The software described in this document is furnished under a license agreement. The software may be used or copied only under the terms of the license agreement. No part of this manual may be photocopied or reproduced in any form without prior written consent from The MathWorks, Inc.

FEDERAL ACQUISITION: This provision applies to all acquisitions of the Program and Documentation by, for, or through the federal government of the United States. By accepting delivery of the Program or Documentation, the government hereby agrees that this software or documentation qualifies as commercial computer software or commercial computer software documentation as such terms are used or defined in FAR 12.212, DFARS Part 227.72, and DFARS 252.227-7014. Accordingly, the terms and conditions of this Agreement and only those rights specified in this Agreement, shall pertain to and govern the use, modification, reproduction, release, performance, display, and disclosure of the Program and Documentation by the federal government (or other entity acquiring for or through the federal government) and shall supersede any conflicting contractual terms or conditions. If this License fails to meet the government's needs or is inconsistent in any respect with federal procurement law, the government agrees to return the Program and Documentation, unused, to The MathWorks, Inc.

Trademarks

MATLAB and Simulink are registered trademarks of The MathWorks, Inc. See www.mathworks.com/trademarks for a list of additional trademarks. Other product or brand names may be trademarks or registered trademarks of their respective holders.

Patents

MathWorks products are protected by one or more U.S. patents. Please see www.mathworks.com/patents for more information.

Revision History

November 1990	First printing	New for Simulink 1
December 1996	Second printing	Revised for Simulink 2
January 1999	Third printing	Revised for Simulink 3 (Release 11)
November 2000	Fourth printing	Revised for Simulink 4 (Release 12)
July 2002	Fifth printing	Revised for Simulink 5 (Release 13)
April 2003	Online only	Revised for Simulink 5.1 (Release 13SP1)
April 2004	Online only	Revised for Simulink 5.1.1 (Release 13SP1+)
June 2004	Sixth printing	Revised for Simulink 5.0 (Release 14)
October 2004	Seventh printing	Revised for Simulink 6.1 (Release 14SP1)
March 2005	Online only	Revised for Simulink 6.2 (Release 14SP2)
September 2005	Eighth printing	Revised for Simulink 6.3 (Release 14SP3)
March 2006	Online only	Revised for Simulink 6.4 (Release 2006a)
March 2006	Ninth printing	Revised for Simulink 6.4 (Release 2006a)
September 2006	Online only	Revised for Simulink 6.5 (Release 2006b)
March 2007	Online only	Revised for Simulink 6.6 (Release 2007a)
September 2007	Online only	Revised for Simulink 7.0 (Release 2007b)
March 2008	Online only	Revised for Simulink 7.1 (Release 2008a)
October 2008	Online only	Revised for Simulink 7.2 (Release 2008b)
March 2009	Online only	Revised for Simulink 7.3 (Release 2009a)
September 2009	Online only	Revised for Simulink 7.4 (Release 2009b)
March 2010	Online only	Revised for Simulink 7.5 (Release 2010a)
September 2010	Online only	Revised for Simulink 7.6 (Release 2010b)
April 2011	Online only	Revised for Simulink 7.7 (Release 2011a)
September 2011	Online only	Revised for Simulink 7.8 (Release 2011b)
March 2012	Online only	Revised for Simulink 7.9 (Release 2012a)
September 2012	Online only	Revised for Simulink 8.0 (Release 2012b)
March 2013	Online only	Revised for Simulink 8.1 (Release 2013a)
September 2013	Online only	Revised for Simulink 8.2 (Release 2013b)
March 2014	Online only	Revised for Simulink 8.3 (Release 2014a)
October 2014	Online only	Revised for Simulink 8.4 (Release 2014b)
March 2015	Online only	Revised for Simulink 8.5 (Release 2015a)
September 2015	Online only	Revised for Simulink 8.6 (Release 2015b)
October 2015	Online only	Rereleased for Simulink 8.5.1 (Release 2015aSP1)
March 2016	Online only	Revised for Simulink 8.7 (Release 2016a)
September 2016	Online only	Revised for Simulink 8.8 (Release 2016b)

Introduction to Simulink

Simulink Basics

1

Start the Simulink Software	1-2
Start the MATLAB Software	1-2
Open the Simulink Editor	1-2
Open the Library Browser	1-3
Create Models and Open Existing Models	1-5
Create a Model	1-5
Use Customized Settings When Creating New Models ..	1-8
Open a Model	1-10
Load Variables When Opening a Model	1-10
Open a Model with Different Character Encoding	1-11
Simulink Model File Types	1-11
Programmatic Modeling Basics	1-13
Load a Model	1-13
Create a Model and Specify Parameter Settings	1-13
Programmatically Load Variables When Opening a Model	1-14
Programmatically Add and Connect Blocks	1-15
Name a Signal Programmatically	1-17
Open the Same Model in Multiple Windows	1-17
Get a Simulink Identifier	1-17
Specify Colors Programmatically	1-21
Build and Edit a Model in the Simulink Editor	1-23
Start Simulink and Create a New Model	1-23
Add Blocks to the Model	1-24
Align and Connect Blocks	1-25

Set Block Parameters	1-26
Add More Blocks	1-26
Branch a Connection	1-28
Organize Your Model	1-30
Simulate Model and View Results	1-33
Modify the Model	1-34
Save a Model	1-37
How to Tell If a Model Needs Saving	1-37
Save a Model	1-37
What Happens When You Save a Model?	1-38
Save Models in the SLX File Format	1-39
Save Models with Different Character Encodings	1-41
Export a Model to a Previous Simulink Version	1-43
Save from One Earlier Simulink Version to Another ..	1-43
Model Editing Environment	1-45
Simulink Editor	1-45
Interactive Model Building	1-47
Model Design Error Detection	1-48
Library Browser	1-48
Setting Properties and Parameters	1-50
Parts of a Model	1-53
About Blocks	1-53
Block Parameters and Properties in Simulink	1-54
Signals	1-56
Preview Content of Hierarchical Items	1-57
What Is Content Preview?	1-57
Enable Content Preview	1-58
What Content Preview Displays	1-58
Use Viewmarks to Save Views of Models	1-60
What Are Viewmarks?	1-60
Create a Viewmark	1-61
Open and Navigate Viewmarks	1-62
Manage Viewmarks	1-62
Refresh a Viewmark	1-63
Update Diagram and Run Simulation	1-64
Updating the Diagram	1-64
Simulation Updates the Diagram	1-64

Update Diagram While Editing	1-64
Simulate a Model	1-65
Print Model Diagrams	1-67
Print Interactively or Programmatically	1-67
Printing Options	1-67
Canvas Color	1-67
Basic Printing	1-69
Print the vdp Model Using Default Settings	1-69
Print a Subsystem Hierarchy	1-71
Select the Systems to Print	1-74
Print Current System	1-74
Print Subsystems	1-74
Print a Model Referencing Hierarchy	1-75
Specify the Page Layout and Print Job	1-76
Page and Print Job Setup	1-76
Set Paper Size and Orientation Without Printing	1-76
Tiled Printing	1-77
Print Multiple Pages for Large Models	1-78
Add a Log of Printed Models	1-79
Add a Sample Time Legend	1-80
Print from the MATLAB Command Line	1-81
Printing Commands	1-81
Print Systems with Multiline Names or Names with Spaces	1-81
Set Paper Orientation and Type	1-82
Position and Size a System	1-82
Use Tiled Printing	1-83
Print to a PDF	1-85
Print Model Reports	1-86
Model Report Options	1-87

Print Models to Image File Formats	1-89
Copy Model Views to Third-Party Applications	1-89
Keyboard and Mouse Actions for Simulink Modeling .	1-90
Object Selection and Clipboard Operations	1-90
Block and Signal Line Shortcuts and Actions	1-91
Signal Name and Label Actions	1-92
Simulation Keyboard Shortcuts	1-93
Debugging and Breakpoints Keyboard Shortcuts	1-93
Zooming and Scrolling Shortcuts	1-93
Library Browser Shortcuts	1-94
File Operations	1-95

Simulation Stepping

2

How Simulation Stepper Helps With Model Analysis . .	2-2
How Stepping Through a Simulation Works	2-3
Simulation Snapshots	2-3
How Simulation Stepper Uses Snapshots	2-4
How Simulation Stepper Differs from Simulink Debugger	2-5
Use Simulation Stepper	2-8
Simulation Stepper Access	2-8
Simulation Stepper Pause Status	2-8
Tune Parameters	2-9
Referenced Models	2-10
Simulation Stepper and Interval Logging	2-10
Simulation Stepper and Stateflow Debugger	2-10
Simulation Stepper Limitations	2-12
Interface	2-12
Model Configuration	2-12
Blocks	2-12
Step Through a Simulation	2-15
Step Forward and Back	2-15

Set Conditional Breakpoints for Stepping a Simulation	2-18
Add and Edit Conditional Breakpoints	2-18
Observe Conditional Breakpoint Values	2-19

How Simulink Works

3

How Simulink Works	3-2
Modeling Dynamic Systems	3-3
Block Diagram Semantics	3-3
Creating Models	3-4
Time	3-4
States	3-5
Block Parameters	3-8
Tunable Parameters	3-8
Block Sample Times	3-9
Custom Blocks	3-9
Systems and Subsystems	3-10
Signals	3-14
Block Methods	3-15
Model Methods	3-16
Simulation Phases in Dynamic Systems	3-17
Model Compilation	3-17
Link Phase	3-18
Simulation Loop Phase	3-18
Solvers	3-21
Fixed-Step Solvers Versus Variable-Step Solvers	3-21
Continuous Versus Discrete Solvers	3-21
Minor Time Steps	3-22
Shape Preservation	3-22
Zero-Crossing Detection	3-24
Demonstrating Effects of Excessive Zero-Crossing Detection	3-24
How the Simulator Can Miss Zero-Crossing Events ...	3-29
Preventing Excessive Zero Crossings	3-30

Zero-Crossing Algorithms	3-32
Understanding Signal Threshold	3-33
How Blocks Work with Zero-Crossing Detection	3-34
Algebraic Loops	3-38
What Is an Algebraic Loop?	3-38
Interpretations of Algebraic Loops	3-39
What is an Artificial Algebraic Loop?	3-42
Why Algebraic Loops Are Undesirable	3-43
Identify Algebraic Loops in Your Model	3-44
How to Handle Algebraic Loops in a Model	3-47
How the Algebraic Loop Solver Works	3-49
Remove Algebraic Loops	3-51
Remove Artificial Algebraic Loops	3-54
How Simulink Eliminates Artificial Algebraic Loops ..	3-65
When Simulink Cannot Eliminate Artificial Algebraic Loops	3-71
Managing Large Models with Artificial Algebraic Loops	3-73
Changing Block Priorities When Using Algebraic Loop Solver	3-74

Modeling Dynamic Systems

Creating a Model

4

Create a Template from a Model	4-2
Connect Blocks	4-3
Automatically Connect Blocks	4-3
Manually Connect Blocks	4-6
Disconnect Blocks	4-12
Describe Models Using Annotations	4-13
Add a Text Annotation	4-13
Resize an Annotation	4-14
Make an Annotation Interactive	4-14
Add an Image Annotation	4-15

Use TeX Commands in an Annotation	4-15
Add Lines to Connect Annotations to Blocks	4-16
Select Font Dialog Box on Linux Machines	4-16
Create an Annotation	4-17
Add and Lay Out an Annotation	4-17
Add a Hyperlink and Format Text	4-18
Add a Bullet List	4-18
Copy and Paste a Web Image	4-19
Add a Numbered List	4-19
Show or Hide Annotations	4-20
Configure an Annotation for Hiding	4-20
Hide Markup Annotations	4-20
Add an Annotation Callback	4-21
Annotation Callback Functions	4-21
Associate a Click Function with an Annotation	4-21
Select and Edit Click-Function Annotations	4-22
Create an Annotation Programmatically	4-23
Annotations API	4-23
Create Annotations Programmatically	4-23
Delete an Annotation Programmatically	4-24
Find Annotations in a Model	4-24
Show or Hide Annotations Programmatically	4-24
TeX for Simulink Model Annotations	4-26
Create a Subsystem	4-28
Subsystem Advantages	4-28
Ways to Create a Subsystem	4-28
Create a Subsystem in a Subsystem Block	4-29
Create a Subsystem from Selected Blocks	4-30
Create a Subsystem Using Context Options	4-31
Configure a Subsystem	4-33
Subsystem Execution	4-33
Label Subsystem Ports	4-33
Control Access to Subsystems	4-33
Control Subsystem Behavior with Callbacks	4-34

Navigate Subsystems in the Model Hierarchy	4-36
Open a Subsystem	4-36
Subsystem Expansion	4-40
What Is Subsystem Expansion?	4-40
Why Expand a Subsystem?	4-41
Subsystems That You Can Expand	4-42
Results of Expanding a Subsystem	4-43
Data Stores	4-44
Expand Subsystem Contents	4-45
Expand a Subsystem	4-45
Expand a Subsystem from the Command Line	4-46
Use Control Flow Logic	4-47
Equivalent C Language Statements	4-47
Conditional Control Flow Logic	4-47
While and For Loops	4-50
Callbacks for Customized Model Behavior	4-56
Model, Block, and Port Callbacks	4-56
What You Can Do with Callbacks	4-56
Avoid run Commands in Callback Code	4-56
Model Callbacks	4-58
Create Model Callbacks	4-58
Model Callback Parameters	4-59
Block Callbacks	4-62
Specify Block Callbacks	4-62
Block Callback Parameters	4-62
Port Callbacks	4-69
Callback Tracing	4-70
Model Workspaces	4-71
Model Workspace Differences from MATLAB Workspace	4-71
Troubleshooting Memory Issues	4-72
Manipulate Model Workspace Programmatically	4-72

Specify Source for Data in Model Workspace	4-74
Data source	4-75
MAT-File and MATLAB File Source Controls	4-75
MATLAB Code Source Controls	4-76
Change Model Workspace Data	4-79
Change Workspace Data Whose Source Is the Model File	4-79
Change Workspace Data Whose Source Is a MAT-File or MATLAB File	4-80
Changing Workspace Data Whose Source Is MATLAB Code	4-80
Use MATLAB Commands to Change Workspace Data	4-81
Symbol Resolution	4-82
Symbols	4-82
Symbol Resolution Process	4-82
Numeric Values with Symbols	4-84
Other Values with Symbols	4-84
Limit Signal Resolution	4-85
Explicit and Implicit Symbol Resolution	4-85
Manage Model Versions and Specify Model Properties	4-87
How Simulink Helps You Manage Model Versions	4-87
Model File Change Notification	4-87
Manage Model Properties	4-88
Log Comments History	4-90
Version Information Properties	4-91
Model Discretizer	4-94
What Is the Model Discretizer?	4-94
Requirements	4-94
Discretize a Model with the Model Discretizer	4-95
View the Discretized Model	4-103
Discretize Blocks from the Simulink Model	4-106
Discretize a Model with the sldiscmdl Function	4-116

5

Consulting the Model Advisor	5-2
Model Advisor Overview	5-2
Start the Model Advisor	5-2
Model Advisor Window	5-4

Working with Sample Times

7

What Is Sample Time?	7-2
Specify Sample Time	7-3
Designate Sample Times	7-3
Specify Block-Based Sample Times Interactively	7-5
Specify Port-Based Sample Times Interactively	7-6
Specify Block-Based Sample Times Programmatically ..	7-7
Specify Port-Based Sample Times Programmatically ...	7-7
Access Sample Time Information Programmatically ...	7-8
Specify Sample Times for a Custom Block	7-8
Determining Sample Time Units	7-8
Change the Sample Time After Simulation Start Time .	7-8
View Sample Time Information	7-9
View Sample Time Display	7-9
Sample Time Legend	7-10
Print Sample Time Information	7-14
Types of Sample Time	7-15
Discrete Sample Time	7-15
Continuous Sample Time	7-16
Fixed-in-Minor-Step	7-16
Inherited Sample Time	7-16
Constant Sample Time	7-17
Variable Sample Time	7-17
Triggered Sample Time	7-18
Asynchronous Sample Time	7-18
Blocks for Which Sample Time Is Not Recommended .	7-20
Best Practice to Model Sample Times	7-20
Appropriate Blocks for the Sample Time Parameter ..	7-21
Specify Sample Time in Blocks Where Hidden	7-21
Block Compiled Sample Time	7-23

Sample Times in Subsystems	7-26
Sample Times in Systems	7-28
Purely Discrete Systems	7-28
Hybrid Systems	7-30
Resolve Rate Transitions	7-34
Automatic Rate Transition	7-34
Visualize Inserted Rate Transition Blocks	7-35
How Propagation Affects Inherited Sample Times ...	7-38
Process for Sample Time Propagation	7-38
Simulink Rules for Assigning Sample Times	7-38
Backpropagation in Sample Times	7-40

Referencing a Model

8

Overview of Model Referencing	8-2
Reference One Model From Another Model	8-2
Model Reference Hierarchies	8-3
Model Block and Referenced Model Ports	8-4
Using Referenced Models as Standalone Models	8-5
Examples of Models That Use Model Referencing	8-5
Simulation of Model Referencing Models	8-6
Code Generation for Referenced Models	8-6
When to Use Model Referencing	8-7
Referenced Model Advantages	8-7
Compare Model Referencing to Other Componentization Techniques	8-8
Create a Referenced Model	8-9
Masking Model Blocks	8-11
Subsystem to Referenced Model Conversion	8-13
When to Convert to Model Referencing	8-13
Subsystems That You Can Convert	8-13
Conversion Process	8-14

Conversion Checking	8-15
Conversion Results	8-15
Conversion Report	8-16
Convert a Subsystem to a Referenced Model	8-17
Determine Whether to Convert the Subsystem	8-17
Update the Model Before Converting the Subsystem ..	8-17
Run the Model Reference Conversion Advisor	8-21
Compare Simulation Results Before and After	
Conversion	8-22
Revert the Conversion Results	8-23
Integrate the Referenced Model into the Parent Model	8-23
Sample Times for Model Referencing	8-26
How Sample-Time Inheritance Works for Model Blocks	8-26
Conditions for Inheriting Sample Times	8-26
Determining Sample Time of a Referenced Model	8-27
Blocks That Depend on Absolute Time	8-27
Blocks Whose Outputs Depend on Inherited Sample	
Time	8-28
Sample Time Consistency	8-29
Simulate Model Referencing Models	8-31
Simulate a Top Model	8-31
Simulate a Referenced Model	8-31
Simulate Models with Multiple Referenced Model	
Instances	8-37
Normal Mode Visibility	8-37
Example Models with Multiple Referenced Model	
Instances	8-37
Configure Models with Multiple Referenced Model	
Instances	8-39
Specify the Instance Having Normal Mode Visibility ..	8-40
View a Model Referencing Hierarchy	8-44

Buses in Referenced Models	8-91

Signal Logging in Referenced Models	8-92
Model Referencing Limitations	8-93
Introduction	8-93
Limitations on All Model Referencing	8-93
Limitations on Normal Mode Referenced Models	8-96
Limitations on Accelerator Mode Referenced Models ..	8-96
Limitations on Rapid Accelerator Mode Referenced Models	8-99
Certain Diagnostic Configuration Parameters Ignored for Models Referenced in Accelerator Mode	8-99
Limitations on SIL and PIL Mode Referenced Models	8-100
Configuration Parameters Changed During Code Generation	8-100

Simulink Units

9

Unit Specification in Simulink Models	9-2
Specify Physical Quantities	9-4
Specify Units in Objects	9-4
Specify Units for Temperature Signals	9-5
Specify Units in MATLAB Function Blocks	9-5
Specify Units for Logging and Loading Signal Data	9-5
Restricting Unit Systems	9-6
Displaying Units	9-8
Unit Consistency Checking and Propagation	9-10
Unit Propagation Between Simulink and Simscape ...	9-13
Converting Units	9-15
Automatic Unit Conversion Limitations	9-15
Update an Existing Model to Use Units	9-17
Troubleshooting Units	9-25
Undefined Units	9-25
Overflow and Underflow Errors or Warning	9-25
Mismatched Units Detected	9-26

Mismatched Units Detected While Loading	9-26
Disallowed Unit Systems	9-26
Automatic Unit Conversions	9-26
Unsuccessful Automatic Unit Conversions	9-27
Simscape Unit Specification Incompatible with Simulink	9-27

Create Conditional Subsystems

10

Conditional Subsystems	10-2
Export-Function Models	10-4
About Export-Function Models	10-4
Requirements for Export-Function Models	10-5
Sample Time for Function-Call Subsystems in Export- Function Models	10-6
Control Export Function Scheduling Using Sample Time	10-8
Execution Order for Function-Call Root-level Inport Blocks	10-10
Workflows for Export-Function Models	10-15
Nested Export-Function Models	10-20
Comparison Between Export-Function Models and Models with Asynchronous Function-Call Inputs	10-21
Create an Enabled Subsystem	10-23
What Are Enabled Subsystems?	10-23
Create an Enabled Subsystem	10-24
Blocks an Enabled Subsystem Can Contain	10-26
Use Blocks with Constant Sample Times in Enabled Subsystems	10-29
Conditionally Reset Block States in a Subsystem ...	10-33
Behavior of Resettable Subsystems	10-33
Comparison of Resettable Subsystems and Enabled Subsystems	10-36
Create a Triggered Subsystem	10-40
What Are Triggered Subsystems?	10-40

Using Model Referencing Instead of a Triggered Subsystem	10-42
Creating a Triggered Subsystem	10-42
Blocks That a Triggered Subsystem Can Contain ...	10-43
Create an Action Subsystem	10-45
What Are Action Subsystems?	10-45
Set States when an Action Subsystem Executes	10-46
Create a Triggered and Enabled Subsystem	10-48
What Are Triggered and Enabled Subsystems?	10-48
Creating a Triggered and Enabled Subsystem	10-49
A Sample Triggered and Enabled Subsystem	10-49
Creating Alternately Executing Subsystems	10-50
Create a Function-Call Subsystem	10-54
What is a Function-Call Subsystem?	10-54
Creating Function-Call Subsystems	10-54
Sample Time Propagation in Function-Call Subsystems	10-54
Conditional Execution Behavior	10-56
What Is Conditional Execution Behavior?	10-56
Propagating Execution Contexts	10-58
Behavior of Switch Blocks	10-59
Displaying Execution Contexts	10-59
Disabling Conditional Execution Behavior	10-60
Displaying Execution Context Bars	10-61
Conditional Subsystem Output Initialization	10-62
Why Initialize Conditional Subsystem Output with Explicit Values?	10-62
Initialization Mode	10-62
When to Use Simplified Initialization	10-63
Simplified Mode Behavior and Requirements	10-64
When to Use Classic Initialization	10-65
Specify or Inherit Conditional Subsystem Initial Values	10-66
Inherit Initial Values from the Input Signal	10-66
Explicitly Specify an Initial Value	10-67
Setting Output Values When the Conditional Subsystem Is Disabled	10-68

Set Initialization Mode to Simplified or Classic	10-69
Convert from Classic to Simplified Initialization Mode	10-70
Address Classic Mode Issues by Using Simplified Mode	10-71
Classic Mode Issues	10-71
Identity Transformation Can Change Model Behavior	10-72
Discrete-Time Integrator or S-Function Block Can Produce Inconsistent Output	10-75
Sorted Order Can Affect Merge Block Output	10-77
Simulink Functions	10-85
What Are Simulink Functions?	10-85
What Are Simulink Function Callers?	10-85
Connect to Local Signals	10-86
Reusable Logic with Functions	10-86
Shared Resources with Functions	10-87
How a Function Caller Identifies a Function	10-88
Reasons to Use a Simulink Function Block	10-89
Choosing to Use a Simulink Function or Reusable Subsystem	10-89
When Not to Use a Simulink Function Block	10-90
Tracing Simulink Functions	10-90
Simulink Functions in Models	10-95
Create Simulink Functions in a Simulink Model	10-95
Call Simulink Functions with a Function Caller Block	10-102
Call Simulink Functions from a MATLAB Function Block	10-105
Call Simulink Functions from a Stateflow Chart	10-107
Call a Simulink Function Block from Multiple Sites	10-109
Simulink Functions in Referenced Models	10-113
Simulink Function Block in Referenced Model	10-113
Function Caller Block in Referenced Model	10-115
Function and Function Caller in Separate Models	10-116
Function and Function Caller in the Same Model	10-118
Private Scoping of Simulink Functions	10-121
Resolve to a Function Hierarchically	10-121
Resolve to a Function by Qualification	10-122

Diagnostics Using a Client-Server Architecture . . .	10-126
Diagnostic Messaging with Simulink Functions	10-126
Client-Server Architecture	10-126
Modifier Pattern	10-128
Observer Pattern	10-130
Create a Model to Initialize and Terminate State . .	10-132
Create Model Algorithm with State	10-132
Initialize Block State	10-134
Reset Block State	10-136
Read and Save Block State	10-139
Prepare Model Component for Testing	10-143
Create a Test Harness to Generate Events	10-146
Reference the Model Component	10-146
Create Stateflow Chart	10-148
Connect Chart to Test Model	10-149

Modeling Variant Systems

11

What Are Variants and When to Use Them	11-2
What Are Variants?	11-2
Advantages of Using Variants	11-4
When to Use Variants	11-4
Options for Representing Variants in Simulink	11-6
Mapping Inports and Outports of Variant Choices	11-7
Working with Variant Choices	11-9
Default Variant Choice	11-10
Active Variant Choice	11-11
Inactive Variant Choice	11-11
Empty Variant Choice	11-11
Open Active Variant	11-12
Introduction to Variant Controls	11-13
Operands	11-13
Operators	11-13
Approaches for Specifying Variant Controls	11-14

Operators and Operands in Variant Condition Expressions	11-20
Create a Simple Variant Model	11-22
Create Variant Controls Programmatically	11-26
Create and Export Variant Controls	11-26
Reuse Variant Conditions	11-26
Enumerated Types as Variant Controls	11-27
Define, Configure, and Activate Variants	11-28
Represent Variant Choices	11-28
Include Simulink Model as Variant Choice	11-32
Configure Variant Activation Conditions	11-34
Prepare Variant-Containing Model for Code Generation	11-36
Convert Variant Control Variables into Simulink.Parameter Objects	11-36
Configure Model for Generating Preprocessor Conditionals	11-38
Set up Model Variants	11-41
Configure the Model Variants Block	11-42
Disable and Enable Model Variants	11-44
Parameterize Model Variants	11-45
Additional Examples	11-45
Visualize Variant Implementations in a Single Layer	11-47
How Variant Sources and Sinks Work	11-47
Advantages of Using Variant Sources and Sinks	11-48
Limitations of Using Variant Sources and Sinks	11-49
Define and Configure Variant Sources and Sinks	11-50
Variant Condition Propagation with Variant Sources and Sinks	11-57
View Variant Condition Annotations	11-57
How Variant Condition Propagation Works	11-60
Condition Propagation with Other Simulink Blocks	11-63
Known Limitations	11-65

Create and Validate Variant Configurations	11-67
Step 1: Open Variant Manager	11-67
Step 2: Define Variant Configuration	11-68
Step 3: Validate Variant Configuration	11-69
Import Control Variables to Variant Configuration .	11-71
Step 1: Open Variant Manager	11-71
Step 2: Import Variant Configuration	11-72
Step 3: View Submodel Configuration	11-73
Define Constraints	11-75
Reduce Models Containing Variant Blocks	11-78
Reduce Model Programmatically	11-85
Condition Propagation with Variant Subsystem	11-86
Propagate Conditions Without Generate Preprocessor Conditionals	11-87
Propagate Conditions with Generate Preprocessor Conditionals	11-89
Known Limitations	11-91
Propagate Conditions Programmatically	11-91
Variants Example Models	11-93
Use Subsystem Variants To Generate Code That Uses C Preprocessor Conditionals	11-94
Variant Source and Variant Sink Blocks	11-101

Exploring, Searching, and Browsing Models

12

Model Explorer Overview	12-2
What You Can Do Using the Model Explorer	12-2
Opening the Model Explorer	12-2
Basic Steps for Using the Model Explorer	12-3

Simulink Project Setup

16

Organize Large Modeling Projects	16-2
What Are Simulink Projects?	16-3

Explore Simulink Project Tools with the Airframe Project	16-5
Explore the Airframe Project	16-5
Set Up Project Files and Open Simulink Project	16-6
View, Search, and Sort Project Files	16-6
Understand Project Startup and Shutdown Tasks	16-8
Create a Startup Shortcut	16-9
Open and Run Frequently Used Files	16-9
Review Changes in Modified Files	16-10
Run Project Integrity Checks	16-12
Run Dependency Analysis	16-12
Commit Modified Files	16-15
View Project and Source Control Information	16-15
Create a Project from a Model	16-18
Create a New Project to Manage Existing Files	16-20
Add Files to the Project	16-22
Create a New Project from an Archived Project	16-24
Create a New Project Using Templates	16-25
Use Project Templates from R2014a or Before	16-25
Open Recent Projects	16-26
Change the Project Name, Root, Description, and Startup Folder	16-28
Specify Project Path	16-30
What Can You Do With Project Shortcuts?	16-32
Automate Startup Tasks with Shortcuts	16-33
Automate Shutdown Tasks with Shortcuts	16-35
Create Shortcuts to Frequent Tasks	16-37
Create Shortcuts	16-37
Group Shortcuts	16-38
Annotate Shortcuts to Use Meaningful Names	16-39
Customize Shortcut Icons	16-40

Use Shortcuts to Find and Run Frequent Tasks	16-41
Using Templates to Create Standard Project Settings	16-44
Create a Template from the Current Project	16-45
Create a Template from a Project Under Version Control	16-46
Edit a Template	16-47
Explore the Example Templates	16-48

Simulink Project File Management

17

Group and Sort File Views	17-2
Search Inside Project Files and Filter File Views	17-4
Project-Wide Search	17-4
Filter Project File Views	17-6
More Ways to Search	17-7
Work with Project Files	17-8
Manage Shadowed and Dirty Model Files	17-11
Identify Shadowed Project Files When Opening a Project	17-11
Find Models and MATLAB Files With Unsaved Changes	17-12
Manage Open Models When Closing a Project	17-12
Move, Rename, Copy, or Delete Project Files	17-13
Move or Add Files	17-13
Automatic Updates When Renaming, Deleting, or Removing Files	17-13
Back Out Changes	17-18

Upgrade Model Files to SLX and Preserve Revision	
History	17-19
Project Tools for Migrating Model Files to SLX	17-19
Upgrade the Model and Commit the Changes	17-19
Verify Changes After Upgrade to SLX	17-22
Create Labels	17-24
Add Labels to Files	17-26
View and Edit Label Data	17-27
Automate Project Management Tasks	17-29
Manipulate a Simulink Project at the Command Line	17-29
Get Simulink Project at the Command Line	17-29
Find Project Commands	17-30
Examine Project Files	17-30
Get a List of Modified Files	17-32
Get File Dependencies	17-33

Working with Block Parameters

34

Set Block Parameter Values	34-2
Programmatically Access Parameter Values	34-2
Specify Parameter Values	34-3
Considerations for Other Modeling Goals	34-8

Share and Reuse Block Parameter Values by Creating Variables	34-11
Reuse Parameter Values in Multiple Blocks and Models	34-11
Define a System Constant	34-12
Control Scope of Parameter Values	34-12
Permanently Store Workspace Variables	34-13
Manage and Edit Workspace Variables	34-15
Package Shared Breakpoint and Table Data for Lookup Tables	34-16
Parameter Interfaces for Reusable Components	34-20
Referenced Models	34-20
Subsystems	34-21
Organize Related Block Parameter Definitions in Structures	34-22
Create and Use Parameter Structure	34-22
Manage Structure Variables	34-24
Define Parameter Hierarchy by Creating Nested Structures	34-24
Group Multiple Parameter Structures into an Array	34-25
Explicitly Specify Field Data Types	34-28
Control Field Data Types and Characteristics by Creating Parameter Object	34-29
Create a Structure of Constant-Valued Signals	34-32
Considerations Before Migrating to Parameter Structures	34-33
Parameter Structures in the Generated Code	34-33
Parameter Structure Limitations	34-33
Package Shared Breakpoint and Table Data for Lookup Tables	34-34
Tune and Experiment with Block Parameter Values	34-36
Iteratively Adjust Block Parameter Value Between Simulation Runs	34-36
Tune Block Parameter Value During Simulation	34-38
Prepare for Parameter Tuning and Experimentation	34-39
Interactively Tune Using Dashboard Blocks	34-40
Which Block Parameters Are Tunable During Simulation?	34-41
Why Did the Simulation Output Stay the Same?	34-42
Tunability Considerations for Other Modeling Goals	34-43

Manage Variables from Block Parameter	34-45
Rename Variable	34-45
Edit Variable Value or Property	34-46
Navigate to Mask Parameter	34-46
Create Variable	34-46
Optimize, Estimate, and Sweep Block Parameter	
Values	34-48
Sweep Parameter Value and Inspect Simulation	
Results	34-48
Capture and Visualize Simulation Results	34-51
Improve Simulation Speed	34-52
Sweep Parameter Values to Analyze System	
Robustness	34-52
Sweep Parameter Values to Test and Verify System .	34-53
Estimate and Calibrate Model Parameters	34-53
Tune and Optimize PID and Controller Parameters . .	34-53
Control Block Parameter Data Types	34-54
Reduce Maintenance Effort with Data Type	
Inheritance	34-54
Techniques to Explicitly Specify Parameter Data	
Types	34-55
Calculate Best-Precision Fixed-Point Scaling for Tunable	
Block Parameters	34-56
Detect Numerical Accuracy Issues Due to Quantization	
and Overflow	34-60
Data Types of Mathematical Expressions	34-60
Block Parameter Data Types in the Generated Code .	34-61
Specify Minimum and Maximum Values for Block	
Parameters	34-63
Specify Block Parameter Value Ranges	34-63
Restrict Allowed Values for Block Parameters	34-65
Specify Range Information for Tunable Fixed-Point	
Parameters	34-65
Switch Between Sets of Parameter Values During	
Simulation and Code Execution	34-67

Working With Block Masks

36

Masking Fundamentals	36-2
Masking Terminology	36-4
Create a Simple Mask	36-7
Step 1: Open Mask Editor	36-7
Step 2: Define the Mask	36-8
Step 3: Operate on Mask	36-14
Manage Existing Masks	36-16
Change a Block Mask	36-16
View Mask Parameters	36-16
Look Under Block Mask	36-16
Remove Mask	36-16

Mask Callback Code	36-18
Add Mask Code	36-18
Execute Drawing Command	36-18
Execute Initialization Command	36-19
Execute Callback Code	36-20
Draw Mask Icon	36-22
Draw Static Icon	36-22
Draw Dynamic Icon	36-24
Initialize Mask	36-26
Dialog Variables	36-27
Initialization Commands	36-28
Mask Initialization Best Practices	36-28
Promote Parameter to Mask	36-30
Promote Underlying Parameters to Block Mask	36-32
Promote Underlying Parameters to Subsystem Mask .	36-34
Best Practices	36-36
Control Masks Programmatically	36-37
Use Simulink.Mask and Simulink.MaskParameter . .	36-37
Use <code>get_param</code> and <code>set_param</code>	36-38
Programmatically Create Mask Parameters and Dialogs	36-39
Pass Values to Blocks Under the Mask	36-44
Mask Linked Blocks	36-47
Guidelines for Mask Parameters	36-49
Mask Behavior for Masked, Linked Blocks	36-49
Mask a Linked Block	36-50
Dynamic Mask Dialog Box	36-51
Show Parameter	36-51
Enable Parameter	36-52
Create Dynamic Mask Dialog Box	36-52
Set Up Nested Masked Block Parameters	36-53
Dynamic Masked Subsystem	36-55
Allow Library Block to Modify Its Contents	36-55
Create Self-Modifying Masks for Library Blocks	36-55
Evaluate Blocks Under Self-Modifying Mask	36-59

Debug Masks That Use MATLAB Code	36-61
Code Written in Mask Editor	36-61
Code Written Using MATLAB Editor/Debugger	36-61
Masking Example Models	36-62

Creating Custom Blocks

37

Types of Custom Blocks	37-2
MATLAB Function Blocks	37-2
MATLAB System Blocks	37-2
Subsystem Blocks	37-3
S-Function Blocks	37-3
Masked Blocks	37-5

Simulation	39-110
Share Data Globally	39-111
When Do You Need to Use Global Data?	39-111
Using Global Data with the MATLAB Function Block	39-111
Choosing How to Store Global Data	39-112
How to Use Data Store Memory Blocks	39-113
How to Use Simulink.Signal Objects	39-115
Using Data Store Diagnostics to Detect Memory Access Issues	39-117
Limitations of Using Shared Data in MATLAB Function Blocks	39-117
Create Custom Block Libraries	39-119
When to Use MATLAB Function Block Libraries ...	39-119
How to Create Custom MATLAB Function Block Libraries	39-119
Example: Creating a Custom Signal Processing Filter Block Library	39-120
Code Reuse with Library Blocks	39-132
Debugging MATLAB Function Library Blocks	39-137

Properties You Can Specialize Across Instances of Library Blocks	39-137
Use Traceability in MATLAB Function Blocks	39-139
Extent of Traceability in MATLAB Function Blocks .	39-139
Traceability Requirements	39-139
Basic Workflow for Using Traceability	39-139
Tutorial: Using Traceability in a MATLAB Function Block	39-140
Include MATLAB Code as Comments in Generated Code	39-143
How to Include MATLAB Code as Comments in the Generated Code	39-143
Location of Comments in Generated Code	39-144
Including MATLAB Function Help Text in the Function Banner	39-146
Limitations of MATLAB Source Code as Comments .	39-146
Integrate C Code Using the MATLAB Function Block	39-148
Call C Code from a Simulink model	39-148
Control Imported Bus and Enumeration Type Definitions	39-150
Enhance Code Readability for MATLAB Function Blocks	39-152
Requirements for Using Readability Optimizations .	39-152
Converting If-Elseif-Else Code to Switch-Case Statements	39-152
Example of Converting Code for If-Elseif-Else Decision Logic to Switch-Case Statements	39-154
Control Run-Time Checks	39-160
Types of Run-Time Checks	39-160
When to Disable Run-Time Checks	39-160
How to Disable Run-Time Checks	39-161
Track Object Using MATLAB Code	39-162
Learning Objectives	39-162
Tutorial Prerequisites	39-162
Example: The Kalman Filter	39-163
Files for the Tutorial	39-166
Tutorial Steps	39-167

Best Practices Used in This Tutorial	39-184
Key Points to Remember	39-184
Filter Audio Signal Using MATLAB Code	39-186
Learning Objectives	39-186
Tutorial Prerequisites	39-186
Example: The LMS Filter	39-187
Files for the Tutorial	39-189
Tutorial Steps	39-191
Encapsulating the Interface to External Code	39-214
Encapsulate Interface to an External C Library ...	39-215
Best Practices for Using coder.ExternalDependency	39-218
Terminate Code Generation for Unsupported External Dependency	39-218
Parameterize Methods for MATLAB and Generated Code	39-218
Parameterize updateBuildInfo for Multiple Platforms	39-219
Update Build Information from MATLAB code	39-220

System Objects

40

What Are System Objects?	40-2
System Design and Simulation in Simulink	40-4
System Objects in MATLAB Code Generation	40-5
System Objects in Generated Code	40-5
System Objects in codegen	40-9
System Objects in the MATLAB Function Block	40-9
System Objects in the MATLAB System Block	40-9
System Objects and MATLAB Compiler Software ...	40-10
System Objects Methods That Support Code Generation	40-11
Code Generation Supported System Objects Methods	40-11

Simulation-Only System Objects Methods	40-11
System Objects in Simulink	40-13
System Objects in the MATLAB Function Block	40-13
System Objects in the MATLAB System Block	40-13
System Object Methods	40-14
What Are System Object Methods?	40-14
Running a System Object	40-14
Common Methods	40-15
System Design in Simulink Using System Objects	40-17
Define New Kinds of System Objects for Use in Simulink	40-17
Test New System Objects in MATLAB	40-22
Add System Objects to Your Simulink Model	40-23

Define New System Objects

41

System Objects Methods for Defining New Objects	41-3
Define Basic System Objects	41-5
Change Number of Inputs or Outputs	41-8
Specify System Block Input and Output Names	41-12
Validate Property and Input Values	41-14
Initialize Properties and Setup One-Time Calculations	41-17
Set Property Values at Construction Time	41-20
Reset Algorithm State	41-22
Define Property Attributes	41-24
Hide Inactive Properties	41-28

Limit Property Values to Finite List	41-30
Process Tuned Properties	41-33
Release System Object Resources	41-35
Define Composite System Objects	41-37
Define Finite Source Objects	41-40
Save System Object	41-42
Load System Object	41-46
Define System Object Information	41-50
Define Block Icon	41-52
Add Header to MATLAB System Block	41-54
Add Data Types Tab to MATLAB System Block	41-56
Add Property Groups to System Object and MATLAB System Block	41-58
Control Simulation Type in MATLAB System Block ..	41-63
Add Button to MATLAB System Block	41-65
Specify Locked Input Size	41-68
Set Output Size	41-70
Set Output Data Type	41-73
Set Output Complexity	41-77
Specify Whether Output Is Fixed- or Variable-Size ..	41-79
Specify Discrete State Output Specification	41-82

Set Model Reference Discrete Sample Time	
Inheritance	41-84
Use Update and Output for Nondirect Feedthrough .	41-86
Enable For Each Subsystem Support	41-89
Methods Timing	41-91
Setup Method Call Sequence	41-91
Running the Object (Step Method) Call Sequence . . .	41-92
Reset Method Call Sequence	41-92
Release Method Call Sequence	41-93
System Object Input Arguments and ~ in Code	
Examples	41-94
What Are Mixin Classes?	41-95
Best Practices for Defining System Objects	41-96
Insert System Object Code Using MATLAB Editor . .	41-99
Define System Objects with Code Insertion	41-99
Create Fahrenheit Temperature String Set	41-102
Create Custom Property for Freezing Point	41-103
Define Input Size As Locked	41-104
Analyze System Object Code	41-106
View and Navigate System object Code	41-106
Example: Go to StepImpl Method Using Analyzer . .	41-106
Define System Object for Use in Simulink	41-109
Develop System Object for Use in System Block . . .	41-109
Define Block Dialog Box for Plot Ramp	41-110
Use Enumerations in System Objects	41-115
Use Global Variables in System Objects	41-116
System Object Global Variables in MATLAB	41-116
System Object Global Variables in Simulink	41-116

MATLAB System Block	42-2
Why Use the MATLAB System Block?	42-2
Choosing the Right Block Type	42-2
System Objects	42-3
Interpreted Execution or Code Generation	42-3
MATLAB System Block Limitations	42-4
MATLAB System and System Objects Examples	42-5
Implement a MATLAB System Block	42-7
Understanding the MATLAB System Block	42-8
Change Blocks Implemented with System Objects ..	42-10
Change Block Icon and Port Labels	42-11
Modify MATLAB System Block Dialog	42-11
Nonvirtual Buses and MATLAB System Block	42-13
Use System Objects in Feedback Loops	42-14
Simulation Modes	42-16
Interpreted Execution vs. Code Generation	42-16
Simulation Using Code Generation	42-17
Mapping System Objects to Block Dialog Box	42-19
System Object to Block Dialog Box Default Mapping .	42-19
System Object to Block Dialog Box Custom Mapping .	42-21
Considerations for Using System Objects in Simulink	42-24
System Objects in Simulink	42-24
System Objects in For Each Subsystems	42-25
Input Validation	42-25
Simulink Engine Interaction with System Object	
Methods	42-27
Simulink Engine Phases Mapped to System Object	
Methods	42-27

Add and Implement Propagation Methods	42-30
When to Use Propagation Methods	42-30
Add Propagation Methods to System Objects	42-30
Implement Propagation Methods	42-31
Share Data with Other Blocks	42-33
Data Sharing with the MATLAB System Block	42-33
Choose How to Store Shared Data	42-34
How to Use Data Store Memory Blocks for the MATLAB System Block	42-35
How to Set Up Simulink.Signal Objects	42-37
Using Data Store Diagnostics to Detect Memory Access Issues	42-40
Limitations of Using Shared Data in MATLAB System Blocks	42-40
Use Shared Data with P-Coded System Objects	42-40
Troubleshoot System Objects in Simulink	42-42
Class Not Found	42-42
Error Invoking Object Method	42-42
Performance	42-43

Design Considerations for C/C++ Code Generation

43

When to Generate Code from MATLAB Algorithms ...	43-2
When Not to Generate Code from MATLAB Algorithms	43-2
Which Code Generation Feature to Use	43-4
Prerequisites for C/C++ Code Generation from MATLAB	43-5

Generation	43-13
MATLAB Features That Code Generation Supports .	43-13
MATLAB Language Features That Code Generation Does Not Support	43-14

Functions, Classes, and System Objects Supported for Code Generation

44

Functions and Objects Supported for C/C++ Code	
Generation — Alphabetical List	44-2
 Functions and Objects Supported for C/C++ Code	
Generation — Category List	44-186
Aerospace Toolbox	44-188
Arithmetic Operations in MATLAB	44-188
Audio System Toolbox	44-190
Bit-Wise Operations MATLAB	44-191
Casting in MATLAB	44-192
Character Functions in MATLAB	44-192
Communications System Toolbox	44-195
Complex Numbers in MATLAB	44-202

Computer Vision System Toolbox	44-203
Control Flow in MATLAB	44-212
Control System Toolbox	44-212
Data and File Management in MATLAB	44-213
Data Types in MATLAB	44-217
Desktop Environment in MATLAB	44-218
Discrete Math in MATLAB	44-219
DSP System Toolbox	44-219
Error Handling in MATLAB	44-232
Exponents in MATLAB	44-232
Filtering and Convolution in MATLAB	44-233
Fixed-Point Designer	44-234
HDL Coder	44-244
Histograms in MATLAB	44-244
Image Acquisition Toolbox	44-245
Image Processing in MATLAB	44-245
Image Processing Toolbox	44-245
Input and Output Arguments in MATLAB	44-261
Interpolation and Computational Geometry in MATLAB	44-262
Linear Algebra in MATLAB	44-266
Logical and Bit-Wise Operations in MATLAB	44-267
MATLAB Compiler	44-268
Matrices and Arrays in MATLAB	44-268
Neural Network Toolbox	44-277
Numerical Integration and Differentiation in MATLAB	44-277
Optimization Functions in MATLAB	44-278
Phased Array System Toolbox	44-279
Polynomials in MATLAB	44-290
Programming Utilities in MATLAB	44-291
Relational Operators in MATLAB	44-291
Robotics System Toolbox	44-292
Rounding and Remainder Functions in MATLAB ..	44-293
Set Operations in MATLAB	44-294
Signal Processing in MATLAB	44-298
Signal Processing Toolbox	44-299
Special Values in MATLAB	44-304
Specialized Math in MATLAB	44-305
Statistics in MATLAB	44-305
Statistics and Machine Learning Toolbox	44-306
System Identification Toolbox	44-320
Trigonometry in MATLAB	44-322
Wavelet Toolbox	44-324

45 System Objects Supported for Code Generation

Code Generation for System Objects 45-2

46 Defining MATLAB Variables for C/C++ Code Generation

Variables Definition for Code Generation 46-2

Best Practices for Defining Variables for C/C++ Code Generation 46-3

- Define Variables By Assignment Before Using Them .. 46-3
- Use Caution When Reassigning Variables 46-5
- Use Type Cast Operators in Variable Definitions 46-5
- Define Matrices Before Assigning Indexed Variables .. 46-6

Eliminate Redundant Copies of Variables in Generated Code 46-7

- When Redundant Copies Occur 46-7
- How to Eliminate Redundant Copies by Defining
 - Uninitialized Variables 46-7
 - Defining Uninitialized Variables 46-8

Reassignment of Variable Properties 46-9

Reuse the Same Variable with Different Properties . 46-10

- When You Can Reuse the Same Variable with Different Properties 46-10
- When You Cannot Reuse Variables 46-10
- Limitations of Variable Reuse 46-13

Avoid Overflows in for-Loops 46-14

Supported Variable Types	46-16
--------------------------------	-------

Defining Data for Code Generation

47

Data Definition for Code Generation	47-2
Code Generation for Complex Data	47-4
Restrictions When Defining Complex Variables	47-4
Code Generation for Complex Data with Zero-Valued Imaginary Parts	47-4
Results of Expressions That Have Complex Operands .	47-7
Code Generation for Character Arrays	47-8
Array Size Restrictions for Code Generation	47-9
See Also	47-9
Code Generation for Constants in Structures and Arrays	47-10

Code Generation for Variable-Size Data

48

What Is Variable-Size Data?	48-2
Variable-Size Data Definition for Code Generation ..	48-3
Bounded Versus Unbounded Variable-Size Data	48-4
Specify Variable-Size Data Without Dynamic Memory Allocation	48-5
Fixing Upper Bounds Errors	48-5
Specifying Upper Bounds for Variable-Size Data	48-5
Variable-Size Data in Code Generation Reports	48-7
What Reports Tell You About Size	48-7

How Size Appears in Code Generation Reports	48-8
How to Generate a Code Generation Report	48-8
Define Variable-Size Data for Code Generation	48-9
When to Define Variable-Size Data Explicitly	48-9
Using a Matrix Constructor with Nonconstant Dimensions	48-9
Inferring Variable Size from Multiple Assignments . .	48-10
Defining Variable-Size Data Explicitly Using <code>coder.ysize</code>	48-11
C Code Interface for Arrays	48-15
C Code Interface for Statically Allocated Arrays	48-15
Diagnose and Fix Variable-Size Data Errors	48-17
Diagnosing and Fixing Size Mismatch Errors	48-17
Diagnosing and Fixing Errors in Detecting Upper Bounds	48-19
Incompatibilities with MATLAB in Variable-Size Support for Code Generation	48-21
Incompatibility with MATLAB for Scalar Expansion .	48-21
Incompatibility with MATLAB in Determining Size of Variable-Size N-D Arrays	48-23
Incompatibility with MATLAB in Determining Size of Empty Arrays	48-24
Incompatibility with MATLAB in Determining Class of Empty Arrays	48-25
Incompatibility with MATLAB in Vector-Vector Indexing	48-26
Incompatibility with MATLAB in Matrix Indexing Operations for Code Generation	48-27
Incompatibility with MATLAB in Concatenating Variable- Size Matrices	48-28
Differences When Curly-Brace Indexing of Variable- Size Cell Array Inside Concatenation Returns No Elements	48-28
Dynamic Memory Allocation Not Supported for MATLAB Function Blocks	48-29
Variable-Sizing Restrictions for Code Generation of Toolbox Functions	48-30
Common Restrictions	48-30

Toolbox Functions with Restrictions For Variable-Size Data	48-31
---	-------

Code Generation for MATLAB Structures

49

Structure Definition for Code Generation	49-2
Structure Operations Allowed for Code Generation ..	49-3
Define Scalar Structures for Code Generation	49-4
Restrictions When Defining Scalar Structures by Assignment	49-4
Adding Fields in Consistent Order on Each Control Flow Path	49-4
Restriction on Adding New Fields After First Use	49-5
Define Arrays of Structures for Code Generation	49-6
Ensuring Consistency of Fields	49-6
Using repmat to Define an Array of Structures with Consistent Field Properties	49-6
Defining an Array of Structures by Using struct	49-7
Defining an Array of Structures Using Concatenation .	49-7
Index Substructures and Fields	49-8
Assign Values to Structures and Fields	49-10
Pass Large Structures as Input Parameters	49-12

Code Generation for Cell Arrays

50

Code Generation for Cell Arrays	50-2
Homogeneous vs. Heterogeneous Cell Arrays	50-2
Controlling Whether a Cell Array Is Homogeneous or Heterogeneous	50-3

Cell Arrays in Reports	50-3
Control Whether a Cell Array Is Variable-Size	50-5
Cell Array Limitations for Code Generation	50-8
Cell Array Element Assignment	50-8
Definition of Variable-Size Cell Array by Using cell	50-9
Cell Array Indexing	50-13
Growing a Cell Array by Using {end + 1}	50-13
Variable-Size Cell Arrays	50-14
Cell Array Contents	50-15
Cell Arrays in Structures	50-15
Passing Cell Arrays to External C/C++ Functions	50-15
Use in MATLAB Function Block	50-15

Code Generation for MATLAB Classes

51

MATLAB Classes Definition for Code Generation	51-2
Language Limitations	51-2
Code Generation Features Not Compatible with Classes	51-3
Defining Class Properties for Code Generation	51-4
Calls to Base Class Constructor	51-5
Inheritance from Built-In MATLAB Classes Not Supported	51-7
Classes That Support Code Generation	51-8
Generate Code for MATLAB Value Classes	51-9
Generate Code for MATLAB Handle Classes and System Objects	51-14
MATLAB Classes in Code Generation Reports	51-17
What Reports Tell You About Classes	51-17
How Classes Appear in Code Generation Reports	51-17

Troubleshooting Code Generation Issues with MATLAB	
Classes	51-20
Class class does not have a property with name name	51-20
Handle Object Limitations for Code Generation	51-22
A Variable Outside a Loop Cannot Refer to a Handle Object Created Inside a Loop	51-22
A Handle Object That a Persistent Variable Refers To Must Be a Singleton Object	51-22
System Objects Requirements and Limitations for Code Generation	51-25

Code Generation for Function Handles

52

Function Handle Limitations for Code Generation . . .	52-2
Code Generation for Anonymous Functions	52-4
Anonymous Function Limitations for Code Generation	52-4

Defining Functions for Code Generation

53

Specify Variable Numbers of Arguments	53-2
Supported Index Expressions	53-3
Apply Operations to a Variable Number of Arguments	53-4
When to Force Loop Unrolling	53-4
Using Variable Numbers of Arguments in a for-Loop . .	53-5
Implement Wrapper Functions	53-6
Passing Variable Numbers of Arguments from One Function to Another	53-6

54 | Calling Functions for Code Generation

Resolution of Function Calls for Code Generation . . .	54-2
Key Points About Resolving Function Calls	54-4
Compile Path Search Order	54-4
When to Use the Code Generation Path	54-5
Resolution of File Types on Code Generation Path . . .	54-6
Compilation Directive %#codegen	54-8
Call Local Functions	54-9
Call Supported Toolbox Functions	54-10
Extrinsic Functions	54-11
Declaring MATLAB Functions as Extrinsic Functions	54-12
Calling MATLAB Functions Using feval	54-16
Resolution of Extrinsic Functions During Simulation .	54-16
Working with mxArrayArrays	54-17
Restrictions on Extrinsic Functions for Code Generation	54-19
Limit on Function Arguments	54-19
Code Generation for Recursive Functions	54-20
Compile-Time Recursion	54-20
Run-Time Recursion	54-21
Disallow Recursion	54-21
Disable Run-Time Recursion	54-21
Recursive Function Limitations for Code Generation .	54-22
Force Code Generator to Use Run-Time Recursion . .	54-23
Make the Input to the Recursive Function Variable- Size	54-23
Assign Output Variable Before the Recursive Call . . .	54-24

Optimization Strategies	55-2
Modularize MATLAB Code	55-5
Eliminate Redundant Copies of Function Inputs	55-6
Inline Code	55-9
Prevent Function Inlining	55-9
Use Inlining in Control Flow Statements	55-9
Control Inlining	55-11
Control Size of Functions Inlined	55-11
Control Size of Functions After Inlining	55-12
Control Stack Size Limit on Inlined Functions	55-12
Fold Function Calls into Constants	55-14
Control Stack Space Usage	55-16
Stack Allocation and Performance	55-17
Allocate Heap Space from Command Line	55-17
Allocate Heap Space Using the MATLAB Coder App .	55-17
Dynamic Memory Allocation and Performance	55-18
When Dynamic Memory Allocation Occurs	55-18
Minimize Dynamic Memory Allocation	55-19
Provide Maximum Size for Variable-Size Arrays	55-20
Disable Dynamic Memory Allocation During Code Generation	55-26
Set Dynamic Memory Allocation Threshold	55-27
Set Dynamic Memory Allocation Threshold Using the MATLAB Coder App	55-27
Set Dynamic Memory Allocation Threshold at the Command Line	55-28

Excluding Unused Paths from Generated Code	55-29
Prevent Code Generation for Unused Execution Paths	55-30
Prevent Code Generation When Local Variable Controls Flow	55-30
Prevent Code Generation When Input Variable Controls Flow	55-31
Generate Code with Parallel for-Loops (parfor)	55-32
Minimize Redundant Operations in Loops	55-34
Unroll for-Loops	55-36
Limit Copying the for-loop Body in Generated Code	55-36
Disable Support for Integer Overflow or Non-Finites	55-39
Disable Support for Integer Overflow	55-39
Disable Support for Non-Finite Numbers	55-40
Integrate External/Custom Code	55-41
Generate Reusable Code	55-47
LAPACK Calls for Linear Algebra in a MATLAB Function Block	55-48

Troubleshooting MATLAB Code in MATLAB Function Blocks

56

Compile-Time Recursion Limit Reached	56-2
Issue	56-2
Cause	56-2
Solution	56-2
Output Variable Must Be Assigned Before Run-Time Recursive Call	56-5
Issue	56-5
Cause	56-5

Solution	56-5
Unable to Determine That Every Element of Cell Array Is Assigned	56-8
Issue	56-8
Cause	56-8
Solution	56-10

Managing Data

Working with Data

Benefits of Using Fixed-Point Hardware	57-24

Scaling, Precision, and Range	57-26
Scaling	57-26
Precision	57-27
Range	57-27
Fixed-Point Data in MATLAB and Simulink	57-29
Fixed-Point Data in Simulink	57-29
Fixed-Point Data in MATLAB	57-31
Scaled Doubles	57-32
Share Fixed-Point Models	57-33
Control Fixed-Point Instrumentation and Data Type Override	57-35
Control Instrumentation Settings	57-35
Control Data Type Override	57-36
Specify Fixed-Point Data Types	57-38
Overriding Fixed-Point Specifications	57-38
Specify Data Types Using Data Type Assistant	57-40
Specifying a Fixed-Point Data Type	57-43
Specify an Enumerated Data Type	57-50
Specify a Bus Object Data Type	57-50
Data Types for Bus Signals	57-53
Data Objects	57-54
Data Class Naming Conventions	57-55
Use Data Objects in Simulink Models	57-55
Data Object Properties	57-58
Create Data Objects from Built-In Data Class Package Simulink	57-59
Create Data Objects from Another Data Class Package	57-60
Create Data Objects Directly from Dialog Boxes	57-61
Create Data Objects for a Model Using Data Object Wizard	57-62
Create Data Objects from External Data Source Programmatically	57-68
Data Object Methods	57-69
Handle Versus Value Classes	57-70
Compare Data Objects	57-72

Create Persistent Data Objects	57-73
Define Data Classes	57-75
Determine Where to Store Variables and Objects for Simulink Models	57-81
Types of Data	57-81
Store Data for Your Design	57-82
Storage Locations	57-84
Edit and Manage Workspace Variables Used by Models	57-88
Finding Variables That Are Used by a Model or Block	57-88
Finding Blocks That Use a Specific Variable	57-91
Finding Unused Workspace Variables	57-92
Editing Workspace Variables	57-94
Rename Variables	57-96
Compare Duplicate Workspace Variables	57-97
Export Workspace Variables	57-99
Importing Workspace Variables	57-101
Configure Data Properties by Using a Table	57-103
Configure Distant Data Items	57-103
Select Data Items in a Block Diagram	57-105
Refine List by Filtering, Sorting, and Grouping	57-106
Navigate to Blocks That Own Data	57-106
Configure Data Interface for Component	57-106
Purpose of Columns	57-107
Model Data Editor Limitations	57-108
Upgrade Level-1 Data Classes	57-110
Associating User Data with Blocks	57-112
Support Limitations for Simulink Software Features	57-113
Supported and Unsupported Simulink Blocks	57-116
Support Limitations for Stateflow Software Features	57-127
ml Namespace Operator, ml Function, ml Expressions	57-127
C Math Functions	57-127
Atomic Subcharts That Call Exported Graphical Functions Outside a Subchart	57-128

Atomic Subchart Input and Output Mapping	57-128
Recursion and Cyclic Behavior	57-128
Custom C or C++ Code	57-130
Machine-Parented Data	57-130
Textual Functions with Literal String Arguments . .	57-130

Enumerations and Modeling

58

Simulink Enumerations	58-2
Simulink Constructs that Support Enumerations	58-2
Simulink Enumeration Limitations	58-5
Use Enumerated Data in Simulink Models	58-7
Define Simulink Enumerations	58-7
Simulate with Enumerations	58-14
Specify Enumerations as Data Types	58-16
Get Information About Enumerated Data Types	58-17
Enumeration Value Display	58-17
Instantiate Enumerations	58-19
Enumerated Values in Computation	58-22

Importing and Exporting Simulation Data

59

Export Simulation Data	59-3
Simulation Data	59-3
Approaches for Exporting Signal Data	59-4
Enable Simulation Data Export	59-6
View Logged Data Using Simulation Data Inspector . .	59-7
Memory Performance	59-7
Signal Data Storage for Loading	59-9
MATLAB Workspace for Signal Data	59-9
Source and Signal Builder Blocks for Signal Data . . .	59-10
MAT-Files for Signal Data	59-11
Spreadsheets for Signal Data	59-11

Data Format for Logged Simulation Data	59-14
Data Format for Block-Based Logged Data	59-14
Data Format for Model-Based Logged Data	59-14
Logged Data Store Format	59-14
Time, State, and Output Data Format	59-14
Dataset Conversion for Logged Data	59-20
Why Convert to Dataset Format?	59-20
Results of Conversion	59-21
Dataset Conversion Limitations	59-23
Convert Logged Data to Dataset Format	59-24
Convert Workspace Data to Dataset	59-24
Convert Structure Without Time to Dataset	59-26
Programmatically Access Logged Dataset Format Data	59-30
Log Signal Data That Uses Units	59-36
Limit Amount of Exported Data	59-39
Decimation	59-39
Limit Data Points	59-40
Logging Intervals	59-40
Log Data Using Persistent Storage	59-42
When to Use Persistent Storage	59-42
General Workflow for Logging to Persistent Storage .	59-44
Supported Logging Techniques	59-44
Use Dataset Format for Logging	59-44
Enable Logging to Persistent Storage	59-45
How Simulation Data is Stored	59-45
Save Logged Data from Successive Simulations	59-45
Access Logged Data from Persistent Storage	59-48
Access Data Logged to Persistent Storage	59-48
Access Data Store Data	59-49
Get List of Dataset Variables	59-49
Create References to Persistent Storage Dataset Objects	59-49
Samples to Export for Variable-Step Solvers	59-53
Output Options	59-53
Refine Output	59-53

Produce Additional Output	59-54
Produce Specified Output Only	59-55

Start the Simulink Software

To build models, use the Simulink Editor and the Library Browser.

Start the MATLAB Software

Before you start Simulink, start MATLAB[®]. See “Startup and Shutdown”.

Configure MATLAB to Start Simulink

The first model that you open in a MATLAB session takes longer to open than subsequent models because, by default, MATLAB starts Simulink when opening the first model. This just-in-time starting of Simulink reduces MATLAB startup time and avoids unnecessary system memory use.

To speed up opening the first model, you can configure MATLAB startup to also start Simulink. To start Simulink without opening models or the Library Browser, use `start_simulink`.

Depending on how you start MATLAB, use the command:

- In the MATLAB `startup.m` file
- At the operating system command line, with the `matlab` command and the `-r` switch

For example, to start Simulink when MATLAB starts on a computer running the Microsoft[®] Windows[®] operating system, create a desktop shortcut with this target:

```
matlabroot\bin\win32\matlab.exe -r start_simulink
```

On Macintosh and Linux[®] computers, use this command to start Simulink when you start MATLAB:

```
matlab -r start_simulink
```

Open the Simulink Editor

To open the Simulink Editor, you can:

- Create a model. On the MATLAB **Home** tab, click **Simulink** and choose a model template.

Alternatively, if you already have the Library Browser open, click the **New Model** button . For additional ways to create a model, see “Create a Model” on page 1-5.

- Open an existing model. To open recent models, on the MATLAB **Home** tab, click **Simulink**.

Alternatively, if you know the name of the model you want, at the MATLAB command prompt, enter the name, such as `vdw`. For additional ways to open a model, see “Open a Model” on page 1-10.

Tip The Simulink Editor opens on top of the MATLAB desktop. To move the MATLAB desktop on top, in the Simulink Editor, select **View > MATLAB Desktop**.

Open the Library Browser

Use any of these techniques to open the Simulink Library Browser from MATLAB:

- On the **Home** tab, click **Simulink**, and choose a model template. In the new model, click the **Library Browser** button .
- At the command prompt, enter `slLibraryBrowser`.

The Library Browser opens and displays a tree view of the Simulink block libraries on your system. As you click libraries in the tree, the contents of the library appear in the right pane.

Note: Simulink comes with block libraries in addition to the Simulink library. These libraries support simulating supplied example models that contain blocks from those libraries. However, you can generate code or modify these blocks only with the relevant product licenses.

“Simulink Model File Types” on page 1-11

Create a Model

- 1 On the MATLAB **Home** tab, click **Simulink**.
- 2 In the Simulink start page, choose a template or search the templates.

Model templates are starting points to apply common modeling approaches. They help you reuse settings and block configurations and share knowledge. Use model and project templates to apply best practices and take advantage of previous modeling solutions.

Click the title of a template to read the description.

To locate templates that are not on the MATLAB search path, click **Open**. Model templates have the extension `.slx`.

- 3 After selecting the template you want, click **Create Model**.

To use a template without reading the description, click the template image. Alternatively, press **Ctrl+N** to use your default template. To set a default template, see “Use Customized Settings When Creating New Models” on page 1-8.

A new model using the template settings and contents opens in the Simulink Editor. For next steps, see “Build and Edit a Model in the Simulink Editor” on page 1-23.

If the built-in templates do not meet your needs, try the **Examples** tab, or you can create your own templates. See “Create a Template from a Model” on page 4-2.

Use Customized Settings When Creating New Models

You can specify a model template to use for all new models.

- 1 Create a model with the configuration settings and blocks you want, then export the model to a template. See “Create a Template from a Model” on page 4-2.
- 2 To reuse these settings in every new model, make the new template your default model template using the Simulink start page or the `Simulink.defaultModelTemplate` function.

In the start page, click the title of a template to expand the description, then click the down arrow next to **Create Model** and select **Set As Default**.

After you set a default model template, every new model uses that template, for example, when you press **Ctrl+N**, when you use new model buttons, or when you use `new_system`. In the Simulink Editor, your default template name is at the top of the list when you select **File > New > MyDefaultTemplateName**.

The default template shows a tick mark in the start page.

Open a Model

Opening a model loads the model into memory and displays it in the Simulink Editor. Use any of these techniques:

- On the MATLAB **Home** tab, click **Simulink**. In the Simulink Start Page, select a recent model or project from the list, or click **Open**.
- In the Simulink Editor, select **File > Open Recent** and choose a recent model.
- At the MATLAB command prompt, enter the name of the model without a file extension, for example, `vdp`. The model must be in the current folder or on the MATLAB search path.
- In the Simulink Library Browser, click the **Open model or library** button .
- Open the model using the Current Folder browser or your operating system file browser.

To clear the list of recent files in the start page, in MATLAB, enter:

```
slhistory.clear
```

Note: To open a model created in a later version of Simulink software in an earlier version, first export the model to the earlier version. See “Export a Model to a Previous Simulink Version” on page 1-43.

Load Variables When Opening a Model

As you build models, you sometimes define variables for a model. For example, suppose that you have a model that contains a Gain block. You can specify the variable **K** as the gain rather than setting the value on the block. When you use this approach, you must define the variable **K** for the model to simulate.

You can use a model callback to load variables when you open a model.

- 1 In a model that uses the Gain block, set the block **Gain** value to **K**.
- 2 Define the variable in a MATLAB script. In MATLAB, select **New > Script**. In the script, enter your variable definitions:

```
K=27
```

- 3 Save the script as `loadvar.m`.

- 4 In the model, open the Property Inspector. Select **View > Property Inspector**. With no selection at the top level of a model, you can use the Property Inspector to set model properties. Otherwise, use **File > Model Properties**.
- 5 In the **Callbacks** section of the model properties, select **PreLoadFcn** as the callback that you want to define. In the pane, enter `loadvar`.
- 6 Save the model.

The next time that you open the model, the `PreloadFcn` callback loads the variables into the MATLAB workspace.

To learn about callbacks, see “Callbacks for Customized Model Behavior” on page 4-56. To define a callback for loading variables programmatically, see “Programmatically Load Variables When Opening a Model” on page 1-14.

Open a Model with Different Character Encoding

If you open an MDL file that uses a particular character set encoding in a MATLAB session that uses a different encoding, a warning appears. For example, suppose that you create an MDL file in a MATLAB session configured for `Shift_JIS` and open it in a session configured for `US_ASCII`. The warning message shows the encoding of the current session and the encoding used to create the model.

SLX files do not warn because they can store characters from any encoding.

If you encounter any problems with corrupted characters, for example when using MATLAB files associated with the model, then try using the `slCharacterEncoding` function to change the character encoding of the current MATLAB session to match the model character encoding.

Simulink can check if models contain characters unsupported in the current locale. For more details, see “Check model for foreign characters” and “Save Models with Different Character Encodings” on page 1-41.

Simulink Model File Types

New models that you create have the `.slx` extension by default. Models created before R2012b have the extension `.mdl`. Models you can edit can have the `.slx` or `.mdl` extension, depending on when they were created or whether you converted them. See “Save Models in the SLX File Format” on page 1-39.

.slxp and .mdlx extensions denote protected models that you cannot open and edit. See “Protected Model” on page 8-83. Model templates have the extension .sltx.

Simulink libraries also use the .slx extension, but you cannot simulate them. To learn more, see “Create a Custom Library” on page 38-3.

Programmatic Modeling Basics

In this section...

“Load a Model” on page 1-13

“Create a Model and Specify Parameter Settings” on page 1-13

“Programmatically Load Variables When Opening a Model” on page 1-14

“Programmatically Add and Connect Blocks” on page 1-15

“Name a Signal Programmatically” on page 1-17

“Open the Same Model in Multiple Windows” on page 1-17

“Get a Simulink Identifier” on page 1-17

“Specify Colors Programmatically” on page 1-21

You can perform most Simulink modeling basics programmatically at the MATLAB command prompt. The commands that correspond to basic modeling operations, such as creating models, adding blocks to models, and setting parameters, are listed in the Functions section of “Model Editing Fundamentals”. These examples show some of these commands and how you can use them.

Load a Model

Loading a model brings it into memory but does not open it in the Simulink Editor for editing. After you load a model, you can work with it programmatically. You can use the Simulink Editor to edit the model only if you open the model.

To load a system, use the `load_system` command. For example, to load the `vdp` model, at the MATLAB command prompt, enter:

```
load_system('vdp')
```

Create a Model and Specify Parameter Settings

You can write a function that creates a model and uses the settings that you prefer. For example, this function creates a model that has a green background and uses the `ode3` solver:

```
function new_model(modelname)
% NEW_MODEL Create a new, empty Simulink model
```

```
% NEW_MODEL('MODELNAME') creates a new model with
% the name 'MODELNAME'. Without the 'MODELNAME'
% argument, the new model is named 'my_untitled'.

if nargin == 0
    modelname = 'my_untitled';
end

% create and open the model
open_system(new_system(modelname));

% set default screen color
set_param(modelname, 'ScreenColor', 'green');

% set default solver
set_param(modelname, 'Solver', 'ode3');

% save the model
save_system(modelname);
```

Programmatically Load Variables When Opening a Model

If you assign a variable as a block parameter value, you must define the value of the variable in the model. See “Load Variables When Opening a Model” on page 1-10. You can define the variable programmatically using the `PreloadFcn` callback with the `set_param` function. Use the function in this form:

```
set_param('mymodel', 'PreloadFcn', 'expression')
```

`expression` is a MATLAB command or a MATLAB script on your MATLAB search path. This command sets the model `PreloadFcn` callback to the value that you specify. Save the model to save the setting.

For example, when you define the variables in a MATLAB script `loadvar.m` for the model `modelname.slx`, use this command:

```
set_param('modelname', 'PreloadFcn', 'loadvar')
```

To assign the variable `K` the value 15, use this command:

```
set_param('modelname', 'PreloadFcn', 'K=15')
```

After you save the model, the `PreloadFcn` callback executes when you next open the model.

Programmatically Add and Connect Blocks

This example shows how to use functions to add blocks and connect the blocks programmatically. Once you have added blocks to the model, you use three different approaches to connect them: routed lines, port handles, and port IDs. Routed lines allow you to specify the exact (x,y) coordinates of all connecting line segment endpoints. Port handles and port IDs allow connecting lines to block ports without having to know the port location coordinates.

Create and open a blank model named 'mymodel'.

Add blocks, including a subsystem block. Use the `position` array in the `set_param` function to set the size and position of the blocks. Set the upper left and lower right block corners using (x,y) coordinates.

```
add_block('simulink/Sources/Sine Wave','mymodel/Sine1');
set_param('mymodel/Sine1','position',[140,80,180,120]);
add_block('simulink/Sources/Pulse Generator','mymodel/Pulse1');
set_param('mymodel/Pulse1','position',[140,200,180,240]);
add_block('simulink/Ports & Subsystems/Subsystem','mymodel/Subsystem1');
set_param('mymodel/Subsystem1','position',[315,120,395,200]);
add_block('simulink/Sinks/Scope','mymodel/Scope1');
set_param('mymodel/Scope1','position',[535,140,575,180]);
```

Inside `Subsystem1`, delete the default connection between `In1` and `Out1`. Also, add a second input port by copying and renaming `In1` from the block library.

```
delete_line('mymodel/Subsystem1','In1/1','Out1/1');
add_block('simulink/Sources/In1','mymodel/Subsystem1/In2');
```

Reposition the internal input and output port blocks inside `Subsystem1`.

```
set_param('mymodel/Subsystem1/In1','position',[50,50,90,70]);
set_param('mymodel/Subsystem1/In2','position',[50,130,90,150]);
set_param('mymodel/Subsystem1/Out1','position',[500,80,540,100]);
```

Insert and position an `Add` block inside `Subsystem1`.

```
add_block('simulink/Math Operations/Add','mymodel/Subsystem1/Add1');
set_param('mymodel/Subsystem1/Add1','position',[250,80,290,120]);
```

Next, add lines to connect all the blocks in the model. Start by connecting the `Sine1` and `Pulse1` blocks using routed lines.

Find the (x,y) coordinates of the `Sine1` output port.

```
Sine1_Port = get_param('mymodel/Sine1','PortConnectivity')
```

```
Sine1_Port =
```

```
struct with fields:
```

```
    Type: '1'  
    Position: [185 100]  
    SrcBlock: []  
    SrcPort: []  
    DstBlock: [1x0 double]  
    DstPort: [1x0 double]
```

`get_param` shows that the port Position is [185 100].

Find the (x,y) coordinates of the Pulse1 output port.

```
Pulse1_Port = get_param('mymodel/Pulse1','PortConnectivity')
```

```
Pulse1_Port =
```

```
struct with fields:
```

```
    Type: '1'  
    Position: [185 220]  
    SrcBlock: []  
    SrcPort: []  
    DstBlock: [1x0 double]  
    DstPort: [1x0 double]
```

`get_param` shows that the port position is [185 220].

Connect the output of Sine1 to the first input of Subsystem1 using three segments of routed line.

```
add_line('mymodel', [185 100; 275 100]);  
add_line('mymodel', [275 100; 275 140]);  
add_line('mymodel', [275 140; 310 140]);
```

Connect the output of Pulse1 to the second input of Subsystem1 using three segments of routed line.

```
add_line('mymodel', [185 220; 275 220]);  
add_line('mymodel', [275 220; 275 180]);  
add_line('mymodel', [275 180; 310 180]);
```

Use `get_param` to get the port handles of the blocks being connected. Then use the block port handles to connect the output of `Subsystem1` to the input of `Scope1`.

```
SubsysPortHandles = get_param('mymodel/Subsystem1','PortHandles');
ScopePortHandles = get_param('mymodel/Scope1','PortHandles');
add_line('mymodel',SubsysPortHandles.Output(1),ScopePortHandles.Inport(1));
```

Use port names and IDs to connect the `Add1` block inside `Subsystem1` to the subsystem inputs and outputs. Simulink uses the most direct path to connect the ports.

```
add_line('mymodel/Subsystem1','In1/1','Add1/1');
add_line('mymodel/Subsystem1','In2/1','Add1/2');
add_line('mymodel/Subsystem1','Add1/1','Out1/1');
```

Name a Signal Programmatically

- 1 Select the block that is the source for the signal line.
- 2 Use `get_param` to assign the port handle of the currently selected block to the variable `p`. Use `get_param` to assign the name of the signal line from that port to the variable `l`. Then set the name of the signal line to `'s9'`.

```
p = get_param(gcf,'PortHandles')
l = get_param(p.Outputport,'Line')
set_param(l,'Name','s9')
```

Open the Same Model in Multiple Windows

When you open a model, the model appears in a Simulink Editor window. For example, if you have one model open and then you open a second model, the second model appears in a second window.

To open the same model in two Simulink Editor windows, at the MATLAB command prompt, enter the `open_system` command and use the `window` argument. For example, if you have the `vdp` model open, to open another instance of the `vdp` model, enter:

```
open_system('vdp','window')
```

Get a Simulink Identifier

Every block in your model has a Simulink Identifier (SID), a unique and unmodifiable identifier. The SID persists for the lifetime of the object and is saved with a model.

If the name of the object changes, the SID stays the same. The SID has the form `model_name:number`. For details, see “Locate Diagram Components Using Simulink Identifiers” on page 1-18.

Locate Diagram Components Using Simulink Identifiers

A Simulink Identifier (SID) is a unique designation automatically assigned to a Simulink block, model annotation, or Stateflow[®] object within a Stateflow chart. The SID helps to identify specific instances of these components in your diagram, especially when sharing models between people within a team.

To highlight a component visually within the model, get the SID and use it with the `Simulink.ID.hilite` function.

The SID has these characteristics:

- Persistent within the lifetime of a Simulink block, model annotation, or Stateflow object
- Saved in the model file
- Remains the same if the block or object name changes
- Cannot be modified

The SID format is:

`model_name:sid_number`

- `model_name` is the name of the model where the block, annotation, or Stateflow object resides.
- `sid_number` is a unique number within the model, assigned by Simulink.

Highlight Block

- 1 To open the model `vdp`, enter `vdp` at the MATLAB command prompt.
- 2 Get the SID of the Mu block.

```
Simulink.ID.getSID('vdp/Mu')
```

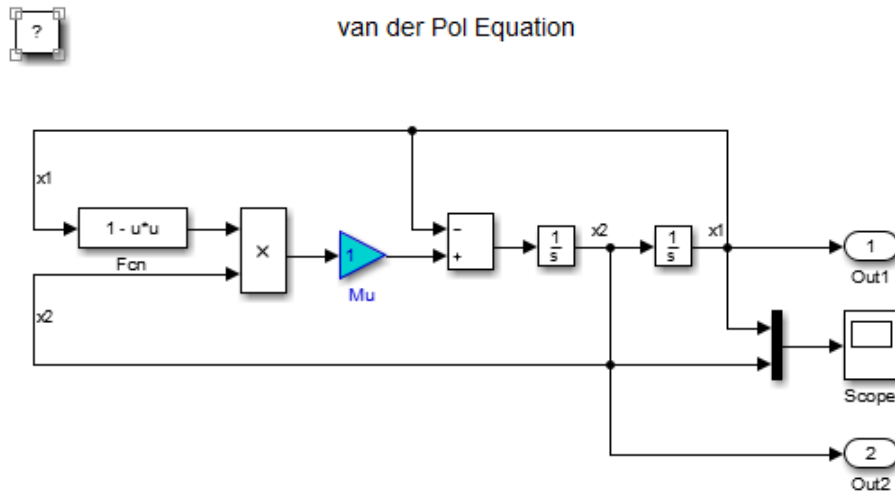

```
ans =
```

```
vdp:4
```

- Use the SID to highlight the block.

```
Simulink.ID.hilite('vdp:4')
```

The block appears highlighted in the model:

Highlight Annotation

- Open the model `vdp`.
- Select the annotation at the top of the diagram.
- Get the annotation object for the selected annotation.

```
ann = getSelectedAnnotations('vdp')
```

```
ann =
```

```
Simulink.Annotation
```

- Get the SID of the annotation.

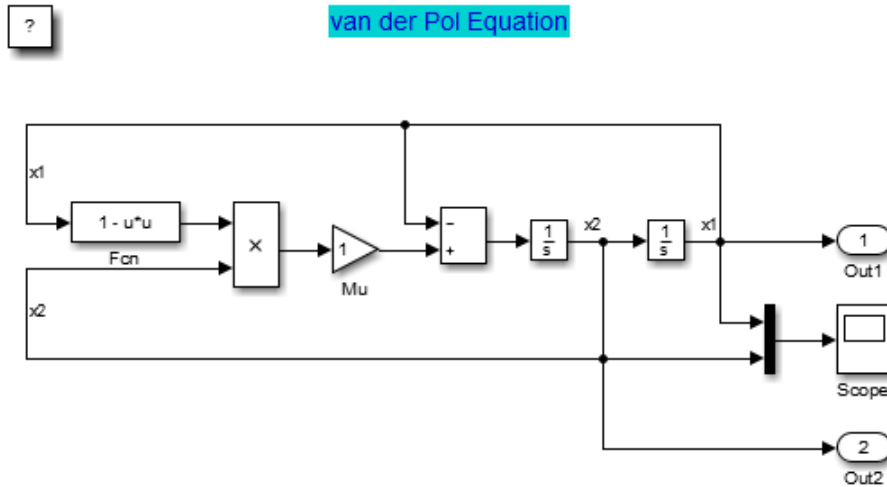

```
ann.SIDFullString
```

```
ans =  
vdp:13
```

- 5 Use the SID to highlight the annotation.

```
Simulink.ID.hilite('vdp:13')
```

The annotation appears highlighted in the model:

Highlight Stateflow Object

- 1 Open the model sf_resolve_signal_object.
- 2 Get the SID of the Signal Object Chart Stateflow object:

```
Simulink.ID.getSID('sf_resolve_signal_object/Signal Object Chart')
```

```
ans =  
sf_resolve_signal_object:1
```

- 3 Use the SID to highlight the object.

```
Simulink.ID.hilite('sf_resolve_signal_object:1')
```

The object appears highlighted in the model.

Resolve Signal Object

Specify Colors Programmatically

You can use the `set_param` command at the MATLAB command line or in a MATLAB program to set parameters that determine the background color of a diagram and the background color and foreground color of diagram elements. The following table summarizes the parameters that control block diagram colors.

Parameter	Determines
ScreenColor	Block diagram background
BackgroundColor	Block and annotation background
ForegroundColor	Block and annotation foreground

Set the color parameter to either a named color or an RGB value.

- Named color: 'black', 'white', 'red', 'green', 'blue', 'cyan', 'magenta', 'yellow', 'gray', 'lightBlue', 'orange', 'darkGreen'
- RGB value: '[r,g,b]'

where **r**, **g**, and **b** are the red, green, and blue components of the color normalized to the range 0.0 to 1.0.

For example, the following command sets the background color of the currently selected system or subsystem to a light green color:

```
set_param(gcs, 'ScreenColor', '[0.3, 0.9, 0.5]')
```

Build and Edit a Model in the Simulink Editor

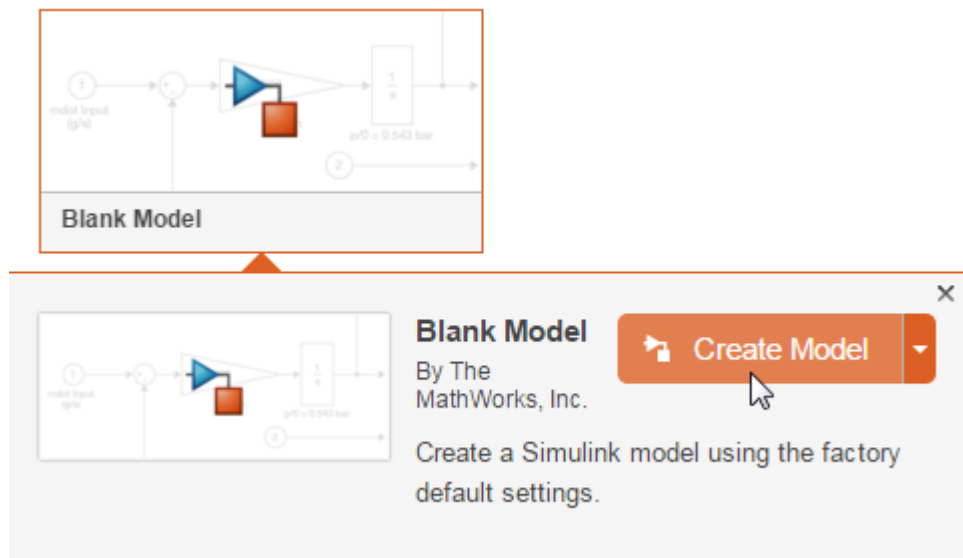

In this section...

- “Start Simulink and Create a New Model” on page 1-23
- “Add Blocks to the Model” on page 1-24
- “Align and Connect Blocks” on page 1-25
- “Set Block Parameters” on page 1-26
- “Add More Blocks” on page 1-26
- “Branch a Connection” on page 1-28
- “Organize Your Model” on page 1-30
- “Simulate Model and View Results” on page 1-33
- “Modify the Model” on page 1-34

This example shows the basics of how to create a model, add blocks to it, connect blocks, and simulate the model. You also learn how to organize your model with subsystems, name parts of a model, and modify the model.

Start Simulink and Create a New Model

- 1 On the MATLAB **Home** tab, click **Simulink**.
- 2 In the Simulink Start Page, click the title of the **Blank Model** template to expand the details, and then click **Create Model**.

A new model opens in the Simulink Editor.

- 3 Open the Library Browser so you can access the blocks you need to create your model. In the Simulink Editor, click the **Library Browser** button .

Add Blocks to the Model

A minimal model takes an input signal, operates on it, and outputs the result. In the Library Browser, the Sources library contains blocks that represent input signals. The Sinks library has blocks that you can use to capture and display outputs. The other libraries contain blocks you can use for a variety of purposes, such as math operations.

In this example, the input is a sine wave, the operation is a gain (which increases the signal value by multiplying), and you output the result to a scope. This example shows different techniques for exploring the library and for adding blocks to your model.

- 1 Open the Sources library. In the tree view of the Library Browser, click the **Sources** library.
- 2 In the right pane, hover over the Sine Wave block to see a tooltip describing its purpose.

- 3 Add a block to your model using a context menu. Right-click the block and select **Add block to model untitled**. (To learn more about the block, select **Help** from the context menu.)
- 4 Add a block to your model by dragging. In the library tree view, click **Math Operations**. In the Math Operations library, locate the Gain block and drag it to your model to the right of the Sine Wave block.
- 5 In the library tree view, click **Simulink** to view the sublibraries as icons in the right pane. This view is an alternative way to navigate the library structure. Double-click the **Sinks** library icon.
- 6 In the Sinks library, locate the Scope block and add it to your model using the context menu or by dragging it.

The figure shows your model so far.

Align and Connect Blocks

Connect the blocks so the model can operate. Reading the model is easier when you line up the blocks according to how they interact with each other. Shortcuts help you to align and connect the blocks.

- 1 Drag the Gain block so it lines up with the Sine Wave block. An alignment guide appears when the blocks line up horizontally. Release the block, and a blue arrow appears as a preview of the suggested connection.

- 2 To make the connection, click the end of the arrow. A solid line appears in place of the guide.
- 3 Line up and connect the Scope block to the Gain block using the same technique.

Tip Use the **Diagram > Arrange** menu for additional alignment options.

Set Block Parameters

You can set parameters on most blocks. Parameters help you to specify how a block operates in your model. You can use the default values or you can set values as needed. Use the Property Inspector to set parameters. Alternatively, you can double-click most blocks to set the parameters using a block dialog box. To understand when to use each approach, see “Setting Properties and Parameters” on page 1-50.

In your model, set the amplitude in the Sine Wave block and the value of the gain in the Gain block.

- 1 Display the Property Inspector. Select **View > Property Inspector**.
- 2 Select the Sine Wave block.
- 3 In the Property Inspector, set the **Amplitude** parameter to 2.
- 4 Select the Gain block and set the **Gain** parameter to 3. The value appears on the block.

Add More Blocks

Suppose that you want to perform another gain but on the absolute value of the output from the Sine Wave block. Add blocks for this purpose, trying different techniques for locating blocks in the library and adding them to your model.

- 1 If you know the name of the block that you want to add, you can use a shortcut. Click in the model where you want to add the block, and type the block name, in this case Gain. A list of possible blocks appears.

- 2 Click the block name or, with the block name highlighted, press **Enter**. You can use the arrow keys to highlight the block name if it is not first in the list. You can use this technique to add blocks anywhere the blue magnifying glass appears, for example when you draw a signal line.
- 3 For many blocks, a prompt appears for entering a value for one of the block parameters. The Gain block prompts you to enter the **Gain** value. Type **3** and press **Enter**.

The name of each additional instance of a block has a number appended that increments for each new copy.

- 4 Add an Abs block to the model. Suppose you do not know the library a block is in or the full name of the block. In this case, you can search for it using the search box in the Library Browser. Enter **abs** in the search box and press **Enter**. When you find the Abs block, add it to the model to the left of the Gain1 block.
- 5 Add another Scope block. You can right-click the existing Scope block and drag to create the copy. Or, you can use **Edit > Copy** and **Edit > Paste**.

The figure shows the current state of your model.

Note: When you name blocks in a model in order numerically (for example Gain1, Gain2, and so on), copying and pasting them creates names that follow standard

sorting order conventions for ASCII characters. This sorting order can result in a sequence of numbers on the block names that is hard to understand. To number blocks so that copying and pasting them creates names that follow a typical reading order, use a leading zero in the block names, for example Gain001, Gain002, and so on.

Branch a Connection

The input to the second gain is the absolute value of the sine wave. To use a single Sine Wave block as the input to both gain operations, create a branch from the Sine Wave block output signal.

- 1 For the first set of blocks in your model, you used the horizontal alignment guides to help you align and connect blocks. You can also use guides to align blocks vertically. Drag the Scope1 block so that it lines up under the Scope block. Release it when the vertical alignment guide shows that the blocks are aligned.

In this figure, the horizontal alignment guide shows that the Scope1 and Gain1 blocks are aligned.

- 2 Align and connect the Abs and Gain1 blocks as shown.

- 3 Create a branch from the Sine Wave block output to the Abs block. With your cursor over the output signal line from the Sine Wave block, press **Ctrl** and drag down. Drag the branch until the end is to next to the Abs block.

- 4 Drag toward the Abs block until the line connects to it. Move the vertex as needed to straighten the line. (A circle appears over the vertex.)

Try these other methods to connect blocks:

- Drag a connection from the output of one block to the input of the other block. Use this technique when your blocks are already aligned, that is, no guideline appears.
- Select the first block and **Ctrl**+click the block you want to connect it to. This technique is useful when you do not want the blocks to align. The connection line bends as needed to make the connection, as shown in the figure.

Note: You can select multiple blocks to connect them to a block that has multiple inputs, such as a bus.

To approximate a diagonal line from line segments, press **Shift** and drag a vertex.

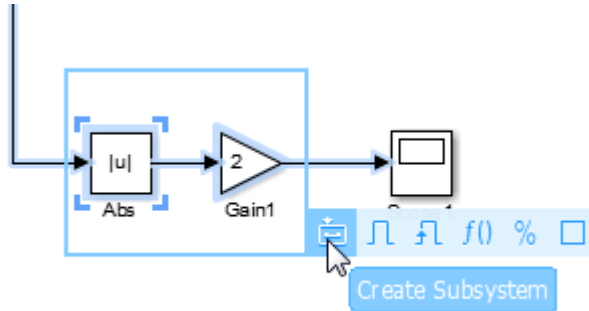

Organize Your Model

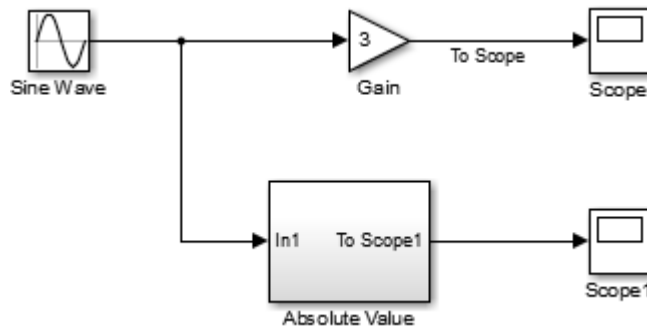

You can group blocks in subsystems and label blocks, subsystems, and signals. For more about subsystems, see “Create a Subsystem” on page 4-28.

- 1 Drag a selection box around the Abs and Gain1 blocks.

- 2 Move your mouse over the prompt that appears at the lower-right corner of the selection box. On the action bar, click **Create Subsystem**.

A subsystem block appears in the model in place of the Abs and Gain1 blocks. To resize the subsystem block for the best fit in your model, use the block handles.

- 3 Double-click the block name and type **Absolute Value** to give the subsystem a meaningful name.
- 4 Open the Absolute Value subsystem by double-clicking it.

Tip To use the Explorer Bar to navigate the model hierarchy, right-click the block and select **Open in New Tab**.

The subsystem contains the Abs and Gain1 blocks that you selected as the basis of the subsystem. They are connected in sequence to two new blocks: In1 (an Inport block) and Out1 (an Outport block). Inport and Outport blocks correspond to the input and output ports on the subsystem.

- 5 Double-click the name Out1 and type **To Scope1**.

- 6 Click the Simulink Editor **Up to Parent** button  to return to the top level of the model. The output port of the Absolute Value subsystem is now named **To Scope1**.
- 7 You can name any signal. Double-click a signal and type the name. For example, double-click the signal from the Gain block and type **To Scope**. Be sure to double-click the signal and not a blank area of the canvas, which instead creates a separate text element (annotation). For other techniques that you can use with signal names, see “Signal Name and Label Actions” on page 1-92.

The figure shows the model after you create the subsystem, name it, rename its output port, and name a signal.

Tip For additional resizing and alignment options, use the **Diagram > Arrange** menu.

Simulate Model and View Results

- 1 You can simulate a model using the **Simulation > Run** command (**Ctrl+T**) or the **Run** button . Simulate the model using the technique that you prefer.

In this example, simulation runs for 10 seconds, the default setting.

- 2 Double-click both scope blocks to open them and view the results. In each scope, click the **Autoscale** button  to view the entire signal.

The figure shows the two results. In the second plot, as expected, the absolute value of the sine wave is always positive.

Modify the Model

You can add blocks on an existing signal and remove blocks from models and redraw connections. To modify this model, add a bias to the input to both branches of your model. Also, replace one of the scopes with a different sink.

- 1 Add a Bias block to the model and set the **Bias** parameter to 2.

- 2 Drag the block and place it on the signal line after the Sine Wave block but before the branch. If you need to make room for the block, drag the Sine Wave block to the left or move the end of the branch by dragging it to the right.

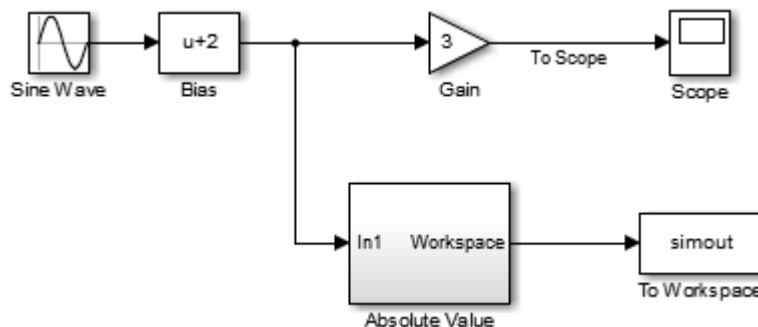

When you drag the block onto the signal line, the block connects to the signal line at both ends. Release the block when you are satisfied with its position.

- 3 Remove the Scope1 block. Press **Shift** and drag the Scope1 block if you want to disconnect it from the model but do not want to delete it. Cut or delete it using the **Edit** menu commands or a keystroke. The broken connection appears as a red dotted line.

When you delete a block with one input and one output, a prompt appears between the broken connection lines. Click the prompt to connect the signals.

- 4 Add a To Workspace block to the model and place it at the end of the broken connection. The To Workspace block outputs the results to a variable in the MATLAB workspace.
- 5 Rename the output port on the Absolute Value subsystem. Open the subsystem and rename the To Scope1 block as Workspace. Then, return to the top level of the model. The figure shows the current model.

- 6 Simulate the model. The `simout` variable appears in the MATLAB workspace. You can double-click the variable to explore the results.

Tip To toggle between simulating the model with and without the effects of the Bias block, right-click the Bias block and select **Comment Through**. The block stays in the model but does not affect the operation. Right-click the Bias block and select **Uncomment** to enable the block. The **Comment Out** command comments out the block's output signal, so signal data does not pass through. Try each of these commands to better understand their effects.

“Export a Model to a Previous Simulink Version” on page 1-43

“Save from One Earlier Simulink Version to Another” on page 1-43

How to Tell If a Model Needs Saving

To tell whether a model needs saving, look at the title bar in the Simulink Editor. If the model needs saving, an asterisk appears next to the model name in the title bar (known as the dirty flag: *).

To determine programmatically whether a model needs saving, use the model parameter `Dirty`. For example:

```
if strcmp(get_param(gcs,'Dirty'),'on')
    save_system;
end
```

Save a Model

To save a model for the first time, in the Simulink Editor, select **File > Save**. Provide a location and name for the model file. For name requirements, see “Model Names” on page 1-38.

To save a previously saved model:

- To replace the file contents, in the Simulink Editor, select **File > Save**.
- To save the model with a new name or location, or to change from MDL to SLX format, in the Simulink Editor, select **File > Save As**.

Note: For details about the SLX format, see “Upgrade Models to SLX” on page 1-39.

- To save the model in a format compatible with the earlier version, select **File > Export Model to > Previous Version**. See “Export a Model to a Previous Simulink Version” on page 1-43.

Model Names

Model file names must start with a letter and can contain letters, numbers, and underscores. The file name must not be:

- A language keyword (e.g., `if`, `for`, `end`)
- A reserved name: `'simulink'`, `'sl'`, `'sf'`
- A MATLAB software command

The total number of characters in the model name must not be greater than a certain maximum, usually 63 characters. To find out whether the maximum for your system is greater than 63 characters, use the MATLAB `namelengthmax` command.

To understand how MATLAB determines which function to call when you specify a model name, see “Function Precedence Order”.

What Happens When You Save a Model?

Simulink saves the model (block diagram) and block properties in the model file.

If you have any pre- or post-save functions, they execute in this order:

- 1 All block `PreSaveFcn` callback routines execute first, then the model `PreSaveFcn` callback routine executes.
- 2 Simulink writes the model file.
- 3 All block `PostSaveFcn` callback routines execute, then the model `PostSaveFcn` executes.

During the save process, Simulink maintains a temporary backup copy (named *modelName.bak*) for restoring in case of an error. If an error occurs during saving or during any callback during the save process, Simulink:

- Restores the original file
- Writes any content saved before the error occurred in a file named *modelName.err*
- Issues an error message

When saving a model loaded from an SLX file, the original SLX file must still be present. Simulink performs incremental loading and saving of SLX files, so if the original file is missing at save-time, Simulink warns that it cannot reconstruct the file fully.

Save Models in the SLX File Format

Save New Models as SLX

Simulink saves new models and libraries in the SLX format by default, with file extension *.slx*. SLX is a compressed package that conforms to the Open Packaging Conventions (OPC) interoperability standard. SLX stores model information using Unicode® UTF-8 in XML and other international formats. Saving Simulink models in the SLX format:

- Typically reduces file size compared to MDL. The file size reduction between MDL and SLX varies depending on the model.
- Solves some problems in previous releases with loading and saving MDL files containing Korean and Chinese characters.
- Enables incremental loading and saving. Simulink optimizes performance and memory usage by loading only required parts of the model and saving only modified parts of the model.

You can specify your file format for saving new models and libraries with the Simulink preference “File format for new models and libraries”.

Upgrade Models to SLX

If you upgrade an MDL file to SLX file format, the file contains the same information as the MDL file, and you always have a backup file. All functionality and APIs that currently exist for working with models, such as the `get_param` and `set_param`

commands, are also available when using the SLX file format. If you upgrade an MDL file to SLX file format without changing the model name or location, then Simulink creates a backup file by renaming the MDL (if writable).

If you save an existing MDL file using **File > Save**, Simulink respects the file’s current format and saves your model in MDL format.

To save an existing MDL file in the SLX file format:

- 1 Select **File > Save As**.
- 2 Leave the default **Save as type** as SLX, and click **Save**.

Simulink saves your model in SLX format, and creates a backup file by renaming the MDL (if writable) to `mymodel.mdl.releaseName`, e.g., `mymodel.mdl.R2010b`.

Alternatively, use `save_system`:

```
save_system mymodel mymodel.slx
```

This command creates `mymodel.slx`, and if the existing file `mymodel.mdl` is writable it is renamed `mymodel.mdl.releaseName`.

SLX files take precedence over MDL files, so if both exist with the same name and you do not specify a file extension, you load the SLX file.

Simulink Projects can help you migrate files to SLX. For an example, see “Upgrade Model Files to SLX and Preserve Revision History” on page 17-19.

Caution If you use third-party source control tools, be sure to register the model file extension `.slx` as a binary file format. If you do not, these third-party tools might corrupt SLX files when you submit them.

Operations with Possible Compatibility Considerations when using SLX	What Happens	Action
Hard-coded references to file names with extension <code>.mdl</code> .	Scripts cannot find or process models saved with new file extension <code>.slx</code> .	Make your code work with both the <code>.mdl</code> and <code>.slx</code> extension. Use functions like <code>which</code> and <code>what</code> instead of file names.

Operations with Possible Compatibility Considerations when using SLX	What Happens	Action
Third-party source control tools that assume a text format by default.	Binary format of SLX files can cause third-party tools to corrupt the files when you submit them.	Register <code>.slx</code> as a binary file format with third-party source control tools. Also recommended for <code>.mdl</code> files. See “Register Model Files with Source Control Tools” on page 19-10.
Changing character encoding.	Some cases are improved, e.g., SLX solves some problems in previous releases with loading and saving MDL files containing Korean and Chinese characters. However, sharing models between different locales remains problematic.	See “SLX Files and Character Encodings” on page 1-42.

The format of content within MDL and SLX files is subject to change. To operate on model data, use documented APIs (such as `get_param`, `find_system`, and `Simulink.MDLInfo` class).

Save Models with Different Character Encodings

- “MDL Files and Character Encodings” on page 1-41
- “SLX Files and Character Encodings” on page 1-42

MDL Files and Character Encodings

When you save a model, the current character encoding is used to encode the text stored in the model file. With MDL files, this can lead to model corruption if you save a model whose original encoding differs from current encoding.

If you change character encoding, it is possible to introduce characters that cannot be represented in the current encoding. If this is the case, the model is saved as `model.mdl.err`, where `model` is the model name, leaving the original model file

unchanged. Simulink also displays an error message that specifies the line and column number of the first character which cannot be represented.

To recover from this error, either:

- Save the model in SLX format (see “Save Models in the SLX File Format” on page 1-39).
- Locate and remove characters one by one.
 - 1 Use a text editor to find the character in the `.err` file at the position specified by the save error message.
 - 2 Find and delete the corresponding character in the open model and resave the model.
 - 3 Repeat this process until you are able to save the model without error.

It’s possible that your model’s original encoding can represent all the text changes made in the current session, albeit incorrectly. For example, suppose you open a model whose original encoding is A in a session whose current encoding is B. Further suppose that you edit the model to include a character that has different encodings in A and B and then save the model. If in addition the encoding for x in B is the same as the encoding for y in A, and if you insert x in the model while B is in effect, save the model, and then reopen the model with A in effect the Simulink software will display x as y. To alert you to the possibility of such corruptions, a warning message appears whenever you save a model in which the current and original encoding differ but the original encoding can encode, possibly incorrectly, all of the characters to be saved in the model file.

SLX Files and Character Encodings

Saving Simulink models in the SLX format typically reduces file size and solves some problems in previous releases with loading and saving MDL files containing Korean and Chinese characters.

Considerations for choosing a model file format:

- Use SLX if you are loading and saving models with Korean or Chinese characters
- Use SLX if you would benefit from a compressed model file
- Whether you use SLX or MDL, Simulink can detect and warn if models contain characters unsupported in the current locale. For SLX, you can use the Model Advisor to help you, see “Check model for foreign characters”.

Export a Model to a Previous Simulink Version

You can export (save) a model created with the latest version of the Simulink software in a format used by an earlier version. For example, to share a model with colleagues who only have access to a previous version of the Simulink product.

To export a model in an earlier format:

- 1 In the Simulink Editor, select **File > Save**. This saves a copy in the latest version of Simulink. This step avoids compatibility problems.
- 2 Simulink Editor, select **File > Export Model to > Previous Version**.

The Export to Previous Version dialog box appears.

- 3 In the dialog box, from the **Save as type** list, select the previous version to which to export the model. The list supports 7 years of previous releases.
- 4 Click the **Save** button.

When you export a model to a previous version's format, the model is saved in the earlier format, regardless of whether the model contains blocks and features that were introduced after that version. If the model does contain blocks or use features that postdate the earlier version, the model might not give correct results when you run it in the earlier version of Simulink software. In addition, Simulink converts blocks that postdate an earlier version into yellow empty masked Subsystem blocks. For example, if you use `save_system` to export a model to Release R2007b, and the model contains Polynomial blocks, Simulink converts the Polynomial blocks into yellow empty masked Subsystem blocks. Simulink also removes any unsupported functionality from the model. See `save_system`.

Save from One Earlier Simulink Version to Another

You can open a model created in an earlier version of Simulink and export that model to a different earlier version. To prevent compatibility problems, use the following procedure if you need to save a model from one earlier version to another earlier version.

- 1 Use the current version of Simulink to open the model created with the earlier version.
- 2 Before you make any changes, save the model in the current version by selecting **File > Save**.

After saving the model in the current version, you can change and resave it as needed.

- 3 Save the model in the earlier version of Simulink by selecting **File > Export Model to > Previous Version**.
- 4 Start the earlier Simulink version and use it to open the model that you exported to that earlier version.
- 5 Save the model in the earlier version by selecting **File > Save**.

You can now use the model in the earlier version of Simulink exactly as you could if it had been created in that version.

See also the Simulink preferences that can help you work with models from earlier versions:

- “Do not load models created with a newer version of Simulink”
- “Save backup when overwriting a file created in an older version of Simulink”

Model Editing Environment

In this section...

“Simulink Editor” on page 1-45

“Interactive Model Building” on page 1-47

“Model Design Error Detection” on page 1-48

“Library Browser” on page 1-48

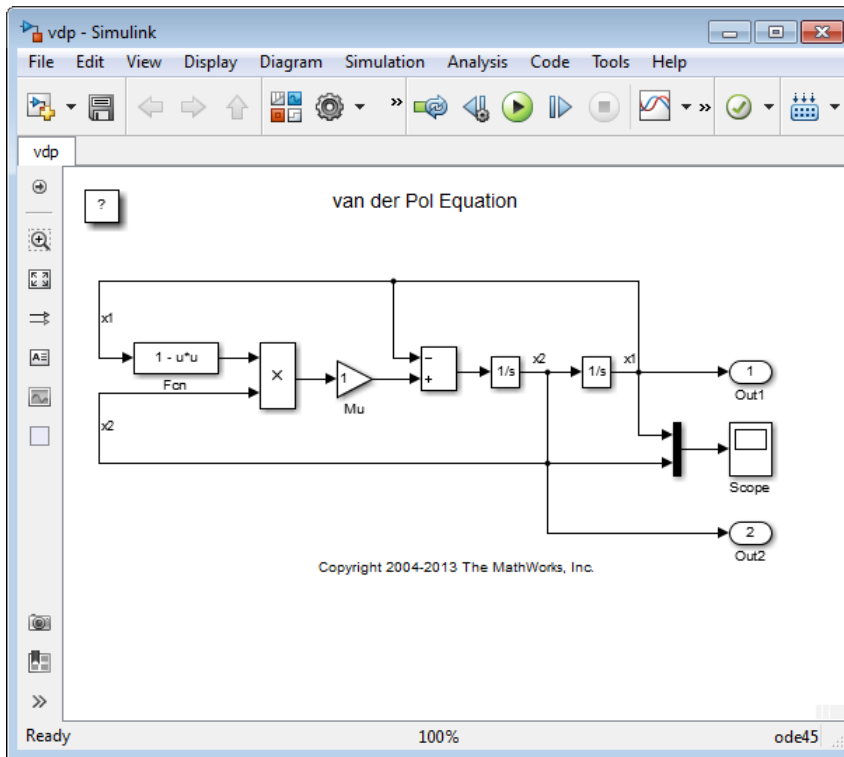

“Setting Properties and Parameters” on page 1-50

The Simulink model editing environment consists of two main tools: the Simulink Editor and the Library Browser. You find the blocks for your model in the Library Browser and build the model by adding and connecting the blocks in the Simulink Editor.

Simulink Editor

The Simulink Editor is an intuitive tool for building models. In addition to providing standard methods for working with diagrams in a vector graphics editor, the editor provides shortcuts that help you to add and connect blocks. The Simulink Editor also gives you access to the tools you need for technical operations such as importing data, simulating your model, and analyzing model performance.

The figure shows the Simulink Editor with the example model vdp open.

The Simulink Editor has menus of commands and a toolbar of shortcuts for performing frequent operations or opening tools. Tooltips appear when you hover over the toolbar buttons. Commands also appear on *context menus*. Context menus appear when you right-click a model element or a blank area of the editor. For example, right-click a block, and the menu displays the commands relevant for working on blocks, such as clipboard and alignment operations. Some commands appear only on a context menu.

Palette

The palette along the left side of the editor provides more shortcuts. The palette shortcuts have to do with the model appearance and how you navigate the model rather than how you build and operate it. For example, the palette includes a shortcut for adding annotations and other visuals, like boxed-in areas for labeling the model. It also provides a zoom button for zooming on a particular part of the model.

The **Hide/Show Explorer Bar** button displays a bar that shows where you are in the model hierarchy as you navigate. The **Hide/Show Model Browser** button displays a hierarchical view of the model that you can use to navigate. See “Explore the Model Hierarchy Using the Model Browser” on page 12-57.

Additional Model Views

The control in the lower-right corner opens additional views of the model. One such view is the interface view, which helps you to trace model interfaces. Click the control to see these views.

Interactive Model Building

When you build a model in the Simulink Editor, you use common techniques for working with graphics objects. Some of these actions include:

- Selection using click, shift-click, and dragging
- Resizing objects using handles and moving objects by dragging
- Clipboard operations, that is, cut, copy, and paste
- Undo/redo (up to 101 operations)

Note: After you undo or redo block parameter changes, a visual cue appears that shows the current values of the affected parameters. Some parameter changes are not affected by the Undo or Redo commands. After you undo or redo changes to block parameters, use the cue to see the parameters affected.

A small subset of parameters do not support Undo. Changing these parameters clears the Undo history, whether you make the change in the Property Inspector or in the block dialog box.

You zoom and scroll the editing area using familiar methods, such as the commands on the **View > Zoom** menu. If you are using a supported touch display platform, you can pinch to zoom and swipe to scroll. The supported touch display devices include Microsoft Windows platforms with a Windows 7 certified or Windows 8 certified touch display and Macintosh platforms with an Apple Magic Trackpad.

The editor supports additional shortcuts for scrolling that are unique to Simulink. Shortcuts and the other interactive model building techniques are summarized in “Keyboard and Mouse Actions for Simulink Modeling” on page 1-90. For a tutorial, see “Build and Edit a Model in the Simulink Editor” on page 1-23.

Model Design Error Detection

The Simulink Editor can provide you with visual cues for some model design issues. In the model editor, highlighted blocks alert you to issues while you edit. To see a description of the issue, hover over a highlighted block and click the error or warning symbol.

Simulink can detect block errors and warnings, such as:

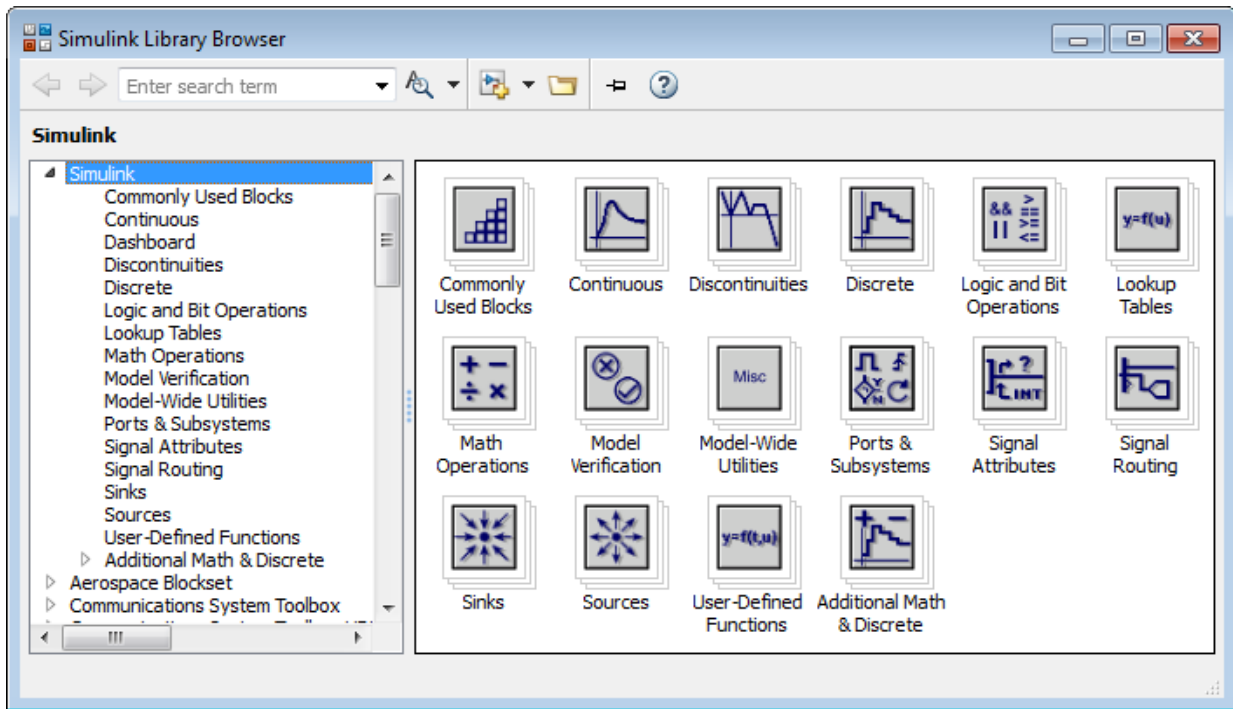

- Goto and From block mismatches.
- Duplicate data store blocks. The value of the Duplicate data store names parameter determines if there is a visual cue, and if the cue is an error or warning.

The **Errors and Warnings** option is enabled by default. To turn off this option, select **Display > Errors & Warnings**.

Library Browser

Use the Library Browser to locate blocks and visuals (annotations) to add to your model. Navigate the libraries using the tree structure in the left pane or by double-clicking sublibraries in the right pane. Sublibraries, blocks, and text and image annotations can appear in the right pane. Hover over any item to see a description.

When you find the item you are looking for, you can drag it into your model, or you can select it and use the context menu to add it.

Tip The Recently Used Blocks structure at the bottom of the tree contains the blocks and libraries from the supplied libraries that you used most recently.

You can search for blocks and annotations using the search controls. To use regular expressions, whole word search, or case-sensitive search, use the **Search for subsystems, blocks, and annotations** button arrow . For annotations, you can search for any of the text in the annotation or any part of its description.

By default, library contents appear in alphabetical order. Subsystems appear first, then blocks, and then annotations. If you prefer to view the contents of the libraries in the order set by the developer of the library, right-click the right pane and select **Sort in library model order**. This setting stays in effect from session to session.

To return to the alphabetical order, right-click and select **Sort in alphabetical order**. Depending on how the library designer set up the library, some items might not appear

in alphabetical order. For example, in the **Simulink** library, the Additional Math & Discrete library appears as the last item regardless of the sorting option you choose.

You can create your own libraries and, optionally, have them appear in the Library Browser. See “Create a Custom Library” on page 38-3. “Setting Properties and Parameters” on page 1-50

Setting Properties and Parameters

As you build a model, you can set parameters and properties on model elements. For example, you can set parameters and properties for blocks that affect how the block functions. You can also set properties on Stateflow charts, signal lines, visual elements such as annotations, and on the model.

Based on your workflow and goals, set parameters and properties using:

- The Property Inspector, which stays open in the editor as you work and updates based on the current selection
- A dialog box that is associated with an element, such as a specific block

When you select **View > Property Inspector**, the interface appears in the Simulink Editor on the right. You can drag it from the default location and dock it in another location in the editor. The figure shows a block selected with the Property Inspector displayed.

The Property Inspector is useful when you are setting parameters and properties as you work, because it is always open and available for setting values for the current selection. Values take effect as soon as you set them. This workflow simplifies your interaction with the interface.

You can alternatively open a dialog box for a selected model element using an item on the **Diagram** menu, such as **Properties** and, for blocks, **Block Parameters**. You can also use the context menu. Double-clicking a block generally opens a block dialog box. (You must use one of the menu commands on Subsystem and Model blocks.) For more information on setting block properties and parameters, see “Block Parameters and Properties in Simulink” on page 1-54.

The Property Inspector and the dialog boxes operate on a single selection. The main difference is that the Property Inspector updates with each selection and the dialog box shows the settings only for the element you opened it from. For this reason, the dialog box is useful if:

- You are moving through the model hierarchy and want to see or set an element’s parameters or properties as you navigate the model.
- You want to compare the parameters or properties of similar elements.
- The settings are advanced and appear only in the dialog box.

Parts of a Model

In this section...

“About Blocks” on page 1-53

“Block Parameters and Properties in Simulink” on page 1-54

“Signals” on page 1-56

You create a Simulink model by adding blocks, specifying block behavior, and using signal lines to connect the blocks to each other according to the dynamics of the system that you want to simulate.

About Blocks

Blocks are the main elements that you use to build models in Simulink. Generally, you add blocks from the supplied Simulink libraries to perform specific operations, such as math, as shown in “Build and Edit a Model in the Simulink Editor” on page 1-23.

You can further classify blocks in Simulink.

- Virtual blocks — These blocks help to organize a model and do not affect simulation. See “Nonvirtual and Virtual Blocks” on page 33-2.
- Subsystem blocks — Subsystems help you to organize your models hierarchically. You use a Subsystem block to encapsulate related parts of a model, that is, a representation of a system within the larger system that you are modeling. See “Model Hierarchy”.
- Masked blocks — You can add a mask to any block in a model. A mask is a custom interface that enables you to show only the block parameters and settings that you want the user of the block to have access to. A mask also provides an interface for setting parameters on blocks inside a subsystem without having to navigate the hierarchy. You can change the block appearance using a mask. See “Block Masks”.
- Referenced models — A model reference is a way to include a model in another model. You use a Model block to reference a model. See “Model Referencing”.
- Linked blocks — A linked block is an instance of a block from a custom library that links to the library block. You can create a library of blocks that you configure for your specific purposes. For example, you can create subsystems and masked blocks and store them in a library for reuse. When you add a block to a model from a library that you created, the block keeps a link to the library version, called a *library link*. You can modify a linked block only by disabling the link. See “Libraries”.

Block Parameters and Properties in Simulink

For most blocks, you can specify parameters that determine how the block works. For example, in the Trigonometric Function block, you specify the trigonometry function that you want the block to perform. For some blocks, you can specify the number of inputs or outputs. Whether the block has parameters that you can set and the nature of those parameters is specific to each block. For detailed information on parameter values, see “Set Block Parameter Values” on page 34-2.

You set block parameters in the Property Inspector or in a block dialog box.

- To open the Property Inspector, select **View > Property Inspector**. Select the block whose parameters you want to view or set. The parameters appear in the **Parameters** tab.
- To open the block dialog box, select **Diagram > Block Parameters** or, for most blocks, double-click the block. You can also use the context menu.

To understand the differences between these approaches, see “Setting Properties and Parameters” on page 1-50.

Some block parameters do not appear in the Property Inspector. For example, some advanced parameters do not appear in the Property Inspector. To open the block dialog box instead, in the Property Inspector, click **Open**. See the documentation for your product to learn more about setting block parameters in the Property Inspector.

Blocks also have properties which are not specific to the block. Block properties enable you to configure the block to execute code when you perform actions such as opening the block or starting simulation. For example, you can set up a MATLAB script to perform tasks such as loading or defining variables for a block or any other callback functions. See “Callbacks for Customized Model Behavior” on page 4-56. Block properties also enable you to annotate the block and define callback functions. See “Specify Block Properties” on page 33-4.

You can set block properties on the **Properties** tab of the Property Inspector. Alternatively, you can use the Block Properties dialog box.

