the 'Code Generation Report' window. The 'MATLAB code' tab is selected, displaying the following code for the function `scalar_exp_test_err1`:

```
1 function y = scalar_exp_test_err1(u) %#codegen
2 y = ones(3);
3 switch u
4     case 0
5         z = 0;
6     case 1
7         z = 1;
8     otherwise
9         z = zeros(3);
10 end
11 y(:) = z;
```

Below the code, the 'Variables' tab is selected, showing a table with the following data:

Order	Variable	Type	Size	Class	Complex
1	y	Output	3 x 3	double	No
2	u	Input	1 x 1	double	No
3	z	Local	:3 x:3	double	No

If you run the MEX function with `u` equal to zero or one, even though `z` is scalar at run time, the generated code does not perform scalar expansion and a run-time error occurs.

```
scalar_exp_test_err1_mex(0)
Sizes mismatch: 9 ~= 1.
```

```
Error in scalar_exp_test_err1 (line 11)
```

```
y(:) = z;
```

Workaround

Use indexing to force `z` to be a scalar value:

```
function y = scalar_exp_test_err1(u) %#codegen
y = ones(3);
switch u
    case 0
        z = 0;
    case 1
        z = 1;
    otherwise
        z = zeros(3);
end
y(:) = z(1);
```

Incompatibility with MATLAB in Determining Size of Variable-Size N-D Arrays

For variable-size N-D arrays, the `size` function can return a different result in generated code than in MATLAB. In generated code, `size(A)` returns a fixed-length output because it does not drop trailing singleton dimensions of variable-size N-D arrays. By contrast, `size(A)` in MATLAB returns a variable-length output because it drops trailing singleton dimensions.

For example, if the shape of array `A` is `:?x:?x:?` and `size(A,3)==1`, `size(A)` returns:

- Three-element vector in generated code
- Two-element vector in MATLAB code

Workarounds

If your application requires generated code to return the same size of variable-size N-D arrays as MATLAB code, consider one of these workarounds:

- Use the two-argument form of `size`.

For example, `size(A,n)` returns the same answer in generated code and MATLAB code.

- Rewrite `size(A)`:

```
B = size(A);  
X = B(1:ndims(A));
```

This version returns X with a variable-length output. However, you cannot pass a variable-size X to matrix constructors such as `zeros` that require a fixed-size argument.

Incompatibility with MATLAB in Determining Size of Empty Arrays

The size of an empty array in generated code might be different from its size in MATLAB source code. The size might be `1x0` or `0x1` in generated code, but `0x0` in MATLAB. Therefore, you should not write code that relies on the specific size of empty matrices.

For example, consider the following code:

```
function y = foo(n) %#codegen  
x = [];  
i = 0;  
while (i < 10)  
    x = [5 x];  
    i = i + 1;  
end  
if n > 0  
    x = [];  
end  
y = size(x);  
end
```

Concatenation requires its operands to match on the size of the dimension that is not being concatenated. In the preceding concatenation the scalar value has size `1x1` and `x` has size `0x0`. To support this use case, the code generator determines the size for `x` as `[1 x :?]`. Because there is another assignment `x = []` after the concatenation, the size of `x` in the generated code is `1x0` instead of `0x0`.

For incompatibilities with MATLAB in determining the size of an empty array that results from deleting elements of an array, see “Size of Empty Array That Results from Deleting Elements of an Array” on page 43-10.

Workaround

If your application checks whether a matrix is empty, use one of these workarounds:

- Rewrite your code to use the `isempty` function instead of the `size` function.

- Instead of using `x=[]` to create empty arrays, create empty arrays of a specific size using `zeros`. For example:

```
function y = test_empty(n) %#codegen
x = zeros(1,0);
i=0;
while (i < 10)
    x = [5 x];
    i = i + 1;
end
if n > 0
    x = zeros(1,0);
end
y=size(x);
end
```

Incompatibility with MATLAB in Determining Class of Empty Arrays

The class of an empty array in generated code can be different from its class in MATLAB source code. Therefore, do not write code that relies on the class of empty matrices.

For example, consider the following code:

```
function y = fun(n)
x = [];
if n > 1
    x = ['a' x];
end
y=class(x);
end
```

`fun(0)` returns `double` in MATLAB, but `char` in the generated code. When the statement `n > 1` is false, MATLAB does not execute `x = ['a' x]`. The class of `x` is `double`, the class of the empty array. However, the code generator considers all execution paths. It determines that based on the statement `x = ['a' x]`, the class of `x` is `char`.

Workaround

Instead of using `x=[]` to create an empty array, create an empty array of a specific class. For example, use `blanks(0)` to create an empty array of characters.

```
function y = fun(n)
x = blanks(0);
if n > 1
```

```
    x = ['a' x];  
end  
y=class(x);  
end
```

Incompatibility with MATLAB in Vector-Vector Indexing

In vector-vector indexing, you use one vector as an index into another vector. When either vector is variable sized, you might get a run-time error during code generation. Consider the index expression $A(B)$. The general rule for indexing is that $\text{size}(A(B)) == \text{size}(B)$. However, when both A and B are vectors, MATLAB applies a special rule: use the orientation of A as the orientation of the output. For example, if $\text{size}(A) == [1\ 5]$ and $\text{size}(B) == [3\ 1]$, then $\text{size}(A(B)) == [1\ 3]$.

In this situation, if the code generator detects that both A and B are vectors at compile time, it applies the special rule and gives the same result as MATLAB. However, if either A or B is a variable-size matrix (has shape $? \times ?$) at compile time, the code generator applies only the general indexing rule. Then, if both A and B become vectors at run time, the code generator reports a run-time error when you run the MEX function. Run-time error checking does not occur for non-MEX builds; the generated code will have unspecified behavior. It is best practice to generate and test a MEX function before generating C code.

Workaround

Force your data to be a vector by using the colon operator for indexing: $A(B(:))$. For example, suppose your code intentionally toggles between vectors and regular matrices at run time. You can do an explicit check for vector-vector indexing:

```
...  
if isvector(A) && isvector(B)  
    C = A(:);  
    D = C(B(:));  
else  
    D = A(B);  
end  
...
```

The indexing in the first branch specifies that C and $B(:)$ are compile-time vectors. As a result, the code generator applies the standard vector-vector indexing rule.

Incompatibility with MATLAB in Matrix Indexing Operations for Code Generation

The following limitations apply to matrix indexing operations for code generation:

- Initialization of the following style:

```
for i = 1:10
    M(i) = 5;
end
```

In this case, the size of M changes as the loop is executed. Code generation does not support increasing the size of an array over time.

For code generation, preallocate M as highlighted in the following code.

```
M = zeros(1,10);
for i = 1:10
    M(i) = 5;
end
```

- $M(i:j)$ where i and j change in a loop

During code generation, memory is not dynamically allocated for the size of the expressions that change as the program executes. To implement this behavior, use for-loops as shown in the following example:

```
...
M = ones(10,10);
for i = 1:10
    for j = i:10
        M(i,j) = 2*M(i,j);
    end
end
...
```

Note: The matrix M must be defined before entering the loop, as shown in the highlighted code.

Incompatibility with MATLAB in Concatenating Variable-Size Matrices

For code generation, when you concatenate variable-size arrays, the dimensions that are not being concatenated must match exactly.

Differences When Curly-Brace Indexing of Variable-Size Cell Array Inside Concatenation Returns No Elements

Suppose that:

- `c` is a variable-size cell array.
- You access the contents of `c` by using curly braces. For example, `c{2:4}`.
- You include the results in concatenation. For example, `[a c{2:4} b]`.
- `c{I}` returns no elements. Either `c` is empty or the indexing inside the curly braces produces an empty result.

For these conditions, MATLAB omits `c{I}` from the concatenation. For example, `[a c{I} b]` becomes `[a b]`. The code generator treats `c{I}` as the empty array `[c{I}]`. The concatenation becomes `[... [c{i}] ...]`. This concatenation then omits the array `[c{I}]`. So that the properties of `[c{I}]` are compatible with the concatenation `[... [c{i}] ...]`, the code generator assigns the class, size, and complexity of `[c{I}]` according to these rules:

- The class and complexity are the same as the base type of the cell array.
- The size of the second dimension is always 0.
- For the rest of the dimensions, the size of `Ni` depends on whether the corresponding dimension in the base type is fixed or variable size.
 - If the corresponding dimension in the base type is variable size, the dimension has size 0 in the result.
 - If the corresponding dimension in the base type is fixed size, the dimension has that size in the result.

Suppose that `c` has a base type with class `int8` and size `10x7x8x?`. In the generated code, the class of `[c{I}]` is `int8`. The size of `[c{I}]` is `0x0x8x0`. The second dimension is 0. The first and last dimensions are 0 because those dimensions are variable size in the base type. The third dimension is 8 because the size of the third dimension of the base type is a fixed size 8.

Inside concatenation, if curly-brace indexing of a variable-size cell array returns no elements, the generated code can have the following differences from MATLAB:

- The class of `[...c{i} ...]` in the generated code can differ from the class in MATLAB.

When `c{I}` returns no elements, MATLAB removes `c{I}` from the concatenation. Therefore, `c{I}` does not affect the class of the result. MATLAB determines the class of the result based on the classes of the remaining arrays, according to a precedence of classes. See “Valid Combinations of Unlike Classes”. In the generated code, the class of `[c{I}]` affects the class of the result of the overall concatenation `[... [c{I}] ...]` because the code generator treats `c{I}` as `[c{I}]`. The previously described rules determine the class of `[c{I}]`.

- In the generated code, the size of `[c{I}]` can differ from the size in MATLAB.

In MATLAB, the concatenation `[c{I}]` is a 0x0 double. In the generated code, the previously described rules determine the size of `[c{I}]`.

Dynamic Memory Allocation Not Supported for MATLAB Function Blocks

You cannot use dynamic memory allocation for variable-size data in MATLAB Function blocks. Use bounded instead of unbounded variable-size data.

Variable-Sizing Restrictions for Code Generation of Toolbox Functions

In this section...
“Common Restrictions” on page 48-30
“Toolbox Functions with Restrictions For Variable-Size Data” on page 48-31

Common Restrictions

The following common restrictions apply to multiple toolbox functions, but only for code generation. To determine which of these restrictions apply to specific library functions, see the table in “Toolbox Functions with Restrictions For Variable-Size Data” on page 48-31.

Variable-length vector restriction

Inputs to the library function must be variable-length vectors or fixed-size vectors. A variable-length vector is a variable-size array that has the shape $1 \times n$ or $n \times 1$ (one dimension is variable sized and the other is fixed at size 1). Other shapes are not permitted, even if they are vectors at run time.

Automatic dimension restriction

When the function selects the working dimension automatically, it bases the selection on the upper bounds for the dimension sizes. In the case of the `sum` function, `sum(X)` selects its working dimension automatically, while `sum(X, dim)` uses `dim` as the explicit working dimension.

For example, if `X` is a variable-size matrix with dimensions $1 \times 3 \times 5$, `sum(x)` behaves like `sum(X, 2)` in generated code. In MATLAB, it behaves like `sum(X, 2)` provided `size(X, 2)` is not 1. In MATLAB, when `size(X, 2)` is 1, `sum(X)` behaves like `sum(X, 3)`. Consequently, you get a run-time error if an automatically selected working dimension assumes a length of 1 at run time.

To avoid the issue, specify the intended working dimension explicitly as a constant value.

Array-to-vector restriction

The function issues an error when a variable-size array that is not a variable-length vector assumes the shape of a vector at run time. To avoid the issue, specify the input explicitly as a variable-length vector instead of a variable-size array.

Array-to-scalar restriction

The function issues an error if a variable-size array assumes a scalar value at run time. To avoid this issue, specify scalars as fixed size.

Toolbox Functions with Restrictions For Variable-Size Data

The following table lists functions that have code generation restrictions for variable-size data. For additional restrictions for these functions, and restrictions for all functions and objects supported for code generation, see “Functions and Objects Supported for C/C++ Code Generation — Alphabetical List”.

Function	Restrictions for Variable-Size Data
all	<ul style="list-style-type: none"> • See “Automatic dimension restriction” on page 48-30. • An error occurs if you pass the first argument a variable-size matrix that is 0-by-0 at run time.
any	<ul style="list-style-type: none"> • See “Automatic dimension restriction” on page 48-30. • An error occurs if you pass the first argument a variable-size matrix that is 0-by-0 at run time.
bsxfun	<ul style="list-style-type: none"> • Dimensions expand only where one input array or the other has a fixed length of 1.
cat	<ul style="list-style-type: none"> • Dimension argument must be a constant. • An error occurs if variable-size inputs are empty at run time.
conv	<ul style="list-style-type: none"> • See “Variable-length vector restriction” on page 48-30. • Input vectors must have the same orientation, either both row vectors or both column vectors.
cov	<ul style="list-style-type: none"> • For <code>cov(X)</code>, see “Array-to-vector restriction” on page 48-30.
cross	<ul style="list-style-type: none"> • Variable-size array inputs that become vectors at run time must have the same orientation.
deconv	<ul style="list-style-type: none"> • For both arguments, see “Variable-length vector restriction” on page 48-30.

Function	Restrictions for Variable-Size Data
detrend	<ul style="list-style-type: none"> For first argument for row vectors only, see “Array-to-vector restriction” on page 48-30 .
diag	<ul style="list-style-type: none"> See “Array-to-vector restriction” on page 48-30 .
diff	<ul style="list-style-type: none"> See “Automatic dimension restriction” on page 48-30. Length of the working dimension must be greater than the difference order input when the input is variable sized. For example, if the input is a variable-size matrix that is 3-by-5 at run time, <code>diff(x,2,1)</code> works but <code>diff(x,5,1)</code> generates a run-time error.
fft	<ul style="list-style-type: none"> See “Automatic dimension restriction” on page 48-30.
filter	<ul style="list-style-type: none"> For first and second arguments, see “Variable-length vector restriction” on page 48-30. See “Automatic dimension restriction” on page 48-30.
hist	<ul style="list-style-type: none"> For second argument, see “Variable-length vector restriction” on page 48-30. For second input argument, see “Array-to-scalar restriction” on page 48-31.
histc	<ul style="list-style-type: none"> See “Automatic dimension restriction” on page 48-30.
ifft	<ul style="list-style-type: none"> See “Automatic dimension restriction” on page 48-30.
ind2sub	<ul style="list-style-type: none"> First input (the size vector input) must be fixed size.
interp1	<ul style="list-style-type: none"> For the <code>xq</code> input, see “Array-to-vector restriction” on page 48-30. If <code>v</code> becomes a row vector at run time, the array to vector restriction applies. If <code>v</code> becomes a column vector at run time, this restriction does not apply.
ipermute	<ul style="list-style-type: none"> Order input must be fixed size.

Function	Restrictions for Variable-Size Data
issorted	<ul style="list-style-type: none"> For optional rows input, see “Variable-length vector restriction” on page 48-30.
magic	<ul style="list-style-type: none"> Argument must be a constant. Output can be fixed-size matrices only.
max	<ul style="list-style-type: none"> See “Automatic dimension restriction” on page 48-30.
mean	<ul style="list-style-type: none"> See “Automatic dimension restriction” on page 48-30. An error occurs if you pass as the first argument a variable-size matrix that is 0-by-0 at run time.
median	<ul style="list-style-type: none"> See “Automatic dimension restriction” on page 48-30. An error occurs if you pass as the first argument a variable-size matrix that is 0-by-0 at run time.
min	<ul style="list-style-type: none"> See “Automatic dimension restriction” on page 48-30.
mode	<ul style="list-style-type: none"> See “Automatic dimension restriction” on page 48-30. An error occurs if you pass as the first argument a variable-size matrix that is 0-by-0 at run time.
mtimes	<ul style="list-style-type: none"> When an input is variable-size, MATLAB determines whether to generate code for a general matrix*matrix multiplication or a scalar*matrix multiplication, based on whether one of the arguments is a fixed-size scalar. If neither argument is a fixed-size scalar, the inner dimensions of the two arguments must agree even if a variable-size matrix input is a scalar at run time.
nchoosek	<ul style="list-style-type: none"> The second input, k, must be a fixed-size scalar. The second input, k, must be a constant for static allocation.. You cannot create a variable-size array by passing in a variable, k, .
permute	<ul style="list-style-type: none"> Order input must be fixed-size.

Function	Restrictions for Variable-Size Data
planerot	<ul style="list-style-type: none"> Input must be a fixed-size, two-element column vector. It cannot be a variable-size array that takes on the size 2-by-1 at run time.
poly	<ul style="list-style-type: none"> See “Variable-length vector restriction” on page 48-30.
polyfit	<ul style="list-style-type: none"> For first and second arguments, see “Variable-length vector restriction” on page 48-30.
prod	<ul style="list-style-type: none"> See “Automatic dimension restriction” on page 48-30. An error occurs if you pass as the first argument a variable-size matrix that is 0-by-0 at run time.
rand	<ul style="list-style-type: none"> For an upper-bounded variable N, <code>rand(1,N)</code> produces a variable-length vector of <code>1x:M</code> where M is the upper bound on N. For an upper-bounded variable N, <code>rand([1 N])</code> may produce a variable-length vector of <code>:1x:M</code> where M is the upper bound on N.
randi	<ul style="list-style-type: none"> For an upper-bounded variable N, <code>randi(imax,1,N)</code> produces a variable-length vector of <code>1x:M</code> where M is the upper bound on N. For an upper-bounded variable N, <code>randi(imax,[1 N])</code> may produce a variable-length vector of <code>:1x:M</code> where M is the upper bound on N.
randn	<ul style="list-style-type: none"> For an upper-bounded variable N, <code>randn(1,N)</code> produces a variable-length vector of <code>1x:M</code> where M is the upper bound on N. For an upper-bounded variable N, <code>randn([1 N])</code> may produce a variable-length vector of <code>:1x:M</code> where M is the upper bound on N.

Function	Restrictions for Variable-Size Data
reshape	<ul style="list-style-type: none"> • If the input is a variable-size array and the output array has at least one fixed-length dimension, do not specify the output dimension sizes in a size vector SZ. Instead, specify the output dimension sizes as scalar values, SZ1, . . . , SZN. Specify fixed-size dimensions as constants. • When the input is a variable-size empty array, the maximum dimension size of the output array (also empty) cannot be larger than that of the input.
roots	<ul style="list-style-type: none"> • See “Variable-length vector restriction” on page 48-30.
shiftdim	<ul style="list-style-type: none"> • If you do not supply the second argument, the number of shifts is determined at compilation time by the upper bounds of the dimension sizes. Consequently, at run time the number of shifts is constant. • An error occurs if the dimension that is shifted to the first dimension has length 1 at run time. To avoid the error, supply the number of shifts as the second input argument (must be a constant). • First input argument must have the same number of dimensions when you supply a positive number of shifts.
std	<ul style="list-style-type: none"> • See “Automatic dimension restriction” on page 48-30. • An error occurs if you pass a variable-size matrix with 0-by-0 dimensions at run time.
sub2ind	<ul style="list-style-type: none"> • First input (the size vector input) must be fixed size.
sum	<ul style="list-style-type: none"> • See “Automatic dimension restriction” on page 48-30. • An error occurs if you pass as the first argument a variable-size matrix that is 0-by-0 at run time.
trapz	<ul style="list-style-type: none"> • See “Automatic dimension restriction” on page 48-30. • An error occurs if you pass as the first argument a variable-size matrix that is 0-by-0 at run time.

Function	Restrictions for Variable-Size Data
typecast	<ul style="list-style-type: none">• See “Variable-length vector restriction” on page 48-30 on first argument.
var	<ul style="list-style-type: none">• See “Automatic dimension restriction” on page 48-30.• An error occurs if you pass a variable-size matrix with 0-by-0 dimensions at run time.

Code Generation for MATLAB Structures

- “Structure Definition for Code Generation” on page 49-2
- “Structure Operations Allowed for Code Generation” on page 49-3
- “Define Scalar Structures for Code Generation” on page 49-4
- “Define Arrays of Structures for Code Generation” on page 49-6
- “Index Substructures and Fields” on page 49-8
- “Assign Values to Structures and Fields” on page 49-10
- “Pass Large Structures as Input Parameters” on page 49-12

Structure Definition for Code Generation

To generate efficient standalone code for structures, you must define and use structures differently than you normally would when running your code in the MATLAB environment:

What's Different	More Information
Use a restricted set of operations.	“Structure Operations Allowed for Code Generation” on page 49-3
Observe restrictions on properties and values of scalar structures.	“Define Scalar Structures for Code Generation” on page 49-4
Make structures uniform in arrays.	“Define Arrays of Structures for Code Generation” on page 49-6
Reference structure fields individually during indexing.	“Index Substructures and Fields” on page 39-80
Avoid type mismatch when assigning values to structures and fields.	“Assign Values to Structures and Fields” on page 39-84

Structure Operations Allowed for Code Generation

To generate efficient standalone code for MATLAB structures, you are restricted to the following operations:

- Define structures as local and persistent variables by assignment and using the `struct` function
- Index structure fields using dot notation
- Define primary function inputs as structures
- Pass structures to local functions

Define Scalar Structures for Code Generation

In this section...

“Restrictions When Defining Scalar Structures by Assignment” on page 49-4
 “Adding Fields in Consistent Order on Each Control Flow Path” on page 49-4
 “Restriction on Adding New Fields After First Use” on page 49-5

Restrictions When Defining Scalar Structures by Assignment

When you define a scalar structure by assigning a variable to a preexisting structure, you do not need to define the variable before the assignment. However, if you already defined that variable, it must have the same class, size, and complexity as the structure you assign to it. In the following example, `p` is defined as a structure that has the same properties as the predefined structure `S`:

```
...
S = struct('a', 0, 'b', 1, 'c', 2);
p = S;
...
```

Adding Fields in Consistent Order on Each Control Flow Path

When you create a structure, you must add fields in the same order on each control flow path. For example, the following code generates a compiler error because it adds the fields of structure `x` in a different order in each `if` statement clause:

```
function y = fcn(u) %#codegen
if u > 0
    x.a = 10;
    x.b = 20;
else
    x.b = 30; % Generates an error (on variable x)
    x.a = 40;
end
y = x.a + x.b;
```

In this example, the assignment to `x.a` comes before `x.b` in the first `if` statement clause, but the assignments appear in reverse order in the `else` clause. Here is the corrected code:

```
function y = fcn(u) %#codegen
if u > 0
    x.a = 10;
    x.b = 20;
else
    x.a = 40;
    x.b = 30;
end
y = x.a + x.b;
```

Restriction on Adding New Fields After First Use

You cannot add fields to a structure after you perform the following operations on the structure:

- Reading from the structure
- Indexing into the structure array
- Passing the structure to a function

For example, consider this code:

```
...
x.c = 10; % Defines structure and creates field c
y = x; % Reads from structure
x.d = 20; % Generates an error
...
```

In this example, the attempt to add a new field `d` after reading from structure `x` generates an error.

This restriction extends across the structure hierarchy. For example, you cannot add a field to a structure after operating on one of its fields or nested structures, as in this example:

```
function y = fcn(u) %#codegen

x.c = 10;
y = x.c;
x.d = 20; % Generates an error
```

In this example, the attempt to add a new field `d` to structure `x` after reading from the structure's field `c` generates an error.

Define Arrays of Structures for Code Generation

In this section...

“Ensuring Consistency of Fields” on page 49-6

“Using repmat to Define an Array of Structures with Consistent Field Properties” on page 49-6

“Defining an Array of Structures by Using struct” on page 49-7

“Defining an Array of Structures Using Concatenation” on page 49-7

Ensuring Consistency of Fields

For code generation, when you create an array of MATLAB structures, corresponding fields in the array elements must have the same size, type, and complexity.

Once you have created the array of structures, you can make the structure fields variable-size using `coder. varsizes`. For more information, see “Declare a Variable-Size Structure Field.”.

Using repmat to Define an Array of Structures with Consistent Field Properties

You can create an array of structures from a scalar structure by using the MATLAB `repmat` function, which replicates and tiles an existing scalar structure:

- 1 Create a scalar structure, as described in “Define Scalar Structures for Code Generation” on page 49-4.
- 2 Call `repmat`, passing the scalar structure and the dimensions of the array.
- 3 Assign values to each structure using standard array indexing and structure dot notation.

For example, the following code creates `X`, a 1-by-3 array of scalar structures. Each element of the array is defined by the structure `s`, which has two fields, `a` and `b`:

```
...  
s.a = 0;  
s.b = 0;  
X = repmat(s,1,3);
```

```
X(1).a = 1;
X(2).a = 2;
X(3).a = 3;
X(1).b = 4;
X(2).b = 5;
X(3).b = 6;
...
```

Defining an Array of Structures by Using `struct`

To create an array of structures using the `struct` function, specify the field value arguments as cell arrays. Each cell array element is the value of the field in the corresponding structure array element. For code generation, corresponding fields in the structures must have the same type. Therefore, the elements in a cell array of field values must have the same type.

For example, the following code creates a 1-by-3 structure array. For each structure in the array of structures, `a` has type `double` and `b` has type `char`.

```
s = struct('a', {1 2 3}, 'b', {'a' 'b' 'c'});
```

Defining an Array of Structures Using Concatenation

To create a small array of structures, you can use the concatenation operator, square brackets (`[]`), to join one or more structures into an array (see “Concatenating Matrices”). For code generation, the structures that you concatenate must have the same size, class, and complexity.

For example, the following code uses concatenation and a local function to create the elements of a 1-by-3 structure array:

```
...
W = [ sab(1,2) sab(2,3) sab(4,5) ];

function s = sab(a,b)
    s.a = a;
    s.b = b;
...
```

Index Substructures and Fields

Use these guidelines when indexing substructures and fields for code generation:

Reference substructure field values individually using dot notation

For example, the following MATLAB code uses dot notation to index fields and substructures:

```

...
substruct1.a1 = 15.2;
substruct1.a2 = int8([1 2;3 4]);

mystruct = struct('ele1',20.5,'ele2',single(100),
                 'ele3',substruct1);

substruct2 = mystruct;
substruct2.ele3.a2 = 2*(substruct1.a2);
...

```

The generated code indexes elements of the structures in this example by resolving symbols as follows:

Dot Notation	Symbol Resolution
substruct1.a1	Field a1 of local structure substruct1
substruct2.ele3.a1	Value of field a1 of field ele3, a substructure of local structure substruct2
substruct2.ele3.a2(1,1)	Value in row 1, column 1 of field a2 of field ele3, a substructure of local structure substruct2

Reference field values individually in structure arrays

To reference the value of a field in a structure array, you must index into the array to the structure of interest and then reference that structure's field individually using dot notation, as in this example:

```

...
y = X(1).a % Extracts the value of field a
           % of the first structure in array X
...

```

To reference all the values of a particular field for each structure in an array, use this notation in a `for` loop, as in this example:

```
...  
s.a = 0;  
s.b = 0;  
X = repmat(s,1,5);  
for i = 1:5  
    X(i).a = i;  
    X(i).b = i+1;  
end
```

This example uses the `repmat` function to define an array of structures, each with two fields `a` and `b` as defined by `s`. See “Define Arrays of Structures for Code Generation” on page 49-6 for more information.

Do not reference fields dynamically

You cannot reference fields in a structure by using dynamic names, which express the field as a variable expression that MATLAB evaluates at run time (see “Generate Field Names from Variables”).

Assign Values to Structures and Fields

When assigning values to a structure, substructure, or field for code generation, use these guidelines:

Field properties must be consistent across structure-to-structure assignments

If:	Then:
Assigning one structure to another structure.	Define each structure with the same number, type, and size of fields.
Assigning one structure to a substructure of a different structure and vice versa.	Define the structure with the same number, type, and size of fields as the substructure.
Assigning an element of one structure to an element of another structure.	The elements must have the same type and size.

For structures with constant fields, do not assign field values inside control flow constructs

In the following code, the code generator recognizes that the structure fields `s.a` and `s.b` are constants.

```
function y = mystruct()
s.a = 3;
s.b = 5;
y = zeros(s.a,s.b);
```

If a field of a structure is assigned inside a control flow construct, the code generator does not recognize that `s.a` and `s.b` are constant. Consider the following code:

```
function y = mystruct(x)
s.a = 3;
if x > 1
    s.b = 4;
else
    s.b = 5;
end
y = zeros(s.a,s.b);
```

If variable-sizing is enabled, `y` is treated as a variable-size array. If variable-sizing is disabled, `y`, the code generator reports an error.

Do not assign mxArray's to structures

You cannot assign mxArray's to structure elements; convert mxArray's to known types before code generation (see "Working with mxArray's" on page 54-17).

Do not assign classes to structure fields

You cannot assign classes to structure fields.

Do not assign cell arrays to structure fields

You cannot assign cell arrays to structure fields.

Pass Large Structures as Input Parameters

If you generate a MEX function for a MATLAB function that takes a large structure as an input parameter, for example, a structure containing fields that are matrices, the MEX function might fail to load. This load failure occurs because, when you generate a MEX function from a MATLAB function that has input parameters, the code generator allocates memory for these input parameters on the stack. To avoid this issue, pass the structure by reference to the MATLAB function. For example, if the original function signature is:

```
y = foo(a, S)
```

where **S** is the structure input, rewrite the function to:

```
[y, S] = foo(a, S)
```

Code Generation for Cell Arrays

- “Code Generation for Cell Arrays” on page 50-2
- “Control Whether a Cell Array Is Variable-Size” on page 50-5
- “Cell Array Limitations for Code Generation” on page 50-8

Code Generation for Cell Arrays

When you generate code from MATLAB code that contains cell arrays, the code generator classifies the cell arrays as *homogeneous* or *heterogeneous*. This classification determines how a cell array is represented in the generated code. It also determines how you can use the cell array in MATLAB code from which you generate code.

When you use cell arrays in MATLAB code that is intended for code generation, you must adhere to certain restrictions. See “Cell Array Limitations for Code Generation” on page 50-8.

Homogeneous vs. Heterogeneous Cell Arrays

A homogeneous cell array has these characteristics:

- The cell array is represented as an array in the generated code.
- All elements have the same properties. The type associated with the cell array specifies the properties of all elements rather than the properties of individual elements.
- The cell array can be variable-size.
- You can index into the cell array with an index whose value is determined at run time.

A heterogeneous cell array has these characteristics:

- The cell array is represented as a structure in the generated code. Each element is represented as a field of the structure.
- The elements can have different properties. The type associated with the cell array specifies the properties of each element individually.
- The cell array cannot be variable-size.
- You must index into the cell array with a constant index or with `for`-loops that have constant bounds.

The code generator uses heuristics to determine the classification of a cell array as homogeneous or heterogeneous. It considers the properties (class, size, complexity) of the elements and other factors, such as how you use the cell array in your program. Depending on how you use a cell array, the code generator can classify a cell array as

homogeneous in one case and heterogeneous in another case. For example, consider the cell array `{1 [2 3]}`. The code generator can classify this cell array as a heterogeneous 1-by-2 cell array. The first element is double scalar. The second element is a 1-by-2 array of doubles. However, if you index into this cell array with an index whose value is determined at run time, the code generator classifies it as a homogeneous cell array. The elements are variable-size arrays of doubles with an upper bound of 2.

Controlling Whether a Cell Array Is Homogeneous or Heterogeneous

For cell arrays with certain characteristics, you cannot control the classification as homogeneous or heterogeneous:

- If the elements have different classes, the cell array must be heterogeneous.
- If the cell array is variable-size, it must be homogeneous.
- If you index into the cell array with an index whose value is determined at run time, the cell array must be homogeneous.

For other cell arrays, you can control the classification as homogeneous or heterogeneous.

- If the cell array is fixed-size, you can force an otherwise homogeneous cell array to be heterogeneous by using `coder.cstructname`. For example:

```
...
c = {1 2 3};
coder.cstructname(c, 'myname');
...
```

- If the cell array elements have the same class, you can force a cell array to be homogeneous by using `coder.varsizes`. See “Control Whether a Cell Array Is Variable-Size” on page 50-5.

Cell Arrays in Reports

To see whether a cell array is homogeneous or heterogeneous, view the variable in the MATLAB Function report.

For a homogeneous cell array, the report has one entry that specifies the properties of all elements. The notation `{:}` indicates that all elements of the cell array have the same properties.

Summary	All Messages (0)	Variables				
Order	Variable	Type	Size	Class	Complex	
1	z	Output	1 x 1	double	No	
2	c	Local	1 x 2	cell	-	
2.1	<i>c{1}</i>	Element	1 x 1	double	No	

For a heterogeneous cell array, the report has an entry for each element. For example, for a heterogeneous cell array `c` with two elements, the entry for `c{1}` shows the properties for the first element. The entry for `c{2}` shows the properties for the second element.

Summary	All Messages (0)	Variables				
Order	Variable	Type	Size	Class	Complex	
1	z	Output	1 x 1	double	No	
2	c	Local	1 x 2	cell	-	
2.1	<i>c{1}</i>	Element	1 x 1	double	No	
2.2	<i>c{2}</i>	Element	1 x 1	char	-

- “MATLAB Function Reports” on page 39-48

Control Whether a Cell Array Is Variable-Size

The code generator classifies a variable-size cell array as homogeneous. The cell array elements must have the same class. In the generated code, the cell array is represented as an array.

To make a cell array variable-size:

- Create the cell array by using the `cell` function. For example:

```
function z = mycell(n, j)
%#codegen
assert (n < 100);
x = cell(1,n);
for i = 1:n
    x{i} = i;
end
z = x{j};
end
```

For code generation, when you create a variable-size cell array by using `cell`, you must adhere to certain restrictions. See “Definition of Variable-Size Cell Array by Using `cell`” on page 50-9.

- Grow the cell array. For example:

```
function z = mycell(n)
%#codegen
c = {1 2 3};
if n > 3
    c = {1 2 3 4};
end
z = c{n};
end
```

- Force the cell array to be variable-size by using `coder. varsize`. Consider this code:

```
function y = mycellfun()
%#codegen
c = {1 2 3};
coder. varsize('c', [1 10]);
y = c{1};
end
```

Without `coder.versize`, `c` is fixed-size with dimensions 1-by-3. With `coder.versize`, `c` is variable-size with an upper bound of 10.

Sometimes, using `coder.versize` changes the classification of a cell array from heterogeneous to homogeneous. Consider this code:

```
function y = mycell()
%#codegen
c = {1 [2 3]};
y = c{2};
end
```

The code generator classifies `c` as heterogeneous because the elements have different sizes. `c` is fixed-size with dimensions 1-by-2. If you use `coder.versize` with `c`, it becomes homogeneous. For example:

```
function y = mycell()
%#codegen
c = {1 [2 3]};
coder.versize('c', [1 10], [0 1]);
y = c{2};
end
```

`c` becomes a variable-size homogeneous cell array with dimensions 1-by-:10.

To force `c` to be homogeneous, but not variable-size, specify that none of the dimensions vary. For example:

```
function y = mycell()
%#codegen
c = {1 [2 3]};
coder.versize('c', [1 2], [0 0]);
y = c{2};
end
```

Cell Array Limitations for Code Generation

When you use cell arrays in MATLAB code that is intended for code generation, you must adhere to these restrictions:

- “Cell Array Element Assignment” on page 50-8
- “Definition of Variable-Size Cell Array by Using `cell`” on page 50-9
- “Cell Array Indexing” on page 50-13
- “Growing a Cell Array by Using `{end + 1}`” on page 50-13
- “Variable-Size Cell Arrays” on page 50-14
- “Cell Array Contents” on page 50-15
- “Cell Arrays in Structures” on page 50-15
- “Passing Cell Arrays to External C/C++ Functions” on page 50-15
- “Use in MATLAB Function Block” on page 50-15

Cell Array Element Assignment

You must assign a cell array element on all execution paths before you use it. For example:

```
function z = foo(n)
%#codegen
c = cell(1,3);
if n < 1
    c{2} = 1;

else
    c{2} = n;
end
z = c{2};
end
```

The code generator considers passing a cell array to a function or returning it from a function as a use of all elements of the cell array. Therefore, before you pass a cell array to a function or return it from a function, you must assign all of its elements. For example, the following code is not allowed because it does not assign a value to `c{2}` and `c` is a function output.

```
function c = foo()
%#codegen
```

```
c = cell(1,3);
c{1} = 1;
c{3} = 3;
end
```

The assignment of values to elements must be consistent on all execution paths. The following code is not allowed because `y{2}` is double on one execution path and char on the other execution path.

```
function y = foo(n)
y = cell(1,3)
if n > 1;
    y{1} = 1;
    y{2} = 2;
    y{3} = 3;
else
    y{1} = 10;
    y{2} = 'a';
    y{3} = 30;
end
```

Definition of Variable-Size Cell Array by Using `cell`

For code generation, before you use a cell array element, you must assign a value to it. When you use `cell` to create a variable-size cell array, for example, `cell(1,n)`, MATLAB assigns an empty matrix to each element. However, for code generation, the elements are unassigned. For code generation, after you use `cell` to create a variable-size cell array, you must assign all elements of the cell array before any use of the cell array. For example:

```
function z = mycell(n, j)
%#codegen
assert(n < 100);
x = cell(1,n);
for i = 1:n
    x{i} = i;
end
z = x{j};
end
```

The code generator analyzes your code to determine whether all elements are assigned before the first use of the cell array. If the code generator detects that some elements are not assigned, code generation fails with a message like this message:

Unable to determine that every element of 'y' is assigned before this line.

Sometimes, even though your code assigns all elements of the cell array, the code generator reports this message because the analysis does not detect that all elements are assigned. See “Unable to Determine That Every Element of Cell Array Is Assigned” on page 56-8.

To avoid this error, follow these guidelines:

- When you use `cell` to define a variable-size cell array, write code that follows this pattern:

```
function z = mycell(n, j)
%#codegen
assert(n < 100);
x = cell(1,n);
for i = 1:n
    x{i} = i;
end
z = x{j};
end
```

Here is the pattern for a multidimensional cell array:

```
function z = mycell(m,n,p)
%#codegen
assert(m < 100);
assert(n < 100);
assert(p < 100);
x = cell(m,n,p);
for i = 1:m
    for j = 1:n
        for k = 1:p
            x{i,j,k} = i+j+k;
        end
    end
end
z = x{m,n,p};
end
```

- Increment or decrement the loop counter by 1.
- Define the cell array within one loop or one set of nested loops. For example, this code is not allowed:

```
function z = mycell(n, j)
```

```

assert(n < 50);
assert(j < 50);
x = cell(1,n);
for i = 1:5
    x{i} = 5;
end
for i = 6:n
    x{i} = 5;
end
z = x{j};
end

```

- Use the same variables for the cell dimensions and loop initial and end values. For example, code generation fails for the following code because the cell creation uses `n` and the loop end value uses `m`:

```

function z = mycell(n, j)
assert(n < 50);
assert(j < 50);
x = cell(1,n);
m = n;
for i = 1:m
    x{i} = 2;
end
z = x{j};
end

```

Rewrite the code to use `n` for the cell creation and the loop end value:

```

function z = mycell(n, j)
assert(n < 50);
assert(j < 50);
x = cell(1,n);
for i = 1:n
    x{i} = 2;
end
z = x{j};
end

```

- Create the cell array with this pattern:

```
x = cell(1,n)
```

Do not assign the cell array to a field of a structure or a property of an object. For example, this code is not allowed:

```
myobj.prop = cell(1,n)
for i = 1:n
    ...
end
```

Do not use the `cell` function inside the cell array constructor `{}`. For example, this code is not allowed:

```
x = {cell(1,n)};
```

- The cell array creation and the loop that assigns values to the cell array elements must be together in a unique execution path. For example, the following code is not allowed.

```
function z = mycell(n)
assert(n < 100);
if n > 3
    c = cell(1,n);
else
    c = cell(n,1);
end
for i = 1:n
    c{i} = i;
end
z = c{n};
end
```

To fix this code, move the assignment loop inside the code block that creates the cell array.

```
function z = cellerr(n)
assert(n < 100);
if n > 3
    c = cell( 1,n);
    for i = 1:n
        c{i} = i;
    end
else
    c = cell(n,1);
    for i = 1:n
        c{i} = i;
    end
end
z = c{n};
```

```
end
```

Cell Array Indexing

- You cannot index cell arrays by using smooth parentheses (). Consider indexing cell arrays by using curly braces{} to access the contents of the cell.
- You must index into heterogeneous cell arrays by using constant indices or by using for-loops with constant bounds.

For example, the following code is not allowed.

```
x = {1, 'mytext'};
disp(x{randi});
```

You can index into a heterogeneous cell array in a for-loop with constant bounds because the code generator unrolls the loop. Unrolling creates a separate copy of the loop body for each loop iteration, which makes the index in each loop iteration constant. However, if the for-loop has a large body or it has many iterations, the unrolling can increase compile time and generate inefficient code.

If A and B are constant, the following code shows indexing into a heterogeneous cell array in a for-loop with constant bounds.

```
x = {1, 'mytext'};
for i = A:B
    disp(x{i});
end
```

Growing a Cell Array by Using {end + 1}

To grow a cell array X, you can use X{end + 1}. For example:

```
...
X = {1 2};
X{end + 1} = 'a';
...
```

When you use {end + 1} to grow a cell array, follow these restrictions:

- In a MATLAB Function block, do not use {end + 1} in a for-loop.
- Use only {end + 1}. Do not use {end + 2}, {end + 3}, and so on.

- Use `{end + 1}` with vectors only. For example, the following code is not allowed because `X` is a matrix, not a vector:

```
...
X = {1 2; 3 4};
X{end + 1} = 5;
```

```
...
```

- Use `{end + 1}` only with a variable. In the following code, `{end + 1}` does not cause `{1 2 3}` to grow. In this case, the code generator treats `{end + 1}` as an out-of-bounds index into `X{2}`.

```
...
X = {'a' { 1 2 3 }};
X{2}{end + 1} = 4;
```

```
...
```

- When `{end + 1}` grows a cell array in a loop, the cell array must be variable-size. Therefore, the cell array must be homogeneous.

This code is allowed because `X` is homogeneous.

```
...
X = {1 2};
for i=1:n
    X{end + 1} = 3;
end
...
```

This code is not allowed because `X` is heterogeneous.

```
...
X = {1 'a' 2 'b'};
for i=1:n
    X{end + 1} = 3;
end
...
```

Variable-Size Cell Arrays

- Heterogeneous cell arrays cannot be variable-size.
- If you use `coder.varsize` to make a variable-size cell array, define the cell array with curly braces. For example:

```
...  
c = {1 [2 3]};  
coder.varsize('c')  
...
```

Do not use the `cell` function. For example, this code is not allowed:

```
...  
c = cell(1,3);  
coder.varsize('c')  
...
```

Cell Array Contents

Cell arrays cannot contain `mxarrays`. In a cell array, you cannot store a value that an extrinsic function returns.

Cell Arrays in Structures

Structures cannot contain cell arrays.

Passing Cell Arrays to External C/C++ Functions

You cannot pass a cell array to `coder.ceval`. If a variable is an input argument to `coder.ceval`, define the variable as an array or structure instead of as a cell array.

Use in MATLAB Function Block

You cannot use cell arrays for Simulink signals, parameters, or data store memory.

MATLAB Classes Definition for Code Generation

To generate efficient standalone code for MATLAB classes, you must use classes differently than when running your code in the MATLAB environment.

What's Different	More Information
Class must be in a single file. Because of this limitation, code generation is not supported for a class definition that uses an @-folder.	"Create a Single, Self-Contained Class Definition File"
Restricted set of language features.	"Language Limitations" on page 51-2
Restricted set of code generation features.	"Code Generation Features Not Compatible with Classes" on page 51-3
Definition of class properties.	"Defining Class Properties for Code Generation" on page 51-4
Use of handle classes.	"Generate Code for MATLAB Handle Classes and System Objects" on page 51-14 "Handle Object Limitations for Code Generation" on page 51-22
Calls to base class constructor.	"Calls to Base Class Constructor" on page 51-5
Global variables containing MATLAB objects are not supported for code generation.	N/A
Inheritance from built-in MATLAB classes is not supported.	"Inheritance from Built-In MATLAB Classes Not Supported" on page 51-7

Language Limitations

Although code generation support is provided for common features of classes such as properties and methods, there are a number of advanced features which are not supported, such as:

- Events

- Listeners
- Arrays of objects
- Recursive data structures
 - Linked lists
 - Trees
 - Graphs
- Overloadable operators `subsref`, `subsassign`, and `subsindex`

In MATLAB, classes can define their own versions of the `subsref`, `subsassign`, and `subsindex` methods. Code generation does not support classes that have their own definitions of these methods.

- The empty method

In MATLAB, classes have a built-in static method, `empty`, which creates an empty array of the class. Code generation does not support this method.

- The following MATLAB handle class methods:
 - `addlistener`
 - `delete`
 - `eq`
 - `findobj`
 - `findpro`
- The `AbortSet` property attribute

Code Generation Features Not Compatible with Classes

- You can generate code for entry-point MATLAB functions that use classes, but you cannot generate code directly for a MATLAB class.

For example, if `ClassNameA` is a class definition, you cannot generate code by executing:

```
codegen ClassNameA
```

- If an entry-point MATLAB function has an input or output that is a MATLAB class, you cannot generate code for this function.

For example, if function `foo` takes one input, `a`, that is a MATLAB object, you cannot generate code for `foo` by executing:

```
codegen foo -args {a}
```

- Code generation does not support classes in matrices or structures. As a workaround, consider using cell arrays because code generation supports classes in cell arrays.
- Code generation does not support assigning an object of a value class into a nontunable property. For example, `obj.prop=v;` is invalid when `prop` is a nontunable property and `v` is an object based on a value class.
- You cannot use `coder.extrinsic` to declare a class or method as extrinsic.
- You cannot pass a MATLAB class to the `coder.ceval` function.
- If you use classes in code in the MATLAB Function block, you cannot use the debugger to view class information.
- The `coder.nullcopy` function does not support MATLAB classes as inputs.

Defining Class Properties for Code Generation

For code generation, you must define class properties differently than you do when running your code in the MATLAB environment:

- Code generation does not support the property restriction syntax. For example, the following class definition is not allowed because it uses the property restriction syntax to restrict the types of the `Number` and `Today` properties.

```
classdef Myclass
    properties
        Number double
        Today char = date;
    end
end
```

- After defining a property, do not assign it an incompatible type. Do not use a property before attempting to grow it.

When you define class properties for code generation, consider the same factors that you take into account when defining variables. In the MATLAB language, variables can change their class, size, or complexity dynamically at run time so you can use the same variable to hold a value of varying class, size, or complexity. C and C++ use static typing. Before using variables, to determine their type, the code generator

requires a complete assignment to each variable. Similarly, before using properties, you must explicitly define their class, size, and complexity.

- Initial values:
 - If the property does not have an explicit initial value, the code generator assumes that it is undefined at the beginning of the constructor. The code generator does not assign an empty matrix as the default.
 - If the property does not have an initial value and the code generator cannot determine that the property is assigned prior to first use, the software generates a compilation error.
 - For System objects, if a nontunable property is a structure, you must completely assign the structure. You cannot do partial assignment using subscripting.

For example, for a nontunable property, you can use the following assignment:

```
mySystemObject.nonTunableProperty=struct('fieldA','a','fieldB','b');
```

You cannot use the following partial assignments:

```
mySystemObject.nonTunableProperty.fieldA = a;
mySystemObject.nonTunableProperty.fieldB = b;
```

- If dynamic memory allocation is enabled, code generation supports variable-size properties for handle classes. Without dynamic memory allocation, you cannot generate code for handle classes that have variable-size properties.
- `coder. varsize` is not supported for class properties.
- MATLAB computes class initial values at class loading time before code generation. If you use persistent variables in MATLAB class property initialization, the value of the persistent variable computed when the class loads belongs to MATLAB; it is not the value used at code generation time. If you use `coder.target` in MATLAB class property initialization, `coder.target('MATLAB')` returns `true (1)`.

Calls to Base Class Constructor

If a class constructor contains a call to the constructor of the base class, the call to the base class constructor must come before `for`, `if`, `return`, `switch` or `while` statements.

For example, if you define a class `B` based on class `A`:

```
classdef B < A
    methods
```

```
function obj = B(varargin)
    if nargin == 0
        a = 1;
        b = 2;
    elseif nargin == 1
        a = varargin{1};
        b = 1;
    elseif nargin == 2
        a = varargin{1};
        b = varargin{2};
    end
    obj = obj@A(a,b);
end
```

```
end
end
```

Because the class definition for **B** uses an **if** statement before calling the base class constructor for **A**, you cannot generate code for function **callB**:

```
function [y1,y2] = callB
x = B;
y1 = x.p1;
y2 = x.p2;
end
```

However, you can generate code for **callB** if you define class **B** as:

```
classdef B < A
    methods
        function obj = NewB(varargin)
            [a,b] = getaandb(varargin{:});
            obj = obj@A(a,b);
        end
    end
end
```

```
end
end
```

```
function [a,b] = getaandb(varargin)
if nargin == 0
    a = 1;
    b = 2;
elseif nargin == 1
    a = varargin{1};
    b = 1;
end
```

```
elseif nargin == 2
    a = varargin{1};
    b = varargin{2};
end
end
```

Inheritance from Built-In MATLAB Classes Not Supported

You cannot generate code for classes that inherit from built-in MATLAB classes. For example, you cannot generate code for the following class:

```
classdef myclass < double
```

Classes That Support Code Generation

You can generate code for MATLAB value and handle classes and user-defined System objects. Your class can have multiple methods and properties and can inherit from multiple classes.

To generate code for:	Example:
Value classes	“Generate Code for MATLAB Value Classes” on page 51-9
Handle classes including user-defined System objects	“Generate Code for MATLAB Handle Classes and System Objects” on page 51-14

For more information, see:

- “Role of Classes in MATLAB”
- “MATLAB Classes Definition for Code Generation” on page 51-2

Generate Code for MATLAB Value Classes

This example shows how to generate code for a MATLAB value class and then view the generated code in the code generation report.

- 1 In a writable folder, create a MATLAB value class, `Shape`. Save the code as `Shape.m`.

```

classdef Shape
% SHAPE Create a shape at coordinates
% centerX and centerY
    properties
        centerX;
        centerY;
    end
    properties (Dependent = true)
        area;
    end
    methods
        function out = get.area(obj)
            out = obj.getarea();
        end
        function obj = Shape(centerX,centerY)
            obj.centerX = centerX;
            obj.centerY = centerY;
        end
    end
end
methods(Abstract = true)
    getarea(obj);
end
methods(Static)
    function d = distanceBetweenShapes(shape1,shape2)
        xDist = abs(shape1.centerX - shape2.centerX);
        yDist = abs(shape1.centerY - shape2.centerY);
        d = sqrt(xDist^2 + yDist^2);
    end
end
end
end

```

- 2 In the same folder, create a class, `Square`, that is a subclass of `Shape`. Save the code as `Square.m`.

```

classdef Square < Shape
% Create a Square at coordinates center X and center Y

```

```

% with sides of length of side
properties
    side;
end
methods
    function obj = Square(side,centerX,centerY)
        obj@Shape(centerX,centerY);
        obj.side = side;
    end
    function Area = getarea(obj)
        Area = obj.side^2;
    end
end
end

```

- 3 In the same folder, create a class, Rhombus, that is a subclass of Shape. Save the code as Rhombus.m.

```

classdef Rhombus < Shape
    properties
        diag1;
        diag2;
    end
    methods
        function obj = Rhombus(diag1,diag2,centerX,centerY)
            obj@Shape(centerX,centerY);
            obj.diag1 = diag1;
            obj.diag2 = diag2;
        end
        function Area = getarea(obj)
            Area = 0.5*obj.diag1*obj.diag2;
        end
    end
end
end

```

- 4 Write a function that uses this class.

```

function [TotalArea, Distance] = use_shape
%#codegen
s = Square(2,1,2);
r = Rhombus(3,4,7,10);
TotalArea = s.area + r.area;
Distance = Shape.distanceBetweenShapes(s,r);

```

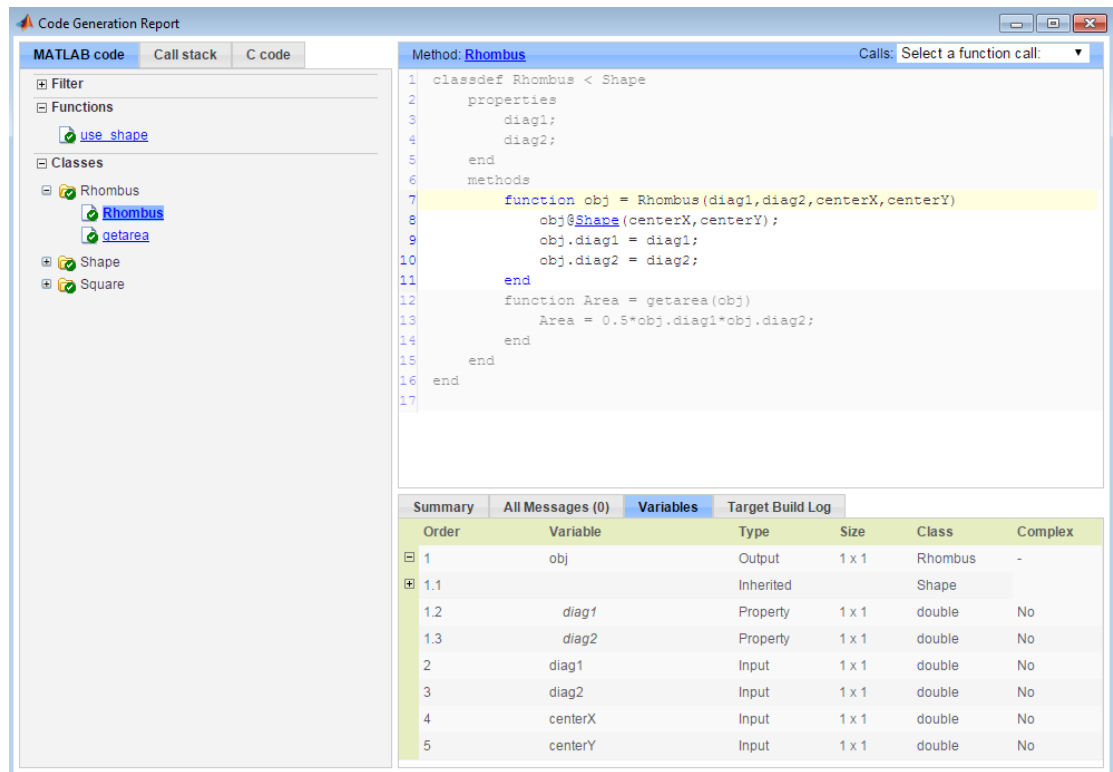

- 5 Generate a static library for use_shape and generate a code generation report.

codegen -config:lib -report use_shape

codegen generates a C static library with the default name, use_shape, and supporting files in the default folder, codegen/lib/use_shape.

- 6 Click the **View report** link.
- 7 In the report, on the **MATLAB code** tab, click the link to the Rhombus class.

The report displays the class definition of the Rhombus class and highlights the class constructor. On the **Variables** tab, it provides details of the variables used in the class. If a variable is a MATLAB object, by default, the report displays the object without displaying its properties. To view the list of properties, expand the list. Within the list of properties, the list of inherited properties is collapsed. In the following report, the lists of properties and inherited properties are expanded.

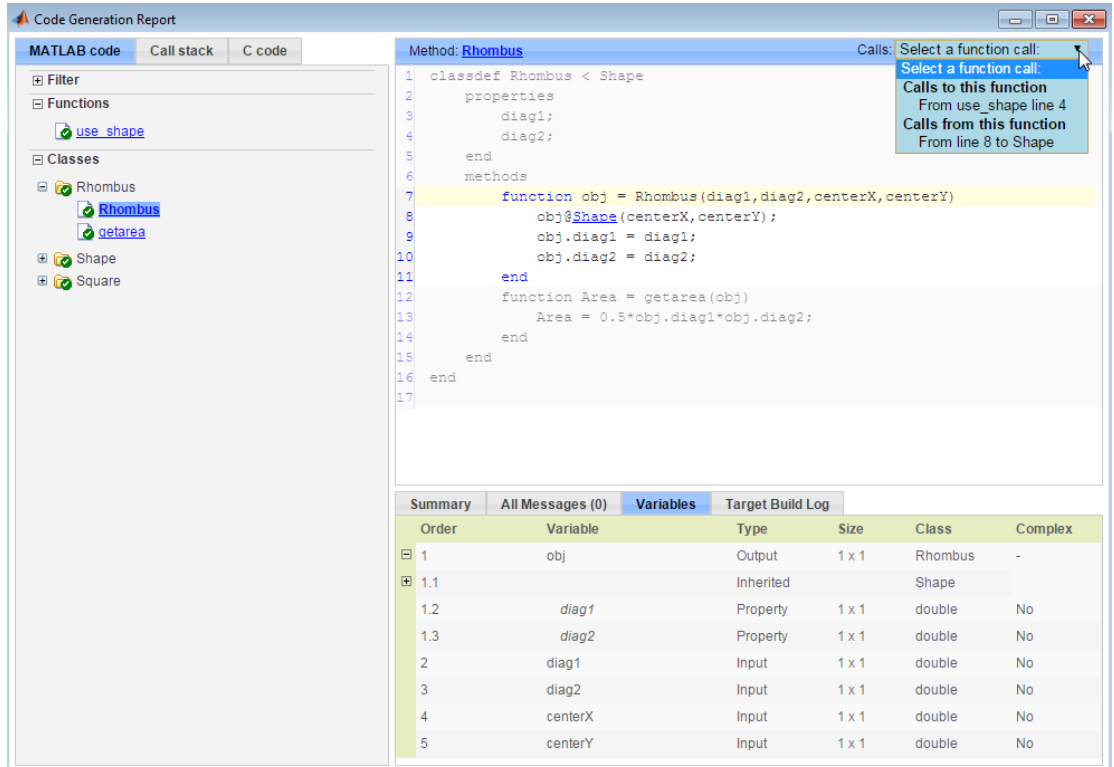

The screenshot shows the Code Generation Report window with the MATLAB code tab selected. The code defines the Rhombus class, its properties (diag1, diag2), and methods (constructor, getarea). The Variables tab is also visible, showing a table of variables used in the code.

Order	Variable	Type	Size	Class	Complex
1	obj	Output	1 x 1	Rhombus	-
1.1		Inherited		Shape	
1.2	diag1	Property	1 x 1	double	No
1.3	diag2	Property	1 x 1	double	No
2	diag1	Input	1 x 1	double	No
3	diag2	Input	1 x 1	double	No
4	centerX	Input	1 x 1	double	No
5	centerY	Input	1 x 1	double	No

- 8 At the top right side of the report, expand the **Calls** list.

The **Calls** list shows that there is a call to the Rhombus constructor from `use_shape` and that this constructor calls the Shape constructor.

The screenshot shows the Code Generation Report window with the following content:

MATLAB code Call stack C code

3	diag2	Input	1 x 1	double	No
4	centerX	Input	1 x 1	double	No
5	centerY	Input	1 x 1	double	No

- 9 The constructor for the Rhombus class calls the Shape method of the base Shape class: `obj@Shape`. In the report, click the Shape link in this call.

The link takes you to the Shape method in the Shape class definition.

The screenshot shows the 'Code Generation Report' window with the 'MATLAB code' tab selected. On the left, a tree view shows the project structure with 'use_shape' under Functions and 'Rhombus', 'Shape', and 'Square' under Classes. The main area displays the MATLAB code for the 'Shape' method, including a constructor and a distance calculation function. Below the code is a table with columns for Summary, All Messages (0), Variables, and Target Build Log. The Variables table lists three variables: 'obj' (Output, 1x1, Rhombus, -), 'centerX' (Input, 1x1, double, No), and 'centerY' (Input, 1x1, double, No).

```
11 methods
12     function out = get.area(obj)
13         out = obj.getarea();
14     end
15     function obj = Shape(centerX,centerY)
16         obj.centerX = centerX;
17         obj.centerY = centerY;
18     end
19 end
20 methods(Abstract = true)
21     getarea(obj);
22 end
23 methods(Static)
24     function d = distanceBetweenShapes(shape1,shape2)
25         xDist = abs(shape1.centerX - shape2.centerX);
26         yDist = abs(shape1.centerY - shape2.centerY);
27         d = sqrt(xDist^2 + yDist^2);
28     end
29 end
30 end
31
```

Order	Variable	Type	Size	Class	Complex
1	obj	Output	1 x 1	Rhombus	-
2	centerX	Input	1 x 1	double	No
3	centerY	Input	1 x 1	double	No

Generate Code for MATLAB Handle Classes and System Objects

This example shows how to generate code for a user-defined System object and then view the generated code in the code generation report.

- 1 In a writable folder, create a System object, `AddOne`, which subclasses from `matlab.System`. Save the code as `AddOne.m`.

```
classdef AddOne < matlab.System
% ADDONE Compute an output value that increments the input by one

    methods (Access=protected)
        % stepImpl method is called by the step method
        function y = stepImpl(~,x)
            y = x+1;
        end
    end
end
```

- 2 Write a function that uses this System object.

```
function y = testAddOne(x)
%#codegen
    p = AddOne();
    y = p.step(x);
end
```

- 3 Generate a MEX function for this code.

```
codegen -report testAddOne -args {0}
```

The `-report` option instructs `codegen` to generate a code generation report, even if no errors or warnings occur. The `-args` option specifies that the `testAddOne` function takes one scalar double input.

- 4 Click the **View report** link.
- 5 In the report, on the **MATLAB Code** tab **Functions** panel, click `testAddOne`, then click the **Variables** tab. You can view information about the variable `p` on this tab.

The screenshot shows the 'Code Generation Report' window with the following content:

MATLAB Classes in Code Generation Reports

What Reports Tell You About Classes

Code generation reports:

- Provide a hierarchical tree of the classes used in your MATLAB code.
- Display a list of methods for each class in the MATLAB code tab.
- Display the objects used in your MATLAB code together with their properties on the **Variables** tab.
- Provide a filter so that you can sort methods by class, size, and complexity.
- List the set of calls from and to the selected method in the **Calls** list.

How Classes Appear in Code Generation Reports

In the MATLAB Code Tab

The report displays an alphabetical hierarchical list of the classes used in the your MATLAB code. For each class, you can:

- Expand the class information to view the class methods.
- View a class method by clicking its name. The report displays the methods in the context of the full class definition.
- Filter the methods by size, complexity, and class by using the **Filter functions and methods** option.

Default Constructors

If a class has a default constructor, the report displays the constructor in italics.

Specializations

If the same class is specialized into multiple different classes, the report differentiates the specializations by grouping each one under a single node in the tree. The report associates the class definition functions and static methods with the primary node. It associates the instance-specific methods with the corresponding specialized node.

For example, consider a base class, **Shape** that has two specialized subclasses, **Rhombus** and **Square**. The **Shape** class has an abstract method, `getarea`, and a static method, `distanceBetweenShapes`. The code generation report, displays a

node for the specialized `Rhombus` and `Square` classes with their constructors and `getarea` method. It displays a node for the `Shape` class and its associated static method, `distanceBetweenShapes`, and two instances of the `Shape` class, `Shape1` and `Shape2`.

Packages

If you define classes as part of a package, the report displays the package in the list of classes. You can expand the package to view the classes that it contains. For more information about packages, see “Packages Create Namespaces”.

In the Variables Tab

The report displays the objects in the selected function or class. By default, for classes that have properties, the list of properties is collapsed. To expand the list, click the + symbol next to the object name. Within the list of properties, the list of inherited properties is collapsed. To expand the list of inherited properties, click the + symbol next to `Inherited`.

The report displays the properties using just the base property name, not the fully qualified name. For example, if your code uses variable `obj1` that is a MATLAB object

with property `prop1`, then the report displays the property as `prop1` not `obj1.prop1`. When you sort the **Variables** column, the sort order is based on the fully qualified property name.

In the Call Stack

The call stack lists the functions and methods in the order that the top-level function calls them. It also lists the local functions that each function calls.

Troubleshooting Code Generation Issues with MATLAB Classes

Class *cClass* does not have a property with name *name*

If a MATLAB class has a method, `mymethod`, that returns a handle class with a property, `myprop`, you cannot generate code for the following type of assignment:

```
obj.mymethod().myprop=...
```

For example, consider the following classes:

```
classdef MyClass < handle
    properties
        myprop
    end
    methods
        function this = MyClass
            this.myprop = MyClass2;
        end
        function y = mymethod(this)
            y = this.myprop;
        end
    end
end

classdef MyClass2 < handle
    properties
        aa
    end
end
```

You cannot generate code for function `foo`.

```
function foo
    h = MyClass;
```

```
    h.mymethod().aa = 12;
```

In this function, `h.mymethod()` returns a handle object of type `MyClass2`. In MATLAB, the assignment `h.mymethod().aa = 12;` changes the property of that object. Code generation does not support this assignment.

Solution

Rewrite the code to return the object and then assign a value to a property of the object.

```
function foo  
h = MyClass;  
  
b=h.mymethod();  
b.aa=12;
```

Handle Object Limitations for Code Generation

The code generator statically determines the lifetimes of handle objects. It can reuse memory rather than rely on a dynamic memory management scheme such as reference counting or garbage collection. It generates code that does not use dynamic memory allocation or incur the overhead of run-time automatic memory management. These characteristics of the generated code are important for some safety-critical and real-time applications.

When you use handle objects, the static analysis that the code generator uses requires that you adhere to the following restrictions:

- “A Variable Outside a Loop Cannot Refer to a Handle Object Created Inside a Loop” on page 51-22
- “A Handle Object That a Persistent Variable Refers To Must Be a Singleton Object” on page 51-22

A Variable Outside a Loop Cannot Refer to a Handle Object Created Inside a Loop

Consider the handle class `mycls` and the function `usehandle1`. The code generator reports an error because `p`, which is outside the loop, has a property that refers to a `mycls` object created inside the loop.

```
classdef mycls < handle
    properties
        prop
    end
end

function usehandle1
    p = mycls;
    for i = 1:10
        p.prop = mycls;
    end
end
```

A Handle Object That a Persistent Variable Refers To Must Be a Singleton Object

If a persistent variable refers to a handle object, the code generator allows only one instance of the object during the program’s lifetime. The object must be a *singleton* object.

To create a singleton handle object, enclose statements that create the object in the `isempty()` guard for the persistent variable.

For example, consider the class `mycls` and the function `usehandle2`. The code generator reports an error for `usehandle2` because `p.prop` refers to the `mycls` object that the statement `inner = mycls` creates. This statement creates a `mycls` object for each invocation of `usehandle2`.

```
classdef mycls < handle
    properties
        prop
    end
end

function usehandle2(x)
    assert(isa(x, 'double'));
    persistent p;
    inner = mycls;
    inner.prop = x;
    if isempty(p)
        p = mycls;
        p.prop = inner;
    end
end
```

If you move the statements `inner = mycls` and `inner.prop = x` inside the `isempty()` guard, code generation succeeds. The statement `inner = mycls` executes only once during the program's lifetime.

```
function usehandle2(x)
    assert(isa(x, 'double'));
    persistent p;
    if isempty(p)
        inner = mycls;
        inner.prop = x;
        p = mycls;
        p.prop = inner;
    end
end
```

Consider the function `usehandle3`. The code generator reports an error for `usehandle3` because the persistent variable `p` refers to the `mycls` object that the statement `myobj = mycls` creates. This statement creates a `mycls` object for each invocation of `usehandle3`.

```
function usehandle3(x)
```

```
assert(isa(x, 'double'));
myobj = mycls;
myobj.prop = x;
doinit(myobj);
disp(myobj.prop);
function doinit(obj)
persistent p;
if isempty(p)
    p = obj;
end
```

If you make `myobj` persistent and enclose the statement `myobj = mycls` inside an `if isempty()` guard, code generation succeeds. The statement `myobj = mycls` executes only once during the program's lifetime.

```
function usehandle3(x)
assert(isa(x, 'double'));
persistent myobj;
if isempty(myobj)
    myobj = mycls;
end

doinit(myobj);

function doinit(obj)
persistent p;
if isempty(p)
    p = obj;
end
```

System Objects Requirements and Limitations for Code Generation

The following usage rules and limitations apply to using System objects in code generated from MATLAB.

Object Construction and Initialization

- If objects are stored in persistent variables, initialize System objects once by embedding the object handles in an `if` statement with a call to `isempty()`.
- Set arguments to System object constructors as compile-time constants.
- You cannot initialize System objects properties with other MATLAB class objects as default values in code generation. You must initialize these properties in the constructor.

Inputs and Outputs

- System objects accept a maximum of 1024 inputs. A maximum of 8 dimensions per input is supported.
- The data type of the inputs should not change.
- If you want the size of inputs to change, verify that variable-size is enabled. Code generation support for variable-size data also requires that the `Enable variable sizing` option is enabled, which is the default in MATLAB.

Note: Variable-size properties in MATLAB Function block in Simulink are not supported. System objects predefined in the software do not support variable-size if their data exceeds the `DynamicMemoryAllocationThreshold` value.

- Do not set System objects to become outputs from the MATLAB Function block.
- Do not use the Save and Restore Simulation State as SimState option for any System object in a MATLAB Function block.
- Do not pass a System object as an example input argument to a function being compiled with `codegen`.
- Do not pass a System object to functions declared as extrinsic (functions called in interpreted mode) using the `coder.extrinsic` function. System objects returned from extrinsic functions and scope System objects that automatically become extrinsic can be used as inputs to another extrinsic function, but do not generate code.

Tunable and Nontunable Properties

- The value assigned to a nontunable property must be a constant and there can be at most one assignment to that property (including the assignment in the constructor).
- For most System objects, the only time you can set their nontunable properties during code generation is when you construct the objects.
 - For System objects that are predefined in the software, you can set their tunable properties at construction time or using dot notation after the object is locked.
 - For System objects that you define, you can change their tunable properties at construction time or using dot notation during code generation. For `getNumInputsImpl` and `getNumOutputsImpl` methods, if you set the return argument from an object property, that object property must have the `Nontunable` attribute.
- Objects cannot be used as default values for properties.

Global Variables

- Global variables are allowed in a System object, unless you will be using that System object in Simulink via the MATLAB System block. To avoid syncing global variables between a MEX file and the workspace, use a coder configuration object. For example:

```
f = coder.MEXConfig;  
f.GlobalSyncMethod = 'NoSync'  
Then, include '-config f' in your codegen command.
```

Methods

- Code generation support is available only for these System object methods:
 - `get`
 - `getNumInputs`
 - `getNumOutputs`
 - `isDone` (for sources only)
 - `isLocked`
 - `release`
 - `reset`
 - `set` (for tunable properties)
 - `step`
- For System objects that you define,

Code generation support is available only for these methods:

- `getDiscreteStateImpl`
- `getNumInputsImpl`
- `getNumOutputsImpl`
- `infoImpl`
- `isDoneImpl`
- `isInputDirectFeedThroughImpl`
- `outputImpl`
- `processTunedPropertiesImpl`
- `releaseImpl` — Code is not generated automatically for this method. To release an object, you must explicitly call the `release` method in your code.
- `resetImpl`
- `setupImpl`
- `stepImpl`
- `updateImpl`
- `validateInputsImpl`
- `validatePropertiesImpl`

Code Generation for Function Handles

- “Function Handle Limitations for Code Generation” on page 52-2
- “Code Generation for Anonymous Functions” on page 52-4

Function Handle Limitations for Code Generation

When you use function handles in MATLAB code intended for code generation, adhere to the following restrictions:

Do not use the same bound variable to reference different function handles

In some cases, using the same bound variable to reference different function handles causes a compile-time error. For example, this code does not compile:

```
function y = foo(p)
x = @plus;
if p
    x = @minus;
end
y = x(1, 2);
```

Do not pass function handles to or from `coder.ceval`

You cannot pass function handles as inputs to or outputs from `coder.ceval`. For example, suppose that `f` and `str.f` are function handles:

```
f = @sin;
str.x = pi;
str.f = f;
```

The following statements result in compilation errors:

```
coder.ceval('foo', @sin);
coder.ceval('foo', f);
coder.ceval('foo', str);
```

Do not associate a function handle with an extrinsic function

You cannot create a function handle that references an extrinsic MATLAB function.

Do not pass function handles to or from extrinsic functions

You cannot pass function handles to or from `feval` and other extrinsic MATLAB functions.

Do not pass function handles to or from entry-point functions

You cannot pass function handles as inputs to or outputs from entry-point functions. For example, consider this function:

```
function x = plotFcn(fhandle, data)

assert(isa(fhandle, 'function_handle') && isa(data, 'double'));

plot(data, fhandle(data));
x = fhandle(data);
```

In this example, the function `plotFcn` receives a function handle and its data as inputs. `plotFcn` attempts to call the function referenced by the `fhandle` with the input `data` and plot the results. However, this code generates a compilation error. The error indicates that the function `isa` does not recognize `'function_handle'` as a class name when called inside a MATLAB function to specify properties of inputs.

Do not try to view function handles from the debugger

You cannot display or watch function handles from the debugger. The function handles appear as empty matrices.

Do not use function handles functions for Simulink signals, parameters, or data store memory

You can use function handles in a MATLAB Function block. You cannot use function handles for Simulink signals, parameters, or data store memory.

More About

- “Declaring MATLAB Functions as Extrinsic Functions” on page 54-12
- “Code Generation for Anonymous Functions” on page 52-4

Code Generation for Anonymous Functions

You can use anonymous functions in MATLAB code intended for code generation. For example, you can generate code for the following MATLAB code that defines an anonymous function that finds the square of a number.

```
sqr = @(x) x.^2;  
a = sqr(5);
```

Anonymous functions are useful for creating a function handle to pass to a MATLAB function that evaluates an expression over a range of values. For example, this MATLAB code uses an anonymous function to create the input to the `fzero` function:

```
b = 2;  
c = 3.5;  
x = fzero(@(x) x^3 + b*x + c,0);
```

Anonymous Function Limitations for Code Generation

The data type of an anonymous function is `function_handle`. Therefore, for code generation, anonymous functions have the same limitations that function handles have. Anonymous functions also have the code generation limitations of handle classes.

You can use anonymous functions in a MATLAB Function block. You cannot use anonymous functions for Simulink signals, parameters, or data store memory.

- “Handle Object Limitations for Code Generation” on page 51-22
- “Parameterizing Functions”

Defining Functions for Code Generation

- “Specify Variable Numbers of Arguments” on page 53-2
- “Supported Index Expressions” on page 53-3
- “Apply Operations to a Variable Number of Arguments” on page 53-4
- “Implement Wrapper Functions” on page 53-6
- “Variable Length Argument Lists for Code Generation” on page 53-7

Specify Variable Numbers of Arguments

You can use `varargin` in a function definition to specify that the function accepts a variable number of input arguments for a given input argument. You can use `varargout` in a function definition to specify that the function returns a variable number of arguments for a given output argument.

When you use `varargin` and `varargout` for code generation, adhere to the following restrictions:

- You cannot use `varargout` in the function definition for a top-level function.
- You cannot use `varargin` in the function definition for a top-level function in a MATLAB Function block in a Simulink model, or in a MATLAB function in a Stateflow diagram.
- If you use `varargin` to define an argument to a top-level function, the code generator produces the function with a fixed number of arguments. This fixed number of arguments is based on the number of example arguments that you provide on the command line or in a MATLAB Coder project test file.

Common applications of `varargin` and `varargout` for code generation are to:

- “Apply Operations to a Variable Number of Arguments” on page 53-4
- “Implement Wrapper Functions” on page 53-6
- Pass property/value pairs

Code generation relies on loop unrolling to produce simple and efficient code for `varargin` and `varargout`. This technique permits most common uses of `varargin` and `varargout`, but some uses are not allowed (see “Variable Length Argument Lists for Code Generation” on page 53-7).

For more information about using `varargin` and `varargout` in MATLAB functions, see [Passing Variable Numbers of Arguments](#).

Supported Index Expressions

In MATLAB, `varargin` and `varargout` are cell arrays. For code generation, to index `varargin` and `varargout`, you must use a syntax that code generation supports. You can use the most common syntax — curly braces `{}`. For example:

```

%#codegen
function [x,y,z] = fcn(a,b,c)
[x,y,z] = subfcn(a,b,c);

function varargout = subfcn(varargin)
for i = 1:length(varargin)
    varargout{i} = varargin{i};
end

```

You can use the following index expressions. The *exp* arguments must be constant expressions or depend on a loop index variable.

Expression		Description
<code>varargin</code> (<i>read only</i>)	<code>varargin{exp}</code>	Read the value of element <i>exp</i>
	<code>varargin{exp1:exp2}</code>	Read the values of elements <i>exp1</i> through <i>exp2</i>
	<code>varargin{:}</code>	Read the values of all elements
<code>varargout</code> (<i>read and write</i>)	<code>varargout{exp}</code>	Read or write the value of element <i>exp</i>

Note: The use of `()` is not supported for indexing into `varargin` and `varargout` arrays.

Apply Operations to a Variable Number of Arguments

You can use `varargin` and `varargout` in `for`-loops to apply operations to a variable number of arguments. To index into `varargin` and `varargout` arrays in generated code, the value of the loop index variable must be known at compile time. Therefore, during code generation, the compiler attempts to automatically unroll these `for`-loops. Unrolling eliminates the loop logic by creating a separate copy of the loop body in the generated code for each iteration. Within each iteration, the loop index variable becomes a constant. For example, the following function automatically unrolls its `for`-loop in the generated code:

```
 %#codegen
function [cmLen,cmwth,cmhgt] = conv_2_metric(inlen,inwth,inhgt)

[cmLen,cmwth,cmhgt] = inch_2_cm(inlen,inwth,inhgt);

function varargout = inch_2_cm(varargin)
for i = 1:length(varargin)
    varargout{i} = varargin{i} * 2.54;
end
```

When to Force Loop Unrolling

To automatically unroll `for`-loops containing `varargin` and `varargout` expressions, the relationship between the loop index expression and the index variable must be determined at compile time.

In the following example, the function `fcn` cannot detect a logical relationship between the index expression `j` and the index variable `i`:

```
 %#codegen
function [x,y,z] = fcn(a,b,c)

[x,y,z] = subfcn(a,b,c);

function varargout = subfcn(varargin)
j = 0;
for i = 1:length(varargin)
    j = j+1;
    varargout{j} = varargin{j};
end
```

As a result, the function does not unroll the loop and generates a compilation error:

Nonconstant expression or empty matrix.
 This expression must be constant because
 its value determines the size or class of some expression.

To fix the problem, you can force loop unrolling by wrapping the loop header in the function `coder.unroll`, as follows:

```

%#codegen
function [x,y,z] = fcn(a,b,c)
    [x,y,z] = subfcn(a,b,c);

function varargout = subfcn(varargin)
    j = 0;
    for i = coder.unroll(1:length(varargin))
        j = j + 1;
        varargout{j} = varargin{j};
    end;
  
```

Using Variable Numbers of Arguments in a for-Loop

The following example multiplies a variable number of input dimensions in inches by 2.54 to convert them to centimeters:

```

%#codegen
function [cmlen,cmwth,cmhgt] = conv_2_metric(inlen,inwth,inhgt)

[cmlen,cmwth,cmhgt] = inch_2_cm(inlen,inwth,inhgt);

function varargout = inch_2_cm(varargin)
for i = 1:length(varargin)
    varargout{i} = varargin{i} * 2.54;
end
  
```

Key Points About the Example

- `varargin` and `varargout` appear in the local function `inch_2_cm`, not in the top-level function `conv_2_metric`.
- The index into `varargin` and `varargout` is a for-loop variable

For more information, see “Variable Length Argument Lists for Code Generation” on page 53-7.

Implement Wrapper Functions

You can use `varargin` and `varargout` to write wrapper functions that accept up to 64 inputs and pass them directly to another function.

Passing Variable Numbers of Arguments from One Function to Another

The following example passes a variable number of inputs to different optimization functions, based on a specified input method:

```
%#codegen
function answer = fcn(method,a,b,c)
answer = optimize(method,a,b,c);

function answer = optimize(method,varargin)
    if strcmp(method,'simple')
        answer = simple_optimization(varargin{:});
    else
        answer = complex_optimization(varargin{:});
    end
    ...
end
```

Key Points About the Example

- You can use `{:}` to read all elements of `varargin` and pass them to another function.
- You can mix variable and fixed numbers of arguments.

For more information, see “Variable Length Argument Lists for Code Generation” on page 53-7.

Variable Length Argument Lists for Code Generation

Use variable length argument lists in top-level functions according to guidelines

When you use `varargout` and `varargin` for code generation, adhere to these restrictions:

- You cannot use `varargout` in the function definition for a top-level function.
- You cannot use `varargin` in the function definition for a top-level function in a MATLAB Function block in a Simulink model, or in a MATLAB function in a Stateflow diagram.
- If you use `varargin` to define an argument to a top-level function, the code generator produces the function with a fixed number of arguments. This fixed number of arguments is based on the number of example arguments that you provide on the command line or in a MATLAB Coder project test file.

A *top-level function* is:

- The function called by Simulink in a MATLAB Function block or by Stateflow in a MATLAB function.
- The function that you provide on the command line to `codegen` or `fiaccl`.

For example, the following code generates compilation errors:

```

%#codegen
function varargout = inch_2_cm(varargin)
for i = 1:length(varargin)
    varargout{i} = varargin{i} * 2.54;
end

```

To fix the problem, write a top-level function that specifies a fixed number of inputs and outputs. Then call `inch_2_cm` as an external function or local function, as in this example:

```

%#codegen
function [cmL, cmW, cmH] = conv_2_metric(inL, inW, inH)
[cmL, cmW, cmH] = inch_2_cm(inL, inW, inH);

function varargout = inch_2_cm(varargin)
for i = 1:length(varargin)
    varargout{i} = varargin{i} * 2.54;
end

```

Use curly braces {} to index into the argument list

For code generation, you can use curly braces {}, but not parentheses (), to index into `varargin` and `varargout` arrays. For more information, see “Supported Index Expressions” on page 53-3.

Verify that indices can be computed at compile time

If you use an expression to index into `varargin` or `varargout`, make sure that the value of the expression can be computed at compile time. For examples, see “Apply Operations to a Variable Number of Arguments” on page 53-4.

Do not write to varargin

Generated code treats `varargin` as a read-only variable. If you want to write to input arguments, copy the values into a local variable.

Calling Functions for Code Generation

- “Resolution of Function Calls for Code Generation” on page 54-2
- “Resolution of File Types on Code Generation Path” on page 54-6
- “Compilation Directive `%#codegen`” on page 54-8
- “Call Local Functions” on page 54-9
- “Call Supported Toolbox Functions” on page 54-10
- “Extrinsic Functions” on page 54-11
- “Code Generation for Recursive Functions” on page 54-20
- “Force Code Generator to Use Run-Time Recursion” on page 54-23

Resolution of Function Calls for Code Generation

From a MATLAB function, you can call local functions, supported toolbox functions, and other MATLAB functions. MATLAB resolves function names for code generation as follows:

Key Points About Resolving Function Calls

The diagram illustrates key points about how MATLAB resolves function calls for code generation:

- Searches two paths, the code generation path and the MATLAB path

See “Compile Path Search Order” on page 54-4.

- Attempts to compile functions unless the code generator determines that it should not compile them or you explicitly declare them to be extrinsic.

If a MATLAB function is not supported for code generation, you can declare it to be extrinsic by using the construct `coder.extrinsic`, as described in “Declaring MATLAB Functions as Extrinsic Functions” on page 54-12. During simulation, the code generator produces code for the call to an extrinsic function, but does not generate the internal code for the function. Therefore, simulation can run only on platforms where MATLAB software is installed. During standalone code generation, the code generator attempts to determine whether the extrinsic function affects the output of the function in which it is called — for example by returning `mxArrays` to an output variable. Provided that the output does not change, code generation proceeds, but the extrinsic function is excluded from the generated code. Otherwise, compilation errors occur.

The code generator detects calls to many common visualization functions, such as `plot`, `disp`, and `figure`. The software treats these functions like extrinsic functions but you do not have to declare them extrinsic using the `coder.extrinsic` function.

- Resolves file type based on precedence rules described in “Resolution of File Types on Code Generation Path” on page 54-6

Compile Path Search Order

During code generation, function calls are resolved on two paths:

- 1 Code generation path

MATLAB searches this path first during code generation. The code generation path contains the toolbox functions supported for code generation.

- 2 MATLAB path

If the function is not on the code generation path, MATLAB searches this path.

MATLAB applies the same dispatcher rules when searching each path (see “Function Precedence Order”).

When to Use the Code Generation Path

Use the code generation path to override a MATLAB function with a customized version. A file on the code generation path shadows a file of the same name on the MATLAB path.

Resolution of File Types on Code Generation Path

MATLAB uses the following precedence rules for code generation:

Compilation Directive `%#codegen`

Add the `%#codegen` directive (or pragma) to your function after the function signature to indicate that you intend to generate code for the MATLAB algorithm. Adding this directive instructs the MATLAB code analyzer to help you diagnose and fix violations that would result in errors during code generation.

```
function y = my_fcn(x) %#codegen  
  
.....
```

Note: The `%#codegen` directive is not necessary for MATLAB Function blocks. Code inside a MATLAB Function block is always intended for code generation. The `%#codegen` directive, or the absence of it, does not change the error checking behavior.

Call Local Functions

Local functions are functions defined in the body of MATLAB function. They work the same way for code generation as they do when executing your algorithm in the MATLAB environment.

The following example illustrates how to define and call a local function `mean`:

```
function [mean, stdev] = stats(vals)
%#codegen

% Calculates a statistical mean and a standard
% deviation for the values in vals.

len = length(vals);
mean = avg(vals, len);
stdev = sqrt(sum(((vals-avg(vals,len)).^2))/len);
plot(vals, '-+');

function mean = avg(array,size)
mean = sum(array)/size;
```

Call Supported Toolbox Functions

You can call toolbox functions directly if they are supported for code generation. For a list of supported functions, see “Functions and Objects Supported for C/C++ Code Generation — Alphabetical List” on page 44-2.

Extrinsic Functions

The code generator attempts to generate code for functions, even if they are not supported for C code generation. The software detects calls to many common visualization functions, such as `plot`, `disp`, and `figure`. The software treats these functions like extrinsic functions but you do not have to declare them extrinsic using `coder.extrinsic`. During simulation, the code generator produces code for these functions, but does not generate their internal code. During standalone code generation, the code generator attempts to determine whether the visualization function affects the output of the function in which it is called. Provided that the output does not change, the code generator proceeds with code generation, but excludes the visualization function from the generated code. Otherwise, compilation errors occur.

For example, you might want to call `plot` to visualize your results in the MATLAB environment. If you generate a MEX function from a function that calls `plot` and then run the generated MEX function, the code generator dispatches calls to the `plot` function to MATLAB. If you generate a library or executable, the generated code does not contain calls to the `plot` function. The code generation report highlights calls from your MATLAB code to extrinsic functions so that it is easy to determine which functions are supported only in the MATLAB environment.

The screenshot shows the MATLAB IDE interface. On the left, there is a 'Filter' pane with a 'Functions' section containing 'stats' and 'stats > avg'. The main editor shows the code for the 'stats' function:

```

1 function [mean, stdev] = stats(vals)
2 %#codegen
3
4 % Calculates a statistical mean and a standard
5 % deviation for the values in vals.
6
7 len = length(vals);
8 mean = avg(vals, len);
9 stdev = sqrt(sum((vals-avg(vals,len)).^2)/len);
10 plot(vals, '-+');
11

```

A tooltip points to the `plot` call on line 10, stating: "Only supported within the MATLAB environment."

For unsupported functions other than common visualization functions, you must declare the functions to be extrinsic (see “Resolution of Function Calls for Code Generation” on page 54-2). Extrinsic functions are not compiled, but instead executed in MATLAB during simulation (see “Resolution of Extrinsic Functions During Simulation” on page 54-16).

There are two ways to declare a function to be extrinsic:

- Use the `coder.extrinsic` construct in main functions or local functions (see “Declaring MATLAB Functions as Extrinsic Functions” on page 54-12).
- Call the function indirectly using `feval` (see “Calling MATLAB Functions Using `feval`” on page 54-16).

Declaring MATLAB Functions as Extrinsic Functions

To declare a MATLAB function to be extrinsic, add the `coder.extrinsic` construct at the top of the main function or a local function:

```
coder.extrinsic('function_name_1', ... , 'function_name_n');
```

Declaring Extrinsic Functions

The following code declares the MATLAB `patch` function extrinsic in the local function `create_plot`. You do not have to declare `axis` as extrinsic because `axis` is one of the common visualization functions that the code generator automatically treats as extrinsic.

```
function c = pythagoras(a,b,color) %#codegen
% Calculates the hypotenuse of a right triangle
% and displays the triangle.
```

```
c = sqrt(a^2 + b^2);
create_plot(a, b, color);
```

```
function create_plot(a, b, color)
%Declare patch as extrinsic
```

```
coder.extrinsic('patch');
```

```
x = [0;a;a];
y = [0;0;b];
patch(x, y, color);
axis('equal');
```

The code generator does not produce code for `patch` and `axis`, but instead dispatches them to MATLAB for execution.

To test the function, follow these steps:

- 1 Convert `pythagoras` to a MEX function by executing this command at the MATLAB prompt:

```
codegen -report pythagoras -args {1, 1, [.3 .3 .3]}
```

- Click the link to the code generation report and then, in the report, view the MATLAB code for `create_plot`.

The report highlights the `patch` and `axis` functions to indicate that they are supported only within the MATLAB environment.

The screenshot shows the MATLAB code generation report for the `pythagoras` function. The code is displayed in a window titled "Function: pythagoras > create_plot". The code includes the following lines:

```

7
8
9 function create_plot(a, b, color)
10 %Declare patch and axis as extrinsic
11
12 coder.extrinsic('patch'); %,'axis');
13
14 x = [0;a;a];
15 y = [0;0;b];
16 patch(x, y, color);
17 axis('equal');

```

The `patch` and `axis` function calls are highlighted in red. A tooltip points to the `axis` function call with the text "Only supported within the MATLAB environment".

- Run the MEX function by executing this command:

```
pythagoras_mex(3, 4, [1.0 0.0 0.0]);
```

MATLAB displays a plot of the right triangle as a red patch object:

When to Use the `coder.extrinsic` Construct

Use the `coder.extrinsic` construct to:

- Call MATLAB functions that do not produce output during simulation, without generating unnecessary code (see “Resolution of Extrinsic Functions During Simulation” on page 54-16).
- Make your code self-documenting and easier to debug. You can scan the source code for `coder.extrinsic` statements to isolate calls to MATLAB functions, which can potentially create and propagate `mxArrays` (see “Working with `mxArrays`” on page 54-17).

- Save typing. With one `coder.extrinsic` statement, each subsequent function call is extrinsic, as long as the call and the statement are in the same scope (see “Scope of Extrinsic Function Declarations” on page 54-15).
- Declare the MATLAB function(s) extrinsic throughout the calling function scope (see “Scope of Extrinsic Function Declarations” on page 54-15). To narrow the scope, use `feval` (see “Calling MATLAB Functions Using `feval`” on page 54-16).

Rules for Extrinsic Function Declarations

Observe the following rules when declaring functions extrinsic for code generation:

- Declare the function extrinsic before you call it.
- Do not use the extrinsic declaration in conditional statements.

Scope of Extrinsic Function Declarations

The `coder.extrinsic` construct has function scope. For example, consider the following code:

```
function y = foo %#codegen
coder.extrinsic('rat','min');
[N D] = rat(pi);
y = 0;
y = min(N, D);
```

In this example, `rat` and `min` are treated as extrinsic every time they are called in the main function `foo`. There are two ways to narrow the scope of an extrinsic declaration inside the main function:

- Declare the MATLAB function extrinsic in a local function, as in this example:

```
function y = foo %#codegen
coder.extrinsic('rat');
[N D] = rat(pi);
y = 0;
y = mymin(N, D);

function y = mymin(a,b)
coder.extrinsic('min');
y = min(a,b);
```

Here, the function `rat` is extrinsic every time it is called inside the main function `foo`, but the function `min` is extrinsic only when called inside the local function `mymin`.

- Call the MATLAB function using `feval`, as described in “Calling MATLAB Functions Using `feval`” on page 54-16.

Calling MATLAB Functions Using `feval`

The function `feval` is automatically interpreted as an extrinsic function during code generation. Therefore, you can use `feval` to conveniently call functions that you want to execute in the MATLAB environment, rather than compiled to generated code.

Consider the following example:

```
function y = foo
coder.extrinsic('rat');
[N D] = rat(pi);
y = 0;
y = feval('min', N, D);
```

Because `feval` is extrinsic, the statement `feval('min', N, D)` is evaluated by MATLAB — not compiled — which has the same result as declaring the function `min` extrinsic for just this one call. By contrast, the function `rat` is extrinsic throughout the function `foo`.

Resolution of Extrinsic Functions During Simulation

The code generator resolves calls to extrinsic functions — functions that do not support code generation — as follows:

During simulation, the code generator produces code for the call to an extrinsic function, but does not generate the internal code for the function. Therefore, you can run the simulation only on platforms where you install MATLAB software.

During code generation, the code generator attempts to determine whether the extrinsic function affects the output of the function in which it is called — for example by returning `mxArrays` to an output variable (see “Working with `mxArrays`” on page 54-17). Provided that the output does not change, code generation proceeds, but the extrinsic function is excluded from the generated code. Otherwise, the code generator issues a compiler error.

Working with `mxArrays`

The output of an extrinsic function is an `mxArray` — also called a MATLAB array. The only valid operations for `mxArrays` are:

- Storing `mxArrays` in variables

- Passing `mxArrays` to functions and returning them from functions
- Converting `mxArrays` to known types at run time

To use `mxArrays` returned by extrinsic functions in other operations, you must first convert them to known types, as described in “Converting `mxArrays` to Known Types” on page 54-18.

Converting `mxArrays` to Known Types

To convert an `mxArray` to a known type, assign the `mxArray` to a variable whose type is defined. At run time, the `mxArray` is converted to the type of the variable assigned to it. However, if the data in the `mxArray` is not consistent with the type of the variable, you get a run-time error.

For example, consider this code:

```
function y = foo %#codegen
coder.extrinsic('rat');
[N D] = rat(pi);
y = min(N, D);
```

Here, the top-level function `foo` calls the extrinsic MATLAB function `rat`, which returns two `mxArrays` representing the numerator `N` and denominator `D` of the rational fraction approximation of `pi`. Although you can pass these `mxArrays` to another MATLAB function — in this case, `min` — you cannot assign the `mxArray` returned by `min` to the output `y`.

If you run this function `foo` in a MATLAB Function block in a Simulink model, the code generates the following error during simulation:

```
Function output 'y' cannot be of MATLAB type.
```

To fix this problem, define `y` to be the type and size of the value that you expect `min` to return — in this case, a scalar double — as follows:

```
function y = foo %#codegen
coder.extrinsic('rat');
[N D] = rat(pi);
y = 0; % Define y as a scalar of type double
y = min(N,D);
```

Restrictions on Extrinsic Functions for Code Generation

The full MATLAB run-time environment is not supported during code generation. Therefore, the following restrictions apply when calling MATLAB functions extrinsically:

- MATLAB functions that inspect the caller, or read or write to the caller workspace do not work during code generation. Such functions include:
 - `dbstack`
 - `evalin`
 - `assignin`
 - `save`
- The MATLAB debugger cannot inspect variables defined in extrinsic functions.
- Functions in generated code can produce unpredictable results if your extrinsic function performs the following actions at run time:
 - Change folders
 - Change the MATLAB path
 - Delete or add MATLAB files
 - Change warning states
 - Change MATLAB preferences
 - Change Simulink parameters

Limit on Function Arguments

You can call functions with up to 64 inputs and 64 outputs.

Code Generation for Recursive Functions

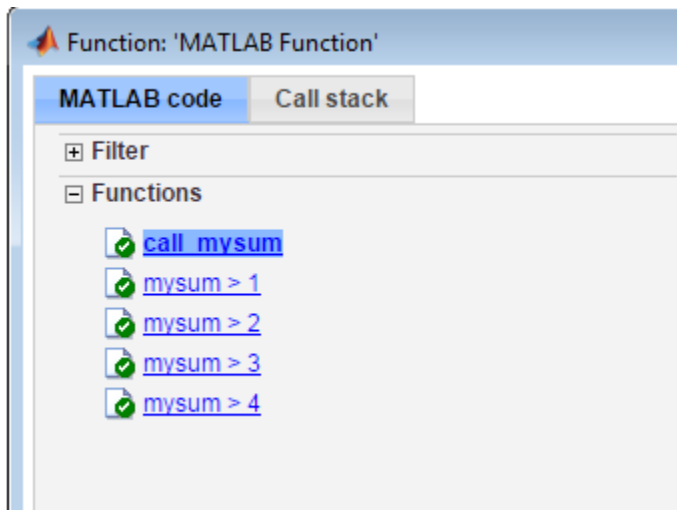

To generate code for recursive MATLAB functions, the code generator uses compile-time recursion or run-time recursion. You can influence whether the code generator uses compile-time or run-time recursion by modifying your MATLAB code. See “Force Code Generator to Use Run-Time Recursion” on page 54-23.

You can disallow recursion or disable run-time recursion by modifying configuration parameters.

When you use recursive functions in MATLAB code that is intended for code generation, you must adhere to certain restrictions. See “Recursive Function Limitations for Code Generation” on page 54-22.

Compile-Time Recursion

With compile-time recursion, the code generator creates multiple copies of a recursive function in the generated code. The inputs to the copies have different sizes or constant values. You can tell that the code generator used compile-time recursion by looking at the MATLAB Function report or the generated C code. Here is an example of compile-time recursion in the report.

Run-Time Recursion

With run-time recursion, the code generator produces a recursive function in the generated code. You can tell that the code generator used run-time recursion by looking at the MATLAB Function report or the generated C code. Here is an example of run-time recursion in the report.

Disallow Recursion

In the model configuration parameters, on the **All Parameters** tab, in the **Simulation Target** category, set the **Compile-time recursion limit for MATLAB functions** configuration parameter to 0.

Disable Run-Time Recursion

Some coding standards, such as MISRA[®], do not allow recursion. To increase the likelihood of generating code that is compliant with MISRA C[®], disable run-time recursion.

In the model configuration parameters, on the **All Parameters** tab, in the **Simulation Target** category, clear the **Enable run-time recursion for MATLAB functions** check box.

If your code requires run-time recursion and run-time recursion is disabled, you must rewrite your code so that it uses compile-time recursion or does not use recursion.

Recursive Function Limitations for Code Generation

When you use recursion in MATLAB code that is intended for code generation, follow these restrictions:

- The top-level function in a MATLAB Function block cannot be a recursive function, but it can call a recursive function.
- Assign all outputs of a run-time recursive function before the first recursive call in the function.
- Assign all elements of cell array outputs of a run-time recursive function.
- Inputs and outputs of run-time recursive functions cannot be classes.
- The **Maximum stack size** parameter is ignored for run-time recursion.

More About

- “Output Variable Must Be Assigned Before Run-Time Recursive Call” on page 56-5
- “Compile-Time Recursion Limit Reached” on page 56-2
- “Compile-time recursion limit for MATLAB functions”
- “MATLAB Function Reports” on page 39-48

Force Code Generator to Use Run-Time Recursion

When your MATLAB code includes recursive function calls, the code generator uses compile-time or run-time recursion. With compile-time recursion, the code generator creates multiple copies of the function in the generated code. With run-time recursion, the code generator produces a recursive function. If compile-time recursion results in too many function copies or if you prefer run-time recursion, you can try to force the code generator to use run-time recursion. Try one of these approaches:

- “Make the Input to the Recursive Function Variable-Size” on page 54-23
- “Assign Output Variable Before the Recursive Call” on page 54-24

Make the Input to the Recursive Function Variable-Size

Consider this code:

```
function z = call_mysum(A)
%#codegen
z = mysum(A);
end

function y = mysum(A)
coder.inline('never');
if size(A,2) == 1
    y = A(1);
else
    y = A(1)+ mysum(A(2:end));
end
end
```

If the input to `mysum` is fixed-size, the code generator uses compile-time recursion. To force the code generator to use run-time conversion, make the input to `mysum` variable-size by using `coder.varsize`.

```
function z = call_mysum(A)
%#codegen
B = A;
coder.varsize('B');
z = mysum(B);
end

function y = mysum(A)
```

```
coder.inline('never');  
if size(A,2) == 1  
    y = A(1);  
else  
    y = A(1)+ mysum(A(2:end));  
end  
end
```

Assign Output Variable Before the Recursive Call

The code generator uses compile-time recursion for this code:

```
function y = callrecursive(n)  
x = 10;  
y = myrecursive(x,n);  
end  
  
function y = myrecursive(x,n)  
coder.inline('never')  
if x > 1  
    y = n + myrecursive(x-1,n-1);  
  
else  
    y = n;  
end  
end
```

To force the code generator to use run-time recursion, modify `myrecursive` so that the output `y` is assigned before the recursive call. Place the assignment `y = n` in the `if` block and the recursive call in the `else` block.

```
function y = callrecursive(n)  
x = 10;  
y = myrecursive(x,n);  
end  
  
function y = myrecursive(x,n)  
coder.inline('never')  
if x == 1  
    y = n;  
else  
    y = n + myrecursive(x-1,n-1);  
end  
end
```

Optimization Strategies

MATLAB Coder introduces certain optimizations when generating C/C++ code or MEX functions from your MATLAB code. For more information, see “MATLAB Coder Optimizations in Generated Code”.

To optimize your generated code further, you can:

- Adapt your MATLAB code.
- Control code generation using the configuration object from the command-line or the project settings dialog box.

To optimize the execution speed of generated code, for these conditions, perform the following actions as necessary:

Condition	Action
You have <code>for</code> -loops whose iterations are independent of each other.	“Generate Code with Parallel for-Loops (<code>parfor</code>)”
You have variable-size arrays in your MATLAB code.	“Minimize Dynamic Memory Allocation”
You have multiple variable-size arrays in your MATLAB code. You want dynamic memory allocation for larger arrays and static allocation for smaller ones.	“Set Dynamic Memory Allocation Threshold”
You want your generated function to be called by reference.	“Eliminate Redundant Copies of Function Inputs”
You are calling small functions in your MATLAB code.	“Inline Code”
You have limited target memory for your generated code. You want to inline small functions and generate separate code for larger ones.	“Control Inlining”
You do not want to generate code for expressions that contain constants only.	“Fold Function Calls into Constants”
You have loop operations in your MATLAB code that do not depend on the loop index.	“Minimize Redundant Operations in Loops”

Condition	Action
You have integer operations in your MATLAB code. You know beforehand that integer overflow does not occur during execution of your generated code.	“Disable Support for Integer Overflow”
You know beforehand that Infs and NaNs do not occur during execution of your generated code.	“Disable Support for Non-Finite Numbers”
You have for-loops with few iterations.	“Unroll for-Loops”
You already have legacy C/C++ code optimized for your target environment.	“Integrate External/Custom Code”
You want to speed up the code generated for linear algebra functions.	“Speed Up Linear Algebra in Generated Standalone Code by Using LAPACK Calls”

To optimize the memory usage of generated code, for these conditions, perform the following actions as necessary:

Condition	Action
You have if/else/elseif statements or switch/case/otherwise statements in your MATLAB code. You do not require some branches of the statements in your generated code.	“Prevent Code Generation for Unused Execution Paths”
You want your generated function to be called by reference.	“Eliminate Redundant Copies of Function Inputs”
You have limited stack space for your generated code.	“Control Stack Space Usage”
You are calling small functions in your MATLAB code.	“Inline Code”
You have limited target memory for your generated code. You want to inline small functions and generate separate code for larger ones.	“Control Inlining”
You do not want to generate code for expressions that contain constants only.	“Fold Function Calls into Constants”

Condition	Action
You have loop operations in your MATLAB code that do not depend on the loop index.	“Minimize Redundant Operations in Loops”
You have integer operations in your MATLAB code. You know beforehand that integer overflow does not occur during execution of your generated code.	“Disable Support for Integer Overflow”
You know beforehand that Inf-s and NaN-s does not occur during execution of your generated code.	“Disable Support for Non-Finite Numbers”
Your MATLAB code has variables that are large arrays or structures. Your variables are not reused in the generated code. They are preserved. You want to see if the extra memory required to preserve the variable names of the large arrays or structures affects performance.	“Reuse Large Arrays and Structures”

Modularize MATLAB Code

For large MATLAB code, streamline code generation by modularizing the code:

- 1** Break up your MATLAB code into smaller, self-contained sections.
- 2** Save each section in a MATLAB function.
- 3** Generate C/C++ code for each function.
- 4** Call the generated C/C++ functions in sequence from a wrapper MATLAB function using `coder.ceval`.
- 5** Generate C/C++ code for the wrapper function.

Besides streamlining code generation for the original MATLAB code, this approach also supplies you with C/C++ code for the individual sections. You can reuse the code for the individual sections later by integrating them with other generated C/C++ code using `coder.ceval`.

Eliminate Redundant Copies of Function Inputs

You can reduce the number of copies in your generated code by writing functions that use the same variable as both an input and an output. For example:

```
function A = foo( A, B ) %#codegen
A = A * B;
end
```

This coding practice uses a reference parameter optimization. When a variable acts as both input and output, the generated code passes the variable by reference instead of redundantly copying the input to a temporary variable. In the preceding example, input `A` is passed by reference in the generated code because it also acts as an output for function `foo`:

```
...
/* Function Definitions */
void foo(double *A, double B)
{
    *A *= B;
}
...
```

The reference parameter optimization reduces memory usage and execution time, especially when the variable passed by reference is a large data structure. To achieve these benefits at the call site, call the function with the same variable as both input and output.

By contrast, suppose that you rewrite function `foo` without the optimization:

```
function y = foo2( A, B ) %#codegen
y = A * B;
end
```

The generated code passes the inputs by value and returns the value of the output:

```
...
/* Function Definitions */
double foo2(double A, double B)
{
    return A * B;
}
...
```

In some cases, the output of the function cannot be a modified version of its inputs. If you do not use the inputs later in the function, you can modify your code to operate on the inputs instead of on a copy of the inputs. One method is to create additional return values for the function. For example, consider the code:

```
function y1=foo(u1) %#codegen
    x1=u1+1;
    y1=bar(x1);
end

function y2=bar(u2)
    % Since foo does not use x1 later in the function,
    % it would be optimal to do this operation in place
    x2=u2.*2;
    % The change in dimensions in the following code
    % means that it cannot be done in place
    y2=[x2,x2];
end
```

You can modify this code to eliminate redundant copies.

```
function y1=foo(u1) %#codegen
    u1=u1+1;
    [y1, u1]=bar(u1);
end

function [y2, u2]=bar(u2)
    u2=u2.*2;
    % The change in dimensions in the following code
    % still means that it cannot be done in place
    y2=[u2,u2];
end
```

The reference parameter optimization does not apply to constant inputs. If the same variable is an input and an output, and the input is constant, the code generator treats the output as a separate variable. For example, consider the function `foo`:

```
function A = foo( A, B ) %#codegen
A = A * B;
end
```

Generate code in which `A` has a constant value 2.

```
codegen -config:lib foo -args {coder.Constant(2) 3} -report
```

The generated code defines the constant A and returns the value of the output.

```
...  
#define A                                (2.0)  
...  
double foo(double B)  
{  
    return A * B;  
}  
...
```

Inline Code

Inlining is a technique that replaces a function call with the contents (body) of that function. Inlining eliminates the overhead of a function call, but can produce larger C/C++ code. Inlining can create opportunities for further optimization of the generated C/C++ code. The code generator uses internal heuristics to determine whether to inline functions in the generated code. You can use the `coder.inline` directive to fine-tune these heuristics for individual functions. For more information, see `coder.inline`.

In this section...

“Prevent Function Inlining” on page 55-9

“Use Inlining in Control Flow Statements” on page 55-9

Prevent Function Inlining

In this example, function `foo` is not inlined in the generated code:

```
function y = foo(x)
    coder.inline('never');
    y = x;
end
```

Use Inlining in Control Flow Statements

You can use `coder.inline` in control flow code. If the software detects contradictory `coder.inline` directives, the generated code uses the default inlining heuristic and issues a warning.

Suppose you want to generate code for a division function that will be embedded in a system with limited memory. To optimize memory use in the generated code, the following function, `inline_division`, manually controls inlining based on whether it performs scalar division or vector division:

```
function y = inline_division(dividend, divisor)

% For scalar division, inlining produces smaller code
% than the function call itself.
if isscalar(dividend) && isscalar(divisor)
    coder.inline('always');
else
```

```
% Vector division produces a for-loop.  
% Prohibit inlining to reduce code size.  
    coder.inline('never');  
end  
  
if any(divisor == 0)  
    error('Can not divide by 0');  
end  
  
y = dividend / divisor;
```

Related Examples

- “Control Inlining”

Control Inlining

Restrict inlining when:

- The size of generated code exceeds desired limits due to excessive inlining of functions. Suppose that you include the statement, `coder.inline('always')`, inside a certain function. You then call that function at many different sites in your code. The generated code can be large due to the function being inlined every time it is called.

The call sites must be different. For instance, inlining does not lead to large code if the function to be inlined is called several times inside a loop.

- You have limited RAM or stack space.

In this section...

“Control Size of Functions Inlined” on page 55-11

“Control Size of Functions After Inlining” on page 55-12

“Control Stack Size Limit on Inlined Functions” on page 55-12

Control Size of Functions Inlined

You can use the MATLAB Coder app or the command-line interface to control the maximum size of functions that can be inlined. The function size is measured in terms of an abstract number of instructions, not actual MATLAB instructions or instructions in the target processor. Experiment with this parameter to obtain the inlining behavior that you want.

- Using the app, in the project settings dialog box, on the **All Settings** tab, set the value of the field, **Inline threshold**, to the maximum size that you want.
- At the command line, create a `codegen` configuration object. Set the value of the property, `InlineThreshold`, to the maximum size that you want.

```
cfg = coder.config('lib');  
cfg.InlineThreshold = 100;
```

Generate code using this configuration object.

Control Size of Functions After Inlining

You can use the MATLAB Coder app or the command-line interface to control the maximum size of functions after inlining. The function size is measured in terms of an abstract number of instructions, not actual MATLAB instructions or instructions in the target processor. Experiment with this parameter to obtain the inlining behavior that you want.

- Using the app, in the project settings dialog box, on the **All Settings** tab, set the value of the field, **Inline threshold max**, to the maximum size that you want.
- At the command line, create a `codegen` configuration object. Set the value of the property, `InlineThresholdMax`, to the maximum size that you want.

```
cfg = coder.config('lib');  
cfg.InlineThresholdMax = 100;
```

Generate code using this configuration object.

Control Stack Size Limit on Inlined Functions

Specifying a limit on the stack space constrains the amount of inlining allowed. For out-of-line functions, stack space for variables local to the function is released when the function returns. However, for inlined functions, stack space remains occupied by the local variables even after the function is executed. The value of the property, `InlineStackLimit`, is measured in bytes. Based on information from the target hardware settings, the software estimates the number of stack variables that a certain value of `InlineStackLimit` can accommodate. This estimate excludes possible C compiler optimizations such as putting variables in registers.

You can use the MATLAB Coder app or the command-line interface to control the stack size limit on inlined functions.

- Using the app, in the project settings dialog box, on the **All Settings** tab, set the value of the field, **Inline stack limit**, to the maximum size that you want.
- At the command line, create a `codegen` configuration object. Set the value of the property, `InlineStackLimit`, to the maximum size that you want.

```
cfg = coder.config('lib');  
cfg.InlineStackLimit = 2000;
```

Generate code using this configuration object.

Related Examples

Fold Function Calls into Constants

This example shows how to specify constants in generated code using `coder.const`. The code generator folds an expression or a function call in a `coder.const` statement into a constant in generated code. Because the generated code does not have to evaluate the expression or call the function every time, this optimization reduces the execution time of the generated code.

Write a function `AddShift` that takes an input `Shift` and adds it to the elements of a vector. The vector consists of the square of the first 10 natural numbers. `AddShift` generates this vector.

```
function y = AddShift(Shift) %#codegen
y = (1:10).^2+Shift;
```

Generate code for `AddShift` using the `codegen` command. Open the Code Generation Report.

```
codegen -config:lib -launchreport AddShift -args 0
```

The code generator produces code for creating the vector. It adds `Shift` to each element of the vector during vector creation. The definition of `AddShift` in generated code looks as follows:

```
void AddShift(double Shift, double y[10])
{
    int k;
    for (k = 0; k < 10; k++) {
        y[k] = (double)((1 + k) * (1 + k)) + Shift;
    }
}
```

Replace the statement

```
y = (1:10).^2+Shift;
```

with

```
y = coder.const((1:10).^2)+Shift;
```

Generate code for `AddShift` using the `codegen` command. Open the Code Generation Report.

```
codegen -config:lib -launchreport AddShift -args 0
```

The code generator creates the vector containing the squares of the first 10 natural numbers. In the generated code, it adds `Shift` to each element of this vector. The definition of `AddShift` in generated code looks as follows:

```
void AddShift(double Shift, double y[10])
{
    int i0;
    static const signed char iv0[10] = { 1, 4, 9, 16, 25, 36,
                                         49, 64, 81, 100 };

    for (i0 = 0; i0 < 10; i0++) {
        y[i0] = (double)iv0[i0] + Shift;
    }
}
```

`coder.const`

Control Stack Space Usage

This example shows how to set the maximum stack space that the generated code uses. Set the maximum stack usage when:

- You have limited stack space, for instance, in embedded targets.
- Your C compiler reports a run-time stack overflow.

The value of the property, `StackUsageMax`, is measured in bytes. Based on information from the target hardware settings, the software estimates the number of stack variables that a certain value of `StackUsageMax` can accommodate. This estimate excludes possible C compiler optimizations such as putting variables in registers.

Control Stack Space Usage Using the MATLAB Coder App

- 1 To open the **Generate** dialog box, on the **Generate Code** page, click the **Generate** arrow .
- 2 Set **Build type** to `Source Code`, `Static Library`, `Dynamic Library`, or `Executable` (depending on your requirements).
- 3 Click **More Settings**.
- 4 On the **Memory** tab, set **Stack usage max** to the value that you want.

Control Stack Space Usage at the Command Line

- 1 Create a configuration object for code generation.

Use `coder.config` with arguments `'lib'`, `'dll'`, or `'exe'` (depending on your requirements). For example:

```
cfg = coder.config('lib');
```

- 2 Set the property, `StackUsageMax`, to the value that you want.

```
cfg.StackUsageMax=400000;
```

More About

- “Stack Allocation and Performance”

Stack Allocation and Performance

By default, local variables are allocated on the stack. Large variables that do not fit on the stack are statically allocated in memory.

Stack allocation typically uses memory more efficiently than static allocation. However, stack space is sometimes limited, typically in embedded processors. MATLAB Coder allows you to manually set a limit on the stack space usage to make your generated code suitable for your target hardware. You can choose this limit based on the target hardware configurations. For more information, see “Control Stack Space Usage”.

For limited stack space, you can choose to allocate large variables on the heap instead of using static allocation. Heap allocation is slower but more memory-efficient than static allocation. To allocate large variables on the heap, do one of the following:

Allocate Heap Space from Command Line

- 1 Create a configuration object. Set the property, `MultiInstanceCode`, to `true`.

```
cfg = coder.config('exe');  
cfg.MultiInstanceCode = true;
```

- 2 Generate code using this configuration object.

Allocate Heap Space Using the MATLAB Coder App

- 1 Using the MATLAB Coder app, in the project settings dialog box, on the **Memory** tab, select the **Generate re-entrant code** check box.
 - Generate code.

Dynamic Memory Allocation and Performance

To achieve faster execution of generated code, minimize dynamic (or run-time) memory allocation of arrays.

MATLAB Coder does not provide a size for unbounded arrays in generated code. Instead, such arrays are referenced indirectly through pointers. For such arrays, memory cannot be allocated during compilation of generated code. Based on storage requirements for the arrays, memory is allocated and freed at run time as required. This run-time allocation and freeing of memory leads to slower execution of the generated code. For more information on dynamic memory allocation, see “Bounded Versus Unbounded Variable-Size Data”.

When Dynamic Memory Allocation Occurs

Dynamic memory allocation occurs when the code generator cannot find upper bounds for variable-size arrays. The software cannot find upper bounds when you specify the size of an array using a variable that is not a compile-time constant. An example of such a variable is an input variable (or a variable computed from an input variable).

Instances in the MATLAB code that can lead to dynamic memory allocation are:

- Array initialization: You specify array size using a variable whose value is known only at run time.
- After initialization of an array:
 - You declare the array as variable-size using `coder.varsize` without explicit upper bounds. After this declaration, you expand the array by concatenation inside a loop. The number of loop runs is known only at run time.
 - You use a `reshape` function on the array. At least one of the size arguments to the `reshape` function is known only at run time.

If you know the maximum size of the array, you can avoid dynamic memory allocation. You can then provide an upper bound for the array and prevent dynamic memory allocation in generated code. For more information, see “Minimize Dynamic Memory Allocation” on page 55-19.

Minimize Dynamic Memory Allocation

When possible, minimize dynamic memory allocation because it leads to slower execution of generated code. Dynamic memory allocation occurs when the code generator cannot find upper bounds for variable-size arrays.

If you know the maximum size of a variable-size array, you can avoid dynamic memory allocation. Follow these steps:

- 1 “Provide Maximum Size for Variable-Size Arrays” on page 55-20.
- 2 Depending on your requirements, do one of the following:
 - “Disable Dynamic Memory Allocation During Code Generation” on page 55-26.
 - “Set Dynamic Memory Allocation Threshold”

Caution If a variable-size array in the MATLAB code does not have a maximum size, disabling dynamic memory allocation leads to a code generation error. Before disabling dynamic memory allocation, you must provide a maximum size for variable-size arrays in your MATLAB code.

More About

- “Dynamic Memory Allocation and Performance”

Provide Maximum Size for Variable-Size Arrays

To constrain array size for variable-size arrays, do one of the following:

- **Constrain Array Size Using `assert` Statements**

If the variable specifying array size is not a compile-time constant, use an `assert` statement with relational operators to constrain the variable. Doing so helps the code generator to determine a maximum size for the array.

The following examples constrain array size using `assert` statements:

- **When Array Size Is Specified by Input Variables**

Define a function `array_init` which initializes an array `y` with input variable `N`:

```
function y = array_init (N)
    assert(N <= 25); % Generates exception if N > 25
    y = zeros(1,N);
```

The `assert` statement constrains input `N` to a maximum size of 25. In the absence of the `assert` statement, `y` is assigned a pointer to an array in the generated code, thus allowing dynamic memory allocation.

- **When Array Size Is Obtained from Computation Using Input Variables**

Define a function, `array_init_from_prod`, which takes two input variables, `M` and `N`, and uses their product to specify the maximum size of an array, `y`.

```
function y = array_init_from_prod (M,N)
    size=M*N;
    assert(size <= 25); % Generates exception if size > 25
    y=zeros(1,size);
```

The `assert` statement constrains the product of `M` and `N` to a maximum of 25.

Alternatively, if you restrict `M` and `N` individually, it leads to dynamic memory allocation:

```
function y = array_init_from_prod (M,N)
    assert(M <= 5);
    assert(N <= 5);
    size=M*N;
    y=zeros(1,size);
```

This code causes dynamic memory allocation because M and N can both have unbounded negative values. Therefore, their product can be unbounded and positive even though, individually, their positive values are bounded.

Tip Place the `assert` statement on a variable immediately before it is used to specify array size.

Tip You can use `assert` statements to restrict array sizes in most cases. When expanding an array inside a loop, this strategy does not work if the number of loop runs is known only at run time.

- **Restrict Concatenations in a Loop Using `coder.versize` with Upper Bounds**

You can expand arrays beyond their initial size by concatenation. When you concatenate additional elements inside a loop, there are two syntax rules for expanding arrays.

- 1 Array size during initialization is not a compile-time constant**

If the size of an array during initialization is not a compile-time constant, you can expand it by concatenating additional elements:

```
function out=ExpandArray(in) % Expand an array by five elements
    out = zeros(1,in);
    for i=1:5
        out = [out 0];
    end
```

- 2 Array size during initialization is a compile-time constant**

Before concatenating elements, you have to declare the array as variable-size using `coder.versize`:

```
function out=ExpandArray() % Expand an array by five elements
    out = zeros(1,5);
    coder.versize('out');
    for i=1:5
        out = [out 0];
    end
```

Either case leads to dynamic memory allocation. To prevent dynamic memory allocation in such cases, use `coder. varsize` with explicit upper bounds. This example shows how to use `coder. varsize` with explicit upper bounds:

Restrict Concatenations Using `coder. varsize` with Upper Bounds

- 1 Define a function, `RunningAverage`, that calculates the running average of an `N`-element subset of an array:

```
function avg=RunningAverage(N)

% Array whose elements are to be averaged
NumArray=[1 6 8 2 5 3];

% Initialize average:
% These will also be the first two elements of the function output
avg=[0 0];

% Place a bound on the argument
coder. varsize('avg',[1 8]);

% Loop to calculate running average
for i=1:N
    s=0;
    s=s+sum(NumArray(1:i));
    avg=[avg s/i];
% Increase the size of avg as required by concatenation
end
```

The output, `avg`, is an array that you can expand as required to accommodate the running averages. As a new running average is calculated, it is added to the array `avg` through concatenation, thereby expanding the array.

Because the maximum number of running averages is equal to the number of elements in `NumArray`, you can supply an explicit upper bound for `avg` in the `coder. varsize` statement. In this example, the upper bound is 8 (the two initial elements plus the six elements of `NumArray`).

- 2 Generate code for `RunningAverage` with input argument of type `double`:

```
codegen -config:lib -report RunningAverage -args 2
```

In the generated code, `avg` is assigned an array of size 8 (static memory allocation). The function definition for `RunningAverage` appears as follows (using built-in C types):

```
void RunningAverage (double N, double avg_data[8], int avg_size[2])
```

- 3** By contrast, if you remove the explicit upper bound, the generated code dynamically allocates `avg`.

Replace the statement

```
coder.varsize('avg',[1 8]);
```

with:

```
coder.varsize('avg');
```

- 4** Generate code for `RunningAverage` with input argument of type `double`:

```
codegen -config:lib -report RunningAverage -args 2
```

In the generated code, `avg` is assigned a pointer to an array, thereby allowing dynamic memory allocation. The function definition for `RunningAverage` appears as follows (using built-in C types):

```
void Test(double N, mxArray_real_T *avg)
```

Note: Dynamic memory allocation also occurs if you precede `coder.varsize('avg')` with the following `assert` statement:

```
assert(N < 6);
```

The `assert` statement does not restrict the number of concatenations within the loop.

- **Constrain Array Size When Rearranging a Matrix**

The statement `out = reshape(in,m,n,...)` takes an array, `in`, as an argument and returns array, `out`, having the same elements as `in`, but reshaped as an `m`-by-`n`-by-`...` matrix. If one of the size variables `m`, `n`, `...` is not a compile-time constant, then dynamic memory allocation of `out` takes place.

To avoid dynamic memory allocation, use an `assert` statement before the `reshape` statement to restrict the size variables `m`, `n`, `...` to `numel(in)`. This example shows how to use an `assert` statement before a `reshape` statement:

Rearrange a Matrix into Given Number of Rows

- 1 Define a function, `ReshapeMatrix`, which takes an input variable, `N`, and reshapes a matrix, `mat`, to have `N` rows:

```
function [out1,out2] = ReshapeMatrix(N)

    mat = [1 2 3 4 5; 4 5 6 7 8]
    % Since mat has 10 elements, N must be a factor of 10
    % to pass as argument to reshape

    out1 = reshape(mat,N,[]);
    % N is not restricted

    assert(N < numel(mat));
    % N is restricted to number of elements in mat
    out2 = reshape(mat,N,[]);
```

- 2 Generate code for `ReshapeArray` using the `codegen` command (the input argument does not have to be a factor of 10):

```
codegen -config:lib -report ReshapeArray -args 3
```

While `out1` is dynamically allocated, `out2` is assigned an array with size 100 (=10 X 10) in the generated code.

Tip If your system has limited memory, do not use the `assert` statement in this way. For an `n`-element matrix, the `assert` statement creates an `n`-by-`n` matrix, which might be large.

More About

- “Dynamic Memory Allocation and Performance”

Disable Dynamic Memory Allocation During Code Generation

To disable dynamic memory allocation using the MATLAB Coder app:

- 1 To open the **Generate** dialog box, on the **Generate Code** page, click the **Generate** arrow .
- 2 Click **More Settings**.
- 3 On the **Memory** tab, under **Variable Sizing Support**, set **Dynamic memory allocation** to **Never**.

To disable dynamic memory allocation at the command line:

- 1 In the MATLAB workspace, define the configuration object:

```
cfg=coder.config('lib');
```
- 2 Set the `DynamicMemoryAllocation` property of the configuration object to `Off`:

```
cfg.DynamicMemoryAllocation = 'Off';
```

If a variable-size array in the MATLAB code does not have a maximum upper bound, disabling dynamic memory allocation leads to a code generation error. Therefore, you can identify variable-size arrays in your MATLAB code that do not have a maximum upper bound. These arrays are the arrays that are dynamically allocated in the generated code.

Related Examples

More About

- “Dynamic Memory Allocation and Performance”

Set Dynamic Memory Allocation Threshold

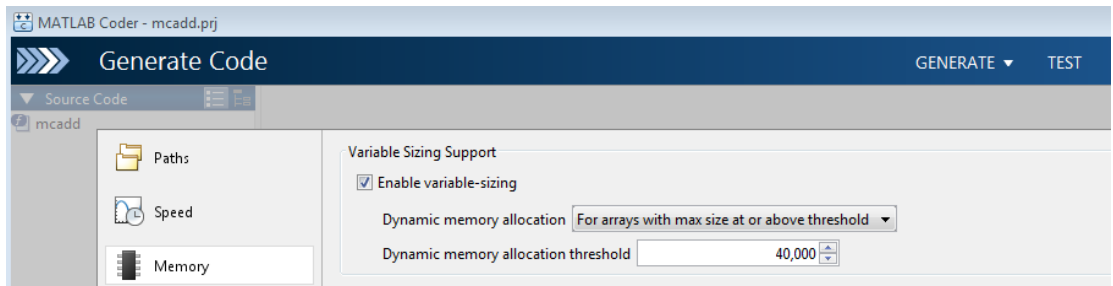

This example shows how to specify a dynamic memory allocation threshold for variable-size arrays. Dynamic memory allocation optimizes storage requirements for variable-size arrays, but causes slower execution of generated code. Instead of disabling dynamic memory allocation for all variable-size arrays, you can disable dynamic memory allocation for arrays less than a certain size.

Specify this threshold when you want to:

- Disable dynamic memory allocation for smaller arrays. For smaller arrays, static memory allocation can speed up generated code. Static memory allocation can lead to unused storage space. However, you can decide that the unused storage space is not a significant consideration for smaller arrays.
- Enable dynamic memory allocation for larger arrays. For larger arrays, when you use dynamic memory allocation, you can significantly reduce storage requirements.

Set Dynamic Memory Allocation Threshold Using the MATLAB Coder App

- 1 To open the **Generate** dialog box, on the **Generate Code** page, click the **Generate** arrow .
- 2 Click **More Settings**.
- 3 On the **Memory** tab, select the **Enable variable-sizing** check box.
- 4 Set **Dynamic memory allocation** to **For arrays with max size at or above threshold**.
- 5 Set **Dynamic memory allocation threshold** to the value that you want.

The **Dynamic memory allocation threshold** value is measured in bytes. Based on information from the target hardware settings, the software estimates the size of the array that a certain value of `DynamicMemoryAllocationThreshold` can accommodate. This estimate excludes possible C compiler optimizations such as putting variables in registers.

Set Dynamic Memory Allocation Threshold at the Command Line

- 1 Create a configuration object for code generation. Use `coder.config` with arguments `'lib'`, `'dll'`, or `'exe'` (depending on your requirements). For example:

```
cfg = coder.config('lib');
```

- 2 Set `DynamicMemoryAllocation` to `'Threshold'`.

```
cfg.DynamicMemoryAllocation='Threshold';
```

- 3 Set the property, `DynamicMemoryAllocationThreshold`, to the value that you want.

```
cfg.DynamicMemoryAllocationThreshold = 40000;
```

The value stored in `DynamicMemoryAllocationThreshold` is measured in bytes. Based on information from the target hardware settings, the software estimates the size of the array that a certain value of `DynamicMemoryAllocationThreshold` can accommodate. This estimate excludes possible C compiler optimizations such as putting variables in registers.

Excluding Unused Paths from Generated Code

In certain situations, you do not need some branches of an: `if`, `elseif`, `else` statement, or a `switch`, `case`, `otherwise` statement in your generated code. For instance:

- You have a MATLAB function that performs multiple tasks determined by a control-flow variable. You might not need some of the tasks in the code generated from this function.
- You have an `if/elseif/if` statement in a MATLAB function performing different tasks based on the nature (type/value) of the input. In some cases, you know the nature of the input beforehand. If so, you do not need some branches of the `if` statement.

You can prevent code generation for the unused branches of an `if/elseif/else` statement or a `switch/case/otherwise` statement. Declare the control-flow variable as a constant. The code generator produces code only for the branch that the control-flow variable chooses.

Related Examples

- “Prevent Code Generation for Unused Execution Paths”

Prevent Code Generation for Unused Execution Paths

In this section...

“Prevent Code Generation When Local Variable Controls Flow” on page 55-30

“Prevent Code Generation When Input Variable Controls Flow” on page 55-31

If a variable controls the flow of an: `if`, `elseif`, `else` statement, or a `switch`, `case`, `otherwise` statement, declare it as constant so that code generation takes place for one branch of the statement only.

Depending on the nature of the control-flow variable, you can declare it as constant in two ways:

- If the variable is local to the MATLAB function, assign it to a constant value in the MATLAB code. For an example, see “Prevent Code Generation When Local Variable Controls Flow” on page 55-30.
- If the variable is an input to the MATLAB function, you can declare it as constant using `coder.Constant`. For an example, see “Prevent Code Generation When Input Variable Controls Flow” on page 55-31.

Prevent Code Generation When Local Variable Controls Flow

- 1 Define a function `SquareOrCube` which takes an input variable, `in`, and squares or cubes its elements based on whether the choice variable, `ch`, is set to `s` or `c`:

```
function out = SquareOrCube(ch,in) %#codegen
    if ch=='s'
        out = in.^2;
    elseif ch=='c'
        out = in.^3;
    else
        out = 0;
    end
```

- 2 Generate code for `SquareOrCube` using the `codegen` command:

```
codegen -config:lib SquareOrCube -args {'s',zeros(2,2)}
```

The generated C code squares or cubes the elements of a 2-by-2 matrix based on the input for `ch`.

- 3 Add the following line to the definition of `SquareOrCube`:

```
ch = 's';
```

The generated C code squares the elements of a 2-by-2 matrix. The choice variable, `ch`, and the other branches of the `if/elseif/if` statement do not appear in the generated code.

Prevent Code Generation When Input Variable Controls Flow

- 1 Define a function `MathFunc`, which performs different mathematical operations on an input, `in`, depending on the value of the input, `flag`:

```
function out = MathFunc(flag,in) %#codegen
    %# codegen
    switch flag
        case 1
            out=sin(in);
        case 2
            out=cos(in);
        otherwise
            out=sqrt(in);
    end
```

- 2 Generate code for `MathFunc` using the `codegen` command:

```
codegen -config:lib MathFunc -args {1,zeros(2,2)}
```

The generated C code performs different math operations on the elements of a 2-by-2 matrix based on the input for `flag`.

- 3 Generate code for `MathFunc`, declaring the argument, `flag`, as a constant using `coder.Constant`:

```
codegen -config:lib MathFunc -args {coder.Constant(1),zeros(2,2)}
```

The generated C code finds the sine of the elements of a 2-by-2 matrix. The variable, `flag`, and the `switch/case/otherwise` statement do not appear in the generated code.

Generate Code with Parallel for-Loops (parfor)

This example shows how to generate C code for a MATLAB algorithm that contains a `parfor`-loop.

- 1 Write a MATLAB function that contains a `parfor`-loop. For example:

```
function a = test_parfor %#codegen
a=ones(10,256);
r=rand(10,256);
parfor i=1:10
    a(i,:)=real(fft(r(i,:)));
end
```

- 2 Generate C code for `test_parfor`. At the MATLAB command line, enter:

```
codegen -config:lib test_parfor
```

Because you did not specify the maximum number of threads to use, the generated C code executes the loop iterations in parallel on the available number of cores.

- 3 To specify a maximum number of threads, rewrite the function `test_parfor` as follows:

```
function a = test_parfor(u) %#codegen
a=ones(10,256);
r=rand(10,256);
parfor (i=1:10,u)
    a(i,:)=real(fft(r(i,:)));
end
```

- 4 Generate C code for `test_parfor`. Use `-args 0` to specify that the input, `u`, is a scalar double. At the MATLAB command line, enter:

```
codegen -config:lib test_parfor -args 0
```

In the generated code, the iterations of the `parfor`-loop run on at most the number of cores specified by the input, `u`. If less than `u` cores are available, the iterations run on the cores available at the time of the call.

- “Reduction Assignments in parfor-Loops”

Minimize Redundant Operations in Loops

This example shows how to minimize redundant operations in loops. When a loop operation does not depend on the loop index, performing it inside a loop is redundant. This redundancy often goes unnoticed when you are performing multiple operations in a single MATLAB statement inside a loop. For example, in the following code, the inverse of the matrix **B** is being calculated 100 times inside the loop although it does not depend on the loop index:

```
for i=1:100
    C=C + inv(B)*A^i*B;
end
```

Performing such redundant loop operations can lead to unnecessary processing. To avoid unnecessary processing, move operations outside loops as long as they do not depend on the loop index.

- 1 Define a function, `SeriesFunc(A,B,n)`, that calculates the sum of n terms in the following power series expansion:

$$C = 1 + B^{-1}AB + B^{-1}A^2B + \dots$$

```
function C=SeriesFunc(A,B,n)

% Initialize C with a matrix having same dimensions as A
C=zeros(size(A));

% Perform the series sum
for i=1:n
    C=C+inv(B)*A^i*B;
end
```

- 2 Generate code for `SeriesFunc` with 4-by-4 matrices passed as input arguments for **A** and **B**:

```
X = coder.typeof(zeros(4));
codegen -config:lib -launchreport SeriesFunc -args {X,X,10}
```

In the generated code, the inversion of **B** is performed n times inside the loop. It is more economical to perform the inversion operation once outside the loop because it does not depend on the loop index.

- 3 Modify `SeriesFunc` as follows:

```
function C=SeriesFunc(A,B,n)

% Initialize C with a matrix having same dimensions as A
C=zeros(size(A));

% Perform the inversion outside the loop
inv_B=inv(B);

% Perform the series sum
for i=1:n
    C=C+inv_B*A^i*B;
end
```

This procedure performs the inversion of **B** only once, leading to faster execution of the generated code.

Unroll for-Loops

Unrolling `for`-loops eliminates the loop logic by creating a separate copy of the loop body in the generated code for each iteration. Within each iteration, the loop index variable becomes a constant.

You can also force loop unrolling for individual functions by wrapping the loop header in a `coder.unroll` function. For more information, see `coder.unroll`.

Limit Copying the for-loop Body in Generated Code

To limit the number of times that you copy the body of a `for`-loop in generated code:

- 1 Write a MATLAB function `getrand(n)` that uses a `for`-loop to generate a vector of length `n` and assign random numbers to specific elements. Add a test function `test_unroll`. This function calls `getrand(n)` with `n` equal to values both less than and greater than the threshold for copying the `for`-loop in generated code.

```
function [y1, y2] = test_unroll() %#codegen
% The directive %#codegen indicates that the function
% is intended for code generation
% Calling getrand 8 times triggers unroll
y1 = getrand(8);
% Calling getrand 50 times does not trigger unroll
y2 = getrand(50);
```

```
function y = getrand(n)
% Turn off inlining to make
% generated code easier to read
coder.inline('never');

% Set flag variable downroll to repeat loop body
% only for fewer than 10 iterations
downroll = n < 10;
% Declare size, class, and complexity
% of variable y by assignment
y = zeros(n, 1);
% Loop body begins
for i = coder.unroll(1:2:n, downroll)
    if (i > 2) && (i < n-2)
        y(i) = rand();
    end;
```

```
end;
% Loop body ends
```

2 Disable support for

In the default output folder, `codegen/lib/test_unroll`, generate C static library code for `test_unroll`:

```
codegen -config:lib test_unroll
```

In `test_unroll.c`, the generated C code for `getrand(8)` repeats the body of the `for`-loop (unrolls the loop) because the number of iterations is less than 10:

```
static void getrand(double y[8])
{
    /* Turn off inlining to make */
    /* generated code easier to read */
    /* Set flag variable downroll to repeat loop body */
    /* only for fewer than 10 iterations */
    /* Declare size, class, and complexity */
    /* of variable y by assignment */
    memset(&y[0], 0, sizeof(double) << 3);

    /* Loop body begins */
    y[2] = b_rand();
    y[4] = b_rand();

    /* Loop body ends */
}
```

The generated C code for `getrand(50)` does not unroll the `for`-loop because the number of iterations is greater than 10:

```
static void b_getrand(double y[50])
{
    int i;
    int b_i;

    /* Turn off inlining to make */
    /* generated code easier to read */
    /* Set flag variable downroll to repeat loop body */
    /* only for fewer than 10 iterations */
    /* Declare size, class, and complexity */
    /* of variable y by assignment */
    memset(&y[0], 0, 50U * sizeof(double));
```

```
/* Loop body begins */
for (i = 0; i < 25; i++) {
    b_i = (i << 1) + 1;
    if ((b_i > 2) && (b_i < 48)) {
        y[b_i - 1] = b_rand();
    }
}
```

3

Disable Support for Integer Overflow or Non-Finites

The code generator produces supporting code for the following situations:

- The result of an integer operation falls outside the range that a data type can represent. This situation is known as integer overflow.
- An operation generates non-finite values (`inf` and `NaN`). The supporting code is contained in the files `rt_nonfinite.c`, `rtGetInf.c`, and `rtGetNaN.c` (with corresponding header files).

If you know that these situations do not occur, you can suppress generation of the supporting code. You therefore reduce the size of the generated code and increase its speed. However, if one of these situations occurs, it is possible that the generated code does not match the behavior of the original MATLAB code.

Disable Support for Integer Overflow

You can use the MATLAB Coder app or the command-line interface to disable support for integer overflow. When you disable this support, the overflow behavior of your generated code depends on your target C compiler. Most C compilers wrap on overflow.

- Using the app:
 - 1 To open the **Generate** dialog box, on the **Generate Code** page, click the **Generate** arrow .
 - 2 Click **More Settings**.
 - 3 On the **Speed** tab, clear **Saturate on integer overflow**.
- At the command line:
 - 1 Create a configuration object for code generation. Use `coder.config` with arguments `'lib'`, `'dll'`, or `'exe'` (depending on your requirements). For example:

```
cfg = coder.config('lib');
```
 - 2 Set the `SaturateOnIntegerOverflow` property to `false`.

```
cfg.SaturateOnIntegerOverflow = false;
```

Disable Support for Non-Finite Numbers

You can use the MATLAB Coder app or the command-line interface to disable support for non-finite numbers(`inf` and `NaN`).

- Using the app:
 - 1 To open the **Generate** dialog box, on the **Generate Code** page, click the **Generate** arrow .
 - 2 Set **Build type** to `Source Code`, `Static Library`, `Dynamic Library`, or `Executable` (depending on your requirements).
 - 3 Click **More Settings**.
 - 4 On the **Speed** tab, clear the **Support non-finite numbers** check box.
- At the command line:
 - 1 Create a configuration object for code generation. Use `coder.config` with arguments `'lib'`, `'dll'`, or `'exe'` (depending on your requirements). For example:

```
cfg = coder.config('lib');
```
 - 2 Set the `SupportNonFinite` property to `false`.

```
cfg.SupportNonFinite = false;
```

Integrate External/Custom Code

This example shows how to integrate external or custom code to enhance performance of generated code. Although MATLAB Coder generates optimized code for most applications, you might have custom code optimized for your specific requirements. For example:

- You have custom libraries optimized for your target environment.
- You have custom libraries for functions not supported by MATLAB Coder.
- You have custom libraries that meet standards set by your company.

In such cases, you can integrate your custom code with the code generated by MATLAB Coder.

This example illustrates how to integrate the function `cublasSgemm` from the NVIDIA® CUDA® Basic Linear Algebra Subroutines (CUBLAS) library in generated code. This function performs matrix multiplication on a Graphics Processing Unit (GPU).

- 1 Define a class `ExternalLib_API` that derives from the class `coder.ExternalDependency`. `ExternalLib_API` defines an interface to the CUBLAS library through the following methods:
 - `getDescriptiveName`: Returns a descriptive name for `ExternalLib_API` to be used for error messages.
 - `isSupportedContext`: Determines if the build context supports the CUBLAS library.
 - `updateBuildInfo`: Adds header file paths and link files to the build information.
 - `GPU_MatrixMultiply`: Defines the interface to the CUBLAS library function `cublasSgemm`.