Additional Parameters and Properties

Simulink has these additional types of parameters and properties.

- Programmatically accessible parameters — Blocks and models have parameters whose value you do not set explicitly in the editor. For example, each block has

a position parameter that is based on where you place the block in the model. There is no single interface to these parameters, but you can query and set any of them programmatically. You can also set any of the block-specific parameters programmatically. See “Common Block Properties” and “Model Parameters”.

- Model configuration parameters — Use configuration parameters (**Simulation > Model Configuration Parameters**) to specify simulation conditions, such as the solver to use, the types of errors and warnings to display, and how you want to store simulation data. See “Configuration Parameters Dialog Box Overview”.
- Model properties — Model properties help you to define callbacks for the model. They also enable you to add a description and specify data to load or scripts to run, along with other settings. You can view and set model properties in the Property Inspector when there is no selection in the top level of a model. Otherwise, use **File > Model Properties**. See “Manage Model Properties” on page 4-88.

Note: Simulink preferences (**File > Simulink Preferences**) help you to customize your model editing environment, such as how your scroll wheel functions and saving options. See “Set Simulink Preferences”.

Setting Parameter Values in Workspaces

Simulink gives you access to two workspaces where you can set values for parameters. Workspaces enable you to set parameters by using variables rather than setting every value on every block in a model. This approach is especially useful when your model is large and complex because you do not need to locate every block whose parameter value you want to set or change. Instead, assign a variable as the value of a parameter and define the variable in a workspace. This mechanism also allows you to use different sets of parameter values for the same model.

In the *MATLAB base workspace*, you can define parameters using any MATLAB mechanism for defining a variable. For example, you can use a MAT-file and load the variables when you open the model (see “Load Variables When Opening a Model” on page 1-10). Using the MATLAB base workspace to define variables is useful when you are using the same set of parameters for more than one model.

You can also define parameters by assigning values to variables in a *model workspace*. You define a set of parameters that are specific to the model and save them with the model. See “Model Workspaces” on page 4-71.

Signals

As you can see in “Build and Edit a Model in the Simulink Editor” on page 1-23, you use signal lines to connect blocks in a model. At a minimum, a model takes an input signal, operates on it, and outputs the result. In the Library Browser, the Sources library contains blocks that represent input signals. The Sinks library contains blocks for capturing and displaying outputs.

Simulink represents signals as lines. The line style varies with the type of signal. You create signals between the output port of one block and the input port of another block by drawing or using shortcuts.

For more on signals, see “Signals” and “Block and Signal Line Shortcuts and Actions” on page 1-91.

Preview Content of Hierarchical Items

In this section...

“What Is Content Preview?” on page 1-57

“Enable Content Preview” on page 1-58

“What Content Preview Displays” on page 1-58

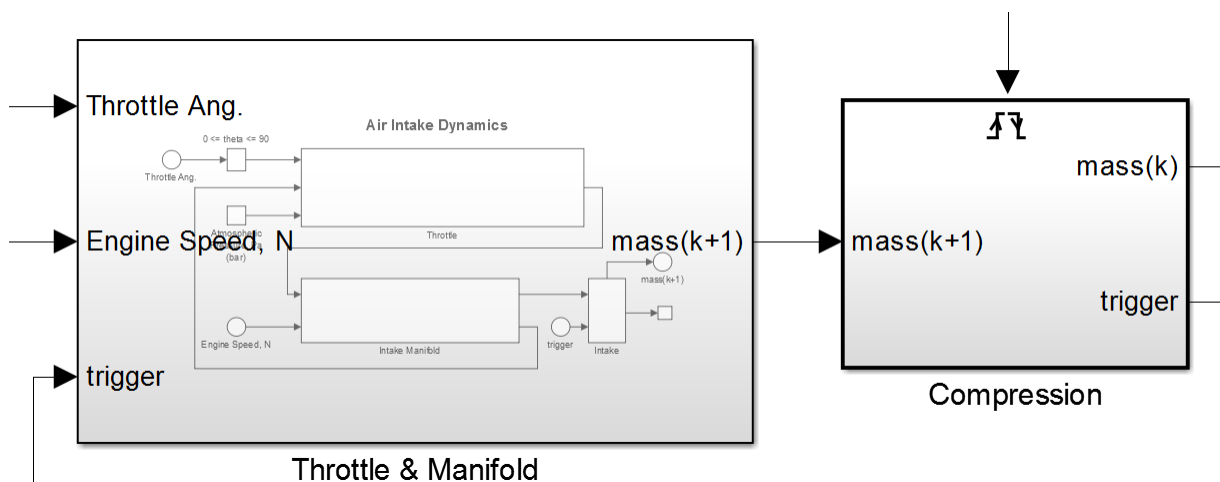

What Is Content Preview?

Content preview displays a representation of the contents of a hierarchical item, such as a subsystem, on the block. Content preview helps you to understand at a glance the kind of processing performed by the hierarchical item.

Hierarchical items that support content preview are:

- Subsystem blocks (but not masked subsystems)
- Model blocks (for referenced models)
- Stateflow charts, subcharts, and graphical functions

By default, the Simulink Editor displays models without content preview. Enable or disable content preview for each block or subsystems. For example, in this model, the Throttle & Manifold subsystem has content preview enabled, and the Compression subsystem does not.

Content preview displays a representation of the contents of a hierarchical item. For details, see “What Content Preview Displays” on page 1-58.

A slight delay can occur in drawing models that contain many hierarchical items that enable content preview if those items contain many blocks.

Enable Content Preview

Content preview settings apply across Simulink sessions.

- 1 In the Simulink or Stateflow Editor, select the Subsystem or Model blocks or charts whose content you want to preview. To enable content preview for multiple instances of the same referenced model, select each Model block.
- 2 From the context menu, select **Format > Content Preview**.
- 3 To see the content preview for a Model block, open the block.

Tip To apply content preview to the whole model, use **Edit > Select All** before enabling content preview.

Enable for Model Blocks

Enabling content preview for Model blocks requires opening the referenced model.

- 1 In the Simulink Editor, right-click the Model block.
- 2 Select **Format > Content Preview**.
- 3 Open the Model block.

What Content Preview Displays

Simulink scales the content preview to fit the size of the block. To improve the readability of the content preview, you can:

- Zoom.
- Resize the block.

In addition to block icons and signals, content preview displays the following, if present in the system:

- Block labels

- Signal labels
- Highlighted blocks for signals with **Highlight Signal to Source** or **Highlight Signal to Destination** enabled
- Sample time color coding
- Stateflow animation

Simulink does not display content preview for:

- Masked blocks
- Hierarchical block icons when they are smaller than their default size in the Library Browser
- Subsystem blocks when they have the **Read/Write permissions** block parameter set to **NoReadOrWrite**.
- Protected Model blocks
- Model blocks whose referenced models are not loaded
- Models that have **Simulink Preferences > Editor Preferences > Use classic diagram theme** enabled.

The content preview image does not show:

- Block icon graphics, including masked block images
- The content of other hierarchical items contained in the content preview
- Signal line styles (for example, for buses)
- Port information such as port values

Use Viewmarks to Save Views of Models

In this section...
“What Are Viewmarks?” on page 1-60
“Create a Viewmark” on page 1-61
“Open and Navigate Viewmarks” on page 1-62
“Manage Viewmarks” on page 1-62
“Refresh a Viewmark” on page 1-63

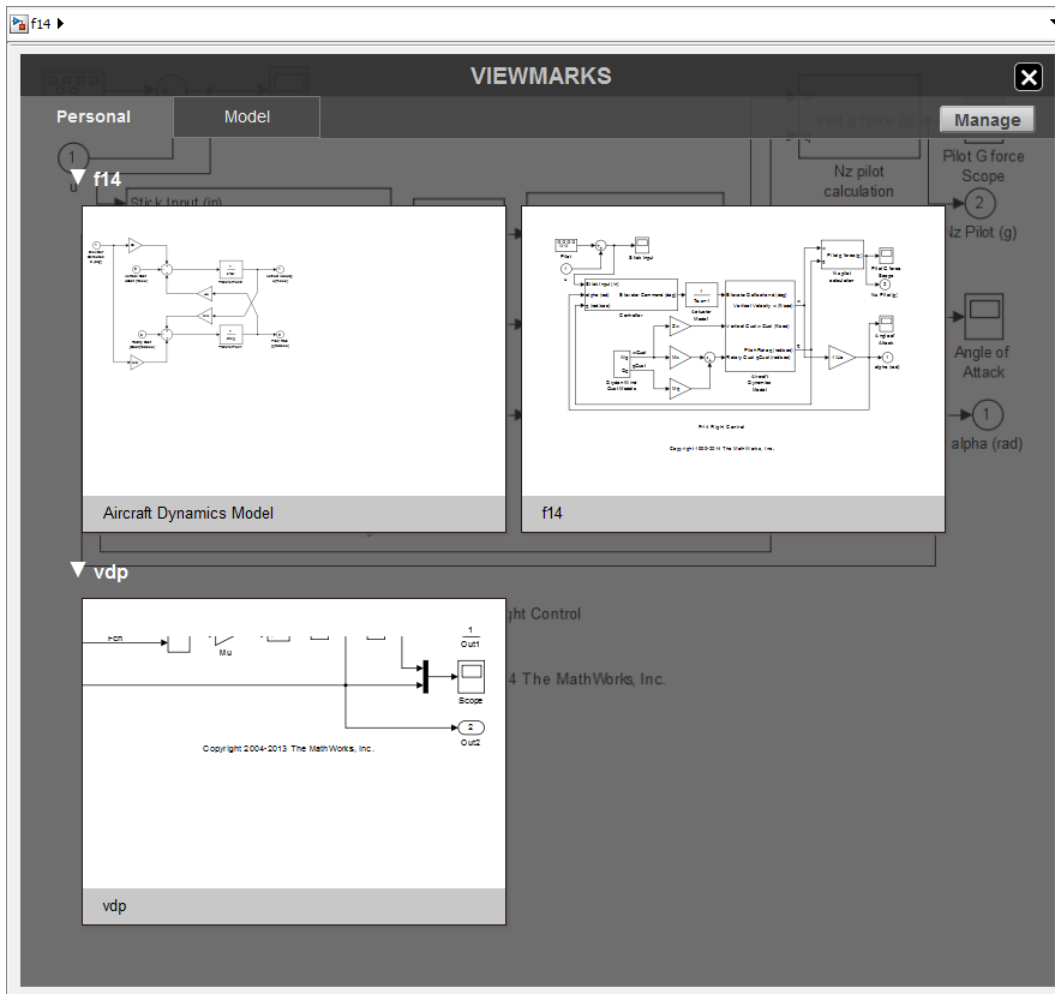

What Are Viewmarks?

Viewmarks are bookmarks to parts of a model. Use viewmarks to capture graphical views of a model so you can navigate directly to that view. You can capture viewmarks for specific levels in a model hierarchy. You can also pan and zoom to capture a point of interest.

Some examples of ways you can use viewmarks include:

- Navigate to specific locations in complex models without opening multiple Simulink Editor tabs or windows.
- Review model designs.
- Visually compare versions of a model.
- Share views of a model by storing viewmarks within the model.

You manage viewmarks in the viewmarks gallery. By default, viewmarks are stored locally on your computer. If you want to include a viewmark to share with a model, see “Save a Viewmark with the Model” on page 1-63. The figure shows the viewmark gallery.

Create a Viewmark

- 1 Navigate to the part of the model that you want to capture in a viewmark.
- 2 Pan and zoom to the part of the system that you want to capture.
- 3 Resize the Simulink Editor window so that it frames the part of the model you want to capture.

- 4 In the palette, click the **Viewmark This View** button .

The viewmark displays briefly and becomes part of the viewmarks gallery.

Open and Navigate Viewmarks

The viewmarks gallery has two tabs. The **Personal** tab consists of viewmarks that you created in a model and are stored locally on your computer. The **Model** tab consists of viewmarks that are saved in the Simulink model file.

- 1 In the Simulink Editor palette, click the **Viewmarks** button .
- 2 Select the tab (**Personal** or **Model**) that contains your viewmark, and then click the viewmark.

The Simulink Editor opens the model, if necessary, and displays the part of the model captured in the viewmark.

Manage Viewmarks

In the viewmarks gallery, you can rename viewmarks, add or edit a description for viewmark, and delete viewmarks. You also use the viewmarks gallery to save viewmarks with the model. You can manage viewmarks only in models saved in SLX format. In models saved in MDL format, the **Manage** button appears dimmed.

- To rename a viewmark, click the name and edit it.
- To add a description, click the viewmark Description button  and enter a description.
- To delete a viewmark, click the **Delete** button  on the viewmark. To delete all the viewmarks for a model, hover over the model name and click **Delete**.

You can replace the generated viewmark name.

- 1 Place the cursor in the viewmark name edit box.
- 2 Enter the new name.

You can also add a viewmark description. For example, you can add a description of the part of the model in the viewmark or add review comments.

- 1 Hover over the viewmark.
- 2 Click the **Description** button .
- 3 In the description edit box, enter the description.

Save a Viewmark with the Model

- 1 In the Simulink Editor palette, click the **Viewmarks** button .
- 2 In the viewmarks gallery, click **Manage**.
- 3 Select the check box in the viewmarks you want to copy to the model.
- 4 Click the **Add viewmarks to model** button .

These viewmarks become part of the model and are saved with the model.

Refresh a Viewmark

A viewmark is a static view of a part of a model. For currently loaded models, you can refresh a viewmark so that it reflects the current model. Open the viewmark gallery and click the **Refresh** button  on the viewmark.

If the viewmark shows a subsystem that has been removed, then the viewmark appears dimmed.

Update Diagram and Run Simulation

Updating the Diagram

You can leave many attributes of a block diagram, such as signal data types and sample times, unspecified. The Simulink software then infers the values of block diagram attributes, based on the block connectivity and attributes that you specify. The process that Simulink uses is known as *updating the diagram*.

Simulink attempts to infer the most appropriate values for attributes that you do not specify. If Simulink cannot infer an attribute, it halts the update and displays an error.

Simulation Updates the Diagram

Simulink updates the diagram at the start of a simulation. The updated diagram provides the simulation with the results of the latest changes that you have made to a model.

Update Diagram While Editing

As you create a model, at any point you can update the diagram. Updating the diagram periodically can help you to identify and fix potential simulation issues as you develop the model. This approach can make it easier to identify the sources of problems by focusing on a set of recent changes. Also, the update diagram processing takes less time than performing a simulation, so you can identify issues more efficiently.

To update the diagram select **Simulation > Update Diagram**, or press **Ctrl+D**.

This example shows the effects of updating the diagram.

- 1 Create the following model.

- 2 Select **Display > Signals & Ports > Port Data Types**.

The data types of the output ports of the Constant and Gain blocks appear. The data type of both ports is **double**, the default value.

- 3 In the **Constant** block dialog box, set **Output data type** to **single**.

The output port data type displays on the block diagram do not show this change.

- 4 Select **Simulation > Update Diagram**.

The updated block diagram shows the change to the output data type for the Constant block.

In this example, Simulink infers a data type for the output of the Gain block because you did not specify a data type for it. The data type inferred is **single**, because single precision is all that is needed to simulate the model accurately given that the precision of the block input is **single**.

Simulate a Model

For any type of model you build in Simulink, you need to know how to simulate. Simulating performs the operations specified by the blocks in the model and its specific configuration and produces results. See “Simulation” for complete information, such as how to configure your model for simulation.

Use any of these methods to simulate a model:

- Select **Simulation > Run**.
- Press **Ctrl+T**.
- Click the **Run** button .

Print Model Diagrams

In this section...

“Print Interactively or Programmatically” on page 1-67

“Printing Options” on page 1-67

“Canvas Color” on page 1-67

Print Interactively or Programmatically

You can print a block diagram:

- Interactively in the Simulink Editor, by selecting **File > Print**
- Programmatically, by using the MATLAB `print` command

To control some additional aspects of printing a block diagram, use the `set_param` command with model parameters. You can use `set_param` with the interactive and programmatic printing interface.

Printing Options

In addition to printing a model using default settings, you can:

- “Select the Systems to Print” on page 1-74.
- “Specify the Page Layout and Print Job” on page 1-76
- “Print Multiple Pages for Large Models” on page 1-78
- “Print Using Print Frames” on page 66-13
- “Print to a PDF” on page 1-85
- “Add a Log of Printed Models” on page 1-79
- “Add a Sample Time Legend” on page 1-80
- “Print Models to Image File Formats” on page 1-89

Canvas Color

By default, the canvas (background) of the printed model is white. To match the color of the model, set the **Simulink Preferences > General > Print** preference.

Basic Printing

In this section...

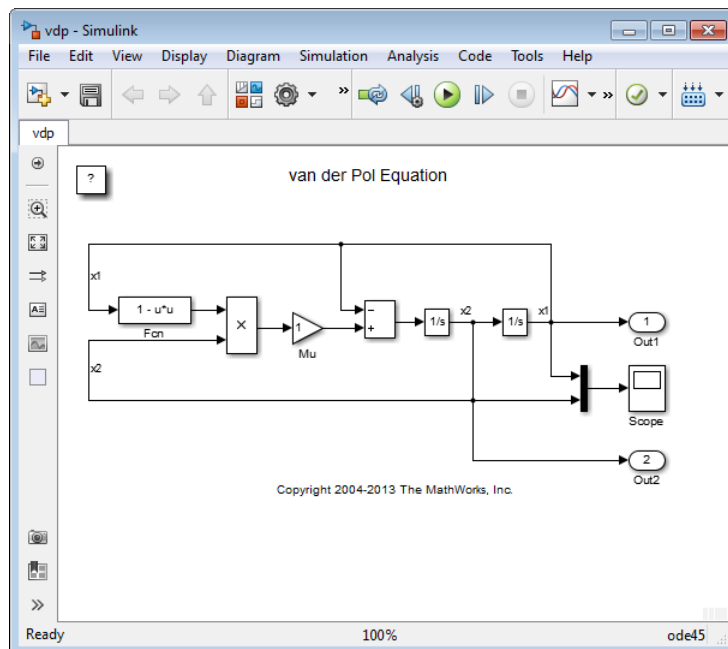

“Print the vdp Model Using Default Settings” on page 1-69

“Print a Subsystem Hierarchy” on page 1-71

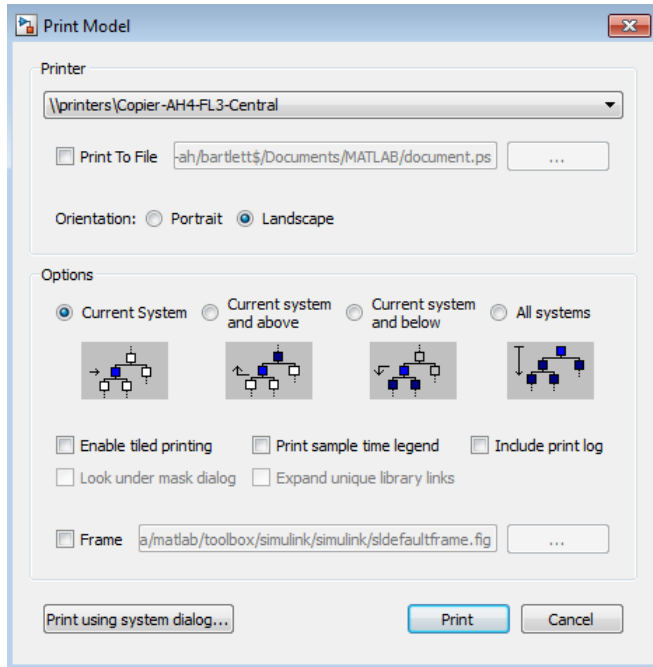

Print the vdp Model Using Default Settings

The default print settings produce good quality printed output for quickly capturing a model in printed form.

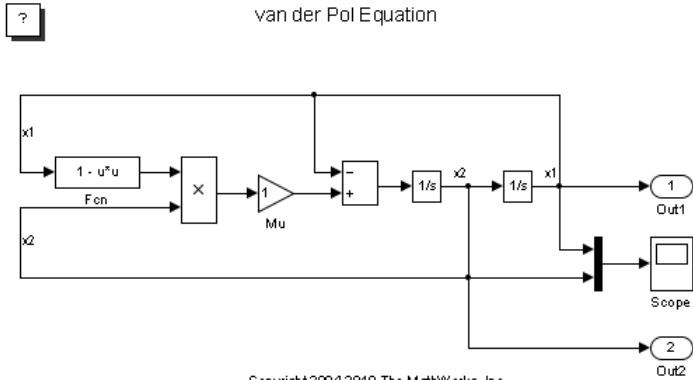

- 1 Open the vdp model.

- 2 In the Simulink Editor, select **File > Print > Print**.
- 3 In the Print Model dialog box, use the default settings. Click **Print**.

The output looks like this. The model, as it appears in the Simulink Editor, prints on a single page, using portrait orientation and not using a print frame.

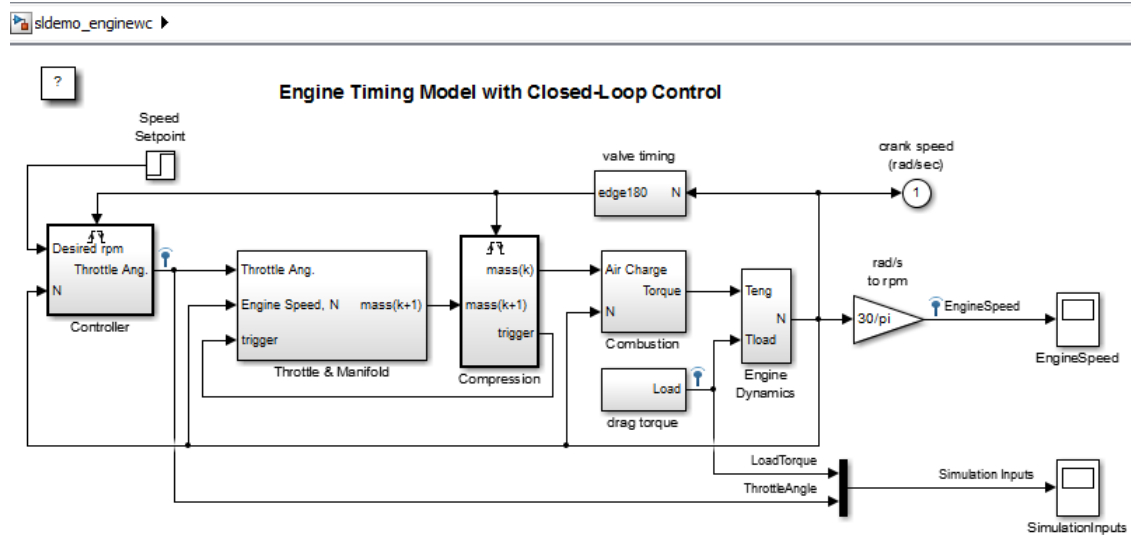

Copyright 2004-2010 The MathWorks, Inc.

Print a Subsystem Hierarchy

You can print levels in nested subsystems.

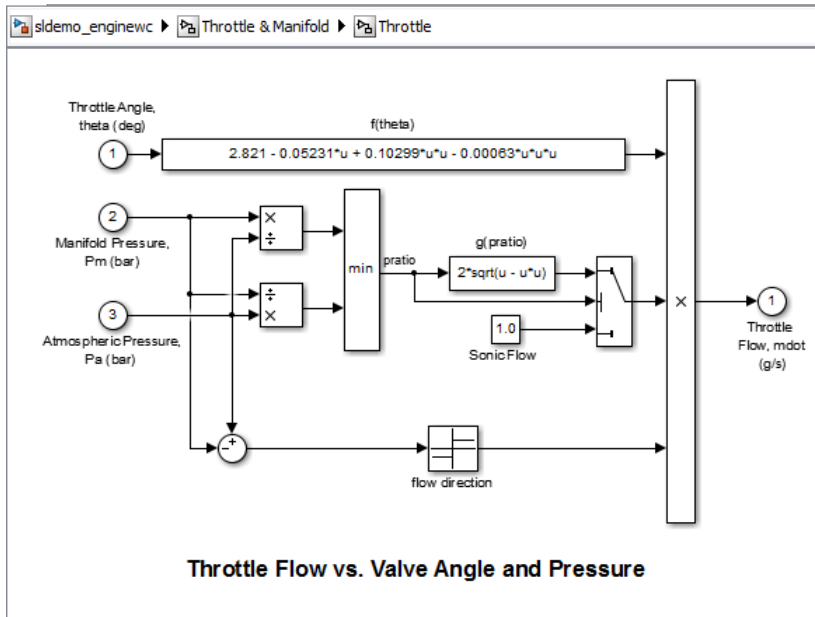

- 1 Open the `sldemo_enginewc` model.

- 2 Open the Throttle & Manifold subsystem.

3 Open the Throttle subsystem.

4 In the Simulink Editor, select **File > Print > Print**.

5 In the Print Model dialog box, click **Current system and above** and click **Print**.

The printed output shows the Throttle subsystem (the current system) and the two levels above it in the subsystem hierarchy.

More About

- “Print Model Diagrams” on page 1-67

Select the Systems to Print

In this section...
“Print Current System” on page 1-74
“Print Subsystems” on page 1-74
“Print a Model Referencing Hierarchy” on page 1-75

Print Current System

To select a specific system in a model to print, display that system in the currently open Simulink Editor tab and select **File > Print > Print**.

Print Subsystems

For models with subsystems, use the Simulink Editor and the Print Model dialog box to specify the systems in the model to print.

By default, Simulink does not print masked subsystems or library links. For information about masked subsystem and library link printing, see “Print Masked Subsystems and Library Links” on page 1-75.

Print All Subsystems in a Model

Use this procedure to print all of the subsystems in a model, including hierarchies of subsystems.

- 1 Display the top-level model in the currently open Simulink Editor tab.
- 2 In the Simulink Editor, select **File > Print > Print**.
- 3 In the Print Model dialog box, select **All systems**.
- 4 Click **Print**.

Print the Contents of a Specific Subsystem

In the currently open Simulink Editor tab, display the subsystem that you want to print and click **Print**.

Print a Subsystem Hierarchy

Use this procedure to print nested subsystems.

- 1 In the current tab of the Simulink Editor, display the subsystem level that you want to use as the starting point for printing the subsystem hierarchy.
- 2 In the Print Model dialog box, select one of the following:
 - **Current system and below**
 - **Current system and above**
- 3 Click **Print**.

Simulink prints the hierarchy for all of the subsystems in the current tab.

Print Masked Subsystems and Library Links

To print the contents of masked subsystems, in the Print Model dialog box, click **Look under mask dialog**.

To print the contents of library links, in the Print Model dialog box, click **Expand unique library links**. Simulink prints one copy, regardless of how many copies of the block the model contains.

If a subsystem is both a masked subsystem and a library link, Simulink uses the **Look under mask dialog** setting and ignores the **Expand unique library links** setting.

Print a Model Referencing Hierarchy

To print a model referencing hierarchy, open each level of the hierarchy and print that level.

Clicking **All systems** does not print different levels in the model referencing hierarchy.

You cannot print the contents of protected models.

More About

- “Model Hierarchy”

Specify the Page Layout and Print Job

In this section...
“Page and Print Job Setup” on page 1-76
“Set Paper Size and Orientation Without Printing” on page 1-76

Page and Print Job Setup

Use the Print Model dialog box to specify the page orientation (portrait or landscape) for the current printing session.

To open the print dialog box for your operating system, in the Print Model dialog box, click **Print using system dialog**. The operating system print dialog box provides additional printing options for models, such as page range, copies, double-sided printing, printing in color (if your print driver supports color printing), and nonstandard paper sizes.

Set Paper Size and Orientation Without Printing

To specify paper size and orientation without printing, use the Page Setup dialog box. To open the dialog box, select **File > Print > Page Setup**.

Only the paper size and orientation are used.

Related Examples

- “Basic Printing” on page 1-69

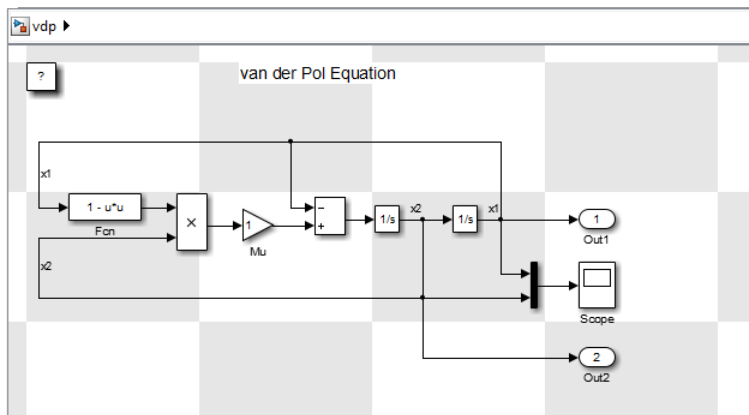

More About

- “Print Model Diagrams” on page 1-67

Tiled Printing

By default, each block diagram is scaled during the printing process so that it fits on a single page. In the case of a large diagram, this automatic scaling can make the printed image difficult to read.

Tiled printing enables you to print even the largest block diagrams without sacrificing clarity and detail. Tiled printing allows you to distribute a block diagram over multiple pages. For example, you can use tiling to divide a model as shown in the figure, with each white box and each gray box representing a separate printed page.

You can control the number of pages over which Simulink prints the block diagram.

Also, you can set different tiled-print settings for each of the systems in your model.

Note: If you enable the print frame option, then Simulink does not use tiled printing.

Related Examples

- “Print Using Print Frames” on page 66-13
- “Print Multiple Pages for Large Models” on page 1-78

Print Multiple Pages for Large Models

- 1 In the Simulink Editor, open the model in the current tab.
- 2 Select **File > Print > Print**.
- 3 In the Print Model dialog box, click **Enable tile printing**.

The default Enable tile printing setting in the Print Model dialog box is the same as the **File > Print > Enable Tiled Printing** setting. If you change the Print Model dialog box **Enable tile printing** setting, the Print Model dialog box setting takes precedence.

- 4 Confirm that tiling divides the model into separate pages the way you want it to appear in the printed pages. In the Simulink Editor, select **File > Print > Show Page Boundaries**. The gray and white squares indicate the page boundaries.
- 5 Optionally, from the MATLAB command line, specify the model scaling, tile margins, or both. See “Set Tiled Page Scaling and Margins” on page 1-83.
- 6 Optionally, specify a subset of pages to print. In the Print Model dialog box, specify the **Page Range**.
- 7 Click **Print**.

Related Examples

- “Use Tiled Printing” on page 1-83

More About

- “Tiled Printing” on page 1-77

Add a Log of Printed Models

A print log lists the blocks and systems printed. To print the print log when you print a model:

- 1 In the Simulink Editor, open the model whose print job you want to log.
- 2 Select **File > Print > Print**.
- 3 In the Print Model dialog box, click **Include print log**.
- 4 Click **Print**.

The print log appears on the last page.

For example, here is the print log for the `sldemo_enginewc` model, with **All systems** enabled and **Enable tiled printing** cleared.

```

Page      System Name
-----
1         sldemo_enginewc
2         sldemo_enginewc/Combustion
3         sldemo_enginewc/Compression
4         sldemo_enginewc/Controller
5         sldemo_enginewc/Controller/prevent windup
6         sldemo_enginewc/Engine Dynamics
7         sldemo_enginewc/More Info
8         sldemo_enginewc/Throttle & Manifold
9         sldemo_enginewc/Throttle & Manifold/Intake Manifold
10        sldemo_enginewc/Throttle & Manifold/Throttle
11        sldemo_enginewc/drag torque
12        sldemo_enginewc/valve timing
13        sldemo_enginewc/valve timing/TDC and BDC detection
14        sldemo_enginewc/valve timing/positive edge to dual
edge conversion

```

More About

- “Print Model Diagrams” on page 1-67

Add a Sample Time Legend

You can print a legend that contains sample time information for your entire system, including any subsystems. The legend appears on a separate page from the model. To print a sample time legend:

- 1 In the Simulink Editor, select **Simulation > Update diagram**.
- 2 Select **File > Print > Print**.
- 3 In the Print Model dialog box, click **Print sample time legend**.
- 4 Click **Print**.

A sample time legend appears on the last page. For example, here is the sample time legend for the `sldemo_enginewc` model, with **All systems** enabled.

Sample Times for 'sldemo_enginewc'

Color	Description	Value
	Continuous	0
	Fixed in Minor Step	[0,1]
	Constant	Inf
	Triggered	Source: FiM

Print from the MATLAB Command Line

In this section...

“Printing Commands” on page 1-81

“Print Systems with Multiline Names or Names with Spaces” on page 1-81

“Set Paper Orientation and Type” on page 1-82

“Position and Size a System” on page 1-82

“Use Tiled Printing” on page 1-83

Printing Commands

The MATLAB `print` command provides several options for printing Simulink models. For example, print the `Compression` subsystem in the `sldemo_enginewc` model to your default printer:

```
open_system('sldemo_enginewc');  
print -sCompression
```

Tip When you use the `print` command, you can print only one system. To print multiple levels in a model, use multiple `print` commands, one for each system that you want to print. To print multiple systems in a model, consider using the Print Model dialog box in the Simulink Editor. For details, see “Select the Systems to Print” on page 1-74.

You can use `set_param` to specify printing options for models. For details, see “Model Parameters”.

You can use `orient` to control the paper orientation.

Print Systems with Multiline Names or Names with Spaces

To print a system whose name appears on multiple lines, assign the newline character to a variable and use that variable in the `print` command. This example shows how to print a subsystem whose name, `Aircraft Dynamics Model`, appears on three lines.

```
open_system('f14');  
open_system('f14/Aircraft Dynamics Model');
```

```
sys = sprintf('f14/Aircraft\nDynamics\nModel');  
print (['-s' sys])
```

To print a system whose name includes one or more spaces, specify the name as a character vector. For example, to print the Throttle & Manifold subsystem, enter:

```
open_system('sldemo_enginewc');  
open_system('sldemo_enginewc/Throttle & Manifold');  
print (['-sThrottle & Manifold'])
```

Set Paper Orientation and Type

To set just the paper orientation, use the MATLAB `orient` command.

You can also set the paper orientation by using `set_param` with the `PaperOrientation` model parameter. Set the paper type with the `PaperType` model parameter.

Position and Size a System

To position and size the model diagram on the printed page, use `set_param` command with the `PaperPositionMode` and `PaperPosition` model parameters.

The value of the `PaperPosition` parameter is a vector of form `[left bottom width height]`. The first two elements specify the bottom-left corner of a rectangular area on the page, measured from the bottom-left corner. The last two elements specify the width and height of the rectangle.

If you set the `PaperPositionMode` parameter to `manual`, Simulink positions (and scales, if necessary) the model to fit inside the specified print rectangle. If `PaperPositionMode` is `auto`, Simulink centers the model on the printed page, scaling the model, if necessary, to fit the page.

For example, to print the `vdp` model in the lower-left corner of a U.S. letter-size page in landscape orientation:

```
open_system('vdp');  
set_param('vdp', 'PaperType', 'usletter');  
set_param('vdp', 'PaperOrientation', 'landscape');  
set_param('vdp', 'PaperPositionMode', 'manual');  
set_param('vdp', 'PaperPosition', [0.5 0.5 4 4]);
```

```
print -svdp
```

Use Tiled Printing

Enable Tiled Printing

- 1 Use `set_param` to set the `PaperPositionMode` parameter to `tiled`.
- 2 Use the `print` command with the `-tileall` argument.

For example, to enable tiled printing for the `Compression` subsystem in the `sldemo_enginewc` model:

```
open_system('sldemo_enginewc');  
set_param('sldemo_enginewc/Compression', 'PaperPositionMode', ...  
'tiled');  
print('-ssldemo_enginewc/Compression', '-tileall')
```

Display Tiled Page Boundaries

To display the page boundaries programmatically, use the `set_param` command, with the model parameter `ShowPageBoundaries` set to `on`. For example:

```
open_system('sldemo_enginewc');  
set_param('sldemo_enginewc', 'ShowPageBoundaries', 'on')
```

Set Tiled Page Scaling and Margins

To scale the block diagram so that more or less of it appears on a single tiled page, use `set_param` with the `TiledPageScale` parameter. By default, the value is 1. Values greater than 1 proportionally scale the model to use a smaller percentage of the tiled page, while values between 0 and 1 proportionally scale the model to use a larger percentage of the tiled page. For example, a `TiledPageScale` of 0.5 makes the printed diagram appear twice its size on a tiled page, while a `TiledPageScale` value of 2 makes the printed diagram appear half its size on a tiled page.

By decreasing the margin sizes, you can increase the printable area of the tiled pages. To specify the margin sizes associated with tiled pages, use `set_param` with the `TiledPaperMargins` parameter. Each margin is 0.5 inches by default. The value of `TiledPaperMargins` is a vector that specifies margins in this order: `[left top right bottom]`. Each element specifies the size of the margin at a particular edge of the page. The value of the `PaperUnits` parameter determines the units of measurement for the margins.

Specify Range of Tiled Pages to Print

To specify a range of tiled page numbers programmatically, use `print` with the `-tileall` argument and the `-pages` argument. Append to `-pages` a two-element vector that specifies the range.

Note: Simulink uses a row-major scheme to number tiled pages. For example, the first page of the first row is 1, the second page of the first row is 2, and so on.

For example, to print the second, third, and fourth pages:

```
open_system('vdp');  
print('-svdp','-tileall','-pages[2 4]')
```

Print to a PDF

You can print a model to a `.pdf` file. Simulink creates one file for all of the systems in the model.

- 1 In the Simulink Editor, select **File > Print > Print**.
- 2 Select the **Print to File** check box.
- 3 Specify a location and file name to save the new `.pdf` file. Include the extension `.pdf` in the file name.
- 4 Click **Print**.

More About

- “Print Model Diagrams” on page 1-67

Print Model Reports

A model report is an HTML document that describes the structure and content of a model. The report includes block diagrams of the model and its subsystems and the settings of its block parameters.

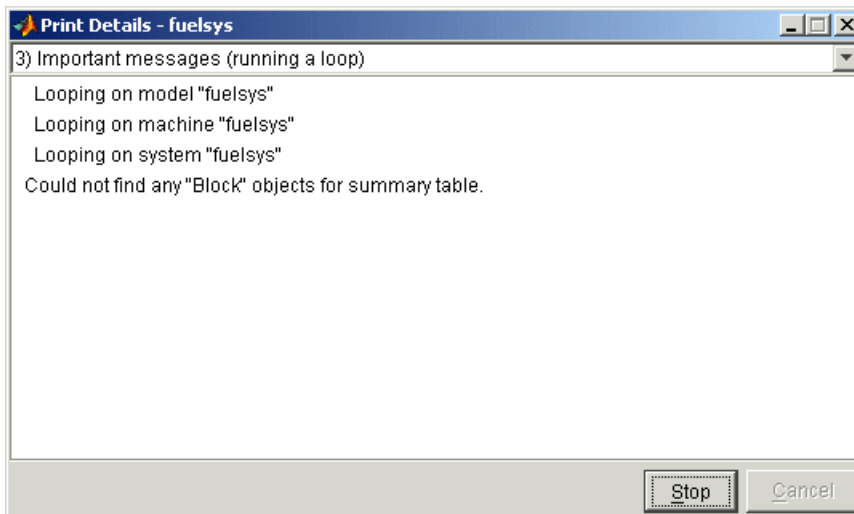

Tip If you have the Simulink Report Generator™ installed, you can generate a detailed report about a system. To do so, in the Simulink Editor, select **File > Reports > System Design Description**. For more information, see “System Design Description”.

To generate a model report for the current model:

- 1 In the Simulink Editor, select **File > Print > Print Details**.
- 2 In the Print Details dialog box, select report options. For details, see “Model Report Options” on page 1-87.
- 3 Select **Print**.

The Simulink software generates the HTML report and displays the report in your default HTML browser.

While generating the report, Simulink displays status messages on a messages pane that replaces the options pane on the Print Details dialog box.

Select the detail level of the messages from the list at the top of the messages pane. When the report generation process begins, the **Print** button changes to a **Stop** button. To stop the report generation, click **Stop**. When the report generation process finishes, the **Stop** button changes to an **Options** button. Clicking this button redisplay the report generation options, allowing you to generate another report without having to reopen the Print Details dialog box.

Model Report Options

Use the Print Details dialog box allows you to specify the following report options.

Directory

The folder where the HTML report is stored. The options include your system's temporary folder (the default), your system's current folder, or another folder whose path you specify in the adjacent edit field.

Increment filename to prevent overwriting old files

Creates a unique report file name each time you generate a report for the same model in the current session. This preserves each report.

Current object

Include only the currently selected object in the report.

Current and above

Include the current object and all levels of the model above the current object in the report.

Current and below

Include the current object and all levels below the current object in the report.

Entire model

Include the entire model in the report.

Look under mask dialog

Include the contents of masked subsystems in the report.

Expand unique library links

Include the contents of library blocks that are subsystems. The report includes a library subsystem only once even if it occurs in more than one place in the model.

More About

- “Print Model Diagrams” on page 1-67
- “Masking Fundamentals” on page 36-2

Print Models to Image File Formats

To print the current view of your model to an image file format such as `.png` or `.jpeg`, use the `-device` argument with the MATLAB `print` command. For example, to print the `vdp` model to a `.png` format, use this command:

```
print -dpng -svdp vdp_model.png
```

By default, the canvas (background) of the exported model matches the color of the model. To use a white or transparent canvas for model files that you export to another file format, set the **Simulink Preferences > Export** preference.

Copy Model Views to Third-Party Applications

On Microsoft Windows platforms, you can copy the current view of your model in either bitmap or metafile format. You can then paste the clipboard image to a third-party application such as word processing software.

On Macintosh platforms, when you copy a model view to the clipboard, Simulink saves the model in a scalable format, in addition to a bitmap format. When you paste from the clipboard to an application, the application selects the format that best meets its requirements.

By default, the canvas (background) of the copied model matches the color of the model. To use a white or transparent canvas for model files that you copy to another application, set the **Simulink Preferences > Clipboard** preference.

- 1 To copy a Simulink model to the operating system clipboard, in the Simulink Editor select **Edit > Copy Current View to Clipboard**.
- 2 Paste the model from the clipboard to a third-party application.

Note: On Macintosh platforms, use the **command** key instead of **Ctrl**.

Object Selection and Clipboard Operations

Objects include blocks, signal lines, signal labels, and annotations.

Task	Action
Select an object	Click
Select additional objects	Shift +click
Select all objects	Ctrl + A
Copy object	Drag with right mouse button Ctrl +drag
Move any object, including signal labels	Drag
Delete selected object	Delete or Backspace Edit > Clear
Cut	Ctrl + X
Paste	Ctrl + V

Task	Action
Duplicate object	Ctrl+C, Ctrl+V
Undo	Ctrl+Z
Redo	Ctrl+Y

Block and Signal Line Shortcuts and Actions

Task	Action
Set the main parameter for selected block	Alt+Enter
Open or hide the Property Inspector	Ctrl+Shift+I
Copy block or model from another Simulink Editor window	Drag between windows
Move block	Arrow keys
Resize block, keeping same ratio of width and height	Shift +drag handle
Resize block from the center	Ctrl +drag handle
Rotate block clockwise	Ctrl+R
Rotate block counterclockwise	Ctrl+Shift+R
Flip block	Ctrl+I
Connect blocks	Select first block, Ctrl +click second block Drag from port to port
Draw branch line	Ctrl +drag line Right-mouse button+drag
Route lines around blocks	Shift +drag while drawing
Disconnect block	Shift +drag block
Create subsystem from selected blocks	Ctrl+G
Open selected subsystem	Enter

Task	Action
Go to parent of selected subsystem	Esc
Find block	Ctrl+F
Mask subsystem	Ctrl+M
Look under block mask	Ctrl+U
Comment through a block	Ctrl+Shift+Y
Comment Out/Uncomment a block	Ctrl+Shift+X
Refresh Model blocks	Ctrl+K
Open Model Explorer	Ctrl+H

Signal Name and Label Actions

The signal name appears in a label on the signal line.

Task	Action
Name a signal line	Double-click signal and type name
Name a branch of a named signal line	Double-click the branch
Name every branch of a signal	Right-click the signal, select Properties , and use the dialog box
Delete signal label and name	Delete characters in label or delete name in Signal Properties dialog box.
Delete signal label only	Right-click label and select Delete Label .
Open signal label text box for edit	Double-click signal line Click label
Move signal label	Drag label to a new location on same signal line
Copy signal label	Ctrl +drag signal label
Change the label font	Select the signal line (not the label) and use Diagram > Format > Font Style

Simulation Keyboard Shortcuts

Task	Action
Open Configuration Parameters dialog box	Ctrl+E
Update diagram	Ctrl+D
Start simulation	Ctrl+T
Stop simulation	Ctrl+Shift+T
Build model (for code generation)	Ctrl+B

Debugging and Breakpoints Keyboard Shortcuts

Task	Action
Step	F10
Step in	F11
Step out	Shift + F11
Run	F5
Set/Clear breakpoint	F12

Zooming and Scrolling Shortcuts

Task	Action
Zoom in	Ctrl++
Zoom out	Ctrl+-
Zoom to normal (100%)	Ctrl+0
Zoom with mouse	Ctrl+scroll wheel Select the File > Simulink Preferences > Editor Preferences > Scroll wheel controls zooming preference to zoom using just the scroll wheel.
Zoom in on object	Drag the Zoom button  from the palette to the object

Task	Action
Fit diagram to screen	Spacebar
Scroll view	Arrow keys Shift +arrow for larger pans
Scroll with mouse	Spacebar +drag Hold the scroll wheel down and drag the mouse

Library Browser Shortcuts

Task	Shortcut
Open a model	Ctrl+O
Open Library Browser from a model	Ctrl+Shift+L
Move selection down in the Blocks or Libraries pane	Down arrow
Move selection up in the Blocks or Libraries pane	Up arrow
Expand a node in the Libraries pane	Right arrow
Collapse a node in the Libraries pane	Left arrow
Refresh Libraries pane	F5
Show parent library in Blocks pane	Esc
Select a block found with the search tool in the Blocks pane	Ctrl+R
Insert the selected block in a new model	Ctrl+I
Increase zoom in the Blocks pane	Ctrl++
Decrease zoom in the Blocks pane	Ctrl+-

Task	Shortcut
Reset zoom to default in the Blocks pane	Alt+1
Find a block	Ctrl+F
Close	Ctrl+W

File Operations

Task	Action
Open model	Ctrl+O
Create a model	Ctrl+N
Print	Ctrl+P
Save	Ctrl+S
Close model	Ctrl+W

How Simulation Stepper Helps With Model Analysis

Simulation Stepper enables you to step through major time steps of a simulation. Using discrete time steps, you can step forward or back to a particular instant in simulation time. At each time step, Stepper displays all of the simulation data the model produces.

Use Simulation Stepper to analyze your model in these ways:

- Step forward and back through a simulation.
- Pause a simulation in progress and step back.
- Continue running a simulation after stepping back.
- Analyze plotted data in your model at a particular moment in simulation time.
- Set conditions before and during simulation to pause a simulation.

How Stepping Through a Simulation Works

In this section...

“Simulation Snapshots” on page 2-3

“How Simulation Stepper Uses Snapshots” on page 2-4

“How Simulation Stepper Differs from Simulink Debugger” on page 2-5

These topics explain how Simulation Stepper steps through a simulation.

Simulation Snapshots

When you set up Simulation Stepper, you specify:

- The number of time steps where Stepper creates ‘snapshots’
- The number of steps to skip between snapshots
- The total number of snapshots stored

A simulation snapshot contains simulation state (SimState) and information related to logged data and visualization blocks. Simulation Stepper stores simulation states in snapshots at the specified interval of time steps when it steps forward through a simulation.

It is important to understand the difference between a Simulation Stepper step and a simulation time step. A simulation time step is the fixed amount of time by which the simulation advances. A Simulation Stepper step is where Simulation Stepper creates a snapshot. Each step (that Simulation Stepper takes) consists of one or more simulation time steps (that you specify).

When you step back through a simulation, the software uses simulation snapshots, stored as SimStates, to display previous states of the simulation. The model does not simulate in reverse when stepping back. Therefore, to enable the step back capability, you must first simulate the model or step it forward to save snapshots.

Keep in mind that snapshots for stepping back are available only during a single simulation. The Simulation Stepper does not save the steps from one simulation to the next.

How Simulation Stepper Uses Snapshots

A simulation snapshot captures all the information required to continue a simulation from that point. When you set up simulation stepping, you specify:

- The maximum number of snapshots to capture while simulating forward. The greater the number, the more memory the simulation uses and the longer the simulation takes to run.
- The number of time steps to skip between snapshots. This setting enables you to save snapshots of simulation state when stepping forward at periodic intervals, such as every three steps. This interval is independent of the number of forward or backward time steps taken. Because taking simulation snapshots affects simulation speed, saving snapshots less frequently can improve simulation speed.

The figure shows how you can step through a simulation depending on how you set the parameters in the Simulation Stepping Options dialog box. Because you can change the stepping parameters as you step through the simulation, you can step through a simulation as shown in this figure: sometimes by single steps and sometimes by two or more steps.

In the figure, the interval for snapshot captures is three.

This next figure shows the advantage of changing the stepping options while stepping forward. At the fourth step, the interval between stored steps changed the snapshot steps from three to one. This enables you to capture more snapshots around a simulation time of interest.

The next figure shows how the snapshot settings of Simulation Stepper can change what happens when stepping back. Suppose that the interval between snapshots is set to three, and starting at state six, the stepper **Move back/forward by** setting is set to one. The stepper first restores the simulation state to the last saved snapshot (state three), and then simulates two major time steps to arrive at the desired state (state five).

Thus, when you step back to a particular time step in a simulation, Simulation Stepper restores the last saved snapshot before that time step. Then, it steps forward to the time step you specify. This capability is helpful for memory usage and simulation performance.

How Simulation Stepper Differs from Simulink Debugger

Simulation Stepper and Simulink Debugger both enable you to start, stop, and step through a model simulation. Both tools allow you to use breakpoints as part of a debugging session. However, you use Simulation Stepper and Simulink Debugger for different purposes. The table shows the actions you can perform with each tool.

Action	Simulation Stepper	Simulink Debugger
Look at state of system after executing a major time step.	✓	✓

Action	Simulation Stepper	Simulink Debugger
Observe dynamics of the entire model from step to step.	✓	
Step simulation back.	✓	
Pause across major steps.	✓	
Control a Stateflow debugging session.	✓	
Step through simulation by major steps.	✓	
Monitor single block dynamics (for example, output and update) during a single major time step.		✓
Look at state of system while executing a major time step.		✓
Observe solver dynamics during a single major step.		✓
Show various stages of Simulink simulation.		✓
Pause within a major step.		✓
Step through a simulation block by block.		✓
Access via a command-line interface.		✓

Understanding the simulation process can help you to better understand the differences between Simulation Stepper and Simulink Debugger.

Simulation Stepper Access

You run Simulation Stepper and access the settings from the Simulink Editor toolbar .

Click the Stepping Options button  to open the Simulation Stepping Options dialog box.

Use the dialog box to enable stepping back through a simulation. When stepping back is enabled, after you start the simulation, the Stepping Options button changes to , and then you can use it to step back. In that case, you can access the dialog box again only by using **Simulation > Stepping Options**.

If you clear the **Enable previous stepping** check box, the software clears the stored snapshot cache.

Simulation Stepper Pause Status

The status bar at the bottom of the Simulink Editor displays the simulation time of the last completed simulation step. While a simulation is running, the editor updates the time display to indicate the simulation progress. This display is approximate because the status bar updates only at every major time step and not at every simulation time step.

When you pause a simulation, the status bar display time catches up to the actual time of the last completed step.

The value (the time of the last completed step) that is displayed on the status bar is not always the same as the time of the solver. This happens because different solvers use different ways to propagate the simulation time in a single iteration of the simulation loop. Simulation Stepper pauses at a single position within the simulation loop. Some solvers perform their time advance before Simulation Stepper pauses. However, other solvers perform their time advance after Simulation Stepper pauses, and the time advance then becomes part of the next step. As a result, for continuous and discrete solvers, the solver time is always one major step ahead of the time of the last model output.

When this condition occurs, and the simulation is paused, the status bar time displays an asterisk. The asterisk indicates that the solver in this simulation has already advanced past the displayed time (which is the time of the last completed simulation step).

Tune Parameters

While using Simulation Stepper, when the simulation is paused, you can change tunable parameters, including some solver settings. However, changes to the solver step size take effect when the solver advances the simulation time. For some solvers, this occurs after the next simulation step is taken.

Simulation Stepper takes into account the size of a movement (**Move back/forward by**) and the frequency of saving steps (**Interval between stored back steps**). If you specify a frequency that is larger than the step size, Simulation Stepper first steps back to the last saved step and then simulates forward until the total step count difference reaches the size of the desired movement. Simulation Stepper applies values for tunable parameters when simulating forward. For this reason, if you change any tunable parameter before stepping back, the resulting simulation output might not match the previous simulation output at that step before the parameter change. This can cause unexpected results when stepping forward from the snapshot to the chosen time step.

For example, assume a snapshot save frequency of three and a step size of one. The stepper first steps back to the last saved step, up to three steps, and then simulates forward until the total step count difference reaches one. If you change tunable

parameters before stepping back, the resulting simulation output might not match the previous simulation output at that step.

Referenced Models

When using Simulation Stepper and the **Model** block, the referenced model shares the stepping options of the top model throughout a simulation. As a result, changing Simulation Stepper settings for the referenced model during simulation changes the Simulation Stepper settings of the top model. When the simulation ends, the settings of the referenced model revert to the original values; the Stepper settings of the top model stay at the changed settings.

- When the model is not simulating, the top model and referenced model retain their own independent stepping options.
- When the model is simulating and you change a referenced model stepping option, the top model stepping option changes to the same value.
- When the model is simulating and you change a top model stepping option, the referenced model stepping option changes to the same value.
- When the model stops simulating, the referenced model stepping options revert to how they were set before simulation started; the top model keeps the values set during simulation.

Simulation Stepper and Interval Logging

When you change the logging interval of a simulation before rolling back, Simulink does not log data for time steps that were outside the original logging interval until the first forward step after a rollback operation. For more information, see “Logging intervals”.

Simulation Stepper and Stateflow Debugger

When you debug a Stateflow chart (for example, when the simulation stops at a Stateflow breakpoint), Simulation Stepper adds buttons to control the Stateflow debugging session. When the Stateflow debugging session ends, the Simulation Stepper interface returns to the default. For more information about controlling the Stateflow debugger using the Simulink Editor toolbar, see “Control Chart Execution from the Stateflow Editor”.

Simulation Stepper Limitations

In this section...
“Interface” on page 2-12
“Model Configuration” on page 2-12
“Blocks” on page 2-12

Interface

- There is no command-line interface for Simulation Stepper.

Model Configuration

- Simulation stepping (forward and backward) is available only for Normal and Accelerator modes.
- The step back capability relies on SimState technology for saving and restoring the state of a simulation. As a result, the step back capability is available only for models that support SimState. For more information, see “Save and Restore Simulation State as SimState” on page 23-37.
- Simulation Stepper steps through the major time steps of a simulation without changing the course of a simulation. Choosing a refine factor greater than unity produces loggable outputs at times between the major time steps of the solver. These times are not major time steps, and you cannot step to a model state at those times.
- If you run a simulation with stepping back enabled, the Simulink software checks whether the model can step back. If it cannot, a warning appears at the MATLAB command prompt. For some simulations, Simulink cannot step back. The step back capability is then disabled until the end of that simulation. Then the setting resets to the value you requested.
- When you place custom code in **Configuration Parameters > Simulation Target > Custom Code > Initialize function** in the **Model Configuration Parameters** dialog box, this gets called only during the first simulation in Simulation Stepper.

Blocks

- Some blocks do not support stepping back for reasons other than SimState support. These blocks are:

- S-functions that have P-work vectors but do not declare their SimState compliance level or declare it to be unknown or disallowed (see “S-Function Compliance with the SimState”)
- Simscape™ Multibody™ First Generation blocks
- Model blocks configured for Accelerator mode
- Legacy (pre-R2016a) SimEvents® blocks
- MATLAB Function blocks generally support stepping back. However, the use of certain constructs in the MATLAB code of these blocks can prevent the block from supporting stepping back. These scenarios prevent the MATLAB Function blocks from stepping back:
 - Persistent variables of opaque data type. Attempts to step back under this condition cause an error message based on the specific variable type.
 - Extrinsic functions calls that can contain state (such as properties of objects or persistent data of functions). No warnings or error messages appear, but the result likely will be incorrect.
 - Calls to custom C code (through MEX function calls) that do not contain static variables. No warnings or error messages appear, but the result likely will be incorrect.
- Some visualization blocks do not support stepping back. Because these blocks are not critical to the state of the simulation, no errors or warnings appear when you step back in a model that contains these blocks:
 - XY Graph
 - Auto Correlator
 - Cross Correlator
 - Spectrum Analyzer
 - Averaging Spectrum Analyzer
 - Power Spectral Density
 - Averaging Power Spectral Density
 - Floating Bar Plot
 - 3Dof Animation
 - MATLAB Animation

- VR Sink
- Any blocks that implement custom visualization in their output method (for example, an S-function that outputs to a MATLAB figure) are not fully supported for stepping back because the block method `Output` does not execute while stepping back. While the state of such blocks remains consistent with the simulation time (if the blocks comply with `SimState`), the visualization component is inconsistent until the next step forward in the simulation.

Because these blocks do not affect the numerical result of a simulation, stepping back is not disabled for these blocks. However, the values these blocks output are inaccurate until the simulation steps forward again.

Step Through a Simulation

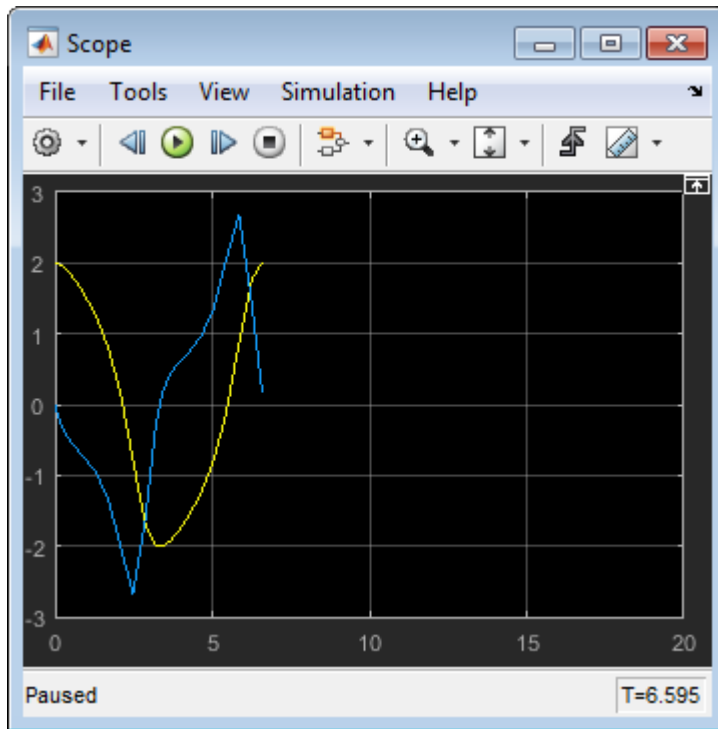

Step Forward and Back

This example shows how to step forward and back through a simulation.

- 1 At the MATLAB prompt, type
`vdp`
- 2 In the Simulink Editor for the `vdp` model, click  to open the Simulation Stepping Options dialog box.
- 3 In the dialog box, select the **Enable stepping back** check box, and then click **OK**.
- 4 In the Simulation toolbar, click the **Step Forward** button  one time.

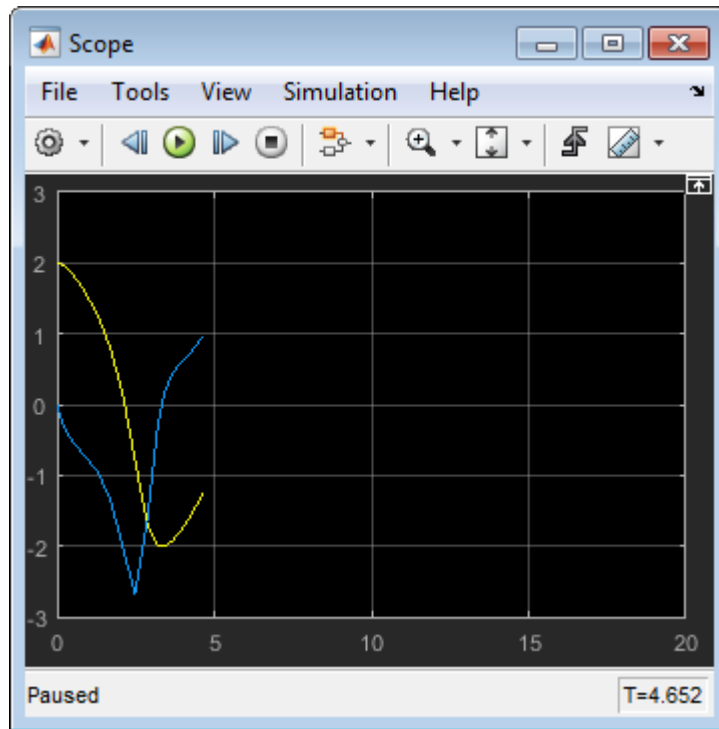

The simulation simulates one step, and the software stores a simulation snapshot for that step.

- 5 Click the Step Forward button again to step forward again and store simulation data. A total of 25 forward steps produces these simulation results:

- 6 You must step forward to create the simulation state that the step backward operation requires. This means you must first step forward before you can step backward through the same steps.

In the Simulation toolbar, click the **Step Back** button  four times to step backward to the simulation snapshot shown below.

Set Conditional Breakpoints for Stepping a Simulation

A conditional breakpoint is triggered based on a specified expression evaluated on a signal. When the breakpoint is triggered, the simulation pauses.

Set conditional breakpoints to stop Simulation Stepper when a specified condition is met. One example of a use for conditional breakpoints is when you want to examine results after a certain number of iterations in a loop.

Simulation Stepper allows you to set conditional breakpoints for scalar signals. These breakpoints appear for signals:

Breakpoint	Description
	Enabled breakpoint. Appears when you add the conditional breakpoint.
	Enabled breakpoint hit. Appears when the simulation reaches the condition specified and triggers the breakpoint.
	Disabled breakpoint. Appears when you disable a conditional breakpoint.
	Invalid breakpoint. Appears when the software determines that a breakpoint is invalid for the signal. An enabled breakpoint image changes to this one when, during simulation, the software determines that the conditional breakpoint is invalid.

When setting conditional breakpoints, keep in mind that:

- When simulation arrives at a conditional breakpoint, simulation does not stop when the block is executed. Instead, simulation stops after the current simulation step completes.
- You can add multiple conditional breakpoints to a signal line.

Add and Edit Conditional Breakpoints

- 1 In a model, right-click a signal and select **Add Conditional Breakpoint**.
- 2 In the **Add Conditional Breakpoint** dialog box, from the drop-down list, select the condition for the signal. For example, select greater than or less than.
- 3 Enter the signal value where you want simulation to pause and click **OK**. For the condition values:
 - Use numeric values. Do not use expressions.

- Do not use NaN.

The affected signal line displays a conditional breakpoint icon: .

- 4 Click the breakpoint to view and edit all conditions set for the signal.

- 5 Simulate the model and notice that the model pauses as simulation steps through the conditional breakpoints.

Conditional Breakpoints Limitations

- You can set conditional breakpoints only on real scalar signals of these data types:
 - double
 - single
 - int
 - bool
 - fixed point (based on the converted double value)
- You cannot set conditional breakpoints (or port value display labels) on non-Simulink signals, such as Simscape or SimEvents signals.
- Conditional breakpoints also have the limitations that port value display have (“Port Value Display Limitations” on page 33-23).

Observe Conditional Breakpoint Values

To observe a conditional breakpoint value of a block signal, use data tips to display block port values. You can add data tips before or after you add conditional breakpoints.

- 1 Enable the value display for a signal. Right-click the signal line that has a conditional breakpoint and select **Show Value Label of Selected Port**.

The data tip for the value display appears.

- 2 Simulate the model and observe the conditional breakpoint and data tip when the simulation triggers the breakpoint.

How Simulink Works

Simulink is a software package that enables you to model, simulate, and analyze systems whose outputs change over time. Such systems are often referred to as dynamic systems. The Simulink software can be used to explore the behavior of a wide range of real-world dynamic systems, including electrical circuits, shock absorbers, braking systems, and many other electrical, mechanical, and thermodynamic systems. This section explains how Simulink works.

Simulating a dynamic system is a two-step process. First, a user creates a block diagram, using the Simulink model editor, that graphically depicts time-dependent mathematical relationships among the system's inputs, states, and outputs. The user then commands the Simulink software to simulate the system represented by the model from a specified start time to a specified stop time.

Block Diagram Semantics

A classic block diagram model of a dynamic system graphically consists of blocks and lines (signals). The history of these block diagram models is derived from engineering areas such as Feedback Control Theory and Signal Processing. A block within a block diagram defines a dynamic system in itself. The relationships between each elementary dynamic system in a block diagram are illustrated by the use of signals connecting the blocks. Collectively the blocks and lines in a block diagram describe an overall dynamic system.

The Simulink product extends these classic block diagram models by introducing the notion of two classes of blocks, nonvirtual blocks and virtual blocks. Nonvirtual blocks represent elementary systems. Virtual blocks exist for graphical and organizational convenience only: they have no effect on the system of equations described by the block diagram model. You can use virtual blocks to improve the readability of your models.

In general, blocks and lines can be used to describe many “models of computations.” One example would be a flow chart. A flow chart consists of blocks and lines, but one cannot describe general dynamic systems using flow chart semantics.

The term “time-based block diagram” is used to distinguish block diagrams that describe dynamic systems from that of other forms of block diagrams, and the term block diagram (or model) is used to refer to a time-based block diagram unless the context requires explicit distinction.

To summarize the meaning of time-based block diagrams:

- Simulink block diagrams define time-based relationships between signals and state variables. The solution of a block diagram is obtained by evaluating these relationships over time, where time starts at a user specified “start time” and ends at a user specified “stop time.” Each evaluation of these relationships is referred to as a time step.
- Signals represent quantities that change over time and are defined for all points in time between the block diagram's start and stop time.
- The relationships between signals and state variables are defined by a set of equations represented by blocks. Each block consists of a set of equations (block methods). These equations define a relationship between the input signals, output signals and the state variables. Inherent in the definition of an equation is the notion of parameters, which are the coefficients found within the equation.

Creating Models

The Simulink product provides a graphical editor that allows you to create and connect instances of block types selected from libraries of block types (see “Block Libraries”) via a library browser. Libraries of blocks are provided representing elementary systems that can be used as building blocks. The blocks supplied with Simulink are called built-in blocks. Users can also create their own block types and use the Simulink editor to create instances of them in a diagram. User-defined blocks are called custom blocks.

Time

Time is an inherent component of block diagrams in that the results of a block diagram simulation change with time. Put another way, a block diagram represents the instantaneous behavior of a dynamic system. Determining a system's behavior over time thus entails repeatedly solving the model at intervals, called time steps, from the start of the time span to the end of the time span. The process of solving a model at successive time steps is referred to as *simulating* the system that the model represents.

States

Typically the current values of some system, and hence model, outputs are functions of the previous values of temporal variables. Such variables are called states. Computing a model's outputs from a block diagram hence entails saving the value of states at the current time step for use in computing the outputs at a subsequent time step. This task is performed during simulation for models that define states.

Two types of states can occur in a Simulink model: discrete and continuous states. A continuous state changes continuously. Examples of continuous states are the position and speed of a car. A discrete state is an approximation of a continuous state where the state is updated (recomputed) using finite (periodic or aperiodic) intervals. An example of a discrete state would be the position of a car shown on a digital odometer where it is updated every second as opposed to continuously. In the limit, as the discrete state time interval approaches zero, a discrete state becomes equivalent to a continuous state.

Blocks implicitly define a model's states. In particular, a block that needs some or all of its previous outputs to compute its current outputs implicitly defines a set of states that need to be saved between time steps. Such a block is said to have states.

The following is a graphical representation of a block that has states:

Blocks that define continuous states include the following standard Simulink blocks:

- Integrator
- State-Space
- Transfer Fcn
- Variable Transport Delay
- Zero-Pole

The total number of a model's states is the sum of all the states defined by all its blocks. Determining the number of states in a diagram requires parsing the diagram to determine the types of blocks that it contains and then aggregating the number of states defined by each instance of a block type that defines states. This task is performed during the Compilation phase of a simulation.

Working with States

The following facilities are provided for determining, initializing, and logging a model's states during simulation:

- The `model` command displays information about the states defined by a model, including the total number of states defined by the model, the block that defines each state, and the initial value of each state.
- The Simulink debugger displays the value of a state at each time step during a simulation, and the Simulink debugger's `states` command displays information about the model's current states (see “Simulink Debugger”).
- The **Data Import/Export** pane of a model's Configuration Parameters dialog box (see “State Information” on page 59-231) allows you to specify initial values for a model's states, and to record the values of the states at each time step during simulation as an array or structure variable in the MATLAB workspace.
- The Block Parameters dialog box (and the `ContinuousStateAttributes` parameter) allows you to give names to states for those blocks (such as the Integrator) that employ continuous states. This can simplify analyzing data logged for states, especially when a block has multiple states.

The Two Cylinder Model with Load Constraints model illustrates the logging of continuous states.

Continuous States

Computing a continuous state entails knowing its rate of change, or derivative. Since the rate of change of a continuous state typically itself changes continuously (i.e., is itself a state), computing the value of a continuous state at the current time step entails integration of its derivative from the start of a simulation. Thus modeling a continuous state entails representing the operation of integration and the process of computing the state's derivative at each point in time. Simulink block diagrams use Integrator blocks to indicate integration and a chain of blocks connected to an integrator block's input to represent the method for computing the state's derivative. The chain of blocks connected to the integrator block's input is the graphical counterpart to an ordinary differential equation (ODE).

In general, excluding simple dynamic systems, analytical methods do not exist for integrating the states of real-world dynamic systems represented by ordinary differential equations. Integrating the states requires the use of numerical methods called ODE solvers. These various methods trade computational accuracy for computational workload. The Simulink product comes with computerized implementations of the most

common ODE integration methods and allows a user to determine which it uses to integrate states represented by Integrator blocks when simulating a system.

Computing the value of a continuous state at the current time step entails integrating its values from the start of the simulation. The accuracy of numerical integration in turn depends on the size of the intervals between time steps. In general, the smaller the time step, the more accurate the simulation. Some ODE solvers, called variable time step solvers, can automatically vary the size of the time step, based on the rate of change of the state, to achieve a specified level of accuracy over the course of a simulation. The user can specify the size of the time step in the case of fixed-step solvers, or the solver can automatically determine the step size in the case of variable-step solvers. To minimize the computation workload, the variable-step solver chooses the largest step size consistent with achieving an overall level of precision specified by the user for the most rapidly changing model state. This ensures that all model states are computed to the accuracy specified by the user.

Discrete States

Computing a discrete state requires knowing the relationship between its value at the current time step and its value at the previous time step. This is referred to this relationship as the state's update function. A discrete state depends not only on its value at the previous time step but also on the values of a model's inputs. Modeling a discrete state thus entails modeling the state's dependency on the systems' inputs at the previous time step. Simulink block diagrams use specific types of blocks, called discrete blocks, to specify update functions and chains of blocks connected to the inputs of discrete blocks to model the dependency of a system's discrete states on its inputs.

As with continuous states, discrete states set a constraint on the simulation time step size. Specifically, the step size must ensure that all the sample times of the model's states are hit. This task is assigned to a component of the Simulink system called a discrete solver. Two discrete solvers are provided: a fixed-step discrete solver and a variable-step discrete solver. The fixed-step discrete solver determines a fixed step size that hits all the sample times of all the model's discrete states, regardless of whether the states actually change value at the sample time hits. By contrast, the variable-step discrete solver varies the step size to ensure that sample time hits occur only at times when the states change value.

Modeling Hybrid Systems

A hybrid system is a system that has both discrete and continuous states. Strictly speaking, any model that has both continuous and discrete sample times is treated as a

hybrid model, presuming that the model has both continuous and discrete states. Solving such a model entails choosing a step size that satisfies both the precision constraint on the continuous state integration and the sample time hit constraint on the discrete states. The Simulink software meets this requirement by passing the next sample time hit, as determined by the discrete solver, as an additional constraint on the continuous solver. The continuous solver must choose a step size that advances the simulation up to but not beyond the time of the next sample time hit. The continuous solver can take a time step short of the next sample time hit to meet its accuracy constraint but it cannot take a step beyond the next sample time hit even if its accuracy constraint allows it to.

You can simulate hybrid systems using any one of the integration methods, but certain methods are more effective than others. For most hybrid systems, `ode23` and `ode45` are superior to the other solvers in terms of efficiency. Because of discontinuities associated with the sample and hold of the discrete blocks, do not use the `ode15s` and `ode113` solvers for hybrid systems.

Block Parameters

Key properties of many standard blocks are parameterized. For example, the Constant value of the Simulink Constant block is a parameter. Each parameterized block has a block dialog that lets you set the values of the parameters. You can use MATLAB expressions to specify parameter values. Simulink evaluates the expressions before running a simulation. You can change the values of parameters during a simulation. This allows you to determine interactively the most suitable value for a parameter.

A parameterized block effectively represents a family of similar blocks. For example, when creating a model, you can set the Constant value parameter of each instance of the Constant block separately so that each instance behaves differently. Because it allows each standard block to represent a family of blocks, block parameterization greatly increases the modeling power of the standard Simulink libraries. See “Block Parameters” on page 3-8 and “Block Libraries” for more information.

Tunable Parameters

Many block parameters are tunable. A *tunable parameter* is a parameter whose value can be changed without recompiling the model (see “Model Compilation” on page 3-17 for more information on compiling a model). For example, the gain parameter of the Gain block is tunable. You can alter the block's gain while a simulation is running. If a parameter is not tunable and the simulation is running, the dialog box control that sets the parameter is disabled.

When you change the value of a tunable parameter, the change takes effect at the start of the next time step. See “Block Parameters” on page 3-8 and “Tune and Experiment with Block Parameter Values” on page 34-36 for more information.

Block Sample Times

Every Simulink block has a sample time which defines when the block will execute. Most blocks allow you to specify the sample time via a `SampleTime` parameter. Common choices include discrete, continuous, and inherited sample times.

Common Sample Time Types	Sample Time	Examples
Discrete	$[T_s, T_o]$	Unit Delay, Digital Filter
Continuous	$[0, 0]$	Integrator, Derivative
Inherited	$[-1, 0]$	Gain, Sum

For discrete blocks, the sample time is a vector $[T_s, T_o]$ where T_s is the time interval or period between consecutive sample times and T_o is an initial offset to the sample time. In contrast, the sample times for nondiscrete blocks are represented by ordered pairs that use zero, a negative integer, or infinity to represent a specific type of sample time (see “View Sample Time Information” on page 7-9). For example, continuous blocks have a nominal sample time of $[0, 0]$ and are used to model systems in which the states change continuously (e.g., a car accelerating). Whereas you indicate the sample time type of an inherited block symbolically as $[-1, 0]$ and Simulink then determines the actual value based upon the context of the inherited block within the model.

Note that not all blocks accept all types of sample times. For example, a discrete block cannot accept a continuous sample time.

For a visual aid, Simulink allows the optional color-coding and annotation of any block diagram to indicate the type and speed of the block sample times. You can capture all of the colors and the annotations within a legend (see “View Sample Time Information” on page 7-9).

For a more detailed discussion of sample times, see “Sample Time”

Custom Blocks

You can create libraries of custom blocks that you can then use in your models. You can create a custom block either graphically or programmatically. To create a custom block graphically, you draw a block diagram representing the block's behavior, wrap

this diagram in an instance of the Simulink Subsystem block, and provide the block with a parameter dialog, using the Simulink block mask facility. To create a block programmatically, you create a MATLAB file or a MEX-file that contains the block's system functions (see “S-Function Basics”). The resulting file is called an S-function. You then associate the S-function with instances of the Simulink S-Function block in your model. You can add a parameter dialog to your S-Function block by wrapping it in a Subsystem block and adding the parameter dialog to the Subsystem block. See “Block Creation” for more information.

Systems and Subsystems

A Simulink block diagram can consist of layers. Each layer is defined by a subsystem. A subsystem is part of the overall block diagram and ideally has no impact on the meaning of the block diagram. Subsystems are provided primarily to help with the organizational aspects of a block diagram. Subsystems do not define a separate block diagram.

The Simulink software differentiates between two different types of subsystems: virtual and nonvirtual. The primary difference is that nonvirtual subsystems provide the ability to control when the contents of the subsystem are evaluated.

Virtual Subsystems

Virtual subsystems provide graphical hierarchy in models. Virtual subsystems do not impact execution. During model execution, the Simulink engine flattens all virtual subsystems, i.e., Simulink expands the subsystem in place before execution. This expansion is very similar to the way macros work in a programming language such as C or C++. Roughly speaking, there will be one system for the top-level block diagram which is referred to as the root system, and several lower-level systems derived from nonvirtual subsystems and other elements in the block diagram. You will see these systems in the Simulink Debugger. The act of creating these internal systems is often referred to as *flattening the model hierarchy*.

Nonvirtual Subsystems

Nonvirtual subsystems, which are drawn with a bold border, provide execution and graphical hierarchy in models. Nonvirtual subsystems are executed as a single unit (atomic execution) by the Simulink engine. You can create conditionally executed subsystems that are executed only when a precondition—such as a trigger, an enable, a function-call, or an action—occurs (see “Conditional Subsystems”). Simulink always computes all inputs used during the execution of a nonvirtual subsystem before executing the subsystem. Simulink defines the following nonvirtual subsystems.

Atomic subsystems

The primary characteristic of an atomic subsystem is that blocks in an atomic subsystem execute as a single unit. This provides the advantage of grouping functional aspects of models at the execution level. Any Simulink block can be placed in an atomic subsystem, including blocks with different execution rates. You can create an atomic subsystem by selecting the **Treat as atomic unit** option on a virtual subsystem (see the `Atomic Subsystem` block for more information).

Enabled subsystems

An enabled subsystem behaves similarly to an atomic subsystem, except that it executes only when the signal driving the subsystem enable port is greater than zero. To create an enabled subsystem, place an `Enable Port` block within a `Subsystem` block. You can configure an enabled subsystem to hold or reset the states of blocks within the enabled subsystem prior to a subsystem enabling action. Simply select the **States when enabling** parameter of the `Enable Port` block. Similarly, you can configure each output port of an enabled subsystem to hold or reset its output prior to the subsystem disabling action. Select the **Output when disabled** parameter in the `Outputport` block.

Triggered subsystems

You create a triggered subsystem by placing a trigger port block within a subsystem. The resulting subsystem executes when a rising or falling edge with respect to zero is seen on the signal driving the subsystem trigger port. The direction of the triggering edge is defined by the `Trigger type` parameter on the trigger port block. Simulink limits the type of blocks placed in a triggered subsystem to blocks that do not have explicit sample times (i.e., blocks within the subsystem must have a sample time of -1) because the contents of a triggered subsystem execute in an aperiodic fashion. A Stateflow chart can also have a trigger port which is defined by using the Stateflow editor. Simulink does not distinguish between a triggered subsystem and a triggered chart.

Function-call subsystems

A function-call subsystem is a subsystem that another block can invoke directly during a simulation. It is analogous to a function in a procedural programming language. Invoking a function-call subsystem is equivalent to invoking the output and update methods of the blocks that the subsystem contains in sorted order. The block that invokes a function-call subsystem is called the function-call initiator. Stateflow, Function-Call Generator, and S-function blocks can all serve as function-call initiators. To create a function-call subsystem, drag a `Function-Call Subsystem` block from the `Ports & Subsystems` library into your model and connect a function-call initiator to the function-call port displayed on top of the subsystem. You can also create a function-call subsystem from scratch by

first creating a Subsystem block in your model and then creating a Trigger block in the subsystem and setting the Trigger block `Trigger type` to `function-call`.

You can configure a function-call subsystem to be triggered (the default) or periodic by setting its `Sample time type` to be `triggered` or `periodic`, respectively. A function-call initiator can invoke a triggered function-call subsystem zero, once, or multiple times per time step. The sample times of all the blocks in a triggered function-call subsystem must be set to `inherited (-1)`.

A function-call initiator can invoke a periodic function-call subsystem only once per time step and must invoke the subsystem periodically. If the initiator invokes a periodic function-call subsystem aperiodically, Simulink halts the simulation and displays an error message. The blocks in a periodic function-call subsystem can specify a noninherited sample time or `inherited (-1)` sample time. All blocks that specify a noninherited sample time must specify the same sample time, that is, if one block specifies `.1` as its sample time, all other blocks must specify a sample time of `.1` or `-1`. If a function-call initiator invokes a periodic function-call subsystem at a rate that differs from the sample time specified by the blocks in the subsystem, Simulink halts the simulation and displays an error message.

Enabled and triggered subsystems

You can create an enabled and triggered subsystem by placing a Trigger Port block and an Enable Port block within a Subsystem block. The resulting subsystem is essentially a triggered subsystem that executes when the subsystem is enabled and a rising or falling edge with respect to zero is seen on the signal driving the subsystem trigger port. The direction of the triggering edge is defined by the `Trigger type` parameter on the trigger port block. Because the contents of a triggered subsystem execute in an aperiodic fashion, Simulink limits the types of blocks placed in an enabled and triggered subsystem to blocks that do not have explicit sample times. In other words, blocks within the subsystem must have a sample time of `-1`.

Resettable subsystems

A resettable subsystem computes its outputs at every sample time hit but also resets the states of the subsystem on triggering. The resettable subsystem resets the states of all blocks within it, triggered by a rising or falling edge with respect to zero. On triggering, the resettable subsystem resets its states and also computes the outputs.

The resettable subsystem supports only single sample time for all the blocks it contains. Different sample times for different blocks within the subsystem result in an error. For more information, see [Resettable Subsystem](#).

Action subsystems

Action subsystems can be thought of as an intersection of the properties of enabled subsystems and function-call subsystems. Action subsystems are restricted to a single sample time (e.g., a continuous, discrete, or inherited sample time). Action subsystems must be executed by an action subsystem initiator. This is either an If block or a Switch Case block. All action subsystems connected to a given action subsystem initiator must have the same sample time. An action subsystem is created by placing an Action Port block within a Subsystem block. The subsystem icon will automatically adapt to the type of block (i.e., If or Switch Case block) that is executing the action subsystem.

Action subsystems can be executed at most once by the action subsystem initiator. Action subsystems give you control over when the states reset via the **States when execution is resumed** parameter on the Action Port block. Action subsystems also give you control over whether or not to hold the output values via the **Output when disabled** parameter on the output block. This is analogous to enabled subsystems.

Action subsystems behave very similarly to function-call subsystems because they must be executed by an initiator block. *Function-call subsystems can be executed more than once at any given time step whereas action subsystems can be executed at most once.* This restriction means that a larger set of blocks (e.g., periodic blocks) can be placed in action subsystems as compared to function-call subsystems. This restriction also means that you can control how the states and outputs behave.

While iterator subsystems

A while iterator subsystem will run multiple iterations on each model time step. The number of iterations is controlled by the While Iterator block condition. A while iterator subsystem is created by placing a While Iterator block within a subsystem block.

A while iterator subsystem is very similar to a function-call subsystem in that it can run for any number of iterations at a given time step. The while iterator subsystem differs from a function-call subsystem in that there is no separate initiator (e.g., a Stateflow Chart). In addition, a while iterator subsystem has access to the current iteration number optionally produced by the While Iterator block. A while iterator subsystem also gives you control over whether or not to reset states when starting via the **States when starting** parameter on the While Iterator block.

For iterator subsystems

A for iterator subsystem will run a fixed number of iterations at each model time step. The number of iterations can be an external input to the for iterator subsystem or

specified internally on the For Iterator block. A for iterator subsystem is created by placing a For Iterator block within a subsystem block.

A for iterator subsystem has access to the current iteration number that is optionally produced by the For Iterator block. A for iterator subsystem also gives you control over whether or not to reset states when starting via the **States when starting** parameter on the For Iterator block. A for iterator subsystem is very similar to a while iterator subsystem with the restriction that the number of iterations during any given time step is fixed.

For each subsystems

The for each subsystem allows you to repeat an algorithm for individual elements (or subarrays) of an input signal. Here, the algorithm is represented by the set of blocks in the subsystem and is applied to a single element (or subarray) of the signal. You can configure the decomposition of the subsystem inputs into elements (or subarrays) using the For Each block, which resides in the subsystem. The For Each block also allows you to configure the concatenation of individual results into output signals. An advantage of this subsystem is that it maintains separate sets of states for each element or subarray that it processes. In addition, for certain models, the for each subsystem improves the code reuse of the code generated by Simulink Coder™.

Signals

The term *signal* refers to a time varying quantity that has values at all points in time. You can specify a wide range of signal attributes, including signal name, data type (e.g., 8-bit, 16-bit, or 32-bit integer), numeric type (real or complex), and dimensionality (one-dimensional, two-dimensional, or multidimensional array). Many blocks can accept or output signals of any data or numeric type and dimensionality. Others impose restrictions on the attributes of the signals they can handle.

On the block diagram, signals are represented with lines that have an arrowhead. The source of the signal corresponds to the block that writes to the signal during evaluation of its block methods (equations). The destinations of the signal are blocks that read the signal during the evaluation of the block's methods (equations).

A good way to understand the definition of a signal is to consider a classroom. The teacher is the one responsible for writing on the white board and the students read what is written on the white board when they choose to. This is also true of Simulink signals: a reader of the signal (a block method) can choose to read the signal as frequently or infrequently as so desired.

For more information about signals, see “Signals”.

Block Methods

Blocks represent multiple equations. These equations are represented as block methods. These block methods are evaluated (executed) during the execution of a block diagram. The evaluation of these block methods is performed within a simulation loop, where each cycle through the simulation loop represents the evaluation of the block diagram at a given point in time.

Method Types

Names are assigned to the types of functions performed by block methods. Common method types include:

- Outputs

Computes the outputs of a block given its inputs at the current time step and its states at the previous time step.

- Update

Computes the value of the block's discrete states at the current time step, given its inputs at the current time step and its discrete states at the previous time step.

- Derivatives

Computes the derivatives of the block's continuous states at the current time step, given the block's inputs and the values of the states at the previous time step.

Method Naming Convention

Block methods perform the same types of operations in different ways for different types of blocks. The Simulink user interface and documentation uses dot notation to indicate the specific function performed by a block method:

`BlockType.MethodType`

For example, the method that computes the outputs of a Gain block is referred to as

`Gain.Outputs`

The Simulink debugger takes the naming convention one step further and uses the instance name of a block to specify both the method type and the block instance on which the method is being invoked during simulation, e.g.,

g1.Outputs

Model Methods

In addition to block methods, a set of methods is provided that compute the model properties and its outputs. The Simulink software similarly invokes these methods during simulation to determine a model's properties and its outputs. The model methods generally perform their tasks by invoking block methods of the same type. For example, the model Outputs method invokes the Outputs methods of the blocks that it contains in the order specified by the model to compute its outputs. The model Derivatives method similarly invokes the Derivatives methods of the blocks that it contains to determine the derivatives of its states.

Simulation Phases in Dynamic Systems

In this section...

“Model Compilation” on page 3-17

“Link Phase” on page 3-18

“Simulation Loop Phase” on page 3-18

Model Compilation

The first phase of simulation occurs when the system’s model is open and you simulate the model. In the Simulink Editor, select **Simulation > Run**. Running the simulation causes the Simulink engine to invoke the model compiler. The model compiler converts the model to an executable form, a process called compilation. In particular, the compiler:

- Evaluates the model's block parameter expressions to determine their values.
- Determines signal attributes, e.g., name, data type, numeric type, and dimensionality, not explicitly specified by the model and checks that each block can accept the signals connected to its inputs.
- A process called attribute propagation is used to determine unspecified attributes. This process entails propagating the attributes of a source signal to the inputs of the blocks that it drives.
- Performs block reduction optimizations.
- Flattens the model hierarchy by replacing virtual subsystems with the blocks that they contain (see “Solvers” on page 3-21).
- Determines the block sorted order (see “Control and Display the Sorted Order” on page 33-26 for more information).
- Determines the sample times of all blocks in the model whose sample times you did not explicitly specify (see “How Propagation Affects Inherited Sample Times” on page 7-38).

These events are essentially the same as what occurs when you update a diagram (“Update Diagram and Run Simulation” on page 1-64). The difference is that the Simulink software starts model compilation as part of model simulation, where compilation leads directly into the linking phase, as described in “Link Phase” on page 3-18. In contrast, you start an explicit model update as a standalone operation on a model.

Link Phase

In this phase, the Simulink engine allocates memory needed for working areas (signals, states, and run-time parameters) for execution of the block diagram. It also allocates and initializes memory for data structures that store run-time information for each block. For built-in blocks, the principal run-time data structure for a block is called the SimBlock. It stores pointers to a block's input and output buffers and state and work vectors.

Method Execution Lists

In the Link phase, the Simulink engine also creates method execution lists. These lists list the most efficient order in which to invoke a model's block methods to compute its outputs. The block sorted order lists generated during the model compilation phase is used to construct the method execution lists.

Block Priorities

You can assign update priorities to blocks (see “Assign Block Priorities” on page 33-40). The output methods of higher priority blocks are executed before those of lower priority blocks. The priorities are honored only if they are consistent with its block sorting rules.

Simulation Loop Phase

Once the Link Phase completes, the simulation enters the simulation loop phase. In this phase, the Simulink engine successively computes the states and outputs of the system at intervals from the simulation start time to the finish time, using information provided by the model. The successive time points at which the states and outputs are computed are called time steps. The length of time between steps is called the step size. The step size depends on the type of solver (see “Solvers” on page 3-21) used to compute the system's continuous states, the system's fundamental sample time (see “Sample Times in Systems” on page 7-28), and whether the system's continuous states have discontinuities (see “Zero-Crossing Detection” on page 3-24).

The Simulation Loop phase has two subphases: the Loop Initialization phase and the Loop Iteration phase. The initialization phase occurs once, at the start of the loop. The iteration phase is repeated once per time step from the simulation start time to the simulation stop time.

At the start of the simulation, the model specifies the initial states and outputs of the system to be simulated. At each step, new values for the system's inputs, states, and

outputs are computed, and the model is updated to reflect the computed values. At the end of the simulation, the model reflects the final values of the system's inputs, states, and outputs. The Simulink software provides data display and logging blocks. You can display and/or log intermediate results by including these blocks in your model.

Loop Iteration

At each time step, the Simulink engine:

- 1** Computes the model's outputs.

The Simulink engine initiates this step by invoking the Simulink model Outputs method. The model Outputs method in turn invokes the model system Outputs method, which invokes the Outputs methods of the blocks that the model contains in the order specified by the Outputs method execution lists generated in the Link phase of the simulation (see “Solvers” on page 3-21).

The system Outputs method passes the following arguments to each block Outputs method: a pointer to the block's data structure and to its SimBlock structure. The SimBlock data structures point to information that the Outputs method needs to compute the block's outputs, including the location of its input buffers and its output buffers.

- 2** Computes the model's states.

The Simulink engine computes a model's states by invoking a solver. Which solver it invokes depends on whether the model has no states, only discrete states, only continuous states, or both continuous and discrete states.

If the model has only discrete states, the Simulink engine invokes the discrete solver selected by the user. The solver computes the size of the time step needed to hit the model's sample times. It then invokes the Update method of the model. The model Update method invokes the Update method of its system, which invokes the Update methods of each of the blocks that the system contains in the order specified by the Update method lists generated in the Link phase.

If the model has only continuous states, the Simulink engine invokes the continuous solver specified by the model. Depending on the solver, the solver either in turn calls the Derivatives method of the model once or enters a subcycle of minor time steps where the solver repeatedly calls the model's Outputs methods and Derivatives methods to compute the model's outputs and derivatives at successive intervals within the major time step. This is done to increase the accuracy of the

state computation. The model Outputs method and Derivatives methods in turn invoke their corresponding system methods, which invoke the block Outputs and Derivatives in the order specified by the Outputs and Derivatives methods execution lists generated in the Link phase.

- 3 Optionally checks for discontinuities in the continuous states of blocks.

A technique called zero-crossing detection is used to detect discontinuities in continuous states. See “Zero-Crossing Detection” on page 3-24 for more information.

- 4 Computes the time for the next time step.

Steps 1 through 4 are repeated until the simulation stop time is reached.

Solvers

A dynamic system is simulated by computing its states at successive time steps over a specified time span, using information provided by the model. The process of computing the successive states of a system from its model is known as solving the model. No single method of solving a model suffices for all systems. Accordingly, a set of programs, known as *solvers*, are provided that each embody a particular approach to solving a model. The Configuration Parameters dialog box allows you to choose the solver most suitable for your model (see “Solver Classification Criteria” on page 23-11).

Fixed-Step Solvers Versus Variable-Step Solvers

The solvers provided in the Simulink software fall into two basic categories: fixed-step and variable-step.

Fixed-step solvers solve the model at regular time intervals from the beginning to the end of the simulation. The size of the interval is known as the step size. You can specify the step size or let the solver choose the step size. Generally, decreasing the step size increases the accuracy of the results while increasing the time required to simulate the system.

Variable-step solvers vary the step size during the simulation, reducing the step size to increase accuracy when a model's states are changing rapidly and increasing the step size to avoid taking unnecessary steps when the model's states are changing slowly. Computing the step size adds to the computational overhead at each step but can reduce the total number of steps, and hence simulation time, required to maintain a specified level of accuracy for models with rapidly changing or piecewise continuous states.

Continuous Versus Discrete Solvers

The Simulink product provides both continuous and discrete solvers.

Continuous solvers use numerical integration to compute a model's continuous states at the current time step based on the states at previous time steps and the state derivatives. Continuous solvers rely on the individual blocks to compute the values of the model's discrete states at each time step.

Mathematicians have developed a wide variety of numerical integration techniques for solving the ordinary differential equations (ODEs) that represent the continuous states

of dynamic systems. An extensive set of fixed-step and variable-step continuous solvers are provided, each of which implements a specific ODE solution method (see “Solver Classification Criteria” on page 23-11).

Discrete solvers exist primarily to solve purely discrete models. They compute the next simulation time step for a model and nothing else. In performing these computations, they rely on each block in the model to update its individual discrete states. They do not compute continuous states.

Note You must use a continuous solver to solve a model that contains both continuous and discrete states. You cannot use a discrete solver because discrete solvers cannot handle continuous states. If, on the other hand, you select a continuous solver for a model with no states or discrete states only, Simulink software uses a discrete solver.

Two discrete solvers are provided: A fixed-step discrete solver and a variable-step discrete solver. The fixed-step solver by default chooses a step size and hence simulation rate fast enough to track state changes in the fastest block in your model. The variable-step solver adjusts the simulation step size to keep pace with the actual rate of discrete state changes in your model. This can avoid unnecessary steps and hence shorten simulation time for multirate models (see “Sample Times in Systems” on page 7-28 for more information).

Minor Time Steps

Some continuous solvers subdivide the simulation time span into major and minor time steps, where a minor time step represents a subdivision of the major time step. The solver produces a result at each major time step. It uses results at the minor time steps to improve the accuracy of the result at the major time step.

Shape Preservation

Usually the integration step size is only related to the current step size and the current integration error. However, for signals whose derivative changes rapidly, you can obtain a more accurate integration results by including the derivative input information at each time step. To do so, enable the **Model Configuration Parameters > Solver > Shape Preservation** option.

“Simulation Phases in Dynamic Systems” on page 3-17

Zero-Crossing Detection

A variable-step solver dynamically adjusts the time step size, causing it to increase when a variable is changing slowly and to decrease when the variable changes rapidly. This behavior causes the solver to take many small steps in the vicinity of a discontinuity because the variable is rapidly changing in this region. This improves accuracy but can lead to excessive simulation times.

The Simulink software uses a technique known as *zero-crossing detection* to accurately locate a discontinuity without resorting to excessively small time steps. Usually this technique improves simulation run time, but it can cause some simulations to halt before the intended completion time.

Two algorithms are provided in the Simulink software: Nonadaptive and Adaptive. For information about these techniques, see “Zero-Crossing Algorithms” on page 3-32.

Demonstrating Effects of Excessive Zero-Crossing Detection

The Simulink software comes with three models that illustrate zero-crossing behavior: `sldemo_bounce_two_integrators`, `sldemo_doublebounce`, and `sldemo_bounce`.

- The `sldemo_bounce_two_integrators` model demonstrates how excessive zero crossings can cause a simulation to halt before the intended completion time unless you use the adaptive algorithm.
- The `sldemo_bounce` model uses a better model design than `sldemo_bounce_two_integrators`.
- The `sldemo_doublebounce` model demonstrates how the adaptive algorithm successfully solves a complex system with two distinct zero-crossing requirements.

The Bounce Model with Two Integrators

Bouncing Ball Model

Two separate Integrators are less efficient than a single Second-Order Integrator for simulating a bouncing ball.
[Click here to see sldemo_bounce for the recommended modeling approach.](#)

- 1 At the MATLAB command prompt, type `sldemo_bounce_two_integrators` to load the example.
- 2 Once the block diagram appears, set the **Model Configuration Parameters** > **Solver** > **Algorithm** parameter to **Nonadaptive**.
- 3 Also in the **Solver** pane, set the **Stop time** parameter to 20 s.
- 4 Run the model. In the Simulink Editor, select **Simulation** > **Run**.
- 5 After the simulation completes, click the Scope block window to see the results.

You may need to click on **Autoscale** to view the results in their entirety.

- 6 Use the scope zoom controls to closely examine the last portion of the simulation. You can see that the velocity is hovering just above zero at the last time point.

- 7 Change the simulation **Stop time** edit box in the Simulink Editor toolbar to 25 seconds, and run the simulation again.
- 8 This time the simulation halts with an error shortly after it passes the simulated 20 second time point.

Excessive chattering as the ball repeatedly approaches zero velocity has caused the simulation to exceed the default limit of 1000 for the number of consecutive zero crossings allowed. Although you can increase this limit by adjusting the **Model Configuration Parameters > Solver > Number of consecutive zero crossings** parameter. In this case, making that change does not allow the simulation to simulate for 25 seconds.

- 9 Also in the **Solver** pane, from the **Algorithm** pull down menu, select the **Adaptive** algorithm.
- 10 Run the simulation again.
- 11 This time the simulation runs to completion because the adaptive algorithm prevented an excessive number of zero crossings from occurring.

Bounce Model with a Second-Order Integrator

The Double-Bounce Model

- 1 At the MATLAB command prompt, type `sldemo_doublebounce` to load the example. The model and an animation window open. In the animation window, two balls are resting on two platforms.
- 2 In the animation window, click the **Nonadaptive** button to run the example using the nonadaptive algorithm. This is the default setting used by the Simulink software for all models.
- 3 The ball on the right is given a larger initial velocity. Consequently, the two balls hit the ground and recoil at different times.
- 4 The simulation halts after 14 seconds because the ball on the left exceeded the number of zero crossings limit. The ball on the right is left hanging in mid air.
- 5 An error message dialog opens. Click **OK** to close it.
- 6 Click on the **Adaptive** button to run the simulation with the adaptive algorithm.
- 7 Notice that this time the simulation runs to completion, even after the ground shifts out from underneath the ball on the left at 20 seconds.

How the Simulator Can Miss Zero-Crossing Events

The bounce and double-bounce models show that high-frequency fluctuations about a discontinuity ('chattering') can cause a simulation to prematurely halt.

It is also possible for the solver to entirely miss zero crossings if the solver error tolerances are too large. This is possible because the zero-crossing detection technique checks to see if the value of a signal has changed sign after a major time step. A sign change indicates that a zero crossing has occurred, and the zero-crossing algorithm will then hunt for the precise crossing time. However, if a zero crossing occurs within a time step, but the values at the beginning and end of the step do not indicate a sign change, the solver steps over the crossing without detecting it.

The following figure shows a signal that crosses zero. In the first instance, the integrator steps over the event because the sign has not changed between time steps. In the second, the solver detects change in sign and so detects the zero-crossing event.

Preventing Excessive Zero Crossings

Use the following table to prevent excessive zero-crossing errors in your model.

Make this change...	How to make this change...	Rationale for making this change...
Increase the number of allowed zero crossings	Increase the value of the Number of consecutive zero crossings option on the Solver pane in the Configuration Parameters dialog box.	This may give your model enough time to resolve the zero crossing.
Relax the Signal threshold	Select Adaptive from the Algorithm pull down and increase the value of the Signal threshold option on the Solver pane in the Configuration Parameters dialog box.	The solver requires less time to precisely locate the zero crossing. This can reduce simulation time and eliminate an excessive number of consecutive zero-crossing errors. However, relaxing the Signal threshold may reduce accuracy.
Use the Adaptive Algorithm	Select Adaptive from the Algorithm pull down on	This algorithm dynamically adjusts the zero-crossing

Make this change...	How to make this change...	Rationale for making this change...
	the Solver pane in the Configuration Parameters dialog box.	threshold, which improves accuracy and reduces the number of consecutive zero crossings detected. With this algorithm you have the option of specifying both the Time tolerance and the Signal threshold .
Disable zero-crossing detection for a specific block	<ol style="list-style-type: none"> 1 Clear the Enable zero-crossing detection check box on the block's parameter dialog box. 2 Select Use local settings from the Zero-crossing control pull down on the Solver pane of the Configuration Parameters dialog box. 	Locally disabling zero-crossing detection prevents a specific block from stopping the simulation because of excessive consecutive zero crossings. All other blocks continue to benefit from the increased accuracy that zero-crossing detection provides.
Disable zero-crossing detection for the entire model	Select Disable all from the Zero-crossing control pull down on the Solver pane of the Configuration Parameters dialog box.	This prevents zero crossings from being detected anywhere in your model. A consequence is that your model no longer benefits from the increased accuracy that zero-crossing detection provides.
If using the <code>ode15s</code> solver, consider adjusting the order of the numerical differentiation formulas	Select a value from the Maximum order pull down on the Solver pane of the Configuration Parameters dialog box.	For more information, see “Maximum order”.

Make this change...	How to make this change...	Rationale for making this change...
Reduce the maximum step size	Enter a value for the Max step size option on the Solver pane of the Configuration Parameters dialog box.	This can insure the solver takes steps small enough to resolve the zero crossing. However, reducing the step size can increase simulation time, and is seldom necessary when using the Adaptive algorithm.

Zero-Crossing Algorithms

The Simulink software includes two zero-crossing detection algorithms: Nonadaptive and Adaptive.

To choose the algorithm, either use the **Algorithm** option in the Solver pane of the Configuration Parameter dialog box, or use the `ZeroCrossAlgorithm` command. The command can either be set to 'Nonadaptive' or 'Adaptive'.

The Nonadaptive algorithm is provided for backwards compatibility with older versions of Simulink and is the default. It brackets the zero-crossing event and uses increasingly smaller time steps to pinpoint when the zero crossing has occurred. Although adequate for many types of simulations, the Nonadaptive algorithm can result in very long simulation times when a high degree of 'chattering' (high frequency oscillation around the zero-crossing point) is present.

The Adaptive algorithm dynamically turns the bracketing on and off, and is a good choice when:

- The system contains a large amount of chattering.
- You wish to specify a guard band (tolerance) around which the zero crossing is detected.

The Adaptive algorithm turns off zero-crossing bracketing (stops iterating) if either of the following are satisfied:

- The zero crossing error is exceeded. This is determined by the value specified in the **Signal threshold** option in the Solver pane of the Configuration Parameters dialog box. This can also be set with the `ZCThreshold` command. The default is `Auto`, but you can enter any real number greater than zero for the tolerance.

- The system has exceeded the number of consecutive zero crossings specified in the **Number of consecutive zero crossings** option in the Solver pane of the Configuration Parameters dialog box. Alternatively, this can be set with the `MaxConsecutiveZCs` command.

Understanding Signal Threshold

The Adaptive algorithm automatically sets a tolerance for zero-crossing detection. Alternatively, you can set the tolerance by entering a real number greater than or equal to zero in the Configuration Parameters Solver pane, **Signal threshold** pull down. This option only becomes active when the zero-crossing algorithm is set to **Adaptive**.

This graphic shows how the Signal threshold sets a window region around the zero-crossing point. Signals falling within this window are considered as being at zero.

The zero-crossing event is bracketed by time steps T_{n-1} and T_n . The solver iteratively reduces the time steps until the state variable lies within the band defined by the signal threshold, or until the number of consecutive zero crossings equals or exceeds the value in the Configuration Parameters Solver pane, **Number of consecutive zero crossings** pull down.

It is evident from the figure that increasing the signal threshold increases the distance between the time steps which will be executed. This often results in faster simulation times, but might reduce accuracy.

How Blocks Work with Zero-Crossing Detection

A block can register a set of zero-crossing variables, each of which is a function of a state variable that can have a discontinuity. The zero-crossing function passes through zero from a positive or negative value when the corresponding discontinuity occurs. The registered zero-crossing variables are updated at the end of each simulation step, and any variable that has changed sign is identified as having had a zero-crossing event.

If any zero crossings are detected, the Simulink software interpolates between the previous and current values of each variable that changed sign to estimate the times of the zero crossings (that is, the discontinuities).

Note: The Zero-Crossing detection algorithm can bracket zero-crossing events only for signals of data type double

Blocks That Register Zero Crossings

The following table lists blocks that register zero crossings and explains how the blocks use the zero crossings:

Block	Description of Zero Crossing
Abs	One: to detect when the input signal crosses zero in either the rising or falling direction.
Backlash	Two: one to detect when the upper threshold is engaged, and one to detect when the lower threshold is engaged.
Compare To Constant	One: to detect when the signal equals a constant.
Compare To Zero	One: to detect when the signal equals zero.
Dead Zone	Two: one to detect when the dead zone is entered (the input signal minus the lower limit), and one to detect when the dead zone is exited (the input signal minus the upper limit).
Enable	One: If an Enable port is inside of a Subsystem block, it provides the capability to detect zero crossings. See the Enable Subsystem block for details “Create an Enabled Subsystem” on page 10-23.
From File	One: to detect when the input signal has a discontinuity in either the rising or falling direction

Block	Description of Zero Crossing
From Workspace	One: to detect when the input signal has a discontinuity in either the rising or falling direction
Hit Crossing	One or two. If there is no output port, there is only one zero crossing to detect when the input signal hit the threshold value. If there is an output port, the second zero crossing is used to bring the output back to 0 from 1 to create an impulse-like output.
If	One: to detect when the If condition is met.
Integrator	If the reset port is present, to detect when a reset occurs. If the output is limited, there are three zero crossings: one to detect when the upper saturation limit is reached, one to detect when the lower saturation limit is reached, and one to detect when saturation is left.
MinMax	One: for each element of the output vector, to detect when an input signal is the new minimum or maximum.
Relational Operator	One: to detect when the specified relation is true.
Relay	One: if the relay is off, to detect the switch-on point. If the relay is on, to detect the switch-off point.
Saturation	Two: one to detect when the upper limit is reached or left, and one to detect when the lower limit is reached or left.
Second-Order Integrator	Five: two to detect when the state x upper or lower limit is reached; two to detect when the state dx/dt upper or lower limit is reached; and one to detect when a state leaves saturation.
Sign	One: to detect when the input crosses through zero.
Signal Builder	One: to detect when the input signal has a discontinuity in either the rising or falling direction
Step	One: to detect the step time.
Switch	One: to detect when the switch condition occurs.
Switch Case	One: to detect when the case condition is met.

Block	Description of Zero Crossing
Trigger	One: If a Triggered port is inside of a Subsystem block, it provides the capability to detect zero crossings. See the Triggered Subsystem block for details: “Create a Triggered Subsystem” on page 10-40.
Enabled and Triggered Subsystem	Two: one for the enable port and one for the trigger port. See the Triggered and Enabled Subsystem block for details: “Create a Triggered and Enabled Subsystem” on page 10-48

Note: Zero-crossing detection is also available for a Stateflow chart that uses continuous-time mode. See “Configure a Stateflow Chart to Update in Continuous Time” in the Stateflow documentation for more information.

Implementation Example: Saturation Block

An example of a Simulink block that registers zero crossings is the Saturation block. Zero-crossing detection identifies these state events in the Saturation block:

- The input signal reaches the upper limit.
- The input signal leaves the upper limit.
- The input signal reaches the lower limit.
- The input signal leaves the lower limit.

Simulink blocks that define their own state events are considered to have *intrinsic zero crossings*. Use the Hit Crossing block to receive explicit notification of a zero-crossing event. See “Blocks That Register Zero Crossings” on page 3-34 for a list of blocks that incorporate zero crossings.

The detection of a state event depends on the construction of an internal zero-crossing signal. This signal is not accessible by the block diagram. For the Saturation block, the signal that is used to detect zero crossings for the upper limit is `zcSignal = UpperLimit - u`, where `u` is the input signal.

Zero-crossing signals have a direction attribute, which can have these values:

- *rising* — A zero crossing occurs when a signal rises to or through zero, or when a signal leaves zero and becomes positive.

- *falling* — A zero crossing occurs when a signal falls to or through zero, or when a signal leaves zero and becomes negative.
- *either* — A zero crossing occurs if either a rising or falling condition occurs.

For the Saturation block's upper limit, the direction of the zero crossing is *either*. This enables the entering and leaving saturation events to be detected using the same zero-crossing signal.

What Is an Algebraic Loop?

In a Simulink model, an *algebraic loop* occurs when a signal loop exists with only direct feedthrough blocks within the loop. *Direct feedthrough* means that the block output depends on the value of an input port; the value of the input directly controls the value of the output.

Some blocks have input ports with direct feedthrough. Simulink cannot compute the output of these blocks without knowing the values of the signals entering the blocks at these input ports at the current time step.

Some examples of blocks with direct feedthrough inputs are:

- Math Function
- Gain
- Product

- State-Space, when the D matrix coefficient is nonzero
- Sum
- Transfer Fcn, when the numerator and denominator are of the same order
- Zero-Pole, when the block has as many zeros as poles

Nondirect feedthrough blocks maintain a State variable. Two examples are Integrator and Unit Delay.

Tip To determine if a block has direct feedthrough, read the **Characteristics** section of the block reference page.

The figure shows an example of an algebraic loop (for demonstration only, not a recommended modeling pattern). The Sum block is an algebraic variable x_a that is constrained to equal the first input u minus x_a (for example, $x_a = u - x_a$).

The solution of this simple loop is $x_a = u/2$.

Interpretations of Algebraic Loops

Mathematical Interpretation

Simulink contains a suite of numerical solvers for simulating *ordinary differential equations (ODEs)*, which are systems of equations that you can write as

$$\dot{x} = f(x, t),$$

where:

- x is the state vector.

- t is the independent time variable.

Some systems of equations contain additional constraints that involve the independent variable and the state vector, but not the derivative of the state vector. Such systems are *differential algebraic equations (DAEs)*, not ODEs.

The term *algebraic* refers to equations that do not involve any derivatives. You can express DAEs that arise in engineering in the semi-explicit form

$$\begin{aligned}\dot{\mathbf{x}} &= \mathbf{f}(\mathbf{x}, \mathbf{x}_a, t) \\ 0 &= \mathbf{g}(\mathbf{x}, \mathbf{x}_a, t),\end{aligned}$$

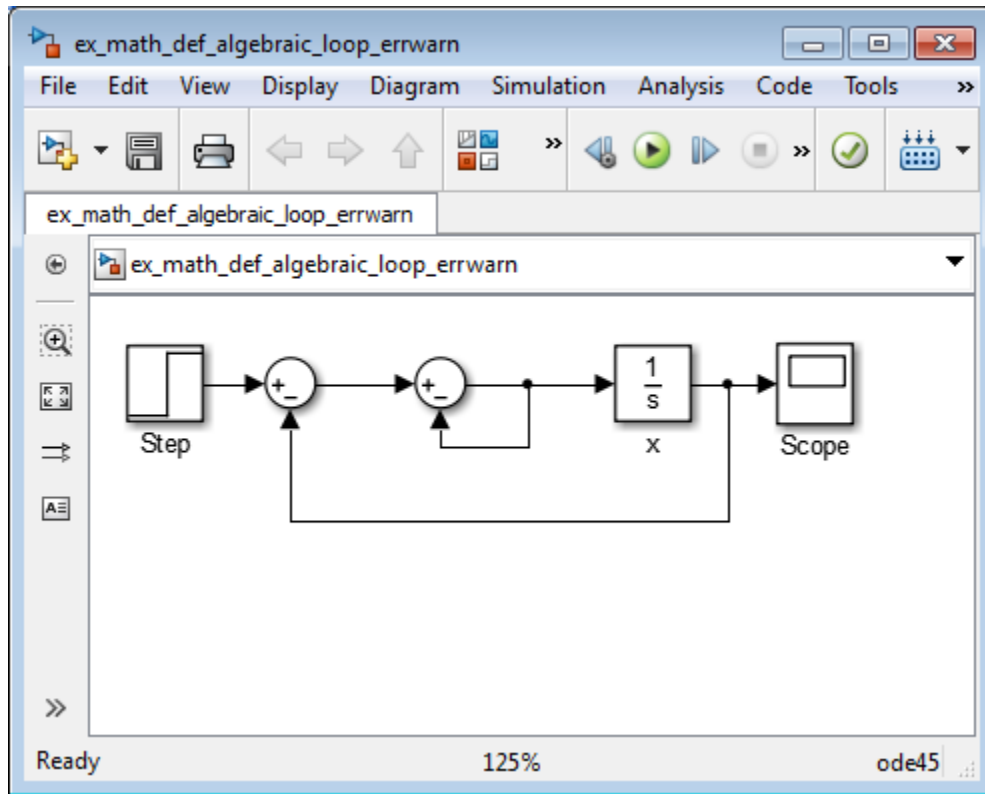

where:

- \mathbf{f} and \mathbf{g} can be vector functions.
- The first equation is the differential equation.
- The second equation is the algebraic equation.
- The vector of differential variables is \mathbf{x} .
- The vector of algebraic variables is \mathbf{x}_a .

In Simulink models, algebraic loops are algebraic constraints. Models with algebraic loops define a system of differential algebraic equations. Simulink does not solve DAEs directly. Simulink solves the algebraic equations (the algebraic loop) numerically for x_a at each step of the ODE solver.

The model in the figure is equivalent to this system of equations in semi-explicit form:

$$\begin{aligned}\dot{x} &= f(x, x_a, t) = x_a \\ 0 &= g(x, x_a, t) = -x + u - 2x_a.\end{aligned}$$

At each step of the ODE solver, the algebraic loop solver must solve the algebraic constraint for x_a before calculating the derivative \dot{x} .

Physical Interpretation

Algebraic constraints:

- Occur when modeling physical systems, often due to conservation laws, such as conservation of mass and energy
- Occur when you choose a particular coordinate system for a model
- Help impose design constraints on system responses in a dynamic system

Use Simscape to model systems that span mechanical, electrical, hydraulic, and other physical domains as physical networks. Simscape constructs the DAEs that characterize

the behavior of a model. The software integrates these equations with the rest of the model and then solves the DAEs directly. Simulink solves the variables for the components in the different physical domains simultaneously, avoiding problems with algebraic loops.

What is an Artificial Algebraic Loop?

An *artificial algebraic loop* occurs when an atomic subsystem or Model block causes Simulink to detect an algebraic loop, even though the contents of the subsystem do not contain an algebraic constraint. When you create an atomic subsystem, all Inport blocks are direct feedthrough, resulting in an algebraic loop.

Example of an Artificial Algebraic Loop

Start with this model, which does not contain an algebraic loop. It simulates without error.

- 1 Enclose the Controller and Plant blocks in a subsystem.
- 2 In the subsystem block dialog box, select **Treat as atomic unit** to make the subsystem atomic.
- 3 In the **Diagnostics** pane of Model Configuration Parameters, set the **Algebraic loop** parameter to error.

When simulating this model, an algebraic loop occurs because the subsystem is direct feedthrough, even though the path within the atomic subsystem is not direct feedthrough. Simulation stops with an algebraic loop error.

Why Algebraic Loops Are Undesirable

If your model contains an algebraic loop:

- You cannot generate code for the model.

- The Simulink algebraic loop solver might not be able to solve the algebraic loop.
- While Simulink is trying to solve the algebraic loop, the simulation can execute slowly.

For most models, the algebraic loop solver is computationally expensive for the first time step. Simulink solves subsequent time steps rapidly because a good starting point for x_a is available from the previous time step.

Identify Algebraic Loops in Your Model

Use these techniques to search for algebraic loops in your model:

- “Highlight Algebraic Loops in the Model” on page 3-44
- “Use The Algebraic Loop Diagnostic” on page 3-45
- “Use The ashow Debugger Command” on page 3-46

Highlight Algebraic Loops in the Model

Use `getAlgebraicLoops` to identify algebraic loops in a model and highlight them in the Simulink Editor. With this approach:

- You can traverse multiple layers of model hierarchy to locate algebraic loops.
- You can identify real and artificial algebraic loops.
- You can visualize all loops in your model simultaneously.
- You do not need to drill in and out of the model, across boundaries.
- You do not need to detect loops in serial order. Also, you do not need to compile the model every time you detect and solve a loop. Therefore you can solve loops quickly.

You perform algebraic loop highlighting on an entire model, not on specific subsystems.

- 1 Open the model.
- 2 In the **Diagnostics** pane of Model Configuration Parameters, set **Algebraic loop** to **none** or **warning**. Setting this parameter to **error** prevents the model from compiling.
- 3 Compile the model without any errors. The model must compile before you can highlight any algebraic loops.
- 4 At the MATLAB command prompt, enter:

```
Simulink.BlockDiagram.getAlgebraicLoops(bdroot)
```

The `getAlgebraicLoops` function highlights algebraic loops in the model, including algebraic loops in subsystems. It also creates a report with information about each loop:

- Solid lines represent real algebraic loops.
- Dotted lines represent artificial algebraic loops.
- A red highlight appears around a block assigned with an algebraic variable.
- The **Loop ID** helps you identify the system that contains a particular loop.

Customize the report by selecting or clearing the **Visible** checkbox for a loop.

Once you have identified algebraic loops in a model, you can remove them by editing the model. Close the highlight report and make changes to the model. You can edit the model only after you close the report. For information on removing real algebraic loops, see “Remove Algebraic Loops” on page 3-51.

Simulink does not save loop highlighting. Closing the model or exiting the display using the table removes the loop highlighting.

Use The Algebraic Loop Diagnostic

Simulink detects algebraic loops during simulation initialization, for example, when you update your diagram. You can set the **Algebraic loop** diagnostic to report an error or warning if the software detects any algebraic loops in your model.

In the **Diagnostics** pane of the Model Configuration Parameters, set the **Algebraic loop** parameter.

Setting	Simulation Response
none	Simulink tries to solve the algebraic loop; reports an error only if the algebraic loop cannot be solved.
warning	Algebraic loops result in warnings. Simulink tries to solve the algebraic loop; reports an error only if the algebraic loop cannot be solved.
error	Algebraic loops stop the initialization. Review the loop manually before Simulink tries to solve the loop.

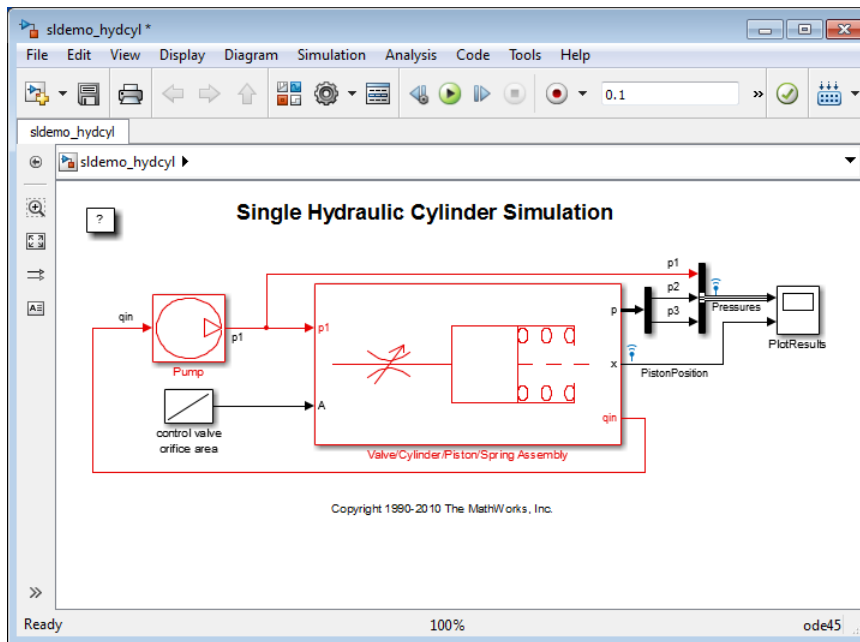

This example shows how to use the algebraic loop diagnostic to highlight algebraic loops in the `sldemo_hydcyl` model.

- 1 Open the `sldemo_hydcyl` model.