ExternalLib_API.m

```
classdef ExternalLib_API < coder.ExternalDependency
    %#codegen

    methods (Static)

        function bName = getDescriptiveName(-)
            bName = 'ExternalLib_API';
```

```
end

function tf = isSupportedContext(ctx)
    if ctx.isMatlabHostTarget()
        tf = true;
    else
        error('CUBLAS library not available for this target');
    end
end

function updateBuildInfo(buildInfo, ctx)
    [~, linkLibExt, ~, ~] = ctx.getStdLibInfo();

    % Include header file path
    % Include header files later using coder.cinclude
    hdrFilePath = 'C:\My_Includes';
    buildInfo.addIncludePaths(hdrFilePath);

    % Include link files
    linkFiles = strcat('libcublas', linkLibExt);
    linkPath = 'C:\My_Libs';
    linkPriority = '';
    linkPrecompiled = true;
    linkLinkOnly = true;
    group = '';
    buildInfo.addLinkObjects(linkFiles, linkPath, ...
        linkPriority, linkPrecompiled, linkLinkOnly, group);

    linkFiles = strcat('libcudart', linkLibExt);
    buildInfo.addLinkObjects(linkFiles, linkPath, ...
        linkPriority, linkPrecompiled, linkLinkOnly, group);

end

%API for library function 'cuda_MatrixMultiply'
function C = GPU_MatrixMultiply(A, B)
    assert(isa(A, 'single'), 'A must be single. ');
    assert(isa(B, 'single'), 'B must be single. ');

    if(coder.target('MATLAB'))
        C=A*B;
    else

        % Include header files
```

```
% for external functions and typedefs
% Header path included earlier using updateBuildInfo
coder.cinclude('cuda_runtime.h');
coder.cinclude('cublas_v2.h');

% Compute dimensions of input matrices
m = int32(size(A, 1));
k = int32(size(A, 2));
n = int32(size(B, 2));

% Declare pointers to matrices on destination GPU
d_A = coder.opaque('float*');
d_B = coder.opaque('float*');
d_C = coder.opaque('float*');

% Compute memory to be allocated for matrices
% Single = 4 bytes
size_A = m*k*4;
size_B = k*n*4;
size_C = m*n*4;

% Define error variables
error = coder.opaque('cudaError_t');
cudaSuccessV = coder.opaque('cudaError_t', ...
    'cudaSuccess');

% Assign memory on destination GPU
error = coder.ceval('cudaMalloc', ...
    coder.wref(d_A), size_A);
assert(error == cudaSuccessV, ...
    'cudaMalloc(A) failed');
error = coder.ceval('cudaMalloc', ...
    coder.wref(d_B), size_B);
assert(error == cudaSuccessV, ...
    'cudaMalloc(B) failed');
error = coder.ceval('cudaMalloc', ...
    coder.wref(d_C), size_C);
assert(error == cudaSuccessV, ...
    'cudaMalloc(C) failed');

% Define direction of copying
hostToDevice = coder.opaque('cudaMemcpyKind', ...
    'cudaMemcpyHostToDevice');
```

```
% Copy matrices to destination GPU
error = coder.ceval('cudaMemcpy', ...
    d_A, coder.rref(A), size_A, hostToDevice);
assert(error == cudaSuccessV, 'cudaMemcpy(A) failed');

error = coder.ceval('cudaMemcpy', ...
    d_B, coder.rref(B), size_B, hostToDevice);
assert(error == cudaSuccessV, 'cudaMemcpy(B) failed');

% Define type and size for result
C = zeros(m, n, 'single');

error = coder.ceval('cudaMemcpy', ...
    d_C, coder.rref(C), size_C, hostToDevice);
assert(error == cudaSuccessV, 'cudaMemcpy(C) failed');

% Define handle variables for external library
handle = coder.opaque('cublasHandle_t');
blasSuccess = coder.opaque('cublasStatus_t', ...
    'CUBLAS_STATUS_SUCCESS');

% Initialize external library
ret = coder.opaque('cublasStatus_t');
ret = coder.ceval('cublasCreate', coder.wref(handle));
assert(ret == blasSuccess, 'cublasCreate failed');

TRANSA = coder.opaque('cublasOperation_t', ...
    'CUBLAS_OP_N');
alpha = single(1);
beta = single(0);

% Multiply matrices on GPU
ret = coder.ceval('cublasSgemm', handle, ...
    TRANSA, TRANSA, m, n, k, ...
    coder.rref(alpha), d_A, m, ...
    d_B, k, ...
    coder.rref(beta), d_C, k);

assert(ret == blasSuccess, 'cublasSgemm failed');

% Copy result back to local host
deviceToHost = coder.opaque('cudaMemcpyKind', ...
    'cudaMemcpyDeviceToHost');
```

```

        error = coder.ceval('cudaMemcpy', coder.wref(C), ...
            d_C, size_C, deviceToHost);
        assert(error == cudaSuccessV, 'cudaMemcpy(C) failed');
    end
end
end
end
end

```

- 2 To perform the matrix multiplication using the interface defined in method `GPU_MatrixMultiply` and the build information in `ExternalLib_API`, include the following line in your MATLAB code:

```
C= ExternalLib_API.GPU_MatrixMultiply(A,B);
```

For instance, you can define a MATLAB function `Matrix_Multiply` that solely performs this matrix multiplication.

```
function C = Matrix_Multiply(A, B) %#codegen
    C= ExternalLib_API.GPU_MatrixMultiply(A,B);
```

- 3 Define a MEX configuration object using `coder.config`. For using the CUBLAS libraries, set the target language for code generation to C++.

```
cfg=coder.config('mex');
cfg.TargetLang='C++';
```

- 4 Generate code for `Matrix_Multiply` using `cfg` as the configuration object and two 2 X 2 matrices of type `single` as arguments. Since `cublasSgemv` supports matrix multiplication for data type `float`, the corresponding MATLAB matrices must have type `single`.

```
codegen -config cfg Matrix_Multiply ...
        -args {ones(2,'single'),ones(2,'single')}
```

- 5 Test the generated MEX function `Matrix_Multiply_mex` using two 2 X 2 identity matrices of type `single`.

```
Matrix_Multiply_mex(eye(2,'single'),eye(2,'single'))
```

The output is also a 2 X 2 identity matrix.

Generate Reusable Code

With MATLAB, you can generate reusable code in the following ways:

- Write reusable functions using standard MATLAB function file names which you can call from different locations, for example, in a Simulink model or MATLAB function library.
- Compile external functions on the MATLAB path and integrate them into generated C code for embedded targets.

See “Resolution of Function Calls for Code Generation”.

Common applications include:

- Overriding generated library function with a custom implementation.
- Implementing a reusable library on top of standard library functions that can be used with Simulink.
- Swapping between different implementations of the same function.

LAPACK Calls for Linear Algebra in a MATLAB Function Block

To improve the simulation speed of MATLAB Function block algorithms that call certain linear algebra functions, Simulink can call LAPACK functions. LAPACK is a software library for numerical linear algebra. If the input arrays for the linear algebra functions meet certain criteria, the simulation calls LAPACK functions in the LAPACK library that is included with MATLAB. MATLAB uses LAPACK in some linear algebra functions such as `eig` and `svd`.

If you use Simulink Coder to generate code for these algorithms, you can specify that the code generator produce LAPACK function calls. The code generator uses the LAPACKE C interface to LAPACK. If you specify that you want to generate LAPACK calls, and the input arrays for the linear algebra functions meet the criteria, the code generator produces LAPACK calls. The build process links to the LAPACK library that you specify. See “Speed Up Linear Algebra in Code Generated from a MATLAB Function Block” in the Simulink Coder documentation.

Troubleshooting MATLAB Code in MATLAB Function Blocks

- “Compile-Time Recursion Limit Reached” on page 56-2
- “Output Variable Must Be Assigned Before Run-Time Recursive Call” on page 56-5
- “Unable to Determine That Every Element of Cell Array Is Assigned” on page 56-8

Compile-Time Recursion Limit Reached

Issue

You see this error message:

```
Compile-time recursion limit reached. Increase CompileTimeRecursionLimit.
```

Cause

With compile-time recursion, the code generator produces copies of the recursive function instead of producing a recursive function in the generated code. The code generator is unable to use compile-time recursion for a recursive function in your MATLAB code because the number of function copies exceeds the limit.

Solution

To address this issue, try one of these solutions:

- “Use Run-Time Recursion by Making the Recursive Function Input Variable-Size” on page 56-2
- “Increase the Compile-Time Recursion Limit” on page 56-3

Use Run-Time Recursion by Making the Recursive Function Input Variable-Size

Consider this function:

```
function z = call_mysum(A)
    %#codegen
    z = mysum(A);
end

function y = mysum(A)
    coder.inline('never');
    if size(A,2) == 1
        y = A(1);
    else
        y = A(1) + mysum(A(2:end));
    end
end
```

```
end
```

If the input to `mysum` is fixed-size, the code generator uses compile-time recursion. If `A` is large enough, the number of function copies exceeds the default limit of 50. To cause the code generator to use run-time conversion, make the input to `mysum` variable-size by using `coder.varsize`.

```
function z = call_mysum(A)
%#codegen
B = A;
coder.varsize('B');
z = mysum(B);
end

function y = mysum(A)
coder.inline('never');
if size(A,2) == 1
    y = A(1);
else
    y = A(1)+ mysum(A(2:end));
end
end
```

Increase the Compile-Time Recursion Limit

The default compile-time recursion limit of 50 is high enough for most recursive functions that require compile-time recursion. Usually, increasing the limit does not fix the issue. However, if you can determine the number of recursive calls and you want compile-time recursion, increase the limit. For example, consider this function:

```
function z = call_mysum()
%#codegen
B = 1:125;
z = mysum(B);
end

function y = mysum(A)
coder.inline('never');
if size(A,2) == 1
    y = A(1);
else
    y = A(1)+ mysum(A(2:end));
end
end
```

You can determine that the code generator produces 125 copies of the `mysum` function. In this case, if you want compile-time recursion, increase the compile-time recursion limit to 125.

To increase the limit, in the model configuration parameters, on the **All Parameters** tab, in the **Simulation Target** category, increase the value of **Compile-time recursion limit for MATLAB functions**.

- “Compile-time recursion limit for MATLAB functions”

Output Variable Must Be Assigned Before Run-Time Recursive Call

Issue

You see one of these messages:

```
All outputs must be assigned before any run-time recursive call. Output 'y' is not assigned.
```

```
Simulink does not have enough information to determine output sizes for this block.
```

Cause

Run-time recursion produces a recursive function in the generated code. The code generator is unable to use run-time recursion for a recursive function in your MATLAB code because an output is not assigned before the first recursive call.

Solution

Rewrite the code so that it assigns the output before the recursive call.

Direct Recursion Example

In the following code, the statement `y = A(1)` assigns a value to the output `y`. This statement occurs after the recursive call `y = A(1) + mysum(A(2:end))`.

```
function z = call_mysum(A)
B = A;
coder.varsize('B');
z = mysum(B);
end

function y = mysum(A)
coder.inline('never');
if size(A,2) > 1
    y = A(1) + mysum(A(2:end));
else
    y = A(1);
end
end
```

Rewrite the code so that assignment $y = A(1)$ occurs in the `if` block and the recursive call occurs in the `else` block.

```
function z = call_mysum(A)
B = A;
coder.varsize('B');
z = mysum(B);
end

function y = mysum(A)
coder.inline('never');

if size(A,2) == 1
    y = A(1);
else
    y = A(1)+ mysum(A(2:end));
end
end
```

Alternatively, before the `if` block, add an assignment, for example, $y = 0$.

```
function z = call_mysum(A)
B = A;
coder.varsize('B');
z = mysum(B);
end

function y = mysum(A)
coder.inline('never');
y = 0;
if size(A,2) > 1
    y = A(1)+ mysum(A(2:end));

else
    y = A(1);
end
end
```

Indirect Recursion Example

In the following code, `rec1` calls `rec2` before the assignment $y = 0$.

```
function z = callrec(n)
z = rec1(n);
end
```

```
function y = rec1(x)
%#codegen

if x >= 0
    y = rec2(x-1)+1;
else
    y = 0;
end
end

function y = rec2(x)
y = rec1(x-1)+2;
end
```

Rewrite this code so that in `rec1`, the assignment `y = 0` occurs in the `if` block and the recursive call occurs in the `else` block.

```
function z = callrec(n)
z = rec1(n);
end

function y = rec1(x)
%#codegen

if x < 0
    y = 0;
else
    y = rec2(x-1)+1;
end
end

function y = rec2(x)
y = rec1(x-1)+2;
end
```

- “Code Generation for Recursive Functions” on page 54-20

Unable to Determine That Every Element of Cell Array Is Assigned

Issue

You see one of these messages:

```
Unable to determine that every element of 'y' is assigned before this line.
```

```
Unable to determine that every element of 'y' is assigned before exiting the function.
```

```
Unable to determine that every element of 'y' is assigned before exiting the recursive
```

Cause

For code generation, before you use a cell array element, you must assign a value to it. When you use `cell` to create a variable-size cell array, for example, `cell(1,n)`, MATLAB assigns an empty matrix to each element. However, for code generation, the elements are unassigned. For code generation, after you use `cell` to create a variable-size cell array, you must assign all elements of the cell array before any use of the cell array.

The code generator analyzes your code to determine whether all elements are assigned before the first use of the cell array. The code generator detects that all elements are assigned when the code follows this pattern:

```
function z = mycell(n, j)
%#codegen
assert(n < 100);
x = cell(1,n);
for i = 1:n
    x{i} = i;
end
z = x{j};
end
```

Here is the pattern for a multidimensional cell array:

```
function z = mycell(m,n,p)
%#codegen
assert(m < 100);
```

```

assert(n < 100);
assert(p < 100);
x = cell(m,n,p);
for i = 1:m
    for j = 1:n
        for k = 1:p
            x{i,j,k} = i+j+k;
        end
    end
end
z = x{m,n,p};
end

```

If the code generator detects that some elements are not assigned, code generation fails. Sometimes, even though your code assigns all elements of the cell array, code generation fails because the analysis does not detect that all elements are assigned.

Here are examples where the code generator is unable to detect that elements are assigned:

- Elements are assigned in different loops

```

...
x = cell(1,n)
for i = 1:5
    x{i} = 5;
end
for i = 6:n
    x{i} = 7;
end
...

```

- The variable that defines the loop end value is not the same as the variable that defines the cell dimension.

```

...
x = cell(1,n);
m = n;
for i = 1:m
    x{i} = 2;
end
...

```

For more information, see “Definition of Variable-Size Cell Array by Using cell” on page 50-9.

Solution

Try one of these solutions:

- “Use recognized pattern for assigning elements” on page 56-10
- “Use repmat” on page 56-10
- “Use coder.nullcopy” on page 56-11

Use recognized pattern for assigning elements

If possible, rewrite your code to follow this pattern:

```
...  
x = cell(1,n);  
for i = 1:n  
    x{i} = i;  
end  
z = x{j};  
...
```

Use repmat

Sometimes, you can use `repmat` to define the variable-size cell array.

Consider this code that defines a variable-size cell array. It assigns the value 1 to odd elements and the value 2 to even elements.

```
function z = mycell2(n, j)  
%#codegen  
assert(n < 100);  
c = cell(1,n);  
for i = 1:2:n-1  
    c{i} = 1;  
end  
for i = 2:2:n  
    c{i} = 2;  
end  
z = c{j};
```

Code generation does not allow this code because:

- More than one loop assigns the elements.
- The loop counter does not increment by 1.

Rewrite the code to first use `cell` to create a 1-by-2 cell array whose first element is 1 and whose second element is 2. Then, use `repmat` to create a variable-size cell array whose element values alternate between 1 and 2.

```
function z = mycell12(n, j)
%#codegen
assert(n < 100);
c = cell(1,2);
c{1} = 1;
c{2} = 2;
c1= repmat(c,1,n);
z = c1{j};
end
```

Use `coder.nullcopy`

As a last resort, you can use `coder.nullcopy` to indicate that the code generator can allocate the memory for your cell array without initializing the memory. For example:

```
function z = mycell13(n, j)
%#codegen
assert(n < 100);
c =cell(1,n);
c1 = coder.nullcopy(c);
for i = 1:4
    c1{i} = 1;
end
for i = 5:n
    c1{i} = 2;
end
z = c1{j};
end
```

Use `coder.nullcopy` with caution. If you access uninitialized memory, results are unpredictable.

About Data Types in Simulink

In this section...

“About Data Types” on page 57-2

“Data Typing Guidelines” on page 57-3

“Data Type Propagation” on page 57-3

About Data Types

The term *data type* refers to the way in which a computer represents numbers in memory. A data type determines the amount of storage allocated to a number, the method used to encode the number's value as a pattern of binary digits, and the operations available for manipulating the type. Most computers provide a choice of data types for representing numbers, each with specific advantages in the areas of precision, dynamic range, performance, and memory usage. To optimize performance, you can specify the data types of variables used in the MATLAB technical computing environment. Simulink builds on this capability by allowing you to specify the data types of Simulink signals and block parameters.

The ability to specify the data types of a model's signals and block parameters is particularly useful in real-time control applications. For example, it allows a Simulink model to specify the optimal data types to use to represent signals and block parameters in code generated from a model by automatic code-generation tools, such as the Simulink Coder product. By choosing the most appropriate data types for your model's signals and parameters, you can dramatically increase performance and decrease the size of the code generated from the model.

Simulink performs extensive checking before and during a simulation to ensure that your model is *typesafe*, that is, that code generated from the model will not overflow or underflow and thus produce incorrect results. Simulink models that use the default data type (**double**) are inherently typesafe. Thus, if you never plan to generate code from your model or use a nondefault data type in your models, you can skip the remainder of this section.

On the other hand, if you plan to generate code from your models and use nondefault data types, read the remainder of this section carefully, especially the section on data type rules (see “Data Typing Guidelines” on page 57-3). In that way, you can avoid introducing data type errors that prevent your model from running to completion or simulating at all.

Data Typing Guidelines

Observing the following rules can help you to create models that are typesafe and, therefore, execute without error:

- Signal data types generally do not affect parameter data types, and vice versa.

A significant exception to this rule is the Constant block, whose output data type is determined by the data type of its parameter.

- If the output of a block is a function of an input and a parameter, and the input and parameter differ in type, Simulink converts the parameter to the input type before computing the output.
- In general, a block outputs the data type that appears at its inputs.

Significant exceptions include Constant blocks and Data Type Conversion blocks, whose output data types are determined by block parameters.

- Virtual blocks accept signals of any type on their inputs.

Examples of virtual blocks include Mux and Demux blocks and unconditionally executed subsystems.

- The elements of a signal array connected to a port of a nonvirtual block must be of the same data type.
- The signals connected to the input data ports of a nonvirtual block cannot differ in type.
- Control ports (for example, Enable and Trigger ports) accept any data type.
- Solver blocks accept only **double** signals.
- Connecting a non-**double** signal to a block disables zero-crossing detection for that block.

Data Type Propagation

Whenever you start a simulation, enable display of port data types, or refresh the port data type display, Simulink performs a processing step called data type propagation. This step involves determining the types of signals whose type is not otherwise specified and checking the types of signals and input ports to ensure that they do not conflict. If type conflicts arise, an error dialog is displayed that specifies the signal and port whose data types conflict. The signal path that creates the type conflict is also highlighted.

Note You can insert typecasting (data type conversion) blocks in your model to resolve type conflicts. For more information, see [Data Type Conversion](#).

Data Types Supported by Simulink

Simulink supports all built-in numeric MATLAB data types except `int64` and `uint64`. The term *built-in data type* refers to data types defined by MATLAB itself as opposed to data types defined by MATLAB users. Unless otherwise specified, the term data type in the Simulink documentation refers to built-in data types.

The following table lists the built-in MATLAB data types supported by Simulink.

Name	Description
<code>double</code>	Double-precision floating point
<code>single</code>	Single-precision floating point
<code>int8</code>	Signed 8-bit integer
<code>uint8</code>	Unsigned 8-bit integer
<code>int16</code>	Signed 16-bit integer
<code>uint16</code>	Unsigned 16-bit integer
<code>int32</code>	Signed 32-bit integer
<code>uint32</code>	Unsigned 32-bit integer

Besides these built-in types, Simulink defines a `boolean` (`true` or `false`) type. The values `1` and `0` represent `true` and `false` respectively. For this data type, Simulink represents real, nonzero numeric values (including `Inf`) as `true` (`1`).

Block Support for Data and Signal Types

All Simulink blocks accept signals of type `double` by default. Some blocks prefer `boolean` input and others support multiple data types on their inputs. For more information on the data types supported by a specific block for parameter and input and output values, in the Simulink documentation see the Data Type Support section of the reference page for that block. If the documentation for a block does not specify a data type, the block inputs or outputs only data of type `double`.

Several blocks support bus objects (`Simulink.Bus`) as data types. See “Data Types for Bus Signals” on page 57-53.

Many Simulink blocks also support fixed-point data types. For more information about fixed-point data, see “Specify Fixed-Point Data Types” on page 57-38. For more

information on the data types supported by a specific block for parameter and input and output values, in the Simulink documentation see the Data Type Support section of the reference page for that block. If the documentation for a block does not specify a data type, the block inputs or outputs only data of type **double**.

To view a table that summarizes the data types supported by the blocks in the Simulink block libraries, execute the following command at the MATLAB command line:

```
showblockdatatypetable
```

Control Signal Data Types

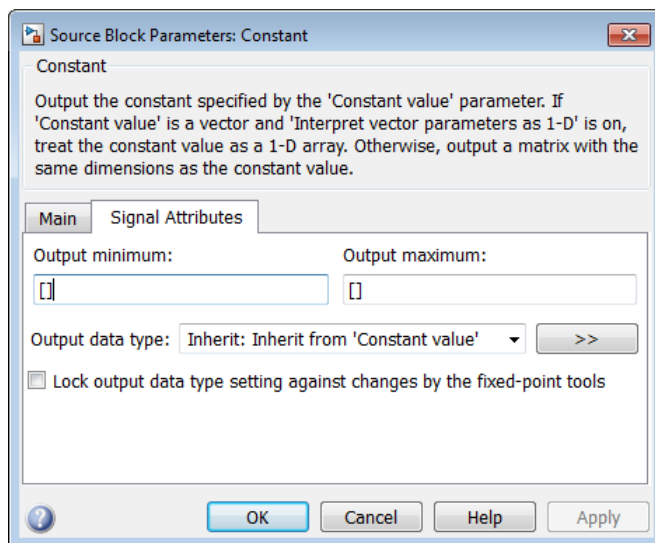

To view the signal data types in your model, in the Simulink Editor, select **Display > Signals & Ports > Port Data Types**. The port data type display is not automatically updated when you change the data type of a diagram element. To refresh the display, press **Ctrl+D**.

To control the data type of a signal in a Simulink model, you specify a data type for the corresponding block output.

You can also introduce a new signal of a specific data type into a model in any of the following ways:

- Load signal data of the desired type from the MATLAB workspace into your model via a root-level **Inport** block or a **From Workspace** block.
- Create a **Constant** block in your model and set its parameter to the desired type.
- Use a **Data Type Conversion** block to convert a signal to the desired data type.

Simulink blocks determine the data type of their outputs by default. Many blocks allow you to override the default type and explicitly specify an output data type, using a block parameter that is typically named **Output data type**. For example, the **Output data type** parameter appears on the **Signal Attributes** pane of the Constant block dialog box.

See the following topics for more information:

For Information About...	See...
Valid data type values that you can specify	“Entering Valid Data Type Values” on page 57-9
An assistant that helps you specify valid data type values	“Specify Data Types Using Data Type Assistant” on page 57-40
Specifying valid data type values for multiple blocks simultaneously	“Using the Model Explorer for Batch Editing” on page 57-12

Entering Valid Data Type Values

In general, you can specify the output data type as any of the following:

- A rule that inherits a data type (see “Data Type Inheritance Rules” on page 57-10)
- The name of a built-in data type (see “Built-In Data Types” on page 57-11)
- An expression that evaluates to a data type (see “Data Type Expressions” on page 57-11)

Valid data type values vary among blocks. You can use the pull-down menu associated with a block data type parameter to view the data types that a particular block supports. For example, the **Data type** pull-down menu on the Data Store Memory block dialog box lists the data types that it supports, as shown here.

For more information about the data types that a specific block supports, see the documentation for the block in the Simulink documentation.

Data Type Inheritance Rules

Blocks can inherit data types from a variety of sources, including signals to which they are connected and particular block parameters. You can specify the value of a data type parameter as a rule that determines how the output signal inherits its data type. To view the inheritance rules that a block supports, use the data type pull-down menu on the block dialog box. The following table lists typical rules that you can select.

Inheritance Rule	Description
Inherit: Inherit via back propagation	Simulink automatically determines the output data type of the block during data type propagation (see “Data Type Propagation” on page 57-3). In this case, the block uses the data type of a downstream block or signal object.

Inheritance Rule	Description
Inherit: Same as input	The block uses the data type of its sole input signal for its output signal.
Inherit: Same as first input	The block uses the data type of its first input signal for its output signal.
Inherit: Same as second input	The block uses the data type of its second input signal for its output signal.
Inherit: Inherit via internal rule	The block uses an internal rule to determine its output data type. The internal rule chooses a data type that optimizes numerical accuracy, performance, and generated code size, while taking into account the properties of the embedded target hardware. It is not always possible for the software to optimize efficiency and numerical accuracy at the same time.

Built-In Data Types

You can specify the value of a data type parameter as the name of a built-in data type, for example, `single` or `boolean`. To view the built-in data types that a block supports, use the data type pull-down menu on the block dialog box. See “Data Types Supported by Simulink” on page 57-5 for a list of all built-in data types that are supported.

Data Type Expressions

You can specify the value of a data type parameter as an expression that evaluates to a numeric data type object. Simply enter the expression in the data type field on the block dialog box. In general, enter one of the following expressions:

- **fixdt Command**

Specify the value of a data type parameter as a command that invokes the `fixdt` function. This function allows you to create a `Simulink.NumericType` object that describes a fixed-point or floating-point data type. See the documentation for the `fixdt` function for more information.

- **Data Type Object Name**

Specify the value of a data type parameter as the name of a data object that represents a data type. Simulink data objects that you instantiate from classes, such as `Simulink.NumericType` and `Simulink.AliasType`, simplify the task of making model-wide changes to output data types and allow you to use custom aliases for data types. See “Data Objects” on page 57-54 for more information about Simulink data objects.

Using the Model Explorer for Batch Editing

Using the Model Explorer (see “Model Explorer Overview” on page 12-2), you can assign the same output data type to multiple blocks simultaneously. For example, the `slexAircraftExample` model that comes with the Simulink product contains numerous Gain blocks. Suppose you want to specify the **Output data type** parameter of all the Gain blocks in the model as `single`. You can achieve this task as follows:

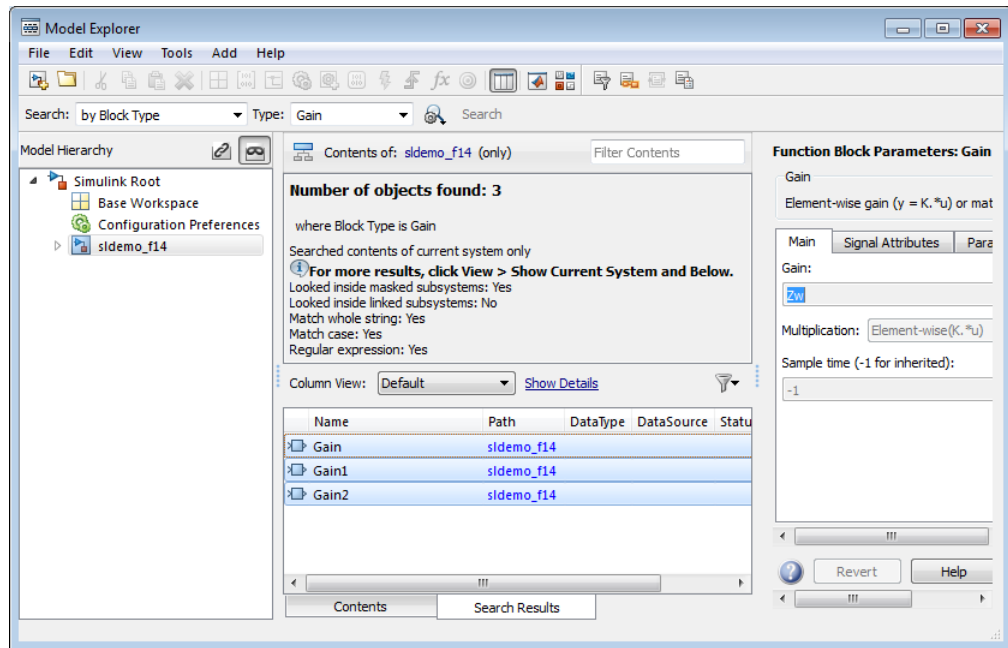

- 1 Use the Model Explorer search bar (see “Search Using Model Explorer” on page 12-60) to identify all blocks in the `slexAircraftExample` model of type `Gain`.

The Model Explorer **Contents** pane lists all Gain blocks in the model.

- 2 In the Model Explorer **Contents** pane, select all the Gain blocks whose **Output data type** parameter you want to specify.

Model Explorer highlights the rows corresponding to your selections.

- 3 In the Model Explorer **Contents** pane, click the data type associated with one of the selected Gain blocks.

Model Explorer displays a pull-down menu with valid data type options.

- 4 In the pull-down menu, enter or select the desired data type, for example, `single`.

Model Explorer specifies the data type of all selected items as `single`.

Use the Model Data Editor for Batch Editing of Inport and Outport Blocks

Use the Model Data Editor to design the interface of your model by configuring data types and other attributes of multiple Inport and Outport blocks at once. See “Configure Data Interface for Component” on page 21-15 and “Configure Data Properties by Using a Table” on page 57-103.

Validate a Floating-Point Embedded Model

You can use data type override mode to switch the data types in your model. This capability allows you to maintain one model but simulate and generate code for multiple data types, and also validate the numerical behavior for each type. For example, if you implement an algorithm using double-precision data types and want to check whether the algorithm is also suitable for single-precision use, you can apply a data type override to floating-point data types to replace all doubles with singles without affecting any other data types in your model.

Apply a Data Type Override to Floating-Point Data Types

To apply a data type override, you must specify the data type that you want to apply and the data type that you want to replace.

You can set a data type override using one of the following methods. In these examples, both methods change all floating-point data types to single.

From the Command Line

For example:

```
set_param(gcs, 'DataTypeOverride', 'Single');  
set_param(gcs, 'DataTypeOverrideAppliesTo', 'Floating-point');
```

Using the Fixed-Point Tool

For example:

- 1** In the Simulink Editor, select **Analysis > Fixed-Point Tool**.

The Fixed-Point Tool opens.
- 2** Select **View > Show Settings for Selected System**.
- 3** In the Fixed-Point Tool right pane, under **Settings for selected system**:
 - a** Set **Data type override** to **Single**.
 - b** Set **Data type override applies** to **Floating-point**.

For more information on data type override settings, see `fxptdlg`.

Validate a Single-Precision Model

This example uses the `ex_single_validation` model to show how you can use data type overrides. It proves that an algorithm, which implements double-precision data types, is also suitable for single-precision embedded use.

About the Model

- The inputs `In2` and `In3` are double-precision inputs to the `Sum` and `Product` blocks.
- The outputs of the `Sum` and `Product` blocks are data inputs to the `Multiport Switch` block.
- The input `In1` is the control input to the `Multiport Switch` block. The value of this control input determines which of its other inputs, the sum of `In2` and `In3` or the product of `In2` and `In3`, passes to the output port. Because `In1` is a control input, its data type is `int8`.

- The **Relational Operator** block compares the output of the **Multiport Switch** block to **In4**, and outputs a Boolean signal.

Run the Example

Open the Model

- 1 Open the `ex_single_validation` model. At the MATLAB command line, enter:

```
addpath(fullfile(docroot, 'toolbox', 'simulink', 'examples'))
ex_single_validation
```

Run Model Advisor Check

- 1 From the model menu, select **Analysis > Model Advisor > Model Advisor**.
- 2 In the System Selector dialog box, click **OK**.

The Model Advisor opens.

- 3 In the Model Advisor, expand the **By Task** node and, under **Modeling Single-Precision Systems**, select the **Identify questionable operations for strict single-precision design** check.
- 4 In the right pane, click **Run This Check**.

The check generates a warning that multiple blocks use double-precision floating-point operations.

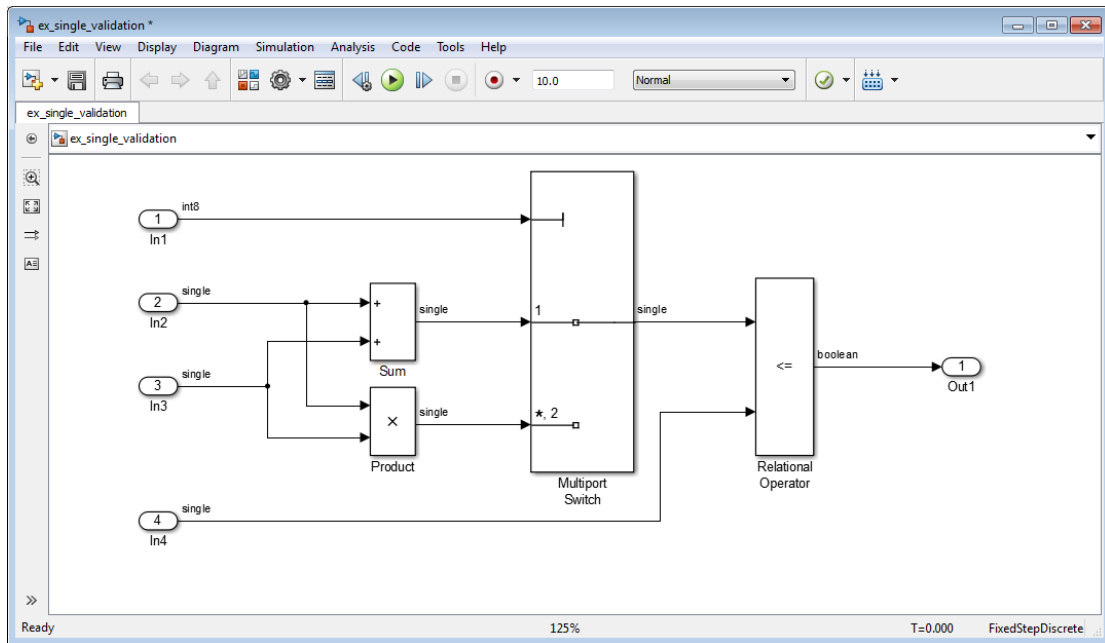

Override Floating-Point Data Types With Singles

- 1 In the Simulink Editor, select **Analysis > Fixed-Point Tool**.

The Fixed-Point Tool opens.

- 2 In the Fixed-Point Tool right pane, under **Settings for selected system**:
 - a Set **Data type override** to **Single**.
 - b Set **Data type override applies to** **Floating-point**.
 - c Click **Apply**.
- 3 In the model menu, select **Simulation > Update Diagram**.

The data type override replaces all the floating-point (**double**) data types in the model with **single** data types, but does not affect the integer or Boolean data types.

Re-run the Model Advisor Check

In the Model Advisor, run the **Identify questionable operations for strict single-precision design** check again.

The check passes indicating that this algorithm is suitable for single-precision embedded use.

Fixed-Point Numbers

In this section...

“Binary Point Interpretation” on page 57-22

“Signed Fixed-Point Numbers” on page 57-23

In digital hardware, numbers are stored in binary words. A binary word is a fixed-length sequence of binary digits (1's and 0's). The way in which hardware components or software functions interpret this sequence of 1's and 0's is described by a data type. There are several distinct differences between fixed-point data types and the built-in integer types in MATLAB®. The most notable difference, is that the built-in integer data types can only represent whole numbers, while the fixed-point data types also contain information on the position of the binary point, or the scaling of the number.

Binary numbers are represented as either fixed-point or floating-point data types. A fixed-point data type is characterized by the word size in bits, the binary point, and whether it is signed or unsigned. The position of the binary point is the means by which fixed-point values are scaled and interpreted. With Fixed-Point Designer, fixed-point data types can be integers, fractionals, or generalized fixed-point numbers. The main difference between these data types is their default binary point. For example, a binary representation of a generalized fixed-point number (either signed or unsigned) is shown below:

where

- b_i is the i^{th} binary digit.
- wl is the word length in bits.
- b_{wl-1} is the location of the most significant, or highest, bit (MSB).
- b_0 is the location of the least significant, or lowest, bit (LSB).
- The binary point is shown four places to the left of the LSB. In this example, therefore, the number is said to have four fractional bits, or a fraction length of four.

Binary Point Interpretation

The binary point is the means by which fixed-point numbers are scaled. It is usually the software that determines the binary point. When performing basic math functions such as addition or subtraction, the hardware uses the same logic circuits regardless of the value of the scale factor. In essence, the logic circuits have no knowledge of a scale factor. They are performing signed or unsigned fixed-point binary algebra as if the binary point is to the right of b_0 .

Fixed-Point Designer supports the general binary point scaling $V=Q*2^E$. V is the real-world value, Q is the stored integer value, and E is equal to `-FractionLength`. In other words, `RealWorldValue = StoredInteger * 2 ^ -FractionLength`.

`FractionLength` defines the scaling of the stored integer value. The word length limits the values that the stored integer can take, but it does not limit the values `FractionLength` can take. The software does not restrict the value of exponent E based on the word length of the stored integer Q . Because E is equal to `-FractionLength`, restricting the binary point to being contiguous with the fraction is unnecessary; the fraction length can be negative or greater than the word length.

For example, a word consisting of three unsigned bits is usually represented in scientific notation in one of the following ways.

$$bbb. = bbb. \times 2^0$$

$$bb.b = bbb. \times 2^{-1}$$

$$b.bb = bbb. \times 2^{-2}$$

$$.bbb = bbb. \times 2^{-3}$$

If the exponent were greater than 0 or less than -3, then the representation would involve lots of zeros.

$$bbb00000. = bbb. \times 2^5$$

$$.bb00. = bbb. \times 2^2$$

$$.00bbb = bbb. \times 2^{-5}$$

$$.00000bbb = bbb. \times 2^{-8}$$

These extra zeros never change to ones, however, so they don't show up in the hardware. Furthermore, unlike floating-point exponents, a fixed-point exponent never shows up in the hardware, so fixed-point exponents are not limited by a finite number of bits.

Consider a signed value with a word length of 8, a fraction length of 10, and a stored integer value of 5 (binary value 00000101). The real-world value is calculated using the formula

$\text{RealWorldValue} = \text{StoredInteger} * 2^{-\text{FractionLength}}$. In this case, $\text{RealWorldValue} = 5 * 2^{-10} = 0.0048828125$. Because the fraction length is 2 bits longer than the word length, the binary value of the stored integer is $x.xx00000101$, where x is a placeholder for implicit zeros. 0.0000000101 (binary) is equivalent to 0.0048828125 (decimal). For an example using a `fi` object, see “Create a `fi` Object With Fraction Length Greater Than Word Length”.

Signed Fixed-Point Numbers

Computer hardware typically represents the negation of a binary fixed-point number in three different ways: sign/magnitude, one's complement, and two's complement. Two's complement is the preferred representation of signed fixed-point numbers and is the only representation used by Fixed-Point Designer.

Negation using two's complement consists of a bit inversion (translation into one's complement) followed by the addition of a one. For example, the two's complement of 000101 is 111011.

Whether a fixed-point value is signed or unsigned is usually not encoded explicitly within the binary word; that is, there is no sign bit. Instead, the sign information is implicitly defined within the computer architecture.

More About

- “Scaling, Precision, and Range” on page 57-26

Benefits of Using Fixed-Point Hardware

Digital hardware is becoming the primary means by which control systems and signal processing filters are implemented. Digital hardware can be classified as either off-the-shelf hardware (for example, microcontrollers, microprocessors, general-purpose processors, and digital signal processors) or custom hardware. Within these two types of hardware, there are many architecture designs. These designs range from systems with a single instruction, single data stream processing unit to systems with multiple instruction, multiple data stream processing units.

Within digital hardware, numbers are represented as either fixed-point or floating-point data types. For both of these data types, word sizes are fixed at a set number of bits. However, the dynamic range of fixed-point values is much less than floating-point values with equivalent word sizes. Therefore, in order to avoid overflow or unreasonable quantization errors, fixed-point values must be scaled. Since floating-point processors can greatly simplify the real-time implementation of a control law or digital filter, and floating-point numbers can effectively approximate real-world numbers, then why use a microcontroller or processor with fixed-point hardware support?

- **Size and Power Consumption** — The logic circuits of fixed-point hardware are much less complicated than those of floating-point hardware. This means that the fixed-point chip size is smaller with less power consumption when compared with floating-point hardware. For example, consider a portable telephone where one of the product design goals is to make it as portable (small and light) as possible. If one of today's high-end floating-point, general-purpose processors is used, a large heat sink and battery would also be needed, resulting in a costly, large, and heavy portable phone.
- **Memory Usage and Speed** — In general fixed-point calculations require less memory and less processor time to perform.
- **Cost** — Fixed-point hardware is more cost effective where price/cost is an important consideration. When digital hardware is used in a product, especially mass-produced products, fixed-point hardware costs much less than floating-point hardware and can result in significant savings.

After making the decision to use fixed-point hardware, the next step is to choose a method for implementing the dynamic system (for example, control system or digital filter). Floating-point software emulation libraries are generally ruled out because of timing or memory size constraints. Therefore, you are left with fixed-point math where binary integer values are scaled.

More About

- “Fixed-Point Numbers” on page 57-21

Scaling, Precision, and Range

In this section...

“Scaling” on page 57-26

“Precision” on page 57-27

“Range” on page 57-27

The dynamic range of fixed-point values is less than floating-point values with equivalent word sizes. To avoid overflow and minimize quantization errors, fixed-point numbers must be scaled.

Scaling

With Fixed-Point Designer, you can select a fixed-point data type whose scaling is defined by its binary point, or you can select an arbitrary linear scaling that suits your needs.

Slope and Bias Scaling

You can represent a fixed-point number by a general slope and bias encoding scheme. The real world value of a slope bias scaled number can be represented by:

$$\text{real-world value} = (\text{slope} \times \text{integer}) + \text{bias}$$

$$\text{slope} = \text{slope adjustment factor} \times 2^{\text{fixed exponent}}$$

The slope and bias together represent the scaling of the fixed-point number. In a number with zero bias, only the slope affects the scaling. A fixed-point number that is only scaled by binary point position is equivalent to a number in slope bias representation that has a bias equal to zero and a slope adjustment factor equal to one. This is referred to as binary point-only scaling or power-of-two scaling.

Binary-Point-Only Scaling

Binary-point-only or power-of-two scaling involves moving the binary point within the fixed-point word. The advantage of this scaling mode is to minimize the number of processor arithmetic operations. The real world value of a binary-point only scaled number can be represented by:

$$\text{real world value} = 2^{-\text{fraction length}} \times \text{integer}$$

Precision

The precision of a fixed-point number is the difference between successive values representable by its data type and scaling, which is equal to the value of its least significant bit. The value of the least significant bit, and therefore the precision of the number, is determined by the number of fractional bits. A fixed-point value can be represented to within half of the precision of its data type and scaling.

For example, a fixed-point representation with four bits to the right of the binary point has a precision of 2^{-4} or 0.0625, which is the value of its least significant bit. Any number within the range of this data type and scaling can be represented to within $(2^{-4})/2$ or 0.03125, which is half the precision.

Rounding Methods

When you represent numbers with finite precision, not every number in the available range can be represented exactly. If a number cannot be represented exactly by the specified data type and scaling, a rounding method is used to cast the value to a representable number. Although precision is always lost in the rounding operation, the cost of the operation and the amount of bias that is introduced depends on the rounding method itself. For more information on the rounding methods available with Fixed-Point Designer, see “Rounding Methods”

Range

Range is the span of numbers that a fixed-point data type and scaling can represent. The range of representable numbers for an unsigned two’s complement fixed-point number of word length ws , scaling S , and bias B is illustrated below:

The following figure illustrates the range of representable numbers for a two’s complement signed fixed-point number:

For both signed and unsigned fixed-point numbers of any data type, the number of different bit patterns is 2^{wl} .

For example, in two's complement, negative numbers must be represented as well as zero, so the maximum value is $2^{wl-1} - 1$. Because there is only one representation for zero, there are an unequal number of positive and negative numbers. This means there is a representation for -2^{wl-1} , but not for 2^{wl-1} .

“Scaled Doubles” on page 57-32

Fixed-Point Data in Simulink

You can use the `fixdt` function in Simulink to specify a fixed-point data type. The `fixdt` function creates a `Simulink.NumericType` object.

Fixed-Point Data Type and Scaling Notation

Simulink data type names must be valid MATLAB identifiers with less than 128 characters. The data type name provides information about container type, number encoding, and scaling.

The following table provides a key for various symbols that appear in Simulink products to indicate the data type and scaling of a fixed-point value.

Symbol	Description	Example
Container Type		
<code>ufix</code>	Unsigned fixed-point data type	<code>ufix8</code> is an 8-bit unsigned fixed-point data type
<code>sfix</code>	Signed fixed-point data type	<code>sfix128</code> is a 128-bit signed fixed-point data type
<code>fltu</code>	Scaled double override of an unsigned fixed-point data type (<code>ufix</code>)	<code>fltu32</code> is a scaled doubles override of <code>ufix32</code>
<code>flts</code>	Scaled double override of a signed fixed-point data type (<code>sfix</code>)	<code>flts64</code> is a scaled doubles override of <code>sfix64</code>
Number Encoding		
<code>e</code>	10^{\wedge}	<code>125e8</code> equals $125 * (10^{\wedge}(8))$
<code>n</code>	Negative	<code>n31</code> equals -31

Symbol	Description	Example
p	Decimal point	1p5 equals 1.5 p2 equals 0.2
Scaling Encoding		
S	Slope	ufix16_S5_B7 is a 16-bit unsigned fixed-point data type with Slope of 5 and Bias of 7
B	Bias	ufix16_S5_B7 is a 16-bit unsigned fixed-point data type with Slope of 5 and Bias of 7
E	Fixed exponent (2 [^]) A negative fixed exponent describes the fraction length	sfix32_En31 is a 32-bit signed fixed-point data type with a fraction length of 31
F	Slope adjustment factor	ufix16_F1p5_En50 is a 16-bit unsigned fixed-point data type with a SlopeAdjustmentFactor of 1.5 and a FixedExponent of -50
C,c,D, or d	Compressed encoding for Bias Note: If you pass this character vector to the <code>sldataTypeAndScale</code> function, it returns a valid <code>fixdt</code> data type.	No example available. For backwards compatibility only. To identify and replace calls to <code>sldataTypeAndScale</code> , use the “Check for calls to <code>sldataTypeAndScale</code> ” Model Advisor check.

Symbol	Description	Example
T or t	Compressed encoding for Slope	No example available. For backwards compatibility only.
	Note: If you pass this character vector to the <code>slDataTypeAndScale</code> , it returns a valid <code>fixdt</code> data type.	To identify and replace calls to <code>slDataTypeAndScale</code> , use the “Check for calls to <code>slDataTypeAndScale</code> ” Model Advisor check.

Fixed-Point Data in MATLAB

To assign a fixed-point data type to a number or variable in MATLAB, use the `fi` constructor. The resulting fixed-point value is called a `fi` object. For example, the following creates `fi` objects `a` and `b` with attributes shown in the display, all of which we can specify when the variables are constructed. Note that when the `FractionLength` property is not specified, it is set automatically to "best precision" for the given word length, keeping the most-significant bits of the value. When the `WordLength` property is not specified it defaults to 16 bits.

```
a = fi(pi)
```

```
a =
```

```
3.1416015625
```

```
    DataTypeMode: Fixed-point: binary point scaling
    Signedness: Signed
    WordLength: 16
    FractionLength: 13
```

```
b = fi(0.1)
```

```
b =
```

```
0.0999984741210938
```

```
    DataTypeMode: Fixed-point: binary point scaling
    Signedness: Signed
    WordLength: 16
    FractionLength: 18
```

Read Fixed-Point Data from the Workspace

Use the `From Workspace` block to read fixed-point data from the MATLAB workspace into a Simulink model. To do this, the data must be in structure format with a `fi` object in the `values` field. In array format, the `From Workspace` block only accepts real, double-precision data.

Write Fixed-Point Data to the Workspace

You can write fixed-point output from a model to the MATLAB workspace via the `To Workspace` block in either array or structure format. Fixed-point data written by a `To Workspace` block to the workspace in structure format can be read back into a Simulink model in structure format by a `From Workspace` block.

Scaled Doubles

Scaled doubles are a hybrid between floating-point and fixed-point numbers. Fixed-Point Designer stores them as doubles with the scaling, sign, and word length information retained. For example, the storage container for a fixed-point data type `sfixed16_E14` is `int16`. The storage container of the equivalent scaled doubles data type, `floats16_E14` is floating-point `double`. Fixed-Point Designer applies the scaling information to the stored floating-point double to obtain the real-world value. Storing the value in a double almost always eliminates overflow and precision issues.

Share Fixed-Point Models

You can edit a model containing fixed-point blocks without having Fixed-Point Designer. However, you must have Fixed-Point Designer to:

- Update a Simulink diagram (**Ctrl+D**) containing fixed-point data types
- Run a model containing fixed-point data types
- Generate code from a model containing fixed-point data types
- Log the minimum and maximum values produced by a simulation
- Automatically scale the output of a model

If you do not have Fixed-Point Designer, you can work with a model containing Simulink blocks with fixed-point settings as follows:

- 1 In the Simulink Editor, select **Analysis > Fixed-Point Tool**.

The Fixed-Point Tool opens.

- 2 Under **System under design**, click **Continue**.
- 3 In the Model Hierarchy pane, right-click the system.
 - Set **Fixed-point instrumentation mode** to **Force off**.
 - Set **Data type override** to **Double** or **Single**.
 - Set **Data type override applies to** **All numeric types**.
- 4 If you use **fi** objects or embedded numeric data types in your model, set the **fipref DataTypeOverride** property to **TrueDoubles** or **TrueSingles** (to be consistent with the model-wide data type override setting) and the **DataTypeOverrideAppliesTo** property to **All numeric types**.

For example, at the MATLAB command line, enter:

```
p = fipref('DataTypeOverride', 'TrueDoubles', ...  
         'DataTypeOverrideAppliesTo', 'AllNumericTypes');
```

Note: If you use **fi** objects or embedded numeric data types in your model or workspace, you might introduce fixed-point data types into your model. You can set **fipref** to prevent the checkout of a Fixed-Point Designer license.

Control Fixed-Point Instrumentation and Data Type Override

In this section...

“Control Instrumentation Settings” on page 57-35

“Control Data Type Override” on page 57-36

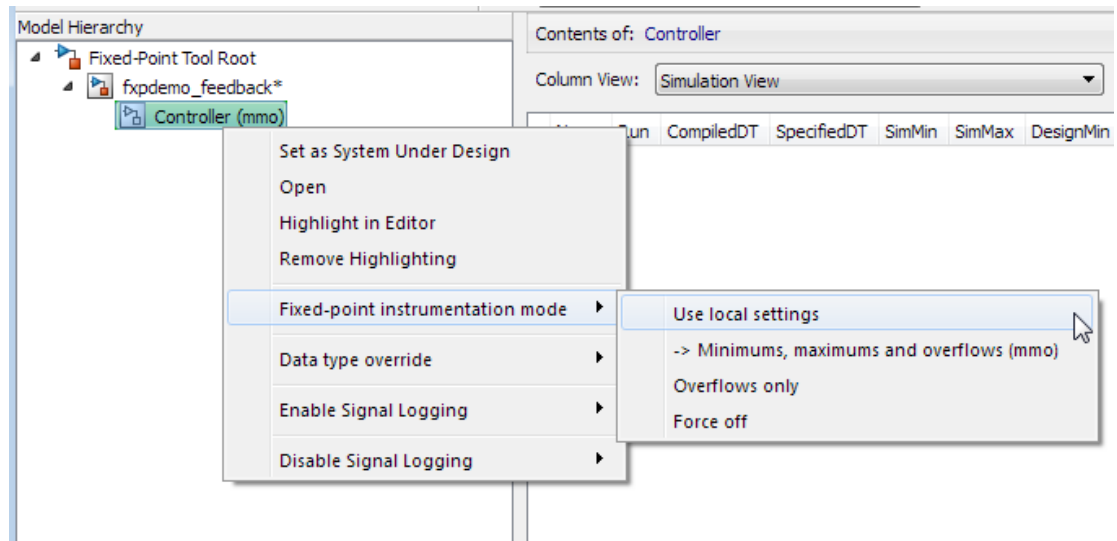

The conversion of a model from floating point to fixed point requires configuring fixed-point instrumentation and data type overrides. However, leaving these settings on after the conversion can lead to unexpected results. If you do not have Fixed-Point Designer, you can work with a model containing Simulink blocks with fixed-point settings by turning off fixed-point instrumentation and setting data type override to scaled doubles.

Control Instrumentation Settings

The fixed-point instrumentation mode controls which objects log minimum, maximum, and overflow data during simulation. Instrumentation is required to collect simulation ranges using the fixed-point tool. These ranges are used to propose data types for the model. When you are not actively converting your model to fixed point, disable the fixed-point instrumentation to restore the maximum simulation speed to your model.

- 1 From the model **Analysis** menu, select **Fixed-Point Tool**.
- 2 Under **System under design**, click **Continue**.
- 3 In the Model Hierarchy pane, the Fixed-Point Tool denotes systems that currently have instrumentation turned on with (mm0), or (o). Right-click the system in the model hierarchy and, under **Fixed-point instrumentation mode**, select the mode you want your model to use.

If you do not have Fixed-Point Designer, select **Force off**.

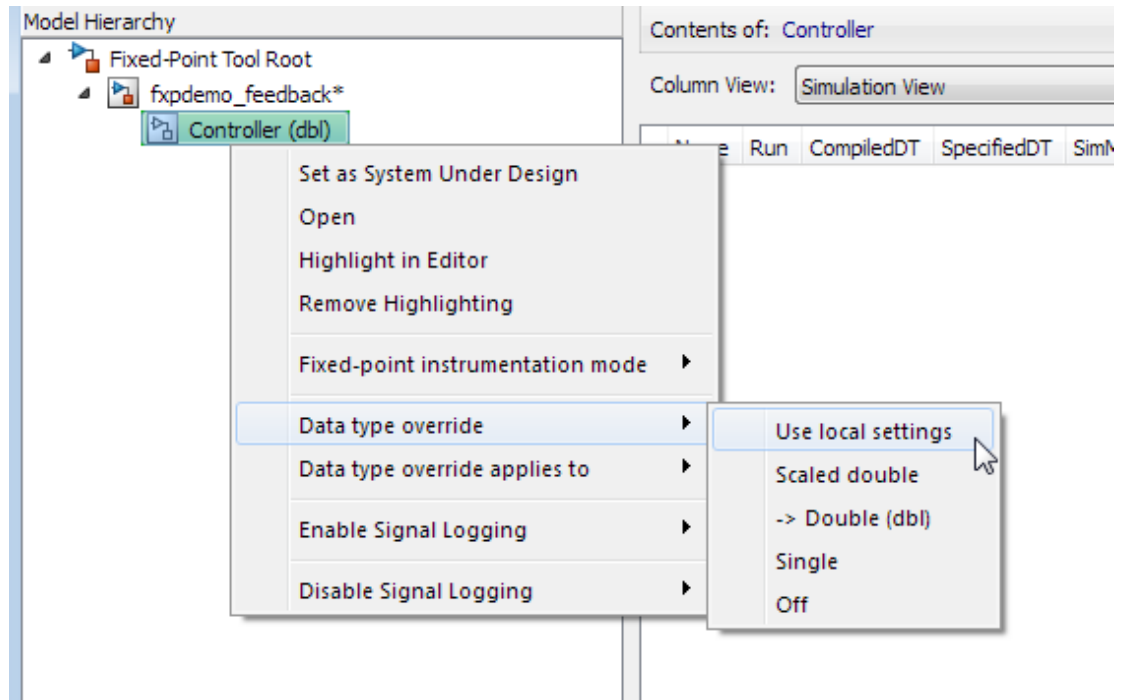

Control Data Type Override

Use data type override to simulate your model using double, single, or scaled double data types. If you do not have Fixed-Point Designer, you can still configure data type override settings to simulate a model that specifies fixed-point data types. Using this setting, the software temporarily overrides fixed-point data types with floating-point data types during simulation. Turn off data type override to observe the true behavior of your model.

- 1 From the model **Analysis** menu, select **Fixed-Point Tool**.
- 2 Under **System under design**, click **Continue**.
- 3 In the Model Hierarchy pane, the Fixed-Point Tool denotes systems that currently have data type override turned on with (dbl), (sgl), or (scl). Right-click the system in the Model Hierarchy pane and under **Data type override**, select the mode you want your model to use.

To observe the true behavior of your model, set data type override to **Use local settings** or **Force off**. If you do not have Fixed-Point Designer, and would like to simulate a model that uses fixed-point data types, select **Double** or **Single**.

More About

- “Share Fixed-Point Models” on page 57-33

Specify Fixed-Point Data Types

Simulink allows you to create models that use fixed-point numbers to represent signals and parameter values. Use of fixed-point data can reduce the memory requirements and increase the speed of code generated from a model.

To execute a model that uses fixed-point numbers, you must have the Fixed-Point Designer product installed on your system. Specifically, you must have the product to:

- Update a Simulink diagram (**Ctrl+D**) containing fixed-point data types
- Run a model containing fixed-point data types
- Generate code from a model containing fixed-point data types
- Log the minimum and maximum values produced by a simulation
- Automatically scale the output of a model using the autoscaling tool

If the Fixed-Point Designer product is not installed on your system, you can execute a fixed-point model as a floating-point model by enabling automatic conversion of fixed-point data to floating-point data during simulation. See “Overriding Fixed-Point Specifications” on page 57-38 for details.

If you do not have the Fixed-Point Designer product installed and do not enable automatic conversion of fixed-point to floating-point data, an error occurs if you try to execute a fixed-point model.

Note: You do not need the Fixed-Point Designer product to edit a model containing fixed-point blocks, or to use the Data Type Assistant to specify fixed-point data types, as described in “Specifying a Fixed-Point Data Type” on page 57-43.

Overriding Fixed-Point Specifications

Most of the functionality in the Fixed-Point Tool is for use with Fixed-Point Designer. However, even if you do not have Fixed-Point Designer, you can configure data type override settings to simulate a model that specifies fixed-point data types. In this mode, Simulink temporarily overrides fixed-point data types with floating-point data types when simulating the model.

Note: If you use `fi` objects or embedded numeric data types in your model or workspace, you might introduce fixed-point data types into your model. You can set `fipref` to prevent the checkout of a Fixed-Point Designer license.

To simulate a model without using Fixed-Point Designer:

- 1 In the Simulink Editor, select **Analysis > Fixed-Point Tool**.

The Fixed-Point Tool opens.

- 2 Under **System under design**, click **Continue**.
- 3 In the Model Hierarchy pane, right-click the system.
 - Set **Fixed-point instrumentation mode** to **Force off**.
 - Set **Data type override** to **Double** or **Single**.
 - Set **Data type override applies to** **All numeric types**.
- 4 If you use `fi` objects or embedded numeric data types in your model, set the `fipref` `DataTypeOverride` property to `TrueDoubles` or `TrueSingles` (to be consistent with the model-wide data type override setting) and the `DataTypeOverrideAppliesTo` property to `All numeric types`.

For example, at the MATLAB command line, enter:

```
p = fipref('DataTypeOverride', 'TrueDoubles', ...  
          'DataTypeOverrideAppliesTo', 'AllNumericTypes');
```

- “Data Types Supported by Simulink” on page 57-5

Specify Data Types Using Data Type Assistant

The **Data Type Assistant** is an interactive graphical tool that simplifies the task of specifying data types for blocks and data objects. The assistant appears on block and object dialog boxes, adjacent to parameters that provide data type control, such as the **Output data type** parameter. For example, it appears on the **Signal Attributes** pane of the Constant block dialog box shown here.

You can selectively show or hide the **Data Type Assistant** by clicking the applicable button:

- Click the **Show data type assistant** button  to display the assistant.
- Click the **Hide data type assistant** button  to hide a visible assistant.

Use the **Data Type Assistant** to specify a data type as follows:

- 1 In the **Mode** field, select the category of data type that you want to specify. In general, the options include the following:

Mode	Description
Inherit	Inheritance rules for data types
Built in	Built-in data types
Fixed point	Fixed-point data types
Enumerated	Enumerated data types
Bus object	Bus object data types
Expression	Expressions that evaluate to data types

The assistant changes dynamically to display different options that correspond to the selected mode. For example, setting **Mode** to **Expression** causes the Constant block dialog box to appear as follows.

- 2 In the field that is to the right of the **Mode** field, select or enter a data type.

For example, suppose that you designate the variable `myDataType` as an alias for a single data type. You create an instance of the `Simulink.AliasType` class and set its `BaseType` property by entering the following commands:

```
myDataType = Simulink.AliasType
```

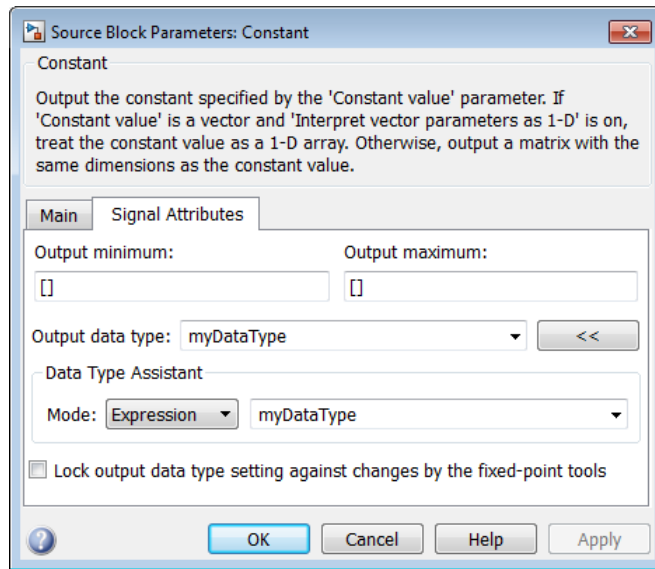

```
myDataType.BaseType = 'single'
```

You can use this data type object to specify the output data type of a Constant block. Enter the data type alias name, `myDataType`, as the value of the expression in the assistant.

- 3 Click the **OK** or **Apply** button to apply your changes.

The assistant uses the data type that you specified to populate the associated data type parameter in the block or object dialog box. In the following example, the **Output data type** parameter of the Constant block specifies the same expression that you entered using the assistant.

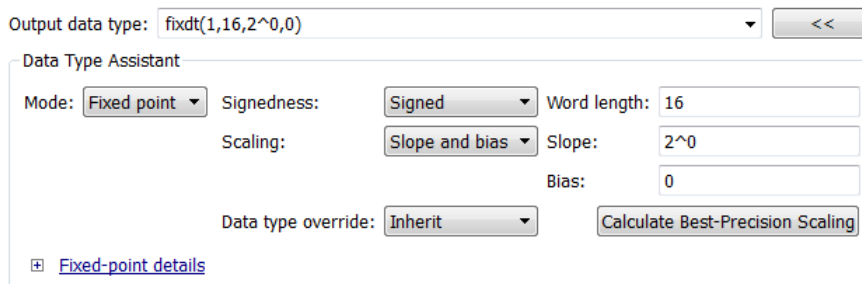

For more information about the data types that you can specify using the **Data Type Assistant**, see “Entering Valid Data Type Values” on page 57-9. For details about specifying fixed-point data types, see “Specify Fixed-Point Data Types with the Data Type Assistant”.

Specifying a Fixed-Point Data Type

When the Data Type Assistant **Mode** is **Fixed point**, the Data Type Assistant displays fields for specifying information about your fixed-point data type. For a detailed discussion about fixed-point data, see “Fixed-Point Basics in MATLAB”. For example, the next figure shows the Block Parameters dialog box for a Gain block, with the **Signal Attributes** tab selected and a fixed-point data type specified.

If the **Scaling** is **Slope** and **bias** rather than **Binary point**, the Data Type Assistant displays a **Slope** field and a **Bias** field rather than a **Fraction length** field:

You can use the Data Type Assistant to set these fixed-point properties:

Signedness

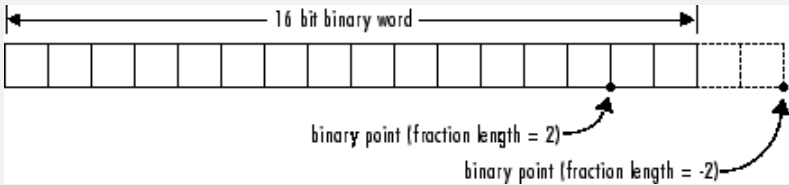

Specify whether you want the fixed-point data to be **Signed** or **Unsigned**. Signed data can represent positive and negative values, but unsigned data represents positive values only. The default setting is **Signed**.

Word length

Specify the bit size of the word that will hold the quantized integer. Large word sizes represent large values with greater precision than small word sizes. Word length can be any integer between 0 and 32. The default bit size is 16.

Scaling

Specify the method for scaling your fixed-point data to avoid overflow conditions and minimize quantization errors. The default method is **Binary point** scaling. You can select one of two scaling modes:

Scaling Mode	Description
Binary point	<p>If you select this mode, the Data Type Assistant displays the Fraction Length field, which specifies the binary point location.</p> <p>Binary points can be positive or negative integers. A positive integer moves the binary point left of the rightmost bit by that amount. For example, an entry of 2 sets the binary point in front of the second bit from the right. A negative integer moves the binary point further right of the rightmost bit by that amount, as in this example:</p>  <p>The default binary point is 0.</p>
Slope and bias	<p>If you select this mode, the Data Type Assistant displays fields for entering the Slope and Bias.</p> <p>Slope can be any positive real number, and the default slope is 1.0. Bias can be any real number, and the default bias is 0.0. You can enter</p>

Scaling Mode	Description
	slope and bias as expressions that contain parameters you define in the MATLAB workspace.

Note Use binary-point scaling whenever possible to simplify the implementation of fixed-point data in generated code. Operations with fixed-point data using binary-point scaling are performed with simple bit shifts and eliminate expensive code implementations, which are required for separate slope and bias values.

For more information about fixed-point scaling, see “Scaling”.

Data type override

When the **Mode** is **Built in** or **Fixed point**, you can use the **Data type override** option to specify whether you want this data type to inherit or ignore the data type override setting specified for its context, that is, for the block, `Simulink.Signal` object or Stateflow chart in Simulink that is using the signal. The default behavior is **Inherit**.

Data Type Override Mode	Description
Inherit (default)	Inherits the data type override setting from its context, that is, from the block, <code>Simulink.Signal</code> object or Stateflow chart in Simulink that is using the signal.
Off	Ignores the data type override setting of its context and uses the fixed-point data type specified for the signal.

The ability to turn off data type override for an individual data type provides greater control over the data types in your model when you apply data type override. For example, you can use this option to ensure that data types meet the requirements of downstream blocks regardless of the data type override setting.

Calculate Best-Precision Scaling

Click this button to calculate best-precision values for both **Binary point** and **Slope and bias** scaling, based on the specified minimum and maximum values. Simulink displays the scaling values in the **Fraction Length** field or the **Slope** and **Bias** fields. For more information, see “Constant Scaling for Best Precision”.

Showing Fixed-Point Details

When you specify a fixed-point data type, you can use the **Fixed-point details** subpane to see information about the fixed-point data type that is currently displayed in the Data Type Assistant. To see the subpane, click the expander next to **Fixed-point details** in the Data Type Assistant. The **Fixed-point details** subpane appears at the bottom of the Data Type Assistant:

Output minimum: Output maximum:

Output data type:

Data Type Assistant

Mode: Signedness: Word length:

Scaling: Slope:

Bias:

Data type override:

[Fixed-point details](#)

Representable maximum:	32767
Output maximum:	<input type="text" value="[]"/>
Constant value:	90
Output minimum:	<input type="text" value="[]"/>
Representable minimum:	-32768

Precision:

The rows labeled **Output minimum** and **Output maximum** show the same values that appear in the corresponding **Output minimum** and **Output maximum** fields above the Data Type Assistant. The names of these fields may differ from those shown. For example, a fixed-point block parameter would show **Parameter minimum** and **Parameter maximum**, and the corresponding **Fixed-point details** rows would be labeled accordingly. See “Signal Ranges” on page 62-41 and “Specify Minimum and Maximum Values for Block Parameters” on page 34-63 for more information.

The rows labeled **Representable minimum**, **Representable maximum**, and **Precision** always appear. These rows show the minimum value, maximum value, and precision that can be represented by the fixed-point data type currently displayed in the Data Type Assistant. For information about these three quantities, see “Fixed-Point Basics in MATLAB”.

The values displayed by the **Fixed-point details** subpane *do not* automatically update if you click **Calculate Best-Precision Scaling**, or change the range limits, the values that define the fixed-point data type, or anything elsewhere in the model. To update the values shown in the **Fixed-point details** subpane, click **Refresh Details**. The Data Type Assistant then updates or recalculates all values and displays the results.

Clicking **Refresh Details** does not change anything in the model, it only changes the display. Click **OK** or **Apply** to put the displayed values into effect. If the value of a field cannot be known without first compiling the model, the **Fixed-point details** subpane shows the value as **Unknown**.

If any errors occur when you click **Refresh Details**, the **Fixed-point details** subpane shows an error flag on the left of the applicable row, and a description of the error on the right. For example, the next figure shows two errors:

Output minimum: Output maximum:

Output data type: <<

Data Type Assistant

Mode: Signedness: Word length:

Scaling: Fraction length:

Data type override:

[Fixed-point details](#)

Representable maximum:	32767	
Output maximum:	50000	Outside representable range by 17233 (17233 x precision)
Output minimum:	MySymbol	Cannot evaluate
Representable minimum:	-32768	

Precision:

The row labeled **Output minimum** shows the error **Cannot evaluate** because evaluating the expression **MySymbol**, specified in the **Output minimum** field, did not return an appropriate numeric value. When an expression does not evaluate successfully, the **Fixed-point details** subpane displays the unevaluated expression (truncating to 10 characters if necessary to save space) in place of the unavailable value.

To correct the error in this case, you would need to define **MySymbol** in an accessible workspace to provide an appropriate numeric value. After you clicked **Refresh Details**,

the value of `MySymbol` would appear in place of its unevaluated text, and the error indicator and error description would disappear.

To correct the error shown for **Output maximum**, you would need to decrease **Output maximum**, increase **Word length**, or decrease **Fraction length** (or some combination of these changes) sufficiently to allow the fixed-point data type to represent the maximum value that it could have.

Other values relevant to a particular block can also appear in the **Fixed-point details** subpane. For example, on a Discrete-Time Integrator block **Signal Attributes** tab, the subpane can look like this:

<input type="checkbox"/> Fixed-point details	
Representable maximum:	32767
Output maximum:	<input type="checkbox"/>
Upper saturation limit:	inf
Initial condition:	1 .. 4
Lower saturation limit:	-inf
Output minimum:	<input type="checkbox"/>
Representable minimum:	-32768
Precision:	1

The values displayed for **Upper saturation limit** and **Lower saturation limit** are greyed out. This appearance indicates that the corresponding parameters are not currently used by the block. The greyed-out values can be ignored.

To conserve space, **Initial condition** displays the smallest value and the largest value in the vector or matrix, using ellipsis to represent the other values. The underlying definition of the vector or matrix is unaffected.

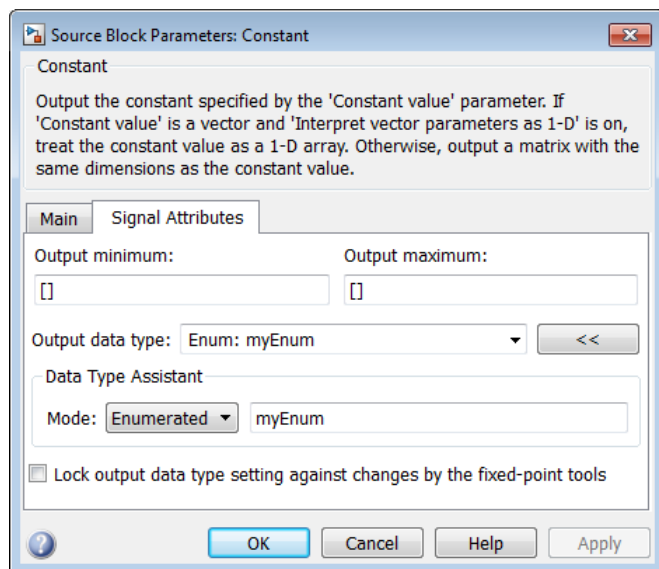

Lock output data type setting against changes by the fixed-point tools

Select this check box to prevent replacement of the current data type with a type that the Fixed-Point Tool or Fixed-Point Advisor chooses. For instructions on autoscaling fixed-point data, see “Scaling”.

Specify an Enumerated Data Type

You can specify an enumerated data type by selecting the **Enum: <class name>** option and specify an enumerated object.

In the **Data Type Assistant**, you can use the **Mode** parameter to specify a bus as a data object for a block. Select the **Enumerated** option and specify an enumerated object.

For details about enumerated data types, see “Data Types”.

Specify a Bus Object Data Type

The blocks listed in the section called “Data Types for Bus Signals” on page 57-53 support your specifying a bus object as a data type. For those blocks, in the **Data type** parameter, select the **Bus: <object name>** option and specify a bus object. You cannot use the **Expression** option to specify a bus object as a data type for a block.

In the **Data Type Assistant**, you can use the **Mode** parameter to specify a bus as a data object for a block. Select the **Bus** option and specify a bus object.

You can specify a bus object as the data type for data objects such as `Simulink.Signal`, `Simulink.Parameter`, and `Simulink.BusElement`. In the Model Explorer, in Properties dialog box for a data object, in the **Data type** parameter, select the **Bus: <object name>** option and specify a bus object. You can also use the **Expression** option to specify a bus object.

For more information on specifying a bus object data type, see “When to Use Bus Objects” on page 63-40.

Data Types for Bus Signals

A bus object (`Simulink.Bus`) specifies the architectural properties of a bus, as distinct from the values of the signals it contains. For example, a bus object can specify the number of elements in a bus, the order of those elements, whether and how elements are nested, and the data types of constituent signals; but not the signal values.

You can specify a bus object as a data type for the following blocks:

- Bus Creator
- Constant
- Data Store Memory
- Inport
- Outport
- Signal Specification

You can specify a bus object as a data type for the following classes:

- `Simulink.BusElement`
- `Simulink.Parameter`
- `Simulink.Signal`

See “Specify a Bus Object Data Type” on page 57-50 for information about how to specify a bus object as a data type for blocks and classes.

“Create Persistent Data Objects” on page 57-73

You can create *data objects* to specify values, value ranges, data types, tunability, and other characteristics of signals, states, and block parameters. You use the object names in Simulink dialog boxes to specify signal, state, and parameter characteristics. The objects exist in a workspace such as the base workspace, a model workspace, or a Simulink data dictionary. Data objects allow you to make model-wide changes to signal, state, and parameter characteristics by changing only the values of workspace objects.

You create data objects as instances of data classes. Memory structures called *data class packages* contain the data class definitions. The built-in package `Simulink` defines two data classes, `Simulink.Signal` and `Simulink.Parameter`, that you can use to create data objects. To store lookup table data for sharing between lookup table blocks (such as n-D Lookup Table), you can use the `Simulink.LookupTable` and `Simulink.Breakpoint` classes.

To decide whether to use data objects to configure signals, including Inport and Outport blocks, see “Store Design Attributes of Signals and States” on page 62-6.

You can customize data object properties and methods by defining subclasses of the built-in data classes. For more information about creating a data class package, see “Define Data Classes” on page 57-75.

Data Class Naming Conventions

Simulink uses dot notation to name data classes:

package.class

- *package* is the name of the package that contains the class definition.
- *class* is the name of the class.

This notation allows you to create and reference identically named classes that belong to different packages. In this notation, the name of the package *qualifies* the name of the class.

Class and package names are case sensitive. For example, you cannot use `MYPACKAGE.MYCLASS` and `mypackage.myclass` interchangeably to refer to the same class.

Use Data Objects in Simulink Models

To specify simulation and code generation options for signals, block parameters, and states by modifying variables in a workspace or data dictionary, use data objects. Associate the objects with signals, parameters, and states in a model diagram.

Use Parameter Objects

You can use parameter objects, instead of numeric MATLAB variables, to specify values for block parameters. For example, to create and use a `Simulink.Parameter` object to specify the **Gain** parameter of a Gain block:

- 1 Create a parameter object. For example, create an object using the built-in package `Simulink`.

```
myParam = Simulink.Parameter;
```

- 2 Assign a numeric value to the `Value` property.

```
myParam.Value = 15.23;
```

- 3 Specify other characteristics for the block parameter by adjusting the object properties. For example, to specify the minimum and maximum values the parameter can take, use the `Min` and `Max` properties.

```
myParam.Min = 10.11;  
myParam.Max = 25.27;
```

- 4 In a block dialog box, specify the value of a parameter as `myParam`. For example, in a Gain block dialog box, specify **Gain** as `myParam`.

During simulation, the **Gain** parameter uses the value `15.23`.

To share lookup table data by using `Simulink.LookupTable` and `Simulink.Breakpoint` objects, see “Package Shared Breakpoint and Table Data for Lookup Tables” on page 34-34.

Use Signal Objects

To use a signal object to control the characteristics of a signal in a model, create the object in a workspace by using the same name as the signal.

- 1 Create a `Simulink.Signal` object. For example, create an object using the built-in package `Simulink`.

```
mySig = Simulink.Signal;
```

- 2 Specify the signal characteristics by adjusting the object properties. For example, to specify the signal data type as `boolean`, use the `DataType` object property.

```
mySig.DataType = 'boolean';
```

- 3 In the Signal Properties dialog box for the signal in the model, specify **Signal name** as `mySig`. Click **Apply**.
- 4 Select the check box next to **Signal name must resolve to Simulink signal object**.

This option forces the model signal to use the properties that the signal object `mySig` defines. To learn how to control the way that signal names resolve to signal objects, see “Symbol Resolution” on page 4-82.

If you do not see the option in the Signal Properties dialog box, set the model configuration parameter **Configuration Parameters > Diagnostics > Data Validity > Signal resolution** to a value other than `None`.

To configure the signal programmatically:

```
% Create the signal object.
```

```

mySig = Simulink.Signal;
mySig.DataType = 'boolean';

% Get a handle to the block port that creates the
% target signal.
portHandles = get_param('myModel/myBlock','portHandles');
outputHandle = portHandles.Outputport;

% Specify the programmatic port parameter 'Name'.
set_param(outputHandle,'Name','mySig')

% Set the port parameter 'MustResolveToSignalObject'.
set_param(outputHandle,'MustResolveToSignalObject','on')

```

You can use a signal object to control the characteristics of a block state, such as that of the Discrete-Time Integrator block.

- 1 Create a `Simulink.Signal` object. For example, create an object using the built-in package `Simulink`.

```
myState = Simulink.Signal;
```

- 2 Specify the state characteristics by adjusting the object properties. For example, to specify the state data type as `int16`, use the `DataType` object property.

```
myState.DataType = 'int16';
```

- 3 In a block dialog box, on the **State Attributes** tab, specify **State name** as `myState`. Click **Apply**.
- 4 Select the check box next to **State name must resolve to Simulink signal object**.

If you do not see this option on the **State Attributes** tab, set the model configuration parameter **Configuration Parameters > Diagnostics > Data Validity > Signal resolution** to a value other than `None`.

To configure the state programmatically:

```

% Create the signal object.
myState = Simulink.Signal;
myState.DataType = 'int16';

% Set the state name in the block.
set_param('myModel/myBlock','StateName','myState')

```

```
% Set the port parameter 'StateMustResolveToSignalObject'.
set_param('myModel/myBlock', 'StateMustResolveToSignalObject', 'on')
```

Data Object Properties

To control parameter and signal characteristics using data objects, you specify values for the data object properties. For example, parameter and signal data objects have a `DataType` property that determines the data type of the target block parameter or signal. Data class definitions determine the names, value types, default values, and valid value ranges of data object properties.

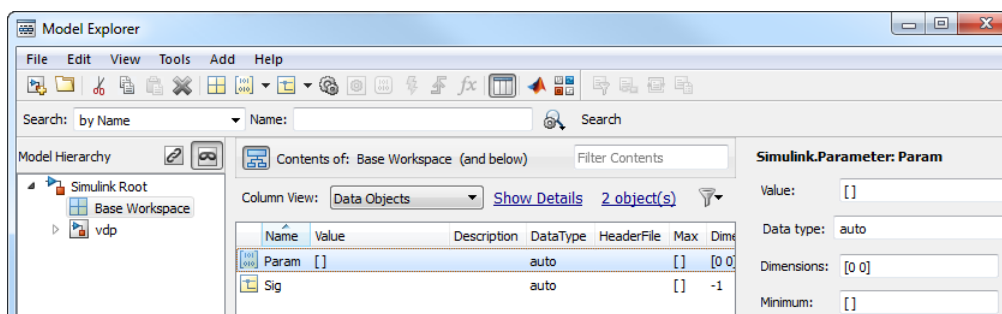

You can use either the Model Explorer or MATLAB commands to change a data object's properties.

For a list of signal object properties, see `Simulink.Signal`. For a list of parameter object properties, see `Simulink.Parameter`.

Use the Model Explorer to Change an Object's Properties

To use the Model Explorer to change an object's properties, select the workspace that contains the object in the Model Explorer's **Model Hierarchy** pane. Then select the object in the Model Explorer's **Contents** pane.

The Model Explorer displays the object's property dialog box in its **Dialog** pane (if the pane is visible).

You can configure the Model Explorer to display some or all of the properties of an object in the **Contents** pane (see “Model Explorer: Contents Pane” on page 12-22). To edit a

property, click its value in the **Contents** or **Dialog** pane. The value is replaced by a control that allows you to change the value.

Use MATLAB Commands to Change an Object's Properties

You can also use MATLAB commands to get and set data object properties. Use the following dot notation in MATLAB commands and programs to get and set a data object's properties:

```
value = obj.property;
obj.property = value;
```

where *obj* is a variable that references either the object if it is an instance of a value class or a handle to the object if the object is an instance of a handle class (see “Handle Versus Value Classes” on page 57-70), **PROPERTY** is the property's name, and **VALUE** is the property's value. For example, the following MATLAB code creates a data type alias object (i.e., an instance of `Simulink.AliasType`) and sets its base type to `uint8`:

```
gain = Simulink.AliasType;
gain.BaseType = 'uint8';
```

You can use dot notation recursively to get and set the properties of objects that are values of other object's properties, e.g.,

```
gain.CoderInfo.StorageClass = 'ExportedGlobal';
```

Create Data Objects from Built-In Data Class Package `Simulink`

The built-in package `Simulink` defines two data object classes `Simulink.Parameter` and `Simulink.Signal`. You can create these data objects using the user interface or programmatically.

Create Data Objects

- 1 In the Model Explorer **Model Hierarchy** pane, select a workspace to contain the data objects. For example, click **Base Workspace**.
- 2 On the toolbar, click the arrow next to **Add Parameter**  or **Add Signal** . From the drop-down list, select **Simulink Parameter** or **Simulink Signal**.

A parameter or signal object appears in the base workspace. The default name for new parameter objects is `Param`. The default name for new signal objects is `Sig`.

- 3 To create more objects, click Add Parameter or Add Signal.

To create `Simulink.LookupTable` and `Simulink.Breakpoint` objects, on the Model Explorer toolbar, select **Add > Add Custom**.

Programmatically Create Data Objects

```
% Create a Simulink.Parameter object named myParam whose value is 15.23.  
myParam = Simulink.Parameter(15.23);
```

```
% Create a Simulink.Signal object named mySig.  
mySig = Simulink.Signal;
```

Convert Numeric Variable into Parameter Object

You can convert a numeric variable into a `Simulink.Parameter` object as follows.

```
/* Define numeric variable in base workspace  
myVar = 5;  
/* Create data object and assign variable value  
myObject = Simulink.Parameter(myVar);
```

Create Data Objects from Another Data Class Package

You can create your own package to define custom data object classes that subclass `Simulink.Parameter` and `Simulink.Signal`. You can use this technique to add your own properties and methods to data objects. If you have an Embedded Coder license, you can define custom storage classes and memory sections in the package. For more information about creating a data class package, see “Define Data Classes” on page 57-75.

Create Data Objects from Another Package

Suppose that you define a data class package called `myPackage`. Before you can create data objects from the package, you must include the package folder on your MATLAB path.

- 1 In the Model Explorer **Model Hierarchy** pane, select a workspace to contain the data objects. For example, click **Base Workspace**.
- 2 Click the arrow next to Add Parameter  or Add Signal  and select **Customize class lists**.

- 3 In the dialog box, select the check box next to the class that you want. For example, select the check boxes next to `myPackage.Parameter` and `myPackage.Signal`. Click **OK**.
- 4 Click the arrow next to Add Parameter or Add Signal. Select the class for the data object that you want to create. For example, select **myPackage.Parameter** or **myPackage.Signal**.

A parameter or signal object appears in the base workspace. The default name for new parameter objects is `Param`. The default name for new signal objects is `Sig`.

- 5 To create more data objects from the package `myPackage`, click Add Parameter or Add Signal again.

Programmatically Create Data Objects from Another Package

Suppose that you define a data class package called `myPackage`. Before you can create data objects from the package, you must include the package folder on your MATLAB path.

```
% Create a myPackage.Parameter object named
% myParam whose value is 15.23.
myParam = myPackage.Parameter(15.23);

% Create a myPackage.Signal object named mySig.
mySig = myPackage.Signal;
```

Create Data Objects Directly from Dialog Boxes

When you open a Signal Properties dialog box or a block dialog box, you can efficiently create a signal or parameter data object in a workspace or data dictionary.

Create Parameter Object from Block Dialog Box

- 1 In a numeric block parameter in the dialog box, specify the name that you want for the data object. For example, specify the name `myParam`.
- 2 Right-click the block parameter edit field. Select **Create Variable**.
- 3 In the **Create New Data** dialog box, specify **Value** as `Simulink.Parameter`.

Alternatively, you can specify the name of a data class that you created, such as `myPackage.Parameter`. You can also use the drop-down list to select from a list of available data object classes.

- 4 Specify **Location** as **Base Workspace** and click **Create**.

You can use the **Location** option to select a workspace to contain the new data object. If a model is linked to a data dictionary, you can choose to create a data object in the dictionary.

- 5 In the dialog box that opens, configure the data object properties. Specify a numeric value for the parameter in the **Value** box. Click **OK**.

The parameter object `myParam` appears in the base workspace.

- 6 In the block parameter dialog box, click **OK**.

Create Signal Object from Signal Properties Dialog Box

- 1 In the **Signal name** box, specify a signal name such as `mySig`. Click **Apply**.
- 2 Right-click the **Signal name** edit field. Select **Create Variable**.
- 3 In the **Create New Data** dialog box, specify **Value** as `Simulink.Signal`.

Alternatively, you can specify the name of a data class that you created, such as `myPackage.Signal`. Also, from the drop-down list, you can select a data object class that exists on the MATLAB path.

- 4 Specify **Location** as **Base Workspace** and click **Create**.

You can use the **Location** option to select a workspace to contain the new data object. If a model is linked to a data dictionary, you can choose to create a data object in the dictionary.

- 5 In the dialog box that opens, configure the data object properties and click **OK**.

The signal object `mySig` appears in the base workspace.

- 6 In the Signal Properties dialog box, select the check box next to **Signal name must resolve to Simulink signal object** and click **OK**.

Create Data Objects for a Model Using Data Object Wizard

To create data objects that represent signals, parameters, and states in a model, you can use the Data Object Wizard. The wizard finds data in the model that do not have corresponding data objects.

Based on specifications in the model, the wizard creates the objects and assigns these characteristics:

- Signal, parameter, or state name.
- Numeric value for parameter objects.
- Data type. For signal objects, includes alias types such as `Sumlink.AliasType` and `Simulink.NumericType`.

1 In the Simulink Editor, select **Code > Data Objects > Data Object Wizard**.

- 2 In the **Model name** box, enter the name of the model that you want to search.

By default, the box contains the name of the model from which you opened the wizard.

- Under **Find options**, select the check boxes next to the data object types that you want to create. The table describes the options.

Option	Description
Root inputs	Named signals from root-level Inport blocks.
Root outputs	Named signals from root-level Outport blocks.
States	States associated with these discrete blocks: Discrete Filter Discrete State-Space Discrete-Time Integrator Discrete Transfer Fcn Discrete Zero-Pole Memory PID Controller PID Controller (2DOF) Unit Delay
Data stores	Data stores. For more information about data stores, see “Local and Global Data Stores” on page 60-3 .
Block outputs	Named signals whose sources are non-root-level blocks.
Parameters	<ul style="list-style-type: none"> Numeric parameters, for example the parameters in these blocks: Constant Gain Relay Stateflow data with Scope set to Parameter. <p>For more information, see “Share Simulink Parameters with Charts” in the Stateflow documentation.</p>
Alias types	Data type replacement names that you specify in Configuration Parameters > Code Generation > Data Type Replacement . If you have an Embedded Coder license, the Data Object Wizard creates <code>Simulink.AliasType</code> objects for these data type replacement names. For more information about data type

Option	Description
	replacement, see “Data Type Replacement” in the Embedded Coder documentation.

4 Click **Find**.

The data object table displays the proposed objects.

5 (Optional) To create objects from a data class other than the default classes, select the check box next to the objects whose class you want to change. To select all of the objects, click **Select All**. Click **Change Class**. In the dialog box that opens, select classes by using the drop-down lists next to **Parameter** and **Signal**.

If the classes that you want do not appear in the drop-down list, select **Customize class lists**. In the dialog box that opens, select the check box next to the classes that you want, and click **OK**.

To change the default parameter and signal classes that the wizard uses to propose objects:

- On the Model Explorer **Model Hierarchy** pane, select a workspace. For example, select **Base Workspace**.
- On the toolbar, click the arrow next to Add Parameter  or Add Signal .
- From the drop-down list, select the class that you want the wizard to use. For example, select **myPackage Parameter** or **myPackage Signal**.

A parameter or signal object appears in the selected workspace. The default name for new parameter objects is **Param**. The default name for new signal objects is **Sig**.

The next time that you use the Data Object Wizard, the wizard proposes objects using the parameter or signal class that you selected in Model Explorer.

- 6 Select the check box next to the proposed objects that you want to create. To select all of the proposed objects, click **Select All**.
- 7 Click **Create**.

The data objects appear in the base workspace. If the target model is linked to a data dictionary, the objects appear in the dictionary.

The wizard changes settings in your model depending on the configuration parameter **Configuration Parameters > Diagnostics > Data Validity > Signal resolution**.

- If you set the parameter to **Explicit only**, the wizard forces the corresponding signals and states in your model to resolve to the new signal objects. The wizard selects the option **Signal name must resolve to Simulink signal object** in each Signal Properties dialog box and **State name must resolve to Simulink signal object** in each block dialog box.
- If you set the parameter to **Explicit and implicit** or **Explicit and warn implicit**, the wizard does not change the setting of **Signal name must resolve to Simulink signal object** or **State name must resolve to Simulink signal object** for any signals or states.

Consider turning off implicit signal object resolution for your model by using the function `disableimplicitsignalresolution`. For more information, see “Explicit and Implicit Symbol Resolution” on page 4-85.

Data Object Wizard Troubleshooting

The Data Object Wizard does not propose creation of data objects for these entities in a model:

- Multiple separate signals that have the same name.
- A signal with the same name as a variable used in a block parameter.
- A signal that lacks a single contiguous source block.
- A signal whose source block is commented out or commented through.
- Data items that are rendered inactive by Variant Source and Variant Sink blocks. The wizard proposes objects only for data items that are associated with active blocks.
- Signals and states when you set the model configuration parameter **Signal resolution** to `None`.

Create Data Objects from External Data Source Programmatically

This example shows how to create data objects based on an external data source (such as a Microsoft Excel file) by using a script.

- 1 Create a new MATLAB script file.
- 2 Place information in the file that describes the data in the external file that you want to convert to data objects. For example, the following information creates two Simulink data objects with the indicated properties. The first is for a parameter and the second is for a signal:

```
% Parameters
ParCon = Simulink.Parameter;
ParCon.CoderInfo.StorageClass = 'Custom'
ParCon.CoderInfo.CustomStorageClass = 'Const';
ParCon.Value = 3;
% Signals
SigGlb = Simulink.Signal;
SigGlb.DataType = 'int8';
```

- 3 Run the script file. The data objects appear in the MATLAB workspace.

If you want to import the target data from the external source, you can write MATLAB functions and scripts that read the information, convert the information to data objects, and load the objects into the base workspace.

You can use these functions to interact with files that are external to MATLAB:

- `xmlread`
- `xmlwrite`
- `xlsread`
- `xlswrite`
- `csvread`
- `csvwrite`
- `dlmread`
- `dlmwrite`

Data Object Methods

Data classes define functions, called methods, for creating and manipulating the objects that they define. A class may define any of the following kinds of methods.

Dynamic Methods

A dynamic method is a method whose identity depends on its name and the class of an object specified implicitly or explicitly as its first argument. You can use either function or dot notation to specify this object, which must be an instance of the class that defines the method or an instance of a subclass of the class that defines the method. For example, suppose class `A` defines a method called `setName` that assigns a name to an instance of `A`. Further, suppose the MATLAB workspace contains an instance of `A` assigned to the variable `obj`. Then, you can use either of the following statements to assign the name `'foo'` to `obj`:

```
obj.setName('foo');  
setName(obj, 'foo');
```

A class may define a set of methods having the same name as a method defined by one of its super classes. In this case, the method defined by the subclass overrides the behavior of the method defined by the parent class. Simulink determines which method to invoke at runtime from the class of the object that you specify as its first or implicit argument. Hence, the term dynamic method.

Note: Most Simulink data object methods are dynamic methods. Unless the documentation for a method specifies otherwise, you can assume that a method is a dynamic method.

Static Methods

A static method is a method whose identity depends only on its name and hence cannot change at runtime. To invoke a static method, use its fully qualified name, which includes the name of the class that defines it followed by the name of the method itself. For example, `Simulink.ModelAdvisor` class defines a static method named `getModelAdvisor`. The fully qualified name of this static method is `Simulink.ModelAdvisor.getModelAdvisor`. The following example illustrates invocation of a static method.

```
ma = Simulink.ModelAdvisor.getModelAdvisor('vdp');
```

Constructors

Every data class defines a method for creating instances of that class. The name of the method is the same as the name of the class. For example, the name of the `Simulink.Parameter` class's constructor is `Simulink.Parameter`. The constructors defined by Simulink data classes take no arguments.

The value returned by a constructor depends on whether its class is a handle class or a value class. The constructor for a handle class returns a handle to the instance that it creates if the class of the instance is a handle class; otherwise, it returns the instance itself (see “Handle Versus Value Classes” on page 57-70).

Handle Versus Value Classes

Simulink classes, including data object classes, fall into two categories: value classes and handle classes.

About Value Classes

The constructor for a *value* class (see “Constructors” on page 57-70) returns an instance of the class and the instance is permanently associated with the MATLAB variable to which it is initially assigned. Reassigning or passing the variable to a function causes MATLAB to create and assign or pass a copy of the original object.

For example, `Simulink.NumericType` is a value class. Executing the following statements

```
x = Simulink.NumericType;
y = x;
```

creates two instances of class `Simulink.NumericType` in the workspace, one assigned to the variable `x` and the other to `y`.

About Handle Classes

The constructor for a *handle* class returns a handle object. The handle can be assigned to multiple variables or passed to functions without causing a copy of the original object to be created. For example, `Simulink.Parameter` class is a handle class. Executing

```
x = Simulink.Parameter;
y = x;
```

creates only one instance of `Simulink.Parameter` class in the MATLAB workspace. Variables `x` and `y` both refer to the instance via its handle.

A program can modify an instance of a handle class by modifying any variable that references it, e.g., continuing the previous example,

```
x.Description = 'input gain';
y.Description
```

```
ans =
input gain
```

Most Simulink data object classes are value classes. Exceptions include `Simulink.Signal` and `Simulink.Parameter` class.

You can determine whether a variable is assigned to an instance of a class or to a handle to that class by displaying the variable at the MATLAB command line. MATLAB appends the text (**handle**) to the name of the object class in the value display, e.g.,

```
>> gain = Simulink.Parameter

gain =

Simulink.Parameter (handle)
      Value: []
      CoderInfo: [1x1 Simulink.CoderInfo]
```

```
Description: ''
  DataType: 'auto'
    Min: []
    Max: []
  Unit: ''
Complexity: 'real'
Dimensions: [0 0]
```

Copy Handle Classes

Use the copy method of a handle class to create copies of instances of that class. For example, `Simulink.ConfigSet` is a handle class that represents model configuration sets. The following code creates a copy of the current model's active configuration set and attaches it to the model as an alternate configuration geared to model development.

```
activeConfig = getActiveConfigSet(gcs);
develConfig = copy(activeConfig);
develConfig.Name = 'develConfig';
attachConfigSet(gcs, develConfig);
```

Compare Data Objects

Simulink data objects provide a method, named `isequal`, that determines whether object property values are equal. This method compares the property values of one object with those belonging to another object and returns true (1) if all of the values are the same or false (0) otherwise. For example, the following code instantiates two signal objects (A and B) and specifies values for particular properties.

```
A = Simulink.Signal;
B = Simulink.Signal;
A.DataType = 'int8';
B.DataType = 'int8';
A.InitialValue = '1.5';
B.InitialValue = '1.5';
```

Afterward, use the `isequal` method to verify that the object properties of A and B are equal.

```
result = isequal(A,B)

result =

     1
```

Create Persistent Data Objects

To preserve data objects so that they persist when you close MATLAB, you can:

- Store the objects in a data dictionary or model workspace. To decide where to permanently store model data, see “Determine Where to Store Variables and Objects for Simulink Models” on page 57-81.
- Use the `save` command to save data objects in a MAT-file and the `load` command to restore them to the MATLAB base workspace in the same or a later session. Configure the model to load the objects from the MAT-file or a script file when the model loads.

To load data objects from a file when you load a model, write a script that creates the objects and configures their properties. Alternatively, save the objects in a MAT-file. Then use either the script or a load command as the `PreLoadFcn` callback routine for the model that uses the objects. Suppose that you save the data objects in a file named `data_objects.mat`, and the model to which they apply is open and active. At the command prompt, entering:

```
set_param(gcs, 'PreLoadFcn', 'load data_objects');
```

sets `load data_objects` as the model's preload function. Whenever you open the model, the data objects appear in the base workspace.

Definitions of the classes of saved objects must exist on the MATLAB path for them to be restored. If the class of a saved object acquires new properties after the object is saved, Simulink adds the new properties to the restored version of the object. If the class loses properties after the object is saved, only the properties that remain are restored.

Define Data Classes

This example shows how to subclass Simulink data classes.

Use MATLAB class syntax to create a data class in a package. Optionally, assign properties to the data class and define custom storage classes.

Use an example to define data classes

- 1 View the `+SimulinkDemos` data class package in the folder `matlabroot/toolbox/simulink/simdemos/dataclasses` (open).

This package contains predefined data classes.

- 2 Copy the folder to the location where you want to define your data classes.
- 3 Rename the folder `+mypkg` and add its parent folder to the MATLAB path.
- 4 Modify the data class definitions.

Manually define data class

- 1 Create a package folder `+mypkg` and add its parent folder to the MATLAB path.
- 2 Create class folders `@Parameter` and `@Signal` inside `+mypkg`.

Note: Simulink requires data classes to be defined inside `+Package/@Class` folders.

- 3 In the `@Parameter` folder, create a MATLAB file `Parameter.m` and open it for editing.
- 4 Define a data class that is a subclass of `Simulink.Parameter` using MATLAB class syntax.

```
classdef Parameter < Simulink.Parameter
end % classdef
```

To use a custom class name other than `Parameter` or `Signal`, name the class folders using the custom name. For example, to define a class `myParameter`:

- Define the data class as a subclass of `Simulink.Parameter` or `Simulink.Signal`.

```
classdef myParameter < Simulink.Parameter
end % classdef
```

- In the class definition, name the constructor method as `myParameter` or `mySignal`.
- Name the class folder, which contains the class definition, as `@myParameter` or `@mySignal`.

Optional: Add properties to data class

The `properties` and `end` keywords enclose a property definition block.

```
classdef Parameter < Simulink.Parameter
    properties % Unconstrained property type
        Prop1 = [];
    end

    properties(PropertyType = 'logical scalar')
        Prop2 = false;
    end

    properties(PropertyType = 'char')
        Prop3 = '';
    end

    properties(PropertyType = 'char',...
        AllowedValues = {'red'; 'green'; 'blue'})
        Prop4 = 'red';
    end
end % classdef
```

Note: The MATLAB editor does not recognize the attributes `PropertyType` and `AllowedValues`, because they are only defined for Simulink data classes. You can suppress `mlint` warnings about these unrecognized attributes by right-clicking the attribute in the MATLAB editor and selecting **Suppress “Unknown attribute name ‘...’” > In This File**.

If you add properties to a subclass of `Simulink.Parameter`, `Simulink.Signal`, or `Simulink.CustomStorageClassAttributes`, you can specify the following property types.

Property Type	Syntax
Double number	<code>properties(PropertyType = 'double scalar')</code>

Property Type	Syntax
int32 number	<code>properties(PropertyType = 'int32 scalar')</code>
Logical number	<code>properties(PropertyType = 'logical scalar')</code>
Character vector (char)	<code>properties(PropertyType = 'char')</code>
Character vector with limited set of allowed values	<code>properties(PropertyType = 'char', AllowedValues = {'a', 'b', 'c'})</code>

Optional: Add initialization code to data class

You can add a constructor within your data class to perform initialization activities when the class is instantiated.

In this example, the constructor initializes the value of object `obj` based on an optional input argument.

```
classdef Parameter < Simulink.Parameter
    methods
        function obj = Parameter(optionalValue)
            if (nargin == 1)
                obj.Value = optionalValue;
            end
        end
    end % methods
end % classdef
```

Optional: Define custom storage classes

Use the `setupCoderInfo` method to configure the `CoderInfo` object of your class. Then, create a call to the `useLocalCustomStorageClasses` method and open the Custom Storage Class Designer.

- 1 In the constructor within your data class, call the `useLocalCustomStorageClasses` method.

```
classdef Parameter < Simulink.Parameter
    methods
        function setupCoderInfo(obj)
            useLocalCustomStorageClasses(obj, 'mypkg');
        end
    end
end
```

```

        obj.CoderInfo.StorageClass = 'Custom';
    end
end % methods
end % classdef

```

- 2 Open the Custom Storage Class Designer for your package.

```
cscdesigner('mypkg')
```

- 3 Define custom storage classes.

Optional: Define custom attributes for custom storage classes

- 1 Create a MATLAB file `myCustomAttribs.m` and open it for editing. Save this file in the `+mypkg/@myCustomAttribs` folder, where `+mypkg` is the folder containing the `@Parameter` and `@Signal` folders.
- 2 Define a subclass of `Simulink.CustomStorageClassAttributes` using MATLAB class syntax. For example, consider a custom storage class that defines data using the original identifier but also provides an alternate name for the data in generated code.

```

classdef myCustomAttribs < Simulink.CustomStorageClassAttributes
    properties(PropertyType = 'char')
        AlternateName = '';
    end
end % classdef

```

- 3 Override the default implementation of the `isAddressable` method to determine whether the custom storage class is writable.

```

classdef myCustomAttribs < Simulink.CustomStorageClassAttributes
    properties(PropertyType = 'logical scalar')
        IsAlternateNameInstanceSpecific = true;
    end

    methods
        function retVal = isAddressable(hObj, hCSCDefn, hData)
            retVal = false;
        end
    end % methods
end % classdef

```

- 4 Override the default implementation of the `getInstanceSpecificProps` method.

For examples, see `CSCTypeAttributes_FlatStructure.m` in the folder `matlabroot\toolbox\simulink\simulink\dataclasses`

\+Simulink\@CSCTypeAttributes_FlatStructure (open) and CSCTypeAttributes_Unstructured.m in the folder *matlabroot*\toolbox\simulink\simulink\dataclasses\+mpt\@CSCTypeAttributes_Unstructured (open).

Note: This is an optional step. By default, all custom attributes are instance-specific and are modifiable for each data object. However, you can limit which properties are allowed to be instance-specific.

- 5 Override the default implementation of the `getIdentifiersForInstance` method to define identifiers for objects of the data class.

Note: In its default implementation, this method queries the name or identifier of the data object and uses that identifier in generated code. By overriding this method, you can control the identifier of your data objects in generated code.

```
classdef myCustomAttribs < Simulink.CustomStorageClassAttributes
    properties(PropertyType = 'char')
        GetFunction = '';
        SetFunction = '';
    end

    methods
        function retVal = getIdentifiersForInstance(hCSCAttrib,...
            hCSCDefn, hData, identifier)
            retVal = struct('GetFunction',...
                hData.CoderInfo.CustomAttributes.GetFunction, ...
                'SetFunction', hData.CoderInfo.CustomAttributes.SetFunction);
        end%
    end % methods
end % classdef
```

- 6 If you are using grouped custom storage classes, override the default implementation of the `getIdentifiersForGroup` method to specify the identifier for the group in generated code.

For an example, see `CSCTypeAttributes_FlatStructure.m` in the folder `matlabroot\toolbox\simulink\simulink\dataclasses\+Simulink\@CSCTypeAttributes_FlatStructure` (open).

Determine Where to Store Variables and Objects for Simulink Models

Model data are objects and variables that you create in workspaces such as the base workspace or a data dictionary. Model data include:

- Numeric values for block parameters, such as `Simulink.Parameter` objects and MATLAB variables
- Signals, such as `Simulink.Signal` objects
- Data types
- Model configuration sets
- Simulation input and output data

You can store, partition, and share model data in a location that is appropriate for your design. The storage locations that you choose can depend on:

- Your modeling goals.
- The model architecture (referenced models, subsystems, and other partitioning strategies) and component structure.
- The types of data that you use.

Types of Data

- *Simulation data* is the set of input data that you use to drive a simulation and the set of output data that a simulation generates. For example, you can use variables to store input data that a simulation imports through `Inport` and `From Workspace` blocks. A simulation can export output data to `Outport` blocks, `To Workspace` blocks, and logged signals.

You can store simulation data for your current session in the base workspace. To permanently store the data, save it in a MAT-file or script file. For more information about loading, generating, and storing simulation data, see “Comparison of Signal Loading Techniques” on page 59-112 and “Export Simulation Data” on page 59-3.

- *Design data* is the set of variables that you use to specify block parameters and signal characteristics in a model. For example, design data includes numeric MATLAB variables, parameter and signal data objects, data type objects, and bus objects.

You can store design data in the base workspace, model workspaces, or the Design Data section of a data dictionary. To permanently store local design data with a model, use model workspaces. To share design data between models, use data dictionaries or the base workspace. Data dictionaries permanently store the data, and you can control the data scope to establish ownership, partition the data to ease readability and maintenance, and track changes. If you use the base workspace, to permanently store the data, you must save it in a MAT-file or script file.

- *Configuration sets* are sets of model configuration parameters. By default, configuration sets reside in the model file, so you do not need to store the sets separately from the model. However, you cannot share these sets with other models.

To share configuration sets between models, you must create `Simulink.ConfigSet` objects. Each object represents a standalone configuration set. You can store these objects in the base workspace or in the Configurations section of a data dictionary. If you use data dictionaries, you can define the scope of each configuration set, compare different configuration sets, and track changes. A data dictionary inherently partitions configuration sets from other kinds of data.

Store Data for Your Design

The table shows the techniques you can use to store, partition, and manage design data and configuration sets.

Modeling Scenario	Scenario Description	Storage Locations and Techniques
Rapid prototyping and model experimentation	<p>You want to create temporary data, such as variables to specify numeric block parameters, while you learn to use Simulink.</p> <p>You want to experiment with modeling techniques. You do not need to</p>	Store data in the base workspace so you can quickly create and change the data.

Modeling Scenario	Scenario Description	Storage Locations and Techniques
	permanently store the data that you create.	
Standalone model	You have a single model that does not depend on other systems for data. The model stands alone because it is not a piece of a larger system.	<p>Store data in the model workspace to improve model portability. Use a data dictionary to store data that you cannot store in the model workspace.</p> <p>Alternatively, store all of the model data in a data dictionary. If you use a dictionary, you can partition the data by using referenced dictionaries.</p>
Standalone hierarchy of referenced models	You have a hierarchy of referenced models that does not depend on other systems for data. The hierarchy stands alone because it is not a piece of a larger system.	<p>Store local model data in each model workspace.</p> <p>Store data that the models share, such as bus objects and configuration sets, in a data dictionary. Link all of the models in the hierarchy to the dictionary.</p> <p>For examples, see “Migrate Model Reference Hierarchy to Use Dictionary” on page 61-8 and Using a Data Dictionary to Manage the Data for a Fuel Control System.</p>

Modeling Scenario	Scenario Description	Storage Locations and Techniques
System of components	One or more teams maintain the components of a system of models. A <i>component</i> is a single model or a hierarchy of referenced models that represents a piece of a larger system.	<p>Store local model data in model workspaces.</p> <p>Store data that the models in a component share, such as bus objects and configuration sets, in a data dictionary. Link all of the models in the component to the dictionary.</p> <p>Use additional referenced dictionaries to store data that the components share.</p> <p>For an example, see “Partition Data for Model Reference Hierarchy Using Data Dictionaries” on page 61-37.</p>

Storage Locations

Choose any of these locations to store data:

- The MATLAB base workspace. Use the base workspace to store variables while you experiment with temporary models.
- A model workspace. Use a model workspace to permanently store data that is local to a model.
- A data dictionary. Use data dictionaries to permanently store global data, share data between models, and track changes made to data.

The chart shows the capabilities and advantages of each storage location.

Capability	Base Workspace	Model Workspace	Data Dictionary
Data-model linkage	implicit	implicit	✓
Unified interface for defining data	✓	✓	✓
Model-data dependency	✓	✓	✓

Capability	Base Workspace	Model Workspace	Data Dictionary
Data entry comparison	✓	✓	✓
Data entry persistence		✓	✓
Shared data	✓		✓
Data grouping			✓
Change tracking for data entries			✓
Change tracking for configuration sets			✓
Data entry merging and reconciliation			✓
Storage and partitioning of auxiliary data			✓
Requirements linking			✓

For information about the way that models interact with workspaces and workspace variables, see “Symbol Resolution” on page 4-82.

Temporary Data: Base Workspace

Use the base workspace to temporarily store data:

- While you learn to use Simulink
- When you need to quickly create variables while experimenting with modeling techniques
- When you do not need to store the data permanently

To create variables in the base workspace, you can use the MATLAB command prompt or the Model Explorer. All open models can use the data that you create in the base workspace.

If you use variables to specify numeric block parameters in the model, you can programmatically change the parameter values during simulation by using commands at the command prompt. To programmatically change the values of parameters that you store in the model workspace or data dictionaries, you must use the function interfaces for those storage locations.

To permanently store base workspace data before you end a MATLAB session, you can save the data in a MAT-file or a script file. During a later session, you can load the data from the file. However, if you make changes to the data in the base workspace, you

must save the data to the file again. Consider instead using a model workspace or data dictionary to permanently store data.

Local Data: Model Workspace

Use a model workspace to store data that you use only in the associated model. This data can include:

- Constant parameters, for example, numeric variables that you use to specify block parameter values.
- Data objects, such as `Simulink.Signal` and `Simulink.Parameter` objects, that you use to control signal and parameter characteristics. However, the objects can use only the `Auto` storage class.
- `Simulink.NumericType` objects that you use to specify data types. However, you cannot use the object as a data type alias. You must set the `ISAlias` property to `false`.
- Model arguments.

You can improve model portability and establish data ownership by storing the data in the model workspace. In this case, the model file permanently stores the data.

In a model reference hierarchy, each model workspace acts as a unique namespace. Therefore, you can use the same variable name in multiple model workspaces. You can then assign a unique variable value for each model.

You can use the Model Explorer to manipulate model workspace data. Alternatively, you can use the command prompt or scripts in conjunction with the model workspace programmatic interface.

For more information about using model workspaces to store local data, see “Model Workspaces” on page 4-71.

Global and Shared Data: Data Dictionary

A data dictionary is a standalone file that permanently stores data. Use data dictionaries instead of the base workspace to partition data, track changes, control access, and share data. If you link a model to a data dictionary, the model does not use variables in the base workspace anymore.

As you can with model workspaces, you can use data dictionaries to directly associate data with a model. You can use this association to scope the data and to establish ownership.

When you use dictionaries, you can partition the data by storing it in additional referenced dictionaries. However, each entry in a dictionary must use a unique name. You must manage each dictionary as a separate file.

Use a data dictionary to store data that multiple models or system components share. This data can include:

- Numeric variables that multiple models use to specify block parameter values.
- `Simulink.AliasType` and `Simulink.NumericType` objects that you use to specify data types in multiple models at once.
- Data objects that use a storage class other than `Auto`. If you have a Simulink Coder license, these objects can represent signals and tunable parameters that appear as global variables in the generated code.
- `Simulink.Bus` objects that you use to define signal interfaces between referenced models.
- `Simulink.ConfigSet` objects that you use to maintain configuration parameter uniformity across multiple models.
- Enumerated type definitions, which you store using `Simulink.data.dictionary.EnumTypeDefinition` objects.

You can use the Model Explorer to manipulate dictionary data. Alternatively, you can use the command prompt or scripts in conjunction with the data dictionary programmatic interface.

For basic information about data dictionaries, see “What Is a Data Dictionary?” on page 61-2.

“Export Workspace Variables” on page 57-99

“Importing Workspace Variables” on page 57-101

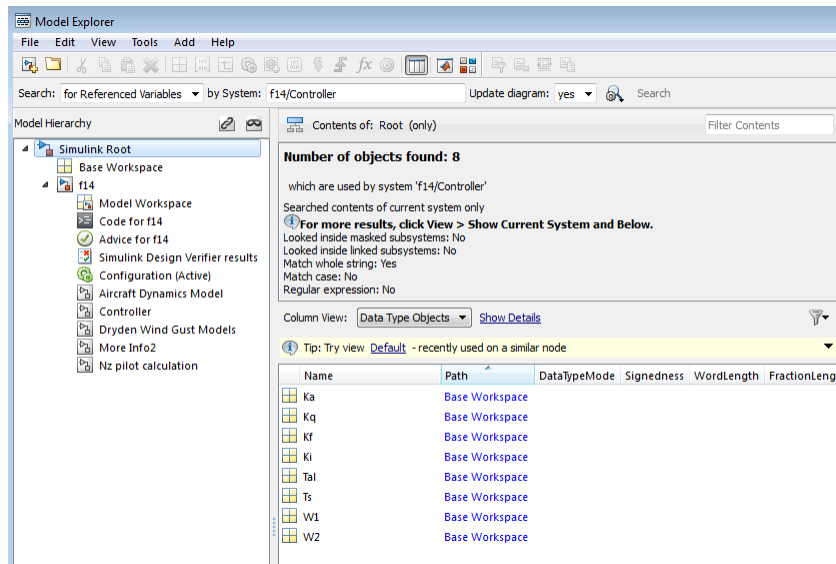

Finding Variables That Are Used by a Model or Block

In the Model Explorer, you can get a list of variables that a model or block uses. The following approach is one way to get that list of variables:

- 1 In the **Contents** pane, right-click the block for which you want to find the variables that it uses.
- 2 Select the **Find Referenced Variables** menu item.

Model Explorer returns results similar to these:

For performance, Model Explorer uses cached information from the last compiled version of the model. If you want to recompile the model, either do so manually or, in the Model Explorer, set the **Update diagram** field to **yes** and repeat the search.

You can also use the following approaches to find variables that a model or block uses:

- In the Model Explorer, in the **Model Hierarchy** pane, right-click a block or model node and select the **Find Referenced Variables** menu item.
- In the Model Explorer, in the search bar, use the **for Referenced Variables** search type option.
- In the Simulink Editor, right-click a block, subsystem, or in the canvas and select the **Find Referenced Variables** menu item. Clicking the canvas returns results for the whole model.

The `Simulink.findVars` function provides additional options for returning information about workspace variables that is not available from the Model Explorer or Simulink Editor.

For information about limitations when finding referenced variables, see the `Simulink.findVars` documentation.

Using the Set of Returned Variables

For a variable in the set of returned variables, you can find the blocks that use that variable (for details, see “Finding Blocks That Use a Specific Variable” on page 57-91). Also, you can export variables from the returned set of variables. For details, see “Export Workspace Variables” on page 57-99.

Finding Blocks That Use a Specific Variable

This example shows how to use Model Explorer to get a list of blocks that use a specific workspace variable.

- 1 Open the model f14.
- 2 Open Model Explorer.
- 3 In the **Model Hierarchy** pane, select the **Base Workspace** node.
- 4 In the **Contents** pane, right-click the variable Mq and select **Find Where Used**.
- 5 In the **Select a system** dialog box, select f14.
- 6 Clear the **Search in referenced models** check box, since f14 does not reference any models, and click **OK**.

With **Search in referenced models** selected, you can find the target variable everywhere it is used in a model reference hierarchy. However, finding the target variable in an entire hierarchy can take more time.

The **Update diagram to include recent changes** check box is cleared by default to save time by avoiding unnecessary model diagram updates. Select the check box to incorporate recent changes you made to the model by forcing a diagram update.

- 7 Click **OK** in response to the message to update the model diagram.

Since you just opened the model, you must update the model diagram at least once before finding a variable. You could have selected **Update diagram to include recent changes** in the **Select a system** dialog box to force an initial diagram update, though you typically use that option when you make changes to the model while performing multiple searches with **Find Where Used**.

- 8 Model Explorer displays the search results:

The property columns whose values include Mq represent the block parameters that use the Mq variable. If those property columns are not already in the view, then the Model Explorer adds them to the end of the search results display.

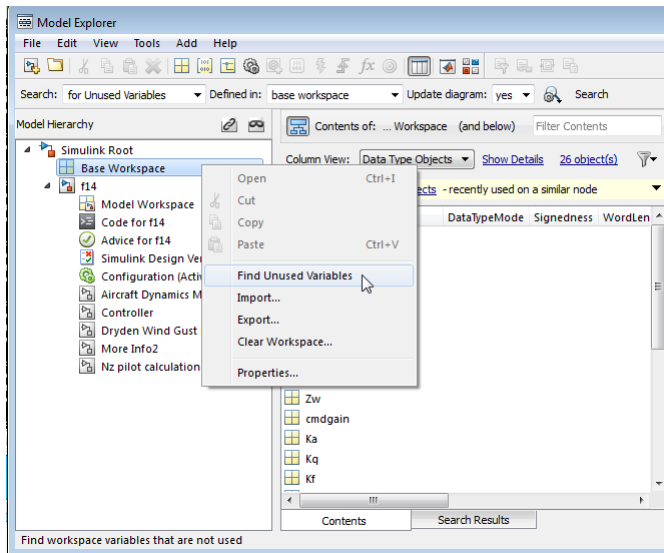

You can also find blocks that use a specific variable by using one of these approaches:

- In the search bar, select the **for Variable Usage** search type option.
- In the **Search Results** pane, right-click a variable and select the **Find Where Used** menu item.

Finding Unused Workspace Variables

You can use the Model Explorer to get a list of variables that are defined in a workspace but not used by a model or block. One way to get that list of variables is to right-click a workspace name in the **Model Hierarchy** pane and select the **Find Unused Variables** menu item. For example:

- 1 Open the f14 model.
- 2 Open the Model Explorer.
- 3 In the search toolbar, set the **Update diagram** field to **yes**.
- 4 In the **Model Hierarchy** pane, right-click the **Base Workspace** node and select the **Find Unused Variables** menu item.

5 The Model Explorer displays output similar to this:

The `Simulink.findVars` function provides additional options for returning information about unused workspace variables that is not available from the Model Explorer or Simulink Editor.

Editing Workspace Variables

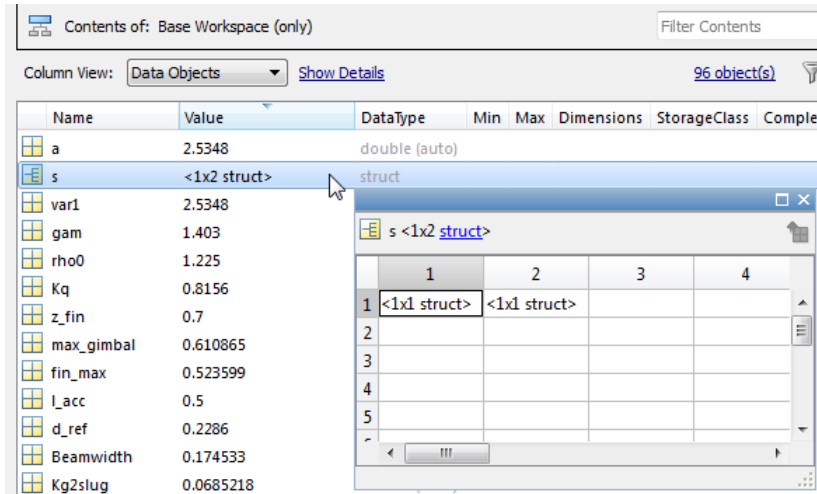

In the Model Explorer **Contents** pane, you can use the Variable Editor to edit variables from the MATLAB workspace or model workspace. The Variable Editor is available for editing large arrays and structures.

To open the Variable Editor for a variable that is an array or structure:

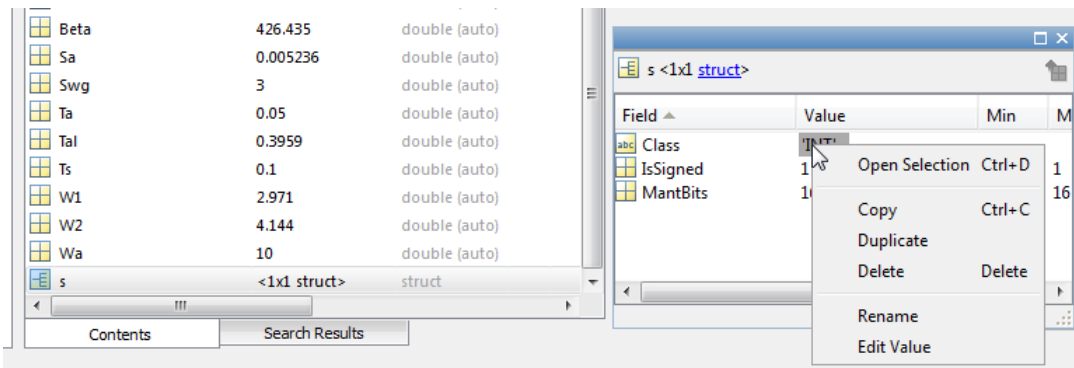

- 1 Click the Value cell for the variable.
- 2 Select the Variable Editor icon.

The Variable Editor opens:

Right-click in an edit box to open a context menu with several editing options:

You can resize and move the Variable Editor. The **Contents** pane reflects the edits that you make in the Variable Editor.

When you finish editing, the Variable Editor closes when you click the **Close** button in the upper right corner of the editor or when you click outside of the editor.

Representation of Arrays with Three or More Dimensions

When the value of a variable or `Simulink.Parameter` object is an array with three or more dimensions, the **Value** column displays the array as an expression that contains a call to the `reshape` function.

To edit the values in the array, modify the first argument of the `reshape` call, which contains all of the array values in a serialized vector. When you add or remove elements along a dimension, you must also correct the argument that represents the length of the modified dimension.

Rename Variables

This example shows how to use Model Explorer to rename a variable everywhere it is used by blocks in Simulink models.

- 1 Open the model `sldemo_absbrake`. The model loads data to the MATLAB base workspace.
- 2 Open Model Explorer.
- 3 In the **Model Hierarchy** pane, select the base workspace.
- 4 In the **Contents** pane, right-click the base workspace variable `m` and select **Rename All**.
- 5 In the **Select a system** dialog box, click the name of the model `sldemo_absbrake` to select it as the context for renaming the variable `m`.
- 6 Clear the **Search in referenced models** check box and click **OK**. The model `sldemo_absbrake` references the model `sldemo_wheelspeed_absbrake`, but only `sldemo_absbrake` uses the variable `m`.

With **Search in referenced models** selected, you can rename the target variable everywhere it is used in a model reference hierarchy. However, renaming the target variable in an entire hierarchy can take more time.

The **Update diagram to include recent changes** check box is cleared by default to save time by avoiding unnecessary model diagram updates. Select the check box to incorporate recent changes you made to the model by forcing a diagram update.

- 7 Click **OK** in response to the message to update the model diagram.

Since you just opened the model, you must update the model diagram at least once before renaming a variable. You could have selected **Update diagram to include**

recent changes in the **Select a system** dialog box to force an initial diagram update, though you typically use that option when you make changes to the model while performing multiple variable renaming operations.

- 8** In the **Rename All** dialog box, type a new name for the variable in the **New name** box and click **OK**.

You can use the hyperlinks in the **Corresponding blocks** section of the **Rename All** dialog box to view the target blocks.

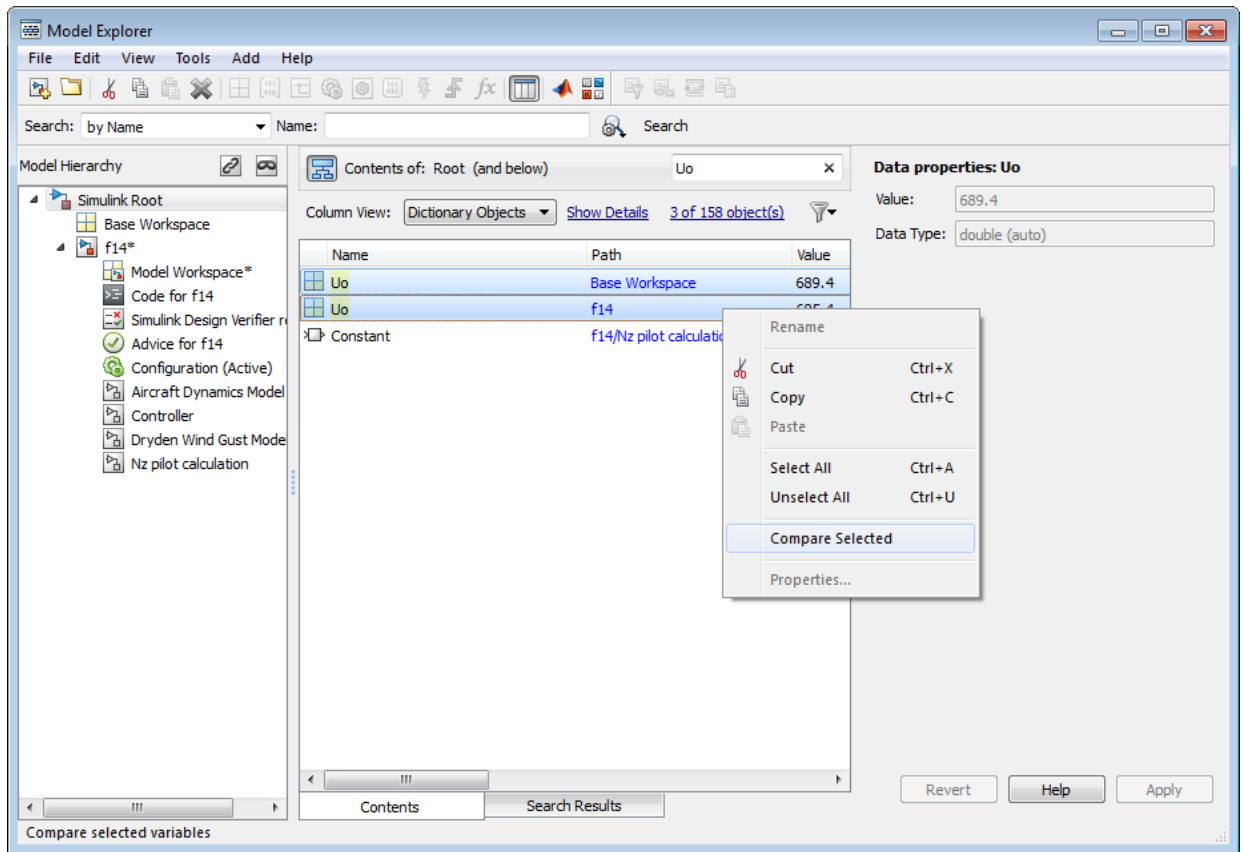

Note: You can rename only variables that the function `Simulink.findVars` supports.

For help with renaming files, use a project. See “Automatic Updates When Renaming, Deleting, or Removing Files” on page 17-13.

Compare Duplicate Workspace Variables

You can compare duplicate variables that are stored in the same workspace or in different workspaces. For example, you can compare a variable stored in the base workspace with its duplicate, which is stored in the model workspace.

- 1** Open a model and the Model Explorer.
- 2** In the search toolbar, search for the variable that is duplicated. Select the rows with the duplicate entries. Then, right-click and select **Compare Selected**.

3 Review the differences in the **Comparison Viewer**.

Export Workspace Variables

You can export (save) a set of variables listed in the Model Explorer, exporting either individual variables or all the variables in the base or model workspace.

One possible workflow is to export the set of variables returned with the **Find Referenced Variables** option or the `Simulink.findVars` function. For details, see “Finding Variables That Are Used by a Model or Block” on page 57-88.

Note: All the variables that you export must be from the same workspace.

To export all the variables in a workspace in the Model Explorer to a MATLAB code file or MAT-file:

- 1 Select the variables that you want to export.

- a To select all the variables in a workspace, right-click the workspace node (for example, **Base Workspace**) and select the **Export** menu item. For example:

- b To select individual variables, in the **Contents** pane, select the variables that you want to export. Right-click one of the highlighted variables and select the **Export Selected** menu item.

If the **Contents** pane has data grouped by a property, selecting the top line in a group does not select all the variables in that group. For details about grouped data, see “Grouping by a Property” on page 12-39.

- 2 Specify whether to save the variables in a MATLAB code file or a MAT-file.

The MATLAB code file format is easier to read, is editable, and supports version control. The MAT-file format is binary, which has performance advantages.

If you specify a MATLAB code file format, the Model Explorer may create an associated MAT-file, reflecting the name of the MATLAB code file, but with an extension of `.mat` instead of `.m`.

- 3 Specify a name and location for the file.
- 4 If the file already exists, Model Explorer displays a dialog box asking you to choose one of these options:
 - **Overwrite entire file**
 - Replaces all variables in the target file with the selected variables, which are stored in alphabetical order.
 - **Update variables that exist in file and append new variables to file**
 - Updates existing variables in place and appends new variables.
 - **Only update variables that exist in file**
 - Updates existing variables, but does not add any new variables, which eliminates potentially extraneous variables.

To permanently store workspace variables for a model, instead of using the base workspace, create a data dictionary. See “What Is a Data Dictionary?” on page 61-2.

Importing Workspace Variables

You can import (load) a set of variables from a file into the base workspace or into a model workspace using the Model Explorer. When you import variables into a workspace, the Model Explorer overwrites existing variables and adds any new variables.

To import variables into a workspace:

- 1 In the **Model Hierarchy** pane, right-click the workspace into which you want to import variables.
- 2 Select the **Import** menu item.
- 3 In the Import from File dialog box, select a MATLAB code file or MAT-file for the variables that you want to import.

Note: If you import a MATLAB code file, then Simulink also imports the associated MAT-file.

Configure Data Properties by Using a Table

Models contain data items such as signals, block parameters (for example, the **Gain** parameter of a Gain block), and data stores. The Model Data Editor enables you to inspect and edit data items in a list that you can sort, group, and filter. You can then configure properties and parameters without having to locate the items in the block diagram.

While creating and debugging a model, you can configure multiple data items at once by selecting the corresponding signals and blocks in the block diagram. Work with the selected items in the Model Data Editor instead of opening individual dialog boxes. Use this technique to more quickly view and compare properties of multiple signals that are close to each other, for example, in a subsystem.

Use the Model Data Editor to configure:

- Instrumentation for signals and data stores, which means you want to view and collect the simulation values. For example, you can configure signals and data stores to stream values to the Simulation Data Inspector.
- Design attributes such as data type, minimum and maximum value, and physical units. You specify these attributes to control:
 - The values of numeric block parameters.
 - The interaction (interface) between components through Inport and Outport blocks and data stores.
- Storage classes, which control the representation of the data in the code that you generate from the model.

To use the Model Data Editor in a model, select **View > Model Data**.

Configure Distant Data Items

The example model `sldemo_fuelsys_dd` represents the fueling system of a vehicle engine. The referenced model `sldemo_fuelsys_dd_controller` controls the rate of fuel flow to the engine. Stream two signals to the Simulation Data Inspector to compare their values. Because the signals are far apart in the model, configure them for streaming by using the Model Data Editor.

Explore Example Models

- 1 Open `sldemo_fuelsys_dd`.

- 2 Open the referenced model, `sldemo_fuelsys_dd_controller`.
- 3 Navigate to the `airflow_calc` subsystem.

The Pumping Constant block contains a lookup table that describes the performance of a fuel pump. You can stream the output of this block to the Simulation Data Inspector.

- 4 Navigate to the root of the model and into the `fuel_calc` subsystem.
- 5 Navigate into the `feedforward_fuel_rate` subsystem.

The Outport block named `ff_fuel_rate` passes feedforward information to the fuel rate control algorithm.

- 6 Navigate back to the `fuel_calc` subsystem and into the `switchable_compensation` subsystem.

The Inport block named `ff_fuel_rate` carries the feedforward information. You can stream the output of this Inport block.

Stream Signals

- 1 Open the root of the `sldemo_fuelsys_dd_controller` model.
- 2 Select **View > Model Data**.

The Model Data Editor opens in the Simulink Editor.

- 3 Activate the **Change Scope** button  to display the contents of the subsystems.

The **Path** column appears.

- 4 Set the **Change View** drop-down list to **Instrumentation**.
- 5 Filter the table by using the text `ff_fuel_rate`.

The table contains multiple rows corresponding to the Inport and Outport blocks named `ff_fuel_rate`.

- 6 Use the **Path** column to find the row that corresponds to the Inport block in the root of the `switchable_compensation` subsystem.
- 7 In the **Stream** column, in the target row, click the check box.

This option configures the output of the block to stream simulation values to the Simulation Data Inspector.

- 8 Select the **Signals** tab.
- 9 Filter the table by using the text **Pumping Constant**.

The table contains one row that corresponds to the output of the Pumping Constant block.

- 10 Configure the output signal of the Pumping Constant block to stream to the Simulation Data Inspector.
- 11 Simulate the system model, `sldemo_fuelsys_dd`. During the simulation, double-click the Manual Switch blocks, such as the one named **Engine Speed Selector**, to disturb the fuel control system.

12

Click the **Simulation Data Inspector** button in the model.

- 13 In the left-hand pane, under **Runs**, expand the node that corresponds to the simulation run.
- 14 Click the check boxes next to the signals that you want to stream.

The Simulation Data Inspector shows both signal values on the same graph.

Select Data Items in a Block Diagram

The example model `sldemo_househeat` has a subsystem named **Heater**. While viewing the contents of the subsystem, configure all of the signals in the subsystem to stream to the Simulation Data Inspector.

- 1 In the example model, open the **Heater** subsystem.
- 2 Open the Model Data Editor and select the **Signals** tab.
- 3 In the subsystem, select all of the signals in the subsystem. Optionally, leave out the output of the Constant block because the signal value does not change during the simulation.

The Model Data Editor highlights only the rows that correspond to the signals you selected.

- 4 In the Model Data Editor, for any of the selected signals, click the check box in the **Stream** column.

The Model Data Editor configures all of the selected signals for streaming.

- 5 Simulate the model.

- 6 In the Simulation Data Inspector, in the left-hand pane, under **Runs**, expand the node that corresponds to the simulation run. You can inspect and compare the values of the streamed signals.

Refine List by Filtering, Sorting, and Grouping

The example model `sldemo_fuelsys_dd_controller` has a subsystem named `airflow_calc`. The model is linked to a data dictionary.

Use the Model Data Editor to find the block parameters in the `airflow_calc` subsystem whose values are set by variables and `Simulink.Parameter` objects in the data dictionary.

- 1 In the example model, open the Model Data Editor and select the **Parameters** tab.
- 2 Activate the **Change Scope** button to display the contents of the subsystems.
- 3 Filter the list by using the text `airflow_calc`.
- 4 Hold **Ctrl** and click on the **Defined In** column header.

The Model Data Editor groups the list by the value in the **Defined In** column.

- 5 In the list, scroll to the group named **Defined In: Dictionary**. This group identifies the block parameters whose values are set by variables and objects stored in the data dictionary.

Navigate to Blocks That Own Data

To navigate from a data item in the Model Data Editor to the block in the diagram that owns the data item, double-click the block icon in the left-most column. The Simulink Editor then focuses on the block. Use this technique to navigate to blocks when you select **Change Scope** to view the contents of subsystems below the current system.

Configure Data Interface for Component

Whether you use referenced models or subsystems to break a large system into components, the components can exchange signal data through Inport and Outport blocks. You can explicitly configure design attributes (such as data type and numeric complexity) of the interface to prevent modeling errors and make integrating the components easier.

After you create the Inport and Outport blocks, you can use the Model Data Editor and the interface display to configure the design attributes (such as data type and numeric complexity) of the blocks. Use this technique to view the entirety of the component interface at once and to trace the pieces of the interface to usage points in the internal block algorithm. You can also use this technique to configure the interface of a component before you develop the internal algorithm, in which case the component contains only Inport and Outport blocks.

For an example, see “Configure Data Interface for Component” on page 21-15.

Purpose of Columns

Use this table to find more information about the purpose of the columns in the Model Data Editor.

Column Name	Purpose and More Information
Signal Name	“Signal Names and Labels” on page 62-4
Test Point	“Test Points” on page 62-55
Stream	“Stream Data to the Simulation Data Inspector” on page 26-6
Log Data	“Export Simulation Data” on page 59-3
Data Type	“Control Signal Data Types” on page 57-7
Dimensions	“Signal Dimensions” on page 62-30
Min and Max	“Signal Ranges” on page 62-41
Unit	“Unit Specification in Simulink Models” on page 9-2
Initial Value	“Specify Initial Value for Data Store” on page 60-11
Resolve	Corresponds to the Signal name must resolve to Simulink signal object check box in the Signal Properties dialog box. See “Use Signal Objects” on page 57-56.
Storage Class	“Control Signals and States in Code by Applying Storage Classes”

Column Name	Purpose and More Information
Header File	Custom attributes for custom storage classes, which you select with Storage Class . See “Control Data Representation by Applying Custom Storage Classes”.
Definition File	
Get Function	
Set Function	
Struct Name	
Value	“Set Block Parameter Values” on page 34-2
Defined In	“Determine Where to Store Variables and Objects for Simulink Models” on page 57-81

Model Data Editor Limitations

You cannot specify these attributes by using the Model Data Editor:

- Design attributes for signals other than Outport blocks and the output signals of Inport blocks.
- Any settings for block parameters other than the parameter value. However, you can create and navigate to variables and `Simulink.Parameter` objects that you use to set block parameter values.
- Any settings for nontunable mask parameters. Some built-in blocks are masked and have nontunable mask parameters.
- Any settings for parameters of Simscape blocks.
- Any settings for block states.
- Any settings for data stores that you define by using `Simulink.Signal` objects instead of Data Store Memory blocks.
- Any settings for data items in referenced models. Instead, open the Model Data Editor in the referenced models.

The Model Data Editor does not show Stateflow data. However, the Model Data Editor shows the data for Simulink Functions that you define inside Stateflow charts.

To manage Stateflow data, events, and messages in a chart, see “Manage Stateflow Data, Events, and Messages in the Symbols Window”.

Related Examples

- “Configure Data Interface for Component” on page 21-15
- “Design Data Interface by Configuring Inport and Outport Blocks”
- “Decide How to Visualize Simulation Data” on page 27-2
- “Configure Generated Code According to Interface Control Document”

Upgrade Level-1 Data Classes

Simulink no longer supports level-1 data classes. You must upgrade data classes that you created using the level-1 data class infrastructure, which was removed in a previous release.

Run the following utility function while specifying the destination folder for the upgraded classes.

Note: Property types defined in level-1 data classes that are not subclasses of `Simulink.Parameter`, `Simulink.Signal`, or `Simulink.CustomStorageClassAttributes` are not preserved during an upgrade. Only subclasses of these three classes will preserve attributes `PropertyType` and `AllowedValues`.

- 1 This command upgrades all your level-1 data class packages. You cannot upgrade selected data packages.

```
Simulink.data.upgradeClasses('C:\MyDataClasses')
```

Here, `C:\MyDataClasses` is the destination folder for your level-2 data classes.

Note: Do not place your upgraded level-2 classes and their equivalent level-1 classes in the same folder.

`Simulink.data.upgradeClasses` uses the `packagedefn.mat` file in your level-1 class packages for the upgrade and creates level-2 classes in the specified destination folder. Then, `Simulink.data.upgradeClasses` adds the folder to top of the MATLAB path and saves the path.

Note: If `Simulink.data.upgradeClasses` cannot save the MATLAB path because of restricted access, a warning appears. In this case, manually add the folder to the top of the MATLAB path and save the path using `savepath`.

- 2 You can change the location of the level-2 package folders after they have been generated. However, you will need to update your MATLAB path so that MATLAB can find these package folders.

- 3 Resave MAT-files and models that contain level-1 data objects.
- 4 Retain your level-1 classes on the MATLAB path until you have resaved all of your models and MAT-files that contain level-1 data objects. Any models or MAT-files that contain level-1 data objects will continue to load successfully while your level-1 data classes are on the MATLAB path.

Note: You cannot use both level-1 and level-2 data classes at the same time. Level-2 classes need to be above the level-1 classes on the MATLAB path so that they are found by MATLAB.

Related Examples

- “Define Data Classes” on page 57-75
- “Data Objects” on page 57-54

Associating User Data with Blocks

You can use the `set_param` command to associate your own data with a block. For example, the following command associates the value of the variable `mydata` with the currently selected block.

```
set_param(gcb, 'UserData', mydata)
```

The value of `mydata` can be any MATLAB data type, including arrays, structures, objects, and Simulink data objects.

Use `get_param` to retrieve the user data associated with a block.

```
get_param(gcb, 'UserData')
```

The following command saves the user data associated with a block in the model file of the model containing the block.

```
set_param(gcb, 'UserDataPersistent', 'on');
```

Note If persistent `UserData` for a block contains any Simulink data objects, the directories containing the definitions for the classes of those objects must be on the MATLAB path when you open the model containing the block.

Support Limitations for Simulink Software Features

Simulink Design Verifier does not support the following Simulink software features. Avoid using these unsupported features.

Not Supported	Description
Variable-step solvers	<p>The software supports only fixed-step solvers.</p> <p>For more information, see “Choose a Fixed-Step Solver” on page 23-15 in the Simulink documentation.</p>
Callback functions	<p>The software does not execute model callback functions during the analysis. The results that the analysis generates, such as the harness model, may behave inconsistently with the expected behavior.</p> <ul style="list-style-type: none"> • If a model or any referenced model calls a callback function that changes any block parameters, model parameters, or workspace variables, the analysis does not reflect those changes. • Changing the storage class of base workspace variables on model callback functions or mask initializations is not supported. • Callback functions called prior to analysis, such as the <code>PreLoadFcn</code> or <code>PostLoadFcn</code> model callbacks, are fully supported.
Model callback functions	<p>The software only supports model callback functions if the <code>InitFcn</code> callback of the model is empty.</p>
Algebraic loops	<p>The software does not support models that contain algebraic loops.</p> <p>For more information, see “Algebraic Loops” on page 3-38 in the Simulink documentation.</p>
Masked subsystem initialization functions	<p>The software does not support models whose masked subsystem initialization modifies any attribute of any workspace parameter.</p>
Complex signals	<p>The software supports only real signals.</p>

Not Supported	Description
	For more information, see “Complex Signals” on page 62-15 in the Simulink documentation.
Variable-size signals	<p>The software does not support variable-size signals. A variable-size signal is a signal whose size (number of elements in a dimension), in addition to its values, can change during model execution.</p> <p>For more information, see “Variable-Size Signal Basics” on page 64-2 in the Simulink documentation.</p>
Multiword fixed-point data types	The software does not support multiword fixed-point data types.
Nonzero start times	<p>Although Simulink allows you to specify a nonzero simulation start time, the analysis generates signal data that begins only at zero. If your model specifies a nonzero start time:</p> <ul style="list-style-type: none"> • If you do not select the Reference input model in generated harness parameter (the default), the harness model is a subsystem. The analysis sets the start time of the harness model to 1 and continues the analysis. • If you select the Reference input model in generated harness parameter, a Model block references the harness model. The software cannot change the start time of the harness model, so the analysis stops and you see a recommendation to set the Start time parameter to 0.

Not Supported	Description
Nonfinite data	<p>The software does not support nonfinite data (for example, NaN and Inf) and related operations.</p> <p>In the Relational Operator block, the software assigns the output as follows:</p> <ul style="list-style-type: none"> • If the Relational operator parameter is <code>isFinite</code>, the output is always 1. • If the Relational operator parameter is <code>isNan</code> or <code>isInf</code>, the output is always 0. <p>In the MATLAB Function block, the software assigns the return value as follows:</p> <ul style="list-style-type: none"> • For the <code>isFinite</code> function, the output is always 1. • For the <code>isNan</code> and <code>isInf</code> functions, the output is always 0.
Concurrent execution	The software does not support models that are configured for concurrent execution.
Signals with nonzero sample time offset	The software does not support models with signals that have nonzero sample time offsets.
Models with no output ports	The software only supports models that have one or more output ports.
Large floating-point constants outside the range $[-\text{realmax}/2, \text{realmax}/2]$	The use of large floating-point constants can cause out of memory errors or substantial loss of precision. Avoid using such constants if possible.
Symbolic Dimensions	The software does not support symbolic dimensions for test generation, property proving, or design error detection.

More About

- “Supported and Unsupported Simulink Blocks” on page 57-116
- “Support Limitations for Stateflow Software Features” on page 57-127

Supported and Unsupported Simulink Blocks

The software provides various levels of support for Simulink blocks:

- Fully supported
- Partially supported
- Not supported

If your model contains unsupported blocks, you can enable automatic stubbing. Automatic stubbing considers the interface of the unsupported blocks, but not their behavior. If any of the unsupported blocks affect the simulation outcome, however, the analysis may achieve only partial results. For details about automatic stubbing, see “Handle Incompatibilities with Automatic Stubbing”.

To achieve 100% coverage, avoid using unsupported blocks in models that you analyze. Similarly, for partially supported blocks, specify only the block parameters that the software recognizes.

The following tables summarize the analysis support for Simulink blocks. Each table lists the blocks in a Simulink library and describes support information for that particular block.

Additional Math and Discrete Library

The software supports all blocks in the Additional Math and Discrete library.

Commonly Used Blocks Library

The Commonly Used Blocks library includes blocks from other libraries. Those blocks are listed under their respective libraries.

Continuous Library

Block	Support Notes
Derivative	Not supported
Integrator	Not supported and not stubbable
Integrator Limited	Not supported and not stubbable
PID Controller	Not supported
PID Controller (2 DOF)	Not supported

Block	Support Notes
Second Order Integrator	Not supported and not stubbable
Second Order Integrator Limited	Not supported and not stubbable
State-Space	Not supported and not stubbable
Transfer Fcn	Not supported and not stubbable
Transport Delay	Not supported
Variable Time Delay	Not supported
Variable Transport Delay	Not supported
Zero-Pole	Not supported and not stubbable

Discontinuities Library

The software supports all blocks in the Discontinuities library.

Discrete Library

Block	Support Notes
Delay	Supported
Difference	Supported
Discrete Derivative	Supported
Discrete Filter	Supported
Discrete FIR Filter	Supported
Discrete PID Controller	Supported
Discrete PID Controller (2 DOF)	Supported
Discrete State-Space	Not supported
Discrete Transfer Fcn	Supported
Discrete Zero-Pole	Not supported
Discrete-Time Integrator	Supported
First-Order Hold	Supported
Memory	Supported
Tapped Delay	Supported

Block	Support Notes
Transfer Fcn First Order	Supported
Transfer Fcn Lead or Lag	Supported
Transfer Fcn Real Zero	Supported
Unit Delay	Supported
Zero-Order Hold	Supported

Logic and Bit Operations Library

The software supports all blocks in the Logic and Bit Operations library.

Lookup Tables Library

Block	Support Notes
Cosine	Supported
Direct Lookup Table (n-D)	Supported
Interpolation Using Prelookup	Not supported when: <ul style="list-style-type: none"> The Interpolation method parameter is Linear and the Number of table dimensions parameter is greater than 4. <p>or</p> <ul style="list-style-type: none"> The Interpolation method parameter is Linear and the Number of sub-table selection dimensions parameter is not 0.
1-D Lookup Table	Not supported when the Interpolation method or the Extrapolation method parameter is Cubic Spline .
2-D Lookup Table	Not supported when the Interpolation method or the Extrapolation method parameter is Cubic Spline .
n-D Lookup Table	Not supported when: <ul style="list-style-type: none"> The Interpolation method or the Extrapolation method parameter is Cubic Spline. <p>or</p>

Chirp Signal	Not supported
Clock	Supported
Constant	Supported unless Constant value is <code>inf</code> .
Counter Free-Running	Supported
Counter Limited	Supported
Digital Clock	Supported
Enumerated Constant	Supported
From File	Not supported. When MAT-file data is stored in MATLAB <code>timeseries</code> format, not stubbable.
From Workspace	Not supported
Ground	Supported
Inport (In1)	Supported
Pulse Generator	Supported
Ramp	Supported
Random Number	Not supported and not stubbable
Repeating Sequence	Not supported
Repeating Sequence Interpolated	Not supported
Repeating Sequence Stair	Supported
Signal Builder	Not supported

Block	Support Notes
Signal Generator	Not supported
Sine Wave	Not supported
Step	Supported
Uniform Random Number	Not supported and not stubbable

User-Defined Functions Library

Block	Support Notes
Fcn	Supports all operators except \wedge , and supports only the mathematical functions <code>abs</code> , <code>ceil</code> , <code>fabs</code> , <code>floor</code> , <code>rem</code> , and <code>sgn</code> . Parameter configurations are not supported. The analysis ignores parameter configurations that you specify for these blocks.
Interpreted MATLAB Function	Not supported
Level-2 MATLAB S-Function	For limitations, see “Support Limitations for S-Functions”.
MATLAB Function	For limitations, see “Support Limitations for MATLAB for Code Generation”.
S-Function	For limitations, see “Support Limitations for S-Functions”.
S-Function Builder	For limitations, see “Support Limitations for S-Functions”.
Simulink Function	Simulink Function blocks with output arguments that are of bus data-type are not supported. Calls to Simulink Functions across model boundaries are not supported.

More About

- “Support Limitations for Stateflow Software Features” on page 57-127

Support Limitations for Stateflow Software Features

shSimulink Design Verifier does not support the following Stateflow software features. Avoid using these unsupported features in models that you analyze.

In this section...

“ml Namespace Operator, ml Function, ml Expressions” on page 57-127

“C Math Functions” on page 57-127

“Atomic Subcharts That Call Exported Graphical Functions Outside a Subchart” on page 57-128

“Atomic Subchart Input and Output Mapping” on page 57-128

“Recursion and Cyclic Behavior” on page 57-128

“Custom C or C++ Code” on page 57-130

“Machine-Parented Data” on page 57-130

“Textual Functions with Literal String Arguments” on page 57-130

ml Namespace Operator, ml Function, ml Expressions

The software does not support calls to MATLAB functions or access to MATLAB workspace variables, which the Stateflow software allows. (See “Access Built-In MATLAB Functions and Workspace Data” in the Stateflow documentation.)

C Math Functions

The software supports calls to the following C math functions:

- abs
- ceil
- fabs
- floor
- fmod
- labs
- ldexp
- pow (only for integer exponents)

The software does not support calls to other C math functions, which the Stateflow software allows. If automatic stubbing is enabled, which it is by default, the software eliminates these unsupported functions during the analysis.

For information about C math functions in Stateflow, see “Call C Functions in C Charts” in the Stateflow documentation.

Note: For details about automatic stubbing, see “Handle Incompatibilities with Automatic Stubbing”.

Atomic Subcharts That Call Exported Graphical Functions Outside a Subchart

The software does not support atomic subcharts that call exported graphical functions, which the Stateflow software allows.

Note: For information about exported functions, see “Export Stateflow Functions for Reuse” in the Stateflow documentation.

Atomic Subchart Input and Output Mapping

If an input or output in an atomic subchart maps to chart-level data of a different scope, the software does not support the chart that contains that atomic subchart.

For an atomic subchart input, this incompatibility applies when the input maps to chart-level data of output, local, or parameter scope. For an atomic subchart output, this incompatibility applies when the output maps to chart-level data of local scope.

Recursion and Cyclic Behavior

The software does not support recursive functions, which occur when a function calls itself directly or indirectly through another function call. Stateflow software allows you to implement recursion using graphical functions.

In addition, the software does not support recursion that the Stateflow software allows you to implement using a combination of event broadcasts and function calls.

Note: For information about avoiding recursion in Stateflow charts, see “Guidelines for Avoiding Unwanted Recursion in a Chart” in the Stateflow documentation.

Stateflow software also allows you to create *cyclic behavior*, where a sequence of steps is repeated indefinitely. If your model has a chart with cyclic behavior, the software cannot analyze it.

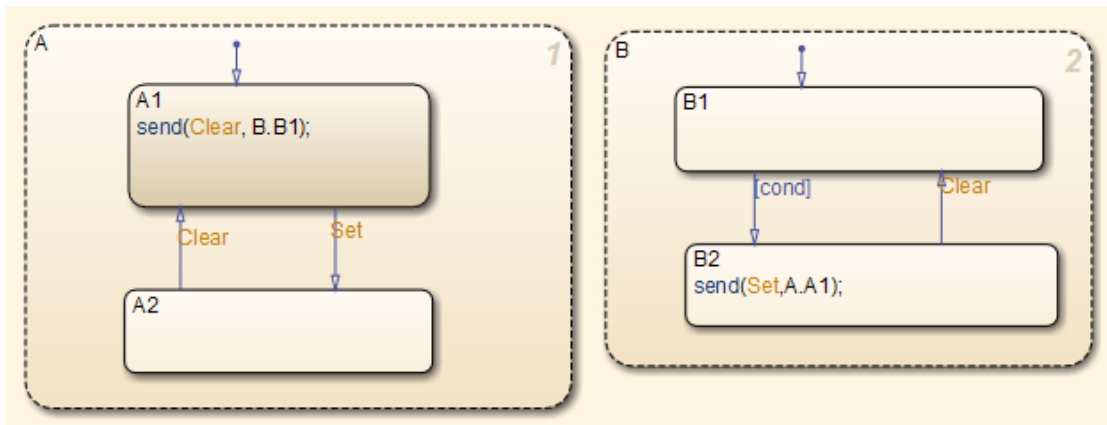

Note: For information about cyclic behavior in Stateflow charts, see “Cyclic Behavior in a Chart” in the Stateflow documentation.

However, you can modify a chart with cyclic behavior so that it is compatible, as in the following example.

The following chart creates cyclic behavior. State A calls state A1, which broadcasts a **Clear** event to state B, which calls state B2, which broadcasts a **Set** event back to state A, causing the cyclic behavior.

If you change the `send` function calls to use directed event broadcasts so that the `Set` and `Clear` events are broadcast directly to the states B1 and A1, respectively, the cyclic behavior disappears and the software can analyze the model.

Note: For information about the benefits of directed event broadcasts, see “Broadcast Events to Synchronize States” in the Stateflow documentation.

Custom C or C++ Code

The software does not support custom C or C++ code, which the Stateflow software allows.

Machine-Parented Data

The software does not support machine-parented data (i.e., defined at the level of the Stateflow machine), which the Stateflow software allows.

For more information, see “Best Practices for Using Data in Charts” in the Stateflow documentation.

Textual Functions with Literal String Arguments

The software does not support literal string arguments to textual functions in a Stateflow chart.

Enumerations and Modeling

- “Simulink Enumerations” on page 58-2
- “Use Enumerated Data in Simulink Models” on page 58-7

Simulink Enumerations

Enumerated data is data that is restricted to a finite set of values. An *enumerated data type* is a MATLAB class that defines a set of *enumerated values*. Each enumerated value consists of an *enumerated name* and an *underlying integer* which the software uses internally and in generated code.

Before you begin to use enumerations in a modeling context, you should understand information provided in “Enumerations”.

To define an enumeration for use in Simulink models, choose one of these techniques:

- Use the function `Simulink.defineIntEnumType`. The enumeration exists for the duration of your MATLAB session.
- Create a permanent enumeration class by subclassing one of these built-in classes:
 - Many of the built-in integer data types such as `int8` and `uint16`
 - `Simulink.IntEnumType`

For more information, see “Define Simulink Enumerations” on page 58-7.

The following examples show how to use enumerations in Simulink and Stateflow.

Example	Shows How To Use...
Data Typing in Simulink	Data types in Simulink, including enumerated data types
Modeling a CD Player/Radio Using Enumerated Data Types	Enumerated data types in a Simulink model that contains a Stateflow chart

For information on using enumerations in Stateflow, see “Enumerated Data”.

Simulink Constructs that Support Enumerations

- “Overview” on page 58-3
- “Block Support” on page 58-3
- “Class Support” on page 58-4
- “Logging Enumerated Data” on page 58-5
- “Importing Enumerated Data” on page 58-5

Overview

In general, all Simulink tools and constructs support enumerated types for which the support makes sense given the purpose of enumerated types: to represent program states and to control program logic. The Simulink Editor, Simulink Debugger, Port Value Displays, referenced models, subsystems, masks, buses, data logging, and most other Simulink capabilities support enumerated types without imposing any special requirements.

Enumerated types are not intended for mathematical computation, so no block that computes a numeric output (as distinct from passing a numeric input through to the output) supports enumerated types. Thus an enumerated type is not considered to be a numeric type, even though an enumerated value has an underlying integer. See “Enumerated Values in Computation” on page 58-22 for more information.

Most capabilities that do not support enumerated types obviously could not support them. Therefore, the Simulink documentation usually mentions enumerated type nonsupport only where necessary to prevent a misconception or describe an exception. See “Simulink Enumeration Limitations” on page 58-5 for information about certain constructs that could support enumerated types but do not.

Block Support

The following Simulink blocks support enumerated types:

- Constant (but Enumerated Constant is preferable)
- Data Type Conversion
- Data Type Conversion Inherited
- Data Type Duplicate
- Display
- MATLAB Function
- Enumerated Constant
- Floating Scope
- From File
- From Workspace
- Inport
- Interval Test

- Interval Test Dynamic
- Multiport Switch
- Output
- Probe (input only)
- Relational Operator
- Relay (output only)
- Repeating Sequence Stair
- Scope
- Signal Specification
- Switch
- Switch Case
- To File
- To Workspace

All members of the following categories of Simulink blocks support enumerated types:

- Bus-capable blocks (see “Bus-Capable Blocks” on page 63-28)
- Pass-through blocks:
 - With state, like the Data Store Memory and Unit Delay blocks.
 - Without state, like the Mux block.

Many Simulink blocks in addition to those named above support enumerated types, but they either belong to one of the categories listed above, or are rarely used with enumerated types. The Data Type Support section of each block reference page describes all data types that the block supports.

Class Support

The following Simulink classes support enumerated types:

- Simulink.Signal
- Simulink.Parameter
- Simulink.AliasType
- Simulink.BusElement

Logging Enumerated Data

Root-level outports, To Workspace blocks, and Scope blocks can all export enumerated values. Signal and State logging work with enumerated data in the same way as with any other data. All logging formats are supported. The From File block does not support enumerated data. Use the From Workspace block instead, combined with some technique for transferring data between a file and a workspace. See “Save Runtime Data from Simulation” for more information.

Importing Enumerated Data

Root-level inports and From Workspace blocks can output enumerated signals during simulation. Data must be provided in a Structure, Structure with Time, or TimeSeries object. No interpolation occurs for enumerated values between the specified simulation times. From File blocks produce only data of type double, so they do not support enumerated types. See “Load Signal Data for Simulation” for more information.

Simulink Enumeration Limitations

- “Enumerations and Scopes” on page 58-5
- “Enumerated Types for Switch Blocks” on page 58-5
- “Nonsupport of Enumerations” on page 58-6

Enumerations and Scopes

When a Scope block displays an enumerated signal, the vertical axis displays the names of the enumerated values only if the scope was open during simulation. If you open the Scope block for the first time before any simulation has occurred, or between simulations, the block displays only numeric values. When simulation begins, enumerated names replace the numeric values, and thereafter appear whenever the Scope block is opened.

When a Floating Scope block displays multiple signals, the names of enumerated values appear on the Y axis only if all signals are of the same enumerated type. If the Floating Scope block displays more than one type of enumerated signal, or any numeric signal, no names appear, and any enumerated values are represented by their underlying integers.

Enumerated Types for Switch Blocks

The control input of a Switch block can be of any data type supported by Simulink. However, the u2 ~=0 mode is not supported for enumerations. If the control input has an

enumeration, choose one of the following methods to specify the criteria for passing the first input:

- Select `u2 >= Threshold` or `u2 > Threshold` and specify a threshold value of the same enumerated type as the control input.
- Use a **Relational Operator** block to do the comparison and then feed the Boolean result of this comparison into the control port of the Switch block.

Nonsupport of Enumerations

The following limitations exist when using enumerated data types with Simulink:

- Packages cannot contain enumeration class definitions.
- The If Action block might support enumerations, but currently does not do so.
- Generated code does not support logging enumerated data.
- Custom Stateflow targets do not support enumerated types.

Use Enumerated Data in Simulink Models

In this section...

“Define Simulink Enumerations” on page 58-7

“Simulate with Enumerations” on page 58-14

“Specify Enumerations as Data Types” on page 58-16

“Get Information About Enumerated Data Types” on page 58-17

“Enumeration Value Display” on page 58-17

“Instantiate Enumerations” on page 58-19

“Enumerated Values in Computation” on page 58-22

Enumerated data is data that is restricted to a finite set of values. An *enumerated data type* is a MATLAB class that defines a set of *enumerated values*. Each enumerated value consists of an *enumerated name* and an *underlying integer* which the software uses internally and in generated code.

For basic conceptual information about enumerations in Simulink, see “Simulink Enumerations” on page 58-2.

For information about generating code with enumerations, see “Use Enumerated Data in Generated Code” in the Simulink Coder documentation.

Define Simulink Enumerations

To define an enumerated data type that you can use in Simulink models, use one of these methods:

- Define an enumeration class using a `classdef` block in a MATLAB file.
- Use the function `Simulink.defineIntEnumType`. You do not need a script file to define the type. For more information, see the function reference page.

Workflow to Define a Simulink Enumeration

- 1 Create a class definition.
- 2 Optionally, customize the enumeration.
- 3 Optionally, save the enumeration in a MATLAB file.

- 4 Optionally, permanently store the enumeration definition in a Simulink data dictionary. See “Permanently Store Enumerated Type Definition” on page 58-14.

Create Simulink Enumeration Class

To create a Simulink enumeration class, in the class definition:

- Define the class as a subclass of `Simulink.IntEnumType`. You can also base an enumerated type on one of these built-in integer data types: `int8`, `uint8`, `int16`, `uint16`, and `int32`.
- Add an `enumeration` block that specifies enumeration values with underlying integer values.

Consider the following example:

```
classdef BasicColors < Simulink.IntEnumType
    enumeration
        Red(0)
        Yellow(1)
        Blue(2)
    end
end
```

The first line defines an integer-based enumeration that is derived from built-in class `Simulink.IntEnumType`. The enumeration is integer-based because `IntEnumType` is derived from `int32`.

The `enumeration` section specifies three enumerated values.

Enumerated Value	Enumerated Name	Underlying Integer
Red(0)	Red	0
Yellow(1)	Yellow	1
Blue(2)	Blue	2

When defining an enumeration class for use in the Simulink environment, consider the following:

- The name of the enumeration class must be unique among data type names and base workspace variable names, and is case-sensitive.

- Underlying integer values in the `enumeration` section need not be unique within the class and across types.
- Often, the underlying integers of a set of enumerated values are consecutive and monotonically increasing, but they need not be either consecutive or ordered.
- For simulation, an underlying integer can be any `int32` value. Use the MATLAB functions `intmin` and `intmax` to get the limits.
- For code generation, every underlying integer value must be representable as an integer on the target hardware, which may impose different limits. See “Select a System Target File” and “Hardware Implementation Pane” for more information.

For more information on superclasses, see “Convert to Superclass Value”. For information on how enumeration classes are handled when there is more than one name for an underlying value, see “How to Alias Enumeration Names”.

Customize Simulink Enumeration

About Simulink Enumeration Customizations

You can customize a Simulink enumeration by implementing specific static methods in the class definition. If you define these methods using the appropriate syntax, you can change the behavior of the class during simulation and in generated code.

The table shows the methods you can implement to customize an enumeration.

Static Method	Purpose	Default Value Without Implementing Method	Custom Return Value	Usage Context
<code>getDefaultValue</code>	Specifies the default enumeration member for the class.	First member specified in the enumeration definition	A character vector containing the name of an enumeration member in the class (see “Instantiate Enumerations” on page 58-19)	Simulation and code generation
<code>getDescription</code>	Specifies a description of the enumeration class.	' '	A character vector containing the description of the type	Code generation

Static Method	Purpose	Default Value Without Implementing Method	Custom Return Value	Usage Context
<code>getHeaderFile</code>	Specifies the name of a header file. The method <code>getDataScope</code> determines the significance of the file.	' '	A character vector containing the name of the header file that defines the enumerated type	Code generation
<code>getDataScope</code>	Specifies whether generated code exports or imports the definition of the enumerated data type. Use the method <code>getHeaderFile</code> to specify the generated or included header file that defines the type.	'Auto'	One of: 'Auto', 'Exported', or 'Imported'	Code generation
<code>addClassNameToEnum</code>	Specifies whether to prefix the class name in generated code.	false	true or false	Code generation

For more examples of these methods as they apply to code generation, see “Customize Enumerated Data Type” in the Simulink Coder documentation.

Specify a Default Enumerated Value

Simulink and related generated code use an enumeration's default value for ground-value initialization of enumerated data when you provide no other initial value. For example, an enumerated signal inside a conditionally executed subsystem that has not yet executed has the enumeration's default value. Generated code uses an enumeration's default value if a safe cast fails, as described in “Type Casting for Enumerations” in the Simulink Coder documentation.

Unless you specify otherwise, the default value for an enumeration is the first value in the enumeration class definition. To specify a different default value, add your own `getDefaultValue` method to the `methods` section. The following code shows a shell for the `getDefaultValue` method:

```

function retVal = getDefaultValue()
    % GETDEFAULTVALUE Specifies the default enumeration member.
    % Return a valid member of this enumeration class to specify the default.
    % If you do not define this method, Simulink uses the first member.
    retVal = ThisClass.EnumName;
end

```

To customize this method, provide a value for *ThisClass.EnumName* that specifies the desired default.

- *ThisClass* must be the name of the class within which the method exists.
- *EnumName* must be the name of an enumerated value defined in that class.

For example:

```

classdef BasicColors < Simulink.IntEnumType
    enumeration
        Red(0)
        Yellow(1)
        Blue(2)
    end
    methods (Static)
        function retVal = getDefaultValue()
            retVal = BasicColors.Blue;
        end
    end
end

```

This example defines the default as `BasicColors.Blue`. If this method does not appear, the default value would be `BasicColors.Red`, because that is the first value listed in the enumerated class definition.

The seemingly redundant specification of *ThisClass* inside the definition of that same class is necessary because `getDefaultValue` returns an instance of the default enumerated value, not just the name of the value. The method, therefore, needs a complete specification of what to instantiate. See “Instantiate Enumerations” on page 58-19 for more information.

Save Enumeration in a MATLAB File

You can define an enumeration within a MATLAB file.

- The name of the definition file must match the name of the enumeration exactly, including case. For example, the definition of enumeration `BasicColors` must reside in a file named `BasicColors.m`. Otherwise, MATLAB will not find the definition.

- You must define each class definition in a separate file.
- Save each definition file on the MATLAB search path. MATLAB searches the path to find a definition when necessary.

To add a file or folder to the MATLAB search path, type `addpath pathname` at the MATLAB command prompt. For more information, see “What Is the MATLAB Search Path?”, `addpath`, and `savepath`.

- You do not need to execute an enumeration class definition to use the enumeration. The only requirement, as indicated in the preceding bullet, is that the definition file be on the MATLAB search path.

Change and Reload Enumerations

You can change the definition of an enumeration by editing and saving the file that contains the definition. You do not need to inform MATLAB that a class definition has changed. MATLAB automatically reads the modified definition when you save the file. However, the class definition changes do not take full effect if any class instances (enumerated values) exist that reflect the previous class definition. Such instances might exist in the base workspace or might be cached.

The following table explains options for removing instances of an enumeration from the base workspace and cache.

If In Base Workspace...	If In Cache...
Do one of the following: <ul style="list-style-type: none"> • Locate and delete specific obsolete instances. • Delete everything from the workspace by using the <code>clear</code> command. 	<ul style="list-style-type: none"> • Delete obsolete instances by closing all models that you updated or simulated while the previous class definition was in effect. • Clear functions and close models that are caching instances of the class.

For more information about applying enumeration changes, see “Automatic Updates for Modified Classes”.

Import Enumerations Defined Externally to MATLAB

If you have enumerations defined externally to MATLAB that you want to import for use within the Simulink environment, you can do so programmatically with calls to the function `Simulink.defineIntEnumType`. This function defines an enumeration

that you can use in MATLAB as if it is defined by a class definition file. In addition to specifying the enumeration class name and values, each function call can specify:

- Character vector that describes the enumeration class.
- Which of the enumeration values is the default.

For code generation, you can specify:

- Header file in which the enumeration is defined for generated code.
- Whether the code generator applies the class name as a prefix to enumeration members — for example, `BasicColors_Red` or `Red`.

As an example, consider the following class definition:

```
classdef BasicColors < Simulink.IntEnumType
    enumeration
        Red(0)
        Yellow(1)
        Blue(2)
    end
    methods (Static = true)
        function retVal = getDescription()
            retVal = 'Basic colors...';
        end
        function retVal = getDefaultValue()
            retVal = BasicColors.Blue;
        end
        function retVal = getHeaderFile()
            retVal = 'mybasiccolors.h';
        end
        function retVal = addClassNameToEnumNames()
            retVal = true;
        end
    end
end
```

The following function call defines the same class for use in MATLAB:

```
Simulink.defineIntEnumType('BasicColors', ...
    {'Red', 'Yellow', 'Blue'}, [0;1;2],...
    'Description', 'Basic colors', ...
    'DefaultValue', 'Blue', ...
    'HeaderFile', 'mybasiccolors.h', ...
```

```
'DataScope', 'Imported', ...
'AddClassNameToEnumNames', true);
```

Permanently Store Enumerated Type Definition

Whether you define an enumeration by using a class file or by using the function `Simulink.defineIntEnumType`, you can permanently store the enumeration definition in a Simulink data dictionary. Models that are linked to the dictionary can use the enumeration. For more information, see “Enumerations in Data Dictionary” on page 61-14.

Simulate with Enumerations

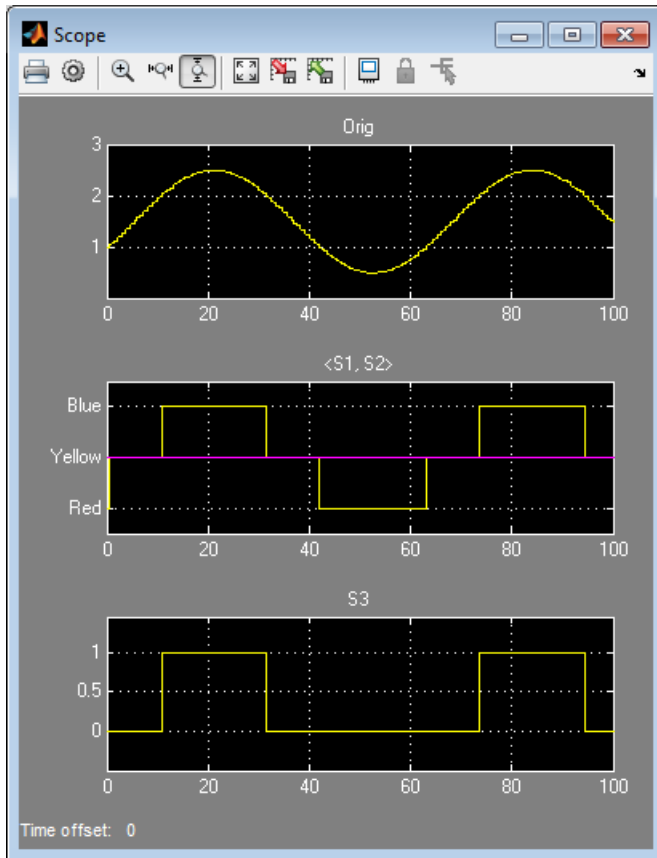

Consider the following enumeration class definition — `BasicColors` with enumerated values `Red`, `Yellow`, and `Blue`, with `Blue` as the default value:

```
classdef BasicColors < Simulink.IntEnumType
    enumeration
        Red(0)
        Yellow(1)
        Blue(2)
    end
    methods (Static)
        function retVal = getDefaultValue()
            retVal = BasicColors.Blue;
        end
    end
end
```

Once this class definition is known to MATLAB, you can use the enumeration in Simulink and Stateflow models. Information specific to enumerations in Stateflow appears in “Enumerated Data”. The following Simulink model uses the enumeration defined above:

The output of the model looks like this:

The Data Type Conversion block **OrigToInt** specifies an **Output data type** of **int32** and **Integer rounding mode: Floor**, so the block converts the **Sine Wave** block output, which appears in the top graph of the **Scope** display, to a cycle of integers: 1, 2, 1, 0, 1, 2, 1. The Data Type Conversion block **IntToColor** uses these values to select colors from the enumerated type **BasicColors** by referencing their underlying integers.

The result is a cycle of colors: **Yellow, Blue, Yellow, Red, Yellow, Blue, Yellow**, as shown in the middle graph. The **Enumerated Constant** block **EnumConst** outputs **Yellow**, which appears in the second graph as a straight line. The **Relational Operator** block compares the constant **Yellow** to each value in the cycle of colors. It

outputs 1 (**true**) when **Yellow** is less than the current color, and 0 (**false**) otherwise, as shown in the third graph.

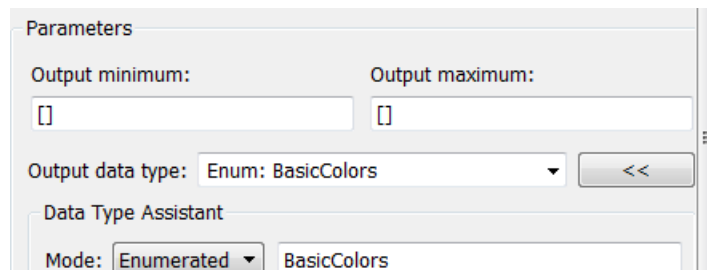

The sort order used by the comparison is the numeric order of the underlying integers of the compared values, *not* the lexical order in which the enumerated values appear in the enumerated class definition. In this example the two orders are the same, but they need not be. See “Specify Enumerations as Data Types” on page 58-16 and “Enumerated Values in Computation” on page 58-22 for more information.

Specify Enumerations as Data Types

Once you define an enumeration, you can use it much like any other data type. Because an enumeration is a class rather than an instance, you must use the prefix **?** or **Enum:** when specifying the enumeration as a data type. You must use the prefix **?** in the MATLAB Command Window. However, you can use either prefix in a Simulink model. **Enum:** has the same effect as the **?** prefix, but **Enum:** is preferred because it is more self-explanatory in the context of a graphical user interface.

Depending on the context, type **Enum:** followed by the name of an enumeration, or select **Enum:** <class name> from a menu (for example, for the **Output data type** block parameter) , and replace <class name>.

To use the Data Type Assistant, set the **Mode** to **Enumerated**, then enter the name of the enumeration. For example, in the previous model, the Data Type Conversion block **IntToColor**, which outputs a signal of type **BasicColors**, has the following output signal specification:

You cannot set a minimum or maximum value for a signal defined as an enumeration, because the concepts of minimum and maximum are not relevant to the purpose of enumerations. If you change the minimum or maximum for a signal of an enumeration from the default value of `[]`, an error occurs when you update the model. See “Enumerated Values in Computation” on page 58-22 for more information.

Get Information About Enumerated Data Types

The functions `enumeration` and `Simulink.data.getEnumTypeInfo` return information about enumerated data types.

Get Information About Enumeration Members

Use the function `enumeration` to:

- Return an array that contains all enumeration values for an enumeration class in the MATLAB Command Window
- Get the enumeration values programmatically
- Provide the values to a Simulink block parameter that accepts an array or vector of enumerated values, such as the **Case conditions** parameter of the Switch Case block

Get Information About Enumerated Class

Use the function `Simulink.data.getEnumTypeInfo` to return information about an enumeration class, such as:

- The default enumeration member
- The name of the header file that defines the type in generated code
- The data type used in generated code to store the integer values underlying the enumeration members

Enumeration Value Display

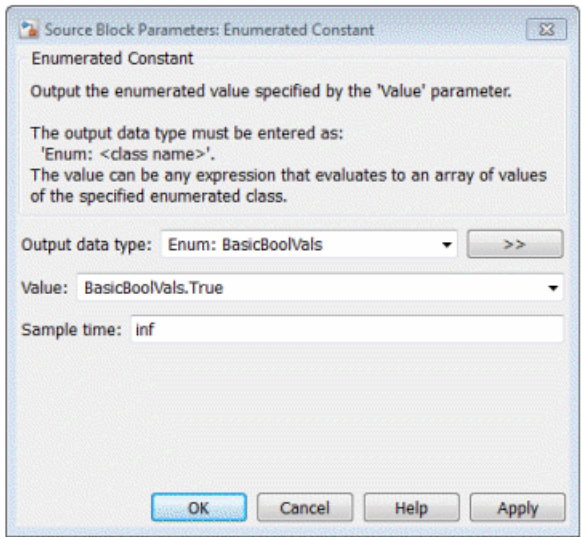

Wherever possible, Simulink displays enumeration values by name, not by the underlying integer value. However, the underlying integers can affect value display in Scope and Floating Scope blocks.

Block...	Affect on Value Display...
Scope	When displaying an enumerated signal, the names of the enumerated values appear as labels on the Y axis. The names appear in the order given by their underlying integers, with the lowest value at the bottom.
Floating Scope	When displaying signals that are of the same enumeration, names appear on the Y axis as they would for a Scope block. If the Floating Scope block displays mixed data types, no names

Block...	Affect on Value Display...
	appear, and any enumerated values are represented by their underlying integers.

Enumerated Values with Non-Unique Integers

More than one value in an enumeration can have the same underlying integer value, as described in “Specify Enumerations as Data Types” on page 58-16. When this occurs, the value on an axis of Scope block output or in Display block output always is the first value listed in the enumerated class definition that has the shared underlying integer. For example:

Although the Enumerated Constant block outputs True, both On and True have the same underlying integer, and On is defined first in the class definition enumeration

section. Therefore, the Display block shows **On**. Similarly, a **Scope** axis would show only **On**, never **True**, no matter which of the two values is input to the Scope block.

Instantiate Enumerations

Before you can use an enumeration, you must instantiate it. You can instantiate an enumeration in MATLAB, in a Simulink model, or in a Stateflow chart. The syntax is the same in all contexts.

Instantiating Enumerations in MATLAB

To instantiate an enumeration in MATLAB, enter *ClassName.EnumName* in the MATLAB Command Window. The instance is created in the base workspace. For example, if **BasicColors** is defined as in “Create Simulink Enumeration Class” on page 58-8, you can type:

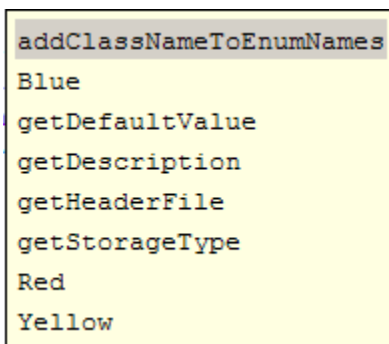

```
bcy = BasicColors.Yellow
```

```
bcy =  
    Yellow
```

Tab completion works for enumerations. For example, if you enter:

```
bcy = BasicColors.<tab>
```

MATLAB displays the elements and methods of **BasicColors** in alphabetical order:

```
addClassNameToEnumNames  
Blue  
getDefaultvalue  
getDescription  
getHeaderFile  
getStorageType  
Red  
Yellow
```

Double-click an element or method to insert it at the position where you pressed **<tab>**. See “Tab Completion” for more information.

Casting Enumerations in MATLAB

In MATLAB, you can cast directly from an integer to an enumerated value:

```
bcb = BasicColors(2)
```

```
bcb =
```

```
Blue
```

You can also cast from an enumerated value to its underlying integer:

```
>> bci = int32(bcb)
```

```
bci =
```

```
2
```

In either case, MATLAB returns the result of the cast in a 1x1 array of the relevant data type.

Although casting is possible, use of enumeration values is not robust in cases where enumeration values and the integer equivalents defined for an enumeration class might change.

Instantiating Enumerations in Simulink (or Stateflow)

To instantiate an enumeration in a Simulink model, you can enter *ClassName.EnumName* as a value in a dialog box. For example, consider the following model:

The Enumerated Constant block **EnumConst**, which outputs the enumerated value Yellow, defines that value as follows:

You can enter any valid MATLAB expression that evaluates to an enumerated value, including arrays and workspace variables. For example, you could enter `BasicColors(1)`, or if you had previously executed `bcy = BasicColors.Yellow` in the MATLAB Command Window, you could enter `bcy`. As another example, you could enter an array, such as `[BasicColors.Red, BasicColors.Yellow, BasicColors.Blue]`.

You can use a **Constant** block to output enumerated values. However, that block displays parameters that do not apply to enumerated types, such as **Output Minimum** and **Output Maximum**.

If you create a `Simulink.Parameter` object as an enumeration, you must specify the **Value** parameter as an enumeration member and the **Data type** with the `Enum:` or `?` prefix, as explained in “Specify Enumerations as Data Types” on page 58-16.

You *cannot* specify the integer value of an enumeration member for the **Value** parameter. See “Enumerated Values in Computation” on page 58-22 for more information. Thus, the following fails even though the integer value for `BasicColors.Yellow` is 1.

The same syntax and considerations apply in Stateflow. See “Enumerated Data” for more information.

Enumerated Values in Computation

By design, Simulink prevents enumerated values from being used as numeric values in mathematical computation, even though an enumerated class is a subclass of the MATLAB `int32` class. Thus, an enumerated type does not function as a numeric type despite the existence of its underlying integers. For example, you cannot input an enumerated signal directly to a Gain block.

You can use a Data Type Conversion block to convert in either direction between an integer type and an enumerated type, or between two enumerated types. That is, you can use a Data Type Conversion block to convert an enumerated signal to an integer signal (consisting of the underlying integers of the enumerated signal values) and input the resulting integer signal to a Gain block. See “Casting Enumerated Signals” on page 58-22 for more information.

Enumerated types in Simulink are intended to represent program states and control program logic in blocks like the Relational Operator block and the Switch block. When a Simulink block compares enumerated values, the values compared must be of the same enumerated type. The block compares enumerated values based on their underlying integers, not their order in the enumerated class definition.

When a block like the Switch block or Multiport Switch block selects among multiple data signals, and any data signal is of an enumerated type, all the data signals must be of that same enumerated type. When a block inputs both control and data signals, as Switch and Multiport Switch do, the control signal type need not match the data signal type.

Casting Enumerated Signals

You can use a Data Type Conversion block to cast an enumerated signal to a signal of any numeric type, provided that the underlying integers of all enumerated values input to the block are within the range of the numeric type. Otherwise, an error occurs during simulation.

Similarly, you can use a Data Type Conversion block to cast a signal of any integer type to an enumerated signal, provided that every value input to the Data Type Conversion block is the underlying integer of some value in the enumerated type. Otherwise, an error occurs during simulation.

You cannot use a Data Type Conversion block to cast a numeric signal of any non-integer data type to an enumerated type. For example, the model used in “Simulate with

Enumerations” on page 58-14 needed two Data Conversion blocks to convert a sine wave to enumerated values.

The first block casts `double` to `int32`, and the second block casts `int32` to `BasicColors`. You cannot cast a complex signal to an enumerated type regardless of the data types of its real and imaginary parts.

Casting Enumerated Block Parameters

You cannot cast a block parameter of any numeric data type to an enumerated data type. For example, suppose that an Enumerated Constant block specifies a **Value** of 2 and an **Output data type** of Enum: `BasicColors`:

An error occurs because the specifications implicitly cast a `double` value to an enumerated type. The error occurs even though the numeric value corresponds arithmetically to one of the enumerated values in the enumerated type.

You cannot cast a block parameter of an enumeration to any other data type. For example, suppose that a Constant block specifies a **Constant value** of `BasicColors.Blue` and an **Output data type** of `int32`.

An error occurs because the specifications implicitly cast an enumerated value to a numeric type. The error occurs even though the enumerated value's underlying integer is a valid `int32`.

Export Simulation Data

In this section...

“Simulation Data” on page 59-3

“Approaches for Exporting Signal Data” on page 59-4

“Enable Simulation Data Export” on page 59-6

“View Logged Data Using Simulation Data Inspector” on page 59-7

“Memory Performance” on page 59-7

Exporting (logging) simulation data provides a baseline for analyzing and debugging a model. Use standard or custom MATLAB functions to generate simulated system input signals and to graph, analyze, or otherwise postprocess the system outputs.

Simulation Data

Simulation data can include any combination of signal, time, output, state, and data store logging data.

Exporting simulation data involves saving signal values to the MATLAB workspace or to a MAT-file during simulation for later retrieval and postprocessing. Exporting data is also known as “data logging” or “saving simulation data.”

You can have data logged in different formats:

- Array
- Structure
- Structure with time
- MATLAB timeseries
- `ModelDataLogs`

Note: The `ModelDataLogs` class is supported for backwards compatibility. Starting in R2016a, you cannot log data in the `ModelDataLogs` format. Signal logging uses the `Dataset` format. In R2016a or later, when you open a model from an earlier release that had used `ModelDataLogs` format, the model simulated in use `Dataset` format.

Consider converting this data to the **Dataset** format, which can simplify the post-processing of data. For more information, see “Dataset Conversion for Logged Data” on page 59-20.

You can also import the exported data to use as input for simulating a model.

Approaches for Exporting Signal Data

Exporting simulation data often involves exporting signal data. You can use various approaches for exporting signal data.

Export Approach	Usage	Documentation
Connect a Scope block or viewer to a signal.	<p>If you use a Scope block for viewing results during simulation, consider also using the Scope block to export data.</p> <p>Save output at a sample rate other than the base sample rate.</p> <p>Scopes store data and can be memory intensive.</p>	Scope
Connect a signal to a To File block.	<p>Consider using a To File block for exporting large amounts of data.</p> <p>Save output at a sample rate other than the base sample rate.</p> <p>Use the MAT-file only after the simulation has completed.</p>	To File
Connect a signal to a To Workspace block.	<p>Document in the diagram the workspace variables used to store signal data.</p> <p>Save output at a sample rate other than the base sample rate.</p>	To Workspace

Export Approach	Usage	Documentation
Connect a signal to a root-level Output block.	Consider using this approach for logging data in a top-level model, if the model already includes an Output block.	Output
Set the signal logging properties for a signal.	<p>Use signal logging to avoid adding blocks.</p> <p>Log signals based on individual signal rates.</p> <p>Data is available only when simulation is paused or completed.</p> <p>Use signal logging to log array of buses signals.</p>	“Export Signal Data Using Signal Logging” on page 59-57

Export Approach	Usage	Documentation
Use the <code>sim</code> command to log simulation data programmatically.	Use <code>sim</code> to export to one data object the time, states, and signal simulation data. Select the Return as single object parameter when simulating the model using the <code>sim</code> command inside a function or a <code>parfor</code> loop.	<code>sim</code>

Enable Simulation Data Export

To export the states and root-level output ports of a model to the MATLAB base workspace during simulation of the model, use one of these interfaces:

- **Configuration Parameters > Data Import/Export** pane (for details, see “Model Configuration Parameters: Data Import/Export”)
- `sim` command

In both approaches, specify:

- The kinds of simulation data that you want to export:
 - Signal logging
 - Time
 - Output
 - State or final state
 - Data store

Each kind of simulation data export has an associated default variable. You can specify your own variables for the exported data.

- The characteristics of the logged data, including:
 - “Data Format for Logged Simulation Data” on page 59-14
 - “Limit Data Logged” on page 59-63
 - “Samples to Export for Variable-Step Solvers” on page 59-53

View Logged Data Using Simulation Data Inspector

To inspect exported simulation data interactively, consider using the Simulation Data Inspector on page 26-48.

The Simulation Data Inspector has some limitations on the kinds of logged data that it displays. See “Limitations of the Simulation Data Inspector” on page 26-62.

Memory Performance

Optimization for Logged Data

When exporting simulation data in a simulation mode other than Rapid Accelerator, Simulink optimizes memory usage in the following situations.

- When time steps happen at regular intervals, Simulink uses compressed time representation. Simulink stores the value for the first timestamp, the length of the interval (time step), and the total number of timestamps.
- When multiple signals use identical sequences of timestamps, the signals share a single stored timestamp sequence. Sharing a single stored timestamp can reduce memory use for logged data by as much as a factor of two. An example when this memory performance can be a critical performance factor is when logging bus signals that have thousands of bus elements.

Logging to Persistent Storage

You can encounter memory issues when you log a large number of signals in a long simulation that has many time steps. Logging to persistent storage can address this kind of memory issue.

To log to persistent storage, in the **Configuration Parameters > Data Import/Export** pane, select **Log Dataset data to file** option. Specify the kinds of logging (for example, signal logging and states logging).

- For logging output and states data, set the **Format** parameter to **Dataset**.
- If you select the **Final states** parameter, clear the **Save complete SimState in final state** parameter.

Using a `Simulink.SimulationData.DatasetRef` object to access signal logging and states logging data loads data into the model workspace incrementally. Accessing data for other kinds of logging loads all of the data at once.

For details, see “Log Data Using Persistent Storage” on page 59-42.

Signal Data Storage for Loading

In this section...

“MATLAB Workspace for Signal Data” on page 59-9

“Source and Signal Builder Blocks for Signal Data” on page 59-10

“MAT-Files for Signal Data” on page 59-11

“Spreadsheets for Signal Data” on page 59-11

Store signal data for loading into a model in these locations:

- MATLAB (base) workspace, or function workspace
- Model workspace
- Function workspace
- Masking workspace
- Blocks
- MAT-files
- Spreadsheets

The MATLAB (base) workspace is the most common workspace to use for loading signal data.

MATLAB Workspace for Signal Data

Consider using the MATLAB (base) workspace when you want to:

- Use a small amount of signal data for iterative simulations.
- Use signal data logged during one simulation as input for another simulation.
- Have multiple models use the same signal data.

Create Signal Data in the MATLAB Workspace

- At the MATLAB command line or editor, create the signal data.
- Use the `xlsread` function to read data from an Excel spreadsheet into the MATLAB workspace.
- Use the `csvread` function to read data from a CSV spreadsheet into the MATLAB workspace.

- Use a model callback to load signal data.
- Use one of these Simulink logging techniques:
 - Signal logging
 - To Workspace block
 - Scope block
 - The **Configuration Parameters > Data Import/Export** pane, the **Output**, **States**, or **Final states** parameters.
 - Data store
 - The `sim` command configured to log simulation data

Load Signal Data from the MATLAB Workspace

To load signal data from a workspace, use one of these techniques:

- Add a From Workspace block.
- Use a root-level input port.
 - Specify workspace variables in the **Configuration Parameters > Data Import/Export > Input** parameter.
 - Use the Root Inport Mapping tool to specify the data for the **Input** parameter.

Source and Signal Builder Blocks for Signal Data

Source blocks, such as the Sine Wave block, generate signals that you can use as inputs to other blocks. Source blocks do not store signal data. Source blocks can be useful for initial prototyping of a model when the generated signal data serves your modeling requirements.

To define signal groups to use as inputs to a model, you can use the Signal Builder block. The Signal Builder block stores the signal group definitions.

Consider using a source block to:

- Avoid having to create the data manually.
- Reduce memory consumption — source blocks do not store signal data.
- Graphically represent in the model the kind of signal data.

Consider using a Signal Builder block to:

- Create and import signal groups for use in testing.

You can use signal groups with Simulink and with these products:

- Simulink Test
- Simulink Verification and Validation
- Switch between signal groups quickly.

MAT-Files for Signal Data

Consider storing signal data in a MAT-file to:

- Load a large amount of signal data efficiently.
- Reuse the same signal data in different models.
- Reduce memory requirements for the model.
- Use different sets of signal data with the same model, with minimal model updates.

Store Signal Data in a MAT-File

To create a MAT-file to store signal data to import, you can use:

- A To File block
- The Root Inport Mapping tool. Export to a MAT-file the signal data that you work on with the tool.
- MATLAB to create signal data that you store in a MAT-file
- `Simulink.saveVars` function to save to a MAT-file the simulation signal data that Simulink stores as workspace variables

Load Signal Data from a MAT-File

To load signal data from a MAT-file into a model, you can use a From File block.

Spreadsheets for Signal Data

Consider using an Excel or CSV spreadsheet to:

- Use an existing spreadsheet that already has the necessary signal data or that you can update easily to contain the signal data.

- Load a large amount of signal data efficiently.
- Reduce memory requirements for the model.
- Use different sets of signal data with the same model, with minimal model updates.
- Share the signal data with other people who do not have Simulink installed.

Store Signal Data in a Spreadsheet

Use one of these approaches:

- Create the signal data directly in the spreadsheet. For spreadsheet requirements, see “Storage Formats” on page 59-142.
- Export MATLAB signal data to an Excel or CSV spreadsheet using the `xlswrite` or `csvwrite` function.

Load Signal Data from a Spreadsheet

Use one of these blocks:

- From Spreadsheet block
- Signal Builder block

The From Spreadsheet and Signal Builder blocks load Microsoft Excel on all platforms. These blocks load CSV spreadsheets only on Microsoft Windows platforms.

The From Spreadsheet incrementally loads the data directly from the spreadsheet, to minimize memory consumption. The Signal Builder block imports all the spreadsheet data into MATLAB memory at one time and saves the data in the block.

Data Format for Logged Simulation Data

In this section...

“Data Format for Block-Based Logged Data” on page 59-14

“Data Format for Model-Based Logged Data” on page 59-14

“Logged Data Store Format” on page 59-14

“Time, State, and Output Data Format” on page 59-14

Data Format for Block-Based Logged Data

You can use the `Scope`, `To File`, or `To Workspace` blocks to export simulation data. Each of these blocks has a data format parameter.

Data Format for Model-Based Logged Data

The data format for model-based exporting of simulation data specifies how Simulink stores the exported data.

Simulink uses different data formats, depending on the kind of data that you export. For details, see:

- “Logged Data Store Format” on page 59-14
- “Time, State, and Output Data Format” on page 59-14

Logged Data Store Format

When you log data store data, Simulink uses a `Simulink.SimulationData.Dataset` object.

For details, see “Accessing Data Store Logging Data” on page 60-41.

Time, State, and Output Data Format

For exported time, states, and output data, use one of the following formats:

- “Dataset” on page 59-15 (default)
- “Array” on page 59-15

- “Structure with Time” on page 59-16
- “Structure” on page 59-18

If you select the **Configuration Parameters > Data Import/Export > Output** check box, Simulink logs fixed-point data as double. To log fixed-point data, consider using one of these approaches:

- Signal logging — For details, see “Export Signal Data Using Signal Logging” on page 59-57.
 - 1 In the Simulink Editor, select one or more signals.
 - 2 Click the **Simulation Data Inspector** button arrow  and click **Log Selected Signals to Workspace**.
- To File block
- To Workspace block — In the To Workspace Block Parameters dialog box, enable the **Log fixed-point data as a fi object** parameter.

For information about the format for logged final state data, see “State Information” on page 59-231.

Dataset

Dataset format:

- Uses MATLAB timeseries objects to store logged data. MATLAB `timeseries` objects allow you to work with logged data in MATLAB without a Simulink license.
- Supports logging multiple data values for a given time step, which can be important for Iterator subsystem and Stateflow signal logging.
- Supports inclusion of units information in logged data for output data
- Does not support logging nonvirtual bus data for code generation or in rapid accelerator mode.

Array

If you select this **Array** option, Simulink saves the states and outputs of a model in a state and output array, respectively.

The state matrix has the name specified in the **Configuration Parameters > Data Import/Export** pane (for example, `xout`). Each row of the state matrix corresponds to a

time sample of the states of a model. Each column corresponds to an element of a state. For example, suppose that your model has two continuous states, each of which is a two-element vector. Then the first two elements of each row of the state matrix contain a time sample of the first state vector. The last two elements of each row contain a time sample of the second state vector.

The model output matrix has the name specified in the **Configuration Parameters > Data Import/Export** pane (for example, `yout`). Each column corresponds to a model output port, and each row to the outputs at a specific time.

Note: Use array format to save your model outputs and states only if the logged data meets *all* these conditions:

- Data is all scalars or all vectors (or all matrices for states)
- Data is all real or all complex
- Data all has the same data type

If your model outputs and states do not meet these conditions, use the **Structure or Structure with time** output formats (see “Structure with Time” on page 59-16).

Structure with Time

If you select this format, Simulink saves the model states and outputs in structures that have their names specified in the **Configuration Parameters > Data Import/Export** pane. By default, the structures are `xout` for states and `yout` for output.

The structure used to save outputs has two top-level fields:

- `time`
Contains a vector of the simulation times.
- `signals`
Contains an array of substructures, each of which corresponds to a model output port.

Each substructure has four fields:

- `values`
Contains the outputs for the corresponding output port.

- If outputs are scalars or vectors — **values** field is a matrix each of whose rows represent an output at the time specified by the corresponding time vector element.
- If the outputs are matrix (2-D) values — **values** field is a 3-D array of dimensions M-by-N-by-T. M-by-N is the dimensions of the output signal and T is the number of output samples.
- If T = 1 — MATLAB drops the last dimension. Therefore, the **values** field is an M-by-N matrix.
- **dimensions**

Specifies the dimensions of the output signal.

- **label**

Specifies the label of the signal connected to the output port, S-Function block, or the type of state (continuous or discrete). The label is **DSTATE** or **CSTATE**, except for S-Function block state labels. For S-Function block state labels for discrete states, the label is the name of the state (instead of **DSTATE**).

- **blockName**

Specifies the name of the corresponding output port or block with states.

- **inReferencedModel**

If the **signals** field records the final state of a block that resides in the reference model, contains a value of 1. Otherwise, the value is false (0).

The following example shows the structure-with-time format for a nonreferenced model.

```
xout.signals(1)
```

```
ans =
```

```

        values: [296206x1 double]
  dimensions: 1
         label: 'CSTATE'
   blockName: 'vdp/x1'
inReferencedModel: 0
```

The structure used to save states has a similar organization. The states structure has two top-level fields:

- `time`

The `time` field contains a vector of the simulation times.

- `signals`

The field contains an array of substructures, each of which corresponds to one of the states of the model.

Each `signals` structure has four fields: `values`, `dimensions`, `label`, and `blockName`. The `values` field contains time samples of a state of the block specified by the `blockName` field. The `label` field for built-in blocks indicates the type of state: either `CSTATE` (continuous state) or `DSTATE` (discrete state). For S-Function blocks, the label contains whatever name is assigned to the state by the S-Function block.

The time samples of a state are stored in the `values` field as a matrix of values. Each row corresponds to a time sample. Each element of a row corresponds to an element of the state. If the state is a matrix, the matrix is stored in the `values` array in column-major order. For example, suppose that the model includes a 2-by-2 matrix state and that 51 samples of the state are logged during a simulation run.

The `values` field for this state would contain a 51-by-4 matrix. Each row corresponds to a time sample of the state, and the first two elements of each row correspond to the first column of the sample. The last two elements correspond to the second column of the sample.

Note: Simulink can read back simulation data saved to the MATLAB workspace in the `Structure with time` output format. See “Examples of Specifying Signal and Time Data” on page 59-228 for more information.

Structure

This format is the same as for `Structure with time` output format, except that Simulink does not store simulation times in the `time` field of the saved structure.

Dataset Conversion for Logged Data

In this section...

“Why Convert to Dataset Format?” on page 59-20

“Results of Conversion” on page 59-21

“Dataset Conversion Limitations” on page 59-23

Why Convert to Dataset Format?

You can use the `Simulink.SimulationData.Dataset` constructor to convert a MATLAB workspace variable that contains data that was logged in one of these formats to `Dataset` format:

- Array
- Structure
- Structure with time
- MATLAB timeseries
- `ModelDataLogs`

Converting data from other Simulink logging formats to `Dataset` format simplifies writing scripts to post-process data logged. For example, a model with multiple To Workspace blocks can use different data formats. Converting the logged data to `Dataset` format avoids the need to write special code to handle different formats.

Different simulation modes have different levels of support for data logging formats. Switching between normal and accelerator modes can require changes to the logging formats used.

The conversion to `Dataset` format also makes it easier to take advantage of features that require `Dataset` format. You can easily convert data logged in earlier releases that used a format other than `Dataset` to work well with `Dataset` data in a more recent release.

The `Dataset` format:

- Uses MATLAB timeseries objects to store logged data, which allows you to work with logging data in MATLAB without a Simulink license. For example, to manipulate the logged data, you can use MATLAB time-series methods such as `filter`, `detrend`, and `resample`.

- Supports logging multiple data values for a given time step, which is important for Iterator subsystem and Stateflow signal logging.

By default, the resulting `Dataset` object uses the variable name as its name. You can use a Name-Value pair to specify a `Dataset` name.

You can use the `Simulink.SimulationData.DataSet.concat` method to combine `Dataset` objects into one concatenated `Dataset` object.

Results of Conversion

`Dataset` objects hold data as elements. To display the elements of a `Dataset` variable, enter the variable name at the MATLAB command prompt. The elements of `Dataset` objects are different types, depending on the data they store. For example, signal logging stores data as `Simulink.SimulationData.Signal` elements and state logging in `Dataset` format stores data as `Simulink.SimulationData.State` elements. Each element holds data as a MATLAB time-series object. At conversion, the elements and time-series field populate as much as possible from the converted object.

Format	Conversion Result Notes
MATLAB time series	<p>If you log nonbus data, during conversion, the software first adds the data as a <code>Simulink.SimulationData.Signal</code> object. It then adds that object as an element of the newly created <code>Dataset</code>.</p> <p>If you log bus data in time-series format, one time series corresponds to each element of a bus. Converting arranges the logged data as a structure with time-series objects as leaf nodes. This structure hierarchy matches the bus hierarchy. Conversion of this type of structure of time-series objects adds the whole structure to a <code>Simulink.SimulationData.Signal</code> object. It then adds that object as an element of the data set.</p> <p>Time-series objects hold relevant information such as block path and timestamps. The conversion tries to preserve this information.</p>

Format	Conversion Result Notes
Structure and structure with time	<p>Structure and structure with time formats do not always contain as much information as if you log in Dataset format. However, before converting structure and structure with time formats, the data structure must have time and signals fields.</p> <p>Conversion populates a Simulink.SimulationData.Signal object with the structure and adds it as an element of the data set. If other information is available, converting also adds it to the element or time-series values. For example, if the structure has a field called blockName, converting adds it to the block path. Otherwise, the block path is empty.</p> <p>When scope data is logged in structure format, the logged structure has a PlotStyle field. The software uses this field to set the interpolation in the Dataset object.</p>
Array	<p>Arrays contain little information. For example, there is no block path information.</p> <p>Conversion adds the array to a Simulink.SimulationData.Signal object and adds it as an element of the Dataset object. The conversion leaves unavailable information such as block path and timestamp fields as either empty or with default values.</p>
ModelDataLogs	<p>Converts data from ModelDataLogs format to Dataset format.</p> <hr/> <p>Note: The ModelDataLogs format is no longer used for signal logging.</p>

Dataset Conversion Limitations

- Converting logged data to **Dataset** format results in a **Dataset** object that contains all the information that the original logged data included. However, if there is no corresponding information for the other **Dataset** properties, the conversion uses default values for that information.
- To log variable-size signals, use the **To Workspace** block. If you convert data logged with **To Workspace** to be **Dataset** format, you lose the information about the variable-size signals.
- When you log a bus signal in array, structure, or structure with time formats, the logged data is organized with:
 - The first column containing the data for the first signal in the bus
 - The second column containing data for the second bus signal, and so on

When you convert that data to **Dataset**, the **Dataset** preserves that organization. But if you log the bus signal in **Dataset** format without conversion, the conversion captures the bus data as a structure of time-series objects.

- If the logged data does not include a time vector, when you convert that data to **Dataset**, the conversion inserts a time vector. There is one time step for each data value. However, the simulation time steps and the **Dataset** time steps can vary.
- **Dataset** format ignores the specification of frame signals. Conversion of structure or structure with time data to **Dataset** reshapes the data for logged frame signals.

Convert Logged Data to Dataset Format

In this section...

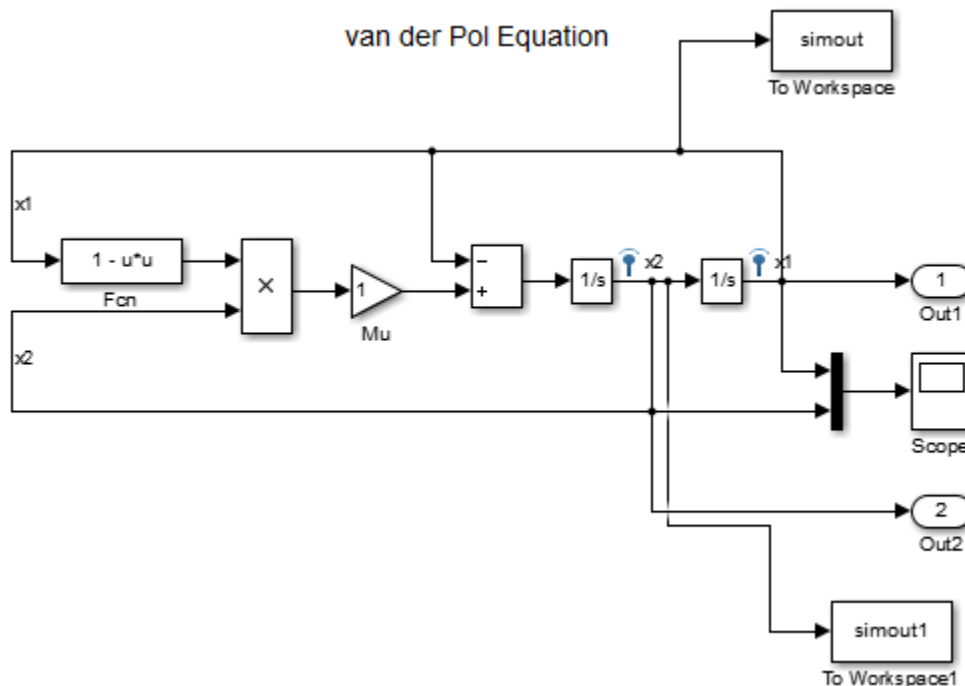

“Convert Workspace Data to Dataset” on page 59-24

“Convert Structure Without Time to Dataset” on page 59-26

“Programmatically Access Logged Dataset Format Data” on page 59-30

Convert Workspace Data to Dataset

This example shows how to convert MATLAB time-series data to **Dataset** format. `myvdp_timeseries` is the `vdp` model with two **To Workspace** blocks configured for `simout` and `simout1` logging data in MATLAB time-series format. Consider using a procedure like this one if you have models that use **To Workspace** blocks to log data to MATLAB time-series format.

Use the `Simulink.SimulationData.Dataset` constructor to convert the MATLAB time-series data to `Dataset` format and then concatenate the two data sets.

- 1 Starting with the `vdp` model, add two To Workspace blocks to the model as shown.
- 2 Set the **Save format** parameter of both blocks. Set `Timeseries`.
- 3 Save the model as `myvdp_timeseries`.
- 4 Simulate the model.

The simulation logs data using the To Workspace blocks.

- 5 Access the signal logging format, `logouts`.

```
logouts
```

```
logouts =
```

```
Simulink.SimulationData.Dataset
Package: Simulink.SimulationData
```

```
Characteristics:
      Name: 'logouts'
  Total Elements: 2
```

```
Elements:
  1: 'x1'
  2: 'x2'
```

```
-Use get or getElement to access elements by index or name.
-Use addElement or setElement to add or modify elements.
```

```
Methods, Superclasses
```

- 6 Convert the MATLAB time-series data from both To Workspace blocks to `Dataset`.

```
ds = Simulink.SimulationData.Dataset(simout);
ds1 = Simulink.SimulationData.Dataset(simout1);
```

`ds` is the variable name of the first To Workspace block data. `ds1` is the variable name of the second To Workspace block data.

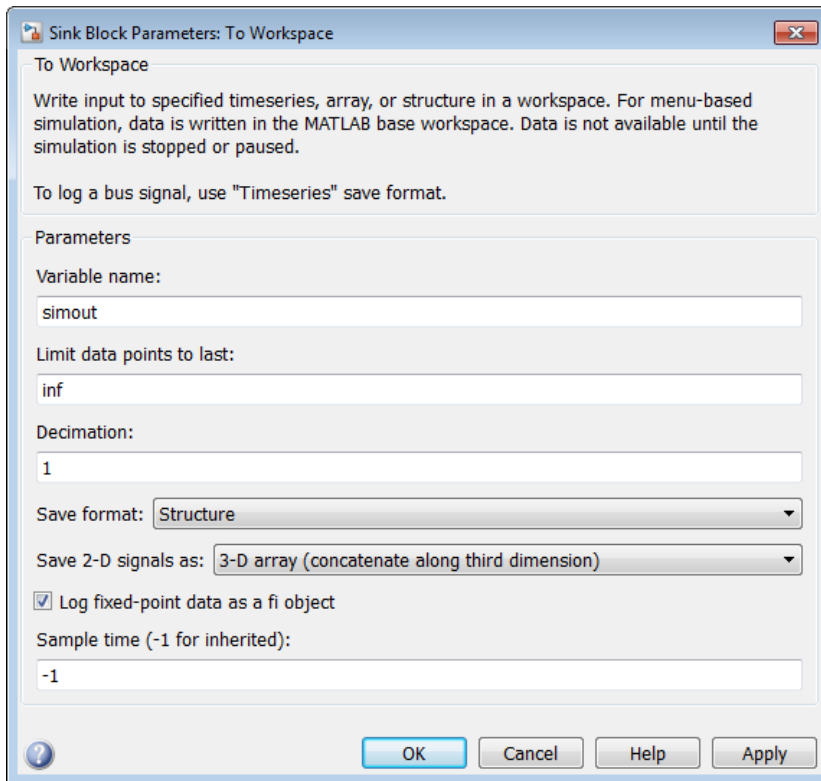

- 7 Concatenate both datasets into `dsfinal`. Observe that the format of `dsfinal` matches that of `logouts`.

```
dsfinal = ds.concat(ds1)
```

```
dsfinal =  
  
    Simulink.SimulationData.Dataset  
    Package: Simulink.SimulationData  
  
    Characteristics:  
        Name: 'simout'  
        Total Elements: 2  
  
    Elements:  
        1: 'x1'  
        2: 'x2'  
  
    -Use get or getElement to access elements by index or name.  
    -Use addElement or setElement to add or modify elements.  
  
    Methods, Superclasses
```

Convert Structure Without Time to Dataset

This example shows how to convert structure without time data to Dataset format. myvdp_structure is the vdp model with two To Workspace blocks configured for simout and simout1 logging data in structure format, as shown.

If you have models that use To Workspace blocks to log data to structure format, consider using a procedure like this one to convert them to **Dataset** format.

- 1 Starting with the vdp model, add two To Workspace blocks to the model as shown.

- 2 In the **Save format** parameter of both blocks, select **Structure**.
- 3 Enable signal logging for the two signals going to the two **To Workspace** blocks to log in **DS** format.
- 4 Save the model as `myvdp_structure`.
- 5 Simulate the model.

The simulation logs data using the **To Workspace** blocks.

- 6 Convert the structure data from both **To Workspace** blocks to **Dataset**.

```
ds = Simulink.SimulationData.Dataset(simout);
ds1 = Simulink.SimulationData.Dataset(simout1);
```

simout is the variable name of the first **To Workspace** block data. *simout1* is the variable name of the second **To Workspace** block data.

With the conversion of structure without time or an array, time starts at $t=0$ and increments by 1.

- 7 Get the values of the first element in *ds*.

```
ds.get(1).Values.Time
```

```
ans =
```

```
0
1
2
3
.
.
.
61
62
63
```

- 8 Get the time values of the first element from signal logging.

```
logslot.get(1).Values.Time
```

```
ans =
```

```
0
0.0001
0.0006
0.0031
.
.
.
19.2802
19.6802
20.0000
```

- 9 Observe the discrepancy in timestamps between
- Data logged in structure without time that you convert to **Dataset** format
 - Data logged in **Dataset** format

Programmatically Access Logged Dataset Format Data

When you use the default `Dataset` signal logging format, Simulink saves the logging data in a `Simulink.SimulationData.Dataset` object. For information about extracting signal data from that object, see the `Simulink.SimulationData.Dataset` reference page.

The `Simulink.SimulationData.Dataset` object contains a `Simulink.SimulationData.Signal` object for each logged signal.

For bus signals, the `Simulink.SimulationData.Signal` object contains a structure of MATLAB `timeseries` objects.

The `Simulink.SimulationData.Dataset` class provides two methods for accessing the signal logging data and its associated information.

Name	Description
<code>Simulink.SimulationData.DataSet.get</code> You can also use the <code>getElement</code> method, which shares syntax and behavior as the <code>get</code> method.	Get element or collection of elements from the dataset, based on index, name, or block path.
<code>Simulink.SimulationData.DataSet.numElements</code>	Get number of elements in the dataset.

For example of accessing signal logging data that uses the `Dataset` format, see `Simulink.SimulationData.Dataset`.

Access Array of Buses Signal Logging Data

Signal logging data for an array of buses uses `Dataset` signal logging format.

The general approach to access data for a specific signal in an array of buses is:

- 1 Use a `Simulink.SimulationData.Dataset.get` (or `getElement`) method to access a specific signal in the logged data (by default, the `logouts` variable).
- 2 To get the values, index within the array of buses.
- 3 Index again to get data for a specific bus.

For example, to obtain the signal logging data for the `Constant6` block in the `ex_log_nested_aob` model, for the `topBus` signal that feeds the `Terminator` block:

```
logouts.getElement('topBus').Values.a(2,2).firstConst.data
```

Here are additional examples of accessing array of buses signal logging data. For another example that shows how to log array of buses data, see `sldemo_md1ref_bus`.

Simple Array of Buses

The `ex_log_simple_aob` model includes an array of buses signal `AoBSig` that combines two bus signals (`busSig1` and `busSig2`).

To access the signal logging data for the array of buses signal, navigate through the structure hierarchy and use an index to access a specific node. This example shows navigation to the `chirpSig` signal value in `busSig2`.

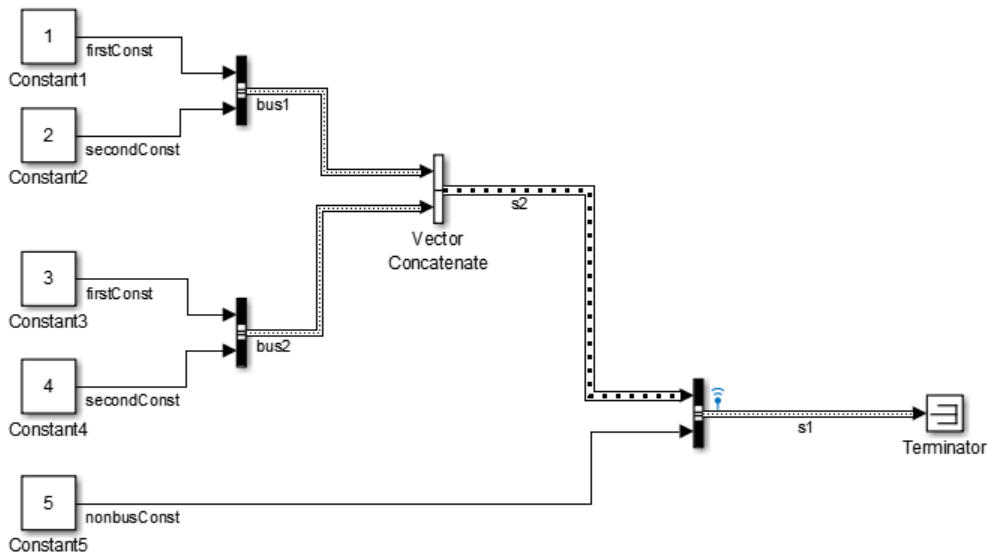

```
logout.getElement('AoBSig').Values(2).chirpSig.Data
```

```
ans=
```

```
0
0.9585
```

Array of Buses in a Bus

The `ex_log_aob_in_bus` model has an array of buses (`s2`) that feeds into bus `s1`.

This example shows navigation to the `Constant3` block, which is a signal in `bus2`.

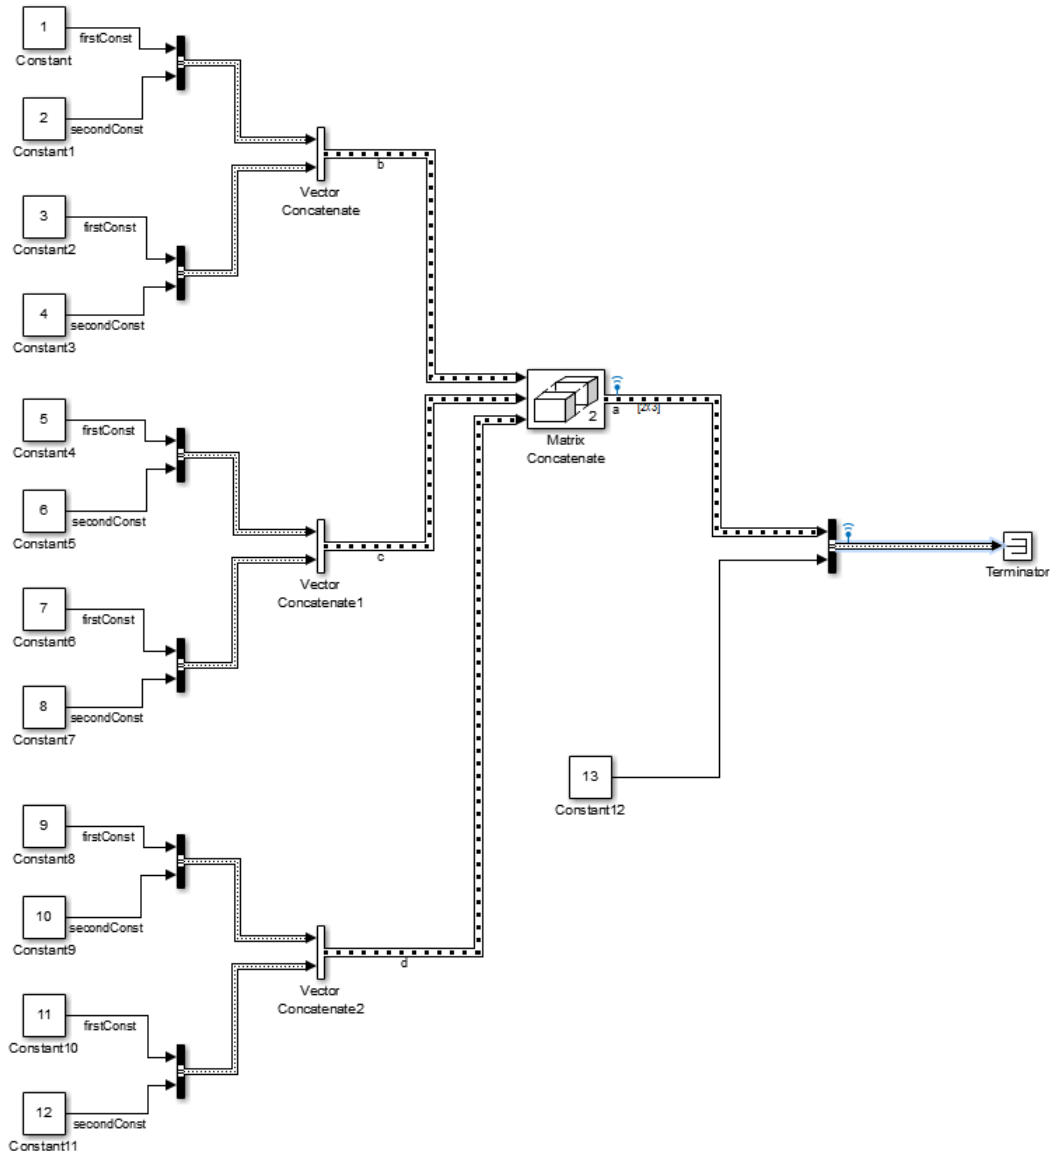

```
logout.getElement('s1').Values.s2(2).firstConst.Data
```

```
ans=
```

```
3

Nested Arrays of Buses

The `ex_log_nested_aob` model has an array of buses (`a`) that is made up of three arrays of buses: `b`, `c`, and `d`. The Matrix Concatenate block combines the nested arrays of buses into array of buses `a`.

This example shows navigation to the Constant6 block.

```
logout.getElement('topBus').Values.a(2,2).firstConst.Data
```

Accessing Data for Signals with a Duplicate Name

For a model with multiple signals that have the same signal name, signal logging data includes a `Simulink.SimulationData.Signal` object for each signal that has a duplicate name.

To access a specific signal that has a duplicate name, use *one* of these approaches:

- To find the data for the specific signal, visually inspect the displayed output of `Simulink.SimulationData.Signal` objects.
- Use the `Simulink.SimulationData.Dataset.getElement` method, specifying the blockpath for the source block of the signal.
- To iterate through the signals with a duplicate signal name, create a script using the `Simulink.SimulationData.Dataset.getElement` method with an index argument.
- Use the Signal Properties dialog box to specify a different name. Consider using this approach when the signals with a duplicate name do not appear in multiple instances of a referenced model in normal mode.
 - 1 In the model, right-click the signal.
 - 2 In the context menu, select **Properties**.
 - 3 In the Signal Properties dialog box, set **Logging name** to **Custom** and specify a different name than the signal name.

- 4 Simulate the model and use the `Simulink.SimulationData.Dataset.getElement` method with a name argument.

Tip Alternatively, you can use the Signal Logging Selector to access a specific signal. For details, see “Override Signal Logging Settings with the Signal Logging Selector” on page 59-80.

Handling Newline Characters in Signal Logging Data

To handle newline characters in logging names in signal logging data that uses `Dataset` format, use a `sprintf` command within a `getElement` call. For example:

```
topOut.getElement(sprintf('INCREMENT\nBUS'))
```

Log Signal Data That Uses Units

To have logged data include the units specified for signals, use the **Dataset** or **Timeseries** logging format, which stores logging information in MATLAB **timeseries** objects.

Signal logging uses **Dataset** format. Output logging (**Configuration Parameters > Data Import/Export > Output**) uses **Dataset** as the default format. The default save format for the To File and To Workspace blocks is **Timeseries**.

If you use **Dataset** or **Timeseries** format for signal logging or for To File block or To Workspace block logging, the logged data includes units information.

To capture units information for output logging:

- 1 Set the **Configuration Parameters > All Parameters > Format** parameter to **Dataset**.
- 2 In the Block Parameters dialog box for Output blocks for which you want to capture units information, set the **Unit** parameter to match the units of the input signal.

For example, in this model the In1 block has its **Unit** parameter set to **newton** and In2 block uses **m** (meters). Open the model. After you simulate the model, you can see the units for the logged data.

- You can view the units in the signal logging data for **signal1** of the bus signal **b**.

```
logout.get('a').Values.signal1.DataInfo
```

```
tsdata.datametadate
Package: tsdata
```

```
Common Properties:
```

```
Units: newton (Simulink.SimulationData.Unit)
```

```
Interpolation: linear (tsdata.interpolation)
```

- You can view the units in the data logged in the To Workspace block.

```
simout1.signal2.DataInfo.Units
```

```
ans =
```

```
Units with properties:
```

```
Name: 'm'
```

This example model shows how to view the data logged in a Time Scope block. Open the model.

To use the Time Scope block to log data, in the scope select **Configuration Properties** > **Logging** > **Log data to workspace** and specify a variable (ScopeData in this example). The In3 block uses m (meters). Simulate the model and then at the MATLAB command line, enter:

```
ScopeData.get(1).Values.DataInfo.Units
```

```
ans =
```

```
Units with properties:
```

```
Name: 'm'
```

Limit Amount of Exported Data

In this section...

“Decimation” on page 59-39

“Limit Data Points” on page 59-40

“Logging Intervals” on page 59-40

You can use several options to reduce the amount of data logged during a simulation. Limiting the amount of exported simulation data reduces memory usage and speeds up simulation. You can use multiple techniques for the same simulation.

Technique	Description
Specify a decimation factor	Skip samples when exporting data.
Limit data points	Limit the number of samples saved to be only the most recent samples
Specify an interval for logging	Specify ranges of time steps for logging

Alternatively, for logging large amounts of data that can cause memory issues, consider logging to persistent storage. This approach preserves all of the logging data, minimizing MATLAB workspace memory usage. For details, see “Log Data Using Persistent Storage” on page 59-42.

Decimation

To skip samples when exporting data, apply a decimation factor. For example, a decimation factor of 2 saves every other sample. By default, decimation is set to 1, which does not skip any samples.

The approach you use to specify a decimation factor depends on the kind of logging data.

Data	How to Specify
Signal logging	Right-click the signal. In the Signal Properties dialog box, select the Decimation parameter.

Data	How to Specify
Data store logging	From the Block Parameters dialog box for that block, open the Logging tab. Apply a decimation factor using the Decimation parameter.
State and output	Enter a value in the field to the right of the Decimation label.

Limit Data Points

To limit the number of samples saved to be only the most recent samples, set the **Limit Data Points** parameter.

The approach you use depends on the kind of logging data.

Data	How to Specify
Signal logging	Right-click the signal. In the Signal Properties dialog box, select the Limit Data Points to Last parameter.
Data store logging	From the Block Parameters dialog box for that block, open the Logging tab. Select the Limit Data Points to Last parameter.
Time, state, and output logging	Select the Configuration Parameters > All Parameters > Limit data points parameter and for the Configuration Parameters > All Parameters > Maximum number of data points parameter, specify the limit.

Logging Intervals

To specify an interval for logging, use the **Configuration Parameters > Data Import/Export > Logging intervals** parameter. Limiting logging to a specified interval allows you to examine specific logged data without changing the model or adding complexity to a model.

The logging intervals apply to data logged for:

- Time
- States
- Output
- Signal logging
- The To Workspace block
- The To File block

The logging intervals do not apply to final state logged data, scopes, or streaming data to the Simulation Data Inspector.

The intervals specified with **Logging intervals** establish the set of times to which the **Decimation** and **Limit data points to last** parameters apply. For example, suppose that you set the logging interval [2, 4; 7, 9] with a fixed-step solver with a fixed-step size of 1. The logged times are 2, 3, 4, 7, 8, and 9.

Log Data Using Persistent Storage

In this section...

“When to Use Persistent Storage” on page 59-42

“General Workflow for Logging to Persistent Storage” on page 59-44

“Supported Logging Techniques” on page 59-44

“Use Dataset Format for Logging” on page 59-44

“Enable Logging to Persistent Storage” on page 59-45

“How Simulation Data is Stored” on page 59-45

“Save Logged Data from Successive Simulations” on page 59-45

You can store logged simulation data to persistent storage in a MAT-file. Using persistent storage minimizes the amount of logged data stored in memory during simulation.

You control logging to persistent storage at the model level. You can enable and disable the feature by changing one model configuration parameter without changing the model layout.

To access the logged data from the file, you can either create reference objects in the MATLAB workspace or load the entire data at once. A reference object identifies the file and the logging variable (for example, `logouts` for signal logging data) for the logged data that you want to access. When you access signal logging and state logging data, Simulink loads that data into the workspace incrementally.

When to Use Persistent Storage

You can encounter memory issues when you log a large number of signals in a long simulation that has many time steps. Logging to persistent storage can address these kinds of memory issues. Persistent storage is also useful for logging when you run simulations in parallel.

By default, logging to persistent storage is disabled, so that logged data is stored in the MATLAB workspace. For many models, logging to the workspace is simpler because it avoids loading and saving logging files.

For very short simulations, logging to the MATLAB workspace can be faster and possibly use less memory than logging to persistent storage.

Limitations for Logging to Persistent Storage

- Only data logged in **Dataset** format is stored in the MAT-file. Data logged in other formats is stored in the MATLAB workspace.
- To use persistent storage for logging final states data, you cannot enable the **Configuration Parameters > Data Import/Export > Save complete SimState in final state**.
- The Simulation Stepper and fast restart do not support logging to persistent storage.
- During simulation, you cannot load data from the persistent storage file directly into the model.

Alternative Approaches for Reducing Logging Memory Usage

If simulating a model that uses logging does cause memory issues, use one of these alternatives instead of logging to persistent storage:

- Limit the amount of simulation data stored in the workspace.

You can limit the amount of simulation data stored in the workspace by using one or more of these techniques. For details, see “Limit Amount of Exported Data” on page 59-39.

Technique	Description
Specify a decimation factor.	Skip samples when exporting data.
Limit data points.	Limit the number of samples saved to be only the most recent samples.
Specify intervals for logging.	Specify ranges of time steps for logging.

However, if you limit the amount of simulation data, the logged data can skip some time steps that are critical for testing and analyzing the model.

- Use a To File block for each signal that you want to log.

Connecting a To File block to signals that you want to log stores the logged data in a MAT-file, rather than in the MATLAB workspace. However, this approach:

- Is a per-signal approach that can clutter a model with multiple To File blocks attached to individual signals.
- Creates a separate MAT-file for each To File block, compared to the one MAT-file used by logging to persistent storage.

General Workflow for Logging to Persistent Storage

Use this workflow to log data to persistent storage and access that data. Use the **Configuration Parameters > Data Import/Export** pane to configure a model to log to persistent storage.

- 1 Select the kinds of logging to perform (for example, signal logging and states logging) and specify the variables for the logging. See “Supported Logging Techniques” on page 59-44.
- 2 Use `Dataset` format for logging the data.
- 3 Enable logging to persistent storage and specify an output MAT-file name. “Enable Logging to Persistent Storage” on page 59-45.
- 4 Simulate the model.
- 5 Get a list of the `Dataset` variables in the MAT-file.
- 6 Create a reference object for each kind of simulation data you want to access from the MAT-file.
- 7 Access the data.

Supported Logging Techniques

You log to persistent storage `Dataset` format data for these kinds of logging:

- Signal logging
- States
- Final states
- Output
- Data stores

Use Dataset Format for Logging

Logging to persistent storage stores `Dataset` format logging data in the MAT-file. Data that is logged in any other format is stored in the workspace.

Signal logging and data store logging use `Dataset` format. The default format for logged output, states, and final states is `Dataset`.

For final states logging, also clear the **Save complete SimState in final state** parameter.

Enable Logging to Persistent Storage

Select the **Log Dataset data to file** parameter. Specify the MAT-file to use. Do not use a file name from one locale in a different locale.

You can programmatically log to persistent storage. To enable logging to persistent storage, use the `LoggingToFile` and `LoggingFileName` name-value pairs with either the `sim` command or `set_param` command.

To enable the logging approaches that you want to use, set these parameters to 'on':

- `SignalLogging`
- `SaveState`
- `SaveFinalState`
- `SaveOutput`
- `DSMLogging`
- To log output, states, and final states data to persistent storage, set the `SaveFormat` parameter to 'Dataset'.
- To log final states data to persistent storage, set the `SaveCompleteFinalSimState` to 'off'.

How Simulation Data is Stored

Logging to persistent storage saves logged simulation data in the specified MAT-file a `Simulink.SimulationData.Dataset` object for the data for each kind of logging that uses `Dataset` format. The data set object name in the file is the name of the variable that you used for logging. For example, if you use the default signal logging variable `logstdout`, then the data set object in the MAT-file is `logstdout`.

Save Logged Data from Successive Simulations

Each time you simulate the model, Simulink overwrites the contents of the MAT-file unless you change the name of the file between simulations. When you use a `Simulink.SimulationData.DatasetRef` object that references data in the MAT-file to retrieve the data in the file, it retrieves the most recent version of the data.

To preserve data from an earlier simulation, you can use one of these approaches:

- Between simulations, use the **Configuration Parameters > Data Import/Export** pane to specify a different name for MAT-file for logging.
- Between simulations, save a copy of the MAT-file, using a different file name than the name that you specify as the MAT-file for persistent storage, or move the MAT-file.
- Programmatically specify a new file name for each simulation run.

If you change the file name used for logging to persistent storage, then to access the logged data, you need to either create new reference objects or change the `Location` property of the reference objects to match the new file name. For details about using reference objects to access logged data, see “Access Logged Data from Persistent Storage” on page 59-48.

Access Logging Metadata

Simulink stores metadata about logging to persistent storage. When you run multiple simulations using parallel simulations or batch processing, specify a different persistent storage MAT-file for each simulation. Then you can use the metadata to provide context for analyzing the logged data stored in each file.

If you use single simulation output, Simulink creates a `Simulink.SimulationMetadata` object, which includes in its `ModelInfo` structure a `LoggingInfo` structure with two fields:

- `LoggingToFile` — Indicates whether logging to persistent storage is enabled ('on' or 'off')
- `LoggingFileName` — Specifies the resolved file name for the persistent storage MAT-file (if `LoggingToFile` is 'on').

The MAT-file used for persistent storage contains a `SimulationMetadata` variable that stores the same simulation metadata as the `Simulink.SimulationMetadata` object. The `SimulationMetadata` is a system-generated name, not a variable name that you specify.

To access the persistent logging storage metadata, use one of these alternatives:

- Load the `SimulationMetadata` variable into memory. For example:

```
load('out', 'SimulationMetadata');
```
- Access the metadata by using the `Simulink.SimulationOutput.getSimulationMetadata` function:

```
metaData = out.getSimulationMetadata
```

Access Logged Data from Persistent Storage

In this section...

“Access Data Logged to Persistent Storage” on page 59-48

“Access Data Store Data” on page 59-49

“Get List of Dataset Variables” on page 59-49

“Create References to Persistent Storage Dataset Objects” on page 59-49

You can access data logged to persistent storage for analysis in MATLAB. Data logged in a format other than `Dataset` format is stored in the MATLAB workspace.

Tip If you saved logging data to more than one MAT-file for persistent storage, you can use the simulation metadata in each file to provide context for analyzing the logged data. For details, see “Access Logging Metadata” on page 59-46.

Access Data Logged to Persistent Storage

To access logged data stored in MAT-file:

- 1 Create a `Simulink.SimulationData.DatasetRef` reference object for each kind of logged data you want to access. For example, to access signal logging data and states logging data in a MAT-file, create two reference objects.
- 2 Use these `Simulink.SimulationData.DatasetRef` methods to access the data:
 - `numElements`
 - `getElementNames`
 - `get` (or the alias `getElement`)

When you access signal logging, output, or states logging data from a MAT-file, Simulink reads the data to the MATLAB workspace incrementally (signal by signal).

When you use a `Simulink.SimulationData.DatasetRef` object that references data in a MAT-file to retrieve the data in the file, it retrieves the most recent version of the data.

For an example of accessing data logged to persistent storage, see “Create References to Persistent Storage Dataset Objects” on page 59-49.

Access Data Store Data

To access logged data store data, use the same approach as for accessing signal logging, output, and states logging data (see “Access Data Logged to Persistent Storage” on page 59-48).

However, when you access output or data store logging information from a MAT-file, Simulink loads all of that data into the MATLAB workspace.

Get List of Dataset Variables

To create a reference to persistent storage `Dataset` objects in the MAT-file that stores the logged data, you need to know the names of the `Dataset` variables in the file. You can use the `Simulink.SimulationData.DatasetRef.getDatasetVariableNames` function to get a list of the `Dataset` variables in a MAT-file.

Tip To get the names of `Dataset` variables in the MAT-file, using the `Simulink.SimulationData.DatasetRef.getDatasetVariableNames` function processes faster than using the `who` or `whos` functions.

Create References to Persistent Storage Dataset Objects

This example shows how to construct and use `Simulink.SimulationData.DatasetRef` objects to access data for a model that logs to persistent storage. This simple example shows the basic steps for logging to persistent storage. This example does not represent a realistic situation for logging to persistent storage, because it shows a short simulation with small memory requirements.

- 1 Open the vdp model.
- 2 In the **Configuration Parameters > Data Import/Export** pane, select these parameters:
 - **States**
 - **Log Dataset data to file**

Set the **Format** parameter to **Dataset**.

Leave the other parameter settings as they are and click **Apply**.

- 3 In the model, right-click a signal and in the Signal Properties dialog box, select **Log signal data**.
- 4 Simulate the model.
- 5 Get a list of `Dataset` variable names in the `out.mat` file.

```
varNames = Simulink.SimulationData.DatasetRef.getDatasetVariableNames('out.mat')
```

```
varNames =
```

```
    'xout'    'logout'
```

- 6 Create a reference to the logged states data that is stored in `out.mat`. The variable for the logged states data is `xout`.

```
statesLogRef = Simulink.SimulationData.DatasetRef('out.mat','xout')
```

```
statesLogRef =
```

```
Simulink.SimulationData.DatasetRef
Package: Simulink.SimulationData

Characteristics:
    Location: out.mat (H:\out.mat)
    Identifier: xout
```

```
Resolved Dataset:
    Name: 'xout'
    Total Elements: 2
```

```
Elements:
    1 : ''
    2 : ''
```

```
Methods, Superclasses
```

- 7 Create a reference to the signal logging data that is stored in `out.mat`. The variable for the signal logging data is `logout`.

```
sigLogRef = Simulink.SimulationData.DatasetRef('out.mat','logout')
```

```
sigLogRef =
```

```
Simulink.SimulationData.DatasetRef
Package: Simulink.SimulationData
```

```

Characteristics:
  Location: out.mat (H:\out.mat)
  Identifier: logstdout

```

```

Resolved Dataset:
  Name: 'logstdout'
  Total Elements: 1

```

```

Elements:
  1 : 'x1'

```

Methods, Superclasses

- 8** Use the `DatasetRef` object to access the number of elements in the logged states data set.

```
statesLogRef.numElements
```

```
ans =
```

```
2
```

- 9** Use the `DatasetRef` to access the first element of the signal logging data set.

```
sigLogRef.get(1)
```

```
ans =
```

```

Simulink.SimulationData.Signal
Package: Simulink.SimulationData

```

Properties:

```

  Name: 'x1'
  PropagatedName: ''
  BlockPath: [1x1 Simulink.SimulationData.BlockPath]
  PortType: 'outport'
  PortIndex: 1
  Values: [1x1 timeseries]

```

Methods, Superclasses

- 10** Delete the persistent storage MAT-file and try to use one of the `DatasetRef` objects.

```

delete('out.mat');
statesLogRef.get(1)

```

File does not exist.

The `statesLogRef` still exists, but it is a reference to a `Dataset` object that is in a file that no longer exists.

Samples to Export for Variable-Step Solvers

In this section...

“Output Options” on page 59-53

“Refine Output” on page 59-53

“Produce Additional Output” on page 59-54

“Produce Specified Output Only” on page 59-55

Output Options

Use the **Output options** list under **Configuration Parameters > Data Import/Export > Additional parameters** to control how much output the simulation generates when your model uses a variable-step solver.

- Refine factor (default)
- Produce additional output
- Produce specified output only

Refine Output

The **Refine output** option provides additional output points when the simulation output does not include as many points as you would like. This parameter provides an integer number of output points between time steps. For example, a refine factor of 2 provides output midway between the time steps and at the steps. The default refine factor is 1.

Suppose that a sample simulation generates output at these times:

0, 2.5, 5, 8.5, 10

Choosing **Refine output** and specifying a refine factor of 2 generates output at these times:

0, 1.25, 2.5, 3.75, 5, 6.75, 8.5, 9.25, 10

To get smoother output more efficiently, change the refine factor instead of reducing the step size. When you change the refine factor, the solver generates additional points by evaluating a continuous extension formula at sample points. This option changes

the simulation step size so that time steps coincide with the times that you specify for additional output.

The refine factor applies to variable-step solvers and is most useful when you are using `ode45`. The `ode45` solver can take large steps. However, when you graph simulation output, the output from this solver sometimes is not sufficiently smooth. In such cases, run the simulation again with a larger refine factor. A value of such as 4 for `ode45` can provide much smoother results.

Note This option helps the solver locate zero crossings, although it does not ensure that Simulink detects all zero crossings (see “Zero-Crossing Detection” on page 3-24).

Produce Additional Output

Use the `Produce additional output` option to specify directly those additional times at which the solver generates output. When you select this option, the **Data Import/Export** pane displays an **Output times** parameter. In this parameter, enter a MATLAB expression that evaluates to an additional time or a vector of additional times. The solver produces hit times at the output times that you specify, in addition to the times it requires for accurate simulation.

Suppose that a sample simulation generates output at these times:

0, 2.5, 5, 8.5, 10

Choosing the `Produce additional output` option and specifying `[0:10]` generates output at these times:

0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10

and perhaps at additional times, depending on the step size chosen by the variable-step solver.

Tips

- This option helps the solver locate zero crossings, although it does not ensure that Simulink detects all zero crossings (see “Zero-Crossing Detection” on page 3-24).
- Set the **Output times** parameter to a value other than the default empty matrix (`[]`).
- For triggered subsystems and function-call subsystems, the calling function must inherit the sampling rate.

Produce Specified Output Only

Simulink generates output at the start and stop times, in addition to the times that you specify.

Suppose that a sample simulation generates output at these times:

0, 2.5, 5, 8.5, 10

Choosing the **Produce specified output only** option and specifying [1:9] generates output at these times:

0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10

This option changes the simulation step size so that time steps coincide with the times that you specify for producing output. The solver can hit other time steps to accurately simulate the model. However, the output does not include these points. This option is useful when you are comparing different simulations to check that the simulations produce output at the same times.

Tips

- This option helps the solver locate zero crossings, although it does not ensure that Simulink detects all zero crossings (see “Zero-Crossing Detection” on page 3-24).
- Set the **Output times** parameter to a value other than the default empty matrix ([]).
- In normal, accelerator, and rapid accelerator modes, Simulink generates output at the start and stop times, as well as at the times that you specify.
- When you simulate a model in normal mode, triggered subsystems and function-call subsystems use:
 - The times that you specify
 - All the time steps in between the values that you specify
 - The simulation start and stop times
- For triggered subsystems and function-call subsystems, the calling function must inherit the sampling rate.

Export Signal Data Using Signal Logging

In this section...

“Signal Logging” on page 59-57

“Signal Logging Workflow” on page 59-57

“Signal Logging in Rapid Accelerator Mode” on page 59-58

“Signal Logging Limitations” on page 59-58

Signal Logging

To capture signal data from a simulation, usually you can use signal logging. Mark the signals that you want to log and enable signal logging for the model. For details, see “Configure a Signal for Logging” on page 59-60 and “Enable Signal Logging for a Model” on page 59-75.

For a summary of other approaches to capture signal data, see “Export Simulation Data” on page 59-3.

Signal Logging Workflow

To collect and use signal logging data, perform these tasks.

- 1 Mark individual signals for signal logging. See “Configure a Signal for Logging” on page 59-60.
- 2 Enable signal logging for a model. See “Enable Signal Logging for a Model” on page 59-75.
- 3 Simulate the model.
- 4 Access the signal logging data. See “Access Signal Logging Data” on page 59-93.

Log Subsets of Signals

One approach for testing parts of a model as you develop it is to mark a superset of signals for logging. Then overriding signal logging settings to select different subsets of signals for logging. You can use the Signal Logging Selector or a programmatic interface. See “Override Signal Logging Settings” on page 59-79.

Use this approach to log signals in models that use model referencing. See “Models with Model Referencing: Overriding Signal Logging Settings” on page 59-83.

Additional Signal Logging Options

With the basic signal logging workflow, you can specify additional options related to the data that signal logging collects and to how that data is displayed. You can:

- Specify a name for the signal logging data for a signal. See “Specify Signal-Level Logging Name” on page 59-62.
- Control how much data the simulation generates for a signal. See “Limit Data Logged” on page 59-63.
- Review the signal logging configuration for a model. See “View the Signal Logging Configuration” on page 59-68.
- Specify the samples for export for models with variable-step solvers. See “Samples to Export for Variable-Step Solvers” on page 59-53.
- Configure the model to display signal logging data in the Simulation Data Inspector. See “View Data in Simulation Data Inspector” on page 59-93.

Signal Logging in Rapid Accelerator Mode

Signal logging in rapid accelerator mode does not log the following kinds of signals. When you update or simulate a model that contains these signals, Simulink displays a warning that those signals are not logged.

- Signals inside Stateflow charts
- Signals that use a custom data type

If you set the **Configuration Parameters > Solver > Periodic sample time constraint** parameter to **Ensure sample time independent**, you cannot use signal logging in rapid accelerator mode.

Signal Logging Limitations

- Rapid accelerator mode supports signal logging, with the requirements and limitations described in “Signal Logging in Rapid Accelerator Mode” on page 59-58.
- Top-model and Model block software-in-the-loop (SIL) and processor-in-the-loop (PIL) simulation modes support signal logging. For a description of limitations, see “Top-Model SIL/PIL Limitations” and “Model Block SIL/PIL Limitations” in the Embedded Coder documentation.

- Array of buses signals support signal logging, with the requirements described in “Import Array of Buses Data” on page 59-159.
- You cannot log signals in For Each subsystems.
- You cannot log local data in Stateflow Truth Table blocks.

Configure a Signal for Logging

In this section...

- “Mark a Signal for Signal Logging” on page 59-60
- “Specify Signal-Level Logging Name” on page 59-62
- “Limit Data Logged” on page 59-63
- “Set Sample Time for a Logged Signal” on page 59-64

Mark a Signal for Signal Logging

Enable logging by marking a signal, using one of the following techniques:

- “Enable Signal Logging Using Simulink Editor Menu Options” on page 59-60
- “Enable Signal Logging Using Signal Properties” on page 59-61
- “Enable Signal Logging by Using the Model Data Editor” on page 59-61
- “Programmatic Interface” on page 59-61

The Simulink Editor menu options generally are the simplest way to mark signals for signal logging.

A signal for which you enable signal logging is a *logged signal*. By default, Simulink displays a logged signal indicator  for each logged signal.

Enable Signal Logging Using Simulink Editor Menu Options

1 In the Simulink Editor, select one or more signals.

2

Click the **Simulation Data Inspector** button arrow  and click **Log Selected Signals to Workspace**.

Alternatively, you can select one or more signals and check **Simulation > Output > Log Selected Signals to Workspace**.

If you select multiple signals, the signal logging configuration that Simulink sets depends on whether any of the selected signals are marked for signal logging.

Signal Logging for Selected Signals	Result of Enabling the Log/Unlog Selected Signals Option
At least one of the selected signals does not have signal logging enabled.	Enables signal logging for all the selected signals
All selected signals have signal logging enabled.	Disables signal logging for all the selected signals

Enable Signal Logging Using Signal Properties

- 1 In the Simulink Editor, right-click the signal.
- 2 From the context menu, select **Signal Properties**.
- 3 In the Signal Properties dialog box, in the **Logging and accessibility** tab, select **Log signal data**.
- 4 Click **OK**.

Enable Signal Logging by Using the Model Data Editor

The Model Data Editor enables you to view a flat list of signals in your model. You can sort, group, and filter the list. Use this technique to enable logging for:

- Many signals at once, especially when the signals are not close to each other in the block diagram.
- Signals that are difficult to locate in a large model or hierarchy of subsystems.

To open the Model Data Editor, in a model, select **View > Model Data**. In the Model Data Editor, on the **Signals** tab, set the **Change View** drop-down list to **Instrumentation** and use the **Log Data** column. For information about the Model Data Editor, see “Configure Data Properties by Using a Table” on page 57-103.

Programmatic Interface

To enable signal logging programmatically for selected blocks, use the output `DataLogging` property. Set this property using the `set_param` command. For example:

- 1 At the MATLAB Command Window, open a model. Type

```
vdp
```
- 2 Get the port handles of the signal that you want to log. For example, for the Mu block outputport signal.

```
ph = get_param('vdp/Mu', 'PortHandles')
```

- 3 Enable signal logging for the desired output signal.

```
set_param(ph.Outport(1), 'DataLogging', 'on')
```

The logged signal indicator appears.

Logging Referenced Model Signals

You can log any logged signal in a referenced model. Use the Signal Logging Selector to configure signal logging for a model reference hierarchy. For details, see “Models with Model Referencing: Overriding Signal Logging Settings” on page 59-83.

Specify Signal-Level Logging Name

You can specify a signal-level logging name to the object that Simulink uses to store logging data for a signal. Specifying a signal-level logging name can be useful for signals that are unnamed or that share a duplicate name with another signal in the model hierarchy. Specifying signal-level logging names, rather than using the names that Simulink generates, can make the logged data easier to analyze.

To specify a signal-level logging name, use *one* of the following approaches:

- “Signal-Level Logging Name in the Editor” on page 59-62
- “Signal-Level Logging Name in Model Explorer” on page 59-63
- “Signal-Specific Logging Name Specified Programmatically” on page 59-63

If you do not specify a custom signal-level logging name, Simulink uses the signal name. If the signal does not have a name, the action Simulink uses a blank name.

Note: The signal-level logging name is distinct from the model-level signal logging name. The model-level signal logging name is the name for the object containing all the logged signal data for the whole model. The default model-level signal logging name is `log sout`. For details about the model-level signal logging name, see “Specify a Name for Signal Logging Data” on page 59-78.

Signal-Level Logging Name in the Editor

- 1 In the Simulink Editor, right-click the signal.
- 2 From the context menu, select **Signal Properties**.

- 3 Specify the logging name:
 - a In the Signal Properties dialog box, select the **Logging and accessibility** tab.
 - b From the **Logging name** list, select **Custom**.
 - c Enter the logging name in the adjacent text field.

Signal-Level Logging Name in Model Explorer

- 1 In the Model Explorer **Model Hierarchy** pane, select the node that contains the signal for which you want to specify a logging name.
- 2 If the **Contents** pane does not display the `LoggingName` property, add the `LoggingName` property to the current view. For details about column views, see “Control Model Explorer Contents Using Views” on page 12-29.
- 3 Enter a logging name for one or more signals using the `LoggingName` column.

Signal-Specific Logging Name Specified Programmatically

Enable signal logging programmatically for selected blocks with the output `DataLogging` property. Set this property using the `set_param` command.

- 1 At the MATLAB Command Window, open a model. For example, type:

```
vdp
```
- 2 Get the port handles of the signal that you want to log. For example, for the Mu block output signal:

```
ph = get_param('vdp/Mu', 'PortHandles');
```

- 3 Enable signal logging for the desired output signal:

```
set_param(ph.Output(1), 'DataLogging', 'on');
```

The logged signal indicator appears.

- 4 Issue commands that use the `DataLoggingNameMode` and `DataLoggingName` parameters. For example:

```
set_param(ph.Output(1), 'DataLoggingNameMode', 'Custom');
set_param(ph.Output(1), 'DataLoggingName', 'x2_log');
```

Limit Data Logged

You can limit the amount of data logged for a signal by:

- Specifying a decimation factor
- Limiting the number of samples saved to be only the most recent samples

You can limit data logged for a signal by using the Signal Properties dialog box, the Model Explorer, the Signal Logging Selector, or programmatically. The following sections describe the first two approaches.

Use Signal Properties to Limit Logged Data

- 1 In the Simulink Editor, right-click the signal.
- 2 From the context menu, select **Signal Properties**.
- 3 In the Signal Properties dialog box, click the **Logging and accessibility** tab. Then select one or both of these options:
 - **Limit data points to last**
 - **Decimation**

Use Model Explorer to Limit Data Logged

- 1 In the Model Explorer **Model Hierarchy** pane, select the node that contains the signal for which you want to limit the amount of data logged.
- 2 If the **Contents** pane does not display the `DataLoggingDecimation` property or the `DataLoggingLimitDataPoints` property, add one or both of those properties to the current view. For details about column views, see “Control Model Explorer Contents Using Views” on page 12-29.
- 3 To specify a decimation factor, edit the `Decimation` and `DecimateData` properties. To limit the number of samples logged, edit the `LimitDataPoints` property.

Set Sample Time for a Logged Signal

To set the sample time for a logged signal, in the Signal Properties dialog box, use the **Sample Time** option. This option:

- Separates design and testing, because you do not need to insert a Rate Transition block to have a consistent sample time for logged signals
- Reduces the amount of logged data for a continuous time signal, for which setting decimation is not relevant
- Eliminates the need to postprocess logged signal data for signals with different sample times

Usage Notes

Do not specify a sample time for:

- Frame-based signals
- Conditional subsystems (for example, function-call or triggered subsystems) and conditional referenced models, which require an inherited sample time

If you simulate in SIL mode, signal logging ignores the sample times you specify for logged signals.

When you mark a signal for signal logging, Simulink inserts a hidden To Workspace block. When you specify a sample time for a logged signal, Simulink inserts a hidden Rate Transition block and a hidden To Workspace block.

Specifying a sample time for signal logging does not affect the simulation result. However, it is possible that the signal logging output for a logged signal varies depending on whether you specify a sample rate. For example, the interpolation method can differ depending on whether you specify a sample time for signal logging. Suppose that a model includes a continuous signal and the sample time is inherited (-1). The logged output for that signal shows that the interpolation method is `linear`.

```
logout.get(1).Values.DataInfo
```

```
tsdata.datametadatas
Package: tsdata
```

```
Common Properties:
    Units: ''
    Interpolation: linear (tsdata.interpolation)
```

If you change the sample time to be continuous (0), the logged output for that signal shows that the interpolation method is ZOH (zero-order hold).

Approaches for Viewing the Signal Logging Configuration

Signal Logging Configuration Viewing Approach	Usage	Documentation
In the Simulink Editor, view signal logging indicators.	<p>Consider using this approach for models that have few signals marked for signal logging and have a shallow model hierarchy.</p> <p>This approach avoids leaving the Simulink Editor.</p> <p>Open the Signal Properties dialog box for each signal.</p>	“Use Simulink Editor to View Signal Logging Configuration” on page 59-69
Use the Signal Logging Selector.	<p>Consider using this approach for models with deep hierarchies.</p> <p>View a model that has signal logging override settings for some signals.</p> <p>View the configuration as part of specifying a subset of signals for logging from all signals marked for signal logging.</p>	“View Logging Configuration with Signal Logging Selector” on page 59-71

Signal Logging Configuration Viewing Approach	Usage	Documentation
	<p>View signal logging configuration without displaying the signal logging indicators in the model.</p> <p>View signal logging configuration information such as decimation and output options in one window.</p>	
Use the Model Explorer.	<p>View signal logging configuration in the context of other model component properties.</p> <p>Adjust the column view to display signal logging properties, if necessary.</p>	“Use Model Explorer to View Signal Logging Configuration” on page 59-73
Use MATLAB commands	Get the handles of the signals in the model and find the ones that have data logging enabled.	“Programmatically Find Signals Configured for Logging” on page 59-74

Use Simulink Editor to View Signal Logging Configuration

By default, Simulink Editor displays an indicator on each signal that is marked for signal logging. To view the signal logging setting for a signal:

- 1 Right-click the signal. From the context menu, select **Signal Properties**.
- 2 Select the **Logging and accessibility** tab.

For example, in the following model the output of the Sine Wave block is logged:

If you use the command-line interface to override logging for a signal, the Simulink Editor continues to display the signal logging indicator for that signal. When you simulate the model, Simulink displays a red signal logging indicator for all signals marked to be logged, reflecting any overrides. For details about configuring a signal for logging, see “Configure a Signal for Logging” on page 59-60.

A logged signal can also be a test point. See “Test Points” on page 62-55 for information about test points.

To hide the logging indicators, clear **Display > Signals & Ports > Testpoint & Logging Indicators**.

View Logging Configuration with Signal Logging Selector

- 1 Open the model for which you want to view the signal logging configuration.
- 2 Open the Signal Logging Selector, using one of the following approaches:
 - In the **Configuration Parameters > Data Import/Export** pane, in the **Signals** area, select the **Configure Signals to Log** button.

If necessary, select **Signal logging** to enable the **Configure Signals to Log** button.

 - For a model that includes a Model block, you can also use the following approach:
 - a In the Simulink Editor, right-click a Model block.
 - b In the context-menu, select **Log Referenced Signals**.
- 3 In the **Model Hierarchy** pane, select the model node for which you want to view the signal logging configuration. For example:

To expand a node in the **Model Hierarchy** pane, right-click the arrow to the left of the node.

If no signals for a node are marked for signal logging, the **Contents** pane is empty.

For a model that references a model, the **Model Hierarchy** pane check box to the left of a model node indicates the override configuration of the node.

Check Box	Signal Logging Configuration
	For the top-level model node, logs all logged signals in the top model. For a Model block node, logs all logged signals in the model reference hierarchy for that block.
	For the top-level model node, disables logging for all logged signals in the top model. For a Model block node, disables logging for all signals in the model reference hierarchy for that block.
	For the top-level model node, logs all logged signals that have the DataLogging setting enabled. For a Model block node, logs all logged signals in the model reference hierarchy for that block that have the DataLogging setting enabled.

View Configuration of Subsystems and Linked Libraries

The following table describes default **Model Hierarchy** pane display of subsystems, masked subsystems, and linked library nodes.

Node	Display Default
Subsystem	Displays subsystems all that include logged signals
Masked subsystem	Does not display masked subsystems
Linked library	Displays all subsystems that include logged signals

You can control how the **Model Hierarchy** pane displays subsystems, masked subsystems, and linked libraries. Use icons at the top of the **Model Hierarchy** pane or use the **View** menu, using the same approach as you use in the Model Explorer. For details, see “Displaying Linked Library Subsystems” on page 12-15 and “Displaying Masked Subsystems” on page 12-16.

- To display all subsystems, including subsystems that do not include signals marked for logging, select the  icon or **View > Show All Subsystems**. This

subsystem setting also applies to masked subsystems, if you specify to display masked subsystems.

- To display masked subsystems with logged signals, use the  icon or **View > Show Masked Subsystems**
- To display linked libraries, use the  icon or **View > Show Library Links**

Filtering Signal Logging Selector Contents

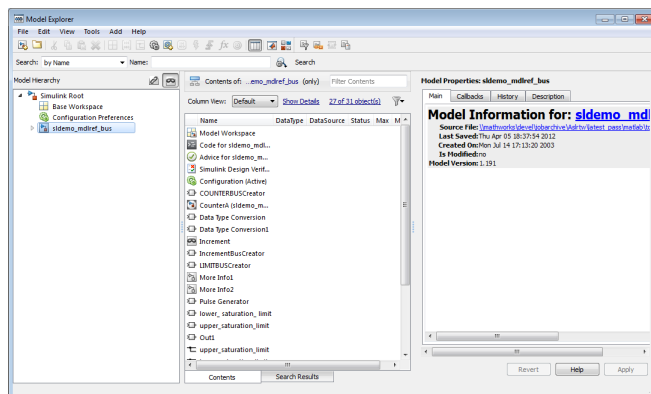

To find a specific signal or property value for a signal, use the **Filter Contents** edit box. Use the same approach as you use in the Model Explorer; for details, see “Filtering Contents” on page 12-50.

Highlighting a Block in a Model

To use the Model Hierarchy pane to highlight a block in model, right-click the block or signal and select **Highlight block in model**.

Use Model Explorer to View Signal Logging Configuration

- 1 To access the logging configuration information for referenced models, open the model for which you want to view the signal logging configuration. Select the top-level model in a model reference hierarchy.
- 2 In the **Contents** pane, set **Column View** to the Signals view.

For further information, see “Model Explorer: Model Hierarchy Pane” on page 12-12 and “Model Explorer: Contents Pane” on page 12-22.

Programmatically Find Signals Configured for Logging

Use MATLAB commands to get the handles of the signals in the model and find the ones that have data logging enabled. For example:

```
mdlsignals = find_system(gcs, 'FindAll', 'on', 'LookUnderMasks', 'all', ...  
    'FollowLinks', 'on', 'type', 'line', 'SegmentType', 'trunk');  
ph = get_param(mdlsignals, 'SrcPortHandle')  
for i=1: length(ph)  
    get_param(ph{i}, 'datalogging')  
end
```

Enable Signal Logging for a Model

In this section...

“Enable and Disable Logging at the Model Level” on page 59-75

“Migrate Scripts That Use ModelDataLogs API” on page 59-75

“Specify a Name for Signal Logging Data” on page 59-78

Enable and Disable Logging at the Model Level

To log a signal, mark it for signal logging. For details, see “Configure a Signal for Logging” on page 59-60.

Enable or disable logging globally for all signals that you mark for signal logging in a model. By default, signal logging is enabled. Simulink logs signals only if **Configuration Parameters > Data Import/Export > Signal logging** parameter is checked. If the option is not checked, Simulink ignores the signal logging settings for individual signals.

To disable signal logging, use *one* of these approaches.

- Clear the **Configuration Parameters > Data Import/Export > Signal logging** parameter.
- Use the `SignalLogging` parameter. For example:

```
set_param(bdroot, 'SignalLogging', 'off')
```

Selecting a Subset of Signals to Log

You can select a subset of signals to log for a model that has:

- Signal logging enabled
- Logged signals

For details, see “Override Signal Logging Settings” on page 59-79.

Migrate Scripts That Use ModelDataLogs API

For scripts that simulate a model created in a release earlier than R2016a that uses `ModelDataLogs` format for logging, update the code to log in `Dataset` format.

If you have already logged signal data in the `ModelDataLogs` format, you can use the `Simulink.ModelDataLogs.convertToDataset` function to update the `ModelDataLogs` signal logging data to use `Dataset` format. For example, to update the `older_model_dataset` from `ModelDataLogs` format to `Dataset` format:

```
new_dataset = logout.convertToDataset('older_model_data')
```

Converting a model from using `ModelDataLogs` format to using `Dataset` format can require that you modify your existing models and to code in callbacks, functions, scripts, or tests. The following table identifies possible issues to address after converting to `Dataset` format. The table provides solutions for each issue.

Possible Issue After Conversion to Dataset Format	Solution
Code in existing callbacks, functions, scripts, or tests that used the <code>ModelDataLogs</code> programmatic interface to access data can result in an error.	<p>Check for code that uses <code>ModelDataLogs</code> format access methods. Update that code to use <code>Dataset</code> format access methods.</p> <p>For example, suppose that existing code includes the following line:</p> <pre>logout.('Subsystem Name').X.data</pre> <p>Replace that code with a <code>Dataset</code> access method:</p> <pre>logout.getElement('x').Values.data</pre>
Logging bus signals requires a configuration parameter change.	<p>Logging buses in <code>Dataset</code> format requires that Configuration Parameters > Diagnostics > Connectivity > Mux blocks used to create bus signals is set to <code>error</code>.</p> <p>To configure a model for proper bus usage, run the Upgrade Advisor with the Check bus usage check.</p>
Mux block signal names are lost.	<p>The <code>Dataset</code> format treats Mux block signals as a vector.</p> <p>To identify signals by signal names, replace Mux blocks with a Bus Creator blocks. Set Configuration Parameters > Diagnostics > Connectivity > Mux blocks used to create bus signals to <code>error</code>.</p>

Possible Issue After Conversion to Dataset Format	Solution
Signal Viewer cannot be used for signal logging.	<p>Simulink does not log signal logging data in the Signal Viewer.</p> <p>Use the signal logging output variable to view the logged data.</p>
The <code>unpack</code> method generates an error.	<p>The <code>unpack</code> method, which is supported for <code>Simulink.ModelDataLogs</code> and <code>Simulink.SubsysDataLogs</code> objects, is <i>not</i> supported for <code>Simulink.SimulationData.Dataset</code> objects.</p> <p>For example, if the data in <code>mlog</code> has three fields: <code>x</code>, <code>y</code>, and <code>z</code>, then:</p> <ul style="list-style-type: none"> • For <code>ModelDataLogs</code> format data, the <code>mlog.unpack</code> method creates three variables in the base workspace. • For <code>Dataset</code> format data, access methods by names. For example: <pre>x = logcout.getElement('x').Values</pre>
The <code>ModelDataLogs</code> and <code>Dataset</code> formats have different naming rules for unnamed signals.	<p>If necessary, add signal names.</p> <ul style="list-style-type: none"> • In <code>ModelDataLogs</code> format, for an unnamed signal coming from a block, Simulink assigns a name in this form: <pre>SL_BlockName+<portIndex></pre> <p>For example, <code>SL_Gain1</code>.</p> • In <code>Dataset</code> format, elements do not need a name, so Simulink leaves the signal name empty. • For both <code>ModelDataLogs</code> and <code>Dataset</code> formats, Simulink assigns the same name to unnamed signals that come from Bus Selector blocks.

Possible Issue After Conversion to Dataset Format	Solution
Test points in referenced models are not logged.	Consider enabling signal logging for test points in a referenced model.
Script uses <code>who</code> or <code>whos</code> functions.	Consider using <code>Simulink.SimulationData.Dataset.find</code> instead.

Specify a Name for Signal Logging Data

You use the model-level signal logging name to access the signal logging data for a model. The default name for the signal logging data is `logstdout`. Specifying a model-level signal logging name can make it easier to identify the source of the logged data. For example, you could specify the signal logging name `car_logstdout` to identify the data as being the signal logging data for the `car` model.

To specify a different model-level signal logging name, use either of these approaches:

- In the edit box next to the **Configuration Parameters > Data Import/Export > Signal logging** parameter, enter the signal logging name.
- Use the `SignalLoggingName` parameter, specifying a signal logging name. For example:

```
set_param(bdroot, 'SignalLoggingName', 'heater_model_signals')
```

Override Signal Logging Settings

In this section...

“Benefits of Overriding Signal Logging Settings” on page 59-79

“Two Interfaces for Overriding Signal Logging Settings” on page 59-79

“Scope of Signal Logging Setting Overrides” on page 59-80

“Override Signal Logging Settings with the Signal Logging Selector” on page 59-80

“Override Signal Logging Settings from MATLAB” on page 59-86

Benefits of Overriding Signal Logging Settings

As you develop a model, you may want to override the signal logging settings for a specific simulation run. You can override signal logging properties without changing the model in the Simulink Editor.

Override signal logging properties to reduce memory overhead and to facilitate the analysis of simulation logging results. By overriding signal logging settings, you can avoid recompiling a model.

Overriding signal logging properties is useful when you want to:

- Focus on only a few signals by disabling logging for most of the signals marked for logging. You can mark a superset of signals for logging, and then select different subsets of them for logging.
- Exclude a few signals from the signal logging output.
- Override specific signal logging properties, such as decimation, for a signal.
- Collect only what you need when running multiple test vectors.

Two Interfaces for Overriding Signal Logging Settings

Use either of two interfaces to override signal logging settings:

- “Override Signal Logging Settings with the Signal Logging Selector” on page 59-80
- “Override Signal Logging Settings from MATLAB” on page 59-86

You can use a combination of the two interfaces. The Signal Logging Selector creates `Simulink.SimulationData.ModelLoggingInfo` objects when

saving the override settings. The command-line interface has properties whose names correspond to the Signal Logging Selector interface. For example, the `Simulink.SimulationData.ModelLoggingInfo` class has a `LoggingMode` property, which corresponds to the **Logging Mode** parameter in the Signal Logging Selector.

Scope of Signal Logging Setting Overrides

When you override signal logging settings, Simulink uses those override settings when you simulate the model.

Simulink saves in the model the signal logging override configuration that you specify. However, Simulink does not change the signal logging settings in the Signal Properties dialog box for each signal in the model.

In the Signal Logging Selector, if you override some signal logging settings, and then set the **Logging Mode** to **Log all signals as specified in model**, the logging settings defined in the model appear in the Signal Logging Selector. The override settings are greyed out, indicating that you cannot override these settings. To reactivate the override settings, set **Logging Mode** to **Override signals**. Using the Signal Logging Selector to override logging for a specific signal does not affect the signal logging indicator for that signal.

If you close and then reopen the model, the logging setting overrides that you made are in effect, if logging mode is set to override signals for that model. When the model displays the signal logging indicators, it displays the indicators for all logged signals, including logged signals that you have overridden.

Note: Simulink rebuilds a model in the following situation:

- 1 The model contains one or more signals marked for signal logging.
 - 2 You simulate the model in Rapid Accelerator mode.
 - 3 You use the Signal Logging Selector or MATLAB command line to modify the signal logging configuration.
 - 4 You simulate the model in Rapid Accelerator mode again.
-

Override Signal Logging Settings with the Signal Logging Selector

- 1 Open the Signal Logging Selector, using one of the following approaches:

- In the **Configuration Parameters > Data Import/Export** pane, in the **Signals** area, select the **Configure Signals to Log** button.

If necessary, select **Signal logging** to enable the **Configure Signals to Log** button.

- For a model that includes a Model block, you can also use the following approach:
 - In the Simulink Editor, right-click a Model block.
 - In the context-menu, select **Log Referenced Signals**.

2 Set **Logging Mode** to **Override signals**.

Note: The **Override signals** setting affects all levels of the model hierarchy. This setting can result in turning off logging for any signal throughout the hierarchy, based on existing settings. To review settings, select the appropriate node in the **Model Hierarchy** pane.

- 3 View the node containing the logged signals that you want to override. If necessary, expand nodes or configure the Model Hierarchy pane to display masked subsystems. See "View Logging Configuration with Signal Logging Selector" on page 59-71.
- 4 Override signal logging settings. Use one of the following approaches, depending on whether or not your model uses model referencing:

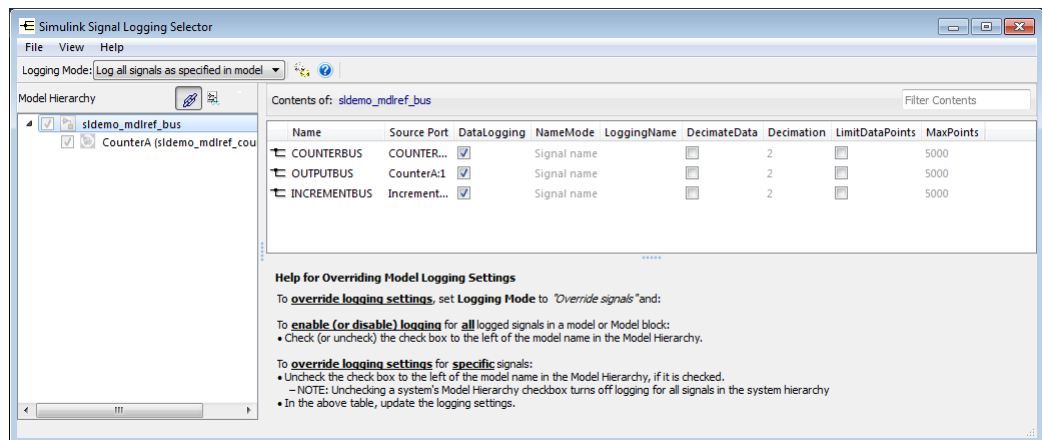

- “Models Without Model Referencing: Overriding Signal Logging Settings” on page 59-82
- “Models with Model Referencing: Overriding Signal Logging Settings” on page 59-83

Tip To open the **Configuration Parameters > Data Import/Export** pane from the Signal Logging Selector, use the  button.

Models Without Model Referencing: Overriding Signal Logging Settings

If your model does not use model referencing (that is, the model does not include any Model blocks), override signal logging settings using the following procedure.

- 1 Open the Signal Logging Selector. In the **Configuration Parameters > Data Import/Export** pane, in the **Signals** area, select the **Configure Signals to Log** button.
 - If necessary, select **Signal logging** to enable the **Configure Signals to Log** button.

- 2 Set **Logging Mode** to **Override signals**.

- 3 View the node containing the logged signals that you want to override. If necessary, expand nodes or configure the Model Hierarchy pane to display masked subsystems. See “View Logging Configuration with Signal Logging Selector” on page 59-71.
- 4 In the **Contents** pane table, select the signal whose logging settings you want to override.
- 5 Override logging settings:
 - To disable logging for a signal, clear the **DataLogging** check box for that signal.
 - To override other signal logging settings (for example, decimation), ensure that the **DataLogging** check box is selected. Then, edit values in the appropriate columns.

Models with Model Referencing: Overriding Signal Logging Settings

If your model uses model referencing (that is, the model includes at least one Model block), override signal logging settings using the one or more of the following procedures:

- “Enable Logging for All Logged Signals” on page 59-83
- “Disable Logging for All Logged Signals in a Model Node” on page 59-84
- “Override Signal Logging for a Subset of Signals” on page 59-84
- “Override Other Signal Logging Properties” on page 59-85

Enable Logging for All Logged Signals

By default, Simulink logs all the logged signals in a model, including the logged signals throughout model reference hierarchies.

If logging is disabled for any logged signals in the top-level model or in the top-level Model block in a model reference hierarchy, then in the **Model Hierarchy** pane, the check box to the left of that node is either solid () , if logging is disabled for some of signals, or empty () , if logging is disabled for all of the signals.

To enable logging of all logged signals for a node:

- 1 Open the Signal Logging Selector. In the **Configuration Parameters > Data Import/Export** pane, in the **Signals** area, select the **Configure Signals to Log** button.
- 2 Set **Logging Mode** to **Override** signals.

- 3 View the node containing the logged signals that you want to override. If necessary, expand nodes or configure the Model Hierarchy pane to display masked subsystems. See “View Logging Configuration with Signal Logging Selector” on page 59-71.
- 4 In the **Model Hierarchy** pane, select the check box to the left of the node, so that the check box has a check mark ().
 - For the top-level model, logging is enabled for all logged signals in the top-level model, but not for logged signals in model reference hierarchies.
 - For a Model block at the top of a model referencing hierarchy, logging is enabled for the whole model reference hierarchy for the selected referenced model.

Disable Logging for All Logged Signals in a Model Node

If signal logging is enabled for any signals in a model node, then in the **Model Hierarchy** pane, the check box to the left of the node is either solid () , if logging is enabled for some signals, or checked () , if logging is enabled for all signals.

To disable logging for all logged signals in a node of a model:

- 1 Open the Signal Logging Selector. In the **Configuration Parameters > Data Import/Export** pane, in the **Signals** area, select the **Configure Signals to Log** button.
- 2 Set **Logging Mode** to **Override** signals.
- 3 View the node containing the logged signals that you want to override. If necessary, expand nodes or configure the Model Hierarchy pane to display masked subsystems. See “View Logging Configuration with Signal Logging Selector” on page 59-71.
- 4 In the **Model Hierarchy** pane, clear the check box to the left of the node, so that the check box is empty ().
 - For the top-level model, logging is disabled for all logged signals in the top-level model, but not for logged signals in model reference hierarchies.
 - For a Model block at the top of a model referencing hierarchy, logging is disabled for the whole model reference hierarchy for the selected reference model.

Override Signal Logging for a Subset of Signals

To log some, but not all, logged signals in a model node:

- 1 Open the Signal Logging Selector. In the **Configuration Parameters > Data Import/Export** pane, in the **Signals** area, select the **Configure Signals to Log** button.
- 2 Set **Logging Mode** to **Override** signals.
- 3 View the node containing the logged signals that you want to override. If necessary, expand nodes or configure the Model Hierarchy pane to display masked subsystems. See “View Logging Configuration with Signal Logging Selector” on page 59-71.
- 4 In the **Model Hierarchy** pane, ensure that the check box for the top-level model or Model block is either solid () , if logging is disabled for some of the signals, or empty () , if logging is disabled for all the signals. Click the check box to cycle through different states.
- 5 In the **Contents** pane table, for the signals that you want to log, select the check box in the **DataLogging** column.

To enable logging for multiple signals, hold the **Shift** or **Ctrl** key and select a range of signals or individual signals. Select the check box in the **DataLogging** column of one of the highlighted signals.

Note: You cannot use the Signal Logging Selector to override a subset of signals for model reference variant systems, including:

- Model reference variants
- Model blocks that contain a Subsystem Variant or model reference variant

You can override programmatically a subset of signals in those configurations. For details, see “Override Signal Logging Settings from MATLAB” on page 59-86.

Override Other Signal Logging Properties

In addition to overriding the setting for the **DataLogging** property for a signal, you can override other signal logging properties, such as decimation.

- 1 Open the Signal Logging Selector. In the **Configuration Parameters > Data Import/Export** pane, in the **Signals** area, select the **Configure Signals to Log** button.
- 2 Set **Logging Mode** to **Override** signals.

- 3 View the node containing the logged signals that you want to override. If necessary, expand nodes or configure the Model Hierarchy pane to display masked subsystems. See “View Logging Configuration with Signal Logging Selector” on page 59-71.
- 4 In the **Model Hierarchy** pane, ensure that the check box for the top-level model or Model block is solid () if logging is disabled for some signals, or empty (), if logging is disabled for all signals. Click the check box to cycle through different states.
- 5 In the **Contents** pane table, for the signals for which you want to override logging properties, enable logging by selecting the check box in the **DataLogging** column.

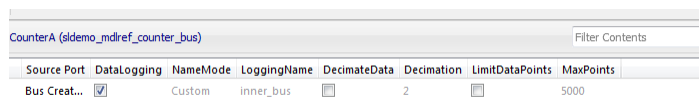

To enable logging for multiple signals, hold the **Shift** or **Ctrl** key and select a range of signals or individual signals. Select the check box in the **DataLogging** column of one of the highlighted signals.

- 6 In the **Contents** pane table, modify the settings for properties, such as **DecimateData** and **Decimation**.

Override Signal Logging Settings from MATLAB

The MATLAB command-line interface for overriding signal logging settings includes:

- The **DataLoggingOverride** model parameter — Use to view or set signal logging override values for a model
- The following classes:
 - **Simulink.SimulationData.ModelLoggingInfo** — Specify signal logging override settings for a model. This class corresponds to the overall Signal Logging Selector interface.
 - **Simulink.SimulationData.SignalLoggingInfo** — Override settings for a specific signal. This class corresponds to a row in the logging property table in the Signal Logging Selector:

Source Port	DataLogging	NameMode	LoggingName	DecimateData	Decimation	LimitDataPoints	MaxPoints
Bus Creat...	<input checked="" type="checkbox"/>	Custom	inner_bus	<input type="checkbox"/>	2	<input type="checkbox"/>	5000

- **Simulink.SimulationData.LoggingInfo** — Overrides for signal logging settings such as decimation. This class corresponds to the editable columns in a row in the logging property table in the Signal Logging Selector.

To query a model for its signal logging override status, use the `DataLoggingOverride` parameter.

To configure signal logging from the command line, use methods and properties of the three classes listed above. To apply the configuration, use `set_param` with the `DataLoggingOverride` model parameter.

The following sections describe how to use the command-line interface to perform some common signal logging configuration tasks.

- “Create a Model Logging Information Object” on page 59-87
- “Specify Which Models to Log” on page 59-88
- “Log a Subset of Signals” on page 59-89
- “Override Other Signal Logging Properties” on page 59-91

Create a Model Logging Information Object

To use the command-line interface for overriding signal logging settings, first create a `Simulink.SimulationData.ModelLoggingInfo` object. For example, use the following commands to create the model logging override object for the `ex_bus_logging` model and automatically add each logged signal in the model to that object:

```
open_system(docpath(fullfile(docroot, 'toolbox', 'simulink', ...
'examples', 'ex_md1ref_counter_bus')));
open_system(docpath(fullfile(docroot, 'toolbox', 'simulink', ...
'examples', 'ex_bus_logging')));
mi = Simulink.SimulationData.ModelLoggingInfo.createFromModel(...
'ex_bus_logging')
```

`mi =`

`ModelLoggingInfo` with properties:

```

        Model: 'ex_bus_logging'
      LoggingMode: 'OverrideSignals'
LogAsSpecifiedByModels: {}
        Signals: [1x4 Simulink.SimulationData.SignalLoggingInfo]
```

The `LoggingMode` property is set to `OverrideSignals`, which configures the model logging override object to log only the signals specified in the `Signals` property.

To apply the model override object settings, use:

```
set_param(ex_bus_logging, 'DataLoggingOverride', mi);
```

Simulink saves the settings when you save the model.

You can control the kinds of systems from which to include logged signals. By default, the `Simulink.SimulationData.ModelLoggingInfo` object includes logged signals from:

- Libraries
- Masked subsystems
- Referenced models
- Active variants

As an alternative, you can use the `Simulink.SimulationData.ModelLoggingInfo` constructor and specify a `Simulink.SimulationData.SignalLoggingInfo` object for each signal. To ensure that you specified valid signal logging settings for a model, use the `verifySignalAndModelPaths` method with the `Simulink.SimulationData.ModelLoggingInfo` object for the model.

Specify Which Models to Log

Use the `LoggingMode` property of a `Simulink.SimulationData.ModelLoggingInfo` object to specify whether to use the signal logging settings as specified in the model and all referenced models, or to override those settings.

You can control whether a top-level model and referenced models use override signal logging settings or use the signal logging settings specified by the model, as described in the `Simulink.SimulationData.ModelLoggingInfo` documentation.

The following example shows how to log all signals as specified in the top model and all referenced models. The signal logging output is stored in `topOut`.

```
open_system(docpath(fullfile(docroot, 'toolbox', 'simulink', ...
    'examples', 'ex_mdhref_counter_bus')));
open_system(docpath(fullfile(docroot, 'toolbox', 'simulink', ...
    'examples', 'ex_bus_logging')));
mi = Simulink.SimulationData.ModelLoggingInfo...
    ('ex_bus_logging');
mi.LoggingMode = 'LogAllAsSpecifiedInModel'

mi =

    ModelLoggingInfo with properties:

        Model: 'ex_bus_logging'
```

```

        LoggingMode: 'LogAllAsSpecifiedInModel'
    LogAsSpecifiedByModels: {}
        Signals: []

```

To apply the model override object settings, use:

```
set_param(ex_bus_logging, 'DataLoggingOverride', mi);
```

The following example shows how to log only signals in the top model:

```

open_system(docpath(fullfile(docroot, 'toolbox', 'simulink', ...
    'examples', 'ex mdlref_counter_bus')));
open_system(docpath(fullfile(docroot, 'toolbox', 'simulink', ...
    'examples', 'ex_bus_logging')));
mi = Simulink.SimulationData.ModelLoggingInfo...
    ('ex_bus_logging');
mi.LoggingMode = 'OverrideSignals';
mi = mi.setLogAsSpecifiedInModel('ex_bus_logging',true);

```

To apply the model override object settings, use:

```
set_param(ex_bus_logging, 'DataLoggingOverride', mi);
```

Simulink saves the settings when you save the model.

Log a Subset of Signals

For a simple model with a limited number of logged signals, you could create an empty `Simulink.SimulationData.ModelDataLogInfo` object. Then create `Simulink.SimulationData.SignalLoggingInfo` objects for each of the signals that you want to log, and assign those objects to the model logging information object.