- 2 In the **Diagnostics** pane of the Model Configuration Parameters, set the **Algebraic loop** parameter to **error**.
- 3 Simulate the model.

When Simulink detects an algebraic loop during initialization, the simulation stops. The Diagnostic Viewer displays an error message and lists all the blocks in the model that are part of that algebraic loop.

In the model, red highlights show the blocks and signals that make up the loop.

- 4 Close the Diagnostic Viewer to remove the highlights.
- 5 Close sldemo_hydcyl model. Do not save the changes.

Use The `ashow` Debugger Command

Use the `ashow` command in the Simulink debugger to highlight algebraic loops and step through a simulation.

- 1 Open the sldemo_hydcyl model.

By default, the **Algebraic loop** parameter for this model is set to `none`.

- 2 Start the Simulink debugger. Select **Simulation > Debug > Debug Model**.

Run the debugger.

- 3 In the MATLAB command prompt, enter:

```
ashow
```

The command returns the algebraic loop in `sldemo_hydcyl` and the number of blocks in the loop.

```
Found 1 Algebraic loop(s):
System#Algebraic loop id, number of blocks in loop
- 0#1, 9 blocks in loop
```

- 4 To list the blocks in this algebraic loop, at the MATLAB command prompt, enter:

```
ashow 0#1
```

The Control Valve Flow subsystem in the Valve/Cylinder/Piston/Spring Assembly subsystem opens with the algebraic loop in the model highlighted. The function lists the nine blocks in the algebraic loop:

```
- sldemo_hydcyl/Valve//Cylinder//Piston//Spring Assembly/Control Valve Flow/IC
- sldemo_hydcyl/Valve//Cylinder//Piston//Spring Assembly/Control Valve Flow/signed sqrt
- sldemo_hydcyl/Valve//Cylinder//Piston//Spring Assembly/Control Valve Flow/Product
- sldemo_hydcyl/Valve//Cylinder//Piston//Spring Assembly/laminar flow pressure drop
- sldemo_hydcyl/Valve//Cylinder//Piston//Spring Assembly/Sum7
- sldemo_hydcyl/Pump/IC
- sldemo_hydcyl/Valve//Cylinder//Piston//Spring Assembly/Control Valve Flow/
Sum1 (algebraic variable)
- sldemo_hydcyl/Pump/Sum1
- sldemo_hydcyl/Pump/leakage (algebraic variable)
```

How to Handle Algebraic Loops in a Model

If Simulink reports an algebraic loop in your model, the algebraic loop solver may be able to solve the loop. If Simulink cannot solve the loop, there are several techniques to eliminate the loop.

Use this workflow to decide how you want to eliminate an algebraic loop.

How the Algebraic Loop Solver Works

When a model contains an algebraic loop, Simulink uses a nonlinear solver at each time step to solve the algebraic loop. The solver performs iterations to determine the solution to the algebraic constraint, if there is one. As a result, models with algebraic loops can run more slowly than models without algebraic loops.

Simulink uses a dogleg trust region algorithm to solve algebraic loops. The tolerance used is smaller than the ODE solver `RelTol` and `Abstol`. This is because Simulink uses the “explicit ODE method” to solve Index-1 differential algebraic equations (DAEs).

For the algebraic loop solver to work,

- There must be one block where the loop solver can break the loop and attempt to solve the loop.
- The model should have real double signals.
- The underlying algebraic constraint must be a smooth function

For example, suppose your model has a Sum block with two inputs—one additive, the other subtractive. If you feed the output of the Sum block to one of the inputs, you create an algebraic loop where all of the blocks include direct feedthrough.

The Sum block cannot compute the output without knowing the input. Simulink detects the algebraic loop, and the algebraic loop solver solves the loop using an iterative loop. In the Sum block example, the software computes the correct result this way:

$$x_a(t) = u(t) / 2.$$

The algebraic loop solver uses a gradient-based search method, which requires continuous first derivatives of the algebraic constraint that correspond to the algebraic loop. As a result, if the algebraic loop contains discontinuities, the algebraic loop solver can fail.

For more information, see Solving Index-1 DAEs in MATLAB and Simulink ¹

Trust-Region and Line-Search Algorithms in the Algebraic Loop Solver

The Simulink algebraic loop solver uses one of two algorithms to solve algebraic loops:

- Trust-Region
- Line-Search

By default, the algebraic loop solver uses the trust-region algorithm.

If the algebraic loop solver cannot solve the algebraic loop with the trust-region algorithm, try simulating the model using the line-search algorithm.

To switch to the line-search algorithm, at the MATLAB command line, enter:

```
set_param(model_name, 'AlgebraicLoopSolver', 'LineSearch');
```

To switch back to the trust-region algorithm, at the MATLAB command line, enter:

```
set_param(model_name, 'AlgebraicLoopSolver', 'TrustRegion');
```

Limitations of the Algebraic Loop Solver

Algebraic loop solving is an iterative process. The Simulink algebraic loop solver is successful only if the algebraic loop converges to a definite answer. When the loop fails to converge, or converges too slowly, the simulation exits with an error.

3. Rabinowitz, Philip, ed. *Numerical Methods for Nonlinear Algebraic Equations*, New York: Gordon and Breach Science Publishers, 1970.

The algebraic loop solver cannot solve algebraic loops that contain any of the following:

- Blocks with discrete-valued outputs
- Blocks with nondouble or complex outputs
- Discontinuities
- Stateflow charts

Remove Algebraic Loops

Use these techniques to remove algebraic loops in a model.

- “Introduce a Delay” on page 3-51
- “Solve Algebraic Loops Manually” on page 3-53
- “Create Initial Guesses Using the IC and Algebraic Constraint Blocks” on page 3-54

Introduce a Delay

Algebraic loops can occur in large models when atomic subsystems create feedback loops.

In the generic model here, there are two algebraic loops that involve subsystems.

- BlackBox_A \rightarrow BlackBox_B \rightarrow BlackBox_C \rightarrow BlackBox_A
- BlackBox_B \rightarrow BlackBox_C \rightarrow BlackBox_B

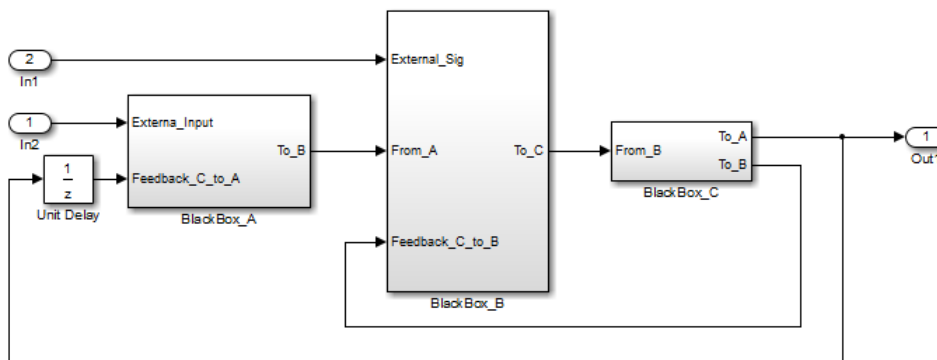

When you update this model, Simulink detects the loop BlackBox_A → BlackBox_B → BlackBox_C → BlackBox_A.

Since you do not know the contents of these subsystems, break the loops by adding a Unit Delay block outside the subsystems. There are three ways to use the Unit Delay to break these loops:

- Add a unit delay between BlackBox_A and BlackBox_C
- Add a unit delay between BlackBox_B and BlackBox_C
- Add unit delays to both algebraic loops

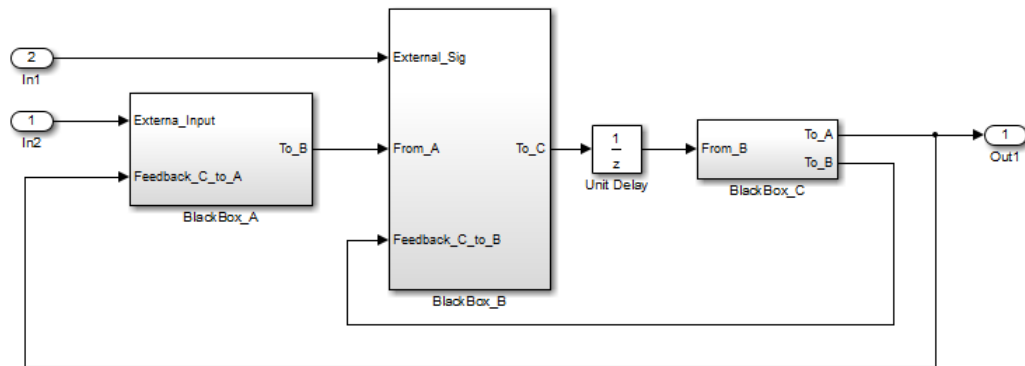

Add a unit delay between BlackBox_A and BlackBox_C

If you add a unit delay on the feedback signal between the subsystems BlackBox_A and BlackBox_C, you introduce the minimum number of unit delays (1) to the system. By introducing the delay before BlackBox_A, BlackBox_B and BlackBox_C use data from the current time step.

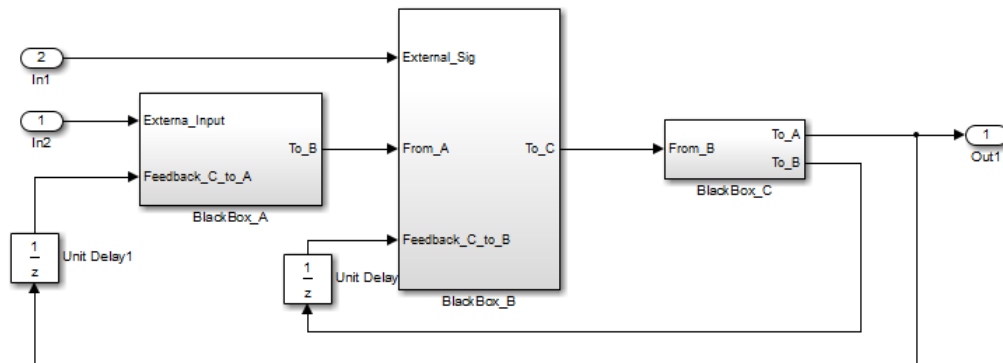

Add a unit delay between BlackBox_B and BlackBox_C

If you add a unit delay between the subsystems BlackBox_B and BlackBox_C, you break the algebraic loop between BlackBox_B and BlackBox_C. In addition, you break the loop between BlackBox_A and BlackBox_C, because that signal completes the algebraic loop. By inserting the Unit Delay block before BlackBox_C, BlackBox_C now works with data from the previous time step only.

Add unit delays to both algebraic loops

In the example here, you insert Unit Delay blocks to break both algebraic loops. In this model, BlackBox_A and BlackBox_B use data from the previous time step. BlackBox_C uses data from the current time step.

Solve Algebraic Loops Manually

If Simulink cannot solve the algebraic loop, the software reports an error. Use one of these techniques to solve the loop manually:

- Restructure the underlying DAEs using techniques such as differentiation or change of coordinates. These techniques put the DAEs in a form that is easier for the algebraic loop solver to solve.
- Convert the DAEs to ODEs, which eliminates any algebraic loops.

- “Create Initial Guesses Using the IC and Algebraic Constraint Blocks” on page 3-54

Create Initial Guesses Using the IC and Algebraic Constraint Blocks

Your model might contain loops for which the loop solver cannot converge without a good, initial guess for the algebraic states. You can specify an initial guess for the algebraic state variables, but use this technique only when you think the loop is legitimate.

There are two ways to specify an initial guess:

- Place an **IC** block in the algebraic loop.
- Specify an initial guess for a signal in an algebraic loop using an **Algebraic Constraint** block.

Remove Artificial Algebraic Loops

Use these techniques to remove artificial algebraic loops in a model:

- “Eliminate Artificial Algebraic Loops Caused by Atomic Subsystems” on page 3-54
- “Bundled Signals That Create Artificial Algebraic Loops” on page 3-55
- “Model and Block Parameters to Diagnose and Eliminate Artificial Algebraic Loops” on page 3-59
- “Block Reduction and Artificial Algebraic Loops” on page 3-60

Eliminate Artificial Algebraic Loops Caused by Atomic Subsystems

If an atomic subsystem causes an artificial algebraic loop, convert the atomic subsystem to a virtual subsystem. This change has no effect on the behavior of the model. When the subsystem is atomic and you simulate the model, Simulink invokes the algebraic loop solver. The solver terminates after one iteration. The algebraic loop is automatically solved because there is no algebraic constant. After you make the subsystem virtual, Simulink does not invoke the algebraic loop solver during simulation.

To convert an atomic subsystem to a virtual subsystem:

- 1 Open the model that contains the atomic subsystem.
- 2 Right-click the atomic subsystem and select **Subsystem Parameters**.
- 3 Clear the **Treat as atomic unit** parameter.
- 4 Save the changes.

If you replace the atomic subsystem with a virtual subsystem and the simulation still fails with an algebraic loop error, examine the model for one of these:

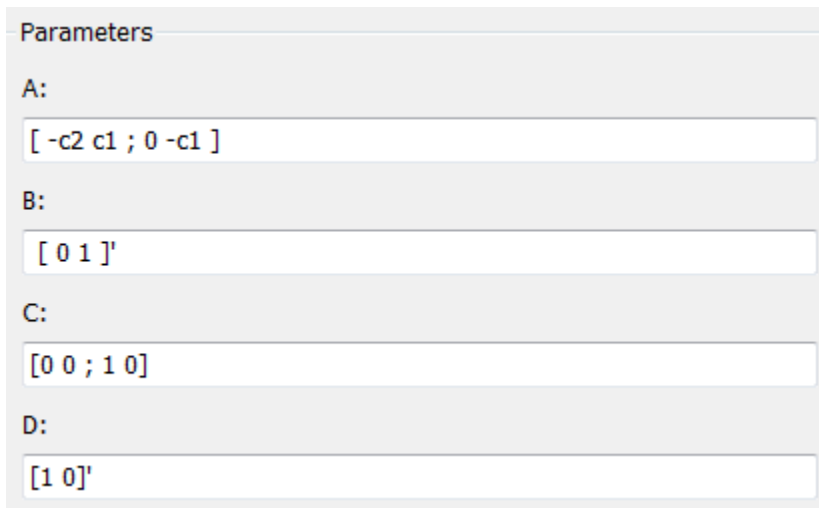

- An algebraic constraint
- An artificial algebraic loop that was not caused by this atomic subsystem

Bundled Signals That Create Artificial Algebraic Loops

Some models bundle signals together. This bundling can cause Simulink to detect an algebraic loop, even when an algebraic constraint does not exist. If you redirect one or more signals, you may be able to remove the artificial algebraic loop.

In this example, a linearized model simulates the dynamics of a two-tank system fed by a single pump. In this model:

- Output q_1 is the rate of the fluid flow into the tank from the pump.
- Output h_2 is the height of the fluid in the second tank.
- The State-Space block defines the dynamic response of the tank system to the pump operation:

Parameters

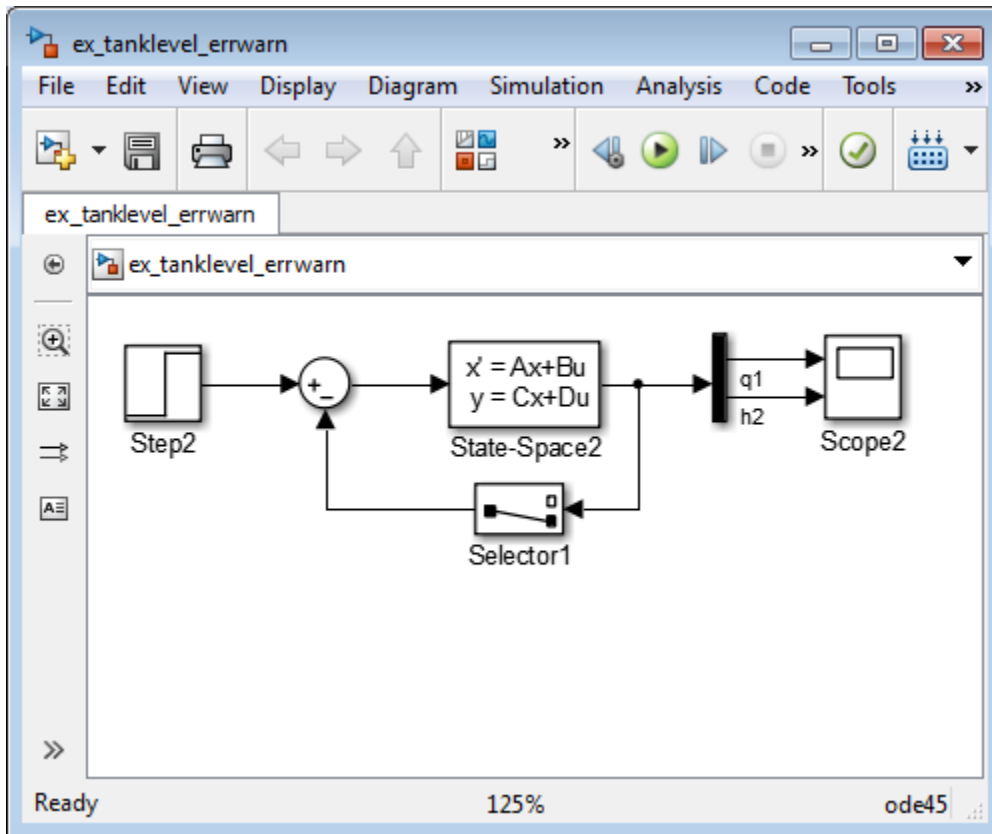

A:
[-c2 c1 ; 0 -c1]

B:
[0 1]'

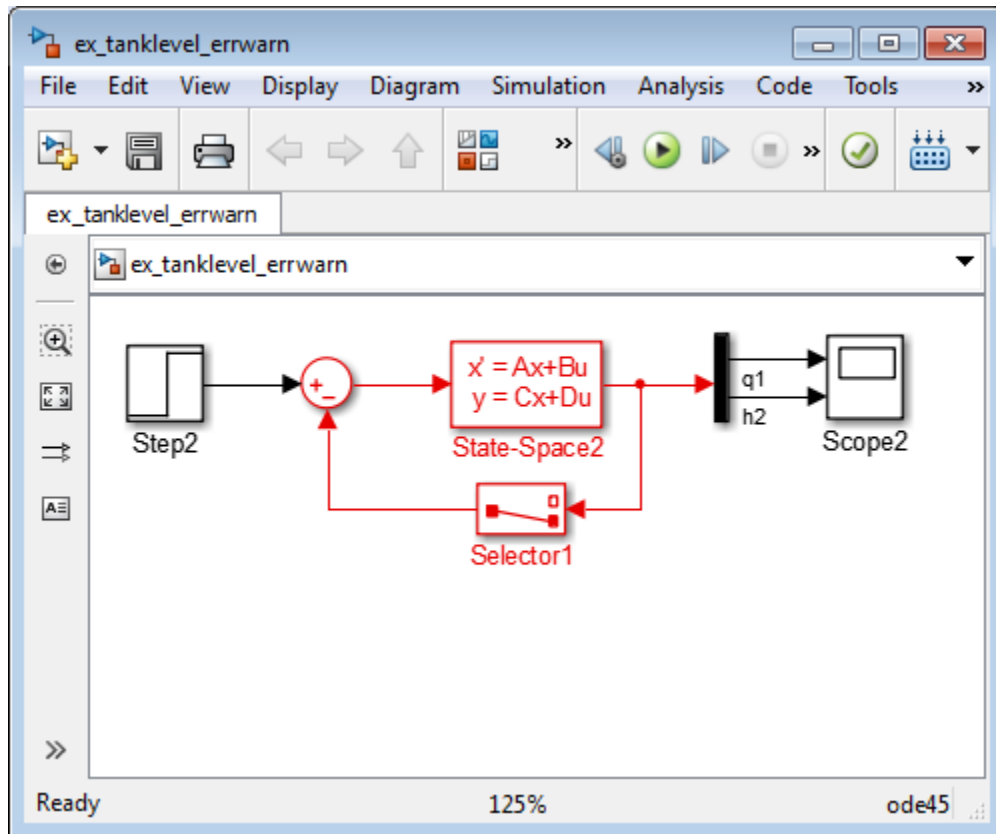

C:
[0 0 ; 1 0]

D:
[1 0]'

- The output from the State-Space block is a vector that contains q_1 and h_2 .

If you simulate this model with the **Algebraic loop** parameter set to warn or error, Simulink identifies the algebraic loop.

To eliminate this algebraic loop:

- 1 Change the C and D matrices as follows:

Parameters

A:
[-c2 c1 ; 0 -c1]

B:
[0 1]'

C:
[1 0]

D:
0

- 2 Pass q1 directly to the Scope instead of through the State-Space block.

Now, the input (q1) does not pass directly to the output (the D matrix is 0), so the State-Space block no longer has direct feedthrough. The feedback signal has only one element now, so the Selector block is no longer necessary, as you can see in the following model.

Model and Block Parameters to Diagnose and Eliminate Artificial Algebraic Loops

There are two parameters to consider when you think that your model has an artificial algebraic loop:

- **Minimize algebraic loop occurrences** parameter — Specify that Simulink try to eliminate any artificial algebraic loops for:
 - Atomic subsystems — In the Subsystem Parameters dialog box, select **Minimize algebraic loop occurrences**.
 - Model blocks — For the referenced model, in the **Model Referencing** pane of Configuration Parameters, select **Minimize algebraic loop occurrences**.
- **Minimize algebraic loop** parameter — Specifies what diagnostic action Simulink takes if the **Minimize algebraic loop occurrences** parameter has no effect.

The **Minimize algebraic loop** parameter is in the **Diagnostics** pane of Configuration Parameters. The diagnostic actions for this parameter are:

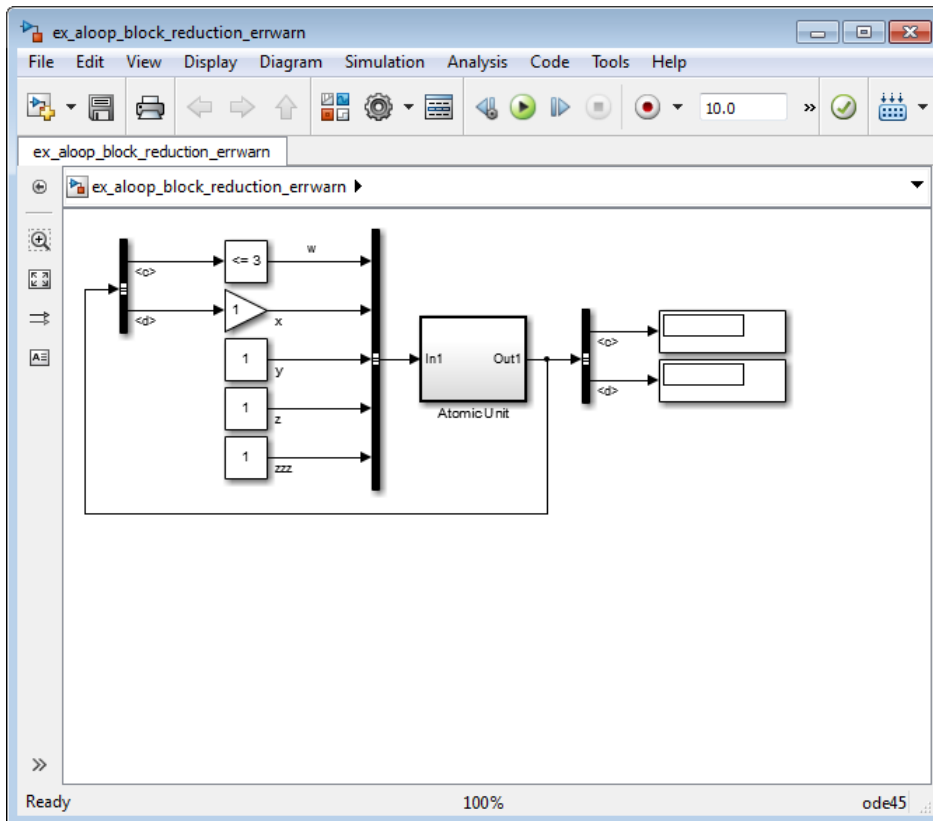

Setting	Simulation Response
none	Simulink takes no action.
warning	Simulink displays a warning that the Minimize algebraic loop occurrences parameter has no effect.
error	Simulink terminates the simulation and displays an error that the Minimize algebraic loop occurrences parameter has no effect.

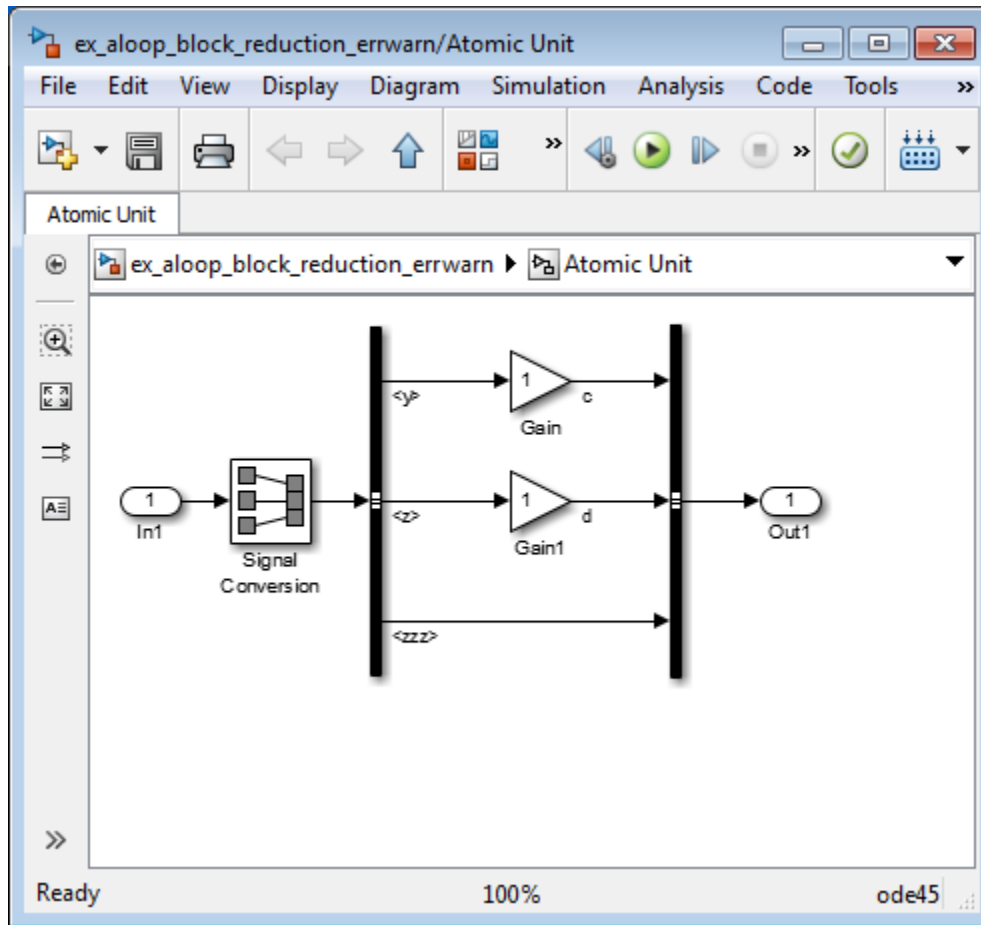

Block Reduction and Artificial Algebraic Loops

When you enable the **Block reduction** optimization in Model Configuration Parameters, Simulink collapses certain groups of blocks into a single, more efficient block, or removes them entirely. Enabling block reduction results in faster execution during model simulation and in generating code.

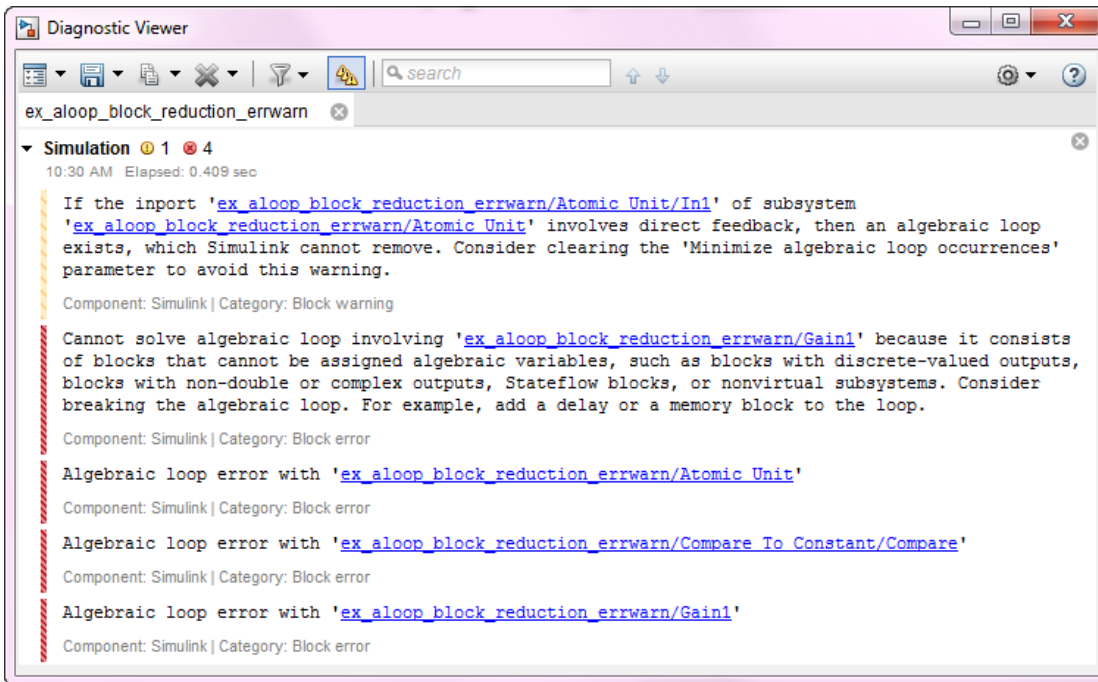

Enabling block reduction can also help Simulink solve artificial algebraic loops.

Consider the following example model.

Initially, block reduction is turned off. When you simulate this model, the Atomic Unit subsystem and Gain and Compare to Constant blocks are part of an algebraic loop that Simulink cannot solve.

If you enable block reduction and sorted order, and resimulate the model, Simulink does not display the sorted order for blocks that have been reduced. You can now quickly see which blocks have been reduced.

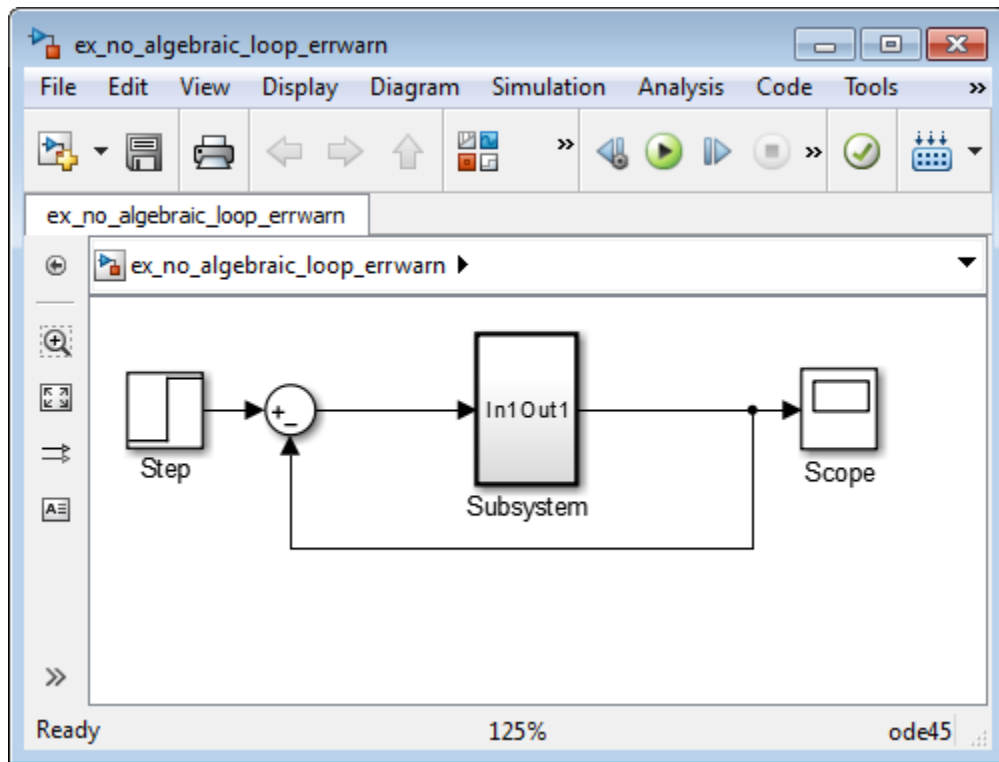

The Compare to Constant and Gain blocks have been eliminated from the model, so they no longer generate an algebraic loop error. The Atomic Unit subsystem generates a warning:

```
Warning: If the inport 'ex_aloop_block_reduction_errwarn/
Atomic Unit/In1' of subsystem 'ex_aloop_block_reduction_errwarn/
Atomic Unit' involves direct feedback, then an algebraic loop
exists, which Simulink cannot remove. Consider clearing the
'Minimize algebraic loop occurrences' parameter to avoid this
warning.
```

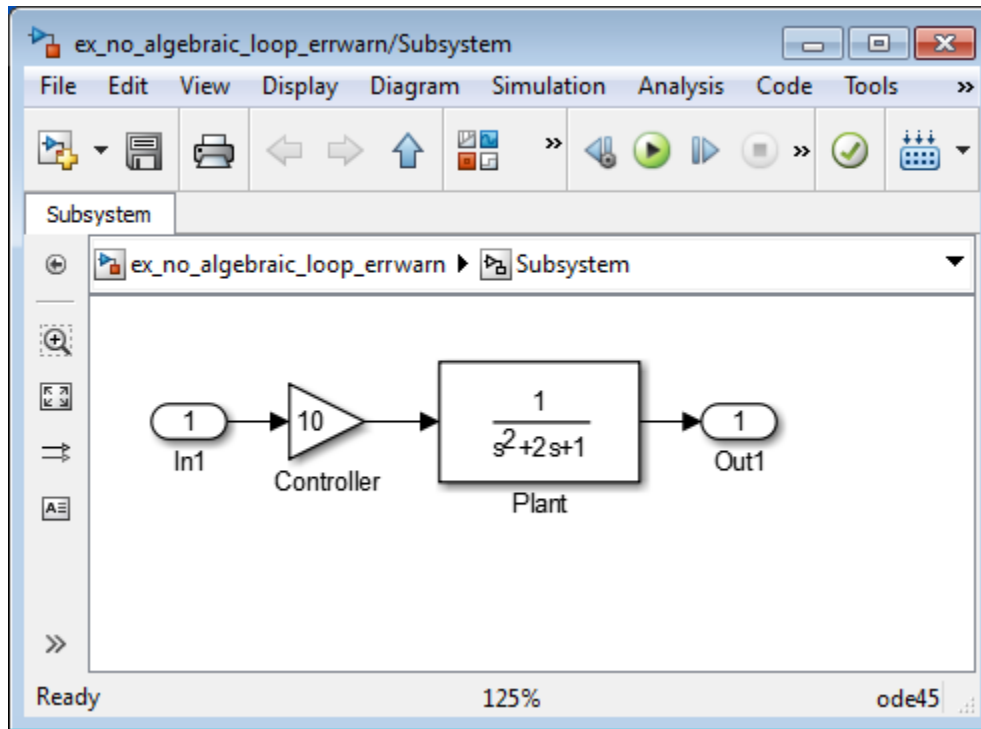

Tip Use Bus Selector blocks to pass only the required signals into atomic subsystems.

How Simulink Eliminates Artificial Algebraic Loops

When you enable **Minimize algebraic loop occurrences**, Simulink tries to eliminate artificial algebraic loops. In this example, the model contains an atomic subsystem that causes an artificial algebraic loop.

The contents of the atomic subsystem are not direct feedthrough, but Simulink identifies the atomic subsystem as direct feedthrough.

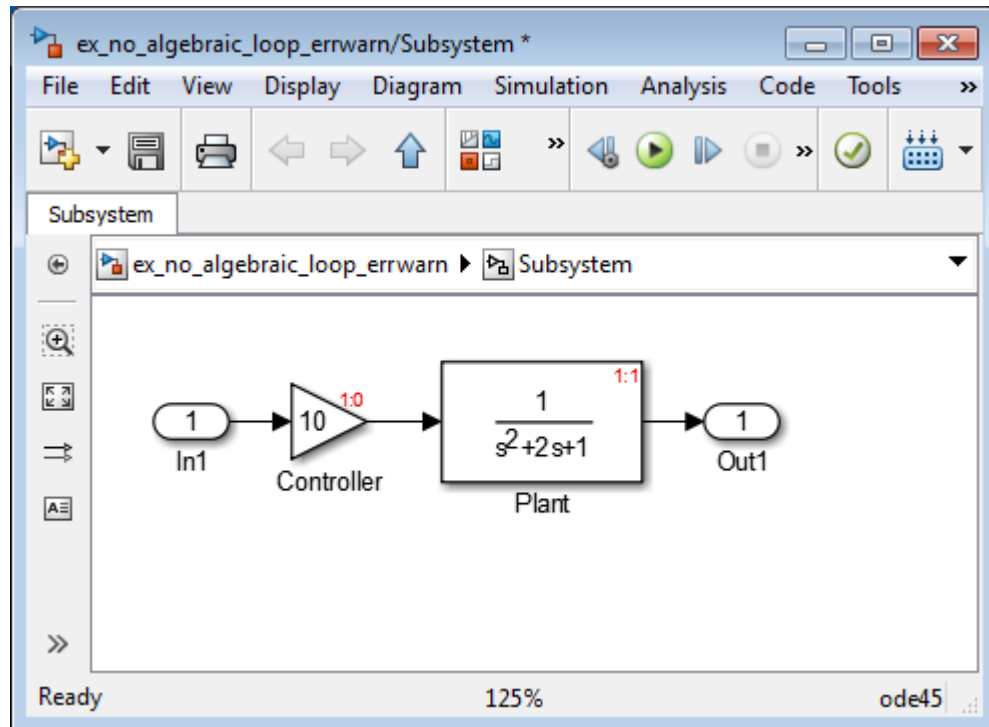

If the **Algebraic loop** diagnostic is set to **error**, simulating the model results in an error because the model contains an artificial algebraic loop involving its atomic subsystem.

To eliminate this algebraic loop,

- 1 Create the model from the preceding graphics, with the atomic subsystem that causes the artificial algebraic loop.
- 2 In the **Diagnostics** pane of Model Configuration Parameters, set the **Algebraic loop** parameter to **warning** or **none**.
- 3 In the **Data Import/Export** pane, make sure the **Signal logging** parameter is disabled. If signal logging is enabled, Simulink cannot eliminate artificial algebraic loops.
- 4 To display the sorted order for this model and the atomic subsystem, select **Display** > **Blocks** > **Sorted Execution Order**.

Reviewing the sorted order can help you understand how to eliminate the artificial algebraic loop.

All the blocks in the subsystem execute at the same level: 1. (0 is the lowest level, indicating the first blocks to execute.)

Note: For more information about sorted order, see “Control and Display the Sorted Order” on page 33-26.

- 5 In the top-level model’s **Subsystem Parameters** dialog box, select **Minimize algebraic loop occurrences**. This parameter directs Simulink to try to eliminate the algebraic loop that contains the atomic subsystem, when it simulates the model. Save the changes.
- 6 Click **Simulation > Update Diagram** to recalculate the sorted order.

Now there are two levels of sorted order inside the subsystem: 1 and 2.

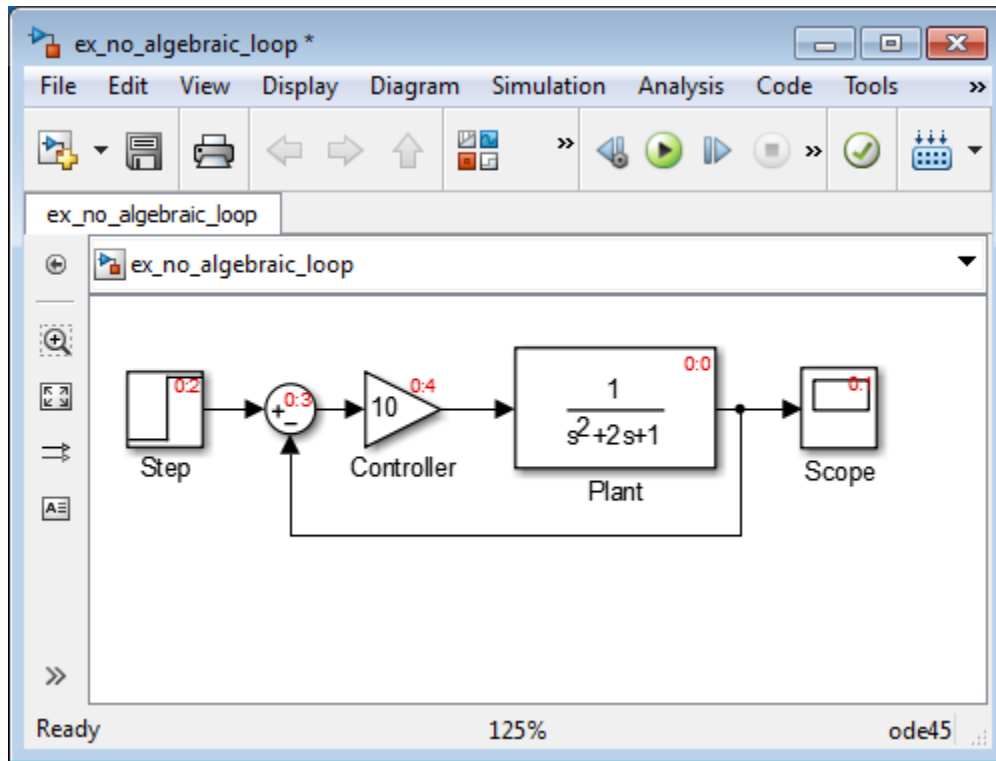

To eliminate the artificial algebraic loop, Simulink tries to make the input of the subsystem or referenced model non-direct feedthrough.

When you simulate a model, all blocks execute methods in this order:

- 1 mdlOutputs
- 2 mdlDerivatives
- 3 mdlUpdate

In the original version of this model, the execution of the `mdlOutputs` method starts with the Plant block because the Plant block is non-direct feedthrough. The execution finishes with the Controller block.

Note: For more information about these methods, see “Block Methods” on page 3-15.

If you enable the **Minimize algebraic loop occurrences** parameter for the atomic subsystem, Simulink divides the subsystem into two atomic units.

These conditions are true:

- Atomic unit 2 is not direct feedthrough.
- Atomic unit 1 has only a `mdlOutputs` method.

Only the `mdlDerivatives` or `mdlUpdate` methods of Atomic unit 2 need the output of Atomic unit 1. Simulink can execute what normally would have been executed during the `mdlOutput` method of Atomic unit 1 in the `mdlDerivatives` methods of Atomic unit 2.

The new execution order for the model is:

- 1 `mdlOutputs` method of model
 - a `mdlOutputs` method of Atomic unit 2
 - b `mdlOutputs` methods of other blocks
- 2 `mdlDerivatives` method of model
 - a `mdlOutputs` method of Atomic unit 1
 - b `mdlDerivatives` method of Atomic unit 2
 - c `mdlDerivatives` method of other blocks

For the **Minimize algebraic loop occurrences** technique to be successful, the subsystem or referenced model must have a non-direct-feedthrough block connected directly to an Inport. Simulink can then set the `DirectFeedthrough` property of the block Inport to `false` to indicate that the input port does not have direct feedthrough.

When Simulink Cannot Eliminate Artificial Algebraic Loops

Setting the **Minimize algebraic loop occurrences** parameter does not always work. Simulink cannot change the `DirectFeedthrough` property of an Inport for an atomic subsystem if the Inport is connected to an Outport only through direct-feedthrough blocks.

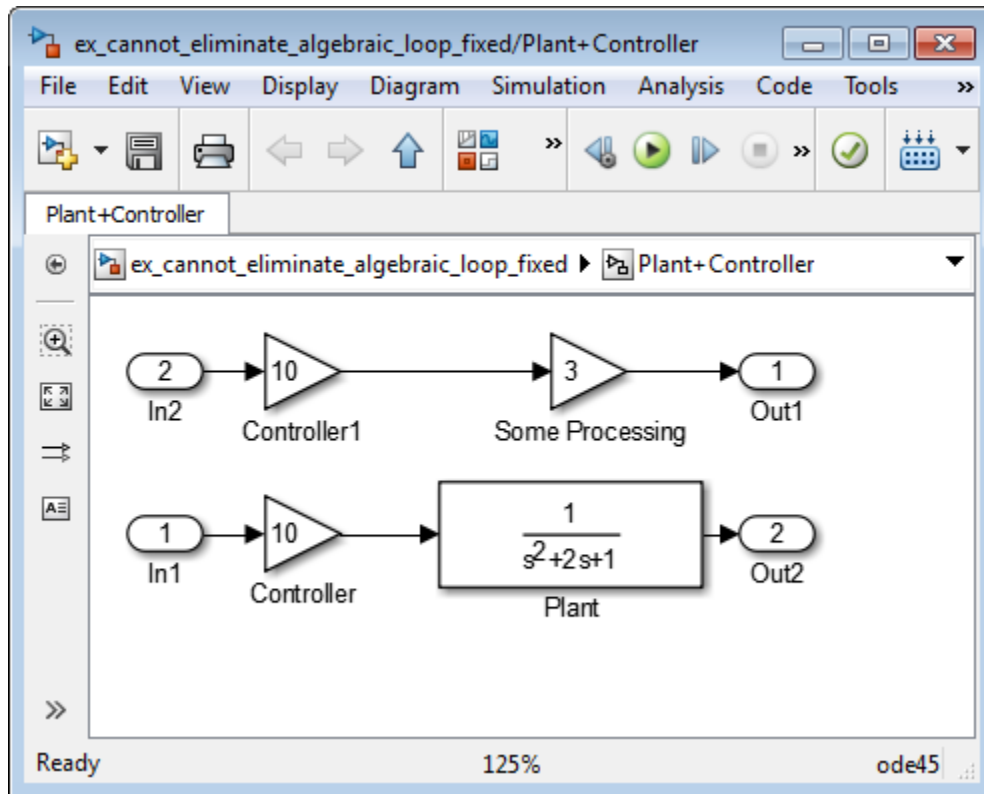

In this model, the subsystem `Plant+Controller` causes an algebraic loop, but it has an extra Gain block and an extra output.

Simulink cannot move the `mdlOutputs` method of the Controller block to the `mdlDerivative` method of an Atomic unit 1 because the output of the atomic subsystem depends on the output of the Controller block. You cannot make the subsystem non-direct-feedthrough.

You can modify this model to eliminate the artificial algebraic loop by redefining the atomic subsystem by adding additional Inport and Gain blocks, as you can see in the model here. Doing so makes In1 non-direct-feedthrough and In2 direct feedthrough, thus breaking the algebraic loop.

Managing Large Models with Artificial Algebraic Loops

Adopt these design techniques for large models with algebraic loops:

- Avoid creating loops that contain discontinuities or nondouble data types. The Simulink algebraic loop solver is gradient-based and must solve algebraic constraints to high precision.
- Develop a scheme for clearly identifying atomic subsystems as direct feedthrough or not direct feedthrough. Use a visual scheme such as coloring the blocks or defining a block-naming convention.
- If you plan to generate code for your model, enable the **Minimize algebraic loop occurrences** parameter for all atomic subsystems. When possible, make sure that

the input ports for the atomic subsystems are connected directly to non-direct-feedthrough blocks.

- Avoid combining non-direct-feedthrough and direct-feedthrough paths using the Bus Creator or Mux blocks. Simulink may not be able to eliminate any resulting artificial algebraic loops. Instead, consider clustering the non-direct-feedthrough and direct-feedthrough objects in separate subsystems.

Use Bus Selector blocks to pass only the required signals into atomic subsystems.

Changing Block Priorities When Using Algebraic Loop Solver

During the updating phase of simulation, Simulink determines the simulation execution order of block methods. This block invocation ordering is the *sorted order*.

If you assign priorities to nonvirtual blocks to indicate to Simulink their execution order relative to other blocks, the algebraic loop solver does not honor these priorities when attempting to solve any algebraic loops.

Create a Template from a Model

Create a Simulink template from a model to reuse or share the settings and contents of the model without copying the model each time. Create templates only from models that do not have external file dependencies (for example, model references, data dictionary, scripts, S-functions, or other file dependencies). If you want to include other dependent files, use a project template instead. See “Using Templates to Create Standard Project Settings” on page 16-44.

- 1 In the model, select **File > Export Model to > Template**.
- 2 In the Export *modelName* to Template dialog box, enter the template title and description of the template.

When you use the template, the Simulink start page displays this title and description.

- 3 In the **Template file** box, select a file name and location for the template SLTX file.

Tip Save the template on the MATLAB path to make it visible in the Simulink start page. If you save in a location that is not on the path, the new template is visible in the start page only in the current MATLAB session. Saving the template does not add the destination folder to the path.

- 4 Click **Export**.

See Also

`Simulink.exportToTemplate`

Connect Blocks

In this section...

“Automatically Connect Blocks” on page 4-3

“Manually Connect Blocks” on page 4-6

“Disconnect Blocks” on page 4-12

Automatically Connect Blocks

You can have the Simulink software connect blocks automatically. This eliminates the need to draw the connecting lines yourself. When connecting blocks, Simulink routes the lines around intervening blocks to avoid cluttering the diagram.

Autoconnect Two Blocks

When connecting two blocks with multiple ports, Simulink draws as many connections as possible between the two blocks.

To autoconnect two blocks:

- 1 Select the source block. In this example, the Sine Wave block is the source block.

- 2 Hold down **Ctrl** and left-click the destination block. In this example, the Integrator block is the destination block.

The source block is connected to the destination block, and the lines are routed around intervening blocks if necessary.

Note: On Macintosh platforms, use the **command** key instead of **Ctrl**.

Connect Groups of Blocks

To connect a group of source blocks to a destination block:

- 1 Select the source blocks.

- 2 Hold down **Ctrl** and left-click the destination block.

To connect a source block to a group of destination blocks:

- 1 Select the *destination* blocks.

- 2 Hold down **Ctrl** and left-click the *source* block.

Manually Connect Blocks

You can draw lines manually between blocks or between lines and blocks. You might want to do this if you need to control the path of the line or to create a branch line.

Draw a Line Between Blocks

You can create lines either from output to input ports, or from input to output ports. For example, to connect the output port of a Constant block to the input port of Gain block:

- 1 Position the cursor over the output port of the Constant block. You do not need to position the cursor precisely on the port.

The cursor shape changes to crosshairs.

- 2 Hold down the left mouse button.
- 3 Drag the cursor to the input port of the Gain block. Position the cursor on or near the port or in the block. If you position the cursor in the block, the line connects to the closest input port.
- 4 Release the mouse button. A connecting line with an arrow showing the direction of the signal flow replaces the port symbol.

The arrow appears at the appropriate input port, and the signal is the same.

Draw a Branch Line

A *branch line* is a line that starts from an existing line and carries its signal to the input port of a block. Both the existing line and the branch line represent the same signal. Use branch lines to connect a signal to more than one block.

This example shows how to connect the Product block output to both the Scope block and the To Workspace block.

To add a branch line:

- 1 Position the cursor on the line where you want the branch line to start.
- 2 While holding down the **Ctrl** key, press and hold down the left or right mouse button.
- 3 Drag the cursor to the input port of the target block, then release the mouse button and the **Ctrl** key.

Draw Line Segments

Manually draw line segments when you want to draw:

- Line segments differently than autoconnect feature draws the lines
- A line, before you copy the block to which the line connects

To draw a line segment:

- 1 Draw a line from the block port to an unoccupied area of the canvas. Release the mouse button where you want the line segment to end.

The cursor turns into a circle, and blue arrow guides appear.

- 2 For each additional line segment, position the cursor over the blue arrow guide that points in the direction in which you want to draw a line segment. The cursor turns into an empty arrowhead.

Tip To reroute the whole line instead of extending it, select the end of the line itself when the circle cursor is displayed and drag the line end to a new location.

- 3 Drag the cursor to draw the second line segment and release the mouse button to finish drawing the line.

Move a Line Segment

To move a line segment:

- 1 Position the cursor on the segment that you want to move.
- 2 Press and hold down the left mouse button.
- 3 Drag the cursor to the desired location and release the mouse button.

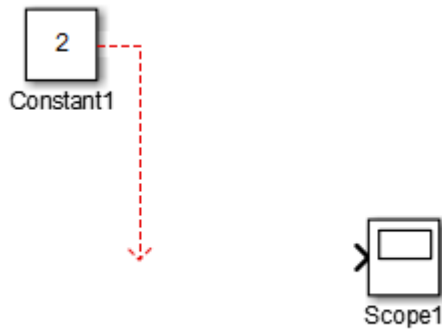

Draw a Diagonal Line

You cannot draw a single diagonal line between two ports. You can draw very short line segments connecting to each port, with a longer diagonal segment in the middle. For example, suppose you position two blocks as shown below:

To approximate a diagonal line:

- 1 Draw a short line segment from the output port of the Constant block.
- 2 At the end of the first line segment, draw a second line segment.

- 3 Draw a third line segment to connect to the Scope block.
- 4 Position the cursor at the bend of the second and third line segments. The cursor turns into a circle.

- 5 Hold the **Shift** key down and drag the cursor to make the second line segment a diagonal.

Move a Line Vertex

To move a vertex of a line:

- 1 Position the cursor on the vertex, then press and hold down the left mouse button.

The cursor changes to a circle.

- 2 Drag the vertex to the desired location.

- 3 Release the mouse button.

Insert a Block in a Line

You can insert a block in a line, if the block has only one input and one output.

- 1 Drag the block over the line in which you want to insert the block.
- 2 Release the mouse button. Simulink inserts the block for you at the point where you drop the block.

Disconnect Blocks

To disconnect a block from its connecting lines, hold down the **Shift** key, then drag the block to a new location.

Related Examples

- “Build and Edit a Model in the Simulink Editor” on page 1-23

Describe Models Using Annotations

Annotations are visual elements that you can use to add descriptive notes and callouts to your model. You can also add annotations that perform an action when you click them. Shortcuts on the Simulink Editor palette help you to create annotations.

Text annotations can contain any combination of:

- Text
- Images
- Equations using TeX commands
- Hyperlinks that open a website or perform MATLAB functions

Also, you can create an annotation that can hold only an image.

Add a Text Annotation

To create a text annotation, use one of these options:

- Double-click the canvas where you want to create the annotation.
- Click the annotation box  on the palette and then click the canvas.
- Drag the annotation box to the canvas.

After you add the text annotation, you can:

- Apply formatting changes to text or insert an image or a table using the formatting toolbar.
- Apply additional formatting, using the **Paragraph** menu on the context menu. For example, you can create bullet and numbered lists from this menu.
- Add hyperlinks using the context menu. You can use hyperlinks to open a website or make an annotation interactive using MATLAB commands.
- Apply properties using the Property Inspector. To view the Property Inspector, select **View > Property Inspector**.

Resize an Annotation

An annotation resizes as you enter content. You can also resize an annotation by dragging the corners. For example, you can hold **Shift** as you drag to resize proportionally.

After you resize an annotation, the annotation stays that size until you resize it again, regardless of the content size. To revert to the original height or width of the annotation, in the Property Inspector, under **Appearance**, clear the **Fixed height** or **Fixed width** check box.

Make an Annotation Interactive

To make the annotation interactive, use a hyperlink on any content of a text annotation.

- 1 In the annotation, select the content that you want to make interactive. To make the entire annotation interactive, select all the content.
- 2 Right-click and select **Hyperlink** from the context menu.
- 3 In the Hyperlink dialog box, either:
 - Select **URL Address** as the target and enter the web address in the **Code** box.
 - Select **MATLAB Code** as the target and enter MATLAB functions in the **Code** box.
- 4 Click **OK**.

For an alternative approach, see “Add an Annotation Callback” on page 4-21

Add an Image Annotation

You can add an annotation that contains only an image. Add an image annotation when you want to be able to resize or move the image independently of text. For example, you can put your company logo in an image and size and position it at a particular location in the model. You can also associate MATLAB functions with a click on the image.

Tip To include an image such as a logo in every new model, add the image to your default template. See “Create a Template from a Model” on page 4-2.

- 1 From the Simulink Editor palette, drag an **Image** box  into the model.
- 2 Add an image to the box. You can either:
 - Double-click the image box and browse to an image.
 - Paste an image from the clipboard. Right-click the image box and select **Paste Image**.

Tip If you resize the image, you can reset it to its original size. Right-click the image and select **Format > Restore Size**.

To associate an action with an image:

- 1 Select the image.
- 2 In the Property Inspector, under **ClickFcn**, add the MATLAB functions that you want to invoke with a click on the image.

Use TeX Commands in an Annotation

You can add TeX formatting commands to your annotation for mathematical and other symbols and Greek letters. For the supported TeX commands, see “TeX for Simulink Model Annotations” on page 4-26

- 1 Add supported TeX commands to your annotation. For example, add this text:
`\sigma \kappa \mu`
- 2 With the annotation selected, or with the text cursor in the annotation, in the Property Inspector, under **Appearance**, select **Enable TeX commands**.

When you click outside the annotation, the TeX commands appear as symbols in the annotation.

Add Lines to Connect Annotations to Blocks

You can add connector lines between an annotation and a block in the model. The connector is similar to a callout, identifying the block that an annotation applies to. If you move the annotation or block, the connector moves or resizes to keep the connection.

- 1 Place the cursor over the annotation outline where you want the connector to start.
- 2 When the cursor is a cross hair, drag the connector line to the block you want to connect to.

Tip To specify the color or width of the connector, right-click it and use the **Format** menu.

Select Font Dialog Box on Linux Machines

On Linux machines configured for English, the **Font style** list in the Select Font dialog box can appear out of order and in another language in some fonts. If the characters in your **Font style** list appear in another language, set the `LANG` environment variable to `en_US.utf-8` before you start MATLAB. For example, at a Linux terminal, enter:

```
setenv LANG en_US.utf-8
matlab
```

Related Examples

- “Add an Annotation Callback” on page 4-21
- “Create an Annotation Programmatically” on page 4-23

Create an Annotation

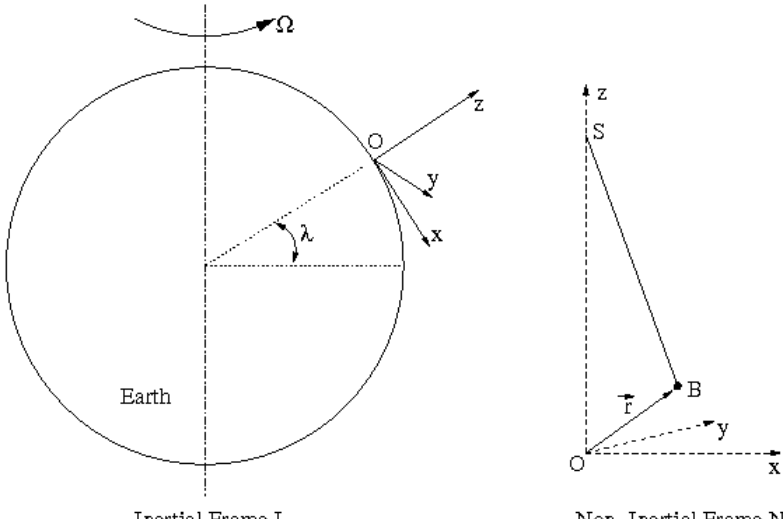

In this example, you create this annotation:

Foucault Pendulums

This model represents a [Foucault pendulum](#).

The pendulum can be modeled as a point mass suspended on a wire of length L . The pendulum is located at the geographical latitude λ . It is convenient to use these reference frames:

- The inertial frame I (relative to the center of the Earth).
- The non-inertial frame N (relative to an observer on Earth's surface). The non-inertial frame accelerates as a result of rotation.

Inertial Frame I Non-Inertial Frame N

Interact with the Model

1. Open the model.
2. Use MATLAB workspace variables to examine and modify initial conditions (g , L , initial conditons, Ω , and λ).
3. Simulate the model.

Add and Lay Out an Annotation

- 1 Open the `sldemo_foucault` model.
- 2 Open the Property Inspector if it is not open. Select **View** > **Property Inspector**.
- 3 Delete the two annotations below the model.

- 4 Double-click to add an annotation, and type **Background**.
- 5 Drag a corner to resize the annotation so that it is about the width of the model and about twice as tall.
- 6 In the Property Inspector, under **Appearance**, select **Shadow**. Under **Internal Margin**, set each of the margins to 10.

Add a Hyperlink and Format Text

- 1 To create a blank line and a new paragraph, place the cursor after the word **Background** and press **Enter** twice.
- 2 Enter this text: This model represents a Foucault pendulum.
- 3 Select the text **Foucault pendulum** and select **Hyperlink** from the context menu.
- 4 In the Hyperlink dialog box, in the **Code** box, enter `en.wikipedia/wiki/Foucault_pendulum` and click **OK**.
- 5 Select the text **Background**. Using the formatting toolbar, make the text bold and font size 12.

Add a Bullet List

- 1 Place the cursor at the end of the paragraph with the hyperlink and press **Enter** twice.
- 2 In the new paragraph, add this text:

The pendulum can be modeled as a point mass suspended on a wire of length L . The pendulum is located at the geographical latitude λ . It is convenient to use these reference frames:
- 3 Press **Enter**. Type ***** and press the spacebar to start a bullet list.
- 4 In the bullet item, enter:

The inertial frame I (relative to the center of the Earth).
- 5 Press **Enter**. For the second bullet, enter this text and press **Enter**.

The non-inertial frame N (relative to an observer on Earth's surface). The non-inertial frame accelerates as a result of rotation.
- 6 Delete the empty bullet.

Copy and Paste a Web Image

- 1 In an SVG-enabled browser (such as Google[®] Chrome), open the Foucault pendulum example.

`http://www.mathworks.com/help/simulink/examples/modeling-a-foucault-pendulum.html`

- 2 In the Analysis and Physics section, copy the image of the two frames.
- 3 In the annotation, place the cursor in a new paragraph below the second bullet. Paste the image.

Add a Numbered List

- 1 Place the cursor after the image and press **Enter** twice.
- 2 In the new paragraph, enter `Interact with the Model`. Press **Enter** twice.
- 3 In the new paragraph, right-click and select **Paragraph > Numbering > Decimal Dot**.
- 4 For the first step, enter `Open the model`.
- 5 For the second step, enter:

`Use MATLAB workspace variables to examine and modify initial conditions (g, L, init`

- 6 For the third step, enter `Simulate the model`.
- 7 Select the text `Interact with the Model`. Using the formatting toolbar, make the text bold and set the size to 12.

Related Examples

- “Describe Models Using Annotations” on page 4-13
- “Show or Hide Annotations” on page 4-20
- “Add an Annotation Callback” on page 4-21
- “Create an Annotation Programmatically” on page 4-23

Show or Hide Annotations

In this section...
“Configure an Annotation for Hiding” on page 4-20
“Hide Markup Annotations” on page 4-20

By default, all annotations appear in the model. To hide an annotation, first configure it for hiding by converting it to markup. Then select **Display > Hide Markup**.

Configure an Annotation for Hiding

You can configure an annotation so that you can hide or display it.

- 1 Right-click the annotation.
- 2 From the context menu, select **Convert to Markup**.

A markup annotation has a light-blue background, regardless of the background color you set. If you change a markup annotation back to a regular annotation, the annotation returns to the background color you set.

To change a markup annotation to a regular annotation (one that you cannot hide), from the annotation context menu, select **Convert to Annotation**.

Hide Markup Annotations

To hide all markup annotations, select **Display > Hide Markup**.

To display hidden markup annotations, select **Display > Show Markup**.

Note: In a model reference hierarchy, **Show Markup** and **Hide Markup** apply only to the current model reference level.

Add an Annotation Callback

In this section...

“Annotation Callback Functions” on page 4-21

“Associate a Click Function with an Annotation” on page 4-21

“Select and Edit Click-Function Annotations” on page 4-22

Annotation Callback Functions

You can associate these callback functions with annotations.

Click Function

You can make an annotation interactive using a link. Alternatively, you can make an annotation interactive by adding a click function callback. A click function is a MATLAB function that Simulink invokes when you click an annotation.

You can add a click function callback programmatically or interactively. To create this association programmatically, see “Annotations API” on page 4-23. To create one interactively, see “Associate a Click Function with an Annotation” on page 4-21.

The text for annotations associated with a click function appears in blue.

Load Function

Simulink invokes a load function when you load the model that contains the associated annotation. To associate a load function with an annotation, set the `LoadFcn` property of the annotation to the desired function (see “Annotations API” on page 4-23).

Delete Function

A delete function is invoked before you delete an annotation. To associate a delete function with an annotation, set the `DeleteFcn` property of the annotation to the desired function (see “Annotations API” on page 4-23).

Associate a Click Function with an Annotation

You can interactively associate a click function with an annotation.

- 1 Add an annotation. Enter the annotation content but do not change any formatting. Changing formatting prevents you from adding a click function using the Simulink Editor.
- 2 Open the Annotation Properties dialog box. Right-click the annotation and select **Properties**.
- 3 Open the **ClickFcn** tab. In the text box under **ClickFcn**, enter the MATLAB code that defines the click function, and click **OK**.

Tip Alternatively, you can use the annotation text as the click function. Then, in the Annotation Properties dialog box, select the **Use annotation text as click callback** check box.

Select and Edit Click-Function Annotations

If you associate an annotation with a click function, sometimes you cannot select the annotation by clicking. Instead, to select it, drag a selection box around it.

You cannot interactively edit the text in an annotation that is associated with a click function. To edit the annotation, right-click it and select **Properties** to use the Annotation Properties dialog box.

More About

- “Describe Models Using Annotations” on page 4-13

Create an Annotation Programmatically

In this section...

“Annotations API” on page 4-23

“Create Annotations Programmatically” on page 4-23

“Delete an Annotation Programmatically” on page 4-24

“Find Annotations in a Model” on page 4-24

“Show or Hide Annotations Programmatically” on page 4-24

Annotations API

Use MATLAB code to get and set the properties of annotations.

- `Simulink.Annotation` class

Set the properties of annotations.

- `getCallbackAnnotation` function

Get the `Simulink.Annotation` object for the annotation associated with the currently executing annotation callback function. Use this function to determine which annotation invoked the current callback. This function is also useful if you write a callback function in a separate MATLAB file that contains multiple callback calls.

Create Annotations Programmatically

To create annotations at the command line or in a MATLAB program, use the `add_block` command. For example:

```
open_system('vdp');  
block = add_block('built-in/Note', ...  
    'vdp/This simulates a nonlinear second order system', ...  
    'Position', [200 250])
```

Alternatively, you can use a `Simulink.Annotation` object to create an annotation. For example:

```
open_system('vdp')
```

```
note = Simulink.Annotation('vdp/This is an annotation');  
note.position = [10,50]
```

Delete an Annotation Programmatically

To delete an annotation programmatically, use the `find_system` function to get the annotation handle. Then use the `delete` function to delete the annotation. For example:

```
delete(find_system(gcs, 'FindAll', 'on', 'type', 'annotation',...  
'text', 'programmatically created'));
```

Find Annotations in a Model

Use command such as this to find all of the annotations in a model.

```
open_system('vdp')  
annotations = find_system(gcs, 'FindAll', 'on', 'Type', 'annotation')  
  
annotations =  
  
    34.0004  
    33.0009
```

See the `find_system` documentation for specifying levels of the model to search.

To identify the annotation handle of annotations, enter:

```
get_param(annotations, 'Name')  
  
ans =  
  
    'Copyright 2004-2014 The MathWorks, Inc.'  
    'van der Pol Equation'
```

Show or Hide Annotations Programmatically

When you create an annotation, by default it appears in the model. You can configure an annotation to be a markup annotation, which you can hide.

To find out whether the first annotation is a markup annotation, use commands such as this:

```
open_system('vdp')
```

```
annotations = find_system(gcs, 'FindAll', 'on', 'Type', 'annotation')
get_param(annotations(1), 'MarkupType')
```

To configure the first annotation in a model so that it can be hidden, use a commands such as this:

```
set_param(annotations(1), 'MarkupType', 'markup')
```

To reconfigure that annotation to always appear, use this command:

```
set_param(annotations(1), 'MarkupType', 'model')
```

To find out whether a model is configured to show or hide markup annotations, use a command such as this for the `vdp` model:

```
get_param(vdp, 'ShowMarkup')
```

To configure a model to hide markup annotations, use a command such as this for the `vdp` model:

```
set_param(vdp, 'ShowMarkup', 'off')
```

TeX for Simulink Model Annotations

The table shows the TeX characters supported in Simulink annotations.

Supported TeX Characters		
alpha	forall	supseteq
beta	exists	supset
gamma	ast	subseteq
delta	cong	subset
epsilon	sim	int
zeta	leq	in
eta	infty	o
theta	clubsuit	copyright
vartheta	diamondsuit	0
iota	heartsuit	ldots
kappa	spadesuit	varpi
lambda	leftarrow	times
mu	uparrow	cdot
nu	rightarrow	vee
xi	downarrow	wedge
pi	circ	perp
rho	pm	mid
sigma	geq	Leftarrow
varsigma	propto	Rightarrow

Supported TeX Characters		
tau	partial	Uparrow
upsilon	bullet	Downarrow
phi	div	prime
chi	neq	nabla
psi	equiv	surd
omega	approx	angle
Gamma	aleph	neg
Delta	Im	lceil
Theta	Re	rceil
Lambda	otimes	lfloor
Xi	oplus	rfloor
Pi	oslash	langle
Sigma	cap	rangle
Upsilon	cup	
Phi		
Psi		
Omega		

Create a Subsystem

In this section...

“Subsystem Advantages” on page 4-28

“Ways to Create a Subsystem” on page 4-28

“Create a Subsystem in a Subsystem Block” on page 4-29

“Create a Subsystem from Selected Blocks” on page 4-30

“Create a Subsystem Using Context Options” on page 4-31

Subsystem Advantages

Subsystems allow you to create a hierarchical model comprising many layers. A subsystem is a set of blocks that you replace with a single Subsystem block. As your model increases in size and complexity, you can simplify it by grouping blocks into subsystems. Using subsystems:

- Establishes a hierarchical block diagram, where a Subsystem block is on one layer and the blocks that make up the subsystem are on another
- Keeps functionally related blocks together
- Helps reduce the number of blocks displayed in your model window

When you make a copy of a subsystem, that copy is independent of the source subsystem. To reuse the contents of a subsystem across a model or across models, use either model referencing or a library.

Ways to Create a Subsystem

You can create a subsystem using these approaches:

- Add a Subsystem block to your model, and then open the block and add blocks to the subsystem window. “Create a Subsystem in a Subsystem Block” on page 4-29.
- Select the blocks that you want in the subsystem, and from the right-click context menu, select **Create Subsystem from Selection**. “Create a Subsystem from Selected Blocks” on page 4-30.
- Copy a model to a subsystem. In the Simulink Editor, copy and paste the model into a subsystem window, or use `Simulink.BlockDiagram.copyContentsToSubSystem`.
- Copy an existing Subsystem block to a model.

- Drag a box around the blocks you want in a subsystem, and select the type of subsystem you want from the context options. “Create a Subsystem Using Context Options” on page 4-31.

Create a Subsystem in a Subsystem Block

Add a Subsystem block to the model, and then add the blocks that make up the subsystem.

- 1 Copy the Subsystem block from the Ports & Subsystems library into your model.
- 2 Open the Subsystem block by double-clicking it.
- 3 In the empty subsystem window, create the subsystem contents. Use Inport blocks to represent input from outside the subsystem and Output blocks to represent external output.

For example, this subsystem includes a Sum block and Inport and Output blocks to represent input to and output from the subsystem.

When you close the subsystem window, the Subsystem block includes a port for each Inport and Output block.

Create a Subsystem from Selected Blocks

- 1 Select the blocks that you want to include in a subsystem. To select multiple blocks in one area of the model, drag a bounding box that encloses the blocks and connecting lines that you want to include in the subsystem.

The figure shows a model that represents a counter. The bounding box selects the Sum and Unit Delay blocks.

- 2 Select **Diagram > Subsystems & Model Reference > Create Subsystem from Selection**.

A Subsystem block appears, which encloses the selected blocks.

Tip Resize the Subsystem block so the port labels are readable.

To edit the subsystem contents, open the Subsystem block. For example:

adds Inport and Outport blocks to represent input from and output to blocks outside the subsystem.

You can change the name of the Subsystem block and modify the block the way that you do with any other block (for example, you can mask the subsystem).

Create a Subsystem Using Context Options

- 1 Drag a box around the blocks you want in your subsystem.

- 2 View the subsystems you can create with these blocks by hovering over the first context option that appears.

3 Select the type of subsystem you want to create from these options.

A Subsystem block appears, which encloses the selected blocks.

Note: You can create only enabled, triggered, virtual, and function-call subsystems using this method.

Related Examples

- “Configure a Subsystem” on page 4-33
- “Navigate Subsystems in the Model Hierarchy” on page 4-36

More About

- “Componentization Guidelines” on page 15-29
- “Subsystem Expansion” on page 4-40
- “Conditional Subsystems”

Configure a Subsystem

In this section...

“Subsystem Execution” on page 4-33

“Label Subsystem Ports” on page 4-33

“Control Access to Subsystems” on page 4-33

“Control Subsystem Behavior with Callbacks” on page 4-34

Subsystem Execution

You can configure a subsystem to execute either conditionally or unconditionally.

- An unconditionally executed subsystem always executes.
- A conditionally executed subsystem executes based on the value of an input signal. For details, see “Conditional Subsystems”.

Label Subsystem Ports

By default, Simulink labels ports on a Subsystem block. The labels are the names of the Inport and Outport blocks that connect the subsystem to blocks outside of the subsystem.

You can specify how Simulink labels the ports of a subsystem.

- 1 Select the Subsystem block.
- 2 Select one of the labeling options from **Diagram > Format > Port Labels** menu (for example, From Port Block Name).

Control Access to Subsystems

You can control user access to subsystems. For example, you can prevent a user from viewing or modifying the contents of a library subsystem while still allowing the user to employ the subsystem in a model.

Note: This method does not necessarily prevent a user from changing the access restrictions. To hide proprietary information that is in a subsystem, consider using protected model referencing models (see “Protected Model” on page 8-83).

To restrict access to a library subsystem, open the subsystem parameter dialog box and set **Read/Write permissions** to one of these values:

- **ReadOnly**: A user can view the contents of the library subsystem but cannot modify the reference subsystem without disabling its library link or changing its **Read/Write permissions** to **ReadWrite**.
- **NoReadOrWrite**: A user cannot view the contents of the library subsystem, modify the reference subsystem, or change reference subsystem permissions.

Both options allow a user to use the library subsystem in models by creating links (see “Libraries”). For more information about subsystem access options, see the **Subsystem** block.

Note: You do not receive a response if you attempt to view the contents of a subsystem whose **Read/Write permissions** parameter is set to **NoReadOrWrite**. For example, when double-clicking such a subsystem, Simulink does not open the subsystem and does not display any messages.

Control Subsystem Behavior with Callbacks

You can use block callbacks to perform actions in response to subsystem modeling actions such as:

- Handling an error
- Deleting a block or line in a subsystem
- Closing a subsystem

For details, see “Specify Block Callbacks” on page 33-5.

Navigate Subsystems in the Model Hierarchy

Open a Subsystem

Subsystems allow you to create a hierarchical model comprising many layers. You can navigate this hierarchy using the “Explore the Model Hierarchy Using the Model Browser” on page 12-57 or with Simulink Editor model navigation commands.

To open a subsystem using the Simulink Editor context menu for the Subsystem block:

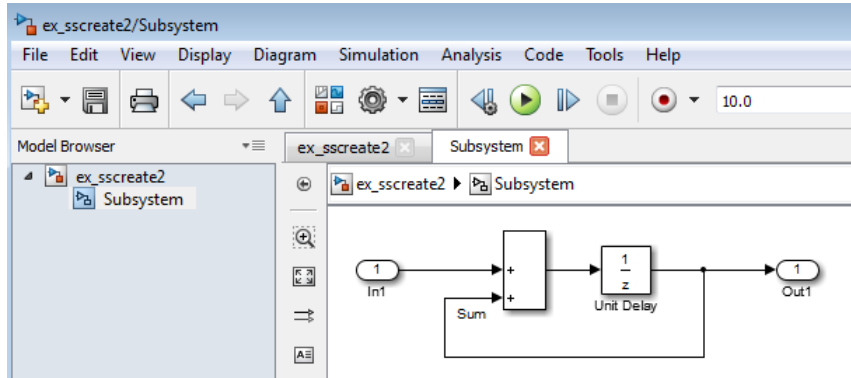

- 1 In the Simulink Editor, right-click the Subsystem block.

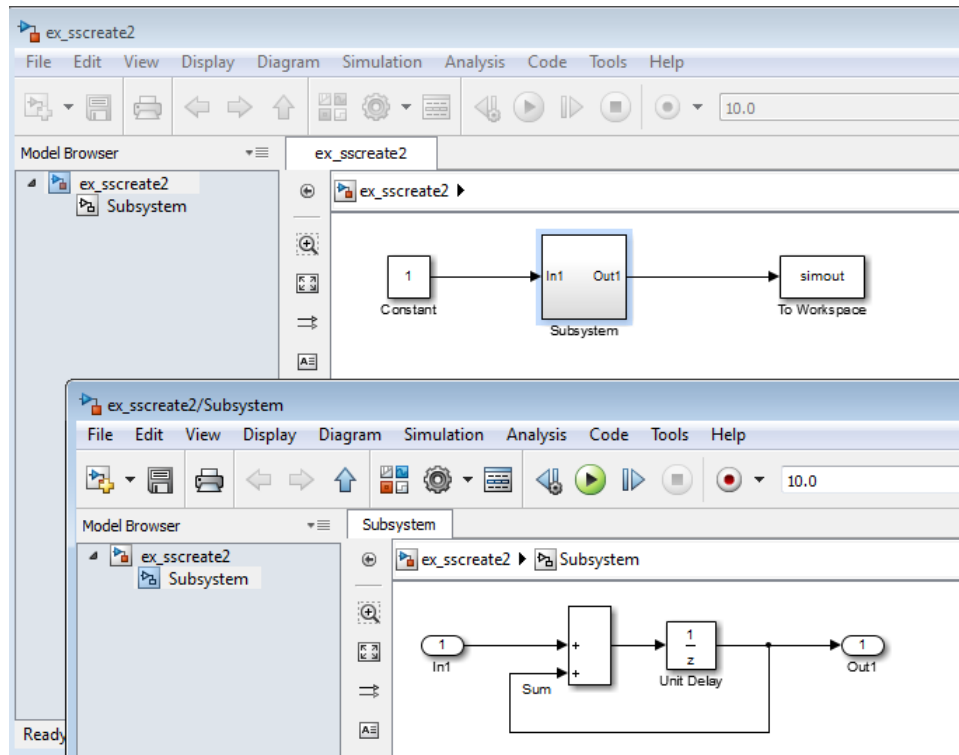

- 2 From the context menu, select one of these options:
 - **Open** — Open the subsystem, in the same window and tab as used for the top model.

- **Open In New Tab** — Open the subsystem, creating an additional tab for the subsystem.

- **Open In New Window** — Open the subsystem, opening a new Simulink Editor window.

For any operation to open a subsystem, you can use a keyboard shortcut to have the subsystem open in a new tab or window:

Where to Open the Subsystem	Keyboard Shortcut
In a new tab	Hold the CTRL key while opening the subsystem.
In a new window	Hold the SHIFT key while opening the subsystem.

Tip To navigate up and out of a subsystem, select **View > Navigate > Up to Parent**. The subsystem you navigated from appears highlighted so you can identify where you came from.

Subsystem Expansion

In this section...

“What Is Subsystem Expansion?” on page 4-40

“Why Expand a Subsystem?” on page 4-41

“Subsystems That You Can Expand” on page 4-42

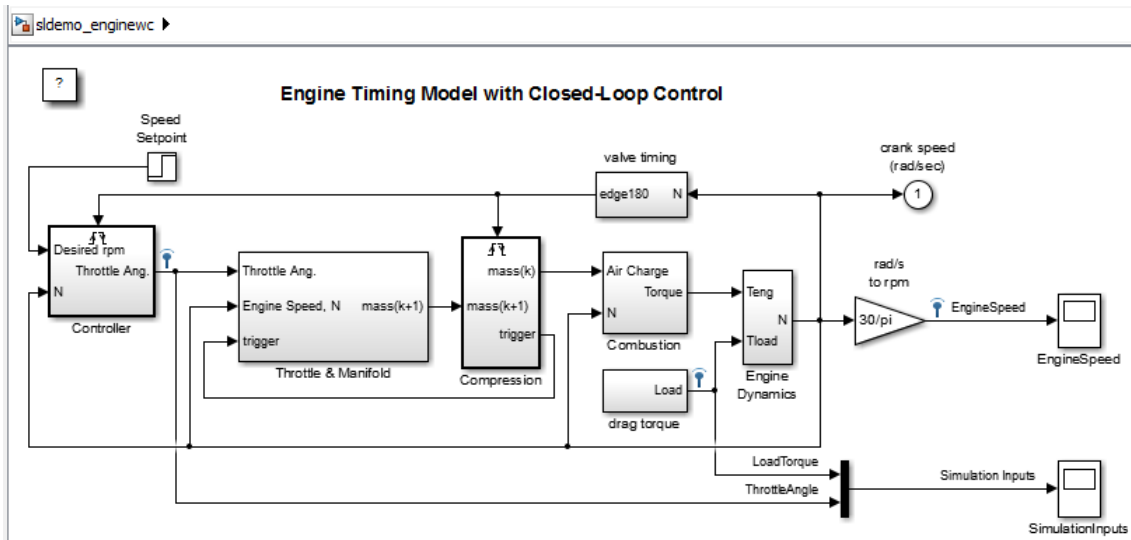

“Results of Expanding a Subsystem” on page 4-43

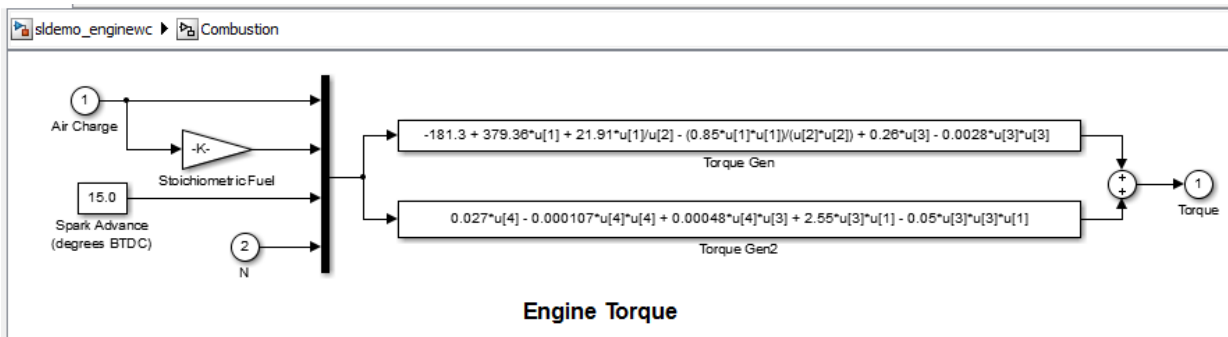

“Data Stores” on page 4-44

What Is Subsystem Expansion?

Subsystem expansion involves moving the contents of a virtual subsystem into the system that contains that subsystem.

For example, the `sldemo_enginewc` model includes the Combustion subsystem.

After you expand the Combustion subsystem, the top level of the `sldemo_enginewc` model includes the blocks and signals of the Combustion subsystem. The expansion removes the Subsystem block and the Inport and Outport blocks.

Why Expand a Subsystem?

Expand a subsystem if you want to flatten a model hierarchy by bringing the contents of a subsystem up one level.

Expanding a subsystem is useful when refactoring a model. Flattening a model hierarchy can be the end result, or just one step in refactoring. For example, you could pull a set of blocks up to the parent system by expanding the subsystem, deselect the blocks that you want to leave in the parent, and then create a subsystem from the remaining selected blocks.

Subsystems That You Can Expand

You can expand virtual subsystems that are not masked, linked, or commented.

Subsystems That You Can Automatically Modify to Enable Expansion

If you try to expand one of these subsystems using the Simulink Editor, a message gives you the option of having Simulink modify the subsystem so that you can then expand it.

Kind of Subsystem	Modification
Masked subsystem	Removes all masking information
Library links	Breaks the link
Commented-out subsystem	Removes the comment-out setting

Subsystems That You Cannot Expand

You cannot expand these subsystems:

- Atomic subsystems
- Conditional subsystems
- Configurable subsystems
- Variant subsystems
- Subsystems in a referenced model
- Subsystems with the **Read/Write permissions** parameter set to `ReadOnly` or `NoReadWrite`
- Subsystems with an `InitFcn`, `StartFcn`, `PauseFcn`, `ContinueFcn`, or `StopFcn` callback
- Subsystems with linked requirements (using Simulink Verification and Validation™ software)

Results of Expanding a Subsystem

When you expand a subsystem, Simulink:

- Removes the Subsystem block
- Removes the root Inport, root Outport, and Simscape Connection Port blocks that were in the subsystem
- Connects the signal lines that went to the input and output ports of the subsystem directly to the ports of the blocks in the model that connected to the subsystem

Block Paths

The paths for blocks that were in the subsystem that you expanded change. After expansion, update scripts and test harnesses that rely on the hierarchical paths to blocks that were in the subsystem that you expanded.

Signal Names and Properties

If you expand a subsystem with a missing connection on the outside or inside of the subsystem, Simulink keeps the line labels, but uses the signal name and properties from just one of the lines. For lines corresponding to:

- A subsystem input port, Simulink uses the signal name and properties from the signal in the system in which the subsystem exists
- A subsystem output port, Simulink uses the signal name and properties from the subsystem

Display Layers

The display layers of blocks (in other words, which blocks appear in front or in back for overlapping blocks) does not change after expansion. Blocks in front of the Subsystem block remain above the expanded contents, and blocks below the Subsystem block remain under the expanded contents.

Sorted Order and Block Priorities

When you compile a model, Simulink sorts the blocks in terms of the order of block execution. Expanding a subsystem can change block path names, which, in rare cases, can impact the block execution order.

If you explicitly set block execution order by setting block priorities within a subsystem, Simulink removes those block priority settings when you expand that subsystem.

Data Stores

Expanding a subsystem that contains a Data Store Memory block that other subsystems read from or write to can change the required data store write and read sequence. You may need to restructure your model. For details, see “Order Data Store Access” on page 60-24.

Related Examples

- “Expand Subsystem Contents” on page 4-45

Expand Subsystem Contents

In this section...

“Expand a Subsystem” on page 4-45

“Expand a Subsystem from the Command Line” on page 4-46

Expand a subsystem to flatten a model hierarchy by bringing the contents of a subsystem up one level.

Expand a Subsystem

- 1 In the Simulink Editor, right-click the Subsystem block for the subsystem that you want to expand.
- 2 From the context menu, select **Subsystem & Model Reference > Expand Subsystem**.

Expand Subsystem is disabled for subsystems that you cannot convert. For some kinds of subsystems, you have the option of having Simulink modify the subsystem so that you can then expand it. For details, see “Subsystems That You Can Automatically Modify to Enable Expansion” on page 4-42.

- 3 If necessary, modify the model layout for readability.

Simulink distributes blocks and routes signals for readability, but you can refine the model layout to enhance readability. Also, you may want to modify the model to adjust for how the subsystem expansion handles aspects of the model such as signal naming. For details, see “Results of Expanding a Subsystem” on page 4-43.

- 4 Update scripts and test harnesses that rely on the hierarchical paths to blocks that were in the subsystem that you expanded.

Nested Subsystems

Subsystem expansion applies to the currently selected subsystem level. Simulink does not expand other subsystems in a nested subsystem hierarchy.

To improve readability when you expand nested subsystems, start by expanding the highest-level subsystem that you want to expand, and then work your way down the hierarchy as far as you want to expand.

Expand a Subsystem from the Command Line

To expand a subsystem programmatically, use the `Simulink.BlockDiagram.expandSubsystem` function.

Use Control Flow Logic

In this section...

“Equivalent C Language Statements” on page 4-47

“Conditional Control Flow Logic” on page 4-47

“While and For Loops” on page 4-50

Equivalent C Language Statements

You can use block diagrams to model control flow logic equivalent to the following C programming language statements:

- for
- if-else
- switch
- while

Conditional Control Flow Logic

You can use the following blocks to perform conditional control flow logic.

C Statement	Equivalent Blocks
if-else	If, If Action Subsystem
switch	Switch Case, Switch Case Action Subsystem

If-Else Control Flow

The following diagram represents if-else control flow.

Construct an **if-else** control flow diagram as follows:

- 1 Provide data inputs to the If block for constructing if-else conditions.

In the If block parameters dialog box, set inputs to the If block. Internally, the inputs are designated as u_1 , u_2 , ..., u_n and are used to construct output conditions.

- 2 In the If block parameters dialog box, set output port if-else conditions for the If block.

In the If block parameters dialog box, set Output ports. Use the input values u_1 , u_2 , ..., u_n to express conditions for the if, elseif, and else condition fields in the dialog box. Of these, only the if field is required. You can enter multiple elseif conditions and select a check box to enable the else condition.

- 3 Connect each condition output port to an Action subsystem.

Connect each if, elseif, and else condition output port on the If block to a subsystem to be executed if the port's case is true.

Create these subsystems by placing an Action Port block in a subsystem. This creates an atomic Action subsystem with a port named Action, which you then connect to a condition on the If block.

Once connected, the subsystem takes on the identity of the condition it is connected to and behaves like an enabled subsystem.

For more detailed information, see the **If** and **Action Port** blocks.

Note All blocks in an Action subsystem driven by an If or Switch Case block must run at the same rate as the driving block.

Switch Control Flow

The following diagram represents switch control flow.

Construct a **switch** control flow statement as follows:

- 1 Provide a data input to the argument input of the Switch Case block.

The input to the Switch Case block is the argument to the **switch** control flow statement. This value determines the appropriate case to execute. Noninteger inputs to this port are truncated.

- 2 Add cases to the Switch Case block based on the numeric value of the argument input.

Using the parameters dialog box of the Switch Case block, add cases to the Switch Case block. Cases can be single or multivalued. You can also add an optional default case, which is true if no other cases are true. Once added, these cases appear as output ports on the Switch Case block.

- 3 Connect each Switch Case block case output port to an Action subsystem.

Each case output of the Switch Case block is connected to a subsystem to be executed if the port's case is true. You create these subsystems by placing an Action Port block in a subsystem. This creates an atomic subsystem with a port named Action, which you then connect to a condition on the Switch Case block. Once

connected, the subsystem takes on the identity of the condition and behaves like an enabled subsystem. Place all the block programming executed for that case in this subsystem.

For more detailed information, see documentation for the Switch Case and Action Port blocks.

Note After the subsystem for a particular case executes, an implied break executes, which exits the switch control flow statement altogether. Simulink switch control flow statement implementations do not exhibit the “fall through” behavior of C switch statements.

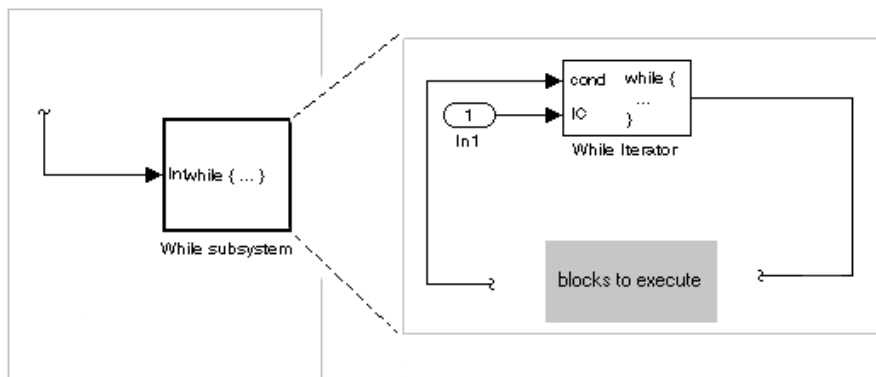

While and For Loops

Use the following blocks to perform while and for loops.

C Statement	Equivalent Blocks
do-while	While Iterator Subsystem
for	For Iterator Subsystem
while	While Iterator Subsystem

While Loops

The following diagram illustrates a while loop.

In this example, Simulink repeatedly executes the contents of the While subsystem at each time step until a condition specified by the While Iterator block is satisfied. In particular, for each iteration of the loop specified by the While Iterator block, Simulink invokes the update and output methods of all the blocks in the While subsystem in the same order that the methods would be invoked if they were in a noniterated atomic subsystem.

Note: Simulation time does not advance during execution of a While subsystem's iterations. Nevertheless, blocks in a While subsystem treat each iteration as a time step. As a result, in a While subsystem, the output of a block with states (that is, a block whose output depends on its previous input), reflects the value of its input at the previous iteration of the `while` loop. The output does *not* reflect that block's input at the previous simulation time step. For example, a Unit Delay block in a While subsystem outputs the value of its input at the previous iteration of the `while` loop, not the value at the previous simulation time step.

Construct a `while` loop as follows:

- 1 Place a While Iterator block in a subsystem.

The host subsystem label changes to `while {...}`, to indicate that it is modeling a while loop. These subsystems behave like triggered subsystems. This subsystem is host to the block programming that you want to iterate with the While Iterator block.

- 2 Provide a data input for the initial condition data input port of the While Iterator block.

The While Iterator block requires an initial condition data input (labeled `IC`) for its first iteration. This must originate outside the While subsystem. If this value is nonzero, the first iteration takes place.

- 3 Provide data input for the conditions port of the While Iterator block.

Conditions for the remaining iterations are passed to the data input port labeled `cond`. Input for this port must originate inside the While subsystem.

- 4 (Optional) Set the While Iterator block to output its iterator value through its properties dialog.

The iterator value is 1 for the first iteration and is incremented by 1 for each succeeding iteration.

- (Optional) Change the iteration of the While Iterator block to **do-while** through its properties dialog.

This changes the label of the host subsystem to **do { ... } while**. With a **do-while** iteration, the While Iteration block no longer has an initial condition (IC) port, because all blocks in the subsystem are executed once before the condition port (labeled **cond**) is checked.

- Create a block diagram in the subsystem that defines the subsystem's outputs.

Note: The diagram must not contain blocks with continuous states (for example, blocks from the Continuous block library). The sample times of all the blocks must be either inherited (**-1**) or constant (**inf**).

For more information, see the **While Iterator** block.

Modeling For Loops

The following diagram represents a **for** loop:

In this example, Simulink executes the contents of the **For** subsystem multiples times at each time step. The input to the **For Iterator** block specifies the number of iterations . For each iteration of the **for** loop, Simulink invokes the update and output methods of all the

blocks in the For subsystem in the same order that it invokes the methods if they are in a noniterated atomic subsystem.

Note: Simulation time does not advance during execution of a For subsystem's iterations. Nevertheless, blocks in a For subsystem treat each iteration as a time step. As a result, in a For subsystem, the output of a block with states (that is, a block whose output depends on its previous input) reflects the value of its input at the previous iteration of the `for` loop. The output does *not* reflect that block's input at the previous simulation time step. For example, a Unit Delay block in a For subsystem outputs the value of its input at the previous iteration of the `for` loop, not the value at the previous simulation time step.

Construct a `for` loop as follows:

- 1 Drag a For Iterator Subsystem block from the Library Browser or Library window into your model.
- 2 (Optional) Set the For Iterator block to take external or internal input for the number of iterations it executes.

Through the properties dialog of the For Iterator block you can set it to take input for the number of iterations through the port labeled `N`. This input must come from outside the For Iterator Subsystem.

You can also set the number of iterations directly in the properties dialog.

- 3 (Optional) Set the For Iterator block to output its iterator value for use in the block programming of the For Iterator Subsystem.

The iterator value is 1 for the first iteration and is incremented by 1 for each succeeding iteration.

- 4 Create a block diagram in the subsystem that defines the subsystem's outputs.

Note: The diagram must not contain blocks with continuous states (for example, blocks from the Continuous block library). The sample times of all the blocks must be either inherited (`-1`) or constant (`inf`).

The For Iterator block works well with the Assignment block to reassign values in a vector or matrix. The following example shows the use of a For Iterator block. Note the matrix dimensions in the data being passed.

The above example outputs the sine value of an input 2-by-5 matrix (2 rows, 5 columns) using a For subsystem containing an **Assignment** block. The process is as follows.

- 1 A 2-by-5 matrix is input to the Selector block and the Assignment block.
- 2 The Selector block strips off a 2-by-1 matrix from the input matrix at the column value indicated by the current iteration value of the For Iterator block.
- 3 The sine of the 2-by-1 matrix is taken.
- 4 The sine value 2-by-1 matrix is passed to an Assignment block.
- 5 The Assignment block, which takes the original 2-by-5 matrix as one of its inputs, assigns the 2-by-1 matrix back into the original matrix at the column location indicated by the iteration value.

The rows specified for reassignment in the property dialog for the Assignment block in the above example are [1,2]. Because there are only two rows in the original matrix, you could also have specified -1 for the rows, (that is, all rows).

Note The Trigonometric Function block is already capable of taking the sine of a matrix. The above example uses the Trigonometric Function block only as an example of changing each element of a matrix with the collaboration of an Assignment block and a For Iterator block.

Callbacks for Customized Model Behavior

In this section...
“Model, Block, and Port Callbacks” on page 4-56
“What You Can Do with Callbacks” on page 4-56
“Avoid run Commands in Callback Code” on page 4-56

Model, Block, and Port Callbacks

Callbacks are commands you can define that execute in response to a specific modeling action, such as opening a model or stopping a simulation. Callbacks define MATLAB expressions that execute when the block diagram or a block is acted upon in a particular way.

Simulink provides model, block, and port callback parameters that identify specific kinds of model actions. You provide the code for a callback parameter. Simulink executes the callback code when the associated modeling action occurs.

For example, the code that you specify for the `PreLoadFcn` model callback parameter executes before the model loads. You can provide code for `PreLoadFcn` that loads the variables that model uses into the MATLAB workspace.

What You Can Do with Callbacks

Callbacks are a powerful way to customize your Simulink model. A callback executes when you perform actions on your model, such as double-clicking a block or starting a simulation. You can use callbacks to execute MATLAB code. You can use model, block, or port callbacks to perform common tasks, such as:

- “Load Variables When Opening a Model” on page 1-10
- “Specify Block Callbacks” on page 4-62
- “Automate Simulation Tasks Using Block Callbacks” on page 24-11

Avoid run Commands in Callback Code

Do not call the `run` command from within model or block callback code. Doing so can result in unexpected behavior (such as errors or incorrect results) if you load, compile, or simulate a Simulink model.

Related Examples

- “Model Callbacks” on page 4-58
- “Block Callbacks” on page 4-62
- “Port Callbacks” on page 4-69

- “Model Methods and Callbacks in Fast Restart” on page 68-11

Model Callbacks

In this section...
“Create Model Callbacks” on page 4-58
“Model Callback Parameters” on page 4-59

Create Model Callbacks

- 1 In the Simulink Editor, open the Property Inspector. Select **View > Property Inspector**.
- 2 With no selection at the top level of your model, in the **Properties** tab, in the **Callbacks** section, select the callback you want to set.
- 3 In the box, enter the functions you want the callback to perform.

To create a model callback programmatically, use the `set_param` function to assign MATLAB code to a model callback parameter. See “Model Callback Parameters” on page 4-59

The execution of callbacks for model referencing reflects the order in which the top model and the model it references execute their callbacks. For example, suppose:

- Model A references model B.
- Model A has a `PostLoadFcn` callback that creates variables in the MATLAB workspace.
- Model B has a `CloseFcn` callback that clears the MATLAB workspace.

Simulating model A triggers rebuilding the referenced model B.

When Simulink rebuilds model B, it opens and closes model B and invokes the model B `CloseFcn` callback. `CloseFcn` clears the MATLAB workspace, including the variables created by the model A `OpenFcn` callback.

Instead of using a `CloseFcn` callback for model B, you can use a `StopFcn` callback in model A to clear the variables used by the model from the MATLAB workspace.

Model Callback Parameters

Model Loading and Closing Callback Parameters

Model Callback Parameter	When Executed
PreLoadFcn	<p>This callback is executed before the model is loaded.</p> <p>Do not use model parameters in a <code>PreLoadFcn</code> model callback because parameters are loaded after the model is loaded. Instead, use a <code>PostLoadFcn</code> callback to work with model parameters when the model is loaded.</p> <p>Defining a callback code for this parameter is useful for loading variables that the model uses.</p> <p>If you want to call your model from a MATLAB file without opening your model, use the <code>load_system</code> function so that the <code>PreLoadFcn</code> executes.</p> <p>For examples, see:</p> <ul style="list-style-type: none"> • “Load Variables When Opening a Model” on page 1-10 • In the Introduction to Managing Data with Model Reference example, click the question mark block at the top, and then select Detailed Workflow for Managing Data with Model Reference. • “Model Referencing Simulation Targets” on page 8-46 <p>Limitations include:</p> <ul style="list-style-type: none"> • For the <code>PreLoadFcn</code> callback, <code>get_param</code> does not return the model parameter values because the model is not yet loaded. Instead, <code>get_param</code> returns: <ul style="list-style-type: none"> • The default value for a standard model parameter such as <code>solver</code> • An error message for a model parameter added with <code>add_param</code> • Programmatic access to Scopes is not supported.

Model Callback Parameter	When Executed
PostLoadFcn	<p>After the model is loaded.</p> <p>Defining callback code for this parameter may be useful for generating an interface requiring a loaded model.</p> <p>Limitations include:</p> <ul style="list-style-type: none"> • If you make structural changes with <code>PostLoadFcn</code>, the function does not set the model <code>Dirty</code> flag to indicate unsaved changes. When you close the model, Simulink does not prompt you to save. • Programmatic access to <code>Scopes</code> is not supported.
CloseFcn	<p>Before the block diagram is closed.</p> <p>Any <code>ModelCloseFcn</code> and <code>DeleteFcn</code> callbacks set on blocks in the model are called prior to the model <code>CloseFcn</code> callback. The <code>DestroyFcn</code> callback of any blocks in the model is called after the model <code>CloseFcn</code> callback.</p>

Model Saving Callback Parameters

Model Callback Parameter	When Executed
PreSaveFcn	Before the model is saved.
PostSaveFcn	<p>After the model is saved.</p> <hr/> <p>Note: If you make structural changes with <code>PostSaveFcn</code>, the function does not set the model <code>Dirty</code> flag to indicate unsaved changes. When you close the model, Simulink does not prompt you to save.</p>

Model Simulation Callback Parameters

Model Callback Parameter	When Executed
InitFcn	<p>Called during update phase before block parameters are evaluated. This is called during model update and simulation.</p> <p>For examples, see:</p>

Model Callback Parameter	When Executed
	<ul style="list-style-type: none"> • “Create Programmatic Hyperlinks” on page 23-62 • “Track Object Using MATLAB Code” on page 39-162 <p>Note:</p> <ul style="list-style-type: none"> • An <code>InitFcn</code> callback in a top model cannot change parameters used by referenced models. • During model compilation, Simulink evaluates variant objects before calling the model <code>InitFcn</code> callback. Do not modify the condition of the variant object in the <code>InitFcn</code> callback. For more information, see “Define, Configure, and Activate Variants” on page 11-28.
<code>StartFcn</code>	<p>Called before the simulation phase. This is not called during model update.</p> <p>For an example, see “Automate Simulation Tasks Using Block Callbacks” on page 24-11.</p>
<code>PauseFcn</code>	After the simulation pauses.
<code>ContinueFcn</code>	Before the simulation continues.
<code>StopFcn</code>	<p>After the simulation stops.</p> <p>Output is written to workspace variables and files before the <code>StopFcn</code> is executed.</p>

Related Examples

Block Callbacks

In this section...

“Specify Block Callbacks” on page 4-62

“Block Callback Parameters” on page 4-62

Specify Block Callbacks

- 1 Open the Property Inspector. Select **View > Property Inspector**.
- 2 Select the block whose callback you want to specify. In the **Properties** tab of the Property Inspector, in the **Callbacks** section, select the callback you want to define.
- 3 In the box, enter the functions you want the callback to perform.

To specify a block callback programmatically, use `set_param` to assign MATLAB code to the block callback parameter.

Block Callback Parameters

If a block callback executes before or after a modeling action takes place, that callback occurs immediately before or after the action.

Block Opening Callback Parameters

Block Callback Parameter	When Executed
OpenFcn	<p>When the block is opened.</p> <p>Generally, use this parameter with Subsystem blocks.</p> <p>The callback executes when you double-click the block or when you use <code>open_system</code> with the block as an argument. The <code>OpenFcn</code> parameter overrides the normal behavior associated with opening a block, which is to display the block dialog box or to open the subsystem. Examples of tasks that you can use <code>OpenFcn</code> for include defining variables for a block, making a call to MATLAB to produce a plot of simulated data, or generating a graphical user interface.</p> <p>For examples of using <code>OpenFcn</code> with model referencing, see:</p>

Block Callback Parameter	When Executed
	<ul style="list-style-type: none"> In the Introduction to Managing Data with Model Reference example, click the question mark block at the top and then select Detailed Workflow for Managing Data with Model Reference. “Model Referencing Simulation Targets” on page 8-46
LoadFcn	<p>After the block diagram is loaded.</p> <p>For Subsystem blocks, the LoadFcn callback is performed for any blocks in the subsystem (including other Subsystem blocks) that have a LoadFcn callback defined.</p>

Block Editing Callback Parameters

Block Callback Parameter	When Executed
MoveFcn	When the block is moved or resized.
NameChangeFcn	<p>After a block name or path changes.</p> <p>When a Subsystem block path changes, the Subsystem block calls the NameChangeFcn callback of its descendant blocks and then calls the NameChangeFcn callback on itself.</p>
PreCopyFcn	<p>Before a block is copied. The PreCopyFcn is also executed if <code>add_block</code> is used to copy the block.</p> <p>If you copy a Subsystem block that contains a block for which the PreCopyFcn callback is defined, that callback executes also.</p> <p>The block CopyFcn callback is called after all PreCopyFcn callbacks are executed, unless PreCopyFcn invokes the <code>error</code> command, either explicitly or via a command used in any PreCopyFcn.</p>
CopyFcn	<p>After a block is copied. The callback is also executed if <code>add_block</code> is used to copy the block.</p> <p>If you copy a Subsystem block that contains a block for which the CopyFcn parameter is defined, the callback is also executed.</p>

Block Callback Parameter	When Executed
ClipboardFcn	When the block is copied or cut to the system clipboard.
PreDeleteFcn	<p>Before a block is graphically deleted (for example, when you graphically delete the block or invoke <code>delete_block</code> on the block).</p> <p>The <code>PreDeleteFcn</code> is not called when the model containing the block is closed. The block's <code>DeleteFcn</code> is called after the <code>PreDeleteFcn</code>, unless the <code>PreDeleteFcn</code> invokes the <code>error</code> command, either explicitly or via a command used in the <code>PreDeleteFcn</code>.</p>
DeleteFcn	<p>After a block is graphically deleted (for example, when you graphically delete the block, invoke <code>delete_block</code> on the block, or close the model containing the block).</p> <p>When the <code>DeleteFcn</code> is called, the block handle is still valid and can be accessed using <code>get_param</code>. If the block is graphically deleted by invoking <code>delete_block</code> or by closing the model, after deletion the block is destroyed from memory and the block's <code>DestroyFcn</code> is called.</p> <p>For Subsystem blocks, the <code>DeleteFcn</code> callback is performed for any blocks in the subsystem (including other Subsystem blocks) that have a <code>DeleteFcn</code> callback defined.</p>
DestroyFcn	<p>When the block has been destroyed from memory (for example, when you invoke <code>delete_block</code> on either the block or a subsystem containing the block or close the model containing the block).</p> <p>If the block was not previously graphically deleted, the <code>blockDeleteFcn</code> callback is called prior to the <code>DestroyFcn</code>. When the <code>DestroyFcn</code> is called, the block handle is no longer valid.</p>
UndoDeleteFcn	When a block deletion is undone.

Block Compilation and Simulation Callback Parameters

Block Callback Parameter	When Executed
InitFcn	Before the block diagram is compiled and before block parameters are evaluated.
StartFcn	After the block diagram is compiled and before the simulation starts. In the case of an S-Function block, StartFcn executes immediately before the first execution of the block's mdlProcessParameters function. For more information, see "S-Function Callback Methods".
ContinueFcn	Before the simulation continues.
PauseFcn	After the simulation pauses.
StopFcn	At any termination of the simulation. In the case of an S-Function block, StopFcn executes after the block's mdlTerminate function executes. For more information, see "S-Function Callback Methods".

Block Saving and Closing Callback Parameters

Block Callback Parameter	When Executed
PreSaveFcn	Before the block diagram is saved. For Subsystem blocks, the PreSaveFcn callback is performed for any blocks in the subsystem (including other Subsystem blocks) that have a PreSaveFcn callback defined.
PostSaveFcn	After the block diagram is saved. For Subsystem blocks, the PostSaveFcn callback is performed for any blocks in the subsystem (including other Subsystem blocks) that have a PostSaveFcn callback defined.
CloseFcn	When the block is closed using close_system . The CloseFcn is not called when you interactively close the block parameters dialog box, when you interactively

Block Callback Parameter	When Executed
	<p>close the subsystem or model containing the block, or when you close the subsystem or model containing a block using <code>close_system</code>.</p> <p>For example, to close all open MATLAB windows, use a command such as:</p> <pre>set_param('my_model','CloseFcn','close all')</pre>
<code>ModelCloseFcn</code>	<p>Before the block diagram is closed.</p> <p>When the model is closed, the block's <code>ModelCloseFcn</code> is called prior to its <code>DeleteFcn</code>.</p> <p>For Subsystem blocks, the <code>ModelCloseFcn</code> callback is performed for any blocks in the subsystem (including other Subsystem blocks) that have a <code>ModelCloseFcn</code> callback defined.</p>

Subsystem Block Callback Parameters

You can use the other block callback parameters with Subsystem blocks, but the callback parameters in this table are specific to Subsystem blocks.

Note: A callback for a masked subsystem cannot directly reference the parameters of the masked subsystem (see “Block Masks”). Simulink evaluates block callbacks in the MATLAB base workspace, whereas the mask parameters reside in the masked subsystem's private workspace. A block callback, however, can use `get_param` to obtain the value of a mask parameter. For example, here `gain` is the name of a mask parameter of the current block:

```
get_param(gcb, 'gain')
```

Block Callback Parameter	When Executed
<code>DeleteChildFcn</code>	<p>After a block or line is deleted in a subsystem.</p> <p>If the block has a <code>DeleteFcn</code> or <code>DestroyFcn</code> callback, those callbacks execute prior to the <code>DeleteChildFcn</code> callback.</p>

Block Callback Parameter	When Executed
ErrorFcn	<p>When an error has occurred in a subsystem.</p> <p>Use the following form for the callback code for the <code>ErrorFcn</code> parameter:</p> <pre>newException = errorHandler(subsys, ... errorType, originalException)</pre> <p>where</p> <ul style="list-style-type: none"> • <code>errorHandler</code> is the name of the function. • <code>subsys</code> is a handle to the subsystem in which the error occurred. • <code>errorType</code> is a character vector indicating the type of error that occurred. • <code>originalException</code> is an <code>MSLException</code> (see “Error Handling in Simulink Using <code>MSLException</code>” on page 24-28). • <code>newException</code> is an <code>MSLException</code> specifying the error message to be displayed to the user. <p>If you provide the original exception, then you do not need to specify the subsystem and the error type.</p> <p>The following command sets the <code>ErrorFcn</code> of the subsystem <code>subsys</code> to call the <code>errorHandler</code> callback:</p> <pre>set_param(subsys, 'ErrorFcn', 'errorHandler')</pre> <p>In such calls to <code>set_param</code>, do not include the input arguments of the callback code. Simulink displays the error message returned by the callback.</p>

Block Callback Parameter	When Executed
ParentCloseFcn	<p>Before closing a subsystem containing the block or when the block is made part of a new subsystem using either:</p> <ul style="list-style-type: none">• The <code>new_system</code> function• In the Simulink Editor, the Diagram > Subsystem & Model Reference > Create Subsystem from Selection option <p>When you close the model, Simulink does not call the <code>ParentCloseFcn</code> callbacks of blocks at the root model level.</p>

Port Callbacks

Block input and output ports have a single callback parameter, `ConnectionCallback`. This parameter allows you to set callbacks on ports that are triggered every time the connectivity of these ports changes. Examples of connectivity changes include adding a connection from the port to a block, deleting a block connected to the port, and deleting, disconnecting, or connecting branches or lines to the port.

Use `get_param` to get the port handle of a port and `set_param` to set the callback on the port. The callback code must have one input argument that represents the port handle. The input argument is not included in the call to `set_param`.

For example, suppose the currently selected block has a single input port. The following code sets `foo` as the connection callback on the input port:

```
phs = get_param(gcf, 'PortHandles');  
set_param(phs.Inport, 'ConnectionCallback', 'foo');
```

where, `foo` is defined as:

```
function foo(portHandle)
```

- “Model Methods and Callbacks in Fast Restart” on page 68-11

Callback Tracing

Use callback tracing to determine the callbacks that Simulink invokes and the order that it invokes them when you open, edit, or simulate a model.

To enable callback tracing, do one of the following:

- In the Simulink Preferences dialog box, select the **Callback tracing** preference.
- Execute `set_param(0, 'CallbackTracing', 'on')`.

The `CallbackTracing` parameter causes the callbacks to appear in the MATLAB Command Window as they are invoked. This option applies to all Simulink models, not just models that are open when you enable the preference.

Model Workspaces

In this section...

“Model Workspace Differences from MATLAB Workspace” on page 4-71

“Troubleshooting Memory Issues” on page 4-72

“Manipulate Model Workspace Programmatically” on page 4-72

Model Workspace Differences from MATLAB Workspace

Each model is provided with its own workspace for storing variable values.

The model workspace is similar to the base MATLAB workspace except that:

- Variables in a model workspace are visible only in the scope of the model.

If both the MATLAB workspace and a model workspace define a variable of the same name, and the variable does not appear in any intervening masked subsystem or model workspaces, the Simulink software uses the value of the variable in the model workspace. A model's workspace effectively provides it with its own name space, allowing you to create variables for the model without risk of conflict with other models.

- When the model is loaded, the workspace is initialized from a data source.

The data source can be a Model file, a MAT-file, a MATLAB file, or MATLAB code stored in the model file. For more information, see “Data source” on page 4-75.

- You can interactively reload and save MAT-file, MATLAB file, and MATLAB code data sources.
- To store a data object in a model workspace, set the storage class of the object to **Auto**. Data objects are objects of these classes:
 - `Simulink.Parameter` and subclasses
 - `Simulink.Signal` and subclasses

If you specify a storage class other than **Auto**, you must store data objects in the base workspace or a data dictionary to ensure the objects are unique within the global Simulink context and accessible to all models.

- In general, parameter variables in a model workspace are not tunable in the code generated from a model.

However, you can tune model workspace variables declared as model arguments for referenced models. For more information, see “Specify Different Value for Each Instance of Reusable Model” on page 8-61.

Note: When resolving references to variables used in a referenced model, the variables of the referenced model are resolved as if the parent model did not exist. For example, suppose a referenced model references a variable that is defined in both the parent model's workspace and in the MATLAB workspace but not in the referenced model's workspace. In this case, the MATLAB workspace is used.

Troubleshooting Memory Issues

When you use a workspace variable as a block parameter, Simulink creates a copy of the variable during the compilation phase of the simulation and stores the variable in memory. This can cause your system to run out of memory during simulation, or in the process of generating code. Your system might run out of memory if you have:

- Large models with many parameters
- Models with parameters that have a large number of elements

This issue does not affect the amount of memory that is used to represent parameters in generated code.

Manipulate Model Workspace Programmatically

An object of the `Simulink.ModelWorkspace` class describes a model workspace. Simulink creates an instance of this class for each model that you open during a Simulink session. The methods associated with this class can be used to accomplish a variety of tasks related to the model workspace, including:

- Listing the variables in the model workspace
- Assigning values to variables
- Evaluating expressions
- Clearing the model workspace
- Reloading the model workspace from the data source
- Saving the model workspace to a specified MAT-file or MATLAB file

- Saving the workspace to the MAT-file or MATLAB file that the workspace designates as its data source

Specify Source for Data in Model Workspace

When you use a model workspace to contain the variables that a model uses, you can choose to store the variables in one of these sources:

- The model file, which can store static variable definitions.
- A separate MAT-file or MATLAB file. You can reload the variables from the external file into the model workspace at any time.
- Your own custom MATLAB code that creates variables. You can save the code as part of the model file, and reload the code at any time.

To specify a data source for a model workspace, in the Model Explorer, use the Model Workspace dialog box. To display the dialog box for a model workspace:

- 1 Open the Model Explorer by selecting **View > Model Explorer**.
- 2 In the **Model Hierarchy** pane, right-click the model workspace.

- 3 Select the **Properties** menu item, which opens the Model Workspace dialog box.

To use MATLAB commands to change data in a model workspace, see “Use MATLAB Commands to Change Workspace Data” on page 4-81.

Data source

The **Data source** field in the Model Workspace dialog box includes the following data source options for a workspace:

- **Model File**

Specifies that the data source is the model itself.

- **MAT-File**

Specifies that the data source is a MAT file. Selecting this option causes additional controls to appear (see “MAT-File and MATLAB File Source Controls” on page 4-75).

- **MATLAB File**

Specifies that the data source is a MATLAB file. Selecting this option causes additional controls to appear (see “MAT-File and MATLAB File Source Controls” on page 4-75).

- **MATLAB Code**

Specifies that the data source is MATLAB code stored in the model file. Selecting this option causes additional controls to appear (see “MATLAB Code Source Controls” on page 4-76).

MAT-File and MATLAB File Source Controls

Selecting **MAT-File** or **MATLAB File** as the **Data source** for a workspace causes the Model Workspace dialog box to display additional controls.

File name

Specifies the file name or path name of the MAT-file or MATLAB file that is the data source for the selected workspace. If you specify a file name, the name must reside on the MATLAB path.

Reinitialize From Source

Clears the workspace and reloads the data from the MAT-file or MATLAB file specified by the **File name** field.

Save To Source

Saves the workspace in the MAT-file or MATLAB file specified by the **File name** field.

MATLAB Code Source Controls

Selecting MATLAB Code as the **Data source** for a workspace causes the Model Workspace dialog box to display additional controls.

Model Workspace

Workspace data

Data source:

MATLAB Code:

Model arguments (for referencing this model):

MATLAB Code

Specifies MATLAB code that initializes the selected workspace. To change the initialization code, edit this field, then select the **Reinitialize from source** button on the dialog box to clear the workspace and execute the modified code.

Reinitialize from Source

Clears the workspace and executes the contents of the **MATLAB Code** field.

Model Arguments (For Referencing This Model)

Specifies arguments that can be passed to instances of a model that another model references. For more information, see “Specify Different Value for Each Instance of Reusable Model” on page 8-61.

Related Examples

- “Determine Where to Store Variables and Objects for Simulink Models” on page 57-81
- “Model Workspaces” on page 4-71
- “Change Model Workspace Data” on page 4-79

Change Model Workspace Data

When you use a model workspace to contain the variables that a model uses, you choose a source to store the variables, such as the model file or an external MAT-file. To modify the variables at the source, you use a different procedure depending on the type of source that you selected.

Change Workspace Data Whose Source Is the Model File

If the data source of a model workspace is the model file, you can use Model Explorer or MATLAB commands to modify the stored variables (see “Use MATLAB Commands to Change Workspace Data” on page 4-81).

For example, to create a variable in a model workspace:

- 1 Open the Model Explorer by selecting **View > Model Explorer** or by pressing **Ctrl +H**.
- 2 In the Model Explorer **Model Hierarchy** pane, expand the node for your model, and select the model workspace.

- 3 Select **Add > MATLAB Variable**.

You can similarly use the **Add** menu or toolbar to add a `Simulink.Parameter` object to a model workspace.

To change the value of a model workspace variable:

- 1 Open the Model Explorer by selecting **View > Model Explorer**.
- 2 In the Model Explorer **Model Hierarchy** pane, select the model workspace.
- 3 In the **Contents** pane, select the variable.
- 4 In the **Contents** pane or in **Dialog** pane, edit the value displayed.

To delete a model workspace variable:

- 1 Open the Model Explorer by selecting **View > Model Explorer**.
- 2 In the Model Explorer **Model Hierarchy** pane, select the model workspace.
- 3 In **Contents** pane, select the variable.
- 4 Select **Edit > Delete**.