```

open_system(docpath(fullfile(docroot, 'toolbox', 'simulink', ...
    'examples', 'ex mdlref_counter_bus')));
open_system(docpath(fullfile(docroot, 'toolbox', 'simulink', ...
    'examples', 'ex_bus_logging')));
mdl = 'ex_bus_logging';
blk = 'ex_bus_logging/IncrementBusCreator';
blkPort = 1;

```

```
load_system(mdl);
```

```
ov = Simulink.SimulationData.ModelLoggingInfo(mdl);
```

```
so = Simulink.SimulationData.SignalLoggingInfo(blk,blkPort);  
  
ov.Signals(1) = so;  
  
% apply this object so the model  
set_param mdl, 'DataLoggingOverride', ov);  
  
% Simulate  
sim(mdl);  
  
% observe that only the signal  
topOut
```

To apply the model override object settings, use:

```
set_param(mdl, 'DataLoggingOverride', ov);
```

Simulink saves the settings when you save the model.

For a model that uses model referencing, or that is complex, to specify a subset of logged signals to log, consider using the `findSignal` method with a `Simulink.SimulationData.ModelLoggingInfo` object. For example, to log only one signal from the referenced model instance referenced by :

```
open_system(docpath(fullfile(docroot, 'toolbox', 'simulink', ...  
    'examples', 'ex_mdhref_counter_bus')));  
open_system(docpath(fullfile(docroot, 'toolbox', 'simulink', ...  
    'examples', 'ex_bus_logging')));  
  
mi = Simulink.SimulationData.ModelLoggingInfo.createFromModel(...  
    'ex_bus_logging');  
pos = mi.findSignal({'ex_bus_logging/CounterA' ...  
    'ex_mdhref_counter_bus/Bus Creator'}, 1)  
  
pos =  
  
    4  
  
for idx=1:length(mi.Signals)  
    mi.Signals(idx).LoggingInfo.DataLogging = (idx == pos);  
end
```

To apply the model override object settings, use:

```
set_param(ex_bus_logging, 'DataLoggingOverride', mi);
```

Simulink saves the settings when you save the model.

Note: You can override programmatically a subset of signals for model reference variant systems, including:

- Model reference variants
- Model blocks that contain a Subsystem Variant or model reference variant

To log a subset of signals for these model reference variant systems, set the `SignalLoggingSaveFormat` parameter to `Dataset`.

Override Other Signal Logging Properties

In addition to overriding the setting for the `DataLogging` property for a signal, you can override other signal logging properties, such as decimation.

Use `Simulink.SimulationData.LoggingInfo` properties to override signal logging properties. The following example shows how to set the decimation override settings.

```
open_system(docpath(fullfile(docroot, 'toolbox', 'simulink', ...
    'examples', 'ex_mdhref_counter_bus')));
open_system(docpath(fullfile(docroot, 'toolbox', 'simulink', ...
    'examples', 'ex_bus_logging')));
mi = Simulink.SimulationData.ModelLoggingInfo.createFromModel...
    ('ex_bus_logging');
pos = mi.findSignal({'ex_bus_logging/CounterA' ...
    'ex_mdhref_counter_bus/Bus Creator'}, 1);
mi.Signals(pos).LoggingInfo.DecimateData = true;
mi.Signals(pos).LoggingInfo.Decimation = 2;
```

To apply the model override object settings, use:

```
set_param(ex_bus_logging, 'DataLoggingOverride', mi);
```

Simulink saves the settings when you save the model.

Access Signal Logging Data

In this section...

“View Signal Logging Data” on page 59-93

“View Data in Simulation Data Inspector” on page 59-93

“Signal Logging Object” on page 59-94

“Access Data Programmatically” on page 59-94

“Handling Spaces and Newlines in Logged Names” on page 59-95

“Access Logged Signal Data in ModelDataLogs Format” on page 59-97

View Signal Logging Data

You can view the signal logging data for a paused or completed simulation, using one of these interfaces:

- The Simulation Data Inspector
- Programmatically, using MATLAB commands

Tip If you do not see logging data for a signal that you marked in the model for signal logging, check the logging configuration. Use the Signal Logging Selector to enable logging for a signal whose logging is overridden. For details, see “View the Signal Logging Configuration” on page 59-68 and “Override Signal Logging Settings” on page 59-79.

View Data in Simulation Data Inspector

You can use the Simulation Data Inspector to view data for signals marked for logging.

- 1 Open the model.
- 2 Select **Simulation > Output > Send Logged Workspace Data to Data Inspector**.
- 3 Select **Simulation > Output > Simulation Data Inspector**.
- 4 Simulate the model.

For additional information about using the Simulation Data Inspector, see “Inspect Signal Data with Simulation Data Inspector” on page 26-2.

Signal Logging Object

Simulink saves signal logging data in a `Simulink.SimulationData.Dataset` object, which is a MATLAB workspace variable. The default name of the signal logging variable is `logout`. You can change the variable name. For details, see “Specify a Name for Signal Logging Data” on page 59-78.

Releases earlier than R2016a also supported a `ModelDataLogs` format. For details, see “Migrate Scripts That Use `ModelDataLogs` API” on page 59-75.

Access Data Programmatically

You can use the `Simulink.SimulationData.Dataset` API to access signal logging data programmatically. To access `Dataset` object elements, use the `get` method. For example, you can access the first element of the `topOut` signal logging `Dataset` object using `get` with an index.

```
open_system(docpath(fullfile(docroot, 'toolbox', 'simulink', ...
'examples', 'ex_mdhref_counter_bus')));
open_system(docpath(fullfile(docroot, 'toolbox', 'simulink', ...
'examples', 'ex_bus_logging')));
sim('ex_bus_logging')
topOut

topOut =

    Simulink.SimulationData.Dataset
    Package: Simulink.SimulationData

    Characteristics:
        Name: 'topOut'
        Total Elements: 4

    Elements:
        1: 'COUNTERBUS'
        2: 'OUTPUTBUS'
        3: 'INCREMENTBUS'
        4: 'inner_bus'
```

- Use `get` or `getElement` to access elements by index, name or block path.
- Use `addElement` or `setElement` to add or modify elements.

Methods, Superclasses

```
element1 = topOut.get(1)
```

```
element1 =
```

```
Simulink.SimulationData.Signal
Package: Simulink.SimulationData
```

Properties:

```
    Name: 'COUNTERBUS'
  PropagatedName: ''
    BlockPath: [1x1 Simulink.SimulationData.BlockPath]
    PortType: 'outport'
    PortIndex: 1
    Values: [1x1 struct]
```

Methods, Superclasses

```
element1.Values
```

```
ans =
```

```
    data: [1x1 timeseries]
    limits: [1x1 struct]
```

To search for specific elements in a `Dataset` object, use the `find` method. To return the names of the `Dataset` object elements, use the `getNames` method.

Tip To call a function on each specified MATLAB `timeseries` object, you can use the `Simulink.SimulationData.forEachTimeseries` function. For example, you can use this function to easily resample every element of a structure of `timeseries` objects obtained by logging a bus signal.

Handling Spaces and Newlines in Logged Names

Signal names in data logs can have spaces or newlines in their names when:

- The signal is named and the name includes a space or newline character.
- The signal is unnamed and originates in a block whose name includes a space or newline character.
- The signal exists in a subsystem or referenced model (or any parent block) whose name includes a space or newline character.

The following three examples show signals whose names contain:

- A space
- A signal whose name contains a newline
- An unnamed signal that originates in a block whose name contains a newline

The following example shows how to handle spaces or new lines in logged names when a model uses the default of `logouts` for the signal logging data.

```
logouts
```

```
logouts =
```

```
Simulink.SimulationData.Dataset
Package: Simulink.SimulationData
```

```
Characteristics:
    Name: 'logouts'
```

```

    Total Elements: 3

    Elements:
    1: ''
    2: 'x y'
    3: 'a
b'

```

To access a signal with a space or newline, use the index. For example, to access the `x y` signal:

```

>> logout.getElement(2)

ans =

    Simulink.SimulationData.Signal
    Package: Simulink.SimulationData

    Properties:
        Name: 'x y'
    PropagatedName: ''
        BlockPath: [1x1 Simulink.SimulationData.BlockPath]
        PortType: 'outport'
        PortIndex: 1
        Values: [1x1 timeseries]

```

Access Logged Signal Data in ModelDataLogs Format

Before R2016a, you could log signals in `ModelDataLogs` format. Starting in R2016a, you cannot log data in the `ModelDataLogs` format. Signal logging uses the `Dataset` format.

However, you can use data that was logged in a previous release using `ModelDataLogs` format.

For more information, see `Simulink.ModelDataLogs`.

Log Signals in For Each Subsystems

In this section...

“Log Signal in Nested For Each Subsystem” on page 59-99

“Log Bus Signals in For Each Subsystem” on page 59-101

The approach you use to log data for a signal in a For Each subsystem depends on whether the signal is a:

- Nonbus signal — Log directly in a For Each subsystem
- A bus or array of buses signal — Use one of these approaches:
 - Use a Bus Selector block to select the signals you want to log and mark those signals for signal logging. This approach works well for many models.
 - Attach the signal to an Outport block and log the signal outside of the For Each subsystem. Use this approach when you want to log a whole bus signal, and that bus signal includes many bus element signals.

Note: You can not log a signal inside a referenced model that is inside a For Each subsystem if either of these conditions exists:

- The For Each subsystem is in a model simulating in rapid accelerator mode.
 - The For Each subsystem itself is in a model referenced by a Model block in accelerator mode.
-

The data for each logged signal in a For Each subsystem is saved in a separate **Dataset** element as a `Simulink.SimulationData.Signal` object. Each signal object contains an array of MATLAB `timeseries` objects as values.

Log Signal in Nested For Each Subsystem

This example logs a signal in a nested For Each subsystem.

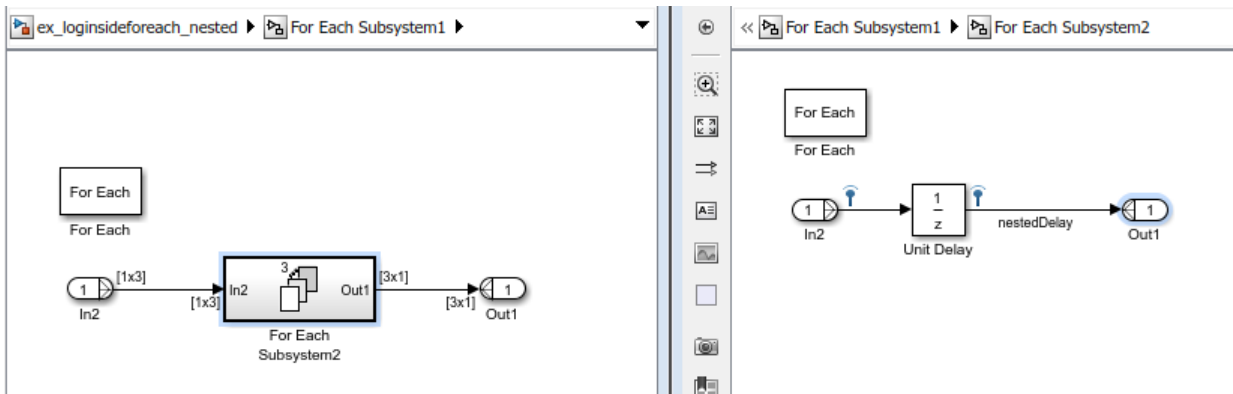

Open the `ex_loginsideforeach_nested` model.

```
open_system(docpath(fullfile(docroot, 'toolbox', 'simulink', ...
```

```
'examples', 'ex_loginsideforeach_nested.slx'))))
```

In the Simulink Editor, open the For Each Subsystem1 block, and inside that subsystem, open the For Each Subsystem2 block.

Simulate the model and examine the signal logging data for the first iteration of the top subsystem and the third iteration of the bottom subsystem.

```
sim('ex_loginsideforeach_nested');
logout.get('nestedDelay')
```

```
ans =
```

```
Simulink.SimulationData.Signal  
Package: Simulink.SimulationData
```

```

Properties:
struct with fields:

        Name: 'nestedDelay'
PropagatedName: ''
        BlockPath: [1x1 Simulink.SimulationData.BlockPath]
        PortType: 'outport'
        PortIndex: 1
        Values: [2x3 timeseries]

```

```
logout.get('nestedDelay').Values(1,3)
```

```
timeseries
```

```

Common Properties:
        Name: 'nestedDelay'
        Time: [5x1 double]
        TimeInfo: [1x1 tsdata.timemetadata]
        Data: [1x1x5 double]
        DataInfo: [1x1 tsdata.datametadata]

```

Log Bus Signals in For Each Subsystem

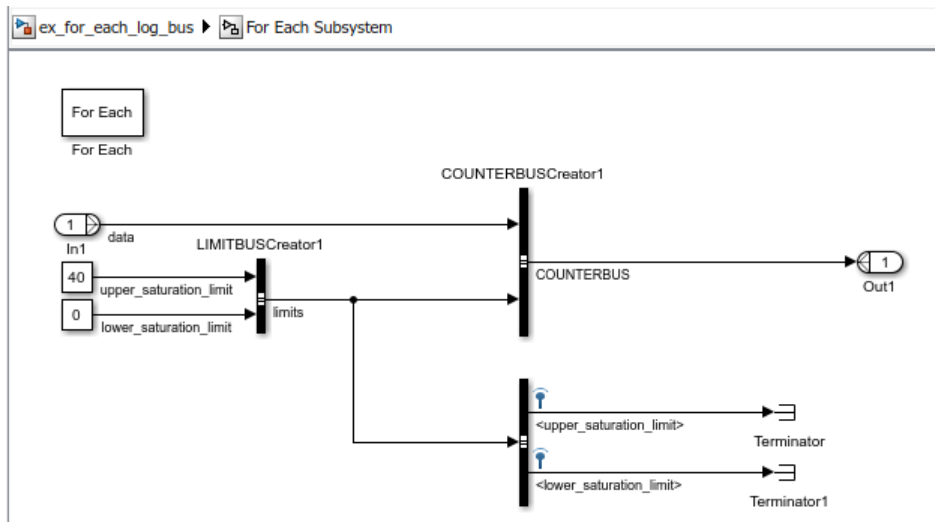

This example logs a two bus signal in a For Each subsystem. For one bus signal, you use a Bus Selector block and then log each selected signal. For the other bus signal, you use Outport blocks and log outside of the For Each subsystem.

Open the `ex_for_each_log_bus` model.

```
open_system(docpath(fullfile(docroot,'toolbox','simulink',...
'examples','ex_for_each_log_bus.slx')))
```

In the Simulink Editor, open the For Each Subsystem block.

To log the signals in the `limits` bus signal, the signal is branched to a Bus Selector block, and each of the bus element signals is marked for signal logging.

To log the whole `COUNTERBUS` signal, the bus signal is connected to an Outputport block. The output signal from the For Each subsystem is marked for signal logging. To have the bus signal cross the subsystem boundary, the Bus Creator block that creates the `COUNTERBUS` signal has the **Output data type** parameter set to `Bus: COUNTERBUS` and **Output as nonvirtual bus** check box selected.

Simulate the model and examine the signal logging output, focusing on one of the bus element signals logged inside the For Each subsystem and on the bus signal logged outside of the For Each subsystem.

```
sim('ex_for_each_log_bus');
logout

logout =

    Simulink.SimulationData.Dataset
    Package: Simulink.SimulationData

    Characteristics:
        Name: 'logout'
        Total Elements: 3
```

```

Elements:
  1 : 'OutsideForEach'
  2 : '<lower_saturation_limit>'
  3 : '<upper_saturation_limit>'

```

`logouts.get(2).Values`

```

logouts.get(2).Values
  3×1 timeseries array with properties:

```

```

  Events
  Name
  UserData
  Data
  DataInfo
  Time
  TimeInfo
  Quality
  QualityInfo
  IsTimeFirst
  TreatNaNasMissing
  Length

```

`logouts.get(1).Values`

```
ans =
```

```
  3×1 struct array with fields:
```

```

  data
  limits  IsTimeFirst

```

Overview of Signal Loading Techniques

In this section...

“Source Blocks” on page 59-104

“Root-Level Input Ports” on page 59-105

“From File Block” on page 59-107

“From Spreadsheet Block” on page 59-108

“From Workspace Block” on page 59-109

“Signal Builder Block” on page 59-110

Simulink provides several techniques for importing signal data into a model. Each of the signal data loading techniques uses blocks to represent signal data sources visually.

For additional details about which technique to use to meet specific modeling requirements, see “Comparison of Techniques” on page 59-114.

Source Blocks

You can add a source block, such as a Sine Wave block, to generate signals to input to another block. To specify how to generate the signal, use the Block Parameters dialog box. For example, in the Sine Wave Block Parameters dialog box, you can specify the `sim` function to use and time-based or sample-based data.

The output data types of source blocks vary. For example, a Sine Wave block outputs a vector of real doubles.

For an example of using a source block, see “Build and Edit a Model in the Simulink Editor” on page 1-23.

Recommended Uses

- Do initial prototyping in a model, when the generated signal data serves your modeling requirements
- Avoid creating the data manually.
- Reduce memory consumption. Source blocks do not store signal data.
- Make the kind of signal data visually clear in the model.

Limitations

Source blocks generate signals based on a predefined algorithm. To use actual data from an external source or to test a model without having to modify the model, use a different signal loading technique.

Root-Level Input Ports

You can import signal data from a workspace and apply it to a root-level input port using one of these blocks:

- Enable
- Inport
- Trigger block that has an edge-based (rising, falling, or either) trigger type

The root-level input ports load external inputs from the MATLAB (base), model, or mask workspace. These blocks import data from the workspace based on the value of the **Configuration Parameters > Data Import/Export > Input** parameter or a **sim** command argument. For an example, see “Import Data to Model a Continuous Plant” on page 59-128.

To import many signals to root-level input ports, consider using the Root Inport Mapping tool. This tool updates the **Inport** configuration parameter based on the signal data that you import and map to root-level input ports. For an example, see “Map Data Using Root Inport Mapping Tool” on page 59-120.

Recommended Uses

Use root input ports to:

- Import many signals to many blocks
- Test your model as a referenced model in a wider context with signals from the workspace, without modifying your model

For importing signal data to meet most modeling requirements and to maintain model flexibility, root-level inport mapping is a convenient technique. Root-level inport mapping:

- Displays signal data for you to inspect without loading all the signal data into MATLAB memory
- Provides memory-efficient signal viewing

Requirements

To ensure that the Simulink variable solver executes at the times that you specify in the imported data, set the **Configuration Parameters > Data Import/Export > Additional parameters > Output options** parameter to Produce additional output.

Limitations

- You cannot use input ports to import buses in external modes. To import bus data in rapid accelerator mode, use **Dataset** format.
- The Root Inport Mapping tool supported map modes depend on the data type of a signal. For details, see “Choose a Base Workspace and MAT-File Format” on page 59-170.

From File Block

A From File block reads data from a MAT-file and outputs the data as a signal.

For an example, see “From File Block Loading Timeseries Data”.

Recommended Uses

Consider using a From File block for loading:

- Large amounts of data. For a Version 7.3 MAT-file, the From File block loads data incrementally from the MAT-file during simulation.

Tip To convert a Version 7.0 file to Version 7.3 (for example, `my_data_file.mat` that contains the variable `var`), at the MATLAB command line, enter:

```
load('my_data_file.mat')
save('my_data_file.mat', 'var', '-v7.3')
```

- Data that was exported to a To File block. The From File block reads data written by a To File block without any you modifying the data or making other special provisions.
- Data stored in a MAT-file that is separate from the model file.

Limitations

- For *Version 7.0* or earlier MAT-file, the From File block reads only array-format data.

- Version 7.3 and Version 7.0 or earlier MAT-files handle multiple variables differently. See “MAT-File Variable” on page 59-143.
- The From File block supports reading nonvirtual bus signals in MATLAB `timeseries` format.
- For array data, the From File block reads only double signal data.
- Code generation that involves building ERT or GRT targets, or using SIL or PIL simulation modes, has some special considerations. See “Code Generation Requirements”.

From Spreadsheet Block

The From Spreadsheet block reads data from Microsoft Excel spreadsheets (all platforms) or CSV spreadsheets (Microsoft Windows platform with Microsoft Office only) and outputs the data as one or more signals.

Recommended Uses

Use the From Spreadsheet block for loading:

- Large Microsoft Excel or CSV spreadsheets. The From Spreadsheet block incrementally reads data from the spreadsheet during simulation, rather than loading the data into Simulink memory.
- Spreadsheets that you expect to modify. The From Spreadsheet block handles changes to worksheet values automatically, because it loads data directly from the spreadsheet.

Limitations

- You cannot import bus data.
- The From Spreadsheet file has requirements for the spreadsheet data. Organize Excel spreadsheet data using the format described in “Supported Microsoft Excel File Formats” on page 59-173.
- Linux and Mac platforms do not support using a From Spreadsheet block to import data from a CSV spreadsheet.

From Workspace Block

The From Workspace block reads signal data from a workspace and outputs the data as a signal. In the Block Parameters dialog box, in the **Data** parameter, enter a MATLAB expression that specifies the workspace data.

For an example of how to use a From Workspace block, see “Use From Workspace Block for Test Case” on page 59-134.

Recommended Uses

Use the From Workspace block for loading:

- A small set of signal data to perform local, temporary testing
- Data from the MATLAB (base), model, mask, or function workspace
- Variable-size signals

- Data that you saved using a To Workspace block in MATLAB `timeseries` format, without manual changes to the data
- Data saved in a previous simulation by a To Workspace block in either `Timeseries` or `Structure with Time` format for use in a later simulation

Limitations

- The data expressions that you specify must evaluate to one of these types of data:
 - A MATLAB `timeseries` object
 - A structure of MATLAB `timeseries` objects
 - An array or structure containing an array of simulation times and corresponding signal values

Signal Builder Block

Using a Signal Builder block, you can create interchangeable groups of piecewise linear signal sources to use in a model.

For examples of how to use a Signal Builder block, see:

- “Import Data for an Input Test Case” on page 59-133
- `sldemo_pid2dof`
- `sf_test_vectors`

Recommended Uses

Use the Signal Builder block to create and load signal groups to use in testing.

These products integrate the Signal Builder block into their workflows:

- Simulink Test
- Simulink Verification and Validation

Limitations

- The Signal Builder block has requirements for the spreadsheet data. Organize Excel spreadsheet data using the format described in “Importing Signal Group Sets” on page 62-78.
- Data stores are not supported.
- The data type for signals must be **double**.

Comparison of Signal Loading Techniques

In this section...

“Techniques” on page 59-112

“Impact of Loading Techniques on Block Diagrams” on page 59-113

“Comparison of Techniques” on page 59-114

Techniques

Simulink provides several techniques for importing signal data into a model. Each signal data loading technique uses a block to represent signal data sources visually. You can use a:

- Source block, such as the Sine Wave block, to generate signal data as input to another block
- Root-level input port (Inport, Enable, or Trigger block). Loading signal data to root-level input ports, either manually or by using the Root Inport Mapping tool. This section uses “Root-level input ports” to address both approaches and “Root Inport Mapping tool” to refer specifically to that approach.
- From File block
- From Spreadsheet block
- From Workspace block
- Signal Builder block

Suggested Signal Loading Techniques

Modeling Requirement	Suggested Signal Loading Technique
Signal values that Source blocks generate meet your requirements	Source block
Initial prototyping	From File, From Spreadsheet, or From Workspace block
System testing, sharing, and code generation	Root-level input port

Modeling Requirement	Suggested Signal Loading Technique
	You can use the Root Inport Mapping tool to create and map

For many models, loading signal data to a root inport block is an effective approach. The Root Inport Mapping tool on page 59-120 provides a convenient way to load data for several signals to root inports.

To identify signal data loading techniques to meet specific modeling requirements, see “Comparison of Techniques” on page 59-114.

Impact of Loading Techniques on Block Diagrams

To test reusable systems, it is helpful to separate signal data loading from the block diagram. Loading root-level input ports provides a good framework for testing complex systems on an ongoing basis. Using the Root Inport Mapping tool allows you to visualize the signal data that is loaded. For standalone systems that you want to test locally,

To perform temporary testing on standalone models, adding data loading blocks can be simpler and make the source of the signal data visible from within the block diagram.

To avoid adding data loading blocks to a model, load the signal data to root-level input ports. You can change the data to use by changing the **Configuration Parameters > Data Import/Export > Input** parameter. You do not need to add or change blocks, or reset block parameters. You can use the Root Inport Mapping tool to update the **Input** parameter so that it reflects the mapping of signal data to the appropriate ports.

Test Harness Models

You can use a test harness models with different test cases to load:

- Different signal data to a port
- Signal data to different ports

The Signal Builder block is useful in test harness models to simplify loading data to multiple input ports.

Alternatively, you can use the Root Inport Mapping tool to create scenarios that you can use instead of creating separate test harness models. Creating separate test harness

models can be simpler to create than setting up root inport mapping. However, you then need to manage the separate test harness models. For an example of using root inport mapping instead of a test harness, see “Converting Harness-Driven Models to Use Harness-Free External Inputs” on page 59-188

Comparison of Techniques

Each technique addresses many of these modeling considerations:

- “Purpose of Importing Signal Data” on page 59-114
- “Signal Data” on page 59-115
- “Data Format or Type” on page 59-115
- “Bus Support” on page 59-116
- “Time Points” on page 59-117
- “Location for Data Storage” on page 59-117
- “Signal Data Inspection” on page 59-118
- “Handling of Loaded Data” on page 59-118
- “Simulation Mode” on page 59-118

Purpose of Importing Signal Data

The model development phase you are in and your goals for loading signal data can influence the signal loading technique that you choose.

Modeling Goal	Supported Techniques
Perform local, temporary testing by importing a small set of signal data	All From File, From Spreadsheet, and From Workspace blocks work well for this goal. Root-level input ports for reusable systems.
Test a model that you want to use as a referenced model	Root-level input ports
Verify a model by using multiple test cases	Root Inport Mapping tool, using exported signal data.

Modeling Goal	Supported Techniques
Represent a continuous plant	All Root-level input ports work well for this goal.
Test a discrete algorithm	All Root-level input ports work well for this goal.

Signal Data

The amount, source, and kind of the signal data can influence the signal loading technique that you choose.

Signal Data	Supported Techniques
Large data set	From File or From Spreadsheet work well for large data sets, because they incrementally load the data.
Data exported by using a To File block	From File.
Data exported by using a To Workspace block	From Workspace.
Excel or CSV spreadsheet	From Spreadsheet or Signal Builder, which can import Microsoft Excel (all platforms) or CSV (Microsoft Windows platform with Microsoft Office only) spreadsheet data directly into Simulink.
Variable-size signals	From Workspace.

Data Format or Type

Each of the signal loading techniques supports a wide range of data formats for signal data (such as array or **Dataset**). A few signal loading techniques have some limitations for specific formats.

Note: Some of the Root Inport Mapping tool map modes do not support all the data types that you can use with the tool. For details, see “Choose a Base Workspace and MAT-File Format” on page 59-170.

Data Format or Type	Supported Techniques
Array	All. For array data in a Version 7.0 MAT-file, the From File block loads only double signal values. Use Version 7.3 MAT-files for other types of signal data.
Structure with time	All.
Structure without time	All.
MATLAB timeseries	All.
Simulink.SimulationData.Dataset	All.
Enumeration	All except that Signal Builder can load, but not output enumerations.
Fixed-point	Signal Builder can load, but not output fixed-point data. From File has a word length limit of less than 33 bits.
Function-call	Root-level input ports (select the Output function call parameter).

Bus Support

You can use any of the signal loading techniques to load bus data. However, you need to use a specific technique for some kinds of bus data.

For the Signal Builder block,

Type of Bus or Bus Element	Supported Techniques
Virtual and nonvirtual buses	All techniques support both types of buses. The Root Inport Mapping tool does not support loading bus data in rapid accelerator mode.
Partial bus specification	For the Signal Builder block, the outputs for loaded bus data are either scalar double signals or a flat virtual bus.

Type of Bus or Bus Element	Supported Techniques
	From File uses ground values for unspecified bus elements.
Array of buses signals	Root-level input ports.

Time Points

The kind of time points in signal data impacts the signal loading technique that you choose.

Time Points for Signal Data	Supported Techniques
Single time point	All.
Continuous	All.
Discrete	All.
Repeated sequence without time	Structure data by using root-level input ports and From Workspace

Location for Data Storage

Whether you want to store the signal data with the model or separate from the model impacts the signal loading technique that you choose.

Location	Supported Techniques
In a block	Signal Builder block
In the base or model workspace	<ul style="list-style-type: none"> • From Workspace block • Root-level input ports or a Trigger, Enable, or Function-Call Subsystem block
In a MAT-file separate from the model file	From File block
In an Excel or CSV spreadsheet	From Spreadsheet block.
	Tip

Location	Supported Techniques
	<ul style="list-style-type: none"> • For Excel and CSV spreadsheet requirements, see “Storage Formats” on page 59-142. • Loading CSV data is supported only for Microsoft Windows platforms. <p>You can use a Signal Builder block to import data from a spreadsheet. However, that block loads all the spreadsheet data into MATLAB memory and stores the data in the model. The From Spreadsheet incrementally loads the data directly from the spreadsheet.</p>

Signal Data Inspection

The Root Inport Mapping tool, From File block, and Signal Builder block each provide an interface for plotting and inspecting the signal data to load.

Handling of Loaded Data

How Simulink processes the signal data as it loads it into a model impacts the signal logging technique that you choose.

Data Loading Handling	Supported Techniques
Incremental data loading	From File and From Spreadsheet.
Interpolation	All.
Extrapolation	From File, From Spreadsheet, and From Workspace. For information about From Workspace extrapolation, see “Form output after final data value by”.
Zero-crossing detection	All except root-level input ports.
Fast restart	All techniques.

Simulation Mode

All signal loading techniques support all simulation modes except for SIL or PIL. Some techniques have limitations for specific simulation modes.

Simulation Modes	Supported Techniques
Normal and accelerator	All.
Rapid accelerator	All, with these rapid accelerator exceptions: <ul style="list-style-type: none"> • Root —level input ports support only array and structure data. • From Workspace does not support <code>timeseries</code> format.
ERT/GRT	All. From Workspace and From File blocks are not tunable.
SIL or PIL	From Workspace block.
External mode	All. Root-level input ports do not load bus data in external mode.

Map Data Using Root Inport Mapping Tool

In this section...

“The Model” on page 59-120

“Create Signal Data” on page 59-121

“Import and Visualize Workspace Signal Data” on page 59-122

“Map the Data to Inports” on page 59-123

“Save the Mapping and Data” on page 59-124

“Simulate the Model” on page 59-124

Use the Root Inport Mapping tool to import, visualize, and map signal and bus data to root-level inports.

Root-level inport mapping imports signal data meets most modeling requirements and maintains model flexibility.

- Test your model with signals from the workspace and use your model as a referenced model in a larger context without any modification. Test signals in your model without disconnecting the inports and connecting sources to them.
- Use the Root Inport Mapping tool to update the **Input** parameter based on the signal data that you import and map to root-level inports.
- Visually inspect signal data without loading all the signal data into MATLAB memory.

To use the Root Inport Mapping tool:

- 1 Create signal data in the MATLAB workspace.
- 2 For a Simulink model, import the data from the workspace. You can visualize the data you import.
- 3 Map the data to root-level inports.
- 4 Simulate the model.
- 5 Save the Root Inport Mapping scenario.

The Model

This model has three root-level Inport blocks. Two of the Inport blocks output scalar signals and the other Inport block outputs bus data. Open the model.

This example shows how you can use the Root Inport Mapping tool to test the model with data. This approach can be useful for performing standalone testing of a model that another model references.

Create Signal Data

You can define the signal data as MATLAB `timeseries` objects.

- 1 Define the time values for the signal data.

```
sampleTime = 0.01;
endTime = 10;
numberOfSamples = endTime * 1/sampleTime + 1;
timeVector = (0:numberOfSamples) * sampleTime;
```

- 2 Create the data for the two scalar signals. Naming the data variable to match the name of the corresponding signal makes it easier to map data to signals.

```
signal_1 = timeseries(sin(timeVector)*10,timeVector);
signal_2 = timeseries(rand(size(timeVector)),timeVector);
```

- 3 Create the signals for the bus.

```
busSignal.busElement_1 = timeseries(cos(timeVector)*2,timeVector);
busSignal.busElement_2 = timeseries(randn(size(timeVector)),timeVector);
```

- 4 Create the bus object for the output data type of the `Bus_1` Inport block. You can create the bus object from the bus signal that you defined. Use a bus object for bus signals that cross model reference boundaries.

```
busInfo = Simulink.Bus.createObject(busSignal);
```

Import and Visualize Workspace Signal Data

Import the signal data that you created from the workspace into the Root Import Mapping tool. Then you can use the tool to visualize the imported data.

- 1 Open the Root Import Mapping tool. Open the Block Parameters dialog box for one of the Import blocks in the model and click **Connect Input**.
- 2 In the Root Import Mapping tool, select the **From Workspace** button.

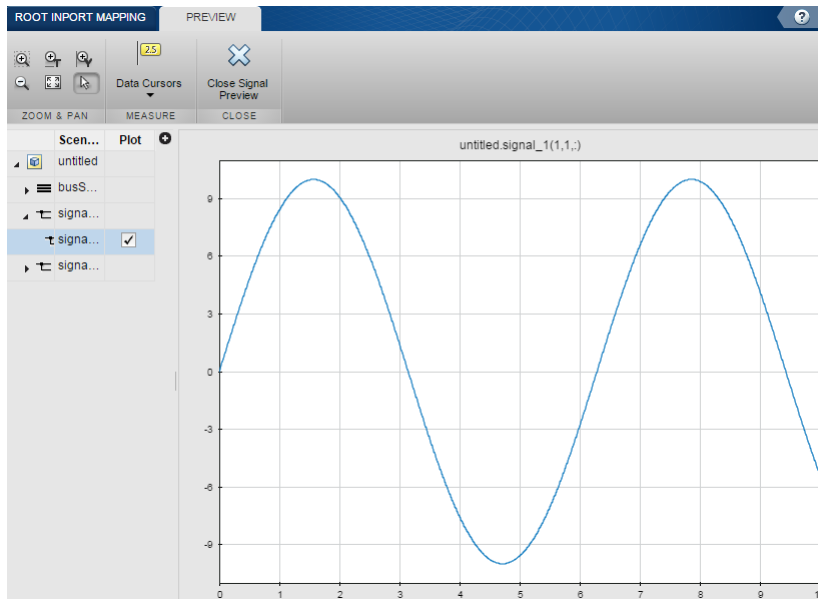

- 3 In the Import dialog box, specify a MAT-file to save signals to. For this example, use the default.
- 4 Click the **Name** check box to clear the data variables. Then click the check boxes for the **busSignal**, **signal_1**, and **signal_2** signals.

<input type="checkbox"/> Name	Format	Source	
<input type="checkbox"/> f0 endTime	Function Call	Base workspace	
<input type="checkbox"/> f0 numberOfSa...	Function Call	Base workspace	
<input type="checkbox"/> f0 sampleTime	Function Call	Base workspace	
<input checked="" type="checkbox"/> signal_1	Multidimensional Time ...	Base workspace	
<input checked="" type="checkbox"/> signal_2	Multidimensional Time ...	Base workspace	

Although in this example you select all the signals, you can select a subset of signals.

- 5 Leave the **Convert signals into a scenario dataset and save to MAT-file** check box enabled and click **OK**.
- 6 You can visualize signals. In the Root Inport Mapping dialog box toolbar, click **Preview Signals**.

The **Preview** tab appears. You can select signals to plot. For example, to see a plot of **signal_1**, in the Navigation pane, expand the scenario data set (in this example, the top node, **untitled**) and then expand the **signal_1** entry. Select the check box for **signal_1(1,1,:)** to plot the data.

- 7 Close the **Preview** tab by clicking the **Close Signal Preview** button.

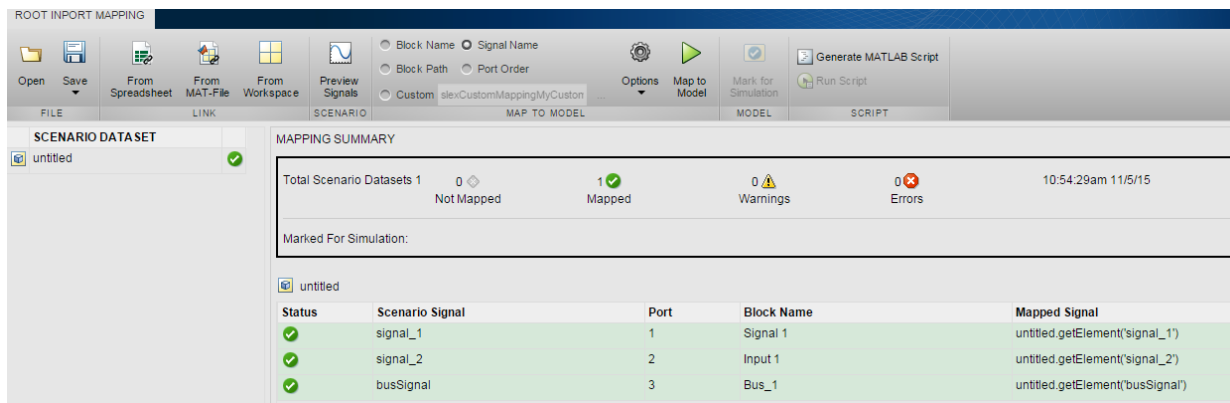

Map the Data to Inports

After you import the data, you map which data to use for specific Inport blocks.

- 1 Select the map mode, which specifies the criteria the mapping uses. In the toolbar, select the **Signal Name** radio button.

The signals in this model have names, so mapping based on signal names makes it very clear which data is going to an Inport block.

- 2 You can specify options for the mapping. In the toolbar, select **Options**. Select **Compile**, which updates the model after you do the mapping. Compiling the model verifies that signal dimensions and data types match between the data and the Inport blocks.
- 3 Map the data. In the Navigation pane, select the scenario data set. In the toolbar, click **Map to Model**. The dialog box shows the mapped data.

Save the Mapping and Data

If you want to reuse the mapping and data that you have set up, you can save it as a scenario. In the Root Inport Mapping tool, click **Save > Save As** and save the scenario as an `.mldatax` file.

Simulate the Model

- 1 In the Navigation pane, select the scenario data set.
- 2 In the toolbar, click **Mark for Simulation**.

The model is now set up to simulate using the workspace signal data that you mapped to root—level Inport blocks.

- 3 Simulate the model.

This model includes a Dashboard block that shows the data used during simulation for `signal_1`. The plot matches the plot you did when you visualized the data as part of the data import process.

Log Simulation Data for Roundtrip Data Loading

In this section...

“Use Dataset Format for Consistent Logged Data” on page 59-126

“Limit the Scope of Logged Data” on page 59-127

A common source of signal data to load into a model is data that you log from a simulation. You can use the signal data captured from a simulation as roundtrip input to:

- Simulate the same model again from a known starting point.
- Test simulation results.
- Simulate another model starting with the captured signal values from a model. For example, you can log signal data when you simulate a model. Then load the signal data from that simulation as inputs to a second model that you want to reference from the first model.

You can capture the signal data from a simulation in a workspace or in a file. Use one of these techniques to capture signal data from a simulation:

- Signal logging
- To Workspace block
- To File block
- Scope block
- In the **Configuration Parameters** > **Data Import/Export** pane, the **Output**, **States**, or **Final states** parameters
- Data store
- The `sim` command configured to log simulation data

For an example of using simulation data for roundtrip signal data loading, see “Import Data to Model a Continuous Plant” on page 59-128.

Use Dataset Format for Consistent Logged Data

Different logging techniques support different data formats. Most logging techniques support the `Dataset` format, which provides a consistent data format for logged signal data. You can use the `Simulink.SimulationData.Dataset` constructor to convert other data formats to `Dataset` format.

Limit the Scope of Logged Data

To log only the data that you require, use the **Configuration Parameters > Data Import/Export > Logging intervals** parameter to specify start and stop time intervals.

Related Examples

- “Import Data to Model a Continuous Plant” on page 59-128
- “Save Runtime Data from Simulation”
- “Export Signal Data Using Signal Logging” on page 59-57

Import Data to Model a Continuous Plant

A continuous plant model uses signal data that is smooth and uninterrupted in time. There is signal data for each time value. A continuous plant model uses a continuous solver (any solver other than an explicit discrete solver). The solver can be fixed-step or variable. The model includes blocks from the Continuous library in Simulink, such as an Integrator block.

To load data to represent a continuous plant, consider using either a root-level input port or a From Workspace block. Using a From Workspace block can be useful when loading data to a port buried deep within a model.

For the signal data:

- Specify a time vector and signal values extracted from a continuous plant. For example, extract from data that you acquire experimentally or from the results of a previous simulation.
- Use any of the data formats listed in “Loading the Data” on page 59-152. Here are recommended formats for the following imported data sources:
 - Another simulation — `Dataset`
 - An equation — MATLAB time expression
 - Experimental data — MATLAB `timeseries`, structure with time, a structure without time, or a data array

For structure data, see “Specify Time Data” on page 59-227.

Use Simulation Data to Model a Continuous Plant

This example illustrates how to reuse signal logging data from the simulation of one model in the simulation of a second model. For more information, see “Load Signal Logging Data” on page 59-150.

When reusing data from a variable step size simulation for simulation in another model, the second simulation must read the data at the same time steps as the first simulation.

- 1 Open the `ex_data_import_continuous` model.

This model uses the ode15s solver and produces continuous signals.

- 2 To use the output of this model as input to the simulation of another model, log the signal that you want to reuse. In the Simulink Editor, select that signal, click the

Simulation Data Inspector button arrow and click **Log Selected Signals to Workspace**.

Note: To enable signal logging, select the **Configuration Parameters > Data Import/Export > Signal logging** parameter. This model has **Signal logging** enabled.

- 3 Simulate the model.

Simulating the model saves a variable-step signal to the workspace, using the `logout` variable. The signal logging output is a `Simulink.SimulationData.Dataset` object.

Use the `Simulink.SimulationData.Dataset.getElement` method to access the logged data. The logged data for individual signals is stored in `Simulink.SimulationData.Signal` objects. For this model, there is one logged signal: `StepResponse`.

- 4 Open a second model, named `ex_data_import_continuous_second`.

You can configure this second model to simulate using the logged data from the first model. In this example, the second model uses a root-level Inport block to import the logged data. The Inport block has the **Interpolate data** option selected.

- 5 In the second model, select the **Configuration Parameters > Data Import/Export > Input** parameter.

Use the `Simulink.SimulationData.Signal.getElement` method to specify the `StepResponse` signal element:

- 6 Specify that for the second model, the Simulink solver runs at the time steps specified in the saved data (u). In the Data Import/Export pane, set the **Output options** parameter to `Produce additional output` and the **Output times** parameter to:

```
logout.getElement('StepResponse').Values.Time
```

- 7 Simulate the second model.

Note: Simulink does not feed minor time-step data through root input ports. For details about minor time steps, see “Minor Time Steps” on page 3-22.

- “Import Data for an Input Test Case” on page 59-133

More About

- “Overview of Signal Loading Techniques” on page 59-104

Import Data to Test a Discrete Algorithm

Discrete signals are signals that you define using evenly-spaced time values. One signal value is read at each time step, using the sample time of the source block.

Use a structure that has an empty time vector, which results in the model using the sample time of the source block. Using this approach avoids possible mismatches between the vector and the Simulink time steps. The double-precision rounding used by computers and the values expected by Simulink can differ.

Suppose you want to import signal data for this very simple model.

- 1 In the Block Parameters dialog box for the Inport block:
 - Set the sample time.
 - Clear the **Interpolate data** parameter.
- 2 For the data that you want to import, specify a structure variable that does *not* include a time vector. For example, for the variable called `import_var`:

```
import_var.time = [];
import_var.signals.values = [0; 1; 5; 8; 10];
import_var.signals.dimension = 1;
```

The input for the first time step is read from the first element of an input port value array. The value is 0. The value for the second time step is read from the second element of the value array (1), and so on.

For details about how to specify the signal value and dimension data, see “Specify Signal Data” on page 59-226.

- 3 Select the **Configuration Parameters > Data Import/Export > Input** parameter and specify `import_var` for the data to import.

If you are using a From Workspace block to import data, use a similar approach. In addition, set the **Form output after final data value by** parameter to a value other than Extrapolation.

Import Data for an Input Test Case

In this section...

“Guidelines for Importing a Test Case” on page 59-133

“Example of Test Case Data” on page 59-134

“Use From Workspace Block for Test Case” on page 59-134

“Use Signal Builder Block for Test Case” on page 59-135

For most input test cases, you try to minimize the number of time points. The signal data you load includes samples with ramps and discontinuities.

Guidelines for Importing a Test Case

Typically when importing a test case data, you want to minimize the number of time points. The test data focuses on discontinuities in the signal data.

- Create a signal that has ramps and steps. In other words, the signal has one or more discontinuities.
- Create the signal using the fewest points possible.
- Have the Simulink solver execute at the specified discontinuities.

To import this signal in Simulink, use a From Workspace, From File, or Signal Builder block, all of which support zero-crossing detection.

You can load data of these types:

- `A Simulink.SimulationData.Dataset`
- Array
- `Simulink.SimulationData.Signal`
- Structure
- A structure array containing data for all input ports.
- Empty matrix — Use an empty matrix for ports for which you want to use ground values, without having to create data values.
- Time expression

Specify a time vector and signal values, but specify only the time steps at points where the shape of the output jumps. For details about specifying a time vector, see “Specify Time Data” on page 59-227.

Use any of the input data formats described in “Loading the Data” on page 59-152, except for MATLAB time expressions.

Example of Test Case Data

The following is an example of test case data:

The following two examples use this test case data.

Use From Workspace Block for Test Case

- 1 Open the model `ex_data_import_test_case_from_workspace`.

- 2 Enable zero-crossing detection. In the From Workspace block dialog, select **Enable zero-crossing detection**. Zero-crossing detection allows you to capture discontinuities accurately.
- 3 Create a signal structure for the test case. At each discontinuity, enter a duplicate entry in the time vector, which generates a zero crossing and forces the variable-step solver to take a time step at this exact time. For details, see “Load Data Using the From Workspace Block” on page 59-213.

Define the `var` structure representing the test case:

```
var.time = [0 1 1 5 5 8 8 10];
var.signals.values = [0 0 2 2 2 3 3 3]';
var.signals.dimensions = 1;
```

- 4 To import the test case structure, in the From Workspace block dialog box, in the **Data** parameter, specify `var`.
- 5 Simulate the model. The Scope block reflects the test case data.

Use Signal Builder Block for Test Case

Instead of using a From Workspace block, you can use a Signal Builder block to either:

- Create a signal interactively
 - Import a signal from a MAT-file
- 1 Open the `ex_data_import_signal_builder` model.

- 2 Create a structure and save it in a MAT-file:

```
var.time = [0 1 1 5 5 8 8 10];
```

```
var.signals.values = [0 0 2 2 2 3 3 3]';  
var.signals.dimensions = 1;  
var.signals.label = 'var';  
save var.mat var
```

- 3** Open the Signal Builder dialog box by double-clicking the Signal Builder block.
- 4** Select **File > Import From File** menu item, and select the `var.mat` file.
- 5** In the **Select** parameter, select **Replace existing dataset**. In the **Data to Import** section, select the **Select All** check box. Confirm the selection and click **OK**.

The Signal Builder block display reflects the test case data.

Specify Data for Root-Level Input Ports

In this section...

- “Root-Level Input Ports” on page 59-137
- “Specify Input Data” on page 59-138
- “Forms of Input Data” on page 59-139
- “Time Data for the Input Parameter” on page 59-139

Root-Level Input Ports

Using a root-level input port to load signal data meets many modeling requirements. This technique is useful for importing many signals to many blocks and testing your model as a referenced model in a wider context with signals from the workspace, without modifying your model.

You can import signal data from a workspace and apply it to these blocks:

- **Inport** block
- **Enable** block
- **Trigger** block that has an edge-based (rising, falling, or either) trigger type

These blocks import data from the workspace based on the value of the **Configuration Parameters > Data Import/Export > Input** parameter.

Tip To import many signals to root-level input ports, consider using the Root Inport Mapping tool. If you use that tool, you do not need to enter values in the **Input** parameter. The tool updates the **Input** parameter based on the signal data you import and the mapping you specify. For more information, see “Map Root Inport Signal Data” on page 59-166.

You can also import data from a workspace using a From Workspace block. For details, see the **From Workspace** documentation and “Import Data for an Input Test Case” on page 59-133.

Specify Input Data

- 1 Select the **Configuration Parameters > Data Import/Export > Input** parameter.
- 2 Enter an external input specification in the adjacent edit box and click **Apply**. For a list of the forms of data you can specify, see “Forms of Input Data” on page 59-139.

In the **Input** box, specify the signal input using one of these approaches:

- Create data at runtime for each simulation time step using the input $u = UT(t)$ for either a MATLAB function (expressed as a string) or MATLAB expression.
- Specify the data directly, using:
 - A `Simulink.SimulationData.Dataset` object. Specify only one `Dataset` object.
 - A 2D array of input values and time for all input ports, in the form $UT = [T, U_1, \dots, U_n]$, where $T = [t_1, \dots, t_m]'$
 - A comma-separated list of variables or MATLAB expressions. Do not include a `Dataset` object in a comma-separated list.

Comma-Separated List

If you specify `Dataset` data, specify only one `Dataset` object for the **Input** parameter. Do not include it in a comma-separated list.

Each variable or expression corresponds to a specific input port. Each variable or expression in the list must evaluate to the appropriate object that corresponds to one of the root-level input ports of the model. The first item corresponding to the first root-level input port, the second to the second root-level input port, and so on.

For an `Enable` or `Trigger` block, the signal driving the enable or trigger port must be the last item in the comma-separated list. If you have both an enable and a trigger port, then specify:

- The enable port as the next-to-last item in the list
- The trigger port as the last item

Use an empty matrix to specify ground values for a port. For example, to load data for input ports `in1` and `in3`, and to use ground values for port `in2`, enter the following in the **Input** parameter:

```
in1, [], in3
```

Forms of Input Data

The input data can take these forms:

- `Simulink.SimulationData.Dataset` object — Collection of logged data in MATLAB timeseries format. For details, see “Create Dataset Data for Root Inport Ports” on page 59-216.
- MATLAB timeseries — For details, see these sections:
 - “Create MATLAB Timeseries Data for Root Inports” on page 59-218
 - “Import Bus Data to Top-Level Input Ports” on page 59-154
- Array — See “Create Data Arrays for Root-Level Inports” on page 59-220.
- `Simulink.SimulationData.Signal` — For details, see “Log Simulation Data for Roundtrip Data Loading” on page 59-126.
- Structure — To simplify the specification of external data to input, you can load data for a subset of root-level input port blocks. This avoids having to create data structures for the ports for which you want to use ground values. For information about ground values, see “Initialize Signals and Discrete States” on page 62-47. See “Create Data Structures for Root Inports” on page 59-225.
- Structure array containing data for all input ports.
- Empty matrix — Use an empty matrix for ports for which you want to use ground values, without having to create data values.
- Time expression — See “Create MATLAB Time Expressions for Root Inports” on page 59-224.

Time Data for the Input Parameter

Time values that you specify in the **Input** parameter have no impact on the times the solver uses. The **Interpolate** parameter setting for the root-level input block (for example, the root-level Inport block) specifies how to handle output at time steps for which no corresponding workspace data exists.

Create Data for a From File Block

In this section...

“Data Saved by a To File Block” on page 59-141

“Supported MAT-File Versions” on page 59-141

“Storage Formats” on page 59-142

“Timestamps” on page 59-143

“Bus Data” on page 59-143

“MAT-File Variable” on page 59-143

Data Saved by a To File Block

The From File block loads data that was written by a To File block without any modifications to the data or any other special provisions.

Supported MAT-File Versions

The supported MAT-file versions are:

- Version 7.0 or earlier
- Version 7.3

For a Version 7.0 and earlier MAT-file, the From File block loads the complete, uncompressed data from the file into memory when the simulation begins. For a Version 7.3 MAT-file, the From File block incrementally loads data from the file during simulation.

For more information about MAT-files, see “MAT-File Versions”.

Convert Version 7.0 and Earlier Version MAT-Files

If you have a Version 7.0 or earlier version MAT-file that you want to use with the From File block, consider converting the file to Version 7.3. Use a Version 7.3 MAT-file if you want the From File block to load data incrementally during simulation or you want to use MATLAB `timeseries` data. For example, to convert a Version 7.0 file named `my_data_file.mat` that contains the variable `var`, at the MATLAB command prompt, enter:

```
load('my_data_file.mat')
save('my_data_file.mat', 'var', '-v7.3')
```

Storage Formats

When the From File block loads data from a MAT-file, that data must be stored in array format or as a MATLAB `timeseries` object.

Array Data

You can use the array format for only vector, double, noncomplex signal data.

For a Version 7.0 MAT-file, the From File block loads array data, but not MATLAB `timeseries` data.

The array format for stored data is a matrix containing two or more rows. The matrix in the MAT-file must have the following form:

$$\begin{bmatrix} t_1 & t_2 & \dots & t_{final} \\ u1_1 & u1_2 & \dots & u1_{final} \\ \dots & & & \\ un_1 & un_2 & \dots & un_{final} \end{bmatrix}$$

The first element of each column contains a timestamp. The remainder of each column contains data for the corresponding output values. Each element must be a double. Elements cannot include a NaN, Inf, or -Inf.

MATLAB Timeseries Data

To use bus data with a From File block, use the MATLAB `timeseries` format.

MATLAB `timeseries` format data can have:

- Any dimensionality and complexity
- Any built-in data type, including **Boolean**
- A fixed-point data type with a word length of up to 32 bits
- An enumerated data type

For data stored using the array format, the width of the From File output depends on the number of rows in the matrix. For a matrix containing m rows, the block outputs a vector of length $m-1$.

The MATLAB `timeseries` format supports the following simulation and code generation modes:

- Normal
- Accelerator
- Rapid accelerator
- Model reference accelerator

See the From File block documentation for an example of creating a MAT-file with MATLAB `timeseries` data load with a From Workspace block.

Timestamps

The timestamps in the file must be monotonically nondecreasing.

Bus Data

The From File block supports loading nonvirtual bus signals.

The data must be in a MATLAB structure that matches the bus hierarchy. Each leaf of the structure must be a MATLAB `timeseries` object.

The structure can underspecify the bus signal, but must not overspecify the bus signal. The structure cannot have any elements that do not have corresponding signals in the bus.

The structure does not require a `timeseries` object for every element in the bus hierarchy. However, the structure must have a `timeseries` object for at least one of the signals in the bus. For signals that do not specify data, the From File block outputs the ground values.

MAT-File Variable

If a MAT-file contains only one variable, then the From File block uses that variable. If the MAT-file contains more than one variable:

- For Version 7.3 MAT-files, the From File block uses the variable that is first alphabetically.
- For Version 7.0 or earlier MAT-files, the From File block uses the first variable. However, for these versions, the ordering algorithm for variables is complicated. Use a MAT-file that contains just the variable with the data that you want the From File block to load.

Create Data for a From Workspace Block

In this section...

“Use Data from a To Workspace Block” on page 59-145

“Specify Variable-Size Signals” on page 59-145

“Data for the From Workspace Block” on page 59-145

“Bus Data” on page 59-148

“Use Data from a To File Block” on page 59-149

Use Data from a To Workspace Block

You can use the From Workspace block to load data exported by a To Workspace block in a previous simulation for use in a later simulation. Save the To Workspace block data in either `Timeseries` or `Structure with Time` format.

Specify Variable-Size Signals

You can use a To Workspace block (with `Structure` or `Structure With Time` format) or a root Output block to log variable-size signals. Then use the To Workspace variable with the From Workspace block.

Alternatively, create a MATLAB structure that contains variable-size signal data. For each `values` field in the structure, include a `valueDimensions` field that specifies the run-time dimensions for the signal. For details, see [Simulink Models Using Variable-Size Signals](#) on page 64-7.

Data for the From Workspace Block

You can load these kinds of data using a From Workspace block:

- A MATLAB timeseries object
- A structure of MATLAB `timeseries` objects
- A structure, with or without time
- A two-dimensional matrix

To use workspace data that is in `Simulink.SimulationData.Dataset` format, extract a MATLAB `timeseries` object from the data set. For example, if you use signal logging

with `Dataset` format and use the default output variable `logout`, for a single logged signal enter:

```
logout.get(1).values
```

MATLAB Timeseries Data

You can use a MATLAB `timeseries` object for any data type, complexity, or fixed dimensions.

Real signals of type `double` can be in any format that the From Workspace block supports. For complex signals and real signals of a data type other than `double`, use any format except `Array`.

Structure of MATLAB timeseries Data

Use a structure of MATLAB `timeseries` objects for bus data. Match the bus hierarchy and specify a `timeseries` object for each leaf signal in the bus.

Structures

You can use a structure for one-dimensional or multidimensional signals, with or without time values. For the structure, use this format:

- A `signals.values` field, which contains a column vector of signal values.
- An optional `signals.dimensions` array, which contains the dimensions of the signal.
- An optional `time` vector of doubles, which is a column vector of timestamps.

The `n`th `time` element is the timestamp of the `n`th `signals.values` element.

The form of a structure that you use depends on whether you are importing data for:

- Discrete signals (the signal is defined at evenly spaced values of time) — Use a structure that has an empty time vector.
- Continuous signals (the signal is defined for all values of time) — The approach that you use depends on whether the data represents a smooth curve or a curve that has discontinuities (jumps) over its range.

For examples, see:

- “Import Data to Test a Discrete Algorithm” on page 59-131
- “Use From Workspace Block for Test Case” on page 59-134

For both discrete and continuous signals, specify a **signals** field, which contains an array of substructures, each of which corresponds to a model input port. For details, see “Specify Signal Data” on page 59-226.

Each **signals** substructure must contain two fields: **values** and **dimensions**.

- The **values** field must contain an array of inputs for the corresponding input port. If you specify a time vector, each input must correspond to a time value specified in the **time** field.

If the inputs for a port are scalar or vector values, the **values** field must be an M-by-N array. If you specify a time vector, M must be the number of time points specified by the **time** field and N is the length of each vector value.

If the inputs for a port are matrices (2-D arrays), the **values** field must be an M-by-N-by-T array. M and N are the dimensions of each matrix input and T is the number of time points. For example, suppose that you want to input 51 time samples of a 4-by-5 matrix signal into one of your model input ports. Then, the corresponding **dimensions** field of the workspace structure must equal [4 5] and the **values** array must have the dimensions 4-by-5-by-51.

- The **dimensions** field specifies the dimensions of the input. If each input is a scalar or vector (1-D array) value, the **dimensions** field must be a scalar value that specifies the length of the vector (1 for a scalar). If each input is a matrix (2-D array), the **dimensions** field must be a two-element vector whose first element specifies the number of rows in the matrix and whose second element specifies the number of columns.

For continuous signals, you can specify a **time** field, which contains a time vector. How you specify the time values depends on the kind of signal data that you want.

For information about defining MATLAB structures, see “Create a Structure Array” in the MATLAB documentation.

Signal Data	Time Data Recommendation
Evenly spaced discrete signals	Use an expression in this form: <code>timeVector = timeStep * [startTime:numSteps-1]'</code> The vector is transposed. Also, because the start time is a time step, you need specify the number of steps you

Signal Data	Time Data Recommendation
	<p>want minus 1. For example, to specify 50 time values at 0.2 time steps:</p> <pre>T1 = 0.2 * [0:49]'</pre> <hr/> <p>Note: Do <i>not</i> use an expression in this form:</p> <pre>timeVector = [startTime:timeStep:endTime]'</pre> <p>For example, do not use:</p> <pre>T2 = [0:0.2:10]'</pre> <p>This time vector form is not equivalent to the form that multiplies by time steps (T1), because of double-precision rounding used by computers. Simulink expects exact values, with no double-precision rounding. Using the T2 form can lead to unexpected simulation results.</p>
Unevenly spaced values	<p>Use any valid MATLAB array expression; for example, [1:5 5:10] or (1 6 10 15).</p> <p>The From Workspace, From File, and Signal Builder blocks support zero-crossing detection. If the root-level input port is connected to one of those blocks, you can specify a zero-crossing time by using a duplicate time entry.</p>

Matrix

You can use a matrix to specify only one-dimensional signals.

The first element of each matrix row is a timestamp. The rest of each row is a scalar or vector of signal values.

Bus Data

To create bus data to load with a From Workspace block, use a structure of MATLAB `timeseries` objects. Match the bus hierarchy and specify a `timeseries` object for each leaf signal in the bus. Set up the data the same way as you do for loading bus signals to a

root-level input port. For details, see “Import Bus Data to Top-Level Input Ports” on page 59-154.

Use Data from a To File Block

Loading data that was exported to a file by a To File block using MATLAB `timeseries` does not require that you change the data.

If you set the To File block **Save format** parameter to `Array`, transpose the exported array data. The data saved by the To File block contains columns with consecutive timestamps, followed by the corresponding data. The transposed data contains rows with consecutive timestamps, followed by the corresponding data. To provide the required format, use MATLAB `load` and `transpose` commands with the MAT-file (see “Reshaping a Matrix”). To avoid transposing the data again later, resave the transposed data.

Load Signal Logging Data

You can use signal logging to log data for specified signals during simulation. Then you can load that saved simulation data as input for another simulation of that model (or the simulation of a different model). For example, using this approach is useful to perform standalone simulation of a referenced model.

- 1 Use the default signal logging output variable, `logout`, or specify a variable using the **Configuration Parameters > Data Import/Export > Signal logging** edit box.
- 2 Simulate the parent model.

The signal logging output is a `Simulink.SimulationData.Dataset` object.

- 3 Use the `Simulink.SimulationData.Dataset.getElement` method to access the logged data. The logging data for individual signals is stored in `Simulink.SimulationData.Signal` objects.
- 4 For the referenced model that you want to simulate standalone, use the `Simulink.SimulationData.Signal.getElement` method to specify signal elements for the **Configuration Parameters > Data Import/Export > Input** parameter.

For example:

- 5 Simulate the referenced model.

For an example of loading signal logging data for a model that uses model referencing, see the `sldemo_mdref_bus` example. After you open the model, double-click the blue block labeled **Interface Specification** and see the sections called:

- Logging Model Reference Signals
- Loading Data

Open the `sldemo_mdref_bus` model.

Also, the “Import Data to Model a Continuous Plant” on page 59-128 example illustrates loading signal logging data.

To import signal logging data for array of buses signals, see “Import Array of Buses Data” on page 59-159.

Load Data to Root-Level Input Ports

You can load data from a workspace and to a root-level inport.

- **Inport** block
- **Enable** block
- **Trigger** block that has an edge-based (rising, falling, or either) trigger type

These blocks import data from the workspace based on the value of the **Configuration Parameters > Data Import/Export > Input** parameter.

Tip To import many signals to root-level input ports, consider using the Root Inport Mapping tool. For more information, see “Map Root Inport Signal Data” on page 59-166.

You can also import data from a workspace using a From Workspace block. For details, see the From Workspace documentation and “Import Data for an Input Test Case” on page 59-133.

Loading the Data

Use the **Configuration Parameters > Data Import/Export > Input** parameter to load data from a workspace and apply it to the root-level input ports of a model during a simulation run.

Note: The use of the **Input** box is independent of the setting of the **Format** list on the **Data Import/Export** pane.

Simulink linearly interpolates or extrapolates input values as necessary if you select the **Interpolate data** option for the corresponding **Inport**, **Enable**, or **Trigger** block.

Simulink resolves symbols used in the external input specification as described in “Symbol Resolution” on page 4-82. See the documentation of the **sim** command for some data import capabilities that are available only for programmatic simulation.

Import Bus Data to Top-Level Input Ports

In this section...

“Imported Bus Data Requirements” on page 59-154

“Import Bus Data to a Top-Level Inport” on page 59-155

“Get Information about Bus Objects” on page 59-158

“Create Structures of Timeseries Objects from Buses” on page 59-158

“Import Array of Buses Data” on page 59-159

You can import bus data to top-level input ports by manually specifying the data in the **Inport** configuration parameter or by using the Root Inport Mapping tool. For information about importing bus data using the Root Inport Mapping tool, see “Import Bus Data” on page 59-176.

Imported Bus Data Requirements

To import bus data to a top-level input port, use a structure of MATLAB `timeseries` objects. The `timeseries` objects represent the bus elements that you want to specify values for. Any bus elements for which you do not include a field in the structure use ground values. You can include a structure of `timeseries` objects as a `Dataset` object element.

In the top-level Inport block, set **Data type** to **BUS** and specify the name of a bus object.

A top-level input port defined by a bus object (see `Simulink.Bus`) can import data from a `Simulink.SimulationData.Dataset` object or from a structure of MATLAB `timeseries` objects. The `Dataset` object or structure represents the bus elements for which you want to specify values. Any bus elements for which you do not include a field in the structure use ground values.

The structure of MATLAB `timeseries` objects must match the bus elements in terms of:

- Hierarchy
- Name of the structure field, which must match the bus element name. (The `name` property of the `timeseries` object does not need to match the bus element name.)
- Data type (for tunable parameters)

- Dimensions
- Complexity

The order of the structure fields does not have to match the order of the bus elements.

You can specify an empty matrix in a comma-separated list. The empty matrix uses the ground values for the bus signal.

For example, to load data for input ports `in1` and `in3`, and to use ground values for port `in2`, enter the following in the **Input** parameter:

```
in1, [], in3
```

Note: If you use a structure of MATLAB `timeseries` objects for a root Inport block in a model with multiple root Inport blocks, all root Inport blocks must use MATLAB `timeseries` objects. Convert any root Inport block data that uses `Simulink.TsArray` or `Simulink.Timeseries` objects to MATLAB `timeseries` objects.

Initialize Bus Signals

You can initialize bus signals, including using partial specification of initialization data. For details, see “Specify Initial Conditions for Bus Signals” on page 63-80.

For details about importing array of bus data to a root Inport block, see “Import Array of Buses Data” on page 59-159.

Limitations for Importing Bus Data to Top-Level Inputs

The signal data that you can use the Root Inport Mapping tool to import and map to a top-level Inport block can include bus data. You cannot use that tool to map bus signals to a top-level Enable or Trigger block.

You cannot use input ports to import buses in external modes. To import bus data in rapid accelerator mode, use `Dataset` format.

Import Bus Data to a Top-Level Inport

This model has two Inport blocks connected to Scope blocks. The data type of the `In1` block is inherited (nonbus data) and the data type of the `In2` block is defined by the bus object `BusObject`. The model has a callback that loads `BusObject`.

The `BusObject` bus object has two elements:

- `c`
- `s1`, which is a subbus that has two elements:
 - `a`
 - `b`

- 1 Open the .
- 2 Create a MATLAB `timeseries` object for `In1`, for which you want to import nonbus data.

For example:

```
t1 = (1:10)';
d1 = sin(t1);
in1 = timeseries(d1,t1);
```

- 3 Create a structure of MATLAB `timeseries` objects, with one `timeseries` object for each leaf bus element for which you do not want to use ground values. This example uses ground values for the `b` bus element, so it does not need a `timeseries` object for that element.

```
t2 = (1:5)';
d2 = cos(t2);
in2.c = timeseries(d1,t1);
in2.s1.a = timeseries(d2,t2);
```

The MATLAB `timeseries` objects that you create must match the corresponding bus elements, as described in “Imported Bus Data Requirements” on page 59-154.

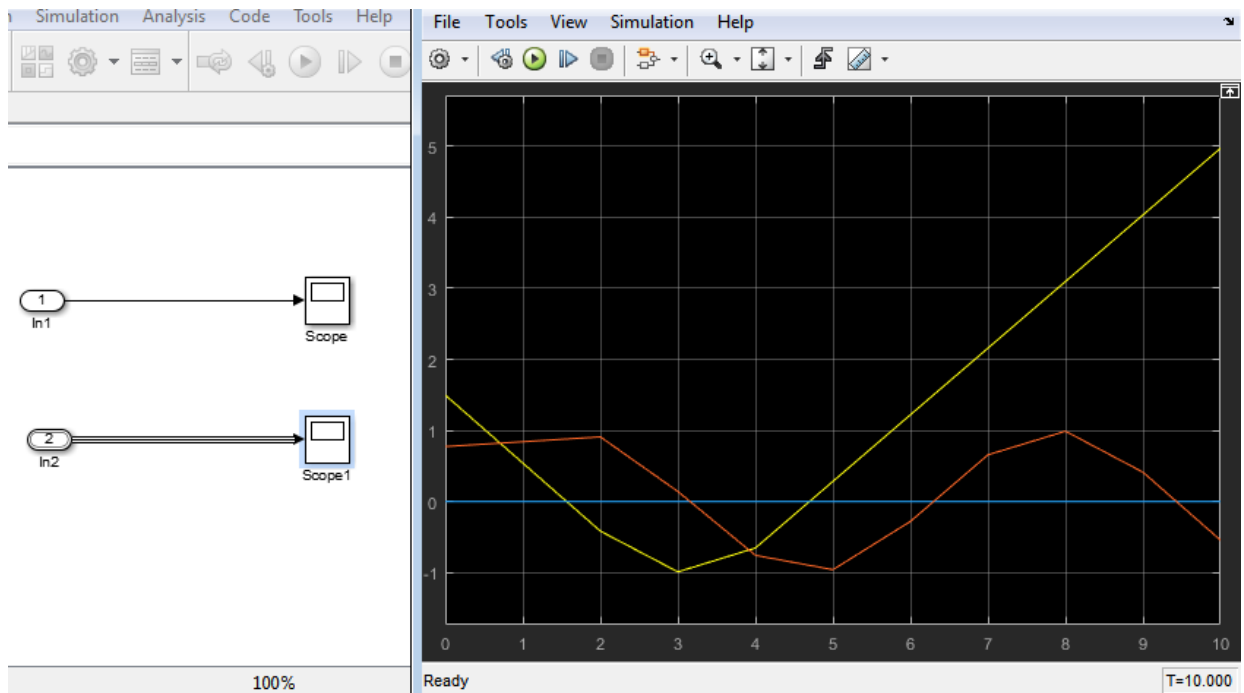

- 4 Create a Dataset object and add `in1` and `in2` to the data set.

```
ds = Simulink.SimulationData.Dataset;
ds = ds.addElement(in1, 'in1_signal');
ds = ds.addElement(in2, 'in2_signal');
```

- 5 In the **Configuration Parameters** > **Import/Export** > **Input** parameter edit box, enter the Dataset object `ds`.

- 6 Simulate the model. The Scope block connected to In2 shows the imported bus data.

Get Information about Bus Objects

To determine the number of MATLAB `timeseries` objects and data type, complexity, and dimensions needed for creating a structure of `timeseries` objects from a bus, use these methods:

- `Simulink.Bus.getNumLeafBusElements`
- `Simulink.Bus.getLeafBusElements`

For example, for the bus object `BusObject`:

```
num_el = BusObject.getNumLeafBusElements
```

```
num_el =
```

```
    3
```

```
el_list = BusObject.getLeafBusElements
```

```
el_list =
```

```
    3x1 BusElement array with properties:
```

```
    Min  
    Max  
    DimensionsMode  
    SampleTime  
    Description  
    Units  
    Name  
    DataType  
    Complexity  
    Dimensions
```

```
el_list(1).Dimensions
```

```
ans =
```

```
    1
```

Create Structures of Timeseries Objects from Buses

If you have `timeseries` objects defined, you can use them to create a structure of `timeseries` objects based on a bus object. Use the

`Simulink.SimulationData.createStructOfTimeseries` function. For example, if you have defined `timeseries` objects `ts1`, `ts2`, and `ts3`, and you have a bus object `MyBusObject`, you can use this command to create a structure of `timeseries` objects:

```
input = Simulink.SimulationData.createStructOfTimeseries('MyBusObject', ...  
{ts1,ts2,ts3});
```

The number of `timeseries` objects in the cell array must match the number of leaf elements in the bus object. The data type, dimensions, and complexity of each `timeseries` object must match those attributes of the corresponding bus object leaf node.

Import Array of Buses Data

To import (load) array of buses data using a root Inport block, use an array of structures of MATLAB `timeseries` objects.

Note: You cannot use an Enable, Trigger, From Workspace, or From File block to import data for an array of buses.

Full Specification of Data

You can use logged data for an array of buses signal from a previous simulation as roundtrip input to a root-level Inport in a subsequent simulation run. The logged data is a full specification of data for the Inport block.

If you construct an array of structures of MATLAB `timeseries` objects to specify fully the data to import:

- Specify the structure fields in the same order as the signals in the bus signals.
- Do not include more fields in the structure than there are signals in the bus.

For leaf fields, match exactly the data type, dimensions, and complexity of the corresponding signal in the bus.

Partial Specification of Data

To specify partial data for array of buses, create a MATLAB array of structures with MATLAB `timeseries` objects at the leaf nodes.

The structure that you create to specify partial data must be consistent with these rules:

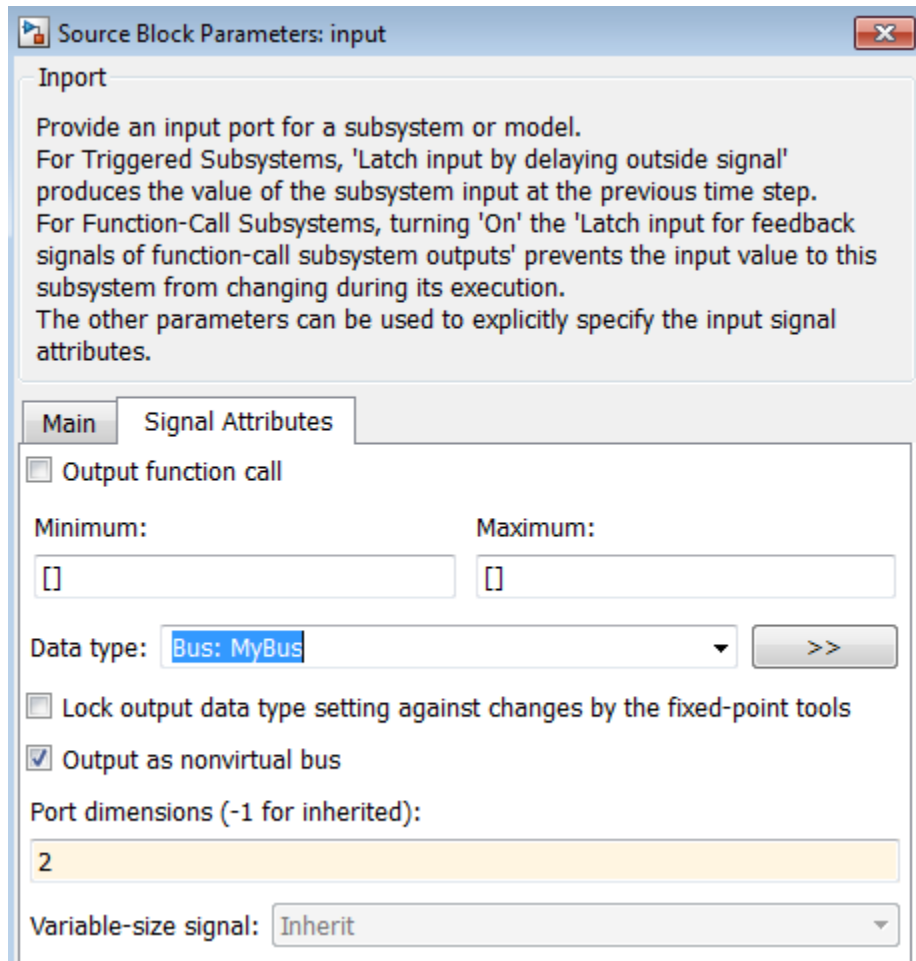

- You can omit fields, including leaf nodes and subbranches. You can also omit dimensions. If you do not specify a field, Simulink uses the ground value for that field.
- For subbus nodes, make the dimension of each field equal to, or smaller than, the dimension for the corresponding node of the array of buses.

This example shows how you can specify partial data to be imported using a root Inport block whose data type is defined as bus object MyBus. You can open the model (ex_partial_loading_aob_model) and the MATLAB code that defines the data to import (ex_partial_loading_aob_data.m).

When you simulate ex_partial_loading_aob_model, you see:

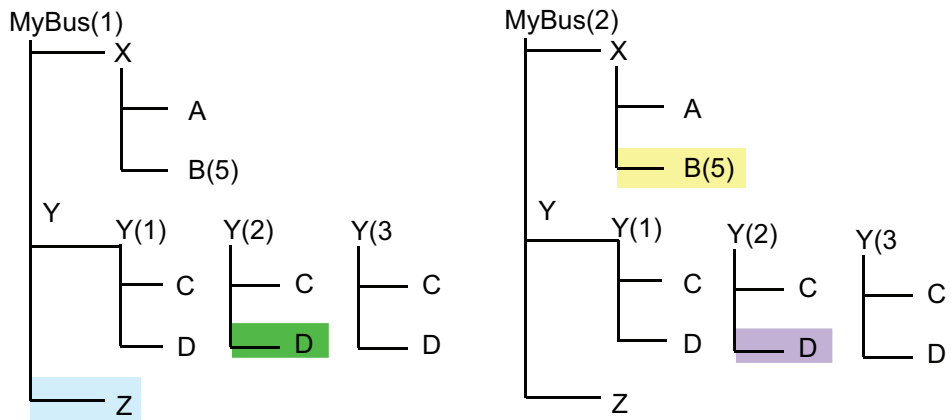

The input Inport block uses the MyBus bus object as its data type.

The MyBus array of buses includes MyBus (1) and MyBus (2). The port dimension is set to 2 to reflect the two buses in the array of buses, and **Output as nonvirtual bus** is enabled.

Here are the elements of the array of buses, which includes MyBus (1) and MyBus (2). The color highlighting shows the nodes of the array of buses for which data is being imported.

Here is MATLAB code that defines the data to import. The color that highlights the code matches the color of the corresponding node in the array of buses. To view the code used in this model, open the MATLAB code file `ex_partial_loading_aob_data.m`.

```

7      %% Create timeseries data for leaf signals
8 -   N = 10; Ts = 1;
9 -   Time = ((0:N)*Ts)';
10 -  [m, n] = size(Time);
11
12 -  ZData = repmat(ex_partial_loading_aob_basicColors.Blue,m,n);
13 -  BData = repmat(ex_partial_loading_aob_basicColors.Yellow,m,5);
14 -  D1Data = repmat(ex_partial_loading_aob_basicColors.Green,m,n);
15 -  D2Data = repmat(ex_partial_loading_aob_basicColors.Purple,m,n);
16
17      %% Create individual timeseries objects to represent Z, B, D1 and D2
18 -  ZT = timeseries(ZData, Time, 'Name', 'Z');
19 -  BT = timeseries(BData, Time, 'Name', 'B');
20 -  D1T = timeseries(D1Data, Time, 'Name', 'D1');
21 -  D2T = timeseries(D2Data, Time, 'Name', 'D2');
22
23      %% Construct MyBusValue(1)
24
25      % Y(2).D
26 -   Y(2) = struct('D',D1T);
27
28      % Set X.B to empty to allow the second element to support specification for
29      % this field
30 -   X = struct('B',[]);
31
32      % MyBusValue(1)
33 -   MyBusValue(1) = struct('Z',ZT,'Y',Y,'X',X);
34 -   clear X Y;
35
36      %% Construct MyBusValue(2)
37
38      % Specify timeseries for MyBusValue(2).X.B
39 -   MyBusValue(2).X.B = BT;
40
41      % Specify timeseries for MyBusValue(2).Y(2).D
42 -   MyBusValue(2).Y(2).D = D2T;
43

```

In the code that defines the import data:

- The `timeseries` object `MyBusValue` specifies the data for the highlighted nodes.
- The `timeseries` object `BT` for `MyBus(2)`, because `BT` is a leaf node, it must match exactly the dimensions, data type, and complexity of the corresponding bus element.
- The structure specifies data for `Y(2)`. You can skip the first and last subbuses of `Y` (that is, `Y(1)` and `Y(3)`).

This example specifies data for `Y(2)`; you can skip the first and last subbuses of `Y` (that is, `Y(1)` and `Y(3)`).

After you define the `MyBusValue` variable for the import data, set the **Configuration Parameters** > **Data Import/Export** > **Input** parameter to `MyBusValue`.

Map Root Inport Signal Data

In this section...

“Open the Root Inport Mapping Tool” on page 59-166

“Command-Line Interface” on page 59-167

“Import and Mapping Workflow” on page 59-167

“Choose a Map Mode” on page 59-167

To import, visualize, and map signal and bus data to root-level inports, use the Root Inport Mapping tool or the `getRootInportMap` function. At the top level of a model or referenced model, root-level inports are ports of one of these blocks:

- Inport block
- Enable block
- Trigger block

Root-level inport blocks import data from the MATLAB workspace based on the value of the **Configuration Parameters > Data Import/Export > Input** parameter.

Root-level inport mapping imports signal data in a way that meets most modeling requirements and maintains model flexibility. You can:

- Test your model with signals from the workspace and use your model as a referenced model in a larger context without any modification.
- Update the **Input** parameter based on the signal data that you import and map to root-level inports.
- Visually inspect signal data without loading all the signal data into MATLAB memory.

Tip To determine whether another data import technique meets your specific modeling requirements (such as the amount of data or the storage location) better, see “Comparison of Signal Loading Techniques” on page 59-112.

Open the Root Inport Mapping Tool

Use either of these approaches to open the Root Inport Mapping tool:

- In the **Configuration Parameters > Data Import/Export** pane, click **Connect Input**.
- In the block parameters dialog box for the Inport block, select **Connect Input**.

Command-Line Interface

You can use the `getRootInportMap` to create a custom object to map signals to root-level inports and `getS1RootInportMap` to create a custom mapping mode. For more information, see “Create and Use Custom Map Modes” on page 59-201.

Import and Mapping Workflow

- 1 Identify and possibly create signal data to import and map on page 59-169.
- 2 Import on page 59-175 and inspect signal data on page 59-179.
- 3 Map the imported signal data on page 59-166. For example, you can map the signal data by block path or signal name.
- 4 Simulate the model using the mapped data. After associating a scenario with the model, you can generate scripts for simulation with scenarios on page 59-200 to perform batch simulations.
- 5 Optionally, save the current Root Inport Mapping scenario on page 59-204 for future reference or to share with other people

Tip To extend the Root Inport Mapping tool map modes, you can create a custom mapping file function to map data to root-level inports.

Choose a Map Mode

To specify how you want the Root Inport Mapping tool to map the signal data to a model, select from these map modes in the **MAP TO MODEL** section of the toolbar:

- Block name — Connect signal data to ports based the name of a root-inport block.
- Block path — Connect signal data to ports based the path of a root-inport block.
- Signal name — Connect signal data to ports based on the name of the signal on a port.
- Port order — Connect sequential port numbers to the imported data.

- Custom — Connect signal data to ports based on the definitions in a custom mapping file.

Each supported input format supports one or more mapping modes. To import MATLAB `timeseries` data, for example, you use any mapping mode . To import data array signal data, use the port order mapping mode.

Create Signal Data for Root Inport Mapping

In this section...

“Identify Signal Data to Import and Map” on page 59-169

“Choose a Naming Convention for Signal and Buses” on page 59-170

“Choose a Base Workspace and MAT-File Format” on page 59-170

“Bus Signal Data for Root Inport Mapping” on page 59-171

“Create Signal Data in a MAT-File for Root Inport Mapping” on page 59-172

“Supported Microsoft Excel File Formats” on page 59-173

The first step for using the Root Inport Mapping tool is to the source of signal data to import and map. You can use existing signal data (for example, in a Microsoft Excel spreadsheet) or create data in a MAT-file.

For a summary of the other steps involved in using the Root Inport Mapping tool, see “Import and Mapping Workflow” on page 59-167.

Identify Signal Data to Import and Map

You can import data from these sources.

- Base workspace — You can selectively import signal data from the base workspace. For more information about supported data formats, see “Choose a Base Workspace and MAT-File Format” on page 59-170.
- Data files — You can selectively import signals contained in MAT-files and Microsoft Excel files. Each time that you import the contents of the file, the contents overwrite data already loaded for the file in the Root Inport Mapping tool.

For more information, see “Choose a Base Workspace and MAT-File Format” on page 59-170 and “Supported Microsoft Excel File Formats” on page 59-173.

Tip To import signal data from an Microsoft Excel spreadsheet, consider using the **From Spreadsheet** block. The **From Spreadsheet** block incrementally loads data from the spreadsheet during simulation. If you use a **From Spreadsheet** block, you do not need to do anything to handle changes to sheet values.

Choose a Naming Convention for Signal and Buses

When identifying signals to import, consider using a naming convention for signals and buses such that this grouping of data (signal group) is interchangeable. For example, you can have two MAT-files whose data has different values but the same variable names. Then you can switch the groups of input data into and out of a model quickly.

Choose a Base Workspace and MAT-File Format

The Root Inport Mapping tool supports these MATLAB data types or formats for imported signal data. For each data type, you can use one or more mapping modes.

Data Formats	Block Name	Block Path	Signal Name	Port Order	Custom
<code>Simulink.SimulationData.Dataset</code>	✓	✓	✓	✓	✓
MATLAB timeseries	✓		✓	✓	✓
<code>Simulink.SimulationData.Signal</code>	✓	✓	✓	✓	✓
<code>Stateflow.SimulationData.State</code>	✓	✓	✓	✓	✓
Structure with time and structure without time				✓	
Data array				✓	
Array of buses	✓		✓	✓	✓
Asynchronous function-call signal on page 10-15	✓		✓	✓	✓

Note: If your MAT-file or base workspace contains data in a format that the Root Inport Mapping tool does not support, the tool ignores that data.

Note: Although the Root Inport Mapping tool accepts these formats, it can only link in a `Simulink.SimulationData.Dataset` object. To convert the data in your MAT-file to a

`Simulink.SimulationData.Dataset` object, in the Root Inport Mapping From dialog box, select the **Convert signals into a scenario dataset and save to MAT-file** check box. Alternatively, use the `convertToSlDataset` function to convert your data.

Dataset Signal Data

If data sets have nonunique element names, use the **Port Order** map mode.

MATLAB Timeseries Signal Data

If you have MATLAB timeseries data with enumeration, and the enumeration class is not on your MATLAB path, the tool ignores that timeseries data.

Structure Signal Data

When converting structure signal data to datasets, the signals are named using the value contained in the label field of the signal field of the structure signal.

Array Signal Data

The Root Inport Mapping tool tries to map the data array to a single inport. In this case, you can choose any of the map modes.

Bus Signal Data for Root Inport Mapping

The signal data that you import and map to a root-level Inport block can include bus data. You cannot map bus signals to a root-level Enable or Trigger block.

- 1** In the MATLAB workspace, create or load a bus object on page 63-40 for the bus data that you want to import and map.
- 2** If you create a bus object in the base workspace, save the bus object definition to a MAT-file, such as `d_myBusObj.mat`.
- 3** Create a separate MAT-file that contains the bus data you want to import for the bus object. Use one of these approaches:
 - Use an existing MAT-file that already contains a MATLAB struct or `Simulink.SimulationData.Dataset` object.
 - Create the bus in the base workspace and then save it to a MAT-file.

- 4 Set up the model to load the bus object.
 - For root-level Inport blocks that you map signals to, set the **Data type** field to **Bus**. Specify the name of the variable for the bus object to be used for signal data mapping.
 - Load into the model the MAT-file that includes the bus objects used for mapping. For example, use a `PreLoadFcn` callback function. For details, see “Alternative Workflows to Load Data” on page 59-194.

Create Signal Data in a MAT-File for Root Inport Mapping

You can create signal data in a MAT-file to use for root-inport mapping. For example, you can import three signals (`signal1`, `signal2`, and `signal3`), and save the signals in a MAT-file. The `Simulink.SimulationData.Signal` objects include signal names, block names, block paths, and port order index values.

You can use the `convertToSlDataset` function convert MAT-files to `Simulink.SimulationData.Dataset` objects.

- 1 In MATLAB, create three `Simulink.SimulationData.Signal` objects, specifying signal names, block paths, and port order index values.

```
signal1 = Simulink.SimulationData.Signal;  
signal1.Name = 'signal1';  
signal1.BlockPath = Simulink.SimulationData.BlockPath('Out1');  
signal1.PortType = 'inport';  
signal1.PortIndex = 1;
```

```
signal2 = Simulink.SimulationData.Signal;  
signal2.Name = 'signal2';  
signal2.BlockPath = Simulink.SimulationData.BlockPath('Out2');  
signal2.PortType = 'inport';  
signal2.PortIndex = 2;
```

```
signal3 = Simulink.SimulationData.Signal;  
signal3.Name = 'signal3';  
signal3.BlockPath = Simulink.SimulationData.BlockPath('Out3');  
signal1.PortType = 'inport';  
signal1.PortIndex = 3;
```

- 2 In the MATLAB workspace, select `signal1`, `signal2`, and `signal3`. Right-click and in the context menu, click **Save as**. Save the file as `mySigData.mat`.

3 Open the MAT-file.

```
open mySigData.mat

ans =

    signal1: [1x1 Simulink.SimulationData.Signal]
    signal2: [1x1 Simulink.SimulationData.Signal]
    signal3: [1x1 Simulink.SimulationData.Signal]
```

You can use the **Signal Name**, **Block Name**, **Block Path**, or **Port Order** map mode with this MAT-file. Based on your map mode, the Root Inport Mapping tool maps the signal data from the MAT-file to corresponding ports.

Supported Microsoft Excel File Formats

You can use the Root Inport Mapping tool to import signal data into Excel spreadsheets. You can also use the Root Inport Mapping tool to import signal data in CSV files on a Windows system with Microsoft Office installed.

- Use sheet names that follow MATLAB variable name rules. If you import from a sheet whose name does not follow these rules, the Root Inport Mapping tool uses a modified sheet name. This modified sheet name follows the MATLAB variable name rules. For example, if you have a sheet name **Group Name**, the Root Inport Mapping uses the modified name **GroupName**.
- For signal names, use the first row of a sheet. Either specify a signal name for every signal or do not specify any signal names. If you do not specify any signal names, the tool assigns signal names by using the format **Signal#**.
- For time values, use the first column of the remaining rows. The time values must increase for each row.
- Put signal values in the remaining columns.

This example of an Microsoft Excel spreadsheet that is set up for root-inport mapping.

- The sheet name is **sigData**, which is a valid MATLAB variable name.
- The first row contains the signal names **signal1**, **signal2**, and **signal3**.
- The first column has six time values.
- In each row with a time value, columns to the right of the first column contain signal data values for each signal.

	A	B	C	D	E
1		signal1	signal2	signal3	
2	0	2	4	6	
3	1	3	5	7	
4	2	2	4	6	
5	3	4	6	8	
6	4	5	7	9	
7	5	6	8	10

Import Signal Data for Root Inport Mapping

In this section...

“Import Signal Data” on page 59-175

“Import Bus Data” on page 59-176

“Import Signal Data from Other Sources” on page 59-177

“Import Test Vectors from Simulink Design Verifier Environment” on page 59-177

Import Signal Data

Before you can import data, identify the signals that you want to import and set up the data to use with root-level inport mapping. See “Create Signal Data for Root Inport Mapping” on page 59-169. For a summary of the other steps involved in using the Root Inport Mapping tool, see “Import and Mapping Workflow” on page 59-167.

For data import purposes, the Root Inport Mapping From Workspace dialog box provides a **Convert signals into a scenario dataset and save to MAT-file** check box, selected by default. Select this check box to convert the data in your MAT-file to a `Simulink.SimulationData.Dataset` object. Alternatively, use the `convertToSldataset` function to convert your data.

Note: The Root Inport Mapping uses the term *link* to refer to the act of importing Simulink data.

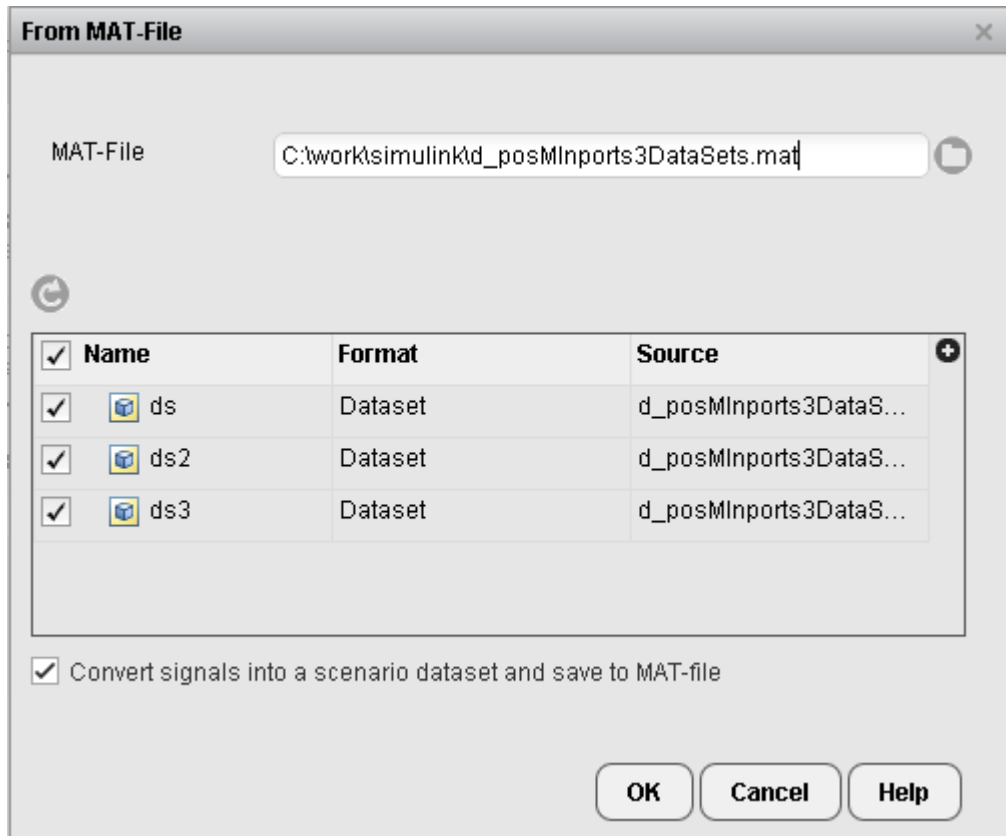

To import signal data for root-inport mapping:

- 1 Open the Root Inport Mapping tool. In the **Configuration Parameters > Data Import/Export** pane, click **Connect Input**.
- 2 In the LINK section, select the data source.
 - To browse to the MAT-file or spreadsheet file that contains the signals you want to import, select **From Spreadsheet** or **From MAT-File**. Click **Open** to return to the LINK section. Then click **OK**.

Note: To import bus data for root inport mapping, see “Import Bus Data” on page 59-176.

- To display a list of base workspace variables that you can import, select **From Workspace**. Select the variables that you want to import and click **OK**.

The From MAT-File dialog box displays the contents of the spreadsheet, file, or base workspace.

- 3 Select the data that you want to import, and then click **OK**.

The Root Inport Mapping tool displays the imported data.

Import Bus Data

Use bus objects for bus data that you want to import and map to root inports.

Store the bus objects in a MAT-file. Use a different MAT-file that contains the bus data that you want to import for the bus object. This file can be an existing MAT-file that already contains a MATLAB `struct`, or you can create the bus in the base workspace and save it to a MAT-file. For more information, “Bus Signal Data for Root Inport Mapping” on page 59-171.

To import the bus data, in the LINK section of the Root Inport Mapping toolstrip, click **From MAT-File**. Select the MAT-file that contains the bus data and click **OK**.

Import Signal Data from Other Sources

Use the Root Inport Mapping tool to import signals from other sources.

- You can import Excel spreadsheet data. The Root Inport Mapping tool imports a worksheet as a `Simulink.SimulationData.Dataset` object that contains timeseries elements.
- To convert and import test vectors from Simulink Design Verifier, see “Import Test Vectors from Simulink Design Verifier Environment” on page 59-177.
- To import signals from models that contain `Signal Builder` blocks, see “Converting Harness-Driven Models to Use Harness-Free External Inputs” on page 59-188.

Import Test Vectors from Simulink Design Verifier Environment

You can import and map Simulink Design Verifier test vectors. This workflow requires a Simulink Design Verifier license.

Import a MAT-file that contains a Simulink Design Verifier test vector structure `sldvData`.

The test vectors are converted during the import to a `Simulink.SimulationData.Dataset` supported by the Root Inport Mapping tool.

Alternatively, you can use the Simulink Design Verifier `sldvsimdata` function to convert a Simulink Design Verifier test structure to a `Simulink.SimulationData.Dataset` object. Save the output to a MAT-file and then import that file into the Root Inport Mapping tool.

More About

- “Map Root Inport Signal Data” on page 59-166

View and Inspect Signal Data

After you import signal or bus data, you can view and inspect signal data.

For a summary of the other steps involved in using the Root Inport Mapping tool, see “Import and Mapping Workflow” on page 59-167.

- 1 In the **ROOT INPORT MAPPING** tab, click **Preview Signals**.
- 2 To plot the signal, in the **Plot** column, select the check box next to the signal. If the format is a bus, click the expander (▶) to see and select the elements of the bus.

- 3 Explore the plots using the **Measure** and **Zoom & Pan** sections on the toolbar.
 - In the **Measure** section, use the **Data Cursors** button to display one or two cursors for the plot. These cursors display the T and Y values of a data point in the plot. To view a data point, click a point on the plot line.
 - In the **Zoom & Pan** section, select how you want to zoom and pan the signal plots. Zooming is only for the selected axis.

Type of Zoom or Pan	Button to Click
Zoom in along the T and Y axes.	
Zoom in along the time axis. After selecting the icon, on the graph, drag the mouse to select an area to enlarge.	
Zoom in along the data value axis. After selecting the icon, on the graph, drag the mouse to select an area to enlarge.	
Zoom out from the graph.	
Fit the plot to the graph. After selecting the icon, click the graph to enlarge the plot to fill the graph.	
Pan the graph up, down, left, or right. Select the icon. On the graph, hold the left mouse button and move the mouse to the area of the graph that you want to view.

Map Signal Data to Root Inports

In this section...

“Select Map Mode” on page 59-181

“Set Options for Mapping” on page 59-182

“Select Data to Map” on page 59-183

“Map Data” on page 59-183

“Understand Mapping Results” on page 59-184

“Converting Harness-Driven Models to Use Harness-Free External Inputs” on page 59-188

“Alternative Workflows to Load Data” on page 59-194

After you import data, map signal data to root inports by selecting map modes and options and selecting data.

For a summary of the other steps involved in using the Root Inport Mapping tool, see “Import and Mapping Workflow” on page 59-167.

Select Map Mode

To map signal data to root-level ports, use one of these map modes in the MAP TO MODEL section of the Root Inport Mapping toolstrip.

Goal	Map Mode
Assign signals to ports according to the name of the root-inport block. If the name of a signal or bus element matches the name of a root-inport block, the data is mapped to the corresponding port.	Block Name
Assign signals to ports according to the block path of the root-inport block. If the block path of a signal matches the block path of a root-inport block, the data is mapped to the corresponding port.	Block Path

Goal	Map Mode
Assign signals to ports according to the name of the signal on the port. If the signal name of a data element matches the name of a signal at a port, the signal is mapped to the corresponding port.	Signal Name
Assign sequential port numbers to the imported data, starting at 1. Map signals to the corresponding inports. <ul style="list-style-type: none"> • If there is more data than inports, the remaining data is mapped to enable and then trigger inports. • If the data is not in the form of a dataset, it is processed in the order in which it appears in the data file. 	Port Order
Assign signals to ports according to the definitions in a custom file. To create a custom mapping mode, see “Create and Use Custom Map Modes” on page 59-201.	Custom

Set Options for Mapping

If you want to set up mapping options, in the MAP TO MODEL section on the Root Inport Mapping toolstrip, click **Options**. To map the signals, see “Map Data” on page 59-183.

Goal	Option
Compile the model and review the data types of root-level inports and imported data.	<p>Compile. Compare the signal data and inport parameters to the root-level port and display the results. If you do not select this option, the tool maps the imported data to the root-level inport but does not compile the model.</p> <p>If your model uses configuration references to reference configuration sets, you cannot compile the model. To compile the model with the Root</p>

Goal	Option
	<p>Inport Mapping tool, use the Model Explorer to activate a configuration set first.</p> <p>See “Understand Mapping Results” on page 59-184. If the data that is in the comparison window is inherited from the connected block, a warning appears.</p>
Import bus data that is only partially defined.	Allow partial. Confirm that any partially specified bus data you import maps properly to root-level inports.

Select Data to Map

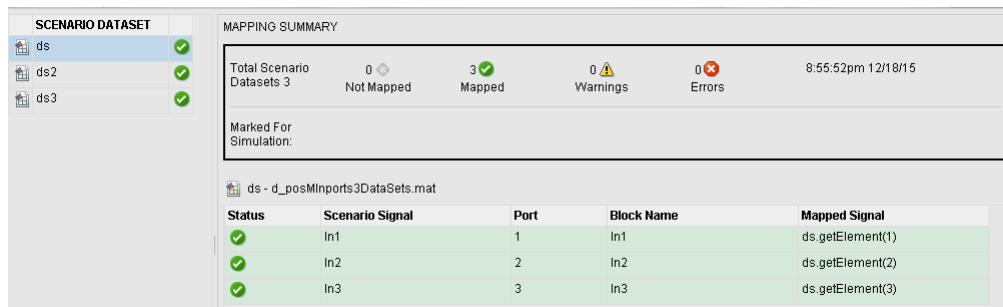

To specify a subset of scenarios to map, click the down arrow on the **Map to Model** button. You can choose different mapping modes for different scenarios.

Goal	Option
Map all the scenario datasets (default).	Map All
Map the datasets of the scenarios currently selected in the SCENARIO DATASET section.	Map Selected
Map the disconnected datasets.	Map Unconnected
Map datasets that previously failed a mapping.	Map Failed
Map datasets that previously caused warnings.	Map Warned

Map Data

After you import signals or buses, you can map data.

- 1 On the Root Inport Mapping toolbar, click **Map to Model**.
The results of a signal mapping appear in the **SCENARIO DATASET** tab.
- 2 In the **FILE** section, click a data set to see the mapping results

- The **MAPPING SUMMARY** tab lists the input data and the status of the mapping.

Note: See “Understand Mapping Results” on page 59-184.

- The mapping definition for the input data is applied to the model.

After you save and close the model, when you load input data of the same signal group to the workspace, the model uses the mapping defined for that signal group.

For an example of mapping signal data to root-level inputs, see “Converting Harness-Driven Models to Use Harness-Free External Inputs” on page 59-188.

After you save the mapping definition for a model, you can automate data loading. For more information, see “Alternative Workflows to Load Data” on page 59-194.

Understand Mapping Results

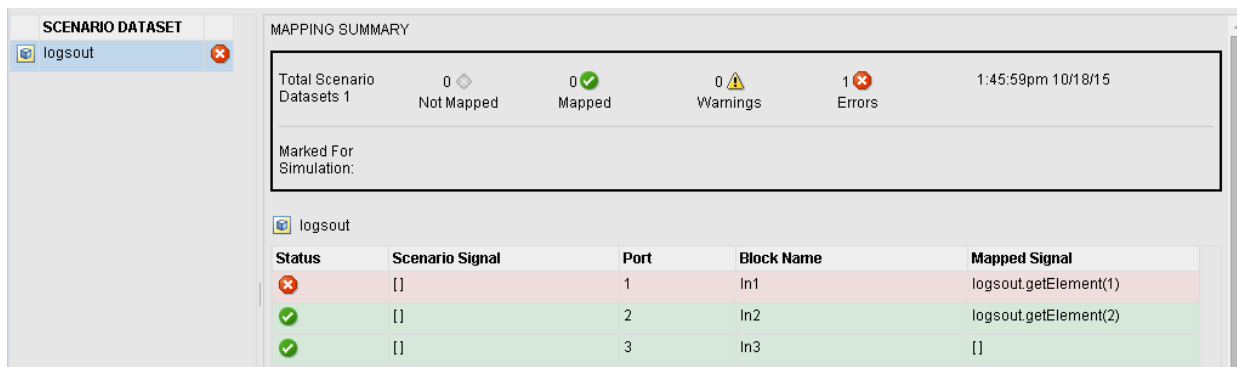

When you complete the import and map process, the **MAPPING SUMMARY** tab displays the results in the status area. The results depend on whether you select the **Compile** option when you set up the mapping.

Status	Compile	Continue Without Compile
✓	The properties of the mapped data and the import are appropriate for simulation.	The data type, dimension, and signal type properties of the data and import are compatible.
⚠	Not applicable	Comparison of data and root-level port data type, dimension, and signal type

Status	Compile	Continue Without Compile
		<p>properties cannot determine whether there is a match. If you do not compile before mapping, the tool cannot evaluate whether all the data types match unless you explicitly specify the inport data types. Confirm that you set these block parameters correctly:</p> <ul style="list-style-type: none"> • Inport block parameter Data type is not set to Inherit:auto. • Inport block parameter Dimension is not set to -1. • Inport block parameter Signal type cannot be auto.
	The properties of the mapped data and the inport are not appropriate for simulation.	One or more of the data types, dimensions, or signal types of the signal data are not compatible with the root-level inport.

Root-level input ports that have not been mapped are displayed as empty ({}).

This figure shows mapping successes and failures.

SCENARIO DATASET
logout

MAPPING SUMMARY

Total Scenario Datasets 1 0  Not Mapped 0  Mapped 0  Warnings 1  Errors 1:45:59pm 10/18/15

Marked For Simulation:

logout

Status	Scenario Signal	Port	Block Name	Mapped Signal
	{}	1	In1	logout.getElement(1)
	{}	2	In2	logout.getElement(2)
	{}	3	In3	{}

In the Root Inport Mapping tool, clicking **Mark for Simulation** selects the **Input** check box in the **Data Import/Export** pane in the model Configuration Parameters dialog box. It also sets the value to the imported data variables. To apply the changes to the model configuration, in the **Data Import/Export** pane, click **OK**.

If your model uses configuration references to reference configuration sets, you cannot mark the model for simulation. To use this data to simulate the model with the Root Inport Mapping tool, use the Model Explorer to activate a configuration set first.

This graphic illustrates the application of the changes to the model configuration for the model in “Map Data” on page 59-183.

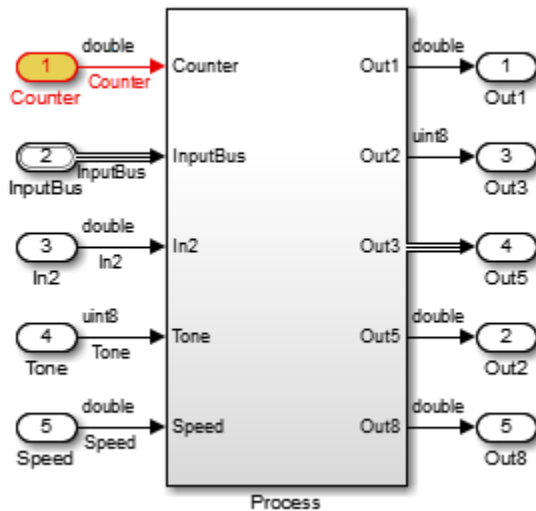

To inspect the imported data, you can:

- Connect the output to a scope, simulate the model, and observe the data.
- Log the signals and use the Simulation Data Inspector tool to observe the data.

To highlight the Inport block that is associated with the signal, select an item in the **MAPPING SUMMARY** tab. If there are warnings or failures, the Inport block associated with the data appears highlighted in the model.

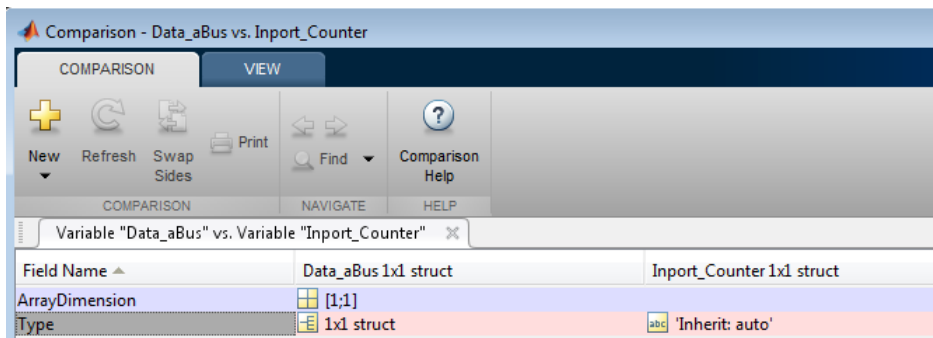

- Failures appear as yellow Inport blocks outlined with bold red.
- Warnings appear as yellow Inport blocks outlined in orange.
- Successes appear as normal Inport blocks outlined with blue.

When you select the Counter block name in the **MAPPING SUMMARY** tab, the Counter block in the model is highlighted. The highlighting indicates an error.

Use the Comparison Tool to evaluate your next action. The Comparison Tool shows the properties for the root-level inport and the signals that you are trying to map to the inport. You can tell from this table whether there is a mismatch that prevents the mapping. For example, if there is a mismatch, you can update the imported signals or edit the root-level inport. When you are done, reimport the data to map it.

To investigate warnings and failures, in the **MAPPING SUMMARY** tab, click the line item that you want to inspect. The Comparison Tool lists the selected variable, including the field name, input data, and root-level inport.

Note: When the input is a bus, click the levels of the bus object to see the individual elements in the bus.

Sometimes the Comparison Tool shows a warning or error, but your investigation of the elements indicates that there is no problem with mapping the data. In these cases, if you did not select the **Compile** check box from the **Options** menu, select it and click **Map** again.

Tip Each time you click a nongreen status item, a new Comparison Tool instance appears. To dock all Comparison Tool instances in one window, click the **Dock** button .

For more information on the Comparison Tool, see “Comparing Files and Folders”.

Converting Harness-Driven Models to Use Harness-Free External Inputs

This example shows how to convert a harness model that uses a Signal Builder block as an input to a harness-free model with root inports. The example collects data from the harness model and stores it in MAT-files, for use by the harness-free model. After storing the data, the example removes the Signal Builder block from the harness model and adds root inports to create a harness-free model. Then, the data in the MAT-files is mapped to the root inports of the model.

Save Harness Data to MAT-Files

Before converting the model to be harness-free, capture the test cases in the harness.

For this example, you will modify the model `sldemo_autotrans` from the **Modeling an Automatic Transmission Controller** example.

Open the example model. In the MATLAB Command Window type `sldemo_autotrans`.

Use MATLAB function `slexAutotransRootInportsSaveActiveGroup` to save the Signal Builder block data of the active group into a MAT-file. At the command line type `slexAutotransRootInportsSaveActiveGroup('slexAutotransRootInport','ManeuversGUI')`. This function creates a MAT-file in the current directory with the same name as the active group. The function `slexAutotransRootInportsSaveActiveGroup` has been provided with this example.

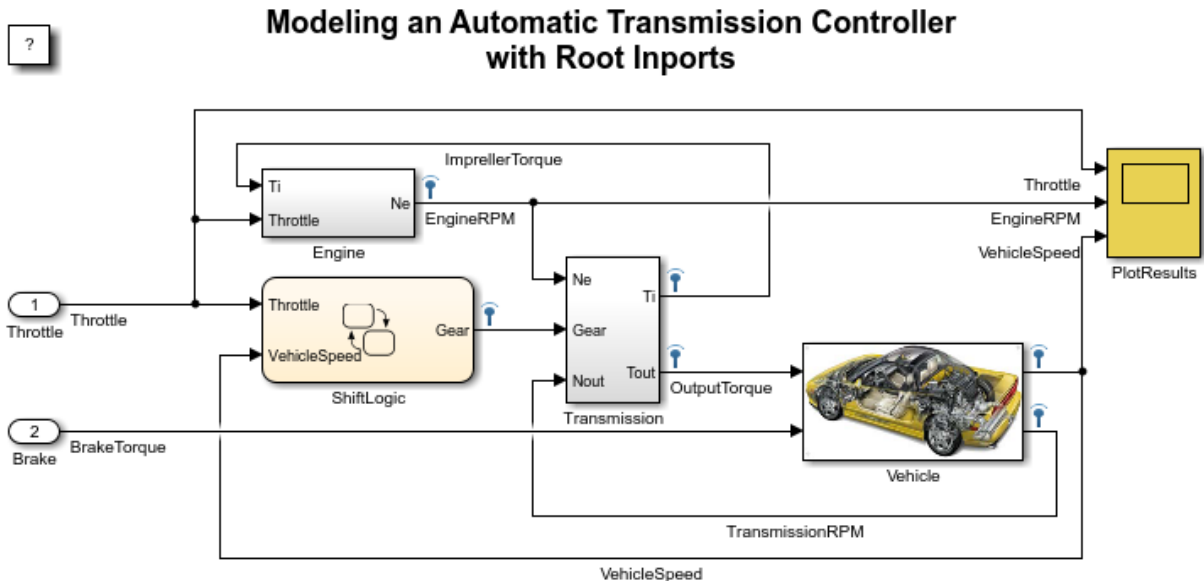

Remove the Signal Builder Block

Remove the Signal Builder block named `ManeuversGUI` and replace it with two inports.

- 1 Delete the Signal Builder block named ManeuversGUI.
- 2 Open the **Simulink Library Browser** and select **Commonly Used Blocks**.
- 3 Drag and drop two **input ports** from the **Library Browser** to the model.
- 4 Connect the input ports to the lines previously connected to the Signal Builder block.
- 5 Rename the inport ports. Name the input port connected to the Throttle line **Throttle**. Name the input port connected to the BrakeTorque line **Brake**.

Save the model as `slexAutotransRootInportsExample1.slx` or use the example `slexAutotransRootInportsExample.slx`.

The remaining steps of this example use the model `slexAutotransRootInportsExample.slx`. If you saved the model with a different name use your model name in the steps going forward.

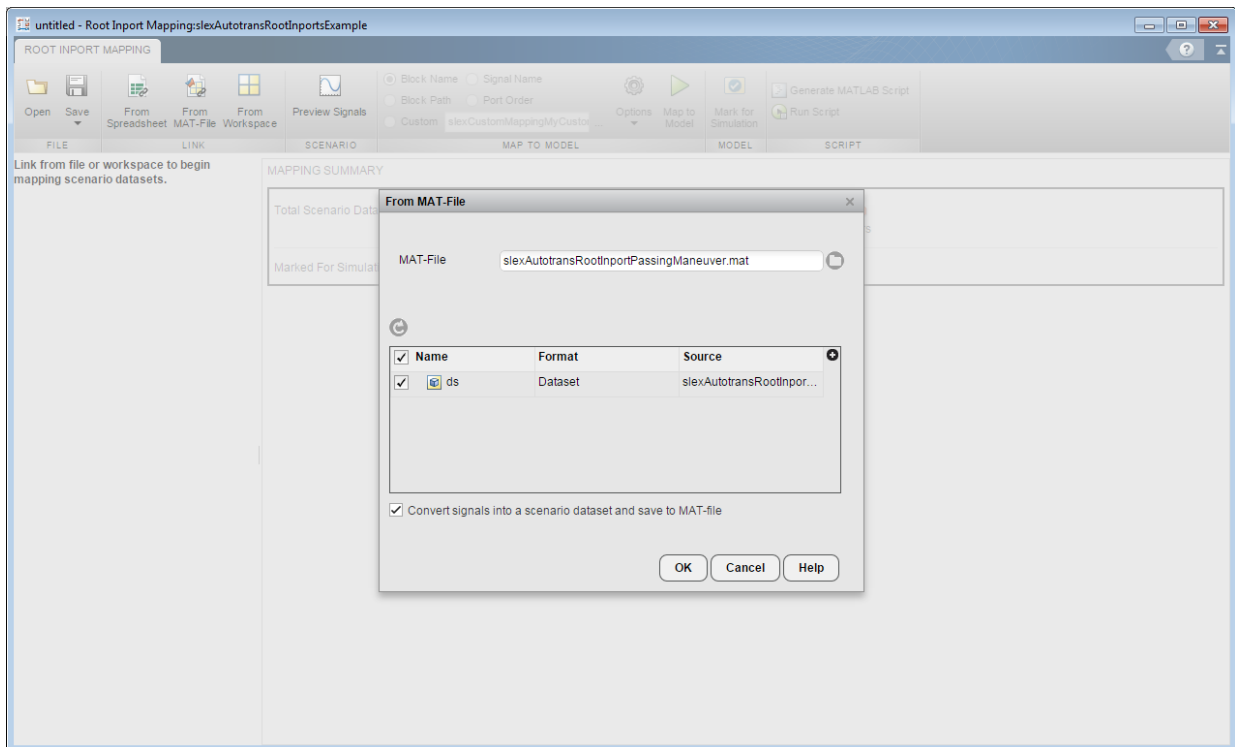

Set Up Harness-Free Inputs

Now that the model is harness-free, set up the inputs that you already saved (See "Save Harness Data to MAT-Files").

From the **Simulation->Model Configuration Parameters->Data Import/Export** pane, click the **Connect Input** button.

Map Signals to Root Inport

The Root Inport Mapping tool opens.

This example uses this tool to set up the model inputs from the MAT-file and map those inputs to an input port, based on a mapping algorithm. To select the MAT-file that contains the input data, click the **From MAT-File** button on the Root Inport Mapping toolbar. When the link dialog appears, click the Open Folder button. In the browser, select the MAT-file that you saved earlier.

Select a Mapping Mode

Once you select the MAT-file `slexAutotransRootInportPassingManeuver.mat` that contains the input data, determine the root input port to which to send input data. Simulink matches input data with input ports based on one of five criteria:

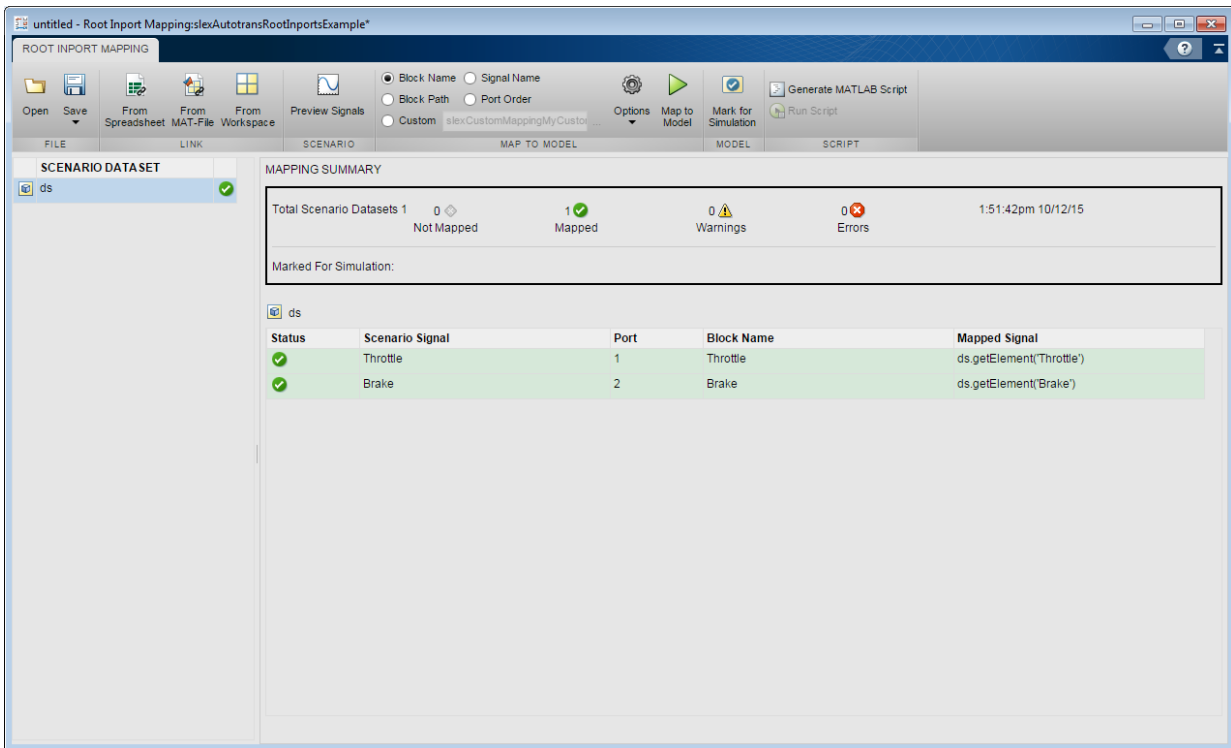

- **Port Order** - Maps in the order it appears in the file to the corresponding port number.
- **Block Name** - Maps by variable name to the corresponding root inport with the matching block name.
- **Signal Name** - Maps by variable name to the corresponding root inport with the matching signal name.
- **Block Path** - Maps by the BlockPath parameter to the corresponding root inport with the matching block path.
- **Custom** - Maps using a MATLAB function.

Earlier in this example, you used the `slexAutotransRootInportsSaveActiveGroup` to save input data to variables of the same name as the harness signals `Throttle` and `Brake`, and you added input ports with names matching the variables. Given the set of conditions for the input data and the model input ports, the best choice for a mapping criteria is **Block Name**. Using this criteria, Simulink tries to match input data variable names to the names of the input ports. To select this option:

- 1 Click the **Block Name** radio button.
- 2 Click the **Options** button and select `Compile` from the dropdown. This will provide some verification on the mapping.
- 3 Click the **Map** button.

When compiling the data, Simulink evaluates inports against the following criteria to determine whether or not there is a compatibility issue. The status of this compatibility is reflected by the table colors green, orange, or red. Clicking a cell in the table which has orange or red color will open the Comparison Tool for further inspection.

- **Data Type** - Double, single, enum,
- **Complexity** - Real or complex
- **Dimensions** - Signal dimensions vs port dimensions

Finalize the Inputs to the Model

Review the results of the mapping compatibility. Click the Scenario Dataset 'ds' in the scenario dataset list. To apply the results of the **Map** action and load the data that was mapped to the input ports from the MAT-file to the base workspace click the **Mark for Simulation** button. This action also sets the **Model Configuration Parameters->Data Import/Export->External Input** edit box with the proper comma-separated list of inputs.

Simulating the Model

With the changes applied you can now simulate the model and view the results. Click the **Play** button on the model. To view the results of the simulation, double-click the Scope Block **PlotResults**.

Alternative Workflows to Load Data

After you save the mapping definition to a model, you can automate data loading and simulation. Consider one of the following methods.

Command Line or Script

To load data and simulate the model from the MATLAB command line, use commands similar to:

```
load('signaldata.mat');
simout = sim('model_name');
```

To automate testing and load different signal groups, consider using a script.

The following example code creates timeseries data and simulates a model after loading each signal group. It:

- Creates signal groups with variable names *In1*, *In2*, and *In3*, and saves these variables to MAT-files.
- Simulates a model after loading each signal group.

Note: The variable names must match the import data variables in the **Configuration Parameters > Data Import/Export > Input** parameter.

```
% Create signal groups
fileName = 'testCase';
for k =1 :3

    % Create the timeseries data
    var1 = timeseries(rand(10,1));
    var2 = timeseries(rand(10,1));
    var3 = timeseries(rand(10,1));

    %create a dataset
    ds = Simulink.SimulationData.Dataset();
    ds = ds.addElement( var1, 'var1');
    ds = ds.addElement( var2, 'var2');
    ds = ds.addElement( var3, 'var3');

    % Save the data
    save([fileName '_' num2str(k) '.mat' ],'ds');
end
clear all

% After mapping and saving the model loop over signal groups and simulate
% Set the filename to append testcase # to
fileName = 'testCase';
% Loop backwards to preallocate
for k=3:-1:1
    % Load the MAT-file.
    load([fileName '_' num2str(k) '.mat']);

    % Simulate the model
    simOut{k} = sim('model_name');
end
```

Use the PreLoadFcn Pane

When you are satisfied with the data and mapping, you can configure your model to load to the MATLAB workspace a MAT-file of the same signal group. Call the `load` function in a `PreLoadFcn` callback in the model properties node.

- 1 After saving the MAT-file, in the Simulink editor, select **File > Model Properties > Model Properties**.
- 2 In the Model Properties window, select the `PreLoadFcn` node.
- 3 Enter a load function that loads the signal data MAT-file. For example,

```
load d_signal_data.mat;
```
- 4 Click **OK** and save the model.

Preview Signal Data

Preview input signal or bus data with the **Signal Preview** window. You can access this window from:

- From `File` block
- `Simulink.SimulationData.DatasetRef` and `Simulink.SimulationData.Dataset` plot methods

1 Preview input signal or bus data with the **Signal Preview** window.

- For `From File` block, browse to a MAT-file that contains the data you want to preview, then plot the data by clicking .
- For `Simulink.SimulationData.Dataset` or `Simulink.SimulationData.DatasetRef` elements, use the `plot` method on the dataset.

- 2 Explore the plots using the **Measure** and **Zoom & Pan** sections on the toolbar.
- In the **Measure** section, use the **Data Cursors** button to display one or two cursors for the plot. These cursors display the T and Y values of a data point in the plot. To view a data point, click a point on the plot line.
 - In the **Zoom & Pan** section, select how you want to zoom and pan the signal plots. Zooming is only for the selected axis.

Type of Zoom or Pan	Button to Click
Zoom in along the T and Y axes.	

Type of Zoom or Pan	Button to Click
Zoom in along the time axis. After selecting the icon, on the graph, drag the mouse to select an area to enlarge.	
Zoom in along the data value axis. After selecting the icon, on the graph, drag the mouse to select an area to enlarge.	
Zoom out from the graph.	
Fit the plot to the graph. After selecting the icon, click the graph to enlarge the plot to fill the graph.	
Pan the graph up, down, left, or right. Select the icon. On the graph, hold the left mouse button and move the mouse to the area of the graph that you want to view.

Generate MATLAB Scripts for Simulation with Scenarios

After associating a scenario with the model, you can generate a MATLAB script to perform batch simulations. These scripts enable you to connect multiple sets of input signals to your Simulink model for interactive or batch simulation. You can run simulations multiple times and quickly generate data. This topic assumes that you have a scenario ready to run (see “Root Inport Mapping Scenarios” on page 59-204).

- 1 Associate your scenario with the model.
- 2 In the **SCRIPT** section, click **Generate MATLAB Script** and supply a script name when prompted.
- 3 To run the script, click **Run Script**.
- 4 To evaluate the results of the simulation, see the base workspace.

More About

- “Root Inport Mapping Scenarios” on page 59-204

Create and Use Custom Map Modes

You can create custom map modes to supplement the map modes that the Root Inport Mapping tool provides (see “Choose a Map Mode” on page 59-167).

For a summary of the other steps involved in using the Root Inport Mapping tool, see “Import and Mapping Workflow” on page 59-167.

Create Custom Mapping File Function

If you do not want to use the map modes in the Root Inport Mapping tool, create a custom mapping file function. For example, consider creating a custom mapping file function if:

- Your signal data contains a common prefix that is not in your model.
- You want to map a signal explicitly.

When the data contains a signal name that does not match one of the block names, a custom mapping function is useful for block name mapping.

For examples, see these files in the folder `matlabroot/help/toolbox/simulink/examples` (open).

File	Description
<code>BlockNameIgnorePrefixMap.m</code>	Custom mapping file function that ignores the prefix of a signal name when importing signals
<code>BlockNameIgnorePrefixData.mat</code>	MAT-file of signal data to be imported
<code>ex_BlockNameIgnorePrefixExample</code>	Model file into which you can import and map data

In addition, see the example Using Mapping Modes with Custom-Mapped External Inputs.

To create a custom mapping file function:

- 1 Create a MATLAB function with these input parameters:
 - Model name

- Signal names specified as a cell array of character vectors
 - Signals specified as a cell array of signal data
- 2 In the function, call the `getRootImportMap` function to create a variable that contains the mapping object (for an example, see `BlockNameIgnorePrefixMap.m`).
 - 3 Save and close the MATLAB function file.
 - 4 Add the path for the new function to the MATLAB path.

To use the custom mapping file function:

- 1 Open the model that you want to import data to (for example, `ex_BlockNameIgnorePrefixExample`).
- 2 Open the Configuration Parameters dialog box for the model and select the **Data Import/Export** pane.
- 3 In the **Load from workspace** section, click **Connect Input**.
- 4 Import your signal (for example, `BlockNameIgnorePrefixData.mat`).
- 5 In the **MAP TO MODEL** section of the toolstrip, click **Custom**.
- 6 In the **Custom** text box, select the MATLAB function file (for example, `BlockNameIgnorePrefixMap.m`) using the browser.

By default, this text box contains `slexcustomMappingMyCustomMap`, which is the custom function for the Attaching Input Data to External Inputs via Custom Input Mappings example.

Tip The Root Inport Mapping tool parses your custom code. Parsing reorders output alphabetically and verifies that data types are consistent.

- 7 Click **Options** and select the **Compile** check box.
- 8 Click **Map**.

The model is compiled and the Root Inport Mapping tool gets updated.

To understand the mapping results, see “Understand Mapping Results” on page 59-184.

- 9 Save and close the model.

After you save the mapping definition for a model, you can automate data loading. The next time that you load input data of the same signal group into the workspace,

the model uses the mapping definition during simulation. For more information, see “Alternative Workflows to Load Data” on page 59-194.

Custom Mapping Modes Similar to Simulink Modes

If your custom mapping mode is similar to a Simulink mapping mode, use the `getSlRootInportMap` function in your custom mapping file function to perform the data mapping.

For an example of a custom mapping function that uses this function, see [Using Mapping Modes with Custom-Mapped External Inputs](#).

Command-Line Interface for Input Variables

Use the `getInputString` function to supply a set of input variables to:

- The `sim` command
- A list of input variables that you can paste in the **Configuration Parameters > Data Import/Export > Input** parameter

Root Inport Mapping Scenarios

In this section...

“Open Scenarios” on page 59-204

“Save Scenarios” on page 59-205

“Open Existing Scenarios” on page 59-205

“Work with Multiple Scenarios” on page 59-206

Use the Root Inport Mapping tool to create scenarios, save scenarios, and load previously saved scenarios. The Root Inport Mapping tool uses scenarios to save a snapshot of the current state of the imported and mapped signals in an MLDATX file. A scenario file contains information about the:

- Location of signal files (MAT-file or Microsoft Excel files)
- Location of the model
- Map mode
- Mapping options
- Mapped state

When sharing scenario files, include the scenario file and signal files (MAT-file or Microsoft Excel). Place the signal files in the last known location (where you used the Root Inport Mapping tool most recently) or the MATLAB path.

Open Scenarios

To open an existing scenario, click **Open**. If you are working in another scenario, the Root Inport Mapping tool displays a message.

To...	Click...
Open a new scenario. Remove the existing scenario without saving it.	No

To...	Click...
Cancel opening a scenario.	Cancel
To save the existing scenario, click Yes . Then click the Open button again to open an existing scenario.	Yes

Save Scenarios

When the **Save** icon turns blue or when the model name in the title bar is has an asterisk (*), you can save a scenario.

- 1 On the Root Inport Mapping toolbar, select **Save > Save As**.
- 2 In the Save As dialog box, browse to a writable folder, specify a scenario file name, and then click **Save**.
 - To save the signals and the scenario file, click **Yes**.

If a MAT-file is already associated with the scenario, the tool appends the base workspace variables to this file.

Save a scenario to an existing file (the file from which the scenario was last loaded):

- 1 On the Root Inport Mapping tool toolbar, click **Save**.
- 2 Browse to the `.mldatx` file in which to save the scenario, and then click **Save**.

If you have not saved the signals from the scenario, the tool prompts you to save the signals to a MAT-file.

Goal	Action
Overwrite the existing <code>.mldatx</code> file.	Yes
Exit the dialog box. The tool does not save the scenario.	No

Open Existing Scenarios

You can open previously saved scenario files in one of the following ways:

- Double-click the previously saved scenario file (`*.mldatx`). The Root Inport Mapping tool opens and loads the model. Alternatively, right-click the file and select **Open**.

- When loading scenario files, the tool looks for the associated model and MAT-file or Microsoft Excel file in the last known location, and then looks on the MATLAB path. If the tool cannot find the model or signal files in these two locations, an error occurs.
- If the previously saved scenario has mapped signals, when you open the scenario, the tool applies the mapping. Also, the tool adds the signals to the base workspace so that you can simulate the model.
- Open the Root Inport Mapping tool for the model, click **Open**, and select the previously saved scenario file.

If the model is already open, the new scenario overwrites the existing scenario for the model. If there are unsaved changes in the open scenario, respond to the prompt.

Goal	Click
Save the existing scenario and associated data before loading the new scenario.	Yes
Open the new scenario without saving the existing scenario. This option also removes the data in the existing scenario.	No

Work with Multiple Scenarios

You can open and work with multiple scenario files simultaneously. Working with multiple scenario files lets you view, edit, group, and nest multiple scenario files. Use multiple scenario files to test more complex systems with interrelated components.

As you open each multiple scenario, the Root Inport Mapping tool adds its data set to the SCENARIO DATASET section. If the scenario contains only signals, convert the signals to the `Simulink.SimulationData.Dataset` format:

- 1 To convert the signals to a `Simulink.SimulationData.Dataset` format, use the `convertToS1Dataset` function.
- 2 Link to the new data set. You do not need to reopen the scenario.

Load Signal Data That Uses Units

Signal data logged in a previous simulation using signal logging or the To File or To Workspace block can include units information for `Dataset` or `Timeseries` logging formats.

Logging root-level Output data from a previous simulation contains units information if:

- These **Data Import/Export** configuration parameter settings:
 - **Output** is enabled.
 - **Format** is `Dataset`.
- For the Output blocks that you log, in the Block Parameters dialog box, you set the **Unit** parameter.

Otherwise, to include units in signal data that you load, for the `Units` property of the MATLAB `timeseries` objects that you want to load, specify a `Simulink.SimulationData.Unit` object.

Loading Bus Signals That Have Units

When you input a bus signal to a root-level Inport or Output block, or you use a From File or From Workspace block, the output data type of the block must be a bus object. When you load the data from these blocks, the units in loaded data must match the units specified for the bus elements in the bus object. If the units for the loaded data do not match the units for a bus element in the bus object, Simulink uses the units specified in the bus object.

Load Data Using the From File Block

In this section...

“Data Loading” on page 59-210

“Sample Time” on page 59-211

“Simulation Time Hits Without Corresponding Time Data” on page 59-211

“Duplicate Timestamps” on page 59-211

“Detect Zero Crossings” on page 59-212

To load signal data with a From File block for use in a model:

- 1 Create a MAT-file with the signal data that you want to load.
- 2 Add a From File block to a model. Connect the From File block to the block that the From File provides input to.
- 3 In Block Parameters dialog box of the From File block, configure the block by specifying:
 - The path to the file that you want to load data from
 - The data format for the From File block output
 - How the data is loaded, including sample time, how to handle data for missing data points, and whether to use zero-crossing detection

Data Loading

For a Version 7.0 and earlier MAT-file, the From File block loads the complete, uncompressed data from the file into memory at the start of simulation. For a Version 7.3 MAT-file, the From File block incrementally loads data from the file during simulation.

For each simulation time hit for which the MAT-file contains no matching timestamp, Simulink uses interpolation or extrapolation to obtain the needed data. You specify the interpolation and extrapolation methods. For details, see “Simulation Time Hits That Have No Corresponding MAT-File Timestamps.”

During simulation, the From File block cannot load data from a MAT-file that a To File block is exporting data to.

Sample Time

The From File block **Sample time** parameter specifies the sample time to load data from a MAT-file. The timestamps in the file must be monotonically nondecreasing. For details, see the From File block documentation.

Simulation Time Hits Without Corresponding Time Data

If a simulation time hit does not have a corresponding MAT-file timestamp, then the From File block output depends on:

- Whether the simulation time hit occurs before the first timestamp, within the range of timestamps, or after the last timestamp
- The interpolation or extrapolation methods that you select
- The data type of the MAT-file data

For details about interpolation and extrapolation options, see the descriptions of the following parameters in “Parameters and Dialog Box”:

- **Data extrapolation before first data point**
- **Data interpolation within time range**
- **Data extrapolation after last data point**

Duplicate Timestamps

Sometimes the MAT-file includes duplicate timestamps (two or more data values that have the same timestamp). When that happens, the From File block action depends on when the simulation time hit occurs, relative to the duplicate timestamps in the MAT-file.

Suppose that the MAT-file contains the following data, with three data values having a timestamp value of 2:

```
time stamps:    0 1 2 2 2 3 4
data values:   2 3 6 4 9 1 5
```

The following table describes the From File block output.

Simulation Time, Relative to Duplicate timestamp Values in MAT-File	From File Block Action
Before the duplicate timestamps	Uses the first of the duplicate timestamp values as the basis for interpolation. (In this example, that timestamp value is 6.)
At or after the duplicate timestamps	Uses the last of the duplicate timestamp values as the basis for interpolation. (In this example, that timestamp value is 9.)

For more information, see the From File block documentation for these parameters:

- **Data extrapolation before first data point**
- **Data interpolation within time range**
- **Data extrapolation after last data point**

Detect Zero Crossings

Zero-crossing detection locates a discontinuity in timestamps, without resorting to excessively small time steps. By default, the From File block does not enable zero-crossing detection.

For the From File block, zero-crossing detection occurs only at timestamps in the file. Simulink examines only the timestamps, not the data values.

For bus signals, Simulink detects zero-crossings across all leaf bus elements.

For more information, see the From File block documentation of the **Enable zero-crossing detection** parameter.

Load Data Using the From Workspace Block

In this section...

- “Specify the Workspace Data” on page 59-213
- “Sample Time” on page 59-214
- “Interpolate Missing Data Values” on page 59-214
- “Specify Output After Final Data” on page 59-214
- “Detect Zero Crossings” on page 59-215

To load signal data with a From Workspace block:

- 1 Create a workspace variable with the signal data that you want to load. See “Create Data for a From Workspace Block” on page 59-145.
- 2 Add a From Workspace block to a model. Connect the From Workspace block to the block that the From Workspace block provides input to.
- 3 In the Block Parameters dialog box of the From Workspace block, configure:
 - The workspace data to load
 - The data format for the From Workspace block output
 - How the data is loaded, including sample time, how to handle data for missing data points, and whether to use zero-crossing detection

An alternative to using a From Workspace block for loading workspace data is to load data to a root-level input port. For more information, see “Root-Level Input Ports” on page 59-105.

Specify the Workspace Data

In the dialog box of the From Workspace block, in the **Data** parameter, specify the workspace data to load. Specify a MATLAB expression (for example, the name of a variable in the MATLAB workspace) that evaluates to one of the following:

- A MATLAB `timeseries` object
- A structure of MATLAB `timeseries` objects
- A structure, with or without time
- A two-dimensional matrix

For example, suppose that the workspace contains a column vector of times named **T** and a column vector of corresponding signal values named **U**. Entering the expression `[T U]` for **Data** parameter yields the required input array. If the required array or structure exists in the workspace, enter the name of the structure or matrix in the **Data** parameter.

If you load a structure that does not specify a time vector:

- 1 Set **Sample time (-1 for inherited)** to a value other than 0 (continuous).
- 2 Clear **Interpolate data**.
- 3 Set **Form output after final data value by** to a value other than **Extrapolation**.

For more information, see “Create Data for a From Workspace Block” on page 59-145.

Sample Time

The From Workspace block **Sample time** parameter specifies the sample time to load data from a workspace. The timestamps in the workspace data must be monotonically nondecreasing. For details, see “Specify Sample Time” on page 7-3.

Interpolate Missing Data Values

To use linear Lagrangian interpolation to compute data values for time hits that occur between the time hits for which the workspace supplies the data, select **Interpolate data**.

For variable-size signals, clear **Interpolate data**.

Specify Output After Final Data

To determine the block output after the last time hit for which workspace data is available, combine the settings of these parameters:

- **Interpolate data**
- **Form output after final data value by**

In the From Workspace block documentation, see the **Form output after final data value by** parameter.

Detect Zero Crossings

By default, the From File block does not enable zero-crossing detection.

Zero-crossing detection locates discontinuities, without resorting to excessively small time steps.

The **Enable zero-crossing detection** parameter applies only if the sample time is continuous (0).

If you select the **Enable zero-crossing detection** parameter, and if an input array contains multiple entries for the same time hit, Simulink detects a zero crossing at that time hit.

For bus signals, Simulink detects zero crossings across all leaf bus elements.

Create Dataset Data for Root Inport Ports

In this section...

“Specify a Dataset Using the Input Parameter” on page 59-216

“Dataset Elements” on page 59-216

“Import Dataset Objects for Buses” on page 59-216

Specify a Dataset Using the Input Parameter

You can use a `Dataset` object as a value for the **Configuration Parameters > Data Import/Export > Input** parameter. Specify only one `Dataset` object and do not include it in a comma-separated list.

Dataset Elements

A `Dataset` object can include elements with different data types. The elements can be:

- A MATLAB `timeseries` object
- A structure, if each leaf node is either empty or is a MATLAB `timeseries` object
- An array that meets one of these requirements:
 - An array with time in the first column and the remaining columns each corresponding to an input port. See “Create Data Arrays for Root-Level Inports” on page 59-220.
 - An $n \times 1$ array for a root inport that drives a function-call subsystem. See “Arrays for Input Ports Driving Function-Call Subsystems” on page 59-221.
- A `Simulink.SimulationData.Signal` object
- An empty matrix

The number of elements in the data set must match the number of root-level input ports.

Import Dataset Objects for Buses

You can use a `Dataset` object to import bus data for a root-level input port. For details, see “Import Bus Data to Top-Level Input Ports” on page 59-154.

Create MATLAB Timeseries Data for Root Imports

In this section...

“Specify Time Dimension” on page 59-218

“Models with Multiple Root Inport Blocks” on page 59-219

A root-level Inport, Enable, Trigger, and From Workspace block can import data specified by a MATLAB `timeseries` object residing in a workspace.

Note: This documentation about importing MATLAB timeseries data includes examples of root Inport blocks. Unless specifically noted otherwise, the examples are applicable to root-level Enable, Trigger, and From Workspace blocks.

Specify Time Dimension

When you create a MATLAB `timeseries` object to import data to Simulink, the time dimension depends on the dimension and the type of signal data.

Signal Data Dimension or Type	Time Dimension Alignment	Example of timeseries Constructor
Scalar or a 1D vector	First	Constructor for a scalar signal. Time is aligned with the first dimension. <pre>t = (0:10)'; ts = timeseries(sin(t), t);</pre>
2D (including row and column vectors) or greater	Last	Constructor for a matrix signal. Time is aligned with the last dimension. <pre>t = 0; ts = timeseries([1 2; 3 4], t);</pre>
2D row vector, and there is only one time step	Last	'InterpretSingleRowDataAs3D', true For example: <pre>t = 0; ts = timeseries([1 2], t, 'Interpret</pre>

Models with Multiple Root Inport Blocks

To use a MATLAB `timeseries` object for a root Inport block in a model that has multiple root Inport blocks, convert all the other root Inport block data that uses `Simulink.TsArray` or `Simulink.Timeseries` objects to one of these formats:

- MATLAB `timeseries` objects
- A structure of MATLAB `timeseries` objects

You can use the `Simulink.Timeseries.convertToMATLABTimeseries` method to convert a `Simulink.Timeseries` object to a MATLAB `timeseries` object. For example, if `sim_ts` is a `Simulink.Timeseries` object, then the following line converts `sim_ts` to a MATLAB `timeseries` object:

```
ts = sim_ts.convertToMATLABTimeseries;
```

Create Data Arrays for Root-Level Inports

In this section...

“Data Array Format” on page 59-220

“Specify the Input Expression” on page 59-220

“Arrays for Input Ports Driving Function-Call Subsystems” on page 59-221

Data Array Format

This import format consists of a real (noncomplex) matrix of data type `double`. The first column of the matrix must be a vector of times in ascending order. The remaining columns specify input values.

- Each column represents the input for a different Inport or Trigger block signal (in sequential order).
- Each row is the input value for the corresponding time point.

For a Trigger block, the signal driving the trigger port must be the last data item.

The total number of columns of the input matrix must equal $n + 1$, where n is the total number of signals entering the model input ports.

Specify the Input Expression

The default input expression for a model is `[t,u]` and the default input format is `Array`. So if you define `t` and `u` in the MATLAB workspace, simply select the **Configuration Parameters > Data Import/Export > Input** parameter to input data from the model workspace.

For example, suppose that you have a model with two Inport blocks:

- The In1 block accepts two signals (the block has the **Port dimensions** parameter set to 2).
- The In2 block accepts one signal (the block uses the default value for the **Port dimensions** parameter).

You define `t` and `u` in the MATLAB workspace:

```

numSteps = 9;
timeStep = 0.1;
t = (timeStep*(0:numSteps))';
u = [sin(t),cos(t),4*cos(t)];

```

When the simulation runs, the signal data $\sin(t)$ and $\cos(t)$ are assigned to In1 and the signal data $4*\cos(t)$ is assigned to In2. Signal data is input for 100 time points.

Note The array input format allows you to load only real (noncomplex) scalar or vector data of type `double`. Use the structure format to input complex data, matrix (2-D) data, and data types other than `double`.

Arrays for Input Ports Driving Function-Call Subsystems

You can use an array to drive a Function-Call Subsystem through a root-level input port. You can use an array or an array that is an element of a `Dataset` object. The array must be an $n \times 1$ array. For the root-level Inport block, select the **Output function call** parameter.

For example, this `Dataset` object has an array element `x`:

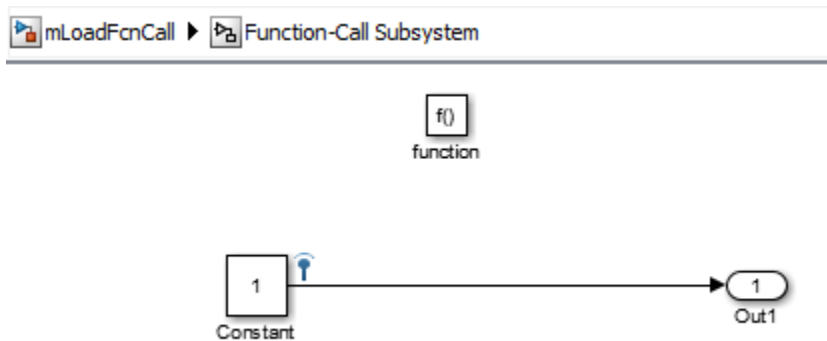

```

ds = Simulink.SimulationData.Dataset;
x = [1 3 7 8]';
ds = ds.addElement(x, 'theElementName');

```

This model uses the `ds` data set in the **Configuration Parameters > Data Import/Export > Input** parameter.

When you simulate the model, the time values of the logged signal data in the Function-Call Subsystem shows that the Function-Call Subsystem was triggered only for the times specified in array stored in `ds`.