Change Workspace Data Whose Source Is a MAT-File or MATLAB File

You can use Model Explorer or MATLAB commands to modify workspace data whose source is a MAT-file or MATLAB file.

To make the changes permanent, in the Model Workspace dialog box, use the **Save To Source** button to save the changes to the MAT-file or MATLAB file.

- 1 Open the Model Explorer by selecting **View > Model Explorer**.
- 2 In the Model Explorer **Model Hierarchy** pane, right-click the workspace.
- 3 Select the **Properties** menu item.
- 4 In the Model Workspace dialog box, use the **Save To Source** button to save the changes to the MAT-file or MATLAB file.

To discard changes to the workspace, in the Model Workspace dialog box, use the **Reinitialize From Source** button.

Changing Workspace Data Whose Source Is MATLAB Code

The safest way to change data whose source is MATLAB code is to edit and reload the source. Edit the MATLAB code and then in the Model Workspace dialog box, use **Reinitialize From Source** button to clear the workspace and re-execute the code.

To save and reload alternative versions of the workspace that result from editing the MATLAB code source or the workspace variables themselves, see “Export Workspace Variables” on page 57-99 and “Importing Workspace Variables” on page 57-101.

Use MATLAB Commands to Change Workspace Data

To use MATLAB commands to change data in a model workspace, first get the workspace for the currently selected model:

```
hws = get_param(bdroot, 'modelworkspace');
```

This command returns a handle to a `Simulink.ModelWorkspace` object whose properties specify the source of the data used to initialize the model workspace. Edit the properties to change the data source.

Use the workspace methods to:

- List, set, and clear variables
- Evaluate expressions in the workspace
- Save and reload the workspace

For example, the following MATLAB code creates variables specifying model parameters in the model workspace, saves the parameters, modifies one of them, and then reloads the workspace to restore it to its previous state.

```
hws = get_param(bdroot, 'modelworkspace');  
hws.DataSource = 'MAT-File';  
hws.FileName = 'params';  
hws.assignin('pitch', -10);  
hws.assignin('roll', 30);  
hws.assignin('yaw', -2);  
hws.saveToSource;  
hws.assignin('roll', 35);  
hws.reload;
```

Symbol Resolution

In this section...
“Symbols” on page 4-82
“Symbol Resolution Process” on page 4-82
“Numeric Values with Symbols” on page 4-84
“Other Values with Symbols” on page 4-84
“Limit Signal Resolution” on page 4-85
“Explicit and Implicit Symbol Resolution” on page 4-85

Symbols

When you create a Simulink model, you can use symbols to provide values and definitions for many types of entities in the model. Model entities that you can define with symbols include block parameters, configuration set parameters, data types, signals, signal properties, and bus architecture.

A symbol that provides a value or definition must be a legal MATLAB identifier. Such an identifier starts with an alphabetic character, followed by alphanumeric or underscore characters up to the length given by the function `namelengthmax`. You can use the function `isvarname` to determine whether a symbol is a legal MATLAB identifier.

A symbol provides a value or definition in a Simulink model by corresponding to some item that:

- Exists in an accessible workspace
- Has a name that matches the symbol
- Provides the required information

Symbol Resolution Process

The process of finding an item that corresponds to a symbol is called *symbol resolution* or *resolving the symbol*. The matching item can provide the needed information directly, or it can itself be a symbol. A symbol must resolve to some other item that provides the information.

When the Simulink software compiles a model, it tries to resolve every symbol in the model, except symbols in MATLAB code that runs in a callback or as part of mask initialization. Depending on the particular case, the item to which a symbol resolves can be a variable, object, or function.

Simulink attempts to resolve a symbol by searching through the accessible workspaces in hierarchical order for a MATLAB variable or Simulink object whose name is the same as the symbol.

The search path is identical for every symbol. The search begins with the block that uses the symbol, or is the source of a signal that is named by the symbol, and proceeds upward. Except when simulation occurs via the `sim` command, the search order is:

- 1 Any mask workspaces, in order from the block upwards (see “Masking Fundamentals” on page 36-2).
- 2 The model workspace of the model that contains the block (see “Model Workspaces” on page 4-71).
- 3 The MATLAB base workspace (see “Create and Edit Variables”). If the model is linked to a data dictionary, Simulink searches in the dictionary instead of the base workspace. For more information about data dictionaries, see “What Is a Data Dictionary?” on page 61-2.

If Simulink finds a matching item in the course of this search, the search terminates successfully at that point, and the symbol resolves to the matching item. The result is the same as if the value of that item had appeared literally instead of the symbol that resolved to the item. An object defined at a lower level shadows any object defined at a higher level.

If no matching item exists on the search path, Simulink attempts to evaluate the symbol as a function. If the function is defined and returns an appropriate value, the symbol resolves to whatever the function returned. Otherwise, the symbol remains unresolved, and an error occurs. Evaluation as a function occurs as the final step whenever a hierarchical search terminates without having found a matching workspace variable.

If the model that contains the symbol is a referenced model, and the search reaches the model workspace but does not succeed there, the search jumps directly to the base workspace or data dictionary *without* trying to resolve the symbol in the workspace of any parent model. Thus a given symbol resolves to the same item, irrespective of whether the model that contains the symbol is a referenced model. For information about model referencing, see “Model Referencing”.

Numeric Values with Symbols

You can specify any block parameter that requires a numeric value by providing a literal value, a symbol, or an expression, which can contain symbols and literal values. Each symbol is resolved separately, as if none of the others existed. Different symbols in an expression can thus resolve to items on different workspaces, and to different types of item.

When a single symbol appears and resolves successfully, its value provides the value of the parameter. When an expression appears, and all symbols resolve successfully, the value of the expression provides the value of the parameter. If any symbol cannot be resolved, or resolves to a value of inappropriate type, an error occurs.

For example, suppose that the **Gain** parameter of a Gain block is given as `cos(a*(b+2))`. The symbol `cos` will resolve to the MATLAB cosine function, and `a` and `b` must resolve to numeric values, which can be obtained from the same or different types of items in the same or different workspaces. If the symbols resolve to numeric values, the value returned by the cosine function becomes the value of the **Gain** parameter.

Other Values with Symbols

Most symbols and expressions that use them provide numeric values, but the same techniques that provide numeric values can provide any type of value that is appropriate for its context.

Another common use of symbols is to name objects that provide definitions of some kind. For example, a signal name can resolve to a signal object (`Simulink.Signal`) that defines the properties of the signal, and a **Bus Creator** block **Data type** parameter can name a bus object (`Simulink.Bus`) that defines the properties of the bus. You can use symbols for many purposes, including:

- Define data types
- Specify input data sources
- Specify logged data destinations

For hierarchical symbol resolution, all of these different uses of symbols, whether singly or in expressions, are the same. Each symbol is resolved, if possible, independently of any others, and the result becomes available where the symbol appeared. The only difference between one symbol and another is the specific item to which the symbol resolves and

the use made of that item. The only requirement is that every symbol must resolve to something that can legally appear at the location of the symbol.

Limit Signal Resolution

Hierarchical symbol resolution traverses the complete search path by default. You can truncate the search path by using the **Permit Hierarchical Resolution** option of any subsystem. This option controls what happens if the search reaches that subsystem without resolving to a workspace variable. The **Permit Hierarchical Resolution** values are:

- All

Continue searching up the workspace hierarchy trying to resolve the symbol. This is the default value.

- None

Do not continue searching up the hierarchy.

- ExplicitOnly

Continue searching up the hierarchy only if the symbol specifies a block parameter value, data store memory (where no block exists), or a signal or state that explicitly requires resolution. Do not continue searching for an implicit resolution. See “Explicit and Implicit Symbol Resolution” on page 4-85 for more information.

If the search does not find a match in the workspace, and terminates because the value is `ExplicitOnly` or `None`, Simulink evaluates the symbol as a function. The search succeeds or fails depending on the result of the evaluation, as previously described.

Explicit and Implicit Symbol Resolution

Models and some types of model entities have associated parameters that can affect symbol resolution. For example, suppose that a model includes a signal named `Amplitude`, and that a `Simulink.Signal` object named `Amplitude` exists in an accessible workspace. If the `Amplitude` signal's **Signal name must resolve to Simulink signal object** option is checked, the signal will resolve to the object. See “Signal Properties Controls” for more information.

If the option is not checked, the signal may or may not resolve to the object, depending on the value of **Configuration Parameters > Data Validity > Signal resolution**.

This parameter can suppress resolution to the object even though the object exists, or it can specify that resolution occurs on the basis of the name match alone. For more information, see “Model Configuration Parameters: Data Validity Diagnostics” > “Signal resolution”.

Resolution that occurs because an option such as **Signal name must resolve to Simulink signal object** requires it is called *explicit symbol resolution*. Resolution that occurs on the basis of name match alone, without an explicit specification, is called *implicit symbol resolution*.

Tip Implicit symbol resolution can be useful for fast prototyping. However, when you are done prototyping, consider using explicit symbol resolution, because implicit resolution slows performance, complicates model validation, and can have nondeterministic effects.

Manage Model Versions and Specify Model Properties

In this section...

“How Simulink Helps You Manage Model Versions” on page 4-87

“Model File Change Notification” on page 4-87

“Manage Model Properties” on page 4-88

“Log Comments History” on page 4-90

“Version Information Properties” on page 4-91

How Simulink Helps You Manage Model Versions

In Simulink, you can manage multiple versions of a model using these techniques:

- Use Simulink Projects to manage your project files, connect to source control, review modified files, and compare revisions. See “Project Management”.
- Use model file change notification to manage work with source control operations and multiple users. See “Model File Change Notification” on page 4-87.
- As you edit a model, Simulink generates version information about the model, including a version number, who created and last updated the model, and an optional comments history log. Simulink saves these version properties with the model.
 - View and edit some of the version information stored in the model and specify history logging in the model properties.
 - The **Model Info** block lets you display version information as an annotation block in a model diagram.
 - You can access Simulink version parameters programmatically.
- See Simulink.MDLInfo class to extract information from a model file without loading the block diagram into memory. You can use MDLInfo to query model version and Simulink version, find the names of referenced models without loading the model into memory, and attach arbitrary metadata to your model file.

Model File Change Notification

You can use a Simulink preference to specify whether to notify you if the model has changed on disk. You can receive this notification when updating or simulating the model, first editing the model, or saving the model. The model can change on disk, for example, with source control operations and multiple users.

In the Simulink Editor, select **File > Simulink Preferences**. In the **Model File** pane, under **Change Notification**, select the appropriate action.

- If you select **First editing the model**, the file has changed on disk, and the block diagram is unmodified in Simulink:
 - Any interactive operation that modifies the block diagram (e.g., adding a block) causes a warning to appear.
 - Any command-line operation that modifies the block diagram (such as a call to `set_param`) causes a warning to appear.
- If you select **Saving the model**, and the file has changed on disk:
 - Saving the model in the Simulink Editor causes a message to appear.
 - The `save_system` function reports an error, unless you use the `OverwriteIfChangedOnDisk` option.

To programmatically check whether the model has changed on disk since it was loaded, use the function `slIsFileChangedOnDisk`.

For more options that help you work with source control and multiple users, see “Project Management”.

Manage Model Properties

You can use the Property Inspector to view and edit model version properties, description history, and callback functions. To open the Property Inspector, select **View > Property Inspector**. Model properties or, if you are in a library model, library properties, appear in the Property Inspector when nothing is selected at the top level of a model.

Specify the Current User

When you create or update a model, your name is logged in the model for version control purposes. Simulink assumes that your name is specified by at least one of the `USER`, `USERNAME`, `LOGIN`, or `LOGNAME` environment variables. If your system does not define any of these variables, Simulink does not update the user name in the model.

UNIX[®] systems define the `USER` environment variable and set its value to the name you use to log in to your system. Thus, if you are using a UNIX system, you do not have to take further action for Simulink to identify you as the current user.

Windows systems can define environment variables for user name that Simulink expects, depending on the version of Windows installed on your system and whether it is connected to a network. Use the MATLAB function `getenv` to determine which of the environment variables is defined. For example, at MATLAB command prompt, enter:

```
getenv('user')
```

This function determines whether the `USER` environment variable exists on your Windows system. If it does not, set it.

Model Information and History

The **Info** tab summarizes information about the current version of the model, such as modifications, version, and last saved date. You can view and edit model information and enable, view, and edit the model's change history.

Use the **Description** section to enter a description of the model. You can then view the model description by entering `help` followed by the model name at the MATLAB command prompt.

The **History** section displays model history information.

- **Model version**

Version number for this model, incremented by 1 each time you save the model.

- **Created by**

Name of the person who created this model based on the value of the `USER` environment variable when the model is created.

- **Created on**

Date and time this model was created. Do not change this value.

- **Last saved by**

Name of the person who last saved this model based on the value of the `USER` environment variable when the model is saved.

- **Last saved on**

Date that this model was last saved, based on the system date and time.

The **Model history** box displays the history of the model. For more information on updating model history, see “Log Comments History” on page 4-90.

Properties

You can view the source file location, specify where to save model design data, and define callbacks in the **Properties** tab of the model properties.

Note: Library properties also enable you to specify the mapping from old library blocks to new library blocks. For information on using forwarding tables for this purpose, see “Forwarding Tables” on page 38-34.

Define Location of Design Data

Use the **Design Data** section to specify the location of the design data that your model uses. You can define design data in the base workspace or in a data dictionary. See “Migrate Single Model to Use Dictionary” on page 61-6.

Callbacks

Use the **Callbacks** section to specify functions to invoke at specific points in the simulation of the model. Select the callback from the list. In the box, enter the function you want to invoke for the selected callback. For information on these callbacks, see “Create Model Callbacks” on page 4-58.

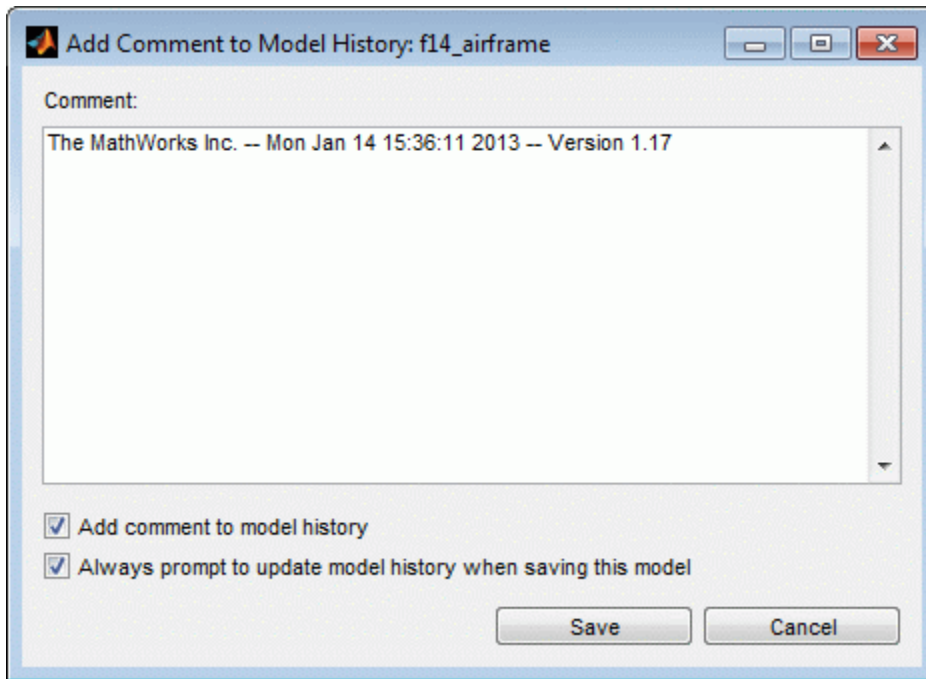

Log Comments History

You can create and store a record of changes with the model. Simulink compiles the history from comments that you or other users enter when saving changes to a model. For more flexibility adding labels and comments to models and submissions, see “Project Management”.

Logging Changes

To enable comment logging, in the **Info** tab of the model properties, in the **History** section, set **Prompt to update model history** to **When saving model**.

The next time you save the model, the Add Comment to Model History dialog box prompts you to enter a comment.

For example, describe the changes you have made to the model since the last time you saved it. To add an item to the model's change history, enter it in the **Comment** box and click **Save**. The information is stored in the model's change history log.

If you do not want to enter an item for this session, clear the **Add comment to model history** check box.

To discontinue change logging, you can either:

- Clear the **Always prompt to update model history when saving this model** check box.
- Change the **Prompt to update model history** model property to **Never**.

Version Information Properties

Some version information is stored as model parameters in a model. You can access this information programmatically using the Simulink `get_param` function.

The table describes the model parameters used by Simulink to store version information.

Property	Description
Created	Date created.
Creator	Name of the person who created this model.
Description	User-entered description of this model. Enter or edit a description on the Description tab of the Model Properties dialog box. You can view the model description by typing <code>help 'mymodelName'</code> at the MATLAB command prompt.
LastModifiedBy	Name of the user who last saved the model.
LastModifiedDate	Date when the model was last saved.
ModifiedBy	Current value of the user name of the person who last modified this model. When you save, this information is saved with the file as <code>LastModifiedBy</code> .
ModifiedByFormat	Format of the <code>ModifiedBy</code> parameter. The value can include the tag <code>%<Auto></code> . The Simulink software replaces the tag with the current value of the <code>USER</code> environment variable.
ModifiedDateFormat	Format used to generate the value of the <code>LastModifiedDate</code> parameter. The value can include the tag <code>%<Auto></code> . Simulink replaces the tag with the current date and time when saving the model.
ModifiedComment	Comment entered by user who last updated this model.
ModifiedHistory	History of changes to this model.
ModelVersion	Version number.
ModelVersionFormat	Format of model version number. The value can contain the tag <code>%<AutoIncrement:#></code> where <code>#</code> is an integer. Simulink replaces the tag with <code>#</code> when displaying the version number. It increments <code>#</code> when saving the model.

`LibraryVersion` is a block parameter for a linked block. `LibraryVersion` is the `ModelVersion` of the library at the time the link was created.

For source control version information, see instead “Project Management”.

Model Discretizer

In this section...

“What Is the Model Discretizer?” on page 4-94

“Requirements” on page 4-94

“Discretize a Model with the Model Discretizer” on page 4-95

“View the Discretized Model” on page 4-103

“Discretize Blocks from the Simulink Model” on page 4-106

“Discretize a Model with the `sldiscmdl` Function” on page 4-116

What Is the Model Discretizer?

Model Discretizer selectively replaces continuous Simulink blocks with discrete equivalents. Discretization is a critical step in digital controller design and for hardware in-the-loop simulations.

You can use the Model Discretizer to:

- Identify a model's continuous blocks
- Change a block's parameters from continuous to discrete
- Apply discretization settings to all continuous blocks in the model or selected blocks
- Create configurable subsystems that contain multiple discretization candidates along with the original continuous block(s)
- Switch among the different discretization candidates and evaluate the resulting model simulations

Requirements

To use Model Discretizer

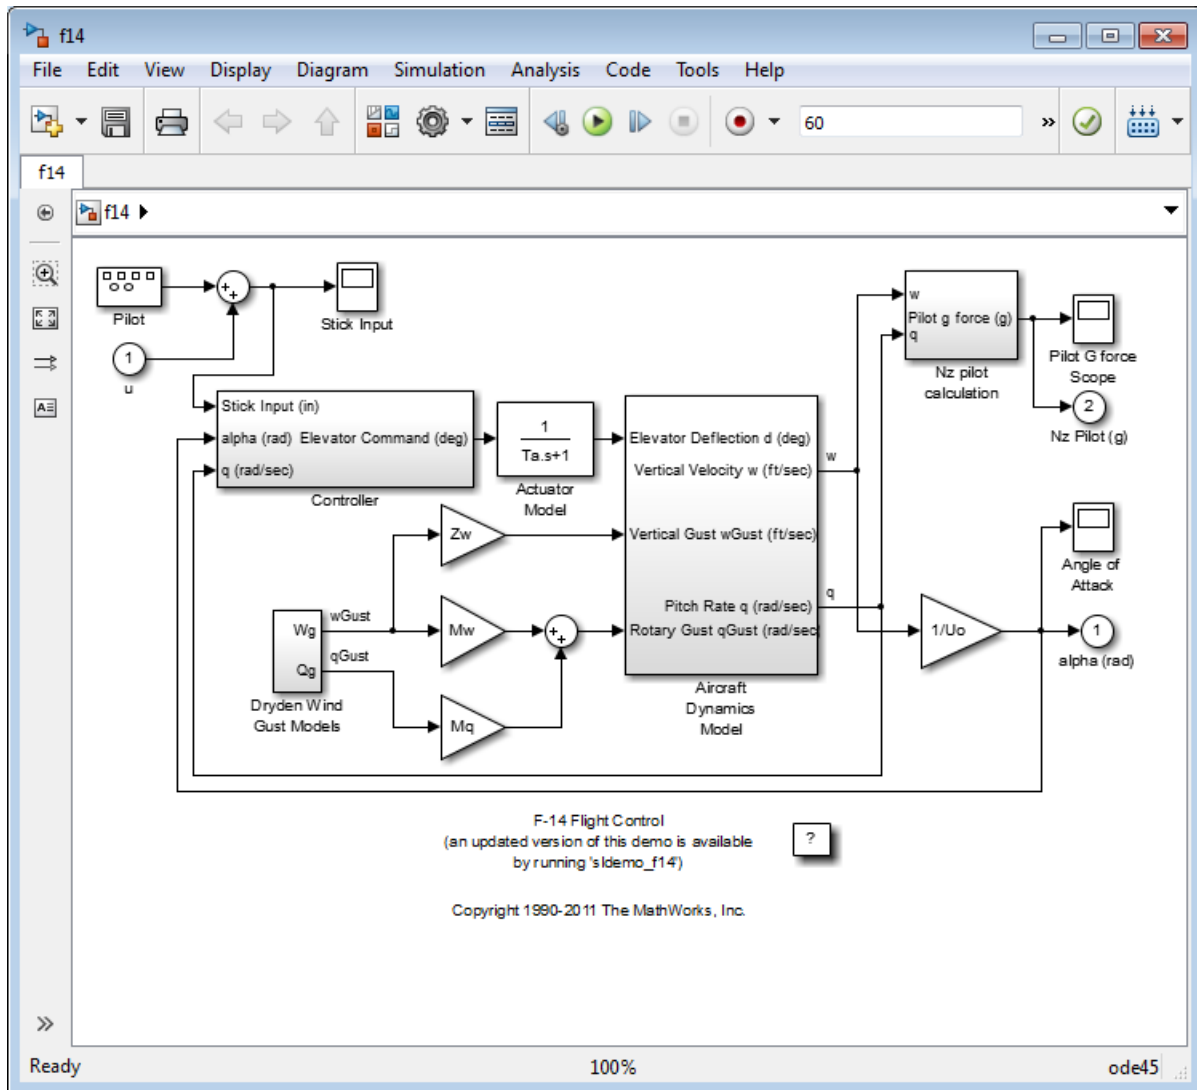

- You must have a Control System Toolbox™ license, Version 5.2 or later.
- Make sure your model does not contain any obsolete blocks and is upgraded to the current Simulink version. For more information, see “Model Upgrades”
- Make sure your model does not contain any masked subsystems. For more information, see “Block Masks”.

Discretize a Model with the Model Discretizer

To discretize a model:

- Start the Model Discretizer
- Specify the Transform Method
- Specify the Sample Time
- Specify the Discretization Method
- Discretize the Blocks

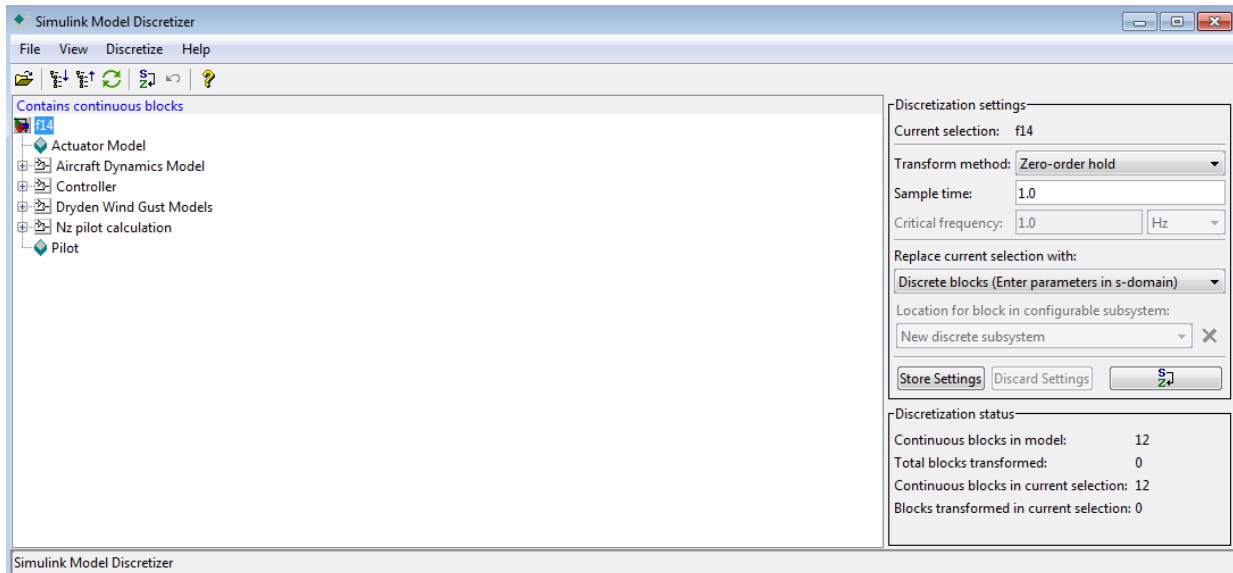

The f14 model shows the steps in discretizing a model.

Start Model Discretizer

To open the tool, in the Simulink Editor, select **Analysis > Control Design > Model Discretizer**.

The **Simulink Model Discretizer** opens.

Alternatively, you can open Model Discretizer from the MATLAB Command Window using the `slmdliscui` function.

The following command opens the **Simulink Model Discretizer** window with the `f14` model:

```
slmdliscui('f14')
```

To open a new model or library from Model Discretizer, select **File > Load model**.

Specify the Transform Method

The transform method specifies the type of algorithms used in the discretization. For more information on the different transform methods, see the Control System Toolbox documentation.

The **Transform method** list contains the following options:

- zero-order hold

Zero-order hold on the inputs.

- `first-order hold`

Linear interpolation of inputs.

- `tustin`

Bilinear (Tustin) approximation.

- `tustin with prewarping`

Tustin approximation with frequency prewarping.

- `matched pole-zero`

Matched pole-zero method (for SISO systems only).

Specify the Sample Time

Enter the sample time in the **Sample time** field.

You can specify an offset time by entering a two-element vector for discrete blocks or configurable subsystems. The first element is the sample time and the second element is the offset time. For example, an entry of [1.0 0.1] would specify a 1.0 second sample time with a 0.1 second offset. If no offset is specified, the default is zero.

You can enter workspace variables when discretizing blocks in the s-domain. See “Discrete blocks (Enter parameters in s-domain)” on page 4-99.

Specify the Discretization Method

Specify the discretization method in the **Replace current selection with** field. The options are

- “Discrete blocks (Enter parameters in s-domain)” on page 4-99

Creates a discrete block whose parameters are retained from the corresponding continuous block.

- “Discrete blocks (Enter parameters in z-domain)” on page 4-100

Creates a discrete block whose parameters are “hard-coded” values placed directly into the block’s dialog.

- “Configurable subsystem (Enter parameters in s-domain)” on page 4-101

Create multiple discretization candidates using s-domain values for the current selection. A configurable subsystem can consist of one or more blocks.

- “Configurable subsystem (Enter parameters in z-domain)” on page 4-101

Create multiple discretization candidates in z-domain for the current selection. A configurable subsystem can consist of one or more blocks.

Discrete blocks (Enter parameters in s-domain)

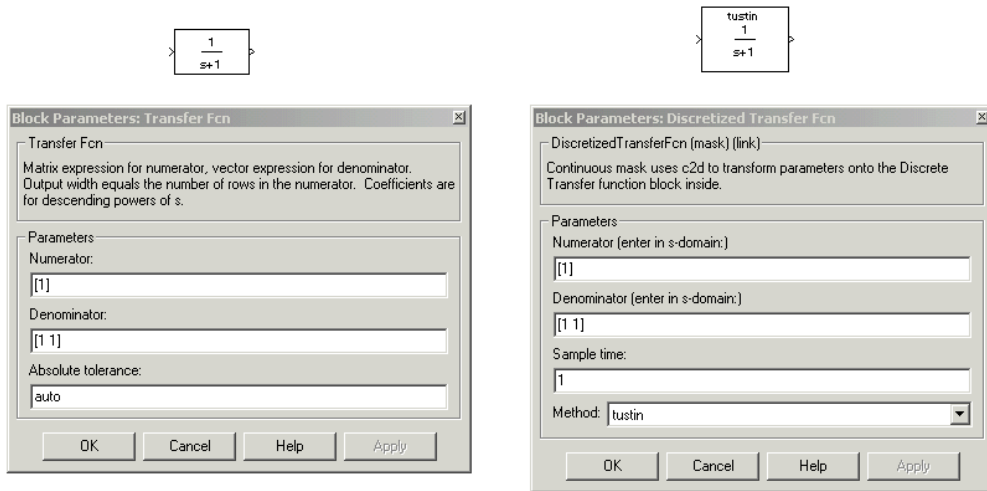

Creates a discrete block whose parameters are retained from the corresponding continuous block. The sample time and the discretization parameters are also on the block's parameter dialog box.

The block is implemented as a masked discrete block that uses `c2d` to transform the continuous parameters to discrete parameters in the mask initialization code.

These blocks have the unique capability of reverting to continuous behavior if the sample time is changed to zero. Entering the sample time as a workspace variable (' `TS` ', for example) allows for easy changeover from continuous to discrete and back again. See “Specify the Sample Time” on page 4-98.

Note If you generated code from a model, parameters are not tunable when **Default parameter behavior** is set to **Inlined** in the model's Configuration Parameters dialog box.

The following figure shows a continuous Transfer Function block next to a Transfer Function block that has been discretized in the s-domain. The Block Parameters dialog box for each block appears below the block.

Discrete blocks (Enter parameters in z-domain)

Creates a discrete block whose parameters are “hard-coded” values placed directly into the block's dialog box. Model Discretizer uses the `c2d` function to obtain the discretized parameters, if needed.

For more help on the `c2d` function, type the following in the Command Window:

```
help c2d
```

The following figure shows a continuous Transfer Function block next to a Transfer Function block that has been discretized in the z-domain. The Block Parameters dialog box for each block appears below the block.

Note If you want to recover exactly the original continuous parameter values after the Model Discretization session, you should enter parameters in the s-domain.

Configurable subsystem (Enter parameters in s-domain)

Create multiple discretization candidates using s-domain values for the current selection. A configurable subsystem can consist of one or more blocks.

The **Location for block in configurable subsystem** field becomes active when this option is selected. This option allows you to either create a new configurable subsystem or overwrite an existing one.

Note The current folder must be writable in order to save the library or libraries for the configurable subsystem option.

Configurable subsystem (Enter parameters in z-domain)

Create multiple discretization candidates in z-domain for the current selection. A configurable subsystem can consist of one or more blocks.

The **Location for block in configurable subsystem** field becomes active when this option is selected. This option allows you to either create a new configurable subsystem or overwrite an existing one.

Note The current folder must be writable in order to save the library or libraries for the configurable subsystem option.

Configurable subsystems are stored in a library containing the discretization candidates and the original continuous block. The library will be named `<model name>_disc_lib` and it will be stored in the current . For example a library containing a configurable subsystem created from the `f14` model will be named `f14_disc_lib`.

If multiple libraries are created from the same model, then the filenames will increment accordingly. For example, the second configurable subsystem library created from the `f14` model will be named `f14_disc_lib2`.

You can open a configurable subsystem library by right-clicking on the subsystem in the model and selecting **Library Link > Go to library block** from the pop-up menu.

Discretize the Blocks

To discretize blocks that are linked to a library, you must either discretize the blocks in the library itself or disable the library links in the model window.

You can open the library from Model Discretizer by selecting **Load model** from the **File** menu.

You can disable the library links by right-clicking on the block and selecting **Library Link > Disable Link** from the pop-up menu.

There are two methods for discretizing blocks.

Select Blocks and Discretize

- 1 Select a block or blocks in the Model Discretizer tree view pane.

To choose multiple blocks, press and hold the **Ctrl** button on the keyboard while selecting the blocks.

Note You must select blocks from the Model Discretizer tree view. Clicking blocks in the editor does not select them for discretization.

- 2 Select **Discretize current block** from the **Discretize** menu if a single block is selected or select **Discretize selected blocks** from the **Discretize** menu if multiple blocks are selected.

You can also discretize the current block by clicking the **Discretize** button, shown below.

Store the Discretization Settings and Apply Them to Selected Blocks in the Model

- 1 Enter the discretization settings for the current block.
- 2 Click **Store Settings**.

This adds the current block with its discretization settings to the group of preset blocks.

- 3 Repeat steps 1 and 2, as necessary.
- 4 Select **Discretize preset blocks** from the **Discretize** menu.

Deleting a Discretization Candidate from a Configurable Subsystem

You can delete a discretization candidate from a configurable subsystem by selecting it in the **Location for block in configurable subsystem** field and clicking the **Delete** button, shown below.

Undoing a Discretization

To undo a discretization, click the **Undo** discretization button, shown below.

Alternatively, you can select **Undo discretization** from the **Discretize** menu.

This operation undoes discretizations in the current selection and its children. For example, performing the undo operation on a subsystem will remove discretization from all blocks in all levels of the subsystem's hierarchy.

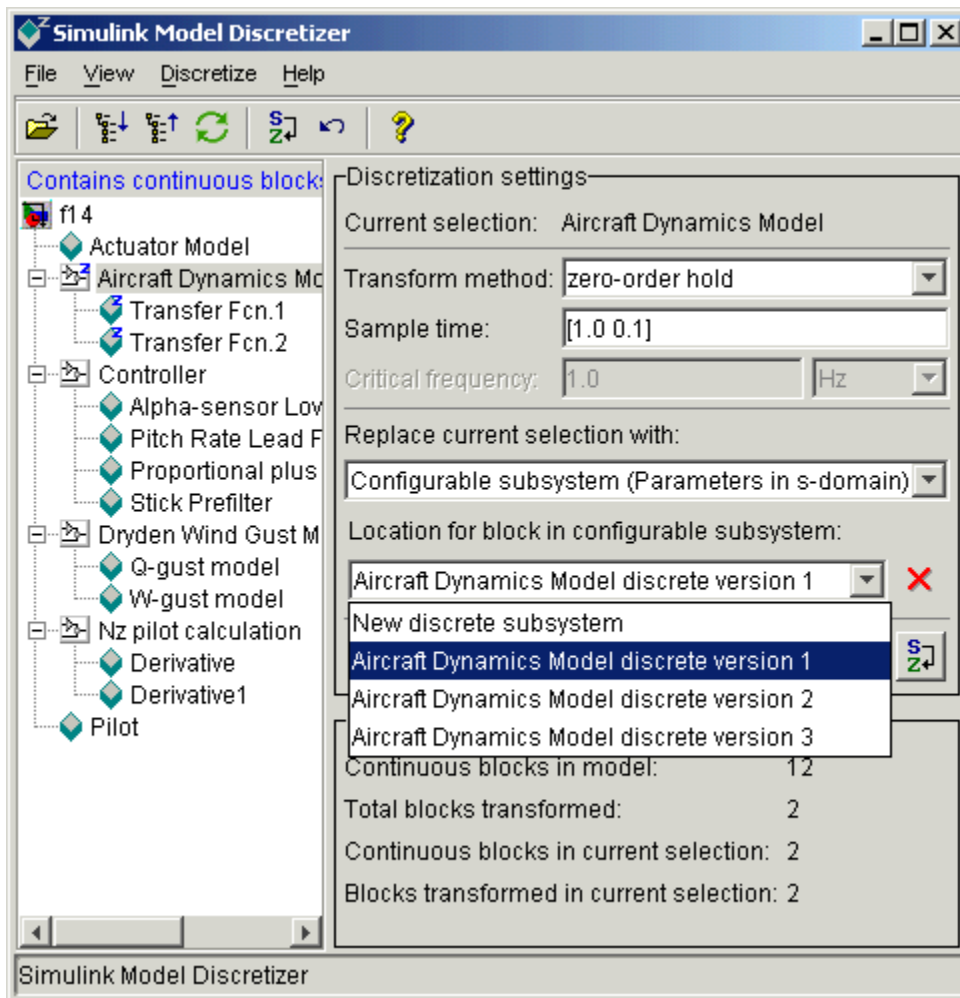

View the Discretized Model

Model Discretizer displays the model in a hierarchical tree view.

Viewing Discretized Blocks

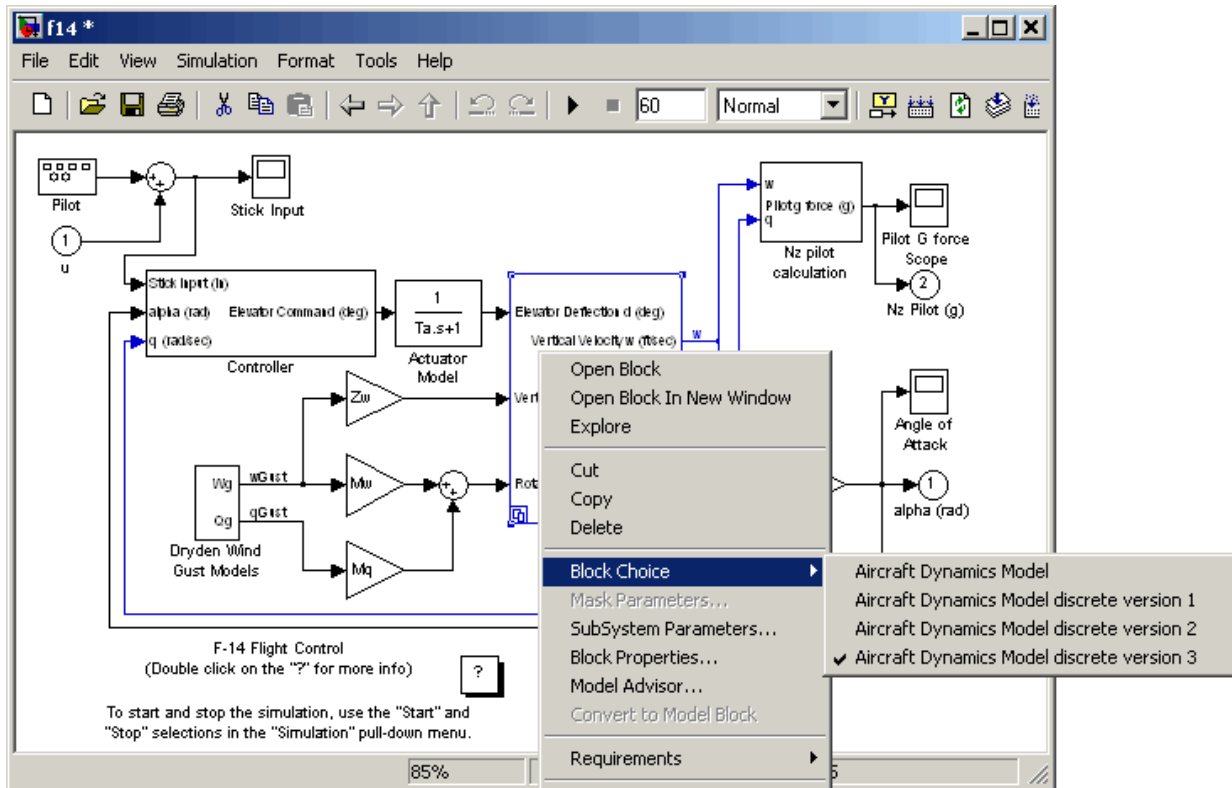

The block's icon in the tree view becomes highlighted with a “z” when the block has been discretized.

The following figure shows that the Aircraft Dynamics Model subsystem has been discretized into a configurable subsystem with three discretization candidates.

The other blocks in this f14 model have not been discretized.

The following figure shows the Aircraft Dynamics Model subsystem of the f14 example model after discretization into a configurable subsystem containing the original continuous model and three discretization candidates.

The following figure shows the library containing the Aircraft Dynamics Model configurable subsystem with the original continuous model and three discretization candidates.

Refreshing Model Discretizer View of the Model

To refresh Model Discretizer's tree view of the model when the model has been changed, click the **Refresh** button, shown below.

Alternatively, you can select **Refresh** from the **View** menu.

Discretize Blocks from the Simulink Model

You can replace continuous blocks in a Simulink software model with the equivalent blocks discretized in the s-domain using the Discretizing library.

The procedure below shows how to replace a continuous Transfer Fcn block in the Aircraft Dynamics Model subsystem of the f14 model with a discretized Transfer Fcn block from the Discretizing Library. The block is discretized in the s-domain with a zero-order hold transform method and a two second sample time.

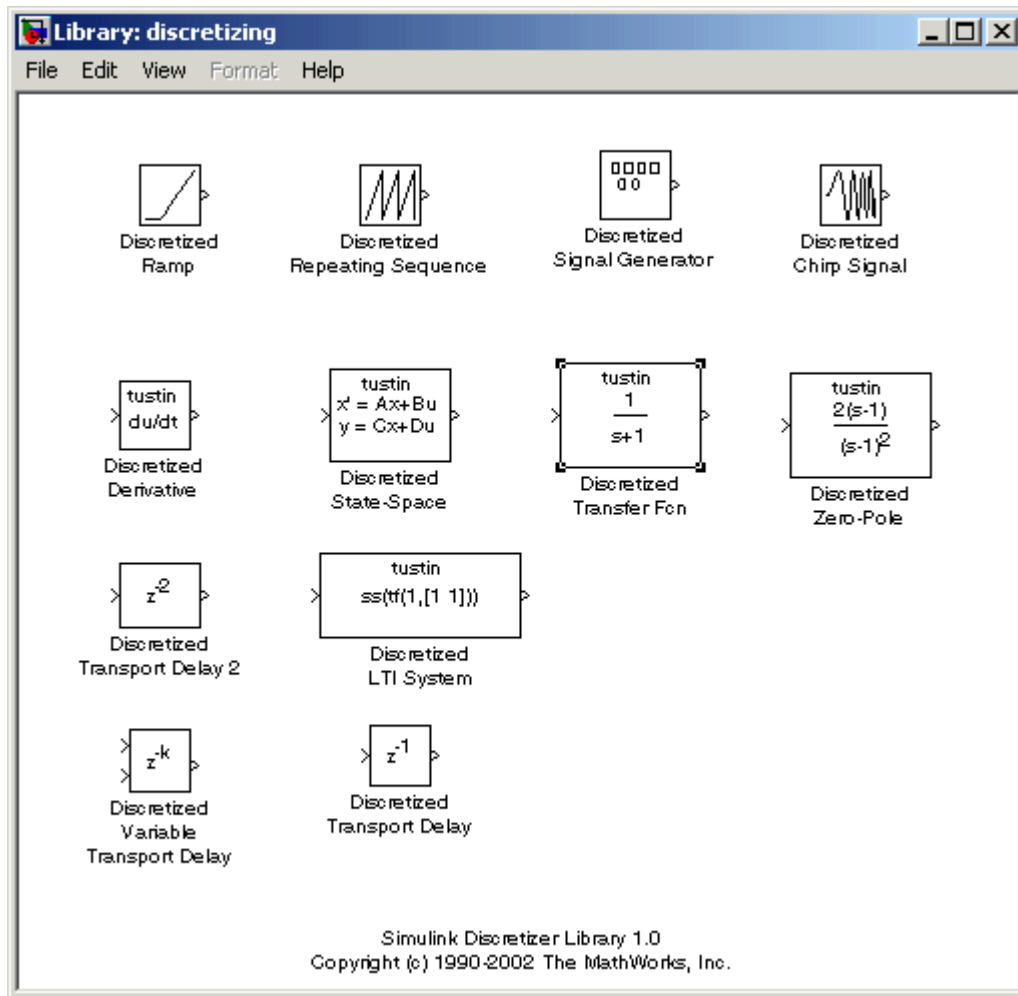

- 1 Open the f14 model.
- 2 Open the Aircraft Dynamics Model subsystem in the f14 model.

3 Open the Discretizing library window.

Enter discretizing at the MATLAB command prompt.

The **Library: discretizing** window opens.

This library contains s-domain discretized blocks.

4 Add the Discretized Transfer Fcn (with initial states) block to the **f14/Aircraft Dynamics Model** window.

- a** Click the Discretized Transfer Fcn block in the **Library: discretizing** window.
- b** Drag it into the **f14/Aircraft Dynamics Model** window.

- 5 Open the parameter dialog box for the Transfer Fcn.1 block.

Double-click the Transfer Fcn.1 block in the **f14/Aircraft Dynamics Model** window.

The Block Parameters: Transfer Fcn.1 dialog box opens.

- 6 Open the parameter dialog box for the Discretized Transfer Fcn block.

Double-click the Discretized Transfer Fcn block in the **f14/Aircraft Dynamics Model** window.

The Block Parameters: Discretized Transfer Fcn dialog box opens.

Copy the parameter information from the Transfer Fcn.1 block's dialog box to the Discretized Transfer Fcn block's dialog box.

- 7 Enter 2 in the **Sample time** field.
- 8 Select zoh from the **Method** drop-down list.

The parameter dialog box for the Discretized Transfer Fcn now looks like this.

- 9 Click **OK**.

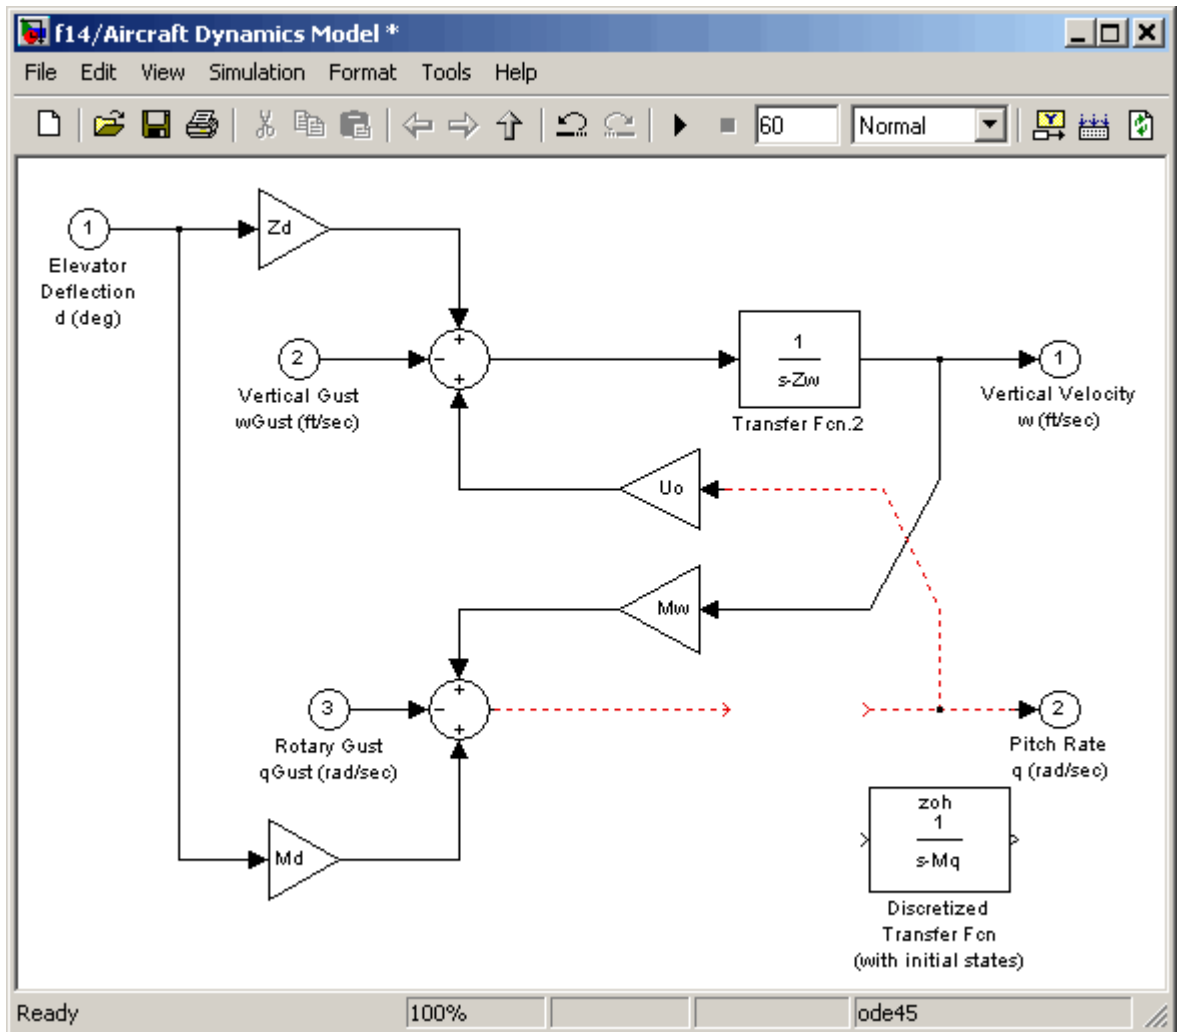

The **f14/Aircraft Dynamics Model** window now looks like this.

10 Delete the original Transfer Fcn.1 block.

- a Click the Transfer Fcn.1 block.
- b Press the **Delete** key.

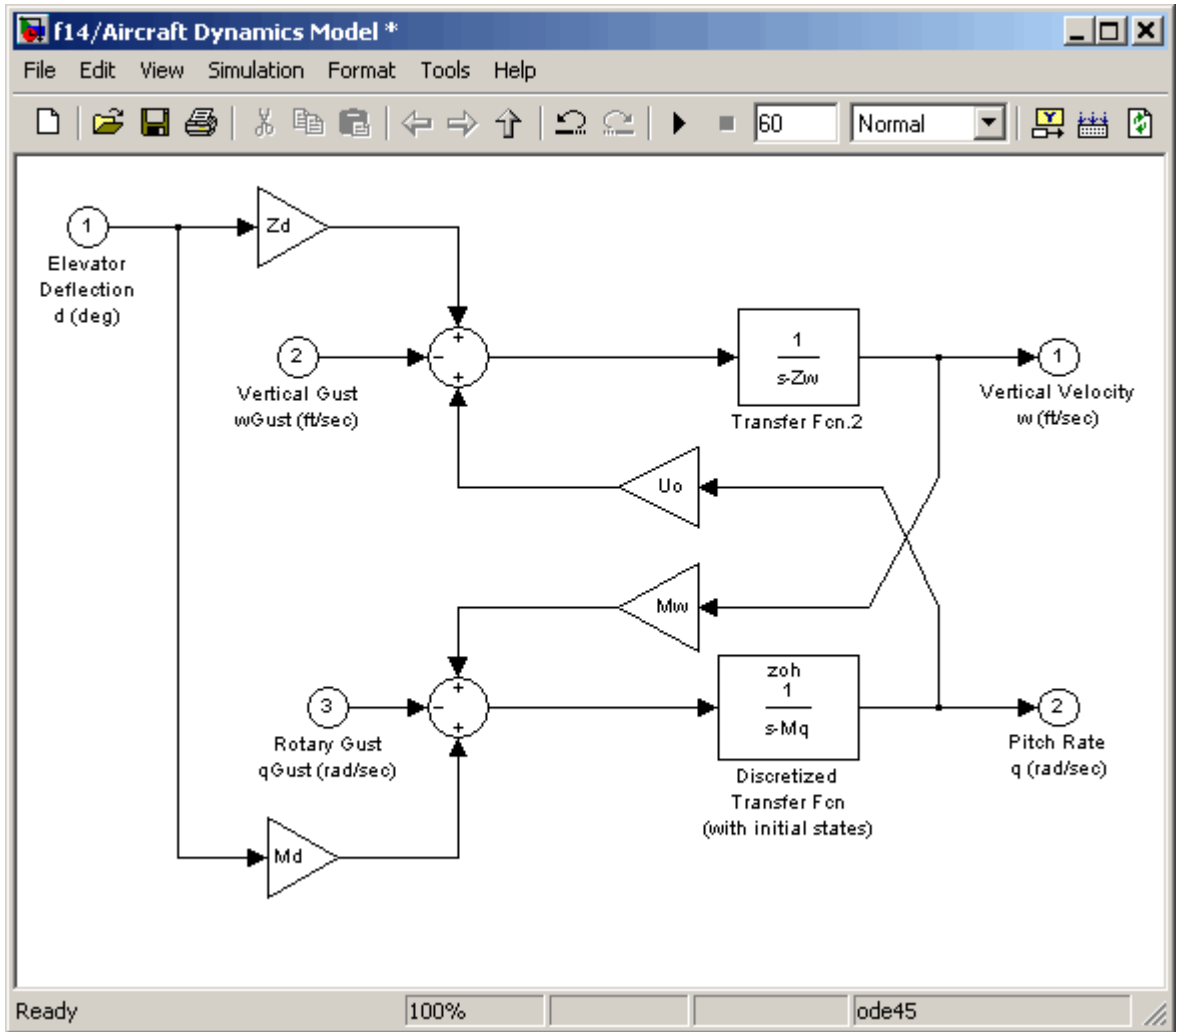

The **f14/Aircraft Dynamics Model** window now looks like this.

11 Add the Discretized Transfer Fcn block to the model.

- a Click the Discretized Transfer Fcn block.
- b Drag the Discretized Transfer Fcn block into position to complete the model.

The **f14/Aircraft Dynamics Model** window now looks like this.

Discretize a Model with the sldiscmdl Function

Use the `sldiscmdl` function to discretize Simulink software models from the MATLAB Command Window. You can specify the transform method, the sample time, and the discretization method with the `sldiscmdl` function.

For example, the following command discretizes the `f14` model in the s-domain with a 1-second sample time using a zero-order hold transform method:

```
sldiscmdl('f14',1.0,'zoh')
```

Model Advisor

Consulting the Model Advisor

Model Advisor Overview

The Model Advisor checks a model or subsystem for conditions and configuration settings that you select, including conditions that cause inaccurate or inefficient simulation of the system that the model represents. If you have a Simulink Coder or Simulink Verification and Validation license, the Model Advisor can check for model settings that cause generation of inefficient code or code unsuitable for safety-critical applications. If you have a Simulink Design Verifier™ license, the Model Advisor can check for design errors. If an error is reported, you can view a test case that reproduces the error.

The Model Advisor produces a report that lists the suboptimal conditions or settings that it finds, proposing better model configuration settings where appropriate.

Software is inherently complex and may not be completely free of errors. Model Advisor checks might contain bugs. MathWorks® reports known bugs brought to its attention on its Bug Report system at <http://www.mathworks.com/support/bugreports/>. The bug reports are an integral part of the documentation for each release. Examine periodically all bug reports for a release as such reports may identify inconsistencies between the actual behavior of a release you are using and the behavior described in this documentation.

While applying Model Advisor checks to your model will increase the likelihood that your model does not violate certain modeling standards or guidelines, their application cannot guarantee that the system being developed will be safe or error-free. It is ultimately your responsibility to verify, using multiple methods, that the system being developed provides its intended functionality and does not include any unintended functionality.

Start the Model Advisor

There are two Model Advisor UIs that you can use to run checks on your model: the Model Advisor window and the Model Advisor dashboard.

Action	Use	Set Preferences
Consistently run the same set of	Model Advisor dashboard. The	1 From the Model Editor, select Analysis > Model Advisor > Preferences .

Action	Use	Set Preferences
checks on your model.	Model Advisor dashboard does not reload checks before executing them, saving analysis time.	<ol style="list-style-type: none"> 2 In the Model Advisor Preferences window, for the Default Mode, select Model Advisor Dashboard.
Select and view checks to run on your model.	Model Advisor window.	<ol style="list-style-type: none"> 1 From the Model Editor, select Analysis > Model Advisor > Preferences. 2 In the Model Advisor Preferences window, for the Default Mode, select Model Advisor.

Before starting the Model Advisor, make sure that your current folder is writable. If the folder is not writable, when you start the Model Advisor, you see an error message.

The Model Advisor uses the `slprj` folder in the code generation folder to store reports and other information. If the `slprj` folder does not exist in the code generation folder, the Model Advisor creates it.

Note: Model Advisor does not analyze blocks that you comment out.

To start the Model Advisor, use one of the following methods.

Open the Model Advisor window or Model Advisor dashboard	For	Action
From the Model Editor	Model or subsystem	<ol style="list-style-type: none"> 1 Select Analysis > Model Advisor > Model Advisor or Model Advisor Dashboard. <p>Alternatively, from the Model Editor toolbar  drop-down list, select Model Advisor or Model Advisor Dashboard.</p>

Open the Model Advisor window or Model Advisor dashboard	For	Action
		<p>2 In the System Selector window, select the model or subsystem that you want.</p> <p>3 Click OK.</p>
From the Model Explorer	Model	In the Contents pane, select Advice for <i>model</i> . <i>model</i> is the name of the model that you want to check. (For more information, see “Model Explorer Overview” on page 12-2.)
From the context menu	Subsystem	Right-click the subsystem that you want to check and select Model Advisor .
Programmatically	Model or subsystem	At the command prompt, enter <code>modeladvisor(<i>model</i>)</code> . <i>model</i> is a handle or name of the model or subsystem that you want to check. For more information, see <code>Simulink.ModelAdvisor</code> .

Model Advisor Window

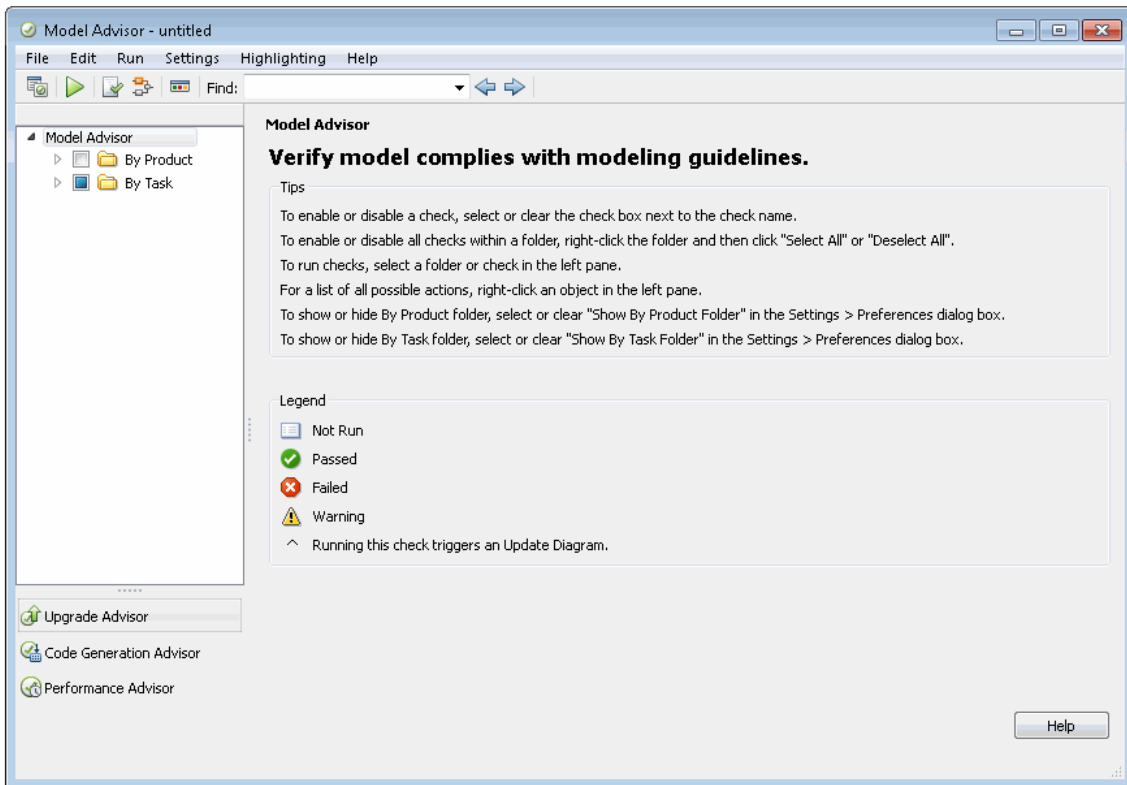

If you want to view and select checks to run on your model, use the Model Advisor window.

If you want to save analysis time, consistently run the same set of checks on your model by using the Model Advisor dashboard. To switch to the dashboard, click the **Switch to**

Model Advisor Dashboard toggle ()

When you start the Model Advisor, the Model Advisor window displays two panes. The left pane lists the folders in the Model Advisor. Expanding the folders displays the available checks. The right pane provides instructions on how to view, enable, and disable checks. It also provides a legend describing the displayed symbols.

When you open the Model Advisor for a model that you have previously checked, the Model Advisor initially displays the check results generated the last time that you checked the model. If you recheck the model, you see the new results in the Model Advisor window.

Setting Model Advisor Window Preferences

The following table summarizes actions you can take to customize the Model Advisor window. On the toolbar, select **Settings > Preferences** to open the Model Advisor Preferences dialog box.

To	On Model Advisor Preferences, select
Display the check available for each product.	Show By Product Folder
Display checks related to specific tasks.	Show By Task Folder
Display the check Title, TitleId, and location of the	Show Source Tab. The Source tab displays check source information.

To	On Model Advisor Preferences, select
MATLAB source code for the check.	
Display checks that are excluded from the Model Advisor analysis.	Show Exclusion tab. The Exclusions tab displays checks that are excluded from the Model Advisor analysis.

Selecting and Running Checks

The following table summarizes actions you can take to select and run checks

To	Action
Display checks related to specific tasks.	Select By Task .
Display the check available for each product.	Select By Product .
Find checks and folders.	Enter text in the Find: field and click the Find Next button (). The Model Advisor searches in check names, folder names, and analysis descriptions.
Reset the status of the checks to not run.	Right-click Model Advisor in the left pane and select Reset from the context menu.
Select some or all of the checks.	Select the check and folder check boxes.
Run the selected checks.	On the toolbar of the Model Advisor window, click Run selected checks ( .

Accessing Other Advisors

You can use the Model Advisor window to access other Advisors.

To	Select
Configure your model to meet code generation objectives.	Code Generation Advisor. See “Application Objectives Using Code Generation Advisor”.

To	Select
Upgrade and improve models with the current release.	Upgrade Advisor. See “Consult the Upgrade Advisor” on page 6-2.
Improve the simulation performance of your model.	Performance Advisor. See “Improve Simulation Performance Using Performance Advisor” on page 29-2.

Viewing Results

After running checks, the Model Advisor displays the results in the right pane. The Model Advisor generates an HTML report of the check results. For more information, see “Address Model Check Results” on page 5-22.

To	Action
View the report in a separate browser window.	Click Open Report () or the Report link at the folder level.
Highlight results for individual checks.	Enable Model Advisor highlighting. In the Model Advisor window, on the toolbar, do one of the following: <ul style="list-style-type: none"> • Select Highlighting > Enable Highlighting. • Click the Enable highlighting toggle (.
Highlight model blocks that are excluded from individual Model Advisor checks.	On the toolbar of the Model Advisor window, select Highlighting > Highlight exclusions . If you have a Simulink Verification and Validation license, you can create or modify exclusions to the Model Advisor checks.

Model Advisor Dashboard

To consistently run the same set of checks on your model, saving analysis time, use the Model Advisor dashboard.

To	Action
Select and view checks.	Use the Model Advisor window. Click the Switch to standard view toggle ()
Run checks.	Click Run checks ()
View the report in a separate browser window.	Click Open Report .
View highlighted results.	Click the Enable highlighting toggle ()

More Information About Checking Your Model

The following table includes links to additional information about using the Model Advisor to run checks on your model.

Action	See
Select and run checks to run on your model.	<ul style="list-style-type: none"> • “Select Checks and Run Model Advisor” on page 5-13 • “Selecting Model Checks” on page 5-10
Run model checks available with Simulink.	“Simulink Checks”

If you have a Simulink Verification and Validation license, create custom checks for your model.	“Create Model Advisor Checks”
If you have a Simulink Verification and Validation license, check for model settings that cause generation of inefficient code or code unsuitable for safety-critical applications.	“Model Guidelines Compliance”

Action	See
If you have a Simulink Design Verifier license, check for design errors.	"Design Error Detection"

Selecting Model Checks

To determine which model checks to run on your model, you can:

- In the Model Advisor window, select **By Task** to display checks related to specific tasks. For example, to run checks to determine if your model is configured for simulation accuracy, select checks in the **Simulation Accuracy** folder.
- In the Model Advisor window, right-click the check and select **What's This?** to open a help browser with check-specific documentation.

The check documentation provides:

- Detailed check descriptions.
- The conditions that result in a check warning or failure, with recommendations for updating your model to pass the check.
- Software capabilities and limitations when using the check.

If you have a license for Simulink Verification and Validation, you can create custom checks to run on your model.

Check Support for Libraries

You can use Model Advisor checks to check library models. When you use the Model Advisor to check a library model, the Model Advisor window indicates (~) checks that do not check libraries. To determine if you can run the check on library models, you can also refer to the check documentation, “Capabilities and Limitations”. You cannot use checks that require model compilation. If you have a license for Simulink Verification and Validation, you can use an API to create custom checks which support library models.

Checks Triggering an Update Diagram

Model Advisor checks that trigger an Update Diagram are marked with ^. An Update Diagram triggers a model compilation. For simulation or code generation, individual checks can sometimes require model compilation.

Related Examples

- “Select Checks and Run Model Advisor” on page 5-13

More About

- “Consulting the Model Advisor” on page 5-2

Model Advisor Limitations

When you use the Model Advisor to check systems, the following limitations apply:

- If you rename a system, you must restart the Model Advisor to check that system.
- In systems that contain a variant subsystem, the Model Advisor checks only the active subsystem.
- Checks do not search in Model blocks or Subsystem blocks with the block parameter **Read/Write** set to **NoReadorWrite**. However, on a check-by-check basis, Model Advisor checks do search in library blocks and masked subsystems.

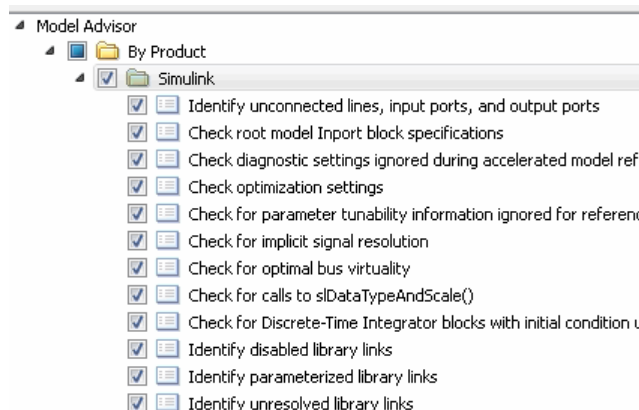

For limitations that apply to specific checks, see the “Capabilities and Limitations” section in the check documentation. For example, for capabilities that apply to the **Identify unconnected lines, input ports, and output ports** check, see “Capabilities and Limitations”.

Select Checks and Run Model Advisor

The Model Advisor checks a model or subsystem for conditions and configuration settings that you select, including conditions that cause inaccurate or inefficient simulation of the system that the model represents. If you have a Simulink Coder or Simulink Verification and Validation license, the Model Advisor can check for model settings that cause generation of inefficient code or code unsuitable for safety-critical applications. If you have a Simulink Design Verifier license, the Model Advisor can check for design errors. If it reports an error, you can view a test case that reproduces the error.

Select Checks and Run Model Advisor

- 1 Open your model. For example, open the Model Advisor example model `sldemo_mdladv`.
- 2 Start the Model Advisor. In your model, select **Analysis > Model Advisor > Model Advisor**.
- 3 In the System Selector dialog box, select the model or system that you want to review, for example, `sldemo_mdladv`. Click **OK**.
- 4 In the left pane of the Model Advisor, expand the **By Product** and **By Task** folders to display the subfolders. The **By Task** folders displays checks related to specific tasks. The **By Product** folders display checks available with specific products. Select **Settings > Preferences** to control the folders that display.
- 5 In the left pane, select the checks to run on your model. For example, select the checks in the **By Product > Simulink** folder.

- 6 To display an HTML report of check results, in the right pane of the Model Advisor, select **Show report after run**.
- 7 Click **Run Selected Checks**. After the Model Advisor runs the checks, the results appear in a browser if you selected the option to show the report.

The screenshot shows the Model Advisor Report for 'sidemo_mdladv.slx'. The interface includes a 'Filter checks' panel on the left with options for 'Passed', 'Failed', 'Warning', and 'Not Run'. A 'Run Summary' table displays the following data:

Pass	Fail	Warning	Not Run	Total
180	0	92	0	272

Below the summary, a 'By Task' section shows two tasks: '1 Code Generation Efficiency' (6 Pass, 0 Fail, 3 Warning, 0 Not Run) and '2 Frequency Response Estimation' (0 Pass, 0 Fail, 1 Warning, 0 Not Run). A detailed view of the 'Identify time-varying source blocks interfering with frequency response estimation' check is shown, with a description: 'This check finds and reports all the time-varying source blocks which are connected to linearization output points currently marked on the model and not specified to be held'.

- 8 In the Model Advisor, expand the folder that contains the checks, for example the Simulink folder. Select a check to see a detailed view of the results in the right pane. For example, select **Identify unconnected lines, input ports, and output ports**. Use this view to examine and exercise a check individually.

The screenshot shows the Model Advisor interface with the 'Identify unconnected lines, input ports, and output ports' check selected in the 'Simulink' folder. The right pane displays the detailed view for this check, including a 'Run This Check' button, a 'Warning' result, and a list of unconnected objects: 'sidemo_mdladv/Gain2' and 'sidemo_mdladv/Out4'. The 'Recommended Action' is to 'Connect the blocks specified in the list'.

- 9 In the Model Advisor, click the **Enable highlighting** button . You can highlight the results of checks that display the  icon. In the model, the blocks causing the

warning appear highlighted. The Model Advisor Highlighting dialog box also opens, and you can click the link to view the results in a browser.

After reviewing the check results in the Model Advisor window, you can choose to fix warnings or failures.

Save Model Analysis Time

You can save analysis time by consistently run the same set of checks on your model using the Model Advisor dashboard. When you use the dashboard, the Model Advisor does not reload the checks before executing them, saving analysis time.

To run checks on your model using the Model Advisor dashboard:

- 1 Open your model. For example, open the Model Advisor model, `sldemo_md1adv`.
- 2 Start the Model Advisor dashboard.
 - a From the Simulink Editor, select **Analysis > Model Advisor > Model Advisor Dashboard**.

Alternatively, from the Simulink Editor toolbar  drop-down list, select **Model Advisor Dashboard**.

- b In the System Selector window, select the model or system that you want to review. For example, `sldemo_md1adv`. Click **OK**.

The Model Advisor dashboard opens.

- 3 Optionally, to select or view checks to run on your model, click the **Switch to standard view** toggle (). The Model Advisor window opens.
 - a For example, in the Model Advisor window, open the **By Product** folder and select checks:
 - Identify unconnected lines, input ports, and output ports**
 - Check root model Inport block specifications**

If the **By Product** folder is not displayed in the Model Advisor window, select **Show By Product Folder** from the **Settings > Preferences** dialog box.

- b Return to the Model Advisor dashboard by clicking the **Switch to Model Advisor Dashboard** toggle ().
- 4 On the Model Advisor dashboard, click **Run checks** ().
- 5 Click the **Enable Highlighting** toggle () to view highlighted results.

- The model window opens. The blocks causing the **Identify unconnected lines, input ports, and output ports** check warning are highlighted in yellow.

- The Model Advisor Highlighting information window opens with a link to the Model Advisor window. In the Model Advisor window, you can find more information about the check results and how to fix the warning condition.

- 6 After reviewing the check results, you can choose to fix warnings or failures. For example, to fix the **Identify unconnected lines, input ports, and output ports** check warning:
 - a Connect model blocks Gain2 and Out4.
 - b On the Model Advisor dashboard, click **Run checks** (▶) to rerun the checks.

The **Identify unconnected lines, input ports, and output ports** check passes.

Run Model Checks in Background

If you have a Parallel Computing Toolbox license, you can run the Model Advisor in the background, allowing you to continue working on your model during analysis. When you start a Model Advisor analysis run in the background, Model Advisor takes a snapshot of your model. The analysis does not reflect changes that you make to your model while Model Advisor is running in the background.

- 1 Open your model.
- 2 Start the Model Advisor.
 - a From the Simulink Editor, select **Analysis > Model Advisor > Model Advisor**.
 - b In the System Selector window, select the model or system that you want to review.
- 3 In the Model Advisor window, click the **Run checks in background** toggle ().
- 4 In the left pane of the Model Advisor window, select the checks that you want to run.
- 5 In the Model Advisor window, select **Run selected checks** (.

Alternatively, you can use the Model Advisor dashboard to run the checks. In the Model Advisor window, switch to the Model Advisor dashboard by clicking the **Switch to Model Advisor Dashboard** toggle (). On the Model Advisor dashboard, click **Run selected checks** (.

The Model Advisor starts an analysis on a parallel processor.

- 6 To stop running checks in the background, in the Model Advisor window, click **Stop background run** (). In the lower-left pane, you see a status of the analysis.

The **Explore Result** option is not available for checks that are run in the background.

Run Model Checks Programmatically

If you have a license for Simulink Verification and Validation, you can create MATLAB scripts and functions that run the Model Advisor programmatically. For example, you can create a function to check whether your model passes a specified set of the Model Advisor checks every time that you open the model and start a simulation. If you have Simulink Coder, the function can generate code from the model.

Address Model Check Results

Highlight Model Check Results

You can use color highlighting on the model diagram to indicate the analysis results for individual Model Advisor checks. Blocks that pass a check, fail a check, or cause a check warning are highlighted in color in the model window. Model Advisor highlighting is available for:

- Simulink blocks
- Stateflow charts

After you run a Model Advisor analysis, checks with highlighted results are indicated with an  icon in the Model Advisor window.

To use Model Advisor color highlighting:

- 1 Run Model Advisor checks on your model.
- 2 Enable Model Advisor highlighting by doing one of the following:
 - On the toolbar of the Model Advisor window, select **Highlighting > Enable Highlighting**.
 - On the toolbar of the Model Advisor window, click the **Enable highlighting**  ().
 - On the toolbar of the Model Advisor Dashboard, click the **Enable Highlighting**  (.
- 3 Optionally, to view model blocks that are excluded from the Model Advisor checks, select **Highlighting > Highlight Exclusions** on the Model Advisor window toolbar. If you have a Simulink Verification and Validation license, you can create or modify exclusions to the Model Advisor checks.
- 4 In the left pane of the Model Advisor window, select a check with highlighted results. Checks with highlighted results are indicated with the  icon. Highlighting is not available for some checks.

The model window and a Model Advisor Highlighting information window open. The Model Advisor Highlighting information window provides a link to the Model Advisor window, where you can review the check results.

Highlighting colors in the model window		
Yellow with orange border		Blocks that cause the check failure or warning.
White with orange border		Subsystem with blocks that cause the check warning or failure.
White with gray border		Blocks or subsystems without highlighting.
Gray with black border		Blocks that are excluded from the check.
White with black border		Subsystems that are excluded from the check.

- 5 After reviewing the check results in the model window and the Model Advisor window, you can choose to fix warnings or failures.
- 6 To view highlighted results for another check, in the left pane of the Model Advisor window, select a check with an  icon.

If a check warns or fails, and the model window highlights blocks in gray, closely examine the results in the Model Advisor window. A Model Advisor check can fail or warn due to your parameter or diagnostic settings.

Fix a Model Check Warning or Failure

Checks fail when a model or referenced model has a suboptimal condition. A warning result is informational. You can fix the reported issue, or move on to the next task. For more information on why a specific check does not pass, see the check documentation.

Manually Fix Warnings or Failures

Checks have an Analysis Result box that describes the recommended actions to manually fix warnings or failures.

To manually fix warnings or failures within a task:

- 1 Optionally, save a model and data restore point so that you can undo your changes.
- 2 In the Analysis Result box, review the recommended actions. Use the information to make changes to your model.
- 3 Rerun the check to verify that it passes.

When you fix a warning or failure, rerun all checks to update the results of all checks. If you do not rerun all checks, the Model Advisor can report an invalid check result.

Automatically Fix Warnings or Failures

Some checks have an Action box that you can use to automatically fix failures. The action box applies all of the recommended actions listed in the Analysis Result box.

To automatically fix all warnings or failures within a check:

- 1 Optionally, save a model and data restore point by clicking the **Modify All** button.
- 2 In the Action box, click **Modify All**.

The Action Result box displays a table of changes.

- 3 Rerun the check to verify that it passes.

When you fix a warning or failure, rerun all checks to update the results of all checks. If you do not rerun all checks, the Model Advisor can report an invalid check result.

Batch-Fix Warnings or Failures

Some checks have an **Explore Result** button that starts the Model Advisor Result Explorer. With the Model Advisor Result Explorer, you can quickly locate, view, and change elements of a model.

The Model Advisor Result Explorer helps you to modify only the items that the Model Advisor is checking.

If a check does not pass, and you want to explore the results and make batch changes:

- 1 Optionally, save a model and data restore point so that you can undo your changes.
- 2 In the Analysis box, click **Explore Result**.
- 3 In the Model Advisor Result Explorer, you can modify block parameters.
- 4 In the Model Advisor window, rerun the check to verify that it passes.

When you fix a warning or failure, rerun all checks to update the results of all checks. If you do not rerun all checks, the Model Advisor can report an invalid check result.

Revert Changes

The Model Advisor provides a model and a data restore point capability for reverting changes that you made in response to recommendations from the Model Advisor. You can also restore the default configuration of the Model Advisor. A *restore point* is a snapshot in time of the model, base workspace, and Model Advisor. The Model Advisor maintains restore points for the model or subsystem through multiple sessions of MATLAB.

Note: A restore point saves only the current working model, base workspace variables, and Model Advisor tree. It does not save other items, such as libraries and referenced models.

Restore Default Configuration

In the Model Advisor window, select **Settings > Restore Default Configuration**.

Save a Restore Point

You can save a restore point and give it a name and description. Or, the Model Advisor can name the restore point.

To save a restore point:

- 1 In the Model Advisor window, select **File > Save Restore Point As**.
- 2 In the **Name** field, enter a name for the restore point.
- 3 In the **Description** field, you can optionally add a description to help you identify the restore point.

4 Click **Save**.

The Model Advisor saves a restore point of the current model, base workspace, and Model Advisor status.

To quickly save a restore point, in the Model Advisor window, select **File > Save Restore Point**. The Model Advisor saves a restore point with the name `autosaven.n`. *n* is the sequential number of the restore point. If you use this method, you cannot change the name of, or add a description to, the restore point.

Load a Restore Point

- 1 Optionally, save a model and data restore point so that you can undo your changes.
- 2 Select **File > Load Restore Point**.
- 3 In the Load Model and Data Restore Point dialog box, select the restore point that you want.
- 4 Click **Load**.

The Model Advisor issues a warning that the restoration removes changes that you made after saving the restore point.

- 5 Click **Load** to load the restore point that you selected.

The Model Advisor reverts the model, base workspace, and Model Advisor status.

- “Consulting the Model Advisor” on page 5-2
- “Selecting Model Checks” on page 5-10

Save and View Model Advisor Reports

When the Model Advisor runs checks, it generates an HTML report of check results. By default, the HTML report is in the `slprj/modeladvisor/model_name` folder.

If you have a Simulink Verification and Validation license, you can generate reports in Adobe® PDF and Microsoft Word .docx formats.

Save Model Advisor Reports

You can save a Model Advisor report to a new location.

- 1 In the Model Advisor window, navigate to the folder with the checks that you ran.
- 2 Select the folder. The right pane of the Model Advisor window displays information about that folder. The pane includes a **Report** box.
- 3 In the Report box, click **Generate Report**.
- 4 In the Generate Model Advisor Report dialog box, enter the path to the folder where you want to generate the report. Provide a file name.
- 5 Click **OK**. The Model Advisor saves the report in HTML format to the location that you specified.

If you rerun the Model Advisor, the report is updated in the working folder, not in the location where you archived the original report.

The full path to the report is in the title bar of the report window.

View Model Advisor Reports

Access a report by selecting a folder and clicking the link in the **Report** box. Or, before a Model Advisor analysis, in the right pane of the Model Advisor window, select **Show report after run**.

Tip Use the Model Advisor window to interactively fix warnings and failures. Model Advisor reports are best for viewing a summary of checks.

As you run checks, the Model Advisor updates the reports with the latest information for each check in the folder. When you run the checks at different times, an informational

message appears in the report. Time stamps indicate when checks have been run. The time of the current run appears at the top right of the report. Checks that occurred during previous runs have a time stamp following the check name.

To	Action
Display results for checks that pass, warn, or fail.	Use the Filter checks check boxes. For example, to display results for only checks that warn, in the left pane of the report, select the Warning check box. Clear the Passed , Failed , and Not Run check boxes.
Display results for checks with keywords or phrases in the check title.	Use the Keywords field. Results for checks without the keyword in the check title are not displayed in the report. For example, to display results for only checks with “setting” in the check title, in the Keywords field, enter “setting”.
Quickly navigate to sections of the report.	Select the links in the table-of-contents navigation pane.
Expand and collapse content in the check results.	Click Show/Hide check details .
Scroll to the top of the report.	Click Scroll to top .
Minimize folder results in the report.	Click the minus sign next to the folder name.

Printed versions of the report do not contain:

- Filtering checks, Navigation, or View panes.
- Content hidden due to filtering or keyword searching.

Some checks have input parameters specified in the right pane of the Model Advisor. For example, **Check Merge block usage** has an input parameter for **Maximum analysis time (seconds)**. When you run checks with input parameters, the Model Advisor displays the values of the input parameters in the HTML report. For more information, see the `EmitInputParametersToReport` property of the `Simulink.ModelAdvisor` class.

More About

- “Consulting the Model Advisor” on page 5-2

Upgrade Advisor

Consult the Upgrade Advisor

Use the Upgrade Advisor to help you upgrade and improve models with the current release. The Upgrade Advisor can identify cases where you can benefit by changing your model to use new features and settings in Simulink. The Advisor provides advice for transitioning to new technologies, and upgrading a model hierarchy.

The Upgrade Advisor can also help identify cases when a model will not work because changes and improvements in Simulink require changes to a model.

The Upgrade Advisor offers options to perform recommended actions automatically or instructions for manual fixes.

You can open the Upgrade Advisor in the following ways:

- From the Model Editor, select **Analysis > Model Advisor > Upgrade Advisor**
- From the MATLAB command line, use the `upgradeadvisor` function:

```
upgradeadvisor modelName
```
- Alternatively, from the Model Advisor, click **Upgrade Advisor**. This action closes the Model Advisor and opens the Upgrade Advisor.

In the Upgrade Advisor, you create reports and run checks in the same way as when using the Model Advisor.

- Select the top Upgrade Advisor node in the left pane to run all selected checks and create a report.
- Select each individual check to open a detailed view of the results in the right pane. View the analysis results for recommended actions to manually fix warnings or failures. In some cases, the Upgrade Advisor provides mechanisms for automatically fixing warnings and failures.

Caution When you fix a warning or failure, rerun all checks to update the results of all checks. If you do not rerun all checks, the Upgrade Advisor might report an invalid check result.

You must run upgrade checks in this order: first the checks that do not require compile time information and do not trigger an Update Diagram, then the compile checks. To guide you through upgrade checks to run both non-compile and compile checks, run the

check **Analyze model hierarchy and continue upgrade sequence**. See “Analyze model hierarchy and continue upgrade sequence”.

For more information on individual checks, see

- “Model Upgrades” for upgrade checks only
- “Simulink Checks” for all upgrade and advisor checks

Upgrade Programmatically

To analyze and upgrade models programmatically, use the `upgradeadvisor` function.

Tip For an example showing how to upgrade a whole project programmatically, see “Upgrade Simulink Models using a Simulink Project”.

Upgrade Advisor Checks

For advice on upgrading and improving models with the current release, use the following Model Advisor checks in the Upgrade Advisor.

- “Check model for block upgrade issues”
- “Check usage of function-call connections”
- “Identify Model Info blocks that can interact with external source control tools”
- “Check for calls to `slDataTypeAndScale`”
- “Identify masked blocks that specify tabs in mask dialog using `MaskTabNames` parameter”
- “Check that the model is saved in SLX format”
- “Check model for SB2SL blocks”
- “Check Model History properties”
- “Identify Model Info blocks that use the Configuration Manager”
- “Identify configurable subsystem blocks for converting to variant subsystem blocks”
- “Check and update masked blocks in library to use promoted parameters”
- “Check and update mask image display commands with unnecessary `imread()` function calls”

- “Check Rapid accelerator signal logging”“Check get_param calls for block CompiledSampleTime”
- “Check model for parameter initialization and tuning issues”
- “Check model for block upgrade issues requiring compile time information”

What Is Sample Time?

The *sample time* of a block is a parameter that indicates when, during simulation, the block produces outputs and if appropriate, updates its internal state. The internal state includes but is not limited to continuous and discrete states that are logged.

Note: Do not confuse the Simulink usage of the term sample time with the engineering sense of the term. In engineering, sample time refers to the rate at which a discrete system samples its inputs. Simulink allows you to model single-rate and multirate discrete systems and hybrid continuous-discrete systems through the appropriate setting of block sample times that control the rate of block execution (calculations).

For many engineering applications, you need to control the rate of block execution. In general, Simulink provides this capability by allowing you to specify an explicit `SampleTime` parameter in the block dialog or at the command line. Blocks that do not have a `SampleTime` parameter have an implicit sample time. You cannot specify implicit sample times. Simulink determines them based upon the context of the block in the system. The `Integrator` block is an example of a block that has an implicit sample time. Simulink automatically sets its sample time to `0`.

Sample times can be port based or block based. For block-based sample times, all of the inputs and outputs of the block run at the same rate. For port-based sample times, the input and output ports can run at different rates. To learn more about rates of execution, see “Types of Sample Time” on page 7-15.

“Determining Sample Time Units” on page 7-8

“Change the Sample Time After Simulation Start Time” on page 7-8

Designate Sample Times

Simulink allows you to specify a block sample time directly as a numerical value or symbolically by defining a sample time vector. In the case of a discrete sample time, the vector is $[T_s, T_o]$ where T_s is the sampling period and T_o is the initial time offset. For example, consider a discrete model that produces its outputs every two seconds. If your base time unit is seconds, you can directly set the discrete sample time by specifying the numerical value of 2 as the `SampleTime` parameter. Because the offset value is zero, you do not need to specify it; however, you can enter $[2, 0]$ in the **Sample time** field.

For nondiscrete blocks, the components of the vector are symbolic values that represent one of the types in “Types of Sample Time” on page 7-15. The following table summarizes these types and the corresponding sample time values. The table also defines the explicit nature of each sample time type and designates the associated color and annotation. Because an *inherited sample time* is explicit, you can specify it as $[-1, 0]$ or as -1 . Whereas, a triggered sample time is implicit; only Simulink can assign the sample time of $[-1, -1]$. (For more information about colors and annotations, see “View Sample Time Information” on page 7-9.)

Designations of Sample Time Information

Sample Time Type	Sample Time	Color	Annotation	Explicit
Discrete	$[T_s, T_o]$	In descending order of speed:	D1, D2, D3, D4, D5, D6, D7,... Di	Yes

Sample Time Type	Sample Time	Color	Annotation	Explicit
		red, green, blue, light blue, dark green, orange		
Continuous	[0, 0]	black	Cont	Yes
Fixed in minor step	[0, 1]	gray	FiM	Yes
Inherited	[-1, 0]	N/A	N/A	Yes
Constant	[Inf, 0]	magenta	Inf	Yes
Variable	[-2, T _{vo}]	brown	V1, V2,... Vi	No
Hybrid	N/A	yellow	N/A	No
Triggered	Source: D1, Source: D2, ... Source: Di	cyan	T1, T2,... Ti	No
Asynchronous	[-1, -n]	purple	A1, A2,... Ai	No

The color that is assigned to each block depends on its sample time relative to other sample times in the model. This means that the same sample time may be assigned different colors in a parent model and in models that it references. (See “Model Referencing”.)

For example, suppose that a model defines three sample times: 1, 2, and 3. Further, suppose that it references a model that defines two sample times: 2 and 3. In this case, blocks operating at the 2 sample rate appear as green in the parent model and as red in the referenced model.

It is important to note that Mux and Demux blocks are simply grouping operators; signals passing through them retain their timing information. For this reason, the lines emanating from a Demux block can have different colors if they are driven by sources having different sample times. In this case, the Mux and Demux blocks are color coded as hybrids (yellow) to indicate that they handle signals with multiple rates.

Similarly, Subsystem blocks that contain blocks with differing sample times are also colored as hybrids, because there is no single rate associated with them. If all the blocks within a subsystem run at a single rate, the Subsystem block is colored according to that rate.

You can use the explicit sample time values in this table to specify sample times interactively or programmatically for either block-based or port-based sample times.

The following model, `ex_specify_sample_time`, serves as a reference for this section.

`ex_specify_sample_time`

In this example, set the sample time of the input sine wave signal to `0.1`. The goal is to achieve an output sample time of `0.2`. The Rate Transition block serves as a zero-order hold. The resulting block diagram after setting the sample times and simulating the model is shown in the following figure. (The colors and annotations indicate that this is a discrete model.)

Sample Time 0.1 Sample Time 0.2

`ex_specify_sample_time` after Setting Sample Times

Specify Block-Based Sample Times Interactively

To set the sample time of a block interactively:

- 1 In the Simulink model window, double-click the block. The block parameter dialog box opens.
- 2 Enter the sample time in the **Sample time** field.
- 3 Click **OK**.

Following is a figure of a parameters dialog box for the Sine Wave block after entering 0.1 in the **Sample time** field.

Specify Port-Based Sample Times Interactively

The Rate Transition block has port-based sample times. You can set the output port sample time interactively by completing the following steps:

- 1 Double-click the Rate Transition block. The parameters dialog box opens.
- 2 Leave the drop-down menu choice of the **Output port sample time options** as **Specify**.
- 3 Replace the -1 in the **Output port sample time** field with 0.2.

4 Click **OK**.

For more information about the sample time options in the Rate Transition parameters dialog box, see the [Rate Transition](#) reference page.

Specify Block-Based Sample Times Programmatically

To set a block sample time programmatically, set its `SampleTime` parameter to the desired sample time using the `set_param` command. For example, to set the sample time of the Gain block in the “Specify_Sample_Time” model to inherited (-1), enter the following command:

```
set_param('Specify_Sample_Time/Gain','SampleTime','[-1, 0]')
```

As with interactive specification, you can enter just the first vector component if the second component is zero.

```
set_param('Specify_Sample_Time/Gain','SampleTime','-1')
```

Specify Port-Based Sample Times Programmatically

To set the output port sample time of the Rate Transition block to 0.2, use the `set_param` command with the parameter `OutPortSampleTime`:

```
set_param('Specify_Sample_Time/Rate Transition',...
```

```
'OutPortSampleTime', '0.2')
```

Access Sample Time Information Programmatically

To access all sample times associated with a model, use the API `Simulink.BlockDiagram.getSampleTimes`.

To access the sample time of a single block, use the API `Simulink.Block.getSampleTimes`.

Specify Sample Times for a Custom Block

You can design custom blocks so that the input and output ports operate at different sample time rates. For information on specifying block-based and port-based sample times for S-functions, see “Sample Times” in *Writing S-Functions* of the Simulink documentation.

Determining Sample Time Units

Since the execution of a Simulink model is not dependent on a specific set of units, you must determine the appropriate base time unit for your application and set the sample time values accordingly. For example, if your base time unit is second, then you would represent a sample time of 0.5 second by setting the sample time to 0.5.

Change the Sample Time After Simulation Start Time

To change a sample time after simulation begins, you must stop the simulation, reset the `SampleTime` parameter, and then restart execution.

“What Is Sample Time?” on page 7-2 | “Types of Sample Time” on page 7-15

View Sample Time Information

In this section...
“View Sample Time Display” on page 7-9
“Sample Time Legend” on page 7-10

View Sample Time Display

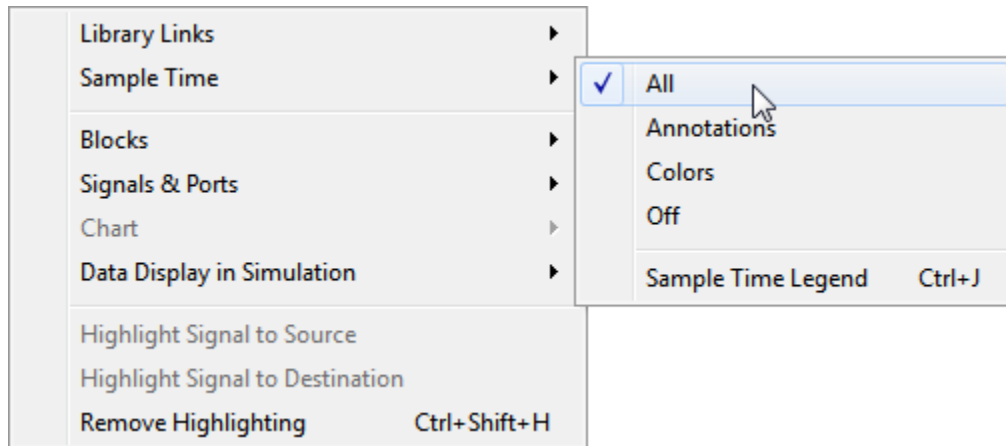

Simulink models can display color coding and annotations that represent specific sample times. As shown in the table Designations of Sample Time Information, each sample time type has one or more colors associated with it. You can display the blocks and signal lines in color, the annotations in black, or both the colors and the annotations. To choose one of these options:

- 1 In the Simulink model window, select **Display > Sample Time**.
- 2 Select **Colors, Annotations, or All**.

Selecting **All** results in the display of both the colors and the annotations. Regardless of your choice, Simulink performs an **Update Diagram** automatically. To turn off the colors and annotations:

- 1 Select **Display > Sample Time**.
- 2 Select **Off**.

Simulink performs another **Update Diagram** automatically.

Your Sample Time Display choices directly control the information that the Sample Time Legend displays.

Note: The discrete sample times in the table Designations of Sample Time Information represent a special case. Five colors indicate the fastest through the fifth fastest discrete rate. A sixth color, orange, represents all rates that are slower than the fifth discrete rate. You can distinguish between these slower rates by looking at the annotations on their respective signal lines.

Sample Time Legend

You can view the Sample Time Legend for an individual model or for multiple models. Additionally, you can prevent the legend from automatically opening when you select options on the **Sample Time** menu.

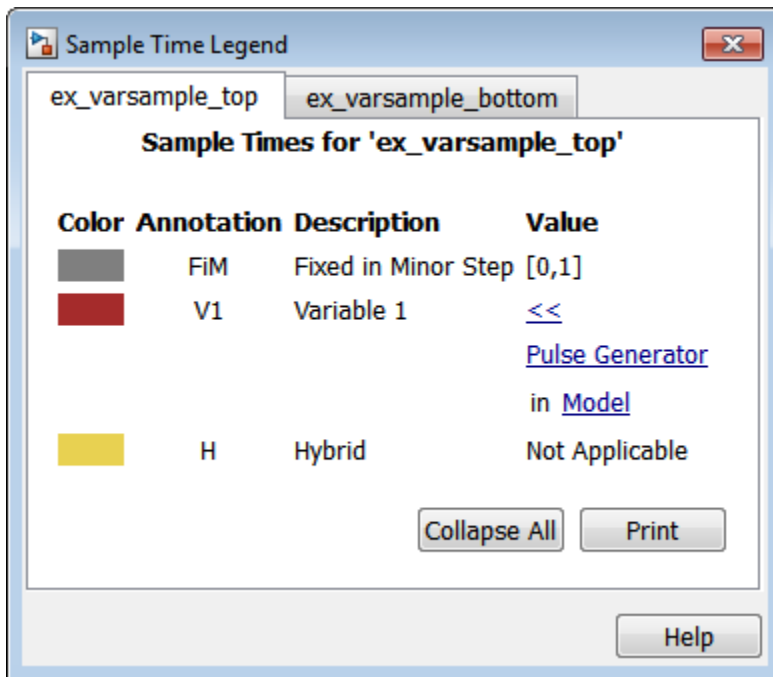

Viewing the Legend

To assist you with interpreting your block diagram, a **Sample Time Legend** is available that contains the sample time color, annotation, description, and value for each sample time in the model. You can use one of three methods to view the legend, but upon first opening the model, you must first perform an **Update Diagram**.

- 1 In the Simulink model window, select **Simulation > Update Diagram**.
- 2 Select **Display > Sample Time > Sample Time Legend** or press **Ctrl +J**.

In addition, whenever you select **Colors**, **Annotations**, or **All** from the **Sample Time** menu, Simulink updates the model diagram and opens the legend by default. The legend contents reflect your **Sample Time Display** choices. By default or if you have selected **Off**, the legend contains a description of the sample time and the sample time value. If you turn colors on, the legend displays the appropriate color beside each description. Similarly, if you turn annotations on, the annotations appear in the legend.

The legend does not provide a discrete rate for all types of sample times. For asynchronous and variable sample times, the legend displays a link to the block that controls the sample time in place of the sample time value. Clicking one of these links highlights the corresponding block in the block diagram. For variable sample times, the legend uses >> to indicate that the controller block of the sample time is in a model reference hierarchy. Click >> to drill down to that block, for example:

The rate listed under hybrid and asynchronous hybrid models is “Not Applicable” because these blocks do not have a single representative sample time.

Note: The Sample Time Legend displays all of the sample times in the model, including those that are not associated with any block. For example, if the fixed step size is 0.1 and all of the blocks have a sample time of 0.2, then both rates (i.e., 0.1 and 0.2) appear in the legend.

For subsequent viewings of the legend, repeat the **Update Diagram** to access the latest known information.

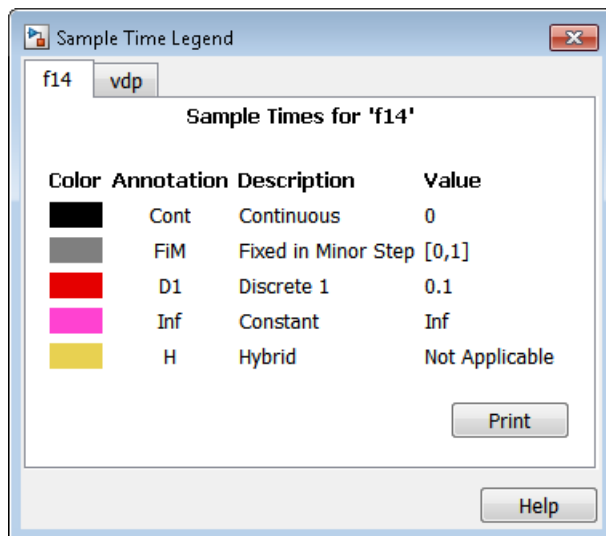

Turning the Legend Off

If you do not want to view the legend upon selecting **Sample Time Display**:

- 1 In the Simulink Editor, select **File > Simulink Preferences**.
- 2 In the **General** pane, clear **Open the sample time legend when the sample time display is changed** and click **Apply**.

Viewing Multiple Legends

If you have more than one model open and you view the **Sample Time Legend** for each one, a single legend window appears with multiple tabs. Each tab contains the name of the model and the respective legend information. The following figure shows the tabbed legends for the **f14** and **vdp** models.

See Also

“What Is Sample Time?” on page 7-2 | “Specify Sample Time” on page 7-3 | “Print Sample Time Information” on page 7-14

Print Sample Time Information

You can print the sample time information in the Sample Time Legend by using either of these methods:

- In the Sample Time Legend window, click **Print**.
- Print the legend from the **Print Model** dialog box:
 - 1** In the model window, select **File > Print**.
 - 2** Under **Options**, select the check box beside **Print Sample Time Legend**.
 - 3** Click **OK**.

Types of Sample Time

In this section...

“Discrete Sample Time” on page 7-15
 “Continuous Sample Time” on page 7-16
 “Fixed-in-Minor-Step” on page 7-16
 “Inherited Sample Time” on page 7-16
 “Constant Sample Time” on page 7-17
 “Variable Sample Time” on page 7-17
 “Triggered Sample Time” on page 7-18
 “Asynchronous Sample Time” on page 7-18

Discrete Sample Time

Given a block with a discrete sample time, Simulink executes the block output or update method at times

$$t_n = nT_s + |T_o|$$

where the sample time period T_s is always greater than zero and less than the simulation time, T_{sim} . The number of periods (n) is an integer that must satisfy:

$$0 \leq n \leq \frac{T_{sim}}{T_s}$$

As simulation progresses, Simulink computes block outputs only once at each of these fixed time intervals of t_n . These simulation times, at which Simulink executes the output method of a block for a given sample time, are referred to as *sample time hits*. Discrete sample times are the only type for which sample time hits are known *a priori*.

If you need to delay the initial sample hit time, you can define an offset, T_o .

The `Unit Delay` block is an example of a block with a discrete sample time.

Continuous Sample Time

Unlike the discrete sample time, continuous sample hit times are divided into major time steps and minor time steps, where the minor steps represent subdivisions of the major steps (see “Minor Time Steps” on page 3-22). The ODE solver you choose integrates all continuous states from the simulation start time to a given major or minor time step. The solver determines the times of the minor steps and uses the results at the minor time steps to improve the accuracy of the results at the major time steps. However, you see the block output only at the major time steps.

To specify that a block, such as the `Derivative` block, is continuous, enter `[0, 0]` or `0` in the **Sample time** field of the block dialog.

Fixed-in-Minor-Step

If the sample time of a block is set to `[0, 1]`, the block becomes *fixed-in-minor-step*. For this setting, Simulink does not execute the block at the minor time steps; updates occur only at the major time steps. This process eliminates unnecessary computations of blocks whose output cannot change between major steps.

While you can explicitly set a block to be fixed-in-minor-step, more typically Simulink sets this condition as either an inherited sample time or as an alteration to a user specification of `0` (continuous). This setting is equivalent to, and therefore converted to, the fastest discrete rate when you use a fixed-step solver.

Inherited Sample Time

If a block sample time is set to `[-1, 0]` or `-1`, the sample time is *inherited* and Simulink determines the best sample time for the block based on the block context within the model. Simulink performs this task during the compilation stage; the original inherited setting never appears in a compiled model. Therefore, you never see inherited (`[-1, 0]`) in the Sample Time Legend. (See “View Sample Time Information” on page 7-9.)

There are some blocks in which the sample time is inherited (`-1`) by default. For these blocks, the parameter is not visible on the block dialog box unless it is set to a noninherited value. Examples of these blocks include the `Gain` and `Rounding Function` blocks. As a good modeling practice, do not change the **Sample time**

parameter for these blocks. For more information, see “Blocks for Which Sample Time Is Not Recommended” on page 7-20.

All inherited blocks are subject to the process of sample time propagation, as discussed in “How Propagation Affects Inherited Sample Times” on page 7-38

Constant Sample Time

In Simulink, a constant is a symbolic name or expression whose value you can change only outside the algorithm or through supervisory control. Blocks, like the constant block, whose outputs do not change during normal execution of the model, are always considered to be constant.

Simulink assigns constant sample time to these blocks. They run their block output method:

- At the start of a simulation.
- In response to runtime changes in the environment, such as tuning a parameter.

For constant sample time, the block sample time assignment is `[inf,0]` or `[inf]`.

For a block to allow constant sample time, these conditions hold:

- The block has no continuous or discrete states.
- The block does not drive an output port of a conditionally executed subsystem (see “Create an Enabled Subsystem” on page 10-23).

S-Function Blocks

The Simulink block library includes several blocks, such as the MATLAB S-Function block, the Level-2 MATLAB S-Function block, and the C S-Function block, whose ports can produce outputs at different sample rates. It is possible for some of the ports of these blocks to have a constant sample time.

Variable Sample Time

Blocks that use a variable sample time have an implicit `SampleTime` parameter that the block specifies; the block tells Simulink when to run it. The compiled sample time is `[-2, T_{vo}]` where T_{vo} is a unique variable offset.

The **Pulse Generator** block is an example of a block that has a variable sample time. Since Simulink supports variable sample times for variable-step solvers only, the Pulse Generator block specifies a discrete sample time if you use a fixed-step solver.

To learn how to write your own block that uses a variable sample time, see “C MEX S-Function Examples”.

Triggered Sample Time

If a block is inside of a triggered-type (e.g., function-call, enabled and triggered, or iterator) subsystem, the block may be constant or have a triggered sample time. You cannot specify the triggered sample time type explicitly. However, to achieve a triggered type during compilation, you must set the block sample time to inherited (-1). Simulink then determines the specific times at which the block computes its output during simulation. One exception is if the subsystem is an asynchronous function call, as discussed in the following section.

Asynchronous Sample Time

An asynchronous sample time is similar to a triggered sample time. In both cases, it is necessary to specify an inherited sample time because the Simulink engine does not regularly execute the block. Instead, a run-time condition determines when the block executes. For the case of an asynchronous sample time, an S-function makes an asynchronous function call.

The differences between these sample time types are:

- Only a function-call subsystem can have an asynchronous sample time. (See “Create a Function-Call Subsystem” on page 10-54.)
- The source of the function-call signal is an S-function having the option `SS_OPTION_ASYNCHRONOUS`.
- The asynchronous sample time can also occur when a virtual block is connected to an asynchronous S-function or an asynchronous function-call subsystem.
- The asynchronous sample time is important to certain code-generation applications. (See “Asynchronous Events” in the *Simulink Coder User's Guide*.)
- The sample time is $[-1, -n]$.

For an explanation of how to use blocks to model and generate code for asynchronous event handling, see “Rate Transitions and Asynchronous Blocks” in the *Simulink Coder User's Guide*.

Blocks for Which Sample Time Is Not Recommended

In this section...

“Best Practice to Model Sample Times” on page 7-20
“Appropriate Blocks for the Sample Time Parameter” on page 7-21
“Specify Sample Time in Blocks Where Hidden” on page 7-21

Some blocks do not enable you to set the **Sample Time** parameter by default. However, you can see and set the **Sample Time** parameter for these blocks in an existing model if the sample time is set to a value other than the default of -1 (inherited sample time). The **Sample Time** parameter is not available on certain blocks because specifying a sample time that is not -1 on blocks such as the Gain, Sum, and n-D Lookup Table causes sample rate transition to be implicitly mixed with block algorithms. This mixing can often lead to ambiguity and confusion in Simulink models.

In most modeling applications, you specify rates for a model on the boundary of your system instead of on a block within the subsystem. You specify the system rate from incoming signals or the rate of sampling the output. You can also decide rates for events you are modeling that enter the subsystem as trigger, function-call, or enable/disable signals. Some global variables (such as Data Store Memory blocks) might need additional sample time specification. If you want to change rate within a system, use a Rate Transition block, which is designed specifically to model rate transitions.

In a future release, you might not be able see or set this parameter on blocks where it is not appropriate.

Best Practice to Model Sample Times

Use these approaches instead of setting the **Sample Time** parameter in the blocks where it is not appropriate:

- Adjust your model by specifying **Sample Time** only in the blocks listed in “Appropriate Blocks for the Sample Time Parameter” on page 7-21, and set **Sample Time** to -1 for all other blocks. To change the sample time for multiple blocks simultaneously, use Model Explorer. For more information, see “Editing Object Properties” on page 12-27.
- Use the **Rate Transition** block to model rate transitions in your model.

- Use the **Signal Specification** block to specify sample time in models that don't have source blocks, such as algebraic loops.
- Specify the simulation rate independently from the block sample times, using the Model Parameter dialog box.

Once you have completed these changes, verify whether your model gives the same outputs as before.

Appropriate Blocks for the Sample Time Parameter

Specify sample time on the boundary of a model or subsystem, or in blocks designed to model rate transitions. Examples include:

- Blocks in the Sources library
- Blocks in the Sinks library
- Trigger ports (if **Trigger type** is set to **function-call**) and Enable ports
- Data Store Read and Data Store Write blocks, as the Data Store Memory block they link to might be outside the boundary of the subsystem
- Rate Transition block
- Signal Specification block
- Blocks in the Discrete library
- Message Receive block
- Function Caller block

Specify Sample Time in Blocks Where Hidden

You can specify sample time in the blocks that do not display the parameter on the block dialog box. If you specify value other than -1 in these blocks, no error occurs when you simulate the model. However, a message appears on the block dialog box advising to set this parameter to -1 (inherited sample time). If you promote the sample time block parameter to a mask, this parameter is always visible on the mask dialog box.

To change the sample time in this case, use the `set_param` command. For example, select a block in the Simulink Editor and, at the command prompt, enter:

```
set_param(gcf, 'SampleTime', '2');
```

7-28

Block Compiled Sample Time

During the compilation phase of a simulation, Simulink determines the sample time of a block from the `SampleTime` parameter (if the block has an explicit sample time), the block type (if it has an implicit sample time), or by the model content. This compiled sample time determines the sample rate of a block during simulation. You can determine the compiled sample time of any block in a model by first updating the model and then getting the block `CompiledSampleTime` parameter, using the `get_param` command.

For example, consider the model `ex_compiled_sample_new`.

Use `get_param` to obtain the block `CompiledSampleTime` parameter for each of the blocks in this example.

```
get_param('model_name/block_name','CompiledSampleTime');
For the Sine Wave3 block,
```

```
get_param('ex_compiled_sample_new/Sine Wave3','CompiledSampleTime');
displays
```

```
0.5000    0
```

The atomic subsystem contains sine wave blocks with sample times of 3 and 4.

When calculating the block `CompiledSampleTime` for this subsystem, Simulink returns a cell array of the sample times present in the subsystem.

```
3  0
4  0
```

The greatest common divisor (GCD) of the two rates is 1. However, this is not necessarily one of the rates in the model.

The Rate Transition block in this model serves as a Zero-Order Hold. Since the `Sample Time Multiple` parameter is set to 3, the input to the rate transition block has a sample rate of 0.5 while the output has a rate of 1.5.

```
rt=get_param('ex_compiled_sample_new/Rate Transition','CompiledSampleTime');
rt{:}
```

```
0.5000  0
1.5000  0
```

The Sample Time Legend shows all of the sample rates present in the model.

Related Examples

- “View Sample Time Information” on page 7-9

Sample Times in Subsystems

Subsystems fall into two categories: triggered and non-triggered. For triggered subsystems, in general, the subsystem gets its sample time from the triggering signal. One exception occurs when you use a Trigger block to create a triggered subsystem. If you set the block **Trigger type** to **function-call** and the **Sample time type** to **periodic**, the `SampleTime` parameter becomes active. In this case, *you* specify the sample time of the Trigger block, which in turn, establishes the sample time of the subsystem.

There are four non-triggered subsystems:

- Virtual
- Enabled
- Atomic
- Action

Simulink calculates the sample times of virtual and enabled subsystems based on the respective sample times of their contents.

The atomic subsystem is a special case in that the subsystem block has a `SystemSampleTime` parameter. Moreover, for a sample time other than the default value of `-1`, the blocks inside the atomic subsystem can have only a value of `Inf`, `-1`, or the identical (discrete) value of the subsystem `SampleTime` parameter. If the atomic subsystem is left as inherited, Simulink calculates the block sample time in the same manner as the virtual and enabled subsystems. However, the main purpose of the subsystem `SampleTime` parameter is to allow for the simultaneous specification of a large number of blocks, within an atomic subsystem, that are all set to inherited. To obtain the sample time set on an atomic subsystem, use this command at the command prompt:

```
get_param(AtomicSubsystemBlock, 'SystemSampleTime');
```

Finally, the sample time of the action subsystem is set by the If block or the Switch Case block.

For non-triggered subsystems where blocks have different sample rates, Simulink returns the Compiled Sample Time for the subsystem as a cell array of all the sample rates present in the subsystem. To see this, use the `get_param` command at MATLAB prompt.

```
get_param(subsystemBlock, 'CompiledSampleTime')
```

Sample Times in Systems

In this section...
“Purely Discrete Systems” on page 7-28
“Hybrid Systems” on page 7-30

Purely Discrete Systems

A purely discrete system is composed solely of discrete blocks and can be modeled using either a fixed-step or a variable-step solver. Simulating a discrete system requires that the simulator take a simulation step at every sample time hit. For a *multirate discrete system*—a system whose blocks Simulink samples at different rates—the steps must occur at integer multiples of each of the system sample times. Otherwise, the simulator might miss key transitions in the states of the system. The step size that the Simulink software chooses depends on the type of solver you use to simulate the multirate system and on the fundamental sample time.

The *fundamental sample time* of a multirate discrete system is the largest double that is an integer divisor of the actual sample times of the system. For example, suppose that a system has sample times of 0.25 and 0.50 seconds. The fundamental sample time in this case is 0.25 seconds. Suppose, instead, the sample times are 0.50 and 0.75 seconds. The fundamental sample time is again 0.25 seconds.

The importance of the fundamental sample time directly relates to whether you direct the Simulink software to use a fixed-step or a variable-step discrete solver to solve your multirate discrete system. A fixed-step solver sets the simulation step size equal to the fundamental sample time of the discrete system. In contrast, a variable-step solver varies the step size to equal the distance between actual sample time hits.

The following diagram illustrates the difference between a fixed-step and a variable-step solver.

Fixed-Step Solver

Variable-Step Solver

In the diagram, the arrows indicate simulation steps and circles represent sample time hits. As the diagram illustrates, a variable-step solver requires fewer simulation steps to simulate a system, if the fundamental sample time is less than any of the actual sample times of the system being simulated. On the other hand, a fixed-step solver requires less memory to implement and is faster if one of the system sample times is fundamental. This can be an advantage in applications that entail generating code from a Simulink model (using Simulink Coder). In either case, the discrete solver provided by Simulink is optimized for discrete systems; however, you can simulate a purely discrete system with any one of the solvers and obtain equivalent results.

Consider the following example of a simple multirate system. For this example, the DTF1 Discrete Transfer Fcn block's **Sample time** is set to $[1 \ 0.1]$, which gives it an offset of 0.1 . The **Sample time** of the DTF2 Discrete Transfer Fcn block is set to 0.7 , with no offset. The solver is set to a variable-step discrete solver.

Running the simulation and plotting the outputs using the `stairs` function

```
simOut = sim('ex_dtf','StopTime', '3');
t = simOut.find('tout')
```

```
y = simOut.find('yout')
stairs(t,y, '-*')
```

produces the following plot.

(For information on the `sim` command, see “Run Simulations Programmatically” on page 24-2.)

As the figure demonstrates, because the DTF1 block has a 0.1 offset, the DTF1 block has no output until $t = 0.1$. Similarly, the initial conditions of the transfer functions are zero; therefore, the output of DTF1, $y(1)$, is zero before this time.

Hybrid Systems

Hybrid systems contain both discrete and continuous blocks and thus have both discrete and continuous states. However, Simulink solvers treat any system that has both

continuous and discrete sample times as a hybrid system. For information on modeling hybrid systems, see “Modeling Hybrid Systems” on page 3-7.

In block diagrams, the term hybrid applies to both hybrid systems (mixed continuous-discrete systems) and systems with multiple sample times (multirate systems). Such systems turn yellow in color when you perform an **Update Diagram** with **Sample Time Display Colors** turned 'on'. As an example, consider the following model that contains an atomic subsystem, “Discrete Cruise Controller”, and a virtual subsystem, “Car Dynamics”. (See `ex_execution_order`.)

Car Model

With the **Sample Time** option set to **All**, an **Update Diagram** turns the virtual subsystem yellow, indicating that it is a hybrid subsystem. In this case, the subsystem is a true hybrid system since it has both continuous and discrete sample times. As shown below, the discrete input signal, D1, combines with the continuous velocity signal, v, to produce a continuous input to the integrator.

Car Model after an Update Diagram

Car Dynamics Subsystem after an Update Diagram

Now consider a multirate subsystem that contains three Sine Wave source blocks, each of which has a unique sample time — 0.2, 0.3, and 0.4, respectively.

Multirate Subsystem after an Update Diagram

An **Update Diagram** turns the subsystem yellow because the subsystem contains more than one sample time. As shown in the block diagram, the Sine Wave blocks have discrete sample times D1, D2, and D3 and the output signal is fixed in minor step.

In assessing a system for multiple sample times, Simulink does not consider either constant $[\text{inf}, 0]$ or asynchronous $[-1, -n]$ sample times. Thus a subsystem consisting of one block that outputs constant value and one block with a discrete sample time will not be designated as hybrid.

The hybrid annotation and coloring are very useful for evaluating whether or not the subsystems in your model have inherited the correct or expected sample times.

“Blocks for Which Sample Time Is Not Recommended” on page 7-20 | “View Sample Time Information” on page 7-9

Resolve Rate Transitions

In general, a rate transition exists between two blocks if their sample times differ, that is, if either of their sample-time vector components are different. The exceptions are:

- Blocks that output constant value never have a rate transition with any other rate.
- A continuous sample time (black) and the fastest discrete rate (red) never has a rate transition if you use a fixed-step solver.
- A variable sample time and fixed in minor step do not have a rate transition.

You can resolve rate transitions manually by inserting rate transition blocks and by using two diagnostic tools. For the single-tasking execution mode, the **Single task rate transition** diagnostic allows you to set the level of Simulink rate transition messages. The **Multitask rate transition** diagnostic serves the same function for multitasking execution mode. These execution modes directly relate to the type of solver in use: Variable-step solvers are always single-tasking; fixed-step solvers may be explicitly set as single-tasking or multitasking.

Automatic Rate Transition

Simulink can detect mismatched rate transitions in a multitasking model during an update diagram and automatically insert Rate Transition blocks to handle them. To enable this, in the **Solver** pane of model configuration parameters, select **Automatically handle rate transition for data transfer**. The default setting for this option is off. When you select this option:

- Simulink handles transitions between periodic sample times and asynchronous tasks.
- Simulink inserts hidden Rate Transition blocks in the block diagram.
- Automatically inserted Rate Transition blocks operate in protected mode for periodic tasks and asynchronous tasks. You cannot alter this behavior. For periodic tasks, automatically inserted Rate Transition blocks operate with the level of determinism specified by the **Deterministic data transfer** parameter in the **Solver** pane. The default setting is **Whenever possible**, which enables determinism for data transfers between periodic sample-times that are related by an integer multiple. For more information, see “Deterministic data transfer”. To use other modes, you must insert Rate Transition blocks and set their modes manually.

Visualize Inserted Rate Transition Blocks

When you select the **Automatically handle rate transition for data transfer** option, Simulink inserts Rate Transition blocks in the paths that have mismatched transition rates. These blocks are hidden by default. To visualize the inserted blocks, update the diagram. Badge labels appear in the model and indicate where Simulink inserted Rate Transition blocks during the compilation phase. For example, in this model, three Rate Transition blocks were inserted between the two Sine Wave blocks and the Multiplexer and Integrator when the model compiled. The ZOH and DbBuf badge labels indicate these blocks.

You can show or hide badge labels using the **Display > Signals and Ports > Hidden Rate Transition Block Indicators** setting.

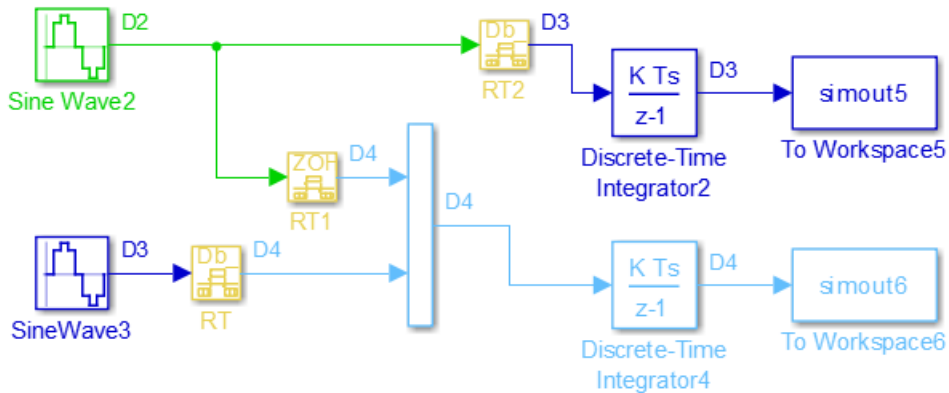

To configure the hidden Rate Transition blocks, right click on a badge label and click on **Insert rate transition block** to make the block visible.

When you make hidden Rate Transition blocks visible:

- You can see the type of Rate Transition block inserted as well as the location in the model.
- You can set the **Initial Conditions** of these blocks.
- You can change data transfer and sample time block parameters.

Validate the changes to your model by updating your diagram.

Displaying inserted Rate Transition blocks is not compatible with:

- Concurrent execution environment
- Export-function models

To learn more about the types of Rate Transition blocks, see [Rate Transition](#).

Note: Suppose you automatically insert rate transition blocks and there is a virtual block specifying sample time upstream of the block you insert. You cannot click the badge of the inserted block to configure the block and make it visible because the sample time on the virtual block causes a rate transition as well. In this case, manually insert a rate transition block before the virtual block. To learn more about virtual blocks, see “Nonvirtual and Virtual Blocks” on page 33-2.

How Propagation Affects Inherited Sample Times

During a model update, for example at the beginning of a simulation, Simulink uses a process called sample time propagation to determine the sample times of blocks that inherit their sample times. The figure below illustrates a Discrete Filter block with a sample time period T_s driving a Gain block.

Because the output of the Gain block is the input multiplied by a constant, its output changes at the same rate as the filter. In other words, the Gain block has an effective sample rate equal to the sample rate of the filter. The establishment of such effective rates is the fundamental mechanism behind sample time propagation in Simulink.

Process for Sample Time Propagation

Simulink uses the following basic process to assign sample times to blocks that inherit their sample times:

- 1 Propagate known sample time information forward.
- 2 Propagate known sample time information backward.
- 3 Apply a set of heuristics to determine additional sample times.
- 4 Repeat until all sample times are known.

Simulink Rules for Assigning Sample Times

A block having a block-based sample time inherits a sample time based on the sample times of the blocks connected to its inputs, and in accordance with the following rules:

Rule	Action
All of the inputs have the same sample time and the block can accept that sample time	Simulink assigns the sample time to the block

Rule	Action
The inputs have different discrete sample times and all of the input sample times are integer multiples of the fastest input sample time	Simulink assigns the sample time of the fastest input to the block . (This assignment assumes that the block can accept the fastest sample time.)
The inputs have different discrete sample times, some of the input sample times are not integer multiples of the fastest sample time, and the model uses a variable-step solver	Simulink assigns a fixed-in-minor-step sample time to the block.
The inputs have different discrete sample times, some of the input sample times are not integer multiples of the fastest sample time, the model uses a fixed-step solver, and Simulink can compute the greatest common integer divisor (GCD) of the sample times coming into the block	Simulink assigns the GCD sample time to the block. Otherwise, Simulink assigns the fixed step size of the model to the block.
The sample times of some of the inputs are unknown, or if the block cannot accept the sample time	Simulink determines a sample time for the block based on a set of heuristics.

See Also

“Blocks for Which Sample Time Is Not Recommended” on page 7-20

More About

- “Backpropagation in Sample Times” on page 7-40

Backpropagation in Sample Times

When you update or simulate a model that specifies the sample time of a source block as inherited (–1), the sample time of the source block may be backpropagated; Simulink may set the sample time of the source block to be identical to the sample time specified by or inherited by the block connected to the source block. For example, in the model below, the Simulink software recognizes that the **Sine Wave** block is driving a **Discrete-Time Integrator** block whose sample time is 1; so it assigns the Sine Wave block a sample time of 1.

You can verify this sample time setting by selecting **Sample Time > Colors** from the Simulink **Display** menu and noting that both blocks are red. Because the Discrete-Time Integrator block looks at its input only during its sample hit times, this change does not affect the results of the simulation, but does improve the simulation performance.

Now replacing the Discrete-Time Integrator block with a continuous Integrator block, as shown in the model below, causes the Sine Wave and Gain blocks to change to continuous blocks. You can test this change by selecting **Simulation > Update Diagram** to update the colors; both blocks now appear black.

Note: Backpropagation makes the sample times of model sources dependent on block connectivity. If you change the connectivity of a model whose sources inherit sample times, you can inadvertently change the source sample times. For this reason, when you update or simulate a model, by default, Simulink displays warnings at the command line if the model contains sources that inherit their sample times.

- “Code Generation for Referenced Models” on page 8-6

Reference One Model From Another Model

You can include one model in another by using `Model` blocks. Each instance of a `Model` block represents a reference to another model, called a *referenced model*. For simulation and code generation, the referenced model effectively replaces the `Model` block that references it. The model that contains a referenced model is its *parent model*. A collection of parent and referenced models constitute a *model reference hierarchy*.

The interface of a referenced model consists of its:

- Input and output ports (and control ports, in the case of a conditional referenced model)
- Parameter arguments

A `Model` block displays inputs and outputs corresponding to the root-level inputs and outputs of the model it references. These ports enable you to incorporate the referenced model into the block diagram of the parent model. The interface of the referenced model, not the context from which the model is referenced, defines the attributes of blocks in the referenced model. For example, attributes such as dimensions and data types do not propagate across `Model` block boundaries. Use the root `Inport` of the referenced model to set the interface attributes.

For example, the `sldemo_mdhref_basic` model includes `Model` blocks that reference three instances of the same referenced model, `sldemo_mdhref_counter`.

Model Reference Hierarchies

A referenced model can itself contain Model blocks and thus reference lower-level models, to any depth. The *top model* is the topmost model in a hierarchy of referenced models. Where only one level of model reference exists, the parent model and top model are the same. To prevent cyclic inheritance, a Model block cannot refer directly or indirectly to a model that is superior to it in the model reference hierarchy. This figure shows cyclic inheritance.

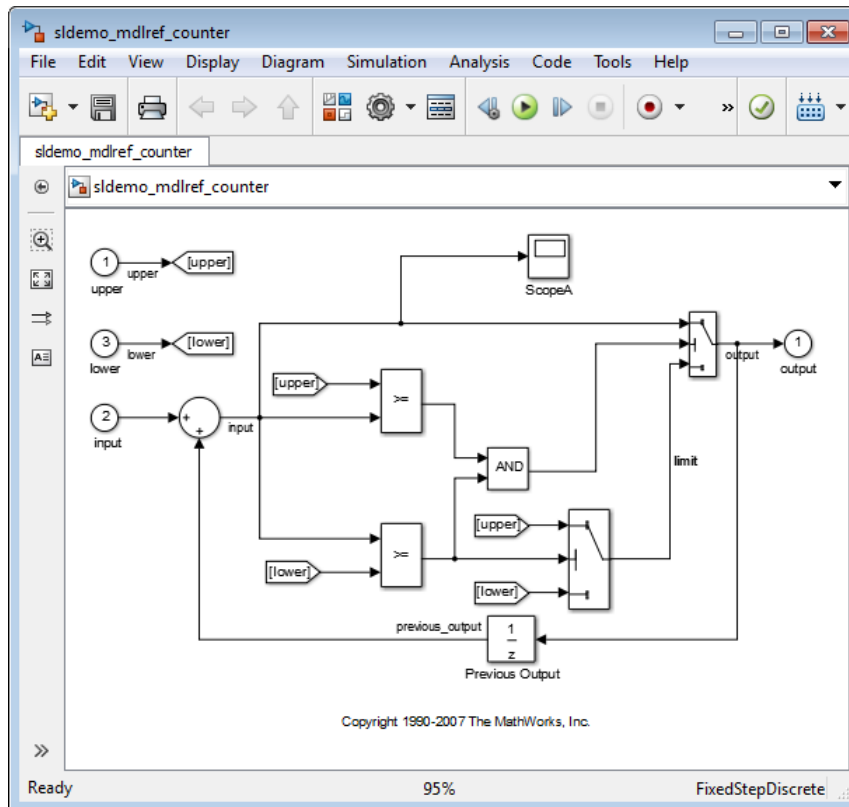

A parent model can contain multiple Model blocks that reference the same referenced model as long as the referenced model does not define global data. The referenced model can also appear in other parent models at any level. You can parameterize a referenced model to provide tunability for all instances of the model. Also, you can parameterize a referenced model to let different Model blocks specify different values for variables that define the behavior of the referenced model. See “Parameterize Instances of a Reusable Referenced Model” on page 8-61 for details.

Model Block and Referenced Model Ports

Use the ports on a Model block to connect the referenced model to other elements of the parent model. Connecting a signal to a Model block port has the same effect as connecting the signal to the corresponding port in the referenced model. For example, the Model block CounterA has three inputs: two Constant blocks and a Pulse Generator block with a sample time of .1. The Model block CounterB also has three inputs: the same two Constant blocks, and a Pulse Generator block with a sample time of .5. Each Model block has an output to a separate Scope block.

The referenced model includes Inport and Outport blocks (and possibly Trigger or Enable blocks) to connect to the parent model. The `sldemo_md1ref_counter` model has three Inport blocks (upper, input, and lower) and one Outport block (output).

Using Referenced Models as Standalone Models

If a referenced model does not depend on data that is available only from a higher-level model, you can use a referenced model as a standalone model. An appropriately configured model can function as both a standalone model and a referenced model, without changing the model or any entities derived from it.

Examples of Models That Use Model Referencing

Simulink includes several models that illustrate model referencing.

The [Introduction to Managing Data with Model Reference](#) example introduces the basic concepts and workflow related to managing data with model

referencing. To explore these topics in more detail, select the **Detailed Workflow for Managing Data with Model Reference** example.

In addition, the `sldemo_absbrake` model represents a wheel speed calculation as a Model block within the context of an anti-lock braking system (ABS).

Simulation of Model Referencing Models

You can simulate a referenced model either interpretively (in normal mode) or by compiling the referenced model to code and executing the code (in accelerator mode). For details, see “Simulate Model Referencing Models” on page 8-31.

Code Generation for Referenced Models

To learn about considerations when generating code for a referenced model, see “Referenced Models”.

When to Use Model Referencing

In this section...

“Referenced Model Advantages” on page 8-7

“Compare Model Referencing to Other Componentization Techniques” on page 8-8

Referenced Model Advantages

Like subsystems, referenced models allow you to organize large models hierarchically. Model blocks can represent major subsystems. Like libraries, referenced models allow you to use the same capability repeatedly without having to redefine it. Referenced models provide several advantages that are unavailable with subsystems and/or library blocks. Several of these advantages result from Simulink compiling a referenced model independent of the context of the referenced model.

- **Modular development**

You can develop a referenced model independently from the models that use it.

- **Model Protection**

You can obscure the contents of a referenced model, allowing you to distribute it without revealing the intellectual property that it embodies.

- **Inclusion by reference**

You can reference a model multiple times without having to make redundant copies, and multiple models can reference the same model.

- **Incremental loading**

Simulink loads a referenced model at the point it needs to use the model, which speeds up model loading.

- **Accelerated simulation**

Simulink can convert a referenced model to code and simulate the model by running the code, which is faster than interactive simulation.

- **Incremental code generation**

Accelerated simulation requires code generation only if the model has changed since the code was previously generated.

- **Independent configuration sets**

The configuration set used by a referenced model can differ from the configuration set of its parent or other referenced models.

For a video summarizing advantages of model referencing, see [Modular Design Using Model Referencing](#).

Compare Model Referencing to Other Componentization Techniques

Model referencing provides many benefits for componentization of a model. However, using subsystems or libraries can meet some modeling requirements better than model referencing. You can use all three componentization techniques in the same model.

For additional information about how model referencing compares to other Simulink componentization techniques, see “Componentization Guidelines” on page 15-29.

- “Model Referencing Limitations” on page 8-93

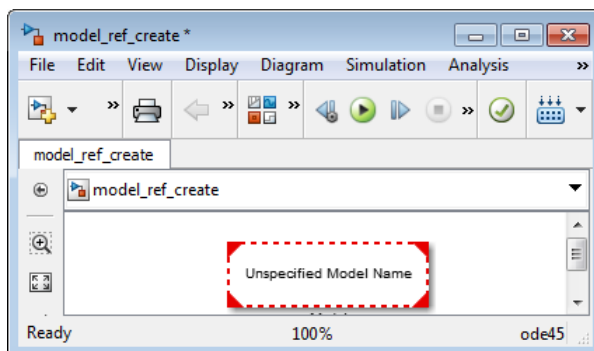

Create a Referenced Model

A model becomes a referenced model when a Model block in some other model references it. Any model can function as a referenced model, and such use does not preclude using it as a separate model also.

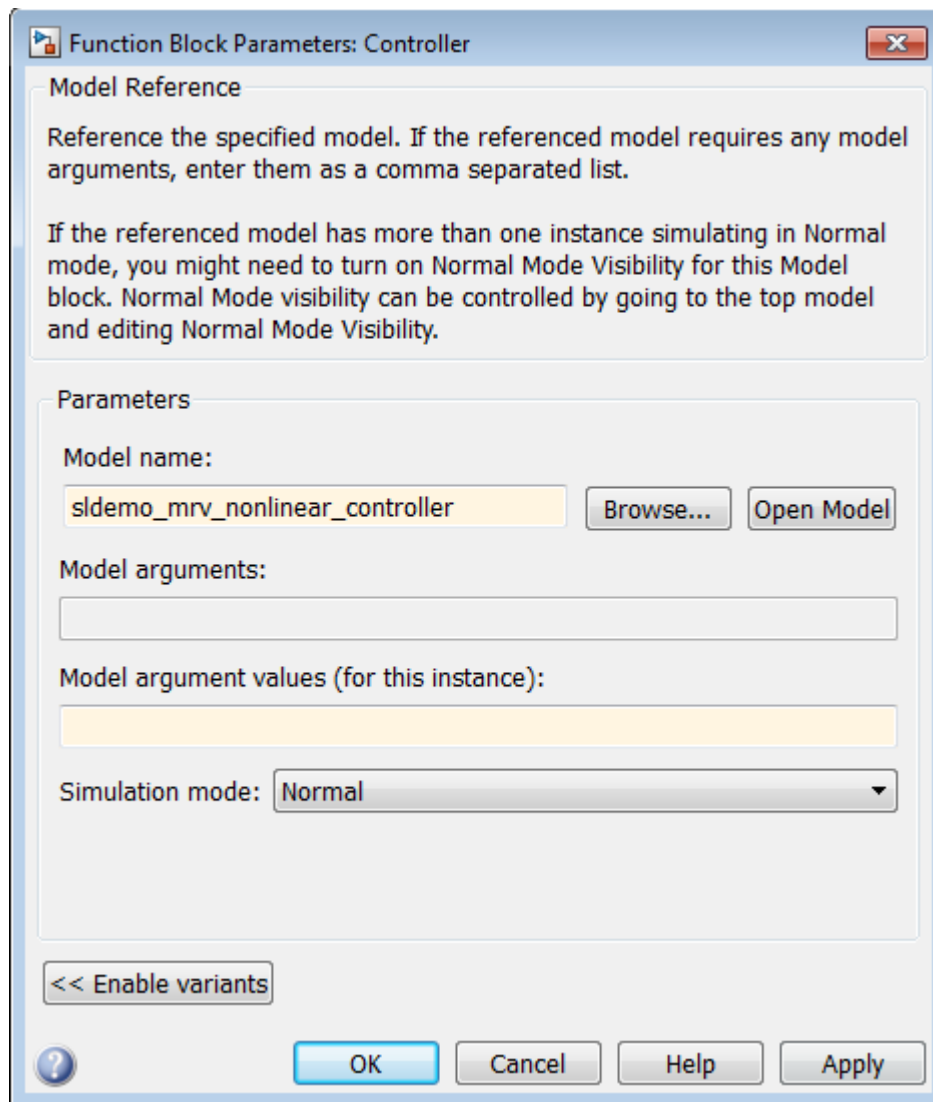

For a video introducing how to create model references, see [Getting Started with Model Referencing](#).

To create a reference to a model (referenced model) in another model (parent model):

- 1 If the folder containing the referenced model you want to reference is not on the MATLAB path, add the folder to the MATLAB path.
- 2 In the referenced model:
 - Set **Configuration Parameters > Model Referencing > Total number of instances allowed per top model** to:
 - **One**, if the hierarchy uses the model at most once
 - **Multiple**, to use the model more than once per top model. To reduce overhead, specify **Multiple** only when necessary.
 - **Zero**, which precludes referencing the model
- 3 Create an instance of the **Model** block in the parent model by dragging a Model block instance from the Ports & Subsystems library to the parent model. The new block is initially unresolved (specifies no referenced model) and has the following appearance:

- 4 Open the new Model block's parameter dialog box by double-clicking the Model block. See “Navigating a Model Block” for more about accessing Model block parameters.

- 5 Enter the name of the referenced model in the **Model name** field. This name must contain fewer than 60 characters. (See “Name Length Requirement” on page 8-55.)
 - For information about **Model Arguments** and **Model argument values**, see “Specify Different Value for Each Instance of Reusable Model” on page 8-61.
 - For information about the **Simulation mode**, see “Simulate Model Referencing Models” on page 8-31.
- 6 Click **OK** or **Apply**.

If the referenced model contains any root-level inputs or outputs, Simulink displays corresponding input and output ports on the Model block instance that you have created. Use these ports to connect the referenced model to other ports in the parent model.

A signal that connects to a Model block is functionally the same signal outside and inside the block. Therefore that signal is subject to the restriction that a given signal can have at most one associated signal object. See `Simulink.Signal` for more information. For information about connecting a bus signal to a referenced model, see “Bus Usage Requirements” on page 8-59.

Masking Model Blocks

You can use the masking facility to create custom dialog boxes and icons for Model blocks. Masked dialog boxes can make it easier to specify additional parameters for Model blocks. For information about block masks, see “Block Masks”.

When to Convert to Model Referencing

Before you convert a subsystem to model referencing, consider whether model referencing is the approach to use to meet your modeling requirements.

Model referencing offers several benefits for modeling large, complex systems and for team-based development. However, subsystems or libraries are better suited for some modeling goals than model referencing. Many large models involve using a combination of subsystems and referenced models. For information to help you to decide whether to convert a subsystem to a referenced model, see “Componentization Guidelines” on page 15-29.

Subsystems That You Can Convert

The types of subsystems that you can convert to a referenced model are:

- Atomic
- Triggered
- Enabled
- Triggered and enabled
- Function-call
- Export-function (functions exported from Simulink models that are invoked by controlling logic from outside the referenced model)

To convert a masked subsystem, use the `Simulink.SubSystem.convertToModelReference` function.

Note: To create a referenced model that accepts asynchronous function calls, see “Asynchronous Support Limitations”.

Conversion Process

The general process for converting a subsystem to a referenced model involves the following tasks. For details, see “Convert a Subsystem to a Referenced Model” on page 8-17.

- 1 Determine whether converting the subsystem to a referenced model meets your modeling requirements.
- 2 Optionally, prepare the model before converting the subsystem.
- 3 To create a referenced model, run the Model Reference Conversion Advisor. Address any issues that the advisor reports and continue the conversion until the advisor reports no issues.

- 4 Optionally, have the advisor compare the results of simulating the model before and after the conversion. Set up signal logging for key signals. Check the consistency of the top model simulation results.
- 5 After you complete the conversion, update the model as necessary.

Command-Line Interface

As an alternative to using the Model Reference Conversion Advisor, you can use the `Simulink.SubSystem.convertToModelReference` function to convert a subsystem to a referenced model. You can convert multiple subsystems using one `Simulink.SubSystem.convertToModelReference` command.

Conversion Checking

The Model Reference Conversion Advisor includes a set of conversion checks and parameters for configuring the advisor.

The advisor runs through the series of checks that help you to prepare the subsystem for successful conversion. If an advisor check reports an issue, before continuing the conversion process, either:

- Allow the advisor to fix the issue.
- Change the model based on the modifications the advisor suggests.

You can have the advisor fix all conversion issues that it can fix. In the **Check Conversion Input Parameters** check, select **Fix errors automatically (if possible)**. This option can make the conversion process faster, but you do not control the fixes that the advisor makes.

Conversion Results

After the advisor runs all the checks successfully, it:

- Creates a referenced model from the subsystem
- Creates the bus objects, signal objects, and tunable parameters that the referenced model requires
- Adds a Model block (by default)
- Inserts the Model block in a wrapper subsystem when the automatic fixes modify the Model block interface by adding ports.

- Creates a conversion summary report
- Checks the consistency of simulation results before and after conversion (if you select that option)

The advisor copies the following elements from the original model to the new referenced model.

- **Configuration set** — If the referencing model uses:
 - A configuration set that is not a referenced configuration set, the advisor copies the entire configuration set to the referenced model.
 - A referenced configuration set, then both the referencing and referenced models use the same referenced configuration set.
- **Variables** — The advisor copies into the model workspace of the referenced model only the model workspace variables that the subsystem used in the original model.

If the model that contains the subsystem uses a data dictionary, then the referenced model uses the same data dictionary.

- **Requirements links** — Requirements links created with the Simulink Verification and Validation software (for example, requirements links to blocks and signals) are copied. The advisor transfers the requirements links from the subsystem to the new Model block.

The conversion summary report describes the elements that it copies.

Conversion Report

The advisor creates an HTML report in the `slprj` folder that it uses while performing the conversion. The report summarizes the results of the conversion process, including the results of the fixes that the advisor performed.

“Integrate the Referenced Model into the Parent Model” on page 8-23

Determine Whether to Convert the Subsystem

Before you convert a subsystem to model referencing, consider whether model referencing is the approach to use to meet your modeling requirements.

Model referencing offers several benefits for modeling large, complex systems and for team-based development. However, subsystems or libraries are better suited for some modeling goals than model referencing. Many large models involve using a combination of subsystems and referenced models. For information to help you to decide whether to convert a subsystem to a referenced model, see “Componentization Guidelines” on page 15-29.

Confirm that the subsystem you want to convert is a type of subsystem that you can convert. See “Subsystems That You Can Convert” on page 8-13.

Update the Model Before Converting the Subsystem

Tip Before you perform the conversion, make sure that the model containing the subsystem that you want to convert compiles successfully.

The advisor fixes or guides you through fixing issues. However, if you are converting a large, complex subsystem, consider taking steps before you convert the model. Preparing the model and subsystem can eliminate or reduce the number of issues the advisor identifies. It can be more efficient to address issues in the model editing environment than to switch repeatedly between the advisor and the Simulink Editor.

Note: You can use Model Reference Conversion Advisor **Fix** option to have the advisor fix some conversion issues.

- 1 Set the **Configuration Parameters > Diagnostics > Data Validity > Signal resolution** parameter to **Explicit only** or **None**.

You can use the Model Reference Conversion Advisor **Fix** option to address this issue automatically.

- 2 Configure these subsystem interfaces to the model.

Subsystem Interface	What to Look For	Model Modification
Goto or From blocks	Crossing of subsystem boundaries	<p>Use an Inport block to replace From blocks that have a corresponding GoTo block that crosses the subsystem boundary.</p> <p>Use an Outport block to replace each GoTo block that has corresponding From blocks that cross the subsystem boundary.</p> <p>Connect the Inport and Outport blocks to the corresponding subsystem ports.</p> <p>You can use the Model Reference Conversion Advisor Fix option to address this issue.</p>
Data stores	Data Store Memory blocks accessed by Data Store Read or Data Store Write blocks from outside of the subsystem	<p>Replace the Data Store Memory block with a global data store. Define a global data store using a <code>Simulink.Signal</code> object. For details, see “Data Stores with Signal Objects” on page 60-20.</p> <p>You can use the Model Reference Conversion Advisor Fix option to address this issue.</p>

Subsystem Interface	What to Look For	Model Modification
Tunable parameters	Global tunable parameters in the dialog box opened using the Configuration Parameters > Optimization > Signals and Parameters > Configure button	<p>Use <code>tunablevars2parameterobjects</code> to create a <code>Simulink.Parameter</code> object for each tunable parameter.</p> <p>The <code>Simulink.Parameter</code> objects must have a storage class other than <code>Auto</code>.</p> <p>For more information, see “Parameterize Instances of a Reusable Referenced Model” on page 8-61 and “Tunable Parameters” on page 3-8.</p> <p>You can use the Model Reference Conversion Advisor Fix option to address this issue.</p>

3 Configure the subsystem and its contents.

Subsystem Configuration	What to Look For	Model Modification
Inactive subsystem variants	Variant Subsystem blocks.	<p>Make the subsystem variant that you want to convert active. The advisor does not convert inactive subsystem variants.</p> <p>To have the new Model block behave similar to the subsystem variant, convert each variant subsystem separately and then use a Model Variants block. For more information, see “Set up Model Variants” on page 11-41.</p>
Function calls	Function-call signals that cross virtual subsystem boundaries.	<p>Move the Function-Call Generator block into the subsystem that you want to convert.</p> <hr/> <p>Note: If you convert an export-function subsystem, then you do</p>

Subsystem Configuration	What to Look For	Model Modification
		not need to move the Function-Call Generator block.
	Function-call outputs.	Change the function-call outputs to data triggers.
	Wide function-call ports.	Eliminate wide signals for function-call subsystems.
Sample times	Sample time of an Inport block that does not match the sample time of the block driving the Inport.	Insert Rate Transition blocks where appropriate.
Inport blocks	Merged Inport blocks.	Configure the model to avoid merged Inport blocks. See the Merge block documentation.
Constant blocks	Constant blocks that input to subsystems.	Consider moving the Constant blocks into the subsystem.
Buses	Bus signals that enter and exit a subsystem.	Match signal names and bus element names for blocks inside the subsystem. Consider using the Configuration Parameters > Diagnostics > Connectivity > Signal label mismatch diagnostic.
	Duplicate signal names in buses.	Make signal names of the bus elements unique.

Subsystem Configuration	What to Look For	Model Modification
	<p>Signal names that are not valid MATLAB identifiers. A valid identifier is a character vector that meets these conditions:</p> <ul style="list-style-type: none"> • The name contains letters, digits, or underscores. • The first character is a letter. • The length of the name is less than or equal to the value returned by the <code>namelengthmax</code> function. 	<p>Change any invalid signal names to be valid MATLAB identifiers.</p>

Run the Model Reference Conversion Advisor

Note: As an alternative to running the Model Reference Conversion Advisor, you can use the `Simulink.SubSystem.convertToModelReference` function.

Before you run the advisor, make sure that the model containing the subsystem that you want to convert compiles successfully.

- 1 Open the model and locate the subsystem that you want to convert.
- 2 For improved conversion performance, close any open Scope block windows.
- 3 Start the Model Reference Conversion Advisor. In the Simulink Editor, right-click the subsystem that you want to convert. Select **Subsystem & Model Reference > Convert Subsystem to > Referenced Model**.
- 4 In the Model Reference Conversion Advisor dialog box, review the default settings under **Input Parameters**. Modify the parameters for running the advisor as needed and click **Apply**.

Tip The advisor provides context-sensitive help for checks. In the advisor, right-click the check (such as **Check conversion input parameters**) and select **What's This?**.

Note: The advisor can compare simulation results for the top model for the referenced model to the results for the baseline model containing the subsystem. Select **Check simulation results after conversion**. For details, see “Compare Simulation Results Before and After Conversion” on page 8-22.

- 5 Click **Convert**.
- 6 Address any issues that the advisor reports. For some issues, the advisor provides a **Fix** button to address an issue.
- 7 After you address each issue, click **Continue** until all the checks pass.

Compare Simulation Results Before and After Conversion

The advisor can compare simulation results before and after the conversion.

Before you convert the subsystem:

- In the Model Reference Conversion Advisor, under **Input Parameters**, select **Replace subsystem with a Model block** and **Check simulation results after conversion**.
- Set these options:
 - **Stop time**
 - **Absolute tolerance**
 - **Relative tolerance**
- Enable signal logging for the subsystem output signals of interest.
- Set the **Model block simulation mode** option in the advisor to the same simulation mode as the original model.

After you convert the model, select **View comparison results**. The results display in the Simulation Data Inspector. A green check mark indicates that the simulation results are the same for the baseline model and the model with the referenced model.

For more information about the Simulation Data Inspector, see “View and Analyze Simulation Results”.

Revert the Conversion Results

If you are not satisfied with the conversion results, you can restore the model to its initial state. Use one of these approaches:

- At any point during the conversion, select **File > Load Restore Point**.
- After you successfully run the **Complete conversion** check, select **Click here to restore the original model**.

Integrate the Referenced Model into the Parent Model

After you complete the conversion, update the model as necessary to meet your modeling requirements.

Add a Model Block, If Necessary

If, before the conversion, you cleared the **Replace the content of a subsystem with a Model block** option, then add a Model block to the parent model manually.

- 1 Delete the Subsystem block.
- 2 Copy the new Model block into the model, where the subsystem was.

Note: If you enable the **Replace the content of a subsystem with a Model block** option, the advisor action depends on whether you use the automatic fix options.

- If you use the automatic fixes, then the advisor replaces the Subsystem block with a Model block unless the automatic fixes change the input or output ports. If the ports change, then the advisor includes the contents of the subsystem in a Model block that is inserted in the Subsystem block.
 - If you do not use the automatic fixes, then the advisor replaces the Subsystem block with a Model block.
-

Inspect Root Inport Blocks in the Referenced Model

If you want to simulate the model with external data, check that the root Inport blocks in the new referenced model have the appropriate **Interpolate data** parameter setting. For details, see the documentation for the **Interpolate data** parameter of the Inport block.

Convert Each Variant Subsystem

If you convert an active variant subsystem, convert each of the variant subsystems to referenced model. Converting each variant subsystem to a referenced model produces similar results to using the Variant Subsystem block.

Sample Times for Model Referencing

In this section...

“How Sample-Time Inheritance Works for Model Blocks” on page 8-26

“Conditions for Inheriting Sample Times” on page 8-26

“Determining Sample Time of a Referenced Model” on page 8-27

“Blocks That Depend on Absolute Time” on page 8-27

“Blocks Whose Outputs Depend on Inherited Sample Time” on page 8-28

“Sample Time Consistency” on page 8-29

How Sample-Time Inheritance Works for Model Blocks

The sample times of a Model block are the sample times of the model that it references. If the referenced model must run at specific rates, the model specifies the required rates. Otherwise, the referenced model inherits its sample time from the parent model.

Placing a Model block in a triggered, function call, or iterator subsystem relies on the ability to inherit sample times. Additionally, allowing a Model block to inherit sample time maximizes its reuse potential. For example, a model can fix the data types and dimensions of all its input and output signals. You could reuse the model with different sample times (for example, discrete at 0.1 or discrete at 0.2, triggered).

Conditions for Inheriting Sample Times

A referenced model inherits its sample time if the model:

- Does not have any continuous states
- Specifies a fixed-step solver and the **Fixed-step size** is **auto**
- Contains no blocks that specify sample times (other than inherited or constant)
- Does not contain any S-functions that use their specific sample time internally
- Has only one sample time (not counting constant and triggered sample time) after sample time propagation
- Does not contain any blocks, including Stateflow charts, that use absolute time, as listed in “Blocks That Depend on Absolute Time” on page 8-27
- Does not contain any blocks whose outputs depend on inherited sample time, as listed in “Blocks Whose Outputs Depend on Inherited Sample Time” on page 8-28.

You can use a referenced model that inherits its sample time anywhere in a parent model. By contrast, you cannot use a referenced model that has intrinsic sample times in a triggered, function call, or iterator subsystem. To avoid rate transition errors, ensure that blocks connected to a referenced model with intrinsic samples times operate at the same rates as the referenced model.

For more information, see “Blocks Whose Outputs Depend on Inherited Sample Time” on page 8-28.

Determining Sample Time of a Referenced Model

To determine whether a referenced model can inherit its sample time, set the **Periodic sample time constraint** on the **Solver** configuration parameters dialog pane to **Ensure sample time independent**. If the model is unable to inherit sample times, this setting causes Simulink to display an error message when building the model. See “Periodic sample time constraint” for more about this option.

To determine the intrinsic sample time of a referenced model, or the fastest intrinsic sample time for multirate referenced models:

- 1 Update the model that references the model
- 2 Select a Model block within the parent model
- 3 Enter the following at the MATLAB command line:

```
get_param(gcb, 'CompiledSampleTime')
```

Blocks That Depend on Absolute Time

The following Simulink blocks depend on absolute time, and therefore preclude a referenced model from inheriting sample time:

- Backlash (only when the model uses a variable-step solver and the block uses a continuous sample time)
- Chirp Signal
- Clock
- Derivative
- Digital Clock
- Discrete-Time Integrator (only when used in triggered subsystems)

- From File
- From Workspace
- Pulse Generator
- Ramp
- Rate Limiter
- Repeating Sequence
- Signal Generator
- Sine Wave (only when the **Sine type** parameter is Time-based)
- Stateflow (when the chart uses absolute-time temporal logic, or the reserved word `t` to reference time)
- Step
- To File
- To Workspace (only when logging to Timeseries or Structure With Time format)
- Transport Delay
- Variable Time Delay
- Variable Transport Delay

Some blocks other than Simulink blocks depend on absolute time. See the documentation for the blocksets that you use.

Blocks Whose Outputs Depend on Inherited Sample Time

Using a block whose output depends on an inherited sample time in a referenced model can cause simulation to produce unexpected or erroneous results. When building a referenced model that does not need a specified rate, Simulink checks for blocks whose outputs are functions of the inherited sample time. This checking includes examining S-Function blocks. If Simulink finds any such blocks, it specifies a default sample time. Simulink displays an error if you have set the **Configuration Parameters > Solver > Periodic sample time constraint** to **Ensure sample time independent**. See “Periodic sample time constraint” for more about this option.

The outputs of the following built-in blocks depend on inherited sample time. The outputs of these blocks preclude a referenced model from inheriting its sample time from the parent model:

- Discrete-Time Integrator
- From Workspace (if it has input data that contains time)
- Probe (if probing sample time)
- Rate Limiter
- Sine Wave

Simulink assumes that the output of an S-function does not depend on inherited sample time unless the S-function explicitly declares the contrary. See “Sample Times” for information on how to create S-functions that declare whether their output depends on their inherited sample time.

In referenced models that inherit their sample time, avoid S-functions in referenced models that fail to declare whether output depends on inherited sample time. Excluding those kinds of S-functions helps to avoid simulation errors. By default, Simulink warns you if your model contains such blocks when you update or simulate the model. See “Unspecified inheritability of sample time” for details.

Sample Time Consistency

Use consistent sample time rates to promote the reliable use of a model referenced by another model. Make the rates of root Inport and Outport blocks in a referenced model consistent with the rates of blocks reading from and writing to those blocks. Simulink generates an error when there are sample time mismatches between:

- The sample times of root Inport blocks and the sample times of blocks to which the Inport block inputs.
- The sample times of root Outport blocks and the sample times of blocks that input to the Outport block.

To address an error that flags a sample time inconsistency in a referenced model, you can use one of these approaches.

Root Inport or Output Block Sample Time is Different From	Possible Solution
All of the blocks to which it connects, and those blocks all have the same sample time as each other	Set the sample time of the Inport or Outport block to match the sample time of the block to which it connects.

Root Inport or Output Block Sample Time is Different From	Possible Solution
One or more blocks and the same as one or more blocks	For blocks that do not match the Inport or Outport block, insert Rate Transition blocks on the signal that connects to the Inport or Outport block.

Simulate Model Referencing Models

In this section...

“Simulate a Top Model” on page 8-31

“Simulate a Referenced Model” on page 8-31

Simulating a model that uses model referencing differs in some ways from simulating a standalone model that does not use model referencing.

Simulate a Top Model

Simulink executes the top model in a model reference hierarchy the same way that it executes models without model referencing. All the Simulink simulation modes are available to the top model. To achieve faster execution of a top model in a model reference hierarchy, you can use Simulink accelerator mode or rapid accelerator mode. For details about accelerator mode, see the “Acceleration” documentation. For information about rapid accelerator mode, see “Accelerate, Refine, and Test Hybrid Dynamic System on Host Computer by Using RSim System Target File”.

When you execute a top model in Simulink accelerator mode or rapid accelerator mode, all referenced models execute in accelerator mode.

Simulate a Referenced Model

You can simulate a referenced model in one of these modes:

- Normal
- Accelerator
- Software-in-the-loop (SIL)
- Processor-in-the-loop (PIL)

For more information about using these simulation modes for referenced models, see “Comparison of Simulation Modes for Referenced Models” on page 8-32.

The simulation modes used for referenced models depend on the simulation mode of the parent model. For details, see “Parent and Referenced Model Simulation Modes” on page 8-35.

Specify the Simulation Mode for Referenced Models

The Model block for each instance of a referenced model controls the simulation mode of the instance. To set or change the simulation mode for a referenced model:

- 1 Access the block parameter dialog box for the Model block. (See “Navigating a Model Block”.)
- 2 Set the **Simulation mode** parameter.
- 3 Click **OK** or **Apply**.

Comparison of Simulation Modes for Referenced Models

You can use rapid accelerator mode for the top model in a model reference hierarchy, but not for referenced models.

The different simulation modes for referenced models share many capabilities and techniques, but they have different implementations, requirements, and limitations.

Tip Accelerator mode execution of a referenced model is different than:

- Accelerator mode execution of a freestanding or top model, as described in “Acceleration”.
- Rapid accelerator mode execution of a freestanding or top model, as described in “Accelerate, Refine, and Test Hybrid Dynamic System on Host Computer by Using RSim System Target File”.

For more information about accelerator mode execution of a referenced model, see “Model Referencing Simulation Targets” on page 8-46.

Simulation Mode	Description	When to Use
Normal	Executes referenced model interpretively.	Simulink executes a normal mode referenced model interpretively. Compared to other simulation modes, normal mode: <ul style="list-style-type: none">• Executes more slowly.• Requires no delay for code generation or compilation.

Simulation Mode	Description	When to Use
		<ul style="list-style-type: none"> • Works with more Simulink and Stateflow tools, supporting tools such as: <ul style="list-style-type: none"> • Scopes, port value display, and other output viewing tools. • Model coverage analysis. • Stateflow debugging and animation. • Provides more accurate linearization analysis. • Supports more S-functions than accelerator mode does. <p>You can use normal mode with multiple instances of a referenced model. For details, see “Simulate Models with Multiple Referenced Model Instances” on page 8-37.</p>
Accelerator	<p>Executes the referenced model by creating a MEX-file (a simulation target) for the referenced model, then running the MEX-file.</p> <p>For more information, see “Model Referencing Simulation Targets” on page 8-46.</p>	<ul style="list-style-type: none"> • Executes faster than normal mode. • Takes time for code generation and code compilation. • Does not fully support some Simulink tools, such as Model Coverage and the Simulink Debugger. • Supports Scope blocks, but requires using the Signal & Scope Manager and adding test points to signals. Adding or removing a test point requires rebuilding the SIM target for a model.

Simulation Mode	Description	When to Use
SIL	<p>Executes referenced model by generating production code. This code is compiled for, and executed on, the host platform.</p> <p>Requires Embedded Coder[®] software. For more information, see “SIL and PIL Limitations” and “Numerical Equivalence Testing” in the Embedded Coder documentation.</p>	<ul style="list-style-type: none"> • Verifies generated source code without modifying the original model. • Supports the reuse of test harnesses for the original model with the generated source code. <p>SIL mode provides a convenient alternative to PIL simulation when the target hardware is not available.</p>
PIL	<p>Executes referenced model by generating production code. This code is cross-compiled for, and executed on, a target processor or an equivalent instruction set simulator.</p> <p>Requires Embedded Coder software. For more information, see “SIL and PIL Limitations” and “Numerical Equivalence Testing” in the Embedded Coder documentation.</p>	<ul style="list-style-type: none"> • Verifies deployment object code on target processors without modifying the original model. • Supports the reuse of test harnesses for the original model with the generated source code.

Note: Simulation results for a given model are nearly identical in normal and accelerator modes. Trivial differences can occur, depending on differences in the optimizations and libraries that you use.

Parent and Referenced Model Simulation Modes

The simulation modes you can use for a referenced model depends on the simulation mode of its parent model.

Parent Model Simulation Mode	Referenced Model Simulation Modes
Normal	<ul style="list-style-type: none"> • Referenced models can use normal, accelerator, SIL, or PIL mode. • If every model that is superior to a referenced model in the model reference hierarchy also executes in normal mode, that referenced model can execute in normal mode.
Accelerator	<ul style="list-style-type: none"> • All subordinate models must also execute in accelerator mode. • When a normal mode model is subordinate to an accelerator mode model, Simulink returns a warning and temporarily overrides the normal mode specification. • When a SIL-mode or PIL-mode model is subordinate to an accelerator mode model, an error occurs.
SIL	<ul style="list-style-type: none"> • If their simulation modes are normal, accelerator, or SIL, all subordinate models also execute in SIL mode. Otherwise, an error occurs. See “Simulation Mode Override Behavior in Model Reference Hierarchy”. • Multiple Model blocks, starting at the top of a model reference hierarchy, can execute in SIL mode. However, during code coverage or code execution profile, only one Model block can execute at a time in SIL mode.
PIL	<ul style="list-style-type: none"> • If their simulation modes are normal, accelerator, or PIL, all subordinate models also execute in PIL mode. Otherwise, an error occurs. See “Simulation Mode Override Behavior in Model Reference Hierarchy”. • Only one Model block, starting at the top of a model reference hierarchy, can execute in PIL mode.

Simulate Models with Multiple Referenced Model Instances

In this section...

“Normal Mode Visibility” on page 8-37

“Example Models with Multiple Referenced Model Instances” on page 8-37

“Configure Models with Multiple Referenced Model Instances” on page 8-39

“Specify the Instance Having Normal Mode Visibility” on page 8-40

Normal Mode Visibility

All instances of a normal mode referenced model are part of the simulation. However, Simulink displays only one instance in a model window. Normal mode visibility includes the display of Scope blocks and data port values.

You set normal mode visibility by selecting in the top model the **Diagram > Subsystem & Model Reference > Model Block Normal Mode Visibility**. The normal mode visibility setting determines the instance that is displayed. If you do not specify normal mode visibility for a specific instance of a referenced model, Simulink picks one instance of the referenced model to display.

After a simulation, if you try to open a referenced model from a Model block that does not have normal mode visibility, Simulink displays a warning.

To set up your model to control which instance of a referenced model in normal mode has visibility and to ensure proper simulation of the model, see “Specify the Instance Having Normal Mode Visibility” on page 8-40.

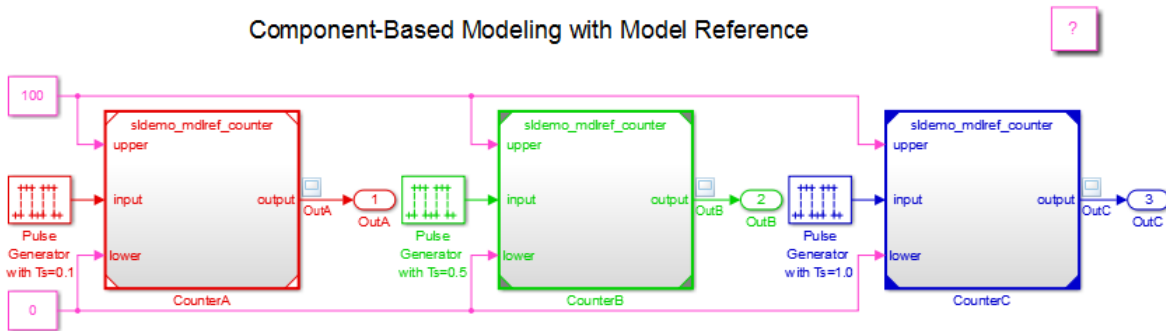

Example Models with Multiple Referenced Model Instances

The `sldemo_mdhref_basic` model and the “Visualizing Model Reference Architectures” featured example show the use of models containing multiple instances of a referenced model.

`sldemo_mdhref_basic`

The `sldemo_mdhref_basic` model has three Model blocks (CounterA, CounterB, and CounterC) that each reference the `sldemo_mdhref_counter` model.

If you update the diagram, the `sldemo_md1ref_basic` displays different icons for each of the three Model blocks that reference `sldemo_md1ref_counter`.

Model Block	Icon Corners	Simulation Mode and Normal Mode Visibility Setting
CounterA	White	Normal mode, with normal mode visibility enabled
CounterB	Gray corners	Normal mode, with normal mode visibility disabled
CounterC	Black corner	Accelerator mode (normal mode visibility is not applicable)

Open and simulate `sldemo_md1ref_basic`. Double-click the CounterA model and open the ScopeA block.

That ScopeA block reflects the results of simulating the CounterA Model block, which has normal mode visibility enabled.

If you try to open mdlref_counter model by double-clicking the CounterB Model block, ScopeA in mdlref_counter still shows the results of the CounterA Model block because that block has normal mode visibility enabled.

Visualizing Model Reference Architectures

The featured example Visualizing Model Reference Architectures shows the use of the Model Dependency Viewer for a model (sldemo_mdref_depgraph) that references multiple instances of a referenced model in normal mode. The example shows how to set up a model with multiple referenced instances in normal mode.

Configure Models with Multiple Referenced Model Instances

- 1 Set the **Configuration Parameters > Model Referencing > Total number of instances allowed per top model** parameter to **Multiple**.
- 2 Set each instance of the referenced model to use normal mode. In the block parameters dialog box for the Model block that references the instance, set the **Simulation Mode** parameter to **Normal**. Ensure that all the ancestors in the hierarchy for that Model block are in normal mode.

The corners of icons for Model blocks that are in normal mode can be white (empty). The corners turn gray after you update the diagram or simulate the model.

- 3 If necessary, modify S-functions used by the model so that they work with multiple instances of referenced models in normal mode. For details, see “Supporting the Use of Multiple Instances of Referenced Models That Are in Normal Mode”.

By default, Simulink assigns normal mode visibility to one of the instances. After you complete the configuration steps, you can specify a non-default instance to have normal mode visibility.

Specify the Instance Having Normal Mode Visibility

Determine Which Instance Has Normal Mode Visibility

To determine which instance currently has normal mode visibility:

- 1 To apply the normal mode visibility setting, update the diagram and make no other changes to the model.
- 2 To examine the Model blocks that reference the model that you are interested in. The Model block that has white corners has normal mode visibility enabled, navigate through the model hierarchy.

When you are editing a model or during compilation, after updating the diagram, use the `ModelReferenceNormalModeVisibilityBlockPath` parameter. The result is a `Simulink.BlockPath` object that is the block path for the Model block that references the model that has normal mode visibility enabled. For example:

```
get_param('sldemo_mdhref_basic',...
'ModelReferenceNormalModeVisibilityBlockPath')

ans =

    Simulink.BlockPath
    Package: Simulink

    Block Path:
        'sldemo_mdhref_basic/CounterA'
```

For a top model that you are simulating or that is in a compiled state, you can use the `CompiledModelBlockInstancesBlockPath` parameter. For example:

```

a = get_param('sldemo_md1ref_depgraph',...
    'CompiledModelBlockInstancesBlockPath')

a =

    sldemo_md1ref_F2C: [1x1 Simulink.BlockPath]
    sldemo_md1ref_heater: [1x1 Simulink.BlockPath]
    sldemo_md1ref_outdoor_temp: [1x1 Simulink.BlockPath]

```

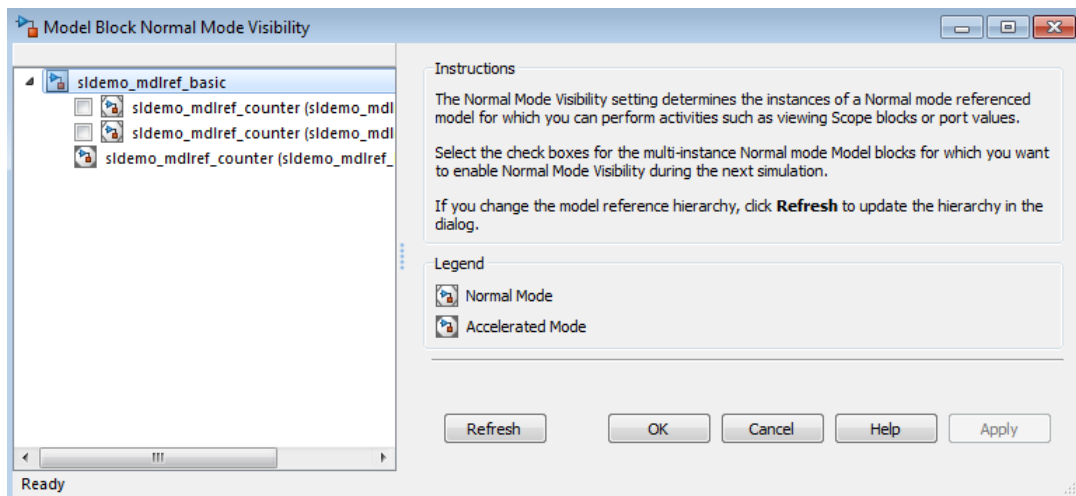

Enable Normal Mode Visibility for an Instance

Note: You cannot change normal mode visibility during simulation.

To enable normal mode visibility for a different instance of the referenced model than the instance that currently has normal mode visibility:

- 1 Navigate to the top model.
- 2 In the Simulink Editor, select the **Diagram > Subsystem & Model Reference > Model Block Normal Mode Visibility**.

The Model Block Normal Mode Visibility dialog box appears. For example, the dialog box for the `sldemo_md1ref_basic` model, with the hierarchy pane expanded, looks like this:

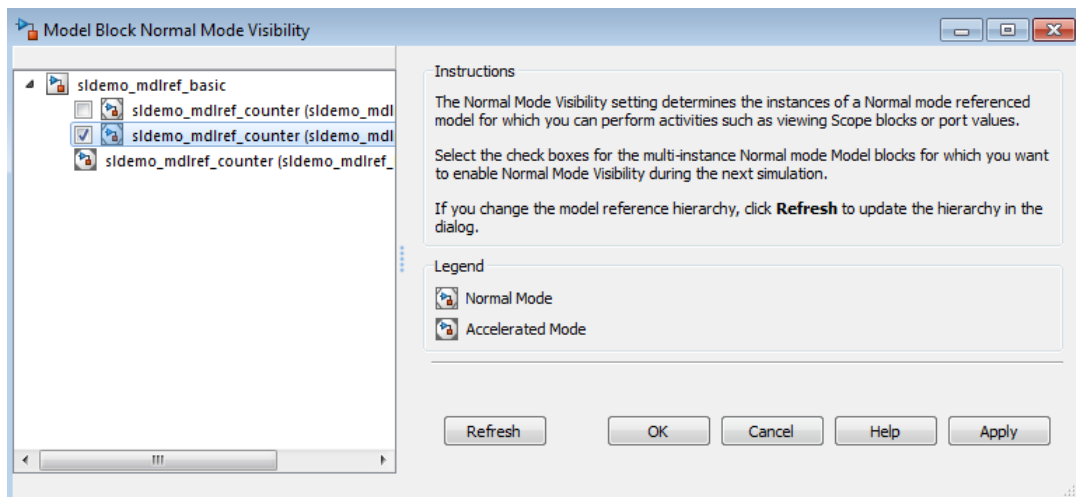

The model hierarchy pane shows a partial model hierarchy for the model from which you opened the dialog box. The hierarchy stops at the first Model block that is not in normal mode. The model hierarchy pane does not display Model blocks that reference protected models.

The dialog box shows the complete model block hierarchy for the top model. The normal mode instances of referenced models have check boxes.

Tip To have the model hierarchy pane of the Model Block Normal Mode Visibility dialog box reflect the current model hierarchy, click **Refresh**.

- 3 Select the instance of the model that you want to have normal mode visibility.

Simulink selects all ancestors of the model and clears all other instances of that model. When a model is cleared, Simulink clears all children of that model.

Tip To open a model from the Model Block Normal Mode Visibility dialog box, right-click the model in the model hierarchy pane and then click **Open**.

- 4 To apply the normal mode visibility setting, simulate the top model in the model reference hierarchy.

As an alternative to using the Model Block Normal Mode Visibility dialog box, at the MATLAB command line you can use the `ModelReferenceNormalModeVisibility` parameter. For input, you can specify one of these values:

- An array of `Simulink.BlockPath` objects. For example:

```
bp1 = Simulink.BlockPath({'mVisibility_top/Model', ...
    'mVisibility_mid_A/Model'});
bp2 = Simulink.BlockPath({'mVisibility_top/Model1', ...
    'mVisibility_mid_B/Model1'});
bps = [bp1, bp2];
set_param(topMdl, 'ModelBlockNormalModeVisibility', bps);
```

- A cell array of cell arrays of character vectors, with the character vectors being paths to individual blocks and models. This example produces the same effect as the object array example:

```
p1 = {'mVisibility_top/Model', 'mVisibility_mid_A/Model'};
p2 = {'mVisibility_top/Model1', 'mVisibility_mid_B/Model1'};
set_param(topMdl, 'ModelBlockNormalModeVisibility', {p1, p2});
```

- An empty array, to specify the use of the Simulink default selection of the instance that has normal mode visibility. For example:

```
set_param(topMdl, 'ModelBlockNormalModeVisibility', []);
```

Using an empty array is equivalent to clearing all the check boxes in the Model Block Normal Mode Visibility dialog box.

View a Model Referencing Hierarchy

Simulink provides tools and functions that you can use to examine a model reference hierarchy:

- Content preview displays a representation of the contents of a referenced model, without opening the Model block. Content preview helps the user of a model understand at a glance the kind of processing performed by the referenced model. For details, see “Preview Content of Hierarchical Items” on page 1-57.
- **Model Dependency Viewer** — Shows the structure the hierarchy lets you open constituent models. The Referenced Model Instances view displays Model blocks differently to indicate normal, accelerator, and PIL modes. See “Model Dependency Viewer” on page 12-64 for more information.
- **view_mdhrefs function** — Invokes the Model Dependency Viewer to display a graph of model reference dependencies.
- **find_mdhrefs function** — Finds all models directly or indirectly referenced by a given model.

Display Version Numbers

To display the version numbers of the models referenced by a model, for the parent model, choose **Display > Blocks > Block Version for Referenced Models**. Simulink displays the version numbers in the icons of the corresponding Model block instances.

The version number displayed on a Model block icon refers to the version of the model used to either:

- Create the block

- Refresh the block most recently changed

See “Manage Model Versions and Specify Model Properties” on page 4-87 and “Refresh Model Blocks” on page 8-87 for more information.

Model Referencing Simulation Targets

In this section...
“Simulation Targets” on page 8-46
“Build Simulation Targets” on page 8-47
“Simulation Target Output File Control” on page 8-48
“Reduce Update Time for Referenced Models” on page 8-50

Simulation Targets

A *simulation target*, or *SIM target*, is a MEX-file that implements a referenced model that executes in accelerator mode. Simulink invokes the simulation target as needed during simulation to compute the behavior and outputs of the referenced model. Simulink uses the same simulation target for all accelerator mode instances of a given referenced model anywhere in a reference hierarchy.

If you have a Simulink Coder license, be careful not to confuse the simulation target of a referenced model with any of these other types of target:

- Hardware target — A platform for which Simulink Coder generates code
- System target — A file that tells Simulink Coder how to generate code for particular purpose
- Rapid Simulation target (RSim) — A system target file supplied with Simulink Coder
- Model reference target — A library module that contains Simulink Coder code for a referenced model

Simulink creates a simulation target only for a referenced model that has one or more accelerator mode instances in a reference hierarchy. A referenced model that executes only in normal mode always executes interpretively and does not use a simulation target. When one or more instance of a referenced model executes in normal mode, and one or more instance executes in accelerator mode:

- Simulink creates a simulation target for the accelerator mode instances.
- The normal mode instances do not use that simulation target.

Because accelerator mode requires code generation, it imposes some requirements and limitations that do not apply to normal mode. Aside from these constraints, you can

generally ignore simulation targets and their details when you execute a referenced model in accelerator mode. See “Limitations on Accelerator Mode Referenced Models” on page 8-96 for details.

Build Simulation Targets

Simulink by default generates the needed target from the referenced model:

- If a simulation target does not exist at the beginning of a simulation
- When you perform an update diagram for a parent model

If the simulation target already exists, then by default Simulink checks whether the referenced model has structural changes since the target was last generated. If so, Simulink regenerates the target to reflect changes in the model. For details about how Simulink detects whether to rebuild a model reference target, see the “Rebuild” parameter documentation.

You can change this default behavior to modify the rebuild criteria or specify that Simulink always or never rebuilds targets. See “Rebuild” for details.

To generate simulation targets interactively for accelerator mode referenced models, do one of these steps:

- Update the diagram on a model that directly or indirectly references the model that is in accelerator mode
- Execute the `slbuild` command with appropriate arguments at the MATLAB command line

While generating a simulation target, Simulink displays status messages at the MATLAB command line to enable you to monitor the target generation process. Target generation entails generating and compiling code and linking the compiled target code with compiled code from standard code libraries to create an executable file.

Reduce Change Checking Time

You can reduce the time that Simulink spends checking whether any or all simulation targets require rebuilding by setting configuration parameter values as follows:

- In all referenced models throughout the hierarchy, set **Configuration Parameters > Diagnostics > Data Validity > Signal resolution** to `Explicit only` or `None`. (See “Signal resolution”.)

- To minimize change detection time, consider setting **Configuration Parameters > Model Referencing > Rebuild options** to **If any changes in known dependencies detected on the top model**. See “Rebuild”.

These parameter values exist in the configuration set of a referenced model, not in the individual Model block, so setting either value for any instance of a referenced model sets it for all instances of that model.

Simulation Target Output File Control

Simulink creates simulation targets in the `slprj` subfolder of the working folder. If `slprj` does not exist, Simulink creates it.

Note: Simulink Coder code generation also uses the `slprj` folder. Subdirectories in `slprj` provide separate places for simulation code, Simulink Coder code, and other files. For details, see “Control the Location for Generated Files”.

By default, the files generated by Simulink diagram updates and model builds are placed in a build folder, the root of which is the current working folder (`pwd`). However, in some situations, you might want the generated files to go to a root folder outside the current working folder. For example:

- You need to keep generated files separate from the models and other source materials used to generate them.
- You want to reuse or share previously-built simulation targets without having to set the current working folder back to a previous working folder.

You might also want to separate generated simulation artifacts from generated production code.

To allow you to control the output locations for the files generated by diagram updates and model builds, the software allows you to separately specify the *simulation cache folder* build folder. The simulation cache folder is the root folder in which to place artifacts used for simulation.

To specify the simulation cache folder, use *one* of these approaches:

- Use the `CacheFolder` MATLAB session parameter.

- In the **Simulink Preferences > General**) dialog box, use the **Simulation cache folder** preference. This preference provides the initial defaults for the MATLAB session parameters.

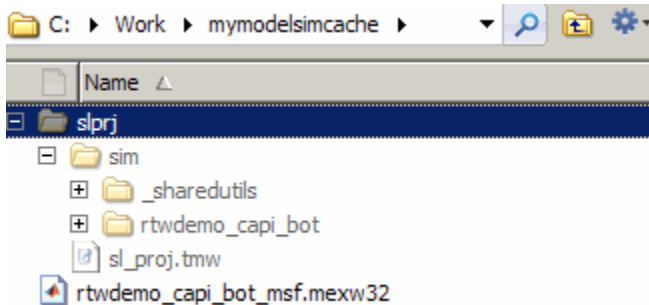

Control Output Location for Model Build Artifacts Used for Simulation

To control the output location for files generated by Simulink diagram updates, in the **Simulink Preferences > General**) dialog box, use the **Simulation cache folder** preference. To specify the root folder location for files generated by Simulink diagram updates, set the preference value by entering or browsing to a folder path, for example:

The folder path that you specify provides the initial default for the MATLAB session parameter `CacheFolder`. When you initiate a Simulink diagram update, any files generated are placed in a build folder at the root location specified by `CacheFolder` (if any), rather than in the current working folder (`pwd`).

For example, using a 32-bit Windows host platform, if you set the **Simulation cache folder** to 'C:\Work\mymodelsimcache' and then simulate the model `rtwdemo_capi`, files are generated into the specified folder as follows:

As an alternative to using the Simulink preferences to set **Simulation cache folder**, you also can get and set the preference value from the command line using `get_param` and `set_param`. For example,

```
>> get_param(0, 'CacheFolder')
```

```
ans =
```

```
''  
>> set_param(0, 'CacheFolder', fullfile('C:', 'Work', 'mymodelsimcache'))  
>> get_param(0, 'CacheFolder')  
  
ans =  
  
C:\Work\mymodelsimcache
```

Also, you can choose to override the **Simulation cache folder** preference value for the current MATLAB session.

Override Build Folder Settings for the Current MATLAB Session

The Simulink preferences **Simulation cache folder** and **Code generation folder** provide the initial defaults for the MATLAB session parameters `CacheFolder` and `CodeGenFolder`, which determine where files generated by Simulink diagram updates and model builds are placed. However, you can override these build folder settings during the current MATLAB session, using the `Simulink.fileGenControl` function. This function allows you to directly manipulate the MATLAB session parameters, for example, overriding or restoring the initial default values. The values you set using `Simulink.fileGenControl` expire at the end of the current MATLAB session. For more information and detailed examples, see the `Simulink.fileGenControl` function reference page.

Reduce Update Time for Referenced Models

- “Parallel Building for Large Model Reference Hierarchies” on page 8-50
- “Parallel Building Configuration Requirements” on page 8-51
- “Update Models in a Parallel Computing Environment” on page 8-51
- “Locate Parallel Build Logs” on page 8-53

Parallel Building for Large Model Reference Hierarchies

In a parallel computing environment, you can increase the speed of diagram updates for models containing large model reference hierarchies by building referenced models that are configured in Accelerator mode in parallel whenever conditions allow. For example, if you have Parallel Computing Toolbox software, updating of each referenced model can be distributed across the cores of a multicore host computer. If you additionally have MATLAB Distributed Computing Server™ software, updating of each referenced model can be distributed across remote workers in your MATLAB Distributed Computing Server configuration.

The performance gain realized by using parallel builds for updating referenced models depends on several factors, including how many models can be built in parallel for a given model referencing hierarchy, the size of the referenced models, and parallel computing resources such as number of local and/or remote workers available and the hardware attributes of the local and remote machines (amount of RAM, number of cores, and so on).

For configuration requirements that might apply to your parallel computing environment, see “Parallel Building Configuration Requirements” on page 8-51.

For a description of the general workflow for building referenced models in parallel whenever conditions allow, see “Update Models in a Parallel Computing Environment” on page 8-51.

Parallel Building Configuration Requirements

The following requirements apply to using parallel builds for updating model reference hierarchies:

- For local pools, the host machine should have an appropriate amount of RAM available for supporting the number of local workers (MATLAB sessions) that you plan to use. For example, using `parpool(4)` to create a parallel pool with four workers results in five MATLAB sessions on your machine, each using approximately 120 MB of memory at startup.
- Remote MATLAB Distributed Computing Server workers participating in a parallel build must use a common platform and compiler.
- A consistent MATLAB environment must be set up in each MATLAB worker session as in the MATLAB client session — for example, shared base workspace variables, MATLAB path settings, and so forth. One approach is to use the `PreLoadFcn` callback of the top model. If you configure your model to load the top model with each MATLAB worker session, its preload function can be used for any MATLAB worker session setup.

Update Models in a Parallel Computing Environment

To take advantage of parallel building for a model reference hierarchy:

- 1 Set up a pool of local and/or remote MATLAB workers in your parallel computing environment.
 - a Make sure that Parallel Computing Toolbox software is licensed and installed.

The **Verbose accelerator builds** option controls the verbosity of build messages both in the MATLAB Command Window and in parallel build log files.

- 4 Optionally, inspect the model reference hierarchy to determine, based on model dependencies, which models will be built in parallel. For example, you can use the Model Dependency Viewer from the Simulink **Analysis > Model Dependencies** menu.
- 5 Update your model. Messages in the MATLAB command window record when each parallel or serial build starts and finishes.

If you need more information about a parallel build, for example, if a build fails, see “Locate Parallel Build Logs” on page 8-53.

Locate Parallel Build Logs

When you update a model for which referenced models are built in parallel, if verbose builds are turned on, messages in the MATLAB Command Window record when each parallel or serial build starts and finishes. For example,

```
### Initializing parallel workers for parallel model reference build.
### Parallel worker initialization complete.
### Starting parallel model reference SIM build for 'bot_model1001'
### Starting parallel model reference SIM build for 'bot_model1002'
### Starting parallel model reference SIM build for 'bot_model1003'
### Starting parallel model reference SIM build for 'bot_model1004'
### Finished parallel model reference SIM build for 'bot_model1001'
### Finished parallel model reference SIM build for 'bot_model1002'
### Finished parallel model reference SIM build for 'bot_model1003'
### Finished parallel model reference SIM build for 'bot_model1004'
```

To obtain more detailed information about a parallel build, you can examine the parallel build log. For each referenced model built in parallel, the build process generates a file named *model_buildlog.txt*, where *model* is the name of the referenced model. This file contains the full build log for that model.

If a parallel build completes, you can find the build log file in the build subfolder corresponding to the referenced model. For example, for a build of referenced model *bot_model1004*, look for the build log file *bot_model1004_buildlog.txt* in the referenced model subfolder *build_folder/slprj/sim/bot_model1004*.

If a parallel builds fails, you might see output similar to the following:

```
### Initializing parallel workers for parallel model reference build.
### Parallel worker initialization complete.
### Starting parallel model reference SIM build for 'bot_model1002'
### Starting parallel model reference SIM build for 'bot_model1003'
```

```
### Finished parallel model reference SIM build for 'bot_model002'  
### Finished parallel model reference SIM build for 'bot_model003'  
### Starting parallel model reference SIM build for 'bot_model001'  
### Starting parallel model reference SIM build for 'bot_model004'  
### Finished parallel model reference SIM build for 'bot_model004'  
### The following error occurred during the parallel model reference SIM build for  
'bot_model001':  
  
Error(s) encountered while building model "bot_model001"  
  
### Cleaning up parallel workers.
```

If a parallel build fails, you can find the build log file in a referenced model subfolder under the build subfolder `/par_md1_ref/model`. For example, for a failed parallel build of model `bot_model001`, look for the build log file `bot_model001_buildlog.txt` in the subfolder `build_folder/par_md1_ref/bot_model001/slprj/sim/bot_model001`.

Simulink Model Referencing Requirements

In this section...

“About Model Referencing Requirements” on page 8-55

“Name Length Requirement” on page 8-55

“Configuration Parameter Requirements” on page 8-55

“Model Structure Requirements” on page 8-59

About Model Referencing Requirements

A model reference hierarchy must satisfy various Simulink requirements, as described in this section. Some limitations also apply, as described in “Model Referencing Limitations” on page 8-93.

Name Length Requirement

The name of a referenced model must contain fewer than 60 characters, exclusive of the `.slx` or `.mdl` suffix. An error occurs if the name of a referenced model is too long.

Configuration Parameter Requirements

A referenced model uses a configuration set in the same way that any other model does, as described in “Manage a Configuration Set” on page 13-11. By default, every model in a hierarchy has its own configuration set. Each model uses its configuration set the same way that it would if the model executed independently.

Because each model can have its own configuration set, configuration parameter values can be different in different models. Furthermore, some parameter values are intrinsically incompatible with model referencing. The Simulink response to an inconsistent or unusable configuration parameter depends on the parameter:

- Where an inconsistency has no significance, or a trivial resolution exists that carries no risk, Simulink ignores or resolves the inconsistency without posting a warning.
- Where a nontrivial and possibly acceptable solution exists, Simulink resolves the conflict silently, resolves it with a warning, or generates an error. See “Diagnostic Configuration Parameter Changes” on page 8-97 for details.

- Where no acceptable resolution is possible, Simulink generates an error. Change some or all parameter values to eliminate the problem.

Manually eliminating all configuration parameter incompatibilities can be tedious when:

- A model reference hierarchy contains many referenced models that have incompatible parameter values
- A changed parameter value must propagate to many referenced models

You can control or eliminate such overhead by using configuration references to assign an externally stored configuration set to multiple models. See “Manage a Configuration Reference” on page 13-18 for details.

Note: Configuration parameters on the **Code Generation** pane of the Configuration Parameters dialog box do not affect simulation in either normal or accelerator mode. **Code Generation** parameters affect only code generation by Simulink Coder itself. Accelerated mode simulation requires code generation to create a simulation target. Simulink uses default values for all **Code Generation** parameters when generating the target, and restores the original parameter values after code generation is complete.

The tables in the following sections list Configuration parameter options that can cause problems if set:

- In certain ways, as indicated in the table
- Differently in a referenced model than in a parent model

Where possible, Simulink resolves violations of these requirements automatically, but most cases require changes to the parameters in some or all models.

Configuration Parameters Changed During Accelerated Simulation and Code Generation

During model referencing simulation in accelerator and rapid accelerator mode, Simulink temporarily sets several **Configuration Parameters > Diagnostics > Data Validity** parameter settings to **None**, if they are set to **Warning** or **Error**. You can use the Model Advisor to check for parameters that change. For details, see “Certain Diagnostic Configuration Parameters Ignored for Models Referenced in Accelerator Mode” on page 8-99.

If the **Configuration Parameters > Code Generation > Symbols** parameters hold identifier information about the name of a referenced model and do not use a\$R token,

code generation prepends the \$R token to the name of the model. You can use the Model Advisor to check for changed model names. See “Configuration Parameters Changed During Code Generation” on page 8-100.

Configuration Requirements for All Referenced Model Simulation

Dialog Box Pane	Option	Requirement
Solver	Start time	The start time of the top model and all referenced models must be the same, but need not be zero.
	Stop time	Simulink uses Stop time of the top model for simulation, overriding any differing Stop time in a referenced model.
	Type Solver	The Type and Solver of the top model apply throughout the hierarchy. See “Solver Requirements” on page 8-58.
Data Import/Export	Initial state	Can be on for the top model, but must be off for a referenced model.
Optimization	Default parameter behavior	If the parent model has this set to Inlined , then the referenced model cannot have this set to Tunable .
	Application lifespan (days)	For code generation, must be the same for parent and referenced models. For simulation, the setting can be different for the parent and referenced models.
Model Referencing	Total number of instances allowed per top model	Must not be Zero in a referenced model. Specifying

Dialog Box Pane	Option	Requirement
		One rather than Multiple is preferable or required in some cases. See “Model Instance Requirements” on page 8-58.

Solver Requirements

Model referencing works with both fixed-step and variable-step solvers. All models in a model reference hierarchy use the same solver, which is always the solver specified by the top model. An error occurs if the solver type specified by the top model is incompatible with the solver type specified by any referenced model.

Top Model Solver Type	referenced model Solver Type	Compatibility
Fixed Step	Fixed Step	Allowed
Variable Step	Variable Step	Allowed
Variable Step	Fixed-step	Allowed unless the referenced model is multi-rate and specifies both a discrete sample time and a continuous sample time
Fixed Step	Variable Step	Error

If an incompatibility exists between the top model solver and any referenced model solver, one or both models must change to use compatible solvers. For information about solvers, see “Solvers” on page 3-21 and “Solvers” on page 23-7.

Model Instance Requirements

A referenced model must specify that it is available to be referenced, and whether it can be referenced at most once or can have multiple instances. The **Configuration Parameters > Model Referencing > Total number of instances allowed per top model** parameter provides this specification. See “Total number of instances allowed per top model” for more information. The possible values for this parameter are:

- **Zero** — A model cannot reference this model. An error occurs if a reference to the model occurs in another model.

- **One** — A model reference hierarchy can reference the model at most once. An error occurs if more than one instance of the model exists. This value is sometimes preferable or required.
- **Multiple** — A model hierarchy can reference the model more than once, if it contains no constructs that preclude multiple reference. An error occurs if the model cannot be multiply referenced, even if only one reference exists.

Setting **Total number of instances allowed per top model** to **Multiple** for a model that is referenced only once can reduce execution efficiency slightly. However, this setting does not affect data values that result from simulation or from executing code Simulink Coder generates. Specifying **Multiple** when only one model instance exists avoids having to change or rebuild the model when reusing the model:

- In the same hierarchy
- Multiple times in a different hierarchy

Some model properties and constructs require setting **Total number of instances allowed per top model** to **One**. For details, see “General Reusability Limitations” on page 8-94 and “Accelerator Mode Reusability Limitations” on page 8-97.

Model Structure Requirements

The following requirements relate to the structure of a model reference hierarchy.

Signal Propagation Requirements

The signal name must explicitly appear on any signal line connected to an **Output** block of a referenced model. A signal connected to an unlabeled line of an **Output** block of a referenced model cannot propagate out of the **Model** block to the parent model.

Bus Usage Requirements

For bus signals that cross model reference boundaries, use the same bus object to specify the properties of the bus in both the parent and the referenced model. For details, see “Bus Data Crossing Model Reference Boundaries” on page 63-123.

Sample Time Requirements

The first nonvirtual block connected to a root-level **Inport** or **Output** block of a referenced model must have the same sample time as the port to which it connects. Use

Rate Transition blocks to match input and output sample times, as illustrated in the following diagram.

Parameterize Instances of a Reusable Referenced Model

When you use model referencing to break a large system into components, each component is a separate model. You can reuse a component by referring to it with multiple Model blocks. Each Model block is an instance of the component. You can then configure a block parameter (such as the **Gain** parameter of a Gain block) to use either the same value or a different value for each instance of the component. To use different values, create and use a model argument to set the value of the block parameter.

For information about setting block parameter values in reusable components, see “Parameter Interfaces for Reusable Components” on page 34-20.

Specify Different Value for Each Instance of Reusable Model

To specify a different value for a block parameter in each instance of a reusable referenced model:

- 1 Create a MATLAB variable or `Simulink.Parameter` object in the referenced model workspace.

Use a MATLAB variable for ease of maintenance. Use a `Simulink.Parameter` object for greater control over the minimum and maximum value, the data type, and other properties of the model argument.

- 2 Set the block parameter value in the model by using the variable or object. Optionally, use the same variable or object to set other block parameter values.

When you simulate this model directly, the block parameters use the value that the variable or object stores in the model workspace. Otherwise, including when you simulate a parent model, the value in the model workspace has no significance.

- 3 Configure the variable or object as a model argument. In the Model Explorer **Model Hierarchy** pane, select the node that corresponds to the referenced model workspace. In the Dialog pane (the right pane), set the value of the **Model arguments** parameter by using the name of the variable or object.

To configure multiple variables or objects in the model workspace as model arguments, set the **Model arguments** parameter value by using a list of the variable or object names. Separate the names by using commas, spaces, or semicolons.

- 4 In each Model block that refers to the reusable model, specify an instance-specific value for the model argument. To set the value, you can use the common techniques

for setting block parameter values (see “Set Block Parameter Values” on page 34-2).

To specify values for multiple arguments in the same Model block, use a list separated by commas, spaces, or semicolons.

Combine Multiple Arguments into a Structure

When you configure a model to use multiple model arguments, consider using a structure instead of separate variables in the model workspace. This technique reduces the effort of maintenance when you want to add, rename, or delete arguments. Instead of manually synchronizing the list of arguments in the model workspace with the list of argument values in Model blocks, you modify structures by using the Variable Editor or the command prompt.

If you have Simulink Coder, this technique can also reduce the ROM consumed by the formal parameters of the referenced model functions, such as the output (`step`) function.

For basic information about creating and using structures to set block parameter values, see “Organize Related Block Parameter Definitions in Structures” on page 34-22.

Parameterize a Referenced Model

This example shows how to configure multiple instances of a referenced model to use different values for the same block parameter.

For an example that involves code generation, see “Specify Instance-Specific Parameter Values for Reusable Referenced Model”.

Configure Referenced Model to Use Model Arguments

Create the model `ex_model_arg_ref`. This model represents a reusable algorithm.

```
open_system('ex_model_arg_ref')
```

In the Model Explorer **Model Hierarchy** pane, expand the node **ex_model_arg_ref** and select **Model Workspace**.

Select **Add > Simulink Parameter** twice. Two Simulink.Parameter objects appear in the **Contents** pane.

Rename the objects as **gainArg** and **coeffArg**.

Set the **Value** property of the objects. For example, set them to 3.17 and 1.05, respectively.

```
modelWorkspace = get_param('ex_model_arg_ref', 'ModelWorkspace');
assignin(modelWorkspace, 'gainArg', Simulink.Parameter(3.17));
assignin(modelWorkspace, 'coeffArg', Simulink.Parameter(1.05));
```

In the **Model Hierarchy** pane, select **Model Workspace** again.

In the Dialog pane (the right-hand pane), set **Model arguments** to **coeffArg, gainArg**.

```
set_param('ex_model_arg_ref', 'ParameterArgumentNames', 'coeffArg, gainArg')
```

Name	Value	Dimensions	Description
gainArg	3.17	[1 1]	
coeffArg	1.05	[1 1]	

Model Workspace

Workspace data

Data source: Model File

Model arguments (for referencing this model):

coeffArg, gainArg

In the `ex_model_arg_ref` model, in the Gain block dialog box, set **Gain** to `gainArg`.

```
set_param('ex_model_arg_ref/Gain', 'Gain', 'gainArg')
```

In the Discrete Filter block dialog box, set **Numerator** to `coeffArg`.

```
set_param('ex_model_arg_ref/Discrete Filter', 'Numerator', 'coeffArg')
```

Save the `ex_model_arg_ref` model.

When you simulate the `ex_model_arg_ref` model by itself, the parameter objects in the model workspace use the values that you specified in the **Value** property. The block parameters also use these values.

Set Model Argument Values in Parent Model

Create the model `ex_model_arg`. This model represents a system model that uses multiple instances of the reusable algorithm.

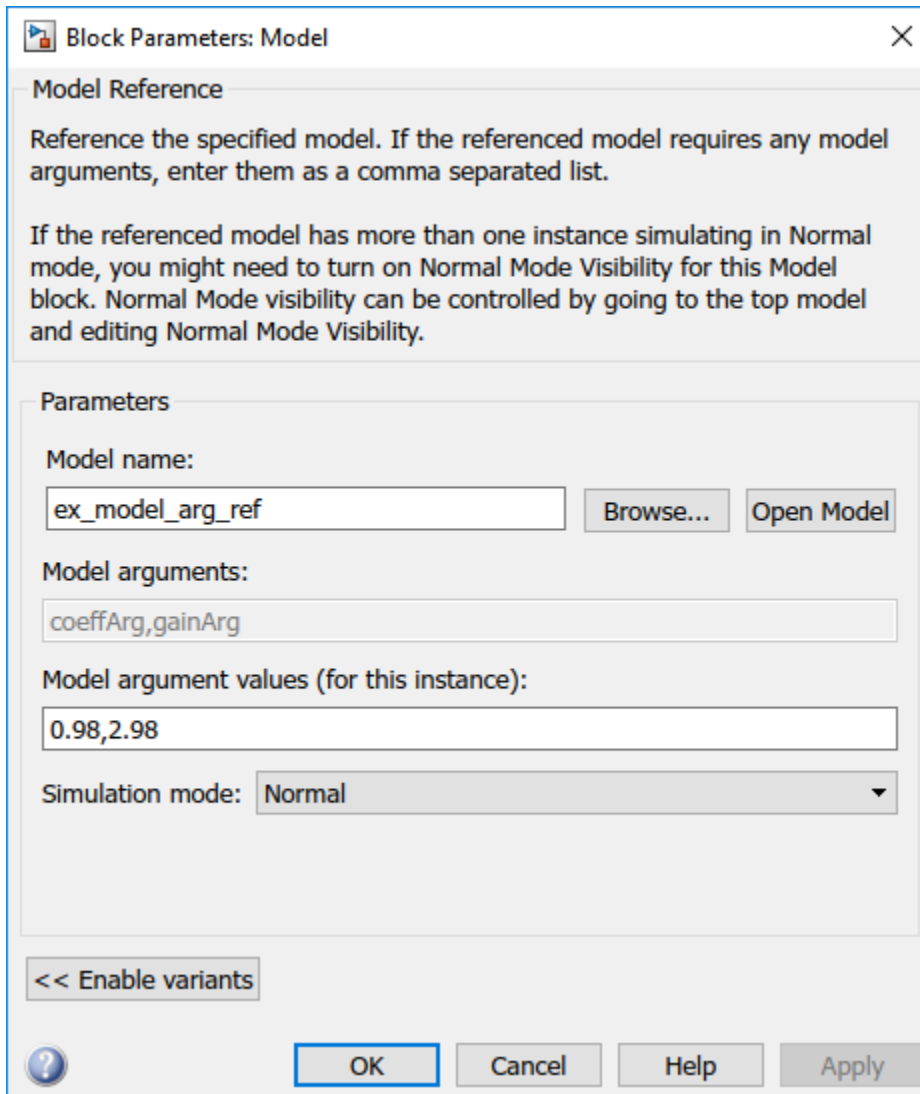

```
open_system('ex_model_arg')
```

Right-click the upper **Model** block and select **Block Parameters**.

Set **Model argument values** by using two numbers separated by a comma. For example, use `0.98,2.98`.

```
set_param('ex_model_arg/Model', 'ParameterArgumentValues', '0.98,2.98')
```

In the other Model block dialog box, set **Model argument values** to two different numbers, for example 1.11,3.34.

```
set_param('ex_model_arg/Model11','ParameterArgumentValues','1.11,3.34')
```

When you simulate the `ex_model_arg` model, each instance of `ex_model_arg_ref` (each Model block) passes the argument values that you specified to the parameter objects in the `ex_model_arg_ref` model workspace. For example, in the upper instance of `ex_model_arg_ref`, the parameter object `gainArg` uses the value 2.98.

Group Multiple Model Arguments into Single Structure

At the command prompt, create a structure. Add one field for each of the parameter objects in the `ex_model_arg_ref` workspace.

```
structForInst1.gain = 3.17;
structForInst1.coeff = 1.05;
```

Store the structure in a `Simulink.Parameter` object.

```
structForInst1 = Simulink.Parameter(structForInst1);
```

Use the Model Explorer to copy the parameter object into the `ex_model_arg_ref` model workspace.

In the model workspace, rename `structForInst1` as `structArg`.

```
assignin(modelWorkspace, 'structArg', copy(structForInst1));
```

In the **Model Hierarchy** pane, select the `ex_model_arg_ref` model workspace. In the Dialog pane, set **Model arguments** to `structArg`.

```
set_param('ex_model_arg_ref', 'ParameterArgumentNames', 'structArg')
```

The screenshot shows the Simulink Model Explorer interface. The left pane displays the contents of the 'Model Workspace*' (only) workspace, showing three data objects: `gainArg`, `coeffArg`, and `structArg`. The right pane shows the 'Model Workspace' dialog, where the 'Data source' is set to 'Model File' and the 'Model arguments (for referencing this model):' field contains the value `structArg`.

Name	Value	Dimensions	Description
gainArg	3.17	[1 1]	
coeffArg	1.05	[1 1]	
structArg	<1x...	[1 1]	

In the `ex_model_arg_ref` model, set the **Gain** parameter of the Gain block to `structArg.gain`.

```
set_param('ex_model_arg_ref/Gain', 'Gain', 'structArg.gain')
```

In the Discrete Filter block dialog box, set **Numerator** to `structArg.coeff`.

```
set_param('ex_model_arg_ref/Discrete Filter',...  
         'Numerator', 'structArg.coeff')
```

Save the `ex_model_arg_ref` model.

At the command prompt, copy the existing structure as `structForInst2`.

```
structForInst2 = copy(structForInst1);
```

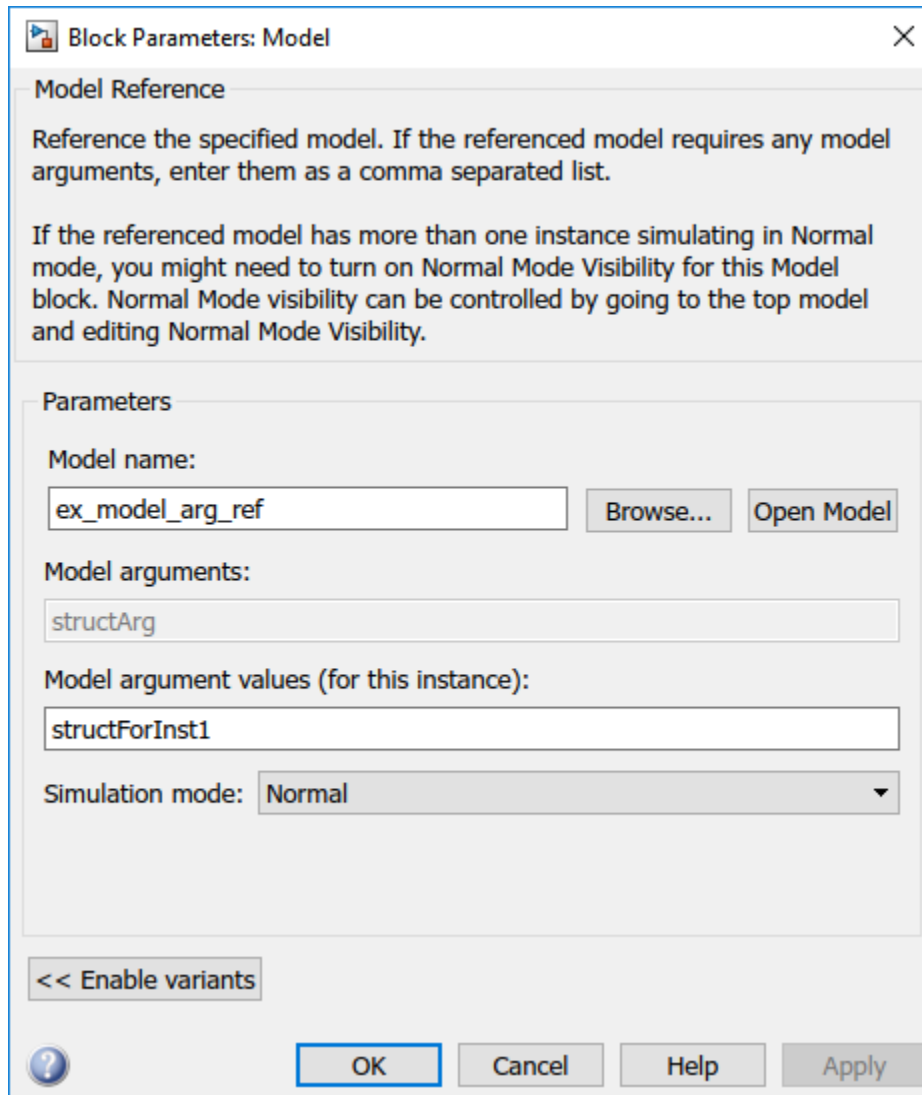

Set the field values in the two structures by using the same numbers that you used to set the model argument values in the Model blocks.

```
structForInst1.Value.gain = 2.98;  
structForInst1.Value.coeff = 0.98;
```

```
structForInst2.Value.gain = 3.34;  
structForInst2.Value.coeff = 1.11;
```

In the upper Model block dialog box, set **Model argument values** to `structForInst1`.

```
set_param('ex_model_arg/Model', 'ParameterArgumentValues', 'structForInst1')
```

In the other Model block dialog box, set **Model argument values** to `structForInst2`.
`set_param('ex_model_arg/Model1', 'ParameterArgumentValues', 'structForInst2')`
With the structures, the mathematical functionality of the models is the same.

Use Bus Object as Data Type of Structures

Optionally, use a `Simulink.Bus` object as the data type of the structures.

Use the function `Simulink.Bus.createObject` to create the bus object. The hierarchy of elements in the object matches the hierarchy of the structure fields. The default name of the object is `slBus1`.

```
Simulink.Bus.createObject(structForInst1.Value);
```

Rename the bus object by copying it.

```
myParamStructType = copy(slBus1);
```

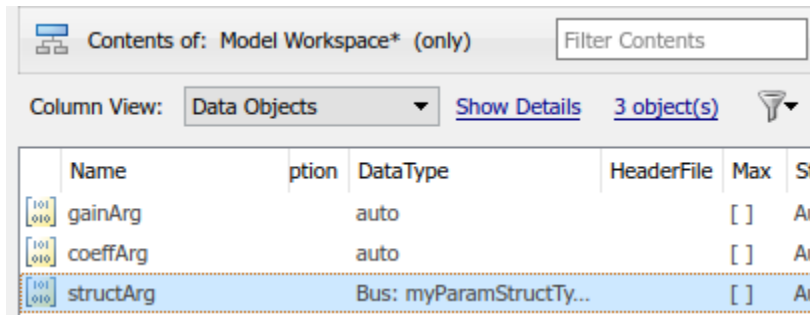

Set the data type of the parameter objects in the base workspace by using the bus object.

```
structForInst1.DataType = 'Bus: myParamStructType';  
structForInst2.DataType = 'Bus: myParamStructType';
```

Use the Model Explorer to view the contents of the `ex_model_arg_ref` model workspace.

Set **Column View** to **Data Objects**. For the parameter object `structArg`, set **DataType** to `Bus: myParamStructType`.

```
temp = getVariable(modelWorkspace, 'structArg');  
temp = copy(temp);  
temp.DataType = 'Bus: myParamStructType';  
assignin(modelWorkspace, 'structArg', copy(temp));
```

Rename Model Argument

To rename a model argument in the context of the referenced model, in the Model Explorer, right-click the variable or object in the referenced model workspace and select **Rename All**. The renaming operation changes the name of the variable or object and changes references to it throughout the model. For more information, see “Manage Variables from Block Parameter” on page 34-45.

Customize User Interface for Reusable Component

When you design a reusable referenced model for use by other members of a team, you can apply a mask to a Model block that references the model. You can then customize the way that your users set model argument values.

- 1 Configure the referenced model to use model arguments.
- 2 Mask a Model block that references the model. Add this block to a custom block library.
- 3 Add mask parameters to the mask. Add one mask parameter per model argument.
- 4 Use the mask parameters to set the argument values in the Model block.

Your users can specify the argument values for each instance of this block by using the custom mask parameters that you define.

Using this technique also makes it easier to programmatically specify argument values. If you create and use a mask parameter named `gainMask`, to programmatically set the argument value to `0.98` for an instance of the block named `myModelBlock`, your users can use this command at the command prompt:

```
set_param('myModelBlock', 'gainMask', '0.98')
```

If you do not mask the block, to set the argument value, your users must locate the value in the list of argument values in the Model block.

For information about masking blocks, see “Masking Fundamentals” on page 36-2. For information about block libraries, see “Create a Custom Library” on page 38-3. For an example model, see “Detailed Workflow for Managing Data with Model Reference”.

Configure Instance-Specific Data for Lookup Tables

When you use `Simulink.LookupTable` objects to store and configure lookup table data for ASAP2 or AUTOSAR code generation (for example, `STD_AXIS` or `CURVE`), you can configure the objects as model arguments. You can then specify unique table data and breakpoint data for each instance of a component.

- 1 In the referenced model workspace, create `Simulink.LookupTable` objects. In lookup table blocks that are in the model, use the objects to set the table and breakpoint data.
- 2 Configure the objects as model arguments by using the **Model arguments** parameter in the Model Explorer.
- 3 Create `Simulink.LookupTable` objects to store the instance-specific data. For example, if you configure a single `Simulink.LookupTable` object in the referenced model workspace as a model argument, to store instance-specific data for two instances of the referenced model (Model blocks in the parent model), create two `Simulink.LookupTable` objects in the base workspace.
- 4 Configure all of the `Simulink.LookupTable` objects to use the same structure type name. In the property dialog box, under **Struct Type definition**, set **Name** to the same value.
- 5 Use the instance-specific objects to set argument values in Model blocks. For example, in each Model block, use one of the instance-specific `Simulink.LookupTable` objects from the base workspace.

You cannot use `Simulink.Breakpoint` objects or `Simulink.LookupTable` objects that refer to `Simulink.Breakpoint` objects as model arguments.

Create Example Models

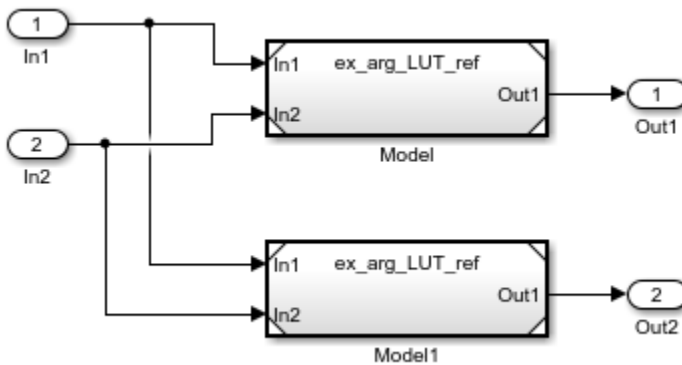

Create the example model `ex_arg_LUT_ref`, which represents a reusable algorithm.

```
open_system('ex_arg_LUT_ref')
```

Create the example model `ex_arg_LUT`, which uses the reusable algorithm twice.

```
open_system('ex_arg_LUT')
```

Configure Model Arguments in Referenced Model

Use the Model Explorer to create a `Simulink.LookupTable` object in the referenced model workspace (`ex_arg_LUT_ref`). Name the object `LUT_arg`.

In the Dialog pane (the right pane) of the Model Explorer, set **Number of table dimensions** to 2. Under **Table** and **Breakpoints**, specify values for the table and breakpoint data. When you simulate or generate code directly from `ex_arg_LUT_ref`, the model uses these values.

Under **Struct Type definition**, set Name to `LUT_arg_Type`.

Click **Apply**.

In the **Model Hierarchy** pane, select the node that corresponds to the referenced model workspace.

In the Dialog pane, set **Model arguments** to LUT_arg. Click **Apply**.

In the referenced model, in the n-D Lookup Table block, set **Data specification** to Lookup table object. Set **Name** to LUT_arg.

Save the referenced model.

At the command prompt, you can use these commands to create and configure the object.

```
temp = Simulink.LookupTable;
temp.Table.Value = [3 4; 1 2];
temp.Breakpoints(1).Value = [1 2];
temp.Breakpoints(2).Value = [3 4];
temp.StructTypeInfo.Name = 'LUT_arg_Type';
mdlwks = get_param('ex_arg_LUT_ref', 'ModelWorkspace');
assignin(mdlwks, 'LUT_arg', copy(temp))
set_param('ex_arg_LUT_ref', 'ParameterArgumentNames', 'LUT_arg')
set_param('ex_arg_LUT_ref/n-D Lookup Table', ...
    'DataSpecification', 'Lookup table object', 'LookupTableObject', 'LUT_arg')
save_system('ex_arg_LUT_ref')
```

Create Instance-Specific Argument Values

At the command prompt, create two Simulink.LookupTable objects in the base workspace.

```
LUTForInst1 = Simulink.LookupTable;
LUTForInst2 = Simulink.LookupTable;
```

Specify breakpoint and table data for each object.

```
LUTForInst1.Table.Value = [8 7; 6 5];
LUTForInst1.Breakpoints(1).Value = [5 6];
LUTForInst1.Breakpoints(2).Value = [3 4];
```

```
LUTForInst2.Table.Value = [9 8; 7 7];
LUTForInst2.Breakpoints(1).Value = [3 4];
LUTForInst2.Breakpoints(2).Value = [5 6];
```

Specify a structure type name. Match this name with the name specified by the object in the referenced model workspace.

```
LUTForInst1.StructTypeInfo.Name = 'LUT_arg_Type';  
LUTForInst2.StructTypeInfo.Name = 'LUT_arg_Type';
```

In the `ex_arg_LUT` model, in the top Model block, set **Model argument values** to `LUTForInst1`.

In the bottom Model block, set **Model argument values** to `LUTForInst2`.

At the command prompt, you can use these commands to configure the Model blocks.

```
set_param('ex_arg_LUT/Model1', 'ParameterArgumentValues', 'LUTForInst1')  
set_param('ex_arg_LUT/Model11', 'ParameterArgumentValues', 'LUTForInst2')
```

Each instance of `ex_arg_LUT_ref` uses the table and breakpoint data stored in one of the `Simulink.LookupTable` objects in the base workspace.

Create and Reference Conditional Referenced Models

In this section...

“Conditional Referenced Models” on page 8-75

“Create Conditional Models” on page 8-76

“Requirements for Conditional Models” on page 8-78

“Reference Conditional Models” on page 8-79

Conditional Referenced Models

You can set up referenced models so that they execute conditionally, similar to conditional subsystems. For information about conditional subsystems, see “Conditional Subsystems” on page 10-2.

You can use these conditionally executed referenced models.

Conditional Referenced Model	Description
Enabled	<p>Use an Enable block to insert an enable port in a model. Add an enable port to a model if you want a referenced model to execute at each simulation step for which the control signal has a positive value.</p> <p>To see an example of an enabled <i>subsystem</i>, see <code>enablesub</code>. A corresponding enabled referenced model uses the same blocks as are in the enabled subsystem.</p>
Triggered	<p>Use a Trigger block to insert a trigger port in a model. To use an external signal to trigger the execution of a model, add a trigger port to the model. You can add a trigger port to a root-level model or to a subsystem.</p> <p>To view a model that illustrates how you can use trigger ports in referenced models, see the Introduction to Managing Data with Model Reference example. In that example, see the “Top Model: Scheduling Calls to the Referenced Model” section.</p>

Conditional Referenced Model	Description
Triggered and Enabled	A triggered and enabled model executes once at the time step for which a trigger event occurs, if the enable control signal has a positive value at that step.
Function-Call	<p>Simulink allows certain blocks to control execution of a referenced model during a time step, using a function-call signal. Examples of such blocks are a Function-Call Generator or an appropriately configured custom S-function. See “Create a Function-Call Subsystem” on page 10-54 for more information.</p> <p>For an example of a function-call model, see the <code>sldemo_mdref_fncall</code> model.</p>

Each kind of conditionally executed model has some model creating requirements. For details, see “Requirements for Conditional Models” on page 8-78.

Create Conditional Models

- 1 At the root level of the referenced model, insert one of the following blocks:

Kind of Model	Blocks to Insert
Enabled	Enable
Triggered	Trigger
Triggered and Enabled	Trigger and Enable
Function-Call	Trigger

For an enabled model, go on to Step 3.

- 2 For the Trigger block, set the **Trigger type** parameter, based on the kind of model:

Kind of Model	Trigger Type Parameter Setting
Triggered	One of the following:
Triggered and enabled	<ul style="list-style-type: none"> • rising • falling • either

Kind of Model	Trigger Type Parameter Setting
Function-Call	function-call

- 3 Create and connect other blocks to implement the model.

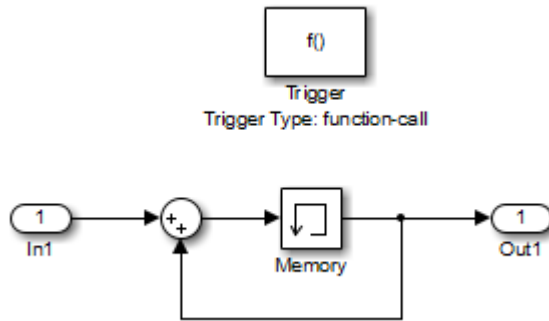

Enabled model example:

Triggered model example:

Function-call model example:

- 4 Ensure that the model satisfies the requirements for a conditional model. See the appropriate section:
- “Enabled Model Requirements” on page 8-78
 - “Triggered Model Requirements” on page 8-78
 - “Function-Call Model Requirements” on page 8-79

Requirements for Conditional Models

Conditional models must meet the requirements for:

- Conditional subsystems (see “Conditional Subsystems”)
- Referenced models (see “Simulink Model Referencing Requirements” on page 8-55)

In addition, conditional models must meet the requirements described below.

Enabled Model Requirements

- Multi-rate enabled models cannot use multi-tasking solvers. You must use single-tasking.
- For models with enable ports at the root, if the model uses a fixed-step solver, the fixed-step size of the model must not exceed the rate for any block in the model.
- The signal attributes of the enable port in the referenced model must be consistent with the input that the Model block provides to that enable port.

Triggered Model Requirements

The signal attributes of the trigger port in the referenced model must be consistent with the input that the Model block provides to that trigger port.

Function-Call Model Requirements

- A function-call model cannot have an output driven only by Ground blocks, including hidden Ground blocks inserted by Simulink. To meet this requirement, do the following:
 - 1 Insert a Signal Conversion block into the signal connected to the output.
 - 2 Enable the **Exclude this block from 'Block reduction' optimization** option of the inserted block.
- The referencing model must trigger the function-call model at the rate specified by the **Configuration Parameters > Solver 'Fixed-step size'** option if the function-call model meets both these conditions:
 - It specifies a fixed-step solver
 - It contains one or more blocks that use absolute or elapsed time

Otherwise, the referencing model can trigger the function-call model at any rate.

- A function-call model must not have direct internal connections between its root-level input and output ports. Simulink does not honor the **None** and **Warning** settings for the **Invalid root Inport/Outport block connection** diagnostic for a referenced function-call model. It reports all invalid root port connections as errors.
- If the **Sample time type** is **periodic**, the sample-time period must not contain an offset.
- The signal connected to a function-call port of a Model block must be scalar.

Reference Conditional Models

To create a reference to a conditional model:

- 1 Add a Model block to the model that you want to reference the triggered model. See “Create a Referenced Model” on page 8-9 for details.

The top of the Model block displays an icon that corresponds to the kind of port used in the referenced model. For example, for a triggered model, the top of the Model block displays the following icon.

For enabled, triggered, and triggered and enabled models, go to Step 3.

- 2 For a function-call model, connect a Stateflow chart, Function-Call Generator block, or other function-call-generating block to the function-call port of the Model block. The signal connected to the port must be scalar.
- 3 Create and connect other blocks to implement the parent model.
- 4 Ensure that the referencing model satisfies the conditions for model referencing. See “Simulink Model Referencing Requirements” on page 8-55 and “Model Referencing Limitations” on page 8-93 for details.

Simulate Conditional Referenced Models

In this section...

“Triggered, Enabled, and Triggered and Enabled Models” on page 8-81

“Function-Call Models” on page 8-81

You can run a standalone simulation of a conditional referenced model. A standalone simulation is useful for unit testing, because it provides consistent data across simulations in terms of data type, dimension, and sample time. Use normal, accelerator, or rapid accelerator mode to simulate a conditional model.

Triggered, Enabled, and Triggered and Enabled Models

Triggered, enabled, and triggered and enabled models require an external input to drive the Trigger or Enable blocks. In the **Signal Attributes** pane of the Trigger or Enable block dialog box, specify values for the signal data type, dimension, and sample time.

To run a standalone simulation, specify the inputs using the **Configuration Parameters > Data Import/Export > Input** parameter. For details about how to specify the input, see “Comparison of Signal Loading Techniques” on page 59-112. The following conditions apply when you use the “Input” parameter for trigger and enable block inputs:

- Use the last data input for the trigger or enable input. For a triggered and enabled model, use the last data input for the trigger input.
- If you do not provide any input values, the simulation uses zero as the default values.

You can log data to determine which signal caused the model to run. For the Trigger or Enable block, in the **Main** pane of the Block Parameters dialog box, select **Show output port**.

Function-Call Models

When you simulate a function-call model, it simulates as if the function-call block were driven by a function call at the fastest rate for the system. You can also configure the model to calculate output at specific times using a variable-step solver (see “Samples to Export for Variable-Step Solvers” on page 59-53).

Protected Model

A protected model provides the ability to deliver a model without revealing the intellectual property of the model. A protected model is a referenced model that hides all block and line information. It does not use encryption technology unless you use the optional password protection available for read-only view, simulation, and code generation. If you choose password protection for one of these options, the software protects the supporting files using AES-256 encryption. Creating a protected model requires a Simulink Coder license. A third party that receives a protected model must match the platform and the version of Simulink for which the protected model was generated.

Simulating a protected model requires that the protected model:

- Be available somewhere on the MATLAB path.
- Be referenced by a Model block in a model that executes in normal, accelerator, or rapid accelerator mode.
- Receives from the Model block the values needed by any defined model arguments.
- Connects via the Model block to input and output signals that match the input and output signals of the protected model.

To locate protected models in your model:

- The MATLAB Folder Browser shows a small image of a lock on the node for the protected model file.
- A Model block that references a protected model shows a small image of a shield in the lower left corner of the Model block.

Note: Protected models do not appear in the model hierarchy in the Model Explorer.

If you use a protected model for operations like viewing a Web view, simulation, or code generation, then the licenses used in the protected model will be checked out before those operations begin. The creator of the protected model can view the licenses of a protected model that will be checked out by looking at the protected model report. To open the report, right-click the protected-model badge icon and select **Display Report**. In the **Summary** of the report, the **Licenses** table lists the licenses required to use the protected model.

For more information, see “Use Protected Model in Simulation” on page 8-85. For more information about creating protected referenced models, see “Protect a Referenced Model”.

Related Examples

- “Use Protected Model in Simulation” on page 8-85

Use Protected Model in Simulation

When you receive a protected model, it might be included in a protected model package. The package could include additional files, such as a harness model and a MAT-file. A protected model file has an `.slxp` extension. A typical workflow for using a protected model in a simulation is:

- 1 If necessary, unpack the files according to any accompanying directions.
- 2 If there is a MAT-file containing workspace definitions, load that MAT-file.
- 3 If there is a harness model, copy the Model block referencing the protected model into your model.
- 4 If the protected model is password protected, then right-click the protected-model badge icon and select **Authorize**. Enter the required passwords, and then click **OK**.
- 5 If a protected model report was generated when the protected model was created, right-click the protected-model badge icon and select **Display Report** to open it. In the **Summary** of the report, check that your Simulink version and platform match the software and platform used to create the protected model.
- 6 Connect signals to the Model block that match its input and output port requirements.
- 7 Provide any needed model argument values. See “Parameterize a Referenced Model” on page 8-62.

There are also other ways to include the protected model into your model:

- Use your own Model block rather than the Model block in the harness model.

Note: When you change a Model block to reference a protected model, the **Simulation mode** of the block is set to **Accelerator**. You cannot change this mode. Furthermore, you cannot use the protected reference model block in **External mode**.

- Start with the harness model, add more constructs to it, and use it in your model.
- Use the protected model as a variant in a Model Variant block, as described in “Set up Model Variants” on page 11-41.
- Apply a mask to the Model block that references the protected model. See “Block Masks”.
- Configure a callback function, such as **LoadFcn**, to load the MAT-file automatically. See “Callbacks for Customized Model Behavior” on page 4-56.

Now you can simulate the model that includes the protected model. Because the protected model is set to accelerator mode, the simulation produces the same outputs that it did when used in accelerator mode in the source model.

Protected Model Web View

The Web view is a read-only reference of the protected model. If the Web view functionality is enabled during creation, you can see this read-only view of a protected model. It is platform independent so you can view it on platforms other than the platform for which you created the protected model. To open the Web view of a protected model, use one of the following methods:

- Right-click the protected-model badge icon and select **Show Web view**.
- Use the `Simulink.ProtectedModel.open` function. For example, to display the Web view for protected model `sldemo_md1ref_counter`, you can call:

```
Simulink.ProtectedModel.open('sldemo_md1ref_counter', 'webview');
```

- Double-click the `.slxp` protected model file in the Current Folder browser.
- In the Block Parameter dialog box for the protected model, click **Open Model**.

Hover over a block in the model Web view to show the parameter values.

If the Web view is password protected, then right-click the protected-model badge icon and select **Authorize**. In the **Model view** box, enter the password, and then click **OK**.

More About

- “Protected Model” on page 8-83

Refresh Model Blocks

Refreshing a Model block updates its internal representation to reflect changes in the interface of the model that it references.

Examples of when to refresh a Model block include:

- Refresh a Model block that references model that has gained or lost a port.
- Refresh all the Model blocks that reference a model whose interface has changed.

You do not need to refresh a Model block if the changes to the interface of the referenced model do not affect how the referenced model interfaces to its parent.

To update a specific Model block, from the context menu of the Model block, select **Subsystem & Model Reference > Refresh Selected Model Block**.

To refresh all Model blocks in a model (as well as linked blocks in a library or model), in the Simulink Editor select **Diagram > Refresh Blocks**. You can also refresh a model by starting a simulation or generating code.

You can use Simulink diagnostics to detect changes in the interfaces of referenced models that could require refreshing the Model blocks that reference them. The diagnostics include:

- **Model block version mismatch**
- **Port and parameter mismatch**

S-Functions with Referenced Models

In this section...
“S-Function Support for Model Referencing” on page 8-88
“Sample Times” on page 8-88
“S-Functions with Accelerator Mode Referenced Models” on page 8-89
“Using C S-Functions in Normal Mode Referenced Models” on page 8-89
“Protected Models” on page 8-90
“Simulink Coder Considerations” on page 8-90

S-Function Support for Model Referencing

Each kind of S-function provides its own level of support for model referencing.

Type of S-Function	Support for Model Referencing
Level-1 MATLAB S-function	Not supported
Level-2 MATLAB S-function	<ul style="list-style-type: none"> • Supports normal and accelerator mode • Accelerator mode requires a TLC file
Handwritten C MEX S-function	<ul style="list-style-type: none"> • Supports normal and accelerator mode • May be inlined with TLC file
S-Function Builder	Supports normal and accelerator mode
Legacy Code Tool	Supports normal and accelerator mode

Sample Times

Simulink software assumes that the output of an S-function does not depend on an inherited sample time unless the S-function explicitly declares a dependence on an inherited sample time.

You can control inheriting sample time by using `ssSetModelReferenceSampleTimeInheritanceRule` in different ways, depending on whether an S-function permits or precludes inheritance. For details, see “Inherited Sample Time for Referenced Models”.

S-Functions with Accelerator Mode Referenced Models

For a referenced model that executes in accelerator mode, set the **Configuration Parameters > Model Referencing > Total number of instances allowed per top model** to **One** if the model contains an S-function that is either:

- Inlined, but has not set the `SS_OPTION_WORKS_WITH_CODE_REUSE` flag
- Not inlined

Inlined S-Functions with Accelerator Mode Referenced Models

For accelerator mode referenced models, if the referenced model contains an S-function that should be inlined using a Target Language Compiler file, the S-function must use the `ssSetOptions` macro to set the `SS_OPTION_USE_TLC_WITH_ACCELERATOR` option in its `mdlInitializeSizes` method. The simulation target does not inline the S-function unless the S-function sets this option.

A referenced model cannot use noninlined S-functions in the following cases:

- The model uses a variable-step solver.
- Simulink Coder generated the S-function.
- The S-function supports use of fixed-point numbers as inputs, outputs, or parameters.
- The model is referenced more than once in the model reference hierarchy. To work around this limitation, use normal mode.
- The S-function uses character vector parameters.

Using C S-Functions in Normal Mode Referenced Models

Under certain conditions, when a C S-function appears in a referenced model that executes in normal mode, successful execution is impossible. For details, see “S-Functions in Normal Mode Referenced Models”.

Use the `ssSetModelReferenceNormalModeSupport` SimStruct function to specify whether an S-function can be used in a normal mode referenced model.

You may need to modify S-functions that are used by a model so that the S-functions work with multiple instances of referenced models in normal mode. The S-functions must indicate explicitly that they support multiple `exec` instances. For details, see “Supporting the Use of Multiple Instances of Referenced Models That Are in Normal Mode”.

Protected Models

A protected model cannot use noninlined S-functions directly or indirectly.

Simulink Coder Considerations

A referenced model in accelerator mode cannot use S-functions generated by the Simulink Coder software.

Noninlined S-functions in referenced models are supported when generating Simulink Coder code.

The Simulink Coder S-function target does not support model referencing.

For general information about using Simulink Coder and model referencing, see “Referenced Models”.

- “S-Function Basics”
- “Simulink Model Referencing Requirements” on page 8-55
- “Model Referencing Limitations” on page 8-93

Buses in Referenced Models

To have bus data cross model reference boundaries, use a bus object (`Simulink.Bus`) to define the bus.

For more information, see “Bus Data Crossing Model Reference Boundaries” on page 63-123. For an example of a model referencing model that uses buses, see `sldemo_mdref_bus`.

More About

- “Bus Data Crossing Model Reference Boundaries” on page 63-123
- “Simulink Model Referencing Requirements” on page 8-55

- “Buses”

Signal Logging in Referenced Models

In a referenced model, you can log any signal configured for signal logging. Use the Signal Logging Selector to select a subset or all of the signals configured for signal logging for a model reference hierarchy. For details, see “Models with Model Referencing: Overriding Signal Logging Settings” on page 59-83.

For additional information, see “Export Signal Data Using Signal Logging” on page 59-57.

“Configuration Parameters Changed During Code Generation” on page 8-100

Introduction

The following limitations apply to model referencing. In addition, a model reference hierarchy must satisfy all the requirements listed in “Simulink Model Referencing Requirements” on page 8-55.

Limitations on All Model Referencing

Index Base Limitations

In two cases, Simulink does not propagate 0-based or 1-based indexing information to referenced-model root-level ports connected to blocks that:

- Accept indexes (such as the Assignment block)
- Produce indexes (such as the For Iterator block)

An example of a block that accepts indexes is the Assignment block. An example of a block that produces indexes is the For Iterator block.

The two cases result in a lack of propagation that can cause Simulink to fail to detect incompatible index connections. These two cases are:

- If a root-level input port of the referenced model connects to index inputs in the model that have different 0-based or 1-based indexing settings, Simulink does not set the 0-based or 1-based indexing property of the root-level **Inport** block.

- If a root-level output port of the referenced model connects to index outputs in the model that have different 0-based or 1-based indexing settings, Simulink does not set the 0-based or 1-based indexing property of the root-level **Output** block.

General Reusability Limitations

If a referenced model has any of the following characteristics, the model must specify **Configuration Parameters > Model Referencing > Total number of instances allowed per top model** as **One**. No other instances of the model can exist in the hierarchy. An error occurs if you do not set the parameter correctly, or if more than one instance of the model exists in the hierarchy. The model characteristics that require that the **Total number of instances allowed per top model** setting be **One** are:

- The model contains any To File blocks
- The model references another model which is set to single instance
- The model contains a state or signal with non-auto storage class
- The model uses any of the following Stateflow constructs:
 - Stateflow graphical functions
 - Machine-parented data

Block Mask Limitations

- Mask callbacks cannot add Model blocks. Also, mask callbacks cannot change the Model block name or simulation mode. These invalid callbacks generate an error.
- If a mask specifies the name of the model that a Model block references, the mask must provide the name of the referenced model directly. You cannot use a workspace variable to provide the name.
- The mask workspace of a Model block is not available to the model that the Mask block references. Any variable that the referenced model uses must resolve to either of these workspaces:
 - A workspace that the referenced model defines
 - The MATLAB base workspace

For information about creating and using block masks, see “Block Masks”.

Simulink Tool Limitations

Working with the Simulink Debugger in a parent model, you can set breakpoints at Model block boundaries. Setting those breakpoints allows you to look at the input and

output values of the Model block. However, you cannot set a breakpoint inside the model that the Model block references. See “Simulink Debugger” for more information.

Stateflow Limitations

You cannot reference a model multiple times in the same model reference hierarchy if that model that contains a Stateflow chart that:

- Contains exported graphical functions
- Is part of a Stateflow model that contains machine-parented data

Subsystem Limitations

- You cannot place a Model block in an iterator subsystem, if the Model block references a model that contains Assignment blocks that are not in an iterator subsystem.
- In a configurable subsystem with a Model block, during model update, do not change the subsystem that the configurable subsystem selects.

S-Function Target Limitation

The Simulink Coder S-function target does not support model referencing.

Other Limitations

- Referenced models can only use asynchronous rates if the model meets *both* of these conditions:
 - An external source drives the asynchronous rate through a root-level Inport block.
 - The root-level Inport block outputs a function-call signal. See **Asynchronous Task Specification**.
- A referenced model can input or output only those user-defined data types that are fixed-point or that `Simulink.DataType` or `Simulink.Bus` objects define.
- To initialize the states of a model that references other models with states, specify the initial states in structure or structure with time format. For more information, see “State Information for Referenced Models” on page 59-235.
- A referenced model cannot directly access the signals in a multirate bus. To overcoming this limitation, see “Connect Multi-Rate Buses to Referenced Models” on page 63-123.
- A continuous sample time cannot be propagated to a Model block that is sample-time independent.

- Goto and From blocks cannot cross model reference boundaries.
- You cannot print a referenced model from a top model.
- To use a masked subsystem in a referenced model that uses model arguments, do not create in the mask workspace a variable that derives its value from a mask parameter. Instead, use blocks under the masked subsystem to perform the calculations for the mask workspace variable.
- An `InitFcn` callback in a top model cannot change parameters used by referenced models.

Limitations on Normal Mode Referenced Models

Normal Mode Visibility for Multiple Instances of a Referenced Model

You can simulate a model that has multiple instances of a referenced model that are in normal mode. All of the instances of the referenced model are part of the simulation. However, Simulink displays only one of the instances in a model window. The normal mode visibility setting determines which instance Simulink displays. Normal mode visibility includes the display of Scope blocks and data port values.

To set up your model to control which instance of a referenced model in normal mode has visibility and to ensure proper simulation of the model, see “Configure Models with Multiple Referenced Model Instances” on page 8-39.

Simulink Profiler

In normal mode, enabling the Simulink Profiler on a parent model does not enable profiling for referenced models. You must enable profiling separately for each referenced model. See “How Profiler Captures Performance Data” on page 28-5.

Limitations on Accelerator Mode Referenced Models

Subsystem Limitations

If you generate code for an atomic subsystem as a reusable function, when you use accelerator mode, the inputs or outputs that connect the subsystem to a referenced model can affect code reuse. See “Reusable Code and Referenced Models” for details.

Simulink Tool Limitations

Simulink tools that require access to the internal data or the configuration of a model have no effect on referenced models executing in accelerator mode. Specifications made

and actions taken by such tools are ignored and effectively do not exist. Examples of tools that require access to model internal data or configuration include:

- Model Coverage
- Simulink Report Generator
- Simulink Debugger
- Simulink Profiler

Runtime Checks

Some blocks include runtime checks that are disabled when you include the block in a referenced model in accelerator mode. Examples of these blocks include Assignment, Selector, and MATLAB Function blocks).

Diagnostic Configuration Parameter Changes

For models referenced in accelerator mode, Simulink ignores certain runtime diagnostics that you set to a value other than `none` or `Disable all`. For details, see “Certain Diagnostic Configuration Parameters Ignored for Models Referenced in Accelerator Mode” on page 8-99.

Data Logging Limitations

The following logging methods have no effect when specified in referenced models executing in accelerator mode:

- To Workspace blocks (for formats other than `Timeseries`)
- Scope blocks
- All types of runtime display, such as Port Values Display

During simulation, the result is the same as if the constructs did not exist.

Accelerator Mode Reusability Limitations

You must set **Configuration Parameters > Model Referencing > Total number of instances allowed per top model** to `One` for a referenced model that executes in accelerator mode and has any of the following characteristics:

- A subsystem that is marked as function
- An S-function that is:
 - Inlined but has not set the option `SS_OPTION_WORKS_WITH_CODE_REUSE`

- Not inlined
- A function-call subsystem that:
 - Has been forced by Simulink to be a function
 - Is called by a wide signal

An error occurs in either of these cases:

- You do not set the parameter correctly.
- Another instances of the model exists in the hierarchy, in either normal mode or accelerator mode

Customization Limitations

Simulation target code generation for referenced models in accelerator mode does not support data type replacement.

S-Function Limitations

- If a referenced model in accelerator mode contains an S-function that should be inlined using a Target Language Compiler file, the S-function must use the `ssSetOptions` macro to set the `SS_OPTION_USE_TLC_WITH_ACCELERATOR` option in its `mdlInitializeSizes` method. The simulation target does not inline the S-function unless the S-function sets this option.
- You cannot use the Simulink Coder S-function target in a referenced model in accelerator mode.
- A referenced model in accelerator mode cannot use noninlined S-functions in the following cases:
 - The model uses a variable-step solver.
 - Simulink Coder generated the S-function.
 - The S-function supports use of fixed-point numbers as inputs, outputs, or parameters.
 - The S-function uses character vector parameters.
 - The model is referenced more than once in the model reference hierarchy. To work around this limitation:
 - 1 Make copies of the referenced model.
 - 2 Assign different names to the copies.

- 3 Reference a different copy at each location that needs the model.

MATLAB Function Block Limitation

A MATLAB Function block in a referenced model that executes in accelerator mode cannot call MATLAB functions.

Other Limitations

- When you create a model, you cannot use that model as an accelerator mode referenced model until you have saved the model to disk. You can work around this limitation by setting the model to normal mode. See “Simulate Model Referencing Models” on page 8-31.
- When the `sim` command executes a referenced model in accelerator mode, the source workspace is always the MATLAB base workspace.
- Accelerator mode does not support the **External mode** option. If you enable the **External mode** option, accelerator mode ignores it.
- In accelerator mode, discrete states of model references are not exposed to linearization. These discrete states are not perturbed during linearization and therefore, they are not truly free in the trimming process.
- The outputs of random blocks are not kept constant during trimming. This can affect the optimization process.

Limitations on Rapid Accelerator Mode Referenced Models

Simulink does not update a Model block with a sim viewing device.

Certain Diagnostic Configuration Parameters Ignored for Models Referenced in Accelerator Mode

For models referenced in accelerator mode, Simulink ignores the values of these configuration parameter settings if you set them to a value other than None:

- **All Parameters > Array bounds exceeded** (ArrayBoundsChecking)
- **Diagnostics > Data Validity > Inf or NaN block output** (SignalInfNanChecking)
- **Diagnostics > Data Validity > Simulation range checking** (SignalRangeChecking)

- **Diagnostics > Data Validity > Division by singular matrix** (CheckMatrixSingularityMsg)
- **Diagnostics > Data Validity > Wrap on overflow** (IntegerOverflowMsg)

Also, for models referenced in accelerator mode, Simulink ignores these **Configuration Parameters > Diagnostics > Data Validity > Data Store Memory block** parameters if you set them to a value other than `Disable all`. For details, see “Data Store Diagnostics” on page 60-3.

- **Detect read before write** (ReadBeforeWriteMsg)
- **Detect write after read** (WriteAfterReadMsg)
- **Detect write after write** (WriteAfterWriteMsg)

You can use the Model Advisor to identify models referenced in accelerator mode for which Simulink ignores the configuration parameters listed above.

- 1 In the Simulink Editor, select **Analysis > Model Advisor**.
- 2 Select **By Task**.
- 3 Run the **Check diagnostic settings ignored during accelerated model reference simulation** check.