```
>> logargout.get(1).Values.Time
```

```
ans =
```

```
1
3
7
8
```

Create MATLAB Time Expressions for Root Inports

Specify the Input Expression

You can use a MATLAB time expression to import data from a workspace. To use a time expression, enter the expression as a string (enclosed in single quotes) in the **Input** field of the **Data Import/Export** pane. The time expression can be any MATLAB expression that evaluates to a row vector equal in length to the number of signals entering the input ports of the model. For example, suppose that a model has one vector Inport that accepts two signals. Furthermore, suppose that `timefcn` is a user-defined function that returns a row vector two elements long. The following are valid input time expressions for such a model:

```
'[3*sin(t), cos(2*t)]'
```

```
'4*timefcn(w*t)+7'
```

The expression is evaluated at each step of the simulation, applying the resulting values to the input ports of the model. Simulink defines the variable `t` when it runs the simulation. Also, you can omit the time variable in expressions for functions of one variable. For example, the expression `sin` is interpreted as `sin(t)`.

Create Data Structures for Root Imports

In this section...

“Data Structures” on page 59-225

“Structures for All Ports or for Each Port” on page 59-226

“Specify Signal Data” on page 59-226

“Specify Time Data” on page 59-227

“Examples of Specifying Signal and Time Data” on page 59-228

Data Structures

The Simulink software can load data from the workspace in the form of a structure, whose name you specify in the **Configuration Parameters > Data Import/Export > Input** parameter.

For information about defining MATLAB structures, see “Create a Structure Array” in the MATLAB documentation.

The structure always includes a signals substructure, which contains a values field and a dimensions field. For details about the signal data, see “Specify Signal Data” on page 59-226. Depending on the modeling task that you want to perform, the structure can also include a time field.

You can specify structures for the model as a whole or on a per-port basis. For information about specifying per-port structures for the **Input** parameter, see “Structures for All Ports or for Each Port” on page 59-226.

The form of a structure that you use depends on whether you are importing data for:

- Discrete signals (the signal is defined at evenly spaced values of time) — Use a structure that has an empty time vector.
- Continuous signals (the signal is defined for all values of time) — The approach that you use depends on whether the data represents a smooth curve or a curve that has discontinuities (jumps) over its range.

For details, see:

- “Import Data to Test a Discrete Algorithm” on page 59-131
- “Import Data to Model a Continuous Plant” on page 59-128
- “Import Data for an Input Test Case” on page 59-133

For both discrete and continuous signals, specify a `signals` field, which contains an array of substructures, each of which corresponds to a model input port. For details, see “Specify Signal Data” on page 59-226.

For continuous signals, you can specify a `time` field, which contains a time vector. See “Specify Time Data” on page 59-227.

Structures for All Ports or for Each Port

You can specify one structure to provide input to all root-level input ports in a model, or you can specify a separate structure for each port.

The per-port structure format consists of a separate structure-with-time or structure-without-time for each port. The input data structure for each has only one `signals` field. To specify this option, enter the names of the structures in the **Input** text field as a comma-separated list, `in1, in2, . . . , inN`. The value `in1` is the data for first input port in the model, `in2` for the second input port, and so on.

The rest of the section about importing structure data focuses on specifying one structure for all ports.

Specify Signal Data

Each `signals` substructure must contain two fields: `values` and `dimensions`.

The Values Field

The `values` field must contain an array of inputs for the corresponding input port. If you specify a time vector, each input must correspond to a time value specified in the `time` field.

If the inputs for a port are scalar or vector values, the `values` field must be an `M-by-N` array. If you specify a time vector, `M` must be the number of time points specified by the `time` field and `N` is the length of each vector value.

If the inputs for a port are matrices (2-D arrays), the `values` field must be an `M-by-N-by-T` array. `M` and `N` are the dimensions of each matrix input and `T` is the number of time points. For example, suppose that you want to input 51 time samples of a 4-by-5 matrix signal into one of the input ports in your model. Then, the corresponding `dimensions` field of the workspace structure must equal `[4 5]` and the `values` array must have the dimensions `4-by-5-by-51`.

The Dimensions Field

The `dimensions` field specifies the dimensions of the input. If each input is a scalar or vector (1-D array) value, the `dimensions` field must be a scalar value specifying the length of the vector (1 for a scalar). If each input is a matrix (2-D array), the `dimensions` field must be a two-element vector whose:

- First element specifies the number of rows in the matrix
- Second element specifies the number of columns

Note Set the `Port dimensions` parameter of the `Inport` or the `Trigger` block to be the same value as the `dimensions` field of the corresponding input structure. If the values differ, an error message is displayed when you try to simulate the model.

Specify Time Data

You can specify a time vector of doubles as part of the data structure to import. For example, specify a time vector when importing signal data to represent a continuous plant or to create a test case. To test a discrete algorithm, use a structure with an empty time vector. This table provides additional recommendations for specifying time values, based on the kind of signal data you want to load.

Signal Data	Time Data Recommendation
Inport or Trigger block with a discrete sample time	Do not specify a time vector. Simulink loads one signal value at each time step.
Evenly spaced discrete signals	Use an expression in this form: <pre>timeVector = timeStep * [startTime:numSteps-1]'</pre> <p>The vector is transposed. Also, because the start time is a time step, you need specify the number of steps you</p>

Signal Data	Time Data Recommendation
	<p>want minus 1. For example, to specify 50 time values at 0.2 time steps:</p> <pre>T1 = 0.2 * [0:49]'</pre> <hr/> <p>Note: Do <i>not</i> use an expression in this form:</p> <pre>timeVector = [startTime:timeStep:endTime]'</pre> <p>For example, do not use:</p> <pre>T2 = [0:0.2:10]'</pre> <p>This time vector form is not equivalent to the form that multiplies by time steps (T1), because of double-precision rounding used by computers. Simulink expects exact values, with no double-precision rounding. Using the T2 form can lead to mismatches between the provided time vector and the time steps taken by Simulink, resulting in unexpected simulation results.</p>
Unevenly spaced values	<p>Use any valid MATLAB array expression; for example, [1:5 5:10] or (1 6 10 15).</p> <p>The From Workspace, From File, and Signal Builder blocks support zero-crossing detection. If the root-level input port is connected to one of those blocks, you can specify a zero-crossing time by using a duplicate time entry.</p>

Examples of Specifying Signal and Time Data

In the first example, consider the following model that has a single input port:

- 1 Create an input structure for loading 11 time samples of a two-element signal vector of type `int8` into the model:

```
N = 10
Ts = 0.1
a.time = Ts*[0:N]';
c1 = int8([0:1:10]');
c2 = int8([0:10:100]');
a.signals(1).values = [c1 c2];
a.signals(1).dimensions = 2;
```

- 2 In the **Configuration Parameters** > **Data Import/Export** > **Input** parameter edit box, specify the variable `a`.
- 3 In the Inport block dialog box, in the **Signal Attributes** tab, set **Port dimensions** to 2 and **Data type** to `int8`.

As another example, consider a model that has two inputs:

Suppose that you want to input a sine wave into the first port and a cosine wave into the second port. Define a structure, `a`, as follows, in the MATLAB workspace:

```
a.time = 0.1*[0:1]';
a.signals(1).values = sin(a.time);
a.signals(1).dimensions = 1;
a.signals(2).values = cos(a.time);
a.signals(2).dimensions = 1;
```

Enter the structure name (`a`) in the **Configuration Parameters** > **Data Import/Export** > **Input** parameter edit box.

Note: In this model you do not need to specify the dimension and data type, because the default values are 1 and `double`.

State Information

In this section...

“Simulation State Information” on page 59-231

“Types of State Information” on page 59-231

“Format for State Information Saved Without SimState” on page 59-234

“State Information for Referenced Models” on page 59-235

Simulation State Information

Some blocks maintain state information that they use during simulation. For example, the state information for a Unit Delay block is the output signal value from the previous simulation step. The block uses the state information for calculating the output signal value for the current simulation step.

Some examples of uses of saved state information include:

- Stopping a simulation for a model and using the saved state information as input when you restart the simulation.
- Simulating one model and using the saved state information as input for the simulation of another model that builds on the results of the first model.
- Examining changes in state information throughout a simulation.

Types of State Information

You can save these kinds of state information.

Type of State Information	Description	Configuration Parameters in Data Import/Export Pane
States for each simulation step	State information of blocks (referred to as partial state data) at each time step of a simulation	States
Final state	State information of blocks at the end of the simulation	Final states

Type of State Information	Description	Configuration Parameters in Data Import/Export Pane
Final state with SimState	Final state with a SimState object that captures additional internal information that Simulink uses during simulation	Final States and Save complete SimState in final state

SimState provides more complete final simulation state information than final states information by itself does. However, if the requirements and limitations of using SimState do not meet your modeling requirements, save final state information without SimState.

Comparison of SimState and Final State Logging

Characteristic	Final State	Final State with SimState
Simulation mode	Supports all simulation modes	Normal or Accelerator.
Model reference	“State Information for Referenced Models” on page 59-235	See “Model Referencing” on page 23-43.
Resumed simulation	Not supported	Supported.
Saved state data	Only logged states — the continuous and discrete states of blocks — which are a subset of the complete simulation state of the model User data, run-time parameters, or logs of the model not saved	Complete state information Does not save user data, run-time parameters, or logs of the model.
Block output	User data, run-time parameters, or logs of the model not saved	Simulink tries to save the output of a block as part of a SimState even if S-functions declare that no SimState states exist in the block. If the block output is of custom type, Simulink displays an error.

Characteristic	Final State	Final State with SimState
Readability	Use structure with time format for best readability	To examine a simplified view of the data, consider using looking at the <code>loggedStates</code> property of the <code>Simulink.SimState.ModelSimState</code> class.
Restoring state data	Can save and restore in different simulation modes. If logged state information is not sufficient, you can obtain different results in the two simulation modes.	Cannot save in normal mode and restore in Accelerator, or conversely save in accelerator mode and restore in normal mode.
Restoring multiple states	You can initialize only one out of multiple logged states in the model.	You restore all states in the model. You cannot load a subset of states.
Structural changes	You can make structural changes between simulation and restoring the simulation.	You cannot make structural changes to the model between when you save the <code>SimState</code> and when you restore the simulation using the <code>SimState</code> . For example, you cannot add or remove a block after saving the <code>SimState</code> without repeating the simulation and saving the new <code>SimState</code> .
Input to model function	To input to model function, use <code>Array</code> format with non-complex data of type <code>double</code> .	You cannot input the <code>SimState</code> to model function.
Code generation	Supported	Not supported

For both `SimState` and final state logging, Simulink saves state information at one of these points:

- At the final time step

- At the execution time at which the simulation paused or stopped

For additional information about `SimState`, see “Limitations of `SimState`” on page 23-42.

Format for State Information Saved Without `SimState`

If you do not use the `SimState` for saving state information, then use **Configuration Parameters > Data Import/Export > Format** to specify the data format for the saved state information.

You can set **Format** to:

- `Dataset` (default)
- `Array`
- `Structure`
- `Structure with time`

The `Array` option for the **Configuration Parameters > Data Import/Export > Format** option supports compatibility with models developed in earlier releases, when Simulink supported only the array format for saving state information.

The array format reflects the order of signals. The order of saved state information can change between simulations when you change any of the following:

- The model (even without changing the signal)
- The simulation mode
- The code generation mode

The `Structure` and `Structure with time` formats are easier to read and consistent across simulations. Also, these two formats are useful when using state information to initialize a model for simulation, allowing you to:

- Associate initial state values directly with the full path name to the states. This association eliminates errors that can occur if Simulink reorders the states, but the order of the initial state array does not change correspondingly.
- Assign a different data type to the initial value of each state.
- Initialize only a subset of the states.
- `Dataset` format:

- Uses MATLAB `timeseries` objects to store logged data. MATLAB `timeseries` objects allow you to work with logged data in MATLAB without a Simulink license.
- Supports logging multiple data values for a given time step, which can be important for Iterator subsystem and Stateflow signal logging
- Does not support logging nonvirtual bus data for code generation or rapid accelerator mode.

State Information for Referenced Models

When Simulink saves states in the structure or structure-with-time format, it adds an `inReferencedModel` subfield to the `signals` field of the structure. The value of this additional subfield is true (1) if the `signals` field records the final state of a block that resides in the reference model. For example:

```
xout.signals(1)
ans =
    values: [101x1 double]
 dimensions: 1
    label: 'DSTATE'
    blockName: [1x66 char]
 inReferencedModel: 1
```

If the `signals` field records a referenced model state, its `blockName` subfield contains a compound path of a top model path and a reference model path. The top model path is the path from the model root to the Model block that references the reference model. The reference model path is the path from the reference model root to the block whose state the `signals` field records. The compound path uses a `|` character to separate the top and reference model paths. For example:

```
>> xout.signals(1).blockName
ans =
sldemo_md1ref_basic/CounterA|sldemo_md1ref_counter/Previous Output
```

Save State Information

In this section...

“Save State Information for Each Simulation Step” on page 59-237

“Save Partial Final State Information” on page 59-237

“Examine State Information Saved Without the SimState” on page 59-238

“Save Final State Information with SimState” on page 59-239

Save State Information for Each Simulation Step

You can save state information for logged states for each simulation step during a simulation. That level of state information can be helpful for debugging.

- 1 Select the **Configuration Parameters > Data Import/Export > States** check box.
- 2 In the **States** edit box, you can specify a different variable for the state information, if you do not want to use the default `xout` variable.
- 3 Also in the **Data Import/Export** pane, set the **Format** parameter to **Dataset**, **Structure**, or **Structure with time**, unless you use array format for compatibility with a legacy model. **Dataset** format does not support code generation or Rapid Accelerator simulation mode.
- 4 Click **Apply**.
- 5 Simulate the model.

Save Partial Final State Information

To save just the logged states (the continuous and discrete states of blocks):

- 1 Select the **Configuration Parameters > Data Import/Export > Final states** check box.
- 2 In the **Final states** edit box, you can specify a different variable for the state information, if you do not want to use the default `xFinal` variable.
- 3 Clear the **Save complete SimState in final state** parameter.
- 4 Set the **Format** parameter to **Dataset**, **Structure**, or **Structure with time**.
- 5 Click **Apply**.

6 Simulate the model.

Examine State Information Saved Without the SimState

If you enable the **Configuration Parameters > Data Import/Export > Final states** or **States** parameters, Simulink saves the state information in the format that you specify with the **Format** parameter. The default variable for **Final state** information is `xFinal`, and the variable for state information for States information is `xout`.

If a model has no states saved, then `xFinal` and `xout` are empty variables. To determine whether a model has states saved, use the `isempty(xout)` command.

Final State Information in Dataset Format

For example, suppose that you saved final state information in **Dataset** format, and use the default `xFinal` variable for the saved state information.

```
xFinal
```

```
xFinal =
```

```
Simulink.SimulationData.Dataset  
Package: Simulink.SimulationData
```

```
Characteristics:  
    Name: 'xFinal'  
    Total Elements: 2
```

```
Elements:  
    1: 'CSTATE'  
    2: 'DSTATE'
```

Examine the first element of the state data set.

```
xFinal.get(1)
```

```
ans =
```

```
Simulink.SimulationData.State  
Package: Simulink.SimulationData
```

```
Properties:  
    Name: 'CSTATE'
```

```
BlockPath: [1x1 Simulink.SimulationData.BlockPath]
Label: CSTATE
Values: [1x1 timeseries]
```

Final State Information in Structure with Time Format

For example, suppose that you saved final state information in a structure with time format, and use the default `xFinal` variable for the saved state information.

To find the simulation time and number of states in the `vdp` model, enter the `xFinal` variable.

```
xFinal
xFinal =
    time: 20
  signals: [1x2 struct]
```

In this case, the simulation time is 20 and there are two states. To examine the first state, use this command.

```
xFinal.signals(1)
ans =
    values: 2.0108
  dimensions: 1
    label: 'CSTATE'
  blockName: 'vdp/x1'
    stateName: ''
  inReferencedModel: 0
```

The `values` and `blockName` fields of the first state structure show that the final value for the output signal of the `x1` block is 2.018.

Note: If you write a script to analyze state information, use a combination of `label` and `blockName` values to identify a specific state uniquely. Do not rely on the order of the states.

Save Final State Information with SimState

To save complete state information, save the `SimState` for a simulation.

- 1 Select the **Configuration Parameters > Data Import/Export > Final states** check box.
- 2 Also in the Data Import/Export pane, select the **Save complete SimState in final state** parameter.
- 3 In the edit box next to the **Save complete SimState in final state** parameter, enter a variable name for the **SimState** and click **Apply**.
- 4 Simulate the model.

For more information about using the **SimState**, see “Save and Restore Simulation State as SimState” on page 23-37.

Related Examples

More About

- “State Information” on page 59-231

Load State Information

In this section...

“Import Initial States” on page 59-241

“Initialize a State” on page 59-241

“Initialize States in Referenced Models” on page 59-242

Import Initial States

To initialize a simulation, you can use:

- Final state information (with or without `SimState`) from a previous simulation
- State information that you create in MATLAB

Use **Configuration Parameters** > **Data Import/Export** parameters to import initial states.

- 1 Enable the **Initial state** parameter.
- 2 In the **Initial state** edit box, enter the name of the variable for the state information that you want to use for initialization.

The initial values that the variable specifies override the initial state values that the blocks in the model specify in initial condition parameters.

You can specify structure or structure with time data. You cannot specify **Dataset** format data.

Initialize a State

You can initialize a specific state. For example, the following commands create an initial state structure that initializes the `x2` state of the `vdp` model. The `x1` state is not initialized in the structure. Therefore, during simulation, Simulink uses the value in the Integrator block associated with the state.

- 1 Obtain an initial state structure.

```
open_system('vdp');  
states = Simulink.BlockDiagram.getInitialState('vdp');
```

- 2 Set the initial value of the signals structure element associated with `x2` to 2.
`states.signals(2).values = 2;`
- 3 Remove the signals structure element associated with `x1`.
`states.signals(1) = [];`
- 4 Use the `states` variable for the vdp model. Enable the **Configuration Parameters > Data Import/Export > Initial state** option. Enter `states` in the edit field.

When you simulate the model, both states have the initial value of 2. The initial value of the `x2` state is assigned in the `states` structure, while the initial value of the `x1` state is assigned in its Integrator block.

Initialize States in Referenced Models

To initialize the states of a top model and the models that it references, use the structure or structure with time format or use `SimState`.

If the top model is in rapid accelerator mode, you cannot load discrete state data.

Working with Data Stores

- “Data Store Basics” on page 60-2
- “Model Global Data by Creating Data Stores” on page 60-13
- “Log Data Stores” on page 60-39

Data Store Basics

A *data store* is a repository to which you can write data, and from which you can read data, without having to connect an input or output signal directly to the data store. Data stores are accessible across model levels, so subsystems and referenced models can use data stores to share data without using I/O ports.

In this section...
“When to Use a Data Store” on page 60-2
“Local and Global Data Stores” on page 60-3
“Data Store Diagnostics” on page 60-3
“Specify Initial Value for Data Store” on page 60-11

When to Use a Data Store

Data stores can be useful when multiple signals at different levels of a model need the same global values, and connecting all the signals explicitly would clutter the model unacceptably or take too long to be feasible. Data stores are analogous to global variables in programs, and have similar advantages and disadvantages, such as making verification more difficult.

In some cases, you may be able to use a simpler technique, **Goto** blocks and **From** blocks, to obtain results similar to those provided by data stores. The principal disadvantage of data Goto/From links is that they generally are not accessible across nonvirtual subsystem boundaries, while an appropriately configured data store can be accessed anywhere. See the **Goto** and **From** block reference pages for more information about Goto/From links.

Data Stores and Software Verification

Data stores can have significant effects on software verification, especially in the area of data coupling and control. Models and subsystems that use only inports and outports to pass data result in clean, well-specified, and easily verifiable interfaces in the generated code.

Data stores, like any type of global data, make verification more difficult. If your development process includes software verification, consider planning for the effect of data stores early in the design process.

For more information, see RTCA DO-331, “Model-Based Development and Verification Supplement to DO-178C and DO-278A,” Section MB.6.3.3.b.

Local and Global Data Stores

You can define two types of data stores:

- A *local data store* is accessible from anywhere in the model hierarchy that is at or below the level at which you define the data store, except from referenced models. You can define a local data store graphically in a model or by creating a model workspace signal object (`Simulink.Signal`).
- A *global data store* is accessible from throughout the model hierarchy, including from referenced models. Define a global data stores only in the MATLAB base workspace, using a signal object. The only type of data store that a referenced model can access is a global data store.

In general, locate a data store at the lowest level in the model that allows access to the data store by all the parts of the model that need that access. Some examples of local and global data stores appear in “Data Store Examples” on page 60-13.

For information about using referenced models, see “Model Referencing”.

Data Store Diagnostics

- “About Data Store Diagnostics” on page 60-3
- “Detecting Access Order Errors” on page 60-4
- “Detecting Multitasking Access Errors” on page 60-6
- “Detecting Duplicate Name Errors” on page 60-8
- “Data Store Diagnostics in the Model Advisor” on page 60-11

About Data Store Diagnostics

Simulink provides various run-time and compile-time diagnostics that you can use to help avoid problems with data stores. Diagnostics are available in the Model Configuration Parameters dialog box and the Data Store Memory block's parameters dialog box. The Simulink Model Advisor provides support by listing cases where data store errors are more likely because diagnostics are disabled.

Detecting Access Order Errors

- “Data Store Diagnostics and Models Referenced in Accelerator Mode” on page 60-5
- “Data Store Diagnostics and the MATLAB Function Block” on page 60-6

You can use data store run-time diagnostics to detect unintended sequences of data store reads and writes that occur during simulation. You can apply these diagnostics to all data stores, or allow each Data Store Memory block to set its own value. The diagnostics are:

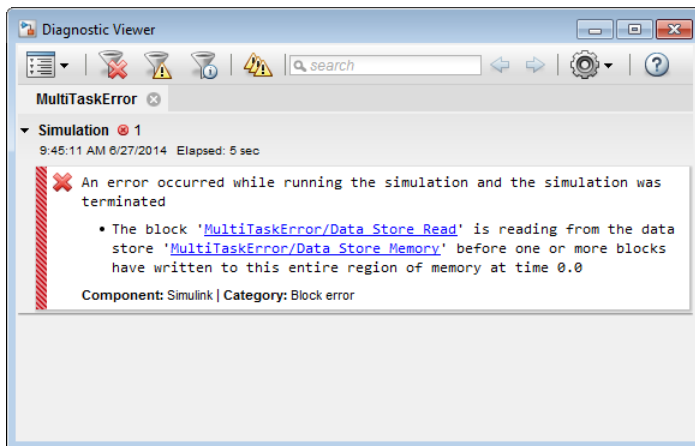

- **Detect read before write:** Detect when a data store is read from before written.
- **Detect write after read:** Detect when a data store is written.
- **Detect write after write:** Detect when a data store is written.

These diagnostics appear in the **Model Configuration Parameters > Diagnostics > Data Validity > Data Store Memory block** pane, where each can have one of the following values:

- **Disable all** — Disables this diagnostic for all data stores accessed by the model.
- **Enable all as warnings** — Displays the diagnostic as a warning in the MATLAB Command Window.
- **Enable all as errors** — Halts the simulation and displays the diagnostic in an error dialog box.
- **Use local settings** — Allow each Data Store Memory block to set its own value for this diagnostic (default).

The same diagnostics also appear in each Data Store Memory block parameters dialog box **Diagnostics** tab. You can set each diagnostic to **none**, **warning**, or **error**. The value specified by an individual block takes effect only if the corresponding configuration parameter is **Use local settings**. See “Model Configuration Parameters: Data Validity Diagnostics” and the **Data Store Memory** documentation for more information.

The most conservative technique is to set all data store diagnostics to **Enable all as errors** in **Model Configuration Parameters > Diagnostics > Data Validity > Data Store Memory block**. However, this setting is not best in all cases, because it can flag intended behavior as erroneous. For example, the next figure shows a model that uses block priorities to force the Data Store Read block to execute before the Data Store Write block:

An error occurred during simulation because the data store A is read from the Data Store Read block before the Data Store Write block updates the store. If the associated delay is intended, you can suppress the error by setting the global parameter **Detect read before write** to **Use local settings**, then setting that parameter to **none** in the **Diagnostics** pane of the Data Store Memory block dialog box. If you use this technique, set the parameter to **error** in all other Data Store Memory blocks aside from those that are to be intentionally excluded from the diagnostic.

Data Store Diagnostics and Models Referenced in Accelerator Mode

For models referenced in Accelerator mode, Simulink ignores the following **Configuration Parameters > Diagnostics > Data Validity > Data Store Memory block** parameters if you set them to a value other than **Disable all**.

- **Detect read before write** (ReadBeforeWriteMsg)

- **Detect write after read** (WriteAfterReadMsg)
- **Detect write after write** (WriteAfterWriteMsg)

You can use the Model Advisor to identify models referenced in Accelerator mode for which Simulink ignores the configuration parameters listed above.

- 1 In the Simulink Editor, select **Analysis > Model Advisor**.
- 2 Select **By Task**.
- 3 Run the **Check diagnostic settings ignored during accelerated model reference simulation** check.

Data Store Diagnostics and the MATLAB Function Block

Diagnostics might be more conservative for data store memory used by MATLAB Function blocks. For example, if you pass arrays of data store memory to MATLAB functions, optimizations such as `A=foo(A)` might result in MATLAB marking the entire contents of the array as read or written, even though only some elements were accessed.

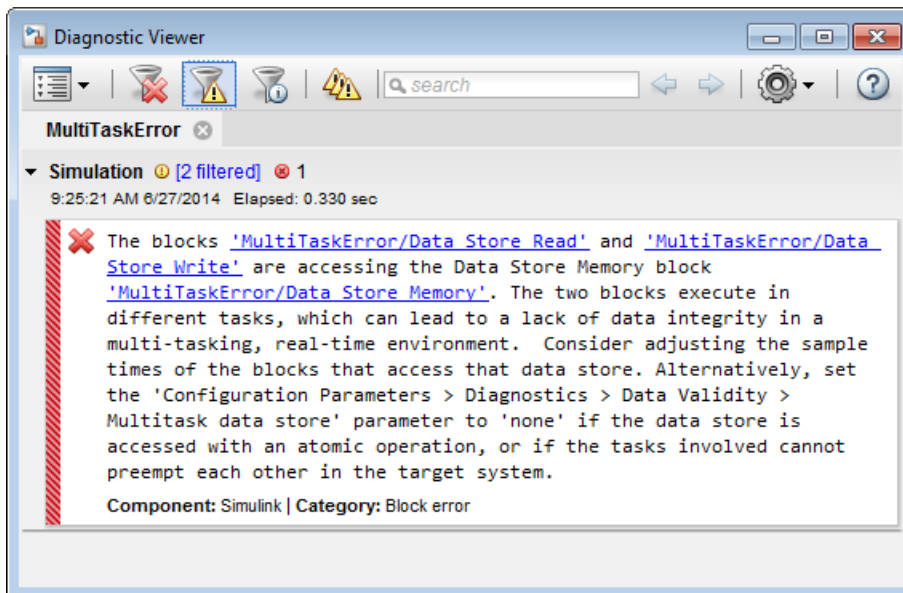

Detecting Multitasking Access Errors

Data integrity may be compromised if a data store is read from in one task and written to in another task. For example, suppose that:

- 1 A task is writing to a data store.
- 2 A second task interrupts the first task.
- 3 The second task reads from that data store.

If the first task had only partly updated the data store when the second task interrupted, the resulting data in the data store is inconsistent. For example, if the value is a vector, some of its elements may have been written in the current time step, while the rest were written in the previous step. If the value is a multi-word, it may be left in an inconsistent state that is not even partly correct.

Unless you are certain that task preemption cannot cause data integrity problems, set the compile-time diagnostic **Model Configuration Parameters > Diagnostics > Data Validity > Data Store Memory block > Multitask data store** to warning (the default) or error. This diagnostic flags any case of a data store that is read from and written to in different tasks. The next figure illustrates a problem detected by setting **Multitask data store** to error:

Since the data store A is written to in the fast task and read from in the slow task, an error is reported, with suggested remedy. This diagnostic is applicable even in the case that a data store read or write is inside of a conditional subsystem. Simulink correctly identifies the task that the block is executing within, and uses that task for the purpose of evaluating the diagnostic.

The next figure shows one solution to the problem shown above: place a rate transition block after the data store read, which previously accessed the data store at the slower rate.

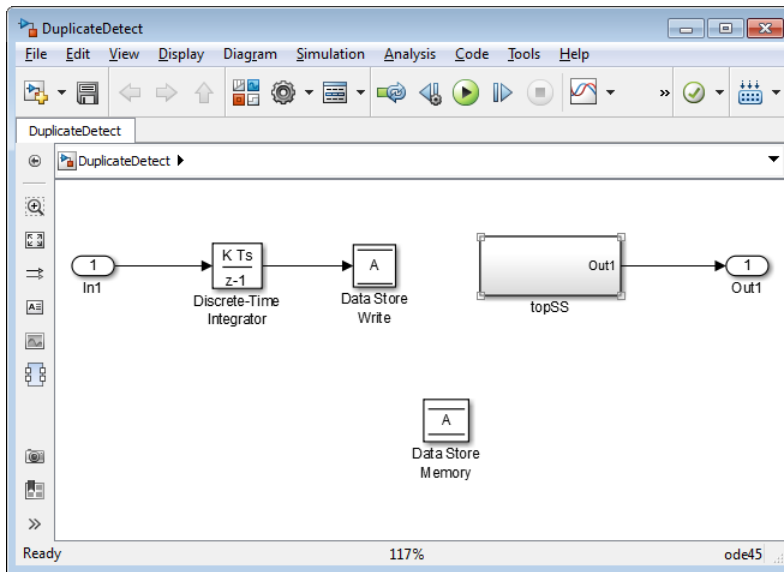

With this change, the data store write can continue to occur at the faster rate. This may be important if that data store must be read at that faster rate elsewhere in the model.

The **Multitask Data Store** diagnostic also applies to data store reads and writes in referenced models. If two different child models execute a data store's reads and writes in differing tasks, the error will be detected when Simulink compiles their common parent model.

Detecting Duplicate Name Errors

Data store errors can occur due to duplicate uses of a data store name within a model. For instance, data store shadowing occurs when two or more data store memories in different nested scopes have the same data store name. In this situation, the data store memory referenced by a data store read or write block at a low level may not be the intended store.

To prevent errors caused by duplicate data store names, set the compile-time diagnostic **Model Configuration Parameters > Diagnostics > Data Validity > Data Store Memory block > Duplicate data store names** to warning or error. By default, the value of the diagnostic is **none**, suppressing duplicate name detection. The next figure shows a problem detected by setting **Duplicate data store names** to **error**:

The data store read at the bottom level of a subsystem hierarchy refers to a data store named A, and two Data Store Memory blocks in the same model have that name, so an

error is reported. This diagnostic guards against assuming that the data store read refers to the Data Store Memory block in the top level of the model. The read actually refers to the Data Store Memory block at the intermediate level, which is closer in scope to the Data Store Read block.

Data Store Diagnostics in the Model Advisor

The Model Advisor provides several diagnostics that you can use with data stores. See these sections for information about Model Advisor diagnostics for data stores:

“Check Data Store Memory blocks for multitasking, strong typing, and shadowing issues”

“Check data store block sample times for modeling errors”

“Check if read/write diagnostics are enabled for data store blocks”

Specify Initial Value for Data Store

In general, to specify an initial value for a data store, you can use the same techniques that you use for other blocks. See “Initialize Signals and Discrete States” on page 62-47.

With most blocks, you can take advantage of scalar expansion to minimize the effort of specifying an initial value for a nonscalar signal. When you specify a scalar initial value, each element in the signal uses that scalar.

However, when you set the **Dimensions** parameter to -1 in a Data Store Memory block (the default), you cannot use scalar expansion. Instead, you must specify an initial value that has the same dimensions as the stored signal. To take advantage of scalar expansion of the initial value, set the **Dimensions** parameter to a specific value such as [1 2] or [1 myDim] (for symbolic dimensions).

A *data store* is a repository to which you can write data, and from which you can read data, without having to connect an input or output signal directly to the data store. Data stores are accessible across model levels, so subsystems and referenced models can use data stores to share data without using I/O ports. To decide whether to use data stores, see “Data Store Basics” on page 60-2.

Data Store Examples

Overview

The following examples illustrate techniques for defining and accessing data stores. See “Order Data Store Access” on page 60-24 for techniques that control data store access over time, such as ensuring that a given data store is always written before it is read. See “Data Store Diagnostics” on page 60-3 for techniques you can use to help detect and correct potential data store errors without needing to run any simulations.

Note: In addition to the following examples, see the `sldemo_mdref_dsm` model, which shows how to use global data stores to share data among referenced models.

Local Data Store Example

The following model illustrates creation and access of a local data store, which is visible only in a model or particular subsystem.

This model uses a data store to permit subsystem A to signal that its output is invalid. If subsystem A's output is invalid, the model uses the output of subsystem B.

Global Data Store Example

The following model replaces the subsystems of the previous example with functionally identical referenced models to illustrate use of a global data store to share data in a model reference hierarchy.

In this example, the top model uses a signal object in the MATLAB workspace to define the error data store. This is necessary because data stores are visible across model boundaries only if they are defined by signal objects in the MATLAB workspace.

Create and Apply Data Stores

Note: To use buses and arrays of buses with data stores, perform *both* the following procedure and “Setting Up a Model to Use Data Stores with Buses and Arrays of Buses” on page 60-31.

The following is a general workflow for configuring data stores. You can perform the tasks in a different order, or separately from the rest, depending on how you use data stores.

- 1 Where applicable, plan your use of data stores to minimize their effect on software verification. For more information, see “Data Stores and Software Verification” on page 60-2.
- 2 Create data stores using the techniques described in “Data Stores with Data Store Memory Blocks” on page 60-17 or “Data Stores with Signal Objects” on page 60-20. For greater reliability, consider assigning rather than inheriting data store attributes, as described in “Specifying Data Store Memory Block Attributes” on page 60-17.

- 3 Add to the model Data Store Write and Data Store Read blocks to write to and read from the data stores, as described in “Access Data Stores with Simulink Blocks” on page 60-22.
- 4 Configure the model and the blocks that access each data store to avoid concurrency failures when reading and writing the data store, as described in “Order Data Store Access” on page 60-24.
- 5 Apply the techniques described in “Data Store Diagnostics” on page 60-3 as needed to prevent data store errors, or to diagnose them if they occur during simulation.
- 6 If you intend to generate code for your model, see “Data Stores in Generated Code” in the Simulink Coder documentation.

To create a data store, you create a **Data Store Memory** block or a `Simulink.Signal` object. The block or signal object represents the data store and specifies its properties. Every data store must have a unique name.

- A **Data Store Memory** block implements a local data store. See “Data Stores with Data Store Memory Blocks” on page 60-17.
- A `Simulink.Signal` object can act as a local or global data store. See “Data Stores with Signal Objects” on page 60-20.

Data stores implemented with **Data Store Memory** blocks:

- Support data store initialization
- Provide control of data store scope and options at specific levels in the model hierarchy
- Require a block to represent the data store
- Cannot be accessed within referenced models
- Cannot be in a subsystem that a **For Each Subsystem** block represents.

Data stores implemented with `Simulink.Signal` objects:

- Provide model-wide control of data store scope and options
- Do not require a block to represent the data store
- Can be accessed in referenced models, if the data store is global

Be careful not to equate local data stores with **Data Store Memory** blocks, and global data stores with `Simulink.Signal` objects. Either technique can define a local data store, and a signal object can define either a local or a global data store.

Data Stores with Data Store Memory Blocks

- “Creating the Data Store” on page 60-17
- “Specifying Data Store Memory Block Attributes” on page 60-17

Creating the Data Store

To use a Data Store Memory block to define a data store, drag an instance of the block into the model at the topmost level from which you want the data store to be visible. The result is a local data store, which is not accessible within referenced models.

- To define a data store that is visible at every level within a given model, except within Model blocks, drag the Data Store Memory block into the root level of the model.
- To define a data store that is visible only within a particular subsystem and the subsystems that it contains, but not within Model blocks, drag the Data Store Memory block into the subsystem.

Once you have added the Data Store Memory block, use its parameters dialog box to define the data store's properties. The **Data store name** property specifies the name of the data store that the Data Store Write and Data Store Read blocks access. See [Data Store Memory](#) documentation for details.

You can specify data store properties beyond those definable with Data Store Memory block parameters by selecting the **Data store name must resolve to Simulink signal object** option and using a signal object as the data store name. See “Specifying Attributes Using a Signal Object” on page 60-18 for details.

Specifying Data Store Memory Block Attributes

A Data Store Memory block can inherit three data attributes from its corresponding Data Store Read and Data Store Write blocks. The inheritable attributes are:

- Data type
- Complexity
- Sample time

However, allowing these attributes to be inherited can cause unexpected results that can be difficult to debug. To prevent such errors, use the Data Store Memory block dialog or a `Simulink.Signal` object to specify the attributes explicitly.

Specifying Attributes Using Block Parameters

You can use the Data Store Memory block dialog box to specify the data type and complexity of a data store. In the next figure, the dialog box sets the **Data type** to `uint16` and the **Signal type** to `real`.

Specifying Attributes Using a Signal Object

You can use a `Simulink.Signal` object to specify data store attributes for a Data Store Memory block.

Tip To establish an implicit data store, as described in “Data Stores with Signal Objects” on page 60-20, use the same general approach as when you explicitly associate a signal object with a Data Store Memory block.

The next figure shows a Data Store Memory block that specifies resolution to a `Simulink.Signal` object, named `A`. To use a signal object for the data store, set **Data**

store name to the name of the signal object. For compile-time checking, open the **Signal Attributes** tab and select the **Data store name must resolve to Simulink signal object** parameter.

The signal object specifies values for all three data attributes that the data store would otherwise inherit. In this example, which defines a local data store, the `Simulink.Signal` object `A` has the following inherited properties: `DataType`, `Complexity`, and `SampleTime`.

`A =`

```
Simulink.Signal (handle)
  CoderInfo: [1x1 Simulink.CoderInfo]
  Description: ''
  DataType: 'auto'
  Min: []
  Max: []
  Unit: ''
  Dimensions: 1
```

```
DimensionsMode: 'auto'  
Complexity: 'auto'  
SampleTime: -1  
InitialValue: 0
```

For more information about specifying signal object attributes for local and global data stores, see “Signal Object Attributes for Data Stores” on page 60-21.

Use Model Data Editor to Configure Data Store Memory Blocks in a List

Use the **Data Stores** tab in the Model Data Editor to configure the parameters of a Data Store Memory block. Use this technique to configure the data store without locating it in the model and to configure the data store together with other interface elements such as Inport and Outport blocks.

To open the Model Data Editor, select **View > Model Data**. For information about using the Model Data Editor, see “Configure Data Properties by Using a Table” on page 57-103.

Data Stores with Signal Objects

- “Creating the Data Store” on page 60-20
- “Local and Global Data Stores” on page 60-20
- “Signal Object Attributes for Data Stores” on page 60-21

Creating the Data Store

To use a `Simulink.Signal` object to define a data store without using a Data Store Memory block, create the signal object in a workspace that is visible to every component that needs to access the data store. The name of the associated data store is the name of the signal object. You can use this name in Data Store Read and Data Store Write blocks, just as if it were the **Data store name** of a Data Store Memory block. Simulink creates an associated data store when you use the signal object for data storage.

Local and Global Data Stores

You can use a `Simulink.Signal` object to define either a local or a global data store.

- If you define the object in the MATLAB base workspace, the result is a global data store, which is accessible in every model within Simulink, including all referenced models.
- If you create the object in a model workspace, the result is a local data store, which is accessible at every level in a model except any referenced models.

Signal Object Attributes for Data Stores

Those data store attributes that a signal object does not define have the same default values that they do in a Data Store Memory block. The parameter values of a signal object used as a data store have different requirements, depending on whether the data store is local or global.

Once you have created the object, set the properties of the signal object to the values that you want the corresponding data store properties to have. For example, the following commands define a data store named `Error` in the MATLAB base workspace:

```
Error = Simulink.Signal;
Error.Description = 'Use to signal that subsystem output is invalid';
Error.DataType = 'boolean';
Error.Complexity = 'real';
Error.Dimensions = 1;
Error.SampleTime = 0.1;
```

Attributes for Local Data Stores

For a local data store, for each parameter listed below, you can either set the value explicitly or you can have the data store inherit the value from the Data Store Write and Data Store Read blocks.

- `DataType`
- `Complexity`
- `SampleTime`

To define a local data store using a Data Store Memory block, you can use a signal object for the **Data store name** parameter. For compile-time checking, in the **Signal Attributes** tab, select the **Data store must resolve to Simulink signal object** parameter. The **Data store must resolve to Simulink signal object** parameter causes Simulink to display an error and stop compilation if Simulink cannot find the signal object or if the signal object properties are inconsistent with the signal object properties.

Attributes for Global Data Stores

The following table describes the parameter requirements for global data stores.

Parameter	Global Data Store Value
<code>DataType</code>	Must be set explicitly

Parameter	Global Data Store Value
Complexity	Must be set explicitly
Dimensions	Can be set or inherited
SampleTime	Can be set or inherited

Access Data Stores with Simulink Blocks

- “Writing to a Data Store” on page 60-22
- “Reading from a Data Store” on page 60-22
- “Accessing a Global Data Store” on page 60-23

Writing to a Data Store

To set the value of a data store at each time step:

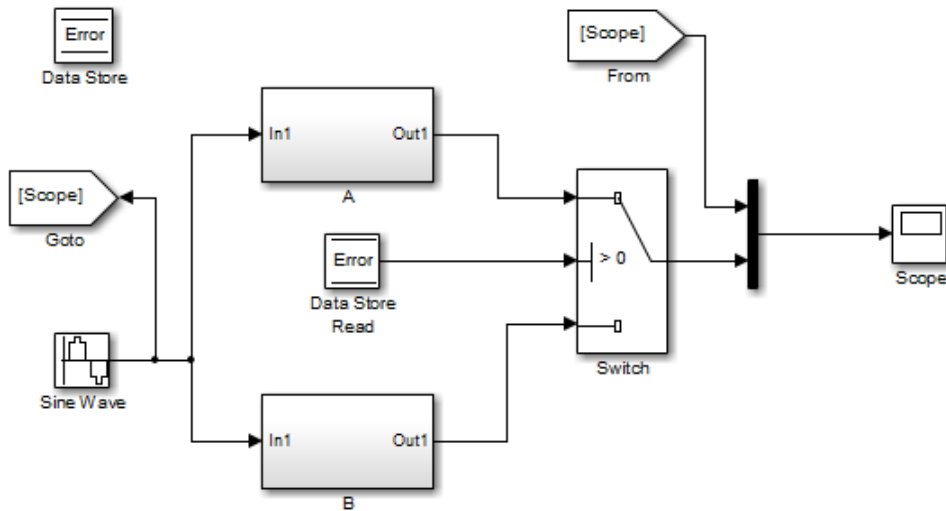

- 1 Create an instance of a **Data Store Write** block at the level of your model that computes the value.
- 2 Set the Data Store Write block **Data store name** parameter to the name of the data store to which you want it to write data.
- 3 Connect the output of the block that computes the value to the input of the Data Store Write block.

Reading from a Data Store

To get the value of a data store at each time step:

- 1 Create an instance of a Data Store Read block at the level of your model that needs the value.
- 2 Set the Data Store Read block **Data store name** parameter to the name of the data store from which you want it to read.
- 3 Connect the output of the Data Store Read block to the input of the block that needs the data store value.

Accessing a Global Data Store

When connected to a global data store (one that is defined by a signal object in the MATLAB workspace), a Data Store Read or Data Store Write block displays the word `global` above the data store name.

Order Data Store Access

- “About Data Store Access Order” on page 60-24
- “Ordering Access Using Function Call Subsystems” on page 60-24
- “Ordering Access Using Block Priorities” on page 60-28

About Data Store Access Order

To obtain correct results from data stores, you must control the order of execution of the data store’s reads and writes. If a data store’s read occurs before its write, latency is introduced into the algorithm: the read obtains the value that was computed and stored in the previous time step, rather than the value computed and stored in the current time step.

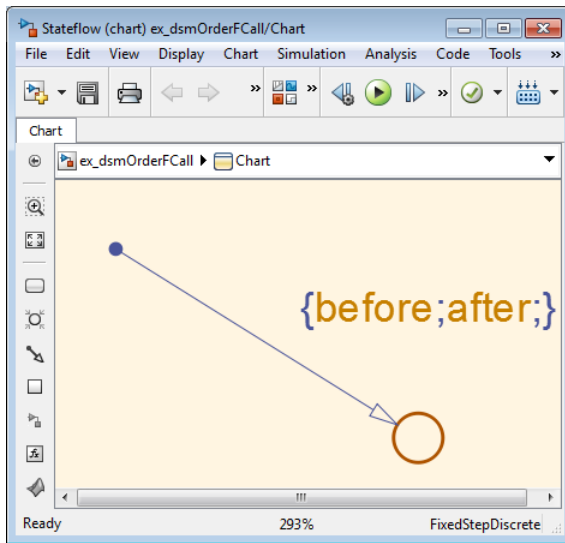

Such latency may cause the system to behave other than as designed, and in some cases may destabilize the system. Even if these problems do not occur, an uncontrolled access order could change from one release of Simulink to the next.

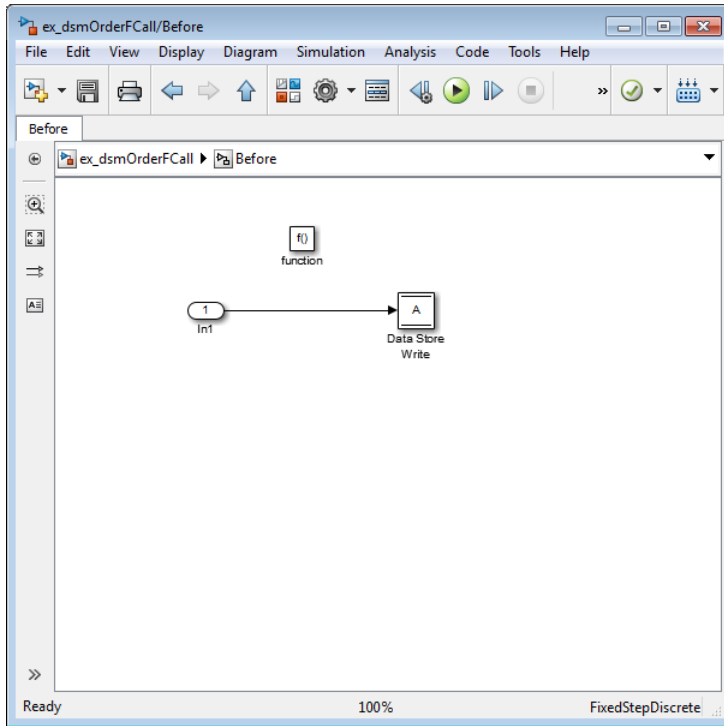

This section describes several strategies for explicitly controlling the order of execution of a data store’s reads and writes. See “Data Store Diagnostics” on page 60-3 for techniques you can use to detect and correct potential data store errors without running simulations.

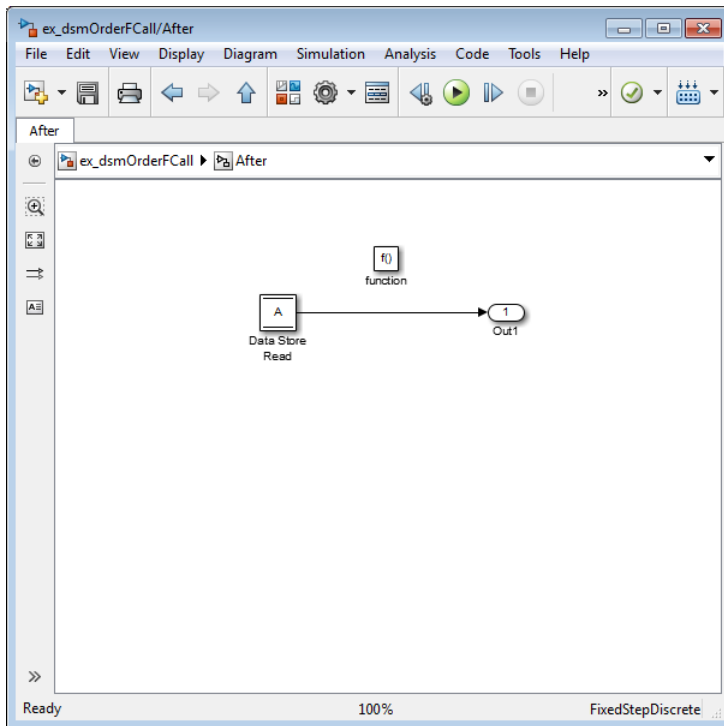

Ordering Access Using Function Call Subsystems

You can use function call subsystems to control the execution order of model components that access data stores. The next figure shows this technique:

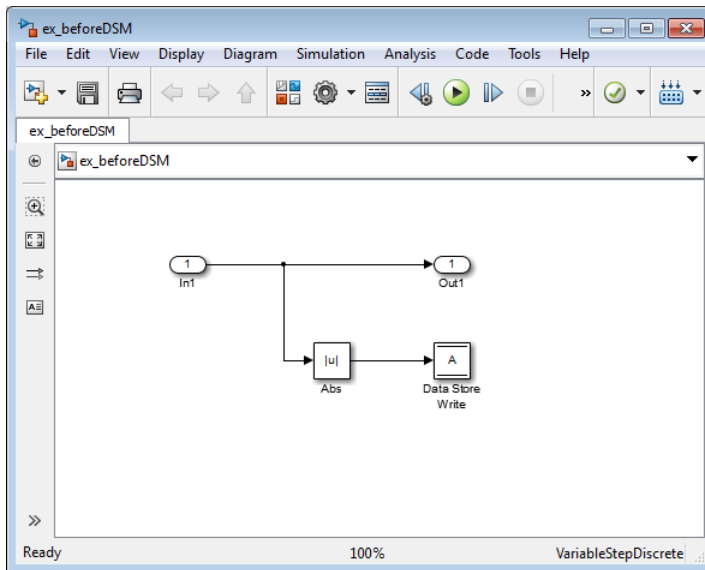

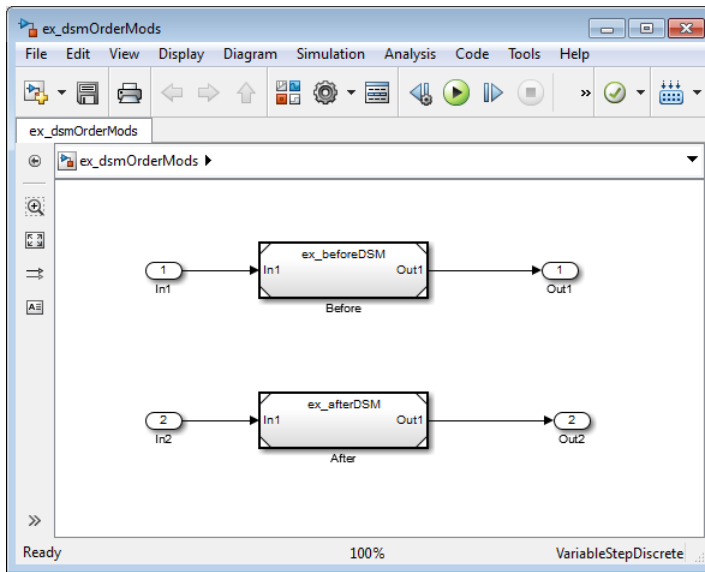

The subsystem **Before** contains the Data Store Write, and the Stateflow chart calls that subsystem before it calls the subsystem **After**, which contains the Data Store Read.

Ordering Access Using Block Priorities

You can embed data store reads and writes inside atomic subsystems or Model blocks whose priorities specify their relative execution order.

The Model block `beforeDSM` has a lower priority than `afterDSM`, so it is guaranteed to execute first. Since `beforeDSM` is atomic, all of its operations, including the Data Store Write, will execute prior to `afterDSM` and all of its operations, including the Data Store Read.

To assign priorities to blocks, see “Assign Block Priorities” on page 33-40.

Data Stores with Buses and Arrays of Buses

Benefits of using data stores with buses and arrays of buses include:

- Simplifying the model layout by associating multiple signals with a single data store
- Producing generated code that represents the data in the store data as structures that reflect the bus hierarchy
- Writing to and reading from data stores without creating data copies, which results in more efficient data access

You cannot use a bus or array of buses that contains:

- Variable-dimension signals

- Frame-based signals

Setting Up a Model to Use Data Stores with Buses and Arrays of Buses

This procedure applies to local and global data stores, and to data stores defined with a Data Store Memory block or a Simulink.Signal object. Before performing the procedure, you must understand how to use data stores in a model, as described in “Create and Apply Data Stores” on page 60-15.

To use buses and arrays of buses with data stores:

- 1 Use the Bus Editor to define a bus object whose properties match the bus data that you want to write to and read from a data store. For details, see “Create Bus Objects with the Bus Editor” on page 63-44.
- 2 Add a data store (using a Data Store Memory block or a Simulink.Signal object) for storing the bus data.
- 3 Specify the bus object as the data type of the data store. For details, see “Specify a Bus Object Data Type” on page 57-50.
- 4 In the **Model Configuration Parameters > Diagnostics > Connectivity** pane, set the **Mux blocks used to create bus** diagnostic to **error**. For details, see “Prevent Bus and Mux Mixtures” on page 63-128.
- 5 If you use a MATLAB structure for the initial value of the data store, then set **Configuration Parameters > All Parameters > Underspecified initialization detection** to **Simplified**. For details, see “Specify Initial Conditions for Bus Signals” on page 63-80 and “Underspecified initialization detection”.
- 6 (Optional) Select individual bus elements to write to or read from a data store. For details, see “Accessing Specific Bus and Matrix Elements” on page 60-31.

Accessing Specific Bus and Matrix Elements

Selecting Specific Bus or Matrix Elements

By default, a model writes and reads all bus and matrix elements to and from a data store.

To select specific bus or matrix elements to write to or read from a data store, use the **Element Assignment** pane of the Data Store Write block and the **Element Selection** pane of the Data Store Read block. Selecting specific bus or matrix elements offers the following benefits:

- Reducing the number of blocks in the model. For example, you can eliminate a Data Store Read and Bus Selector block pair or a Data Store Write and Bus Assignment block pair for each specific bus element that you want to access).
- Faster simulation of models with large buses and arrays of buses.

Writing Specific Elements to a Data Store

Note: The following procedure describes how to use the Data Store Write block interface to write specific elements to a data store. You can also perform this task at the command line, using the `DataStoreElements` parameter to specify elements. For details, see “Specification using the command line” on page 60-36.

To assign specific bus or matrix elements to write to a data store:

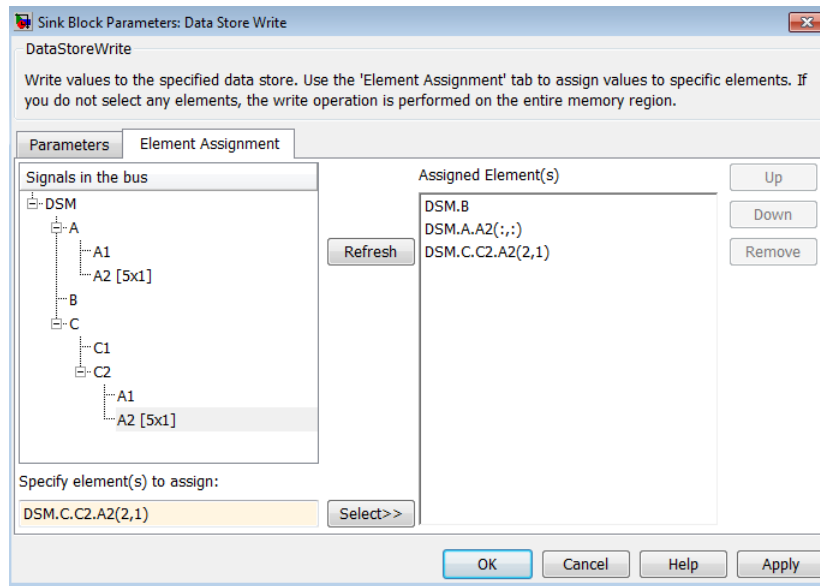

- 1 Select the Data Store Write block and in the parameters dialog box, select the **Element Assignment** pane. For example, suppose you are using a bus with a data store named DSM:

- 2 Expand all the elements in the **Signals in the bus** list.

- 3** Specify the elements that you want to write to the data store. For example:
- In the **Signals in the bus** list, click B. Then click **Select>>** to select the element B.
 - To write all the elements of A2 (in the A subbus), select A2 [5x1]. Then click **Select>>**.
 - To write the second element of A2 in the C2 subbus, select the A2 [5x1] element. In the **Specify element(s) to assign** text box, edit the text to say `DSM.C.C2.A2(2,1)`.

For more examples, see “Specifying Elements to Assign or Select” on page 60-35.

- 4 (Optional) Reorder the assigned elements, which changes the order of the ports of the Data Store Write block.
 - To reorder an assigned element, in the **Assigned element(s)** list, select the element that you want to move, and click **Up** or **Down**.
 - To remove an assigned element, click **Remove**.
- 5 To apply the assigned elements, click **OK**.

The Data Store Write block has a port for each assigned element. The names of the selected elements that correspond to each port appear in the block icon. If you assign several signals, these additions may diminish the readability of the model. To improve readability, you can expand the size of the block or create multiple Data Store Write blocks.

Reading Specific Elements from a Data Store

Reading specific elements from a data store involves very similar steps as described in “Writing Specific Elements to a Data Store” on page 60-32. The Data Store Read block differs slightly from the Data Store Write block. A Data Store Read block has:

- An **Element Selection** pane instead of an **Element Assignment** pane
- A **Selected element(s)** list instead of an **Assigned element(s)** list

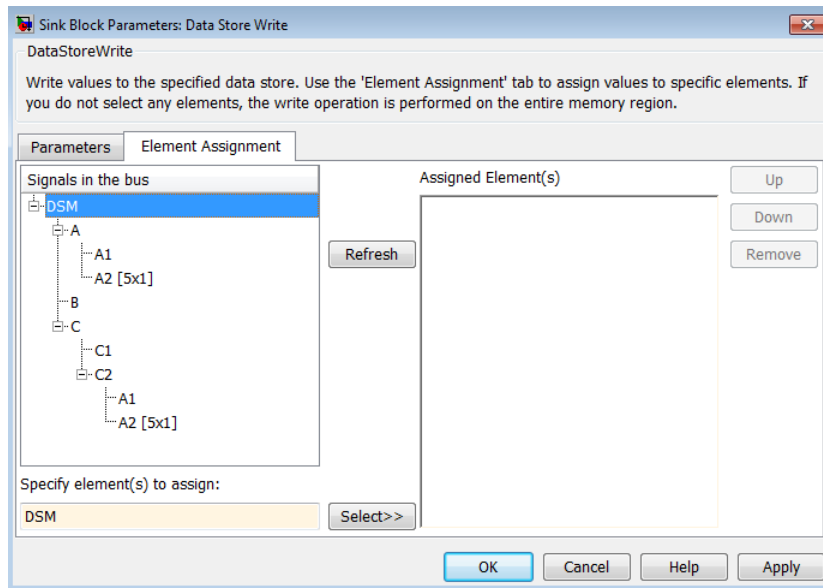

Specifying Elements to Assign or Select

Use MATLAB matrix element syntax to specify specific elements. For details about specifying matrices in MATLAB, see “Creating and Concatenating Matrices”.

Note: To select matrix elements, you cannot use dynamic indexing with the **Element Assignment** and **Element Selection** panes of Data Store Read and Bus Assignment block pairs or Data Store Write and Bus Selector block pairs. You can, however, use a MATLAB `Function` block for dynamic indexing.

Valid element specifications

The following table shows examples of valid syntax for specifying elements to assign or select. These examples use the **A2** subbus of the **A** bus, as shown in the bus hierarchy used in “Writing Specific Elements to a Data Store” on page 60-32.

Valid Syntax	Description
<code>DSM.A.A2 (:, :)</code>	Selects all elements in every dimension
<code>DSM.A.A2 ([1, 3, 5], 1)</code>	Selects the first, third, and fifth elements
<code>DSM.A.A2 (2:5, 1)</code>	Selects the second through the fifth element

Invalid element specifications

The following table shows examples of invalid syntax for specifying elements to assign or select. These examples use the A2 subbus of the A bus, as shown in the bus hierarchy used in “Writing Specific Elements to a Data Store” on page 60-32.

Invalid Syntax	Reason the Syntax Is Invalid
<code>DSM.A.A2 (:)</code>	You must specify a colon for each dimension. For the bus hierarchy used in these examples, you must use two colons.
<code>DSM.A.A2 (2:end, 1)</code>	You cannot use the <code>end</code> operator.
<code>DSM.A.A2 (idx, 1)</code>	You cannot use variables to specify indices. Consider using a <code>MATLAB Function</code> block.
<code>DSM.A.A2 (-1, 1)</code>	The dimension <code>-1</code> is not within the valid dimension bounds.

Specification using the command line

To set the elements to write to or read from, use the `DataStoreElements` parameter. Use a pound sign (`#`) to delimit multiple elements. For example, select the Data Store Write or Data Store Read block for which you want to specify elements and enter a command such as:

```
set_param(gcb, 'DataStoreElements', 'DSM.A#DSM.B#DSM.C(3,4)')
```

This specification results in the block now having three ports corresponding to the elements that you specified.

Rename Data Stores

- “Rename Data Store Defined by Block” on page 60-37
- “Rename Data Store Defined by Signal Object” on page 60-37

Rename Data Store Defined by Block

Rename a data store everywhere it is used by Data Store Read and Data Store Write blocks in a model.

- 1 In a Data Store Memory block dialog box, type a new name in the **Data store name** box, and click **Rename All**.
- 2 In the **Rename All** dialog box, confirm the new data store name in the **New name** field, and click **OK**

Note: You cannot use **Rename All** to rename a data store if you create a `Simulink.Signal` object in a workspace to control the code generated for the data store. Instead, you must rename the corresponding `Simulink.Signal` object using Model Explorer. For an example, see “Rename Data Store Defined by Signal Object” on page 60-37.

Rename Data Store Defined by Signal Object

This example shows how to rename a data store defined by a `Simulink.Signal` object. You can use Model Explorer to rename the object everywhere it is used by Data Store Read and Data Store Write blocks in a model or in a model reference hierarchy.

- 1 Open the model `sldemo_mdhref_dsm`. The model creates a `Simulink.Signal` object `ErrorCond` in the MATLAB base workspace and uses the object as a global data store in a model reference hierarchy.
- 2 Open Model Explorer.
- 3 In the **Model Hierarchy** pane, select the base workspace.
- 4 In the **Contents** pane, right-click the data store `ErrorCond` and select **Rename All**.
- 5 In the **Select a system** dialog box, click the name of the model `sldemo_mdhref_dsm` to select it as the context for renaming the data store `ErrorCond`.
- 6 Select **Search in referenced models** since `ErrorCond` is a global data store that is used in a referenced model. Click **OK**.

The **Update diagram to include recent changes** check box is cleared by default to save time by avoiding unnecessary model diagram updates. Select the check box to incorporate recent changes you made to the model by forcing a diagram update.

- 7 Click **OK** in response to the message to update the model diagram.

Since you just opened the model, you must update the model diagram at least once before renaming a variable such as `ErrorCond`. You could have selected **Update diagram to include recent changes** in the **Select a system** dialog box to force an initial diagram update, though you typically use that option when you make changes to the model while performing multiple variable renaming operations.

- 8 In the **Rename All** dialog box, type the new name for the data store in the **New name** box and click **OK**.

Customized Data Store Access Functions in Generated Code

Embedded Coder provides a custom storage class that you can use to specify customized data store access functions in generated code. See “Control Data Representation by Applying Custom Storage Classes” and “Access Data Through Functions with Custom Storage Class GetSet”.

Log Data Stores

In this section...

“Logging Local and Global Data Store Values” on page 60-39

“Supported Data Types, Dimensions, and Complexity for Logging Data Stores” on page 60-39

“Data Store Logging Limitations” on page 60-40

“Logging Data Stores Created with a Data Store Memory Block” on page 60-40

“Logging Icon for the Data Store Memory Block” on page 60-40

“Logging Data Stores Created with a Simulink.Signal Object” on page 60-41

“Accessing Data Store Logging Data” on page 60-41

Logging Local and Global Data Store Values

You can log the values of a local or global data store data variable for all the steps in a simulation. Two common uses of data store logging are for:

- Model debugging – view the order of all data store writes
- Confirming a model modification – use the logged data to establish a baseline for comparing results for identifying the impact of a model modification

For an example of logging a global data store, see “Using Data Stores Across Multiple Models”.

Supported Data Types, Dimensions, and Complexity for Logging Data Stores

You can log data stores that use the following data types:

- All built-in data types
- Enumerated data types
- Fixed-point data types

You can log data stores that use any dimension level or complexity.

Data Store Logging Limitations

Limitations for using data store logging in a model are:

- To log data for a data store memory:
 - Simulate the top-level model in Normal mode.
 - For local data stores, the model containing the Data Store Memory block must be in Model Reference Normal mode.
 - Any block in a referenced model that writes to the data store memory must be executed in model reference Normal mode.
- In the Solver pane of the Configuration Parameters dialog box, if **Treat each discrete rate as a separate task** is selected, you cannot log Data Store Memory blocks that use asynchronous sample times or hybrid sample times (that is, sample times resulting from when different data sources for the data store have different sample times).

For details about viewing information about sample times, see “View Sample Time Information” on page 7-9.

- You cannot log data stores that use custom data types.

Logging Data Stores Created with a Data Store Memory Block

To log a local data store that you create with a Data Store Memory block:

- 1 In the Block Parameters dialog box for the Data Store Memory block that you want to log, select the **Logging** pane.
- 2 Select the **Log signal data** check box.
- 3 Optionally, specify limits for the amount of data logged, using the **Minimum** and **Maximum** parameters.
- 4 Enable data store logging with the **Model Configuration Parameters > Data Import/Export > Data stores** parameter.
- 5 Simulate the model.

Logging Icon for the Data Store Memory Block

When you enable logging for a model, and you configure a local data store for logging, the Data Store Memory block displays a blue icon. If you do not enable logging for the model, then the icon is gray.

Logging Data Stores Created with a Simulink.Signal Object

You can create local and global data stores using a `Simulink.Signal` object. See “Data Stores with Signal Objects” on page 60-20 for details.

To log a data store that you create with a `Simulink.Signal` object:

- 1 Create a `Simulink.Signal` object in a workspace that is visible to every component that needs to access the data store, as described in “Data Stores with Signal Objects” on page 60-20.
- 2 Use the name of the `Simulink.Signal` object in the **Data store name** block parameters of the Data Store Read and Data Store Write blocks that you want to write to and read from the data store.
- 3 From the MATLAB command line, set `DataLogging` (which is a property of the `LoggingInfo` property of `Simulink.Signal`) to 1.

For example, if you use a `Simulink.Signal` object called `DataStoreSignalObject` to create a data store, use the following command:

```
DataStoreSignalObject.LoggingInfo.DataLogging = 1
```

- 4 Optionally, specify limits for the amount of data logged, using the following properties, which are properties of the `LoggingInfo` property of the `Simulink.Signal` object: `Decimation`, `LimitDataPoints`, and `MaxPoints`.
- 5 Enable data store logging with the **Model Configuration Parameters > Data Import/Export > Data stores** parameter.
- 6 Simulate the model.

Accessing Data Store Logging Data

The following Simulink classes represent data from data store logging and provide methods for accessing that data:

Class	Description
<code>Simulink.SimulationData.BlockPath</code>	Represents a fully specified Simulink block path; use for capturing the full model reference hierarchy
<code>Simulink.SimulationData.Dataset</code>	Stores logged data elements and provides searching capabilities; use to group <code>Simulink.SimulationData.Element</code> objects in a single object
<code>Simulink.SimulationData.DataStoreMemory</code>	Stores logging information from a data store during simulation

You can also convert data logged in formats other than Dataset. For more information, see “Dataset Conversion for Logged Data” on page 59-20.

Viewing Data Store Data

To view data store logging data from the command line, view the output data set in the base workspace. The default variable for the data store logging data set is `dsmout`.

The `sldemo_mdref_dsm` model illustrates approaches for viewing data store logging data.

Accessing Elements in the Data Store Logging Data

To find an element in the data store logging data, based on the `Name` or `BlockType` property, use the `getElement` method of `Simulink.SimulationData.Dataset`. For example:

```
dsmout.getElement('RefSignalVal')

ans =
Simulink.SimulationData.DataStoreMemory
Package: Simulink.SimulationData

Properties:
    Name: 'RefSignalVal'
    Blockpath: [1x1 Simulink.SimulationData.BlockPath]
    Scope: 'local'
    DSMWriterBlockPaths: [1x2 Simulink1.SimulationData.BlockPath]
    DSMWriters: [101x1 uint32]
    Values: 101x1 timeseries]
```

To access an element by index, use the `Simulink.SimulationData.Dataset.getElement` method.

What Is a Data Dictionary?

A data dictionary is a persistent repository of data that are relevant to your model. You can also use the base workspace to store design data that are used by your model during simulation. However, a data dictionary provides more capabilities.

The dictionary stores design data, which define parameters and signals, and include data that define the behavior of the model. The dictionary does not store simulation data, which are inputs or outputs of model simulation.

In this section...

“Dictionary Capabilities” on page 61-2

“Sections of a Dictionary” on page 61-3

“Manage and Edit Entries in a Dictionary” on page 61-4

“Dictionary Referencing” on page 61-4

“Import and Export File Formats” on page 61-4

Dictionary Capabilities

Dictionary Capability	Benefit
Dictionary as data source	All entries in a dictionary are persistent. You do not need to reload data during development.
Explicit data-model linkage	You can define a data dictionary as the data source for a model. During model simulation and code generation, the model retrieves design data from the data dictionary.
Change tracking	When you modify an entry, its status is updated in the dictionary and stored as metadata that can be tracked. The dictionary also tracks who made the changes and when. You can also view or revert changes.
Entry comparison	Compare values of entries in two dictionaries.
Data grouping into reference dictionaries	Partition and organize data items into reference dictionaries.
Model-data dependency	Discover how entries are used in the model.

Dictionary Capability	Benefit
Store and partition reference data	Store and partition data that are relevant to a model, such as equipment specifications, but not used by the model during simulation.
Unified interface for defining data	Use the Model Explorer to work with design data in a dictionary.
Incremental update in memory	Improved performance and scalability with minimal footprint on memory.
Requirements traceability linking	Navigate from a data dictionary entry to a location in a requirements document.

Sections of a Dictionary

A Simulink data dictionary is made up of three parts called sections.

- 1 **Design Data:** Contains the variables and data types that define parameters, signals, and design data that determine the behavior of the model. Design data created or imported in a dictionary are stored in this section.

This section can store only certain classes and data types. See “Valid Design Data Classes” on page 61-11 for more information.

- 2 **Configurations:** Contains configuration sets, which are objects of the `Simulink.ConfigSet` class, that determine how the model is configured during simulation. These objects control attributes such as sample time and simulation start time.

When you store configuration sets in a data dictionary, you use configuration references to access the configuration sets. Models that are linked to a dictionary resolve configuration references to configuration sets in the dictionary. For more information about configuration references, see “About Configuration References” on page 13-28.

This section can also store variant configuration objects, which belong to the `Simulink.VariantConfigurationData` class. These objects store information about variant configurations, active and default variant settings, and definitions of the control variable associated with each configuration.

- 3 **Other Data:** Contains information that is relevant to your model but not used by the model during simulation. Use this section to store reference information such as

data that describe physical equipment and processes that are represented by your model.

This section can store almost any built-in or custom class or data type. See “Invalid Other Data Classes” on page 61-12 for more information.

Manage and Edit Entries in a Dictionary

To create, modify, and view the entries in a data dictionary, use the Model Explorer. For more information, see “Edit and Manage Workspace Variables Used by Models” on page 57-88 and “View and Revert Changes to Dictionary Data” on page 61-27.

To manage entries in a dictionary programmatically, see “Store Data in Dictionary Programmatically” on page 61-52.

Dictionary Referencing

You can reference one or more dictionaries in a parent dictionary. The data in the referenced dictionaries are visible in the parent dictionary. Use this technique to meaningfully partition data, especially for model reference hierarchies. For more information, see “Partition Dictionary Data Using Referenced Dictionaries” on page 61-34 and “Partition Data for Model Reference Hierarchy Using Data Dictionaries” on page 61-37.

Import and Export File Formats

File Format	Import to Dictionary	Export from Dictionary
MAT-file	✓	✓
MATLAB script	✓	✓

Migrate Models to Use Simulink Data Dictionary

A Simulink data dictionary permanently stores model data including MATLAB variables, data objects, and data types. For basic information about data dictionaries, see “What Is a Data Dictionary?” on page 61-2.

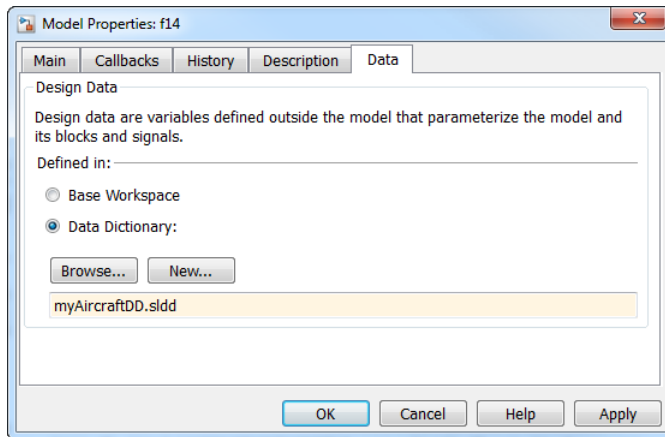

In this section...
“Migrate Single Model to Use Dictionary” on page 61-6
“Migrate Model Reference Hierarchy to Use Dictionary” on page 61-8
“Considerations before Migrating to Data Dictionary” on page 61-9

Migrate Single Model to Use Dictionary

This example shows how to link a single standalone model to a single data dictionary.

Note: Simulink does not import simulation data such as Timeseries objects into the data dictionary.

- 1 Open the `f14` model, which loads design data into the base workspace.
- 2 Save a copy of the model to your current folder. Open the copy.
- 3 In the Simulink Editor, click **File > Model Properties > Link to Data Dictionary**.
- 4 In the **Model Properties** dialog box, set **Defined in** to **Data Dictionary** and click **New** to create a data dictionary.

- 5 Name the data dictionary, save it, and click **Apply**.
- 6 Click **Add path**, if you see the message to add the dictionary location to the MATLAB path.
- 7 Click **Yes** in response to the message that explains how Simulink migrates design data stored in the base workspace.

- 8 Click **Yes** in response to the message about removing imported items from the base workspace.
- 9 Click **OK** in the **Model Properties** dialog box.

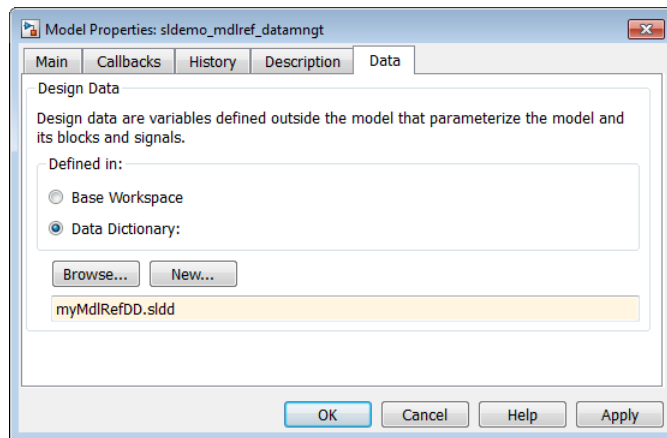

A notification appears in the Simulink Editor, reporting that your model is now linked to the data dictionary.

- 10 In the Simulink Editor, click the data dictionary badge  in the bottom left corner to open the dictionary.

Migrate Model Reference Hierarchy to Use Dictionary

This example shows how to link a parent model and all its referenced models to a single data dictionary.

- 1 Open the example model `sldemo_mdhref_datamngt`, which references the model `sldemo_mdhref_counter_datamngt`.
- 2 Save copies of the models to your current folder.
- 3 Open the top model, `sldemo_mdhref_datamngt`.
- 4 In the Simulink Editor, click **File > Model Properties > Link to Data Dictionary**.
- 5 In the **Model Properties** dialog box, set **Defined in** to **Data Dictionary** and click **New** to create a data dictionary.

- 6 Name the data dictionary, save it, and click **Apply**.
- 7 Click **Yes** in response to the message that explains how Simulink migrates design data stored in the base workspace.

- 8 Click **Yes** in response to the message about removing the imported items from the base workspace.
- 9 Click **OK** in response to the message about migrating enumerated types.

Considerations before Migrating to Data Dictionary

- “Check for Data-Loading Callbacks” on page 61-9
- “Check Scripts” on page 61-10
- “Check Tunable Parameters for Code Generation” on page 61-10
- “Data Shared by Model References” on page 61-11
- “Valid Design Data Classes” on page 61-11
- “Invalid Other Data Classes” on page 61-12
- “Data Dictionary Limitations” on page 61-12

Check for Data-Loading Callbacks

You can use model callbacks such as the `PreLoadFcn` callback to load design data from a file into the base workspace when a model is loaded. For example, the following callback loads design data from the MAT file `myData.mat`.

```
load myData
```

After you migrate to a data dictionary, these callbacks will continue to load design data into the base workspace. Since the model then derives design data from the dictionary, manually remove or comment out these data-loading callbacks.

You can use the Simulink Manifest Tools to find data-loading callbacks. See “Analyze Model Dependencies” on page 18-25.

Check Scripts

If you make explicit references to the base workspace by using the handle `base` in your scripts, consider changing these references. When you move any of your data to a data dictionary, the model no longer looks into the base workspace to find design data.

After you migrate design data to a data dictionary, explicit references to the base workspace cannot resolve and errors can occur.

Consider this example. Here, the script searches the base workspace for variable `sensor` and sets the parameter `enable` depending on the value of `sensor.noiseEnable`.

```
if evalin('base','sensor.noiseEnable')
    enable = 'Enabled';
else
    enable = 'Disabled';
end
```

When you migrate to a data dictionary, replace these explicit references to `base` as follows:

```
if Simulink.data.evalinGlobal(myExampleModel,...
'sensor.noiseEnable')
    enable = 'Enabled';
else
    enable = 'Disabled';
end
```

The `Simulink.data.evalinGlobal` function evaluates an expression in the global scope of the specified model. Here, the global scope can be in a data dictionary or the base workspace, if the model is not linked to a dictionary.

Check Tunable Parameters for Code Generation

- If your model is linked to a data dictionary, Simulink ignores storage class information specified in the Model Parameter Configuration dialog box.
- If you use the Simulink interface to migrate a model to use a data dictionary, Simulink also migrates the storage class information of the model. If your model contains storage class information for variables in the base workspace, Simulink converts these variables into `Simulink.Parameter` objects during migration. Then, Simulink sets the storage class of these `Simulink.Parameter` objects using the storage class information from the model.
- If you migrate this model back to the base workspace, Simulink does not restore the storage class information in the model. To preserve the storage class for these

variables, use the parameter objects from the data dictionary. You can also manually reset the storage class information in the model.

- If you set the `DataDictionary` property of a model from the command line, convert tunable variables to `Simulink.Parameter` objects using the `tunablevars2parameterobjects` function.

Data Shared by Model References

When you use model referencing to break a large system of models into smaller components and subcomponents, you can create data dictionaries to segregate the *design data*. Design data is the set of workspace variables that the models use to specify block parameters and signal characteristics.

The models in a model reference hierarchy typically share data. Data ownership, the number of shared variables, and the complexity of your sharing strategy can influence the way that you use dictionaries. For more information, see “Determine Where to Store Variables and Objects for Simulink Models” on page 57-81.

Valid Design Data Classes

You can import, store, or create MATLAB variables that use Simulink supported data types, such as `boolean` and `int32`, and structures in the **Design Data** section of a Simulink data dictionary. You can also use objects of these classes and objects of most classes that subclass these classes:

- `Simulink.AliasType`
- `Simulink.Bus`
- `Simulink.NumericType`
- `Simulink.Parameter`
- `Simulink.LookupTable`
- `Simulink.Breakpoint`
- `Simulink.Signal`
- `Simulink.Variant`
- `Simulink.data.dictionary.EnumTypeDefinition`
- `embedded.fi`
- `embedded.fimath`
- `numlti`

In addition, you can import, store, or create configuration objects of the following classes in the **Configurations** section of a Simulink data dictionary.

- `Simulink.ConfigSet`
- `Simulink.VariantConfigurationData`

Invalid Other Data Classes

You can import, store, or create data objects of many built-in and custom classes or data types in the **Other Data** section of a Simulink data dictionary, except for the following:

- Arrays of objects created from built-in or custom classes
- Custom classes that have a property with any of these names:
 - `LastModified`
 - `LastModifiedBy`
 - `DataSource`
 - `Status`
 - `Variant`

Data Dictionary Limitations

- Simulink cannot automatically migrate variables used only by inactive variant models into a data dictionary.
- You cannot import certain kinds of design data such as `meta` class objects and `timeseries` objects into the Design Data section of a data dictionary.
- Simulink does not allow implicit signal resolution for a model linked to a data dictionary. To use a data dictionary, set the model configuration parameter **Signal resolution** to `Explicit only` or `None`.
- The data dictionary does not support models that contain From Workspace blocks. Further, Simulink does not import simulation data such as `timeseries` objects into the Design Data section of a data dictionary. You can migrate such models in one of the following ways.
 - Before migration, replace From Workspace blocks in your model with other source blocks or a combination of source blocks.
 - Migrate the model without replacing From Workspace blocks. After migration, replace the From Workspace blocks.

- If a model reference hierarchy is already linked to a data dictionary, you can protect a referenced model that is part of the hierarchy. However, if you migrate a model reference hierarchy that includes a protected model, simulation will fail.

In other words, migrate a model to use a data dictionary before protecting it.

Enumerations in Data Dictionary

A Simulink data dictionary permanently stores model data including MATLAB variables, data objects, and data types including enumerated types. For basic information about data dictionaries, see “What Is a Data Dictionary?” on page 61-2.

In this section...

“Migrate Enumerated Types into Data Dictionary” on page 61-14

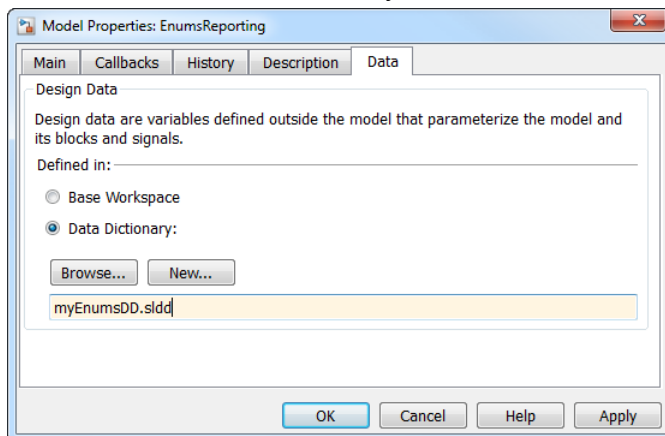

“Manipulate Enumerations in Data Dictionary” on page 61-18

Migrate Enumerated Types into Data Dictionary

This example shows how to migrate enumerated types that are used by a model into a data dictionary.

Import Design Data

- 1 Open a model that uses enumerated types for design data or for blocks in the model.
- 2 In the Simulink Editor, click **File > Model Properties > Link to Data Dictionary**.
- 3 In the **Model Properties** dialog box, set **Defined in** to **Data Dictionary** and click **New** to create a data dictionary.

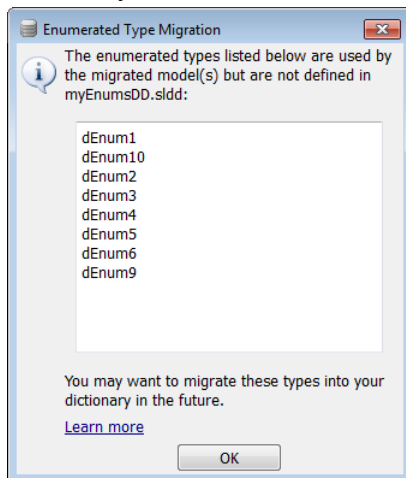

- 4 Name the data dictionary, save it, and click **Apply**.
- 5 Click **Add path**, if you see the message to add the dictionary location to the MATLAB path.

- Click **Yes** in response to the message that explains how Simulink migrates design data stored in the base workspace.

A message appears, reporting the number of items imported from the base workspace to the data dictionary.

- Simulink reports the enumerated types that were not imported into the data dictionary.

- Click **OK**.

A notification appears in the Simulink Editor, reporting that your model is now linked to the data dictionary.

Import Enumerated Types

Import the definitions of enumerated types only after you import all the design data that were creating using the types. When you import enumerated types to a data dictionary,

Simulink disables MATLAB files or P-files that contain the type definitions, causing variables that remain in the MATLAB base workspace to lose their definitions.

- 1 At the MATLAB command prompt, get the names of enumerated types that are used in model blocks.

```
% Find all variables and enumerated types used in model blocks
usedTypesVars = Simulink.findVars('EnumsReporting','IncludeEnumTypes',true);
% Here, EnumsReporting is the name of the model and
% usedTypesVars is an array of Simulink.VariableUsage objects

% Find indices of enumerated types that are defined by MATLAB files or P-files
enumTypesFile = strcmp({usedTypesVars.SourceType},'MATLAB file');

% Find indices of enumerated types that are defined using the function
% Simulink.defineIntEnumType
enumTypesDynamic = strcmp({usedTypesVars.SourceType},'dynamic class');

% In one array, represent indices of both kinds of enumerated types
enumTypesIndex = enumTypesFile | enumTypesDynamic;

% Use logical indexing to return the names of used enumerated types
enumTypeNames = {usedTypesVars(enumTypesIndex).Name}'

enumTypeNames =

    'dEnum1'
    'dEnum10'
    'dEnum2'
    'dEnum3'
    'dEnum4'
    'dEnum5'
    'dEnum6'
    'dEnum9'
```

- 2 Open the data dictionary, and represent it with a `Simulink.data.Dictionary` object.

```
ddConnection = Simulink.data.dictionary.open('myEnumsDD.sidd')

ddConnection =

    Dictionary with properties:

        DataSources: {0x1 cell}
```

```

    HasUnsavedChanges: 0
    NumberOfEntries: 3

```

3 Import the enumerated types that are used by blocks in the model.

```

[successfulMigrations, unsuccessfulMigrations] = ...
importEnumTypes(ddConnection,enumTypeNames)

```

```

successfulMigrations =

```

```

1x6 struct array with fields:

```

```

    className
    renamedFiles

```

```

unsuccessfulMigrations =

```

```

1x2 struct array with fields:

```

```

    className
    reasons

```

When enumerated types are imported, `importEnumTypes` renames the enumerated class definition file by appending `.save` to the file name. For example, if the original enumerated class definition is named `Enum1.m`, Simulink renamed the file as `Enum1.m.save`.

The structure `unsuccessfulMigrations` reports enumerated types that are not be migrated. In this example, two enumerated type instances are defined in the model workspace and can be imported after closing the model. Close the model to import these enumerated types.

4 Open the dictionary to view the migrated enumerated types.

Manipulate Enumerations in Data Dictionary

These examples show how to operate on existing enumerations in a data dictionary.

- “Rename Enumerated Type Definition” on page 61-18
- “Rename Enumeration Members” on page 61-19
- “Delete Enumeration Members” on page 61-19
- “Change Underlying Value of Enumeration Member” on page 61-19

Rename Enumerated Type Definition

- 1 In the data dictionary, create a copy of the enumerated type, and rename the copy instead.
- 2 Find enumeration objects used by your model that are derived from the type with the old name.
- 3 Replace these objects with those derived from the renamed type.
- 4 Delete the type with the old name.

Rename Enumeration Members

Use one of the following approaches.

- Select the enumeration within the dictionary, and rename one or more enumeration members.
- If your model references enumeration members, change these references to match the renamed member.

Delete Enumeration Members

- 1 Find references in your model to an enumeration member you want to delete.
- 2 Replace these references with an alternate member.
- 3 Delete the original member from the enumeration.

Change Underlying Value of Enumeration Member

You can change the values of enumeration members when you represent these values as MATLAB variables or by using **Value** field of **Simulink.Parameter** objects.

- 1 Find references in your model to an enumeration member whose value you want to change.
- 2 Make a note of these references.
- 3 Change the value of the enumeration member.
- 4 Manually update references to the enumeration member in your model.

Import and Export Dictionary Data

A Simulink data dictionary permanently stores model data including MATLAB variables, data objects, and data types. For basic information about data dictionaries, see “What Is a Data Dictionary?” on page 61-2.

In this section...
“Import Data to Dictionary from File” on page 61-20
“Export Design Data from Dictionary” on page 61-25

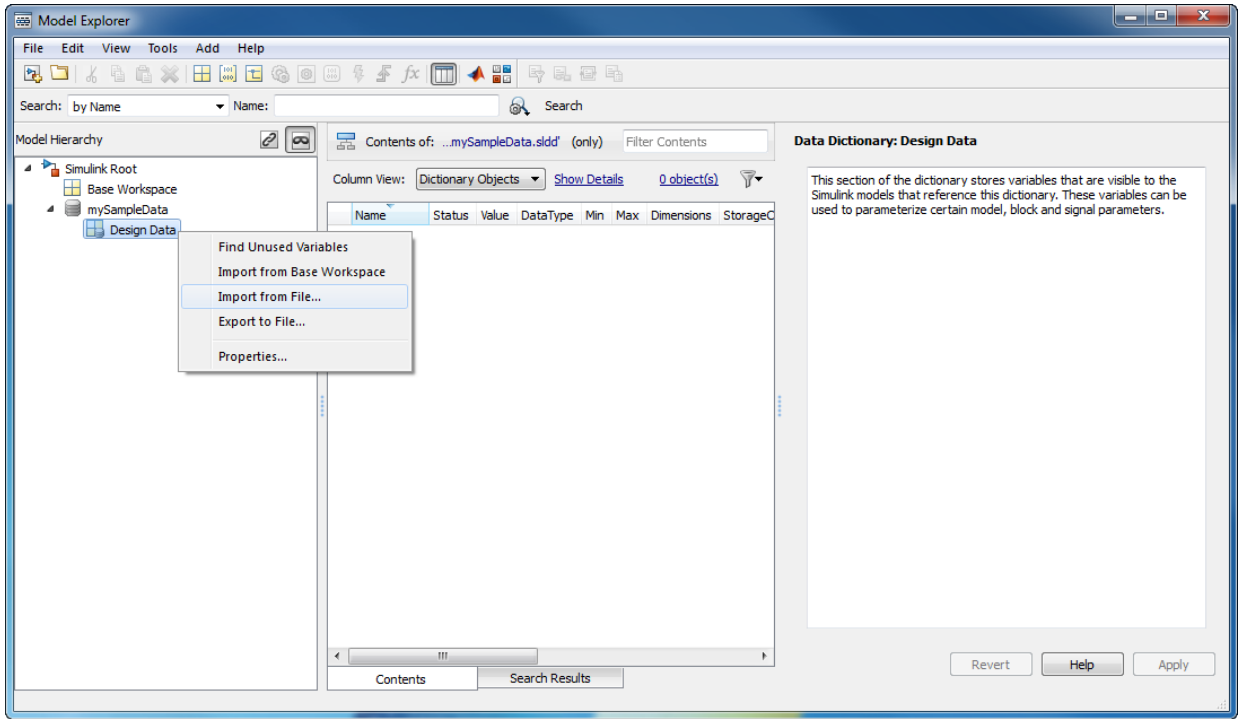

Import Data to Dictionary from File

You can import data from a MATLAB file or MAT-file to a data dictionary using the Model Explorer window. Import variables and data objects that are used by a model during simulation to the Design Data section of a dictionary. Import variables and objects that you want to store with a model, but that are not used by the model during simulation, to the Other Data section of a dictionary.

Import Design Data from File

This example shows how to import design data from a file into the Design Data section of a dictionary.

- 1 In the Simulink Editor, select **View > Model Explorer** to open the Model Explorer.
- 2 Click **File > Open**. Then browse to an existing dictionary.
- 3 In the **Model Hierarchy** pane, right-click the **Design Data** section of the dictionary and select **Import from File**. Then browse to and select the MAT-file or MATLAB file that contains the data to import.

Design data from the MAT-file populate the dictionary. Data appear with **DataSource** set to the name of the dictionary.

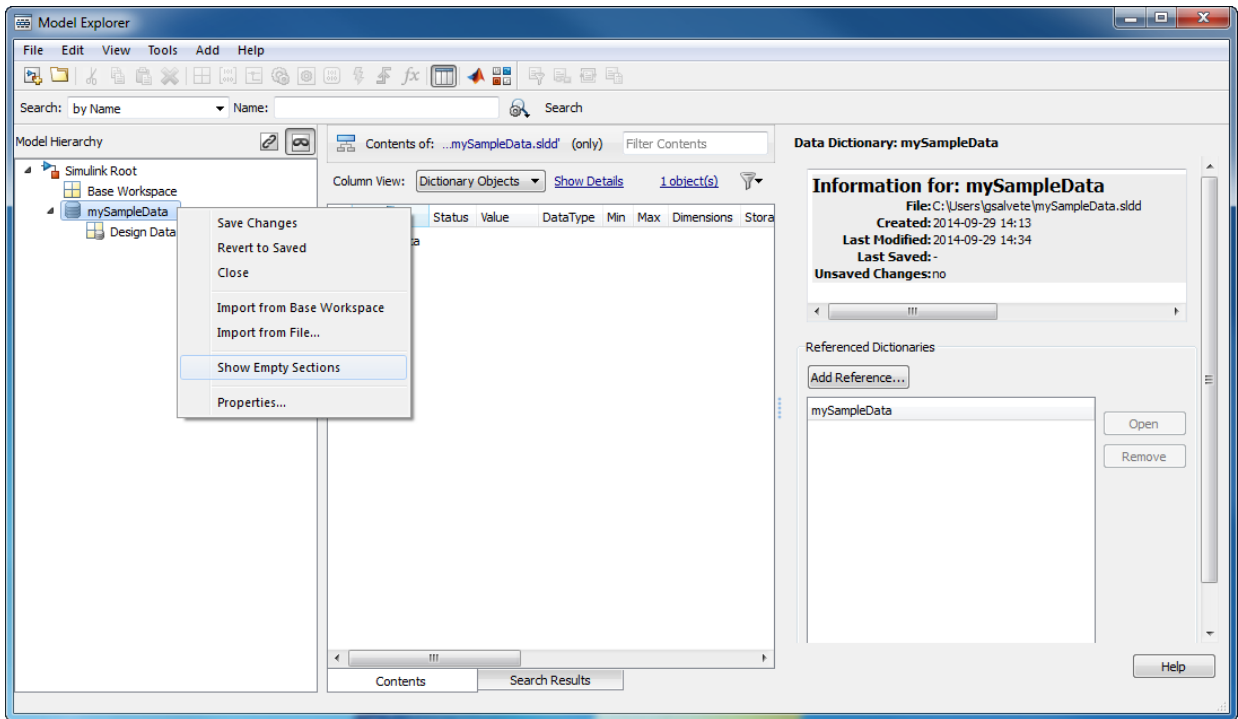

If you import from the same MAT-file again, Simulink only imports changed or new entries into the dictionary.

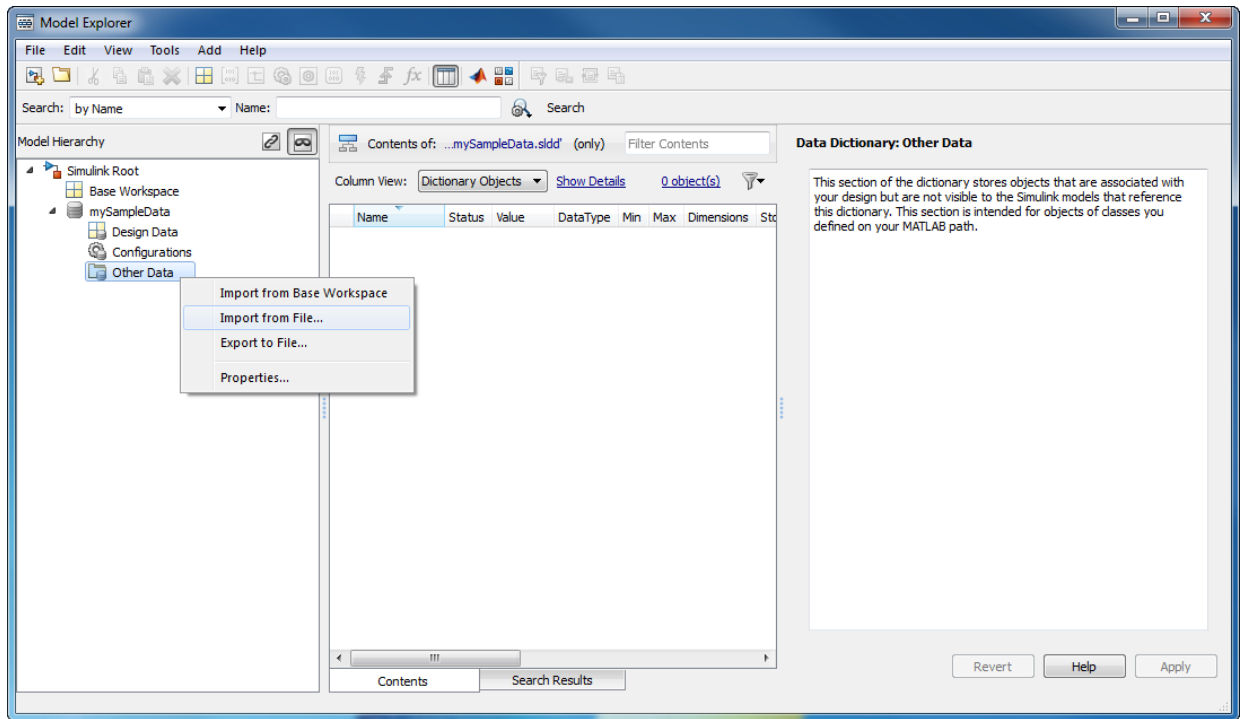

Import Other Data from File

This example shows how to import data from a file into the Other Data section of a data dictionary. Use this section to store reference information that is not used by Simulink during simulation, such as data that describe physical equipment and processes that are represented by your model.

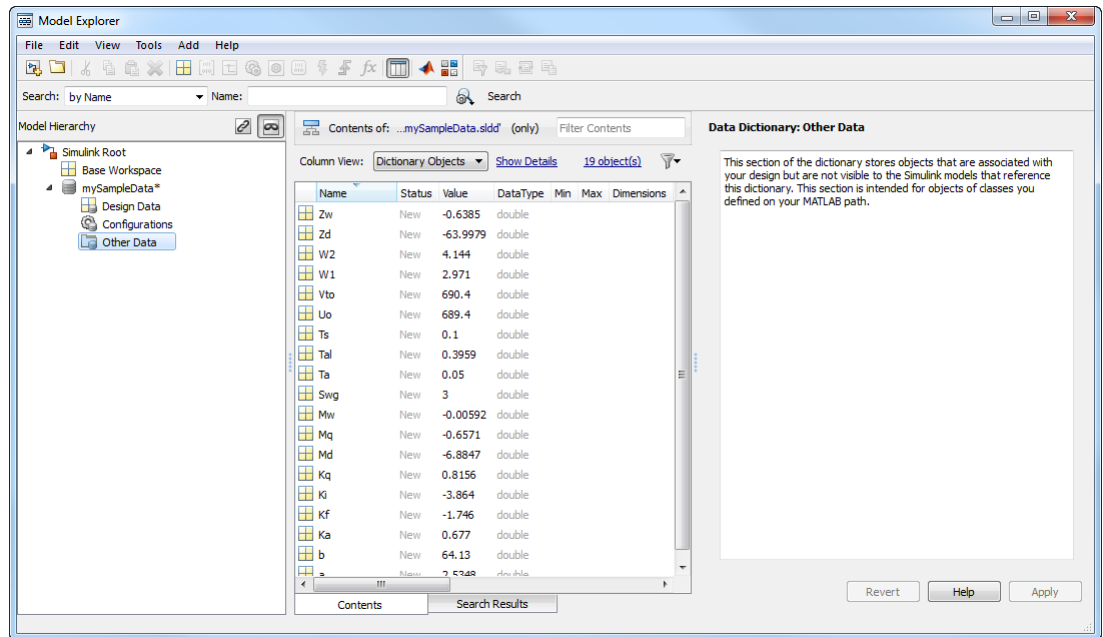

- 1 In the Simulink Editor, select **View > Model Explorer** to open the Model Explorer.
- 2 Click **File > Open**. Then browse to an existing dictionary.
- 3 In the **Model Hierarchy** pane, right-click the dictionary node and select **Show Empty Sections**. Model Explorer reveals the **Other Data** and **Configurations** sections of the dictionary, even if they are empty, in addition to the **Design Data** section.

- 4 In the **Model Hierarchy** pane, right-click the **Other Data** section of the dictionary and select **Import from File**. Then browse to and select the MAT-file or MATLAB file that contains the reference data to import.

Data from the MAT-file populate the Other Data section of the dictionary. Data appear with **DataSource** set to the name of the dictionary.

If you import from the same MAT-file again, Simulink only imports changed or new entries into the dictionary.

Export Design Data from Dictionary

This example shows how to export model design data from a data dictionary into a MAT-file or MATLAB script.

- 1 In the Simulink Editor, select **View > Model Explorer** to open the Model Explorer.
- 2 Open a data dictionary using **File > Open Data Dictionary**.
- 3 In the **Model Hierarchy** pane, expand the dictionary node and select **Design Data > Export to File**. Then save the design data to a MAT-file or MATLAB script.

“View and Revert Changes to Dictionary Entries” on page 61-27

“View and Revert Changes to Entire Dictionary” on page 61-31

View and Revert Changes to Dictionary Entries

This example shows how to view unsaved changes to dictionary entries, who made them, and when. You can view changes to entries in any section, including data stored in the Other Data section and configuration sets stored in the Configurations section.

- 1 Open the `sldemo_fuelsys_dd_controller` model.
- 2 Open the data dictionary linked to this model by clicking the data dictionary badge  in the bottom left corner of each model.

- 3 In the **Contents** pane, change `st_range` to `0.0002` and `zero_thresh` to `200`.

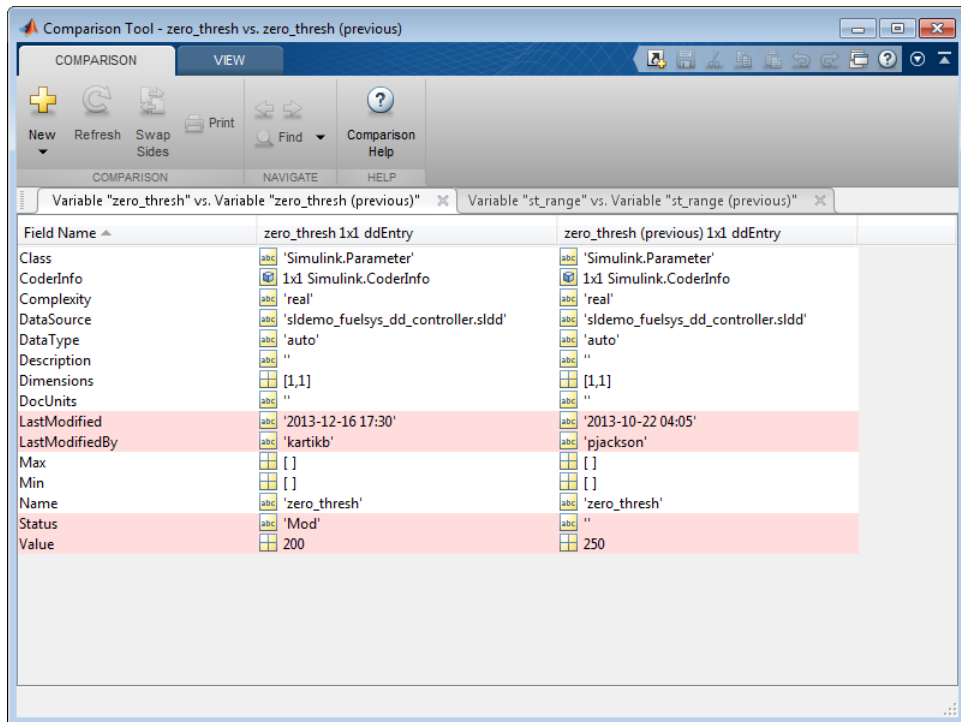

The **Status** column of these entries changes to **Mod**, indicating that they have been modified.

- 4 Click the heading of the **Status** column to sort the entries. Then, select the modified entries, which are indicated by the **Mod** status.

5 Right-click and select **Show Changes**.

The Comparison Tool appears, displaying changed entries in separate tabs. The tool highlights changed values.

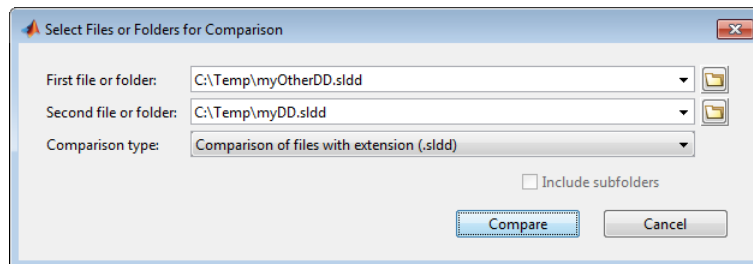

- 6 In the **Contents** pane of the Model Explorer, right-click `zero_thresh` and select **Revert to Saved**.

Simulink reverts `zero_thresh` to its value at the time of the last save action.

- 7 You can merge entries between dictionaries using the Comparison Tool. From the MATLAB desktop, on the **Home** tab, in the **File** section, click **Compare**.
- 8 Select the dictionaries to compare and merge.

- 9 In the comparison report, select the merge direction for each dictionary entry.

View and Revert Changes to Entire Dictionary

If you store model variables in a data dictionary, you can view and manage the changes that you make while you work. You can use the Comparison Tool to see the changes made to a dictionary, which compares the modified dictionary with the most recent saved version.

When you view the changes to a dictionary, you can choose to discard changes to individual entries or dictionary references, which reverts to the last saved state. You can use this technique to recover entries that you delete in your modified version or dictionary references that you remove.

If you view changes to a dictionary that references other dictionaries, the Comparison Tool also reports changes made to the entries in the referenced dictionaries.

- 1 View the example data dictionary `sldemo_fuelsys_dd` in Model Explorer.

```
dictionary = Simulink.data.dictionary.open('sldemo_fuelsys_dd.sldd');
show(dictionary)
```

The dictionary contains entries that are defined in several referenced dictionaries, including `sldemo_fuelsys_dd_controller` and `sldemo_fuelsys_dd_plant`.

- 2 Run the script `ex_dictionary_changes`, which makes changes to `sldemo_fuelsys_dd`. Later, you can use the Comparison Tool to investigate the changes.
- 3 In the **Model Hierarchy** pane of Model Explorer, right-click the node `sldemo_fuelsys_dd` and select **Show Changes**.

The Comparison Tool displays the changes made to the dictionary.

sldemo_fuelsys_dd.sldd

Show Changes in Dictionary - sldemo_fuelsys_dd.sldd

Click on a column header to sort the table

Saved Entries				Unsaved Changes				Change Summary	Last Modified	Action (no undo)

PressVect	Design Data	sldemo_fuelsys_dd_controller.sldd	Simulink Parameter					deleted	2013-10-22 04:05	Recover from Saved
min_throt	Design Data	sldemo_fuelsys_dd_controller.sldd	Simulink Parameter	min_throt	Design Data	sldemo_fuelsys_dd_controller.sldd	Simulink Parameter	modified (compare)	2015-03-11 09:05	Revert to Saved

Dictionary references in sldemo_fuelsys_dd.sldd			
Saved References		Unsaved Changes	
Name	Name	Change Summary	Action (no undo)
sldemo_fuelsys_dd_plant.sldd		removed	Recover Reference

- 4 In the table at the top of the report, click **compare** in the Change Summary column of the row that corresponds to the entry `min_throt`.

A new tab shows the changes made to `min_throt`. The script changed the parameter data type from `auto` to `int8` and the parameter value from `3` to `4`.

- 5 Click the tab that shows the changes made to the dictionary. In the Action column of the row that corresponds to the entry `min_throt`, click **Revert to Saved**.

The entry reverts to the definition from the last saved version of the dictionary.

- 6 The remaining row in the report shows that the script deleted the entry `PressVect`, which was defined in the referenced dictionary `sldemo_fuelsys_dd_controller`. Click **Recover from Saved**, which recovers the entry in the referenced dictionary.

- 7 The table **Dictionary references in sldemo_fuelsys_dd.sldd** shows that the script removed the reference to the dictionary `sldemo_fuelsys_dd_plant`. In the Action column, click **Recover Reference**.

The report shows that there are no more unsaved changes to `sldemo_fuelsys_dd`.

Partition Dictionary Data Using Referenced Dictionaries

This example shows how to partition a data dictionary into reference dictionaries that can be shared in a team. A Simulink data dictionary permanently stores model data including MATLAB variables, data objects, and data types.

Open dictionary for partitioning

- 1 Open the Model Explorer. In the Simulink Editor, select **View > Model Explorer**.
- 2 Click **File > Open**.

Browse and locate your dictionary.

Create reference dictionary

Use a reference dictionary to store a subset of entries from the main dictionary.

- 1 Click **File > New > Data Dictionary**.

Name the reference dictionary and save it.

Both dictionaries appear as nodes in the **Model Hierarchy** pane.

- 2 In the **Model Hierarchy** pane, select the dictionary that serves as the parent.
- 3 In the dialog box pane, in the **Referenced Dictionaries** section, click **Add Reference**. Browse to the location of the reference dictionary and add it as a reference.

Move entries into reference dictionary

- 1 In the **Model Hierarchy** pane, select the **Design Data** node of the parent dictionary.
- 2 In the **Contents** pane, select the entries you want to move to the reference dictionary.
- 3 For one of the selected entries, set **DataSource** to the reference dictionary using the dropdown menu. You can also drag and drop entries between dictionaries.

To make the **DataSource** column visible, click **Show Details** in the **Contents** pane. In the text box, enter **DataSource**, and add **DataSource** to the list of displayed columns.

Organize display of entries

- 1 Click the name of the **DataSource** column to sort the entries by the dictionaries that define them.

- 2 Right-click the name of the **DataSource** column and select **Group by This Column** to group the entries. The **Contents** pane creates a group for each dictionary that defines the entries.

- “What Is a Data Dictionary?” on page 61-2

Partition Data for Model Reference Hierarchy Using Data Dictionaries

When you use model referencing to break a large system of models into smaller components and subcomponents, you can create data dictionaries to segregate the *design data*. Design data is the set of workspace variables that the models use to specify block parameters and signal characteristics. For basic information about data dictionaries, see “What Is a Data Dictionary?” on page 61-2.

You can migrate all of the models in a model reference hierarchy to use one or more data dictionaries using either of these techniques:

- Migrate all of the models in the hierarchy at once to use a single dictionary. Then, create separate referenced dictionaries to organize the design data.
- Incrementally migrate by beginning with the models at the bottom of the hierarchy. Use this technique if you cannot migrate all of the models at once.

Create a Dictionary for Each Component

This example shows how to partition design data into dictionaries. When you finish, each component and subcomponent in the system has a dictionary, and dictionary references allow the components and subcomponents to share data.

Explore Example Model Hierarchy

- 1 Navigate to the folder `matlabroot/help/toolbox/simulink/examples` (open).
- 2 Copy these files to a writable folder:
 - `ProjectData.mat`
 - `ex_SystemModel`
 - `ex_PlantComp_Lv11`
 - `ex_PlantComp_Lv12`
 - `ex_ContrComp`
 - `ex_ContrComp_Sub1_Lv11`
 - `ex_ContrComp_Sub1_Lv12`
 - `ex_ContrComp_Sub2_Lv11`

- `ex_ContrComp_Sub2_Lvl2`
- 3 Load the MAT-file `ProjectData.mat` to create design data in the base workspace.
 - 4 Open the example model `ex_SystemModel`. This model is at the top of a reference hierarchy that includes the other example models.
 - 5 Select **Analysis > Model Dependencies > Model Dependency Viewer > Models Only**. The model reference hierarchy contains a system model, a plant component with two models, and a controller component. The controller component contains two subcomponents, each of which consist of two models.

- 6 In the model, update the diagram. The signals in the model use the `Simulink.Bus` objects `SensorBus` and `CtrlBus` in the base workspace.

The referenced models `ex_PlantComp_Lvl1` and `ex_ContrComp` also use the bus objects. Therefore, the plant and controller components share the objects.

- 7 In the MATLAB base workspace, double-click the bus object `SensorBus` to view it in the Bus Editor. The data type of each signal element is set to `FloatType`, which is a `Simulink.NumericType` object in the base workspace.

All of the models in the hierarchy use `FloatType` to control the data types of signals and parameters.

- 8 In the Model Explorer **Model Hierarchy** pane, expand the node `ex_SystemModel`.

The node Reference to SimConfigSet appears. SimConfigSet is a Simulink.ConfigSet object in the base workspace. All of the models in the hierarchy use references to SimConfigSet to maintain configuration parameter uniformity for simulation.

- 9 Right-click the node Controller (ex_ContrComp) and select **Open**. In the Model Explorer **Model Hierarchy** pane, expand the new node ex_ContrComp.

The nodes Reference to SimConfigSet and Reference to CodeGenConfigSet appear. CodeGenConfigSet is a Simulink.ConfigSet object in the base workspace. All of the models in the controller component use references to CodeGenConfigSet to maintain configuration parameter uniformity for code generation. The models in the plant component do not use CodeGenConfigSet.

- 10 In the **Model Hierarchy** pane, select **Base Workspace**. In the **Contents** pane, right-click the variable diff and select **Find Where Used**. In the **Select a system** dialog box, select ex_SystemModel and click **OK**. If you see a message about updating the diagram, click **OK**.

In the **Contents** pane, the variable diff is used by Constant blocks in the models ex_ContrComp_Sub1_Lvl1 and ex_ContrComp_Sub1_Lvl2, which make up the first controller subcomponent. Similarly, other models in the hierarchy share the base workspace variables coeff, init, and mu.

The table shows the models that share each variable in the base workspace.

Variable Name	Models Using the Variable	Scope of Sharing
SimConfigSet	All models in the hierarchy	Shared globally by entire system
FloatType	All models in the hierarchy	Shared globally by entire system
CtrlBus	All models in the hierarchy	Shared globally by entire system
SensorBus	All models in the hierarchy	Shared globally by entire system
CodeGenConfigSet	All models in the controller component	Shared by controller subcomponents

Variable Name	Models Using the Variable	Scope of Sharing
init	ex_ContrComp_Sub1_Lv11 and ex_ContrComp_Sub2_Lv11	Shared by controller subcomponents
diff	ex_ContrComp_Sub1_Lv11 and ex_ContrComp_Sub1_Lv12	Shared by models in the first controller subcomponent
coeff	ex_ContrComp_Sub2_Lv11 and ex_ContrComp_Sub2_Lv12	Shared by models in the second controller subcomponent
mu	ex_PlantComp_Lv11 and ex_PlantComp_Lv12	Shared by models in plant component

Suppose that three teams of developers maintain the plant component and the two controller subcomponents. You can use data dictionaries to store and scope the shared design data.

Create System Dictionary

- 1 In the model `ex_SystemModel`, select **File > Model Properties > Link to Data Dictionary**.
- 2 In the dialog box, under **Defined in**, select **Data Dictionary**. Click **New**.
- 3 Set the new dictionary name to **System** and click **Save**.
- 4 In the **Model Properties** dialog box, click **OK**.
- 5 Click **Yes** in response to the message about migrating workspace data.
- 6 Click **Yes** in response to the message about removing imported items from the base workspace.
- 7 Save the model.

You can simulate and generate code from the models in the hierarchy. All of the models in the hierarchy are linked to the dictionary. All of the variables in the base workspace now reside in the new dictionary `System.slidd`.

Create Dictionary for Plant Component

- 1 Open the model `ex_PlantComp_Lv11`.
- 2 Select **File > Model Properties > Link to Data Dictionary**.

- 3 In the dialog box, under **Defined in**, click **New**.
- 4 Set the new dictionary name to **Plant** and click **Save**.
- 5 In the **Model Properties** dialog box, click **OK**.
- 6 In response to the message, click **Move Data**.
- 7 Click **Yes** in response to the message about migrating data.
- 8 Save the model.

The models in the plant component, `ex_PlantComp_Lv11` and `ex_PlantComp_Lv12`, are linked to the new dictionary `Plant.sldd`. The other models in the hierarchy remain linked to `System.sldd`. Because the model `ex_PlantComp_Lv11` uses globally shared variables such as `CtrlBus` and `FloatType`, the migration process moves the variables to `Plant.sldd`. However, `System.sldd` references `Plant.sldd`, so all of the models in the hierarchy can continue to use the globally shared variables.

The variable that the plant models share, `mu`, also resides in `Plant.sldd`. Other variables such as `init` and `diff` remain in `System.sldd`.

The plant component can stand alone from the rest of the system because all of its data is in `Plant.sldd`. However, the controller component depends on the shared data that is also defined in `Plant.sldd`.

Create Dictionary for Controller Component

Open the model `ex_ContrComp`, which is the top model in the controller component. Link this model to a new dictionary named `Contr.sldd`. Then, save the model.

When you finish, the five models in the controller component are linked to `Contr.sldd`. Because the globally shared variables such as `CtrlBus` and `FloatType` still reside in the dictionary `Plant.sldd`, the dictionary `Contr.sldd` references `Plant.sldd`. Due to this reference, the models in the controller component can continue to use the globally shared variables.

The variables that the controller models share, such as `diff`, `init`, and `CodeGenConfigSet`, now reside in `Contr.sldd`.

Create Dictionary for First Controller Subcomponent

Open the model `ex_ContrComp_Sub1_Lv11`. Link this model to a new dictionary named `ContrSub1.sldd`. Then, save the model.

When you finish, the models in the first controller subcomponent, `ex_ContrComp_Sub1_Lv11` and `ex_ContrComp_Sub1_Lv12`, are linked to `ContrSub1.sldd`. The models in the second subcomponent remain linked to the dictionary `Contr.sldd`.

Create Dictionary for Second Controller Subcomponent

Open the model `ex_ContrComp_Sub2_Lv11`. Link this model to a new dictionary named `ContrSub2.sldd`. Then, save the model.

The controller dictionary `Contr.sldd` references the subcomponent dictionaries, `ContrSub1.sldd` and `ContrSub2.sldd`. Therefore, the controller dictionary can use all of the data defined in the subcomponent dictionaries.

The first subcomponent dictionary, `ContrSub1.sldd`, defines data that the subcomponents share, such as `CodeGenConfigSet`. The second subcomponent dictionary, `ContrSub2.sldd`, references `ContrSub1.sldd` so that the second subcomponent can use this shared data.

The subcomponent dictionaries `ContrSub1.sldd` and `ContrSub2.sldd` reference `Plant.sldd`. Therefore, all of the models in the hierarchy can continue to use globally shared variables such as `SensorBus` and `SimConfigSet`, which are defined in `Plant.sldd`.

Inspect Data Storage

In the Model Explorer **Model Hierarchy** pane, select the dictionary node `System`. In the **Contents** pane, to view the contents of `System.sldd`, click the **Show Current System**

and Below button . The contents of the Design Data and Configurations sections appear.

Column View: Dictionary Objects [Show Details](#) 11 object(s)

	Name	DataType	Status	DataTypeMode	DataSource	StorageClass
	diff	FloatType			ContrSub1.sldd	Auto
	init	FloatType			ContrSub1.sldd	Auto
	CodeGenConfigSet				ContrSub1.sldd	
	coeff	FloatType			ContrSub2.sldd	ExportedGlobal
	CtrlBus				Plant.sldd	
	FloatType			Single	Plant.sldd	
	SensorBus				Plant.sldd	
	mu	FloatType			Plant.sldd	Auto
	SimConfigSet				Plant.sldd	
	Design Data					
	Configurations					

The **DataSource** column shows the variables that each dictionary stores.

All of the globally shared variables, such as `FloatType` and `SimConfigSet`, reside in `Plant.sldd`. The variable `init`, which both of the controller subcomponents share, resides in `ContrSub1.sldd`. Due to dictionary references created by the migration process, the models can still share these variables.

If the development teams assigned to the controller subcomponents must make changes to the globally shared variables, they must access the plant dictionary file. Similarly, if the team assigned to the second controller subcomponent must make changes to the variable `init`, they must access the first subcomponent dictionary file.

Optimize Data Sharing Using Reference Dictionaries

To share global variables such as `SimConfigSet`, `FloatType`, and `SensorBus` by clearly defining variable scope, you can create a reference dictionary. Add the new dictionary as a reference to all of the component and subcomponent dictionaries that require the shared data.

- 1 Close all of the models that you have open.

```
bdclose all
```

- 2 In Model Explorer, select **File > New > Data Dictionary**.
- 3 Set the new dictionary name to **GlobalShare** and click **Save**.
- 4 In the **Model Hierarchy** pane, select the node **ContrSub2**. In the Dialog pane, click **Add Reference**.
- 5 Double-click **GlobalShare.sldd**.
- 6 In the **Model Hierarchy** pane, right-click the node **ContrSub2** and select **Save Changes**.
- 7 Add **GlobalShare.sldd** as a reference to the dictionaries **ContrSub1.sldd** and **Plant.sldd**. Save each dictionary after you add the reference.
- 8 In the **Model Hierarchy** pane, select the node **System**.
- 9 In the **Contents** pane, select the globally shared variables:
 - **CtrlBus**
 - **SensorBus**
 - **SimConfigSet**
 - **FloatType**
- 10 In the **DataSource** column, select **GlobalShare.sldd** for any of the selected variables.

All of the variables move from **Plant.sldd** to **GlobalShare.sldd**.
- 11 Save changes to the dictionary **System.sldd**.

Now, if any of the three development teams need to make changes to the globally shared variables such as **SimConfigSet** and **CtrlBus**, they can access the dictionary **GlobalShare.sldd**. This dictionary contains only the variables that all of the models in the system share. Because the component and subcomponent dictionaries **Plant.sldd**, **ContrSub1.sldd**, and **ContrSub2.sldd** all reference the globally shared dictionary **GlobalShare.sldd**, all of the models in the hierarchy can use the data.

To further partition and scope the shared data, create another reference dictionary to contain the variables that the controller subcomponents share: **init** and **CodeGenConfigSet**.

- 1 In Model Explorer, select **File > New > Data Dictionary**.
- 2 Set the new dictionary name to **ContrShare** and click **Save**.
- 3 In the **Model Hierarchy** pane, select the dictionary node **ContrSub2**. In the Dialog pane, select **Add Reference**.

- 4 In the dialog box, double-click `ContrShare.sldd`.
- 5 In the **Model Hierarchy** pane, right-click the node `ContrSub2` and select **Save Changes**.
- 6 Add `ContrShare.sldd` as a reference to `ContrSub1.sldd` and save the dictionary `ContrSub1.sldd`.
- 7 Add `GlobalShare.sldd` as a reference to `ContrShare.sldd` and save the dictionary `ContrShare.sldd`.
- 8 In the **Model Hierarchy** pane, select the node `System`.
- 9 In the **Contents** pane, select these variables:
 - `CodeGenConfigSet`
 - `init`
- 10 In the **DataSource** column, select `ContrShare.sldd` for any of the selected variables.

All of the variables move from `ContrSub2.sldd` to `ContrShare.sldd`.
- 11 Save changes to the dictionary `System.sldd`.

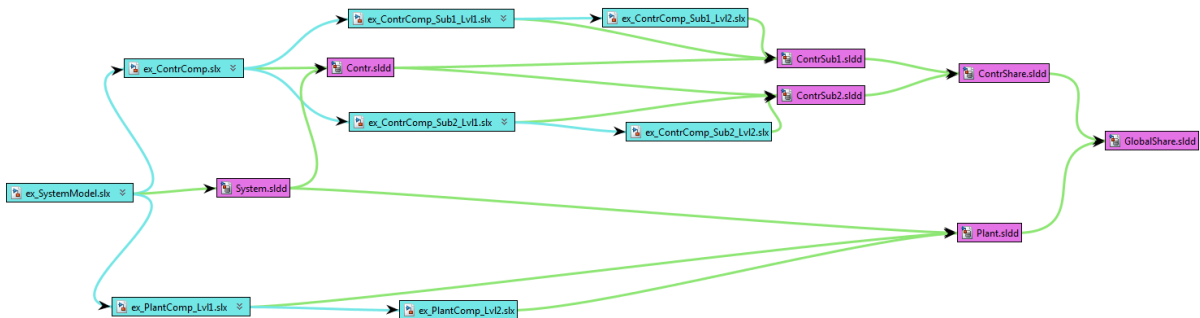

To further optimize the dictionary hierarchy, remove the unnecessary references that the migration process created. Also, remove the unnecessary references that you created from `ContrSub1.sldd` and `ContrSub2.sldd` to `GlobalShare.sldd`. Because `ContrShare.sldd` references `GlobalShare.sldd`, the controller subcomponent dictionaries can use the data in `GlobalShare.sldd` without referencing `GlobalShare.sldd`.

- 1 In the Model Explorer **Model Hierarchy** pane, select the dictionary node `ContrSub2`. In the Dialog pane, in the **Referenced Dictionaries** list, select `Plant` and click **Remove**. Remove the references to `GlobalShare.sldd` and `ContrSub1.sldd`. Save the changes to `ContrSub2.sldd`.
- 2 Remove the references to `GlobalShare.sldd` and `Plant.sldd` from `ContrSub1.sldd`. Save the changes to `ContrSub1.sldd`.
- 3 Remove the reference to `Plant.sldd` from `Contr.sldd`. Save the changes to `Contr.sldd`.

Inspect Dictionary Hierarchy

To view the entire dictionary and model hierarchy, you can perform a dependency analysis in a Simulink project.

- 1 Open your saved model `ex_SystemModel`. Select **File > Simulink Project > Create Project from Model**.
- 2 Specify a name for the project in the **Project name** box. Click **Create**.
- 3 In the Simulink Project, click **Dependency Analysis**. Click **Analyze**.

The system model, `ex_SystemModel`, is linked to the dictionary `System.sldd`. The plant component, the controller component, and the controller subcomponents are each linked to a separate dictionary. These dictionaries form a reference hierarchy. To access the shared data, the component and subcomponent dictionaries reference the dictionaries `ContrShare.sldd` and `GlobalShare.sldd`.

To inspect the data in the dictionaries, use Model Explorer.

- 1 In your saved model `ex_SystemModel`, click the data dictionary badge .
- 2 In the Model Explorer **Contents** pane, click the column name **DataSource** to sort the design data. The dictionaries in the hierarchy partition the data based on the shared scope of each variable.

You can also right-click the column name and select **Group by This Column** to group the entries by the dictionaries that define them.

- 3 In the **Model Hierarchy** pane, under the node `System`, click the node `Configurations`. In the **Contents** pane, the `Simulink.ConfigSet` objects `CodeGenConfigSet` and `SimConfigSet` are stored in the shared dictionaries.

Strategies to Discover Shared Data

To learn how the models in a model reference hierarchy share data, use these techniques:

- In an open model, select **Edit > Find Referenced Variables**. The Model Explorer displays the variables that the model uses, as well as the variables that referenced models use. You can then right-click a variable and select **Find Where Used** to display all of the models that use the variable. For more information, see “Edit and Manage Workspace Variables Used by Models” on page 57-88.
- At the command prompt, use the function `Simulink.findVars` to determine the variables a model uses. You can then use the function `intersect` to determine the variables two models, components, or subcomponents share.

Migrate Model Hierarchy to Dictionaries Incrementally

If you cannot migrate all of the models in a model reference hierarchy to a single dictionary at once, you can migrate an individual model, component, or subcomponent at the bottom of the hierarchy. Over time, you can migrate the entire hierarchy.

If you want to simulate and generate code from the hierarchy after you migrate each component, the components that you migrate cannot share any design data with other models in the hierarchy. In the example “Create a Dictionary for Each Component” on page 61-37, the components and subcomponents of a model reference hierarchy share data in the base workspace, such as `Simulink.Bus` and `Simulink.Parameter` objects. Due to these dependencies, if you migrate the hierarchy incrementally from the bottom, you cannot simulate or generate code from the hierarchy until you migrate all of the models.

Similarly, if you use configuration set references to maintain configuration parameter uniformity throughout the hierarchy, the component that you choose to migrate cannot share a configuration set with other models in the hierarchy. To permit simulation and code generation after you migrate the component, you must eliminate the dependency that the component has on the shared configuration set.

For example, when you migrate the component, copy the shared configuration set from the base workspace into the new dictionary. Then, rename the configuration set in the data dictionary, and set all of the models in the migrated component to use this renamed configuration set. The models in the migrated component use the configuration set in the data dictionary, while the rest of the models in the hierarchy use the configuration set in the base workspace. As you migrate additional components, set the models in each component to use the configuration set in the data dictionary.

If you choose to migrate a model reference hierarchy incrementally by using this technique, you must begin with the models or components at the bottom of the hierarchy. In the example “Create a Dictionary for Each Component” on page 61-37, a

controller model references two subcomponents, each of which contains two models. You cannot migrate the controller model before you migrate the models in the controller subcomponents.

Explore Example Model Hierarchy

- 1 Navigate to the folder `matlabroot/help/toolbox/simulink/examples` (open).
- 2 Copy these files to a writable folder:
 - `ProjectData_ind.mat`
 - `ex_SystemModel_ind`
 - `ex_Plant_L1_ind`
 - `ex_Plant_L2_ind`
 - `ex_Contr_L1_ind`
 - `ex_Contr_L2_ind`
- 3 Load the MAT-file `ProjectData_ind.mat` to create design data in the base workspace.
- 4 Open the example model `ex_SystemModel_ind`. This model is at the top of a reference hierarchy that includes the other example models.
- 5 Select **Analysis > Model Dependencies > Model Dependency Viewer > Models Only**. The model reference hierarchy contains a system model, a plant component with two models, and a controller component with two models.

- 6 In the Model Explorer **Model Hierarchy** pane, select **Base Workspace**. In the **Contents** pane, right-click the variable `diff` and select **Find Where Used**. In the **Select a system** dialog box, select `ex_SystemModel_ind` and click **OK**. If you see a message about updating the diagram, click **OK**.

In the **Contents** pane, the variable `diff` is used by Constant blocks in the models `ex_Contr_L1_ind` and `ex_Contr_L2_ind`, which make up the controller component. Similarly, other models in the hierarchy share the base workspace variable `mu`.

The table shows the models that share each workspace variable.

Variable Name	Models Using the Variable	Scope of Sharing
<code>diff</code>	<code>ex_ContrComp_Lv11</code> and <code>ex_ContrComp_Lv12</code>	Shared by models in the controller component
<code>mu</code>	<code>ex_PlantComp_Lv11</code> and <code>ex_PlantComp_Lv12</code>	Shared by models in plant component

Suppose that two teams of developers maintain the plant component and the controller component. You can use data dictionaries to store and scope the design data. The teams can incrementally migrate the components to use data dictionaries.

Create Data Dictionary for Controller Component

Suppose that only the controller component team is ready to migrate their models to a data dictionary. You can independently migrate these two models.

- 1 Open the example model `ex_Contr_L1_ind`. This model is at the top of the controller component.
- 2 Select **File > Model Properties > Link to Data Dictionary**.
- 3 In the dialog box, under **Defined in**, select **Data Dictionary** and click **New**.
- 4 Set the new dictionary name to `Contr` and click **Save**.
- 5 In the **Model Properties** dialog box, click **OK**.
- 6 Click **Yes** in response to the message about migrating workspace data.
- 7 Click **Yes** in response to the message about removing imported items from the base workspace.
- 8 Save the model.

You can simulate and generate code from the model hierarchy. The models in the controller component use the data in the dictionary `Contr`, which contains the variable `diff`. The other models in the hierarchy continue to use the data in the base workspace.

Create Data Dictionary for Plant Component

Open the example model `ex_Plant_L1_ind`. Link this model to a new data dictionary `Plant.sldd`. After you link the model to the new dictionary, save the model.

The migration process moves the variable `mu` into the new dictionary.

Create Data Dictionary for System Model

Open the example model `ex_SystemModel_ind`. Link this model to a new data dictionary `System.sldd`. After you link the model to the new dictionary, save the model.

The migration process causes the new dictionary, `System.sldd`, to reference the other dictionaries that you created.

Inspect Dictionary Hierarchy

Each of the components has a data dictionary. To view the entire dictionary and model hierarchy, you can perform a dependency analysis in a Simulink project.

- 1 In your saved model `ex_SystemModel_ind`, select **File > Simulink Project > Create Project from Model**.
- 2 Specify a name for the project in the **Project name** box. Click **Create**.
- 3 In the Simulink Project, click **Dependency Analysis**. Click **Analyze**.

Each team's models are linked to the appropriate dictionaries. The system dictionary references the component dictionaries.

To inspect the data in the dictionaries, use the Model Explorer.

- 1 In your saved model `ex_SystemModel_ind`, click the data dictionary badge .
- 2 In the Model Explorer **Contents** pane, the data source for each entry is the dictionary for the appropriate component.

- “Sweep Data Dictionary Parameter Using Parallel Simulation” on page 61-60

A data dictionary stores Simulink model data and offers more data management features than the MATLAB base workspace or the model workspace (see “What Is a Data Dictionary?” on page 61-2). To interact with the data in a dictionary programmatically:

- 1 Create a `Simulink.data.Dictionary` object that represents the target dictionary.
- 2 Create a `Simulink.data.dictionary.Section` object that represents the target section, for example the Design Data section. Use the object to interact with the entries stored in the section and to add entries.
- 3 Optionally, create `Simulink.data.dictionary.Entry` objects that each represent an entry in the target section. Use these objects to interact with individual entries in the target section.

Add Entry to Design Data Section of Data Dictionary

- 1 Represent the Design Data section of the data dictionary `myDictionary_ex_API.sldd` with a `Simulink.data.dictionary.Section` object named `dDataSectObj`.

```
myDictionaryObj = Simulink.data.dictionary.open('myDictionary_ex_API.sldd');
dDataSectObj = getSection(myDictionaryObj, 'Design Data');
```

- 2 Add an entry to the Design Data section of `myDictionary_ex_API.sldd` an entry `myNewEntry` with value 237.

```
addEntry(dDataSectObj, 'myNewEntry', 237)
```

Increment Value of Data Dictionary Entry

- 1 Represent the data dictionary entry `fuelFlow` with a `Simulink.data.dictionary.Entry` object named `fuelFlowObj`. `fuelFlow` is defined in the data dictionary `myDictionary_ex_API.sldd`.

```
myDictionaryObj = Simulink.data.dictionary.open('myDictionary_ex_API.sldd');
dDataSectObj = getSection(myDictionaryObj, 'Design Data');
fuelFlowObj = getEntry(dDataSectObj, 'fuelFlow');
```

- 2 Store the value of the target entry in a temporary variable. Increment the value of the temporary variable by one.

```
temp = getValue(fuelFlowObj);
temp = temp+1;
```

- 3 Set the value of the target entry by using the temporary variable.