To see the results of running the identified diagnostics with settings to produce warnings or errors, simulate the model in normal mode. Inspect the diagnostic warnings and then simulate in accelerator mode.

Limitations on SIL and PIL Mode Referenced Models

See:

- “Simulation Mode Override Behavior in Model Reference Hierarchy”
- “SIL and PIL Limitations”

Configuration Parameters Changed During Code Generation

For referenced models, if these **Configuration Parameters > Code Generation > Symbols** parameters have settings that do not contain a `$R` token (which represents the name of the reference model), code generation prepends the `$R` token to the identifier format:

- **Global variables** (CustomSymbolStrGlobalVar)
- **Global types** (CustomSymbolStrType)
- **Subsystem methods** (CustomSymbolStrFcn)
- **Constant macros** (CustomSymbolStrMacro)

You can use the Model Advisor to identify models in a model referencing hierarchy for which code generation changes configuration parameter settings.

- 1** In the Simulink Editor, select **Analysis > Model Advisor**.
- 2** Select **By Task**.
- 3** Run the **Check code generation identifier formats used for model reference** check.

If a script that operates on generated code uses identifier formats that code generation changes, then update the script to use the updated identifier format (which includes an appended \$R token).

For more information about identifiers, in the Embedded Coder documentation, see “Identifier Format Control”.

Simulink Units

Unit Specification in Simulink Models

Simulink enables you to specify physical units as attributes on signals at the boundaries of model components. Such components can be:

- Subsystems
- Referenced Simulink models
- **Simulink-PS Converter** and **PS-Simulink Converter** blocks that interface between Simulink and components developed in Simscape and its associated physical modeling products
- Stateflow charts, state transition tables, or truth tables
- MATLAB Function blocks

By specifying, controlling, and visualizing signal units, you can ensure the consistency of calculations across the various components of your model. For example, this added degree of consistency checking is useful if you are integrating many separately developed components into a large, overall system model.

In Simulink models, you specify units from a *unit database*. The unit database comprises units from the following unit systems:

- **SI** — International System of Units
- **SI (extended)** — International System of Units (extended)
- **English** — English System of Units
- **CGS** — Centimetre-gram-second System of Units

Based on the type of system you are modeling, you can use any combination of units from these supported unit systems. For more information about supported unit systems and the units they contain, see [Allowed Units](#).

You can assign units to signals through these blocks:

- **Inport**
- **Outport**
- **Signal Specification**
- **MATLAB Function**

- Stateflow Chart

and these objects:

- `Simulink.Signal`
- `Simulink.BusElement`
- `Simulink.Parameter`

When you add a supported block to your model, the **Unit** parameter on the block is set to `inherit` by default. This setting means that the block inherits the unit from a connecting signal that has an explicitly specified unit.

You can explicitly specify units for signals using the **Unit** parameter of a supported block. For this parameter, the dialog box provides matching suggestions to help you:

If you do not provide a correctly formed unit expression, you get an error. Correctly formed unit expressions are a combination of unit names or symbols with properly

balanced parentheses and `*`, `/`, and `^` characters. Special characters such as `[`, `]`, `{`, `}`, `<`, `>`, `\`, `"`, `&`, and so forth are not supported.

By default, a block port has an *empty* (that is, unspecified) unit and the **Unit** parameter is set to `inherit`. When you specify a unit for one port, Simulink checks the unit setting of any port connected to it. If a port has an empty unit, you can connect it to another port that has any supported unit. If a port unit parameter is set to `inherit`, it inherits the unit from a connected port that has a specified unit.

Specify Physical Quantities

When you model a physical system, it is possible to use the same unit expression for two or more signals that represent different physical quantities. For example, a unit expression of `N*m` can represent either torque or energy. To prevent mistaken connection of two ports with the same unit but representing different physical quantities, you can add a physical quantity to the unit expression. For example, for the same unit of `N*m`, you can specify different physical quantities of `N*m@torque` and `N*m@energy`. Similar to units, the dialog box provides suggestions as you type the names of physical quantities.

Physical quantities help you to enforce an extra degree of unit consistency checking between connected ports. When you attempt to connect ports with different physical quantities, the model displays a warning.

Specify Units in Objects

By default, `Simulink.Signal`, `Simulink.BusElement`, and `Simulink.Parameter` objects have empty units. In the case of a:

- `Simulink.Signal` object, the empty unit means that the corresponding signal can inherit a unit from an upstream or downstream port.
- `Simulink.BusElement` object, the empty unit means that the corresponding bus element signal also has an empty unit. You can connect the signal to a port with any unit, but the signal does not inherit a unit from the port.
- `Simulink.Parameter` object, the object does not attach a unit to the corresponding parameter value.

If you specify a unit in a `Simulink.Signal` or `Simulink.BusElement` object, Simulink applies the attribute to the corresponding signal line when:

- The `Simulink.Signal` object resolves to a signal in the model

- You use a bus element signal that is associated with a `Simulink.Bus` object with a Bus Creator, Bus Selector, or Bus Assignment block.

If you use either of these objects with a Data Store block, Simulink does not display any unit attribute.

For the `Simulink.Parameter` object, Simulink does not apply any attribute. For all objects, if the **Unit** parameter has a value that is not formed correctly, you see an error. If the unit is formed correctly but is undefined, you see a warning when you compile the model. If the unit expression contains special characters such as `[,]`, `{ , }`, `< , >`, `\`, `"`, `&`, and so forth, Simulink replaces them with underscores (`_`).

Specify Units for Temperature Signals

When modeling absolute temperature quantities, use units such as K, degC, degF, and degR. When modeling temperature *difference* quantities, use units such as deltaK, deltadegC, deltadegF, and deltadegR. If you connect a signal that has a temperature difference unit to a block that specifies an *absolute* temperature unit, Simulink detects the mismatch.

Specify Units in MATLAB Function Blocks

You can specify units for input and output data of MATLAB Function blocks by using the **Unit** parameter on the Ports and Data Manager.

During model update, Simulink checks for inconsistencies in units between input or output data ports and the corresponding signals.

Specify Units for Logging and Loading Signal Data

You can include units in signal data that you log or load.

You specify units for logging and loading using `Simulink.SimulationData.Unit` objects. When you log using `Dataset` or `Timeseries` format, Simulink stores the unit information using `Simulink.SimulationData.Unit` objects. If you create MATLAB timeseries data to load, you can specify `Simulink.SimulationData.Unit` object for the `Units` property of the `timeseries` object.

For details, see “Log Signal Data That Uses Units” on page 59-36 and “Load Signal Data That Uses Units” on page 59-208.

Restricting Unit Systems

By default, you can specify units from any of the supported unit systems. However, in large modeling projects, to enforce consistency, you might want to restrict the unit systems that certain components of your model can use. To specify available unit systems for a model, in the configuration parameter **Allowed unit systems**, enter **all** or a comma-separated list containing one or more of **SI**, **SI (extended)**, **CGS**, and **English**. Do not use quotation marks. If your model contains referenced models, you can use the **Allowed unit systems** to restrict units in each of those referenced models. If your model contains subsystems, you can use the **Unit System Configuration** block to restrict units in the subsystems. You can also optionally use a **Unit System Configuration** block in a model. In this case, the settings in the **Unit System Configuration** block override whatever you specify in **Allowed unit systems**.

To restrict unit systems in a model:

- 1 In the **Unit** parameter of the Inport, Outport, or Signal Specification block, click the link.

If a **Unit System Configuration** block exists in your model, this link opens the block dialog box. Otherwise, the link opens the **Allowed unit systems** configuration parameter.

- 2 Specify one or more the desired unit systems, **SI**, **SI (extended)**, **English**, or **CGS**, in a comma-delimited list, or **all**, without quotation marks.

In a parent-child relationship (for example, a top model with a referenced model or subsystem), you can specify different unit systems for each component. However, if a child propagates a unit into a parent that is not in the unit systems specified for the parent, you get a warning.

To check whether there are unit mismatches caused by restricted unit systems in your model hierarchy:

- Press **Ctrl+D** and visually inspect the model for warning badges.
- Use the Model Advisor check **Identify disallowed unit systems**.

- “Troubleshooting Units” on page 9-25

Displaying Units

To display signal units in your model, select **Display > Signals & Ports > Port Units**. To select this option programmatically, use the command-line property `ShowPortUnits`.

With this option selected, the model dynamically updates port and signal labels to show any changes that you make to units. You do not need to press **Ctrl+D** to update the model. When you simulate your model, the **Scope** block displays units for connected signals as *y*-axis labels.

Note: When you explicitly specify units on inport or outport blocks, block port labels and signal lines display those units. If a port is set to inherit units or has empty units, port labels and signal lines do not show labels.

Note: With the option to display units cleared, you do not see port and signal labels, even when you press **Ctrl+D** to update your model. However, you do see warning or error badges for any unit inconsistency problems that exist in the model.

You can also see units in the interface view of your model. Select **Display > Interface**.

- “Troubleshooting Units” on page 9-25

Unit Consistency Checking and Propagation

Simulink performs unit consistency checking between components. Ports that you connect together — sometimes via intermediate blocks that propagate units — must have the same units. For example, you cannot connect a port with unit ft/s to a port with unit m/s^2 .

By default, Simulink shows the mismatch warning  when it detects a mismatch in units between two connected ports. You can press **Ctrl+D** to show mismatched units in your model.

To make this connection valid, you can:

- Explicitly set both port units to the same unit.
- Set the **Unit** parameter of one of the connecting ports to `inherit`.
- Insert a **Unit Conversion** block between the mismatched units if they are separated by a scaling factor or offset, or if they are inverse units. These units are *convertible*. For more information, see “Converting Units” on page 9-15.
- Select the **Allow automatic unit conversions** configuration parameter. For more information, see “Converting Units” on page 9-15.

Note: Simulink supports variations on unit expressions. For example, one port can have a unit of m/s^2 and a connected port can have a unit of $m/s/s$. In these cases, Simulink does not display a warning for mismatched units.

When Simulink detects one of these conditions, it displays the inconsistency warning :

- Disallowed unit system
- Undefined unit

Simulink checks the consistency of unit settings and propagates units across component boundaries. In a model that contains a referenced model, Simulink compiles the referenced model independently of the top model. This independent compilation means that the referenced model cannot inherit units from the top model.

If a port in a referenced model has **Unit** set to `inherit`, it can inherit a unit from any upstream or downstream block in the referenced model. If the port does not inherit a unit from an upstream or downstream block, you can connect it to a port in the top model with any unit.

Simulink passes units through the following blocks that do not change data, known as *noncomputation* blocks:

- Bus Creator
- Bus Selector
- Bus to Vector
- Data Type Conversion
- Demux
- From
- Goto
- Inport
- Merge
- Model
- Mux
- Outport
- Rate Transition
- Signal Conversion
- Signal Specification
- Subsystem
- Variant Sink
- Variant Source

Note: If you supply two or more signals with different units to a Mux block, Simulink applies empty units to the vector signal that the Mux block outputs. Vector signals must have a common unit.

Note: If you have a nonvirtual bus in your model (see “Virtual and Nonvirtual Buses” on page 63-4), Simulink sets the unit of the bus to empty. A nonvirtual bus cannot have a unit. However, if the bus element signals themselves have units, Simulink does not change these.

Simulink does not propagate units through blocks that produce new data as output. When signals with units pass through these blocks, the units of these signals become empty. Examples of blocks that do not preserve units because they produce new data as an output include:

- Sum
- Gain
- Filter
- Product

Unit Propagation Between Simulink and Simscape

When modeling physical systems, you might want to integrate components developed in Simulink with components developed in Simscape and its associated physical modeling products. Simscape components use physical signals instead of regular Simulink signals. Therefore, you need **Simulink-PS Converter** and **PS-Simulink Converter** converter blocks to connect signals between Simulink and Simscape components.

To specify units for the input and output signals of your Simscape component, you can explicitly specify the units on the converter blocks. When you specify units on a **PS-Simulink Converter** block that converts a signal from Simscape to Simulink, Simulink propagates the unit settings to the connected Simulink port. However, Simulink cannot propagate a signal unit from Simulink into your Simscape component. To do that, you must explicitly specify the unit on the **Simulink-PS Converter** block. For more information, see “Physical Units” in the Simscape documentation.

Converting Units

Simulink can convert units between ports when it detects discrepancies that have known mathematical relationships such as:

- Scaling factors
- Conversion factors and offsets, such as F (Fahrenheit) to C (Celsius)
- Scaled, inverse units, such as mpg (miles per gallon) and L/km (liters per kilometer).

For example, if you connect one port with a unit of cm to one with a unit of mm, Simulink can automatically scale one unit to work with the other.

To enable Simulink to convert unit mismatches in your model automatically, select the **Allow automatic unit conversions** configuration parameter.

- When Simulink successfully converts signal units at a block port, it displays .
- When Simulink detects that an automatic conversion is not possible, it displays .

To manually convert units separated by a conversion factor or offset:

- 1 Clear the **Allow automatic unit conversions** configuration parameter.
- 2 Insert a **Unit Conversion** block between the ports whose units you want to convert.

Tip Automatic conversion of units is a convenience. For better control of units, when Simulink detects a mismatch, consider modifying the units specified at one or the other of the two connected ports.

Automatic Unit Conversion Limitations

Simulink does not support automatic conversion:

- At the boundaries of virtual subsystems. Virtual subsystems have the **Treat as atomic unit** parameter cleared. For more information, see “Nonvirtual and Virtual Blocks” on page 33-2.
- At the root level of models configured for concurrent execution or export-function models. For more information, see “Configure Your Model for Concurrent Execution” on page 14-24 and “Export-Function Models” on page 10-4.

- For fixed-point and integer signals.
- At an input port of a Merge block.
- At any port of an asynchronous Rate Transition block.
- At an input port of a function-call subsystem.
- For bus signals.

Update an Existing Model to Use Units

This example shows how to add units to an existing model. You see how to:

- Use an incremental workflow to add units to components in your model
- Integrate components that use different unit systems
- Specify units for individual elements of a bus object
- Troubleshoot unit mismatch problems

The model in the example is a fuel control system. The controller (Fuel Rate Controller) and plant (Engine Gas Dynamics) components of the model are nonvirtual subsystems. Nonvirtual subsystems have the **Treat as atomic unit** parameter selected. You introduce units to the plant before introducing units to the controller and connecting signals. You also specify units for the individual elements of a bus object in the model.

Open the `ex_units_fuelsys` example model.

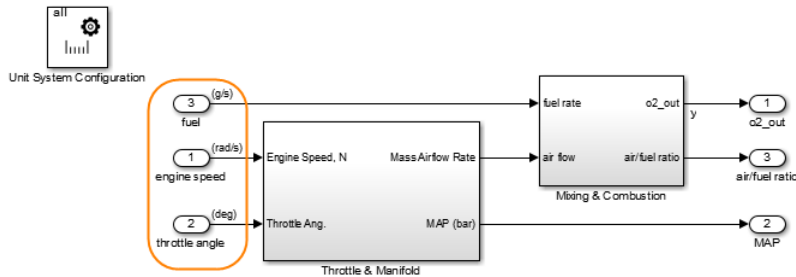

For the top model, the **Allowed unit systems** configuration parameter determines the unit systems the model can use. For each of the plant and controller subsystems, a Unit System Configuration block determines the allowed unit systems.

Component	Allowed Unit Systems
Top model	SI
Fuel Rate Controller subsystem (controller)	all
Engine Gas Dynamics subsystem (plant)	all

In the plant subsystem, on the **Signal Attributes** tab of each inport block dialog box, set the **Unit** parameter to a value appropriate for the connected physical signal.

Block	Physical Signal	Unit Parameter Setting
1	engine speed	rad/s (radians per second)
2	throttle angle	deg (degrees)
3	fuel rate	g/s (grams per second)

To display units on ports and signals in the model, select **Display > Signals & Ports > Port Units**.

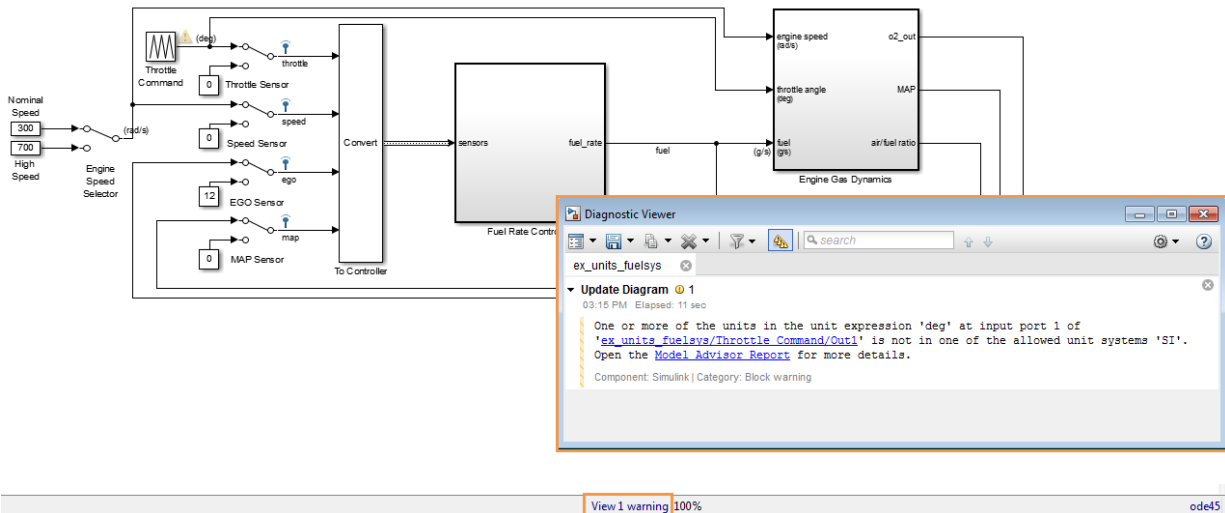

In the plant subsystem, you see units on the inport blocks and connected signals.

Navigate back to the top model. To compile the model, press **Ctrl+D**, which also performs unit consistency checking.

The model displays a warning to indicate that there is a disallowed unit for the `throttle angle` signal. Clicking the warning icon displays a link to a Model Advisor report that gives you more detail.

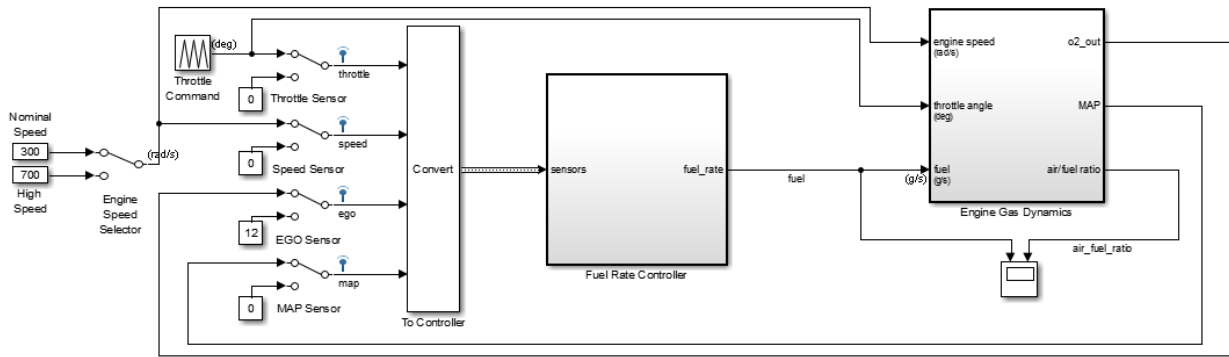

The model also displays the warning at the bottom of the model editing window.

In the plant subsystem, you specified a unit of `deg` (degrees) for the `throttle angle` signal. However, the warning message indicates that degrees are not in the SI unit system. As determined by the **Allowed unit systems** configuration parameter, SI is the only unit system that the top model currently allows. To resolve this warning, you have two options:

- In the plant subsystem, specify a unit for the `throttle angle` signal that the SI unit system supports. For more information about supported unit systems and the units they contain, see [Allowed Units](#).
- In the top model, change the **Allowed unit systems** configuration parameter to expand the set of allowed unit systems.

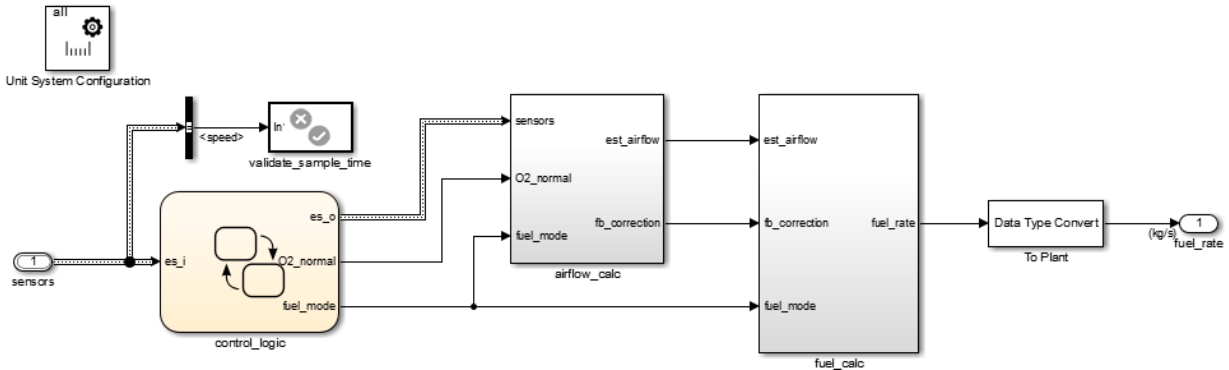

In this case, a unit of `deg` for the `throttle angle` signal is appropriate. Instead, to resolve the warning, expand the set of allowed unit systems for the top model. Set the **Allowed unit systems** configuration parameter of the top model to `all`. To recompile the model, press **Ctrl+D**.

100%

The top model no longer displays warnings.

Now that you have introduced units to the plant and successfully resolved unit inconsistency problems, you can add units to the controller. In the Fuel Rate Controller subsystem, set the **Unit** parameter of the fuel_rate outport block to kg/s (kilograms per second).

Navigate back to the top model. To recompile it, press **Ctrl+D**.

The top model now shows a warning for mismatched units between the controller and plant. To resolve this error, you can:

- Explicitly insert a Unit Conversion block between the two components.
- Select the **Allow automatic unit conversions** configuration parameter.

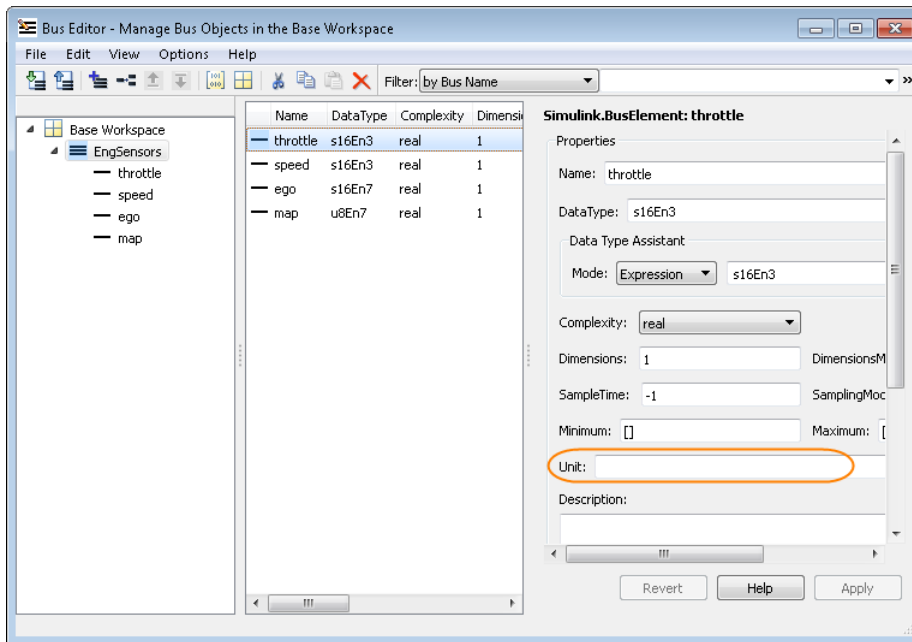

Both options convert units in the same way. A situation in which you might disallow automatic conversions and insert conversion blocks instead is when you are integrating many components in a large system model. In that case, manually inserting conversion blocks can give you an added degree of control of unit conversions in the model. Also, with a conversion block, you can control the data type of the converted signal. This is useful, for instance, when you are modeling for fixed-point precision.

In this case, to enable Simulink to resolve the unit mismatch automatically, select **Allow automatic unit conversions**. To recompile the model, press **Ctrl+D**.

Simulink automatically converts units between the controller and the plant. An automatic conversion icon replaces the warning.

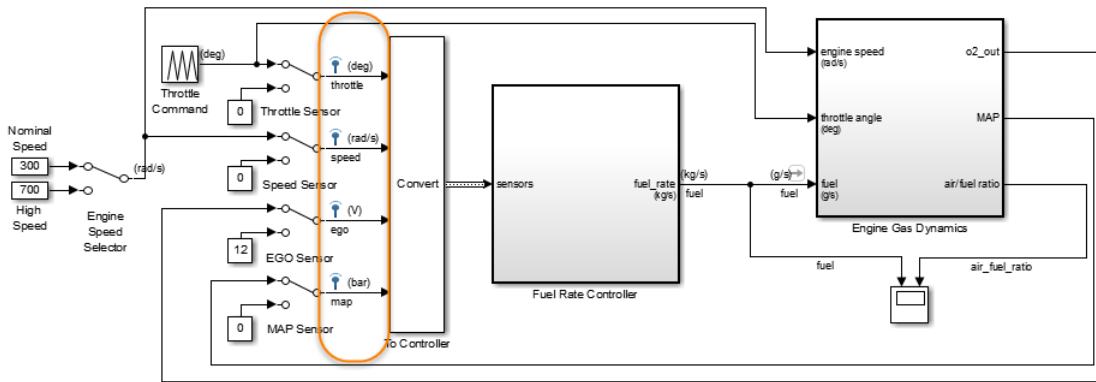

The top model includes a `EngSensors` bus object that passes various sensor signals as a composite signal to the controller. To use the Bus Editor to add units to individual elements of the bus object, select **Edit > Bus Editor**.

For the `EngSensors` bus object, set the **Unit** parameter of each element.

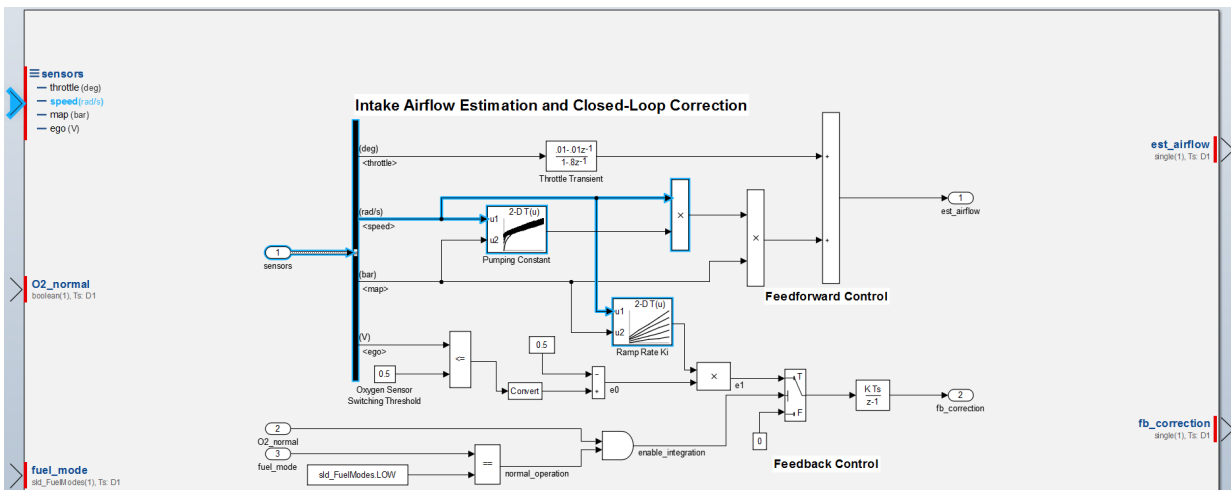

Signal	Unit Parameter Setting
throttle	deg (degrees)
speed	rad/s (radians per second)
ego	V (volts)
map	bar (bars)

To recompile the model, press **Ctrl+D**.

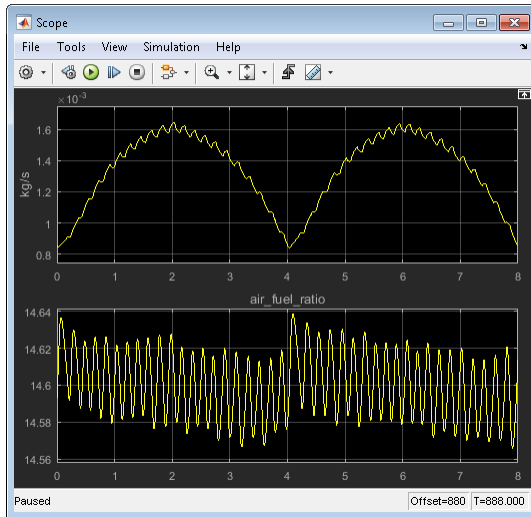

The model shows units on the individual elements of the bus object.

You can also see the units in the interface view of your model. Select **Display > Interface**.

The `airflow_calc` block of the controller subsystem displays units on the individual elements of the bus object, both at the component interface and within the component.

After you introduce units incrementally and resolve inconsistency and mismatch issues, you can simulate the model.

For the fuel signal that is connected to the scope, the plot window displays the associated units of kg/s as a y-axis label.

“Unsuccessful Automatic Unit Conversions” on page 9-27

“Simscape Unit Specification Incompatible with Simulink” on page 9-27

To help you troubleshoot issues with unit settings, Simulink uses Model Advisor checks to generate a report useful for larger models.

By default, Simulink flags unit usage issues, such as mismatched units, with warnings. Warnings enable you to continue working despite mismatched units. You can reduce the number of warnings you see by setting the configuration parameter **Units inconsistency messages** to **none**.

Undefined Units

Simulink does not support custom unit specifications. For more information about supported unit systems and the units they contain, see Allowed Units.

The Model Advisor check “Identify undefined units in the model” identifies undefined units.

Overflow and Underflow Errors or Warning

You can get overflow and underflow errors or warnings when using the Unit Conversion block. If you get:

- Overflow messages, change the data type at the output port to one with a better range
- Underflow messages, change the data type at the output port to one with better precision

Mismatched Units Detected

At the boundary of a component, Simulink detects if the units of two ports do not match. To see the tooltip, hover over the warning badge. If the unit is convertible, Simulink displays advice on fixing the issue.

The Model Advisor check “Identify unit mismatches in the model” identifies mismatched units.

Mismatched Units Detected While Loading

At the boundary of a component, Simulink detects if the units of two ports do not match. To see the tooltip, hover the warning badge. When possible, Simulink displays advice on fixing the issue.

The Model Advisor check “Identify unit mismatches in the model” identifies mismatched units.

Disallowed Unit Systems

Simulink supports only the unit systems listed in the tables of allowed units.

The Model Advisor check “Identify disallowed unit systems in the model” identifies unit systems that are not allowed in the configured units systems.

Automatic Unit Conversions

If the **Allow automatic unit conversions** configuration parameter is set, Simulink supports the automatic conversion of units. Simulink flags automatically converted units with the  badge.

For a list of the automatic unit conversions, use the Model Advisor check “Identify automatic unit conversions in the model”.

Unsuccessful Automatic Unit Conversions

If the **Allow automatic unit conversions** configuration parameter is set, Simulink supports the automatic conversion of units. If Simulink cannot perform the automatic unit conversion, Simulink returns a warning (). In such cases, consider manually specifying the unit.

Tip Automatic unit conversion is a convenience. For better control of units, you can manually set the units for two connecting ports.

Simscape Unit Specification Incompatible with Simulink

If these are true:

- You define a new unit to your unit registry by using the `pm_addunit` function.
- You use the new unit with the Simulink-PS Converter or PS-Simulink Converter block.
- Your new unit conflicts with an existing one in the Simulink database.

Simulink returns a warning about a potential incorrect calculation (.

Conditional Subsystems

A subsystem is a group of blocks within a single Subsystem block.

A conditional subsystem (also known as a conditionally executed subsystem) is a special kind of subsystem where you can control execution with an external signal. The external signal that controls whether a subsystem executes is called the *control signal*. The signal enters a subsystem block at the *control input*.

Conditional subsystems can be very useful when you are creating complex models that contain components whose execution depends on other components. Simulink supports the following types of conditional subsystems:

- An *enabled subsystem* executes while the control signal is positive. It starts execution at the time step where the control signal crosses zero (from the negative to the positive direction) and continues execution as long as the control signal remains positive. For a more detailed discussion, see “Create an Enabled Subsystem” on page 10-23.
- A *triggered subsystem* executes once each time a trigger event occurs. A trigger event can occur on the rising or falling edge of a trigger signal, which can be continuous or discrete. For more information about triggered subsystems, see “Create a Triggered Subsystem” on page 10-40.
- A *triggered and enabled subsystem* executes once at the time step for which a trigger event occurs if the enable control signal has a positive value at that step. See “Create a Triggered and Enabled Subsystem” on page 10-48 for more information.
- A *control flow subsystem* executes one or more times at the current time step when enabled by a control flow block. A control flow block implements control logic similar to that expressed by control flow statements of programming languages (e.g., `if-then`, `while-do`, `switch`, and `for`). See “Use Control Flow Logic” on page 4-47 for more information.

Note The Simulink software imposes restrictions on connecting blocks with a constant sample time to the output port of a conditional subsystem. See “Use Blocks with Constant Sample Times in Enabled Subsystems” on page 10-29 for more information.

“Comparison Between Export-Function Models and Models with Asynchronous Function-Call Inputs” on page 10-21

About Export-Function Models

Simulink provides the capability to export functions from Simulink models that are invoked by controlling logic that is outside the model. Such models are called export-function models, and their functional blocks are made up exclusively of function-call subsystems, function-call model blocks or other export-function models. These blocks are invoked using function-call triggers passed via root-level Inport blocks. Execute these functions by providing model inputs through root-level Inport blocks or by referencing this model in a top model to invoke the function-calls. The execution of these functions is subject to the guidelines described in “Requirements for Export-Function Models” on page 10-5.

The figure shows an export-function model and the resulting generated functions.

Requirements for Export-Function Models

To set up a model to export functions, first meet these requirements. These requirements ensure that the executable components of the model are made up only of function-call blocks.

- The model solver must be a fixed-step discrete solver.
- Configure each root-level Inport block triggering a function-call subsystem to output a function-call trigger. These Inport blocks cannot be connected to an Asynchronous Task Specification block.
- Export-function models generate functions to be integrated with an external environment. Simulink does not generate a step function or a terminate function, and all blocks in these models must be executed in a function-call context. Thus, the model must contain only the following blocks at root level:
 - Function-call blocks, such as Function-Call Subsystem, S-functions, and Simulink Function blocks. Function-call Model blocks can be placed at the root-level only if their model parameter **Configuration Parameters > Solver > Tasking and sample time options > Periodic sample time constraint** is set to **Ensure sample time independent**.
 - Inport and Outport blocks
 - Blocks with a sample time of Inf

- Merge and Data Store Memory blocks
- Virtual connection blocks (Function-Call Split, Mux, Demux, Bus Creator, Bus Selector, Signal Specification, and any virtual subsystem that contains any of the blocks listed.)
- Blocks inside function-call subsystems must support code generation. These blocks can use absolute or elapsed time if they are inside a periodic function-call subsystem with a discrete sample time specified on the corresponding function-call root-level Inport block.
- Data signals connected to root-level Inport and root-level Outport blocks cannot be a virtual bus.
- Data logging and signal-viewer blocks, such as the Scope block, are not allowed at the root level and within the function-call blocks.

Sample Time for Function-Call Subsystems in Export-Function Models

There are two blocks for each function-call subsystem in export-function models where you need to specify the sample time. These blocks are the function-call root-level Inport block and the Trigger block inside the function-call subsystem. The table shows how to specify these sample times.

	Function-call root-level Inport block with inherited sample time (-1) specified	Function-call root-level Inport block with discrete sample time specified
Trigger block of function-call subsystem has sample time type set to Periodic	Configuration not allowed.	Set sample time of Trigger block to inherited (-1) or the sample time of the function-call root-level Inport block. The subsystem executes at the specified rate. Periodic function-call run-time checks apply if the export-function model is used as a referenced model in normal simulation mode. These subsystems can contain blocks that use

		<p>elapsed time (e.g., Discrete-Time Integrator) and blocks that use absolute time (e.g., Digital Clock).</p> <p>You cannot set the model configuration parameter Fixed-step size (fundamental sample time) to auto.</p>
<p>Trigger block of function-call subsystem has sample time type set to Triggered</p>	<p>No sample time specification.</p>	<p>No sample time specification. The subsystem executes at the specified rate.</p> <p>You cannot set the model configuration parameter Fixed-step size (fundamental sample time) to auto.</p>

Sample Time in Top Model Function-Call Initiators

The blocks that output function-call signals to the function-call root-level Inport blocks of the export-function models are called *function-call initiators*. When a top model references an export-function model, the blocks that supply the function-call inputs to the referenced model are the function-call initiators in the top model.

Top model function-call initiators that drive function-call blocks in the referenced export-function model can have different sample times. You can also mux function-call initiator blocks with different sample times before feeding them to the referenced export-function model. In the Solver pane of the Configuration Parameters dialog box, when you clear the **Treat each discrete rate as a separate task** check box, function-call initiator blocks with smaller sample times execute first.

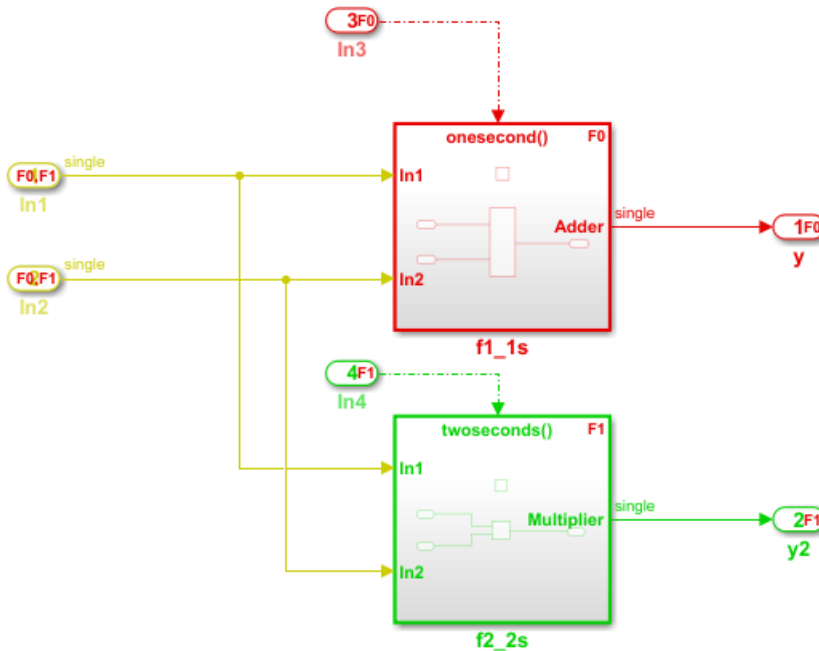

The sample time of function-call initiators must be an integer multiple of the sample time of the corresponding data inputs to the export-function model. The initiators must invoke a function-call subsystem in an export-function model at simulation times that are integer multiples of the sample time of the function-call root-level Inport block of the subsystem.

When you mux function-call initiator blocks in the top-level model, the function-call blocks they invoke do not receive the name of the initiator.

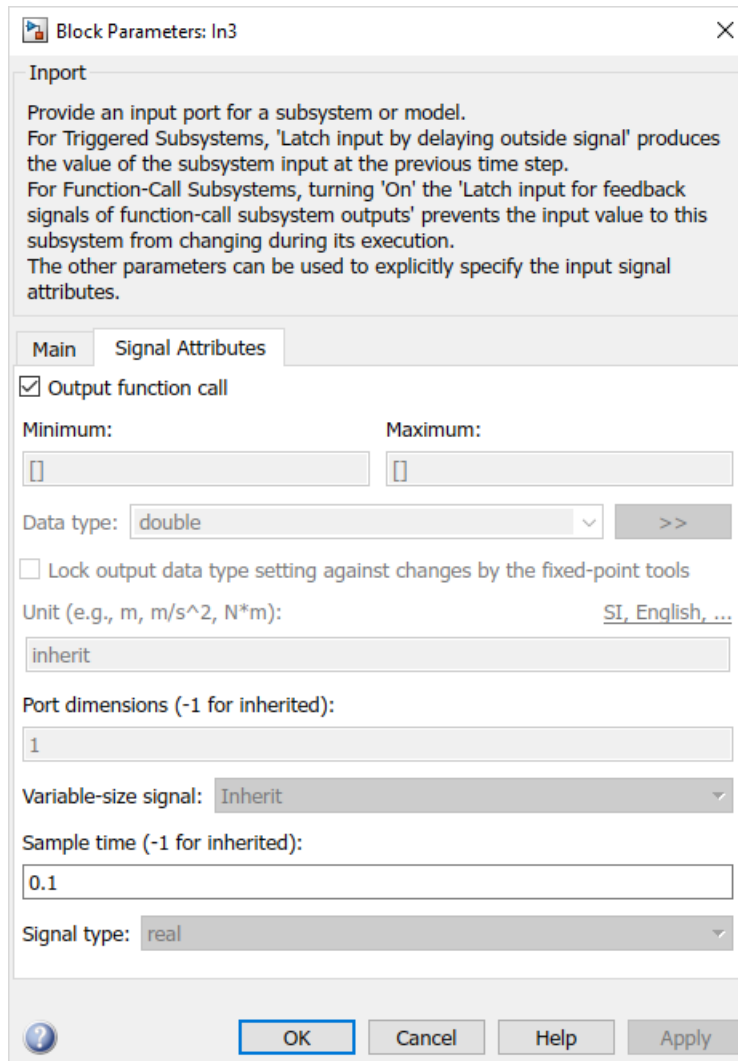

Control Export Function Scheduling Using Sample Time

You can use the sample time of each export function call in your model to control the scheduling of triggers. In the following example, notice that the order of the function-call triggers are determined by the sample times of their corresponding export-function blocks.

In this example, the function calls are scheduled based on the sample time specified on the function-call port. Based on the color-coded display, `onesecond` (F0) executes every 0.1 time steps while function `twoseconds` (F1) executes every 0.2 time steps.

You specify the sample time on the root-level function-call input ports.

Using the sample time, you can have more fine-grained control over how function-call triggers are scheduled in your model.

For standalone export-function models, the ordering rules for function calls are as follows:

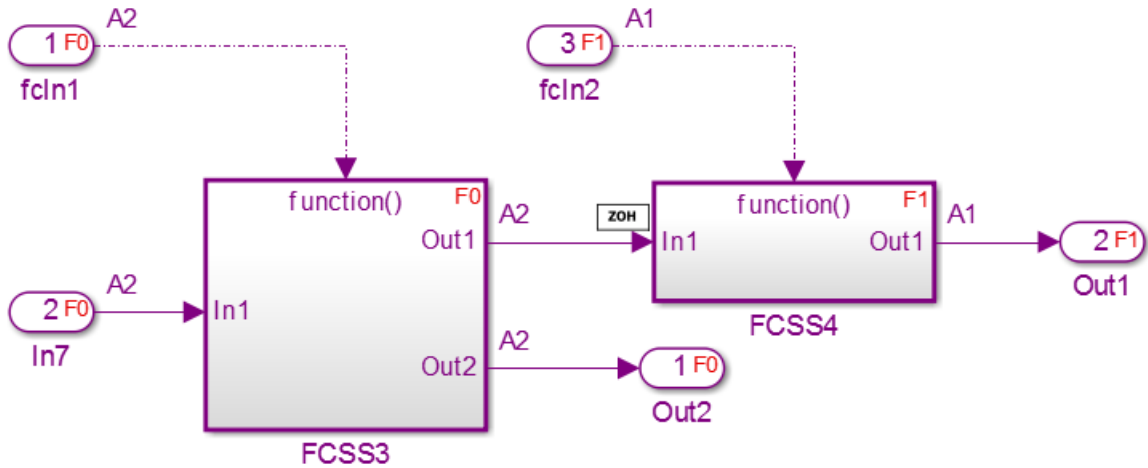

- Irrespective of the sample time, the block with the highest block sorting priority executes first, followed by blocks with decreasing sorting priorities. Two blocks with the same priority are not supported.
- If two blocks do have the same priority, the block that specified the faster rate executes first.
- If the rates of two blocks are also the same, the block with the lower port index runs first.

For example, consider three function calls with input ports specified as follows: A1 (Ts = 2), A2 (Ts = 3, Priority = 10), A3 (Ts = 2, Priority = 11).

The execution order in this case is A2, A3, A1.

Execution Order for Function-Call Root-level Inport Blocks

You can display the sorted execution order to interpret simulation results. This display has no impact on generated code. To display the sorted execution order, select **Display > Blocks > Sorted Execution Order**. In the following example, notice the sorted order for both the function-call triggers. Based on sorted order display labels, fcIn1 (F0) executes before fcIn2 (F1) when both have a sample hit at the same time step.

The referenced export-function model in the top model shows the local execution order of the Inport and Outport blocks in the model.

Simulink compares Inport block properties to determine their relative execution order. Simulink checks the block properties in this order:

- 1 Priority (lower priority executes first)
- 2 Sample time (smaller sample time executes first)
- 3 Port number (smaller port number executes first)

When two blocks have different values for the **Priority** parameter, the block with the lower priority executes first. If the **Priority** parameter is equal, the block with the faster rate executes first. If **Priority** and sample time are the same for both of the blocks, the block with the lower port number executes first. This example shows how relative execution order is calculated.

Note: When the simulation mode of the top model is **Accelerator** or **Rapid Accelerator**, Simulink does not perform run-time checks for the execution order of function-call root-level Inport blocks inside referenced export-function models.

Determine Relative Execution Order

Suppose that an export function model has five function-call root-level Inport blocks, A to E, with block properties as shown in the table. To determine their relative execution order, Simulink compares their sample times (if distinct and noninherited), **Priority** parameter, and port number, in order.

function-call root-level Inport	A	B	C	D	E
Priority	10	30	40	40	30
Sample Time	-1	0.2	0.1	0.1	-1
Port Number	5	4	3	2	1

Block A has the lowest priority of all five blocks. A executes first.

Using the same logic, B and E execute after A but before C and D. Since B and E have the same priority, Simulink compares their sample time to determine execution order. E has a sample time of -1 (inherited), which is smaller than 0.2, the sample time of B. E executes before B.

C and D have the same priority and the same distinct, noninherited sample times. The port number for D (2) is smaller than C (3), D executes before C.

The relative execution order of these Inport blocks, then, is A, E, B, D, and C.

Scheduling Restrictions for Referenced Export-Function Models

If a top model references an export-function model, there are restrictions on function-call subsystems within the export-function model. These restrictions ensure consistency with standalone simulation results.

- In the top model, the same function-call initiator must output function-calls originating with the same sample time. You cannot use two function-call initiators with the same sample time. You cannot disable this restriction.
- The function-call inputs from the top model must follow the execution order of the function-call Inport blocks in the referenced export-function model. You can disable this restriction.

- The sample time of the function-call root-level Inport block must be inherited (-1) or match the sample time of the function-call initiator block that drives it. If you disable this restriction, the sample time of the function-call root-level Inport block must be inherited (-1) or an integer multiple of the sample time of the function-call initiator block.

To disable the restrictions, clear the check box **Model Configuration Parameters > Model Referencing > Enable strict scheduling checks for referenced export-function models**.

An error appears if the top model calls the referenced model functions out of order at any time step. For information on sorted execution order, see “Control and Display the Sorted Order” on page 33-26.

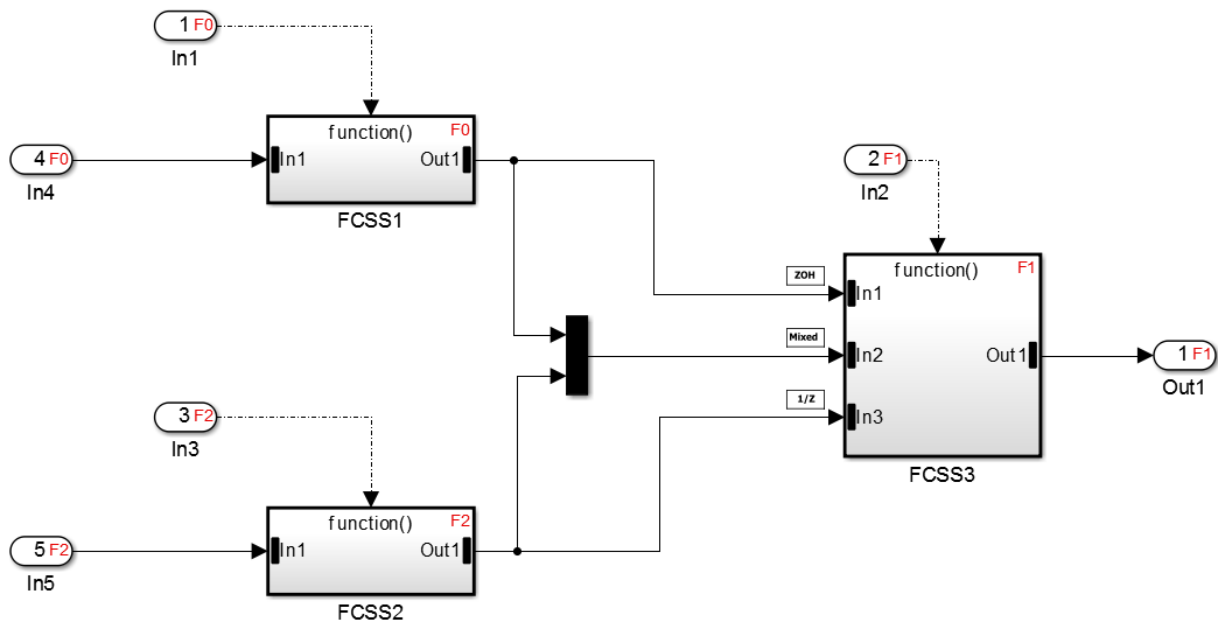

Data Transfer Between Function-Call Subsystems

You must know the timing of the data being transferred between function-call subsystems to understand and interpret simulation results.

To display which subsystem executes first during simulation, the signal lines are annotated with different symbols at the input ports of the subsystems:

- **ZOH** indicates that all source function-call subsystems execute before the function-call block reading this signal.
- **1/z** indicates that all source function-call subsystems execute after the function-call block reading this signal.
- **Mixed** indicates that some source function-call subsystems execute before and some function-call subsystems execute after the function-call block reading this signal.

In the block diagram, notice the sorted execution order for each block. We can see that for the input port **In1** of subsystems **FCSS3** (F1), the source subsystem **FCSS1** (F0) executes before **FCSS3** (F1). Hence, a badge of **ZOH** is added next to **In1**. Similarly, **FCSS2** (F2) executes after **FCSS3** (F1). Hence, Simulink adds a badge of **1/z** next to **In3** of subsystem **FCSS3** (F1). Port **In2** inputs signals from both **FCSS1** (F0) and **FCSS2** (F2). Hence, it has a badge **Mixed** next to it.

You can latch Inport blocks in function-call subsystems to ensure data integrity. If your function-call subsystems have Inport blocks that are latched, then the root-level data Inport block of the export-function model is latched only if all the data Inport blocks it is feeding to are latched. For more information, see “Latch input for feedback signals of function-call subsystem outputs”.

When referencing an export function model or a model with asynchronous function-call inputs, the data input to the referenced model is latched if all function-call block inputs it feeds inside the referenced model are latched.

Note: Data transfer signals are unprotected in the generated code by default. You must prevent data corruption in these signals due to pre-emption in the target environment or implementing protection using custom storage classes.

Workflows for Export-Function Models

The most common workflow is to test function-call behavior through simulation and generate the functions using standalone code generation.

Standalone Simulation

When function-call sequencing is simple enough to be specified as a model input, standalone simulation is the preferred workflow. For a standalone simulation, create data sets for the function-call and data root-level Inport blocks. For more information on function-call inputs, see “Specifying Function-Call Inputs” on page 10-15.

You can also specify the execution order for function-call subsystems. For more information, see “Execution Order for Function-Call Root-level Inport Blocks” on page 10-10.

Specifying Function-Call Inputs

You can create data sets for the function-call and data root-level Inport blocks in **Simulation > Model Configuration Parameters > Data Import/Export > Input**.

For function-call inputs, specify a time-vector indicating when events occur.

- The time vector data type must be double and monotonically increasing.
- All time data must be integer multiples of the model sample time.
- To specify multiple function-calls at a given time step, repeat the time value accordingly. For example, to specify three events at $t = 1$ and two events at $t = 9$, list 1 three times and 9 twice in your time vector, $\mathbf{t} = [1\ 1\ 1\ 9\ 9]'$.

The normal data input can use any other supported format as described in “Forms of Input Data” on page 59-139.

Consider the following export-function model with one function-call input port **fcIn1** and one data input **In2**.

In the **Configuration Parameters > Data Import/Export** pane, set the **Input** parameter to t , tu .

t is a column vector containing the times of events for the Inport block. tu is a table of input values versus time for the In2 block.

The table describes how to specify the vector t .

	Root-level Inport block with inherited sample time (-1) specified	Root-level Inport block with discrete sample time specified
Function-call subsystem trigger port sample time type is Periodic	Not applicable	Use an empty matrix([]). The function-call subsystem executes at every sample time hit of the root-level Inport block invoking it.
Function-call subsystem trigger port sample time type is Triggered	Use a nondecreasing column vector. Each element in the column vector must be an integral multiple of the fundamental sample time of the model. The function-call subsystem executes at the times specified by the column vector.	Use a nondecreasing column vector. Each element in the column vector must be an integral multiple of discrete sample time of the function-call root-level Inport block. The function-call subsystem executes at

	Root-level Inport block with inherited sample time (-1) specified	Root-level Inport block with discrete sample time specified
	If you specify an empty matrix (<code>[]</code>), the function-call subsystem does not execute.	the times specified by the column vector. Alternatively, specify an empty matrix (<code>[]</code>), and the function-call subsystem executes at every sample time hit.

Top-Model Simulation Using Model Reference

The more common simulation workflow of export-function models is by referencing export-function models. When function-call sequencing is too complicated to specify with data sets in a standalone simulation, create a harness top model to mimic target environment behavior. Use this top model to give inputs to the export-function model. There are two forms to mimic behavior of the scheduling environment:

- Common function-call initiator, in which you fully control the scheduling process. Use Stateflow or S-functions to create arbitrary call sequences.

Note: Simulink does not simulate pre-empting function-calls.

- Multiple function-call initiators with distinct sample times: Use Simulink scheduling for simulation, which is useful when the rate monotonic scheduling behavior in Simulink is similar to the target OS behavior.

Note: When using export-function models in top-model simulations, do not change the enable/disable status of the model during the simulation. Enable it at the start of the simulation and use function-calls to call it.

Standalone Code Generation

For standalone code generation, specify an ERT code-generation target, such as `ert.tlc`, and select **Code > C/C++ Code > Build Model** to generate code. In the generated code, each function-call root Inport generates a void-void function. The function name for each function-call root Inport block is the name of the output function-call signal of the block. If there is no signal name, then the function name is derived from the name of the root Inport block. Building the model generates a model initialization function but does not generate a model step function or an enable/disable function.

To customize the model initialize function name for the referenced export-function model, open the top model and complete these steps:

- Select **Model Configuration Parameters > Code Generation > Interface**.
- Click **Configure Model Functions**.

- In the Model Interface dialog box, set **Function specification** to **Model specific C prototypes** and click **Validate**.
- Type the function name in the **Initialize function** name text box and click **Apply**.
- Generate code again to see the new function name.

Nested Export-Function Models

Nested export-function models provide an additional layer of organization for your model. The schematic below explains how the user may export functions at the vehicle level or the individual feature level.

Note: An export-function model cannot contain a model with asynchronous function-call inputs, but can contain function-call subsystems and function-call models. A model with asynchronous function-call inputs can contain an export-function model, function-call subsystem or a function-call model.

Comparison Between Export-Function Models and Models with Asynchronous Function-Call Inputs

An export-function models capability is available for models with asynchronous function-call inputs. You use these models primarily in the Simulink environment where the Simulink scheduler calls generated functions.

	Export-Function Models	Models with Asynchronous Function-Call Inputs
Definition	These models have function-call root-level Inport blocks that are not connected to an Asynchronous Task Specification block. These Inport blocks trigger function-call subsystems or referenced models with function-call trigger inputs.	These models have function-call root-level Inport blocks connected to Asynchronous Task Specification blocks. These Inport blocks trigger function-call subsystems or referenced models with function-call trigger inputs.
Root-level blocks	Only blocks executing in a function-call context are allowed at the root level.	Blocks executing in a non-function-call context are also allowed.
Data transfer	Use data transfer indicators to interpret simulation results. Data transfer in export-function models is not protected by default in generated code. For more details, see “Data Transfer Between Function-Call Subsystems” on page 10-13.	Use Rate Transition blocks to protect data transferred between function-call subsystems running at different rates. For more information, see Rate Transition.
Simulation support	These models support standalone simulation and top-model simulation in all simulation modes.	These models support top-model simulation in all simulation modes and standalone simulation in normal, accelerator, and rapid accelerator modes.
Code generation support	Top-model and standalone code generation is supported.	Top-model and standalone code generation is supported.

“Use Blocks with Constant Sample Times in Enabled Subsystems” on page 10-29

What Are Enabled Subsystems?

Enabled subsystems are subsystems that execute at each simulation step for which the control signal has a positive value.

An enabled subsystem has a single control input, which can be a scalar or a vector.

- If the input is a scalar, the subsystem executes if the input value is greater than zero.
- If the input is a vector, the subsystem executes if *any one* of the vector elements is greater than zero.

For example, if the control input signal is a sine wave, the subsystem is alternately enabled and disabled. This behavior is shown in the following figure, where an up arrow signifies enable and a down arrow disable.

The Simulink software uses the zero-crossing slope method to determine whether an enable event is to occur. If the signal crosses zero and its slope is positive, then the subsystem becomes enabled. If the slope is negative at the zero crossing, then the

subsystem becomes disabled. Note that a subsystem is only enabled or disabled at major time steps. Therefore, if zero-crossing detection is turned off and the signal crosses zero during a minor time step, then the subsystem will not become enabled (or disabled) until the next major time step.

Create an Enabled Subsystem

You create an enabled subsystem by copying an Enable block from the Ports & Subsystems library into a Subsystem block. An enable symbol and an enable control input port is added to the Subsystem block.

To set the initial conditions for an Output block in an enabled subsystem, see “Specify or Inherit Conditional Subsystem Initial Values” on page 10-66.

Set States When the Subsystem Becomes Enabled

When an enabled subsystem executes, you can choose whether to hold the subsystem states at their previous values or reset them to their initial conditions.

To do this, open the **Block Parameters: Enable** dialog box and select one of the choices for the **States when enabling** parameter:

- Choose **held** to cause the states to maintain their most recent values.
- Choose **reset** to cause the states to revert to their initial conditions. However, enabled subsystems reset their states on enabling only if they are disabled for at least one time step. To reset the states of your subsystem without disabling its execution, use resettable subsystems. For more information, see “Comparison of Resettable Subsystems and Enabled Subsystems” on page 10-36.

In simplified initialization mode, the subsystem elapsed time is always reset during the first execution after becoming enabled, whether or not the subsystem is configured to reset on enable. For more information on simplified initialization mode, see “Underspecified initialization detection”.

Note: For nested subsystems whose Enable blocks have different parameter settings, the settings on the child subsystem's dialog box override those inherited from the parent subsystem.

Output the Enable Control Signal

An option on the Enable block dialog box lets you output the enable control signal. To output the control signal, select the **Show output port** check box.

This feature allows you to pass the control signal down into the enabled subsystem, which can be useful where logic within the enabled subsystem is dependent on the value or values contained in the control signal.

Blocks an Enabled Subsystem Can Contain

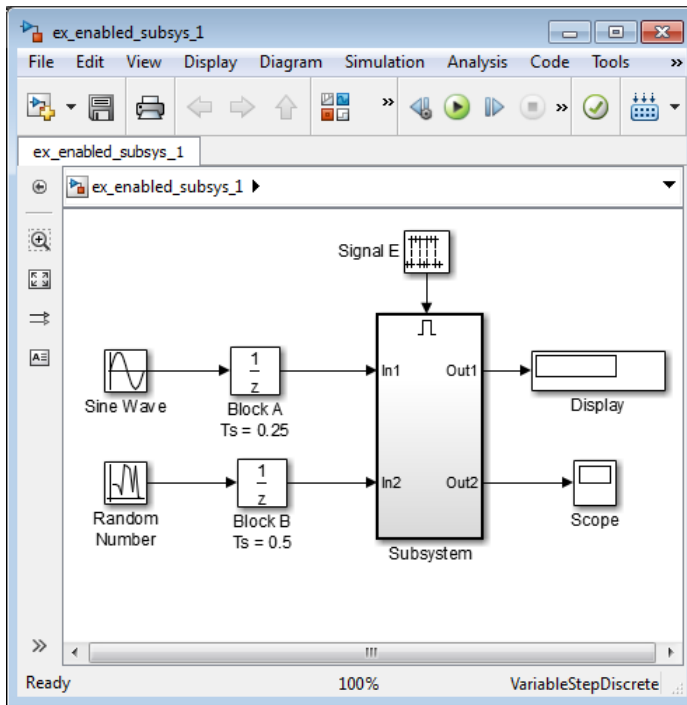

An enabled subsystem can contain any block, whether continuous or discrete. Discrete blocks in an enabled subsystem execute only when the subsystem executes, and only when their sample times are synchronized with the simulation sample time. Enabled subsystems and the model use a common clock.

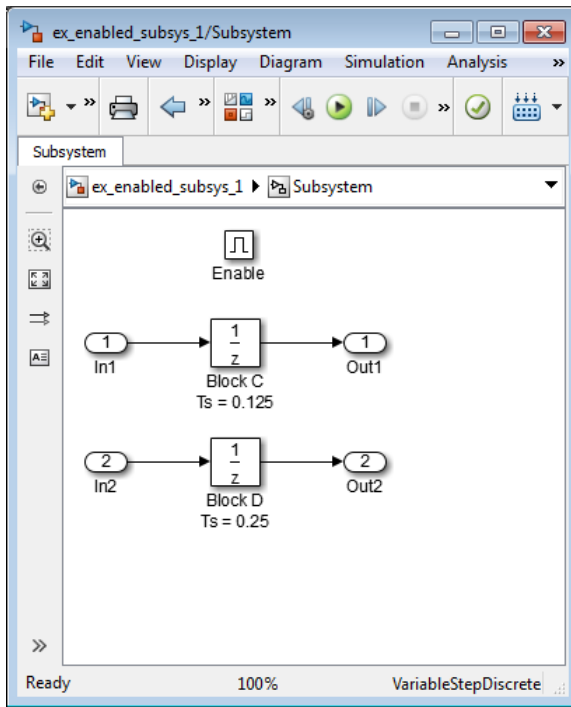

Note Enabled subsystems can contain Goto blocks. However, only state ports can connect to Goto blocks in an enabled subsystem. In the `sldemo_clutch` model, see the `Locked` subsystem for an example of how to use Goto blocks in an enabled subsystem.

For example, this system contains four discrete blocks and a control signal. The discrete blocks are:

- Block A, which has a sample time of 0.25 second
- Block B, which has a sample time of 0.5 second
- Block C, within the enabled subsystem, which has a sample time of 0.125 second
- Block D, also within the enabled subsystem, which has a sample time of 0.25 second

The enable control signal is generated by a Pulse Generator block, labeled Signal E, which changes from 0 to 1 at 0.375 second and returns to 0 at 0.875 second.

The chart below indicates when the discrete blocks execute.

Blocks A and B execute independently of the enable control signal because they are not part of the enabled subsystem. When the enable control signal becomes positive, blocks C

and D execute at their assigned sample rates until the enable control signal becomes zero again. Note that block C does not execute at 0.875 second when the enable control signal changes to zero.

Use Blocks with Constant Sample Times in Enabled Subsystems

Certain restrictions apply when you connect blocks with constant sample times (see “Constant Sample Time” on page 7-17) to the output port of a conditional subsystem.

- An error appears when you connect a Model or S-Function block with constant sample time to the output port of a conditional subsystem.
- The sample time of any built-in block with a constant sample time is converted to a different sample time, such as the fastest discrete rate in the conditional subsystem.

To avoid the error or conversion, either manually change the sample time of the block to a non-constant sample time or use a Signal Conversion block. The example below shows how to use the Signal Conversion block to avoid these errors.

Consider the following model `ex_enabled_subsys_2.mdl`.

The two Constant blocks in this model have constant sample times. When you simulate the model, the Simulink software converts the sample time of the Constant block inside the enabled subsystem to the rate of the Pulse Generator. If you simulate the model with sample time colors displayed (see “View Sample Time Information” on page 7-9), the Pulse Generator and Enabled Subsystem blocks are colored red. However, the Constant and Outport blocks outside of the enabled subsystem are colored magenta, indicating that these blocks still have a constant sample time.

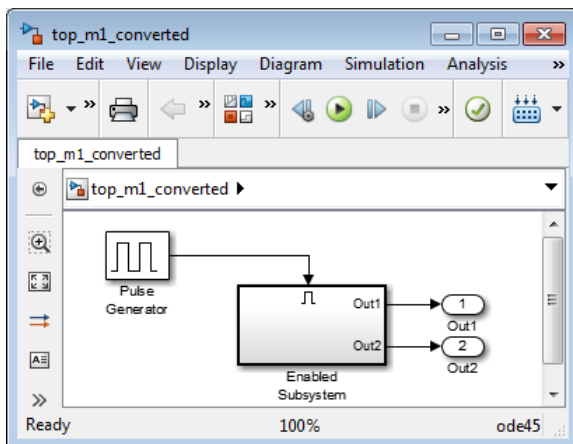

Suppose the model above is referenced from a Model block inside an enabled subsystem, as shown below. (See “Model Referencing”.)

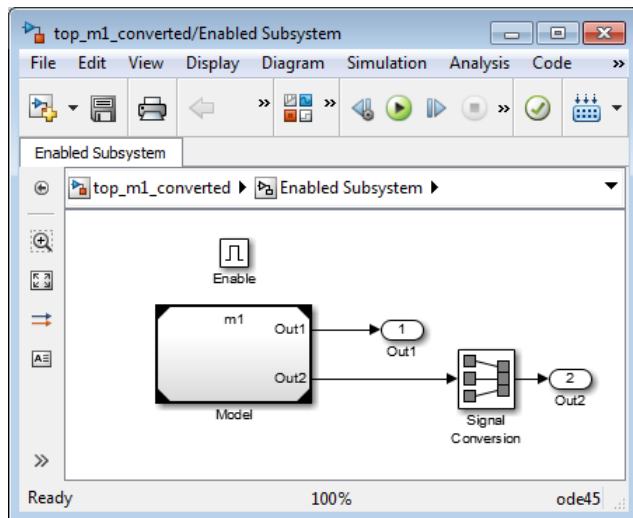

An error appears when you try to simulate the top model, indicating that the second output of the Model block may not be wired directly to the enabled subsystem output port because it has a constant sample time. (See “Model Referencing”.)

To avoid this error, insert a Signal Conversion block between the second output of the Model block and the Outport block of the enabled subsystem.

This model simulates with no errors. With sample time colors displayed, the Model and Enabled Subsystem blocks are colored yellow, indicating that these are hybrid systems. In this case, the systems are hybrid because they contain multiple sample times.

Conditionally Reset Block States in a Subsystem

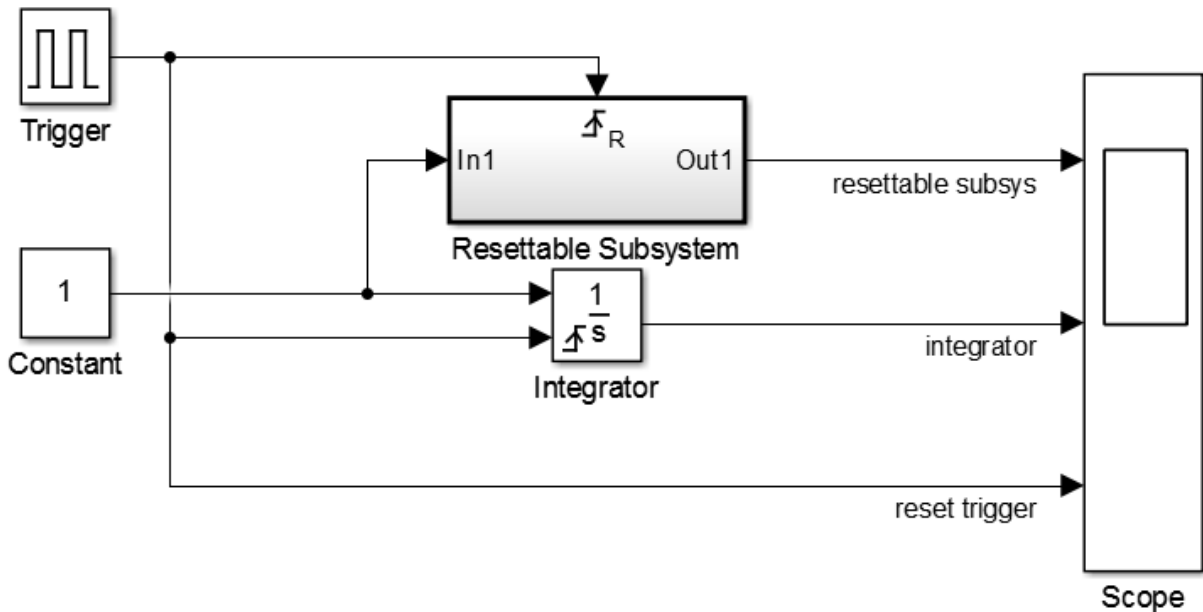

In this section...

“Behavior of Resettable Subsystems” on page 10-33

“Comparison of Resettable Subsystems and Enabled Subsystems” on page 10-36

Behavior of Resettable Subsystems

Use resettable subsystems when you want to conditionally reset the states of all blocks within a subsystem. A resettable subsystem executes at every time step but conditionally resets the states of blocks within it when a trigger event occurs at the reset port. This behavior is similar to the reset behavior of blocks with reset ports, except that a resettable subsystem resets the states of all blocks inside it.

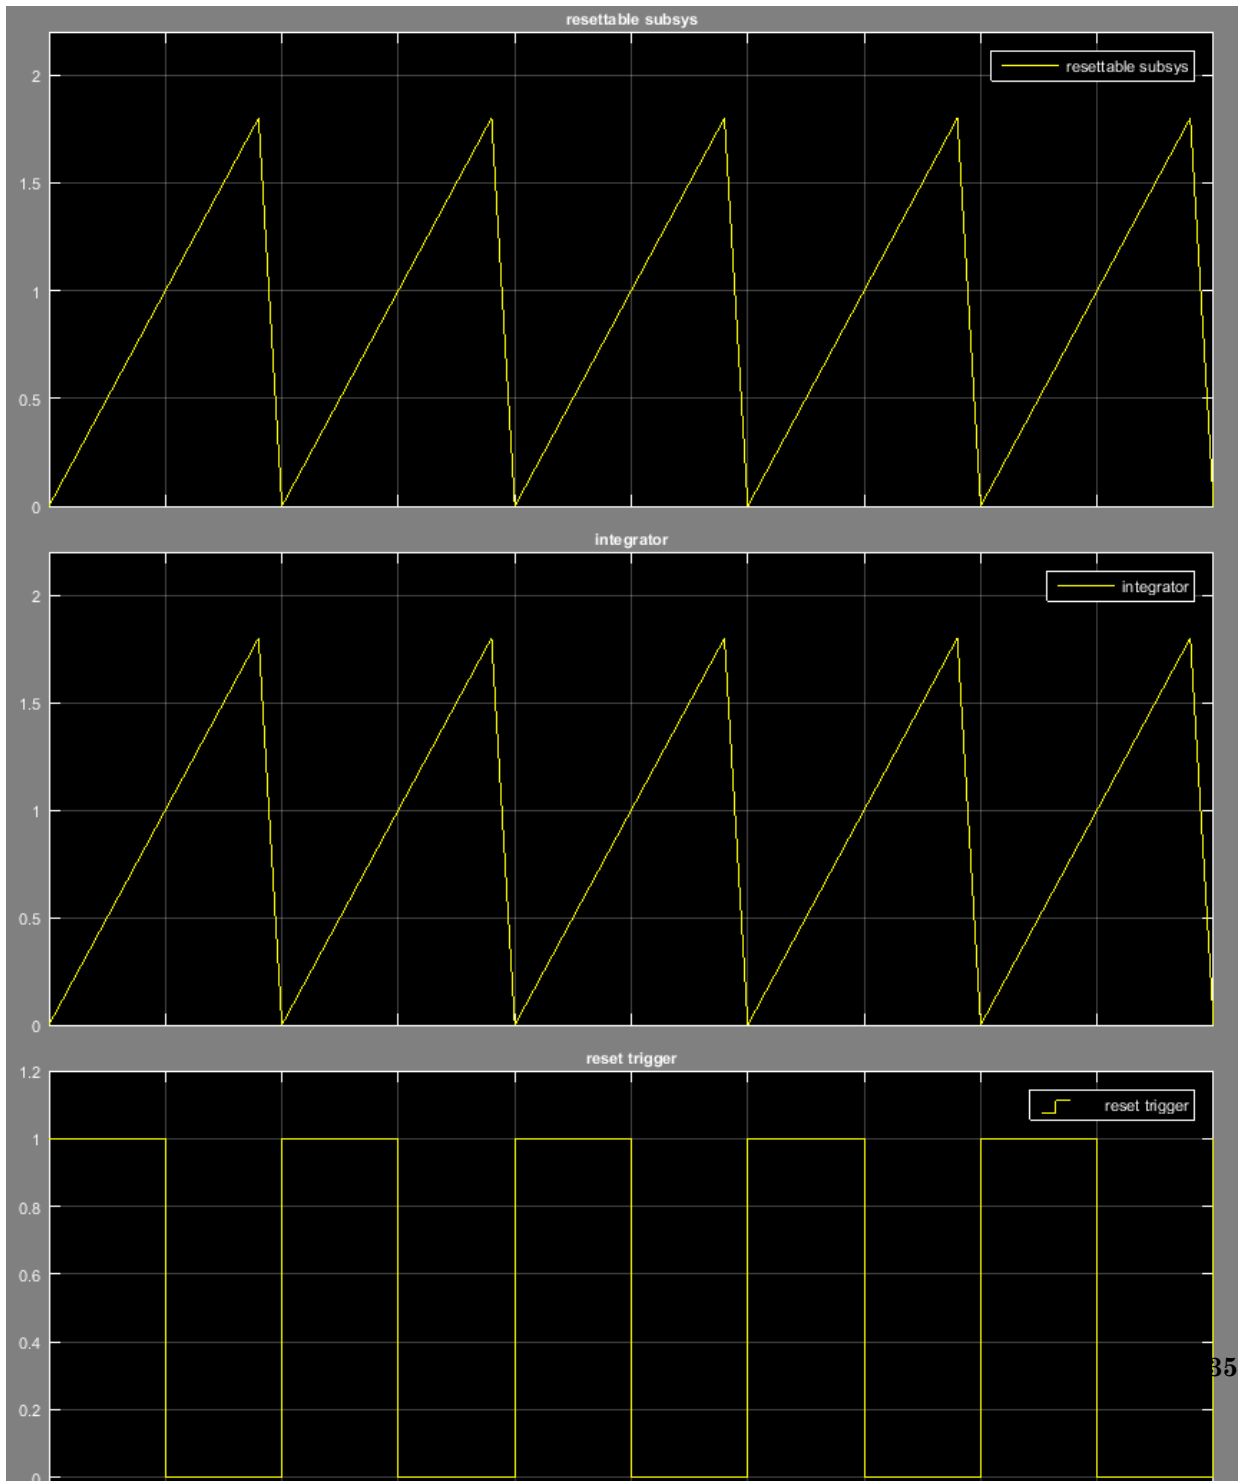

Using resettable subsystems over other methods of resetting states of your block or subsystem has these advantages:

- When you want to reset the states of multiple blocks in a subsystem, displaying and connecting the reset port of each block is cumbersome and makes the block diagram hard to read. Instead, place all of the blocks in a resettable subsystem and configure the Reset block in the subsystem.
- Some blocks, such as the **Discrete State-Space** block, have states but do not have reset ports. You cannot reset these blocks individually, and you must reset the subsystem they are inside. In such cases, it is useful to place these blocks in a resettable subsystem.
- You can also reset blocks in enabled subsystems by setting the **States when enabling** parameter on the enable port to **reset**. However, for this behavior, you must disable the subsystem and then reenable it at a later time step. To reset your block states at the same time step, use resettable subsystems. For more information, see “Comparison of Resettable Subsystems and Enabled Subsystems” on page 10-36.

All blocks in a resettable subsystem must have the same sample time, and they execute at every sample time hit of the subsystem. Resettable subsystems and the model use a common clock.

This model shows that the behavior of block reset ports and resettable subsystems is the same. A resettable subsystem enables you to reset the states of all blocks inside it. The resettable subsystem contains an integrator block that is configured similar to the root-level Integrator block, but the block does not have a reset port. The subsystem resets the states of the integrator block inside it in the same manner as the reset port of the Integrator block. You can see this by running the model and viewing the output in the scope.

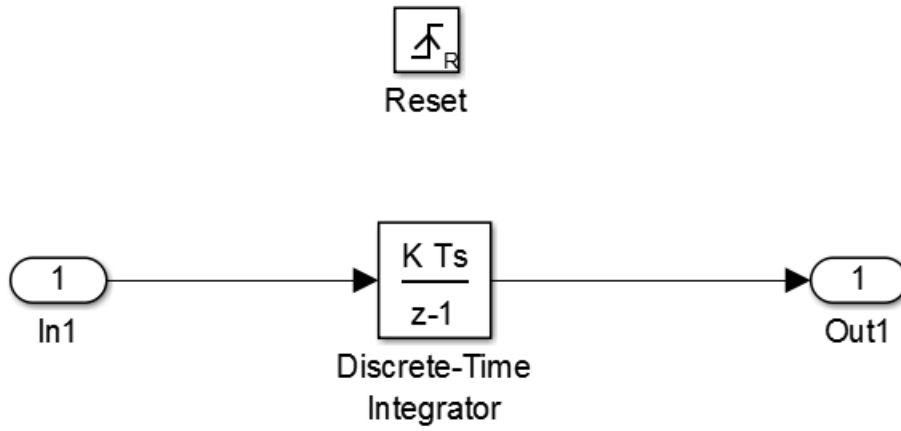

Comparison of Resettable Subsystems and Enabled Subsystems

You can use enabled subsystems to reset the states of your blocks if you set the **States when enabling** parameter on the enable port to `reset`. However, you must disable the subsystem for at least one time step and then reenabling it for the states to reset. In contrast, resettable subsystems always execute and reset the states of their blocks instantaneously.

This model shows the difference in the execution behavior of these subsystems. It contains an enabled subsystem and a resettable subsystem whose control ports are fed by a pulse generator. The resettable subsystem is set to reset on the rising edge of the control signal, and the enabled subsystem has the **States when enabling** parameter set to `reset` in the enable port.

The subsystems contain identical Discrete-Time Integrator blocks, whose input is the Constant block at the root level of the model. The figure shows the contents of the resettable subsystem.

The figure shows the simulation output.

When the control signal is 0, the enabled subsystem is disabled and the integrator does not change its output while the resettable subsystem is executing. The rising edge of the control signal triggers the reset port of the resettable subsystem and enables the enabled subsystem. Both subsystems reset their states at this time step.

Notice that the enabled subsystem is disabled for at least one time step before its states can be reset. The resettable subsystem does not have this limitation.

Create a Triggered Subsystem

In this section...

“What Are Triggered Subsystems?” on page 10-40

“Using Model Referencing Instead of a Triggered Subsystem” on page 10-42

“Creating a Triggered Subsystem” on page 10-42

“Blocks That a Triggered Subsystem Can Contain” on page 10-43

What Are Triggered Subsystems?

Triggered subsystems are subsystems that execute each time a trigger event occurs.

A triggered subsystem has a single control input, called the *trigger input*, that determines whether the subsystem executes. You can choose from three types of trigger events to force a triggered subsystem to begin execution:

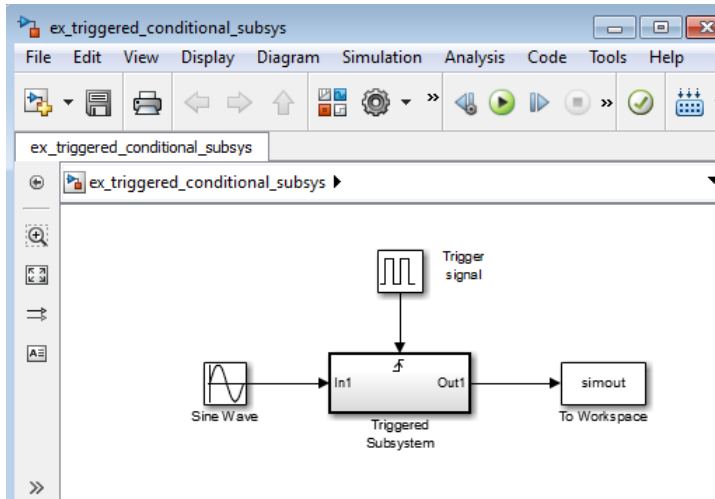

- **rising** triggers execution of the subsystem when the control signal rises from a negative or zero value to a positive value (or zero if the initial value is negative).
- **falling** triggers execution of the subsystem when the control signal falls from a positive or a zero value to a negative value (or zero if the initial value is positive).
- **either** triggers execution of the subsystem when the signal is either rising or falling.

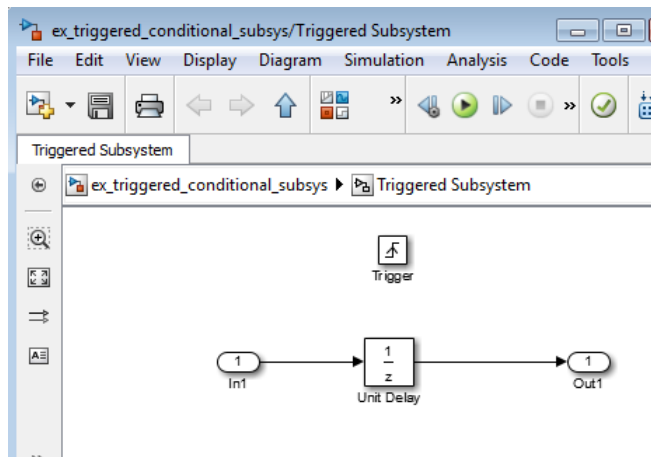

Note For discrete systems: If after rising, a signal remains at zero for more than one time step, then and only then, does the subsequent rising of the signal constitute a trigger event. Similarly, a falling trigger event occurs only if there are at least two time steps between two occurrences of the signal falling. This trigger event scheme eliminates false triggers caused by control signal sampling.

For example, in the following timing diagram for a discrete system, a rising trigger (R) does not occur at time step 3 because the signal remains at zero for only one time step prior to the rise.

A simple example of a triggered subsystem is illustrated.

In this example, the subsystem is triggered on the rising edge of the square wave trigger control signal.

Using Model Referencing Instead of a Triggered Subsystem

You can use triggered ports in referenced models. Add a trigger port to a referenced model to create a simpler, cleaner model than when you include either:

- A triggered subsystem in a referenced model
- A Model block in a triggered subsystem

For information about using trigger ports in referenced models, see “Create and Reference Conditional Referenced Models” on page 8-75.

To convert a subsystem to use model referencing, see “Convert a Subsystem to a Referenced Model” on page 8-17.

Creating a Triggered Subsystem

You create a triggered subsystem by copying the Trigger block from the Ports & Subsystems library into a subsystem. The Simulink software adds a trigger symbol and a trigger control input port to the Subsystem block.

To select the trigger type, open the Trigger block dialog box and select one of the choices for the **Trigger type** parameter.

Different symbols appear on the Trigger and Subsystem blocks to indicate rising and falling triggers (or either). This figure shows the trigger symbols on Subsystem blocks.

Outputs and States Between Trigger Events

Unlike enabled subsystems, triggered subsystems always hold their outputs at the last value between triggering events. Also, triggered subsystems cannot reset their states when triggered; the states of any discrete block is held between trigger events.

Outputting the Trigger Control Signal

An option on the Trigger block dialog box lets you output the trigger control signal. To output the control signal, select the **Show output port** check box.

In the **Output data type** field, specify the data type of the output signal as `auto`, `int8`, or `double`. The `auto` option causes the data type of the output signal to be the data type (either `int8` or `double`) of the port to which the signal connects.

Blocks That a Triggered Subsystem Can Contain

All blocks in a triggered subsystem must have either inherited (-1) or constant (`inf`) sample time. This is to indicate that the blocks in the triggered subsystem run only when the triggered subsystem itself runs, for example, when it is triggered. This requirement means that a triggered subsystem cannot contain continuous blocks, such as the Integrator block.

Create an Action Subsystem

In this section...

“What Are Action Subsystems?” on page 10-45

“Set States when an Action Subsystem Executes” on page 10-46

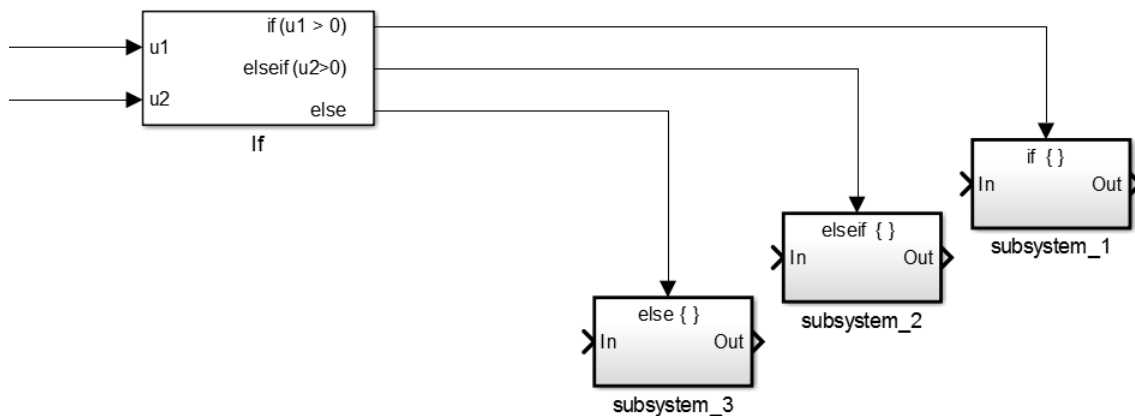

What Are Action Subsystems?

Action subsystems are subsystems that execute in response to a conditional output from an **If** block or a **Switch Case** block. In essence, they are subsystems with an **Action** port, which allow for block execution based on conditional inputs from an **If** block or **Switch Case** block.

Simulink has two types of action subsystems, based on the type of block they receive conditional input from.

If Action Subsystem

The **If Action Subsystem** is preconfigured to serve as a starting point for creating a subsystem whose execution is triggered by an **If** block. To implement an if-else condition, connect **If Action Subsystem** blocks to the outputs of an **If** block.

Switch Case Action Subsystem

The Switch Case Action Subsystem is preconfigured to serve as a starting point for creating a subsystem whose execution is triggered by a **Switch Case** block. To implement a switch condition, connect Switch Case Action Subsystem blocks to the outputs of a **Switch Case** block.

Set States when an Action Subsystem Executes

When an action subsystem is triggered to execute, you can choose whether to hold the subsystem states at their previous values or reset them to their initial conditions.

- 1 Open the **Action Port** block inside the action subsystem.
- 2 Select one of the following for the **States when execution is resumed** parameter:
 - **held** if you want the states to maintain their most recent values
 - **reset** if you want the states to revert to their initial conditions

Note: For nested subsystems whose Action Port blocks have different parameter settings, the settings on the child subsystem’s dialog box override those inherited from the parent subsystem.

Create a Triggered and Enabled Subsystem

In this section...

“What Are Triggered and Enabled Subsystems?” on page 10-48

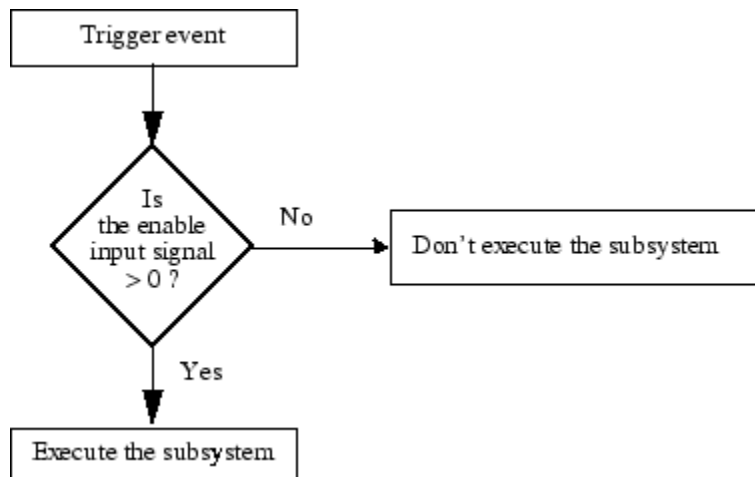

“Creating a Triggered and Enabled Subsystem” on page 10-49

“A Sample Triggered and Enabled Subsystem” on page 10-49

“Creating Alternately Executing Subsystems” on page 10-50

What Are Triggered and Enabled Subsystems?

A third kind of conditional subsystem combines two types of conditional execution. The behavior of this type of subsystem, called a *triggered and enabled* subsystem, is a combination of the enabled subsystem and the triggered subsystem, as shown by this flow diagram.

A triggered and enabled subsystem contains both an enable input port and a trigger input port. When the trigger event occurs, the enable input port is checked to evaluate the enable control signal. If its value is greater than zero, the subsystem is executed. If both inputs are vectors, the subsystem executes if at least one element of each vector is nonzero.

The subsystem executes once at the time step at which the trigger event occurs.

Creating a Triggered and Enabled Subsystem

You create a triggered and enabled subsystem by dragging both the Enable and Trigger blocks from the Ports & Subsystems library into an existing subsystem. The Simulink software adds enable and trigger symbols and enable and trigger control inputs to the Subsystem block.

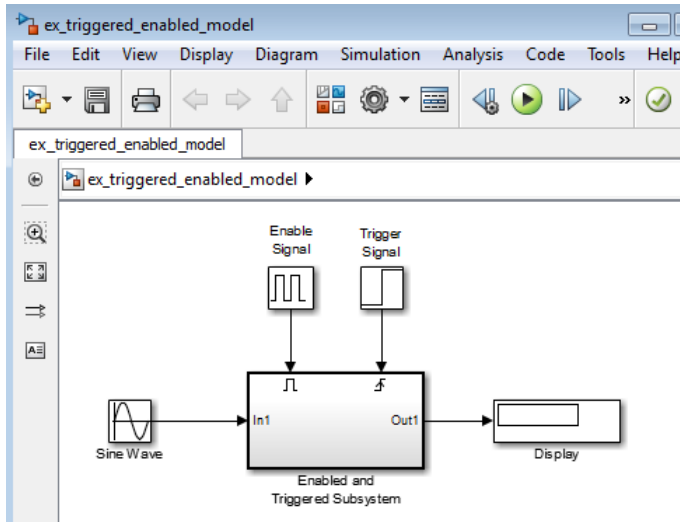

You can set output values when a triggered and enabled subsystem is disabled as you would for an enabled subsystem. For more information, see “Setting Output Values When the Conditional Subsystem Is Disabled” on page 10-68. Also, you can specify what the values of the states are when the subsystem is reenabled. See “Set States When the Subsystem Becomes Enabled” on page 10-24.

Set the parameters for the Enable and Trigger blocks separately. The procedures are the same as those described for the individual blocks.

A Sample Triggered and Enabled Subsystem

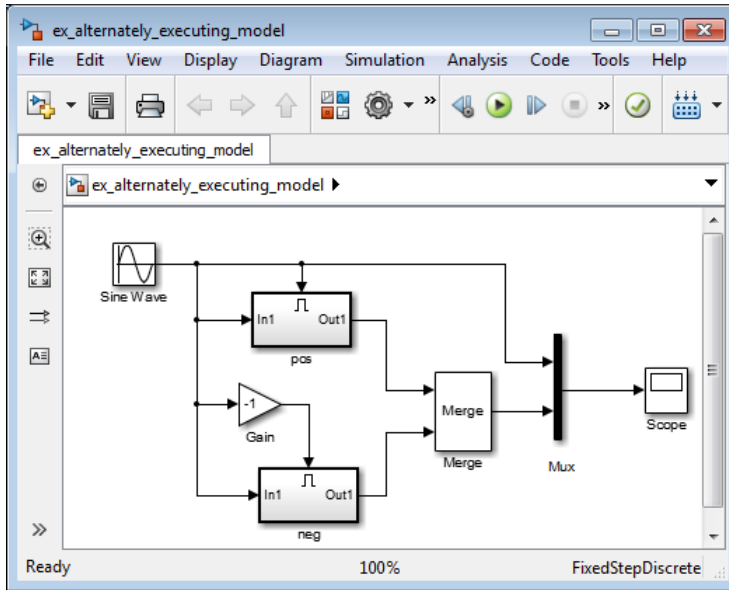

A simple example of a triggered and enabled subsystem is illustrated in the following model.

Creating Alternately Executing Subsystems

You can use conditional subsystems in combination with Merge blocks to create sets of subsystems that execute alternately, depending on the current state of the model.

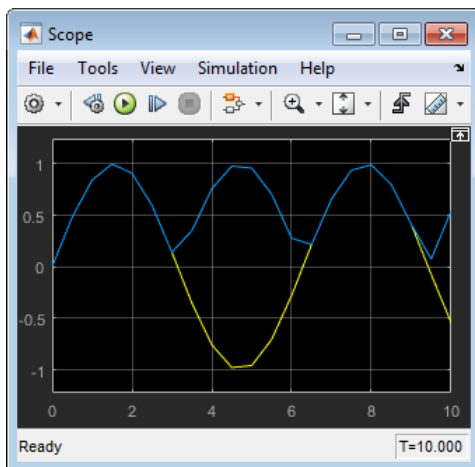

The following figure shows a model that uses two enabled blocks and a Merge block to model a full-wave rectifier – a device that converts AC current to pulsating DC current.

The block labeled `pos` is enabled when the AC waveform is positive; it passes the waveform unchanged to its output. The block labeled `neg` is enabled when the waveform is negative; it inverts the waveform. The Merge block passes the output of the currently enabled block to the Mux block, which passes the output, along with the original waveform, to the Scope block.

The Scope creates the following display.

Create a Function-Call Subsystem

What is a Function-Call Subsystem?

A function-call subsystem is a subsystem that another block can invoke directly during a simulation. It is analogous to a function in a procedural programming language. Invoking a function-call subsystem is equivalent to invoking the output methods (See “Block Methods” on page 3-15) of the blocks that the subsystem contains in sorted order (See “How Simulink Determines the Sorted Order” on page 33-37). The block that invokes a function-call subsystem is called the function-call initiator. Stateflow, Function-Call Generator, and S-function blocks can all serve as function-call initiators.

Creating Function-Call Subsystems

To create a function-call subsystem, drag a **Function-Call Subsystem** block from the Ports & Subsystems library into your model and connect a function-call initiator to the function-call port displayed on top of the subsystem. You can also create a function-call subsystem from scratch. First create a **Subsystem** block in your model and then create a **Trigger** block in the subsystem. Next, on the Trigger block parameters pane, set the **Trigger type** to function-call.

Sample Time Propagation in Function-Call Subsystems

You can configure a function-call subsystem to be triggered (the default) or periodic by setting the **Sample time type** of its Trigger port to be **triggered** or **periodic**, respectively. A function-call initiator can invoke a triggered function-call subsystem zero, one, or multiple times per time step. The sample times of all the blocks in a triggered function-call subsystem must be set to inherited (-1).

A function-call initiator can invoke a periodic function-call subsystem only once per time step and must invoke the subsystem periodically. If the initiator invokes a periodic function-call subsystem aperiodically, the simulation is halted and an error message is displayed. The blocks in a periodic function-call subsystem can specify a noninherited sample time or inherited (-1) sample time. All blocks that specify a noninherited sample time must specify the same sample time. For example, if one block specifies 0.1 as the sample time, all other blocks must specify a sample time of 0.1 or -1. If a function-call initiator invokes a periodic function-call subsystem at a rate that differs from the sample time specified by the blocks in the subsystem, the simulation halts and an error message appears.

Note: During range checking, the design minimum and maximum are back-propagated to the actual source port of the function-call subsystem, even when the function-call subsystem is not enabled.

To prevent this back propagation, add a Signal Conversion block and a Signal Specification block after the source port, set the **Output** of the Signal Conversion block to **Signal copy**, and specify the design minimum and maximum on the Signal Specification block instead of specifying them on the source port.

For more information, see in “Writing S-Functions” in the online documentation.

Conditional Execution Behavior

In this section...

“What Is Conditional Execution Behavior?” on page 10-56

“Propagating Execution Contexts” on page 10-58

“Behavior of Switch Blocks” on page 10-59

“Displaying Execution Contexts” on page 10-59

“Disabling Conditional Execution Behavior” on page 10-60

“Displaying Execution Context Bars” on page 10-61

What Is Conditional Execution Behavior?

To speed up the simulation of a model, by default the Simulink software avoids unnecessary execution of blocks connected to **Switch**, **Multiport Switch**, and of conditionally executed blocks. This behavior is *conditional execution (CE)* behavior. You can disable this behavior for all Switch and Multiport Switch blocks in a model, or for specific conditional subsystems. See “Disabling Conditional Execution Behavior” on page 10-60.

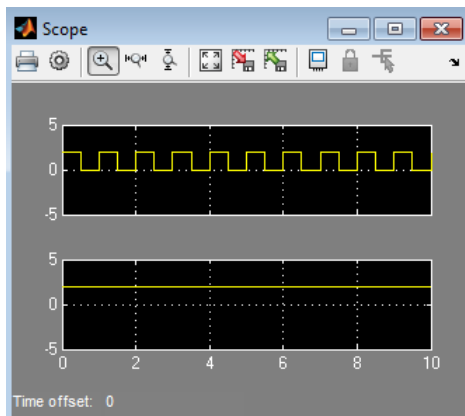

The following model illustrates conditional execution behavior.

ex_execution_contexts ▶

The Scope block shows the simulation result:

This model:

- Has the **Display > Signals & Ports > Execution Context Indicator** menu option enabled.
- The **Pulse Generator** block has the following parameter settings:
 - **Pulse type** — Sample based
 - **Period** — 100
 - **Pulse width** — 50
 - **Phase delay** — 50
 - **Sample Time** — 0.01
- The **Gain** block's sorted order (1:2) is second (2) in the enabled subsystem's execution context (1).

- The Enabled Subsystem block has the **Propagate execution context across subsystem boundary** parameter enabled.
- In the enabled subsystem, the Out1 block has the following parameter settings:
 - **Initial output** — []
 - **Output when disabled** — held

The outputs of the Constant block and Gain blocks are computed only while the enabled subsystem is enabled (for example, at time steps 0.5 to 1.0 and 1.0 to 1.5). This behavior is necessary because the output of the Constant block is required and the input of the Gain block changes only while the enabled subsystem is enabled. When CE behavior is off, the outputs of the Constant and Gain blocks are computed at every time step, regardless of whether the outputs are needed or change.

In this example, the enabled subsystem is regarded as defining an execution context for the Constant and Gain blocks. Although the blocks reside graphically in the root system of the model, the Simulink software invokes the block methods during simulation as if the blocks reside in the enabled subsystem. This is indicated in the sorted order labels displayed on the diagram for the Constant and Gain blocks. The notations list the subsystem's (id = 1) as the execution context for the blocks even though the blocks exist graphically at the root level (id = 0) of the model. The Gain block's sorted order (1:2) is second (2) in the enabled subsystem's execution context (1).

Propagating Execution Contexts

In general, the Simulink software defines an *execution context* as a set of blocks to be executed as a unit. At model compilation time, the Simulink software associates an execution context with the model's root system and with each of its nonvirtual subsystems. Initially, the execution context of the root system and each nonvirtual subsystem is simply the blocks that it contains.

When compiling, each block in the model is examined to determine whether it meets the following conditions:

- The block output is required only by a conditional subsystem or the block input changes only as a result of the execution of a conditionally executed subsystem.
- The execution context of the subsystem can propagate across the subsystem boundaries.
- The output of the block is not a test point (see “Test Points” on page 62-55).

- The block is allowed to inherit its conditional execution context.

The Simulink software does not allow some built-in blocks, such as the Delay block, ever to inherit their execution context. Also, S-Function blocks can inherit their execution context only if they specify the `SS_OPTION_CAN_BE_CALLED_CONDITIONALLY` option.

- The block is not a multirate block.
- The block sample time is set to inherited (-1).

If a block meets these conditions and execution context propagation is enabled for the associated conditional subsystem (see “Disabling Conditional Execution Behavior” on page 10-60), the Simulink software moves the block into the execution context of the subsystem. This ensures that the block methods execute during the simulation loop only when the corresponding conditional subsystem executes.

Note: Execution contexts are not propagated to blocks having a constant sample time.

Behavior of Switch Blocks

This behavior treats the input branches of a **Switch** or **Multiport Switch** block as invisible, conditional subsystems, each of which has its own execution context. This conditional execution is enabled only when the control input of the switch selects the corresponding data input. As a result, switch branches execute only when selected by switch control inputs.

If a switch branch gets its input from a conditional subsystem, then that branch always executes, irrespective of conditional execution optimization settings.

Displaying Execution Contexts

To determine the execution context to which a block belongs, in the Simulink Editor, select **Display > Blocks > Sorted Execution Order**. The sorted order index for each block in the model is displayed in the upper-right corner of the block. The index has the format `s:b`, where `s` specifies the subsystem to whose execution context the block belongs and `b` is an index that indicates the block sorted order in the execution context of the subsystem. For example, 0:0 indicates that the block is the first block in the execution context of the root subsystem.

If a bus is connected to a block input, the block sorted order is displayed as **s:B**. For example, **0:B** indicates that the block belongs to the execution context of the root system and has a bus connected to its input.

The sorted order index of conditional subsystems is expanded to include the system ID of the subsystem itself in curly brackets as illustrated in the following figure.

In this example, the sorted order index of the enabled subsystem is **0:1{1}**. The **0** indicates that the enabled subsystem resides in the root system of the model. The first **1** indicates that the enabled subsystem is the second block on the sorted list of the root system (zero-based indexing). The **1** in curly brackets indicates that the system index of the enabled subsystem itself is 1. Thus any block whose system index is 1 belongs to the execution context of the enabled subsystem and hence executes when it does. For example, the fact that the Constant block has an index of **1:0** indicates that it is the first block on the sorted list of the enabled subsystem, even though it resides in the root system.

Disabling Conditional Execution Behavior

To disable conditional execution behavior for all Switch and Multipoint Switch blocks in a model, turn off the **Conditional input branch execution** optimization on the **All Parameters** tab of the Configuration Parameters dialog box. To disable conditional execution behavior for a specific conditional subsystem, clear the **Propagate execution context across subsystem boundary** check box on the subsystem parameter dialog box.

Even if this option is enabled, the execution context of the subsystem cannot propagate across its boundaries under the following circumstances:

- The subsystem is a triggered subsystem with a latched input port.

- The subsystem has one or more output ports that specify an initial condition other than []. In this case, a block connected to the subsystem output cannot inherit the execution context of the subsystem.
- You are linearizing the root-level block diagram using `linearize` or `linmod` in the MATLAB Command Window or the Time Based Linearization block.

Displaying Execution Context Bars

Simulink can optionally display bars next to the ports of subsystems across which execution contexts cannot propagate. To display the bars, select **Display > Signals & Ports > Execution Context Indicator**.

For example, it displays bars on subsystems from which no block can inherit its execution context. In the following figure, the context bars appear next to the In1 and Out1 ports of the Enabled Subsystem block.

Conditional Subsystem Output Initialization

In this section...

“Why Initialize Conditional Subsystem Output with Explicit Values?” on page 10-62

“Initialization Mode” on page 10-62

“When to Use Simplified Initialization” on page 10-63

“Simplified Mode Behavior and Requirements” on page 10-64

“When to Use Classic Initialization” on page 10-65

Why Initialize Conditional Subsystem Output with Explicit Values?

By default, Simulink uses values from the inputs to a conditional subsystem during simulation. Alternatively, you can explicitly set the initial values, which can be useful for:

- Specifying initial behaviors that meet your modeling goals, such as testing a model
- Setting initial values that reduce simulation time by reaching steady state faster
- Making the model behavior easier to understand without having to trace input signals to determine the initial values

For details, see “Specify or Inherit Conditional Subsystem Initial Values” on page 10-66.

Initialization Mode

Initialization mode controls how Simulink handles the initialization values for conditionally executed subsystems.

The initialization mode also specifies how Simulink handles the initial values for **Merge** blocks, subsystem elapsed time, and **Discrete-Time Integrator** blocks. Usually the main impact of the initialization mode for Merge blocks and Discrete-Time Integrator blocks is in the context of those blocks being used with a conditional subsystem.

The default initialization mode is **Simplified**. **Classic** mode was the only way that Simulink handled initial conditions prior to R2008b. **Simplified** mode uses enhanced processing, which can improve consistency of simulation results compared to **Classic**

mode. For examples of some of the issues that simplified mode addresses, see “Address Classic Mode Issues by Using Simplified Mode” on page 10-71.

Note: When saving a new model configuration set as a `Simulink.ConfigSet` object, the parameter **Configuration Parameters > All Parameters > Underspecified initialization detection** is set to **Classic**.

To help you choose which initialization mode to use, see:

- “When to Use Simplified Initialization” on page 10-63
- “Simplified Mode Behavior and Requirements” on page 10-64
- “When to Use Classic Initialization” on page 10-65

For details about setting initialization mode, see “Set Initialization Mode to Simplified or Classic” on page 10-69.

When to Use Simplified Initialization

In general, using simplified initialization mode helps you to:

- Attain the same simulation results with the same inputs when using the same blocks in a different model.
- Avoid unexpected changes to simulation results as you modify a model.

Use simplified initialization mode for models that contain one or more of the following blocks:

- Conditional subsystem
- Merge block
- Discrete-Time Integrator block

Use simplified mode if your model uses features that require simplified initialization mode, such as:

- Specify a structure to initialize a bus.
- Branch merged signals inside a conditional subsystem.

Determine whether using simplified mode meets your modeling requirements. For details, see “Simplified Mode Behavior and Requirements” on page 10-64.

Simplified Mode Behavior and Requirements

Simplified mode affects the output of the conditional subsystem and the behavior of some blocks. Also, simplified mode has some model configuration requirements.

Output

- The output signal of a conditional subsystem is stored in separate memory that is not shared by with any other Outputport block. The initialization behavior of the memory is fully specified at the start of simulation.
- Conditional subsystem output ports can either explicitly specify an initial condition value or inherit that value from the block within the subsystem that is connected to the Outputport block input port.
- Simplified mode always uses the initial value as both the initial and reset value for output for a Discrete-Time Integrator block.

Output Blocks

Simplified mode has the following behavior with Outputport blocks:

- If the **Source of initial output value** parameter is set to `Input signal`, in simplified mode Simulink assumes the **Initial output** value is derived from the input signal. This can result in initialization behavior that is different from classic mode. However, the initialization behavior in simplified mode is generally more robust.
- The Outputport block can inherit the initial output value from a limited number of blocks. If it inherits from outside this limited list of blocks, then the Outputport block uses the default initial value of the output data type. For details, see “Specify or Inherit Conditional Subsystem Initial Values” on page 10-66.

You cannot use a `Simulink.Signal` object to specify the **Initial output** value.

Merge Blocks

- If a root Merge block has an empty matrix (`[]`) for its initial output value, Simulink uses the default ground value of the output data type. A root Merge block is any Merge block with an output port that does not connect to another Merge block.
- You cannot use single-input Merge blocks.

Discrete-Time Integrator Blocks

Discrete-Time Integrator block behaves differently in simplified mode than it does in classic mode. The changes for simplified mode promote more robust and consistent model

behavior. For details, see “Behavior in Simplified Initialization Mode” in the Discrete-Time Integrator block reference documentation.

Library Blocks

Simulink creates a library assuming that classic mode is in effect. If you use a library block that is affected by simplified mode in a model that uses simplified mode, then use the Model Advisor to identify changes you need to make so that the library block works with simplified mode.

When to Use Classic Initialization

Simplified initialization mode offers many benefits, compared to classic mode. **Classic** mode was the default initialization mode for Simulink models created in R2013b or before. You can continue to use classic mode on those models if:

- The model does not include any modeling elements affected by simplified mode.
- The behavior and requirements of simplified mode do not meet your modeling goals. See “Simplified Mode Behavior and Requirements” on page 10-64.
- The work involved in converting to simplified mode is greater than the benefits of simplified mode. See “Convert from Classic to Simplified Initialization Mode” on page 10-70.

Specify or Inherit Conditional Subsystem Initial Values

In this section...
“Inherit Initial Values from the Input Signal” on page 10-66
“Explicitly Specify an Initial Value” on page 10-67
“Setting Output Values When the Conditional Subsystem Is Disabled” on page 10-68

To initialize the input values of a conditional subsystem, initialize its Output block, using one of these approaches:

- Explicitly specify the initial values by listing them in the Block Parameters dialog box of the Output block.
- Inherit the initial values from the input signals.

Note: If the conditional subsystem is driving a Merge block in the same model, you do not need to specify an initial condition for the subsystem’s Output block.

Inherit Initial Values from the Input Signal

Valid sources for the Output block to inherit its initial output value from are:

- Output port of another conditionally executed subsystem
- Merge block
- Function-Call model reference block
- Constant block (simplified initialization mode only)
- IC block (simplified initialization mode only)
- Stateflow chart

How you configure the Output block for inheriting initial values depends on whether the model uses simplified or classic initialization mode. For details about initialization modes, see “Set Initialization Mode to Simplified or Classic” on page 10-69.

- 1 Set the **Source of initial output value** parameter to **Dialog**.
- 2 In the **Initial output** parameter, enter an empty matrix ([]).

3 Set the **Output when disabled** parameter to held.

Alternatively, if you use simplified initialization mode, you can inherit initial values by setting the **Source of initial output value** to **Input signal**.

When you update the block diagram in simplified mode, a badge appears next to the Outport block, as shown in the figure below. If an initial condition source is not a valid source for inheriting an initial value or if you choose not to inherit the initial value, no badge appears and the Outport block uses the default initial value of the output data type. For more information, see “Initialize Signals and Discrete States” on page 62-47.

Explicitly Specify an Initial Value

- 1 Set the **Source of initial output value** parameter to **Dialog**.
- 2 In the **Initial output** parameter, enter the initial value. Valid values include an empty matrix ([]) but not Inf or NaN.

When you select **Dialog**, you can also specify whether to hold or reset the output when the conditional subsystem is disabled. For more information, see “Setting Output Values When the Conditional Subsystem Is Disabled” on page 10-68.

Note: To explicitly specify an initial value in simplified initialization mode, do not specify an empty matrix ([]) or a `Simulink.Signal` object.

Setting Output Values When the Conditional Subsystem Is Disabled

Although a conditional subsystem does not execute while it is disabled, the output signal is still available to other blocks. While a conditional subsystem is disabled and you have specified not to inherit initial conditions from an input signal, you can hold the subsystem outputs at their previous values or reset them to their initial conditions.

Open the block dialog box for each Output block. For the **Output when disabled** parameter:

- Select **held** to maintain the most recent value.
- Select **reset** to revert to the initial condition. Set the **Initial output** to the initial value of the output.

Note: If you are connecting the output of a conditionally executed subsystem to a Merge block, set **Output when disabled** to **held** to ensure consistent simulation results.

If you are using simplified initialization mode, you must select **held** when connecting a conditionally executed subsystem to a Merge block. For more information, see “Underspecified initialization detection”.

Note: If an Output in an enabled subsystem resets its output on disabling at a different rate from the rate of execution of subsystem contents, both the disabled and execution outputs write to the subsystem output. Hence, the subsystem might output unexpected results.

More About

- “Address Classic Mode Issues by Using Simplified Mode” on page 10-71
- “Convert from Classic to Simplified Initialization Mode” on page 10-70

Set Initialization Mode to Simplified or Classic

- 1 Determine which initialization mode to use.

In most situations, using simplified mode offers many benefits. To determine which mode to use, see:

- “When to Use Simplified Initialization” on page 10-63
- “Simplified Mode Behavior and Requirements” on page 10-64
- “When to Use Classic Initialization” on page 10-65

- 2 Set the initialization mode using the **Configuration Parameters > All Parameters > Underspecified initialization detection** parameter. Set the parameter to either **Classic** (default) or **Simplified**.
- 3 If you use simplified mode, you might need to modify your model to change the initialization mode for an existing model that is in classic mode to use simplified mode. For details, see “Convert from Classic to Simplified Initialization Mode” on page 10-70.

- “Conditional Subsystems” on page 10-2
- “Specify or Inherit Conditional Subsystem Initial Values” on page 10-66
- “Address Classic Mode Issues by Using Simplified Mode” on page 10-71
- “Convert from Classic to Simplified Initialization Mode” on page 10-70

Convert from Classic to Simplified Initialization Mode

If you switch the initialization mode from classic to simplified mode, you can encounter several issues that you need to address, one-by-one. For most models, the following approach helps you to address conversion issues more efficiently.

- 1 Save the existing model and simulation results for the model.

Because you might need to make several changes to your model during the conversion process, it is helpful to have the original model for reference and for comparing simulation results.

- 2 Set the **Configuration Parameters > Diagnostics > Connectivity > Mux blocks used to create bus signals** diagnostic to `error`.
- 3 Simulate the model and address any warnings.
- 4 In the Model Advisor, in the Simulink checks section, run the checks in the folder “Migrating to Simplified Initialization Mode Overview”.
- 5 Address the issues that Model Advisor identifies.
- 6 Simulate the model to make sure that there are no errors.
- 7 Rerun the Model Advisor checks in the folder “Migrating to Simplified Initialization Mode Overview” check to confirm that the modified model addresses the issues related to initialization.

For examples of models that have been converted from classic initialization mode to simplified initialization mode, see “Address Classic Mode Issues by Using Simplified Mode” on page 10-71.

Address Classic Mode Issues by Using Simplified Mode

In this section...

“Classic Mode Issues” on page 10-71

“Identity Transformation Can Change Model Behavior” on page 10-72

“Discrete-Time Integrator or S-Function Block Can Produce Inconsistent Output” on page 10-75

“Sorted Order Can Affect Merge Block Output” on page 10-77

Classic Mode Issues

Using classic initialization mode can result in one or more of the following issues. You can address these issues by using simplified mode. The description of each issue includes an example of the behavior in classic mode, the behavior when you use simplified mode, and a summary of the changes you need to make to use simplified mode.

- “Identity Transformation Can Change Model Behavior” on page 10-72.

Conditional subsystems that include identical subsystems can display different initial values before the first execution if both of these apply:

- The model uses classic initialization mode.
 - One or more of the identical subsystems outputs to an identity transformation block.
- “Discrete-Time Integrator or S-Function Block Can Produce Inconsistent Output” on page 10-75

Conditional subsystems that use classic initialization mode and whose output connects to a Discrete-Time Integrator block or S-Function block can produce inconsistent output.

- “Sorted Order Can Affect Merge Block Output” on page 10-77

The sorted order of conditional subsystems that used classic mode initialization, when connected to a Merge block, can affect the output of that Merge block. A change in block execution order can produce unexpected results.

- When you rename the Merge block's source subsystem blocks, the initial output of the Merge block can change.

When two or more subsystems are feeding different initial output values to a Merge block that does not specify its own initial output value, renaming one of the subsystems can affect the initial output of the Merge block in classic initialization mode.

For additional information about the tasks involved to convert a model from classic to simplified mode, see “Convert from Classic to Simplified Initialization Mode” on page 10-70.

Identity Transformation Can Change Model Behavior

Conditional subsystems that include identical subsystems can display different initial values before the first execution if both of these apply:

- The model uses classic initialization mode.
- One or more of the identical subsystems outputs to an identity transformation block.

An identity transformation block is a block that does not change the value of its input signal. Examples of identify transform blocks are a Signal Conversion block or a Gain block with a value of 1.

In the `ex_identity_transform_cl` model, subsystems A and B are identical, but B outputs to a Gain block, which in turn outputs to an Outport block.

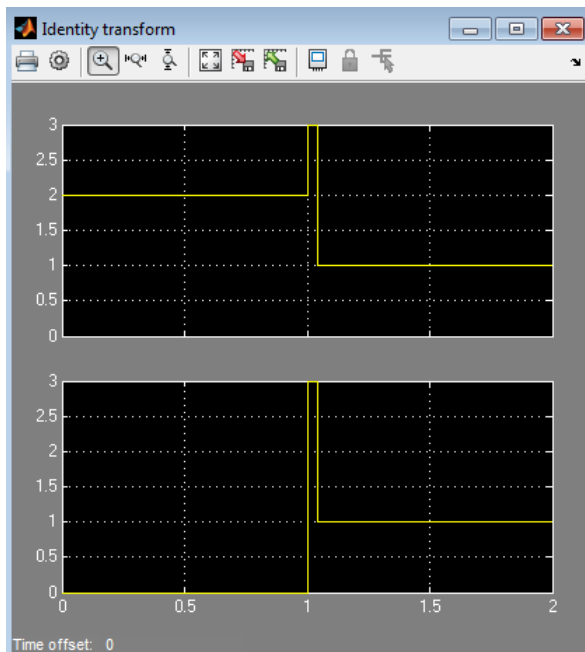

ex_identity_transform_cl ▶ Enabled Subsystem ▶

ex_identity_transform_cl ▶ Enabled Subsystem ▶ A

When you simulate the model, the initial value for A (the top signal in the Scope block) is 2, but the initial value of B is 0, even though the subsystems are identical.

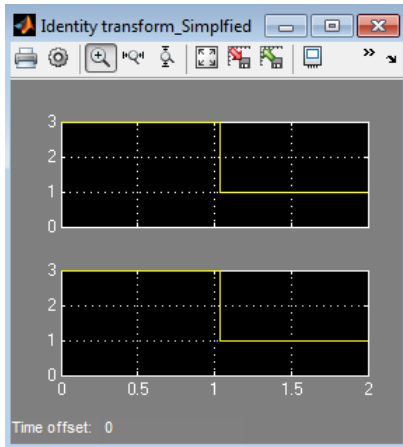

If you update the model to use simplified initialization mode (see `ex_identity_transform_simpl`), the model looks the same. The steps required to convert `ex_identity_transform_cl` to `ex_identity_transform_simpl` are:

- 1 Set **Configuration Parameters > Diagnostics > Connectivity > Mux blocks used to create bus signals** to **error**.
- 2 Set **Configuration Parameters > All Parameters > Underspecified initialization detection** to **Simplified**.
- 3 For the Outport blocks in subsystems A and B, set the **Source of initial output value** parameter to **Input signal**.

You can also get the same behavior by setting the **Source of initial output value** parameter to **Dialog** and the **Initial output** parameter to **3**.

When you simulate the updated model, the connection of an identity transformation does not change the result. The output is consistent in both cases.

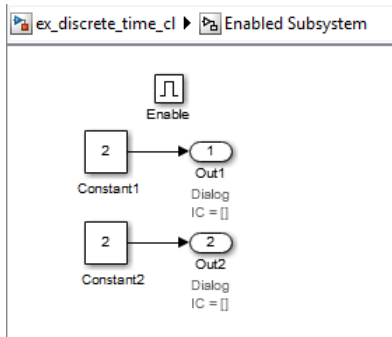

Discrete-Time Integrator or S-Function Block Can Produce Inconsistent Output

Conditional subsystems that use classic initialization mode and whose output connects to a Discrete-Time Integrator block or S-Function block can produce inconsistent output.

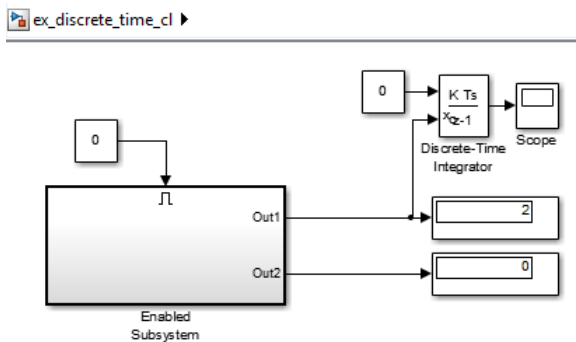

In the `ex_discrete_time_cl` model, the enabled subsystem includes two Constant blocks and outputs to a Discrete-Time Integrator block. The enabled subsystem outputs to two Display blocks.

`ex_discrete_time_cl` ▶

When you simulate the model, the two display blocks show different values.

The Constant1 block, which is connected to the Discrete-Time Integrator block, executes, even though the conditional subsystem is disabled. The top Display block shows a value of 2, which is the value of the Constant1 block. The Constant2 block does not execute, so the bottom Display block shows a value of 0.

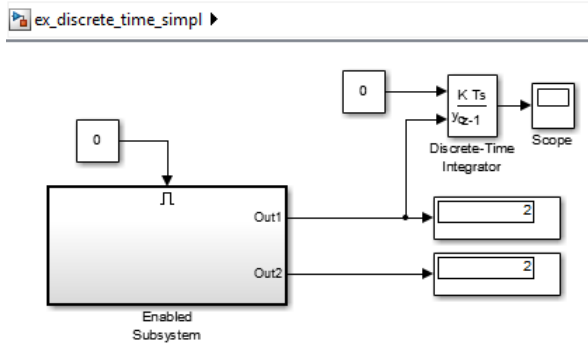

If you update the model to use simplified initialization mode (see `ex_discrete_time_simpl`), the model looks the same. The updated model corrects the inconsistent output issue by using simplified mode. The steps required to convert `ex_discrete_time_cl` to `ex_discrete_time_simpl` are:

- 1 Set **Configuration Parameters > Diagnostics > Connectivity > Mux blocks used to create bus signals** to **error**.
- 2 Set **Configuration Parameters > All Parameters > Underspecified initialization detection** to **Simplified**.

- 3 For the Outport blocks Out1 and Out2, set the **Source of initial output value** parameter to `Input signal`. This setting explicitly inherits the initial value, which in this case is 2.

You can also get the same behavior by setting the **Source of initial output value** parameter to `Dialog` and the **Initial output** parameter to 2.

When you simulate the updated model, the Display blocks show the same output. The output value is 2 because both Outport blocks inherit their initial value.

Sorted Order Can Affect Merge Block Output

The sorted order of conditional subsystems that used classic mode initialization, when connected to a Merge block, can affect the output of that Merge block. A change in block execution order can produce unexpected results. The behavior depends on how you set the **Output When Disabled** parameter.

Example Using Default Setting for the Output When Disabled Parameter

The `ex_basic_merge_sorted_order_1_cl` model has two identical enabled subsystems (Enable A and Enable B) that connect to a Merge block. When you simulate the model, the red numbers show the sorted execution order of the blocks.

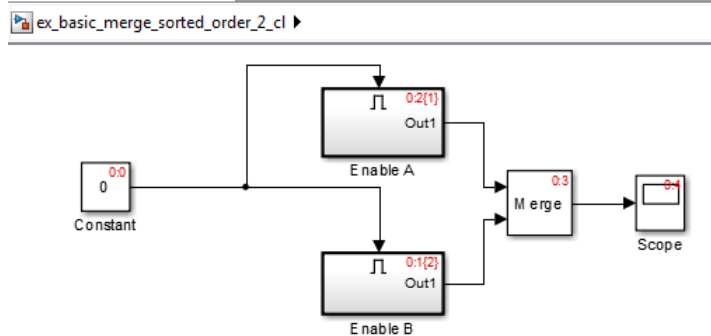

When you simulate the model, the Scope block looks like this:

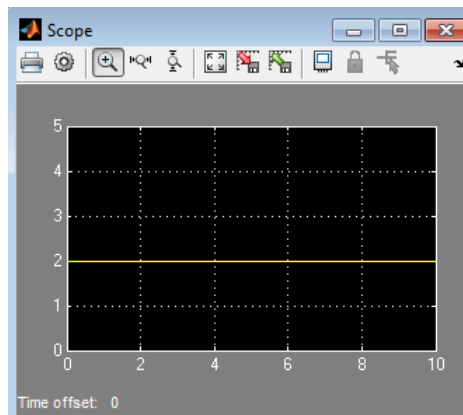

The `ex_basic_merge_sorted_order_2_cl` model is the same as `ex_merge_sorted_1_cl`, except that the block execution order is the reverse of the default execution order. To change the execution order:

- 1 Open the Properties dialog box for the Enable A subsystem and set the **Priority** parameter to 2.
- 2 Set the **Priority** of the Enable B subsystem to 1.

When you simulate the model using the different execution order, the Scope block looks like this:

The change in sorted order produces different results from identical conditional subsystems.

To update the models to use simplified initialization mode (see `ex_basic_merge_sorted_order_1_simpl` and `ex_basic_merge_sorted_order_2_simpl`):

- 1 Set **Configuration Parameters > Diagnostics > Connectivity > Mux blocks used to create bus signals** to **error**.
- 2 Set **Configuration Parameters > All Parameters > Underspecified initialization detection** to **Simplified**.

The **Initial Output** parameter of the Merge block is an empty matrix, `[]`, by default. Hence, the initial output value is set to the default initial value for this data type, which is 0. For information on default initial value, see “Initializing Signal Values” on page 62-16. When you simulate each simplified mode model, both models produce the same results.

Example Using Output When Disabled Parameter Set to Reset

The `ex_merge_sorted_1_cl` model has two enabled subsystems (Enable A and Enable B) that connect to a Merge block. When you simulate the model, the red numbers show the sorted execution order of the blocks.

ex_merge_sorted_1_cl ▶ Enable A

ex_merge_sorted_1_cl ▶ Enable B

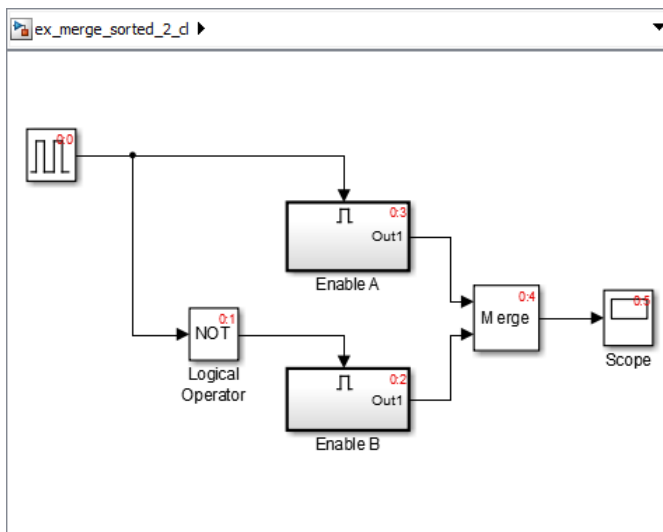

When you simulate the model, the Scope block looks like this:

The `ex_merge_sorted_2_cl` model is the same as `ex_merge_sorted_1_cl`, except that the block execution order is the reverse of the default execution order. To change the execution order:

- 1 Open the Properties dialog box for the Enable A subsystem and set the **Priority** parameter to 2.
- 2 Set the **Priority** of the Enable B subsystem to 1.

When you simulate the model using the different execution order, the Scope block looks like this:

The change in sorted order produces different results from identical conditional subsystems.

To update the models to use simplified initialization mode (see `ex_merge_sorted_1_simpl` and `ex_merge_sorted_2_simpl`):

- 1 Set **Configuration Parameters > Diagnostics > Connectivity > Mux blocks used to create bus signals** to **error**.
- 2 Set **Configuration Parameters > All Parameters > Underspecified initialization detection** to **Simplified**.
- 3 For the Output blocks in Enable A and Enable B, set the **Output when disabled** parameter to **held**. Simplified mode does not support `reset` for outports of conditional subsystems driving Merge blocks.

When you simulate each simplified mode model, both models produce the same results.

What Are Simulink Functions?

A Simulink function in a Simulink model is a computational unit that calculates a set of outputs when provided with a set of inputs. The function header uses a notation similar to programming languages such as MATLAB and C++. You can implement a Simulink function in several ways:

- **Simulink Function block** — Function defined using Simulink blocks within a Simulink Function block. See **Simulink Function** block reference.
- **Stateflow graphical function** — Function defined with state transitions within a Stateflow chart, and then exported to a Simulink model.
- **Stateflow MATLAB function** — Function defined with MATLAB language statements within a Stateflow chart, and then exported to a Simulink model.

What Are Simulink Function Callers?

A Simulink function caller invokes the execution of a Simulink function. You can call a function from anywhere in a model or chart hierarchy.

- **Function Caller block** — In a Simulink model, calls a function defined in Simulink or exported from Stateflow. See **Function Caller** block reference.

- **Stateflow chart transition** — In a Stateflow chart, calls functions defined in Simulink or exported from Stateflow.
- **MATLAB Function block** — In a Simulink model, calls a function from a MATLAB language script.

Connect to Local Signals

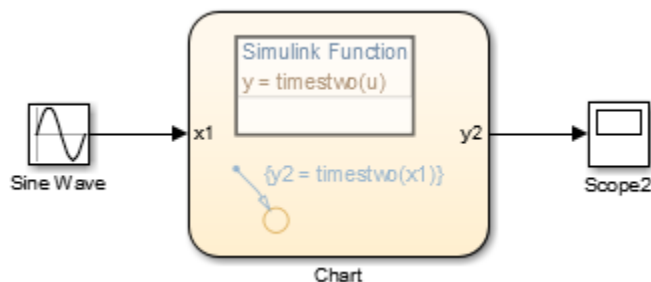

In addition to Argument Inport and Argument Outport blocks, a Simulink Function block can interface to signals in the local environment of the block through **Inport** or **Outport** blocks. These signals are hidden from the caller. You can use port blocks to connect and communicate between two Simulink Function blocks or connect to root Inport and Outport blocks that represent external I/O.

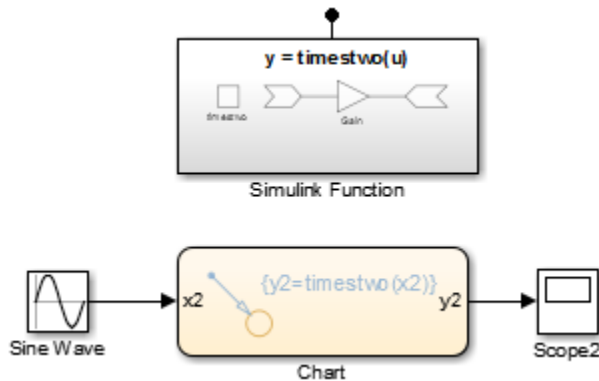

You can also connect the Outport blocks to sink blocks including logging (To File, To Workspace) and viewing (Scope, Display) blocks. However, these blocks execute last after all other blocks.

Reusable Logic with Functions

Use functions when you need reusable logic across a model hierarchy. Consider an example where a Simulink Function with reusable logic is in a Stateflow chart.

You can move the reusable logic from inside the Stateflow chart to a Simulink Function block. The logic is then reusable by function callers in Simulink subsystems (Subsystem and Model blocks) and in Stateflow charts at any level in the model hierarchy.

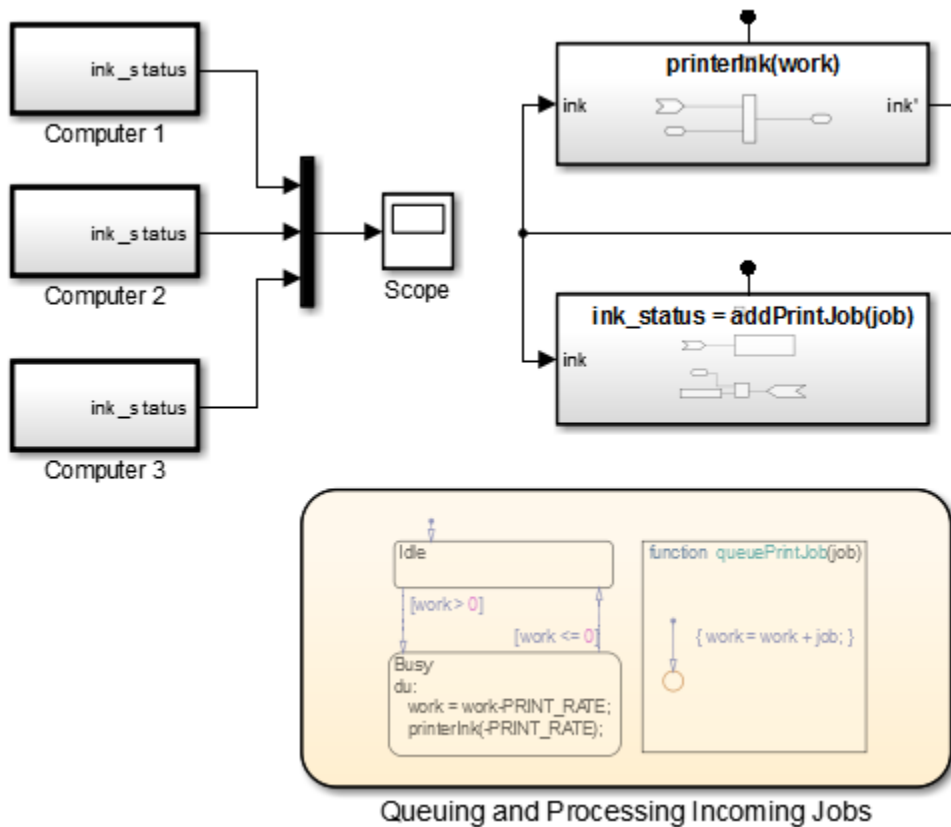

The result is added flexibility for structuring your model for reuse.

Note: Input and output argument names (`x2`, `y2`) for calling a function from a Stateflow chart do not have to match the argument names in the function prototype (`u`, `y`) of a Simulink Function block.

Shared Resources with Functions

Use functions when you model a shared resource, such as a printer. The model `slexPrinterExample` uses Simulink Function blocks as a common interface between multiple computers and a single Stateflow chart that models a printer process.

How a Function Caller Identifies a Function

The function interface uses MATLAB syntax to define the name of a function and its input and output arguments. The model hierarchy can contain only one function definition with the identified function name. Simulink verifies that:

- The arguments in the **Function prototype** parameter for a Function Caller block matches the arguments specified in the function. For example, a function with two input arguments and one output argument appears as:

```
y = MyFunction(u1, u2)
```

- The data type, dimension, and complexity of the arguments must agree. For a Function Caller block, you can set the **Input argument specifications** and **Output argument specifications** parameters, but usually you do not need to specify these parameters manually. Simulink derives the specification from the function.

The only case where you must specify the argument parameters is when the Function Caller block cannot find the function in the model or in any child model it references. This situation can happen when the Functions Caller block and called function are in separate models that referenced by a common parent model. See “Simulink Functions in Referenced Models” on page 10-113.

Reasons to Use a Simulink Function Block

Function-Call Subsystem blocks with direct signal connections for triggering provide better signal traceability than Simulink Function blocks, but Simulink Function blocks have other advantages.

- **Eliminate routing of signal lines.** The Function Caller block allows you to execute functions defined with a Simulink Function block without a connecting signal line. In addition, functions and their callers can reside in different models or subsystems. This approach eliminates signal routing problems through a hierarchal model structure and allows greater reuse of model components.
- **Use multiple callers to the same function.** Multiple Function Caller blocks or Stateflow charts can call the same function. If the function contains state (e.g., a Unit Delay block), the state is shared between the different callers.
- **Separate function interface from function definition.** Functions separate their interface (input and output arguments) from their implementation. Therefore, you can define a function using a Simulink Function block, an exported graphical function from Stateflow, or an exported MATLAB function from Stateflow. The caller does not need to know how or where the function was implemented.

Choosing to Use a Simulink Function or Reusable Subsystem

A consideration for using a Simulink Function block or a Subsystem block has to do with shared state between function calls. A Simulink Function block has shared state while a Subsystem block, even if specified as a reusable function, does not.

- For a Simulink Function block, when one block has multiple callers, code is always generated for one function. If the Simulink Function block contains blocks with state

(for example, Delay or Memory), the state is persistent and shared between function callers. In this case, the order of calls is an important consideration.

- For a Subsystem block, when a block has multiple instances and is configured as a reusable function, code is usually generated for one function as an optimization. If the Subsystem block contains blocks with state, code is still generated for one function, but a different state variable is passed to the function. State is not shared between the instances.

When Not to Use a Simulink Function Block

Simulink Function blocks allow you to implement functions graphically, but there are times when using a Simulink Function block is not the best solution.

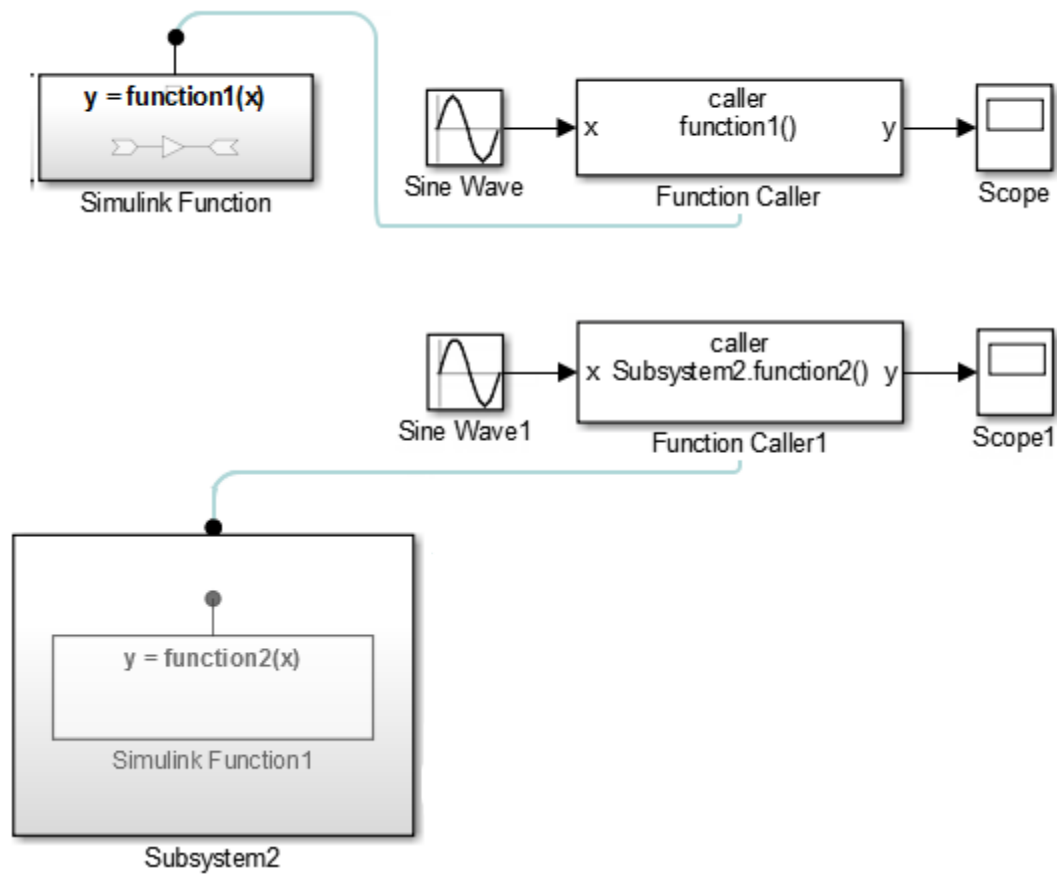

For example, when modeling a PID controller or a digital filter and you have to model the equations defining the dynamic system. Use an S-Function, Subsystem, or Model block to implement systems of equations, but do not use a Simulink Function block, because these conditions can occur:

- **Persistence of state between function calls.** If a Simulink Function block contains any blocks with state (for example, Unit Delay or Memory), then their state values are persistent between calls to the function. If there are multiple calls to that function, the state values are also persistent between the calls originating from different callers. For more on this topic, see “Call a Simulink Function Block from Multiple Sites” on page 10-109.
- **Inheriting continuous sample time.** A Simulink Function block cannot inherit a continuous sample time. Therefore, do not use this block in systems that use continuous sample times to model continuous system equations.

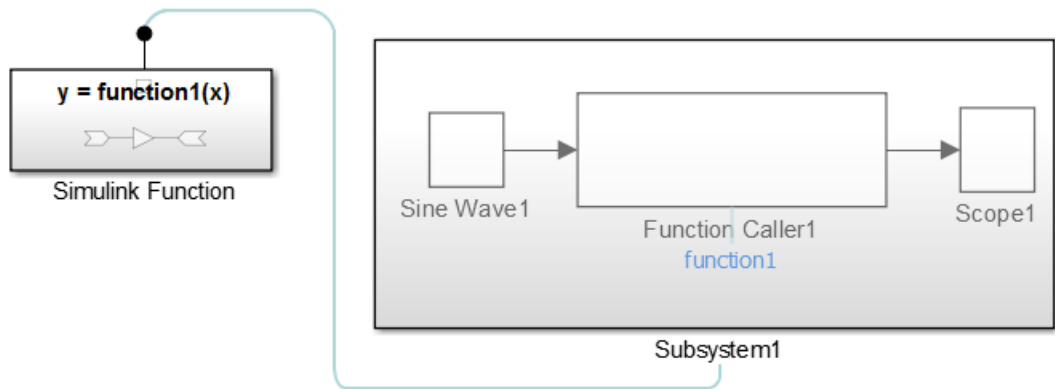

Tracing Simulink Functions

Visually display connections between a Simulink function and their callers with lines that connect callers to functions:

- Turning on/off tracing lines — From the Simulink Editor menu, Select **Display > Function Connectors**.
- Direction of tracing lines — Lines connected at the bottom of a block are from a function caller. Lines connected at the top of a block are to a Simulink function or a subsystem containing the function.

- Navigation to functions — A function caller can be within a subsystem.

Navigate from a caller in a subsystem to a function by first opening the subsystem, and then clicking a link to the function.

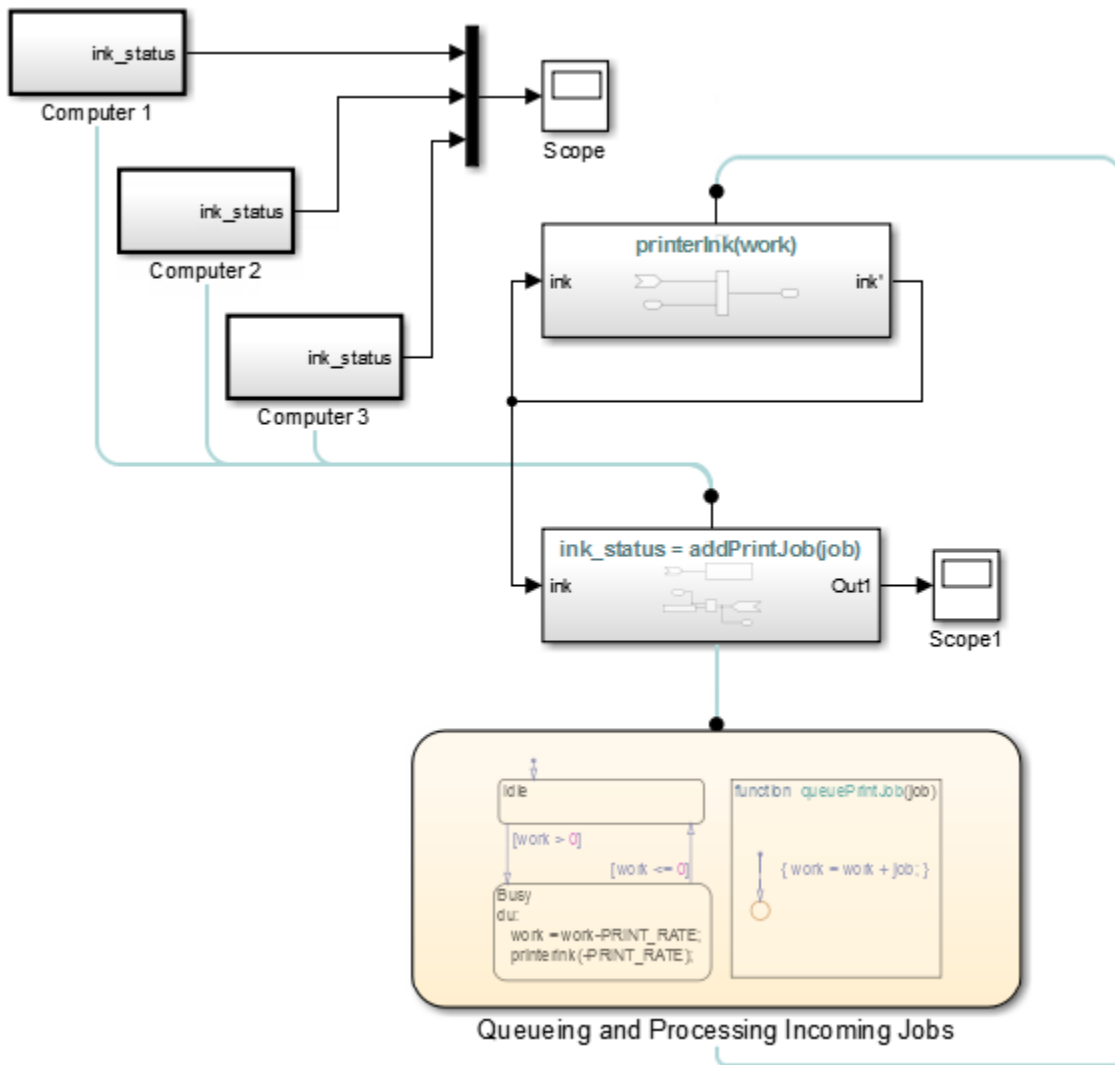

If the function is at the root level of a model, the function opens. If the function is within a subsystem, the subsystem containing the function opens.

Monitoring Ink Status on a Shared Printer Using Simulink Functions

After selecting **Display > Function Connectors**, the model `slexPrinterExample` shows the relationships between callers and functions.

In this example, the Function Caller in the Simulink Function block `addPrintJob`, calls the exported Stateflow function `queuePrintJob`. The subchart `Busy` calls the Simulink Function block `printerInk`. Tracing lines are drawn into and out of the Stateflow chart.

Create Simulink Functions in a Simulink Model

Simulink functions have a function interface with input and output arguments similar to programming languages. You create the function definitions:

- Graphically, using Simulink blocks in a Simulink Function block, or Stateflow state transitions in a graphical function exported from a Stateflow chart.
- Textually, using MATLAB code in a MATLAB function exported from a Stateflow chart.

Simulink Function Block

Set up a Simulink Function block to receive data through an input argument from a function caller. Multiply the input argument by 2, and then pass the calculated value back through an output argument.

- 1 Add a Simulink Function block from the User-Defined Functions library into your model.
- 2 On the block, enter this function prototype to set the function name to `timestwo`, the input argument to `u`, and the output argument to `y`:

```
y = timestwo(u)
```

- 3 Double-click the block to open the subsystem defining the function.
- 4 Add a Gain block and set the **Gain** parameter to 2.

Export Graphical Function from Stateflow Chart

Set up a graphical function in a Stateflow chart to receive data through an input argument from a function caller. Multiply the input argument by 2, and then pass the calculated value back through an output argument. Set chart parameters to export the function to a Simulink model.

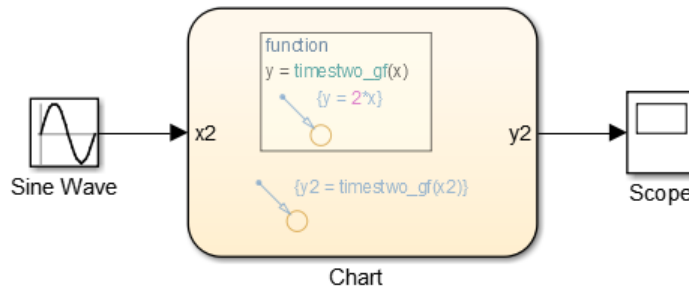

Define a Graphical Function

Create a graphical function in a Stateflow chart. Define the function interface and function definition.

- 1 Add a Stateflow Chart to your Simulink model. From the Simulink Editor menu, select **File > New > Chart**.
- 2 Drag the new chart to your model. Double-click the chart to open it.
- 3 Add a graphical function. From the left-side toolbar, click and drag the graphical function icon  onto the chart.
- 4 Define the function interface. In the function box, replace the ? with the function interface `y = timestwo_gf(x)`.
- 5 Define the function. Click the transition arrow and replace the ? with the MATLAB code `{y = 2*x}`.

- 6 Add a transition in the chart. Connect the chart input to a Sine Wave input and the output to a Scope.

- 7 Run a simulation to test the function.

Set Argument Parameters for a Graphical Function

Specify the size, complexity, and type of the function input and output arguments. A chart can export only functions with fully specified prototypes.

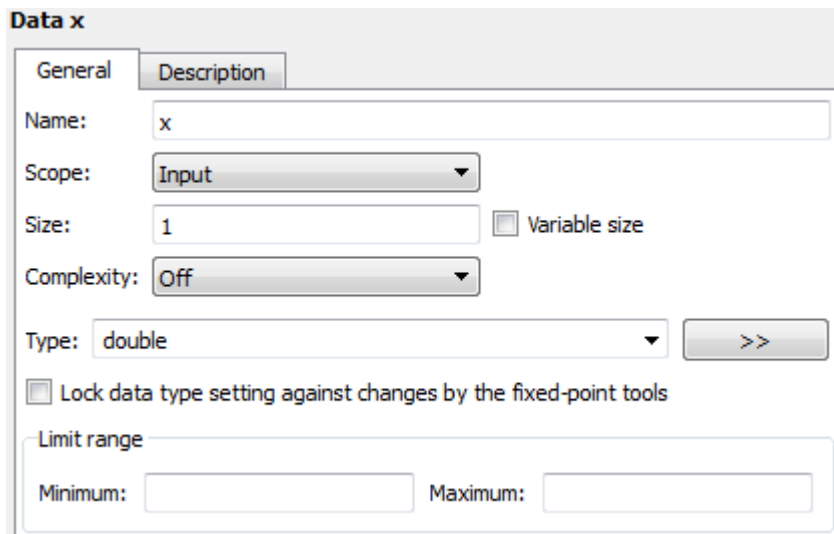

- 1 Open Model Explorer. In the left pane, select the graphical function.

- 2 From the **Column View** list in the middle pane, select **Stateflow**. Select the filter icon , and then select **All Stateflow Objects**. From the table at the bottom of the pane, select an input or output argument.

- 3 In the right pane, enter 1 (scaler) for Size, select Off (real number) for **Complexity**, and select **double** for **Type**.

- 4 Repeat steps 2 and 3 with the remaining function arguments.

Set Export Function Parameters for a Graphical Function

Set parameters to export the graphical function during a simulation.

- 1 From the left pane, select the chart containing the graphical function.

Alternatively, open the chart and from the menu, select **Chart > Properties**.

- 2 In the property dialog box, select **Export Chart Level Functions (Make Global)** and **Allow exported functions to be called by Simulink** check boxes.

If you are calling the exported graphical function from another Stateflow chart (not the chart that exported the graphical function), you do not need to select the **Allow exported functions to be called by Simulink** check box.

Export MATLAB Function from Stateflow Chart

Set up a MATLAB function in a Stateflow chart to receive data through an input argument from a function caller. Multiply the input argument by 2, and then pass the calculated value back through an output argument. Set chart parameters to export the function to a Simulink model.

Define MATLAB Function

Create a graphical function in a Stateflow chart. Define the function interface and function definition.

- 1 Add a Stateflow Chart to your Simulink model. From the Simulink Editor menu, select **File > New > Chart**. A new chart opens in a new model.
- 2 Drag the new chart to your model. Double-click the chart to open it.
- 3 Add a graphical function. From the left-side toolbar, click and drag the graphical function icon  onto the chart.
- 4 Define the function interface. In the function box, replace the ? with the function interface `y = timestwo_mf(x)`.

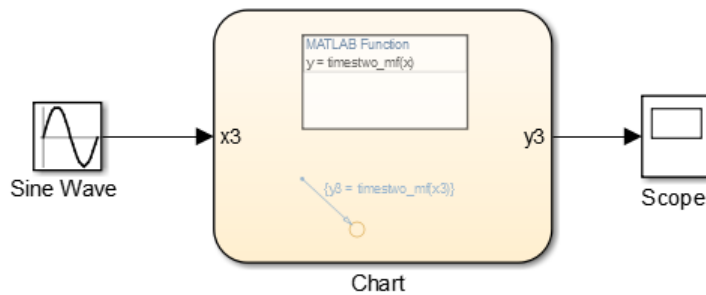

- 5 Double-click the function box to open the MATLAB code editor. Define the function with the MATLAB code.

```

Editor - Stateflow (MATLAB Function) ev...
timestwo_mf* x timestwo_ml* x +
1 function y = timestwo_mf(x)
2
3 y = 2*x;
    
```

- 6 Add a transition to test the MATLAB function. Add a Sine Wave input and connect the output to a Scope.

- 7 Run a simulation to test the function.

Set Argument Parameters

Specify the size, complexity, and type of the function input and output arguments. A chart can export only functions with fully specified prototypes.

- 1 Open Model Explorer. In the left pane, select the MATLAB function.

- 2 In the middle pane, from the **Column View** list, select **Stateflow**. From the table, select an input or output argument.

- 3 In the right pane, enter 1 (scaler) for **Size**, select Off (real number) for **Complexity**, and select double for **Type**.

- 4 Repeat steps 2 and 3 with the remaining function arguments.

Set Export Function Parameters

Set parameters to export the MATLAB function during a simulation.

- 1 From the left pane, select the chart containing the graphical function.

Alternatively, open the chart and from the menu, select **Chart > Properties**.

- 2 In the property dialog box, select **Export Chart Level Function (Make Global)** and **Allow exported functions to be called by Simulink** check boxes.

If you are calling the exported graphical function from another Stateflow chart (not the chart that exported the graphical function), you do not need to select the **Allow exported functions to be called by Simulink** check box.

Call Simulink Functions with a Function Caller Block

The following examples show how to use a Function Caller block to call:

- Simulink Function block.
- Exported Graphical function from a Stateflow chart.
- Exported MATLAB function from a Stateflow chart.

The functions multiply a value from the caller by 2, and then send the calculated value back to the caller.

Because the Function Caller block cannot determine function arguments at compile time, you have to name the Function Caller block input and output arguments. The argument names in the **Function prototype** must match the function argument names.

Function Caller Block to Call Simulink Function Block

Set up a Function Caller block to send data through an input argument to a Simulink Function block. Receive data back from the function through an output argument.

- 1 Add a Function Caller block from the User-Defined Functions library into your model.
- 2 In the Function Caller dialog box, in the **Function prototype** box, enter `y = timestwo(u)`. This function prototype creates an input port `u` and output port `y` on the Function Caller block.
- 3 Add a Sine Wave block to the input and a Scope block to the output.

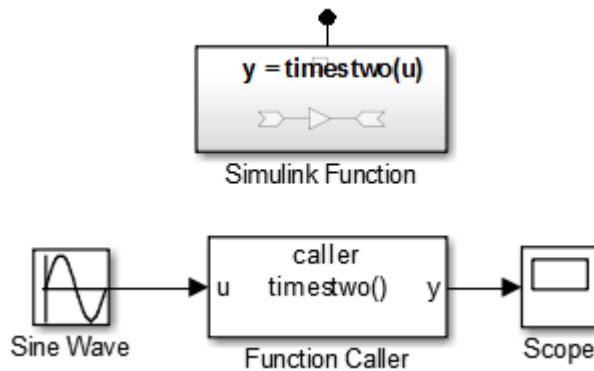

- 4 Set up a Simulink Function block as described in “Simulink Function Block” on page 10-95.

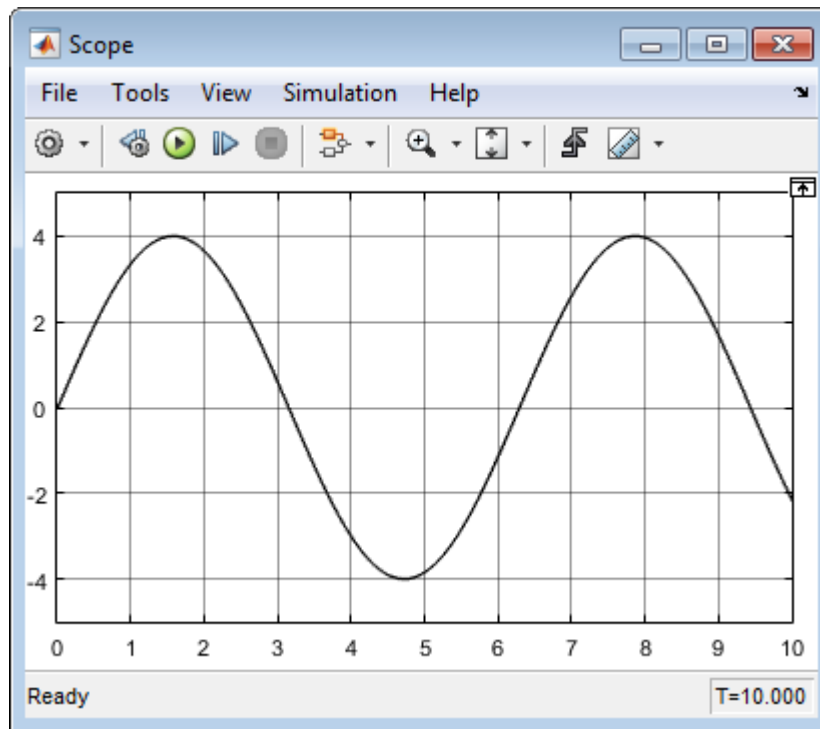

Simulate the Model

After you create a function using a Simulink Function block and setup a call to that function using a Function Caller block, you can simulate the model.

- 1 Return to the top level of the model.

- 2 Run a simulation.
- 3 To view the signal results, double-click the Scope block. The input sine wave with an amplitude of 2 is doubled.

Function Caller Block to Call Exported Graphical Function

Calling an exported graphical function from Stateflow is no different than calling a Simulink Function block. Points to consider:

- The input and output argument names for an exported function and the prototype for a Function Caller block must match exactly.
- If the Function Caller block is within a Model block (referenced model), you must define the **Input argument specification** and **Output argument specification**.

To create an exported graphical function, see “Export Graphical Function from Stateflow Chart” on page 10-96.

Function Caller Block to Call Exported MATLAB Functions

Calling an exported graphical function from Stateflow is no different than calling a Simulink Function block. Points to consider:

- The input and output argument names for an exported function and the prototype for a Function Caller block must match exactly.
- If the Function Caller block is within a Model block (referenced model), you must define the **Input argument specification** and **Output argument specification**.

To create an exported MATLAB function, see “Export MATLAB Function from Stateflow Chart” on page 10-99.

Call Simulink Functions from a MATLAB Function Block

A MATLAB Function block can call another function. The following examples show how to use a MATLAB Function block to call:

- Simulink Function block.
- Exported Graphical function from a Stateflow chart.
- Exported MATLAB function from a Stateflow chart.

The functions multiply a value from the caller by 2, and then send the calculated value back to the caller.

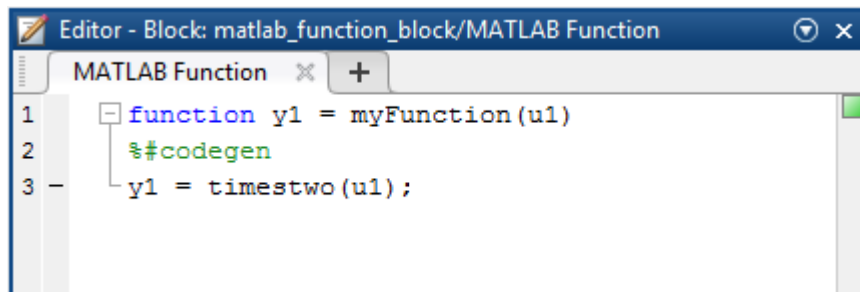

MATLAB Function blocks only support discrete and fixed-in-minor sample times. When using a Sine Wave block as an input signal, setup the model and block parameters for a sample time compatible with the MATLAB Function block:

- Discrete — Open the model Configuration Parameters dialog box to the Solver pane. Set **Type** to Fixed-step and enter a value for **Fixed-step size** (fundamental sample time). Open the Sine Wave Block Parameters dialog box and set **Sample time** to the model sample time you entered.
- Fixed-In-Minor step — Open the Sine Wave Block Parameters dialog box. In the **Sample time** box, enter [0 1].

MATLAB Function Block to Call Simulink Function Block

Set up a MATLAB Function block to send data through an input argument to a Simulink Function block. Receive data back from the function through an output argument.

- 1 Add a MATLAB Function block to your model.
- 2 Double-click the block, which opens the MATLAB editor. Enter the function call `y1 = timestwo(u1)`.

```

Editor - Block: matlab_function_block/MATLAB Function
MATLAB Function
1 function y1 = myFunction(u1)
2     %#codegen
3     y1 = timestwo(u1);

```

Note: The argument names for the function you define in the MATLAB Function block do not have to match the argument names for the function that you define in the Simulink Function block. For a Function Caller block that calls a Simulink Function block, argument names must match.

- 3 Add a Sine Wave block for an input signal and a Scope block to view the output signal.

- 4 For the Sine Wave block, set the **Sample time** to 0.01. For the model, open the Configuration Parameters dialog box to the solver pane. Set **Type** to Fixed-step and **Fixed-step size** to 0.01.
- 5 Set up a Simulink Function block as described in “Simulink Function Block” on page 10-95.

MATLAB Function Block to Call Exported Graphical Function

Calling an exported graphical function from a MATLAB Function block is the same as calling a Simulink Function block. See “MATLAB Function Block to Call Simulink Function Block” on page 10-105.

MATLAB Function Block to Call Exported MATLAB Function

Calling an exported MATLAB function from a MATLAB Function block is the same as calling a Simulink Function block. See “MATLAB Function Block to Call Simulink Function Block” on page 10-105.

Call Simulink Functions from a Stateflow Chart

The following examples show how to use a Stateflow chart to call functions external to the chart but accessible in a Simulink model:

- Simulink Function block
- Exported Stateflow graphical function
- Exported Stateflow MATLAB function

There are no limitations to a function call from a Stateflow chart:

- Caller argument names can be different from the function argument names.
- Input signals to a Stateflow chart can be either continuous or discrete.

Create Stateflow Chart with a Transition

- 1 Add a Stateflow Chart to your Simulink model. From the Simulink Editor menu, select **File > New > Chart**. A new chart opens in a new model.
- 2 Drag the new chart to your model. Double-click the chart to open it.

- 3 Add a graphical function. From the left-side toolbar, click and drag the transition icon  onto the chart.
- 4 Add input port.
 - a From the menu, select **Chart > Add Inputs & Outputs > Data Input From Simulink**.
 - b In the Data dialog box, set **Name** to x1.
- 5 Add output port.
 - a From the menu, select **Chart > Add Inputs & Outputs > Data Output To Simulink**.
 - b In the Data dialog box, set **Name** to y1.
- 6 Add a Sine Wave block and connect signal output to the chart input port. Add a Scope block and connect input to the chart output port.
- 7 Edit transition code to call a function. For example, to call the Simulink Function block, enter:

```
{y1=timestwo_sf(x1);}
```

- 8 Set up a Simulink Function block as described in “Simulink Function Block” on page 10-95.

Stateflow Chart to Call Exported Graphical Function

Calling an exported graphical function from a Stateflow chart is the same as calling a Simulink Function block. See “Call Simulink Functions from a Stateflow Chart” on page 10-107.

- 1 Open a Stateflow chart.
- 2 Click transition and enter

```
{y2=timestwo_gf(x2);}
```

Stateflow Chart to Call Exported MATLAB Functions

Calling an exported MATLAB function from a Stateflow chart is the same as calling a Simulink Function block. See “Call Simulink Functions from a Stateflow Chart” on page 10-107.

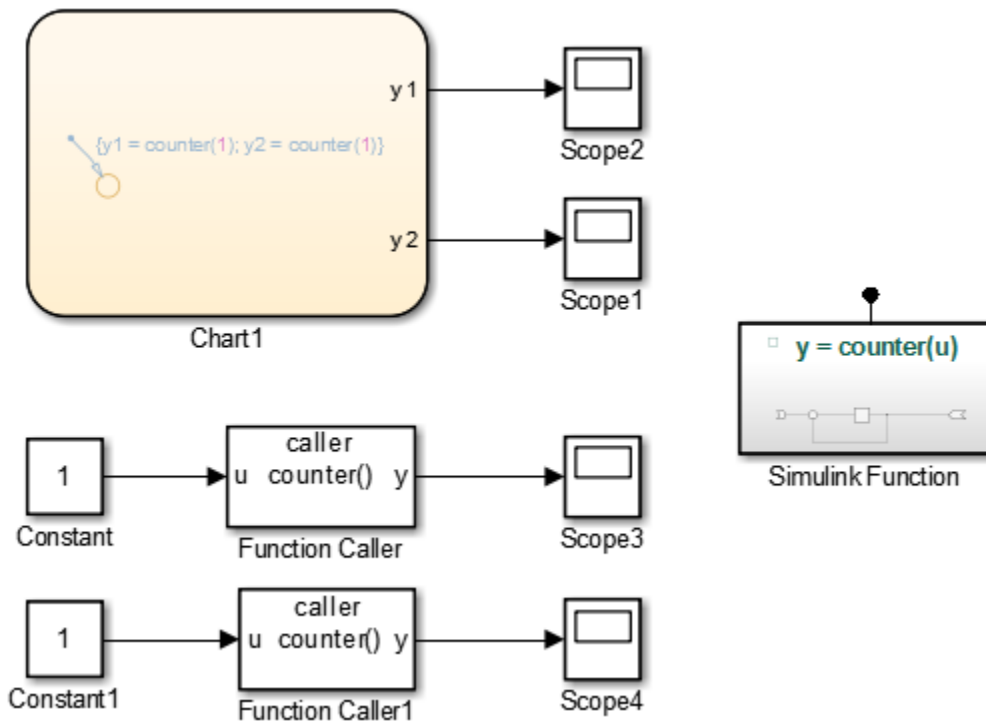

- 1 Open Stateflow chart.
- 2 Click transition and enter:

```
{y3=timestwo_sf(x3);}
```

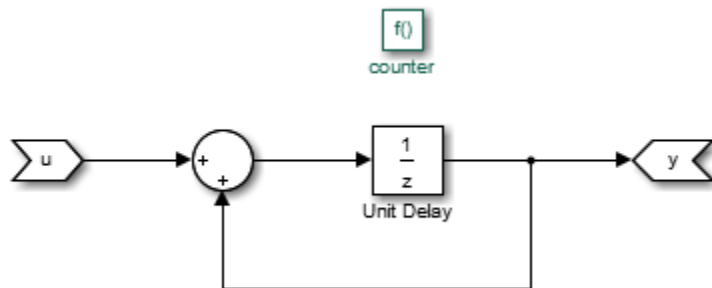

Call a Simulink Function Block from Multiple Sites

If you call a Simulink Function block from multiple sites, all call sites share the state of the function. For example, suppose that you have a Stateflow chart with two calls and two Function Caller blocks with calls to the same function.

A function defined with a Simulink Function block is a counter that increments by 1 each time it is called with an input of 1.

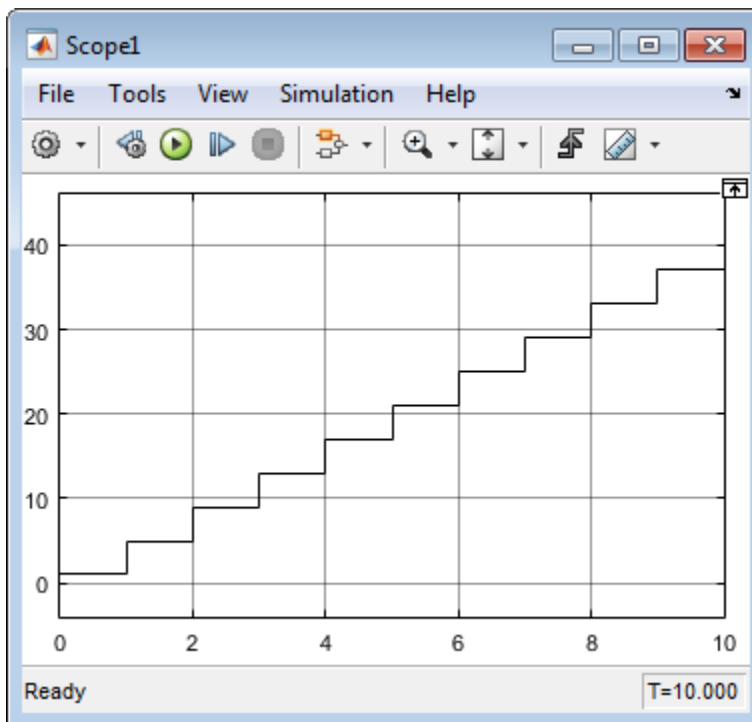

The Unit Delay block has state because the block value is persistent between calls from the two Function Caller blocks and the Stateflow chart. Conceptually, you can think of this function being implemented in MATLAB code:

```
function y = counter(u)
persistent state;
if isempty(state)
    state = 0;
end
y = state;
state = state + u;
```

Simulink initializes the state value of the Unit Delay block at the beginning of a simulation. After that, each time the function is called, the state value is updated.

In this example, the output observed in Scope1 increments by 4 at each time step. Scope2, Scope3, and Scope4 show a similar behavior. The only difference is a shift in the observed signal due to the execution sequence of the function calls.

For multiple callers to share a function or call two different functions with a shared state, each caller must have the same sample time. This condition ensures data integrity and consistency in real-time code.

“Create Stateflow Chart with a Transition” on page 10-107

Simulink Functions in Referenced Models

In this section...

“Simulink Function Block in Referenced Model” on page 10-113

“Function Caller Block in Referenced Model” on page 10-115

“Function and Function Caller in Separate Models” on page 10-116

“Function and Function Caller in the Same Model” on page 10-118

You can place Simulink Function and Function Caller blocks in a referenced model, but doing so requires some special considerations:

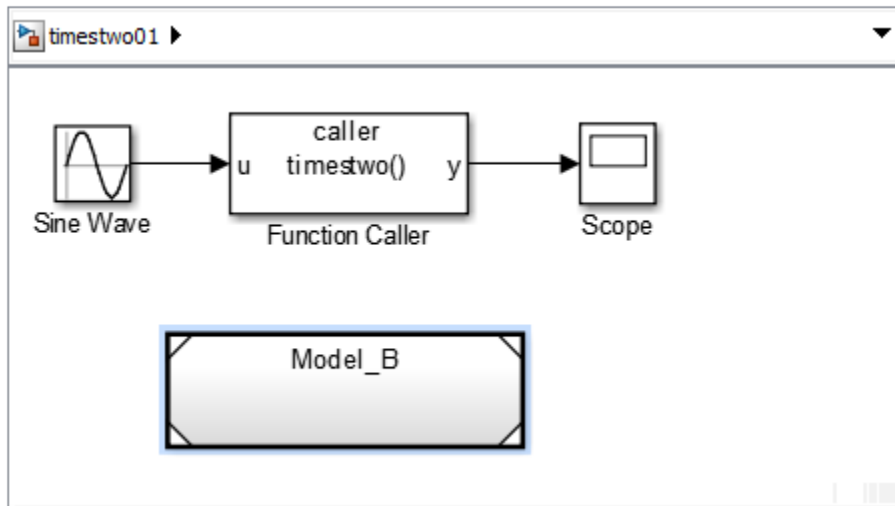

- The referenced model must follow export-function model rules. See “Export-Function Models” on page 10-4.
- In some cases, you need to explicitly define the argument data types for a Function Caller block.

These examples show four relationships between Function Caller blocks, Simulink Function blocks, and referenced models.

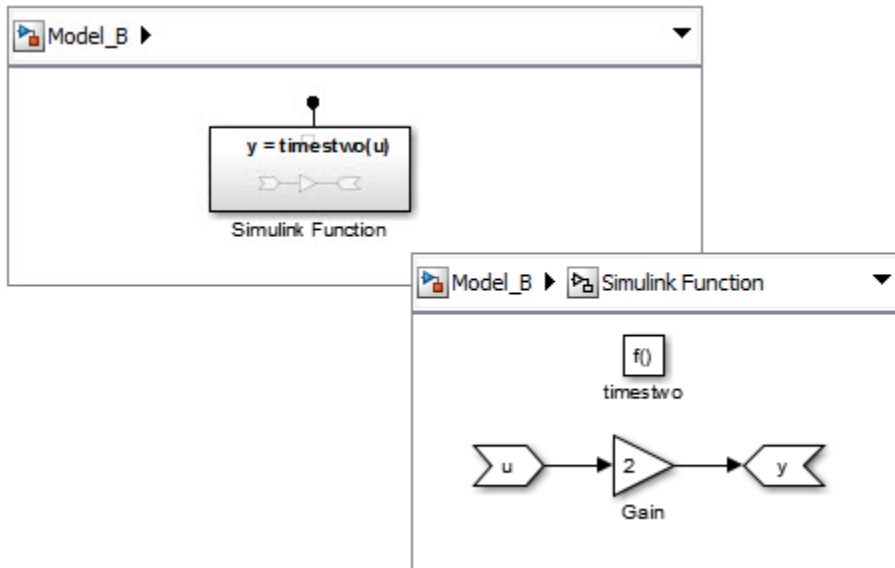

Simulink Function Block in Referenced Model

In this example, the parent model contains a Function Caller block, and the referenced model, `Model_B`, contains a Simulink Function block. `Model_B` must follow export-function model rules.

Since the Function Caller block is a parent of the function, it can determine the argument data types of the function. In the Function Caller block, you do not need to define the **Input argument specification** and **Output argument specification** parameters.

Model_B contains a Simulink Function block that defines a function for multiplying the input by 2. Because this model contains only a Simulink Function block, it satisfies export-function model rules. See “Export-Function Models” on page 10-4.

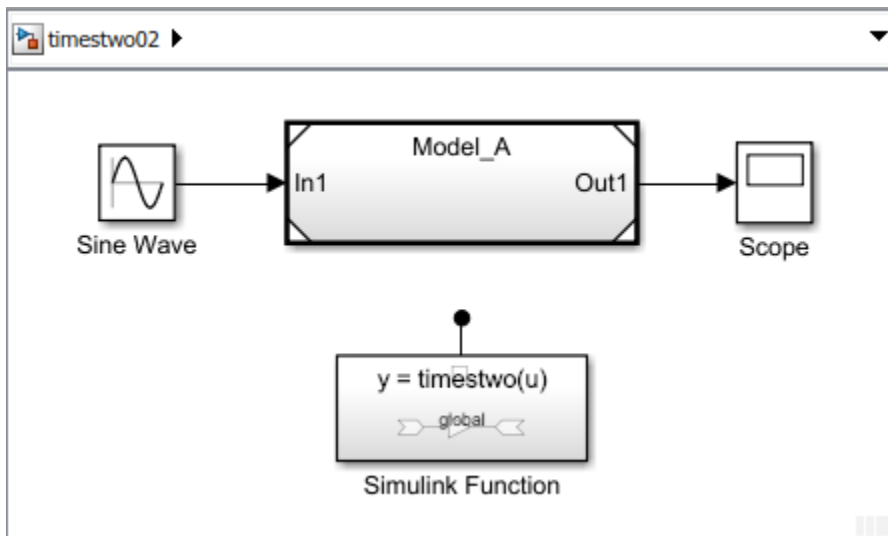

For Model_B, set the Configuration Parameters for the solver to satisfy export-function model rules:

- **Type:** Fixed-step.
- **Solver:** discrete (no continuous states).

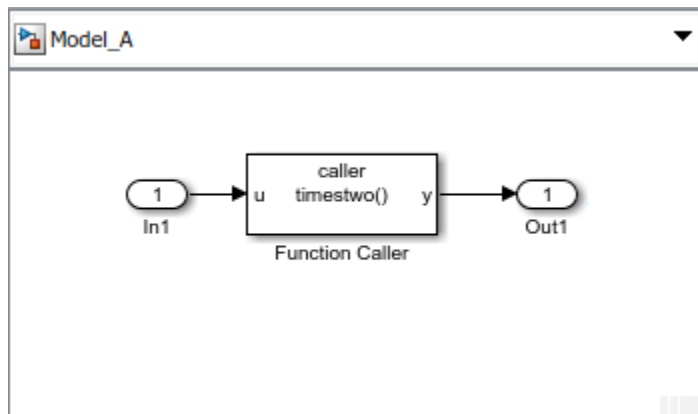

Function Caller Block in Referenced Model

In this example, the parent model contains a Simulink Function block, and a referenced model, Model_A, contains a Function Caller block.

For the parent model, you can set the solver type to Variable-step or Fixed-step.

Model_A contains a Function Caller block.

Since the Function Caller block cannot find the function in `Model_A` or in a model it references, you must specify the Function Caller block argument parameters:

- **Input argument specification:** Specify to match the Simulink Function block input argument data types, for example, `double(1.0)`.

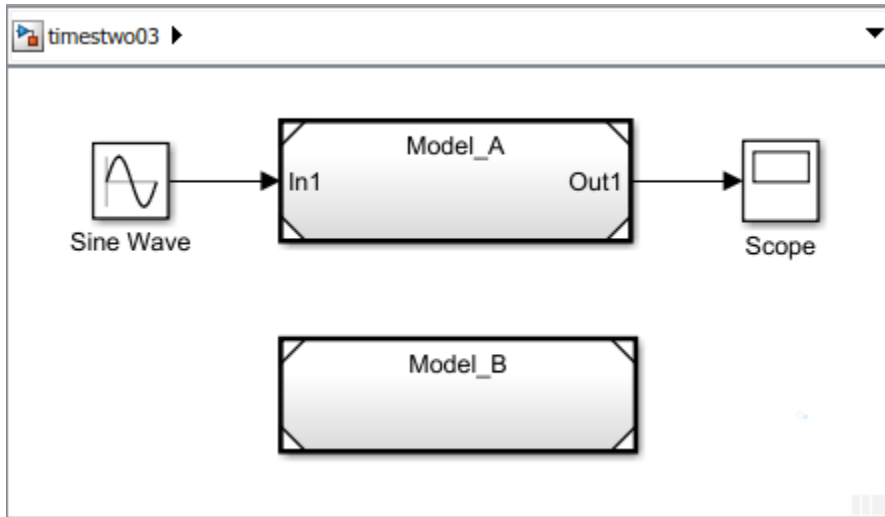

Specify the argument specification for a Simulink Function block with the **Data type** parameter in the Input Argument and Output Argument blocks.

- **Output argument specification:** Specify to match the Simulink Function block output argument data types, for example, `double(1.0)`.

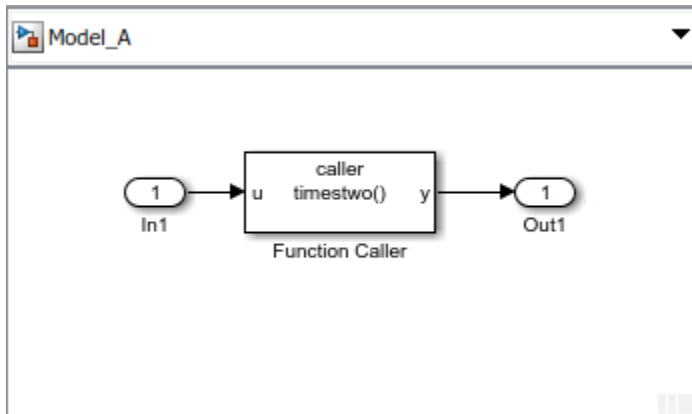

Function and Function Caller in Separate Models

In this example, the parent model contains two referenced models. `Model_A` is a referenced model with a Function Caller block. `Model_B` is a referenced model with a Simulink Function block. Only `Model_B` with a Simulink Function block needs to follow export-function rules.

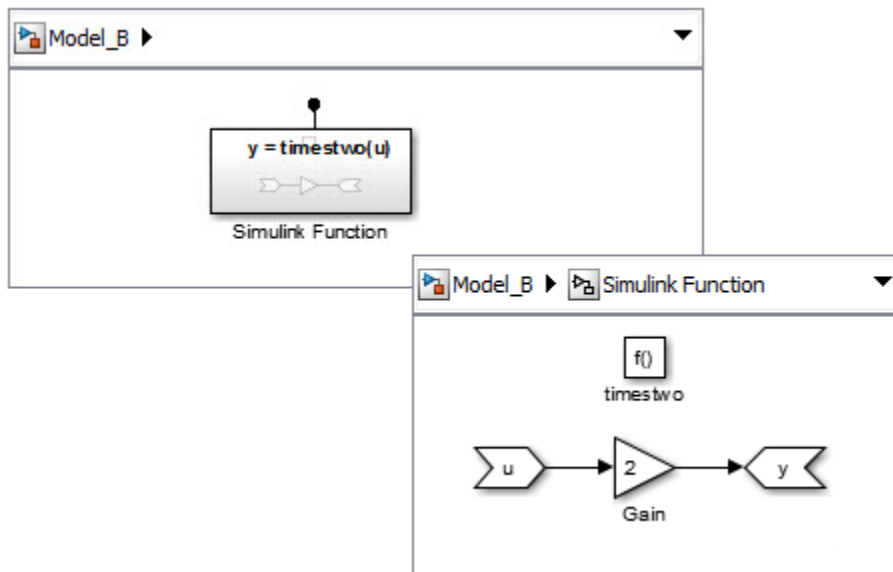

For `Model_A`, specify parameters as you do for the referenced model in “Function Caller Block in Referenced Model” on page 10-115. For `Model_B`, specify parameters as you do for the referenced model in “Simulink Function Block in Referenced Model” on page 10-113.

Model_A contains a Function Caller block.

Model_B contains a Simulink Function block that defines a function for multiplying the input by 2. Because this model contains only a Simulink Function block, it satisfies export-function model rules. See “Export-Function Models” on page 10-4.

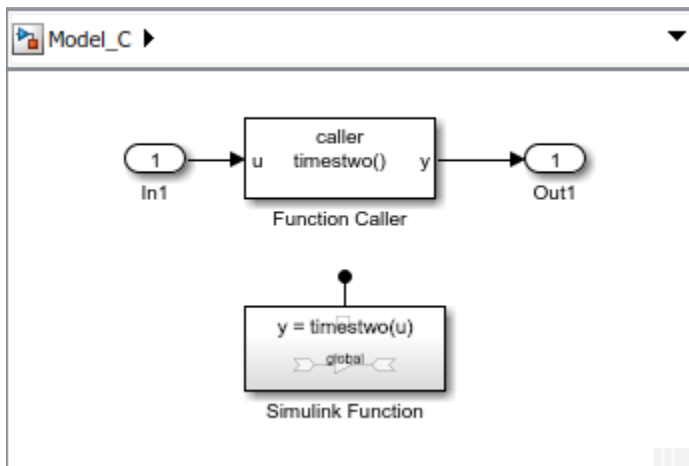

Function and Function Caller in the Same Model

In this example, the parent model contains one referenced model, `Model_C`, with both a Function Caller block and a Simulink Function block. Because both function and caller are in the same model, `Model_C` doesn't need to follow export-function rules.

Model_C contains both a Function Caller block and a Simulink Function block.

More About

- “Simulink Functions” on page 10-85

Private Scoping of Simulink Functions

The scope of a Simulink function is defined within the context of a model. If you place a function in any subsystem, the function scope is private to the model. Access to the function from outside the model is prohibited. You can place a function:

- In a virtual subsystem — You can access the function from within the subsystem without qualifying the function name, or you can access the function from outside the subsystem by qualifying the function name with the subsystem name.
- In an atomic subsystem — You can call functions from within the subsystem, but not from outside the subsystem by qualifying the name.

Placing a virtual subsystem at the root level of a model enables you to create a library of Simulink functions. The functions are then accessible from anywhere in your model.

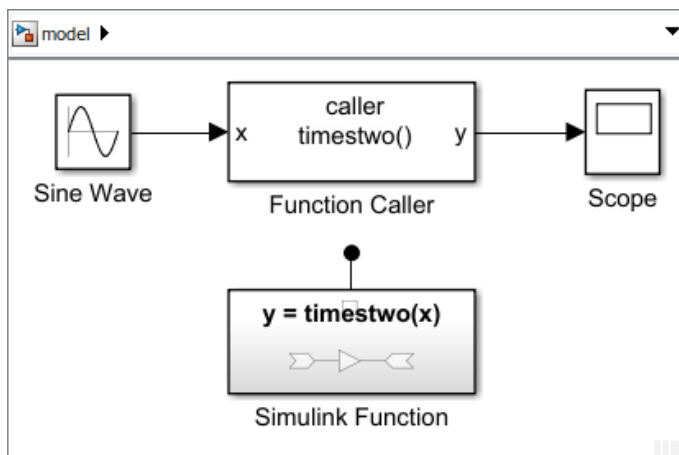

Resolve to a Function Hierarchically

Placing a Simulink Function block within any Subsystem block limits access to the function and removes the function name from the global namespace. You can call the function from inside the subsystem without qualification. For example:

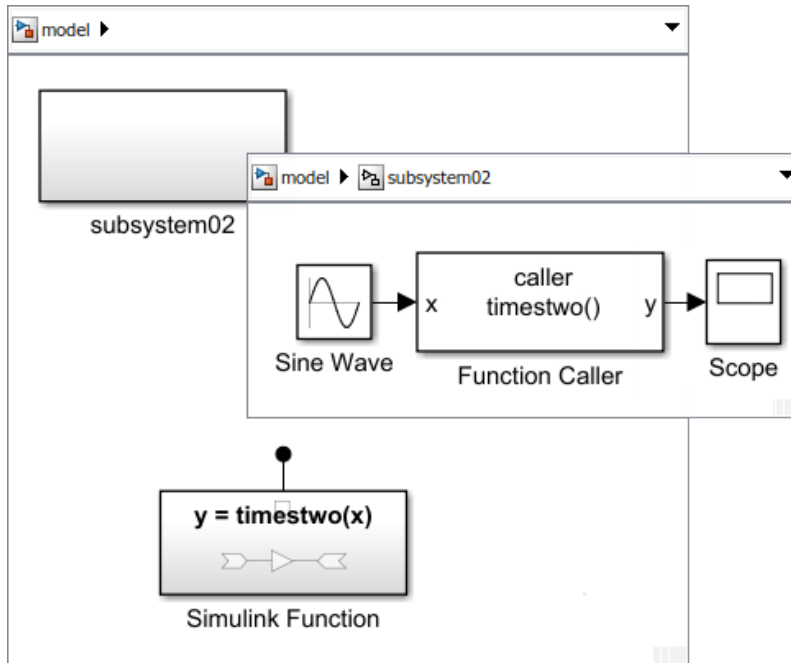

```
y = function_name(x)
```

The function caller can be:

- At the same hierarchic level as the function

- In a subsystem one or more levels below the hierarchic level of the function

You can also call a private Simulink Function block from a MATLAB Function block or a Stateflow chart.

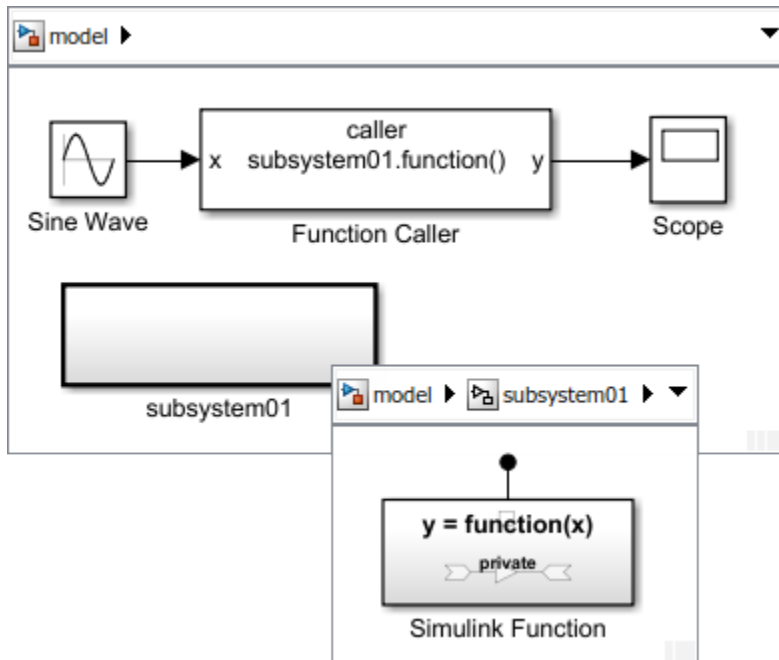

Resolve to a Function by Qualification

When you place a Simulink Function block in a virtual Subsystem block, the function name is not visible outside the subsystem. To call the function from outside the subsystem, qualify the function name with the subsystem name. For example:

```
y = subsystem01.function(x)
```

A function caller can be at a level where it can hierarchically resolve to the subsystem containing the function:

- Outside the subsystem one hierarchic level above the function

- In another subsystem at the same hierarchic level as the function

- In another subsystem one or more levels below the hierarchic level of the function

Diagnostics Using a Client-Server Architecture

In this section...
“Diagnostic Messaging with Simulink Functions” on page 10-126
“Client-Server Architecture” on page 10-126
“Modifier Pattern” on page 10-128
“Observer Pattern” on page 10-130

Diagnostic Messaging with Simulink Functions

Use Simulink functions when you define a diagnostic service where callers pass an error code. The service tracks error codes for all errors that occur. One way to implement this service is to use an indexed Data Store Memory block. A diagnostic monitoring system can then periodically check for the occurrence of specific errors and modify system behavior accordingly.

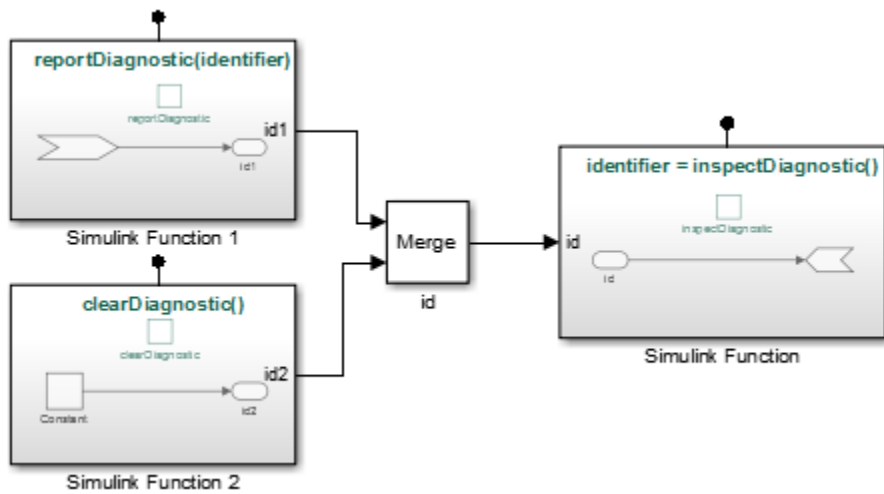

Client-Server Architecture

You can use Simulink Function blocks and Function Caller blocks to model client-server architectures. Uses for this architecture include memory storage and diagnostics.

As an example, create a model of a simple distributed system consisting of multiple control applications (clients), each of which can report diagnostics throughout execution. Since client-server architectures are typically constructed in layers, add a service layer to model the diagnostic interface.

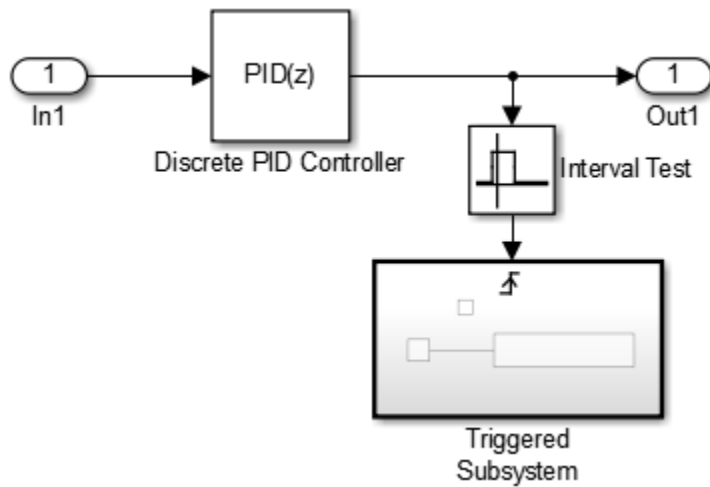

The services (servers), modeled using Simulink Function blocks, are in a separate model. Add the service model to your system model as a referenced model.

The control applications (clients) interact with the diagnostic interface using Function Caller blocks.

Modifier Pattern

Application 1 reports a diagnostic condition by invoking the `reportDiagnostic` interface within the service layer. The application calls this function while passing in a diagnostic identifier.

The interval test determines when to create a diagnostic identifier.

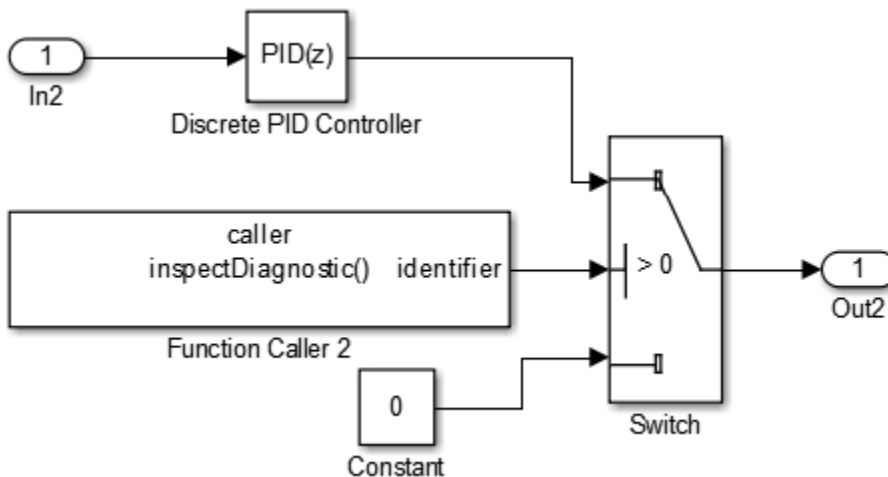

The implementation of the function (Simulink Function 1) tracks the passed-in identifier by transferring the value to a graphical output of the function. A graphical output is a server-side signal that is not part of the server interface but facilitates communication between service functions through function arguments. The value of graphical outputs are held between function invocations.

The `reportDiagnostic` function is an example of a modifier pattern. This pattern helps to communication of data from the caller to the function and later computations based on that data.

Observer Pattern

Application 2 invokes the `inspectDiagnostic` interface within the service layer to inspect whether diagnostics were reported.

The implementation of the function (Simulink Function) uses a graphical input (`id`) to observe the last reported diagnostic and transfer this value as an output argument (`identifier`) to the caller. A graphical input is a server-side signal that is not part of the server interface.

The `inspectDiagnostic` function is an example of an observer pattern. This pattern helps to communication of data from the function to the caller.

Create a Model to Initialize and Terminate State

In this section...

“Create Model Algorithm with State” on page 10-132

“Initialize Block State” on page 10-134

“Reset Block State” on page 10-136

“Read and Save Block State” on page 10-139

“Prepare Model Component for Testing” on page 10-143

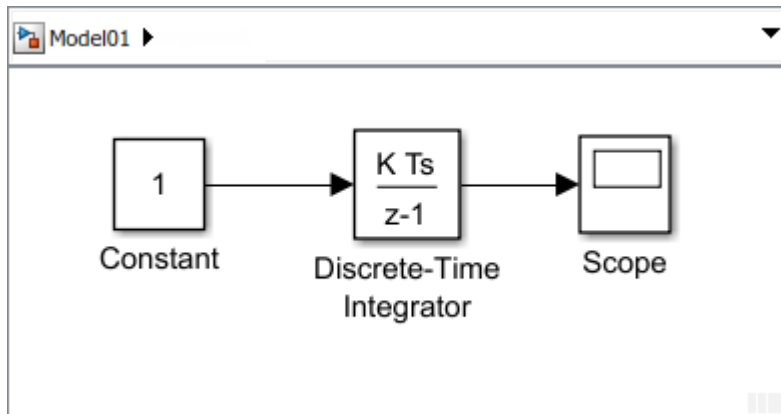

Some blocks maintain state information that they use during a simulation. For example, the Unit Delay block uses the current state of the block to calculate the output signal value for the next simulation step. To initialize and save the state of blocks, you can use the State Writer and State Reader blocks.

You can use the Initialize Function and Terminate Function blocks to control the execution of a component in response to an initialize, reset, or terminate event at any level of a model hierarchy. These blocks contain an Event Listener block that triggers the execution of a function. To create a Reset Function block, set the **Event** parameter of the Event Listener block to **Reset**.

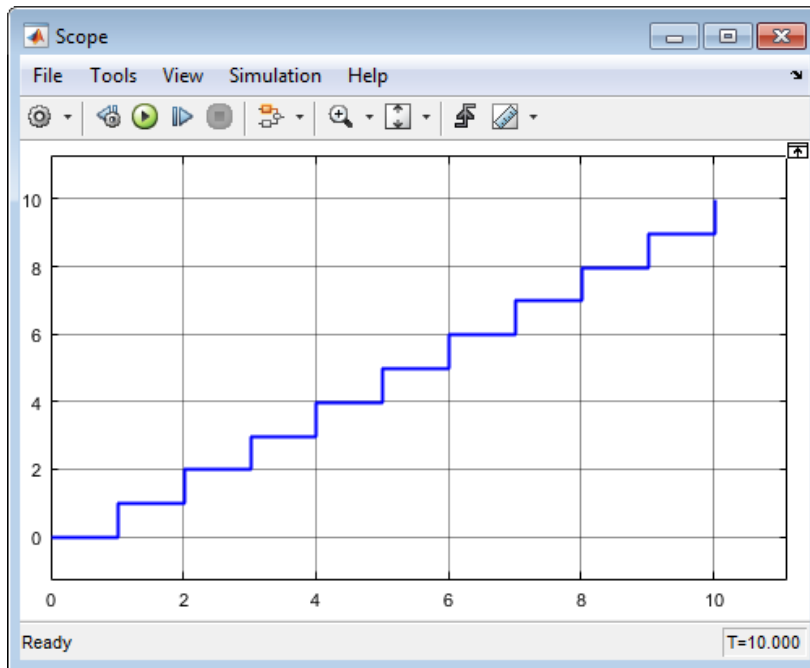

Create Model Algorithm with State

You can define model algorithms using Simulink blocks. In this example, a single Discrete-Time Integrator block defines the algorithm for integrating an input signal.

- 1 Open a new Simulink model.
- 2 Add a Discrete-Time Integrator block. Set the block **Gain value** to **1.0**, **Initial condition** to **0**, **Initial condition setting** to **State (most efficient)**, and **Sample time** to **-1**.
- 3 Connect a Constant block to the input of the Discrete-Time Integrator block to model an input signal. Connect a Scope block to the output signal.

- 4 Open the Configuration Parameters dialog box. Set the simulation parameters for the Solver **Type** to **Fixed-step** and **Fixed-step size** to 1.
- 5 Run a simulation. The output signal increases by 1 at each time step.

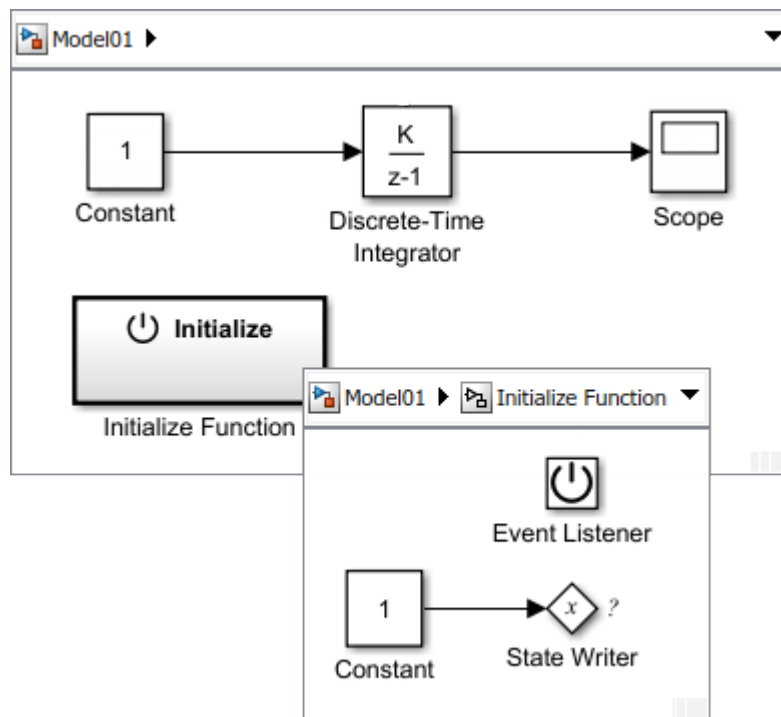

Initialize Block State

Some model algorithms contain states that you can initialize. For example, with an algorithm that reads a sensor value, you can perform a computation to set the initial sensor state.

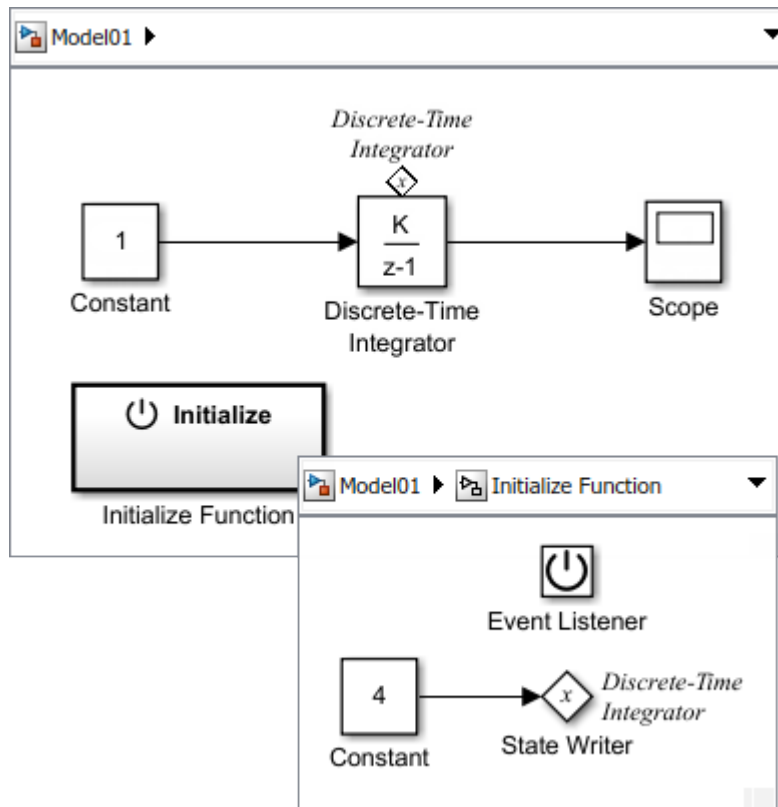

At the beginning of a simulation, initialize the state of a block using a State Writer block. To control when initialization occurs, use an Initialize Function block that includes a State Writer block.

- 1 Add an Initialize Function block.

By default, the Initialize Function block includes an Event Listener block with the **Event** parameter set to **Initialize**. The block also includes a State Writer block, and a Constant block as a placeholder for the source of the initial state value.

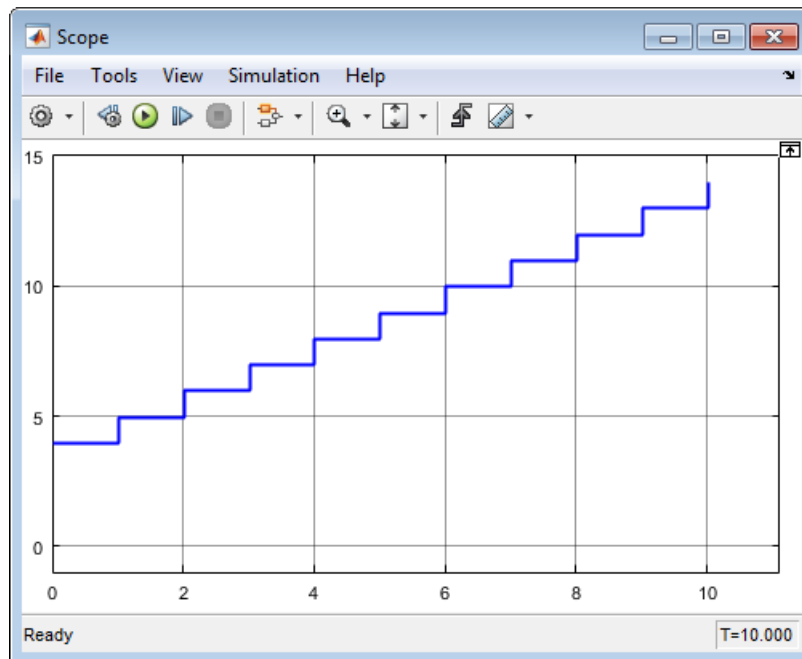

- 2 Model initial conditions. In this example, set the **Constant value** parameter for the Constant block to 4.
- 3 Connect the state writer with the state owner. Open the State Writer dialog box. Expand the State Owner Selector Tree and select **Discrete-Time Integrator**.

The State Writer block displays the name of the state owner block. The state owner block displays a tag indicating a link to a State Writer block. If you click above the tag, a list opens with a link for navigating to the State Writer block.

- 4 Run a simulation to confirm that your model simulates without errors.

The Initialize Function block executes at the beginning of a simulation. The output signal starts at the initial value of 4 and then increases by 1 until the end of the simulation.

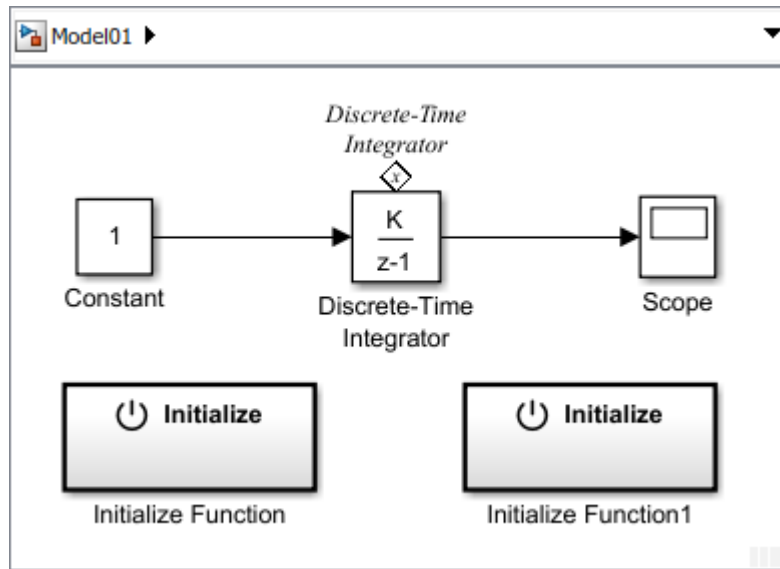

Reset Block State

During a simulation, you can reset the state of a block using a State Writer block. To control when reset occurs, use an Initialize Function block that you configure to a Reset Function block.

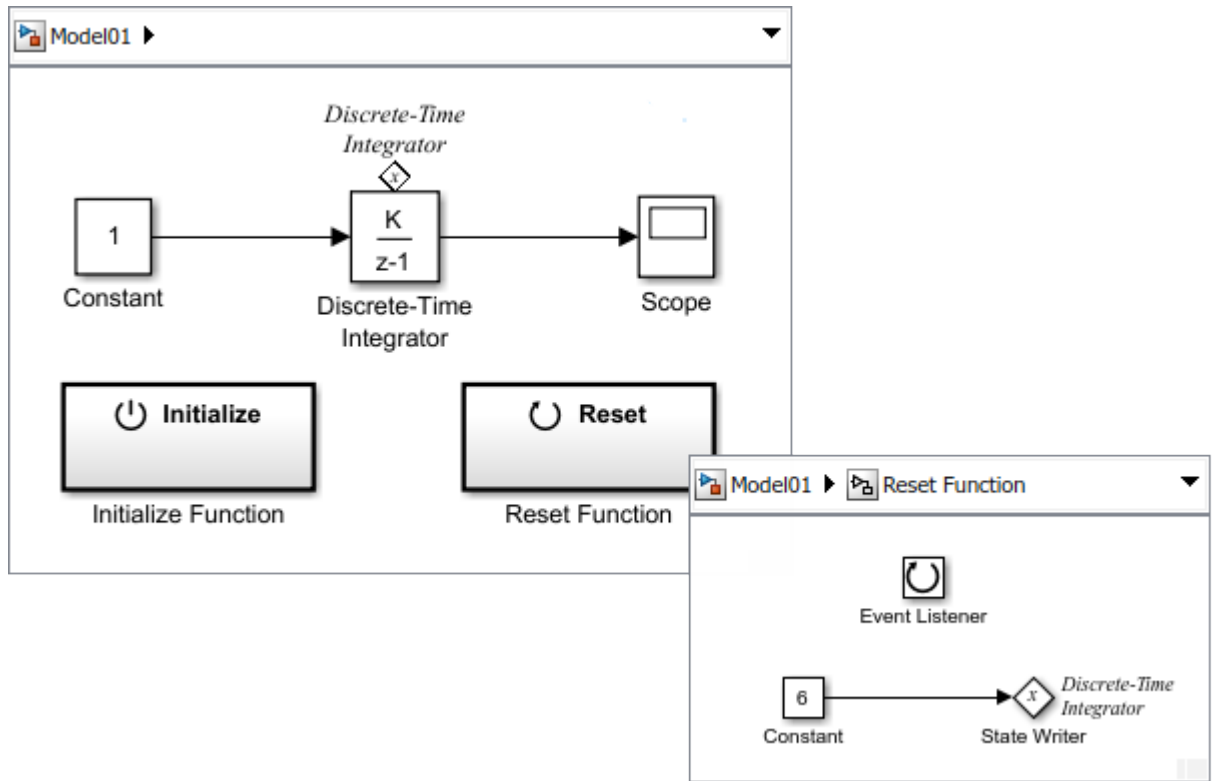

- 1 Add an Initialize Function block.

The Initialize Function block by default includes an Event Listener block with the **Event** parameter set to **Initialize**. The block also includes a State Writer block, and a Constant block as a place holder for the source of the initial state value.

- 2 Open the new Initialize Function block.
- 3 Configure block for reset. Open the Block Parameter dialog box for the Event Listener block. From the **Event type** drop-down list, select **Reset**. In the **Event name** box, enter an event name. For example, enter **Reset**. Close the dialog box.
- 4 Model reset conditions. In this example, set the **Constant value** parameter for the Constant block to 6.
- 5 Connect state writer with the state owner. Open the State Writer dialog box. Expand the State Owner Selector Tree and select **Discrete-Time Integrator**. Close the dialog box.
- 6 Navigate to the top level of Model01. Rename the block from **Initialize Function1** to **Reset Function**.

After updating your model, the event name for the **Reset Function** block is displayed on the face of the block.

If you click above the tag, a list opens with a link for navigating to the State Writer blocks located in the Initialize Function block and the Reset Function block.

- 7 Run a simulation to confirm that your model simulates without errors.

The Reset Function block does not execute during the simulation. It needs an event signal.

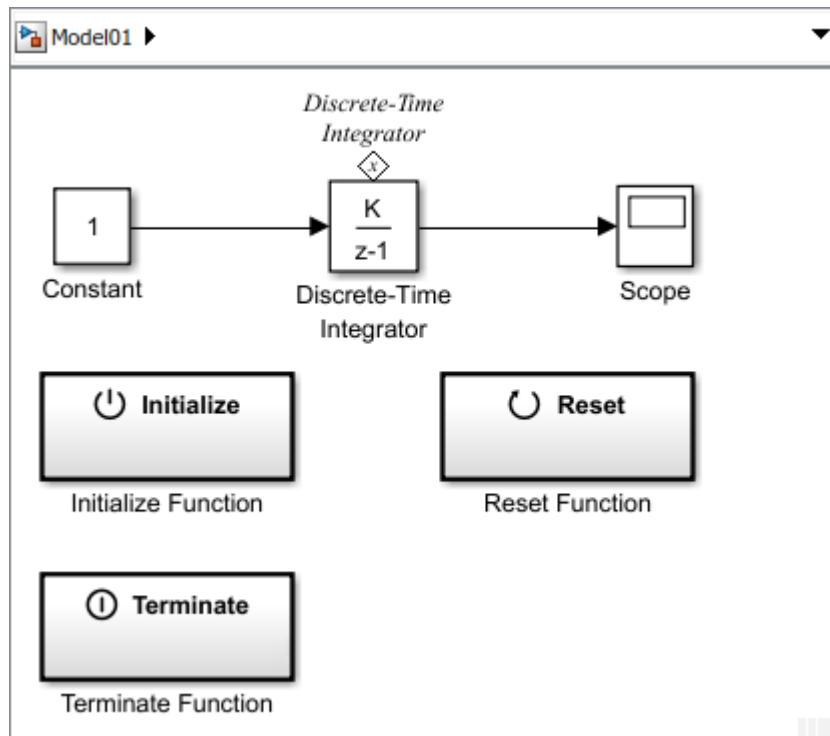

Read and Save Block State

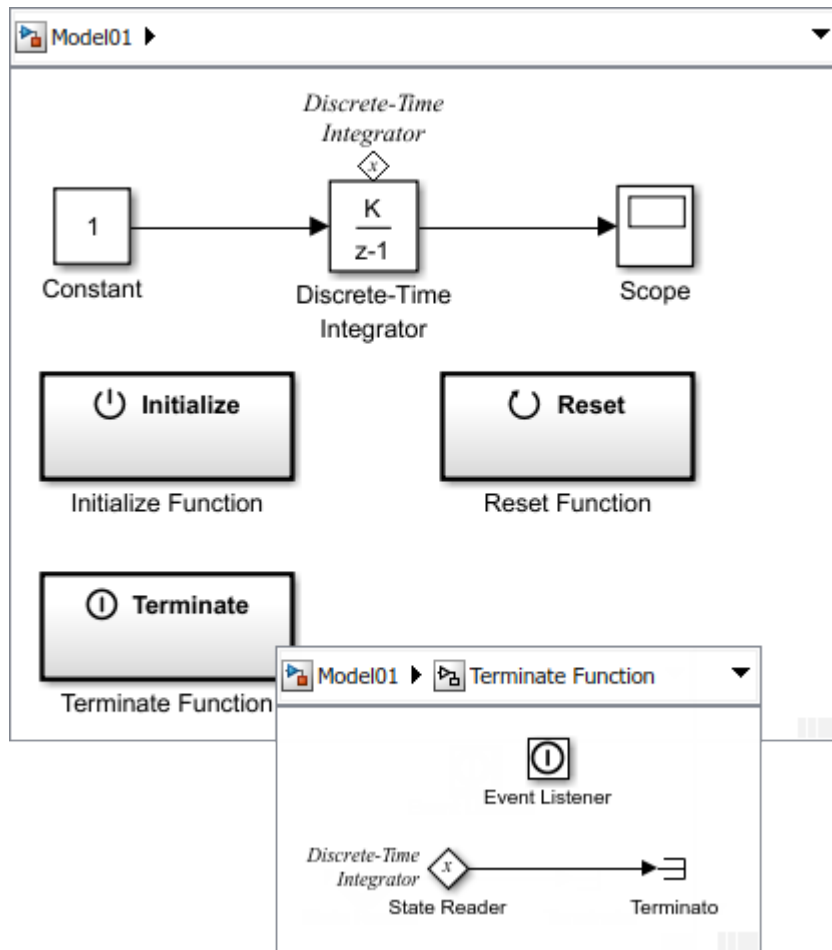

At the end of a simulation, you can read the state of a block, and save that state.

- 1 Add a Terminate Function block.

By default, the Terminate Function block includes an Event Listener block with the parameter **Event** set to **Terminate**. The block also includes a State Reader block, and a Terminator block as a placeholder for saving the state value.

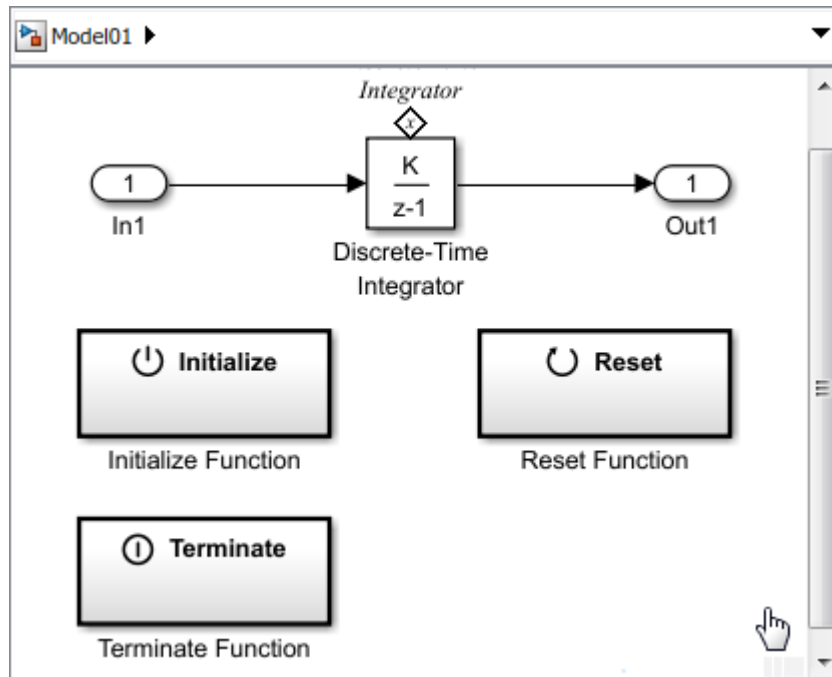

- 2 Connect the state reader with the state owner. Open the State Reader dialog box. From the State Owner Selector Tree, select **Discrete-Time Integrator**. Click **OK**.

- 3 Run a simulation to confirm that your model simulates without errors. The Terminate Function block executes at the end of a simulation.

- 4 Delete the blocks that you added for testing. Replace the Constant block with an Inport block and the Scope block with an Outport block.

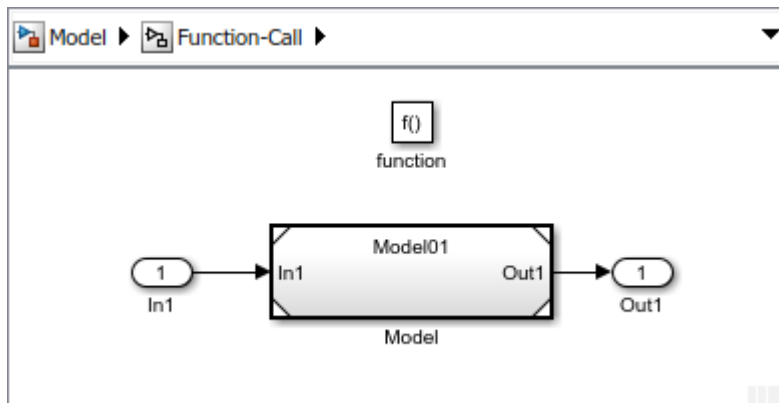

Prepare Model Component for Testing

After you finish creating a model component, you can place it in a simulation test harness. But, because a simulation test harness only supports export-function models, you have to modify the component to follow export-function rules.

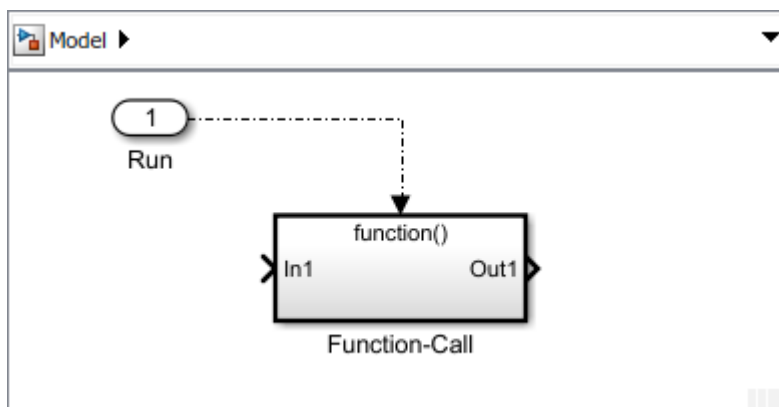

Export-function models contain only Function-Call Subsystem, Inport, and Outport blocks at the root level. See “Export-Function Models” on page 10-4

- 1 Create a new Simulink model. Save this model with the name `Model1`.
- 2 Add a Function-Call Subsystem block. Open the subsystem by double-clicking the block.
- 3 Add a Model block and set **Model name** to `Model01`. Add Inport and Outport blocks.

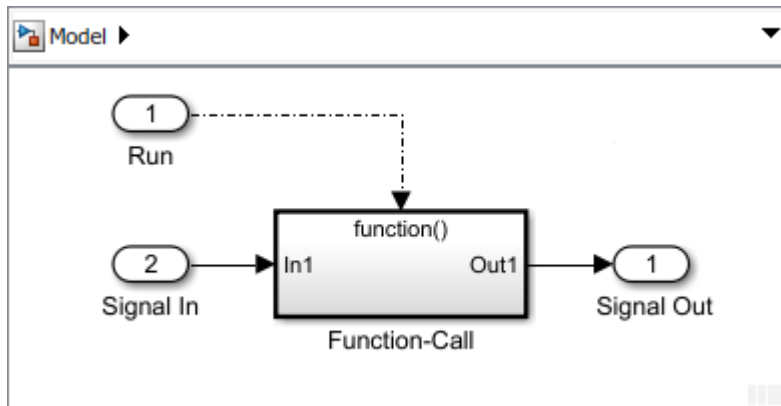

- 4 Navigate to the top-level of the model. Add an Inport block. This block is the control signal for running the subsystem. Change the block name to **Run** and connect it to the `function()` port.

Open the block parameters dialog box, and on the Signal Attributes tab, select the **Output function call** check box.

- 5 Add a second Inport block and rename it to **Signal In**. Connect it to the `In1` port of the subsystem. This block is the signal to integrate.

Add an Outport block, rename it to **Signal Out**, and then connect it to the `Out1` port of the subsystem. This block is the integrated signal.

- 6 Open the Configuration Parameters dialog box. Set the **Total number of instances allowed per top model** to one. Confirm that the solver **Type** is Fixed-step, Solver is auto. Change the **Fixed-step size** from 1 to auto.
- 7 Open the Block Parameters dialog box for the Discrete-Time Integrator block. Set **Integrator method** to Accumulation:Forward Euler.

This change avoids a simulation error caused by having multiple sample times in a Function-Call Subsystem.

Create a Test Harness to Generate Events

In this section...

“Reference the Model Component” on page 10-146

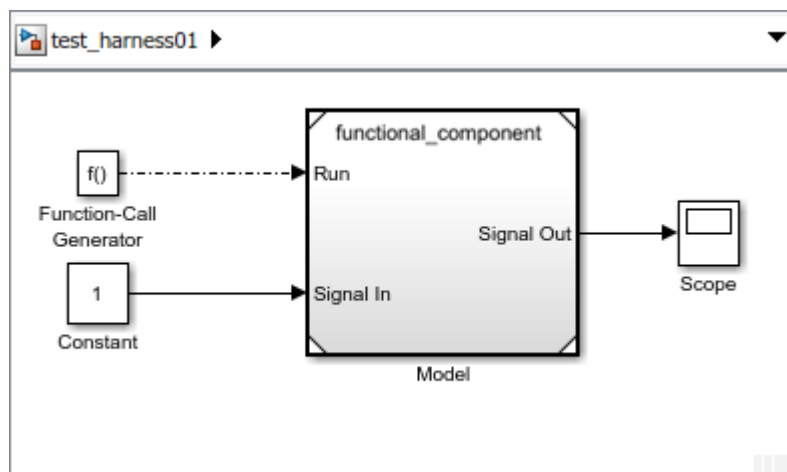

“Create Stateflow Chart” on page 10-148

“Connect Chart to Test Model” on page 10-149

A test harness is a Simulink model that you use to develop, test, and debug a model component. To perform these actions, reference the model component in the test model and add a Stateflow chart to model an event scheduler.

Reference the Model Component

- 1 Create a new Simulink model. Set Model Configuration Parameters for solver **Type** to **Fixed-step**, Solver to **auto**, and **Fixed-step size** to 1. SubSystem: Function-Call
- 2 Add a Model block. Open the Model parameters dialog box. In the **Model name** text box, enter the name of your model with state. In this example, enter `functional_component`.
- 3 Test the referenced component model by connecting a Function-Call Generator block to the **Run** port. Connect a Constant block to the **Signal In** port and a Scope block to the **Signal Out** port.

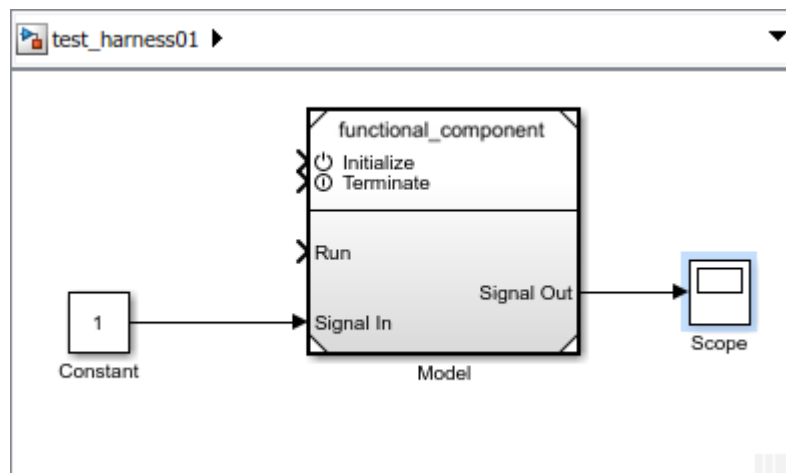

Run a simulation to verify your model simulates correctly from the parent model. When the model is simulated without event ports, the Initialize Function block executes at the beginning of a simulation and the Terminate Function block executes at the end of the simulation.

- 4 Add event ports. Right-click the Model block and select **Block Parameters**. In the Block Parameters dialog box, select the **Show model initialize port** and **Show model terminate port** check boxes. Delete the Function-Call Generator block.

Note: You must open and save a model created from a previous version of Simulink, before the check boxes appear.

- 5 Update the model by pressing **Ctrl-D**.

When you activate the **Initialize** event port on a Model block, the model does not execute until it receives an initialize event. The reception of an event signal triggers the execution of the model initialize function, and then executes the Initialize Function block contents.

The reception of an event signal on the **Terminate** port triggers the execution of the Terminate Function block contents and then executes the model terminate function. The model then stops running. To execute the model again, reinitialize the model by sending an event signal to the **Initialize** port.

Create Stateflow Chart

Use a Stateflow chart model and event schedule and generate the Initialize and Terminate event signals.

- 1 Add a Stateflow Chart.
- 2 Open the chart and add two state blocks, one above the other.
- 3 Add a default transition and connect it to the top state block.
- 4 Add a transition from the top block to the bottom block. Edit the label to:

```
[step == 2]/{Initialize}
```

- 5 Add a transition from the bottom block to top block. Edit the label:

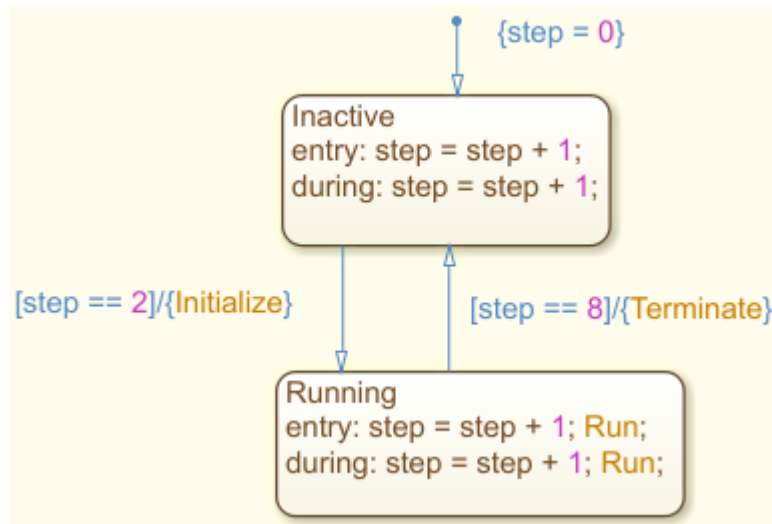

```
[step == 8]/{Terminate}
```

- 6 Edit the content of top the top block:

```
Inactive  
entry: step = step + 1;  
during: step = step + 1;
```

- 7 Edit the content of the bottom block:

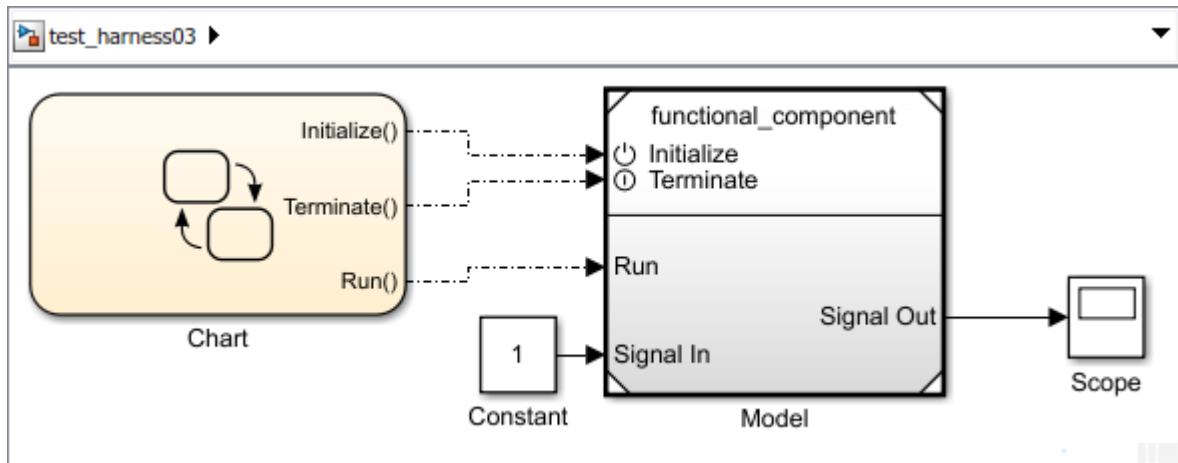

```
Running  
entry: step = step + 1; Run;  
during: step = step + 1; Run;
```

Connect Chart to Test Model

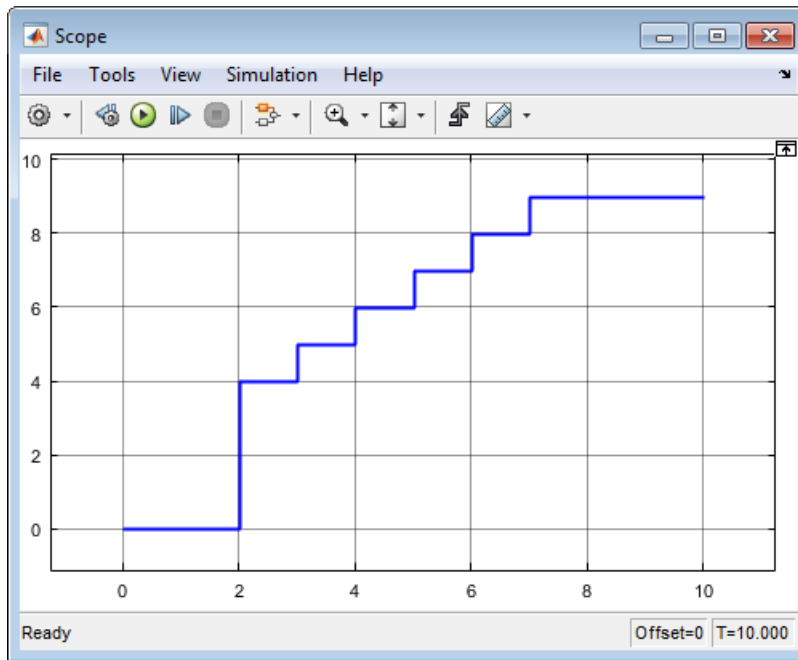

Create event outputs on the chart to control and run the model component.

- 1 Open Model Explorer.
- 2 From the menu, select **Add > Data**. In the Data dialog box, enter **Step** for the **Name**.
- 3 Select **Add > Event**. In the Event dialog box, enter **Initialize** for the Name, select **Output to Simulink** for the **Scope**.
- 4 Select **Add > Event**. In the Event dialog box, enter **Terminate** for the Name, select **Output to Simulink** for the **Scope**.
- 5 Select **Add > Event**. In the Event dialog box, enter **Run** for the Name, select **Output to Simulink** for the **Scope**.
- 6 Navigate to the top-level of the model. Connect the **Initialize**, **Terminate**, and **Run** ports on the chart to the **Initialize**, **Terminate**, and **Run** input ports on the Model block.

7 Run a simulation.

The model does not execute until the second time step, when the block state is initialized to 4. At the eighth time step, the subsystem stops executing and the block state remains constant.

If the model receives a run signal before an initialize event, a simulation error occurs.

What Are Variants and When to Use Them

In this section...

“What Are Variants?” on page 11-2

“Advantages of Using Variants” on page 11-4

“When to Use Variants” on page 11-4

“Options for Representing Variants in Simulink” on page 11-6

“Mapping Inports and Outports of Variant Choices” on page 11-7

What Are Variants?

In Simulink, you can use the variant blocks to create a single model that caters to multiple variant requirements. Such models have a fixed common structure and a finite set of variable components. The variable components are activated depending on the variant choice that you select. Thus, the resultant active model is a combination of the fixed structure and the variable components based on the variant choice.

The use of variant blocks in a model helps in reusability of the model for different conditional expressions called variant choices. This approach helps you to meet diverse customer requirements based on application, cost, or operational considerations.

You can use these variants blocks depending on the model design:

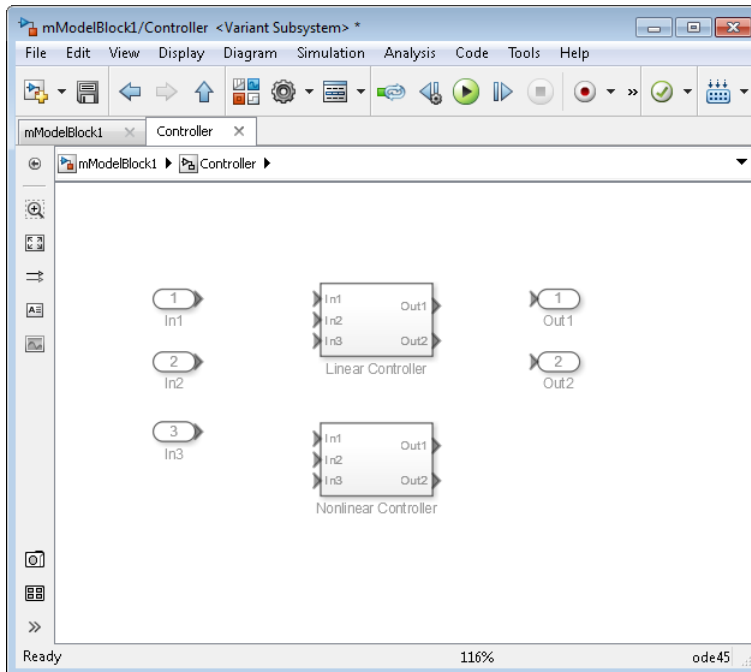

- **Variant Subsystem:** For hierarchical model structure.
- **Inline Variants:** For flat model structure.
 - Variant Source
 - Variant Sink
 - Manual Variant Source
 - Manual Variant Sink
- **Model Variants**

Note: You can convert a Subsystem block available in a model to a Variant Subsystem block. To do so, right-click the Subsystem block, in the context menu, click **Subsystem & Model Reference > Convert Subsystem to > Variant Subsystem**.

Suppose you want to simulate a model that represents an automobile with several configurations. These configurations, although similar in several aspects, can differ in properties such as fuel consumption, engine size, or emission standard. Instead of designing multiple models that together represent all possible configurations, you can use variants to model only the varying configurations. This approach keeps the common components fixed.

This model contains two variant choices inside a single Variant Subsystem block. Variant choices are two or more configurations of a component in your model.

Advantages of Using Variants

Using variants in Model-Based Design provides several advantages:

- Variants provide you a way to design one model for many systems.
- You can rapidly prototype design possibilities as variants without having to comment out sections of your model.
- Variants help you develop modular design platforms that facilitate reuse and customization. This approach improves workflow speed by reducing complexity.
- If a model component has several alternative configurations, you can efficiently explore these varying alternatives without altering the fixed, unvarying components.
- You can use different variant configurations for simulation or code generation from the same model.
- You can simulate every design possibility in a combinatorial fashion for a given test suite.
- If you are working with large-scale designs, you can distribute the process of testing these designs on a cluster of multicore computers. Alternatively, you can map different test suites to design alternatives for efficiently managing design-specific tests.
- You can generate a reduced model with a subject of configuration from a master model with many variants.

When to Use Variants

Variants help you specify multiple implementations of a model in a single, unified block diagram. Here are three scenarios where you can use variants:

- Models that represent multiple simulation, code generation, or testing workflows.

Figure 1. Model of an ideal actuator for basic simulation.

Figure 2. Detailed actuator for simulating customizations.

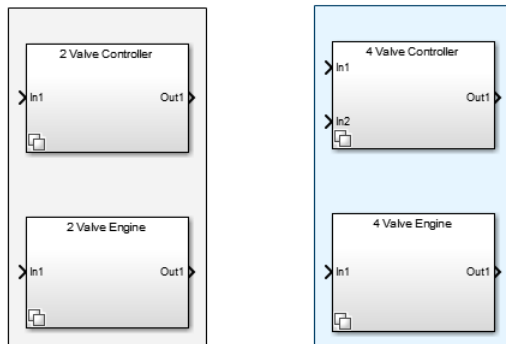

Figure 3. Model that is configured for Hardware-in-the-Loop simulation.

- Models that contain multiple design choices at the component level.

Subsystem blocks representing variant choices can have inports and outports that differ in number from the inports and outports in the parent Variant Subsystem block. See “Mapping Inports and Outports of Variant Choices” on page 11-7.

- Models that are mostly similar but have slight variations, such as in cases where you want to separate a test model from a debugging model.

The test model on the left has a fixed design. On the right, the same test model includes a variant that is introduced for debugging purposes.

Simulink selects the active variant during update diagram time and during code compile time.

Options for Representing Variants in Simulink

You can represent one or more variants as variant choices inside these blocks.

	Variant Source and Variant Sink blocks	Variant Subsystem block	Model Variant block
Variant choice representation	Number of ports	Subsystem or Model block	Only Model block
Allows choice hierarchy	No	Yes	Yes
Mismatched number of inports and outports among variant choices	Simulink disables inactive ports	Simulink disables inactive ports	Requires manual resolution of disconnected signal lines
Option to specify default variant	Yes	Yes	No
Supports control ports	No	No	Yes
Can be saved as standalone file	No	No	Yes

	Variant Source and Variant Sink blocks	Variant Subsystem block	Model Variant block
Supports physical modeling connection ports	No	Partially	No
Comment choice	Yes	No	No

In addition, you can represent variant choices using Variant Source and Variant Sink block. These blocks enable the propagation of variant conditions and they allow you to visualize variant choices in a single layer of your model.

You can create variants at several levels inside your model hierarchy.

Mapping Inports and Outports of Variant Choices

A Variant Subsystem is a container of variants choices that are represented as Subsystem or Model blocks. The inputs that the Variant Subsystem block receives from upstream models components map to the inports and outports of the variant choices.

Subsystem and Model blocks representing variant choices can have inports and outports that differ in number from the inports and outports in the parent Variant Subsystem block. However, the following conditions must be satisfied:

- The names of the inports of a variant choice are a subset of the inport names used by the parent variant subsystem.
- The names of the outports of a variant choice are a subset of the outport names used by the parent variant subsystem.

During simulation, Simulink disables the inactive ports in a Variant Subsystem block. If you are specifying variant choices in a Model Variant block, resolve any disconnected signal lines manually when you switch between choices.

Working with Variant Choices

In this section...
“Default Variant Choice” on page 11-10
“Active Variant Choice” on page 11-11
“Inactive Variant Choice” on page 11-11
“Empty Variant Choice” on page 11-11
“Open Active Variant” on page 11-12

Each variant choice in your model is associated with a conditional expression called variant control. The way you specify your variant controls determines the state of variant choice activation.

This image shows the block parameters dialog box of a Variant Subsystem block that contains four variant choices:

- The first choice is empty and has been commented out by adding the % symbol before the variant control.
- The second choice is the default and is activated when no variant control evaluates to `true`.
- The third choice is activated when the expression `mode==3 && version==2` evaluates to `true`.
- The fourth choice is activated when the expression `mode==2 && version==1` evaluates to `true`.

Default Variant Choice

You can specify one variant choice as the default for the model. As shown in the image above, the **Linear Controller** subsystem is defined as the default variant choice. During model compilation, if Simulink finds that no variant control evaluates to `true`, it uses the default choice.