```
setValue(fuelFlowObj, temp)
```

Data Dictionary Management

Use `Simulink.data.Dictionary` objects to interact with entire data dictionaries.

Goal	Use
Represent existing data dictionary with <code>Simulink.data.Dictionary</code> object	<code>Simulink.data.dictionary.open</code>
Create and represent data dictionary with <code>Simulink.data.Dictionary</code> object	<code>Simulink.data.dictionary.create</code>
Interact with data dictionary	<code>Simulink.data.Dictionary</code> class
Import variables to data dictionary from MATLAB base workspace	<code>Simulink.data.Dictionary.importFromBaseWorkspace</code> method

Goal	Use
Add reference dictionary to a data dictionary	<code>Simulink.data.Dictionary.addDataSource</code> method
Remove reference dictionary from a data dictionary	<code>Simulink.data.Dictionary.removeDataSource</code> method
Save changes to data dictionary	<code>Simulink.data.Dictionary.saveChanges</code> method
Discard changes to data dictionary	<code>Simulink.data.Dictionary.discardChanges</code> method
View a list of entries stored in data dictionary	<code>Simulink.data.Dictionary.listEntry</code> method
Import enumerated type definitions to data dictionary	<code>Simulink.data.Dictionary.importEnumTypes</code> method
Return file name and path of data dictionary	<code>Simulink.data.Dictionary.filepath</code> method
Show data dictionary in Model Explorer window	<code>Simulink.data.Dictionary.show</code> method
Hide data dictionary from Model Explorer window	<code>Simulink.data.Dictionary.hide</code> method
Close connection between data dictionary and <code>Simulink.data.Dictionary</code> object	<code>Simulink.data.Dictionary.close</code> method
Identify data dictionaries that are open	<code>Simulink.data.dictionary.getOpenDictionaryPaths</code>
Close all connections to all open data dictionaries	<code>Simulink.data.dictionary.closeAll</code>

Dictionary Section Management

Data dictionaries store data as entries contained in sections, and by default all dictionaries have at least three sections named Design Data, Other Data, and Configurations. Use `Simulink.data.dictionary.Section` objects to interact with data dictionary sections.

Goal	Use
Represent data dictionary section with <code>Section</code> object.	<code>Simulink.data.Dictionary.getSection</code> method
Interact with data dictionary section	<code>Simulink.data.dictionary.Section</code> class
Import variables to data dictionary section from MAT-file or MATLAB file	<code>Simulink.data.dictionary.Section.importFromFile</code> method
Export entries in data dictionary section to MAT-file or MATLAB file	<code>Simulink.data.dictionary.Section.exportToFile</code> method
Delete entry from data dictionary section	<code>Simulink.data.dictionary.Section.deleteEntry</code> method
Evaluate MATLAB expression in data dictionary section	<code>Simulink.data.dictionary.Section.evalIn</code> method
Search for entries in data dictionary section	<code>Simulink.data.dictionary.Section.find</code> method
Determine whether entry exists in data dictionary section	<code>Simulink.data.dictionary.Section.exist</code> method

Dictionary Entry Manipulation

A variable that is stored in a data dictionary is called an entry of the dictionary. Entries have additional properties that store status information, such as the time and date the entry was last modified. Use `Simulink.data.dictionary.Entry` objects to manipulate data dictionary entries.

Goal	Use
Represent data dictionary entry with <code>Entry</code> object	<code>Simulink.data.dictionary.Section.getEntry</code> method
Add data dictionary entry to section and represent with <code>Entry</code> object	<code>Simulink.data.dictionary.Section.addEntry</code> method
Manipulate data dictionary entry	<code>Simulink.data.dictionary.Entry</code> class

Goal	Use
Assign new value to data dictionary entry	<code>Simulink.data.dictionary.Entry.setValue</code> method
Display changes made to data dictionary entry	<code>Simulink.data.dictionary.Entry.showChanges</code> method
Save changes made to data dictionary	<code>Simulink.data.Dictionary.saveChanges</code> method
Discard changes made to data dictionary entry	<code>Simulink.data.dictionary.Entry.discardChanges</code> method
Search in an array of data dictionary entries	<code>Simulink.data.dictionary.Entry.find</code> method
Return value of data dictionary entry	<code>Simulink.data.dictionary.Entry.getValue</code> method
Delete data dictionary entry	<code>Simulink.data.dictionary.Entry.deleteEntry</code> method
Store enumerated type definition in dictionary	<code>Simulink.data.dictionary.EnumTypeDefinition</code> class

Transition to Using Data Dictionary

These functions help you transition to data dictionaries by operating on Simulink model data either in the base workspace or in a data dictionary, as appropriate for the model.

Goal	Use
Change value of data dictionary entry or workspace variable in context of Simulink model	<code>Simulink.data.assignInGlobal</code>
Evaluate MATLAB expression in context of Simulink model	<code>Simulink.data.evalInGlobal</code>
Determine existence of data dictionary entry or workspace variable in context of Simulink model	<code>Simulink.data.existsInGlobal</code>

Programmatically Migrate Single Model to Use Dictionary

To change the data source of a Simulink model from the MATLAB base workspace to a new data dictionary, use this example code as a template.

```
% Define the model name and the data dictionary name
modelName = 'f14';
dictionaryName = 'myNewDictionary.slidd';

% Load the target model
load_system(modelName);

% Identify all model variables that are defined in the base workspace
varsToImport = Simulink.findVars(modelName, 'SourceType', 'base workspace');
varNames = {varsToImport.Name};

% Create the data dictionary
dictionaryObj = Simulink.data.dictionary.create(dictionaryName);

% Import to the dictionary the model variables defined in the base
% workspace, and clear the variables from the base workspace
[importSuccess,importFailure] = importFromBaseWorkspace(dictionaryObj,...
    'varList',varNames,'clearWorkspaceVars',true);

% Link the dictionary to the model
set_param(modelName,'DataDictionary',dictionaryName);
```

Note: This code does not migrate the definitions of enumerated data types that were used to define model variables. If you import model variables of enumerated data types to a data dictionary but do not migrate the enumerated type definitions, the dictionary is less portable and might not function properly if used by someone else. To migrate enumerated data type definitions to a data dictionary, see “Enumerations in Data Dictionary” on page 61-14.

Import Directly From External File to Dictionary

This example shows how to use a custom MATLAB function to import data directly from an external file to a data dictionary without creating or altering variables in the base workspace.

- 1 Create a two-dimensional lookup table in one sheet of a Microsoft Excel workbook. Use the upper-left corner of the sheet to provide names for the two breakpoints and for the table. Use column B and row 2 to store the two breakpoints, and use the rest of the sheet to store the table. For example, your lookup table might look like this:

	A	B	C	D	E	F	G	H
1		bkpt2Name						
2	bkpt1Name	tableName	0.1	0.2	0.3	0.4	0.5	
3		0.25	0.35	0.6	0.85	1.1	1.35	
4		0.5	0.45	0.7	0.95	1.2	1.45	
5		0.75	0.55	0.8	1.05	1.3	1.55	
6		1	0.65	0.9	1.15	1.4	1.65	
7		1.25	0.75	1	1.25	1.5	1.75	
8								

Save the workbook in your current folder as `my2DLUT.xlsx`.

- 2 Copy this custom function definition into a MATLAB file, and save the file in your current folder as `importLUTToDD.m`.

```
function importLUTToDD(workbookFile,dictionaryName)
% IMPORTLUTTODD(workbookFile,dictionaryName) imports data for a
% two-dimensional lookup table from a workbook directly into a data
% dictionary. The two-dimensional lookup table in the workbook can be
% any size but must follow a standard format.

% Read in the entire first sheet of the workbook.
[data,names,-] = xlsread(workbookFile,1, '');

% Divide the raw imported data into the breakpoints, the table, and their
% names.
% Assume breakpoint 1 is in the first column and breakpoint 2 is in the
% first row.
% Assume cells A1, B1, and B2 define the breakpoint names and table name.
bkpt1 = data(2:end,1);
bkpt2 = data(1,2:end);
table = data(2:end,2:end);
bkpt1Name = names{2,1};
bkpt2Name = names{1,2};
tableName = names{2,2};

% Prepare to import to the Design Data section of the target data
% dictionary.
myDictionaryObj = Simulink.data.dictionary.open(dictionaryName);
dDataSectObj = getSection(myDictionaryObj,'Design Data');
```

```

% Create entries in the dictionary to store the imported breakpoints and
% table. Name the entries using the breakpoint and table names imported
% from the workbook.
addEntry(dDataSectObj,bkpt1Name,bkpt1);
addEntry(dDataSectObj,bkpt2Name,bkpt2);
addEntry(dDataSectObj,tableName,table);

% Save changes to the dictionary and close it.
saveChanges(myDictionaryObj)
close(myDictionaryObj)

```

- 3 At the MATLAB command prompt, create a data dictionary to store the lookup table data.

```
myDictionaryObj = Simulink.data.dictionary.create('myLUTDD.sldd');
```

- 4 Call the custom function to import your lookup table to the new data dictionary.

```
importLUTToDD('my2DLUT.xlsx','myLUTDD.sldd')
```

- 5 Open the data dictionary in Model Explorer.

```
show(myDictionaryObj)
```

Three new entries store the imported breakpoints and lookup table. These entries are ready to use in a 2-D Lookup Table block.

Programmatically Partition Data Dictionary

To partition a data dictionary into reference dictionaries, use this example code as a template. You can use reference dictionaries to make large data dictionaries more manageable and to contain standardized data that is useful for multiple models.

```

% Define the names of a parent data dictionary and two
% reference data dictionaries
parentDDName = 'myParentDictionary.sldd';
typesDDName = 'myTypesDictionary.sldd';
paramsDDName = 'myParamsDictionary.sldd';

% Create the parent data dictionary and a
% Simulink.data.Dictionary object to represent it
parentDD = Simulink.data.dictionary.create(parentDDName);

% Create a Simulink.data.dictionary.Section object to represent
% the Design Data section of the parent dictionary
designData_parentDD = getSection(parentDD,'Design Data');

```

```
% Import some data to the parent dictionary from the file partDD_Data_ex_API.m
importFromFile(designData_parentDD, 'partDD_Data_ex_API.m');

% Create two reference dictionaries
Simulink.data.dictionary.create(typesDDName);
Simulink.data.dictionary.create(paramsDDName);

% Create a reference dictionary hierarchy by adding reference dictionaries
% to the parent dictionary
addDataSource(parentDD, typesDDName);
addDataSource(parentDD, paramsDDName);

% Migrate all Simulink.Parameter objects from the parent data dictionary to
% a reference dictionary
paramEntries = find(designData_parentDD, '-value', '-class', 'Simulink.Parameter');
for i = 1:length(paramEntries)
    paramEntries(i).DataSource = 'myParamsDictionary.slidd';
end

% Migrate all Simulink.NumericType objects from the parent data dictionary
% to a reference dictionary
typeEntries = find(designData_parentDD, '-value', '-class', 'Simulink.NumericType');
for i = 1:length(typeEntries)
    typeEntries(i).DataSource = 'myTypesDictionary.slidd';
end

% Save all changes to the parent data dictionary
saveChanges(parentDD)
```

Sweep Data Dictionary Parameter Using Parallel Simulation

To use parallel simulation to sweep a model parameter that is defined in a data dictionary, use this code as a template. Change the names and values of the model, data dictionary, and swept parameter to match your application.

You cannot use this code for rapid accelerator simulations when you call the `sim` function by setting `RapidAcceleratorUpToDateCheck` to `'off'`. In this case, use `RapidAcceleratorParameterSets` to pass new parameter values directly to the simulation. For more information, see “`sim` in parfor with Rapid Accelerator Mode” on page 24-21. For an example of parallel simulation using rapid accelerator mode, see “Parallel Simulations Using Parfor: Parameter Sweep in Rapid Accelerator Mode”.

You must have a Parallel Computing Toolbox license to perform parallel simulation.

```

% For convenience, define names of model and data dictionary
model = 'myParamSweepMdl';
dd = 'myParamSweepDD.sidd';

% Define parameter sweeping values
ParamValues = [20 35 49 78 106 123 148 192 205 225];

% Grant each worker in the parallel pool an independent data dictionary
% so they can use the data without interference
spmd
    Simulink.data.dictionary.setupWorkerCache
end

% Determine the number of times to simulate
numberOfSims = length(ParamValues);

% Prepare a nondistributed array to contain simulation output
simOut = cell(1,numberOfSims);

parfor index = 1:numberOfSims
    % Create objects to interact with dictionary data
    % You must create these objects for every iteration of the parfor-loop
    dictObj = Simulink.data.dictionary.open(dd);
    sectObj = getSection(dictObj,'Design Data');
    entryObj = getEntry(sectObj,'SpeedVect');
    % Suppose SpeedVect is a Simulink.Parameter stored in the data dictionary

    % Modify the value of the Simulink.Parameter stored in the data dictionary
    temp = getValue(entryObj);
    temp.Value = ParamValues(index);
    setValue(entryObj,temp);

    % Simulate and store simulation output in the nondistributed array
    simOut{index} = sim(model);

    % Each worker must discard all changes to the data dictionary and
    % close the dictionary when finished with an iteration of the parfor-loop
    discardChanges(dictObj);
    close(dictObj);
end

% Restore default settings that were changed by the function

```

```
% Simulink.data.dictionary.setupWorkerCache
% Prior to calling cleanupWorkerCache, close the model
bdclose(model)
spmd
    Simulink.data.dictionary.cleanupWorkerCache
end
```

Note: If data dictionaries are open, you cannot use the command `Simulink.data.dictionary.cleanupWorkerCache`. To identify open data dictionaries, use `Simulink.data.dictionary.getOpenDictionaryPaths`.

Signal Basics

In this section...

“About Signals” on page 62-2

“Creating Signals” on page 62-3

“Signal Line Styles” on page 62-3

“Signal Properties” on page 62-4

“Store Design Attributes of Signals and States” on page 62-6

“Testing Signals” on page 62-6

About Signals

A *signal* is a time-varying quantity that has values at all points in time. You can specify a wide range of signal attributes, including:

- Signal name
- Data type (for example, 8-bit, 16-bit, or 32-bit integer)
- Numeric type (real or complex)
- Dimensionality (one-dimensional, two-dimensional, or multidimensional array)

Many blocks can accept or output signals of any data or numeric type and dimensionality. Other blocks impose restrictions on the attributes of the signals that they can handle.

In Simulink, signals are the outputs of dynamic systems represented by blocks in a Simulink diagram and by the diagram itself. The lines in a block diagram represent mathematical relationships among the signals defined by the block diagram. For example, a line connecting the output of block A to the input of block B indicates that the signal output of B depends on the signal output of A.

Simulink block diagrams represent signals with lines that have an arrowhead. The source of the signal corresponds to the block that writes to the signal during evaluation of its block methods (equations). The destinations of the signal are blocks that read the signal during the evaluation of the block methods (equations).

Note Simulink signals are mathematical, not physical, entities. The lines in a block diagram represent mathematical, not physical, relationships among blocks. Simulink

signals do not travel along the lines that connect blocks in the same way that electrical signals travel along a wire. Block diagrams do not represent physical connections between blocks.

Creating Signals

Create a signal by adding a source block to your model. For example, you can create a signal that varies sinusoidally with time by adding an instance of the Sine block from the Simulink Sources library into your model. For information about blocks that create signals in a model, see “Sources” .

You can use the Signal & Scope Manager to create signals in your model without using blocks. For more information, see “Signal and Scope Manager” on page 25-73 .

Signal Line Styles

A Simulink model can include many different types of signals. For details, see “Signal Types” on page 62-8. Different line styles help you to differentiate the signal types.

As you construct a block diagram, all signal types appear as a thin, solid line. After you update the diagram or start simulation, the signals appear with the specified line styles. The only line style that you can customize is the nonscalar signal type. For information about this option, see “Wide Nonscalar Lines” on page 62-61.

Signal Type	Line Style
Scalar and nonscalar	
Nonscalar (with the Wide nonscalar lines option enabled—see “Display Signal Attributes” on page 62-58)	
Control signal	
Virtual bus	
Nonvirtual bus	
Array of buses	

Signal Type	Line Style
Variable-size	

Signal Properties

Specify Signal Properties

Use the Property Inspector to specify properties for:

- Signal names and labels
- Signal logging
- Simulink Coder to use to generate code
- Documentation of the signal

To access the signal properties in the Property Inspector, first display the Property Inspector. Select **View > Property Inspector**. When you select a signal, the properties appear in the Property Inspector. Alternatively, you can right-click a signal and select **Properties** to use the Signal Properties dialog box. For information about the benefits of each approach, see “Setting Properties and Parameters” on page 1-50.

Programmatically Specify Signal Properties

To specify signal properties programmatically, use a function such as `get_param` to get a handle to the block output port that creates the signal line. Then, use `set_param` to set the programmatic parameters of the port.

For an example, see “Name a Signal Programmatically” on page 1-17.

To learn how to map signal properties to programmatic port parameters, see “Signal Properties Dialog Box Overview”.

Signal Names and Labels

You can name a signal. By default, the signal name appears below a signal, displayed as a *signal label*. You can name a signal interactively in the model or by using the Signal Properties dialog box. You can also name the signal at the command prompt (see “Name a Signal Programmatically” on page 1-17). For a summary of how to work with signal names and labels in the Simulink Editor, see “Signal Name and Label Actions” on page 1-92.

The syntactic requirements for a signal name depend on how you use the name. The most common cases are:

- The signal name can resolve to a `Simulink.Signal` object. (See `Simulink.Signal`.) The signal name must then be a legal MATLAB identifier. This identifier starts with an alphabetic character, followed by alphanumeric or underscore characters up to the length given by the function `namelengthmax`.
- The signal has a name so the signal can be identified and referenced by name in a data log. (See “Export Signal Data Using Signal Logging” on page 59-57.) Such a signal name can contain space and newline characters. These characters can improve readability but sometimes require special handling techniques, as described in “Handling Spaces and Newlines in Logged Names” on page 59-95
- The signal name exists only to clarify the diagram and has no computational significance. Such a signal name can contain anything and does not need special handling.
- The signal is an element of a bus object. Use a valid C language identifier for the signal name.
- Inputs to a Bus Creator block must have unique names. If there are duplicate names, the Bus Creator block appends (`signal#`) to all input signal names, where `#` is the input port index.

Making every signal name a legal MATLAB identifier handles a wide range of model configurations. Unexpected requirements can require changing signal names to follow a more restrictive syntax. You can use the function `isvarname` to determine whether a signal name is a legal MATLAB identifier.

Signal Display Options

Displaying signal attributes in the model diagram can make the model easier to read. For example, in the Simulink Editor, use the **Display > Signals & Ports** menu to include in the model layout information about signal attributes, such as:

- Port data types
- Design ranges
- Signal dimensions
- Signal resolution

For details, see “Display Signal Attributes” on page 62-58.

You can also highlight a signal and its source or destination blocks. For details, see “Display Signal Sources and Destinations” on page 62-38.

Store Design Attributes of Signals and States

You can use block parameters to specify signal design attributes such as data type, minimum and maximum values, physical unit, and numeric complexity. You can also specify code generation settings by using signal properties, which you access through the Model Data Editor or signal properties dialog boxes. To configure states, you can use block parameters. When you use these block parameters and signal properties, you store the specifications in the model file.

Alternatively, you can specify these attributes by using the properties of a `Simulink.Signal` object that you store in a workspace or data dictionary. See `Simulink.Signal` and “Data Objects” on page 57-54.

Choose which strategy to use based on your modeling goals.

- To improve model portability, readability, and ease of maintenance, store these specifications in the model file. You do not need to save and manage external `Simulink.Signal` objects. Consider setting the model configuration parameter **Signal resolution** to `None`, which disables the use of `Simulink.Signal` objects by the model.
- To separate these specifications from the model so that you can manage each independently, use `Simulink.Signal` objects. You can then configure the specifications in a flat list that you can sort, group, and filter with the Model Explorer. To determine where to permanently store the objects, see “Determine Where to Store Variables and Objects for Simulink Models” on page 57-81.

To configure design attributes and code generation settings for root-level Inport and Output blocks by using a list that you can sort, group, and filter, consider the Model Data Editor. You can also use the Model Data Editor to configure code generation settings for internal signals. With this technique, you store the specifications in the model file instead of using `Simulink.Signal` objects. See “Configure Data Properties by Using a Table” on page 57-103.

Testing Signals

You can perform the following kinds of tests on signals:

- “Minimum and Maximum Values” on page 62-7
- “Connection Validation” on page 62-7

Minimum and Maximum Values

For many Simulink blocks, you can specify a range of valid values for the output signals. Simulink provides a diagnostic for detecting when blocks generate signals that exceed their specified ranges during simulation. For details, see “Signal Ranges” on page 62-41.

Connection Validation

Many Simulink blocks have limitations on the types of signals that they accept. Before simulating a model, Simulink checks all blocks to ensure that the blocks can accommodate the types of signals output by the ports to which the blocks connect and reports errors about incompatibilities.

To detect signal compatibility errors before running a simulation, update the diagram.

Signal Groups

The **Signal Builder** block displays interchangeable groups of signal sources. Use the Signal Builder to create or edit groups of signals and to switch the groups into and out of a model.

Signal groups can help with testing a model, especially when you use them with Simulink **Assertion** blocks and the Model Coverage Tool in the Simulink Verification and Validation product.

For details, see “Signal Groups” on page 62-63.

Signal Types

In this section...

“Summary of Signal Types” on page 62-8

“Control Signals” on page 62-8

“Composite (Bus) Signals” on page 62-9

Summary of Signal Types

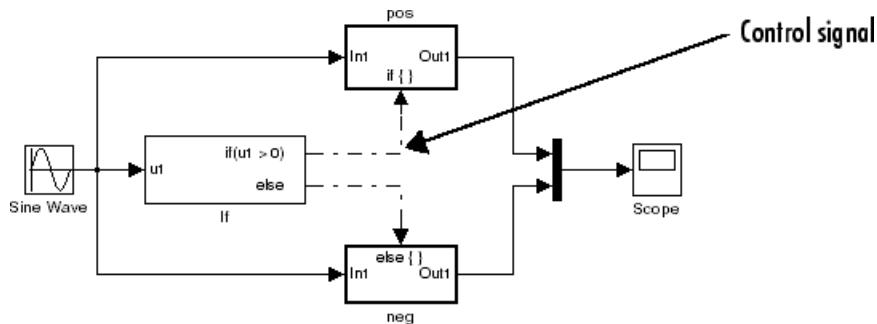

You can use many different kinds of signals in a model. The following table summarizes the signal types, and links to sections that describe each type in detail.

Signal Type	Description
Array of buses	An array whose elements are buses. See “Combine Buses into an Array of Buses” on page 63-91.
Bus (Composite)	A Simulink composite signal made up of other signals, optionally including other bus signals. See “Composite (Bus) Signals” on page 62-9.
Control	Signal used by one block to initiate execution of another block. For example, a signal that executes a function-call or action subsystem. For details, see “Control Signals” on page 62-8.
Nonvirtual	Signal that occupies its own storage. A nonvirtual bus reads inputs and writes outputs by accessing copies of the component signals.
Mux	A virtual vector created with a Mux block. See “Mux Signals” on page 62-11.
Variable-Size	Signal whose size (the number of elements in a dimension), in addition to its values, can change during a model simulation.
Virtual	Signal that represents another signal or set of signals. A virtual signal is used for graphical purposes and has no functional effect. See “Virtual Signals” on page 62-11.

Control Signals

A *control signal* is a signal used by one block to initiate execution of another block. For example, a signal that executes a function-call or action subsystem is a control signal.

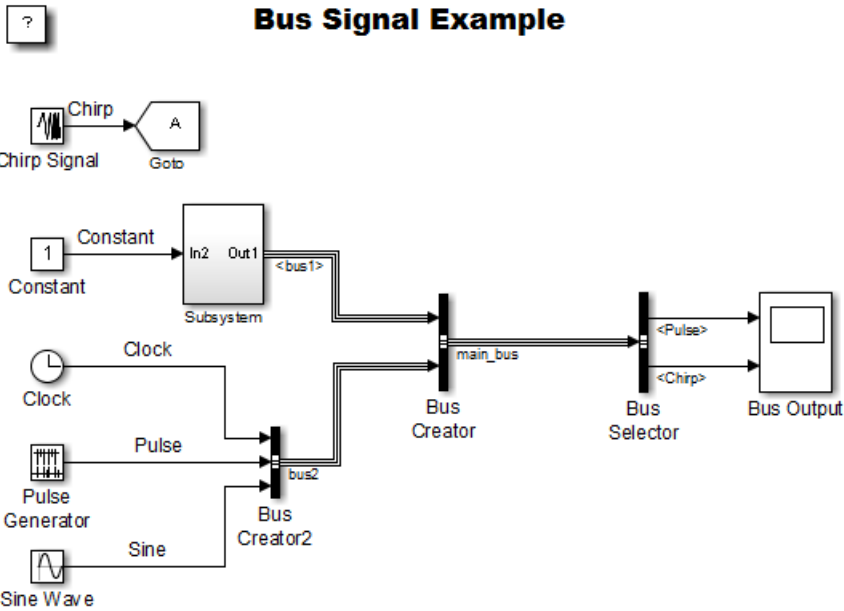

When you update or simulate a block diagram, Simulink uses a dash-dot pattern to redraw lines representing the control signals.

Composite (Bus) Signals

You can group multiple signals into a hierarchical composite signal, called a *bus*, route the bus from block to block, and extract constituent signals from the bus where needed. When you have many parallel signals, buses can simplify the appearance of a model and help to clarify generated code. A bus can be either virtual or nonvirtual.

For example, if you open and simulate the `Bus Signal` example model, the `bus1`, `bus2`, and `main_bus` signals are bus signals. These virtual bus signals use the triple line style.

For details, see “Buses” on page 63-3.

Virtual Signals

In this section...

“About Virtual Signals” on page 62-11

“Mux Signals” on page 62-11

About Virtual Signals

A *virtual signal* is a signal that graphically represents other signals or parts of other signals. Virtual signals are purely graphical entities; they have no mathematical or physical significance. Simulink ignores them when simulating a model, and they do not exist in generated code. Some blocks, such as the Mux block, always generate virtual signals. Others, such as Bus Creator, can generate either virtual or nonvirtual signals.

The nonvirtual components of a virtual signal are called *regions*. A virtual signal can contain the same region more than once. For example, if the same nonvirtual signal is connected to two input ports of a Mux block, the block outputs a virtual signal that has two regions. The regions behave as they would if they had originated in two different nonvirtual signals, even though the resulting behavior duplicates information.

Bus signals can also be virtual or nonvirtual. For details, see “Virtual and Nonvirtual Buses” on page 63-4.

Mux Signals

A Simulink *mux* is a virtual signal that graphically combines two or more scalar or vector signals into one signal line. A Simulink mux is not a hardware multiplexer, which combines multiple data streams into a single channel. A Simulink mux does not combine signals in any functional sense: it exists only virtually, and its only purpose is to simplify the visual appearance of a model. Using a mux has no effect on simulation or generated code.

You can use a mux anywhere that you could use an ordinary (contiguous) vector. For example, you can perform calculations on a mux. The computation affects each constituent value in the mux just as if the values existed in a contiguous vector, and the result is a contiguous vector, not a mux. Using a mux to perform computations on multiple vectors avoids the overhead of copying the separate values to contiguous storage.

The Simulink documentation refers, sometimes interchangeably, to “muxes”, “vectors”, and “wide signals”, and all three terms appear in Simulink GUI labels and API names. This terminology can be confusing, because most vector signals, which are also called wide signals, are nonvirtual and hence are not muxes. To avoid confusion, reserve the term “mux” to refer specifically to a virtual vector.

A mux is a *virtual* vector signal. The constituent signals of a mux retain their separate existence in every way, except visually. You can also combine scalar and vector signals into a *nonvirtual* vector signal, by using a **Vector Concatenate** block. The signal output by a Vector Concatenate block is an ordinary contiguous vector, inheriting no special properties from the fact that it was created from separate signals.

To create a composite signal whose constituent signals retain their identities and can have different data types, use a **Bus Creator** block rather than a Mux block. For details, see “Overview of Composite Signal Techniques” on page 63-3. Although you can use a Mux block to create a composite signal in some cases, MathWorks discourages this practice. See “Prevent Bus and Mux Mixtures” on page 63-128 for more information.

Using Muxes

The Signal Routing library provides two virtual blocks for implementing muxes:

Mux

Combine several input signals into a mux (virtual vector) signal

Demux

Extract and output the values in a mux (virtual vector) signal

To implement a mux signal:

- 1 Select a Mux and Demux block from the Signal Routing library.
- 2 Set the Mux block **Number of inputs** and the Demux block **Number of outputs** block parameters to the desired values.
- 3 Connect the Mux, Demux, and other blocks as needed to implement the desired signal.

The next figure shows three signals that are input to a Mux block, transmitted as a mux signal to a Demux block, and output as separate signals.

The Mux and Demux blocks are the left and right vertical bars, respectively. To reduce visual complexity, neither block displays a name. In this example, the line connecting the blocks, representing the mux signal, is wide because the model has been built with **Display > Signals & Ports > Wide Nonscalar Lines** option enabled. See “Display Signal Attributes” on page 62-58 for details.

Signals input to a Mux block can be any combination of scalars, vectors, and muxes. The signals in the output mux appear in the order in which they were input to the Mux block. You can use multiple Mux blocks to create a mux in several stages, but the result is flat, not hierarchical, just as if the constituent signals had been combined using a single mux block.

The values in all signals input to a Mux block must have the same data type.

If a Demux block attempts to output more values than exist in the input signal, an error occurs. A Demux block can output fewer values than exist in the input mux, and can group the values it outputs into different scalars and vectors than were input to the Mux block. However, the Demux block cannot rearrange the order of those values. For details, see Demux.

Note: MathWorks discourages using Mux and Demux blocks to create and access buses under any circumstances. See “Prevent Bus and Mux Mixtures” on page 63-128 for details.

Signal Values

In this section...

“Signal Data Types” on page 62-15

“Signal Dimensions, Size, and Width” on page 62-15

“Complex Signals” on page 62-15

“Initializing Signal Values” on page 62-16

“Viewing Signal Values” on page 62-16

“Displaying Signal Values in Model Diagrams” on page 62-17

“Exporting Signal Data” on page 62-18

Signal Data Types

Data type refers to the format used to represent signal values internally. By default, the data type of Simulink signals is double. You can create signals of other data types. Simulink signals support the same range of data types as MATLAB. See “About Data Types in Simulink” on page 57-2 for more information.

Signal Dimensions, Size, and Width

Simulink blocks can output one-dimensional, two-dimensional, or multidimensional signals. The Simulink user interface and documentation generally refer to 1-D signals as vectors and 2-D or multidimensional signals as matrices. A one-element array is frequently referred to as a scalar.

The size of a signal refers to the number of elements that a signal contains. The size of a matrix (2-D) signal is generally expressed as M-by-N, where M is the number of columns and N is the number of rows making up the signal. The size of a vector signal is referred to as the width of the signal.

For more information, see “Signal Dimensions” on page 62-30.

Complex Signals

The values of signals can be complex numbers or real numbers. A signal whose values are complex numbers is a complex signal. Create a complex-valued signal using one of the following approaches:

- Load complex-valued signal data from the MATLAB workspace into the model via a root-level Inport block.
- Create a **Constant** block in your model and set its value to a complex number.
- Create real signals corresponding to the real and imaginary parts of a complex signal, then combine the parts into a complex signal, using the **Real - Imag to Complex** conversion block.

Manipulate complex signals via blocks that accept them. If you are not sure whether a block accepts complex signals, see the documentation for the block.

Initializing Signal Values

If a signal does not have an explicit initial value, the initial value that Simulink uses depends on the data type of the signal.

Signal Data Type	Default Initial Value
Numeric (other than fixed-point)	Zero
Fixed-point	Ground value
Boolean	False
Enumerated	Default value

You can specify the non-default initial values of signals for Simulink to use at the beginning of simulation.

- For any signal, you can define a signal object (`Simulink.Signal`), and use that signal object to specify an initial value for the signal.
- For some blocks, such as **Outport**, **Data Store Memory**, and **Memory**, you can use either a signal object or a block parameter, or both, to specify the initial value of a block state or output.

For details, see “Initialize Signals and Discrete States” on page 62-47.

Viewing Signal Values

You can use either blocks or the signal viewers (such as the Signal & Scope Manager) to display the values of signals during a simulation. For example, you can use either

the Scope block or the Signal & Scope Manager to graph time-varying signals on an oscilloscope-like display during simulation. For general information about options for viewing signal values, see “Scope Blocks and Scope Viewer Overview” on page 25-8. For detailed information about:

- Blocks that you can use to display signals in a model, see “Sinks”
- Signal viewers, see “Floating Scope and Scope Viewer Tasks” on page 25-65
- The Signal & Scope Manager, see “Signal and Scope Manager” on page 25-73
- Test points, which are signals that Simulink guarantees to be observable when using a Floating Scope block in a model, see “Test Points” on page 62-55.

Displaying Signal Values in Model Diagrams

To include graphical displays of signal values in a model diagram, use one of the following approaches:

- “Display Data Tips During Simulation” on page 62-17
- “Display Signal Value After Simulation” on page 62-17

Display Data Tips During Simulation

For many blocks, Simulink can display block output (port values) as data tips on the block diagram while a simulation is running.

- 1 In the Simulink Editor, select **Display > Data Display in Simulation**.
- 2 From the submenu, select either **Show Value Labels When Hovering** or **Show Value Labels When Clicked**.
- 3 To change display options, use the **Options** submenu.

For details, see “Display Port Values for Debugging” on page 33-15.

Display Signal Value After Simulation

To display, below a specific signal, the signal value after simulation:

- 1 Right-click the signal.
- 2 In the context menu, select **Show Value Label of Selected Port**.

Exporting Signal Data

You can save signal values to the MATLAB workspace during simulation, for later retrieval and postprocessing. For a summary of different approaches, see “Approaches for Exporting Signal Data” on page 59-4.

Signal Label Propagation

In this section...

- “Propagated Signal Labels” on page 62-19
- “Blocks That Support Signal Label Propagation” on page 62-19
- “Display Propagated Signal Labels” on page 62-20
- “How Simulink Propagates Signal Labels” on page 62-21

Propagated Signal Labels

When you enable the display of signal label propagation for output signals of the blocks listed in “Blocks That Support Signal Label Propagation” on page 62-19:

- If there is a user-specified signal name that Simulink can propagate, the propagated signal label includes the name in angle brackets (for example, <sig1>).
- If there is no signal name to propagate, Simulink displays an empty set of angle brackets (<>) for the label.

For example, in the following model, the output signal from the Subsystem block is configured for signal label propagation. The propagated signal label (<const>) is based on the name of the upstream output signal of the Constant block (const).

For more information on how Simulink creates propagated signal labels, see “How Simulink Propagates Signal Labels” on page 62-21.

Blocks That Support Signal Label Propagation

You can use signal label propagation with output signals for several *connection* blocks, which route signals through the model without changing the data. Connection blocks perform no signal transformation.

Also, Model blocks support signal label propagation.

The connection blocks that support signal label propagation are:

- Enable
- From
- Function Call Split
- Goto
- Inport (subsystem only; not root inports)
- Signal Specification
- Subsystem (through subsystem Inport and Outport blocks)
- Trigger
- Two-Way Connection (a Simscape block)

The Bus Creator and Bus Selector blocks do *not* support signal label propagation. However, if you want to view the hierarchy for any bus signal, use the “Signal Hierarchy Viewer” on page 63-22.

The Signal Properties dialog box for a signal indicates whether that signal supports signal label propagation. The **Show propagated signals** parameter is available only for blocks that support signal label propagation. For details, see “Display Propagated Signal Labels” on page 62-20.

Display Propagated Signal Labels

To display a propagated signal label:

- 1 Set **Model Configuration Parameters** > **Diagnostics** > **Connectivity** > **Mux blocks used to create bus signals** to **error**.
- 2 Right-click the signal for which you want to display a propagated signal label and select **Properties**.
- 3 In the Signal Properties dialog box, select **Show propagated signals**.

The **Show propagated signals** parameter is available only for output signals from blocks that support signal label propagation.

To enable this signal property programmatically, create a handle to the signal line, and specify `signalPropagation` as 'on'. For example, you can use this code to enable or disable the property for all of the signals in a model diagram.

```
% Create an array of handles to every signal line in the diagram
signalLines = find_system(gcs, 'FindAll', 'on', 'type', 'line');

% Enable or disable the property for each signal line
for i = 1:length(signalLines)

    % set(signalLines(i), 'signalPropagation', 'off');
    set(signalLines(i), 'signalPropagation', 'on');
end
```

If a signal already has a label, then an *alternative* approach for displaying a propagated signal label is:

- 1 In the model diagram, click the signal label.
- 2 Remove the label text.
- 3 In the signal label text box, enter an angle bracket (<).
- 4 Click outside the signal label.

Simulink displays the propagated signal label.

How Simulink Propagates Signal Labels

Understanding how Simulink propagates signal labels helps you to:

- Anticipate the scope of the signal label propagation, from source to final destination
- Configure your model to display signal labels for the signals that you want

For output signals from supported blocks, you can choose to have Simulink display propagated signal labels. For a list of supported blocks, see “Blocks That Support Signal Label Propagation” on page 62-19.

In general, Simulink performs signal label propagation consistently:

- For different modeling constructs (for example, non-bus and bus signals, virtual and nonvirtual buses, subsystem and model variants, model referencing, and libraries)
- In models with or without hidden blocks, which Simulink inserts in certain cases to enable simulation
- At model load, edit, update, and simulation times

For information about some special cases, see:

- “Processing for Referenced Models” on page 62-26
- “Processing for Variants and Configurable Subsystems” on page 62-28

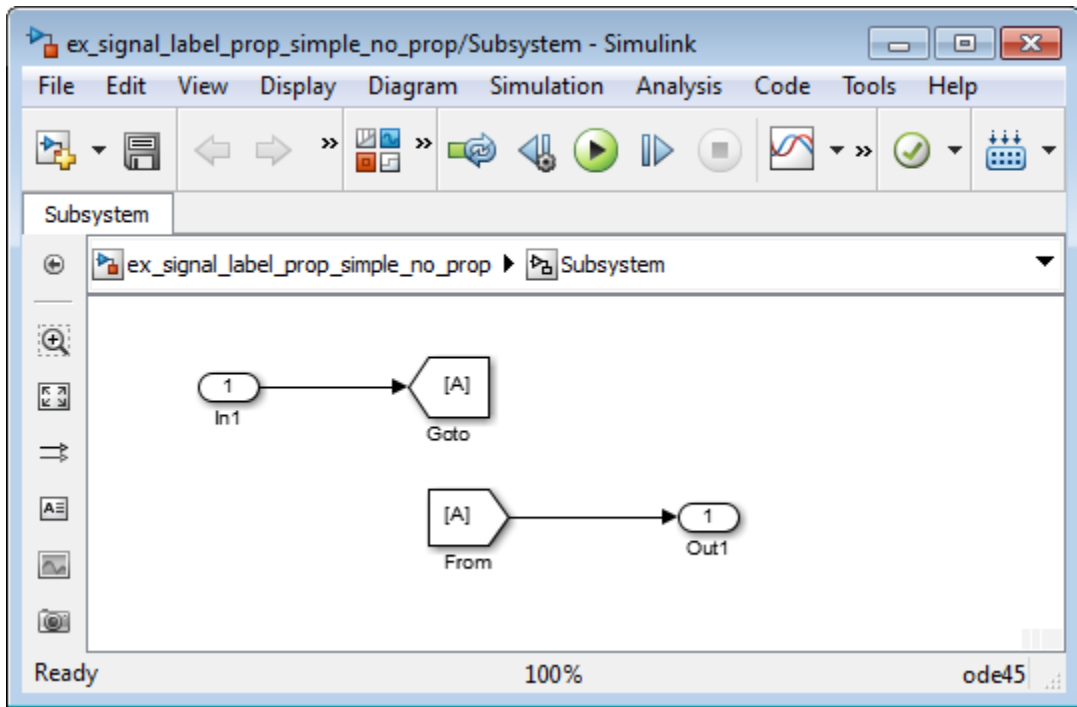

General Signal Label Propagation Processing

In general, when you enable signal label propagation for an output signal of a block (for example, BlockA), Simulink performs the following processing to find the source signal name to propagate:

- 1** Checks the block whose output signal connects to BlockA, and if necessary, continues checking upstream blocks, working backward from the closest block to the farthest block.
- 2** Stops when it encounters a block that either:
 - Supports signal label propagation and has a signal name
 - Does not support signal label propagation
- 3** Obtains the signal name, if any, of the output signal for the block at which Simulink stops.
- 4** Uses that signal name for the propagated signal label of any output signals of downstream blocks for which you enable signal label propagation.

For example, in the following model, suppose that you enable signal label propagation for the output signal for the Subsystem block (that is, the signal connected to the **Out1** port).

Simulink checks inside the subsystem, checks upstream from the From and GoTo blocks (which support signal label propagation and do not have a name), and then checks farther upstream, to the Constant block, which does not support signal label propagation.

Simulink uses the signal name of the Constant block output signal, `const`. The propagated signal label for the Subsystem output signal is `<const>`.

If the output signal from the Constant block did not have a signal name, then the propagated signal label would be an empty set of angle brackets (`<>`).

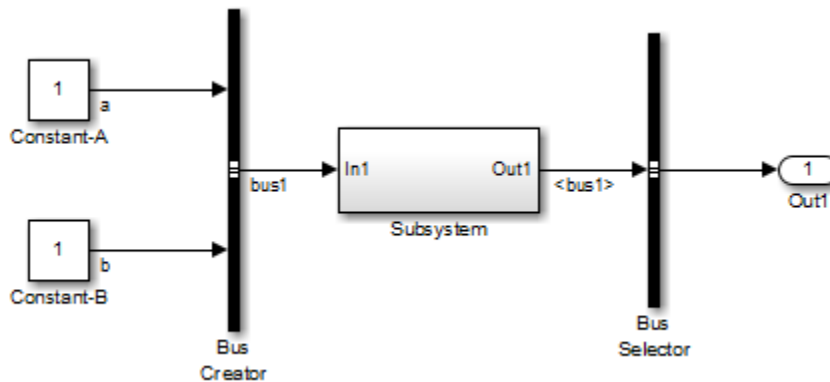

Suppose that in the Subsystem block you enable signal label propagation for the output signal from the In1 block, and you use the Signal Properties dialog box to specify the signal name `const - from` for the output signal of the From block, as shown below.

The propagated signal label for the Subsystem output signal changes to `<const - from>`, because that is the first named signal that Simulink encounters in its signal label propagation processing.

In the following model, the signal label propagation for the output signal of the Subsystem block uses the signal name `bus1`, which is the name of the output bus signal of the Bus Creator block. The propagated signal label does not include the names of the bus element signals (`a` and `b`).

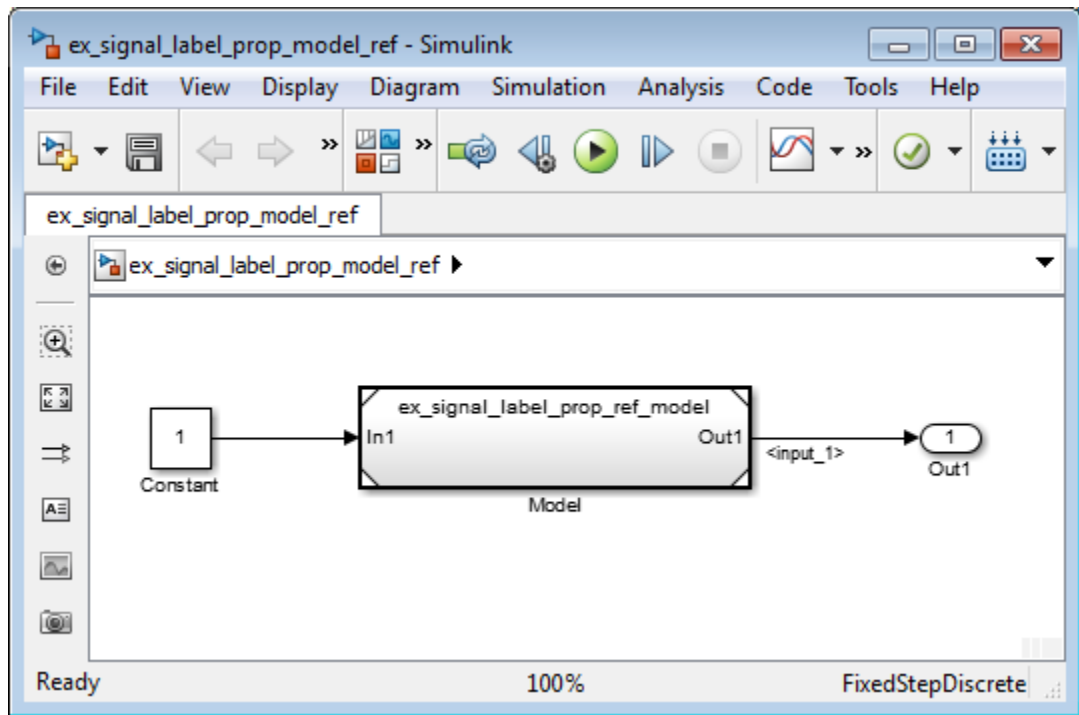

Processing for Referenced Models

To enable signal label propagation for referenced models, in addition to the steps described in “Display Propagated Signal Labels” on page 62-20, use the default setting for the **Model Configuration Parameters > Model Referencing > Propagate all signal labels out of the model** parameter. In other words, make sure the parameter is enabled.

If you make a change inside a referenced model that affects signal label propagation, the propagated signal labels outside of the referenced model do not reflect those changes until after you update the diagram or simulate the model.

For example, the model `ex_signal_label_prop_model_ref` has a referenced model that includes an output signal from the `In1` block that has a signal name of `input_1`.

If you enable signal label propagation for the signal from the `Out1` port of the Model block, that signal does *not* reflect the name `input_1` until after you update the diagram or simulate the model.

Processing for Variants and Configurable Subsystems

Simulink updates the propagated signal label (if enabled) for the output signal of the Subsystem or Model block, when *both* of these conditions occur:

- The output signals for model reference variants have different signal names.
- You change the active variant model or variant subsystem.

For Subsystem blocks, the signal label updates at edit time. For Model blocks, the update occurs when you update diagram or simulate the model.

Signal Dimensions

In this section...

“About Signal Dimensions” on page 62-30

“Simulink Blocks that Support Multidimensional Signals” on page 62-31

About Signal Dimensions

Simulink blocks can output one-dimensional, two-dimensional, or multidimensional signals. The Simulink user interface and documentation generally refer to 1-D signals as *vectors* and 2-D or multidimensional signals as *matrices*. A one-element array is frequently referred to as a *scalar*. A *row vector* is a 2-D array that has one row. A *column vector* is a 2-D array that has one column.

- A one-dimensional (1-D) signal consists of a series of one-dimensional arrays output at a frequency of one array (vector) per simulation time step.
- A two-dimensional (2-D) signal consists of a series of two-dimensional arrays output at a frequency of one 2-D array (matrix) per block sample time.
- A multidimensional signal consists of a series of multidimensional (two or more dimensions) arrays output at a frequency of one array per block sample time. You can specify multidimensional arrays with any valid MATLAB multidimensional expression, such as [4 3]. See “Multidimensional Arrays” for information on multidimensional arrays.

Simulink blocks vary in the dimensionality of the signals they can accept or output. Some blocks can accept or output signals of any dimension. Some can accept or output only scalar or vector signals. To determine the signal dimensionality of a particular block, see the block documentation. See “Determine Output Signal Dimensions” on page 62-32 for information on what determines the dimensions of output signals for blocks that can output nonscalar signals.

Note: Simulink does not support dynamic signal dimensions during a simulation. That is, the dimension of a signal must remain constant while a simulation is executing. However, you can change the size of a signal during a simulation. See “Variable-Size Signal Basics” on page 64-2.

Simulink Blocks that Support Multidimensional Signals

The Simulink Block Data Type Support table includes a column identifying the blocks with multi-dimension signal support.

- 1 In the Simulink editor, from the **Help** menu, click **Simulink > Block Data Types & Code Generation Support > All Tables**.

A separate window with the Simulink Block Data Type Support table opens.

- 2 In the Block column, locate the name of a Simulink block. Columns to the right are data types or features. An **X** in a column indicates support for that feature.

Simulink supports signals with up to 32 dimensions. Do not use signals with more than 32 dimensions.

Determine Output Signal Dimensions

In this section...

“About Signal Dimensions” on page 62-32

“Determining the Output Dimensions of Source Blocks” on page 62-32

“Determining the Output Dimensions of Nonsource Blocks” on page 62-33

“Signal and Parameter Dimension Rules” on page 62-33

“Scalar Expansion of Inputs and Parameters” on page 62-34

About Signal Dimensions

If a block can emit nonscalar signals, the dimensions of the signals that the block outputs depend on the block parameters, if the block is a source block; otherwise, the output dimensions depend on the dimensions of the block input and parameters.

Determining the Output Dimensions of Source Blocks

A *source* block is a block that has no inputs. Examples of source blocks include the **Constant** block and the **Sine Wave** block. See “Sources” for a complete listing of Simulink source blocks. The output dimensions of a source block are the same as those of its output value parameters if the block’s **Interpret vector parameters as 1-D** parameter is off (that is, not selected in the block parameter dialog box). If the **Interpret vector parameters as 1-D** parameter is on, the output dimensions equal the output value parameter dimensions unless the parameter dimensions are N-by-1 or 1-by-N. In the latter case, the block outputs a vector signal of width N.

As an example of how a source block’s output value parameter(s) and **Interpret vector parameters as 1-D** parameter determine the dimensionality of its output, consider the **Constant** block. This block outputs a constant signal equal to its **Constant value** parameter. The following table illustrates how the dimensionality of the **Constant value** parameter and the setting of the **Interpret vector parameters as 1-D** parameter determine the dimensionality of the block’s output.

Constant Value	Interpret vector parameters as 1-D	Output
scalar	off	one-element array
scalar	on	one-element array

Constant Value	Interpret vector parameters as 1-D	Output
1-by-N matrix	off	1-by-N matrix
1-by-N matrix	on	N-element vector
N-by-1 matrix	off	N-by-1 matrix
N-by-1 matrix	on	N-element vector
M-by-N matrix	off	M-by-N matrix
M-by-N matrix	on	M-by-N matrix

Simulink source blocks allow you either to specify the dimensions of the signals that they output or specify values from which Simulink infers the dimensions. You can therefore use the source blocks to introduce signals of various dimensions into your model.

Determining the Output Dimensions of Nonsource Blocks

If a block has inputs, the dimensions of its outputs are, after scalar expansion, the same as those of its inputs. (All inputs must have the same dimensions, as discussed in “Signal and Parameter Dimension Rules” on page 62-33).

Signal and Parameter Dimension Rules

When creating a Simulink model, you must observe the following rules regarding signal and parameter dimensions.

Input Signal Dimension Rule

All nonscalar inputs to a block must have the same dimensions.

A block can have a mix of scalar and nonscalar inputs as long as all the nonscalar inputs have the same dimensions. Simulink expands the scalar inputs to have the same dimensions as the nonscalar inputs (see “Scalar Expansion of Inputs and Parameters” on page 62-34).

Block Parameter Dimension Rule

In general, block parameters must have the same dimensions as the dimensions of the inputs to the block. Simulink performs some processing that provides flexibility relating to that general rule.

- A block can have scalar parameters corresponding to nonscalar inputs. In this case, Simulink expands a scalar parameter to have the same dimensions as the corresponding input (see “Scalar Expansion of Inputs and Parameters” on page 62-34).
- If an input is a vector, the corresponding parameter can be either an N-by-1 or a 1-by-N matrix. In this case, Simulink applies the N matrix elements to the corresponding elements of the input vector. This exception allows use of MATLAB row or column vectors, which are actually 1-by-N or N-by-1 matrices, respectively, to specify parameters that apply to vector inputs.

Vector or Matrix Input Conversion Rules

Simulink converts vectors to row or column matrices and row or column matrices to vectors under the following circumstances:

- If a vector signal is connected to an input that requires a matrix, Simulink converts the vector to a one-row or one-column matrix.
- If a one-column or one-row matrix is connected to an input that requires a vector, Simulink converts the matrix to a vector.
- If the inputs to a block consist of a mixture of vectors and matrices and the matrix inputs all have one column or one row, Simulink converts the vectors to matrices having one column or one row, respectively.

Note You can configure Simulink to display a warning or error message if a vector or matrix conversion occurs during a simulation. See “Vector/matrix block input conversion” for more information.

Scalar Expansion of Inputs and Parameters

Scalar expansion is the conversion of a scalar value into a nonscalar array. Many Simulink blocks support scalar expansion of inputs and parameters. Block-specific descriptions indicate whether Simulink applies scalar expansion to a block's inputs and parameters.

Scalar expansion of inputs refers to the expansion of scalar inputs to match the dimensions of other nonscalar inputs or nonscalar parameters. When the input to a block is a mix of scalar and nonscalar signals, Simulink expands the scalar inputs into nonscalar signals having the same dimensions as the other nonscalar inputs. For

example, a scalar of 4 is expanded to the vector [4 4 4] if the associated nonscalar has a dimension of 3.

Scalar expansion of parameters refers to the expansion of scalar block parameters to match the dimensions of nonscalar inputs.

Input(s)	Associated Block Parameter	Scalar Expansion
Scalar	Nonscalar	Input expanded to match parameter dimensions. See “Scalar Input and Nonscalar Parameter” on page 62-35.
Nonscalar	Scalar	Scalar parameter expanded to match number of elements of input. See “Nonscalar Input and Scalar Parameter” on page 62-36.
Combination of scalar and nonscalar	No corresponding parameter	Scalar inputs expanded to match dimensions of largest nonscalar input. See “Scalar and Nonscalar Inputs and No Associated Parameter” on page 62-36.

Scalar Input and Nonscalar Parameter

In this example, the Constant block input to the Gain block is scalar. The Gain block **Gain** parameter is a nonscalar. Simulink expands the scalar input to match the dimensions of a nonscalar **Gain** parameter, as reflected in the simulation results in the Display block.

Nonscalar Input and Scalar Parameter

In this example, the Constant block input to the Gain block is nonscalar. The Gain block **Gain** parameter is a scalar. Simulink expands the scalar parameter to match the dimensions of a nonscalar input from the Constant block, as reflected in the simulation results in the Display block.

Scalar and Nonscalar Inputs and No Associated Parameter

In this example, the Constant1 block input to the Sum block is nonscalar, and the Constant2 block input is scalar. The Sum block has no associated parameter. Simulink expands the scalar input from Constant2 to match to the dimensions of the nonscalar Constant1 block input. The input is expanded to the vector [3 3 3].

Display Signal Sources and Destinations

In this section...
“About Signal Highlighting” on page 62-38
“Highlighting Signal Sources” on page 62-38
“Highlighting Signal Destinations” on page 62-39
“Removing Highlighting” on page 62-40
“Resolving Incomplete Highlighting to Library Blocks” on page 62-40

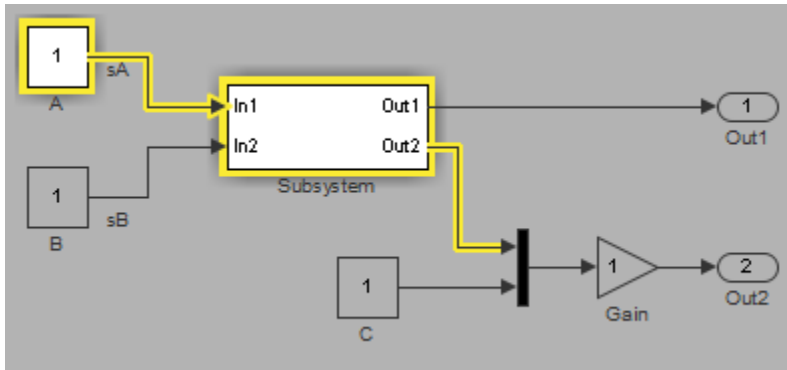

About Signal Highlighting

You can highlight a signal and its source or destination block(s), then remove the highlighting once it has served its purpose. Signal highlighting crosses subsystem boundaries, allowing you to trace a signal across multiple subsystem levels. Highlighting does not cross the boundary into or out of a referenced model. If a signal is composite, all source or destination blocks are highlighted. (See “Overview of Composite Signal Techniques” on page 63-3.)

Highlighting Signal Sources

To display the source block(s) of a signal, select the **Highlight Signal to Source** option from the context menu for the signal. This option highlights:

- All branches of the signal anywhere in the model
- All virtual blocks through which the signal passes
- The nonvirtual block(s) that write the value of the signal

Highlighting Signal Destinations

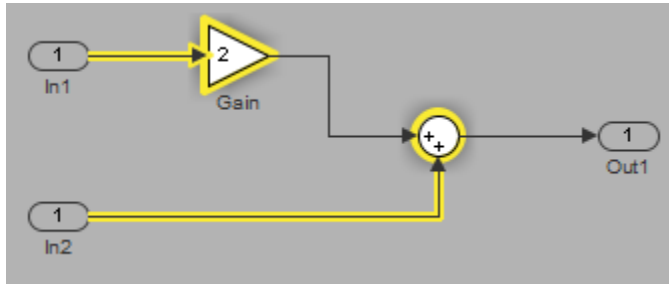

To display the destination blocks of a signal, select the **Highlight Signal to Destination** option from the context menu for the signal. This option highlights:

- All branches of the signal anywhere in the model
- All virtual blocks through which the signal passes
- The nonvirtual block(s) that read the value of the signal
- The signal and destination block for all blocks that are duplicates of the inport block for the line that you select

In this example, the selected signal highlights the Gain block as the destination block.

In the next example, selecting the signal from In2 and choosing the **Highlight Signal to Destination** option highlights the signal and destination block for In2 and In1, because In1 and In2 are duplicate import blocks.

Removing Highlighting

To remove all highlighting, select **Remove Highlighting** from the model's context menu, or select **Display > Remove Highlighting**.

Resolving Incomplete Highlighting to Library Blocks

If the path from a source block or to a destination block includes an unresolved reference to a library block, the highlighting options highlight the path from or to the library block, respectively. To display the complete path, first update the diagram (for example, by pressing **Ctrl+D**). The update of the diagram resolves all library references and displays the complete path to a destination block or from a source block.

Signal Ranges

In this section...

“About Signal Ranges” on page 62-41

“Blocks That Allow Signal Range Specification” on page 62-41

“Specifying Ranges for Signals” on page 62-42

“Checking for Signal Range Errors” on page 62-43

“Optimize Generated Code” on page 62-46

About Signal Ranges

Many Simulink blocks allow you to specify a range of valid values for their output signals. Simulink provides a diagnostic that you can enable to detect when blocks generate signals that exceed their specified ranges during simulation. See the sections that follow for more information.

Blocks That Allow Signal Range Specification

The following blocks allow you to specify ranges for their output signals:

- Abs
- Constant
- Data Store Memory
- Data Type Conversion
- Difference
- Discrete Derivative
- Discrete-Time Integrator
- Gain
- Inport
- Interpolation Using Prelookup
- 1-D Lookup Table
- 2-D Lookup Table
- n-D Lookup Table
- Math Function

- MinMax
- Multiport Switch
- Outport
- Product, Divide, Product of Elements
- Relay
- Repeating Sequence Interpolated
- Repeating Sequence Stair
- Saturation
- Saturation Dynamic
- Signal Specification
- Sum, Add, Subtract, Sum of Elements
- Switch

Specifying Ranges for Signals

In general, use the **Output minimum** and **Output maximum** parameters that appear on a block parameter dialog box to specify a range of valid values for the block output signal. Exceptions include the **Data Store Memory**, **Inport**, **Outport**, and **Signal Specification** blocks, for which you use their **Minimum** and **Maximum** parameters to specify a signal range. See “Blocks That Allow Signal Range Specification” on page 62-41 for a list of applicable blocks.

When specifying minimum and maximum values that constitute a range, enter only expressions that evaluate to a scalar, real number with **double** data type. The default values for the minimum and maximum are [] (unspecified). The scalar values that you specify are subject to expansion, for example, when the block inputs are nonscalar or bus signals (see “Scalar Expansion of Inputs and Parameters” on page 62-34).

Note: You cannot specify the minimum or maximum value as NaN, inf, or -inf.

Specifying Ranges for Complex Numbers

When you specify an **Output minimum** and/or **Output maximum** for a signal that is a complex number, the specified minimum and maximum values apply separately to the real part and to the imaginary part of the complex number. If the value of either part of the number is less than the minimum, or greater than the maximum, the complex

number is outside the specified range. No range checking occurs against any combination of the real and imaginary parts, such as $(\text{sqr}t(a^2+b^2))$

Checking for Signal Range Errors

Simulink provides a diagnostic named **Simulation range checking**, which you can enable to detect when signals exceed their specified ranges during simulation. When enabled, Simulink compares the signal values that a block outputs with both the specified range (see “Specifying Ranges for Signals” on page 62-42) and the block data type. That is, Simulink performs the following check:

$$\text{DataTypeMin} \leq \text{MinValue} \leq \text{VALUE} \leq \text{MaxValue} \leq \text{DataTypeMax}$$

where

- **DataTypeMin** is the minimum value representable by the block data type.
- **MinValue** is the minimum value the block should output, specified by, e.g., **Output minimum**.
- **VALUE** is the signal value that the block outputs.
- **MaxValue** is the maximum value the block should output, specified by, e.g., **Output maximum**.
- **DataTypeMax** is the maximum value representable by the block data type.

Note: It is possible to overspecify how a block handles signals that exceed particular ranges. For example, you can specify values (other than the default values) for both signal range parameters and enable the **Saturate on integer overflow** parameter. In this case, Simulink displays a warning message that advises you to disable the **Saturate on integer overflow** parameter.

Enabling Simulation Range Checking

To enable the **Simulation range checking** diagnostic:

- 1 In your model window, select **Simulation > Model Configuration Parameters**.
Simulink displays the Configuration Parameters dialog box.
- 2 In the **Select** tree on the left side of the Configuration Parameters dialog box, click the **Diagnostics > Data Validity** category. On the right side under **Signals**, set the **Simulation range checking** diagnostic to error or warning.

Signals			
Signal resolution:	Explicit only	Wrap on overflow:	warning
Division by singular matrix:	none	Saturate on overflow:	warning
Underspecified data types:	none	Inf or NaN block output:	none
Simulation range checking:	none	"rt" prefix for identifiers:	Detect Inf or NaN block outputs during simulation

3 Click **OK** to apply your changes and close the Configuration Parameters dialog box.

See “Simulation range checking” for more information.

Simulating Models with Simulation Range Checking

To check for signal range errors or warnings:

- 1 Enable the **Simulation range checking** diagnostic for your model (see “Enabling Simulation Range Checking” on page 62-43).
- 2 In your model window, select **Simulation > Run** to simulate the model.

Simulink simulates your model and performs signal range checking. If a signal exceeds its specified range when the **Simulation range checking** diagnostic specifies **error**, Simulink stops the simulation and displays an error message:

Otherwise, if a signal exceeds its specified range when the **Simulation range checking** diagnostic specifies **warning**, Simulink displays a warning message in the MATLAB Command Window:

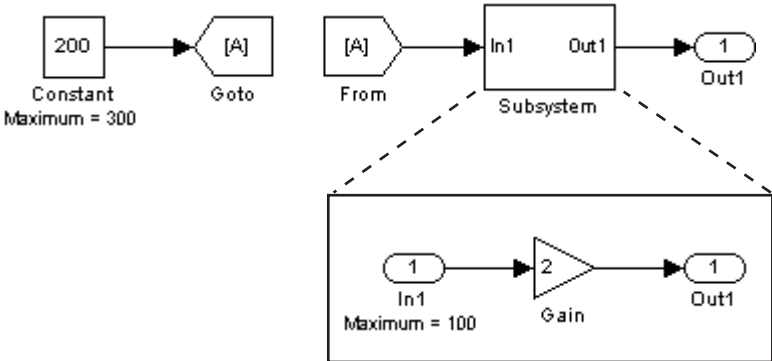

```
Warning: Inconsistent numeric values for port 1  
of 'example/Gain': Output value (21) at major  
time step 4.2 is greater than maximum (20) from  
'example/Gain'.
```

Each message identifies the block whose output signal exceeds its specified range, and the time step at which this violation occurs.

Signal Range Propagation for Virtual Blocks

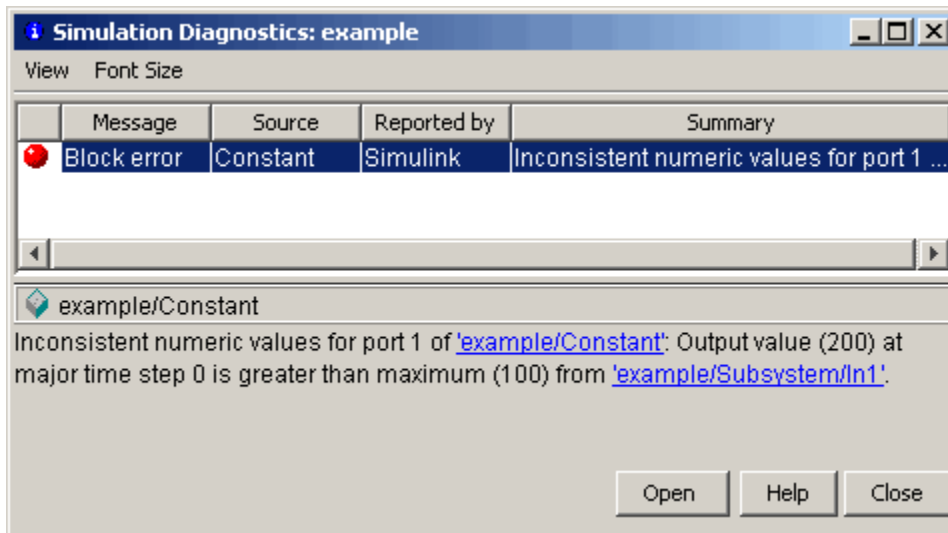

Some virtual blocks (see “Nonvirtual and Virtual Blocks” on page 33-2) allow you to specify ranges for their output signals, for example, the **Inport** and **Outport** blocks. When the **Simulation range checking** diagnostic is enabled for a model that contains such blocks, the signal range of the virtual block propagates backward to the first instance of a nonvirtual block whose output signal it receives. If the nonvirtual block specifies different values for its own range, Simulink performs signal range checking with the *tightest* range possible. That is, Simulink checks the signal using the larger minimum value and the smaller maximum value.

For example, consider the following model:

In this model, the Constant block specifies its **Output maximum** parameter as 300, and that of the Inport block is set to 100. Suppose you enable the **Simulation range checking** diagnostic and simulate the model. The Inport block back propagates its maximum value to the nonvirtual block that precedes it, i.e., the Constant block.

Simulink then uses the smaller of the two maximum values to check the signal that the Constant block outputs. Because the Constant block outputs a signal whose value (200) exceeds the tightest range, Simulink displays the following error message:

Optimize Generated Code

If you have Embedded Coder, Simulink Coder can optimize the code that you generate from the model by taking into account the minimum and maximum values that you specify for signals and parameters. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values”.

“Initialization Behavior Summary for Signal Objects” on page 62-52

About Initialization

Note: For information about initializing bus signals, see “Specify Initial Conditions for Bus Signals” on page 63-80.

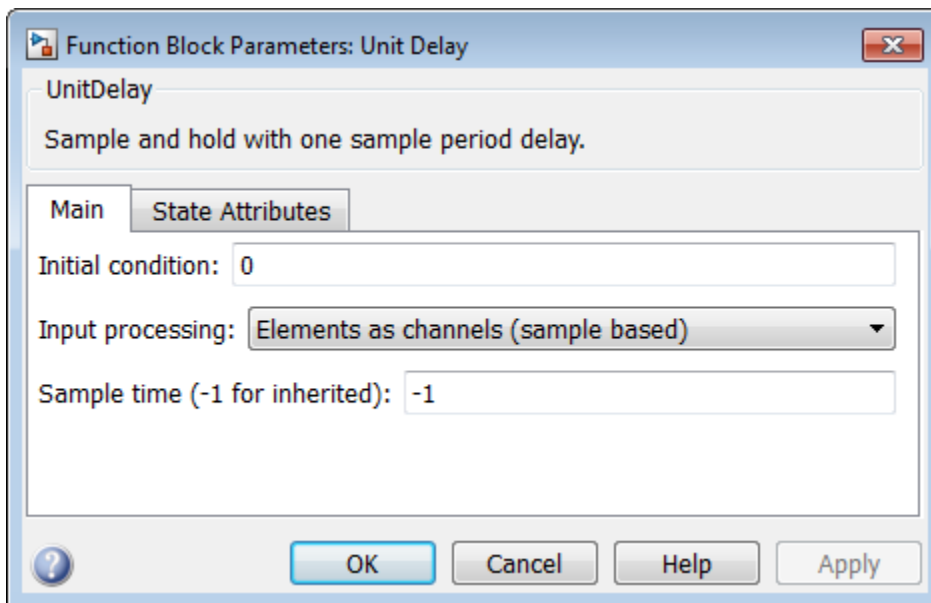

Simulink allows you to specify the initial values of signals and discrete states, i.e., the values of the signals and discrete states at the **Start time** of the simulation. You can use signal objects to specify the initial values of any signal or discrete state in a model. In addition, for some blocks, e.g., **Outport**, **Data Store Memory**, or **Memory**, you can use either a signal object or a block parameter or both to specify the initial value of a block state or output. In such cases, Simulink checks to ensure that the values specified by the signal object and the parameter are consistent.

When you specify a signal object for signal or discrete state initialization, or a variable as the value of a block parameter, Simulink resolves the name that you specify to an appropriate object or variable, as described in “Symbol Resolution” on page 4-82.

A given signal can be associated with at most one signal object under any circumstances. The signal can refer to the object more than once, but every reference must resolve to exactly the same object. A different signal object that has exactly the same properties will not meet the requirement for uniqueness. A compile-time error occurs if a model associates more than one signal object with any signal. For more information, see `Simulink.Signal` and the `Merge` block.

Using Block Parameters to Initialize Signals and Discrete States

For blocks that have an initial value or initial condition parameter, you can use that parameter to initialize a signal. For example, the following Block Parameters dialog box initializes the signal for a Unit Delay block with an initial condition of 0.

Use Signal Objects to Initialize Signals and Discrete States

You can use signal objects that have a storage class other than 'auto' or 'SimulinkGlobal' to initialize

- Discrete states with an initial condition parameter
- Signals in a model except bus signals and blocks that output constant value

To specify an initial value, use the Model Explorer or MATLAB commands to do the following:

- 1 Create the signal object.

On the Model Explorer toolbar, select **Add > Simulink Signal**. The signal object appears in the base workspace with a default name. Rename the object as **S1**. Alternatively, use this command at the command prompt:

```
S1 = Simulink.Signal;
```

The name of the signal object must be the same as the name of the signal that the object is initializing. Although not required, consider setting the **Signal name must resolve to Simulink signal object** option in the Signal Properties dialog box. This setting makes signal objects in the MATLAB workspace consistent with signals that appear in your model.

Consider using the Data Object Wizard to create signal objects. The Data Object Wizard searches a model for signals for which signal objects do not exist. You can then selectively create signal objects for multiple signals listed in the search results with a single operation. For more information about the Data Object Wizard, see “Create Data Objects for a Model Using Data Object Wizard” on page 57-62 in the Simulink documentation.

- 2 Set the signal object's storage class to a value other than **auto** or **SimulinkGlobal**. In the Model Explorer **Contents** pane, select the signal object. In the Dialog pane, set **Storage class** to **ExportedGlobal**. Alternatively, use this command at the command prompt:

```
S1.CoderInfo.StorageClass = 'ExportedGlobal';
```

- 3 Set the initial value. You can specify a MATLAB expression, including the name of a workspace variable, that evaluates to a numeric scalar value or array.

The Simulink engine converts the initial value so the type, complexity, and dimension are consistent with the corresponding block parameter value. If you specify an invalid value or expression, an error message appears when you update the model.

In the Model Explorer Dialog pane, set **Initial value** to **0.5**. Alternatively, use this command at the command prompt:

```
S1.InitialValue = '0.5'
```

If you can also use a block parameter to set the initial value of the signal or state, you should set the parameter either to empty (`[]`) or to the same value as the initial value of the signal object. If you set the parameter value to empty, Simulink uses

the value specified by the signal object to initialize the signal or state. If you set the parameter to any other value, Simulink compares the parameter value to the signal object value and displays an error if they differ.

Some initial value settings may depend on the initialization mode. For more information, see “Underspecified initialization detection”.

Classic initialization mode: In this mode, initial value settings for signal objects that represent the following signals and states override the corresponding block parameter initial values if undefined (specified as []):

- Output signals of conditionally executed subsystems and Merge blocks
- Block states

Simplified initialization mode: In this mode, initial values of signal objects associated with the output of the following blocks are ignored. The initial values of the corresponding blocks are used instead.

- Output signals of conditionally executed subsystems
- Merge blocks

Using Signal Objects to Tune Initial Values

Simulink allows you to use signal objects as an alternative to parameter objects (see `Simulink.Parameter`) to tune the initial values of block outputs and states that can be specified via a tunable parameter. To use a signal object to tune an initial value, create a signal object with the same name as the signal or state and set the signal object's initial value to an expression that includes a variable defined in the MATLAB workspace. You can then tune the initial value by changing the value of the corresponding workspace variable during the simulation.

For example, suppose you want to tune the initial value of a `Memory` block state named `M1`. To do this, you might create a signal object named `M1`, set its storage class to `'ExportedGlobal'`, set its initial value to `K` (`M1.InitialValue='K'`), where `K` is a workspace variable in the MATLAB workspace, and set the corresponding initial condition parameter of the `Memory` block to [] to avoid consistency errors. You could then change the initial value of the `Memory` block's state any time during the simulation by changing the value of `K` at the MATLAB command line and updating the block diagram (e.g., by typing **Ctrl+D**).

Example: Using a Signal Object to Initialize a Subsystem Output

The following example shows a signal object specifying the initial output of an enabled subsystem.

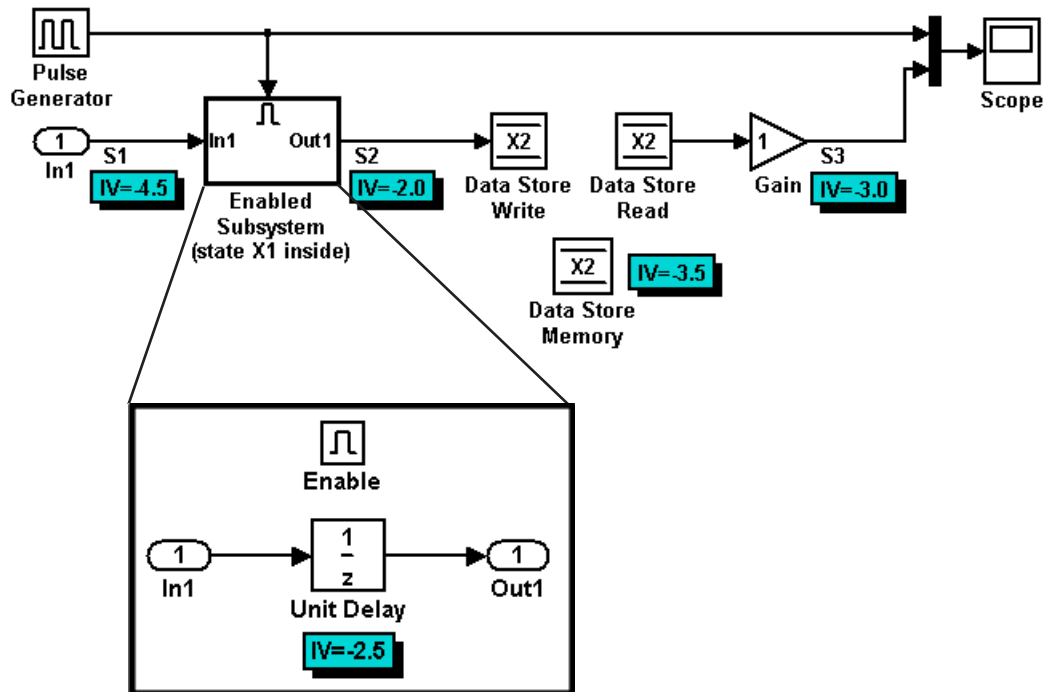

Signal `s` is initialized to 4.5. To avoid a consistency error, the initial value of the enabled subsystem's Output block must be `[]` or 4.5.

If you need a signal object and its initial value setting to persist across Simulink sessions, see "Create Persistent Data Objects" on page 57-73.

Initialization Behavior Summary for Signal Objects

The following model and table show different types of signals and discrete states that you can initialize and the simulation behavior that results for each.

Signal or Discrete State	Description	Behavior
S1	Root inport	<ul style="list-style-type: none"> Initialized to <code>S1.InitialValue</code>. If you use the Data Import/Export pane of the Configuration Parameters dialog to specify values for the root inputs, the initial value is overwritten and may differ at each time step. Otherwise, the value remains constant.
X1	Unit Delay block — Block with a discrete state that	<ul style="list-style-type: none"> Initialized to <code>X1.InitialValue</code>. Simulink checks whether <code>X1.InitialValue</code> matches the initial condition specified for the block and displays an error if a mismatch occurs.

Signal or Discrete State	Description	Behavior
	has an initial condition	<ul style="list-style-type: none"> At first write, the output equals <code>X1.InitialValue</code> and the state equals <code>S1</code>. At each time step after the first write, the output equals the state and the state is updated to equal <code>S1</code>. If the block is inside an enabled subsystem, you can use the initial value as a reset value if the subsystem's Enable block parameter States when enabling is set to reset.
X2	Data Store Memory block	<ul style="list-style-type: none"> Data type work (DWork) vector initialized to <code>X2.InitialValue</code>. For information on work vectors, see “DWork Vector Basics”. Simulink checks whether <code>X2.InitialValue</code> matches the initial condition specified for the block, and displays an error if a mismatch occurs. Data Store Write blocks overwrite the value.
S2	Output of an enabled subsystem	<ul style="list-style-type: none"> Initialized to <code>S2.InitialValue</code> or the value of the Outputport block. If multiple initial values are specified for the same signal, all initial values must be the same. The first write occurs when the subsystem is enabled. The block feeding the subsystem output sets the value. The initial value is also used as a reset value if the subsystem's Enable block parameter States when enabling or Outputport block parameter Output when disabled is set to reset.
S3	Persistent signals	<ul style="list-style-type: none"> Initialized to <code>S3.InitialValue</code>. The output value is reset by the block at each time step. Affects code generation only. For simulation, setting the initial value for <code>S3</code> is irrelevant because the values are overwritten at the model's simulation start time.

Test Points

In this section...

“What Is a Test Point?” on page 62-55

“Configure Signals as Test Points” on page 62-55

“Displaying Test Point Indicators” on page 62-56

What Is a Test Point?

A *test point* is a signal that Simulink guarantees to be observable when using a **Floating Scope** block in a model. Simulink allows you to designate any signal in a model as a test point.

Designating a signal as a test point exempts the signal from model optimizations, such as signal storage reuse (see “Signal storage reuse”) and block reduction (see “Implement logic signals as Boolean data (vs. double)”). These optimizations render signals inaccessible and hence unobservable during simulation.

Signals designated as test points will not have algebraic loops minimized, even if **Minimize algebraic loop occurrences** is selected (for more information about algebraic loops, see “Algebraic Loops” on page 3-38).

Test points are primarily intended for use when generating code from a model with Simulink Coder. For more information about test points in the context of code generation, see “Signals with Test Points”.

Marking a signal as a test point has no impact on signal logging that uses the **Dataset** logging format. For information about logging signals, see “Export Signal Data Using Signal Logging” on page 59-57.

Configure Signals as Test Points

Use one of the following ways to designate a signal as a test point:

- Open the signal's **Signal Properties** dialog and check **Test Point** in the **Logging and accessibility** section.
- Use the Model Data Editor for batch configuration and for signals that are difficult to locate in a large model or hierarchy of subsystems. On the **Signals** tab, set the

Change View drop-down list to **Instrumentation** and use the **Test point** column. For information about the Model Data Editor, see “Configure Data Properties by Using a Table” on page 57-103.

- To configure Stateflow data in a chart as test points, see “Monitor Test Points in Stateflow Charts”.

To configure a signal as a test point programmatically:

- 1 Get handles to the ports of the block.

```
portHandles = get_param('myModel/myBlock','portHandles');
```

portHandles is a structure. Each field stores a handle to a block port.

- 2 Extract a handle to the output port that creates the target signal line.

```
outportHandle = portHandles.Outputport;
```

- 3 Set the port parameter TestPoint to 'on'.

```
set_param(outportHandle,'TestPoint','on')
```

Displaying Test Point Indicators

By default, Simulink displays an indicator on each signal whose **Signal Properties > Test point** option is enabled. For example, in the following model signals **s2** and **s3** are test points:

Note: Simulink does not display an indicator on a signal that is specified as a test point by a `Simulink.Signal` object, because such a specification is external to the graphical model.

A signal that is a test point can also be logged. See “Export Signal Data Using Signal Logging” on page 59-57 for information about signal logging. The appearance of the indicator changes to indicate signals for which logging is also enabled.

To turn display of test point indicators on or off, in the Simulink Editor, select or clear **Display > Signals & Ports > Testpoint & Logging Indicators**.

Display Signal Attributes

In this section...

“Ports & Signals Menu” on page 62-58

“Port Data Types” on page 62-59

“Design Ranges” on page 62-59

“Signal Dimensions” on page 62-60

“Signal to Object Resolution Indicator” on page 62-60

“Wide Nonscalar Lines” on page 62-61

Ports & Signals Menu

The **Display > Signals & Ports** submenu of the Simulink Editor offers the following options for displaying signal properties on the block diagram:

- Linearization Indicators
- Port Data Types (See “Port Data Types” on page 62-59)
- Design Ranges (See “Design Ranges” on page 62-59)
- Signal Dimensions (See “Signal Dimensions” on page 62-60)
- Storage Class
- Testpoint/Logging Indicators
- Signal Resolution Indicators (See “Signal to Object Resolution Indicator” on page 62-60)
- Viewer Indicators
- Wide Nonscalar Lines (See “Wide Nonscalar Lines” on page 62-61)

In addition, you can display sample time information. If you first select **Display > Sample Time**, a submenu provides the choices of **Colors**, **Annotations** and **All**. The **Colors** option allows the block diagram signal lines and blocks to be color-coded based on the sample time types and relative rates. The **Annotations** option provides black codes on the signal lines which indicate the type of sample time. **All** causes both the colors and the annotations to display. All of these options cause a Sample Time Legend to appear. The legend contains a description of the type of sample time and the sample time

rate. If **Colors** is turned 'on', color codes also appear in the legend. The same is true if **Annotations** are turned 'on'.

Port Data Types

Displays the data type of a signal next to the output port that emits the signal.

The notation (c) following the data type of a signal indicates that the signal is complex.

Design Ranges

Displays the compiled design range of a signal next to the output port that emits the signal. The ranges are computed during an update diagram.

Ranges are displayed in the format [min..max]. In the above example, the design range at the output port of the Mux block is displayed as [-10..mixed], because the two

signals the Mux block combines have the same design minimum but different design maximums.

You can also use command-line parameters `CompiledPortDesignMin` and `CompiledPortDesignMax` to access the design minimum and maximum of port signals, respectively, at compile time. For more information, see “Common Block Properties”.

Signal Dimensions

Display the dimensions of nonscalar signals next to the line that carries the signal.

The format of the display depends on whether the line represents a single signal or a bus. If the line represents a single vector signal, Simulink displays the width of the signal. If the line represents a single matrix signal, Simulink displays its dimensions as $[N_1 \times N_2]$ where N_i is the size of the i th dimension of the signal. If the line represents a bus carrying signals of the same data type, Simulink displays $N\{M\}$ where N is the number of signals carried by the bus and M is the total number of signal elements carried by the bus. If the bus carries signals of different data types, Simulink displays only the total number of signal elements $\{M\}$.

Signal to Object Resolution Indicator

The Simulink Editor by default graphically indicates signals that must resolve to signal objects. For any labeled signal whose **Signal name must resolve to signal object** property is enabled, a signal resolution icon appears to the left of the signal name. The icon looks like this:

A signal resolution icon indicates only that a signal's **Signal name must resolve to signal object** property is enabled. The icon does not indicate whether the signal is actually resolved, and does not appear on a signal that is implicitly resolved without its **Signal name must resolve to signal object** property being enabled.

Where multiple labels exist, each label displays a signal resolution icon. No icon appears on an unlabeled branch. In the next figure, signal `x2` must resolve to a signal object, so a signal resolution icon appears to the left of the signal name in each label:

To suppress the display of signal resolution icons, in the model window deselect **Display > Signals & Ports > Signal to Object Resolution Indicator**, which is selected by default. To restore signal resolution icons, reselect **Signal to Object Resolution Indicator**. Individual signals cannot be set to show or hide signal resolution indicators independently of the setting for the whole model. For additional information, see:

- “Symbol Resolution” on page 4-82
- “Initialize Signals and Discrete States” on page 62-47
- Simulink.Signal

Wide Nonscalar Lines

Draws lines that carry vector or matrix signals wider than lines that carry scalar signals.

See “Mux Signals” on page 62-11 for more information about vector and matrix signals.

“Simulating with Signal Groups” on page 62-111

“Simulation Options Dialog Box” on page 62-112

About Signal Groups

The **Signal Builder** block displays and allows you to create or edit interchangeable groups of signal sources and quickly switch the groups into and out of a model.

Signal groups can greatly facilitate testing a model, especially when you use them with conjunction with **Simulink Assertion** blocks and the **Model Coverage Tool** from the **Simulink Verification and Validation**. For a description of the **Model Coverage Tool**, see “**Model Coverage Collection Workflow**”.

Model Configuration Parameter Solver pane settings can affect the **Signal Builder** block output. See “**Simulation Phases in Dynamic Systems**” on page 3-17 and “**Solvers**” on page 3-21 for a description of how solvers affect simulation.

Using the Signal Builder Block with Fast Restart

After you turn on fast restart:

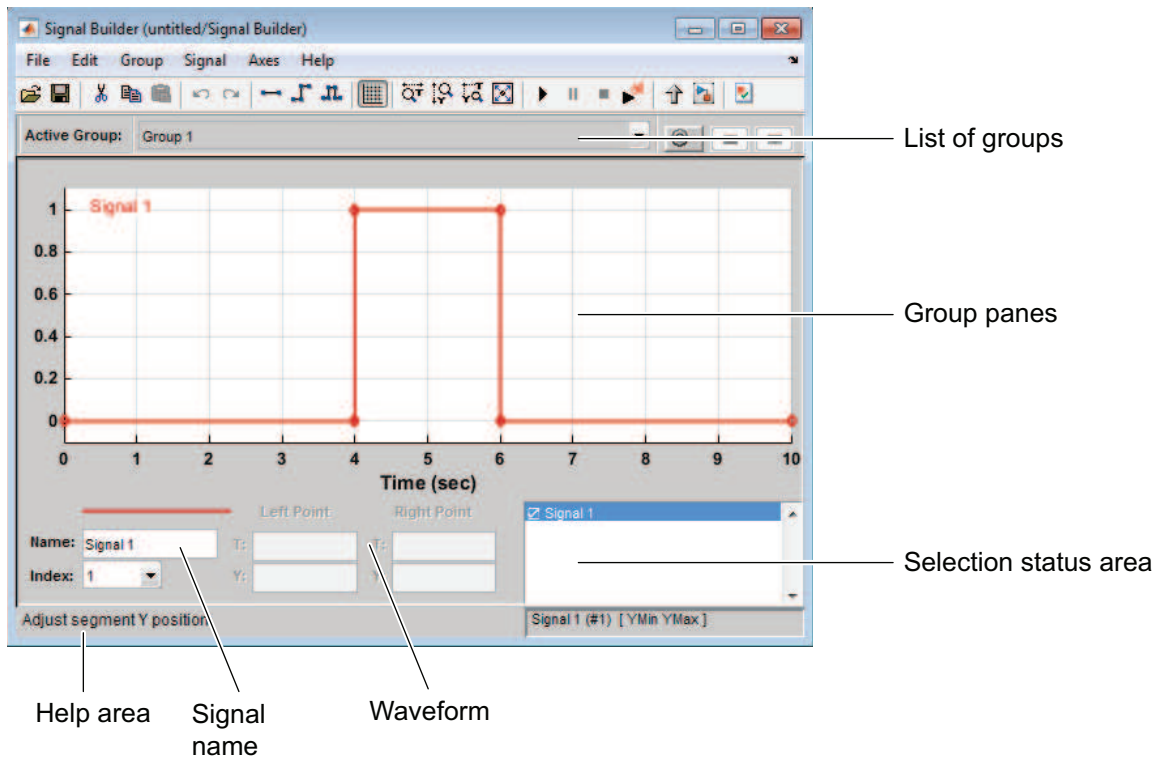

- In between runs, you can change data, rename signals and signal groups, and add new groups. You cannot:
 - Import signals or signal groups

- Change signal output settings
- You can click the **Run all** button once. To reenale the **Run all** button, toggle the fast restart button on the Simulink Editor tool bar. However, **Run all** does not use fast restart.

Signal Builder Window

The Signal Builder block window allows you to define the shape of the signals (waveform) output by the block. You can specify any waveform that is piecewise linear.

To open the window, double-click the block. The Signal Builder window appears.

The Signal Builder window allows you to create and modify signal groups represented by a Signal Builder block. The Signal Builder window includes the following controls.

Group Pane

Displays the set of interchangeable signal source groups represented by the block. The pane for each group displays an editable representation of each waveform in the group. The name of the group appears at the top of the pane. Only one pane is visible at a time. To display a group that is not visible, from the list, select the group name. The block outputs the group of signals whose pane is currently visible. Each pane occupies a pane in the Signal Builder block dialog box.

Signal Axes

The signals appear on separate axes that share a common time range (see “Signal Builder Time Range” on page 62-109). This presentation allows you to compare the relative timing of changes in each signal. The Signal Builder automatically scales the range of each axis to accommodate the signal that it displays. Use the Signal Builder **Axes** menu to change the time (T) and amplitude (Y) ranges of the selected axis.

Signal List

Displays the names and visibility (see “Editing Signals” on page 62-67) of the signals that belong to the currently selected signal group. Clicking an entry in the list selects the signal. Double-clicking a signal entry in the list hides or displays the waveform on the group pane.

Selection Status Area

Displays the name of the currently selected signal and the index of the currently selected waveform segment or point.

Waveform Coordinates

Displays the coordinates of the currently selected waveform segment or point. You can change the coordinates by editing the displayed values (see “Editing Waveforms” on page 62-104).

Name

Name of the currently selected signal. You can change the name of a signal by editing this field (see “Renaming a Signal” on page 62-73).

Index

Index of the currently selected signal. The index indicates the output port at which the signal appears. An index of 1 indicates the topmost output port, 2 indicates the second

port from the top, and so on. You can change the index of a signal by editing this field (see “Changing a Signal Index” on page 62-76).

Help Area

Displays context-sensitive tips on using Signal Builder window features.

Editing Signal Groups

The Signal Builder window allows you to create, rename, move, then delete signal groups from the set of groups represented by a Signal Builder block.

Creating and Deleting Signal Groups

To create a signal group:

- 1** In Signal Builder, copy an existing signal group.
- 2** Modify it to suit your needs.

To copy an existing signal group:

- 1** In Signal Builder, select the group from the list.
- 2** Select **Group > Copy**.

A new group is created.

To delete a group, select the group from the list, and select **Group > Delete**.

Renaming Signal Groups

To rename a signal group:

- 1** In Signal Builder, select the group from the list,
- 2** Select **Group > Rename**.

A dialog box appears.

- 3** Edit the existing name in the dialog box or enter a new name. Click **OK**.

Moving Signal Groups

To reposition a group in the stack of group panes:

- 1** In Signal Builder, select the pane.
- 2** To move the group lower in the stack, select **Group > Move Down**.
- 3** To move the pane higher in the stack, select **Group > Move Up**.

Editing Signals

Signal Builder allows you to create, cut and paste, hide, and delete signals from signal groups.

Creating Signals

To create a signal in the currently selected signal group:

- 1 In Signal Builder, from the Active Group list, select the group you want to add the signal to.
- 2 Select **Signal > New**.

The menu lists the waveforms you can add (described in the table).

Waveform	Description	Inputs
Constant	Constant waveform	None.
Step	Step waveform	None.
Pulse	Pulse waveform	None.
Square	Square waveform	<ul style="list-style-type: none"> • Frequency Waveform frequency, in hertz • Amplitude Waveform amplitude • Offset Waveform vertical offset • % Duty cycle Percent of the period the signal is positive (a value between 0 and 100)
Triangle	Triangle waveform	<ul style="list-style-type: none"> • Frequency Waveform frequency, in hertz. • Amplitude Waveform amplitude

Waveform	Description	Inputs
		<ul style="list-style-type: none"> • Offset Waveform vertical offset
Sampled Sin	Sampled sinewave waveform	<ul style="list-style-type: none"> • Frequency (Hz) Waveform frequency, in hertz • Amplitude Waveform amplitude • Offset Waveform vertical offset • Samples Per Period Number of samples per waveform period
Sampled Gaussian Noise	Sampled Gaussian noise waveform based on a Gaussian distribution with input mean and standard deviation at input frequency	<ul style="list-style-type: none"> • Frequency Waveform frequency, in hertz • Mean The mean value of the random variable output • Standard Deviation The standard deviation squared of the random variable output • Seed (empty to use current state) The initial seed value for the random number generator

Waveform	Description	Inputs
Pseudorandom Noise	Pseudorandom noise waveform based on a binomial distribution with upper and lower values at input frequency	<ul style="list-style-type: none"> • Frequency Frequency with which waveform fluctuates between Upper value and Lower value, in hertz • Upper value Upper limit of signal • Lower value Lower limit of signal • Seed The initial seed value for the random number generator
Poisson Random Noise	Poisson random noise waveform that alternates between 0 and 1	<ul style="list-style-type: none"> • Avg rate (1/sec) Average rate of transition between 0 and 1 • Seed (empty to use current state) The initial seed value for the random number generator

Waveform	Description	Inputs
Custom	Custom piecewise linear waveform; custom values must fit within the display area	<ul style="list-style-type: none"> <li data-bbox="863 302 1074 329">• Time values <p data-bbox="902 361 1233 418">Vector of two or more time coordinates</p> <li data-bbox="863 435 1020 463">• Y values <p data-bbox="902 494 1325 586">Vector of two or more signal amplitudes that correspond to the values in Time values</p> <p data-bbox="863 618 1322 805">The entries in either field can be any MATLAB expression that evaluates to a vector, including the results from the evaluation of a MATLAB workspace variable. The resulting vectors must be of equal length.</p> <hr/> <p data-bbox="863 869 1288 994">Note: Signal Builder displays a warning if you add a custom waveform with a large number of data points (100,000,000 or more).</p>

- 3 Select the waveform you want to add.
- 4 Specify the inputs (in prompt), and click **OK**.

If you select a standard waveform, Signal Builder adds a signal with that waveform to the group. If you select a custom waveform, you are prompted for **Time values** and **Y values**.

You can also use MATLAB workspace variables to create new signals.

- 1 In the MATLAB Command Window, create data for two variables, t and y .

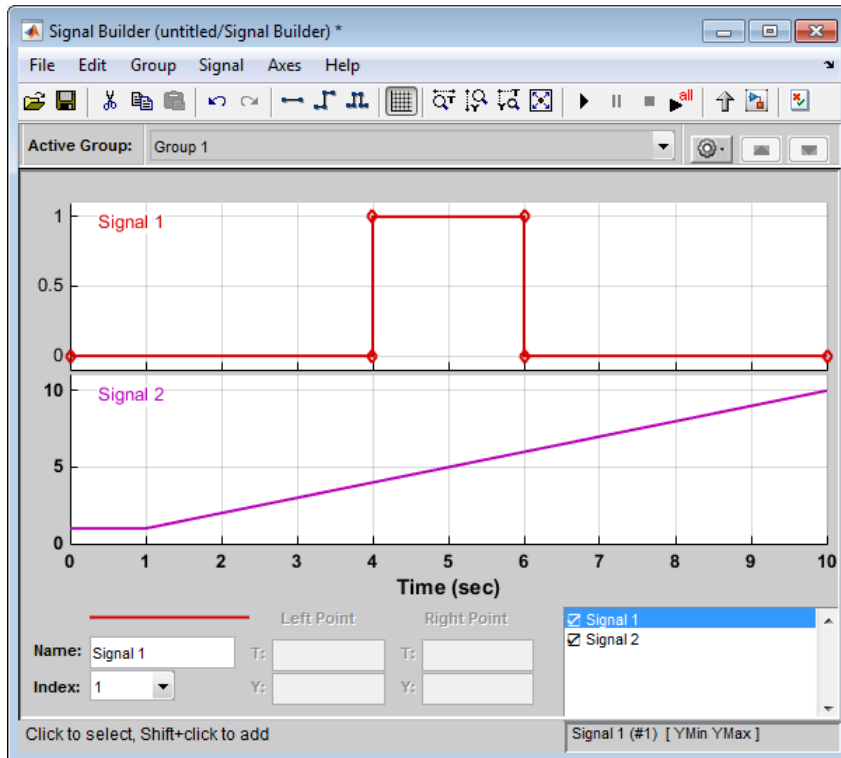

```
t = 1:10
y = 1:10
```

These vectors must be the same size.

- 2 Create a model and add a Signal Builder block.
- 3 Double-click the Signal Builder block.

- 4 Select **Signal > New > Custom**.
- 5 In the Custom Waveform window, enter t in the **Time values** field and y in the **Y values** field and then click **OK**.

The Signal Builder block window displays the new signal as Signal 2.

Defining Signal Output

To specify the type of output to use for sending test signals:

- 1 In Signal Builder, select **Signal > Output**.
- 2 From the list, select:
 - **Ports**

Default. Sends individual signals from the block. An output port named Signal *N* appears for each Signal *N*.

- **Bus**

Sends single, virtual, nonhierarchical bus of signals from the block. An output port named Bus appears.

Tip

- You cannot use the **Bus** option to create a bus of nonvirtual signals.
 - The **Bus** option enables you to change your model layout without having to reroute Signal Builder block signals. Use the **Bus Selector** block to select the signals from this bus.
 - If you create a Signal Builder block using the Signal & Scope Manager or using the **Create & Connect Generator** option from a signal line context menu, you cannot define signal output. In these cases, the block sends individual signals.
-

Copying and Pasting Signals

To copy a signal from one group and paste it into another group as a new signal:

- 1 In Signal Builder, select the signal you want to copy.
- 2 Select **Edit > Copy**.
- 3 Select the group you want to paste the signal into.
- 4 Select **Edit > Paste**.

To copy a signal from one axis and paste it into another axis to replace its signal:

- 1 Select the signal you want to copy.
- 2 Select **Edit > Copy**.
- 3 Select the signal on the axis that you want to update.
- 4 Select **Edit > Paste**.

Deleting Signals

To delete a signal, in Signal Builder, select the signal and choose **Delete** or **Cut** from the **Edit** menu. Signal Builder deletes the signal from the current group. Because each

signal group must contain the same number of signals, Signal Builder also deletes all signals sharing the same index in the other groups.

Renaming a Signal

To rename a signal:

- 1 In Signal Builder, select **Signal > Rename**.

A dialog box appears with an edit field that displays the current name of the signal.

- 2 Edit or replace the current name with a new name.
- 3 Click **OK**.

You can also edit the signal name in the **Name** field in the lower-left corner of the Signal Builder window.

Replacing a Signal

To replace a signal:

- 1 In Signal Builder, select the signal, then select **Signal > Replace with**.

A menu of waveforms appears. It includes a set of standard waveforms (**Constant**, **Step**, and so on) and a **Custom** waveform option.

- 2 Select one of the waveforms.

If you select a standard waveform, the Signal Builder replaces a signal in the currently selected group with that waveform. For other waveforms, the Signal Builder displays a dialog to allow you to provide input for the requested waveform.

Waveform	Description	Inputs
Constant	Constant waveform.	None.
Step	Step waveform.	None.
Pulse	Pulse waveform.	None.
Square	Square waveform.	<ul style="list-style-type: none"> • Frequency Waveform frequency, in Hertz. • Amplitude Waveform amplitude.

Waveform	Description	Inputs
		<ul style="list-style-type: none"> • Offset Waveform vertical offset. • % Duty cycle Percent of the period in which the signal is positive. Enter a value between 0 and 100.
Triangle	Triangle waveform.	<ul style="list-style-type: none"> • Frequency Waveform frequency, in Hertz. • Amplitude Waveform amplitude • Offset Waveform vertical offset.
Sampled Sin	Sampled sinewave waveform.	<ul style="list-style-type: none"> • Frequency (Hz) Waveform frequency, in Hertz. • Amplitude Waveform amplitude • Offset Waveform vertical offset. • Samples Per Period Number of samples per waveform period.

Waveform	Description	Inputs
Sampled Gaussian Noise	Sampled Gaussian noise waveform based on a Gaussian distribution with input mean and standard deviation at input frequency.	<ul style="list-style-type: none"> • Frequency Waveform frequency, in Hertz. • Mean The mean value of the random variable output. • Standard Deviation The standard deviation squared of the random variable output. • Seed (empty to use current state) The initial seed value for the random number generator.
Pseudorandom Noise	Pseudorandom noise waveform based on a binomial distribution with upper and lower values at input frequency.	<ul style="list-style-type: none"> • Frequency Frequency with which waveform fluctuates between Upper value and Lower value, in Hertz. • Upper value Upper limit of signal. • Lower value Lower limit of signal. • Seed The initial seed value for the random number generator

Waveform	Description	Inputs
Poisson Random Noise	Poisson random noise waveform that alternates between 0 and 1.	<ul style="list-style-type: none"> • Avg rate (1/sec) Average rate of transition between 0 and 1. • Seed (empty to use current state) The initial seed value for the random number generator
Custom	Custom piecewise linear waveform. Custom values must fit within the display area.	<ul style="list-style-type: none"> • Time values Vector of two or more time coordinates. • Y values Vector of two or more signal amplitudes that correspond to the values in Time values. <p>The entries in either field can be any MATLAB expression that evaluates to a vector. The resulting vectors must be of equal length.</p> <p>Note: Signal Builder returns a warning if you add a custom waveform with a large number of data points (100,000,000 or more). You can then cancel the action.</p>

You can also edit the signal name in the **Name** field in the lower-left corner of the Signal Builder window.

Changing a Signal Index

To change a signal index:

- 1 In Signal Builder, select the signal, then select **Signal > Change Index**.

A dialog box appears with a drop-down list field containing the existing index of the signal.

- 2 From the drop-down list, another index and select **OK**. Or select an index from the **Index** list in the lower-left corner of the Signal Builder window.

Hiding Signals

By default, the Signal Builder window displays the group waveforms in the group pane. To hide a waveform:

- 1 In Signal Builder, select the waveform, then select **Signal > Hide**.
- 2 To redisplay a hidden waveform, select the **Group** pane, then select **Signal > Show**.
- 3 Select the signal from the list. Alternatively, you can hide and redisplay a hidden waveform by double-clicking its name in the Signal Builder signal list (see “Signal List” on page 62-65).

Creating Signal Group Sets

You can create signal groups in the **Signal Builder** block by:

- “Creating Signal Group Sets Manually” on page 62-77
- “Importing Signal Group Sets” on page 62-78
- “Importing Data with Custom Formats” on page 62-103

You can also use the `signalbuilder` function to populate the Signal Builder block.

Creating Signal Group Sets Manually

This topic describes how to create signal group sets manually. If you have signal data files, such as those from test cases, consider importing this data as described in “Importing Signal Group Sets” on page 62-78.

To create an interchangeable set of signal groups:

- 1 Drag an instance of the Signal Builder block from the Simulink Sources library and drop it into your model.

By default, the block represents a single signal group containing a single signal source that outputs a square wave pulse.

- 2 Use the block signal editor (see “Signal Builder Window” on page 62-64) to create additional signal groups, add signals to the signal groups, modify existing signals and signal groups, and select the signal group that the block outputs.

Note: Each signal group must contain the same number of signals.

- 3 Connect the output of the block to your diagram.

The block displays an output port for each signal that the block can output.

You can create as many Signal Builder blocks as you like in a model, each representing a distinct set of interchangeable groups of signal sources. When a group has multiple signals, the signals might have different end times. However, **Signal Builder** block requires the end times of signals within a group to match. If a mismatch occurs, **Signal Builder** block matches the end times by holding the last value of the signal with the smaller end time.

See “Simulating with Signal Groups” on page 62-111 for information on using signal groups in a model.

Importing Signal Group Sets

The topics in this section describe how to import signal data into the Signal Builder block. You should already have a signal data file whose contents you want to import. For example, you might have signal data from previously run test cases. See “Importing

Signal Groups from Existing Data Sets” on page 62-79 for a description of the data formats that the Signal Builder block accepts. The procedures in the following topics use the file `3Grp_3Sig.xls` in the folder `matlabroot\help\toolbox\simulink\ug\examples\signals` (open).

Signal Builder accepts signals only of type double.

Importing Signal Groups from Existing Data Sets

You might have existing signal data sets that you want to enter into the Signal Builder block. The **File > Import from File** command on the Signal Builder window starts the Import File dialog box. This dialog box is modal, which means that focus cannot change to another MATLAB window while the dialog box is running. If you want to see changes in the Signal Builder window after you import data, do one of the following:

- Close the Import File dialog box.
- Set up the Import File dialog box and Signal Builder window side by side.

Note: You cannot undo the results of importing a signal data file. In addition, you cannot undo the last action performed before opening the Import File dialog box. When you close the Import File dialog box, the **Undo last edit** and **Redo last edit** buttons on the Signal Builder window are grayed out. These buttons are grayed out regardless of whether you imported a data file.

The Import File dialog box accepts the following appropriately formatted file types:

- Microsoft Excel (`.xls`, `.xlsx`)
- Comma-separated value (CSV) text files (`.csv`)
- MAT-files (`.mat`)

Note: Signal Builder block uses the `xlsread` function. See the `xlsread` documentation for information on supported platforms.

You can import your data set file only if it is appropriately formatted.

For Microsoft Excel spreadsheets:

- The Signal Builder block interprets the first row as signal name. If you do not specify a signal name, the Signal Builder block assigns a default one with the format `Imported_Signal #`, where `#` increments with each additional unnamed signal.
- The Signal Builder block interprets the first column as time. In this column, the time values must increase.
- The Signal Builder block interprets the remaining columns as signals.
- If there are multiple sheets:
 - Each sheet must have the same number of signals (columns).
 - Each sheet must have the same set of signal names (if any).
 - Each column on each sheet must have the same number of rows.
- Signal Builder block interprets each worksheet as a signal group.

This example contains an acceptably formatted Microsoft Excel spreadsheet. It has three worksheets named Group1, Group2, and Group3, representing three signal groups.

Time must be first column

1	Time	DC In	Trigger	AC In
2		0	1	2
3		1	2	3
4		2	3	4
5		3	4	5
6		4	5	6
7		5	6	7
8		6	7	8
9		7	8	9
10		8	9	10
11		9	10	11
12		10	11	12
13		11	12	13
14		12	13	14
15		13	14	15
16		14	15	16
17		15	16	17
18				

Signal names (optional)

Worksheets - equivalent to signal group

For CSV text files:

- Each file contains only numbers. Do not name signals in a CSV file.
- The Signal Builder block interprets the first column as time. In this column, the time values must increase.
- The Signal Builder block interprets the remaining columns as signals.
- Each column must have the same number of entries.
- The Signal Builder block interprets each file as one signal group.
- The Signal Builder block assigns a default signal name to each signal with the format `Imported_Signal #`, where `#` increments with each additional signal.

This example contains an acceptably formatted CSV file. The contents represent one signal group.

```
0,0,0,5,0
1,0,1,5,0
2,0,1,5,0
3,0,1,5,0
4,5,1,5,0
5,5,1,5,0
6,5,1,5,0
7,0,1,5,0
8,0,1,5,1
9,0,1,5,1
10,0,1,5,0
```

For MAT-files:

- The Signal Builder block supports data store logging that the Simulink.SimulationData.Dataset object represents and interprets this data as a single group.
- The Signal Builder block supports Simulink output saved as a structure with time.
- The Signal Builder block supports the Signal Builder data format. This format is a group of cell arrays that must be labeled:
 - time
 - data
 - sigName
 - groupName

sigName and groupName are optional.

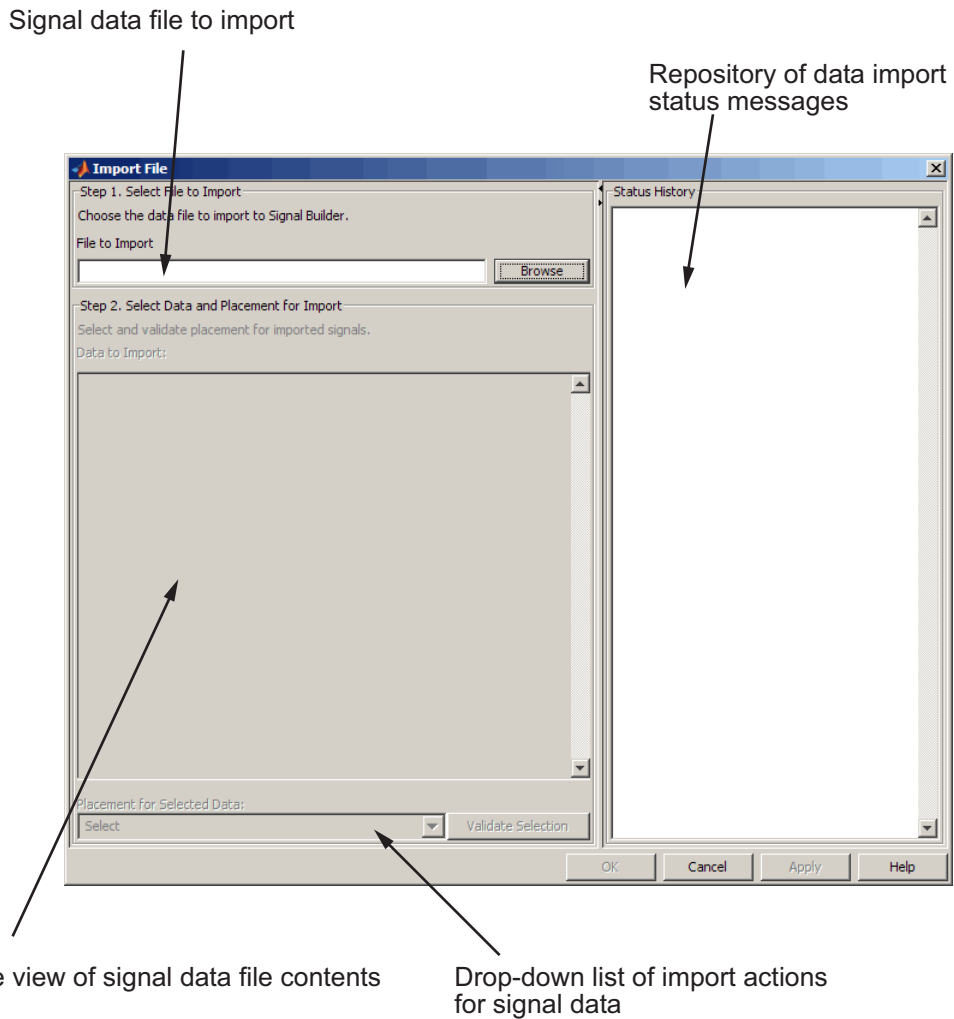

- For backwards compatibility, the Signal Builder block supports logged data from the Simulink.ModelDataLogs object and interprets this data as a single group. The ModelDataLogs format will be removed in a future release.
- Signal Builder block does not support:
 - Simulink output as only a structure
 - Simulink output as only an array

Note: Signal Builder returns a warning if you import a large number of data points (100,000,000 or more). You can then cancel the action.

This example contains an acceptably logged MATLAB workspace. Use the MATLAB workspace **Save** command to save the variables to a MAT-file. Import this file to the Signal Builder block.

Signal Builder Block Import File Dialog Box

The Signal Builder Import File dialog box allows you to import existing signal data files into the Signal Builder block.

Replacing All Signal Data with Selected Data

Simulink software creates a default Signal Builder block with one signal. To replace this signal and all other signal data that the block might display:

- 1 Create a model and drag a Signal Builder block into that model.
- 2 Double-click the block.

The Signal Builder window appears with its default Signal 1.

- 3 In Signal Builder, select **File > Import from File**.

The Import File dialog box appears.

- 4 In the **File to Import** field, enter a signal data file name or click **Browse**.

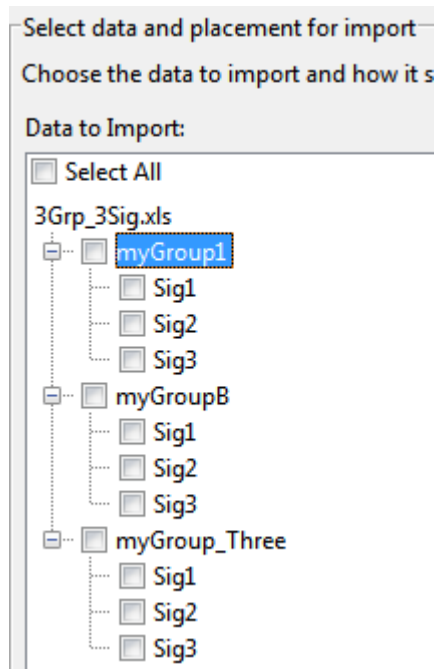

The file browser appears.

- 5 If you select the file browser, navigate to and select a signal data file. For example, select 3Grp_3Sig.xls.

Note: If you try to import an improperly formatted data file, an error message pops up. When you click to dismiss this window, the **Status History** pane displays a more detailed error message (if there is one). For example:

```
File 'signals.mat' format does not  
comply with Signal Builder required format.  
There is no 'time' parameter defined.  
.....
```

The **Data to Import** pane contains the signal data from the file. Click the expander to display all the signals.

- 6 Select the signals you want to import. To import all the signals, click **Select All**.
- 7 From the **Placement for Selected Data** list, select the action to take on the signal data. For example, select **Replace existing dataset**.

The **Confirm Selection** button is activated. Validate your signal selection before the Signal Builder block performs the specified action. If the signal data selection is not appropriate, **Confirm Selection** remains grayed out. For example, **Confirm Selection** remains grayed out if the number of signals you select is not the same as the number of signals in the Signal Builder group that you want to replace.

- 8 Click the **Confirm Selection** button.

If the requested action is a valid one, the Status History pane displays messages to indicate the status. For example:

Current data in Signal Builder will be replaced
by new data.

Number of groups: 3

Group name(s):
myGroup1
myGroupB
myGroup_Three

Number of signals per group: 3

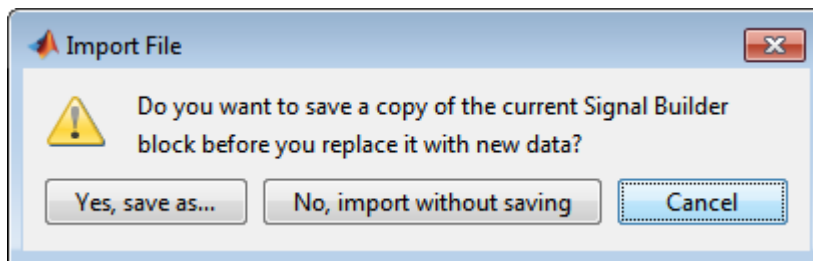

Signal name(s):
Sig1
Sig2
Sig3

(Names may have been renamed for uniqueness.)
.....

The confirmation also enables the **OK** and **Apply** buttons.

- 9 If you are satisfied with the status message, click **Apply** to replace the existing signal data with the contents of this file.

When selecting **Replace existing dataset**, the software gives you the opportunity to save the existing contents of the Signal Builder block.

- 10 Click a button, as follows:

To...	Click...
Save the contents of the Signal Builder block before replacing it with the new signal data.	Yes, save as

To...	Click...
Note: This selection prompts you to save the Signal Builder block in a model name of your choice. The software saves only the Signal Builder block and no other model content.	
Replace the contents of the Signal Builder block without saving them first.	No, import without saving
Stop the replacement process.	Cancel

For this example, select **No, import without saving** to replace the contents of the Signal Builder block.

- 11 The Signal Builder block updates with the new signal data. Click **OK** to close the Import File dialog box and inspect the Signal Builder block.

- 12 Click **OK**.
- 13 Inspect the updated Signal Builder window to confirm that your signal data is intact.
- 14 Close the Signal Builder window and save and close the model. For example, save the model as `signalbuilder1`.

Appending Selected Signals to All Existing Signal Groups

You can import signals from a signal data file and append selected signals to the end of all existing signal groups. If the signal names to be appended are not unique, the software renames them by incrementing each name by 1 or higher until it is a unique signal name. For example, if the block and data file contain signals named `thermostat`, the software renames the imported signal to `thermostat1` upon appending. If you add another signal named `thermostat`, the software names that latest version `thermostat2`.

This topic uses `signalbuilder1` from the procedure in “Replacing All Signal Data with Selected Data” on page 62-84.

- 1 In the MATLAB Command Window, type `signalbuilder1`.
- 2 Double-click the Signal Builder block.

The Signal Builder window appears.

- 3 In the Signal Builder window, select **File > Import from File**.

The Import File dialog box appears.

- 4 In the **File to Import** field, enter a signal data file name or click **Browse**.

The file browser is displayed.

- 5 If you select the file browser, navigate to and select a signal data file. For example, select `3Grp_3Sig.xls`.

Note: If you try to import an improperly formatted signal data file, an error message pops up. When you click to dismiss this window, the **Status History** pane displays an error message. For example:

```
File 'signals.mat' format does not  
comply with Signal Builder required format.  
There is no 'time' parameter defined.  
.....
```

The **Data to Import** pane contains the signal data from the file. Click the expander to display all the signals.

- 6 Select the signals you want to import. In this example, there are three groups, `myGroup1`, `myGroupB`, and `myGroup_Three`. Select all the signals in `myGroup1`.

- 7 From the **Placement for Selected Data** list, select the action to take on the signal data. For example, select `Append selected signals to all groups`.

The **Confirm Selection** button is activated. Validate your signal selection before the Signal Builder block performs the specified action. If the signal data selection is not appropriate, **Confirm Selection** remains grayed out. For example, **Confirm Selection** remains grayed out if the number of signals you select is not the same as the number of signals in the Signal Builder group that you want to replace.

- 8 Click the **Confirm Selection** button.

If the requested action is a valid one, the Status History pane displays messages to indicate the state. For example:

```

3 signal(s) will be appended to each group.
Selected signal name(s):
Before:
  Sig1
  Sig2
  Sig3

After:
  Sig4
  Sig5
  Sig6

Signal name(s) in the block:
Before:
  Sig1
  Sig2
  Sig3

After:
  Sig1
  Sig2
  Sig3
  Sig4
  Sig5
  Sig6

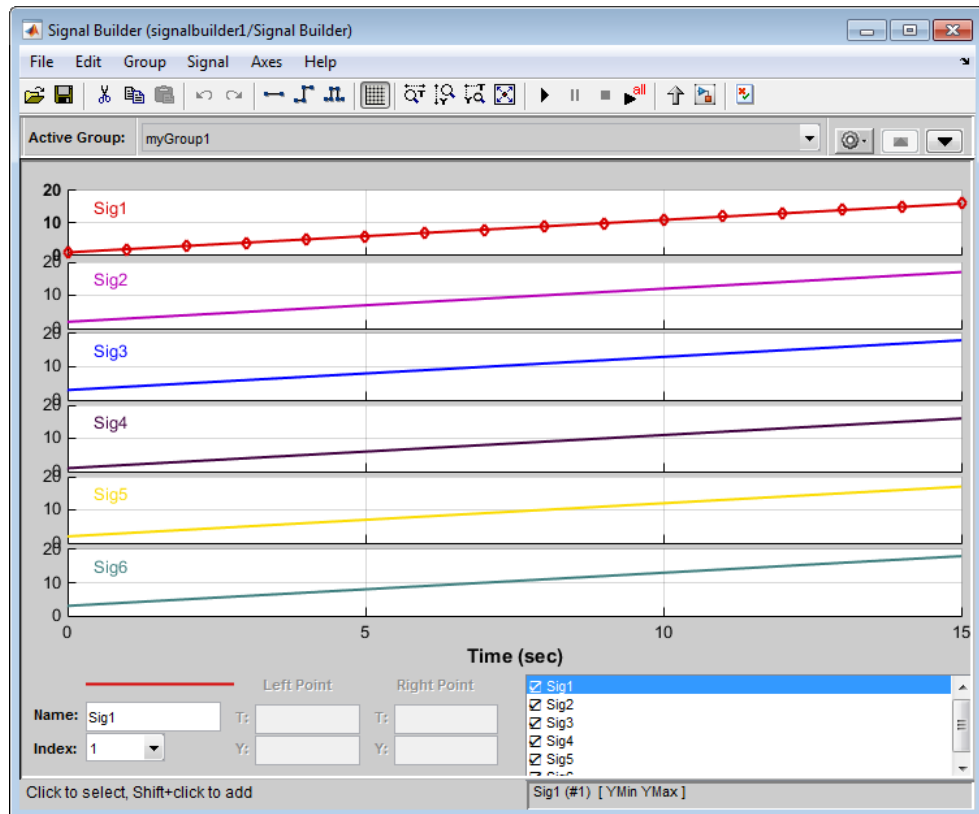

(Name(s) may have been renamed for uniqueness.)
.....

```

The confirmation also enables the **OK** and **Apply** buttons.

Observe the **Before** and **After** headings for the signals. These sections indicate the names of the block and imported data signals before and after the append action.

- 9 If you are satisfied with the status message, click **Apply** to append the selected signals to all the signal groups in the Signal Builder block.
- 10 The Signal Builder block updates with the new signal data. Click **OK** to close the Import File dialog box and inspect the Signal Builder block.

- 11 Click **OK**.
- 12 Inspect the updated Signal Builder window to confirm that your signal data is intact. Notice that the software has renamed the signals Sig1, Sig2, and Sig3 from the signal data file to Sig4, Sig5, and Sig6 in the Signal Builder block.
- 13 Close the Signal Builder window and save and close the model. For example, save the model as `signalbuilder2`.

Appending Selected Signals to Sequential Existing Signal Groups

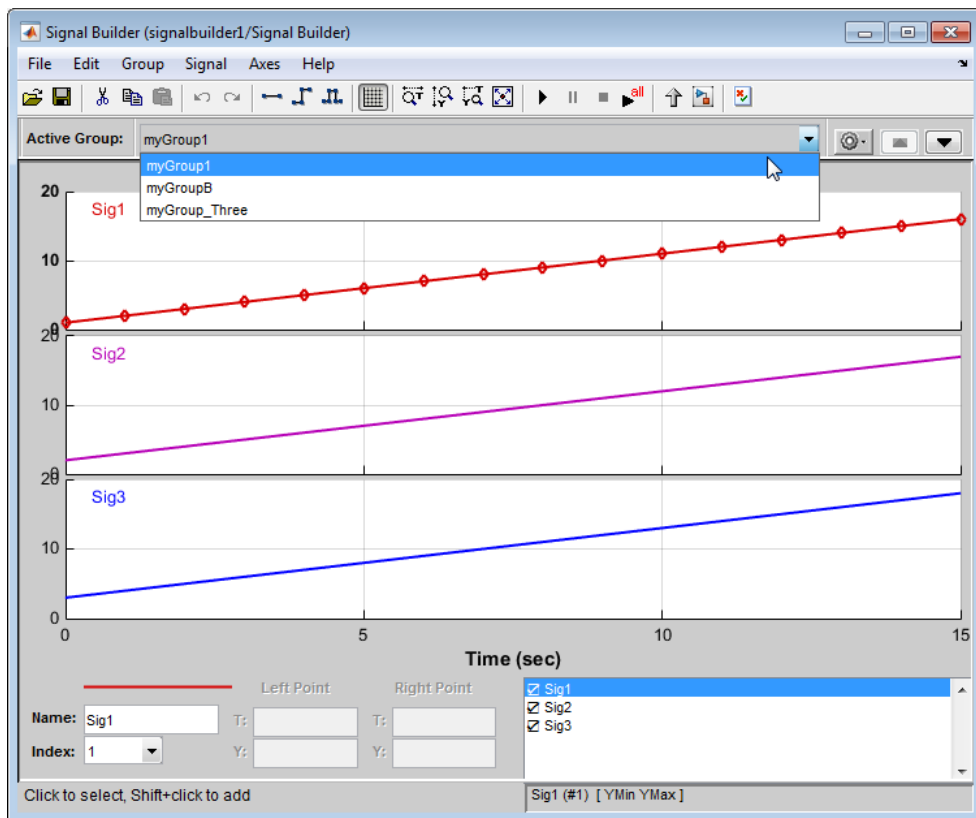

You can append signals, in the order in which they are selected, to the end of sequential signal groups. This statement means that you select the same number of signals as there are signal groups, and sequentially append each signal to a different group. The software renames each appended signal to the name of the last appended signal.

This topic uses `signalbuilder1` from the procedure in “Replacing All Signal Data with Selected Data” on page 62-84.

- 1 In the MATLAB Command Window, type `signalbuilder1`.
- 2 Double-click the Signal Builder block.

The Signal Builder window appears.

- 3 Note how many groups exist in the Signal Builder block. For example, this Signal Builder block has three groups, `myGroup1`, `myGroupB`, and `myGroup_Three`.

- 4 In the Signal Builder window, select **File > Import from File**.

The Import File dialog box appears.

- 5 In the **File to Import** field, enter a signal data file name or click **Browse**.

The file browser appears.

- 6 If you select the file browser, navigate to and select a signal data file. For example, select 3Grp_3Sig.xls.

Note: If you try to import an improperly formatted signal data file, an error message popup window. When you click to dismiss this window, the **Status History** pane displays an error message. For example:

```
File 'signals.mat' format does not  
comply with Signal Builder required format.  
There is no 'time' parameter defined.  
.....
```

The **Data to Import** pane contains the signal data from the file. Click the expander to display all the signals.

- 7 Select the signals you want to import. In this example, there are three groups, myGroup1, myGroupB, and myGroup_Three. Select all the signals in myGroup1.

- 8 From the **Placement for Selected Data** list, select the action to take on the signal data. For example, select **Append selected signals to different groups (in order)**.

The **Confirm Selection** button is activated. Validate your signal selection before the Signal Builder block performs the specified action.

- 9 Click the **Confirm Selection** button.

If the requested action is a valid one, the Status History pane displays messages to indicate the state. For example:

1 signal will be appended to each group.

Selected signal names:

Before:

Sig1

Sig2

Sig3

Selected unique signal name:

After:

Sig4

The confirmation also enables the **OK** and **Apply** buttons.

- 10** If you are satisfied with the status message, click **Apply** to append the signals.

The Signal Builder block updates with the new signal data. Click **OK** to close the Import File dialog box and inspect the three groups of the Signal Builder block.

The topmost signal group, myGroup1, shows all signals by default, including the new Sig4.

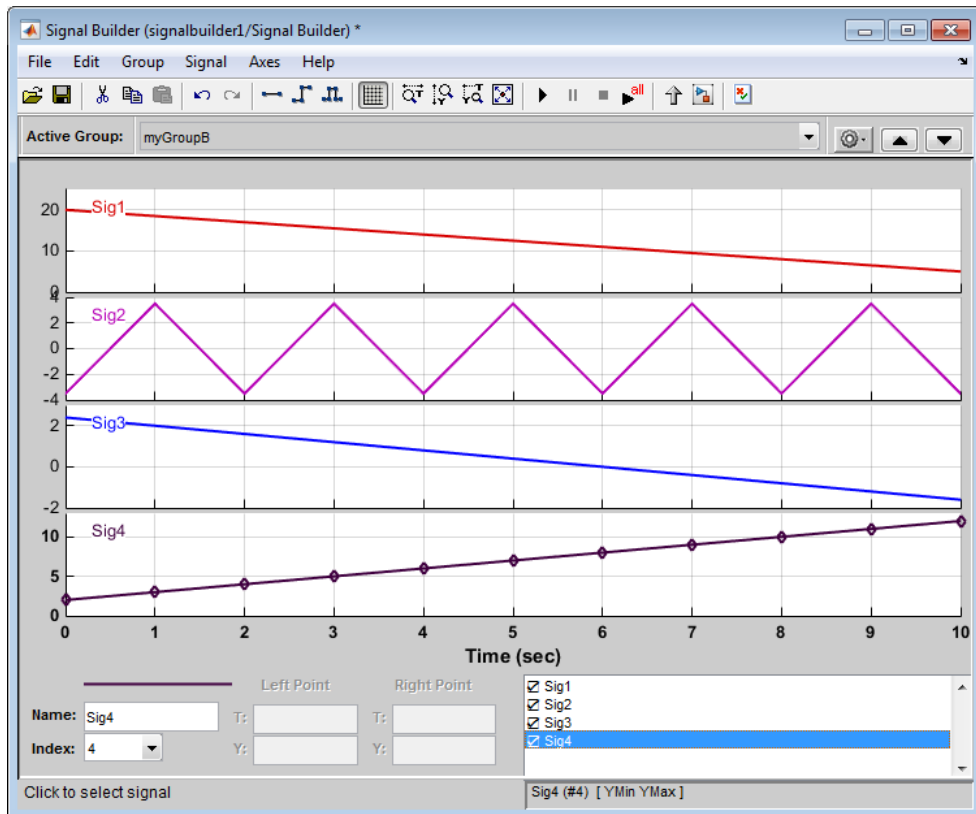

- Click another group name, for example, myGroupB. Notice that Sig4 exists for the group, hidden by default.

Sig4 appears in signal list, but does not appear in group pane

- 12 To show Sig4 on this pane, double-click Sig4 in the Selection Status area of the pane. The graph is updated to reflect Sig4.

- 13** Close the Signal Builder window and save and close the model. For example, save the model as `signalbuilder3`.

Appending Signal Groups to Existing Groups

You can append one or more signal groups to the end of the list of existing signal groups. If the block already has a signal group with the same name as the one you are adding, the software increments the group name by 1 or higher until it is unique before adding it. For example, if the block and data file contain groups named `MyGroup1`, the software renames the imported group to `MyGroup2` upon appending. If you add another group named `MyGroup1`, the software names that latest version `MyGroup3`.

This topic uses `signalbuilder1` from the procedure in “Replacing All Signal Data with Selected Data” on page 62-84.

- 1 In the MATLAB Command Window, type `signalbuilder1`.
- 2 Double-click the Signal Builder block.

The Signal Builder window appears.

- 3 Note how many groups exist in the Signal Builder block, and how many signals exist in each group. The Signal Builder block requires that all groups have the same number of signals. For example, this Signal Builder block has three groups, `myGroup1`, `myGroupB`, and `myGroup_Three`. Three signals exist in each group.

- 4 Double-click the block.
- 5 In the **File to Import** text field, enter a signal data file name or click **Browse**.

The file browser appears.

- 6 If you select the file browser, navigate to and select a signal data file. For example, select `3Grp_3Sig.xls`.

The **Data to Import** pane contains the signal data from the file. Click the expander to display all the signals.

- 7 Evaluate the number of signals in the groups of this data file. If the number of signals in each group equals the number of signals in the groups that exist in the block, you can append one of these groups to the block.
- 8 Select the group you want to import. In this example, there are three groups, myGroup1, myGroupB, and myGroup_Three. Select myGroupB.

- 9 From the **Placement for Selected Data** list, select the action to take on the signal group. For example, select **Append groups**.

The **Confirm Selection** button is activated. Validate your signal selection before the Signal Builder block performs the specified action.

- 10 Click the **Confirm Selection** button.

If the requested action is a valid one, the Status History pane displays messages to indicate the state. For example:

1 group(s) (each with 3 signal(s)),
will be appended to the existing block.

Selected group name(s):

Before:

myGroupB

After:

myGroupB1

Signal name(s) in selected group(s):

Before:

Sig1

Sig2

Sig3

Signal name(s) in the block:

Before:

Sig1

Sig2

Sig3

After:

Sig1

Sig2

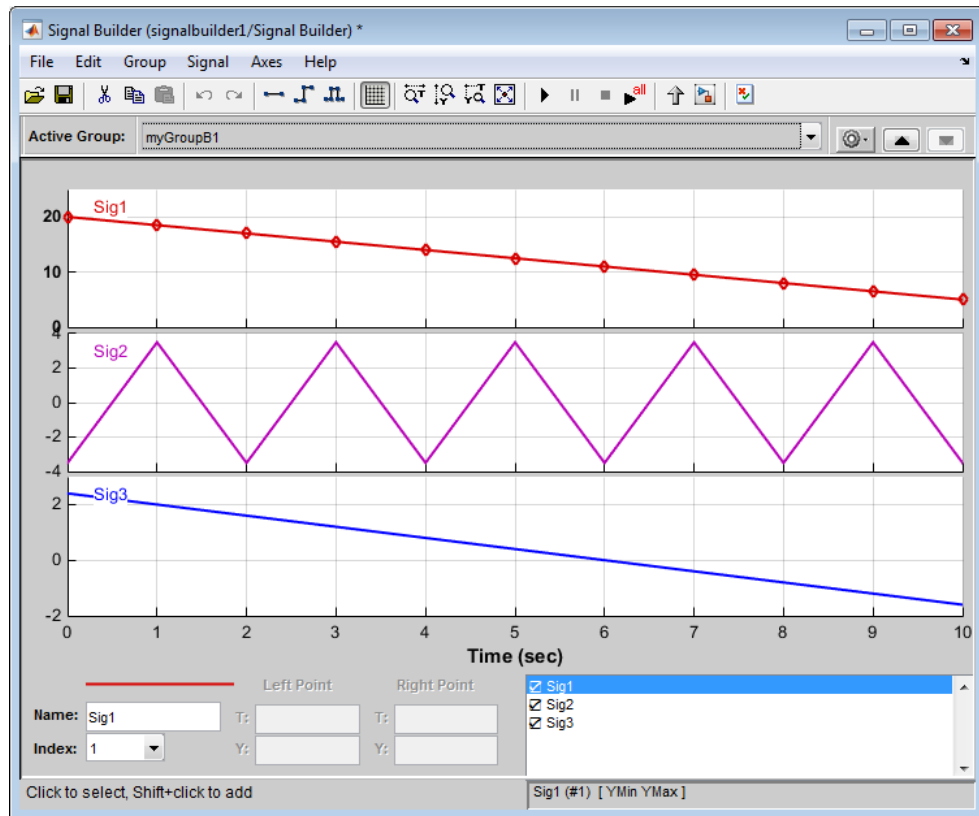

Sig3

The confirmation also enables the **OK** and **Apply** buttons.

- 11 If you are satisfied with the status message, click **Apply** to append the signals.

The Signal Builder block updates with the new signal data. Click **OK** to close the Import File dialog box and inspect the groups of the Signal Builder block.

Notice the addition of the new signal group as the last pane. Because there is already a signal group named myGroupB, the software automatically increments the new signal group name by 1. Select myGroupB.

- 12** Close the Signal Builder window and save and close the model. For example, save the model as `signalbuilder4`.

Appending Signals with the Same Name to Existing Signal Groups

If you append a signal whose name is the same as a signal that exists in the Signal Builder block, the software increments the name of the appended signal by 1. The software repeats incrementing until the appended signal name is unique. For example:

- 1** Assume your Signal Builder block has a signal group, `myGroup1`, with the signals `Sig1`, `Sig2`, and `Sig3`.
- 2** Append a signal named `Sig1` to `myGroup1`.
- 3** Observe that the software increments `Sig1` to `Sig4` before appending it to `myGroup1`.

Appending a Group of Signals with Different Signal Names

If you append a signal group whose signal names differ from those that exist in the Signal Builder block, the software changes the names of the existing signals to be the same as the appended signals. For example,

- 1 Assume your Signal Builder block has a signal group, `myGroup1`, with the signals `Sig1`, `Sig2`, and `Sig3`.
- 2 Append a signal group named `myGroup2` whose signal names are `SigA`, `SigB`, and `SigC`.
- 3 Observe that the software:
 - Appends `myGroup2`.
 - Renames the signals in `myGroup1` to be the same as those in `myGroup2`.

Importing Data with Custom Formats

This topic describes how to import signal data formatted in a custom format. You should already have a signal data from a file whose contents you want to import. See “Importing Signal Groups from Existing Data Sets” on page 62-79 for a description of the data formats that the Signal Builder block accepts. If your data is not formatted using one of these data formats, use the following workflow to import the custom formatted data. This workflow uses the following files, located in the folder `matlabroot\help\toolbox\simulink\ug\examples\signals` (open), as examples:

- `SigBldCustomFile.xls` — Signal data Microsoft Excel file using a format that Signal Builder block does not accept, for example:

Group1	Time	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
	Signal1	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16
	Signal2	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16
	Signal3	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16
	Signal4	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16
Group2	Signal1	1.6	2.6	3.6	4.6	5.6	6.6	7.6	8.6	9.6	10.6	11.6	12.6	13.6	14.6	15.6	16.6
	Signal2	1.8	2.8	3.8	4.8	5.8	6.8	7.8	8.8	9.8	10.8	11.8	12.8	13.8	14.8	15.8	16.8
	Signal3	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17
	Signal4	2.2	3.2	4.2	5.2	6.2	7.2	8.2	9.2	10.2	11.2	12.2	13.2	14.2	15.2	16.2	17.2

- `createSignalBuilderSupportedFormat.m` — Custom MATLAB function that uses `xlsread` to read Microsoft Excel spreadsheets. This example function reformats the custom data, in a format that the Signal Builder block supports, as follows:
 - `grpNames` — Cell array that contains group name character vectors with number of rows = 1, number of columns = number of groups.

- *sigNames* — Cell array that contains signal name character vectors with number of rows = 1, columns = number of signals.
- *time* — Cell array that contains time data with number of rows = number of signals, columns = number of groups.
- *data* — Cell array that contains signal data with number of rows = number of signals, columns = number of groups.

Signal Builder has the following requirements for this custom function:

- Number of signals in each group must be the same.
- Signal names in each group must be the same.
- Number of data points in each signal must be the same.
- Each element in the *time* and *data* cell array holds a matrix of real numbers. This matrix can be [1xN] or [Nx1], where N is the number of data points in every signal.

- 1 Identify the format of your custom signal data, for example:

```
SigBldCustomFile.xls
```

- 2 Create a custom MATLAB function that:

- a Uses a MATLAB I/O function, such as `xlsread`, to read your custom formatted signal data. For example, `createSignalBuilderSupportedFormat.m`.
- b Formats the custom formatted signal data to one that the Signal Builder block accepts, for example, a MAT-file.

- 3 Use your custom MATLAB function to write your custom formatted signal data to a file that Signal Builder block accepts. For example:

```
createSignalBuilderSupportedFormat('SigBldCustomFile.xls', 'OutputData.mat')
```

- 4 Import the reformatted signal data file, `OutputData.mat`, into the Signal Builder block (see “Importing Signal Group Sets” on page 62-78).

Editing Waveforms

Signal Builder allows you to change the shape, color, and line style and thickness of the waveforms output by a group.

Reshaping a Waveform

Signal Builder allows you to change the waveform by selecting and dragging its line segments and points with the mouse or arrow keys or by editing the coordinates of segments or points.

Selecting a Waveform

To select a waveform, left-click the mouse on any point on the waveform.

The Signal Builder displays the waveform points to indicate that the waveform is selected.

To deselect a waveform, left-click any point on the waveform axis that is not on the waveform itself or press the **Esc** key.

Selecting Points

To select a point of a waveform, first select the waveform. Then position the mouse cursor over the point. The cursor changes shape to indicate that it is over a point.

Left-click the point with the mouse. The Signal Builder draws a circle around the point to indicate your selection.

To deselect the point, press the **Esc** key.

Selecting Segments

To select a line segment, first select the waveform that contains it. Then left-click the segment. The Signal Builder thickens the segment to indicate that it is selected.

To deselect the segment, press the **Esc** key.

Moving Waveforms

To move a waveform, select it and use the arrow keys on your keyboard to move the waveform in the desired direction. Each key stroke moves the waveform to the next location on the snap grid (see “Snap Grid” on page 62-108) or by 0.1 inches if the snap grid is not enabled.

Dragging Segments

To drag a line segment to a new location, position the mouse cursor over the line segment. The mouse cursor changes shape to show the direction in which you can drag the segment.

Press the left mouse button and drag the segment in the direction indicated to the desired location. You can also use the arrow keys on your keyboard to move the selected line segment.

Dragging points

To drag a point along the signal amplitude (vertical) axis, move the mouse cursor over the point. The cursor changes shape to a circle to indicate that you can drag the point. Drag the point parallel to the *y*-axis to the desired location. To drag the point along the time (horizontal) axis, press the **Shift** key while dragging the point. You can also use the arrow keys on your keyboard to move the selected point.

Snap Grid

Each waveform axis contains an invisible snap grid that facilitates precise positioning of waveform points. The origin of the snap grid coincides with the origin of the waveform axis. When you drop a point or segment that you have been dragging, the Signal Builder moves the point or the segment points to the nearest point or points on the grid, respectively. The Signal Builder **Axes** menu allows you to specify the grid horizontal (time) axis and vertical (amplitude) axis spacing independently. The finer the spacing, the more freedom you have in placing points but the harder it is to position points precisely. By default, the grid spacing is 0, which means that you can place points anywhere on the grid; i.e., the grid is effectively off. Use the **Axes** menu to select the spacing that you prefer.

Inserting and Deleting points

To insert a point, first select the waveform. Then hold down the **Shift** key and left-click the waveform at the point where you want to insert the point. To delete a point, select the point and press the **Del** key.

Editing Point Coordinates

To change the coordinates of a point, first select the point. The Signal Builder displays the current coordinates of the point in the **Left Point** edit fields at the bottom of the Signal Builder window. To change the amplitude of the selected point, edit or replace the value in the **Y** field with the new value and press **Enter**. The Signal Builder moves the point to its new location. Similarly edit the value in the **T** field to change the time of the selected point.

Editing Segment Coordinates

To change the coordinates of a segment, first select the segment. The Signal Builder displays the current coordinates of the endpoints of the segment in the **Left Point**

and **Right Point** edit fields at the bottom of the Signal Builder window. To change a coordinate, edit the value in its corresponding edit field and press **Enter**.

Changing the Color of a Waveform

To change the color of a waveform, select the waveform and then select **Color** from the Signal Builder **Signal** menu. The Signal Builder displays the MATLAB color chooser. Choose a new color for the waveform. Click **OK**.

Changing a Waveform Line Style and Thickness

The Signal Builder can display a waveform as a solid, dashed, or dotted line. It uses a solid line by default. To change the line style of a waveform, select the waveform, then select **Line Style** from the Signal Builder **Signal** menu. A menu of line styles pops up. Select a line style from the menu.

To change the line thickness of a waveform, select the waveform, then select **Line Width** from the **Signal** menu. A dialog box appears with the line current thickness. Edit the thickness value and click **OK**.

Signal Builder Time Range

The Signal Builder time range determines the span of time over which its output is explicitly defined. By default, the time range runs from 0 to 10 seconds. You can change both the beginning and ending times of a block time range (see “Changing a Signal Builder Time Range” on page 62-110).

If the simulation starts before the start time of a block time range, the block extrapolates its initial output from its first two defined outputs. If the simulation runs beyond the block time range, the block by default outputs values extrapolated from the last defined signal values for the remainder of the simulation. The Signal Builder **Simulation Options** dialog box allows you to specify other final output options (see “Signal values after final time” on page 62-113 for more information).

Note: When you click the **Start simulation** button on the Signal Builder block toolbar, the simulation uses the stop time of the model. The end of the time range specified in the waveform is not the stop time for the model.

Changing a Signal Builder Time Range

To change the time range, select **Change Time Range** from the Signal Builder **Axes** menu. A dialog box appears.

Edit the **Min time** and **Max time** fields as necessary to reflect the beginning and ending times of the new time range, respectively. Click **OK**.

Exporting Signal Group Data

To export the data that define a Signal Builder block signal groups to the MATLAB workspace, select **Export to Workspace** from the block **File** menu. A dialog box appears.

The Signal Builder exports the data by default to a workspace variable named **channels**. To export to a differently named variable, enter the variable name in the **Variable name** field. Click **OK**. The Signal Builder exports the data to the workspace as the value of the specified variable.

The exported data is an array of structures. The structure **xData** and **yData** fields contain the coordinate points defining signals in the currently selected signal group. You can access the coordinate values defining signals associated with other signal groups from the structure **allXData** and **allYData** fields.

Printing, Exporting, and Copying Waveforms

Signal Builder allows you to print, export, and copy the waveforms visible in the active signal group.

To print the waveforms to a printer, select **Print** from the block **File** menu.

You can also export the waveforms to other destinations by using the **Export** option from the block **File** menu. From this submenu, select one of the following destinations:

- **To File** — Converts the current view to a graphics file.

Select the format of the graphics file from the **Save as type** drop-down list on the resulting **Export** dialog box.

- **To Figure** — Converts the current view to a MATLAB figure window.

To copy the waveforms to the system clipboard for pasting into other applications, select **Copy Figure To Clipboard** from the block **Edit** menu.

Simulating with Signal Groups

You can use standard simulation commands to run models containing Signal Builder blocks or you can use the **Run** or **Run all** button in the Signal Builder window (see “Running All Signal Groups” on page 62-112).

If you want to capture inputs and outputs that the **Run all** button generates, consider using the SystemTest™ software.

Activating a Signal Group

During a simulation, a Signal Builder block always outputs the active signal group. The active signal group is the group selected in the Signal Builder window for that block, if the dialog box is open. Otherwise, the active group is the group that was selected when the dialog box was last closed. To activate a group, open the group Signal Builder window and select the group.

Running Different Signal Groups in Succession

The Signal Builder toolbar includes the standard Simulink buttons for running a simulation. This facilitates running several different signal groups in succession. For example, you can open the dialog box, select a group, run a simulation, select another group, run a simulation, etc., all from the Signal Builder window.

Running All Signal Groups

To run all the signal groups defined by a Signal Builder block, open the block dialog box and click the **Run all** button

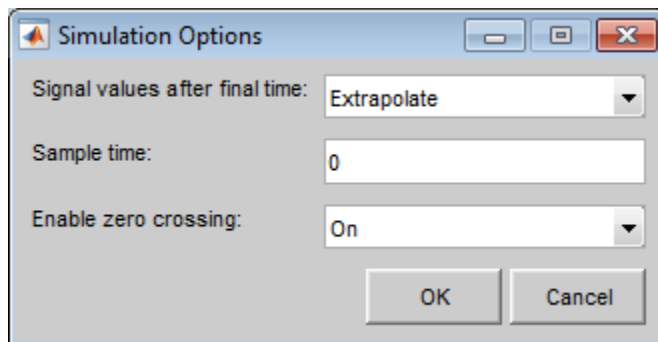

from the Signal Builder toolbar. The **Run all** button runs a series of simulations, one for each signal group defined by the block. If you installed Simulink Verification and Validation on your system and are using the Model Coverage Tool, the **Run all** button configures the tool to collect and save coverage data for each simulation in the MATLAB workspace and display a report of the combined coverage results at the end of the last simulation. This allows you to quickly determine how well a set of signal groups tests your model.

Note To stop a series of simulations started by the **Run all** command, enter **Ctrl+C** at the MATLAB command line.

Simulation Options Dialog Box

The **Simulation Options** dialog box allows you to specify simulation options pertaining to the Signal Builder. To display the dialog box, select **Simulation Options** from the **File** menu of the Signal Builder window. The dialog box appears.

The dialog box allows you to specify the following options.

Signal values after final time

The setting of this control determines the output of the Signal Builder block if a simulation runs longer than the period defined by the block. The options are

- Hold final value

Selecting this option causes the Signal Builder block to output the last defined value of each signal in the currently active group for the remainder of the simulation.

- Extrapolate

Selecting this option causes the Signal Builder block to output values extrapolated from the last defined value of each signal in the currently active group for the remainder of the simulation.

- Set to zero

Selecting this option causes the Signal Builder block to output zero for the remainder of the simulation.

Sample time

Determines whether the Signal Builder block outputs a continuous (the default) or a discrete signal. If you want the block to output a continuous signal, enter 0 in this field. For example, the following display shows the output of a Signal Builder block set to output a continuous Gaussian waveform over a period of 10 seconds.

If you want the block to output a discrete signal, enter the sample time of the signal in this field. The following example shows the output of a Signal Builder block set to emit a discrete Gaussian waveform having a 0.5 second sample time.

Enable zero crossing

Specifies whether the Signal Builder block detects zero-crossing events (enabled by default). This block sets the zero-crossing detection on the **From Workspace** block that you use to create the Signal Builder signal groups. For more information, see “Zero-Crossing Detection” on page 3-24.

Overview of Composite Signal Techniques

In this section...

“Buses” on page 63-3

“Arrays of Buses” on page 63-6

“Muxes” on page 63-8

“Concatenated Contiguous Output Signals” on page 63-8

You can use composite signals to reduce visual complexity in a model. A *composite signal* is a signal that is composed of other signals. The individual element signals originate separately and join to form the composite signal. You can extract individual signals from the composite signal downstream and use the extracted signal as if it never was part of a composite signal.

Use one or more of these techniques to combine signals into a composite signal.

- “Buses” on page 63-3
- “Arrays of Buses” on page 63-6
- “Muxes” on page 63-8
- “Concatenated Contiguous Output Signals” on page 63-8

To select a composite signal technique that meets your modeling requirements, see “Select a Composite Signal Technique” on page 63-10.

Buses

A *bus signal* (also called a *bus*) is analogous to a bundle of wires held together by tie wraps. Simulink implements a bus as a name-based hierarchical structure. A Simulink bus is not like a hardware bus, such as the bus in computer hardware architecture. A Simulink bus is more like a programmatic structure defined in a language such as MATLAB or C.

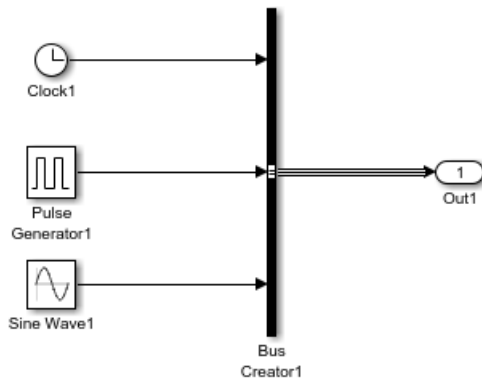

A bus is composed of signals that are called *elements*. The constituent signals retain their separate identities within the bus and can be of any type or types, including other buses nested to any level. The elements of a bus can be:

- Mixed data type signals (for example, double, integer, fixed-point)

- Mixed scalar and vector elements
- Mixed of real and complex signals
- Other buses
- Multidimensional signals

Not all blocks can accept buses. See “Bus-Capable Blocks” on page 63-28 for more information about which blocks can handle which types of buses. Also, see “Use Buses for Inports and Outports” on page 63-76.

For example, this model has a bus signal `bus1`, composed of the bus elements `Clock`, `Pulse`, and `Sine`.

For complete examples using buses, see “Getting Started with Buses” on page 63-13.

Virtual and Nonvirtual Buses

A bus can be either *virtual* or *nonvirtual*. Virtual and nonvirtual buses provide the same visual simplification, but Simulink handles them differently.

Bus	Functional Effect	Signal Storage	Generated Code
Virtual	Exists only graphically; has no functional effect.	Each bus element signal occupies its own storage in memory, but the bus signal is not stored in memory. A block connected to a <i>virtual</i> bus reads inputs and	Do not appear in generated code; only the constituent signals appear.

Bus	Functional Effect	Signal Storage	Generated Code
		writes outputs by accessing the memory allocated to the component signals. These signals are typically noncontiguous. Information about the size and data type of signals propagates from the signal sources.	
Nonvirtual	Can have functional effects.	Bus signal occupies its own storage in contiguous memory. A block connected to a <i>nonvirtual</i> bus reads inputs and writes outputs by accessing copies of the component signals. The copies are maintained in a contiguous area of memory allocated to the bus.	Appear as structures in generated code.

When you simulate or update diagram a model that contains buses, Simulink uses different line styles for virtual and nonvirtual bus signals.

Virtual Bus	
Nonvirtual Bus	

Bus Objects

A bus can have an associated *bus object*, which provides bus properties that Simulink uses to validate the bus signal. Bus objects are optional for virtual buses, but required for nonvirtual buses.

A bus object is an instance of class `Simulink.BUS` that can be stored in a location such as the base workspace. The object defines the structure of the bus and the

properties of its elements, such as nesting, data type, and size. See “When to Use Bus Objects” on page 63-40 for more information. You can create bus objects programmatically or by using the Simulink Bus Editor, which you can use to interactively create and manage bus objects. You can save bus objects as MATLAB code or as a MAT-file. For more information, see “Create Bus Objects with the Bus Editor” on page 63-44.

Generated Code for Buses

For simulation, virtual buses and nonvirtual buses are similar, except that all elements of a nonvirtual bus must have the same sample time. However, the type of bus can make a significant difference in the efficiency, size, and readability of generated code. For an example of this difference, see “Generate Code for Buses” on page 63-18.

If you intend to generate code for a model that uses buses, for information about the best techniques to use, see “Generate Efficient Code for Bus Signals” in the Simulink Coder documentation.

Buses and Muxes

In the context of a model, do not use bus and mux mixtures. A bus and mux mixture occurs when some blocks treat a signal as a mux, while other blocks treat that same signal as a bus. For information about addressing the resulting issues, see “Prevent Bus and Mux Mixtures” on page 63-128.

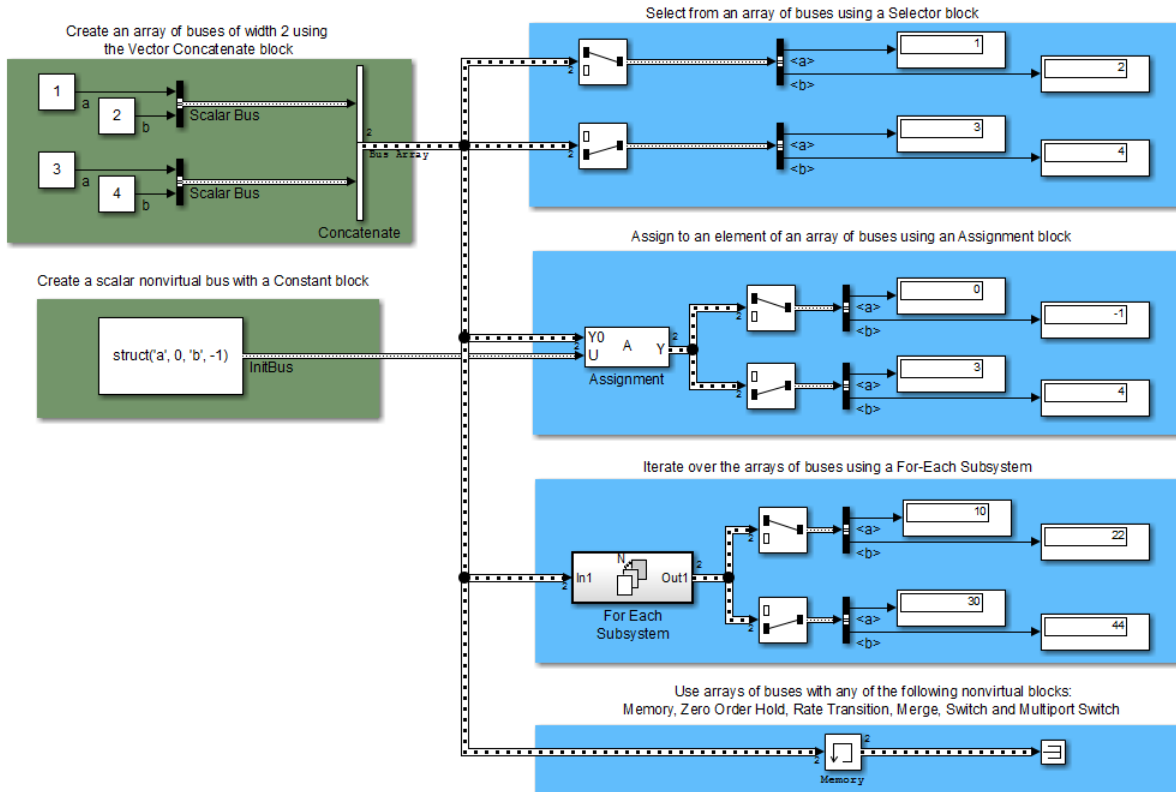

Arrays of Buses

You can combine multiple nonvirtual buses with identical properties into an array of buses. An array of buses is an array whose elements are buses. Each bus object has the same signal name, hierarchy, and attributes for its bus elements. An array of buses is equivalent to an array of structures in MATLAB.

An example of using an array of buses is to model a multi-channel system. You can model all the channels using the same bus object, although each of the channels could have a different value.

For an example of a model that uses an array of buses, open the `sldemo_bus_arrays` model. In this example, the nonvirtual bus input signals connect to a Vector Concatenate or Matrix Concatenate block that creates an array of bus signals. Here is how the simulated model appears.

Modeling Arrays of Bus Signals

The model uses the array of buses with:

- An Assignment block, to assign values to a bus in the array
- A For Each Subsystem block, to perform iterative processing over each bus in the array
- A Memory block, to output the array of buses input from the previous time step

See “Combine Buses into an Array of Buses” on page 63-91.

Muxes

If all signals in a composite signal have the same type, generally you can use a mux, which is a special type of noncontiguous vector (virtual) vector. If a block or modeling configuration requires a bus, then do not use a mux.

This model has three signals that are input to a Mux block, transmitted as a mux signal to a Demux block, and output as separate signals.

The Mux and Demux blocks are the left and right vertical bars, respectively. To reduce visual complexity, neither block displays a name.

For more information, see “Mux Signals” on page 62-11.

Concatenated Contiguous Output Signals

You can concatenate input signals of same data type to create contiguous output signal. You can use a Vector Concatenate or Matrix Concatenate block to . The block concatenates the signals at its inputs to create an output signal whose elements reside in contiguous locations in memory.

For example, this model sets the Matrix Concatenate block parameter **Concatenate dimension** to 2. Inputs are 2-D matrices. The Matrix Concatenate block performs horizontal matrix concatenation and places the input matrices side by side to create the output matrix.

Choose the composite signal technique that meets your modeling requirements. For background information about each technique, see “Overview of Composite Signal Techniques” on page 63-3.

Virtual Bus Usage Guidelines

Use virtual buses to reduce signal clutter in a block diagram. In general, using a virtual bus is simpler and can be more efficient than using a nonvirtual bus. However, some modeling features require nonvirtual buses, such as bus data that crosses MATLAB Function block or Stateflow chart boundaries. For example, use a virtual bus for bus signals that:

- Have bus elements that have different sample rates
- Cross model reference boundaries, if the referenced model only uses a few of the bus elements.

Compared with nonvirtual buses, virtual buses reduce memory requirements. Virtual buses do not require a separate contiguous storage block. During simulation, virtual buses execute faster because they do not require copying data to and from that block. The generated code also executes faster for virtual buses than for nonvirtual buses.

Nonvirtual Bus Usage Guidelines

Use nonvirtual buses to:

- Construct an array of buses.
- Package bus data as structures in the generated C code.
- Have bus data cross MATLAB Function block or Stateflow chart boundaries.
- Interface with external code either through an S-function.

Generated code represents a nonvirtual bus as a structure. The structure can be helpful for tracing the correspondence between the model and the code. Generated code for nonvirtual buses can result in multiple copies of some bus signals. For an example of the difference in generated code for virtual and nonvirtual buses, see “Generate Code for Buses” on page 63-18. For additional guidelines for generating code for nonvirtual buses, see “Group Signals into Structures in the Generated Code Using Buses”.

All signals in a nonvirtual bus input to a block must use the same sample time, even if the elements of the associated bus object specify inherited sample times. You can use a `Rate Transition` block to change the sample time of an individual signal, or of all signals in a bus.

Array of Buses Usage Guidelines

Combine multiple nonvirtual buses into an array. An array of buses is equivalent to an array of structures in MATLAB. An example of using an array of buses is to model a multi-channel system. You can model all the channels using the same bus object, although each of the channels can have a different value.

Each element in an array of buses must be nonvirtual and must have the same bus object. Each bus object has the same signal name, hierarchy, and attributes for its bus elements. Arrays of buses require the use of bus objects. For details, see “Combine Buses into an Array of Buses” on page 63-91.

Mux Usage Guidelines

To combine signals of same type into a vector, you can use a Mux block. A mux is a special kind of noncontiguous (virtual) vector. You can use a mux anywhere that you could use an ordinary (contiguous) vector. For example, you can perform calculations on a mux. The computation affects each constituent value in the mux, as if the values existed in a contiguous vector. Using a mux to perform computations on multiple vectors avoids the overhead of copying the separate values to contiguous storage. Also, you can use a Mux block to create a vector of function calls.

If you want index-based access, use a Mux block. For name-based access, use a bus.

Concatenated Contiguous Output Signal Guidelines

You can combine a vector or matrix by using a `Vector Concatenate` or `Matrix Concatenate` block. These blocks are useful for creating an output signal that is

contiguous. You can use this concatenation in mathematical operations. For examples of using these blocks, see the `Vector Concatenate` and `Matrix Concatenate` block documentation.

Getting Started with Buses

In this section...

“Create and Use Virtual Buses” on page 63-13

“Create and Use Nonvirtual Buses” on page 63-16

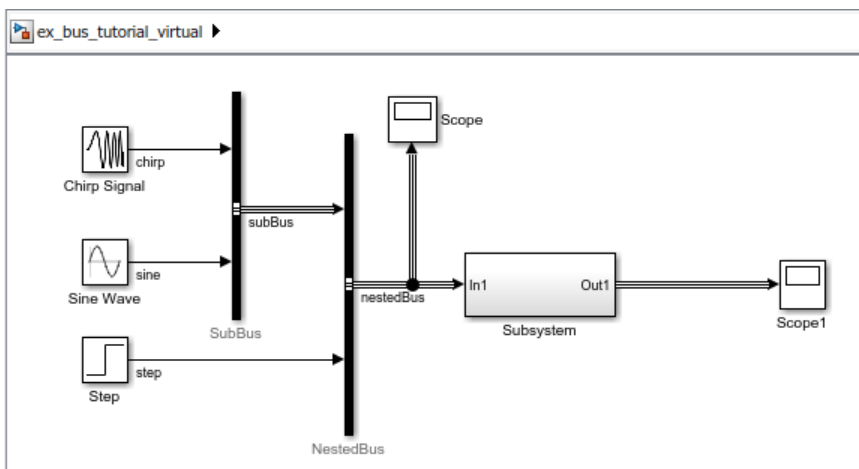

“Generate Code for Buses” on page 63-18

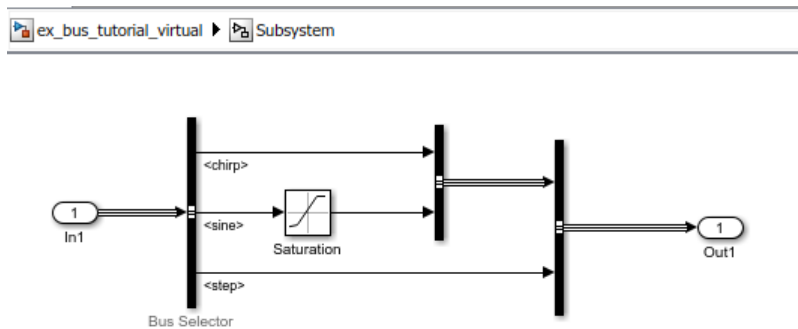

You can combine signals into a bus signal and then access the bus as a whole or select specific signals from the bus. These examples are simple, to focus on the basic steps in creating and using buses. Buses are most useful when you have many signals that make sense to combine to reduce visual complexity. The examples also include steps to label blocks and signals, to clarify the relationship between signals and buses and between blocks. If you choose to build the example models step-by-step, you can skip those steps if you like.

Create and Use Virtual Buses

This example shows how to combine signals into virtual buses. The model selects individual signals (bus elements) from a virtual bus and uses the bus elements as individual signals.

To see the completed model, open the `ex_bus_tutorial_virtual` model. When you simulate the model, the bus signal lines indicate that the buses are virtual.

Perform these steps to gain experience creating and using virtual buses.

- 1 From the Simulink Start Page, select a blank model template.
- 2 In the Simulink Editor, add a Chirp Signal block and a Sine Wave block.
- 3 Create a bus for the signals from the two blocks. Drag to select the blocks and in the action bar that appears, click **Create Bus**.

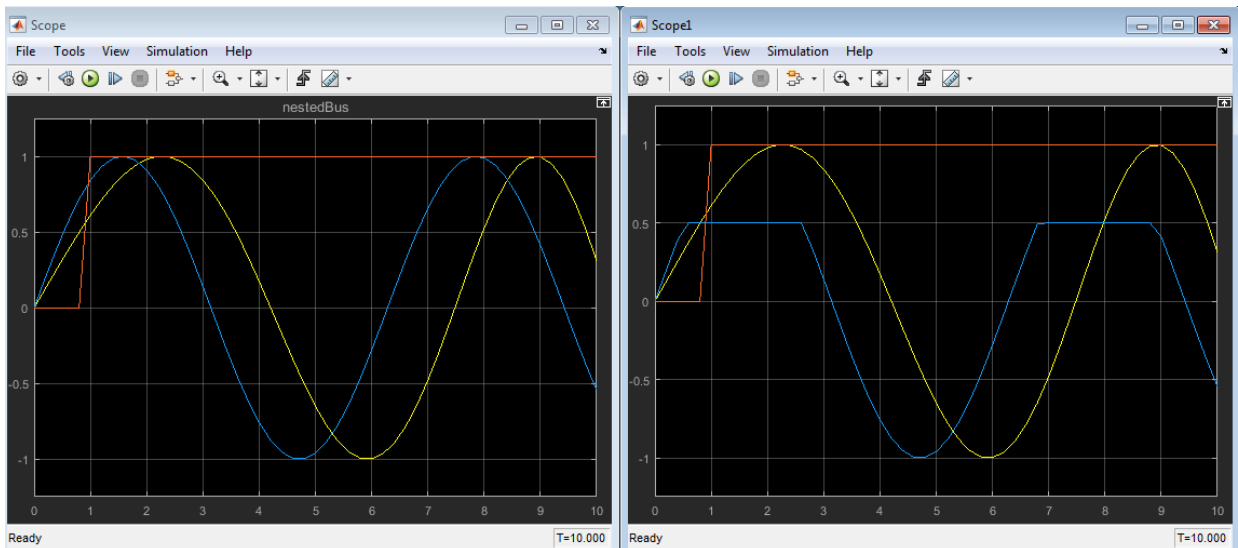

Simulink adds a Bus Creator block and connects the input signals to that block.

- 4 By default, the Bus Creator block name does not appear. To add a block name, select the block and from the action bar that appears, select **Show Block Name**. Then edit the name, changing it from **Bus Creator** to **SubBus**.
- 5 You do not have to label the signals in a bus. However, labeling makes it easier to see the relationship between bus element signals and bus signals. Label the output signal for the Chirp Signal block. Right-click the signal and select **Properties**. In the **Signal name** property, enter **chirp**. Similarly, set the Sine Wave signal name to **sine**.

Note: Inputs to a Bus Creator block must have unique names. If there are duplicate names, the Bus Creator block appends (**signal#**) to all input signal names, where **#** is the input port index.

- 6 Add a Step block below the Sine Wave block.
- 7 To create a nested bus, add a Bus Creator block to the right of the current blocks. Connect the signal from the **SubBus** block and the signal from the Step block to the second Bus Creator block.

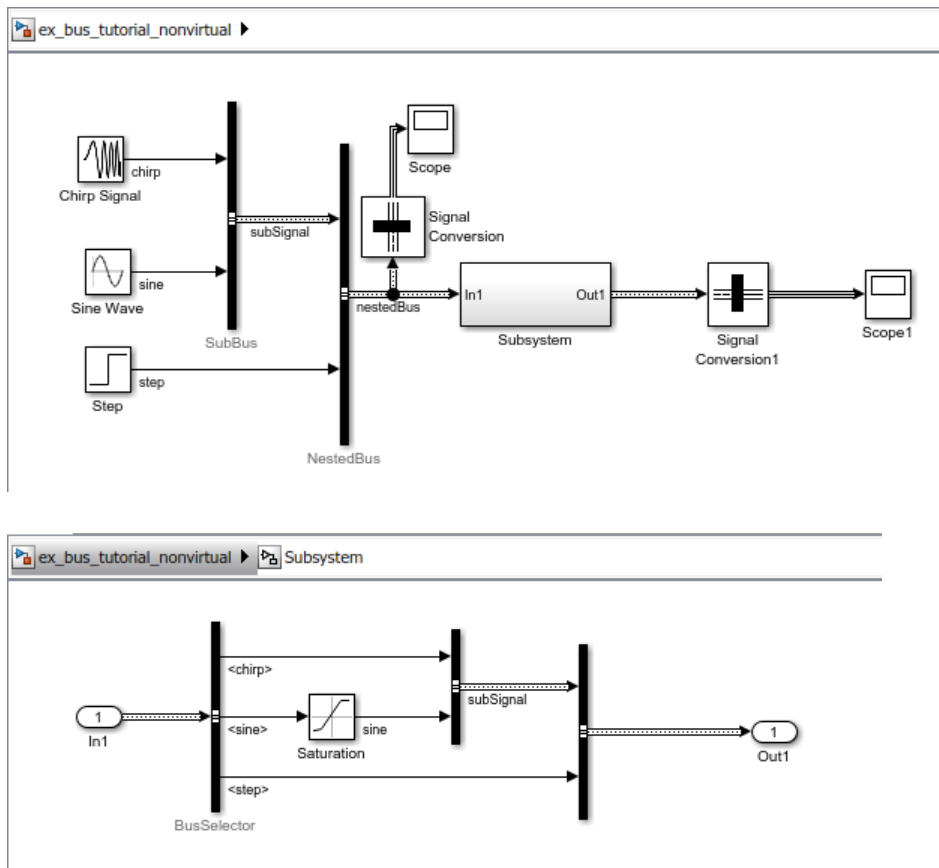

- 8 Label the output signal from the SubBus block `subBus` and the signal from the Step block `step`.
- 9 Show the block name for the Bus Creator block that creates the nested bus. Change the name to `NestedBus`.
- 10 Attach a Scope block to the `nestedBus` signal.
- 11 To the right of the `NestedBus` block, add a Subsystem block and connect the `NestedBus` output signal to the subsystem.
- 12 Connect the Subsystem block output port to a Scope block.
- 13 In the subsystem, disconnect the Inport and Outport blocks and insert a Bus Selector block to the right of the Inport block. Connect the Inport block to a Bus Selector block.
- 14 Show the Bus Selector block name. Change the name to `BusSelector`.
- 15 To the right of the Bus Selector block, add a Saturation block and set its **Lower limit** parameter to `-inf`.
- 16 Combine the `chirp` signal and the Saturation block output signal into a bus.
- 17 Combine the bus signal and the `step` signal into a nested bus.
- 18 Connect the nested bus to the Outport block.
- 19 To see the simulation results, simulate the model and open the Scope blocks.

Create and Use Nonvirtual Buses

This example changes the virtual buses used in the `ex_bus_tutorial_virtual` model to nonvirtual buses. To see the completed model, open the `ex_bus_tutorial_nonvirtual` model. Nonvirtual buses are required for certain modeling situations. Generating code for a nonvirtual bus represents the bus as a structure. For more information about when to use nonvirtual buses, see “Nonvirtual Bus Usage Guidelines” on page 63-10.

When you simulate the model, the bus signal lines indicate that the virtual are converted to nonvirtual buses.

Perform these steps to gain experience creating and using nonvirtual buses.

- 1 Open the `ex_bus_tutorial_virtual` model.
- 2 For the `SubBus` block, specify to produce nonvirtual bus output. In the Block Parameters dialog box, set **Output data type** to `Bus: subBus`. This setting uses the `subBus` bus object, which provides bus properties that Simulink uses to validate the bus signal.

Also, select the **Output as nonvirtual bus** parameter.

Note: When you use bus objects to create nonvirtual buses, the bus object must be in the base workspace before simulating the model. You need to define the bus object or use an already defined bus object. To simplify this example, when you open the model, a model callback loads the necessary bus objects into the base workspace. To see the callback, open **File > Model Properties > Model Properties** and open the **Callbacks** tab.

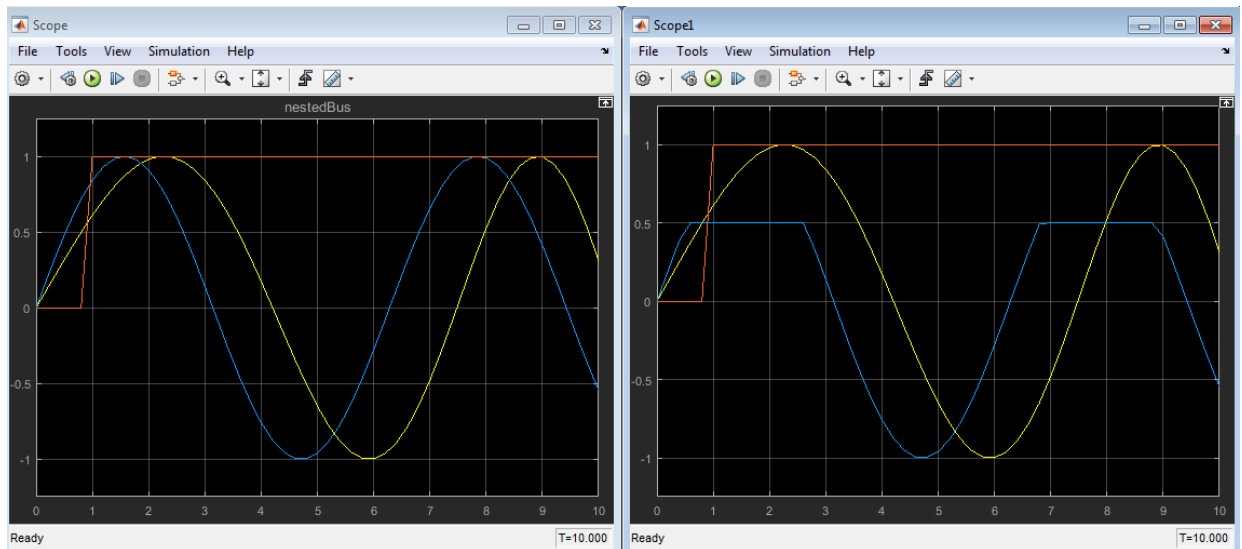

For information about creating bus objects, see “Create Bus Objects” on page 63-44.

- 3 In the `NestedBus` block, set **Output data type** to `Bus: topBus` and select the **Output as nonvirtual bus** parameter.
- 4 The `ex_bus_tutorial_virtual` model that you are modifying uses Scope blocks, which require virtual signals. Convert the nonvirtual bus input signals for the Scope blocks to virtual bus signals by inserting a Signal Conversion block before each of the Scope blocks.
- 5 Bus signals do not specify whether they are virtual or nonvirtual; they inherit that specification from the block in which they originate. Every block that creates or requires a nonvirtual bus must have an associated bus object.

For the `SubBus` Bus Creator block, set **Output data type** to `Bus: subBus` and select the **Output as nonvirtual bus** parameter.

- 6 The `subBus` bus object expects the second input signal in the bus to be called `sine`. Although the Bus Selector block selected the `sine` signal from the bus, the default name of the output signal of the Saturation block is not `sine`. Use the **Signal Properties** dialog box to name the Saturation block output signal `sine`.
- 7 For the `NestedBus` block, set **Output data type** to `Bus: topBus` and select the **Output as nonvirtual bus** parameter.

- 8 The `topBus` bus object expects the first input signal in the bus to be called `subSignal`. Use the **Signal Properties** dialog box to name the bus signal `subSignal`.
- 9 To see the simulation results, simulate the model and open the Scope blocks. The results are the same as when you simulate the `ex_bus_tutorial_virtual` model that you used as a base for this model.

Generate Code for Buses

The simulation results are the same for the model that uses virtual buses (`ex_bus_tutorial_virtual`) and for the model that uses nonvirtual buses `ex_bus_tutorial_nonvirtual`. However, the generated code is different.

Adding a Unit Delay block and an Outport block after the Subsystem block in each of the bus models helps to highlight the differences in the generated code. For the nonvirtual bus model, the **Output data type** is set to `Bus: topBus`.

ex_bus_tutorial_virtual_code_gen ▶

Generated Code for the Virtual Bus Model

Generate code from the `ex_bus_tutorial_virtual_code_gen` model.

The virtual buses do not affect the generated code. For example, in the generated file `ex_bus_tutorial_virtual_code_gen.c`, the algorithm in the model `step` function effectively implements three Unit Delay blocks (one for each meaningful signal, such as `chirp`, that passes through the block).

```

/* UnitDelay: '<Root>/Unit Delay' */
rtb_chirp = ex_bus_tutorial_virtual_code_DW.UnitDelay_1_DSTATE;

/* UnitDelay: '<Root>/Unit Delay' */
rtb_signal2 = ex_bus_tutorial_virtual_code_DW.UnitDelay_2_DSTATE;

/* UnitDelay: '<Root>/Unit Delay' */
rtb_step = ex_bus_tutorial_virtual_code_DW.UnitDelay_3_DSTATE;

```

Generated Code for the Nonvirtual Bus Model

Generate code from the `ex_bus_tutorial_nonvirtual_code_gen` model.

The nonvirtual buses appear in the generated code as structures. Each `Simulink.Bus` object appears as a structure type. The type definitions appear in `ex_bus_tutorial_nonvirtual_code_gen_types.h`.

```
typedef struct {
```

```
    real_T chirp;
    real_T sine;
} subBus;

typedef struct {
    subBus subSignal;
    real_T step;
} topBus;
```

The algorithm in the model `step` function can implement the Unit Delay block as a single line of code. The block state and output are structures of type `topBus`.

```
/* UnitDelay: '<Root>/Unit Delay' */
rtb_UnitDelay = ex_bus_tutorial_nonvirtual_c_DW.UnitDelay_DSTATE;
```

Display Information About Buses

In this section...
“Signal Hierarchy Viewer” on page 63-22
“Port Value Display” on page 63-24
“CompiledBusType and SignalHierarchy Parameters” on page 63-26

To view information about buses, use one of these approaches:

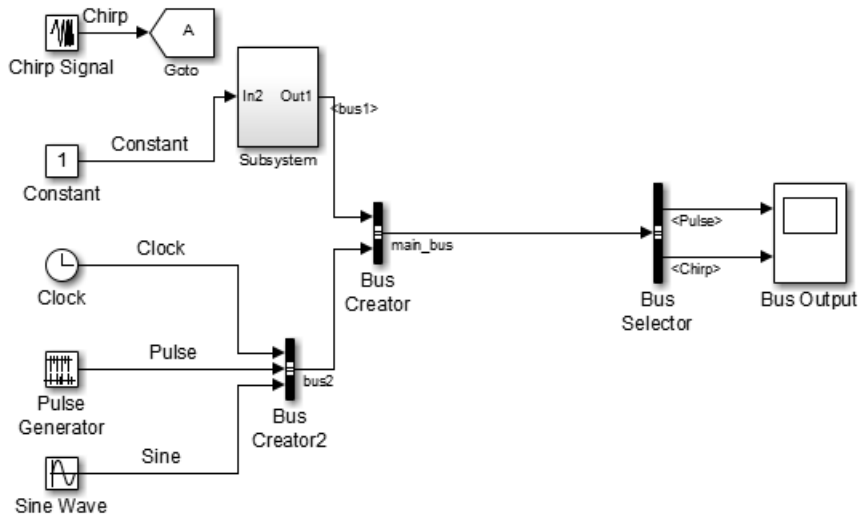

- To display bus signals in a bus hierarchy interactively, use the “Signal Hierarchy Viewer” on page 63-22.
- To display the value of a specific port or port values for a block before simulation, right click on the signal and select **Show Value Label of Selected Port**. For details, see “Port Value Display” on page 63-24.
- To display at the MATLAB command line the type and hierarchy of a bus signal use the `CompiledType` and `SignalHierarchy` parameters. For details, see “CompiledBusType and SignalHierarchy Parameters” on page 63-26.

Signal Hierarchy Viewer

You can use the Signal Hierarchy Viewer to display information about a signal. To display the bus hierarchy:

- 1 Check that the **Configuration Parameters > Diagnostics > Connectivity > Mux blocks used to create bus signals** parameter is set to `error`.
- 2 Right-click a signal line.
- 3 Select the **Signal Hierarchy** option. The Signal Hierarchy Viewer dialog box appears.

For example, open the `busdemo` model.

Right-click the `main_bus` signal (output signal for the Bus Creator block), and select **Signal Hierarchy**.

Each Signal Hierarchy Viewer is associated with a specific model. If you edit a model while the associated Signal Hierarchy Viewer is open, the Signal Hierarchy Viewer reflects those updates.

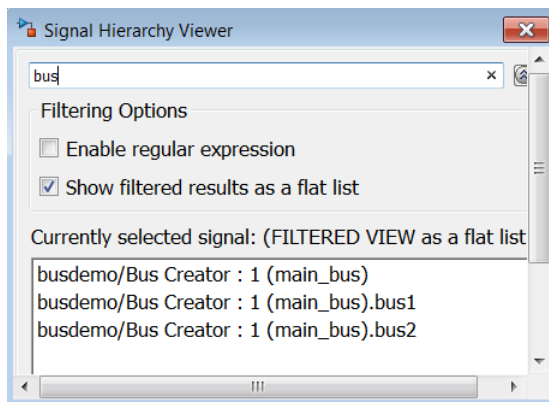

You can also open the Signal Hierarchy Viewer in the Simulink Editor.

- 1 Select **Diagram > Signals & Ports > Signal Hierarchy**.
- 2 Select a signal.

Note: To produce accurate results at edit time, the Signal Hierarchy Viewer requires that the model compiles successfully.

To filter the displayed signals, click the **Options** button on the right-hand side of the **Filter by name** edit box (🔍).

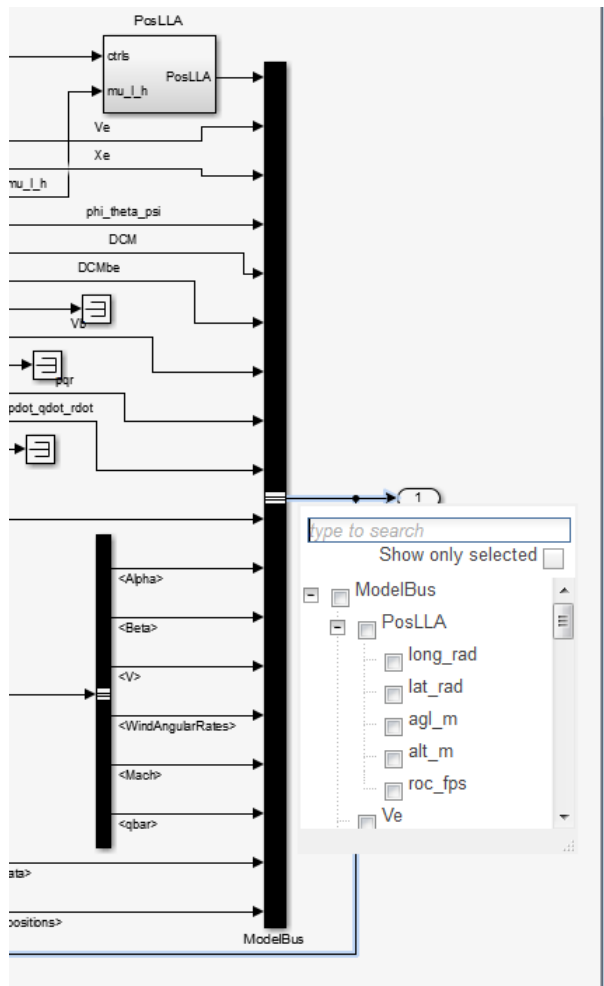

- To use MATLAB regular expressions for filtering signal names, select **Enable regular expression**. For example, to display all signals whose names end with a lowercase `r` (and their immediate parents), enter `r$` in the **Filter by name** edit box. For details, see “Regular Expressions”.
- To use a flat list format to display the list of filtered signals, based on the search text in the **Filter by name** edit box, select **Show filtered results as a flat list**. The flat list format uses dot notation to reflect the hierarchy of bus signals. This example shows a flat list format for a filtered set of nested bus signals.

Port Value Display

To display the value of a specific port or port values for a block before simulation, right click on the signal and select **Show Value Label of Selected Port**.

For bus signals, the **Show Value Label of Selected Port** option opens a dialog box where you can select from all signals in the bus. For example, in this model, you can see the dialog box for all signals that are contained in ModelBus.

For more information about port value display, see “Display Value for a Specific Port” on page 33-19.

CompiledBusType and SignalHierarchy Parameters

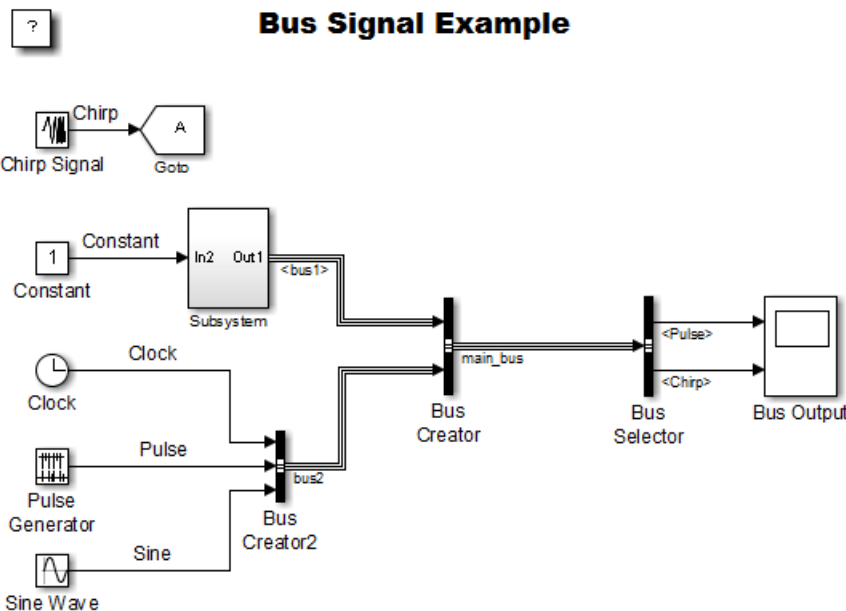

To get information about the type and hierarchy of a bus signal in a compiled model, use these parameters with the `get_param` command:

- **CompiledBusType** — For a compiled model, returns information about whether the signal connected to a port is a bus and whether the signal is a virtual or nonvirtual bus.
- **SignalHierarchy** — If the signal is a bus, returns the name and hierarchy of the signals in the bus.

Before you use these commands:

- 1 Set the **Configuration Parameters > Diagnostics > Connectivity > Mux blocks used to create bus signals** diagnostic to **error**.
- 2 For **CompiledBusType**, update the diagram or simulate the model.

For example, open and simulate the `busdemo` model.

This code illustrates how you can use the `SignalHierarchy` and `CompiledBusType` parameters:

```
mdl = 'busdemo';
open_system(mdl)
% Obtain the handle a port
ph = get_param([mdl '/Bus Creator'], 'PortHandles');
% SignalHierarchy is available at edit time
sh = get_param(ph.Outport, 'SignalHierarchy')
% Compile the model
busdemo([],[],[],'compile');
bt = get_param(ph.Outport, 'CompiledBusType')
% Terminate the model
busdemo([],[],[],'term');
```

Bus-Capable Blocks

Bus-capable blocks can accept bus signals as input, produce bus signals as output, or both. Some bus-capable blocks work with nonvirtual buses, but not with virtual buses. Some bus-capable blocks have additional requirements for bus signals; see the block documentation for details.

Block	Input	Output
All virtual blocks	✓	✓
Assignment(nonvirtual buses)	✓	✓
Bus Assignment	✓	✓
Bus Creator	✓	✓
Bus Selector	✓	✓
Constant (nonvirtual buses)		✓
Data Store Memory (nonvirtual buses)	Has no input port, can store bus signals	
Data Store Read (nonvirtual buses)		✓
Data Store Write (nonvirtual buses)	✓	
Delay	✓ (special requirements)	✓ (special requirements)
From File (nonvirtual buses)		✓
From Workspace (nonvirtual buses)		✓
Interpolation Using Prelookup	✓	
Manual Switch	✓	✓
Memory	✓ (special requirements)	
Merge	✓ (special requirements))	

Block	Input	Output
Multiport Switch	✓ (special requirements)	
Prelookup		✓ (special requirements)
Rate Transition	✓ (special requirements)	
Signal Conversion	✓	✓ (special requirements)
Signal Specification	✓	✓
Switch	✓ (special requirements)	✓
To File (nonvirtual buses)	✓ (special requirements)	
To Workspace (nonvirtual buses)	✓

Vector Concatenate(nonvirtual buses)	✓	✓
Zero-Order Hold	✓	✓

These modeling patterns support the use of buses. See the documentation for those features for any special considerations relating to the use of buses. Subsystems, model , and S-functions support the use of buses.

- Subsystems
- Model referencing
- S-Functions
- Stateflow charts
- MATLAB Function blocks
- MATLAB System blocks

Buses that contain signals of enumerated data types do not pass through a block that requires a nonzero scalar initial value (such as a `Unit Delay` block). Use a structure value to initialize signals with enumerated types.

Root level bus outputs are not logged when you select the **Configuration Parameters > Data Import/Export > Output** parameter. Use standard signal logging instead, as described in “Export Signal Data Using Signal Logging” on page 59-57.

Do not use signal logging for bus or array of buses signals directly from within a For Each subsystem. Either use a Bus Selector block to select the bus element signals to log or add an Outport block outside of the subsystem and then log that signal. For details, see “Log Signals in For Each Subsystems” on page 59-99.

Nested Buses

You can nest buses to any depth. To create a nested bus, use a **Bus Creator** block. If one of the inputs to the Bus Creator block is a bus, then the output is a nested bus. To select a signal within a nested bus, use a **Bus Selector** block.

For example, in the next model, the **Bus3** bus signal combines two signals, **motor3** and **motor4**. The **Bus2** signal combines the **Bus3** bus signal and the **motor1** and **motor2** signals. The **Bus1** signal combines the **Bus2** bus signal and the **motor5** signal.

All the signals retain their separate identities, as if no bus creation and selection occurred. You can use Bus Selector blocks to select individual signals from a nested bus.

The Simulink software automatically handles most of the complexities involved. For example, you can have Simulink repair broken selections in the Bus Selector and Bus Assignment block parameter dialog boxes due to upstream bus hierarchy changes. To enable these automatic repairs, in the **Configuration Parameters > Diagnostics > Connectivity** pane, set the **Repair bus selections** diagnostic to **Warn and repair**. The repairs occur when you update a model. To save the repairs, save the model.

Circular Dependency in Bus Definitions

Nesting buses can produce a loop of Bus Creator, Bus Selector, and bus-capable blocks that inadvertently includes a bus as an element of itself. The resulting circular definition cannot be resolved and therefore causes an error.

The error message that appears specifies the location at which the Simulink software determined that the circular structure exists. The error is not really at any one location: the structure as a whole is in error. Nonetheless, the location cited in the error message can be useful for beginning to trace the definition cycle. However, the circular structure is not always obvious on visual inspection.

- 1 Begin by selecting a signal line associated with the location cited in the error message.
- 2 Right-click a signal and choose **Highlight to Signal to Source** or **Highlight Signal to Destination**. See “Display Signal Sources and Destinations” on page 62-38 for more information.
- 3 Continue choosing signals and highlighting their sources and destinations until the cycle becomes clear.
- 4 Restructure the model to eliminate the circular bus definition.

Because the problem is a circular definition rather than a circular computation, the cycle cannot be broken by inserting additional blocks. You cannot fix the circular definition the way that you can break an algebraic loop by inserting a Unit Delay block. Restructure the model to eliminate the circular bus definition.

Assign Signal Values to a Bus

To assign the values of a signal to bus element, you can use a Bus Assignment block. Use a Bus Assignment block to change bus element values without adding Bus Selector and Bus Creator blocks that select bus elements and reassemble them into a bus.

Connect to the Bus Assignment block ports:

- The bus signal to which you want to assign the signal values
- The signals whose values you want to assign to specified bus elements

Connect the bus signal to the first input port of the Bus Assignment block, and one or more signals to be assigned to the other ports. The Block Parameters dialog box lists the signals available for assignment in the bus. The bus can be virtual or nonvirtual. Select the elements to which you want to assign signal values. If you specify more than one signal to assign values to, the Bus Assignment block adds ports.

The signals that you assign values to can be nonbus or bus signals. The signals must match the attributes of the signals in the original bus.

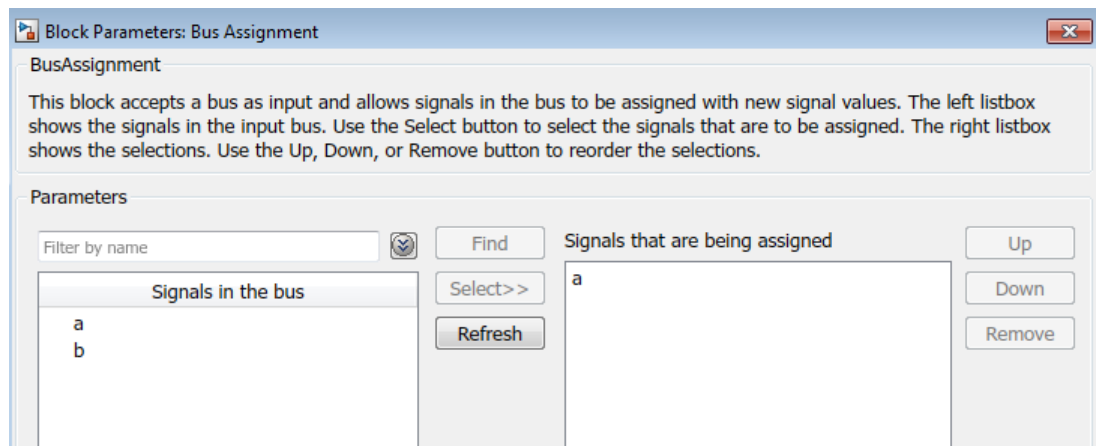

Update a Bus Element

This simple example illustrates the mechanics of using the Bus Assignment block. In more complex models, using a Bus Assignment block simplifies updating a bus to reflect the processing that occurs in a separate component, such as a subsystem or referenced model. Here is the model after you simulate it.

Some key steps in constructing this model are:

- 1 Connect two Constant blocks to a Bus Creator block. The value of signal **a** is 1, and the value of signal **b** is 2.
- 2 Connect the Bus Creator output signal **const_bus** to the first port of a Bus Assignment block. The bus elements **a** and **b** are available to assign new values to them.
- 3 Connect the Constant block output signal **c** output signal to the second port of the Bus Assignment block.
- 4 For the Bus Assignment block, in the Block Parameters dialog box **Signals in bus** list, select the **a** signal and click **Select>>**.

- 5 Use a Bus Selector to select signals **a** and **b** from the **const_bus** signal and connect those signals to Display blocks.
- 6 Simulate the model. The Display blocks show that the value of signal **a**, which was 1 when the **const_bus** bus was created, is now 3, reflecting the assignment of the **c** signal from the **Const3** block.

Specify Bus Signal Sample Times

In this section...
“Sample Times for Nonvirtual Buses” on page 63-36
“Specify Sample Times for Signal Elements” on page 63-38

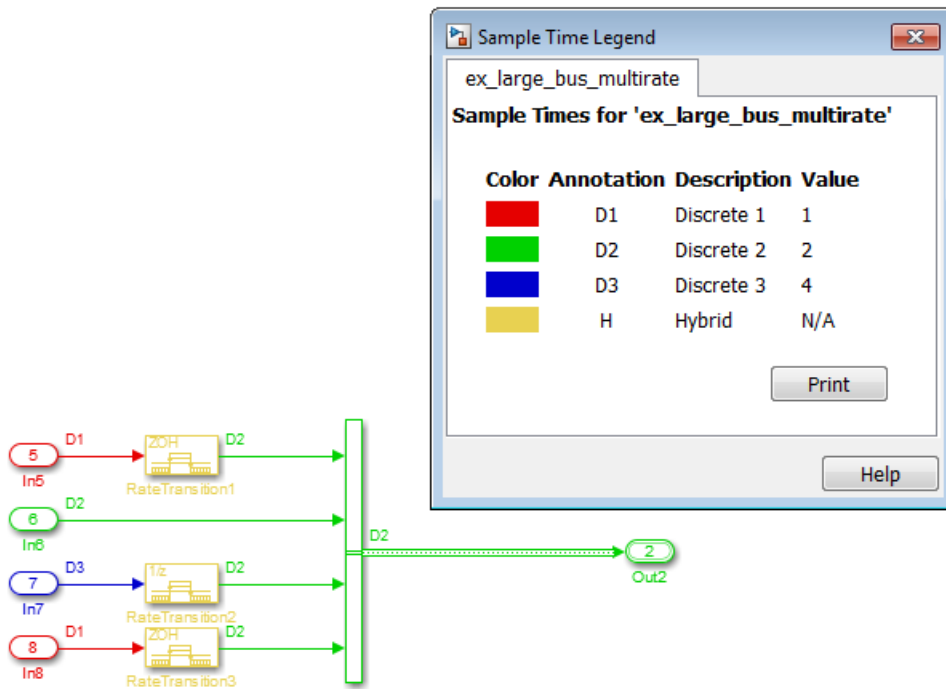

The technique that you use to combine signals that use different sample times depends on the virtuality of the bus.

- Virtual buses can combine signals that have different sample times.
- Nonvirtual buses require that every element signal has the same sample time.

Sample Times for Nonvirtual Buses

All signals in a nonvirtual bus must have the same sample time, even if the elements of the associated bus object specify inherited sample times. Any bus operation that results in a nonvirtual bus that violates this requirement generates an error. All buses and signals input to a Bus Creator block that outputs a nonvirtual bus must have the same sample time.

To include the signal or bus in a nonvirtual bus, you can use a `Rate Transition` block to change the sample time of an individual signal, or of all signals in a bus. Upstream of the Bus Creator block, use `Rate Transition` blocks to apply the same sample time to each signal element.

However, some blocks, such as root-level Outport blocks, automatically convert virtual buses to nonvirtual buses. In this case, you can use a single Rate Transition block after a Bus Creator block to transition all the signal elements to a single sample time.

For more information about automatic conversion of virtual buses to nonvirtual buses, see “Bus Conversion” on page 63-126.

Specify Sample Times for Signal Elements

To control the sample time of each signal element in a bus, specify the sample time in the Block Parameters dialog box of the block that generates the signal element.

To specify a sample time for a signal in a `Simulink.BUS` object, a best practice is to use the default `SampleTime` value of -1.

When to Use Bus Objects

In this section...
“Required Uses of Bus Objects” on page 63-41
“Optional Uses of Bus Object” on page 63-41
“Bus Object Use with Blocks” on page 63-41
“Bus Object Workflow” on page 63-43

A bus can have an associated bus object, which provides properties that Simulink uses to validate the bus signal. Bus objects are optional for virtual buses, but required for nonvirtual buses.

A bus object specifies only the architectural properties of a bus, as distinct from the values of the signals it contains. For example, a bus object can specify the number of elements in a bus, the order of those elements, whether and how elements are nested, and the data types of constituent signals; but not the signal values. A bus object is analogous to a structure definition in C: it defines the members of the bus but does not create a bus. Another way of thinking of a bus object is that it is similar to a cable connector. The connector defines all the pins and their configuration and controls what types of wires can be connected to it. Similarly, a bus object defines the configuration and properties of the signals that the associated bus must have.

A bus object is an instance of class `Simulink.BUS` that can be stored in a location such as the base workspace. The object defines the structure of the bus and the properties of its elements, such as nesting, data type, and size.

A bus object serves as the root of an ordered hierarchy of bus elements, which are instances of class `Simulink.Buselement`. Each element completely specifies the properties of a signal in a bus, such as its name, data type, and dimensionality. The order of the elements contained in the bus object defines the order of the signals in the bus. A bus object can also specify properties that were not defined by constituent signals, but were left to be inherited.

You can use the Simulink Bus Editor to create and manage bus objects, as described in “Create Bus Objects with the Bus Editor” on page 63-44, or you can use the Simulink API, as described in “Create Bus Objects Programmatically” on page 63-54. After you create a bus object and specify its attributes, you can associate it with any block that needs to use the bus definition that the object provides.

You can save bus objects as MATLAB code or as a MAT-file.

Required Uses of Bus Objects

You must use bus objects for these modeling configurations:

- Bus data that crosses model reference boundaries
- MATLAB Function block or Stateflow charts that input or output buses
- S-function or Legacy Code Tool interface with external code

Optional Uses of Bus Object

If you use Bus Creator block parameters to specify bus signal properties, all blocks downstream from the bus inherit the same properties.

You can use Bus Creator block parameters to define virtual buses and perform limited error checking. To perform thorough error checking on a bus, associate a bus object with that bus. Using bus objects to check bus signals for errors is important when you want to create reusable and shareable model components.

To make it easier to trace the correspondence between the model and the generated code for a bus, use a nonvirtual bus. The generated code for a nonvirtual bus produces a structure, but also can result in multiple copies of some bus signals.

Bus Object Use with Blocks

You can associate a bus object with several blocks. Some blocks require that you specify a bus object if the block has a bus input or bus output. When a bus object governs a signal output by a block, the signal is a bus that has exactly the properties specified by the object. When a bus object governs a signal input by a block, the signal must be a bus that has exactly the properties specified by the object. Any variance causes an error.

Signal Specification	
State Reader	✓
Unit Delay	

To associate a block with a bus, in the Block Parameters dialog box, set **Data type** to Bus: <object name> and replace <object name> with the bus object name.

If a subsystem that is in a library contains a block that uses a bus object, all instances of that block must match the bus object specification.

Note: Do not set the minimum and maximum values for bus data on blocks with bus object data type. Simulink ignores these settings. Instead, set the minimum and maximum values for bus elements of the bus object specified as the data type. The values should be finite real double scalar.

For information on the `Minimum` and `Maximum` properties of a bus element, see `Simulink.BusElement`.

Bus Object Workflow

Using bus objects in a model involves performing these tasks, in many cases iteratively.

- 1 Determine where you need or want to use bus objects.
- 2 Determine how you want to manage the bus objects, to keep track of the bus objects used by a model and the models that use the bus objects.
- 3 Create the bus objects in the MATLAB base workspace.
- 4 Export the bus objects from the base workspace to a MATLAB code file or a MAT-file.
- 5 Import bus objects from files to models that use the bus objects.

Create Bus Objects with the Bus Editor

In this section...

“Open the Bus Editor” on page 63-44

“Create Bus Objects” on page 63-44

“Create Bus Elements for the Bus Object” on page 63-46

“Nest Bus Object Definitions” on page 63-49

“Use the Bus Objects in the Model” on page 63-52

To create a bus object and its elements interactively, use the Simulink Bus Editor. The bus objects that you create with the Bus Editor are stored in the MATLAB base workspace. To simulate a block that uses a bus object, the bus object must be in the base workspace or in a data dictionary. To save bus object definitions to associate with models, export the bus objects from the base workspace into a MATLAB code file or MAT-file (see “Save and Import Bus Objects” on page 63-63).

You can specify the bus object to be the data type of a block either before or after defining the bus object. However, before you simulate the model, the bus object and the corresponding bus signal must have the same number of bus elements, in the same order. Also, each bus element in the bus object and in the corresponding signal in the model must have the same attributes.

During model development, you can modify bus signals to match bus objects or modify bus objects to match buses.

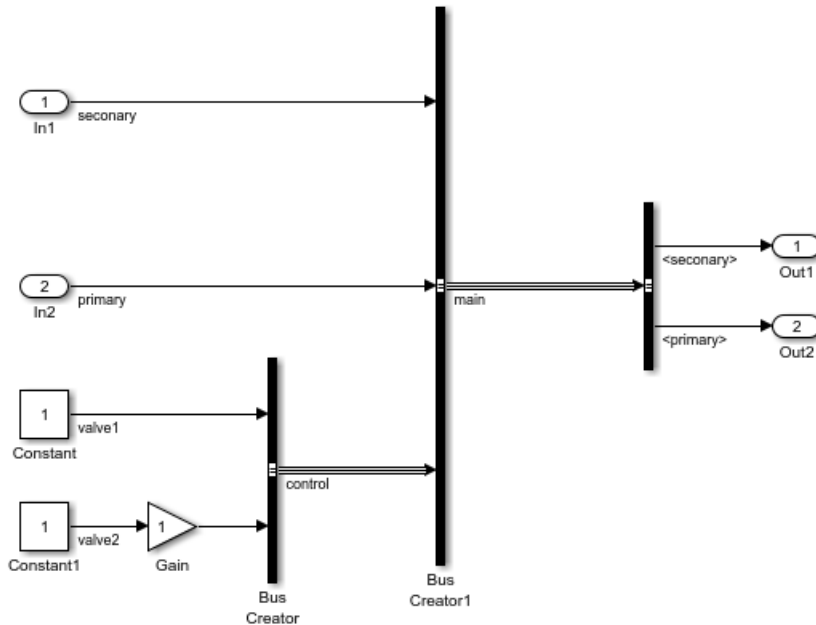

Open the Bus Editor

Open the Bus Editor using one of these approaches:

- In the Simulink Editor, select **Edit > Bus Editor**.
- At the MATLAB command line, enter `buseditor`.
- In the Model Explorer, in a bus object dialog box, click the **Launch Bus Editor** button.

Create Bus Objects

Suppose that your model has two buses, with one bus nested inside the other bus.

This example shows how to create bus objects corresponding to the `control` and `main` bus signals. To complete the definition of the bus objects and use those objects, also perform the steps in these examples:

- “Create Bus Elements for the Bus Object” on page 63-46
- “Nest Bus Object Definitions” on page 63-49
- “Use the Bus Objects in the Model” on page 63-52

- 1 Open the model.
- 2 In the Simulink Editor, select **Edit > Bus Editor**.
- 3 In the Bus Editor, select **File > Add Bus**.

This action creates a bus object with a default name and properties. The object appears in the **Hierarchy** pane and its properties appear in the **Dialog** pane.

- 4 Specify the name for the bus object, using the **Name** property. To make it easier to see how the bus object is used in a model, use a name that reflects the bus signal

associated with the bus object. The bus signal that combines the valve inputs is named `control`, therefore, name the bus object `CONTROL`.

- 5 You can provide documentation about the bus object by using the **Description** property. Enter `Combines two valve signals`.
- 6 Click **Apply**.
- 7 Create the second bus object. In the **Hierarchy** pane, select the `CONTROL` bus object and in the toolbar select the **Add Bus** button ()
- 8 In the **Dialog** pane, set **Name** to `MAIN` and **Description** to `Defines a bus object for a bus that contains three signals, including the control bus signal`.
- 9 Click **Apply**.

The **Hierarchy** pane displays bus objects in alphabetical order.

Do not close MATLAB without exporting the bus objects to a MATLAB code file or MAT-file. Otherwise, you lose the bus object definitions.

To define bus element objects for the bus objects, perform the steps in “Create Bus Elements for the Bus Object” on page 63-46.

Create Bus Elements for the Bus Object

This example builds on bus objects that you created in “Create Bus Objects” on page 63-44. The example shows how to define the bus element objects for the `CONTROL` and `MAIN` bus objects for the model.

Note: In this example, the name for the bus element and the corresponding signals are different, to try to highlight that they are distinct entities. If you change the default value for the **Element name mismatch** diagnostic to error, then the signal name and corresponding bus element name must match exactly to run on all platforms.

Also, the Bus Creator blocks in this model use the default setting for the **Override signal names from inputs** block parameter. The default setting of `ON` propagates the signal names of the signals in model, not of the names of the bus elements in the bus object.

To complete the definition of the bus objects and use those objects, also perform the steps in these examples:

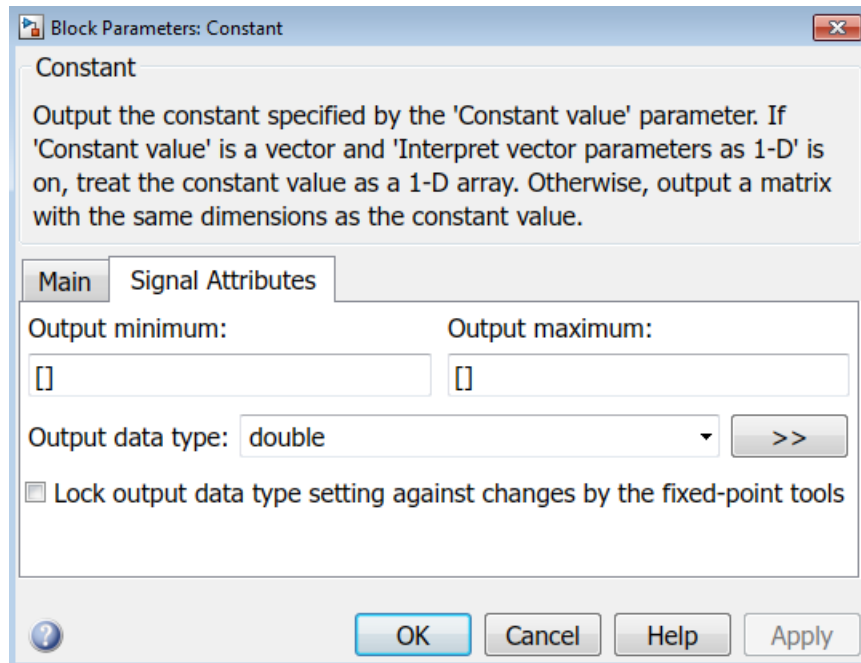

- “Nest Bus Object Definitions” on page 63-49
- “Use the Bus Objects in the Model” on page 63-52

- 1 In the Bus Editor **Hierarchy** pane, select the CONTROL bus object.
- 2 Select **File > Add/Insert BusElement**.

A new bus element with a default name and properties is created in the CONTROL bus object. The bus element appears in the **Hierarchy** pane below the CONTROL bus object.

- 3 In the **Dialog** pane, set **Name** to VALVE1, to reflect the name of the top signal in the bus.
- 4 For the **Constant** block, open the Block Parameters dialog box and select the **Signal Attributes** tab.

- 5 In the Bus Editor **Dialog** pane, set **DataType** property to **double**, to match the **Output data type** block parameter setting for the Constant block. Use the default setting for the other bus element object properties.
 - 6 Click **Apply**.
 - 7 Create a second bus element object that corresponds to the `valve2` bus element signal. In the **Hierarchy** pane, select the VALVE1 bus element object and click the **Add/Insert Bus Element** button ().
 - 8 For the Constant1 block, open Block Parameters dialog box and select the **Signal Attributes** tab.
- The **Output data type** is `int8`.
- 9 In the Bus Editor **Dialog** pane, for the VALVE2 bus element object, set **DataType** property to `int8`. Use the default setting for the other bus element object properties.
 - 10 Click **Apply**.

- 11 Create a bus element object for the **secondary** bus element signal of the **main** bus. In the **Hierarchy** pane, select the **MAIN** bus object and click the **Add/Insert Bus Element** button.
- 12 Set the **Name** property to **SECONDARY** and the **Data type** property to **int32**, matching the **In1** block output signal data type. Click **Apply**.
- 13 Create a bus element object for the **primary** bus element signal of the **main** bus. In the **Hierarchy** pane, select the **secondary** bus element object and click the **Add/Insert Bus Element** button.
- 14 Set the **Name** property to **PRIMARY** and the **Data type** property to **boolean**, matching the **In2** block output signal data type. Click **Apply**.

To define a bus element object for the control bus, which is the third bus element of the main bus, perform the steps in “Nest Bus Object Definitions” on page 63-49.

Nest Bus Object Definitions

Any signal in a bus can be another bus, which can in turn contain subordinate buses, to any depth. Describing nested buses with bus objects requires nesting the bus object definitions that the objects provide.

Every bus object defines a data type whose properties are specified by the object. To nest one bus object definition in another, assign to a bus element of one bus object a data type that is defined by another bus object. The bus element object represents a nested bus. The bus object that specifies the data type of the bus element object defines the nested bus elements.

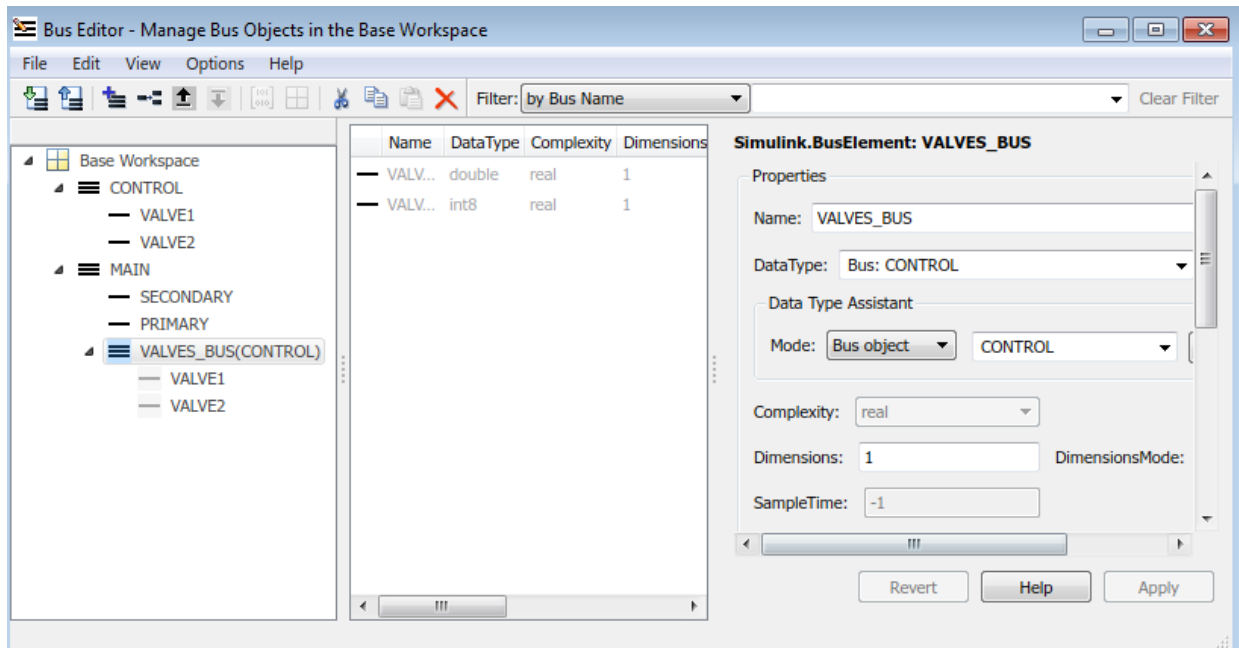

A data type defined by a bus object is called a *bus type*. Nesting buses by assigning bus types to elements allows the same bus definition to be used conveniently in multiple contexts without unwanted interactions.

This example builds on the bus objects and bus elements that you created for the model in “Create Bus Objects” on page 63-44 and “Create Bus Elements for the Bus Object” on page 63-46.

- 1 In the Bus Editor **Hierarchy** pane, select the PRIMARY bus element object and click the **Add/Insert Bus Element** button.
- 2 In the **Dialog** pane, set the **Name** property to VALVES_BUS.
- 3 For the **Data type** property, use the Bus: <object name> template, replacing <object name> with CONTROL, which is the name of the bus object for the control bus.
- 4 Click **Apply**.

If you expand the VALVES_BUS bus element object, you see the two bus element objects for the CONTROL bus object, VALVE1 and VALVE2.

- 5 You have finished defining bus objects for this example. Consider exporting the bus objects to a MATLAB code file. In the Bus Editor, select **File > Export to File**. In the Export dialog box, specify a file name for the bus object MAT-file.

To use the bus objects to create nonvirtual buses, perform the steps in “Use the Bus Objects in the Model” on page 63-52.

Avoid Circular Nested Bus Object Definitions

You can nest a bus object in as many different bus objects as desired, and as many times in the same bus object as desired. You can nest bus objects to any depth, but you cannot define a circular structure by directly or indirectly nesting a bus object within itself.

If you define a circular structure, the Bus Editor posts a warning and sets the data type of the element that would have completed the cycle to **double**. Click **OK** to close the warning and continue using the editor.

Use the Bus Objects in the Model

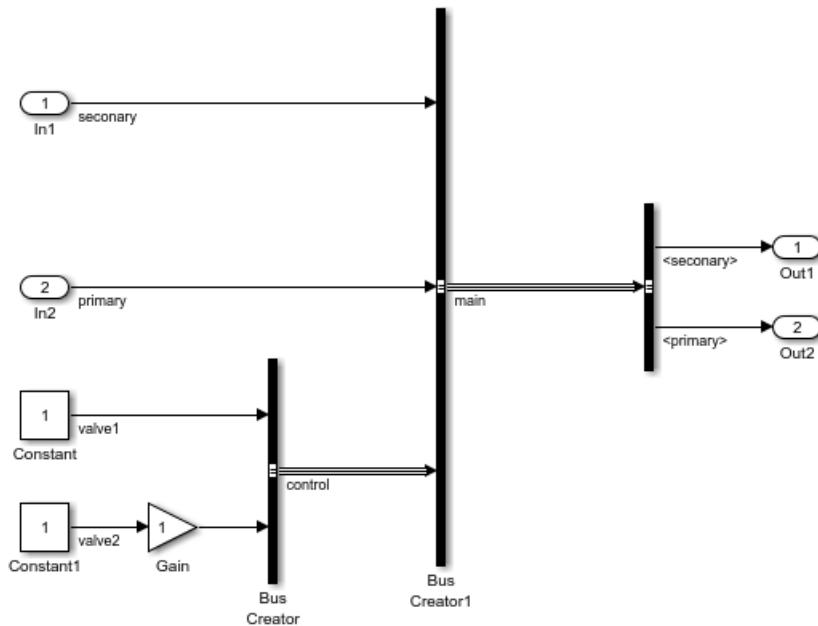

The buses in the `ex_bus_object_tutorial` model that you defined in the “Create Bus Objects” on page 63-44 example and its associated examples are virtual buses. To use the bus objects you defined in those examples to change the virtual buses to nonvirtual buses:

- 1 Open the `Bus Creator` Block Parameters dialog box. Set **Output data type** to `Bus: CONTROL` and select **Output as nonvirtual bus**.

Note: You can use a bus object to specify the data type for a block without specifying that the bus is a nonvirtual bus. You must specify a bus object for a nonvirtual bus, but it is optional for a virtual bus.

- 2 Open the `Bus Creator1` Block Parameters dialog box. Set **Output data type** to `Bus: MAIN` and select **Output as nonvirtual bus**.
- 3 Add another `Outport` block after the `Bus Creator1` block and connect it to the `main` signal.
- 4 Open the `Out3` Block Parameters dialog box. In the **Signal Attributes** tab, set the **Data type** to `Bus: MAIN` and select **Output as nonvirtual bus in parent model**.

The model uses the bus objects that you defined. When you simulate the model, you see that the buses are now nonvirtual.

- “When to Use Bus Objects” on page 63-40
- “Create Bus Objects Programmatically” on page 63-54
- “Modify Bus Objects” on page 63-57
- “Save and Import Bus Objects” on page 63-63
- “Map Bus Objects to Models” on page 63-69

Create Bus Objects Programmatically

To create a bus object and its bus elements programmatically, use one of these approaches:

- “Create Simulink.Bus and Simulink.BusElement Objects Directly” on page 63-54 — Construct a `Simulink.Bus` object and define its properties. Construct `Simulink.BusElement` objects for the elements of the bus.
- “Create Bus Objects from Blocks” on page 63-55 — Create a bus object and its bus element objects based on a block in a model.
- “Create Bus Objects from MATLAB Data” on page 63-55 — Create a bus object and its bus elements based on a MATLAB structure or cell array.

As you create bus objects programmatically, you can store them in either the MATLAB workspace or in a MATLAB code file. After you create a bus object, you can use MATLAB commands to save the bus objects to a MAT-file (see “Save and Load Workspace Variables”). To simulate a block that uses a bus object, that bus object must be in the base workspace or in a data dictionary.

You can specify the bus object to be the data type of a block either before or after defining the bus object. However, before you simulate the model, the bus object and the corresponding bus signal must have the same number of bus elements, in the same order. Also, each bus element in the bus object and in the corresponding bus element signal must have the same data type and dimensions.

During model development, you can modify bus signals to match bus objects or modify bus objects to match buses.

Create Simulink.Bus and Simulink.BusElement Objects Directly

You can create a `Simulink.Bus` object and its `Simulink.BusElement` objects programmatically. The bus objects are stored in the base workspace. For each bus element object, specify the name, dimensions, and data type. The other bus element object properties are optional. For the bus object, specify the bus elements. The other bus object properties are optional. For example, this code creates two bus element objects that are then used as the elements of the `CONTROL` bus object.

```
clear elems;
elems(1) = Simulink.BusElement;
elems(1).Name = 'VALVE1';
```

```

elems(1).Dimensions = 1;
elems(1).DimensionsMode = 'Fixed';
elems(1).DataType = 'double';
elems(1).SampleTime = -1;
elems(1).Complexity = 'real';

elems(2) = Simulink.BusElement;
elems(2).Name = 'VALVE2';
elems(2).Dimensions = 1;
elems(2).DimensionsMode = 'Fixed';
elems(2).DataType = 'double';
elems(2).SampleTime = -1;
elems(2).Complexity = 'real';

CONTROL = Simulink.Bus;
CONTROL.Elements = elems;

```

This script is similar to the file you get if you save a bus object to a MATLAB file and choose the `Object` format. For information about saving bus objects, see “Save and Import Bus Objects” on page 63-63.

Create Bus Objects from Blocks

You can create a bus object and its bus elements programmatically based on a block in a model. Use the `Simulink.Bus.createObject` function and specify the model and blocks for which to create bus objects for. Before you use the function, the model must be compilable. For example, if you specify a Bus Creator block that is at the highest level of a nested bus hierarchy, the function creates bus objects for all of the buses in the hierarchy. You can specify to have the bus objects created in the base workspace or to save them in a MATLAB code file. For an example, see “Use Bus Creator Blocks to Create a Bus Object”.

Create Bus Objects from MATLAB Data

You can create a bus object from cell arrays of bus information in MATLAB, using the `Simulink.Bus.cellToObject` function. Each cell subordinate cell array represents a bus object and includes the following data, reflecting `Simulink.Bus` object properties:

```
{BusName,HeaderFile,Description,DataScope,Alignment,Elements}
```

The `Elements` field is a cell array defining these properties for each `Simulink.BusElement` object:

{ElementName,Dimensions,DataType,SampleTime,Complexity,DimensionsMode,Min,Max,Units,De

You can create a bus object from a MATLAB structure of `timeseries` objects, using the `Simulink.Bus.createObject` function. For an example, see “Use a Structure of Timeseries Objects to Create a Bus Object”. Alternatively, you can specify a numeric MATLAB structure. You can specify to have the bus objects created in the base workspace or to save them in a MATLAB code file.

Related Examples

- “When to Use Bus Objects” on page 63-40
- “Create Bus Objects with the Bus Editor” on page 63-44
- “Save and Import Bus Objects” on page 63-63
- “Modify Bus Objects” on page 63-57
- “Map Bus Objects to Models” on page 63-69

Modify Bus Objects

In this section...

“Edit Bus Objects” on page 63-58

“Edit Bus Element Objects” on page 63-58

“Copy and Paste Bus Objects and Elements” on page 63-58

“Change the Order of Bus Elements” on page 63-58

“Delete Bus Objects and Bus Elements” on page 63-59

“Filter Displayed Bus Objects” on page 63-59

Modify a bus object or its bus element objects if you change the associated bus signal to:

- Add or delete a bus element signal.
- Reorder bus element signals.
- Change the data type or dimensions of a bus element signal.

If you modify a bus object to reflect changes to a bus signal, confirm that the bus object continues to work in other places it is used. To find where a bus object is used in a model, see “Finding Blocks That Use a Specific Variable” on page 57-91.

If you do not want to change the bus object, you can:

- Create a bus object that matches the changes to the bus signal and use the new bus object for the blocks that the changed bus connects to.
- Revert the bus signal changes so that the bus signal continues to match the associated bus object.

You can use the Bus Editor to change and delete existing bus objects and bus elements. The Bus Editor displays all the bus objects in the base workspace. Changes that create, reorder, or delete entities take effect immediately in the base workspace. Changes to properties take effect when you apply them. The Bus Editor does not provide an undo capability.

If you have saved a bus object in a MATLAB code file, you can edit it programmatically. For details, see “Create Simulink.Bus and Simulink.BusElement Objects Directly” on page 63-54.

Edit Bus Objects

- 1 Open the Bus Editor.
- 2 In the **Hierarchy** pane, expand **Base Workspace** (if necessary) and select the bus object to edit.

Tip If the base workspace contains many bus objects, you can reduce the number of displayed bus objects by using a Bus Editor filter. For details, see “Filter Displayed Bus Objects” on page 63-59.

- 3 In the **Dialog** pane, edit the bus object properties.
- 4 Click **Apply**.

Edit Bus Element Objects

- 1 Open the Bus Editor.
- 2 In the **Hierarchy** pane, expand **Base Workspace** (if necessary) and select the bus object whose bus element object you want to modify.
- 3 In the **Contents** pane, select the bus element whose properties you want to edit. You can make the edits in the **Dialog** pane or in the **Contents** pane. To make the same edit to a property in multiple bus elements, use the **Contents** pane. Hold the **Ctrl** key while you select multiple bus elements and enter the new value in the property for one of the selected bus elements. The change applies to all the selected bus elements.
- 4 If you made edits in the **Dialog** pane, click **Apply**.

Copy and Paste Bus Objects and Elements

You can use the Bus Editor to copy and paste bus objects or bus element objects. Right-click an object and use the context menu to copy and paste the bus object. Copying a bus object also copies its bus elements. The copied objects have the same property values as the original objects. Change the name of the objects and modify other properties as necessary.

Change the Order of Bus Elements

To change the order of bus elements in a bus object, in the **Hierarchy** pane, select a bus element and move it up or down in the list, using the **Move Element Up**

or the **Move Element Down**  button.

Delete Bus Objects and Bus Elements

To delete a bus object, in the **Hierarchy** pane, select the bus object and click the **Delete**

button or **Delete** key. Deleting a bus object deletes its bus element objects.

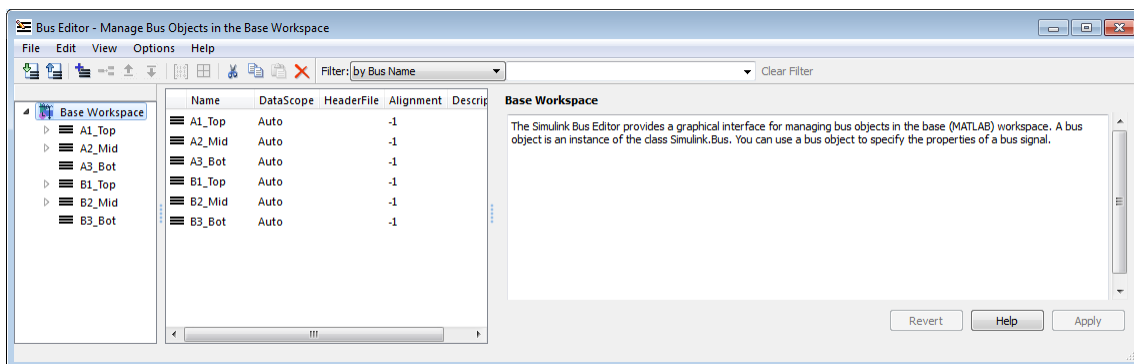

If you delete a bus object, in the Simulink Editor, update any blocks that use that bus object. To find where a bus object is used in a model, see “Finding Blocks That Use a Specific Variable” on page 57-91.

Filter Displayed Bus Objects

By default, the Bus Editor displays all bus objects that exist in the base workspace, in alphabetical order. When there are many bus objects, you can have the Bus Editor display only those bus objects that have:

- Names that match a given search term or regular expression
- A specified relationship to a specified bus object

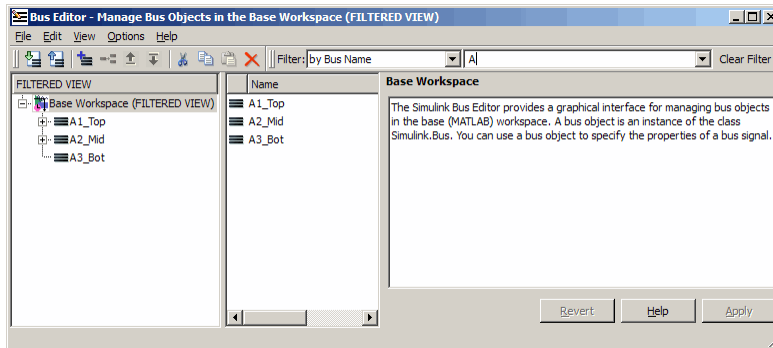

To set a filter, specify values in the **Filter** boxes to the right of the tools in the toolbar. Depending on the specified type of filtering, one or two boxes appear to the right of the **Filter Type** box. In this example, the Bus Editor displays the bus objects that are in the base workspace:

The bus objects shown form two disjoint hierarchies. **A1_Top** is the parent of **A2_Mid**, which is the parent of **A3_Bot**. Similarly, **B1_Top** > **B2_Mid** > **B3_Bot**.

Filter by Name

Set **Filter Type** to **by Bus Name** and in **Object Name**, enter a character vector. See “Regular Expressions” for complete information about MATLAB regular expression syntax. As you type, the Bus Editor updates dynamically to show only the bus objects whose names match the expression that you have typed. The comparison is case-sensitive. For example, entering **A** displays:

Filter by Relationship

Set **Filter Type** box to **by Bus Object Dependency**. In the **Relationship** box, select the type of relationship to display:

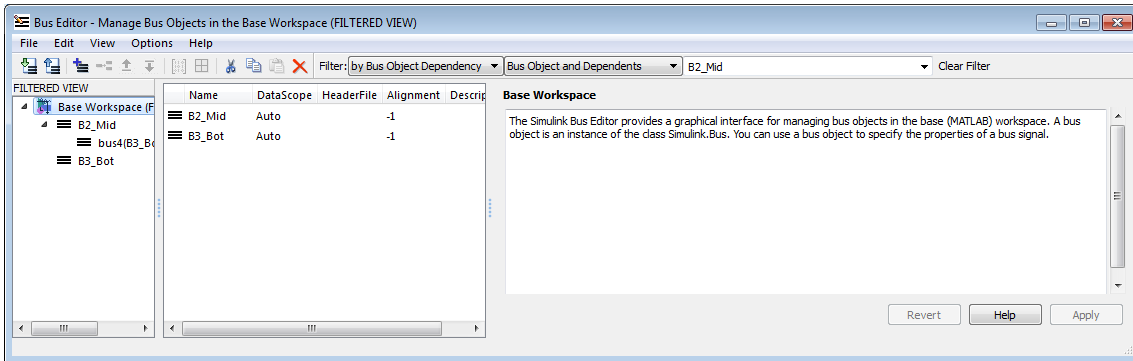

- **Bus Object and Parents** — Show a specified bus object and all superior bus objects in the hierarchy (default).
- **Bus Object and Dependents** — Show a specified bus object and all subordinate bus objects in the hierarchy.
- **Bus Object and Related Objects** — Show a specified bus object and all superior and subordinate bus objects.

In **Object Name**, specify a bus object by name, using a character vector. Use the list to select any existing bus object name, or type a name. As you type, the editor:

- Dynamically completes the field to indicate the first bus object that alphabetically matches what you have typed

- Updates the display panes to show only the specified object and any objects that have the specified relationship to it

For example, assuming that `A1_Top` is the parent of `A2_Mid`, which is the parent of `A3_Bot`, if you enter `B2`, the Bus Editor displays for **Bus Object and Dependents**:

Change Filtered Objects

You can work with any bus object that is visible in a filtered display exactly as in an unfiltered display. If you change the name or dependency of an object so that it no longer passes the current filter, the object disappears from the display. Conversely, if some activity outside the Bus Editor changes a filtered object so that it passes the current filter, the object immediately becomes visible.

If you create a bus object but do not see it in the editor, check the filter. The new object (whose name always begins with `BusObject`) can exist but be invisible. Bus objects created or imported from outside the Bus Editor are not visible until you reopen the Bus Editor, regardless of whether a filter is in effect.

Operations performed in the **Hierarchy** pane on the **Base Workspace** affect only visible objects. An object that is invisible because a filter is being used is unaffected by the operation. To act on all existing bus objects, clear the filter by clicking **Clear Filter**.

Save and Import Bus Objects

In this section...

“Locations for Saving Bus Objects” on page 63-64

“Data Dictionary” on page 63-65

“MATLAB Code File” on page 63-65

“MAT-File” on page 63-66

“Database or Other External Files” on page 63-68

When you create bus objects in the base workspace, before you close MATLAB, save (export) the bus objects to one of these locations:

- Data dictionary
- MATLAB code file
- MAT-file
- Database or other external files

If you do not save the bus objects, then when you reopen the model that uses the bus objects, you need to recreate the bus objects.

The technique you use for creating a bus object determines where the bus object is stored initially.

Bus Creation Technique	Initial Storage Location
Bus Editor	Base workspace
<code>Simulink.Bus</code> and <code>Simulink.BusElement</code> object definition	Base workspace
<code>Simulink.Bus.cellToObject</code>	Base workspace
<code>Simulink.createObject</code>	Base workspace or MATLAB code file

When you save bus objects using the Bus Editor, you can save them in a MAT-file or MATLAB code file. When you save bus objects using the `Simulink.Bus.save` or `matlab.io.saveVariablesToScript` function, the bus objects in the base workspace

are saved in a MATLAB code file in object form. You can use any MATLAB technique that saves the contents of the base workspace. However, the resulting file contains everything in the base workspace, not just bus objects.

Tip You can configure the Bus Editor so that closing it posts a reminder to save bus objects. To enable the reminder, select **Options > Always Warn Before Closing**. When you select this option and try to close the Bus Editor, a reminder appears about saving bus objects before closing. You can disable the reminder by clearing **Options > Always Warn Before Closing**.

You can customize bus object export and import by providing a custom function that writes to or reads from a location outside MATLAB. For example, the exported bus objects could be saved as records in a corporate database. See “Customize Bus Object Import and Export” on page 63-71 for details.

When you import and modify bus objects, resave them and possibly modify the mechanism (such as a model callback) that you use for importing them.

Locations for Saving Bus Objects

Before you choose where to save bus objects, consider how you want to associate bus objects with models. For more information, see “Map Bus Objects to Models” on page 63-69.

Location	Usage Considerations
Data dictionary	Use for large model componentization. When you save to a data dictionary from the base workspace, you get all the variables used by the model, not just the bus objects. Before you save to a data dictionary, read “Considerations before Migrating to Data Dictionary” on page 61-9.
MATLAB code file	Use for when you want to use MATLAB for traceability and model differencing.
MAT-file	Use for faster bus object saving and loading.

Location	Usage Considerations
Database or other external files	Use for comparing bus interface information with design documents stored in an external data source.

Data Dictionary

Save Bus Objects

To save bus objects (and other base workspace variables used by the model) to a data dictionary:

- 1 Link the model to a data dictionary, using the **Model Properties** dialog box.
- 2 Create a data dictionary.
- 3 Migrate data from the base workspace to the data dictionary.

For an example showing the complete procedure, see “Migrate Single Model to Use Dictionary” on page 61-6.

MATLAB Code File

Save Bus Objects

To use the Bus Editor to export all bus objects from the base workspace to a MATLAB code file using the Bus Editor:

- 1 In the Bus Editor, choose **File > Export to File**.
- 2 In the Export dialog box, specify the name for the export file. You do not have to specify a file extension.
- 3 Set **Save as type** to **MATLAB files (*.m)**.
- 4 Click **Save**.
- 5 In the dialog box that appears, select the format:
 - **Cell** — Stores the bus objects in a compressed format.
 - **Object** — Store the bus objects in `Simulink.Bus` object format, which is easier to read and edit.

All the bus objects that are in the base workspace, and nothing else, are exported to the specified MATLAB code file.

Note: Operations performed on the **Base Workspace** in the **Hierarchy** pane, such as exporting bus objects, affect only visible objects. An object that is invisible because a filter is being used is unaffected by the operation. To export all existing bus objects, before performing the export, clear any filter that is in use.

To export only selected bus objects from the base workspace to a file:

- 1 In the Bus Editor **Contents** pane, select one or more bus objects and right-click.
- 2 To export only the selected bus objects, in the context menu, select **Export to File**. To include nested bus objects used by the selected objects, select **Export with Related Bus Objects to File**.
- 3 Use the Export dialog box to export the selected bus objects.

When you create bus objects using `Simulink.Bus.createObject`, you can specify a MATLAB code file to store the bus objects. If you store the bus objects in a file, by default the objects are stored in cell format, which is a compressed format. To store the objects in a more readable format, use `'object'` as the last argument, after the file name. For example:

```
Simulink.Bus.createObject('busdemo','busdemo/Bus Creator2',...  
'bus_objs','object'),
```

Import Bus Objects

You can use a model callback, using the `load` function, to load the MATLAB code file.

If a model uses only a few bus objects, consider copying the bus object code directly into the callback, instead of loading a file. For an example, open the model and examine the callback.

You can use the Bus Editor to import the definitions from a MAT-file to the base workspace. The import loads the complete contents of the file, not just the bus objects.

- 1 Choose **File > Import into Base Workspace**.
- 2 Use the Open File dialog box to navigate to and import the desired file.

MAT-File

Save Bus Objects

To export all bus objects from the base workspace to a MAT-file using the Bus Editor:

- 1 In the Bus Editor, choose **File > Export to File**.
- 2 In the Export dialog box, specify the name for the export file. You do not have to specify a file extension.
- 3 Set **Save as type** to **MAT-files (*.mat)**.
- 4 Click **Save**.

All bus objects in the base workspace, and nothing else, are exported to the specified MAT-file.

Note: Operations performed on the **Base Workspace** in the **Hierarchy** pane, such as exporting bus objects, affect only visible objects. An object that is invisible because a filter is in use is unaffected by the operation. To export all existing bus objects, before performing the export, clear any filter that is in effect.

To export only selected bus objects from the base workspace to a file:

- 1 In the Bus Editor **Contents** pane, select one or more bus objects and right-click.
- 2 To export only the selected bus objects, in the context menu select **Export to File**. To export any nested bus objects used by the selected objects, select **Export with Related Bus Objects to File**.
- 3 Use the Export dialog box to export the selected bus objects.

When you create bus objects using `Simulink.Bus.createObject` or `Simulink.Bus.cellToObject`, you can save the bus objects as a MATLAB code file. When you use the `Simulink.saveVars` function to save variables from the base workspace, the objects are saved in a MATLAB code file.

Import Bus Objects

You can use a model callback, using the `load` function to load the MAT-file.

You can use the Bus Editor to import the definitions from a MAT-file to the base workspace. Importing the file loads the complete contents of the file, not just the bus objects.

- 1 Choose **File > Import into Base Workspace**.
- 2 Use the Open File dialog box to navigate to and import the desired file.

Database or Other External Files

Save Bus Objects

You can capture bus interface information in a database or other external source, and use scripts and Database Toolbox™ functionality to read that information into MATLAB.

Import Bus Objects

You can use `sl_customization.m` to customize the Bus Editor to import bus data from a database or other external source. For details, see “Customize Bus Object Import and Export” on page 63-71.

- “Create Bus Objects with the Bus Editor” on page 63-44
- “Create Bus Objects Programmatically” on page 63-54
- “Migrate Models to Use Simulink Data Dictionary” on page 61-6

Map Bus Objects to Models

As models become complex, it is important to identify the bus objects that a model uses and the models that use a specific bus object.

Before you simulate a model, all the bus objects it uses must be loaded into the base workspace. For automation and consistency across models, it is important to map bus objects to models.

- By identifying all of the bus objects a model needs, you can ensure that those objects are loaded before model execution.
- By identifying all models that use a bus object, you can ensure that changes to a bus object do not cause unexpected changes in any of the models that use that bus object.

To map bus objects to models, consider:

- Including the bus objects in a data dictionary. You can link the data dictionary to one or more models. For details, see “Migrate Single Model to Use Dictionary” on page 61-6.
- Using Simulink Projects:
 - 1 Serialize the files that contain the bus objects as part of a project.
 - 2 Loading that data upon project open.

For details, see “Project Management”.

- Capturing the mapping information in an external data source, such as a database.

To find where a bus object is used in an open model, see “Finding Blocks That Use a Specific Variable” on page 57-91.

Use a Rigorous Naming Convention

Using a rigorous and standard naming convention is very helpful for mapping bus object usage. For example, consider the model and data required for an actuator control function. Naming the model `Actuator` and the input and output ports `Actuator_bus_in` and `Actuator_bus_out`, respectively, makes the connection between the bus objects and the model clear.

Note that this approach can cause issues if the output from one model reference is fed directly to another model reference. In this case, the naming mismatch results in an error.

- “Save and Import Bus Objects” on page 63-63

Customize Bus Object Import and Export

In this section...
“Required Background Knowledge” on page 63-71
“Write a Bus Object Export Function” on page 63-72
“Write a Bus Object Import Function” on page 63-72
“Register Customizations” on page 63-73
“Change Customizations” on page 63-74

You can use the Bus Editor to import bus objects to the base workspace and to export bus objects from the base workspace, as described in “Save and Import Bus Objects” on page 63-63. By default, the Bus Editor can save bus objects to, and import bus objects from, a MATLAB code file or MAT-file. The files must be in a location that is accessible using an ordinary **Open** or **Save** dialog box.

You can write customized MATLAB functions that provide alternative import or export (or both) functionality. For example, you can write a customized function that stores the objects as records in a database, in a format that your organization uses.

After you design and implement a custom bus object import or export function, use the Simulink Customization Manager to register the function. The registration process establishes custom import and export functions as callbacks for the Bus Editor **Import to Base Workspace** and **Export to File** commands. The callbacks replace the default capabilities of the Bus Editor. Customizing the Bus Editor import and export capabilities has no effect on other MATLAB or Simulink functions. Canceling import or export customization restores the default Bus Editor capabilities for that operation without affecting the other.

Required Background Knowledge

Customizing bus object import or export requires that you understand:

- MATLAB language and programming techniques
- Simulink bus object syntax
- The proprietary format into which you translate bus objects, and the techniques necessary to access the facility that stores the objects.

- Any platform-specific techniques for obtaining data from the user, such as the name of the location in which to store or access bus objects.

Write a Bus Object Export Function

A custom bus object export function requires at least one argument. You can use additional arguments to handle special actions by the function. The value of the first argument is a cell array containing the names of all bus objects that the Bus Editor has selected. You can use functions, global variables, or any other MATLAB technique, to provide values for any additional arguments. The general algorithm of a customized export function is:

- 1 Iterate over the list of object names in the first argument.
- 2 Obtain the bus object corresponding to each name.
- 3 Translate the bus object to the proprietary syntax.
- 4 Save the translated bus object in the local repository.

This example shows the syntactic shell of such an export callback function is:

```
function myExportCallback(selectedBusObjects)
disp('Custom export was called!');
for idx = 1:length(selectedBusObjects)
    disp([selectedBusObjects{idx} ' was selected for export.']);
end
```

Although this function does not export any bus objects, it is syntactically valid and can be registered. It accepts a cell array of bus object names, iterates over them, and prints each name. An operational export function:

- Uses each name to retrieve the corresponding bus object from the base workspace
- Converts the object to proprietary format
- Stores the converted object

The additional logic is enterprise-specific.

Write a Bus Object Import Function

A custom bus object import function can take zero or more arguments to perform its task. You can use functions, global variables, or any other MATLAB technique to provide argument values. Also, the function can poll the user for information, such as a

designation of where to obtain bus object information. The general algorithm of a custom bus object import function is:

- 1 Obtain bus object information from the local repository.
- 2 Translate each bus object definition to a `Simulink.Bus` object.
- 3 Save each bus object to the MATLAB base workspace.

This example shows the syntactic shell of an import callback function is:

```
function myImportCallback
disp('Custom import was called!');
```

Although this function does not import any bus objects, it is syntactically valid and can be registered with the Simulink Customization Manager. An operational import function:

- Gets a designation of where to obtain the bus objects to import
- Converts each bus object to a `Simulink.Bus` object
- Stores the object in the base workspace

The additional logic is enterprise-specific.

Register Customizations

To customize bus object import or export, provide a customization registration function that inputs and configures the Customization Manager whenever you start Simulink software or refresh Simulink customizations. The steps for using a customization registration function are:

- 1 Create a file named `sl_customization.m` to contain the customization registration function. Alternatively, you can use an existing customization file.
- 2 At the top of the file, create a function named `sl_customization` that takes a single argument (or use the customization function in an existing file). When the function is invoked, the value of this argument is the Customization Manager.
- 3 Configure the `sl_customization` function to set `importCallbackFcn` and `exportCallbackFcn` to be function handles that specify your customized bus object import and export functions.
- 4 If `sl_customization.m` is a new customization file, put it anywhere on the MATLAB search path. Two frequently used locations are `matlabroot` and the current working folder. Alternatively, you can extend the search path.

Here is a simple example of a customization registration function:

```
function sl_customization(cm)
disp('My customization file was loaded. ');
cm.BusEditorCustomizer.importCallbackFcn = @myImportCallback;
cm.BusEditorCustomizer.exportCallbackFcn = @(x)myExportCallback(x);
```

When Simulink starts up, it traverses the MATLAB search path looking for files named `sl_customization.m`. Simulink loads each such file that it finds (not just the first file) and executes the `sl_customization` function at its top, establishing the customizations that the function specifies.

Executing the example customization function displays a message (which an actual function probably would not). The function establishes that the Bus Editor uses a function named `myImportCallback()` to import bus objects, and a function named `myExportCallback(x)` to export bus objects.

The function corresponding to a handle that appears in a callback registration can be undefined when the registration occurs. However, it must be defined when the Bus Editor calls the function. The same latitude and requirement applies to any functions or global variables used to provide the values of additional arguments.

Other functions can also exist in the `sl_customization.m` file. However, the Simulink software ignores files named `sl_customization.m`, except when it starts up or refreshes customizations. Any changes to functions in the customization file are ignored until one of those events occurs. By contrast, changes to other MATLAB code files on the MATLAB path take effect immediately.

For more information, see “Registering Customizations” on page 65-26.

Change Customizations

You can change the handles established in the `sl_customization` function by:

- Changing the function to specify the changed handles
- Saving the function
- Refreshing customizations by executing `sl_refresh_customizations`

Simulink traverses the MATLAB path and reloads all `sl_customization.m` files that it finds, executing the first function in each one, just as it did on Simulink startup.

You can revert to default import or export behavior by setting in the `sl_customization` function the appropriate `BusEditorCustomizer` element to `[]` and then refreshing customizations. Alternatively, you can eliminate both customizations in one operation by executing:

```
cm.BusEditorCustomizer.clear
```

where `cm` was previously set to a customization manager object (see “Register Customizations” on page 63-73).

Changes to the import and export callback functions themselves, as distinct from changes to the handles that register them as customizations, take effect immediately, unless they are in the `sl_customization.m` file itself. If the callback functions are in the `sl_customization.m` file, they take effect next time you refresh customizations. Keeping the callback functions in separate files usually provides more flexible and modular results.

Use Buses for Inports and Outports

In this section...

“Use Buses with Root-Level Inports” on page 63-76

“Use Buses with Root-Level Outports” on page 63-76

“Buses for Atomic Subsystem Nonvirtual Inports” on page 63-77

“Buses with Model Referencing” on page 63-79

For information about using buses as inputs to, or outputs from, a referenced model, see “Bus Data Crossing Model Reference Boundaries” on page 63-123.

Use Buses with Root-Level Inports

To have a root-level Inport block in a model that does not specify a bus object produce a bus signal, in the Inport block:

- Set the **Data type** parameter to **Bus: <object name>**
- Replace **<object name>** with the name of the bus object name that defines the bus that the Inport produces.

For more information, see “Import Bus Data to Top-Level Input Ports” on page 59-154.

Use Buses with Root-Level Outports

A root level Outport of a model can accept a virtual bus only if all elements of the bus have the same data type. The Outport block automatically unifies the bus to a vector having the same number of elements as the bus, and outputs that vector.

To have a root-level Outport of a model accept a bus signal that contains mixed data types, use the Block Parameters dialog box of the Outport block.

- Set **Data type** to **Bus: <object name>**.
- Replace **<object name>** with the name of the bus object name that defines the bus that the Outport produces.

If the bus signal in a top-level model in a model reference hierarchy is virtual, the signal is converted to nonvirtual (see “Bus Conversion” on page 63-126).

Buses for Atomic Subsystem Nonvirtual Inports

By default, an Inport block is a virtual block and accepts a bus as input. However, an Inport block is nonvirtual if:

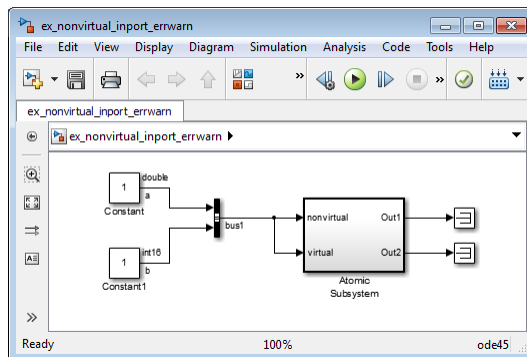

- The Inport block is in an atomic subsystem.
- The signal or any of its elements (if the signal is a bus) are directly connected to the output of the subsystem.

The Inport block can accept a bus when either of these conditions is true:

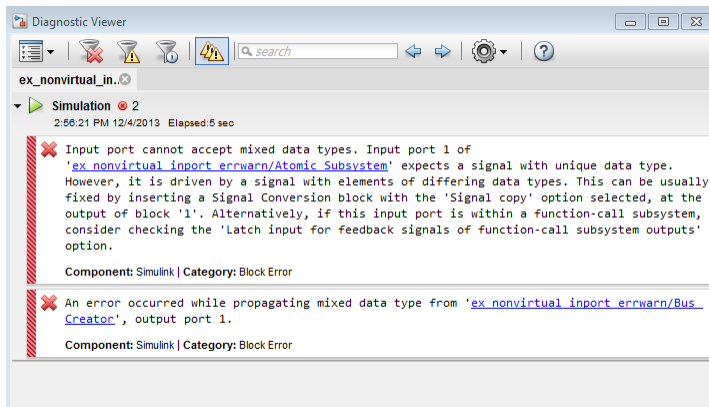

- All elements of the bus can be converted to a vector (for example, all the elements must have the same data type).
- The bus is a nonvirtual bus.

If the bus elements have different data types, attempting to simulate the model halts the simulation and produces an error message. To avoid this problem without changing the semantics of your model, insert a **Signal Conversion** block between the Inport block and the Output block to which it was originally connected.

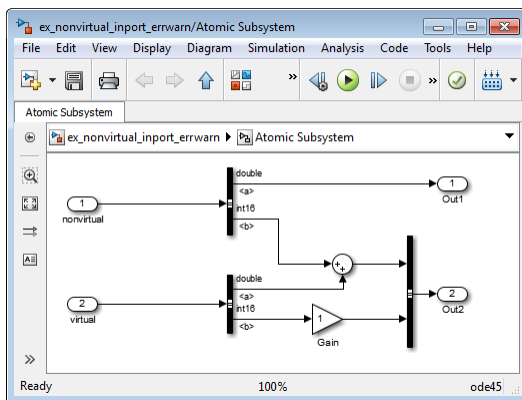

For example, the following model, which includes an atomic subsystem, does not simulate.

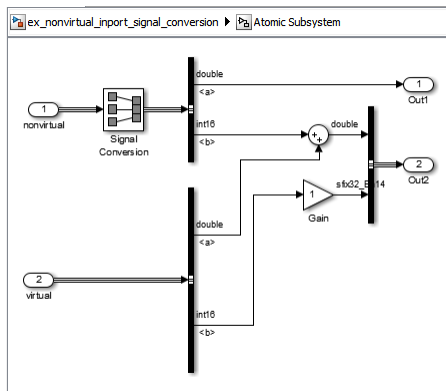

Starting the simulation generates the following error messages:

In the subsystem, the Inport block labeled `nonvirtual` is nonvirtual because it resides in an atomic subsystem and one of its bus elements (labeled `a`) is directly connected to one of the subsystem outputs. Further, the bus (`bus1`) connected to the subsystem inputs has elements of differing data types. As a result, you cannot simulate this model.

To break the direct connection to the subsystem output, insert a Signal Conversion block. Set the Signal Conversion block **Output** parameter to `Signal copy`. Inserting the Signal Conversion Diagram block enables you to simulate the model.

Buses with Model Referencing

Specify Initial Conditions for Bus Signals

In this section...

“Bus Signal Initialization” on page 63-80

“Create Initial Condition Structures” on page 63-81

“Initialize Bus Signals Using Block Parameters” on page 63-86

“Set Diagnostics to Support Bus Signal Initialization” on page 63-89

Bus Signal Initialization

Bus signal initialization is a special form of signal initialization. For general information about initializing signals, see “Initialize Signals and Discrete States” on page 62-47.

Bus signal initialization specifies the bus element values that Simulink uses for the first execution of a block that uses that bus signal. By default, the initial value for a bus element is the ground value (represented by 0). Bus initialization involves specifying nonzero initial conditions (ICs).

You can use bus signal initialization features to:

- Specify initial conditions for signals that have different data types
- Apply a different initial condition for each signal in the bus
- Specify initial conditions for a subset of signals in a bus without specifying initial conditions for all the signals
- Use the same initial conditions for multiple blocks, signals, or models

You can initialize array of buses signals. For details, see “Initialize Arrays of Buses” on page 63-105.

Initialize Bus Signals Using Initial Condition Structures

Setting up your model to use initial condition structures to initialize bus signals properly involves three main tasks. You can vary the order of the tasks.

Task	Documentation
Determine whether you can initialize the bus signal	<ul style="list-style-type: none"> • “Blocks That Support Bus Signal Initialization” on page 63-81 • “Buses with Variable-Size or Frame-Based Elements” on page 63-81

Task	Documentation
Define an IC structure	“Create Initial Condition Structures” on page 63-81
Use an IC structure to specify a nonzero initial condition.	“Initialize Bus Signals Using Block Parameters” on page 63-86
Set Configuration Parameters dialog box diagnostics	“Set Diagnostics to Support Bus Signal Initialization” on page 63-89

Blocks That Support Bus Signal Initialization

You can initialize bus signal values that input to a block if that block meets both of these conditions:

- It has an initial value or initial condition block parameter.
- It supports bus signals.

The following blocks support bus signal initialization:

- Data Store Memory
- Memory
- Merge
- Output (when the block is inside a conditionally executed context)
- Rate Transition
- Unit Delay

For example, the Unit Delay block is a bus-capable block and the Block Parameters dialog box for the Unit Delay block has an **Initial conditions** parameter.

buses with Variable-Size or Frame-Based Elements

You cannot initialize a bus that has:

- Variable-size signals
- Frame-based signals

Create Initial Condition Structures

You can create partial or full IC structures to represent initial values for a bus signal. Create an IC structure by either:

- Defining a MATLAB structure in the MATLAB base or Simulink model workspace
- Using the Block Parameters dialog box for a block that supports bus signal initialization to specify for the initial condition parameter an expression that evaluates to a structure.

For information about defining MATLAB structures, see “Create a Structure Array” in the MATLAB documentation.

Full and Partial Initial Condition Structures

A full initial condition structure provides an initial value for every element of a bus signal. This IC structure mirrors the bus hierarchy and reflects the attributes of the bus elements.

A partial IC structure provides initial values for a subset of the elements of a bus signal. If you use a partial IC structure, during simulation, Simulink creates a full IC structure to represent all the bus signal elements. Simulink assigns the respective ground value to each element for which the partial IC structure does not explicitly assign a value.

Specifying partial structures for block parameter values can be useful during the iterative process of creating a model. Partial structures enable you to focus on a subset of signals in a bus. When you use partial structures, Simulink initializes unspecified signals implicitly.

Specifying full structures during code generation offers these advantages:

- Generates more readable code
- Supports a modeling style that explicitly initializes all signals

Match IC Structure Values to Bus Elements

The field that you specify in an IC structure must match the following data attributes of the bus element exactly:

- Name
- Dimension
- Complexity

For example, suppose that you define a bus element to be a real [2x2] double array. Then in the IC structure, define the value to initialize that bus element to be a real [2x2] double array.

Explicitly specify fields in the IC structure for every bus element that has an enumerated (enum) data type.

When you define a partial IC structure:

- Include only fields that are in the bus.
- You can omit fields that are in the bus.
- Make the field in the IC structure correspond to the nesting level of the bus element.
- Within the same nesting level in both the structure and the bus, you can specify the structure fields in a different order than the bus elements.

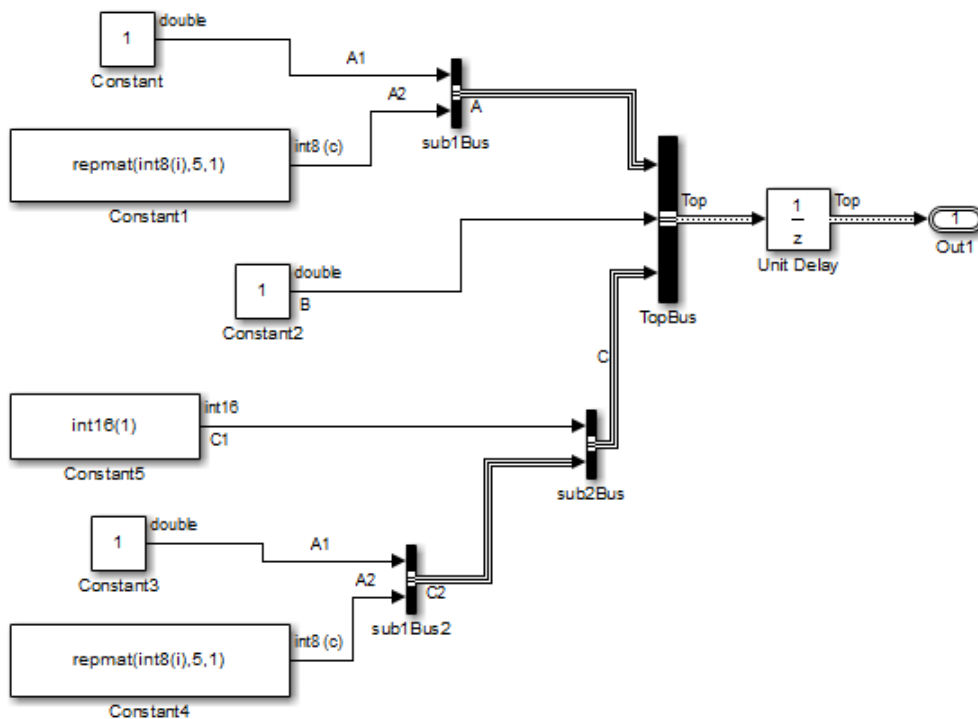

Note: The value of an IC structure must lie within the design minimum and maximum range of the corresponding bus element. Simulink performs this range checking during an update diagram and when you run the model.

Examples of Partial Structures

Suppose that you have a bus, `Top`, composed of three elements: `A`, `B`, and `C`, with these characteristics:

- `A` is a nested bus, with two signal elements.
- `B` is a single signal.
- `C` is a nested bus that includes bus `A` as a nested bus.

The following model, `ex_busic` includes the nested `Top` bus. The screen capture shows the model after it has been updated. .

The following diagram summarizes the Top bus hierarchy and the data type, dimension, and complexity of the bus elements.

Top

```

A (sub1)
  A1 (double)
  A2 (int8, 5x1, complex)
B (double)
C (sub2)
  C1 (int16)
  C2 (sub1)
    A1 (double)
    A2 (int8, 5x1, complex)
  
```

Valid Partial IC Structures

In the following examples, K is an IC structure specified for the initial value of the Unit Delay block. The IC structure corresponds to the Top bus in the ex_busic model.

The following table shows valid initial condition specifications.

Valid Syntax	Description
<code>K.A.A1 = 3</code>	Initializes the bus element <code>Top.A.A1</code> using the value 3.
<code>K = struct('C',struct('C1',int16(4)))</code>	The bus element <code>Top.C.C1</code> is <code>int16</code> . The corresponding structure field explicitly specifies <code>int16(4)</code> . Alternatively, you could specify the field value as 4 without specifying an explicit data type.
<code>K = struct('B',3,'A',struct('A1',4))</code>	Bus element <code>Top.B</code> and <code>Top.A</code> are at the same nesting level in the bus. For bus elements at the same nesting level, the order of corresponding structure fields does not matter.

Invalid Partial IC Structures

In the following examples, `K` is an IC structure specified for the initial value of the Unit Delay block. The IC structure corresponds to the `Top` bus in the `ex_busic` model.

These three initial condition specifications are *not* valid:

Invalid Syntax	Reason the Syntax Is Invalid
<code>K.A.A2 = 3</code>	Value dimension and complexity do not match. The bus element <code>Top.A.A2</code> is <code>5x1</code> , but <code>K.A.A2</code> is <code>1x1</code> ; <code>Top.A.A2</code> is complex, but <code>K.A.A2</code> is real.
<code>K.C.C2 = 3</code>	You cannot use a scalar value to initialize IC substructures.
<code>K = struct('B',3,'X',4)</code>	You cannot specify fields that are not in the bus (<code>X</code> does not exist in the bus).

Creating Full IC Structures Using `Simulink.Bus.createMATLABStruct`

Use the `Simulink.Bus.createMATLABStruct` function to streamline the process of creating a full MATLAB initial condition structure with the same hierarchy, names, and data attributes as a bus signal. This function fills all the elements that you do not specify with the ground values for those elements.

You can use several different kinds of input with the `Simulink.Bus.createMATLABStruct` function, including

- A bus object name
- An array of port handles

You can invoke the `Simulink.Bus.createMATLABStruct` function from the Bus Editor. Select the bus object for which you want to create a full MATLAB structure, and then use one of these approaches:

- Select the **File > Create a MATLAB structure** menu item.
- Click the **Create a MATLAB structure** icon () from the toolbar.

You can then edit the MATLAB structure in the MATLAB Editor.

For details, see the `Simulink.Bus.createMATLABStruct` documentation.

Check for Partial Structures with Model Advisor

To detect when structure parameters are not consistent in shape (hierarchy and names) with the associated bus signal, in the Simulink Editor, use the **Analysis > Model Advisor > By Product > Simulink “Check structure parameter usage with bus signals”** check. This check identifies partial IC structures.

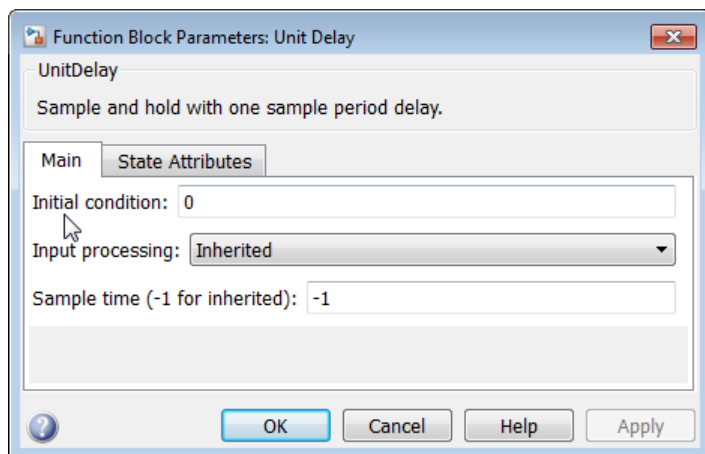

Control Data Types of Structure Fields

If any of the signal elements of the target bus use a data type other than `double`, you can use different techniques to control the data types of the fields of initial condition structures. The technique that you choose can influence the efficiency and readability of the generated code. See “Control Data Types of Initial Condition Structure Fields” on page 63-143.

Initialize Bus Signals Using Block Parameters

Initialize a bus signal by setting the initial condition parameter for a block that receives a bus signal as input and that supports bus initialization (see “Blocks That Support Bus Signal Initialization” on page 63-81).

For example, the Block Parameters dialog box for the Unit Delay block has an **Initial conditions** parameter.

For a block that supports bus signal initialization, you can replace the default value of 0 using one of these approaches:

- “MATLAB Structure for Initialization” on page 63-87
- “MATLAB Variable for Initialization” on page 63-88
- “Simulink.Parameter For Initialization” on page 63-89

All three approaches require that you define an IC structure (see “Create Initial Condition Structures” on page 63-81). You cannot specify a nonzero scalar value or any other type of value other than 0, an IC structure, or `Simulink.Parameter` object to initialize a bus signal.

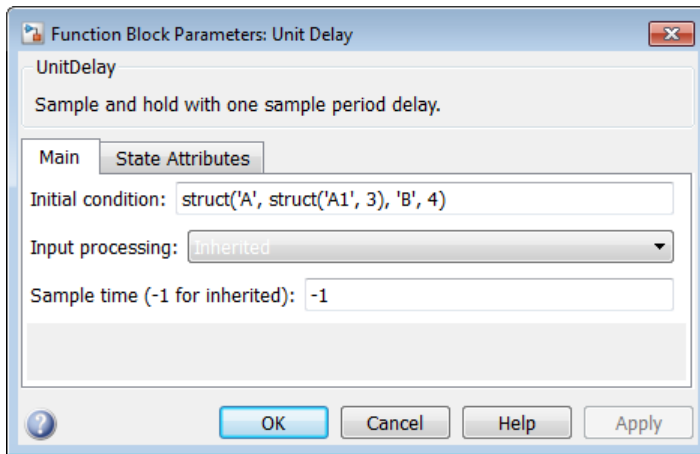

Defining an IC structure as a MATLAB variable, rather than specifying the IC structure directly in the Block Parameters dialog box offers several advantages, including:

- Reuse of the IC structure for multiple blocks
- Using the IC structure as a tunable parameter in the generated code

MATLAB Structure for Initialization

You can initialize a bus signal using a MATLAB structure that explicitly defines the initial conditions for the bus signal.

For example, in the **Initial conditions** parameter of the Unit Delay block, you could type in a structure.

MATLAB Variable for Initialization

You can initialize a bus signal using a MATLAB variable that you define as an IC structure with the appropriate values.

For example, you could define the following partial structure in the base workspace:

```
K = struct('A', struct('A1', 3), 'B', 4);
```

You can then specify the K structure as the **Initial conditions** parameter of the Unit Delay block:

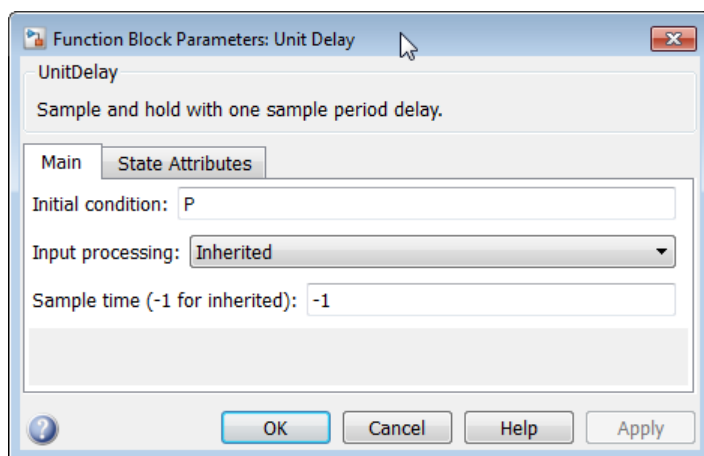

Simulink.Parameter For Initialization

You can initialize a bus signal using a Simulink.Parameter object that uses an IC structure for the Value property.

For example, you could define the partial structure **P** in the base workspace (reflecting the `ex_busic` model discussed in the previous section):

```
P = Simulink.Parameter;
P.DataType = 'Bus: Top';
P.Value = Simulink.Bus.createMATLABStruct('Top');
P.Value.A.A1 = 3;
P.Value.B = 5;
```

You can then specify the **P** structure as the **Initial conditions** parameter of the Unit Delay block:

Set Diagnostics to Support Bus Signal Initialization

To enable bus signal initialization, before you start a simulation, set the following two Configuration Parameter diagnostics as indicated:

- In the **Configuration Parameters > Diagnostics > Connectivity** pane, set “**Mux blocks used to create bus signals**” to error.
- On the **Configuration Parameters > All Parameters** tab, set “**Underspecified initialization detection**” to simplified.

The documentation for these diagnostics explains how to convert your model to handle error messages the diagnostics generate.

Combine Buses into an Array of Buses

In this section...
“What Is an Array of Buses?” on page 63-91
“Benefits of an Array of Buses” on page 63-92
“Define an Array of Buses” on page 63-93

Tip Simulink provides several techniques for combining signals into a composite signal. For a comparison of techniques, see “Overview of Composite Signal Techniques” on page 63-3.

What Is an Array of Buses?

An array of nonvirtual buses is an array whose elements are buses. Each bus object has the same signal name, hierarchy, and attributes for its bus elements.

An example of using an array of buses is to model a multi-channel system, such as a communications system. You can model all the channels using the same bus object, although each of the channels could have a different value.

To use an arrays of buses:

- Use a bus object as a data type (see “Specify a Bus Object Data Type” on page 57-50).
- Specify dimensions for the bus and bus elements.

For an example of a model that uses an array of buses, open the `sldemo_bus_arrays` model. In this example, the nonvirtual bus input signals connect to a Vector Concatenate or Matrix Concatenate block that creates an array of bus signals. Here is the diagram after you update it:

Modeling Arrays of Bus Signals

The model uses the array of buses with:

- An Assignment block, to assign a bus in the array
- A For Each Subsystem block, to perform iterative processing over each bus in the array
- A Memory block, to output the array of buses input from the previous time step

Benefits of an Array of Buses

Use an array of buses to:

- Represent structured data compactly.

- Reduce model complexity.
- Reduce maintenance by centralizing algorithms used for processing multiple buses.
- Streamline iterative processing of multiple buses of the same type, for example, by using a For Each Subsystem with the array of buses.
- Simplify changing the number of buses, without your having to restructure the rest of the model or make updates in multiple places in the model.
- Use built-in blocks, such as the Assignment or Selector blocks, to manipulate arrays of buses just like arrays of any other type. Using a array of buses avoids the need for you to create custom S-functions to manage packing and unpacking structure signals.
- Use the combined bus data across subsystem boundaries, model reference boundaries, and into or out of a MATLAB Function block.
- Keep all the logic in the Simulink model, rather than splitting the logic between C code and the Simulink model. This approach supports integrated consistency and correctness checking, maintaining metadata in the model, and avoids the need to manage model components in two different environments.
- Generate code that has an array of C structures, which you can integrate with legacy C code that uses arrays of structures. This approach simplifies indexing into an array for Simulink computations, using a for loop on indexed structures.

Define an Array of Buses

For information about the kinds of buses that you can combine into an array of buses, see “Bus Requirements” on page 63-96.

To define an array of buses, use a **Concatenate** block. The table describes the array of buses input requirements and output for each of the Vector Concatenate and the Matrix Concatenate versions of the Concatenate block.

Block	Bus Signal Input Requirement	Output
Vector Concatenate	Vectors, row vectors, or column vectors	If any of the inputs are row or column vectors, output is a row or column vector.
Matrix Concatenate	Signals of any dimensionality (scalars, vectors, and matrices)	Trailing dimensions are assumed to be 1 for lower dimensionality inputs.

Block	Bus Signal Input Requirement	Output
		Concatenation is on the dimension that you specify with the Concatenate dimension parameter.

Note: Do not use a Mux block or a Bus Creator block to define an array of buses. Instead, use a Bus Creator block to create scalar bus signals.

- 1 Define *one* bus object for *all* of the buses that you want to combine into an array of buses. For information about defining bus objects, see “Create Bus Objects” on page 63-44.

The `sldemo_bus_arrays` model defines an `sldemo_bus_arrays_busobject` bus object, which both of the Bus Creator blocks use for the input bus signals (Scalar Bus) for the array of buses.

- 2 Add a **Vector Concatenate** or **Matrix Concatenate** block to the model and open the Block Parameters dialog box.

The `sldemo_bus_arrays_busobject` model uses a Vector Concatenate block, because the inputs are scalars.

- 3 Set the **Number of inputs** parameter to be the number of buses that you want to be in the array of buses.

The block icon displays the number of input ports that you specify.

- 4 Set the **Mode** parameter to match the type of the input bus data.

In the `sldemo_bus_arrays` model, the input bus data is scalar, so the **Mode** setting is **Vector**.

- 5 If you use a Matrix Concatenation block, set the **Concatenate dimension** parameter to specify the output dimension along which to concatenate the input arrays. Enter one of the following values:

- 1 — concatenate input arrays vertically
- 2 — concatenate input arrays horizontally
- A higher dimension than 2 — perform multidimensional concatenation on the inputs

- 6 Connect to the Concatenate block all the buses that you want to be in the array of buses.

Use Arrays of Buses in Models

In this section...

“Array of Buses Requirements and Limitations” on page 63-96

“Blocks That Support Arrays of Buses” on page 63-97

“Set Diagnostic” on page 63-99

“Signal Line Style” on page 63-99

Array of Buses Requirements and Limitations

Bus Requirements

All buses combined into an array of buses must:

- Be nonvirtual
- Have the same bus type (that is, same name, hierarchies, and attributes for the bus elements)
- Have no variable-size signals or frame-based signals

Supported Blocks

You can use arrays of buses with these blocks:

- Virtual blocks
- Several nonvirtual blocks, such as:
 - Some signal routing blocks (for example, Data Store Memory, Merge, and Switch)
 - Rate Transition and Zero-Order Hold blocks
- Several additional blocks, such as Assignment, MATLAB Function, and Signal Conversion

For a complete list, see “Blocks That Support Arrays of Buses” on page 63-97. That section describes requirements for using the supported blocks.

Structure Parameter Requirements

To initialize an array of buses with structure parameters, you can use:

- The number 0. In this case, all the individual signals in the array of buses use the initial value 0.

- A scalar `struct` that represents the same hierarchy of fields and field names as the bus type. In this case, the scalar structure expands to initialize each of the individual signals in the array of buses.
- An array of structures that specifies an initial value for each of the individual signals in the array of buses.

If you use an array of structures, all the structures in the array must have the same hierarchy of fields. Each field in the hierarchy must have the same characteristics across the array:

- Field name
- Numeric data type, such as `single` or `int32`
- Complexity
- Dimensions

You cannot use partial structures.

For more information about specifying initial conditions for bus signals, see “Initialize Arrays of Buses” on page 63-105.

Signal Logging Limitation

Simulink does not log array of buses signals inside referenced models in rapid accelerator mode.

Stateflow Limitations

Stateflow action language does not support arrays of buses.

Blocks That Support Arrays of Buses

The following blocks support arrays of buses:

- Virtual blocks (see “Nonvirtual and Virtual Blocks” on page 33-2)
- These nonvirtual blocks:
 - Data Store Memory
 - Data Store Read
 - Data Store Write
 - Memory

- Merge
- Multiport Switch
- Rate Transition
- Switch
- Unit Delay
- Zero-Order Hold
- Assignment
- MATLAB Function
- Matrix Concatenate
- Selector
- Signal Conversion
- Vector Concatenate
- Width
- Two-Way Connection (a Simscape block)

Block Parameter Settings

Using an array of buses signal with some blocks requires specific block parameter settings.

This information is also in the reference pages for each of these blocks. For usage information for bus-related blocks, see “Work with Array of Buses Signals” on page 63-101.

Block	Block Parameters Settings
Memory	<p>Initial condition — You can specify this parameter with:</p> <ul style="list-style-type: none"> • The value 0. In this case, all the individual signals in the array of buses use the initial value 0. • An array of structures that specifies an initial condition for each of the individual signals in the array of buses. • A single scalar structure that specifies an initial condition for each of the elements that the bus type

Block	Block Parameters Settings
	defines. Use this technique to specify the same initial conditions for each of the buses in the array.
Merge	<ul style="list-style-type: none"> • Allow unequal port widths — Clear this parameter. • Number of inputs — Set to a value of 2 or greater. • Initial condition — You can specify this parameter with: <ul style="list-style-type: none"> • The value 0. In this case, all the individual signals in the array of buses use the initial value 0. • An array of structures that specifies an initial condition for each of the individual signals in the array of buses. • A single scalar structure that specifies an initial condition for each of the elements that the bus type defines. Use this technique to specify the same initial conditions for each of the bus signals in the array.
Multipoint Switch	Number of data ports — Set to a value of 2 or greater.
Signal Conversion	Output — Set to Signal copy.
Switch	Threshold — Specify a scalar threshold.

Set Diagnostic

Before you run a simulation on a model that uses an array of buses, in the **Configuration Parameters > Diagnostics > Connectivity** pane, check that the **Mux blocks used to create bus signals** parameter uses the default setting of **error**.

Signal Line Style

After model simulation, the line style for the array of buses signal is a thicker version of the signal line style for a nonvirtual bus signal.

For example, in the `sldemo_bus_arrays` model, the **Scalar Bus** signal is a nonvirtual bus signal, and the **Bus Array** output signal of the Concatenate block is an array of buses signal.

Work with Array of Buses Signals

In this section...

- “Set Up Model for Arrays of Buses” on page 63-101
- “Perform Iterative Processing” on page 63-102
- “Assign Values into an Array of Buses” on page 63-103
- “Select Bus Elements from an Array of Buses” on page 63-103
- “Import Array of Buses Data” on page 63-104
- “Log Array of Buses Signals” on page 63-104
- “Initialize Arrays of Buses” on page 63-105
- “Code Generation” on page 63-107

To select a signal within an array of buses, use a:

- 1 Selector block to find the appropriate bus within the array of buses.
- 2 Bus Selector block to select the signal.

To assign a value to a signal within an array of buses, use:

- 1 A Bus Assignment block to assign a value to a bus element
- 2 An Assignment block to assign the bus to the array of buses

Bus Selector and Bus Assignment blocks can only accept scalar buses, not arrays of buses.

A **Bus Creator** block can accept an array of buses as input, but cannot have an array of buses as output.

Set Up Model for Arrays of Buses

Setting up a model to use an array of buses usually involves these basic tasks:

- 1 Define the array of buses (see “Define an Array of Buses” on page 63-93).
- 2 Add a subsystem for performing iterative processing on each element of the array of buses. For example, use a For Each Subsystem block or an Iterator block. Connect

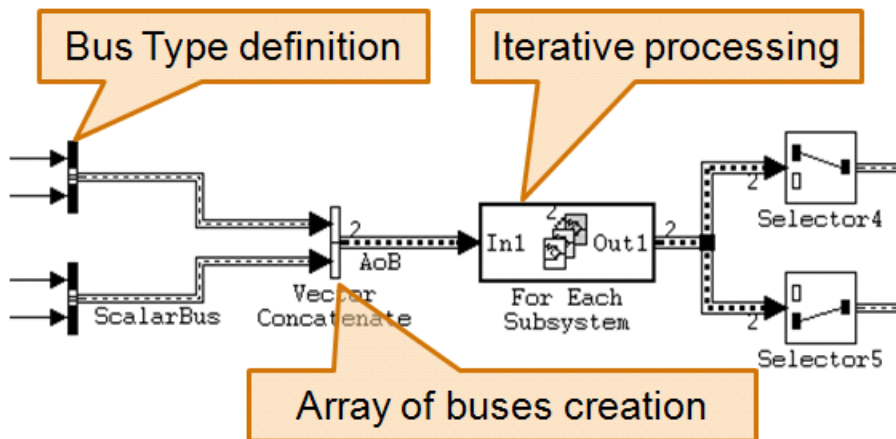

the array of buses signal from the Concatenate block to the iterative processing subsystem. See “Perform Iterative Processing” on page 63-102.

- 3 Model your scalar algorithm within the iterative processing subsystem (for example, a For Each subsystem).
 - a Operate on the array of buses (using Selector and Assignment blocks).
 - b Use the Bus Selector and Bus Assignment blocks to select elements from, or assign elements to, a scalar bus within the subsystem.

See “Assign Values into an Array of Buses” on page 63-103 and “Select Bus Elements from an Array of Buses” on page 63-103.

- 4 Optionally, import or log array of buses data. See “Import Array of Buses Data” on page 63-104 and “Log Array of Buses Signals” on page 63-104

The resulting model includes these components.

Perform Iterative Processing

You can perform iterative processing on the bus signal data of an array of buses using blocks such as a For Each Subsystem block, a While Iterator Subsystem block, or a For Iterator Subsystem block. You can use one of these blocks to perform the same kind of processing on:

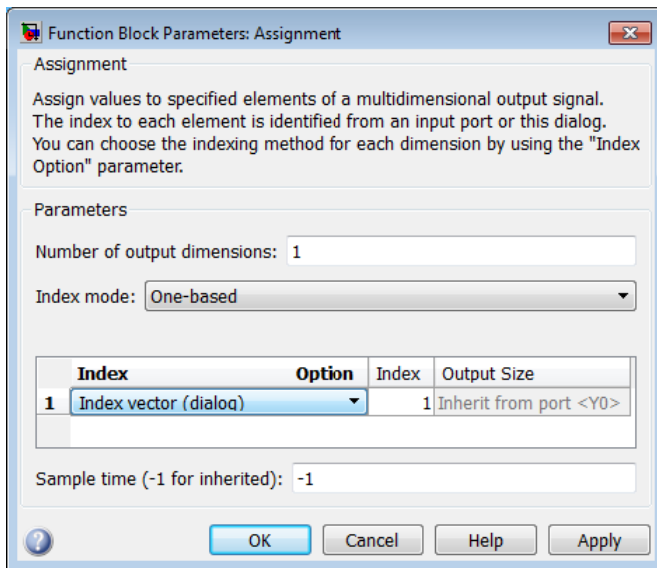

- Each bus in the array of buses

- A selected subset of buses in the array of buses

Assign Values into an Array of Buses

Use an Assignment block to assign values to specified elements in a bus array.

For example, in the `sldemo_bus_arrays` model, the Assignment block assigns the value to the first element of the array of buses.

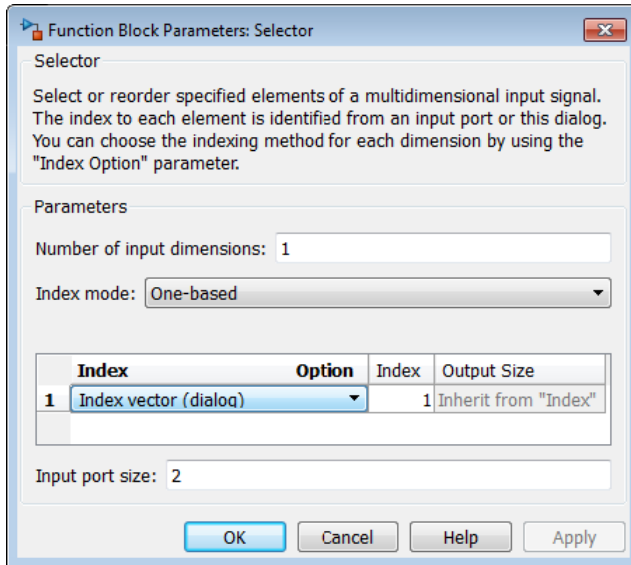

To assign bus elements within a bus signal, use the `Bus Assignment` block. The input for the `Bus Assignment` block must be a scalar bus signal.

Select Bus Elements from an Array of Buses

Use a `Selector` block to select elements of an array of buses. The input array of buses can have any dimension. The output bus signal of the `Selector` block is a selected or reordered set of elements from the input array of buses.

For example, the `sldemo_bus_arrays` model uses `Selector` blocks to select elements from the array of buses signal that the `Assignment` and `For Each Subsystem` blocks

outputs. In this example, here is the Block Parameters dialog box for the Selector block that selects the first element:

To select bus elements within a bus signal, use the **Bus Selector** block. The input for the Bus Selector block must be a scalar bus signal.

Import Array of Buses Data

Use a root Import block to import (load) an array of structures of MATLAB `timeseries` objects for an array of buses. You can import partial data into the array of buses.

For details, see “Import Array of Buses Data” on page 59-159.

You cannot use a From Workspace or From File block to import data for an array of buses.

Log Array of Buses Signals

To export an array of buses signal, mark the signal for signal logging. For more information, see “Save Runtime Data from Simulation”.

Note: Simulink does not log signals inside referenced models in rapid accelerator mode.

To access the signal logging data for a specific signal in an array of buses, navigate through the structure hierarchy and specify the index to the specific signal. For details, see “Access Array of Buses Signal Logging Data” on page 59-30.

Initialize Arrays of Buses

To specify a unique initial value for each of the individual signals in an array of buses, you can use an array of initial condition structures. Each structure in the array initializes one of the buses.

Here is an example that shows how to initialize an array of buses. Suppose that you define the bus types `MyData` and `PressureBus`.

Suppose that you set the data type of the signal element `temperature` to `int16`, and the data type of the elements `s1` and `s2` to `double`.

To specify initial conditions for an array of buses, you can create a variable whose value is an array of initial condition structures.

```

initValues(1).temperature = int16(5);
initValues(1).pressure.s1 = 9.87;
initValues(1).pressure.s2 = 8.71;

```

```

initValues(2).temperature = int16(20);
initValues(2).pressure.s1 = 10.21;
initValues(2).pressure.s2 = 9.56;

```

```

initValues(3).temperature = int16(35);

```

```
initValues(3).pressure.s1 = 8.98;
initValues(3).pressure.s2 = 9.17;
```

The variable `initValues` provides initial conditions for a signal that is an array of three buses. You can use `initValues` to specify the **Initial condition** parameter of a block such as Unit Delay.

Alternatively, you can use a single scalar structure to specify the same initial conditions for all the buses in the array.

```
initStruct.temperature = int16(15);
initStruct.pressure.s1 = 10.32;
initStruct.pressure.s2 = 9.46;
```

If you specify `initStruct` in the **Initial condition** parameter of a block, each bus in the array uses the same initial value, 15, for the signal element `temperature`. Similarly, the buses use the initial value 10.32 for the element `pressure.s1` and the value 9.46 for the element `pressure.s2`.

To create an array of structures for a bus that uses a large hierarchy of signal elements, consider using the function `Simulink.Bus.createMATLABStruct`.

This example shows how to initialize a nested array of buses. Create an initial condition structure for a complicated signal hierarchy that includes nested arrays of buses.

- 1 In the Bus Editor, create the bus objects `MyData` and `PressureBus`.

- 2 In the hierarchy pane, select the bus element `pressure`. Set the **Dimensions** property to `[1 3]`.
- 3 Create an array of four initialization structures by using the function `Simulink.Bus.createMATLABStruct`. Store the array in the variable `initStruct`. Initialize all the individual signals to the ground value, 0.

```
initStruct=Simulink.Bus.createMATLABStruct('MyData',[1,1 4]);
```

- 4 In the base workspace, double-click the variable `initStruct` to view it in the variable editor.

The four structures in the array each have the fields `temperature` and `pressure`.

- 5 To inspect a `pressure`, double-click one of the fields.

The value of each of the four `pressure` fields is an array of three substructures. Each substructure has the fields `s1` and `s2`.

- 6 To provide unique initialization values for the signals in an array of buses, you can specify the values manually using the variable editor.

Alternatively, you can write a script. For example, to access the field `s1` of the second substructure `pressure` in the third structure of `initStruct`, use this code:

```
initStruct(3).pressure(2).s1 = 15.35;
```

Code Generation

Code generation for array of buses signals produces structures with a specific format. See “Code Generation for Arrays of Buses” on page 63-150.

Convert Models to Use Arrays of Buses

There are several reasons to convert a model to use an array of buses (see “Benefits of an Array of Buses” on page 63-92). For example:

- The model was developed before Simulink supported arrays of buses (introduced in R2010b), and the model contains many subsystems that perform the same kind of processing.
- The model has grown in complexity.

General Conversion Approach

Here is a general approach for converting a model that contains buses to a model that uses an array of buses. The method that you use depends on your model. For details about these techniques, see “Combine Buses into an Array of Buses” on page 63-91 and “Use Arrays of Buses in Models” on page 63-96.

This workflow refers to a stylized example model. The example shows the original modeling pattern and a new modeling pattern that uses an array of buses.

Original modeling pattern

New modeling pattern

In the original modeling pattern:

- The target bus signal to be converted is named **MainBus**, and it has three elements, each of type **BusObject**.
- The **ScalarAlgorithm1**, **ScalarAlgorithm2**, and **ScalarAlgorithm3** subsystems encapsulate the algorithms that operate on each of the bus elements. The subsystems all have the same content.
- A **Bus Selector** block picks out each element of **MainBus** to drive the subsystems.

The construction in the original modeling pattern is inefficient for two reasons:

- A copy of the subsystem that encapsulates the algorithm is made for each element of the bus that is to be processed.
- Adding another element to `MainBus` involves changing the bus object definition and the Bus Selector block, and adding a subsystem. Each of these changes is a potential source of error.

To convert the original modeling pattern to use an array of buses:

- 1 Identify the target bus and associated algorithm that you want to convert. Typically, the target bus signal is a bus of buses, where each element bus signal is of the same type.
 - The bus that you convert must be a nonvirtual bus. If all elements of the target bus have the same sample time (or if the sample time is inherited), you can convert a virtual bus to a nonvirtual bus.
 - The target bus cannot have variable-dimensioned and frame-based elements.
- 2 Use a Concatenate block to convert the original bus of buses signal to an array of buses.

In the example, the new modeling pattern uses a Vector Concatenate block to replace the Bus Creator block that creates the `MainBus` signal. The output of the Vector Concatenate block is an array of buses, where the type of the bus signal is `BusObject`. The new model eliminates the wrapper bus signal (`MainBus`).

- 3 Replace all identical copies of the algorithm subsystem with a single For Each subsystem that encapsulates the scalar algorithm. Connect the array of buses signal to the For Each subsystem.

The new model eliminates the Bus Selector blocks that separate out the elements of the `MainBus` signal in the original model.

- 4 Configure the For Each Subsystem block to iterate over the input array of buses signal and concatenate the output bus signal.

The scalar algorithm within the For Each subsystem cannot have continuous states. For additional limitations, see the `FOR Each Subsystem` block documentation.

Repeat an Algorithm Using a For Each Subsystem

If you repeat algorithms in a diagram by copying and pasting blocks and subsystems, maintaining the model can become difficult. Individual signal lines and subsystems can crowd the diagram, reducing readability and making simple changes difficult. At the same time, many variables can crowd workspaces, reducing model portability. A model can develop these efficiency issues as you add to the design over time.

To repeat an algorithm, you can iterate the algorithm over signals, subsystems, and parameters that are grouped into arrays and structures. This example shows how to convert an inefficiently complex repetitive algorithm into a compact form that is easier to manage.

In this section...

“Repeat an Algorithm” on page 63-116

“Organize Parameters into Arrays of Structures” on page 63-119

“Inspect the Converted Model” on page 63-121

Explore Example Model

- 1 Open the example model `ex_repeat_algorithm`. The model creates about 30 variables in the base workspace.
- 2 Inspect the subsystem `Burner_1_Analysis`. This subsystem executes an algorithm by using the base workspace variables as parameters in blocks such as Constant and Discrete-Time Integrator.
- 3 Inspect the subsystems `Burner_2_Analysis` and `Burner_3_Analysis`. All three subsystems execute the same algorithm but use different workspace variables to parameterize the blocks.
- 4 Inspect the three `Analysis_Delay` subsystems. These subsystems repeat a different algorithm from the one in the Analysis subsystems.
- 5 Return to the top level of the model. The Memory blocks delay the input signals before they enter the `Analysis_Delay` subsystems.
- 6 Look at the **Data Import/Export** pane of the Configuration Parameters dialog box. The model uses the variables `SensorsInput` and `t` as simulation inputs.

During simulation, each of the nine columns in the matrix variable `SensorsInput` provides input data for an Inport block at the top level of the model.

Reduce Signal Line Density with Buses

You can use buses to group related signals into a single structured signal, reducing line density and improving model readability.

Each subsystem in the example model requires three signal inputs. You can combine each group of three signals into a single bus.

You could modify all the subsystems in the example model to use buses. However, because some of the subsystems are identical, you can delete them and later replace them with For Each Subsystem blocks.

- 1 Open the Bus Editor.

```
buseditor
```

- 2 Create a bus type `SensorData` with three signal elements: `sensor1`, `sensor2`, and `sensor3`.

- 3 Delete the blocks as shown in the figure, leaving only the `Burner_1_Sensor1` and `Burner_1_Delay1` blocks as inputs to the two remaining subsystems.

- 4 On the **Signal Attributes** tab of the Burner_1_Sensor1 Inport block dialog box, set **Data type** to Bus: SensorData.

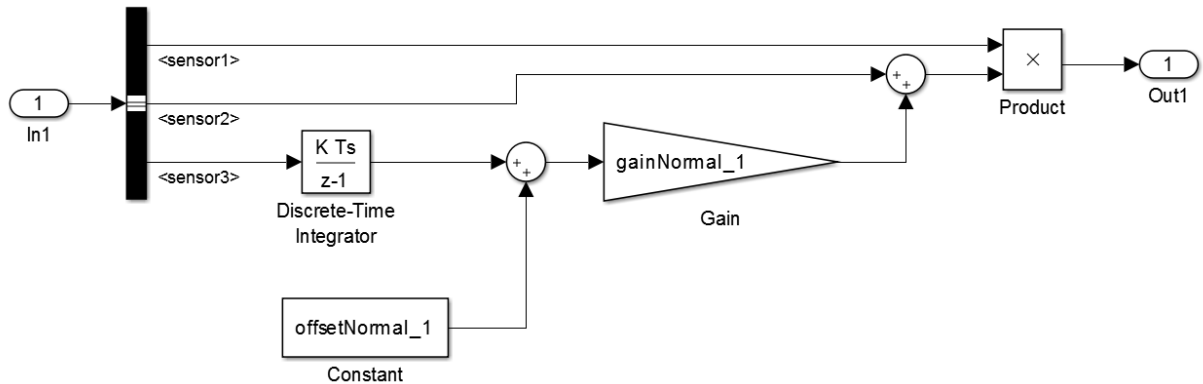

The output of the block is a bus signal that contains the three signal elements sensor1, sensor2, and sensor3.

- 5 Open the subsystem Burner_1_Analysis. Delete the signal output lines of the three Inport blocks. Delete the In2 and In3 Inport blocks.
- 6 Add a Bus Selector block to the right of the In1 Inport block. Connect the Inport block output to the Bus Selector block.
- 7 In the Bus Selector block dialog box, select the signals sensor1, sensor2, and sensor3.

The Bus Selector block extracts the three signal elements from the input bus. Other blocks in the model can use the extracted signal elements.

- 8 In the subsystem, connect the blocks as shown.

- 9 In the subsystem `Burner_1_Analysis_Delay`, use a Bus Selector block to extract the signals in the bus. Use the same technique as you did in the subsystem `Burner_1_Analysis`.

Repeat an Algorithm

A For Each Subsystem block partitions an input signal, and sequentially executes an algorithm on each partition. For example, if the input to the subsystem is an array of six signals, you can configure the subsystem to execute the same algorithm on each of the six signals.

You can use For Each subsystems to repeat an algorithm in an iterative fashion. This approach improves model readability and makes it easy to change the repeated algorithm .

- 1 Add two For Each Subsystem blocks to the model. Name one of the subsystems `Burner_Analysis`. Name the other subsystem `Burner_Analysis_Delay`.
- 2 Copy the contents of the subsystem `Burner_1_Analysis` into the subsystem `Burner_Analysis`. Before you paste the blocks, delete the Inport and Outport blocks in the For Each subsystem.
- 3 In the For Each block dialog box in the `Burner_Analysis` subsystem, select the check box to partition the input `In1`.
- 4 Copy the contents of the subsystem `Burner_1_Analysis_Delay` into the subsystem `Burner_Analysis_Delay`.

- 5 In the For Each block dialog box in the Burner_Analysis_Delay subsystem, select the check box to partition the input In1.
- 6 At the top level of the model, delete the subsystems Burner_1_Analysis and Burner_1_Analysis_Delay. Connect the new For Each Subsystem blocks in their place.
- 7 On the **Signal Attributes** tab of the Burner_1_Sensor1 Inport block dialog box, set **Port dimensions** to 3.

The block output is a three-element array of buses. The For Each subsystems in the model repeat an algorithm for each of the three buses in the array.

- 8 Create a Simulink.SimulationData.Dataset object that the Inport block can use to import the simulation data. You can use this code to create the object and store it in the variable SensorsInput.

```
% First, create an array of structures whose field values are
% timeseries objects.

for i = 1:3 % Burner number

    % Sensor 1
    eval(['tempInput(1,' num2str(i) ').sensor1 = ' ...
          'timeseries(t,SensorsInput(:, ' num2str(3*(i-1)+1) ');'])

    % Sensor 2
    eval(['tempInput(1,' num2str(i) ').sensor2 = ' ...
          'timeseries(t,SensorsInput(:, ' num2str(3*(i-1)+2) ');'])

    % Sensor 3
    eval(['tempInput(1,' num2str(i) ').sensor3 = ' ...
          'timeseries(t,SensorsInput(:, ' num2str(3*(i-1)+3) ');'])

end

% Create the Dataset object.

SensorsInput = Simulink.SimulationData.Dataset;
SensorsInput = addElement(SensorsInput,tempInput,'element1');

clear tempInput t i
```

The code first creates a variable `tempInput` that contains an array of three structures. Each structure has three fields that correspond to the signal elements

in the bus type `SensorData`, and each field stores a MATLAB `timeseries` object. Each `timeseries` object stores one of the nine columns of data from the variable `SensorsInput`, which stored the simulation input data for each of the sensors.

The code then overwrites `SensorsInput` with a new `Simulink.SimulationData.Dataset` object, and adds `tempInput` as an element of the object.

- 9 On the **Data Import/Export** pane of the Configuration Parameters dialog box, set **Input** to `SensorsInput`.

Since `SensorsInput` provides simulation input data in the form of `timeseries` objects, you do not need to specify a variable that contains time data.

- 10 Create an array of structures that initializes the remaining Memory block, and store the array in the variable `initForDelay`. Specify the structure fields with the values of the existing initialization variables such as `initDelay_1_sensor1`.

```
for i = 1:3 % Burner number

    % Sensor 1
    eval(['initForDelay(' num2str(i) ').sensor1 = ' ...
          'initDelay_' num2str(i) '_sensor1;'])

    % Sensor 2
    eval(['initForDelay(' num2str(i) ').sensor2 = ' ...
          'initDelay_' num2str(i) '_sensor2;'])

    % Sensor 3
    eval(['initForDelay(' num2str(i) ').sensor3 = ' ...
          'initDelay_' num2str(i) '_sensor3;'])
end
```

To view the contents of the new variable `initForDelay`, double-click the variable name in the base workspace. The variable contains an array of three structures that each has three fields: `sensor1`, `sensor2`, and `sensor3`.

Fields	sensor1	sensor2	sensor3
1	17.5000	13.2000	27.8000
2	5.2000	6.9000	1.7000
3	19.4000	14.9000	22.3000

- 11 In the Memory block dialog box, set **Initial condition** to `initForDelay`.

The Memory block output is an array of buses that requires initialization. Each signal element in the array of buses acquires an initial value from the corresponding field in the array of structures.

Organize Parameters into Arrays of Structures

The base workspace contains many variables that the example model uses for block parameters. To reduce the number of workspace variables, package them into arrays of structures, and use the individual structure fields to specify block parameters.

A For Each Subsystem block can partition an array of values that you specify as a mask parameter. Each iteration of the subsystem uses a single partition of the array to specify block parameters. If you specify the parameter as an array of structures, each iteration of the subsystem can use one of the structures in the array.

- 1 Create an array of structures that parameterizes the Burner_Analysis For Each subsystem, and store the array in the variable `paramsNormal`. Specify the structure fields by using the values of existing parameter variables such as `gainNormal_1`, `offsetNormal_1`, and `initDelayed_1`.

```
for i = 1:3
    eval(['paramsNormal(' num2str(i) ').gain = gainNormal_' num2str(i) ';' ])
    eval(['paramsNormal(' num2str(i) ').offset = offsetNormal_' num2str(i) ';' ])
    eval(['paramsNormal(' num2str(i) ').init = initNormal_' num2str(i) ';' ])
end
```

The variable contains an array of three structures that each has three fields: `gain`, `offset`, and `init`.

- 2 In the model, right-click the Burner_Analysis For Each subsystem and select **Mask > Create Mask**.
- 3 On the **Parameters & Dialog** pane of the dialog box, under **Parameter**, click **Edit**. For the new mask parameter, set **Prompt** to `Parameter` structure and **Name** to `paramStruct`. Click **OK**.
- 4 In the mask for the Burner_Analysis subsystem, set **Parameter structure** to `paramsNormal`.
- 5 Open the subsystem. In the For Each block dialog box, on the **Parameter Partition** pane, select the check box to partition the parameter `paramStruct`. Set **Partition dimension** to 2.
- 6 For the blocks in the subsystem, set these parameters.

Block	Parameter Name	Parameter Value
Gain	Gain	<code>paramStruct.gain</code>
Discrete-Time Integrator	Initial condition	<code>paramStruct.init</code>
Constant	Constant value	<code>paramStruct.offset</code>

- 7 Create an array of structures that parameterizes the Burner_Analysis_Delay For Each subsystem, and store the array in the variable `paramsForDelay`.

```
for i = 1:3
    eval(['paramsForDelay(' num2str(i) ').gain = gainDelayed_' num2str(i) ';'])
    eval(['paramsForDelay(' num2str(i) ').offset = offsetDelayed_' num2str(i) ';'])
    eval(['paramsForDelay(' num2str(i) ').init = initDelayed_' num2str(i) ';'])
end
```

- 8 At the top level of the model, right-click the Burner_Analysis_Delay For Each subsystem and select **Mask > Create Mask**.
- 9 On the **Parameters & Dialog** pane of the dialog box, under **Parameter**, click **Edit**. For the new mask parameter, set **Prompt** to `Parameter` structure and **Name** to `paramStruct`. Click **OK**.
- 10 In the mask for the For Each Subsystem block, set **Parameter structure** to `paramsForDelay`.
- 11 Open the subsystem. In the For Each block dialog box, on the **Parameter Partition** pane, select the check box to partition the parameter `paramStruct`. Set **Partition dimension** to 2.
- 12 For the blocks in the subsystem, set these parameters.

Block	Parameter Name	Parameter Value
Gain	Gain	paramStruct.gain
Discrete-Time Integrator	Initial condition	paramStruct.init
Constant	Constant value	paramStruct.offset

- 13** Clear the unnecessary variables from the base workspace.

```
% Clear the old parameter variables that you replaced
% with arrays of structures
clear -regexp _

% Clear the iteration variables
clear i
```

The model requires few variables in the base workspace.

Inspect the Converted Model

To view the new signal and subsystem organization, update the diagram.

The model input is an array of three bus signals. The model uses two For Each subsystems to execute the two algorithms on each of the three bus signals in the input array.

In the base workspace, arrays of structures replace the many variables that the model used. Mathematically, the modified model behaves the same way it did when you started because the arrays of structures contain the values of all the old variables.

To view the completed model, open the example model `ex_repeat_algorithm_complete`.

Tip You can log nonbus signals in a For Each subsystem. However, you cannot use signal logging for bus or array of buses signals from within a For Each subsystem. Either use a Bus Selector block to select the bus element signals that you want to log or add an Output block outside of the subsystem and then log that signal. For details, see “Log Signals in For Each Subsystems” on page 59-99.

Bus Data Crossing Model Reference Boundaries

A model reference boundary refers to the boundary between a model that contains a Model block and the referenced model. If you have bus data in a model that is passed to a Model block, then that data crosses the boundary to the referenced model. You need to set up your model so that the bus data input to the Model block is consistent with the bus data that the referenced model requires.

For bus data that crosses model reference boundaries:

- 1 Use a bus object (`Simulink.Bus`) to define the bus. For details, see “When to Use Bus Objects” on page 63-40 and “Create Bus Objects” on page 63-44.

You can use a nonvirtual or a virtual bus as an input to a referenced model.

- 2 Decide whether to use a virtual or nonvirtual bus. Using a nonvirtual bus provides a well-defined data interface for code generation. See “Virtual and Nonvirtual Buses” on page 63-4.

To use a multi-rate bus signal across a model referenced boundary requires a specific configuration of parameters in the parent and referenced models.

Connect Multi-Rate Buses to Referenced Models

You can input a single-rate bus to a referenced model. To input the signals in a multi-rate bus to a referenced model, insert blocks into the parent and referenced model as follows:

- 1 **In the parent model:** To convert the multi-rate bus to a single-rate bus, insert a **Rate Transition** block. The Rate Transition block must specify a rate in its **Block Parameters > Output port sample time** field unless one of the following is true:
 - The **Configuration Parameters > Solver** pane specifies a rate with these settings:
 - The **Periodic sample time constraint** parameter is set to **Specified**.
 - The **Sample time properties** parameter contains the specified rate.
 - The **Inport** block that accepts the bus in the referenced model specifies a rate in its **Block Properties > Signal Attributes > Sample time** field.

- In the referenced model:** Use a `Bus Selector` block to pick out signals of interest, and use `Rate Transition` blocks to convert the signals to the desired rates.

Limitations for Virtual Buses

If you use a bus signal as an input to or an output from a referenced model:

- The bus cannot contain a variable-size signal element.

As a workaround, use a nonvirtual bus instead.

- For code generation, you cannot configure the `I/O arguments step method` style of C++ class interface for the referenced model.

As a workaround, use a nonvirtual bus instead. Alternatively, use the `Default` style of C++ class interface.

- For code generation, you cannot configure function prototype control for the referenced model.

As a workaround, use a nonvirtual bus instead.

Use the Upgrade Advisor to fix models saved before R2016a that engage these limitations. See “Update Models Saved Before R2016a” on page 63-124.

Update Models Saved Before R2016a

The behavior of models that meet these criteria is different than it is in R2016a and later releases:

- The model was saved in a release earlier than R2016a.
- The model has referenced models with bus inputs and outputs configured to be treated as virtual buses.

Use the Upgrade Advisor **Check for virtual bus across model reference boundaries** check to avoid errors that the behavior differences can trigger. Run the **Analyze model hierarchy and continue upgrade sequence** check on the top-level model and then down through the model reference hierarchy.

Bus Conversion

When updating a diagram prior to simulation or code generation, Simulink automatically converts a virtual bus to a nonvirtual bus (and nonvirtual buses to virtual buses) in cases such as when the virtual bus is an input to, or output from:

- An S-Function block
- A Stateflow chart

When you pass a bus signal into a referenced model, Simulink makes the bus a virtual or nonvirtual bus to match the type of bus specified for the Inport block it feeds. Bus signal outputs are virtual or nonvirtual, based on the specification for the Outport block. For bus signals driving a root-level Outport block, Simulink performs a similar conversion. For more information, see “Bus Data Crossing Model Reference Boundaries” on page 63-123.

The conversion consists of inserting hidden **Signal Conversion** blocks into the model where needed. If no bus object is specified at the port to which the virtual bus connects, conversion to a nonvirtual bus fails.

To avoid the need for automatic bus conversion, manually insert a **Signal Conversion** block. For details, see the **Signal Conversion** documentation.

Buses and Libraries

When you define a library block, the block can input, process, and output buses just as an ordinary subsystem can.

Provide the appropriate input bus signal if:

- You have a bus routing block (Bus Creator, Bus Selector, or Bus Assignment) block that is in a library.
- That block depends on signals that are input to the library.

To change that block in a library, perform these steps. For details about modifying library links, see “Libraries”.

- 1 Copy the library block that uses that block to a model that connects an input bus.
- 2 Disable the link to the library block in this model.
- 3 Edit the bus routing block within the context of the outside model.
- 4 Resolve the link to the library.
- 5 In the Link Tool, in **Push/Restore Mode**, select **PUSH** to place the edited content into the library.
- 6 Save the library.

Alternatively, to have the library supply an appropriate bus signal, use a bus object to lock in the data type at the interface of a library subsystem block.

Prevent Bus and Mux Mixtures

In this section...

“What Are Bus and Mux Signal Mixtures?” on page 63-128

“Why Avoid Mixing Bus and Mux Signals?” on page 63-129

“When to Prevent Bus and Mux Mixtures?” on page 63-130

“Two Upgrade Procedures” on page 63-130

What Are Bus and Mux Signal Mixtures?

A Simulink mux signal is a virtual signal that graphically combines two or more scalar or vector signals into one signal line. All the signals in a mux signal must have the same data type and complexity. For more information, see “Mux Signals” on page 62-11.

Bus signals can contain signals of different data types and complexities.

A bus and mux mixture occurs when some blocks treat a signal as a mux, while other blocks treat that same signal as a bus.

Mux Block That Creates a Virtual Bus

One way that a model can mix bus and mux signals is when a Mux block creates a virtual bus. For example:

- A signal from a Mux block connects to a Bus Selector block.

- Mux and Demux blocks combine a signal with different attributes (for example, data type or complexity).

Bus Signal Treated as a Mux Signal

A second way that a model can mix bus and mux signals is when the model treats a bus signal as a mux signal. For example:

- Bus Creator block that creates a signal to be used as a vector.

- Bus Creator block that creates a signal to be used as a vector.

Why Avoid Mixing Bus and Mux Signals?

Mixing bus and mux signals in a model causes your model to be less robust. Configuring your model to prevent bus and mux mixtures:

- Improves loop handling
- Produces clear error messages

- Contributes to consistent edit and compile-time behavior

Configuring your model to prevent bus and mux mixtures also allows you to update your model to take advantage of several features that you could not otherwise use, including:

- Nonzero initialization of bus signals
- Bus support for blocks such as Constant, Data Store Memory, From File, From Workspace, To File, and To Workspace
- Signal Hierarchy Viewer
- Signal label propagation enhancements
- Arrays of buses

When to Prevent Bus and Mux Mixtures?

Configure a model to prevent bus and mux mixtures if *all* of the following conditions apply — the model:

- Was created before R2013b
- Contains one of the following: Bus Creator, Bus Selector, or Bus Assignment block, or a bus object
- Has **Configuration Parameters > Diagnostics > Connectivity > Mux blocks used to create bus signals** set to none or warning

Even if a model created before R2013b does not require that you configure it to prevent bus and mux mixtures, consider updating it anyway. Doing so facilitates modifying the model to use buses or features that require that the model is configured to prevent bus and mux mixtures.

Starting in R2013b, when you create a model, Simulink automatically configures the model to avoid bus and mux mixtures. Simulink sets the **Mux blocks used to create bus signals** parameter to **error**. Then, when you do a model update or simulate the model, if you introduce a bus and mux mixture Simulink reports an error.

Two Upgrade Procedures

Configuring a model to prevent bus and mux mixtures involves performing these procedures:

- “Correct Mux Blocks That Create Bus Signals” on page 63-132

- “Correct Buses Used as Muxes” on page 63-137

The procedure to correct muxes that create bus signals:

- Configures your model to identify when you introduce a bus and mux mixture
- Automatically changes your model to correct many of the instances of such mixtures

Correct Mux Blocks That Create Bus Signals

In this section...

“Choose the Appropriate Procedure” on page 63-132

“Models Without Model Referencing” on page 63-132

“Models with Model Referencing” on page 63-133

“Address Compatibility Issues After Running Upgrade Advisor” on page 63-133

Choose the Appropriate Procedure

The procedure that you perform depends on whether a model uses model referencing. Use the appropriate procedure, as described in:

- “Models Without Model Referencing” on page 63-132
- “Models with Model Referencing” on page 63-133

Models Without Model Referencing

- 1 Save a copy of the existing model and simulation results for the model. The conversion process often requires making several changes to your model. It can help to have the original model for reference and for comparing simulation results.
- 2 Open the Upgrade Advisor. In the Simulink Editor, select **Analysis > Model Advisor > Upgrade Advisor**.
- 3 Select **Check for Mux blocks used to create bus signals**.
- 4 Click **Run this check**.
- 5 Click **Modify**. The Upgrade Advisor replaces Mux blocks with Bus Creator blocks and sets the **Mux blocks used to create bus signals** configuration parameter to error.

The Upgrade Advisor closes any models that it checks that contain library links.

- 6 If necessary, reopen the model. To confirm that the model passes, rerun the check. If the check fails, go to step 7.
- 7 To address the applicable modeling patterns described in “Address Compatibility Issues After Running Upgrade Advisor” on page 63-133 and rerun the check to update your model.

Models with Model Referencing

In a model that uses model referencing, the Upgrade Advisor upgrades the top model, but not the referenced model. To make the upgrade process more efficient for models that use model referencing, use *one* of these approaches:

- For models that reference a few models (for example, five), in the Upgrade Advisor, run the **Analyze model hierarchy for upgrade issues** check. This check addresses bus and mux signal mixture issues for each referenced model.

The steps for using the Upgrade Advisor are the same as described in “Models Without Model Referencing” on page 63-132.

- For models that have many referenced models (for example, more than five), use `find_mdrefs` and `sreplace_mux` to find Mux blocks and replace them with Bus Creator blocks. You can create a script based on the following pattern.

```
[refMdl,~] = find_mdrefs mdl, true);

% run through reference models and top model
for i = 1:length(refMdl)
    load_system(refMdl{i});

    % Add code if any model uses referenced configuration sets

    sreplace_mux(refMdl{i},false) % reportonly = false;

    save_system(refMdl{i});
    close_system(refMdl{i});
end
```

If a model does not compile, address the applicable modeling patterns described in “Address Compatibility Issues After Running Upgrade Advisor” on page 63-133 and rerun the **Analyze model hierarchy for upgrade issues** check or, for models with many referenced models, the script.

Address Compatibility Issues After Running Upgrade Advisor

For many models, running the Upgrade Advisor modifies your model so that Mux blocks no longer create bus signals. However, for some models you can encounter compatibility issues even after running the check. Modify your model manually to address those issues.

After you compile the model using Upgrade Advisor, the Simulink Editor sometimes indicates that you need to save the model (the model is dirty), even though you did not make any changes. To prevent this issue from reoccurring for this model, save the model.

Modeling Pattern	Issue	Solution
Demux block with Bus selection mode enabled	You cannot use a Demux block to select bus signals.	<p>Replace the Demux block with a Bus Selector block.</p> <p>If a Demux block has input from a Mux block, change the Mux block to a Bus Creator.</p>
Data Store Memory block with Data Type set to Inherit: auto	A Data Store Memory block whose associated Data Store Read or Data Store Write blocks read or write bus signal data must use a bus object.	In the Data Store Memory block, set the Data Type signal attribute to Bus: <BusObject> .
Signal Conversion block Output parameter matches input bus type	<p>A Signal Conversion block whose Output parameter is set to Nonvirtual bus requires a virtual bus input.</p> <p>A Signal Conversion block whose Output parameter is set to Virtual bus requires a nonvirtual bus input.</p>	To create a copy of the input signal, set Output to Signal copy .
Merge, Switch, or Multiport Switch block with multiple bus inputs	Merge, Switch, or Multiport Switch blocks with multiple bus inputs require all those inputs to have the same names and hierarchy.	<p>Reconfigure the model so that the bus inputs all have the same names and hierarchy.</p> <p>To view the names and hierarchy of the bus signals, use the “Signal Hierarchy Viewer” on page 63-22 .</p>
Root Inport block outputting a virtual bus and specifying a value for Port dimensions	A root Inport block that outputs to a virtual bus must inherit the dimensions.	Set the Inport block Port dimensions signal attribute to 1 or -1 (inherit).

Modeling Pattern	Issue	Solution
Mux block with nonvirtual bus inputs	A Mux block cannot accept nonvirtual bus signals.	To treat the output as an array, replace the Mux block with a Vector Concatenate block. If you want a virtual bus output, use a Bus Creator block to combine the signals.
Bus to Vector block without a virtual bus signal input	A nonbus signal does not need a Bus to Vector block.	Remove the Bus to Vector block.
Assignment block with virtual bus inputs	The Upgrade Advisor converts the Assignment block Y0 port bus input to a vector.	Add a Bus to Vector block before the Assignment block.
S-function using a nonvirtual bus	An S-function that is not a Level-2 C S-function does not support nonvirtual bus signals.	Change the S-function to be a Level-2 C S-function. Consider using an S-Function Builder block to create a Level-2 C S-function.
Stateflow chart with parameterized data type	In a Stateflow chart, you cannot parameterize the data type of an input or output in terms of another input or output if the data type is a bus object.	For the parameterized port, set Data Type to Bus: <object name> .
Subsystem with bus operations in a Stateflow chart	An Inport block inside a subsystem in a Stateflow chart requires a bus object data type if its signal is a bus.	In the Inport block, set Data type to Bus: <object name> .
Ground block used as a bus source	The output signal of a Ground block cannot be a source for a bus.	Use a Constant block with Constant value set to 0 and the Output data type signal attribute set to Bus: <object name> .
Root Outport block with a single-element bus object data type	The input to the Outport block must be a bus if it specifies a bus object as its data type.	In the Outport block, set Data type to Inherit: auto .

Correct Buses Used as Muxes

In this section...

“Three Approaches” on page 63-137

“Use the Model Advisor” on page 63-137

“Explicitly Add Bus to Vector Blocks” on page 63-137

“Reorganize the Model” on page 63-139

“Bus to Vector Block Compatibility Issues” on page 63-140

Three Approaches

The three approaches that you can use to correct bus signals used as muxes are:

- “Use the Model Advisor” on page 63-137
- “Explicitly Add Bus to Vector Blocks” on page 63-137
- “Reorganize the Model” on page 63-139

Generally, using the Model Advisor is the most efficient approach.

Use the Model Advisor

Before you use the Model Advisor to correct bus signals used as muxes, perform the steps described in “Correct Mux Blocks That Create Bus Signals” on page 63-132.

- 1 Open the Model Advisor from the Upgrade Advisor, or in the Simulink Editor, select **Analysis > Model Advisor > Model Advisor**.
- 2 Select and run the **Simulink > Check bus usage** check.

The Model Advisor reports any cases of bus signals treated as muxes.

- 3 Follow the Model Advisor suggestions for correcting errors reported by the check.

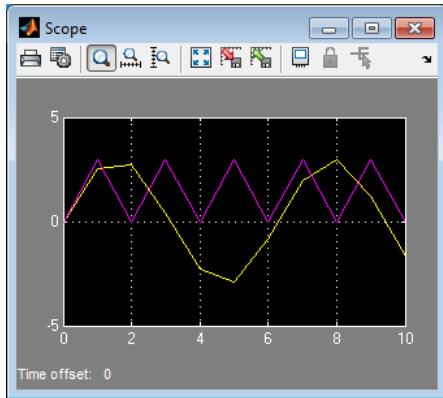

For additional information about using the Model Advisor, see “Consulting the Model Advisor” on page 5-2.

Explicitly Add Bus to Vector Blocks

You can explicitly add **Bus to Vector** blocks to convert the bus signal to a mux (vector), using one of these approaches:

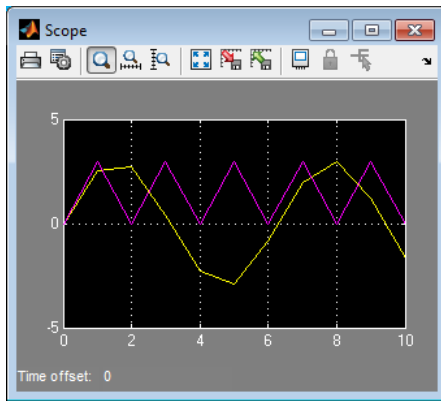

- To explicitly convert the bus to a mux (vector), insert the Bus to Vector block into any bus used implicitly as a mux.
- Use the `Simulink.BlockDiagram.addBusToVector` function, which automatically inserts Bus to Vector blocks wherever needed.

For example, this model uses a bus signal as a mux signal by using the bus as an input to a Gain block. The Scope block shows the simulation results.

This figure shows the same model, rebuilt after inserting a Bus to Vector block after the Bus Creator block.

The results of simulation are the same in either case. The Bus to Vector block is virtual, and does not affect simulation results, code generation, or performance.

Reorganize the Model

You can replace blocks manually to avoid using bus signals as muxes. Change the sources for a block that require vector inputs to avoid feeding a bus signal into a block that requires vector input.

For example, in the following model, the Gain block requires a vector signal. However, the input signal is a bus signal created by a Bus Creator block.

Change the Bus Creator block to a Mux block to provide the required vector signal for the Gain block.

Challenges with reorganizing the model manually include:

- Identifying all the occurrences in a model. (The Model Advisor check identifies all occurrences in the model and helps you to correct them.)
- Dealing with many occurrences in a model is time-consuming and error-prone.
- Reorganizing the model to address this issue can interfere with other aspects of the model.

Bus to Vector Block Compatibility Issues

If you use **Save As** to save a model in a version of the Simulink product before R2007a (V6.6), Simulink:

- Sets the `StrictBusMsg` parameter to `error` if its value is `WarnOnBusTreatedAsVector` or `ErrorOnBusTreatedAsVector`.
- Replaces each Bus to Vector block in the model with a null subsystem that outputs nothing.

The resulting model specifies strong type checking for Mux blocks used to create buses. Before you can use the model, reconnect or otherwise correct each signal that contained a Bus to Vector block but is now interrupted by a null subsystem.

Buses in the Generated Code

If you have Simulink Coder, the various techniques for defining buses are essentially equivalent for simulation, but the techniques can make a significant difference in the efficiency, size, and readability of generated code. For example, a nonvirtual bus appears as a structure in generated code, and only one copy exists of any algorithm that uses the bus. The use of a structure in the generated code can be helpful when tracing the correspondence between the model and the code. For example, here is the generated code for the Bus Creator block in the `ex_bus_logging` model.

```

50
51     /* BusCreator: '<Root>/COUNTERBUSCreator' incorporates:
52      * BusCreator: '<Root>/LIMITBUSCreator'
53      * Constant: '<Root>/lower_saturation_limit'
54      * Constant: '<Root>/upper_saturation_limit'
55      */
56     ex_bus_logging_B.COUNTERBUS_n.data = rtb_data;
57     ex_bus_logging_B.COUNTERBUS_n.limits.upper_saturation_limit = 40;
58     ex_bus_logging_B.COUNTERBUS_n.limits.lower_saturation_limit = 0;
59

```

A virtual bus does not appear as a structure or any other coherent unit in generated code. A separate copy of any algorithm that manipulates the bus exists for each element. In general, virtual buses do not affect the generated code.

To group signals into structures in the generated code, use nonvirtual buses. See “Group Signals into Structures in the Generated Code Using Buses”.

When you create a MATLAB structure to initialize a bus that contains non-double signal elements, you need to set the values of structure fields. The technique that you choose to set the values can influence the efficiency and readability of the generated code. See “Control Data Types of Initial Condition Structure Fields” on page 63-143.

When you generate code for a bus signal that is input to or output from a referenced model, there are some code generation limitations. See “Limitations for Virtual Buses Crossing Model Reference Boundaries” on page 63-149.

Code generation for array of buses signals produces structures with a specific format. See “Code Generation for Arrays of Buses” on page 63-150.

Control Data Types of Initial Condition Structure Fields

You can use a MATLAB structure to initialize the signal elements in a bus. See “Specify Initial Conditions for Bus Signals” on page 63-80.

If the signal elements of the target bus use numeric data types other than `double`, in general:

- To avoid manually matching the field data types with the data types of the signal elements, use untyped expressions to set the field values. As you develop and rapidly prototype a model, use this technique for convenience.
- To generate more efficient production code and to avoid floating-point storage in the code, match the data types of the structure fields with the data types of the corresponding signal elements.

The technique that you choose can influence the efficiency and readability of the generated code.

For examples and more information about tunable initial conditions in the generated code, see “Control Signal and State Initialization in the Generated Code”.

Inline Numeric Values of Structure Fields in the Generated Code

If you set **Configuration Parameters > Optimization > Signals and Parameters > Default parameter behavior** to `Inlined`, by default, the field values of the initial condition structure appear in the generated code as inlined numbers (non-tunable). For these structures, use untyped expressions to set the field values in Simulink. The field values do not require data types because the structure is not tunable in the generated code.

However, if you later set **Default parameter behavior** to `Tunable` or apply a storage class to the structure by using a `Simulink.Parameter` object, the code can contain floating-point storage and inefficient explicit typecasts and bit shifts. To avoid these issues, consider matching the data types of the structure fields with the data types of the corresponding signal elements.

Generate Tunable Structure Specified Directly in a Block Dialog Box

Suppose that you specify an initial condition structure directly in a block dialog box, or in a `Simulink.Signal` object, with an expression such as

`struct('signal1',5,'signal2',7.2)` (instead of storing the structure in a variable or `Simulink.Parameter` object). In this case, to generate a tunable structure in the code, you set **Default parameter behavior** to **Tunable**.

Use the table to decide how to control the data types of the fields in these initial condition structures.

Goal		Technique
Use a nonvirtual bus.		Use untyped expressions to set the field values.
Use a virtual bus.	Avoid manually matching the field data types with those of the signal elements.	Use untyped expressions to set the field values.
	Generate more efficient code and avoid floating-point storage.	Match the structure field data types with the signal element types. Store the data type information in the <code>struct</code> by using typed expressions to set the field values.

Generate Tunable Structure Stored in a Variable or Parameter Object

Suppose that you store an initial condition structure in a variable or `Simulink.Parameter` object that you create in the base workspace or a data dictionary. For example, you use this technique to share the structure between multiple blocks, or to generate a tunable structure when you set **Default parameter behavior** to **Inlined**. In this case, use the table to decide how to control the data types of the fields in the initial condition structure.

Goal		Technique
Avoid manually matching the field data types with those of the signal elements.		Use untyped expressions to set the field values. In the generated code, the structure fields use the data type <code>double</code> . The generated algorithm uses explicit typecasts to reconcile the data type mismatches.
Generate more efficient code and avoid floating-point storage.		Match the structure field data types with the signal element types. Store the data type information in the structure fields or use a <code>Simulink.Bus</code> object to control the data types of the fields and the signal elements simultaneously.

Goal	Technique
	To use the Model Advisor to check your model for potentially expensive data type mismatches, see “Check structure parameter usage with bus signals”.
Initialize an array of buses in a referenced model by using an array of structures. Pass the array of structures to the referenced model as the value of a model argument in the Model block.	<p>Match the structure field data types with the signal element types. Store the data type information in the structure fields or use a <code>Simulink.Bus</code> object to control the data types of the structure fields and the signal elements simultaneously.</p> <p>If you do not pass the structure to the referenced model as a model argument, follow the other guidelines for nonvirtual buses to decide how to control the data types.</p>

Use Untyped Expressions to Set Field Values

You can use untyped expressions to set the structure field values. The fields implicitly use the data type `double`. Set the field values to represent the ideal, real-world initialization values.

You avoid manually matching the field data types with the data types of the corresponding signal elements. However, depending on the virtuality of the bus signal, the method that you use to apply the initial condition, and other factors, you can introduce floating-point storage and potentially inefficient typecasts in the generated code.

Suppose that you create a bus signal `myBusSig` with these signal elements. Each element uses a specific data type.

```
myBusSig
    signalElement1 (int32)
    signalElement2 (boolean)
    signalElement3 (single)
```

Create an initial condition structure `initStruct`. Use untyped expressions to specify the field values. Optionally, to enhance readability of the Boolean field `signalElement2`, use the value `false` instead of `0`.

```
initStruct.signalElement1 = 3;
initStruct.signalElement2 = false;
initStruct.signalElement3 = 17.35;
```

If you use the function `Simulink.Bus.createMATLABStruct` to create the structure, the function stores data type information in the structure fields. After you create the structure, you can optionally use untyped expressions to change the field values. See “Use `Simulink.Bus.createMATLABStruct` to Create Structure” on page 63-147.

Store Data Type Information in Structure Fields

To store data type information in the structure fields, use typed expressions to set the field values, or use the function `Simulink.Bus.createMATLABStruct` to create the structure. Use these techniques to generate efficient code by eliminating floating-point storage and potentially inefficient explicit typecasts.

To avoid manually applying new data types to the structure fields when you change the data types of the corresponding signal elements, consider using a `Simulink.Bus` object to control the data types in the structure and the bus simultaneously.

Use Typed Expressions to Set Field Values

Suppose that you create a bus signal `myBusSig` with this hierarchy of signal elements. Each element uses a specific data type.

```
myBusSig
    signalElement1 (int32)
    signalElement2 (boolean)
    signalElement3 (single)
```

Create an initial condition structure `initStruct` by using typed expressions to set the field values. Match the data types of the fields with the data types of the corresponding signal elements.

```
initStruct.signalElement1 = int32(3);
initStruct.signalElement2 = false;
initStruct.signalElement3 = single(17.35);
```

The structure fields store data type information. If you later change the data type of a signal element, manually apply the new data type to the corresponding structure field.

To match a fixed-point data type, set the field value by using a `fi` object.

Change Field Value by Preserving Data Type Information

Suppose that you change the value of a field in an existing initial condition structure. To preserve the data type information in the field you can use subscripted assignment, with the syntax `(:)`.

```
initStruct.signalElement3(:) = 16.93;
```

If you do not use subscripted assignment, you must remember to preserve the data type by using a typed expression.

```
initStruct.signalElement3 = single(16.93);
```

If you do not use either of these techniques, the field loses the data type information.

```
initStruct.signalElement3 = 16.93; % Field data type is now 'double'.
```

Use `Simulink.Bus.createMATLABStruct` to Create Structure

You can use the function `Simulink.Bus.createMATLABStruct` to create a structure whose fields all have ground values, typically 0. If you configure the data types of the signal elements before using the function, for example by setting the output data types of the blocks that generate the signal elements, each field in the output structure uses the same data type as the corresponding signal element. The fields store the data type information as if you use typed expressions to set the values.

You can initialize some of the signal elements with a value other than ground by passing a partial structure to the function. When you create this partial structure, match the data type of each field with the data type of the corresponding signal element by using typed expressions. For more information and examples, see `Simulink.Bus.createMATLABStruct`.

When you later change the value of a field in the structure, choose one of these techniques to set the new value:

- Untyped expression. The field value no longer stores the data type information.
- Typed expression or subscripted assignment. The field value continues to store the data type information.

Use Bus Object as Data Type of Initial Condition Structure

Whether you store data type information in the structure fields or use untyped expressions to set the field values, you can use a `Simulink.Bus` object as the data type of the entire initial condition structure. You can then manage the field values and data types independently.

If you use this technique, consider using untyped expressions to set the field values. Then, you do not need to match the field data types manually when you change the

data types of the signal elements. To control the data types of the fields and the signal elements, use the `DataType` property of the elements in the bus object.

Suppose that you use a Bus Creator block to create a bus signal `myBusSig` with these signal elements.

```
myBusSig
  signalElement1 (int32)
  signalElement2 (boolean)
  signalElement3 (single)
```

- 1 Open the Bus Editor.

```
buseditor
```

- 2 Create a bus object, `myBus`, that corresponds to the bus signal.

- 3 Create an initial condition structure `initStruct`. Used untyped expressions to set the field values. To enhance readability of the field `signalElement2`, use the Boolean value `false` instead of `0`.

```
initStruct.signalElement1 = 3;
initStruct.signalElement2 = false;
initStruct.signalElement3 = 17.35;
```

- 4 To represent the structure, create a `Simulink.Parameter` object.

```
initStruct = Simulink.Parameter(initStruct);
```

- 5 Use the parameter object to specify an initial condition for the bus signal. For example, in a Unit Delay block dialog box, set **Initial condition** to `initStruct`.

- 6 Use the bus object to specify the data type of the parameter object.

```
initStruct.DataType = 'Bus: myBus';
```

- 7 Use the bus object to specify the data type of the bus signal. For example, in the Bus Creator block dialog box, set **Output data type** to `Bus: myBus`.

During simulation and in the generated code, the structure fields and the signal elements use the data types that you specify in the bus object. Before simulation and code generation, the parameter object casts the structure fields to the data types that you specify in the bus object.

For basic information about bus objects, see “When to Use Bus Objects” on page 63-40.

Configure Data Types for Existing Structure

To remove data type information from all the fields of a structure, you can write a custom function that replaces the field values with `double` numbers. Use the example function `castStructToDbl` as a template.

To convert a structure that uses doubles to one that stores data type information, you can create a reference structure using the function `Simulink.Bus.createMATLABStruct`. You can then write a custom function to cast the field values to the data types in the reference structure. Use the example function `castStructFromDbl` as a template.

Check for Mismatched Data Types with Model Advisor

To detect when the data types of structure fields are not consistent with the associated bus signal elements, in the Simulink Editor, use the **Analysis > Model Advisor > By Product > Simulink “Check structure parameter usage with bus signals”** check.

Limitations for Virtual Buses Crossing Model Reference Boundaries

If you use a bus signal as an input to or an output from a referenced model (Model block):

- You cannot configure the `I/O arguments step method` style of C++ class interface for the referenced model.

As a workaround, use a nonvirtual bus instead. Alternatively, use the `Default` style of C++ class interface.

- You cannot configure function prototype control for the referenced model.

As a workaround, use a nonvirtual bus instead.

For more information about using buses as inputs to or outputs from a referenced model, see “Bus Data Crossing Model Reference Boundaries” on page 63-123. For more information about bus virtuality, see “Virtual and Nonvirtual Buses” on page 63-4.

Code Generation for Arrays of Buses

When you generate code for a model that includes an array of buses, a `typedef` that represents the underlying bus type appears in the `*_types.h` file.

Code generation produces an array of C structures that you can integrate with legacy C code that uses arrays of structures. As necessary, code for bus variables (arrays) is generated in the following structures:

- Block IO
- States
- External inputs
- External outputs

Here is a simplified example of some generated code for an array of buses.

```
typedef struct {  
    real_T a;  
    real_T b;           /* Block signals (auto storage) */  
} BusObject;          typedef struct {  
                        BusObject ForEachSubsystem_IterInp_0[2];  
                        } BlockIO_aob1;
```

For basic information about code generation for nonvirtual buses, which appear in the code as structures, see “Group Signals into Structures in the Generated Code Using Buses”.

Variable-Size Signal Basics

In this section...

“About Variable-Size Signals” on page 64-2

“Creating Variable-Size Signals” on page 64-2

“How Variable-Size Signals Propagate” on page 64-3

“Programmatically Determine Whether Signal Line Has Variable Size” on page 64-4

“Empty Signals” on page 64-5

“Subsystem Initialization of Variable-Size Signals” on page 64-5

About Variable-Size Signals

A Simulink signal can be a scalar, vector (1-D), matrix (2-D), or N-D. For information about these types of signals, see “Signal Basics” on page 62-2 in the *Simulink User's Guide*.

A Simulink variable-size signal is a signal whose size (the number of elements in a dimension), in addition to its values, can change during a model simulation. However, during a simulation, the number of dimensions cannot change. This capability allows you to model systems with varying resources, constraints, and environments.

Creating Variable-Size Signals

You can create variable-size signals in your Simulink model by using:

- Switch or Multiplex blocks with different input ports having fixed-size signals with different sizes. The output is a variable-size signal.
- A selector block and the **Starting and ending indices (port)** indexing option. The index port signal can specify different subregions of the input data signal which produce an output signal of variable size as the simulation progresses.
- The S-function block with the output port configured for a variable-size signal. The output includes not only the values but also the dimension of the signal.

How Variable-Size Signals Propagate

In the Simulink environment, variable-size signals can change their size during model execution in one of two ways:

- **At every step of model execution.**

Various blocks in the model modify the sizes of the signals during execution of the output method.

- **Only during initialization of conditionally executed subsystems.**

Size changes occur during distinct mode-switching events in subsystems such as Action, Enable, and Function-Call subsystems.

You can see the key difference by considering a Discrete 2-Tap Filter block with states.

Discrete 2-Tap Filter

Assume that the input signal dimension to this filter changes from 4 to 1 during simulation. It is ambiguous when and how the states of the Unit Delay blocks should adapt from 4 to 1 to continue processing the input. To ensure consistency, both Unit Delay blocks must change their state behavior synchronously. To prevent ambiguity, Simulink generally disallows blocks whose number of states depends on input signal sizes in contexts where signal sizes change at any point during execution.

In contrast, consider the same Discrete 2-Tap Filter block in a Function-Call subsystem. Assume that this subsystem is using the second way to propagate variable-size signals. In this case, the size of the input signal changes from 4 to 1 only at the initialization

of the subsystem. At initialization, the subsystem resets all of its states (including the states of the two Unit Delay blocks) to their initial values. Resetting the subsystem ensures no ambiguity on the assignment of states to the input signal of the filter.

“Mode-Dependent Variable-Size Signals” on page 64-15 shows how you can use the two ways of propagating variable-size signals in a complementary fashion to model complex systems.

Programmatically Determine Whether Signal Line Has Variable Size

This example shows how to use commands at the command prompt or in a script to determine whether a signal line has a variable size. In a large model or hierarchy of subsystems or referenced models, use this technique to determine whether a signal has a variable size due to an upstream block.

The example model `sldemo_varsize_basic` contains a signal `a` that is downstream of a Switch block. Use commands at the command prompt to determine whether `a` has a variable size.

- 1 Open the example model.
- 2 Select the Sum block whose output signal is labeled `a`.
- 3 At the command prompt, set the model to a compiled state (similar to a diagram update).

```
sldemo_varsize_basic([],[],[],'compile')
```

- 4 Get a handle to the block output port.

```
portHandles = get_param(gcf,'portHandles');  
outPortHandle = portHandles.Outport;
```

- 5 Query the programmatic parameter `CompiledPortDimensionsMode` of the output port.

```
varSize = get_param(outPortHandle,'CompiledPortDimensionsMode')
```

```
varSize =
```

```
1
```

The value of the variable `varSize` is 1, which indicates that the signal `a` has variable size.

The value 0 indicates that a signal does not have variable size.

- 6 Terminate the model compilation.

```
sldemo_varsize_basic([],[],[], 'term')
```

Empty Signals

An empty signal is a signal with a length of 0. For example, signals with size [0], [0x3], [2x0], and [2x0x3] are all empty signals. Simulink allows empty signals with variable-size signals and supports most element-wise operations. However, Simulink does not support empty signals for blocks that modify signal dimensions. Unsupported blocks include Reshape, Permute, and Sum along a specified dimension.

Subsystem Initialization of Variable-Size Signals

The initial signal size from an Outputport block in a conditionally executed subsystem varies depending on the parameters you select.

If you set the **Propagate sizes of variable-size signals** parameter in the parent subsystem to **During execution**, the **Initial output** parameter for the Output block must not exceed the maximum size of the input port. If the **Initial output** parameter value is:

Initial output parameter	Initial output signal size
A nonscalar matrix	The initial output signal size is the size of the Initial output parameter.
A scalar	The initial output signal size is a scalar.
The default []	The initial output size is an empty signal (dimensions are all zeros).

If you set the **Propagate sizes of variable-size signals** parameter in the parent subsystem to **Only when enabling**, the **Initial output** parameter for the Output block must be a scalar value.

- When size is repropagated for the input of the Outputport block, the initial output value is set using scalar expansion from the scalar parameter value.
- If the **Initial output** parameter is the default value [], Simulink treats the initial output as a grounded value.

- If the model does not activate the parent subsystem at start time ($t = 0$), the current size of the subsystem output corresponding to the Outport block is set to maximum size.
- When its parent subsystem repropagates signal sizes, the values of the subsystem variable-size output signals are also reset to their initial output parameter values.

Simulink Models Using Variable-Size Signals

In this section...

“Variable-Size Signal Generation and Operations” on page 64-7

“Variable-Size Signal Length Adaptation” on page 64-11

“Mode-Dependent Variable-Size Signals” on page 64-15

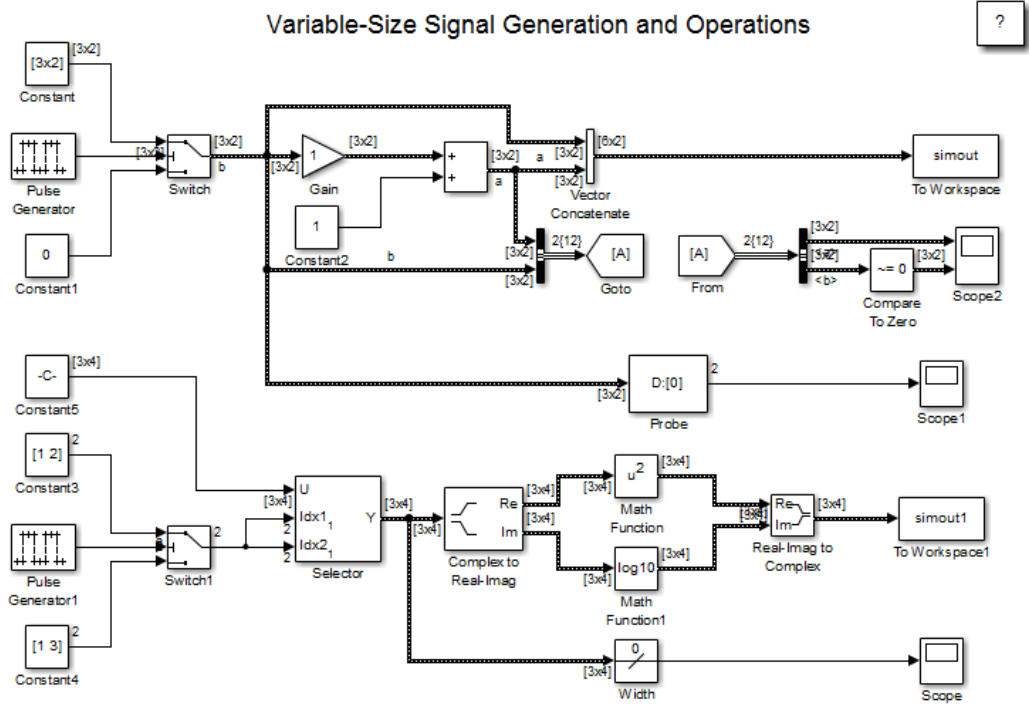

Variable-Size Signal Generation and Operations

This example model shows how to create a variable-size signal from multiple fixed-size signals and from a single data signal. It also shows some of the operations you can apply to variable-size signals.

For a complete list of blocks that support variable-size signals, see “Simulink Block Support for Variable-Size Signals” on page 64-24.

- 1 In the MATLAB Command Window, type
`sldemo_varsize_basic`
- 2 In the Simulink Editor, select **Display > Signals & Ports > Signal Dimensions**. Run a simulation or press **Ctrl-D**.

The Simulink Editor displays the signal dimensions and line styles. See “Signal Basics” on page 62-2 for an interpretation of signal line styles.

Creating a Variable-Size Signal from Fixed-Size Signals

One way to create a variable-size signal is to use the Switch block. The input signals to the Switch block can differ in their number of dimensions and in their size.

Output from the Switch block is a 2-D variable-size signal with a maximum size of 3×2 . When you select the **Allow different data input sizes** parameter on the Switch block, Simulink does not expand the scalar value from the Constant1 block.

Saving Variable-Size Signal Data

You could add a To Workspace block to the output from the Switch block. Since the model already has a To Workspace block, the second To Workspace block would save data to a signal array named `simout2`. The `values` field logs the actual signal values. If logged signal data is smaller than the maximum size, values are padded with NaNs or appropriate values. To obtain these signal values, type:

```
simout2.signals.values
```

```
ans(:,:,1) =
```

```
    1    -1
   -2     2
   -3     3
```

```
ans(:,:,2) =
```

```
    1    -1
   -2     2
   -3     3
```

```
ans(:,:,3) =
```

```

0    NaN
NaN  NaN
NaN  NaN

```

The `valueDimensions` field logs the dimensions of a variable-size signal. To obtain the dimensions, type:

```
simout2.signals.valueDimensions
```

The signal dimensions for the first three time steps are shown.

```
ans =
```

```

3    2
3    2
1    1

```

Creating a Variable-Size Signal from a Single Data Signal

The data signal (Constant5) is a 3x4 matrix. The Pulse Generator represents a control signal that selects a starting and ending index value ([1 2] or [1 3]). The Selector block then uses the index values to select different parts of the data signal at each time step and output a variable-size signal.

Viewing Changes in Signal Size

The output from the Selector block is either a 2x2 or 3x3 matrix. Because the maximum dimension for a variable-size signal is the 3x4 matrix from the data signal, the logged output signals are padded with NaNs.

Use the Probe or Width blocks to inspect the current dimensions and width of a variable-size signal. In addition, you can display variable-size signals on Scope blocks and save variable-size signals to the workspace using the To Workspace block.

Processing Variable-Size Signals

The remainder of the model shows various operations that are possible with variable-size signals. Operations include using the Gain block, the Sum block, the Math Function block, the Matrix Concatenate block. You can connect variable-size signals with the From, Goto, Bus Assignment, Bus Creator, and Bus Selector blocks.

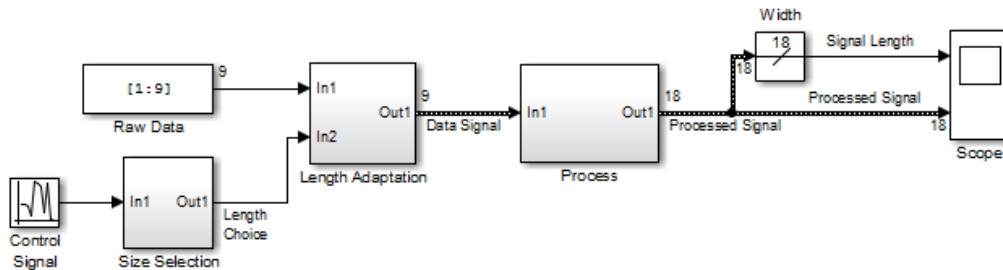

Variable-Size Signal Length Adaptation

This example model corresponds to a hypothetical system where the model adapts the length of a signal over time. Length adaptation is based on the value of a control signal. When the control signal falls within one of three predefined ranges, the fixed-size raw data signal changes to a variable-size data signal.

The variable-size signal connects to a processing block, where blocks that support variable-size signals operate on it. A MATLAB Function block with both input and output signals of variable size allow more flexibility than other blocks supporting variable-size signals. See “Simulink Block Support for Variable-Size Signals” on page 64-24.

To open the example model, in the MATLAB Command Window, type:

```
sldemo_varsize_dataLengthAdapt
```

Creating a Variable-Size Signal by Adapting the Length of a Data Signal

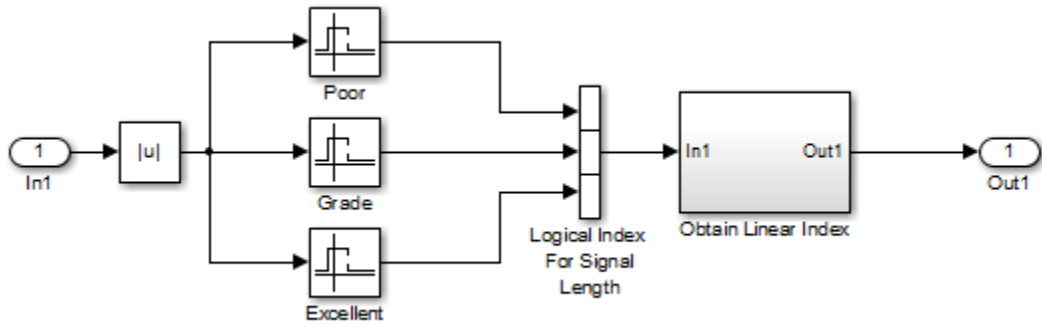

This model generates a data signal and converts the signal to a variable-size signal. The size of the signal depends on the value of a control signal. The raw data signal is a column vector with values from 1 to 9.

```
[1:9].'
```

```
ans =
```

```
1
2
3
4
5
6
7
8
9
```

The Size Selection subsystem determines the quality of the data signal and outputs a quality value (1, 2, or 3). This value helps to select the length of the data signal in the Length Adaptation subsystem.

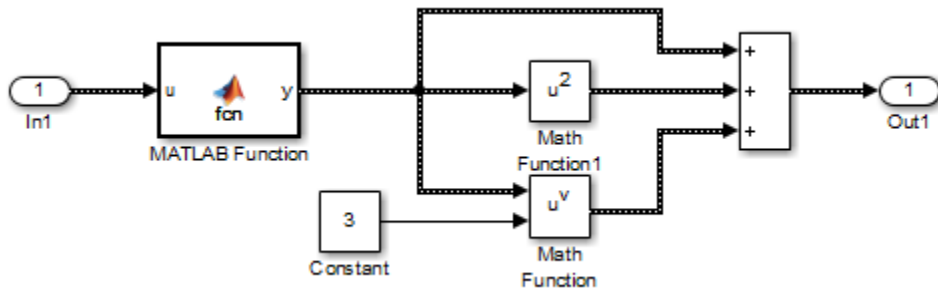

In the Length Adaptation subsystem, the Signal Size subsystem generates an index based on the quality value from the Size Selection subsystem (In2). The Data Selector block uses the starting and ending indices to adapt the length of the data signal (In1) and output a variable-size signal.

Processing a Variable-Size Signal

The center section of the model processes the variable-size signal. The MATLAB Function block adds zeros between the data values in a way that is similar to upsampling a signal. The dimension of the signal changes from 9 to 18. The Math Function blocks shows various manipulations you can do with variable-size signals.

Visualizing a Variable-Size Signal

The right section of the model determines the signal width (size) and uses a scope to visualize the width and the processed data signal.

Mode-Dependent Variable-Size Signals

This example model represents a system that has three operation modes. For each mode, the data signal to process has a different size.

The Process subsystem in this model receives a variable-size signal where the size of the signal depends on the operation mode of the system. For each mode change, the Stateflow chart, Mode Control Logic, detects when the data signal size changes. It then generates a function call to reset the blocks in the Process subsystem.

To open the model, In the MATLAB Command Window, type:

```
sldemo_varsize_multimode
```

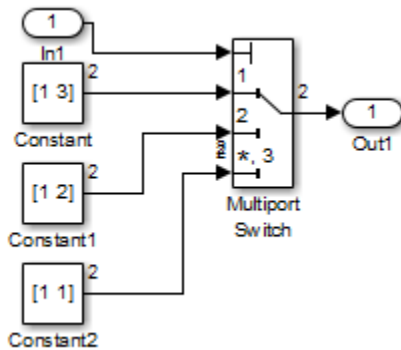

Creating a Variable-Size Signal Based on Mode

The Mode Selection subsystem determines the mode for processing a data signal and outputs a mode value (1, 2, or 3). This value helps to select the length of the data signal using the Size Selection and Data subsystems.

The Size Selection subsystem creates an index value from the mode value. In this example, the index values are [1 3], [1 2], and [1 1].

The Data subsystem takes a data signal (Constant block) and selects part of the data signal dependent on the mode. The output is a variable-size signal with a matrix size of 3×3 , 2×2 , and 1×1 .

The dimensions of the raw data signal (Constant block) is a 3×3 . After connecting a To Workspace block to a signal line, you can view the signal in the MATLAB Command Window by typing:

```
simout.signals.values
```

```
ans(:,:,1) =
```

```

1     4     7
2     5     8
3     6     9
```

The variable-size signal generated from the Data subsystem is also a 3×3 matrix. For shorter signals, the matrix is padded with NaNs.

```
simout.signals.values
```

```
ans(:,:,1) =
```

```
    1   NaN   NaN
   NaN   NaN   NaN
   NaN   NaN   NaN
```

```
ans(:,:,2) =
```

```
    1    4   NaN
    2    5   NaN
   NaN   NaN   NaN
```

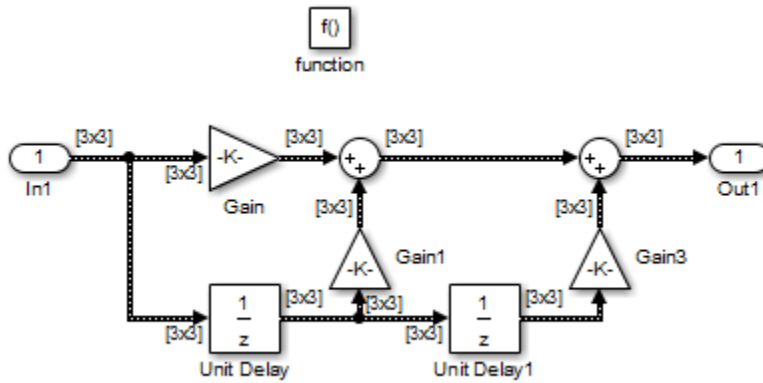

```
ans(:,:,3) =
```

```
    1    4    7
    2    5    8
    3    6    9
```

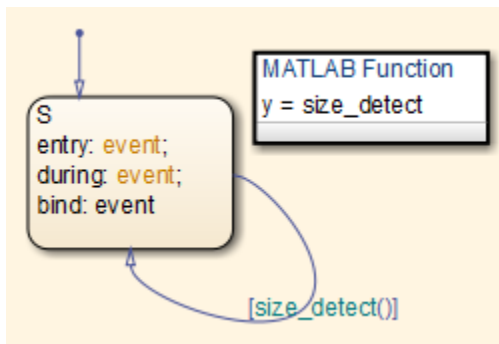

Processing a Variable-Size Signal with a Conditionally Executed Subsystem

Because the Process subsystem contains a Delay block, the subsystem resets and repropagates the signal at each time step. This model uses a Stateflow chart to detect a signal size change and reset the Process subsystem.

In the function block dialog, and from the **Propagate sizes of variable-size signals** list, choose **Only when enabling**. When the model enables this subsystem, selecting this option directs the Simulink software to propagate sizes for variable-size signals inside the conditionally executed subsystem. Signal sizes can change only when they transition from disabled to enabled. For an explanation of handling signal-size changes with blocks containing states, see “How Variable-Size Signals Propagate” on page 64-3.

The Stateflow chart determines if there is a change in the size of the signal. The function `size_detect` calculates the width of the variable-size signal at each time step, and compares the current width to the previous width. If there is a change in signal size, the chart outputs a function-call output event that resets and repropagates the signal sizes within the Process subsystem.

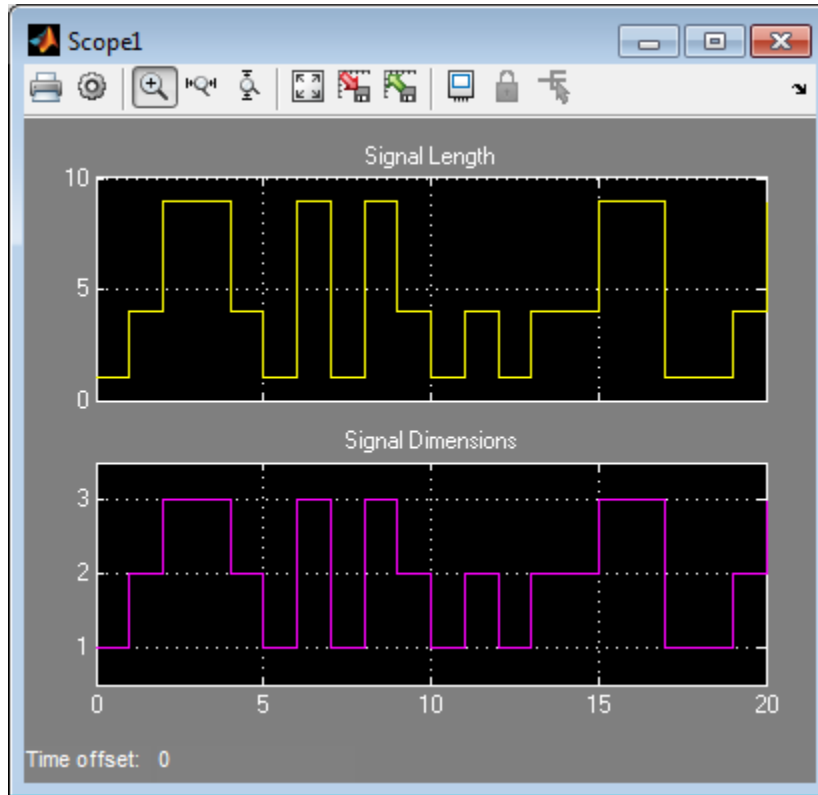

Visualizing Data

Use the Probe block to visualize signal size and signal dimension.

Since the signals are $n \times n$ matrices, the signal dimension lines overlap in the Scope display.

You can use a Display block and the Simulink Debugger to visualize signal values at each time step.

S-Functions Using Variable-Size Signals

In this section...

“Level-2 MATLAB S-Function with Variable-Size Signals” on page 64-21

“C S-Function with Variable-Size Signals” on page 64-22

Level-2 MATLAB S-Function with Variable-Size Signals

Both Level-2 MATLAB S-Functions and C S-Functions support variable-size signals when you set the **DimensionMode** for the output port to **Variable**. You also need to consider the current dimension of the input and output signals in the input and output update methods.

To open this example model, in the MATLAB Command Window, type:

```
msfcdemo_varsize
```

matlabroot\toolbox\simulink\simdemos\simfeatures\msfcn_varsize_expand.m

matlabroot\toolbox\simulink\simdemos\simfeatures\tlc_c\msfcn_varsize_expand.tlc

matlabroot\toolbox\simulink\simdemos\simfeatures\msfcn_varsize_holdStatesUntilReset.m

matlabroot\toolbox\simulink\simdemos\simfeatures\tlc_c\msfcn_varsize_holdStatesUntilReset.tlc

The Enabled subsystem includes a Level-2 MATLAB S-Function which shows how to implement a block that holds its states until reset. Because this block contains states and delays the input signal, the input size can change only when a reset occurs.

The Expand block is a Level-2 MATLAB S-Function that takes a scalar input and outputs a vector of length indicated by its input value. The output is by $1:n$ where n is the input value.

C S-Function with Variable-Size Signals

To open this example model, in the MATLAB Command Window, type:

```
sfcn_demo_varsize
```

The enabled subsystems have two S-Functions:

- `sfun_varsize_holdStatesUntilReset` is a C S-Function that has states and requires its DWorks vector to reset whenever the sizes of the input signal changes.

- `sfun_varsize_concat1D` is a C S-function that implements the concatenation of two unoriented vectors. You can use this function within an enabled subsystem by itself.

Simulink Block Support for Variable-Size Signals

In this section...
“Simulink Block Data Type Support” on page 64-24
“Conditionally Executed Subsystem Blocks” on page 64-24
“Switching Blocks” on page 64-25

Simulink Block Data Type Support

The Simulink Block Data Type Support table includes a complete list of blocks that support variable-size signals.

To view the table:

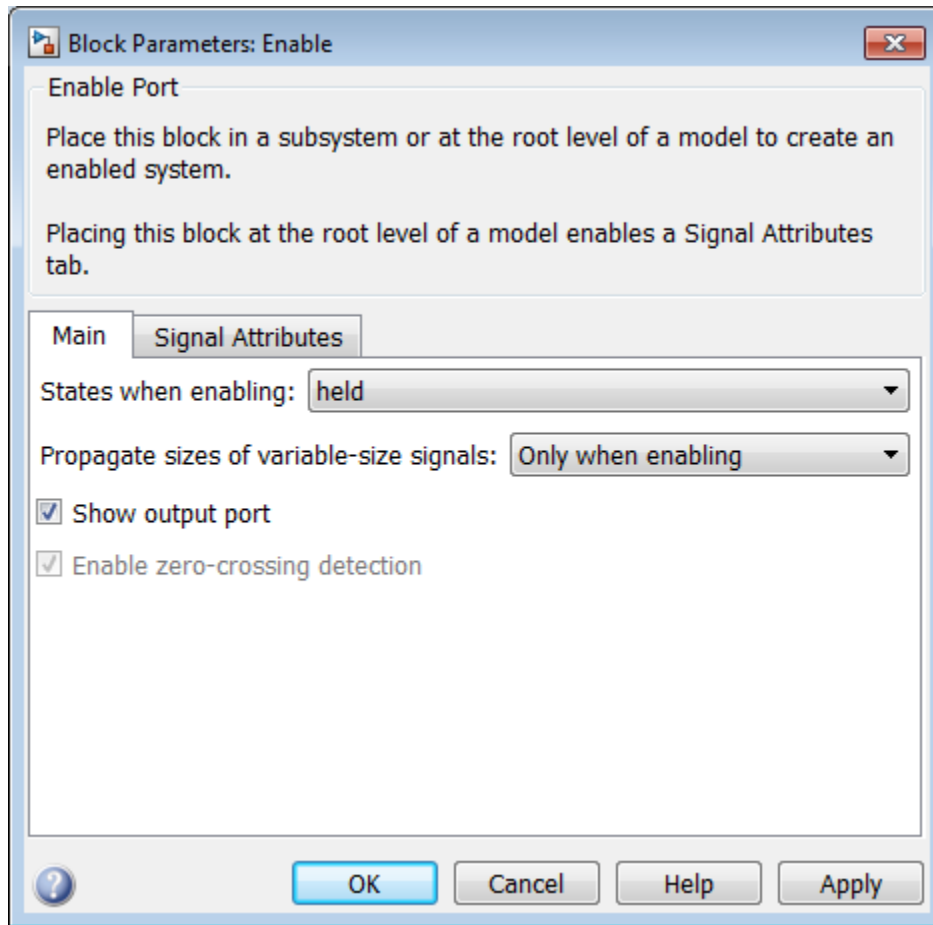

- 1 Open a Simulink model.
- 2 Select **Help > Simulink > Block Data Types & Code Generation Support > Simulink**.

An X in the **Variable-Size Support** column indicates support for that block.

Tip You can also view the table by entering `showblockdatatypetable` at the command prompt.

Conditionally Executed Subsystem Blocks

Control port blocks are in conditionally executed subsystems. You can set the **Propagate sizes of variable-size signals** parameter for these blocks to **During execution**, **Only when execution is resumed** (Action Port), and **Only when enabling** (Enable and Trigger or Function-Call).

- Action Port
- Enable
- Trigger — **Trigger type** set to function-call

Switching Blocks

Switching blocks support variable-size signals by allowing input signals with different sizes and propagating the size of the input signal to the output signal. You can set the

Allow different data input sizes parameter for these blocks on the Signal Attributes pane to either on or off.

- Switch
- Multiport Switch
- Manual Switch

Variable-Size Signal Limitations

The following table is a list of known limitations and workarounds.

Limitation	Workaround
Array format logging does not support variable-size signals.	Use a Structure or Structure With Time format for logging variable-size signals.
Right-click signal logging does not support variable-size signals.	Use a To Workspace block (with Structure or Structure With Time format) or a root Outport block for logging variable-size signals.
A frame-based variable-size signal cannot change the frame length (first dimension size), but it can change the second dimension size (number of channels). Using frame-based signals requires DSP System Toolbox software.	Use the Frame Conversion block to convert a signal into sample-based signal.
Variable-size signals must have a discrete sample time.	—
Embedded Coder does not support variable-size signals with ERT S-functions, custom storage classes, function prototype control, the AUTOSAR, C++ interface, and the ERT reusable code interface.	—
Simulink does not support variable-size parameter or DWork vectors.	—
Rapid accelerator mode does not support models having root-level input ports with variable-size signals.	—
Virtual buses that you use as inputs to or outputs from a referenced model (Model block) do not support variable-size signals.	Configure the bus signal as nonvirtual. For more information about using buses as inputs to or outputs from a referenced model, see “Bus Data Crossing Model Reference Boundaries” on page 63-123. For more information about controlling

Limitation	Workaround
	bus virtuality, see “Virtual and Nonvirtual Buses” on page 63-4.
You cannot apply a storage class to a root-level Outport block (see “Use Model Data Editor to Configure Data Interface”) if the signal that enters the block has a variable size.	Apply the storage class to the signal line instead of the Outport block.

About Adding Items

You can add commands and submenus to these menu locations for the Simulink Editor and Stateflow Editor:

- The end of top-level menus
- The menu bar
- The beginning or end of a context menu

To add an item to an editor menu:

- For each item, create a function, called a *schema function*, that defines the item (see “Define Menu Items” on page 65-4).
- Register the menu customizations with the Simulink customization manager at startup, e.g., in an `sl_customization.m` file on the MATLAB path (see “Register Menu Customizations” on page 65-10).
- Create callback functions that implement the commands triggered by the items that you add to the menus.

Code for Adding Menu Items

The following `sl_customization.m` file adds four items to the Simulink Editor’s **Tools** menu.

```
function sl_customization(cm)
    %% Register custom menu function.
```

```

    cm.addCustomMenuFcn('Simulink:ToolsMenu', @getMyMenuItems);
end

%% Define the custom menu function.
function schemaFcns = getMyMenuItems(callbackInfo)
    schemaFcns = {@getItem1,...
        @getItem2,...
        {@getItem3,3}... %% Pass 3 as user data to getItem3.
        @getItem4};
end

%% Define the schema function for first menu item.
function schema = getItem1(callbackInfo)
    schema = sl_action_schema;
    schema.label = 'Item One';
    schema.userdata = 'item one';
    schema.callback = @myCallback1;
end

function myCallback1(callbackInfo)
    disp(['Callback for item ' callbackInfo.userdata ' was called']);
end

function schema = getItem2(callbackInfo)
    % Make a submenu label 'Item Two' with
    % the menu item above three times.
    schema = sl_container_schema;
    schema.label = 'Item Two';
    schema.childrenFcns = {@getItem1, @getItem1, @getItem1};
end

function schema = getItem3(callbackInfo)
    % Create a menu item whose label is
    % 'Item Three: 3', with the 3 being passed
    % from getMyItems above.

    schema = sl_action_schema;
    schema.label = ['Item Three: ' num2str(callbackInfo.userdata)];
end

function myToggleCallback(callbackInfo)
    if strcmp(get_param(gcs, 'ScreenColor'), 'red') == 0
        set_param(gcs, 'ScreenColor', 'red');
    else
        set_param(gcs, 'ScreenColor', 'white');
    end
end

%% Define the schema function for a toggle menu item.
function schema = getItem4(callbackInfo)
    schema = sl_toggle_schema;
    schema.label = 'Red Screen';
    if strcmp(get_param(gcs, 'ScreenColor'), 'red') == 1
        schema.checked = 'checked';
    else

```

```
        schema.checked = 'unchecked';
    end
    schema.callback = @myToggleCallback;
end
```

Define Menu Items

You define a menu item by creating a function that returns an object, called a *schema* object, that specifies the information needed to create the menu item. The menu item that you define may trigger a custom action or display a custom submenu. See the following sections for more information.

- “Defining Menu Items That Trigger Custom Commands” on page 65-4
- “Defining Custom Submenus” on page 65-7

Defining Menu Items That Trigger Custom Commands

To define an item that triggers a custom command, your schema function must accept a callback info object (see “Callback Info Object” on page 65-10) and create and return an action schema object (see “Action Schema Object” on page 65-5) that specifies the item's label and a function, called a *callback*, to be invoked when the user selects the item. For example, the following schema function defines a menu item that displays a message when selected by the user.

```
function schema = getItem1(callbackInfo)

    %% Create an instance of an action schema.
    schema = sl_action_schema;

    %% Specify the menu item's label.
    schema.label = 'My Item 1';
    schema.userdata = 'item1';
    %% Specify the menu item's callback function.
    schema.callback = @myCallback1;

end

function myCallback1(callbackInfo)
    disp(['Callback for item ' callbackInfo.userdata
        ' was called']);
end
```

Action Schema Object

This object specifies information about menu items that trigger commands that you define, including the label that appears on the menu item and the function to be invoked when the user selects the menu item. Use the function `sl_action_schema` to create instances of this object in your schema functions. Its properties include:

- `tag`

Optional character vector that identifies this action, for example, so that it can be referenced by a filter function.

- `label`

Character vector specifying the label that appears on a menu item that triggers this action.

- `state`

Property that specifies the state of this action. Valid values are 'Enabled' (the default), 'Disabled', and 'Hidden'.

- `statustip`

Character vector specifying text to appear in the editor's status bar when the user selects the menu item that triggers this action.

- `userdata`

Data that you specify. May be of any type.

- `accelerator`

Character vector specifying a **Ctrl** and key combination to use to trigger this action. You can add a keyboard shortcut only for custom menu items that appear on menu bar menus and cannot redefine accelerators that come with the Simulink Editor. For example, **Ctrl+D** is an accelerator for **Update Diagram** in the Simulink Editor, so you cannot redefine it.

To specify this value, use the form 'Ctrl+K', where *K* is the shortcut key. For example, use 'Ctrl+Alt+T' for an accelerator invoked by holding down **Ctrl** and **Alt** and pressing **T**.

- `callback`

Character vector specifying a MATLAB expression to be evaluated or a handle to a function to be invoked when a user selects the menu item that triggers this action. This function must accept one argument: a callback info object.

- `autoDisableWhen`

Property that controls when a menu item is automatically disabled.

Setting	When Menu Items Are Disabled
'Locked'	(default) When the active editor is locked or when the model is busy
'Busy'	Only if the model is busy
'Never'	Never

Toggle Schema Object

This object specifies information about a menu item that toggles some object on or off. Use the function `sl_toggle_schema` to create instances of this object in your schema functions. Its properties include:

- `tag`

Optional character vector that identifies this toggle action, for example, so that it can be referenced by a filter function.

- `label`

Character vector specifying the label that appears on a menu item that triggers this toggle action.

- `checked`

Specify whether the menu item displays a check mark. Valid values are 'unchecked' (default) and 'checked'

- `state`

State of this toggle action, specified as 'Enabled' (default), 'Disabled', and 'Hidden'.

- `statustip`

Character vector specifying text to appear in the editor's status bar when the user selects the menu item that triggers this toggle action.

- `userdata`

Data that you specify. May be of any type.

- `accelerator`

Character vector specifying a **Ctrl** and key combination to use to trigger this action. You can add a keyboard shortcut only for custom menu items that appear on menu bar menus and cannot redefine accelerators that come with the Simulink Editor. For example, **Ctrl+D** is an accelerator for **Update Diagram** in the Simulink Editor, so you cannot redefine it.

To specify this value, use the form '`Ctrl+K`', where *K* is the shortcut key. For example, use '`Ctrl+Alt+T`' for an accelerator invoked by holding down **Ctrl** and **Alt** and pressing **T**.

- `callback`

Character vector specifying a MATLAB expression to be evaluated or a handle to a function to be invoked when a user selects the menu item that triggers this action. This function must accept one argument: a callback info object.

- `autoDisableWhen`

Property that controls when a menu item is automatically disabled.

Setting	When Menu Items Are Disabled
'Locked'	(default) When the active editor is locked or when the model is busy
'Busy'	Only if the model is busy
'Never'	Never

Defining Custom Submenus

To define a submenu, create a schema function that accepts a callback info object and returns a container schema object (see “Container Schema Object” on page 65-8) that specifies the schemas that define the items on the submenu. For example, the following schema function defines a submenu that contains three instances of the menu

item defined in the example in “Defining Menu Items That Trigger Custom Commands” on page 65-4.

```
function schema = getItem2( callbackInfo )
    schema = sl_container_schema;
    schema.label = 'Item Two';
    schema.childrenFcns = {@getItem1, @getItem1, @getItem1};
end
```

Container Schema Object

A container schema object specifies a submenu’s label and its contents. Use the function `sl_container_schema` to create instances of this object in your schema functions. Properties of the object include

- **tag**
Optional character vector that identifies this submenu.
- **label**
Character vector specifying the submenu’s label.
- **state**
Character vector that specifies the state of this submenu. Valid values are 'Enabled' (the default), 'Disabled', and 'Hidden'.
- **statustip**
Character vector specifying text to appear in the editor's status bar when the user selects this submenu.
- **childrenFcns**
Cell array that specifies the contents of the submenu. Each entry in the cell array can be
 - A pointer to a schema function that defines an item on the submenu (see “Define Menu Items” on page 65-4)
 - A two-element cell array whose first element is a pointer to a schema function that defines an item entry and whose second element is data to be inserted as user data in the callback info object (see “Callback Info Object” on page 65-10) passed to the schema function

- 'separator', which causes a separator to appear between the item defined by the preceding entry in the cell array and the item defined in the following entry. The case is ignored for this entry (for example, 'SEPARATOR' and 'Separator' are both valid entries). A separator is also suppressed if it appears at the beginning or end of the submenu and separators that would appear successively are combined into a single separator (for example, as a result of an item being hidden).

For example, the following cell array specifies two submenu entries:

```
{@getItem1, 'separator', {@getItem2, 1}}
```

In this example, a 1 is passed to `getItem2` via a callback info object.

- `generateFcn`

Pointer to a function that returns a cell array defining the contents of the submenu. The cell array must have the same format as that specified for the container schema objects `childrenFcns` property.

Note: The `generateFcn` property takes precedence over the `childrenFcns` property. If you set both, the `childrenFcns` property is ignored and the cell array returned by the `generateFcn` is used to create the submenu.

- `userdata`

Data of any type that is passed to `generateFcn`.

- `autoDisableWhen`

Property that controls when a menu item is automatically disabled.

Setting	When Menu Items Are Disabled
'Locked'	(default) When the active editor is locked or when the model is busy
'Busy'	Only if the model is busy
'Never'	Never

Register Menu Customizations

You must register custom items to be included on a Simulink menu with the customization manager. Use the `sl_customization.m` file for a Simulink installation (see “Registering Customizations” on page 65-26) to perform this task. In particular, for each menu that you want to customize, your system's `sl_customization` function must invoke the customization manager's `addCustomMenuFcn` method. Each invocation should pass the tag of the menu (see “Menu Tags” on page 65-11) to be customized and a custom menu function that specifies the items to be added to the menu (see “Creating the Custom Menu Function” on page 65-10). For example, the following `sl_customization` function adds custom items to the Simulink Tools menu.

```
function sl_customization(cm)
    %% Register custom menu function.
    cm.addCustomMenuFcn('Simulink:ToolsMenu', @getMyItems);
```

Creating the Custom Menu Function

The custom menu function returns a cell array of schema functions that define custom items that you want to appear on the model editor menus (see “Define Menu Items” on page 65-4). The custom menu function returns a cell array similar to that returned by the `generateFcn` function.

Your custom menu function should accept a callback info object (see “Callback Info Object” on page 65-10) and return a cell array that lists the schema functions. Each element of the cell array can be either a handle to a schema function or a two-element cell array whose first element is a handle to a schema function and whose second element is user-defined data to be passed to the schema function. For example, the following custom menu function returns a cell array that lists three schema functions.

```
function schemas = getMyItems(callbackInfo)
    schemas = {@getItem1, ...
              @getItem2, ...
              {@getItem3,3} }; % Pass 3 as userdata to getItem3.
end
```

Callback Info Object

Instances of these objects are passed to menu customization functions. Methods and properties of these objects include:

- `uiObject`

Method to get the handle to the owner of the menu for which this is the callback. The owner can be the Simulink Editor or the Stateflow Editor.

- `model`

Method to get the handle to the model being displayed in the editor window.

- `userdata`

User data property. The value of this property can be any type of data.

Debugging Custom Menu Callbacks

On systems using the Microsoft Windows operating system, selecting a custom menu item whose callback contains a breakpoint can cause the mouse to become unresponsive or the menu to remain open and on top of other windows. To fix these problems, use the MATLAB code debugger keyboard commands to continue execution of the callback.

Menu Tags

A menu tag identifies a Simulink Editor or the Stateflow Editor menu bar or menu. You need to know a menu's tag to add custom items to it (see “Register Menu Customizations” on page 65-10). You can configure the editor to display all (see “Displaying Menu Tags” on page 65-13) but these tags.

Tag	What it adds
Simulink tags	
<code>Simulink:MenuBar</code>	Menu to Simulink Editor's menu bar
<code>Simulink:PreContextMenu</code>	Item to the beginning of Simulink Editor's context menu
<code>Simulink:ContextMenu</code>	Item to the end of Simulink Editor's context menu
<code>Simulink:FileMenu</code>	Item near the end of the Simulink Editor's File menu, but before the Exit MATLAB item
<code>Simulink>EditMenu</code>	Item to the end of the Simulink Editor's Edit menu
<code>Simulink:ViewMenu</code>	Item to the end of the Simulink Editor's View menu

Tag	What it adds
Simulink:DisplayMenu	Item to the end of the Simulink Editor's Display menu
Simulink:DiagramMenu	Item to the end of the Simulink Editor's Diagram menu
Simulink:SimulationMenu	Item to the end of the Simulink Editor's Simulation menu
Simulink:AnalysisMenu	Item to the end of the Simulink Editor's Analysis menu
Simulink:CodeMenu	Item to the end of the Simulink Editor's Code menu
Simulink:ToolsMenu	Item to the end of the Simulink Editor's Tools menu
Simulink:HelpMenu	Item to the end of Simulink Editor's Help menu
Stateflow tags	
Stateflow:MenuBar	Menu to Stateflow Editor's menu bar
Stateflow:PreContextMenu	Item to the beginning of Stateflow Editor's context menu.
Stateflow:ContextMenu	Items to the end of Stateflow Editor's context menu.
Stateflow:FileMenu	Item near the end of the Stateflow Editor's File menu, but before the Exit MATLAB item
Stateflow>EditMenu	Item to the end of Stateflow Editor's Edit menu
Stateflow:ViewMenu	Item to the end of the Stateflow Editor's View menu
Stateflow:DisplayMenu	Item to the end of the Stateflow Editor's Display menu
Stateflow:ChartMenu	Item to the end of the Stateflow Editor's Chart menu
Stateflow:SimulationMenu	Item to the end of the Stateflow Editor's Simulation menu
Stateflow:AnalysisMenu	Item to the end of the Stateflow Editor's Analysis menu

Tag	What it adds
Stateflow:CodeMenu	Item to the end of the Stateflow Editor's Code menu
Stateflow:ToolsMenu	Item to the end of the Stateflow Editor's Tools menu
Stateflow:HelpMenu	Item to the end of the Stateflow Editor's Help menu

Displaying Menu Tags

You can configure the Simulink and Stateflow software to display the tag for a menu item next to the item's label, allowing you to determine at a glance the tag for a menu. The `Simulink:TagName` customizations appear only if the current editor is the Simulink Editor. The `Stateflow:TagName` customizations appear only if the current editor is the Stateflow Editor.

To configure the editor to display menu tags, at the MATLAB command line, set the customization manager's `showWidgetIdAsToolTip` property to `true`. For example:

```
cm = sl_customization_manager;  
cm.showWidgetIdAsToolTip=true;
```

The tag of each menu item appears next to the item's label on the menu:

To turn off tag display, enter the following command at the command line:

```
cm.showWidgetIdAsToolTip=false;
```

Note: Some menu items may not work while menu tag display is enabled. To ensure that all items work, turn off menu tag display before using the menus.

Simulink and Stateflow Editor Menu Customization

Use the same general procedures to customize Stateflow Editor menus as you use for Simulink Editor. The addition of custom menu functions to the ends of top-level menus depends on the active editor:

- Menus bound to `Simulink:FileMenu` only appear when the Simulink Editor is active.
- Menus bound to `Stateflow:FileMenu` only appear when the Stateflow Editor is active.
- To have a menu to appear in both of the editors, call `addCustomMenuFcn` twice, once for each tag. Check that the code works in both editors.

Disable and Hide Model Editor Menu Items

In this section...

“About Disabling and Hiding Model Editor Menu Items” on page 65-16

“Example: Disabling the New Model Command on the Simulink Editor's File Menu” on page 65-16

“Creating a Filter Function” on page 65-16

“Registering a Filter Function” on page 65-17

About Disabling and Hiding Model Editor Menu Items

You can disable or hide items that appear on the Simulink Editor menus. To disable or hide a menu item, you must:

- Create a filter function that disables or hides the menu item (see “Creating a Filter Function” on page 65-16).
- Register the filter function with the customization manager (see “Registering a Filter Function” on page 65-17).

Example: Disabling the New Model Command on the Simulink Editor's File Menu

```
function sl_customization(cm)
    cm.addCustomFilterFcn('Simulink:NewModel',@myFilter);
end
```

```
function state = myFilter(callbackInfo)
    state = 'Disabled';
end
```

Creating a Filter Function

Your filter function must accept a callback info object and return the state that you want to assign to the menu item. Valid states are

- 'Hidden'
- 'Disabled'

- 'Enabled'

Your filter function may have to compete with other filter functions and with Simulink itself to assign a state to an item. Who succeeds depends on the strength of the state that each assigns to the item. 'Hidden' is the strongest state. If any filter function or Simulink assigns 'Hidden' to the item, it is hidden. 'Enabled' is the weakest state. For an item to be enabled, all filter functions and the Simulink or Stateflow products must assign 'Enabled' to the item. The 'Disabled' state is of middling strength. It overrides 'Enabled' but is itself overridden by 'Hidden'. For example, if any filter function or Simulink or Stateflow assigns 'Disabled' to a menu item and none assigns 'Hidden' to the item, the item is disabled.

Note: The Simulink software does not allow you to filter some menu items, for example, the **Exit MATLAB** item on the Simulink **File** menu. An error message is displayed if you attempt to filter a menu item that you are not allowed to filter.

Registering a Filter Function

Use the customization manager's `addCustomFilterFcn` method to register a filter function. The `addCustomFilterFcn` method takes two arguments: a tag that identifies the menu or menu item to be filtered (see “Displaying Menu Tags” on page 65-13) and a pointer to the filter function itself. For example, the following code registers a filter function for the **New Model** item on the Simulink **File** menu.

```
function sl_customization(cm)
    cm.addCustomFilterFcn('Simulink:NewModel',@myFilter);
end
```

Disable and Hide Dialog Box Controls

In this section...

“About Disabling and Hiding Controls” on page 65-18

“Disable a Button on a Dialog Box” on page 65-18

“Write Control Customization Callback Functions” on page 65-19

“Dialog Box Methods” on page 65-20

“Dialog Box and Widget IDs” on page 65-20

“Register Control Customization Callback Functions” on page 65-21

About Disabling and Hiding Controls

Simulink includes a customization API that allows you to disable and hide controls (also referred to as *widgets*), such as text fields and buttons, on most dialog boxes. The customization API allows you to disable or hide controls on an entire class of dialog boxes, for example, parameter dialog boxes, by way of a single method call.

Before you customize a Simulink dialog box or class of dialog boxes, first make sure that the dialog box or class of dialog boxes is customizable. Any dialog box that appears in the dialog pane of Model Explorer is customizable. In addition, any dialog box that has dialog and widget IDs is customizable. To determine whether a dialog box is customizable, open the dialog box, enable dialog and widget ID display (see “Dialog Box and Widget IDs” on page 65-20), and hover over a widget. If a widget ID appears, you can customize the dialog box.

Once you have determined that a dialog box or class of dialog boxes is customizable, write MATLAB code to customize the dialog boxes. This entails writing callback functions that disable or hide controls for a specific dialog box or class of dialog boxes (see “Write Control Customization Callback Functions” on page 65-19) and registering the callback functions using the customization manager (see “Register Control Customization Callback Functions” on page 65-21). Simulink invokes the callback functions to disable or hide the controls whenever you open the dialog boxes.

Disable a Button on a Dialog Box

This `s1_customization.m` file disables the **Browse** button on the **Code Generation** pane of the Configuration Parameters dialog box for any model whose name contains engine.

```

function sl_customization(cm)

% Disable for standalone Configuration Parameters dialog box.
cm.addDlgPreOpenFcn('Simulink.ConfigSet',@disableRTWBrowseButton)
% Disable for Configuration Parameters dialog box
cm.addDlgPreOpenFcn('Simulink.RTWCC',@disableRTWBrowseButton)

end

function disableRTWBrowseButton(dialogH)
    hSrc = dialogH.getSource; % Simulink.RTWCC
    hModel = hSrc.getModel;
    modelName = get_param(hModel, 'Name');

    if ~isempty(strfind(modelName, 'engine'))
        % Takes a cell array of widget Factory ID.
        dialogH.disableWidgets({'Tag_ConfigSet_RTW_Browse'})
    end
end
end

```

To test this customization:

- 1 Save the `sl_customization.m` file on the MATLAB path.
- 2 Refresh the customizations by entering `sl_refresh_customizations` at the command line or by restarting MATLAB (see “Registering Customizations” on page 65-26).
- 3 Open the `sldemo_engine` model, for example, by entering the command `sldemo_engine` at the command prompt.
- 4 Open the Configuration Parameters dialog box and look at the **Code Generation** pane to see if the **Browse** button is disabled.

Write Control Customization Callback Functions

A callback function for disabling or hiding controls on a dialog box accepts one argument: a handle to the dialog box object that contains the controls you want to disable or hide. The dialog box object provides methods that the callback function can use to disable or hide the controls that the dialog box contains.

The dialog box object also provides access to objects containing information about the current model. Your callback function can use these objects to determine whether to disable or hide controls. For example, this callback function uses these objects to disable the **Browse** button on the **Code Generation** pane of the Configuration Parameters dialog box for any model whose name contains `engine`.

```
function disableRTWBrowseButton(dialogH)

    hSrc = dialogH.getSource; % Simulink.RTWCC
    hModel = hSrc.getModel;
    modelName = get_param(hModel, 'Name');

    if ~isempty(strfind(modelName, 'engine'))
        % Takes a cell array of widget Factory ID.
        dialogH.disableWidgets({'Tag_ConfigSet_RTW_Browse'})
    end
```

Dialog Box Methods

Dialog box objects provide these methods for enabling, disabling, and hiding controls:

- `disableWidgets(widgetIDs)`
- `hideWidgets(widgetIDs)`

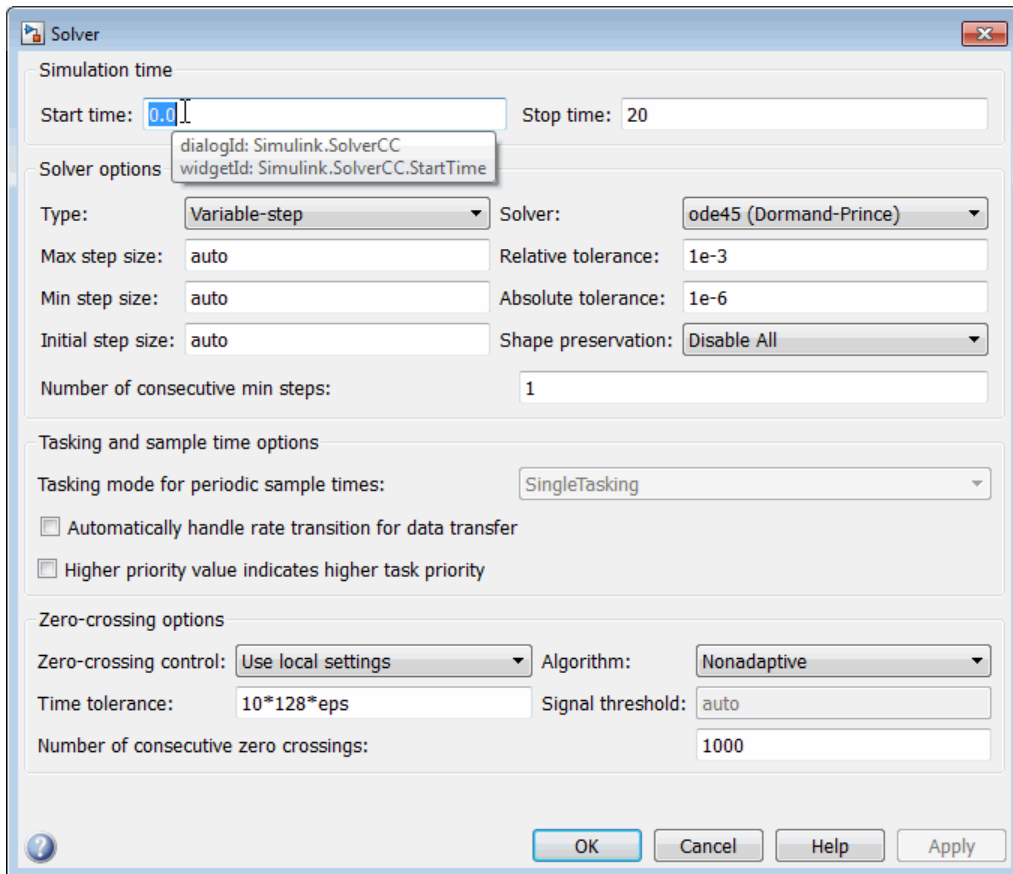

`widgetIDs` is a cell array of widget identifiers (see “Dialog Box and Widget IDs” on page 65-20) that specify the widgets to disable or hide.

Dialog Box and Widget IDs

Dialog box and widget IDs identify a control on a Simulink dialog box. To determine the dialog box and widget ID for a particular control, execute the following code at the command line:

```
cm = sl_customization_manager;
cm.showWidgetIdAsToolTip = true
```

Open the dialog box that contains the control and hover over the control to display a tooltip listing the dialog box and the widget IDs. For example, hovering over the **Start time** field on the **Solver** pane of the Configuration Parameters dialog box shows that the dialog box ID for the **Solver** pane is `Simulink.SolverCC` and the widget ID for the **Start time** field is `Simulink.SolverCC.StartTime`.

Note: The tooltip displays not customizable for controls that are not customizable.

Register Control Customization Callback Functions

To register control customization callback functions for an installation of Simulink, include code in the installation's `sl_customization.m` file (see "Registering Customizations" on page 65-26) that invokes the customization manager's `addDlgPreOpenFcn` method on the callbacks.

`addDlgPreOpenFcn` takes two arguments. The first argument is a dialog box ID (see “Dialog Box and Widget IDs” on page 65-20) and the second is a pointer to the callback function to register. Invoking this method causes the registered function to be invoked for each dialog box of the type specified by the dialog box ID. The function is invoked before the dialog box is opened.

This example registers a callback that disables the **Browse** button on the **Code Generation** pane of the Configuration Parameters dialog box (see “Write Control Customization Callback Functions” on page 65-19).

```
function sl_customization(cm)

    % Disable for standalone Configuration Parameters dialog box.
    cm.addDlgPreOpenFcn('Simulink.ConfigSet',@disableRTWBrowseButton)

    % Disable for Configuration Parameters dialog box.
    cm.addDlgPreOpenFcn('Simulink.RTWCC',@disableRTWBrowseButton)

end
```

Note: Registering a customization callback causes Simulink to invoke the callback for every instance of the class of dialog boxes specified by the method’s dialog box ID argument. You can therefore use a single callback to disable or hide a control for an entire class of dialog boxes. In particular, you can use a single callback to disable or hide the control for a parameter that is common to most built-in blocks. Most built-in block dialog boxes are instances of the same dialog box super class.

Customize Library Browser Appearance

In this section...

“Reorder Libraries” on page 65-23

“Disable and Hide Libraries” on page 65-24

“Expand or Collapse Library in Browser Tree” on page 65-25

Reorder Libraries

A library’s name and sort priority determines its order in the tree view of the Library Browser. Libraries appear in ascending order of priority. Libraries that have the same priority are sorted alphabetically.

The Simulink library has a sort priority of -1 by default. All other libraries have a sort priority of 0 by default. These sort priorities cause the Simulink library to display first in the Library Browser by default.

You can reorder libraries by changing their sort priorities. To change library sort priorities, add code in this form to an `sl_customization.m` file on the MATLAB path:

```
cm.LibraryBrowserCustomizer.applyOrder({'LIBNAME1',PRIORITY1, ...
                                         'LIBNAME2',PRIORITY2, ...
                                         .
                                         'LIBNAMEN',PRIORITYN});
```

`LIBNAMEn` is the name of the library (or its model file) and `PRIORITYn` is an integer indicating the library's sort priority. For example, this code moves the Simulink Extras library to the top of the Library Browser’s tree view.

```
cm.LibraryBrowserCustomizer.applyOrder({'Simulink Extras',-2});
```

After adding or modifying the `sl_customization.m` file, enter `sl_refresh_customizations` at the MATLAB command prompt to see the customizations take effect.

For more information on the customization functions, see “Registering Customizations” on page 65-26.

Disable and Hide Libraries

To disable or hide libraries, sublibraries, or library blocks, insert code in this form in an `sl_customization.m` file (see “Registering Customizations” on page 65-26) on the MATLAB path:

```
cm.LibraryBrowserCustomizer.applyFilter({'Item1','State', ...  
                                         'Item2','State', ...  
                                         .  
                                         'ItemN','State'});
```

- `ItemN` is the library, sublibrary, or block to disable or hide. Specify the item in the form `'LibraryName/Sublibrary/Block'`.
 - `LibraryName` is the library name as it appears in the browser. For a custom library, you set this value in the `slblocks.m` file with the `Browser.Name` property.
 - `Sublibrary` is the name of the sublibrary or, for a custom library, a `Subsystem` block. You can specify a block inside the subsystem in your library or in a library that you open by way of the subsystem's `OpenFcn` callback. See “Create a Custom Library” on page 38-3.
 - `Block` is the block name.
- `'State'` is `'Disabled'` or `'Hidden'`.

For example, this code hides the `Sources` sublibrary of the `Simulink` library and disables the `Sinks` sublibrary.

```
cm.LibraryBrowserCustomizer.applyFilter({'Simulink/Sources','Hidden'});  
cm.LibraryBrowserCustomizer.applyFilter({'Simulink/Sinks','Disabled'});
```

This code disables the `Sqrt` block in the sublibrary opened by way of the `Subsystem2` block in the custom library `'My Library'`.

```
cm.LibraryBrowserCustomizer.applyFilter({'My Library/Subsystem2/Sqrt','Disabled'});
```

After adding or modifying the `sl_customization.m` file, enter `sl_refresh_customizations` at the MATLAB command prompt to see the customizations take effect.

Expand or Collapse Library in Browser Tree

You can add a customization to expand or collapse any library in the Library Browser tree by default. For example, the Simulink library is expanded by default. You can specify to instead collapse it by default. Add code in this form to your `sl_customization.m` file:

```
cm.LibraryBrowserCustomizer.applyNodePreference({'libraryName' ,logical});
```

Use `true` to expand the library and `false` to collapse it.

For example, this code collapses the Simulink library and expands the Stateflow library:

```
function sl_customization(cm)
    cm.LibraryBrowserCustomizer.applyNodePreference({'Simulink',false,'Simscape',true});
end
```

This code collapses a custom library named 'My Library'.

```
function sl_customization(cm)
    cm.LibraryBrowserCustomizer.applyNodePreference({'My Library',false});
end
```

After adding or modifying the `sl_customization.m` file, enter `sl_refresh_customizations` at the MATLAB command prompt to see the customizations take effect.

Registering Customizations

About Registering Customizations in Simulink

Register your customizations using the MATLAB function `sl_customization.m`. Place the function on the MATLAB path of the Simulink installation that you want to customize or in the current folder.

You can have more than one `sl_customization.m` file. The customizations in each file takes effect, with conflicts handled by each customization. For example, if you specify priorities for libraries in multiple `sl_customization` files, only one takes effect. If you add the same menu item twice, it appears twice. To ensure that customizations are loading as expected, refresh the customizations, as described in “Reading and Refreshing the Customization File” on page 65-27.

The `sl_customization` function accepts one argument: a handle to the customization manager object, that is, `cm`. For example:

```
function sl_customization(cm)
```

In your `sl_customization` function, use customization manager object properties and methods specific to your application to register customizations. You can use customization properties and methods to:

- “Add Items to Model Editor Menus” on page 65-2
- “Disable and Hide Model Editor Menu Items” on page 65-16
- “Disable and Hide Dialog Box Controls” on page 65-18
- “Add Libraries to the Library Browser” on page 38-9
- “Customize Library Browser Appearance” on page 65-23
- “Customize Bus Object Import and Export” on page 63-71
- “Import Lookup Table Data from MATLAB” on page 35-31

Additional MathWorks products use the customization manager object and the `sl_customization.m` file. Refer to your product documentation to learn about the methods and properties that apply to your product.

Reading and Refreshing the Customization File

The `sl_customization.m` file is read when Simulink starts. If you change the `sl_customization.m` file, either restart Simulink or enter this command to see the changes:

```
sl_refresh_customizations
```

This command runs all `sl_customization.m` files on the MATLAB path and in the current folder. Some side-effects of running `sl_refresh_customizations` include:

- Rebuilding all Simulink Editor menus and toolbars
- Rebuilding the Library Browser menus and toolbars
- Clearing the Library Browser cache and refreshing the Library Browser
- Reloading the Signal and Scope Manager data

Print Frames

In this section...

“What Are Print Frames?” on page 66-2

“PrintFrame Editor” on page 66-3

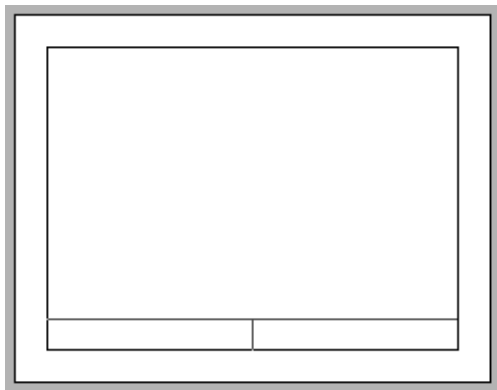

“Single Use or Multiple Use Print Frames” on page 66-4

“Text and Variable Content” on page 66-5

What Are Print Frames?

Print frames are borders of a printed page that contain information about a block diagram, such as the model name or the date of printing. After you create a print frame, use the Simulink or Stateflow Editor to print a block diagram or chart with that print frame.

The default print frame has two rows:

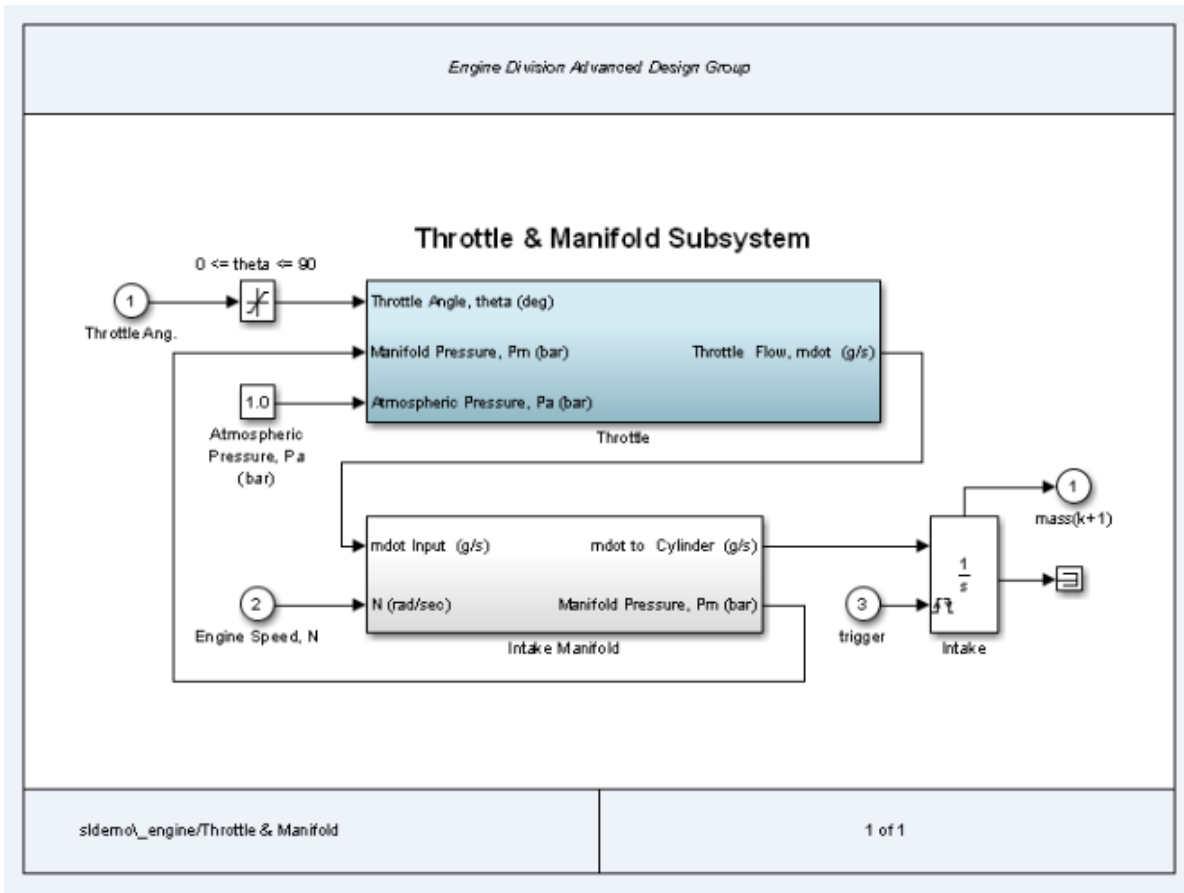

Rows contain one or more cells. You can add content entries to cells. You can also add new rows and cells.

For example, the print frame below includes:

- An additional row at the top of the frame for a title

- A middle row, which includes the block diagram
- A bottom row, in which one cell has the path to the subsystem and another cell has the page number

PrintFrame Editor

Use the PrintFrame Editor to create and edit print frames.

To open the PrintFrame Editor, at the MATLAB command line, enter the `frameedit` command.

Use the PrintFrame Editor to:

- Set up the printed page
- Add or remove rows and cells in the print frame
- Add content to cells, such as text, the date, and page numbers
- Format cell content

To open an existing print frame, use `frameedit` command with the `filename` parameter, where `filename` is an existing print frame (a `.fig` file).

Single Use or Multiple Use Print Frames

You can design a print frame for one particular block diagram, or you can design a more generic print frame for printing multiple block diagrams.

Text and Variable Content

In cells, you can include text (such as the name and address of your organization) and variable content (such as the current date).

See Also

frameedit

Related Examples

- “Create a Print Frame” on page 66-6
- “Print Using Print Frames” on page 66-13

Create a Print Frame

- 1 At the MATLAB prompt, type `frameedit` to open the PrintFrame Editor.
- 2 In the PrintFrame Editor, select **File > Page Setup**.

If necessary, change default page setup for the print frame, which is:

- Paper type — usletter
- Orientation — landscape

Note: The paper orientation you specify does not control the paper orientation used for printing. For example, assume you specify a landscape-oriented print frame in the PrintFrame Editor. If you want the printed page to have a landscape orientation, you must specify that using the Print Model dialog box.

- Margins — .75 inches on all sides
- 3 Set up the layout of the print frame and add content. See:
 - “Add Rows and Cells to Print Frames” on page 66-7
 - “Add Content to Print Frame Cells” on page 66-9
 - 4 Save the print frame as a `.fig` file. Select **File > Save As**.

- “Print Frames” on page 66-2

Add Rows and Cells to Print Frames

In this section...

“Add and Remove Rows” on page 66-7

“Add and Remove Cells” on page 66-7

“Resize Rows and Cells” on page 66-7

Tip Specify the print frame page setup before you create rows and cells or add content (see “Create a Print Frame” on page 66-6).

Add and Remove Rows

You can add a row above the row that you select.

- 1 Click in a cell to select a row.

When you select a row, handles appear on all four corners. If you select only a line, handles appear on two corners.

- 2 Click **Add Row**.

The new row appears above the row that you selected.

To remove a row, select the row and click **Delete Row**.

Add and Remove Cells

You can add cells within a row.

- 1 Select the cell that you want to split.

- 2 Click **Split Cell**.

The cell splits into two cells.

To remove a cell, select the cell and click **Delete Cell**.

Resize Rows and Cells

You can change the dimensions of a row or cell by selecting the bordering line.

1 Click the line you want to move.

A handle appears on both ends of the line.

2 Drag the line to resize the row or cell.

For example, to make a row taller, click on the top line that forms the row. Then drag the line up and the height of the row increases.

To change the overall dimensions of the print frame, see “Create a Print Frame” on page 66-6.

Add Content to Print Frame Cells

In this section...

- “Types of Content” on page 66-9
- “Add Content to Cells” on page 66-9
- “Block Diagram” on page 66-10
- “Variables” on page 66-10
- “Text” on page 66-11
- “Format Content in Cells” on page 66-12

Types of Content

You can add text or variables, or both, to a cell.

You must add a **Block Diagram** variable to one of the cells.

For details about the types of content, see:

- “Block Diagram” on page 66-10
- “Variables” on page 66-10
- “Text” on page 66-11

Add Content to Cells

- 1 Select the cell that you want to add content to.
- 2 From the list, select the type of content that you want to add.
- 3 Click **Add**.

The type of content that you added appears in the cell.

Tip If you click **Add** and nothing happens, it might be because you did not select a cell first.

- 4 If you add text, select the edit box and type in the text. For details, see “Text” on page 66-11.

Tip To make it easier to read and edit the content that you add, you can click the **Zoom in +** button.

Include Multiple Entries in a Cell

- 1 Select a cell that has a content entry.
- 2 Add another content type item from the list.

The new entry is added after the last entry in that cell.

You can also add descriptive text to any of the variable entries without using the **Text** item.

- 1 Double-click in the cell.
- 2 Type text in the edit box before or after the entry.
- 3 To end editing mode, click outside of the cell.

Note: You cannot include multiple entries or text in the cell that contains the **Block Diagram** variable. `%<blockdiagram>` must be the only content in that cell.

Block Diagram

Use the **Block Diagram** variable to indicate the cell in which to print the block diagram. Every print frame must include one **Block Diagram** variable. If you do not specify a **Block Diagram** in one of the cells, you cannot save the print frame and cannot print a block diagram with it.

Do not add any other content in a cell that contains a **Block Diagram** variable.

Variables

In addition to the **Block Diagram** variable, you can add other variables, such as the current date, to cells. Simulink supplies variable content at the time of printing.

Variable entries include:

- **Block Diagram** — Add this variable in the cell in which you want the block diagram to print. For details, see “Block Diagram” on page 66-10.

- **Date** — The date that the block diagram and print frame are printed, in `dd-mmm-yyyy` format.
- **Time** — The time that the block diagram and print frame are printed, in `hh:mm` format.
- **Page Number** — The page of the block diagram being printed.
- **Total Pages** — The total number of pages being printed for the block diagram, which depends on the printing options specified.
- **System Name** — The name of the block diagram being printed.
- **Full System Name** — The name of the block diagram being printed, including its position from the root system through the current system, for example, `engine/Throttle & Manifold`.
- **File Name** — The file name of the block diagram, for example, `sldemo_engine.mdl`.
- **Full File Name** — The full path and file name for the block diagram, for example, `\matlab\toolbox\simulink\simdemos\automotive\sldemo_engine.mdl`.

When you enter a variable, the cell displays the type of content in brackets, `<>`, preceded by a percent sign, `%`. For example, if you add a **Page Number** variable, it appears as `%<page>`.

Note: Do not edit the text of a variable entry, because then the variable content does not print. For example, if you accidentally remove the `%` from the `%<page>` entry, the text `<page>` prints, instead of the actual page number.

Text

For **Text** content, type the text that you want to include in that cell (for example, the name of your organization). To type additional text on a new line, press the **Enter** key. When you are finished editing, click outside of the edit box.

You can copy and paste text from another document into a cell. Any formatting of the copied text is lost.

To type special characters (for example, superscripts and subscripts, Greek letters, and mathematical symbols), use embedded TeX sequences. For a list of allowable sequences, see the `text` command **String** property (in **Text Properties**).

Format Content in Cells

You can align cell contents using the left, center, and right alignment buttons. (Block diagrams are always center aligned.)

You can change font properties, such as size or style (for example, italics or bold). To change font properties, select the cell, then right-click the contents and use the context menu to format the text.

More About

- “Print Frames” on page 66-2

Print Using Print Frames

To print using a print frame, you specify an existing print frame. If you want to build a print frame, see “Create a Print Frame” on page 66-6.

Note: If you enable the print frame option, then Simulink does not use tiled printing.

- 1 In the Simulink Editor or Stateflow Editor, select **File > Print > Print**.
- 2 In the Print Model dialog box, select the **Frame** check box.

- 3 Supply the file name for the print frame you want to use. Either type the path and file name directly in the edit box, or click the ... button and select a print frame file you saved using the PrintFrame Editor. The default print frame file name, `sldefaultframe.fig`, appears in the file name edit box until you specify a different file name.
- 4 Specify other printing options in the Print Model dialog box.

Note: The paper orientation you specify with the PrintFrame Editor does not control the paper orientation used for printing. For example, assume you specify a landscape-oriented print frame in the PrintFrame Editor. If you want the printed page to have a landscape orientation, you must specify that using the Print Model dialog box.

5 Click **OK**.

The block diagram prints with the print frame that you specify.

Running Models on Target Hardware

About Run on Target Hardware Feature

- “Simulink Supported Hardware” on page 67-2
- “Tune and Monitor Models Running on Target Hardware” on page 67-3
- “Block Produces Zeros or Does Nothing in Simulation” on page 67-8

Simulink Supported Hardware

As of this release, Simulink supports the following hardware.

Support Package	Vendor	Earliest Release Available	Last Release Available
Apple iOS Devices	Apple	R2015a	Current
Arduino Hardware	Arduino	R2012a	Current
BeagleBoard Hardware	BeagleBoard	R2012a	R2016a
LEGO MINDSTORMS NXT Hardware	LEGO	R2012a	Current
LEGO MINDSTORMS EV3 Hardware	LEGO	R2014a	Current
Raspberry Pi Hardware	Raspberry Pi	R2013a	Current
Android Devices	Android	R2014a	Current

For a complete list of supported hardware, see [Hardware Support](#).

Tune and Monitor Models Running on Target Hardware

In this section...

“Overview of Using External Mode” on page 67-3

“Run Your Simulink Model in External Mode” on page 67-4

“Stop External Mode” on page 67-5

“External Mode Control Panel” on page 67-5

Overview of Using External Mode

You can use External mode to tune parameters and monitor a model running on your target hardware.

External mode enables you to tune model parameters and evaluate the effects of different parameter values on model results in real time. Doing so helps you find the optimal values to achieve desired performance. This process is called *parameter tuning*.

External mode accelerates parameter tuning because you do not have to rerun the model each time you change parameters. You can also use External mode to develop and validate your model using the actual data and hardware for which it is designed. This software-hardware interaction is not available solely by simulating a model.

This workflow lists the tasks usually required to tune parameters with External mode:

- 1 In the model on your host computer, enable External mode.
- 2 (Optional) Place one or more sink blocks in your model. For example, use **Display** or **Scope** blocks to visualize data, or use a **To File** block to log signal data.
- 3 Give the Simulink software command to run the model on the target hardware.
- 4 (Optional) Observe the data External mode sends from the target hardware to sink blocks in the model on the host computer.
- 5 Change and apply parameter values in the model on your host computer.
- 6 Find the optimal parameter values by making adjustments and observing the results.
- 7 Save the new parameter values, disable External mode, and save the model.

Run Your Simulink Model in External Mode

Note: If you have the Embedded Coder or Simulink Coder software, you can use External mode with a model that contains Model blocks (uses the “Model reference”).

- 1 Connect the target hardware to your host computer.

Different types of target hardware can use different types of connections. Check the External mode topic for your target hardware to determine which type of connection to use.

- 2 On the model toolbar, set **Simulation mode** to External.

- 3 Set the **Simulation stop time** parameter, located to the left of **Simulation mode** on the model toolbar. The default value is 10.0 seconds. To run the model for an indefinite period, enter `inf`.
- 4 Click the **Run** button.

If your model does not contain a sink block, the MATLAB Command Window displays a warning message. For example:

```
Warning: No data has been selected for uploading.
> In C:\Program Files (x86)\MATLAB\R2013a Student1\toolbox\
realtime\realtime\+realtime\extModeAutoConnect.p>
extModeAutoConnect at 17
In C:\Program Files (x86)\MATLAB\R2013a Student1\toolbox\
realtime\realtime\sl_customization.p>myRunCallback at 149
```

You can disregard this warning or add a sink block to the model.

After several minutes, Simulink starts running your model on the board.

- 5 Change parameter values in the model on your host computer.

Observe the corresponding changes in the model running on the hardware.

Any Simulink Sinks blocks in your model receive data from the hardware and display it on your host computer.

Note: External mode increases the processing burden of the model running on the board, and can cause overruns.

Stop External Mode

To stop the model running in External mode, click the black square Stop button located on the model toolbar, as shown here.

This action stops the process for the model running on the target hardware, and stops the model simulation running on your host computer.

If the **Simulation stop time** parameter is set to a specific number of seconds, External mode stops when that time elapses.

When you are finished using External mode, set **Simulation mode** back to Normal.

External Mode Control Panel

Using External Mode Control Panel provides additional control of External mode operations, including:

- Connect or disconnect the model on the host computer to/from the model running on the target hardware.
- Start and stop the model running on the target hardware.
- Gather changes to parameter values in a batch before applying them concurrently to the model running on the target hardware.

To open the External Mode Control Panel dialog box, in the model window, select **Code > External Mode Control Panel**.

The **Connect/Disconnect** button connects or disconnects the model on your host computer to/from the model running on the target hardware. If the model is not running on the target hardware, clicking **Connect** automatically deploys and runs the model on the target hardware.

- The **Start Real-Time Code/Stop Real-Time Code** button starts or stops the model running on the target hardware.
- **Batch download** enables you to gather changes before using the **Download** button to simultaneously apply those changes to the model running on the hardware:
 - While **Batch download** is disabled, clicking **OK** or **Apply** in a block dialog box sends updated block parameter values from the block to the model running on the target hardware.
 - When you enable **Batch download**, clicking **OK** or **Apply** in a block dialog box stores updated block parameter values on the host computer. You can complete a set of changes before clicking **Download** to simultaneously send all of the updated values to the model running on the target hardware. This feature is useful for avoiding error conditions when a model contains blocks whose parameter values must be changed concurrently.

External Mode Control Panel displays **Parameter changes pending...** to the right of the **Download** button until the model running on the target hardware has applied the new parameter values.

“Tune and Monitor Model Running on Arduino Mega 2560 Hardware”

Block Produces Zeros or Does Nothing in Simulation

If you simulate a model on your host computer without running it on your target hardware:

- Input blocks produce zeros.
- Output blocks do nothing.

This is the expected behavior.

For example, in a model, if you select **Simulation > Mode > Normal** and then select **Simulation > Run**, the following happens:

- The sensor block and Digital Input block send zeros to the model.
- The Digital Output block does nothing.

To see the blocks work normally, run your model on target hardware or use External mode.

To run the model on target hardware, select **Tools > Run on Target Hardware > Prepare to Run**. Then, click the Deploy to Hardware button.

To use External mode, select **Simulation > Mode > External**. Then, select **Simulation > Run**.

- “Fast Restart Methodology” on page 68-11
- “Factors Affecting Fast Restart” on page 68-15

How Fast Restart Improves Iterative Simulations

In the classic Simulink workflow, when you simulate a model, Simulink:

- 1 Compiles the model
- 2 Simulates the model
- 3 Terminates the simulation

While developing a model, you typically simulate a model repeatedly as you iterate the design. For example, you might calibrate input values or block parameters for a particular response. Changing these values or parameters does not always require compiling the model before simulating again. However, in the classic workflow, each simulation compiles the model, even if the changes do not alter the model structurally. Each compile slows down the process and increases overall simulation time.

Fast restart allows you to perform iterative simulations without compiling a model or terminating the simulation each time. Using fast restart, you compile a model only once. You can then tune parameters and root inputs and simulate the model again without spending time on compiling. Fast restart associates multiple simulation phases to a single compile phase to make iterative simulations more efficient.

Use fast restart when your workflow does not require structural changes to the model. Also, fast restart is better suited if the workflow involves any of these factors:

- The model requires multiple simulations in which simulation inputs or parameters change in every iteration.
- The compile time of the model is several seconds or longer.

You can use fast restart in normal and accelerator simulation modes. When you use fast restart in accelerator mode, you reduce simulation time and perform only a single compilation.

- “Factors Affecting Fast Restart” on page 68-15

Fast Restart Workflow

When you need to simulate a model iteratively to tune parameters, achieve a desired response, or automate testing, use fast restart to avoid compiling again.

- 1 Turn on fast restart using the **Fast restart** button on the Simulink Editor toolbar or from the command line.
- 2 Simulate the model. The first simulation requires the model to compile, initialize and save a `SimState`. Once the simulation is complete, it does not terminate. Instead, the model is initialized again in fast restart.
- 3 Perform any of these actions:
 - Change tunable parameters.
 - Tune root-level inputs.
 - Modify base workspace, model workspace variables and data dictionary entries that are referenced by tunable parameters.
 - Change inputs to From File and From Workspace blocks.

Once you have initialized a model in fast restart, you cannot

- Change the dimension, type, or complexity of a signal or variable.
- Make changes to a nontunable parameter such as sample time.
- Make structural changes such as adding or deleting blocks or connections.

These changes require you to compile the model again. To make changes like these, turn off fast restart, make your changes, and repeat this procedure.

- 4 Simulate the model. The model uses the new values of parameters and inputs that you provided but does not compile again.
- 5 Once you have achieved the desired response, turn off fast restart.

Note: When you turn off fast restart, Simulink does not store any compile information for the model. The model compiles when you next simulate the model.

More About

- “How Fast Restart Improves Iterative Simulations” on page 68-2
- “Factors Affecting Fast Restart” on page 68-15
- “Save and Restore Simulation State as SimState” on page 23-37

Get Started with Fast Restart

In this section...

“Prepare a Model to Use Fast Restart” on page 68-6

“Enable Fast Restart” on page 68-6

Prepare a Model to Use Fast Restart

Before you simulate a model in fast restart, ensure that the model meets these requirements:

- If you have enabled callbacks in the model, make sure they do not attempt to make structural changes when the model is reinitialized. For example, callbacks such as mask initialization commands get called at the beginning of each simulation. Therefore, avoid using mask initialization code that makes structural changes to the model.
- All blocks in the model must support `SimState`.
- The simulation mode is Normal or Accelerator mode.

Caution When fast restart is on, you cannot save changes to the model after it compiles. Saving changes requires Simulink to discard information about the compiled state. To save any changes to the model, turn off fast restart first.

Enable Fast Restart

Use one of these methods to enable fast restart:

- Click the **Fast restart** button  on the Simulink Editor toolbar.
- At the MATLAB Command prompt, use `set_param` to enable fast restart. Type `set_param(model, 'FastRestart', 'on')`

Related Examples

- “Fast Restart Workflow” on page 68-4

- “Simulate a Model Using Fast Restart” on page 68-8

More About

- “Fast Restart Methodology” on page 68-11
- “Factors Affecting Fast Restart” on page 68-15

Simulate a Model Using Fast Restart

After you load your model and turn on fast restart, simulate the model.

- 1 Simulate the model by calling `sim` or clicking the **Play** button  in the Simulink Editor toolstrip. The first simulation in fast restart requires the model to compile and save a `SimState`.

Once the simulation is complete, the status bar shows that the model is initialized in fast restart.

- 2 Adjust tunable parameters in the model, such as the gain value of a Gain block, or tune root-level input values. You can also make changes to base workspace variables. You cannot adjust nontunable parameters such as sample time, because doing so requires the model to compile once more.
- 3 Simulate the model again. This time, the model does not compile. When you click the **Play** button or step forward, Simulink updates blocks that have new values as well as blocks that reference workspace variables.
- 4 When you are satisfied with your results, turn off fast restart by clicking the **Fast restart** button off.
- 5 To keep your changes, save the model.

Note: After a model is initialized in fast restart, Simulink displays a warning if you attempt to make a structural change to the model. To make such changes, you must turn off fast restart.

Stop Simulation and Exit Fast Restart

In this section...

“Stop a Simulation” on page 68-10

“Exit Fast Restart” on page 68-10

Stop a Simulation

When you click **Stop** in the middle of a fast restart simulation:

- Simulation does not terminate.
- The model is in the initialized state.
- You can now change tunable parameters in the model
- You can terminate the simulation and exit fast restart by clicking the **Fast restart** button off.

Exit Fast Restart

You can exit fast restart only when the model is in the initialized state. After simulating, click the **Fast restart** button off. To do this programmatically, type:

```
set_param(model, 'FastRestart', 'off')
```

- Simulink terminates simulation.
- Simulink discards any compiled information about the model.
- The model must compile again the next time you simulate.

“Custom Code in the Initialize Function” on page 68-13

Simulation Modes

You can use fast restart in Normal and Accelerator simulation modes.

Tuning Parameters Between Simulations

- When a model is initialized in fast restart, in addition to block values and base workspace variables, you can tune parameters in the **Data Import/Export** and **Solver** panes in the **Simulation > Model Configuration Parameters** dialog box.
- Certain parameters are tunable between simulations only when the model is initialized in fast restart. They include:
 - **Initial Value** parameter of the IC block
 - **Initial Output** parameter of the Merge block
 - **Data** parameter of the From Workspace block
 - **Signal** parameter and signal groups of the Signal Builder block.

Model Methods and Callbacks in Fast Restart

When fast restart is on, Simulink calls model and block methods and callbacks as follows:

- 1 Call model `InitFcn` callback.
- 2 Call model `SetupRuntimeResources` method.
 - a Call `mdlSetupRuntimeResources` S-function method.

- 3 Call model `Start` method.
 - a Call `mdlStart` S-function method.
- 4 Call model `Initialize` method.
 - a Call `mdlInitializeConditions` S-function method.

Note: Use the `ssIsFirstInitCond` flag to guard code that should run only during the initialization phase of any simulation, including the first and subsequent initializations in fast restart.

- 5 Call model and block `StartFcn` callbacks.

Note: Steps 1–5 apply to all simulations in Simulink (with or without fast restart).

- 6 For the first simulation in fast restart, capture a simulation snapshot. A simulation snapshot contains simulation state (`SimState`) and information related to logged data and visualization blocks. As part of the snapshot capture, call `mdlGetSimState` S-function method.
- 7 This is a standard execution phase of any simulation, with or without fast restart.
 - Call model `Outputs`.
 - Call model `Update`.
 - Call model `Derivatives`.
 - Repeat these steps in a loop until stop time or a stop is requested.
- 8 Call model `Terminate` method.
 - a Call `mdlTerminate` S-function method.
- 9 After simulation ends, call model and block `StopFcn` callbacks. This is a standard phase of any simulation, with or without fast restart.
- 10 Restore the simulation snapshot taken for fast restart. As part of the restore, call `mdlSetSimState` S-function method.
- 11 Wait in a reinitialized state until one of these actions:
 - To run another simulation (programmatically or using the Simulink Editor) in fast restart, return to step 3.
 - To end Fast Restart mode and uncompile the model:

- a Call the model method `CleanupRuntimeResources` and the `mdlCleanupRuntimeResources` S-function method.
- b Do not call `StopFcn` callbacks again at this point.

In some cases, the `Start` and `Terminate` methods are only called once and not for each successive Fast Restart simulation. In these cases, these method calls are combined with calls to `SetupRuntimeResources` and `CleanupRuntimeResources`, respectively. These cases are as follows:

- When an S-function contains custom `SimState` save and restore methods.
- When an S-function sets the flag `SS_OPTION_CALL_TERMINATE_ON_EXIT`.
- When an S-function is placed inside the accelerated mode of a referenced model.

For more information on model callbacks, see “Callbacks for Customized Model Behavior” on page 4-56.

SimState and Initial State Values

You can change initial state values, including `SimState`, in between fast restart simulations.

When a `SimState` object for initial state is used in fast restart, every new simulation resets to the start time of the model and not the snapshot time of each `SimState` object. Thereafter, on the first step forward, Simulink checks to see if a `SimState` has been specified. If yes, Simulink restores it before computing the next step. Thus, the first simulation step effectively fast forwards to the snapshot time of the specified `SimState` object.

Analyze Data Using the Simulation Data Inspector

Fast restart supports data logging using the Simulation Data Inspector. Every simulation in fast restart creates an SDI object with the name `<modelname> fast restart run <number>`. The value of `number` increments for each simulation.

Custom Code in the Initialize Function

When you place custom code in the **Configuration Parameters > Simulation Target > Custom Code > Initialize function** pane in the **Model Configuration Parameters** dialog box, this gets called only during the first simulation in fast restart.

More About

- “Factors Affecting Fast Restart” on page 68-15
- “What Is a SimState?”

Factors Affecting Fast Restart

There are some limitations to simulating in fast restart.

- Fast restart does not support these modes:
 - Rapid Accelerator
 - External
- When a model is in the reinitialized state, you cannot:
 - Make structural changes.
 - Make changes to nontunable parameters such as sample time.
 - Save changes to the model. You must turn off fast restart to save any changes to the model.
- You cannot turn on fast restart in a model if it contains blocks that do not support `SimState`. These blocks include:
 - Legacy (pre-R2016a) `SimEvents` blocks
 - Simscape Multibody Link First Generation blocks
 - MATLAB function blocks that contain system objects
 - S-functions that do not implement `SimState` `get` and `set` methods but have `Pwork` vectors declared
 - From Multimedia File
 - To Multimedia File
 - From Audio Device
 - To Audio Device
 - Multipath Rician Fading Channel
 - Multipath Rayleigh Fading Channel
 - Derepeat
 - DC Blocker
 - Stack
 - Queue
 - Read Binary File
 - Write Binary File

- Video Viewer
- Frame Rate Display
- Video From Workspace
- Video To Workspace
- Between simulations, fast restart does not handle changes to design data, such as bus properties.
- When you use fast restart for model references in Accelerator mode, you cannot tune block parameters.
- The Fixed-Point Tool provides limited support when a model is simulated in fast restart. You must exit fast restart to collect simulation and derived ranges, and propose data types.
- When fast restart is on, you cannot change the variant that a variant subsystem or variant model uses. This is because the inactive subsystems are not compiled in the first simulation.
- When there are multiple model references to the same submodel, you cannot change the model visibility when the model is in the reinitialized state.
- Fast restart is not compatible with these tools:
 - Simulink Profiler
 - Simulink Debugger
- When simulating a model in fast restart, you cannot run checks using Model Advisor.
- When you enable fast restart, the `sim` command supports only the single output `Simulink.SimulationOutput` form, regardless of the syntax you use in the command.
- When you enable fast restart, you cannot pass non-tunable parameters as arguments to `sim`.