Note: You cannot specify a model as the default if that model is a variant choice in a Model block. Instead, you can add that model as a variant choice in a Subsystem block, and then specify that model as the default variant.

In the dialog box, select the variant choice and change its **Variant control** property to `(default)`.

Active Variant Choice

While each variant choice is associated with a variant control, only one variant control can evaluate to `true` at a time. When a variant control evaluates to `true`, Simulink activates the variant choice that corresponds to that variant control.

In this example, you can activate either the `Model` variant choice or the `Nonlinear Controller` variant choice by specifying appropriate values for `mode` and `version`.

Value of <code>mode</code>	Value of <code>version</code>	Active variant choice
2	1	Nonlinear Controller
3	2	Model

You can specify the values of `mode` and `version` at the MATLAB Command Window.

You can also override the active variant choice with another variant. Right-click the active variant block in the Simulink Editor, and select **Variant > Override using**. Then select your variant choice.

Inactive Variant Choice

When a variant control activates one variant choice, Simulink considers the other variant choices to be inactive. Simulink ignores inactive variant choices during simulation. However, Simulink continues to execute block callbacks inside the inactive variant choices.

Empty Variant Choice

When you are prototyping variant choices, you can create empty Subsystem blocks with no inputs or outputs inside the Variant Subsystem block. The empty subsystem recreates the situation in which that subsystem is inactive without the need for completely modeling the variant choice.

For an empty variant choice, you can either specify a variant activation condition or comment out the variant condition by placing a `%` symbol before the condition.

If this variant choice is active during simulation, Simulink ignores the empty variant choice. However, Simulink continues to execute block callbacks inside the empty variant choices.

Open Active Variant

When you open a model, variant blocks display the name of the variant that was active the last time that you saved your model. Use the **Variant** menu to open the active variant. Right-click the block and select **Variant > Open**. Then select the active variant.

Use this command to find the current active variant block:

```
get_param(gcb, 'ActiveVariant')
```

Use this command to find the path to the current active variant block:

```
get_param(gcb, 'ActiveVariantBlock')
```

Note: The `ActiveVariantBlock` parameter is supported only for the Variant Subsystem block.

Introduction to Variant Controls

In this section...

“Operands” on page 11-13

“Operators” on page 11-13

“Approaches for Specifying Variant Controls” on page 11-14

“Operators and Operands in Variant Condition Expressions” on page 11-20

The components of a Simulink model that contain Variants are activated or deactivated based on the variant choice that you select.

Each variant choice in your model is associated with a conditional expression called variant control. Variant controls determine which variant choice is active. By changing the value of a variant control, you can switch the active variant choice.

While each variant choice is associated with a variant control, only one variant control can evaluate to true at a time. When a variant control evaluates to `true`, Simulink activates the variant choice that corresponds to that variant control.

A variant control is a Boolean expression that activates a specific variant choice when it evaluates to `true`.

Note: You can specify variant controls in the MATLAB workspace or a data dictionary.

You can specify variant controls as `Simulink.Variant` objects or as expressions that contain one or more of these operands and operators.

Operands

- Variable names that resolve to MATLAB variables or `Simulink.Parameter` objects with integer or enumerated data type and scalar literal values
- Variable names that resolve to `Simulink.Variant` objects
- Scalar literal values that represent integer or enumerated values

Operators

- Parentheses for grouping

- Arithmetic, relational, logical, or bit-wise operators

For more information, see “Operators and Operands in Variant Condition Expressions” on page 11-20.

When you compile the model, Simulink determines that a variant is active if its variant control evaluates to `true`.

Approaches for Specifying Variant Controls

You can use many approaches for switching between variant choices—from options to use while prototyping to options required for generating code from your model.

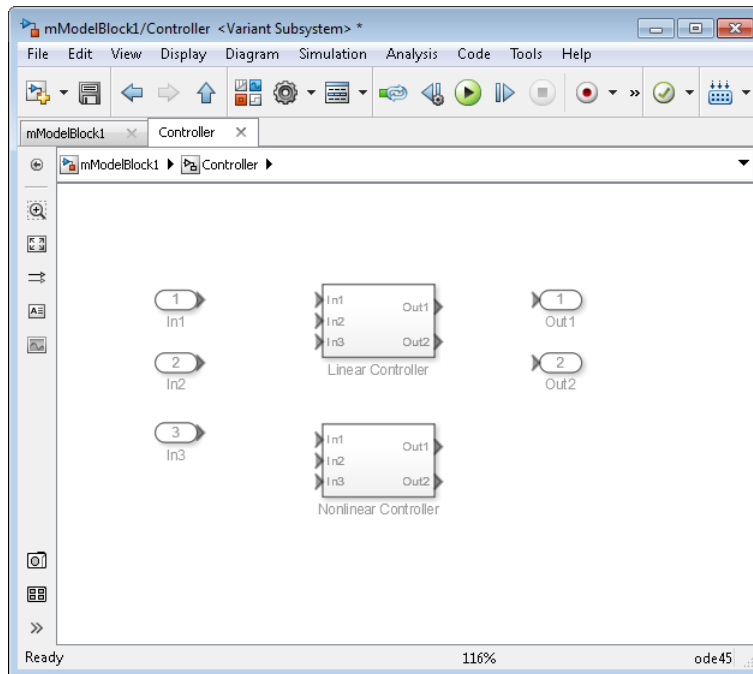

Specification	Purpose	Example
Scalar variable	Rapid prototyping	<code>A == 1</code>
<code>Simulink.Variant</code> object	Reuse variant conditions	<code>LinearContoller = Simulink.Variant('FUEL==2 && EMIS==1');</code>
<code>Simulink.Parameter</code> object	Generate preprocessor conditionals for code generation	<code>mode == 1</code> , where <code>mode</code> is a <code>Simulink.Parameter</code> object
Enumerated type	Improved code readability because condition values are represented as meaningful names instead of integers	<code>LEVEL == Level.Advanced</code>

You can convert MATLAB variables in variant control expressions into `Simulink.Parameter` object using the function `Simulink.VariantManager.findVariantControlVars`.

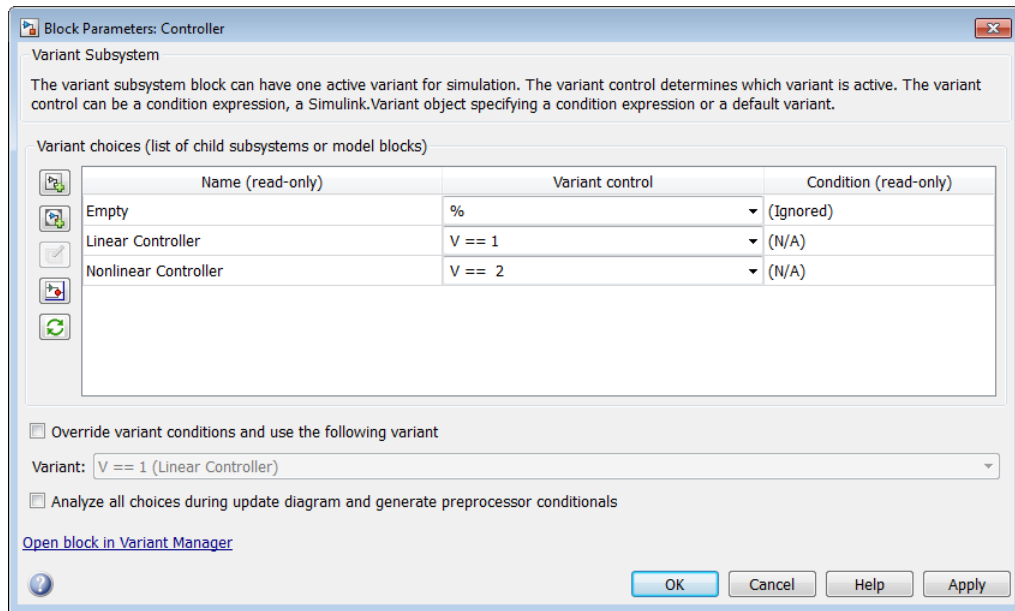

Scalar Variables for Rapid Prototyping

Scalar MATLAB variables allow you to rapidly prototype variant choices when you are still building your model. They help you focus more on building your variant choices than on developing the expressions that activate those choices.

Consider a model that contains two variant choices, each represented by a Variant Subsystem block.

You can specify variant controls in their simplest form as scalar variables in the block parameters dialog box of the Variant Subsystem block.

The **Condition** field for both the **Linear Controller** and **Nonlinear Controller** are N/A, because the variant control itself is the condition.

You can activate one of the variant choices by defining a scalar variable **V** and setting its value to 1 at the MATLAB Command Window.

```
V = 1;
```

This condition activates the **Linear Controller** variant choice.

Similarly, if you change the value of V to 2, Simulink activates the **Nonlinear Controller** variant choice.

Simulink.Variant Objects for Variant Condition Reuse

After identifying the variant choices that your model requires, you can construct complex variant conditions to control the activation of your variant choices. Define variant conditions as `Simulink.Variant` objects.

`Simulink.Variant` objects enable you to reuse common variant conditions across models and help you encapsulate complex variant condition expressions.

Consider an example where variant controls are already defined in the base workspace.

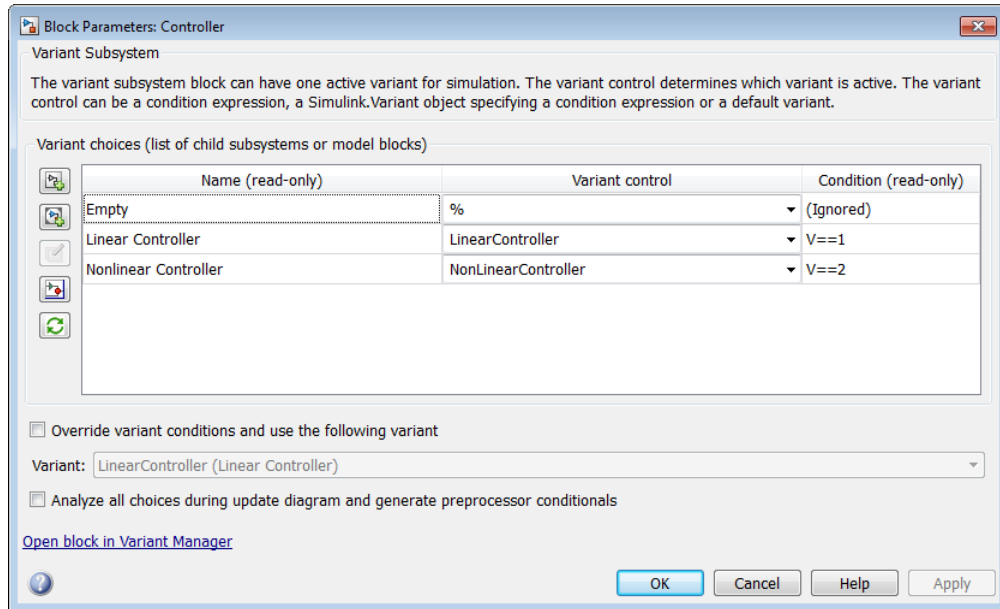

```
V=1;
V=2;
```

You can convert these controls into condition expressions encapsulated as `Simulink.Variant` objects.

```
LinearController=Simulink.Variant('V==1');
```

```
NonLinearController=Simulink.Variant('V==2');
```

You can then specify these `Simulink.Variant` objects as the variant controls in the block parameters dialog box of the Variant Subsystem block.

The **Condition** field now reflects the encapsulated variant condition. Using this approach, you can develop complex variant condition expressions that are reusable.

Simulink.Parameter Objects for Code Generation

If you intend to generate code for a model containing variant choices, specify variant control variables as `Simulink.Parameter` objects. In addition to enabling parameter value specification, `Simulink.Parameter` objects allow you to specify other attributes (such as data type) that are required for generating code.

```
VSSMODE = Simulink.Parameter;
VSSMODE.Value = 1;
VSSMODE.DataType = 'int32';
VSSMODE.CoderInfo.StorageClass = 'Custom';
VSSMODE.CoderInfo.CustomStorageClass = 'ImportedDefine';
VSSMODE.CoderInfo.CustomAttributes.HeaderFile = ...
'rtwdemo_importedmacros.h';
```

Variant control variables defined as `Simulink.Parameter` objects can have one of these storage classes:

- `Define` or `ImportedDefine` with header file specified
- `CompilerFlag`
- `SystemConstant` (AUTOSAR)
- Your own custom storage class that defines data as a macro

You can also convert a scalar variant control variable into a `Simulink.Parameter` object. See “Convert Variant Control Variables into `Simulink.Parameter` Objects” on page 11-36.

Enumerated Types for Improving Code Readability

Use enumerated types to give meaningful names to integers used as variant control values.

- 1 In the MATLAB Editor, define the classes that map enumerated values to meaningful names.

```
classdef sldemo_mrv_CONTROLLER_TYPE < Simulink.IntEnumType
    enumeration
        NONLINEAR (1)
        SECOND_ORDER (2)
    end
end
classdef sldemo_mrv_BUILD_TYPE < Simulink.IntEnumType
    enumeration
        PROTOTYPE (1)
        PRODUCTION (2)
    end
end
```

- 2 Define `Simulink.Variant` objects for these classes in the base workspace.

```
VE_NONLINEAR_CONTROLLER = Simulink.Variant...
('E_CTRL==sldemo_mrv_CONTROLLER_TYPE.NONLINEAR')
VE_SECOND_ORDER_CONTROLLER = Simulink.Variant...
('E_CTRL==sldemo_mrv_CONTROLLER_TYPE.SECOND_ORDER')
VE_PROTOTYPE = Simulink.Variant...
('E_CURRENT_BUILD==sldemo_mrv_BUILD_TYPE.PROTOTYPE')
VE_PRODUCTION = Simulink.Variant...
('E_CURRENT_BUILD==sldemo_mrv_BUILD_TYPE.PRODUCTION')
```

Using enumerated types simplifies the generated code because it contains the names of the values rather than integers.

Operators and Operands in Variant Condition Expressions

Simulink evaluates condition expressions within variant controls to determine the active variant. You can include the following operands in a condition expression:

- Scalar variables
- `Simulink.Parameter` objects that are not structures and that have data types other than `Simulink.Bus` objects
- Enumerated types
- Parentheses for grouping

Variant condition expressions can contain MATLAB operators, provided the expression evaluates to a Boolean value. In these examples, `A` and `B` are expressions that evaluate to an integer, and `x` is a constant integer literal.

MATLAB Expressions That Support Generation of Preprocessor Conditionals	Equivalent Expression in C Preprocessor Conditional
Arithmetic	
<ul style="list-style-type: none"> • <code>A + B</code> • <code>+A</code> 	<ul style="list-style-type: none"> • <code>A + B</code> • <code>A</code>
<ul style="list-style-type: none"> • <code>A - B</code> • <code>-A</code> 	<ul style="list-style-type: none"> • <code>A - B</code> • <code>-A</code>
<code>A * B</code>	<code>A * B</code>
<code>idivide(A,B)</code>	<code>A / B</code> If the value of the second operand (<code>B</code>) is 0, the behavior is undefined.
<code>rem(A,B)</code>	<code>A % B</code> If the value of the second operand (<code>B</code>) is 0, the behavior is undefined.
Relational	

MATLAB Expressions That Support Generation of Preprocessor Conditionals	Equivalent Expression in C Preprocessor Conditional
A == B	A == B
A ~= B	A != B
A < B	A < B
A > B	A > B
A <= B	A <= B
A >= B	A >= B
Logical	
~A	!A, where A is not an integer
A && B	A && B
A B	A B
Bit-wise (A and B cannot both be constant integer literals)	
bitand(A,B)	A & B
bitor(A,B)	A B
bitxor(A,B)	A ^ B
bitcmp(A)	~A
bitshift(A,x)	A << x
bitshift(A,-x)	A >> x

- “Create Variant Controls Programmatically” on page 11-26
- “Working with Variant Choices” on page 11-9

More About

- “Create a Simple Variant Model” on page 11-22

Create a Simple Variant Model

- 1 Create a model that contains variant blocks. For example, see `sldemo_variant_subsystem` that contains a Variant Subsystem block (**Controller**).

Components of 'Controller' block

- 2 Define variant control variables that determine the condition under which a variant choice is active.
 - a Right-click the variant block and click **Block Parameters**. The Block Parameters dialog box for the variant block opens.
 - b Use the options available on the Block Parameter dialog box to add variant controls and its corresponding variant condition.

Note: The variables used to specify the variant control and variant condition must be defined in the base workspace or data dictionary for the model.

- Specify a default variant condition to be used when there is no active variant choice. Use the **Variant control** dropdown menu to specify the default.

- 4 To activate a variant choice, type the variant choice in MATLAB command window. For example, type `VSS_MODE = 2`.
- 5 To simulate the model, click **Simulation > Run**. The model simulates for the specified active choice.
- 6 Modify the active choice and simulate the model again, if necessary.
- 7 Generate code for the variants model with preprocessor conditionals.

Note: You must have Embedded Coder license to generate code.

- a In the Block Parameters dialog box, select the **Analyze all choice during update diagram and generate preprocessor conditionals** check box.
- b In the **Code Generation** section of Configuration Parameters dialog box, specify the **System target file** as `ert.tlc`.
- c In Model Explorer, define the variables used to specify the variant choice as a `Simulink.Parameter`. The data type of the variable can be of type `Integer`, `Boolean`, or `Enumerated` and the storage class can be either `importedDefine (Custom)`, `Define (Custom)`, or `CompilerFlag`.

Tip To avoid failure during code generation, the signal properties (like signal dimension, port width, and storage class) at input port of the Variants Subsystem block must be same and signals must not have name conflicts.

- 8 For the variants that are defined in the base workspace, export the control variables to a MAT-file. For example, type the following in the MATLAB command window:
 - a `save <MAT-File Name> <Variable Name>`
 - b `PostLoadCallback > load MAT-File Name`

Note: To update or refresh active models that contain Variant Subsystem blocks, click **Diagram > Refresh Blocks** (Ctrl + K) or **Simulink > Update Diagram** (Ctrl + D) in Simulink.

Create Variant Controls Programmatically

In this section...

- “Create and Export Variant Controls” on page 11-26
- “Reuse Variant Conditions” on page 11-26
- “Enumerated Types as Variant Controls” on page 11-27

Create and Export Variant Controls

Create control variables, define variant conditions, and export control variables.

- 1 Create control variables in the base workspace or a data dictionary.

```
FUEL=2;  
EMIS=1;
```

- 2 Use the control variables to define the control condition using a `Simulink.Variant` object.

```
LinearContoller=Simulink.Variant('FUEL==2 && EMIS==1');
```

Note: Before each simulation, define `Simulink.Variant` objects representing the variant conditions.

- 3 If you saved the variables in the base workspace, select the control variables to export. Right-click and click **Save As** to specify the name of a MAT-file.

Reuse Variant Conditions

If you want to reuse common variant conditions across models, specify variant control conditions using `Simulink.Variant` objects.

Reuse `Simulink.Variant` objects to change the model hierarchy dynamically to reflect variant conditions by changing the values of the control variables that define the condition expression.

The example models `AutoMRVar` and `AutoSSVar` show the use of `Simulink.Variant` objects to define variant control conditions.

Enumerated Types as Variant Controls

Use enumerated types to give meaningful names to integers used as variant control values.

- 1 In the MATLAB Editor, define the classes that map enumerated values to meaningful names.

```
classdef sldemo_mrv_CONTROLLER_TYPE < Simulink.IntEnumType
    enumeration
        NONLINEAR (1)
        SECOND_ORDER (2)
    end
end
classdef sldemo_mrv_BUILD_TYPE < Simulink.IntEnumType
    enumeration
        PROTOTYPE (1)
        PRODUCTION (2)
    end
end
```

- 2 Define `Simulink.Variant` objects for these classes in the base workspace.

```
VE_NONLINEAR_CONTROLLER = Simulink.Variant...
('E_CTRL==sldemo_mrv_CONTROLLER_TYPE.NONLINEAR')
VE_SECOND_ORDER_CONTROLLER = Simulink.Variant...
('E_CTRL==sldemo_mrv_CONTROLLER_TYPE.SECOND_ORDER')
VE_PROTOTYPE = Simulink.Variant...
('E_CURRENT_BUILD==sldemo_mrv_BUILD_TYPE.PROTOTYPE')
VE_PRODUCTION = Simulink.Variant...
('E_CURRENT_BUILD==sldemo_mrv_BUILD_TYPE.PRODUCTION')
```

Using enumerated types simplifies the generated code because it contains the names of the values rather than integers.

Define, Configure, and Activate Variants

In this section...

“Represent Variant Choices” on page 11-28

“Include Simulink Model as Variant Choice” on page 11-32

“Configure Variant Activation Conditions” on page 11-34

Represent Variant Choices

Variant choices are two or more configurations of a component in your model. This example shows how to represent variant choices inside a Variant Subsystem block in your model. For other ways to represent design variants, see “Options for Representing Variants in Simulink” on page 11-6.

- 1 Add a Variant Subsystem block to your model and name it.

This block serves as the container for the variant choices.

- 2 Double-click the Variant Subsystem block. Add import and output blocks so that they match the inputs into and outputs from this block.

Note: You can add only Inport, Outport, Subsystem, and Model blocks inside a Variant Subsystem block.

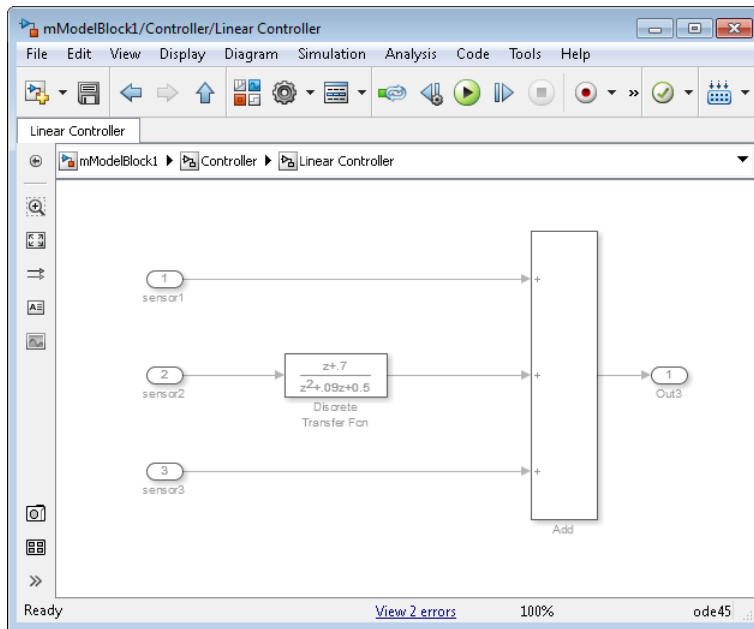

- 3 Right-click the Variant Subsystem block and select **Block Parameters (Subsystem)**.
- 4 In the block parameters dialog box, click the  button for each subsystem variant choice you want to add.

Simulink creates empty Subsystem blocks inside the Variant Subsystem block. The new blocks have the same number of inports and outports as the containing Variant Subsystem block.

Tip (If your variant choices have different numbers of inports and outports, see “Mapping Inports and Outports of Variant Choices” on page 11-7.)

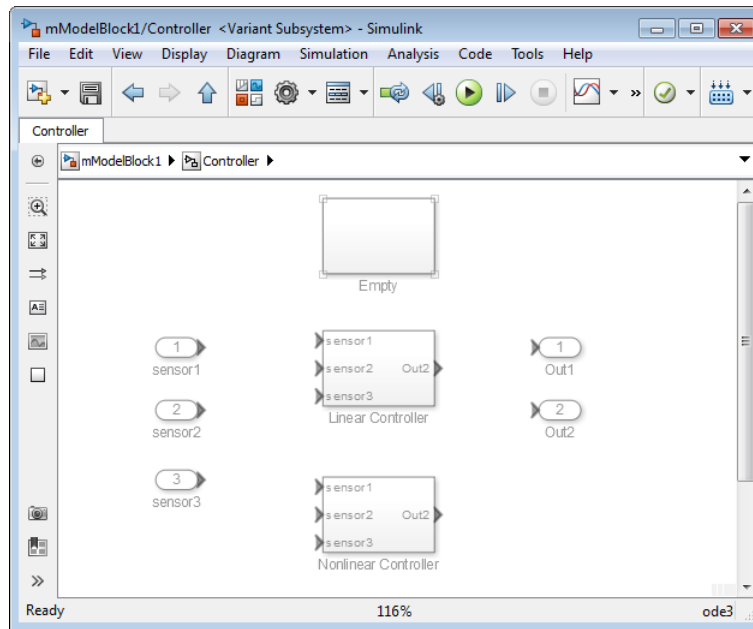

- 5 Open each Subsystem block and create the model that represents a variant choice.

- 6 When you are prototyping variants, you can create empty Subsystem blocks with no inputs or outputs inside the Variant Subsystem block. The empty subsystem recreates the situation in which a subsystem is inactive without the need for completely modeling the variant. For an empty variant choice, either specify a variant activation condition or comment out the variant condition by placing a % symbol before the condition.

If the empty variant choice is active during simulation, Simulink ignores it.

Include Simulink Model as Variant Choice

You can include a Simulink model as a variant choice inside a Variant Subsystem block.

- 1 Create a model that you want to include as a variant choice. Make sure that it has the same number of inports and outports as the containing Variant Subsystem block.

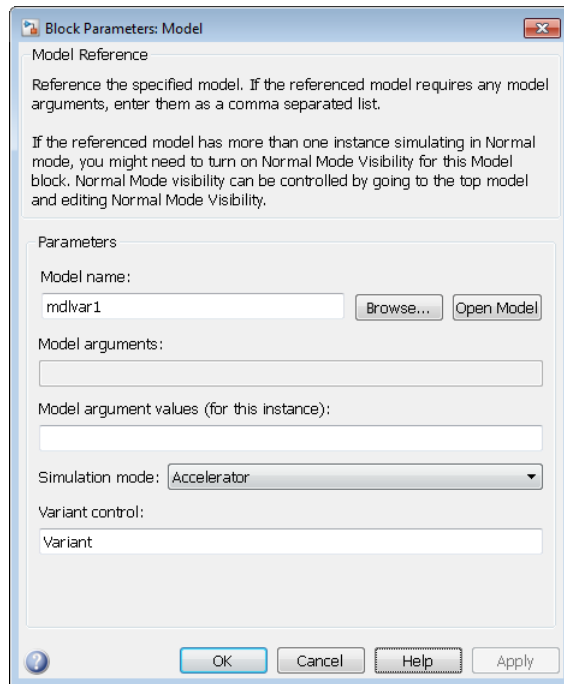

Note: If your model has different numbers of inports and outports, see “Mapping Inports and Outports of Variant Choices” on page 11-7.

- 2 In your model, right-click the Variant Subsystem block that contains variant choices and select **Block Parameters (Subsystem)**.
- 3 In the block parameters dialog box, click the  button to add a model variant choice.

Simulink creates an unresolved model reference block in the Variant Subsystem block.

- 4 Double-click the unresolved model block. In the **Model name** box, enter the names of the model you want to use as a model variant choice and click **OK**.

Configure Variant Activation Conditions

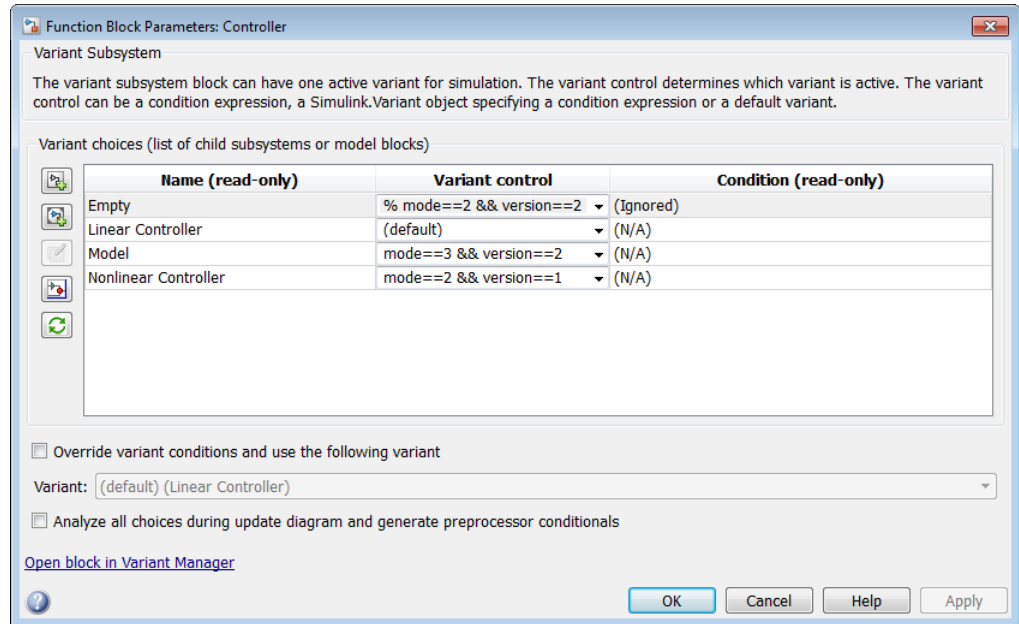

You can specify the conditions for activating a variant choice using variant controls. You can also specify one variant choice as the default.

- 1 At the MATLAB command prompt, specify the control variables that create an activation condition when combined.

```
mode = 3;  
version = 2;
```

- 2 Right-click the Variant Subsystem block that is the container for variant choices in your model and select **Block Parameters (Subsystem)**.
- 3 In the block parameters dialog box, in the **Variant control** column, select **(default)** next to one of the choices.

Simulink verifies that only one variant is active for simulation. When the control condition does not activate a variant, Simulink uses the default variant for simulation.

- 4 Enter the activation condition for each of the other choices. If you are using an empty variant choice, you can enter an activation condition for the choice. You can also comment out an existing activation condition by prefixing it with a % symbol.
- 5 Click **Apply**; otherwise, your changes are not saved.

Prepare Variant-Containing Model for Code Generation

In this section...

“Convert Variant Control Variables into Simulink.Parameter Objects” on page 11-36

“Configure Model for Generating Preprocessor Conditionals” on page 11-38

Using Embedded Coder, you can generate code from Simulink models containing one or more variant choices. The generated code contains preprocessor conditionals that control the activation of each variant choice.

Convert Variant Control Variables into Simulink.Parameter Objects

MATLAB variables allow you to rapidly prototype variant control expressions when you are building your model. However, if you want to generate preprocessor conditionals for code generation, convert MATLAB variables into `Simulink.Parameter` objects.

In addition to enabling parameter value specification, `Simulink.Parameter` objects allow you to specify other attributes (such as data type) that are required for generating code.

- 1 Specify the model in which you want to replace MATLAB variant control variables with `Simulink.Parameter` objects.

```
model = 'my_model_containing_variant_choices';
open_system(model);
```

- 2 Get the variables that are referenced in variant control expressions.

```
vars = Simulink.VariantManager.findVariantControlVars(model)
```

```
vars =
```

```
4x1 struct array with fields:
```

```
    Name
    Value
    Exists
    Source
    SourceType
```

- 3 Create an external header file for specifying variant control values so that the variable definitions are imported when the code runs.

```
headerFileName = [model '_importedDefines.h'];
```

```

headerPreamble = strep(upper(headerFileName), '.', '_');

fid = fopen(headerFileName, 'w+');
fidErr = (fid == -1);
if (fidErr)
    fprintf('There was an error creating header file %s:...
\n', headerFileName);
else
    fprintf('+++ Creating header file ''%s'' with variant control...
variable definitions.\n\n', headerFileName);
    fprintf(fid, '#ifndef %s\n', headerPreamble);
    fprintf(fid, '#define %s\n', headerPreamble);
end

```

Variant control variables defined as `Simulink.Parameter` objects can have one of these storage classes.

- Define or ImportedDefine with header file specified
 - CompilerFlag
 - SystemConstant (AUTOSAR)
 - Your own custom storage class that defines data as a macro
- 4** Loop through all the MATLAB variables to convert them into `Simulink.Parameter` objects.

```

count = 0;
for countVars = 1:length(vars)
    var = vars(countVars).Name;
    val = vars(countVars).Value;
    if isa(val, 'Simulink.Parameter')
        % Do nothing
        continue;
    end
    count = count+1;

% Create and configure Simulink.Parameter objects corresponding to the
% control variable names. Specify the custom storage class as
% ImportedDefine so that the values are specified
% by an external header file.
newVal = Simulink.Parameter(val);
newVal.DataType = 'int16';
newVal.CoderInfo.StorageClass = 'Custom';
newVal.CoderInfo.CustomStorageClass = 'ImportedDefine';
newVal.CoderInfo.CustomAttributes.HeaderFile = headerFileName;

```

```
assigninGlobalScope(model, var, newVal);  
  
if ~fidErr  
    fprintf(fid, '#endif\n');  
    fclose(fid);  
end  
end
```

Configure Model for Generating Preprocessor Conditionals

If you represent variant choices inside a Variant Subsystem block or a Model Variant block, code generated for each variant choice is enclosed within C preprocessor conditionals `#if`, `#else`, `#elif`, and `#endif`.

If you represent variant choices using a Variant Source block or a Variant Sink block, code generated for each variant choice is enclosed within C preprocessor conditionals `#if` and `#endif`.

Therefore, the active variant is selected at compile time and the preprocessor conditionals determine which sections of the code to execute.

- 1 In the Simulink editor, select **Simulation > Model Configuration Parameters**.
- 2 Select the **Code Generation** pane, and set **System target file** to `ert.tlc`.
- 3 In the **Report** pane, select **Create code generation report**.
- 4 Select the **Code Generation** pane, and clear **Ignore custom storage classes** and **Apply**.
- 5 In your model, right-click the block containing the variant choices (Variant Subsystem, Variant Source, Variant Sink, or Model Variant) and select **Block Parameters**.
- 6 Select the option **Analyze all choices during update diagram and generate preprocessor conditionals**.

Simulink analyzes all variant choices during an update diagram or simulation. This analysis provides early validation of the code generation readiness for all variant choices.

- 7 Clear the option **Override variant conditions and use following variant**.
- 8 Build the model.

Set up Model Variants

In this section...

“Configure the Model Variants Block” on page 11-42

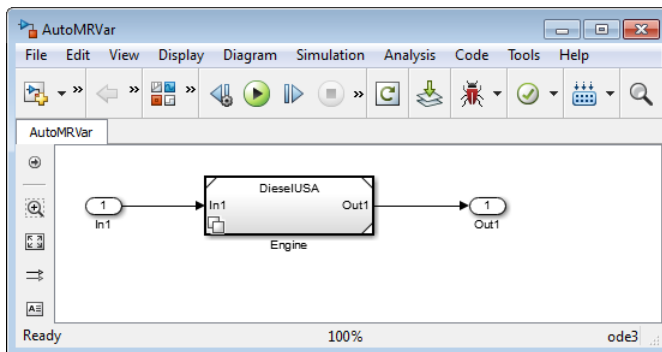

“Disable and Enable Model Variants” on page 11-44

“Parameterize Model Variants” on page 11-45

“Additional Examples” on page 11-45

Open the example model AutoMRVar. You can also open the model from the MATLAB prompt:

```
addpath([docroot ' /toolbox/simulink/ug/examples/variants/mdlref/']);
open('AutoMRVar');
```

The symbol  appears in the lower-left corner of the block to indicate that it uses variants. The name of the variant that was active the last time you saved the model appears on the block.

When you change the active variant, the variant block refreshes. The name changes to reflect the current active variant.

When you open the example model, the `load` function loads a MAT-file that populates the base workspace with the variables and objects used by the model.

Workspace	
Name ^	Value
DE	<1x1 Simulink.Variant>
DU	<1x1 Simulink.Variant>
EMIS	1
FUEL	2
GE	<1x1 Simulink.Variant>
GU	<1x1 Simulink.Variant>

The example shows the use of variants for the following cases:

- The automobile can use a diesel or a gasoline engine.
- Each engine must meet the European or United States (USA) emission standard.

AutomRVar implements the automobile application using the **Model Variants** block named **Engine**. The **Engine** block specifies four referenced models. Each referenced model represents one permutation of engine fuel and emission standards. The table shows the variant choices.

Model Name	Variant Control	Condition (read only)
GasolUSA	GU	FUEL==1 && EMIS==1
GasolEuro	GE	FUEL==1 && EMIS==2
DieselUSA	DU	FUEL==2 && EMIS==1
DieselEuro	DE	FUEL==2 && EMIS==2

Note: You can use condition expressions directly in the **Variant control** field. You do not need to create `Simulink.Variant` objects.

Configure the Model Variants Block

You can configure a Model block and specify your variant choices.

- 1 Create a model.
- 2 From the **Ports & Subsystems** library, add a Model block to the model.
- 3 Right-click the Model block and select **Block Parameters (ModelReference)** from the context menu.

- Under **Variant choices**, specify the model choices in the **Model name** column. To specify a protected model, use the extension `.slxp` or `.mdl`. For more information, see “Protected Model” on page 8-83.

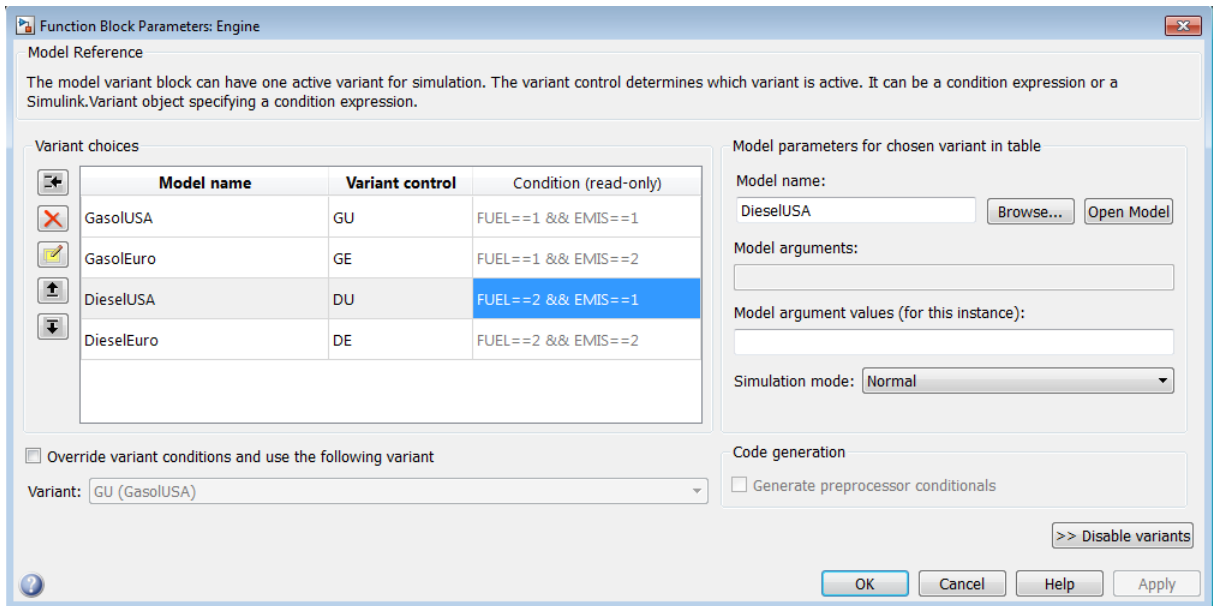

Note: You cannot specify a model as the default variant if that model is a variant choice in a Model block. Instead, you can add that model as a variant choice in a Subsystem block, and then specify that model as the default variant.

- For each model choice, specify the variant control in the **Variant control** column. Use a Boolean condition expression or a `Simulink.Variant` object representing a Boolean condition expression.

Populate the **Variant control** column for each choice. You cannot comment out (%) variant control values for the Model block. However, for Variant Subsystem blocks, you can comment out variant choices.

- To edit the condition that determines the active variant choice, click the **Create/Edit selected variant** button . In the dialog box, enter the condition and click **OK**.

- 7 If you want, specify the model arguments and the **Simulation mode**. All simulation modes work with model variants. For more information, see “Parameterize Model Variants” on page 11-45 and “Simulate Model Referencing Models” on page 8-31.
- 8  If you want to add more variant choices, click the **Add a new variant** button.
- 9 After you have specified referenced models and added variant choices, click **OK**.

For next steps, see “Working with Variant Choices” on page 11-9.

Disable and Enable Model Variants

You can disable model variants without losing your variant settings. After you enable variants, they remain enabled until you explicitly disable them.

Disabling variants:

- Hides and ignores the content of the **Variant choices** section of the dialog box
- Retains the active variant as the model name

- Ignores subsequent changes to variant control variables and other models, other than the current model

To disable variants from a Model block:

- 1 Right-click the block and select **Block Parameters (ModelReference)** to open the block parameters dialog box.
- 2 Click **Disable Variants**.

To enable variants, click **Enable Variants**. The Model block selects an active variant according to the current base workspace variables and conditions.

Parameterize Model Variants

You can apply a parameter to a variant control. Parameter values are the same as for a referenced model.

- 1 In the block parameters dialog box, under **Variant choices**, select the row for the variant control that you want to parameterize.
- 2 In the **Model argument values (for this instance)** text box, specify the parameter.
- 3 Click **Apply**.

For more information, see “Parameterize Instances of a Reusable Referenced Model” on page 8-61.

Additional Examples

For additional examples of model reference variants, in the Help browser, select **Simulink > Examples > Modeling Features > Model Reference > Model Reference Variants**.

The example `sldemo_md1ref_variants` shows a model variant.

Visualize Variant Implementations in a Single Layer

Simulink provides two blocks that you can use to visualize all possible implementations of variant choices in a model. These blocks are called Variant Source and Variant Sink.

When you compile the model, Simulink determines which variant control evaluates to true. Simulink then deactivates blocks that are not tied to the variant control being true and visualizes the active connections.

How Variant Sources and Sinks Work

The Variant Source block has one or more input ports and one output port. You can define variant choices as blocks that are connected to the input port so that, at most, one choice is active. The active choice is connected directly to the output port of the Variant Source and the inactive choices are eliminated during simulation.

The Variant Sink block has one input port and one or more output ports. You can define variant choices as blocks that are connected to the output port so that, at most, one choice is active. The active choice is connected directly to the input port of the Variant Sink, and the inactive choices are eliminated during simulation.

Connect one or more blocks to the input port of the Variant Source block or the output port of the Variant Sink block. Then, you define variant controls for each variant choice entering the Variant Source block and exiting the Variant Sink block. For more information, see “Variant Condition Propagation with Variant Sources and Sinks” on page 11-57.

Advantages of Using Variant Sources and Sinks

Using Variant Source and Variant Sink blocks in Model-Based Design provides these advantages:

- The blocks enable the propagation of variant conditions and allow you to visualize variant choices in a single layer of your model.
- By visualizing all possible implementations of variant choices, you can improve the readability of your model.
- During model compilation, Simulink eliminates inactive blocks throughout the model, improving the runtime performance of your model.

- Variant sources and sinks provide variant component interfaces that you can use to quickly model variant choices.

Limitations of Using Variant Sources and Sinks

- Variant Source and Variant Sink blocks work with time-based, function-call, or action signals. You cannot use SimEvents, Simscape Multibody, or other non-time-based signals with these blocks.
- When the Variant Source or Variant Sink blocks are configured to generate preprocessor conditionals, the global memory in the generated code is not guarded conditionally.
- The code generation variant report does not contain Variant Source and Variant Sink blocks.

Related Examples

- “Define and Configure Variant Sources and Sinks” on page 11-50

More About

- “Variant Condition Propagation with Variant Sources and Sinks” on page 11-57

Define and Configure Variant Sources and Sinks

Simulink provides two blocks that you can use to visualize all possible implementations of variant choices in a model graphically. These blocks are called Variant Source and Variant Sink.

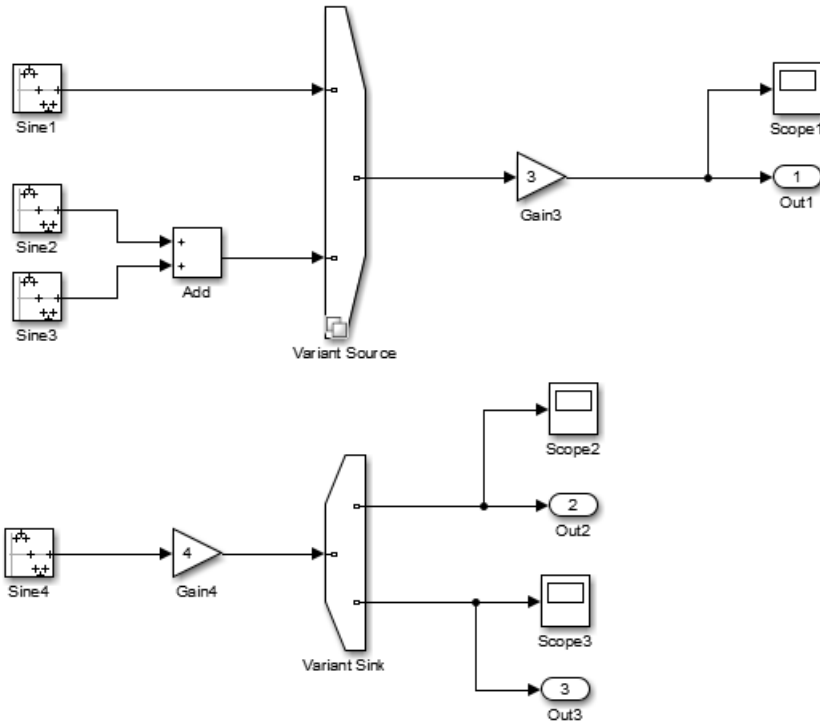

When you compile the model, Simulink determines which variant control evaluates to true. Simulink then deactivates blocks that are not tied to the variant control being true and visualizes the active connections.

- 1 Add Variant Source and Variant Sink blocks to your model.

These blocks enable ports that activate variant choices.

- 2 Using blocks from the Simulink Library Browser, create sources and sinks that represent variant choices. Connect choices to the input and output ports of the Variant Source and Variant Sink blocks.

- 3 At the MATLAB command prompt, specify the control variable that creates an activation condition for the variant source.

```
V = Simulink.Parameter(1);
```

- 4 Right-click the Variant Source block and select **Block Parameters (VariantSource)**.
- 5 In the block parameters dialog box, in the **Variant control** column, type $V==1$ next to one of the choices and $V==2$ next to the other. Click **Apply**; otherwise, your changes are not saved.

Simulink verifies that only one variant is active for simulation. When the control condition does not activate a variant, Simulink uses the default variant for simulation.

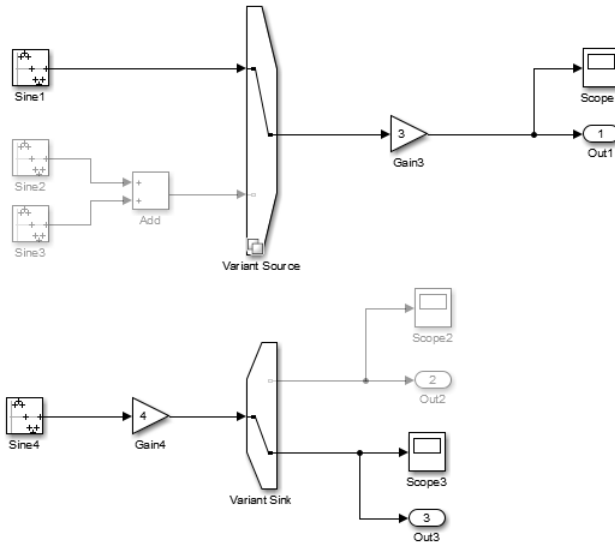

- 6 At the MATLAB command prompt, specify the control variable that creates an activation condition for the variant sink.

```
W = Simulink.Parameter(2);
```

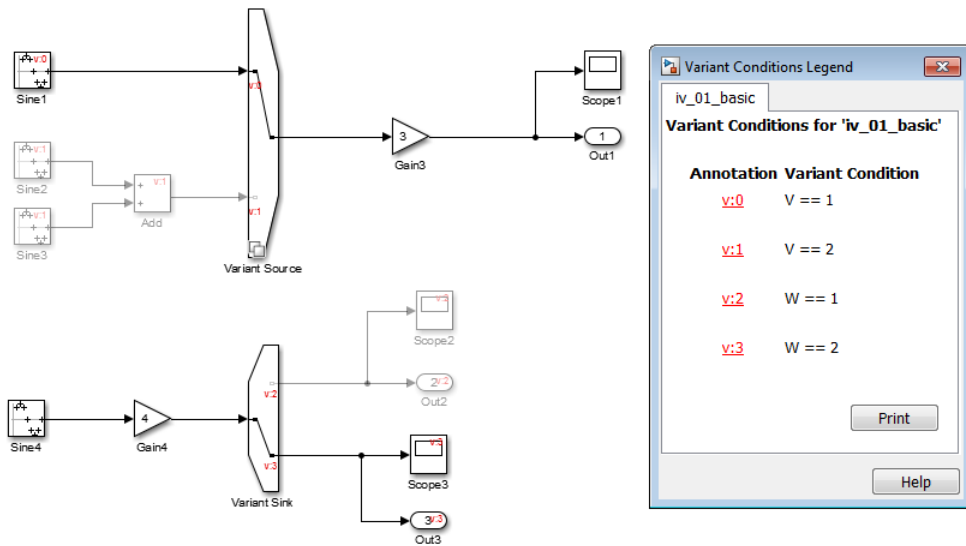

- 7 Double-click the Variant Sink. In the block parameters dialog box, in the **Variant control** column, type $W=1$ next to one of the choices and $W=2$ next to the other.

- 8 Click **Apply**; otherwise, your changes are not saved.
- 9 Simulate the model. Simulink propagates the variant conditions to identify which model components to activate.

- 10 You can visualize the conditions that activate each variant choice by selecting **Display > Blocks > Variant Conditions**.

- In the Variant Condition Legend dialog box, click through the hyperlinked variant condition annotations to observe which parts of the model each condition activates.

Variant Condition Propagation with Variant Sources and Sinks

When you specify variant conditions in models containing Variant Source and Variant Sink blocks, Simulink propagates these conditions to determine which components of the model are active during simulation.

In this section...

“View Variant Condition Annotations” on page 11-57

“How Variant Condition Propagation Works” on page 11-60

“Condition Propagation with Other Simulink Blocks” on page 11-63

“Known Limitations” on page 11-65

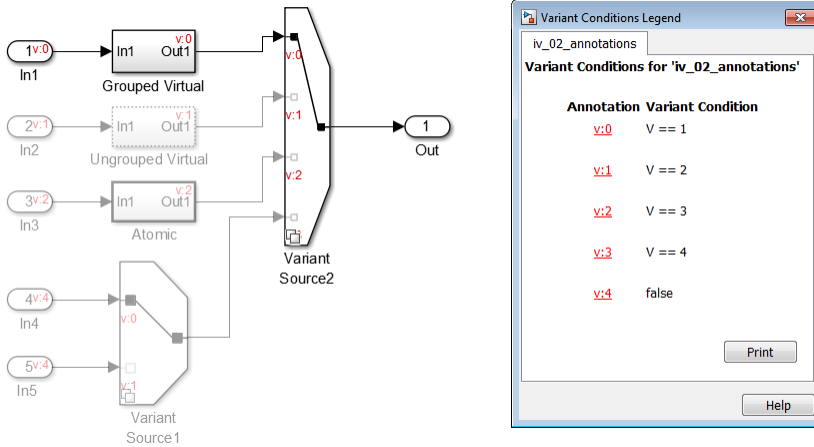

View Variant Condition Annotations

When you develop a model that contains Variant Source or Variant Sink blocks, you can visualize the conditions that activate each variant choice. Simulink annotates these models with their corresponding variant conditions.

Consider this model containing multiple variant choices feeding into Variant Source blocks. A specific variant condition activates each variant choice.

To visualize the variant conditions, select **Display > Blocks > Variant Conditions**.

The **Variant Condition Legend** dialog box appears. Variant conditions on blocks are annotated as **v:C**, where **v** is the variant semantic indicator and **C** represents the variant condition index. The dialog box also shows the expression associated with each condition.

In the **Variant Condition Legend** dialog box, you can click through the hyperlinked variant annotations to observe which parts of the model each condition activates. For example, if you click **v:3**, Simulink highlights the parts of the model that are activated when the condition **V==3** evaluates to **true**.

Variant condition annotations have these properties:

- There are no annotations on unconditional blocks. Therefore, the Out block is not annotated.
- To reduce clutter, the legend only displays the final computed conditions. For example, if you enter a variant condition in a Variant Source block, that condition appears in the annotations only when you apply your changes.
- The conditions in the legend are sorted during display.
- In the legend, a condition is set to **false** if Simulink assesses that the blocks associated with that condition are never active.

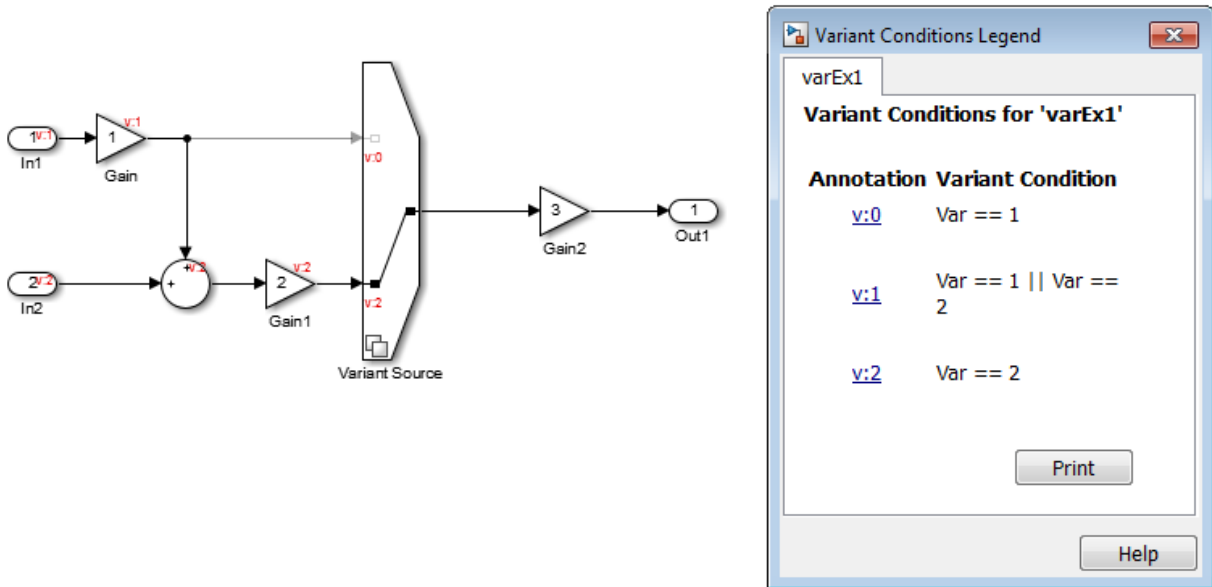

For example, the In4 block is connected to the Variant Source1 block, whose condition is $V==1$. Variant Source1 is connected to the Variant Source2 block, which activates Variant Source1 only when $V==4$. Therefore, In4 can only be active when $V==1 \ \&\& \ V==4$, a condition that is always **false**.

How Variant Condition Propagation Works

When you compile a model containing Variant Source or Variant Sink blocks, Simulink determines which variant control evaluates to `true`. Simulink then deactivates blocks that are not tied to the variant control being `true` and visualizes the active connections.

Cross-Coupling of Inputs and Outputs

In this model, two inputs feed the Variant Source block. The first input is active when `Var == 1`, and it branches into the second input before connecting to the Variant Source block. The second input is the default variant choice.

During simulation, this model exhibits three modes of operation:

- When `Var == 1`, the first input is active and its branch into the second input is inactive.
- When `Var == 1 || Var == 2`, the second input is active and the branch of the first input is active.
- When `Var == 2`, the second input is active and the output is active.

Cascading Blocks and Compounding Conditions

In this model, two Variant Source blocks, each fed by two input ports, are connected in a cascading manner. The inputs to Variant Source are active when $\text{Var1} == 1$ or $\text{Var1} == 2$. The output of Variant Source branches into one of the inputs of Variant Source1. The inputs to Variant Source1 are active when $\text{Var2} == 1$ or $\text{Var2} == 2$.

During simulation, this model exhibits eight modes of operation:

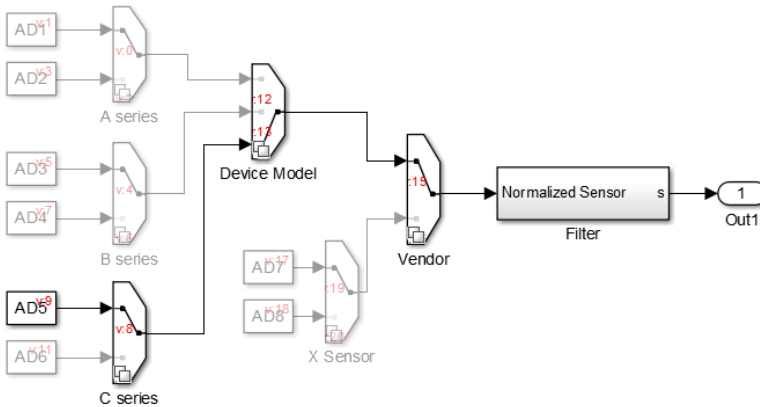

- When $\text{Var1} == 1$ && $\text{Var2} == 1$, the first inputs of Variant Source and Variant Source1 are active.
- When $\text{Var1} == 1$ && $\text{Var2} == 2$, the first input of Variant Source and the second input of Variant Source1 are active.
- When $\text{Var1} == 2$ && $\text{Var2} == 1$, the second input of Variant Source and the first input of Variant Source1 are active.
- When $\text{Var1} == 2$ && $\text{Var2} == 2$, the second inputs of Variant Source and Variant Source1 are active.
- When $\text{Var1} == 1$ && $\text{Var2} != (1,2)$, only the first input of Variant Source is active.
- When $\text{Var1} == 2$ && $\text{Var2} != (1,2)$, only the second input of Variant Source is active.

- When $\text{Var1} \neq (1,2) \ \&\& \ \text{Var2} == 1$, none of the inputs or outputs is active.
- When $\text{Var1} \neq (1,2) \ \&\& \ \text{Var2} == 2$, only the second input of **Variant Source1** is active.
- When $\text{Var1} \neq (1,2) \ \&\& \ \text{Var2} \neq (1,2)$, none of the inputs or outputs is active.

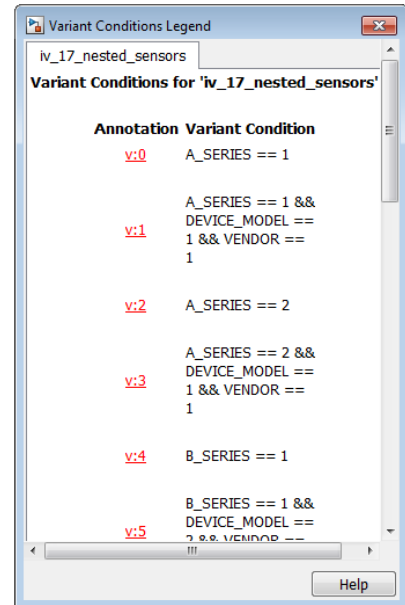

Hierarchical Nesting of Sources or Sinks

In this model, multiple Variant Source blocks are used to create hierarchical nesting of variant choices. Choices are first grouped by series: **A Series**, **B Series**, and **C Series**. A combination of one or more series is provided as input for a device model. The resulting device model is provided as input to the vendor by including or excluding a sensor selection.

Simulink propagates complex variant control conditions to determine which model components are active during compilation.

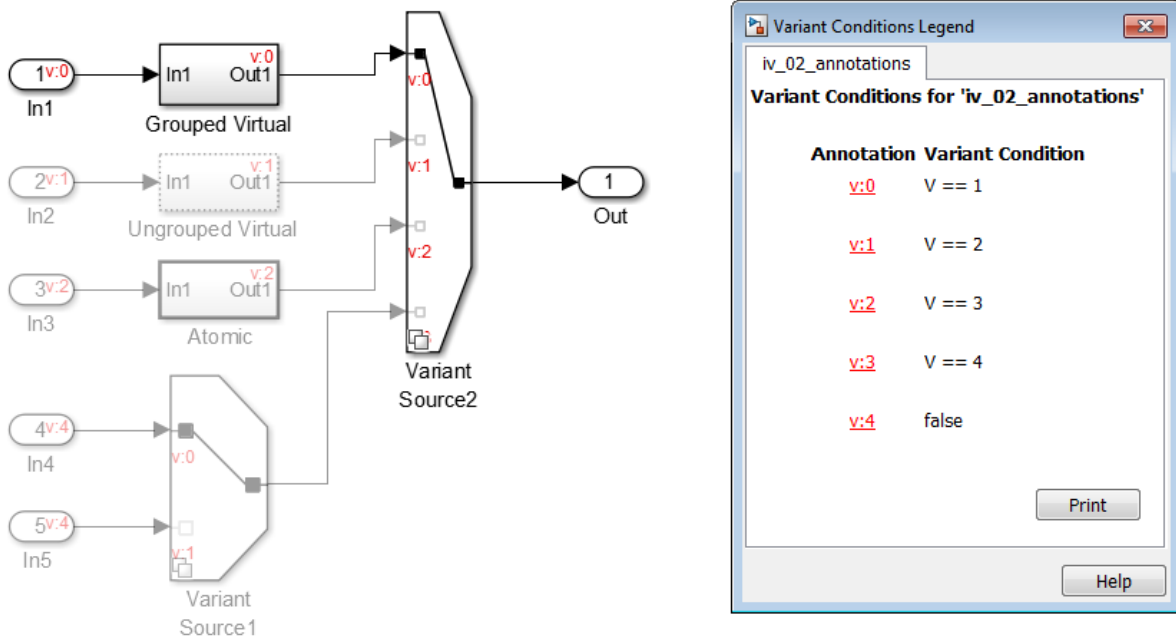

Copyright 2015 The MathWorks Inc.
MathWorks Confidential

Treatment of Subsystems as Grouped and Ungrouped

Depending on the type of subsystem, Simulink propagates variant conditions differently. In this model, three types of subsystems are provided as input to the block **Variant Source2**.

- The first one is a virtual subsystem, which is activated when $V == 1$. For this subsystem, the option to **Treat as grouped when propagating variant conditions** is enabled. Simulink propagates the variant activation condition to all the blocks in the subsystem.
- The second one is a virtual subsystem, which is activated when $V == 2$. This subsystem is not treated as grouped for condition propagation, as indicated by its dotted outline. Simulink propagates the variant activation condition to all the blocks in the subsystem.
- The third one is an atomic subsystem, which is activated when $V == 3$. Simulink does not propagate the variant activation condition into this subsystem

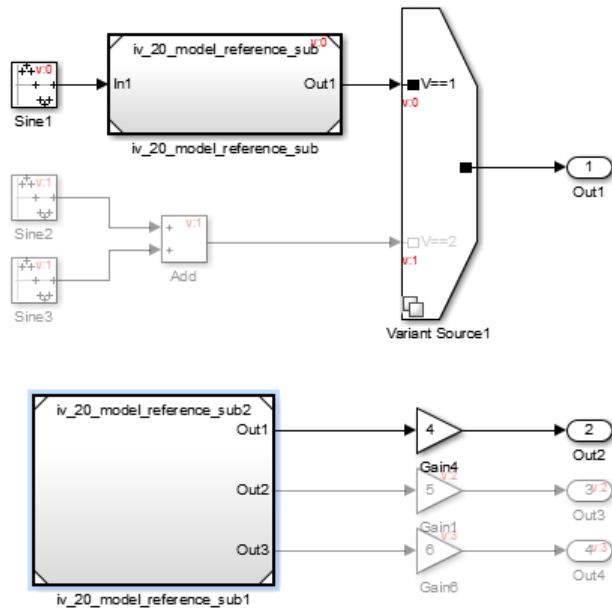

Condition Propagation with Other Simulink Blocks

- Model block

Simulink compiles referenced models before propagating variant conditions. A variant condition can activate or deactivate a Model block, but variant conditions cannot

propagate into the referenced model. A Model block can propagate variant conditions from its output port, if that variant condition originates at a port inside the model.

In this example, variant condition $V==1$ activates the model block `iv_20_model_reference_sub`. However, the condition does not propagate into the model referenced by the block. Model block `iv_20_model_reference_sub2` propagates the same variant condition from its output port.

- Simulink Function block

Argument Inport and Argument Outport blocks interfacing with Simulink Function blocks cannot be connected to Variant Source or Variant Sink blocks. One variant condition must control the entire Simulink Function.

In this example, the function-call port block within the Simulink Function block has the **Enable variant condition** option checked. This selection enables the option to **Generate preprocessor conditionals** and changes the visual appearance of the port on the Simulink Function block. The **Variant control** parameter of the function-call port is specified as $V==1$. If you change the value of V , the function caller block becomes inactive. As a result, the entire model becomes inactive.

Note: The **Configure Model Functions** button on the **Code Generation > Interface** pane provides you flexible control over the model function prototypes that are generated for a model. If the inport and the outport share an argument name and have propagated variant conditions, the flexible control over the model function prototypes is not supported.

- Subsystem block

A variant condition can activate or deactivate a Subsystem block, but variant conditions cannot propagate into the subsystem. A Subsystem block can propagate variant conditions from its output port if that variant condition originates at a port inside the subsystem.

- Bus block

A Variant Source block can accept either virtual or nonvirtual bus inputs. When generating code with preprocessor conditionals, the bus types and hierarchies of all bus inputs must be the same. In addition, all elements of a bus signal must have the same variant condition. Elements of a bus cannot have different variant conditions.

Known Limitations

- Variant condition propagation to physical port and Simulink Function inside Stateflow block is not supported.

- Variant condition propagation is not supported for models with callback code that modifies the model during compilation.
- C++ code generation is not supported for models that contain propagated variant conditions.

Create and Validate Variant Configurations

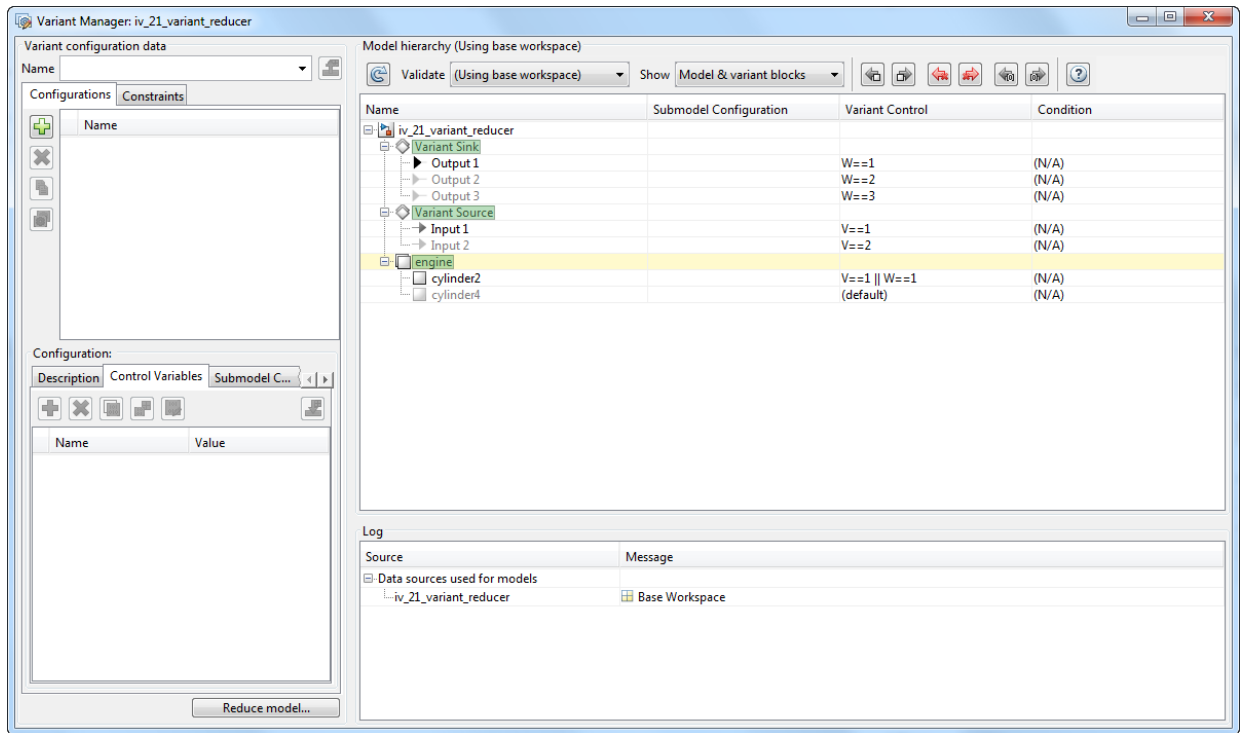

This example shows how to create and validate variant configurations for a model.

Step 1: Open Variant Manager

- 1 Open the model in which you want to create variant configurations. For example, consider a model containing a Variant Source, Variant Sink, and a Variant Subsystem block.

- 2 Right-click the variant block and select **Variant > Open in Variant Manager**.

Step 2: Define Variant Configuration

You can use the **Variant configuration data** pane to define and store a variant configuration. For detailed information on each pane, see “Variant Manager Overview”.

- 1 In the variant configuration data pane, click the **Configurations** tab.
- 2 . A variant configuration is added. Type a name for this configuration in the **Name** column.
- 3 Click the **Control Variables** tab in the controls section of the **Configuration** pane.
- 4 To import the control variables for the variant configuration from the global workspace, click  or  to add new control variables to the model.

- 5 Type a name for the variant configuration in the **Name** box available at the top-left of Variant Manager.

- 6 To export the variant configuration information to the global workspace, click . The variant configuration for the model is now created.

Variant Manager: iv_21_variant_reducer

Variant configuration data

Name: Vconfig

Configurations: Configuration1

Configuration: Configuration1

Control Variables

Name	Value
V	1
W	2

Model hierarchy (Configuration: Configuration1)

Name	Submodel Configuration	Variant Control	Condition
iv_21_variant_reducer			
Variant Sink			
Output 1		W==1	(N/A)
Output 2		W==2	(N/A)
Output 3		W==3	(N/A)
Variant Source1

cylinder2		V==1 W==1	(N/A)
cylinder4		(default)	(N/A)

Log

Source	Message
Data sources used for models	
iv_21_variant_reducer	Configuration 'Configuration1' of unexported variant configuration data object 'Vconfig'

Reduce model...

Step 3: Validate Variant Configuration

- 1 In the Model hierarchy pane, select a variant configuration from the Validate drop-down menu. Simulink validates the new configuration against the model and returns the validation results.

2

To revalidate a variant condition, click .

Note: To reduce a model based on a variant condition, click **Reduce model**. For more information, see “Reduce Models Containing Variant Blocks” on page 11-78

Related Examples

More About

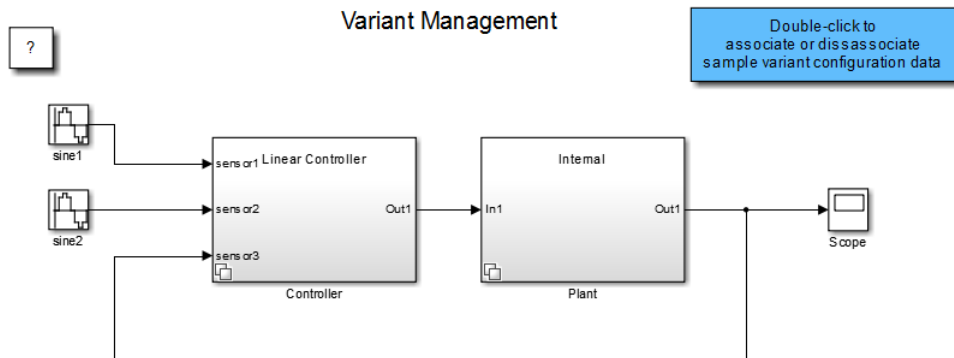

- “Approaches for Specifying Variant Controls” on page 11-14

Import Control Variables to Variant Configuration

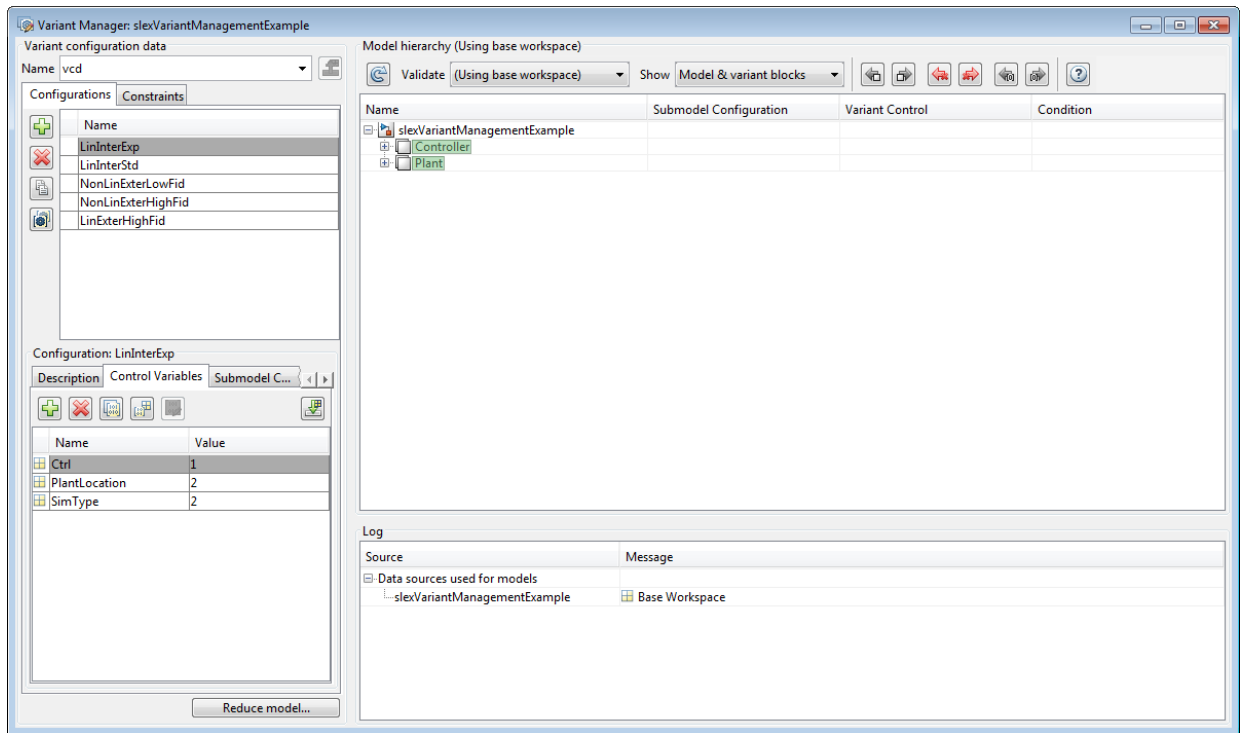

This example shows how to import control variables to a variant configuration and associate a configuration with a referenced submodel.

Step 1: Open Variant Manager

- 1 Open `slexVariantManagementExample`, which contains the variant configurations.

- 2 Double-click the blue block at the top to associate variant configuration data with the model.
- 3 Select **View > Variant Manager**.

Variant configuration data vcd is associated with the model.

Step 2: Import Variant Configuration

- 1 In the Variant Manager, in the **Configurations** tab, select **LinExterHighFid**.
- 2 In the **Control Variables** tab, click the **Import control variables from the base workspace** button .

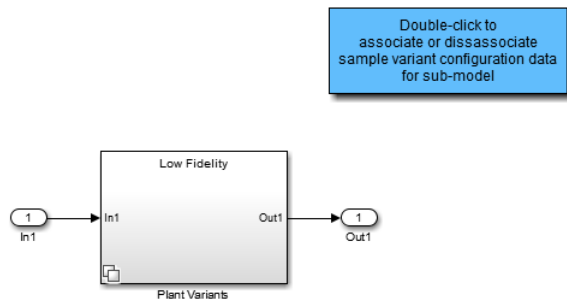

The variables are imported.

Configuration: LinExterHighFid

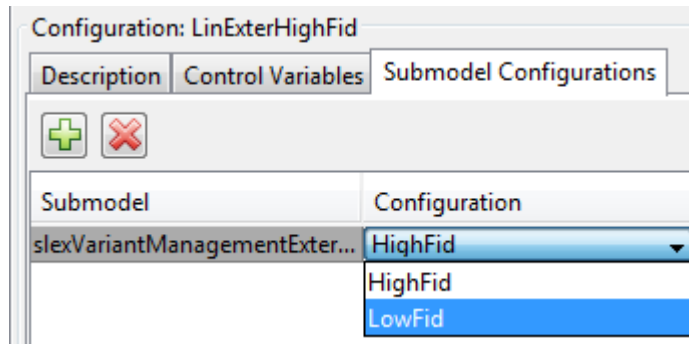

Description		Control Variables	Submodel Configurations
<div style="display: flex; justify-content: space-between; align-items: center;"> + ✖ 📄 📄 📄 📄 </div>			
Name	Value		
Ctrl	1		
SmartSensor1Mod	0		
SimType	2		
PlantLocation	2		

Step 3: View Submodel Configuration

- 1 Open the referenced model `slexVariantManagementExternalPlantMdlRef`.

- 2 Double-click the blue block at the top to associate variant configuration data with the referenced model.
- 3 In the Variant Manager that is opened from `slexVariantManagementExample`, select `slexVariantManagementExternalPlantMdlRef` under the **Submodel Configurations** tab.
- 4 Select the `LOWFid` configuration from the dropdown menu.

- 5 To validate the model using the `LinExterHighFid` variant configuration, select `LinExterHighFid` from the **Validate** dropdown menu.

Simulink validates the new configuration against the model and returns the validation results.

More About

- “Introduction to Variant Controls” on page 11-13

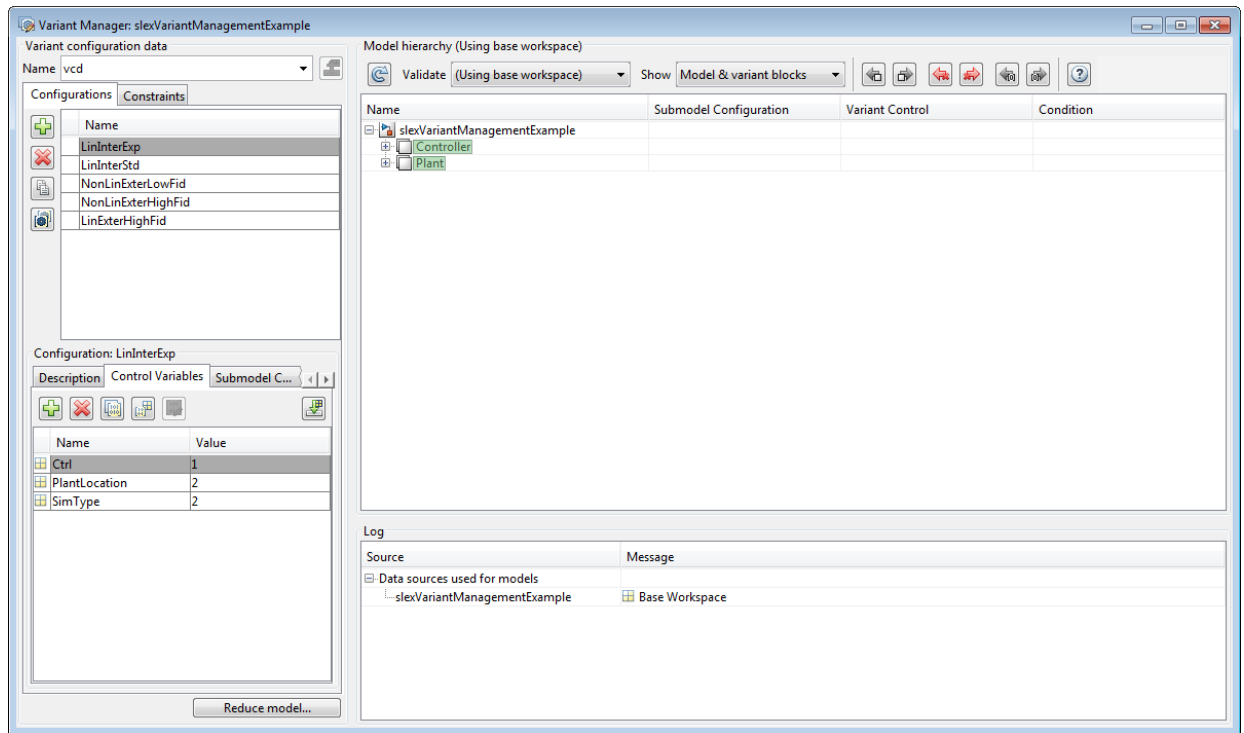

Define Constraints

This example shows how to define constraints that must evaluate to true for a variant configuration to become active.

- 1 Open `slexVariantManagementExample`.

- 2 Select **View > Variant Manager**.

- 3 In the Variant Manager, in the **Constraints** tab, click .
- 4 Enter **LinNotExtern** as the **Name** and **(Ctrl~=1) || (PlantLocation ~=1)** as the **Condition** for the constraint.

This constraint activates variants that do not use the Linear Controller and External Plant Controller configurations.

- 5 To validate the constraint, click the **Refresh and validate** button .

Reduce Models Containing Variant Blocks

Note: You require a Simulink Design Verifier license to reduce your model.

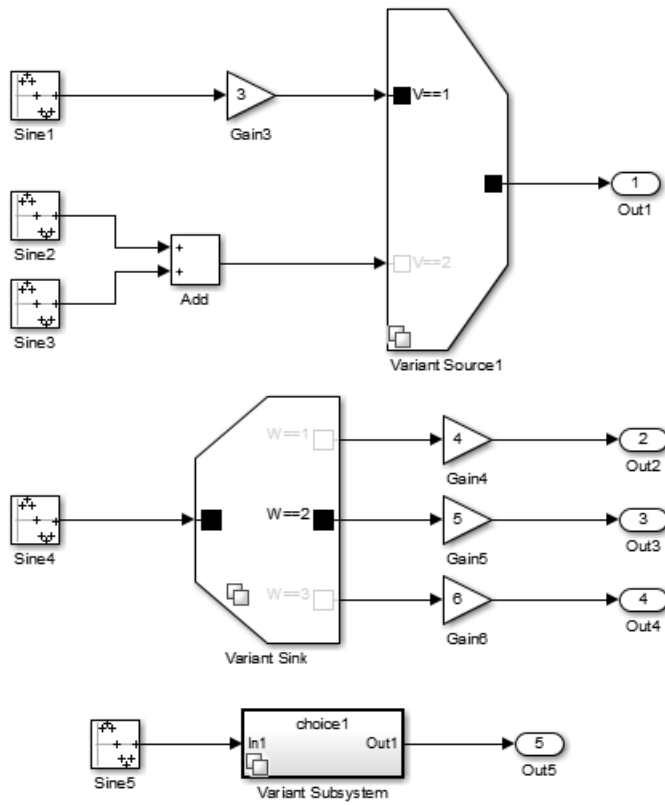

A variant model can contain multiple variable structure and a single fixed structure. The combination of the variable structure and the fixed structure to create a model depends on different combinations of the variant choices that you select. Each combination of the variant choices can be stored as a variant configuration.

Variant models can be reduced to simplified, standalone model depending on the selected variant configurations.

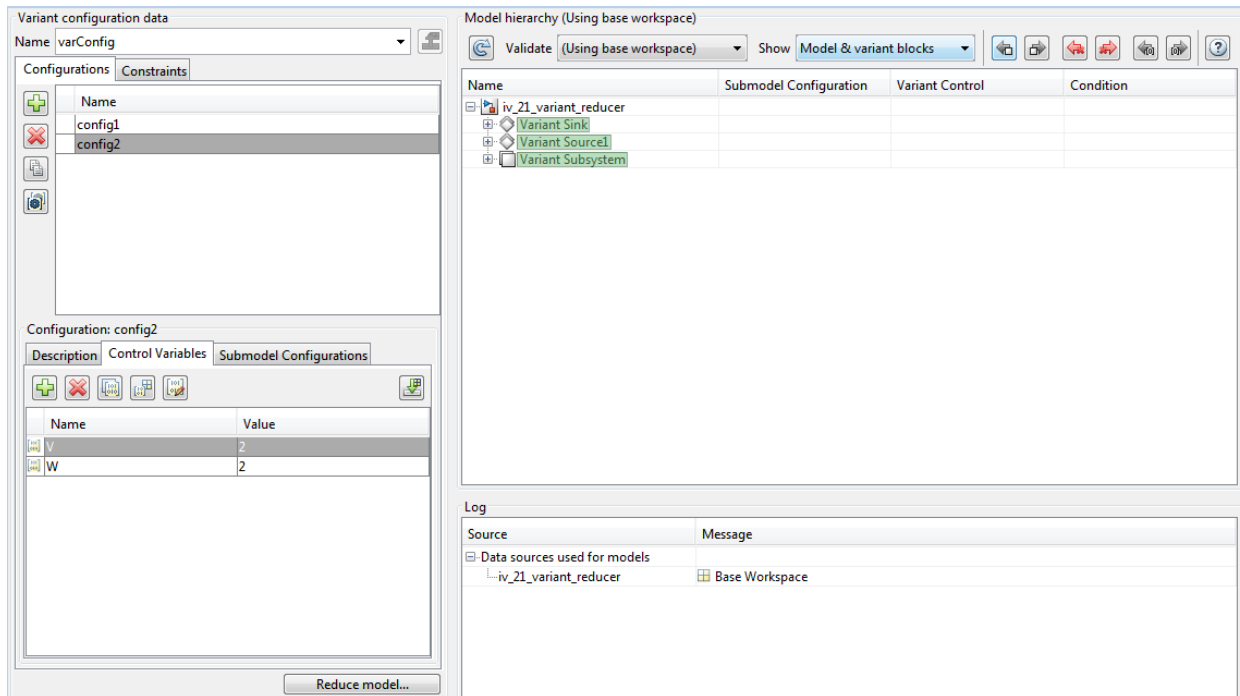

Consider a model that contains a Variant Source block, a Variant Sink block, and a Variant Subsystem block with these variant choices:

- Variant Source: $V==1$ and $V==2$
- Variant Sink: $W==1$, $W==2$, and $W==3$
- Variant Subsystem: $V==1$ and $V==2$

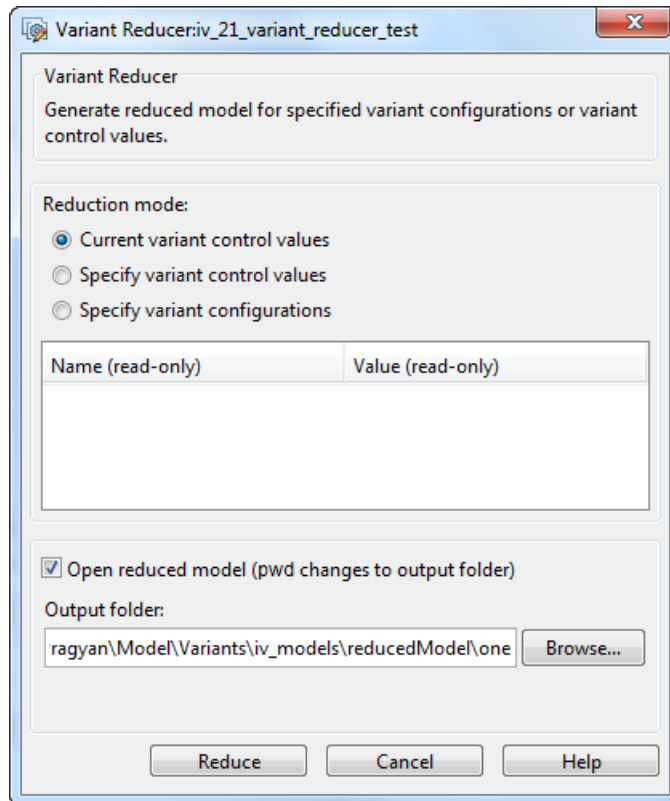

Assume that the model has two predefined variant configurations, named `config1` ($V==1$ && $W==2$) and `config2` ($V==2$ && $W==2$). These configurations are saved in a variant configuration data object, `varConfig`.

- 1 Right-click the variant badge, and select **Open in Variant Manager**. The Variant Manager opens displaying the predefined configurations.

2 Click **Reduce model**. The Variant Reducer dialog box opens.

- 3 In the **Reduction mode** section, select:
- **Current variant control values** (default) : To reduce the model based on its variant control variable values in the global workspace.

Reduction mode:

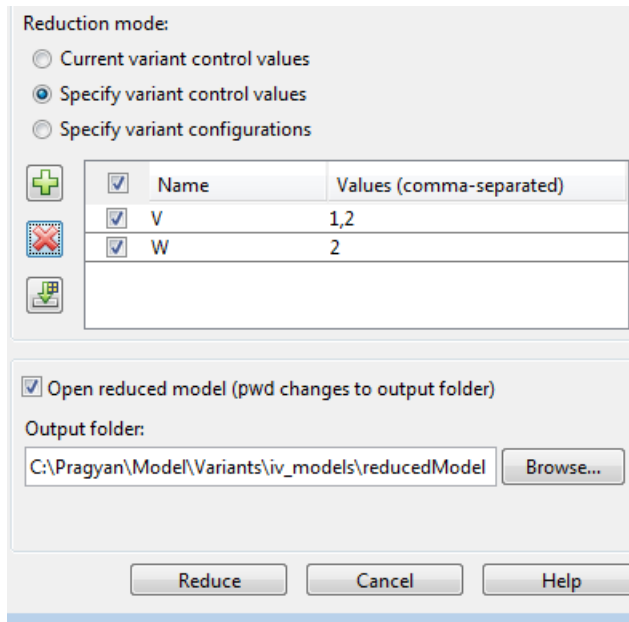

Current variant control values
 Specify variant control values
 Specify variant configurations

Name (read-only)	Value (read-only)
V	1
W	2

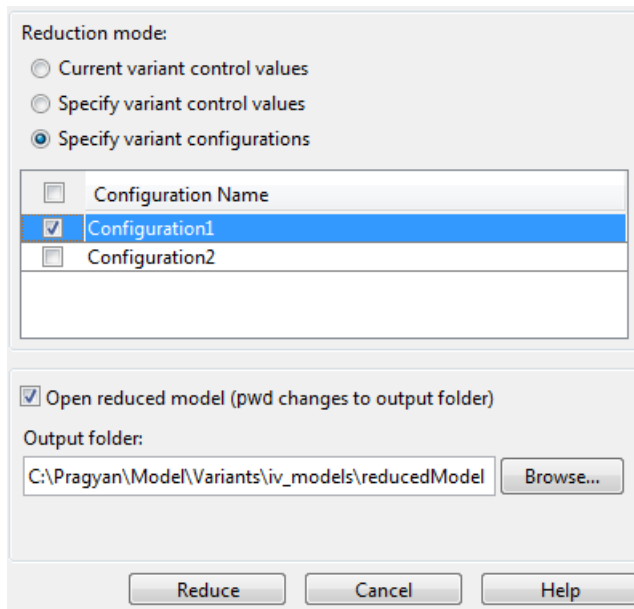

Open reduced model (pwd changes to output folder)

Output folder:
C:\Pragyan\Model\Variants\iv_models\reducedModel

- **Specify variant control values:** To reduce the model based on the variant control variable values specified as a comma separated list.

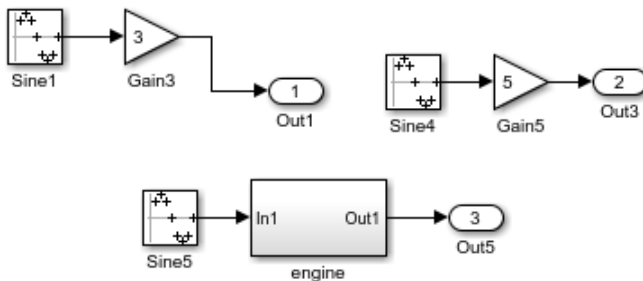

- **Specify variant configurations:** To reduce the model that is associated with a variant configuration data object and configurations to be retained in the reduced model.

- 4 Specify the output folder to store the reduced model.

Note: To make the output folder as current working folder, select the **Open reduced model** check box

- 5 Click **Reduce**. The reduced model for the required configuration is now created. The reduced model gets its name from the parent model with `_r` appended to it.

Reduce Model Programmatically

To reduce a model programmatically by using the below syntax:

```
Simulink.VariantManager.reduceModel(model, <Configuration>, <OutputFolder>)
```

For example,

- To reduce the model based on its variant control variable values in the global workspace.

```
Simulink.VariantManager.reduceModel('sldemo_variant_subsystems')
```

- To reduce the model based on its variant control variable values in the global workspace to a specified folder.

```
Simulink.VariantManager.reduceModel('sldemo_variant_subsystem', [], 'outdir')
```

- To reduce the model that is associated with a variant configuration data object and configurations to be retained in the reduced model.

```
Simulink.VariantManager.reduceModel('slexVariantManagementExample',...
{'LinInterStd', 'NonLinExterHighFid'})
```

- To reduce the model by specifying configurations in the form of a structure of variant control variables.

```
Simulink.VariantManager.reduceModel('iv_model', struct('V', 1, 'W', [1 2]))
```

Here, two configurations are specified corresponding to {V=1, W=1} and {V=1, W=2}, respectively.

Condition Propagation with Variant Subsystem

When you specify variant conditions in models containing Variant Subsystem blocks, Simulink propagates these conditions to determine which components of the model are active during simulation. A variant condition can be a condition expression or a variant object.

The variant condition annotations help you visualize the propagated conditions. To view the variant condition annotations, click **Display > Blocks > Variant Condition Legend**.

Note: The **Variant Condition Legend** option is available only when **Display > Blocks > Variant Condition** is active.

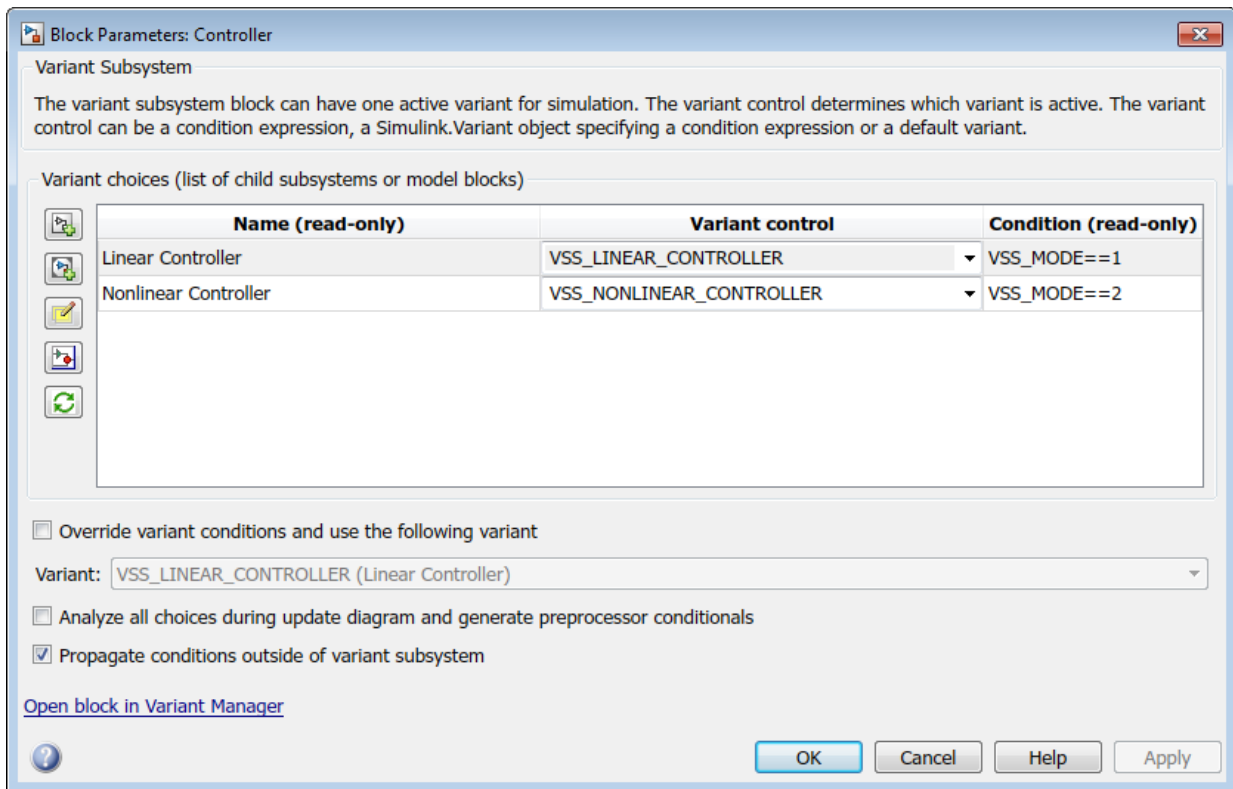

Consider this model containing a Variant Subsystem block with variant choices. A specific variant condition activates each block.

In the Variant Subsystem (Controller), sensor1 and sensor3 are used both in the Linear Controller and Nonlinear Controllers but sensor2 is used only in the Linear Controller. Hence, the sensor2 block is executed only when the Linear Controller choice is active and is not executed for any other choice. To ensure that the components outside of the Variant Subsystem (Controller) are aware of the active or inactive state of blocks with the Variant Subsystem, the block condition must propagate outside of the Variant Subsystem.

Propagate Conditions Without Generate Preprocessor Conditionals

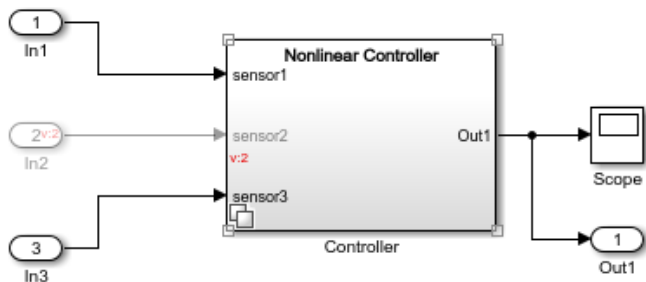

To propagate conditions outside of Variant Subsystems without generate preprocessor conditionals, select the **Propagate conditions outside of variant subsystem** check box in the **Block Parameter** dialog box of the Variant Subsystem block. By default, **Propagate conditions outside of variant subsystem** is not selected.

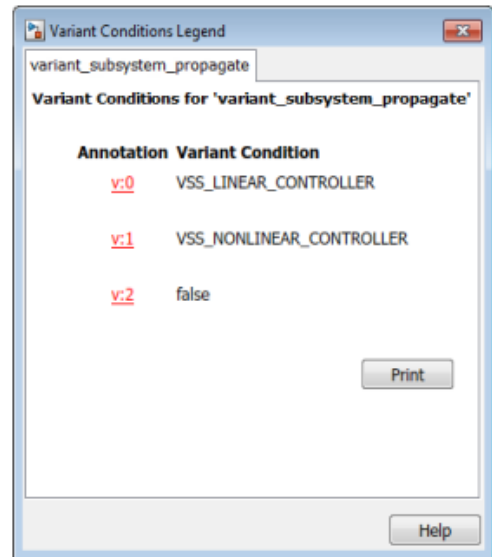

When you simulate the model with the active choice as Nonlinear Controller and the **Propagate condition outside of variant subsystem** selected, only the active choice is analyzed. Notice that the **Analyze all choices during update diagram and generate preprocessor conditional** check box is not selected.

The **Variant Condition Legend** displays the inactive conditions as `false`. Here, `sensor2` is inactive with variant choice as Nonlinear Controller and is marked as

false. The annotations are displayed on the `sensor2` port and the inactive block that is connected to `sensor2`.

Components of 'Controller' block

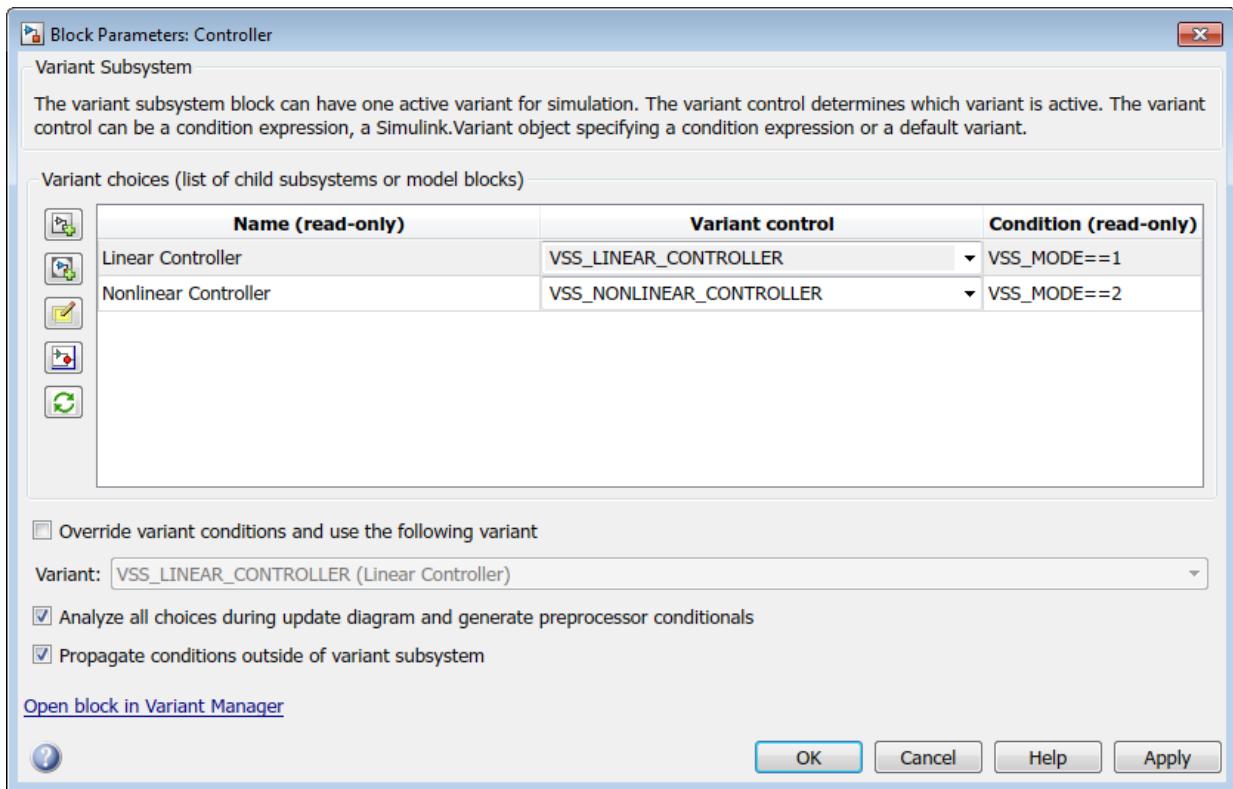

When you generate code for condition propagation without generate preprocessor conditionals, the inactive blocks are ignored. In this example, the input port `In2` is not shown in the generated code.

```

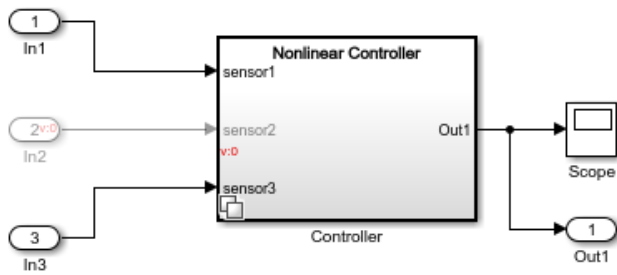

/* External inputs (root inport signals with auto storage) */
typedef struct {
    real_T In1;                /* '<Root>/In1' */
    real_T In3;                /* '<Root>/In3' */
} EXTU_variant_subsvstem_propagate_T;
    
```

Propagate Conditions with Generate Preprocessor Conditionals

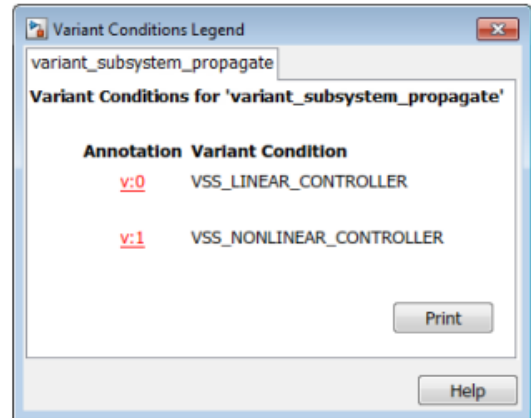

To propagate conditions outside of Variant Subsystem with generate preprocessor conditionals, select the **Propagate conditions outside of variant subsystem** check box and the **Analyze all choice during update diagram and generate preprocessor conditionals** check box in the **Block Parameter** dialog box of the Variant Subsystem.

When you simulate the model with active choice as Nonlinear Controller and **Propagate conditions outside of variant subsystem** check box and the **Analyze all choice during update diagram and generate preprocessor conditionals** check box selected, all the variant choices are analyzed. The **Variant Condition Legend** displays the variant conditions associated with the model.

Components of 'Controller' block

When you generate code for condition propagation with generate preprocessor conditionals, the model is analyzed for all the choices. In this example, the input port In2 is guarded with necessary conditions.

```

/* External inputs (root inport signals with auto storage) */
typedef struct {
    real_T In1;                /* '<Root>/In1' */

#ifdef VSS_LINEAR_CONTROLLER

    real_T In2;                /* '<Root>/In2' */

#define EXTU_VARIANT_SUBSYSTEM_PROPAGATE_T_VARIANT_EXISTS
#endif                        /* VSS_LINEAR_CONTROLLER */

    real_T In3;                /* '<Root>/In3' */
} EXTU_variant_subsystem_propagate_T;

```

Known Limitations

- Variant condition propagation to physical port and Simulink Function inside Stateflow block is not supported.
- Variant condition propagation is not supported for models with callback code that modifies the model during compilation.
- C++ code generation is not supported for models that contain propagated conditions outside of a Variant Subsystem.
- The propagated conditions to a Variant Subsystem choice block must be a subset of the variant condition on the variant subsystem block itself.

Propagate Conditions Programmatically

To propagate conditions outside of Variant Subsystem programmatically, use one of these syntaxes:

- Propagate conditions without generate preprocessor conditionals:

```
set_param(VariantSubsystemName, 'PropagateVariantConditions', 'on')
```

For example,

```
set_param('sldemo_variant_subsystems/Controller', 'PropagateVariantConditions','on')
```

- Propagate conditions with generate preprocessor conditionals:

```
set_param(VariantSubsystemName, 'PropagateVariantConditions','on', 'GeneratePreprocessorConditionals','on')
```

For example,

```
set_param('sldemo_variant_subsystems/Controller', 'PropagateVariantConditions','on',  
'GeneratePreprocessorConditionals','on')
```

- “Variant Condition Propagation with Variant Sources and Sinks” on page 11-57

Use Subsystem Variants To Generate Code That Uses C Preprocessor Conditionals

This example shows how to use Simulink® variant subsystems to generate C preprocessor conditionals that control which child subsystem of the variant subsystem is active in the generated code produced by the Simulink® Coder™.

Overview of Variant Subsystems

A Variant Subsystem block contains two or more child subsystems where one child is active during model execution. The active child subsystem is referred to as the *active variant*. You can programmatically switch the active variant of the Variant Subsystem block by changing values of variables in the base workspace, or by manually overriding variant selection using the Variant Subsystem block dialog. The *active variant* is programmatically wired to the Inport and Outport blocks of the Variant Subsystem by Simulink® during model compilation.

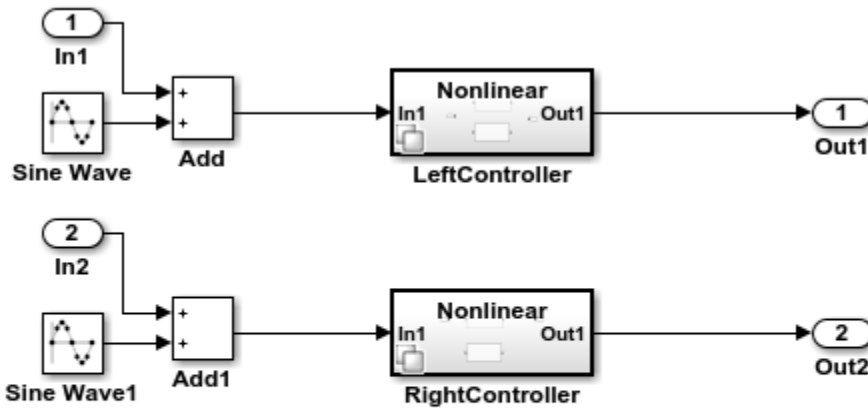

To programmatically control variant selection, a `Simulink.Variant` object is associated with each child subsystem in the Variant Subsystem block dialog. `Simulink.Variant` objects are created in the MATLAB® base workspace. These objects have a property named `Condition`, an expression, which evaluates to a Boolean value and is used to determine the active variant child subsystem.

When you generate code, you can only generate code for the active variant. You can also generate code for all variants of a Variant Subsystem block and defer the choice of active variant until it is time to compile the generated code.

Specifying Variants for a Subsystem Block

Opening the example model `rtwdemo_preprocessor_subsys` will run the `PostLoadFcn` defined in the "File: ModelProperties: Callbacks" dialog. This will populate the base workspace with the variables for the Variant Subsystem blocks.

```
open_system('rtwdemo_preprocessor_subsys')
```

This model shows the generation of preprocessor conditionals for variant subsystems.

Copyright 2009-2014 The MathWorks, Inc.

The LeftController variant subsystem contains two child subsystems: Linear and Nonlinear. The LeftController/Linear child subsystem executes when the Simulink.Variant object LINEAR evaluates to true, and the LeftController/Nonlinear child subsystem executes when the Simulink.Variant object NONLINEAR evaluates to true.

Simulink.Variant objects are specified for the LeftController subsystem by right-clicking the LeftController subsystem and selecting **Subsystem Parameters**, which will open the LeftController subsystem block dialog.

```
open_system('rtwdemo_preprocessor_subsys/LeftController');
```

The LeftController subsystem block dialog creates an association between the Linear and Nonlinear subsystems with the two Simulink.Variant objects, LINEAR and NONLINEAR, that exist in the base workspace. These objects have a property named Condition, an expression, which evaluates to a Boolean value and determines the active variant child subsystem (Linear or Nonlinear). The condition is also shown in the subsystem block dialog. In this example, the conditions of LINEAR and NONLINEAR are 'VSSMODE == 0' and 'VSSMODE == 1', respectively.

In this example, the Simulink.Variant objects are created in the base workspace.

```
LINEAR = Simulink.Variant;
LINEAR.Condition = 'VSSMODE==0';
NONLINEAR = Simulink.Variant;
NONLINEAR.Condition = 'VSSMODE==1';
```

Specifying a Variant Control Variable

Variant objects allow you to reuse arbitrarily complex conditions throughout a model. Multiple Variant Subsystem blocks can use the same Simulink.Variant objects, allowing you to toggle the activation of subsystem variants as a set. You can toggle the set prior to simulation by changing the value of VSSMODE in the MATLAB environment or when compiling the generated code, as explained in the next section. In this example,

LeftController and RightController reference the same variant objects, so that you can toggle them simultaneously.

The nonlinear controller subsystems implement hysteresis, while the linear controller subsystems act as simple low-pass filters. Open the subsystem for the left channel. The subsystems for the right channel are similar.

The generated code accesses the variant control variable `VSSMODE` as a user-defined macro. In this example, `rtwdemo_importedmacros.h` supplies `VSSMODE`. Within the MATLAB environment, you specify `VSSMODE` using a `Simulink.Parameter` object. Its value will be ignored when generating code including preprocessor conditionals. However, the value is used for simulation. The legacy header file specifies the value of the macro to be used when compiling the generated code, which ultimately activates one of the two specified variants in the embedded executable.

Variant control variables can be defined as `Simulink.Parameter` objects with one of these storage classes:

- `Define` or `ImportedDefine` with header file specified
- `CompilerFlag`
- `SystemConstant` (AUTOSAR)
- User-defined custom storage class that defines data as a macro in a specified header file

```
VSSMODE = Simulink.Parameter;  
VSSMODE.Value = 1;  
VSSMODE.DataType = 'int32';  
VSSMODE.CoderInfo.StorageClass = 'Custom';  
VSSMODE.CoderInfo.CustomStorageClass = 'ImportedDefine';  
VSSMODE.CoderInfo.CustomAttributes.HeaderFile = 'rtwdemo_importedmacros.h';
```

Simulating the Model with Different Variants

Because you set the value of `VSSMODE` to 1, the model uses the nonlinear controllers during simulation.

```
sim('rtwdemo_preprocessor_subsys')  
youtnl = yout;
```

If you change the value of `VSSMODE` to 0, the model uses the linear controllers during simulation.

```
VSSMODE.Value = int32(0);  
sim('rtwdemo_preprocessor_subsys')  
yout1 = yout;
```

You can plot and compare the response of the linear and nonlinear controllers:

```
figure('Tag','CloseMe');  
plot(tout, youtnl.signals(1).values, 'r-', tout, youtl.signals(1).values, 'b-')  
title('Response of Left Channel Linear and Nonlinear Controllers');  
ylabel('Response');  
xlabel('Time (seconds)');  
legend('nonlinear','linear')  
axis([0 100 -0.8 0.8]);
```

Using C Preprocessor Conditionals

This example model has been configured to generate C preprocessor conditionals. You can generate code for the model by selecting Code > C/C++ Code > Build Model.

To activate code generation of preprocessor conditionals, check whether the following conditions are true:

- Select an Embedded Coder® target in **Code Generation > System target file** in the Configuration Parameters dialog box
- In the Variant Subsystem block parameter dialog box, clear the option to **Override variant conditions and use following variant**
- In the Variant Subsystem block parameter dialog box, Select the option to **Analyze all choices during update diagram and generate preprocessor conditionals**.

The Simulink® Coder™ code generation report contains sections in the Code Variants report dedicated to the subsystems that have variants controlled by preprocessor conditionals.

In this example, the generated code includes references to the Simulink.Variant objects `LINEAR` and `NONLINEAR`, as well as the definitions of macros corresponding to those variants. Those definitions depend on the value of `VSSMODE`, which is supplied in an external header file `rtwdemo_importedmacros.h`. The active variant is determined by using preprocessor conditionals (`#if`) on the macros (`#define`) `LINEAR` and `NONLINEAR`.

The macros `LINEAR` and `NONLINEAR` are defined in the generated `rtwdemo_preprocessor_subsys_types.h`, header file:

```
#ifndef LINEAR
#define LINEAR      (VSSMODE == 0)
#endif

#ifndef NONLINEAR
#define NONLINEAR   (VSSMODE == 1)
#endif
```

In the generated code, the code related to the variants is guarded by C preprocessor conditionals. For example, in `rtwdemo_preprocessor_subsys.c`, the calls to the step and initialization functions of each variant are conditionally compiled:

```
/* Outputs for atomic SubSystem: '<Root>/LeftController' */
#if LINEAR
```

```
        /* Output and update for atomic system: '<S1>/Linear' */  
#elif NONLINEAR  
        /* Output and update for atomic system: '<S1>/Nonlinear' */  
#endif
```

Close the model, figure, and workspace variables from the example.

```
bdclose('rtwdemo_preprocessor_subsys')  
close(findobj(0,'Tag','CloseMe'));  
clear LINEAR NONLINEAR VSSMODE  
clear tout yout youl1 youn1
```

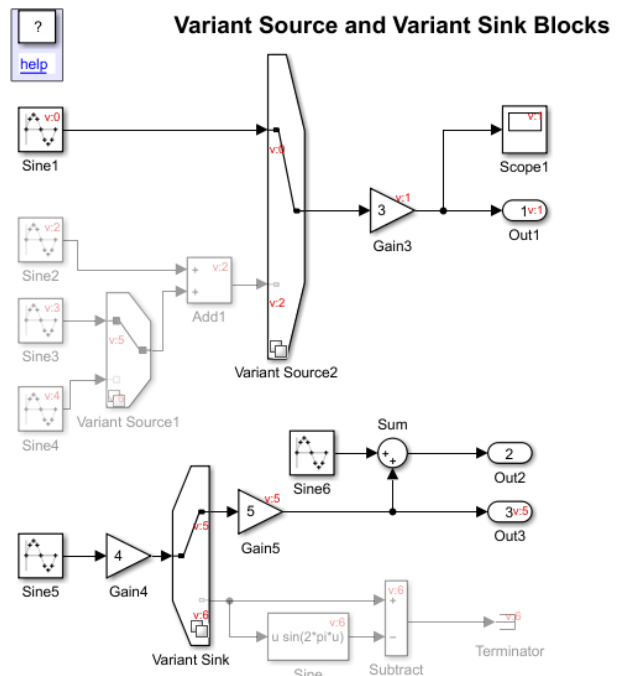

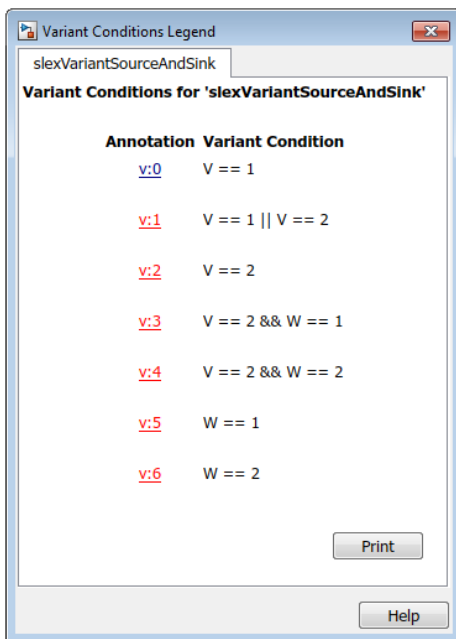

Variant Source and Variant Sink Blocks

Define variant choice regions in the Variant Source and Sink blocks based on the block connectivity. The variant choice regions are computed by Simulink when you update diagram (**Simulation > Update Diagram**).

The process of computing the variant choice regions is called **variant condition propagation**. The Variant Source block provides variation on the source of a signal, and the Variant Sink blocks provides variation on the destination (sink) of a signal.

Consider a model containing two Variant Source blocks (Variant Source1, Variant Source2) and a Sink block (Variant Sink).

The variant conditions at the inports and outports of Variant Source and Sink blocks, respectively, determine the activation and deactivation of the blocks connected to them. To view the annotations and the variant conditions, click **Display > Blocks > Variant Conditions**.

Let's analyze the variant conditions and the block activation state.

- In **Variant Source1**, when $W==1$, the **Sine3** block is active, and when $W==2$, the **Sine4** block is active.
- In **Variant Source2**, when $V==1$, the **Sine1** block is active, and when $V==2$, the **Add1** block is active.
- At **Add1** block the condition propagation continues making **Variant Source1** block to be active only when the $V==2$. This further propagates to **Sine3** block and **Sine4** block, making the **Sine3** block active at $V==2 \ \&\& \ W==1$ the **Sine3** block active at $V==2 \ \&\& \ W==2$, respectively.
- The **Gain3** block is active when either $V==1$ or $V==2$, and hence the condition $V==2 \ | \ W==1 \ |$. The variant condition is further propagated to **Scope1** and **Out1**.
- The blocks connected to the output of **Variant Sink** are active when $W==1$ (**Gain5**), or $W==2$ (**Sine**, **Subtract**, **Terminator**).
- The **Sum** block illustrates two key concepts in variant condition propagation: Signals are only variant if explicitly marked or when all paths can be proven to be variant. To make the **Sine Wave**, **Sum**, **Out2** variant, place a Single-Input Single-Output Variant Source before **Out2** (or after the **Sine Wave**). Reading an inactive signal is equivalent to reading ground. When $W \neq 1$, then the bottom input to the **Sum** block is inactive and $Out2 = Sine6 + ground$.

If you select the **Analyze all choices during update diagram and generate preprocessor conditionals** parameter for the **Variant Source** and **Variant Sink** block, the generated code contains the code for the active and the inactive (`#if COND`). If this parameter is not selected, then code is generated only for the active choices.

“Focusing on Specific Elements of a Model or Chart” on page 12-9

What You Can Do Using the Model Explorer

Use the Model Explorer to view, modify, and add elements of Simulink models, Stateflow charts, and workspace variables. The Model Explorer lets you focus on specific elements (for example, blocks, signals, and properties) without navigating through the model or chart.

Opening the Model Explorer

To open the Model Explorer, use one of these approaches:

- From the Simulink Editor **View** menu, select **Model Explorer** or select the Model Explorer icon  from the toolbar.
- In an open model in the Simulink Editor, right-click a block and from the context menu, select **Explore**.
- In an open Stateflow chart, right-click in the drawing area and from the context menu, select **Explore**.
- At the MATLAB command line, enter `daexplr`.

Basic Steps for Using the Model Explorer

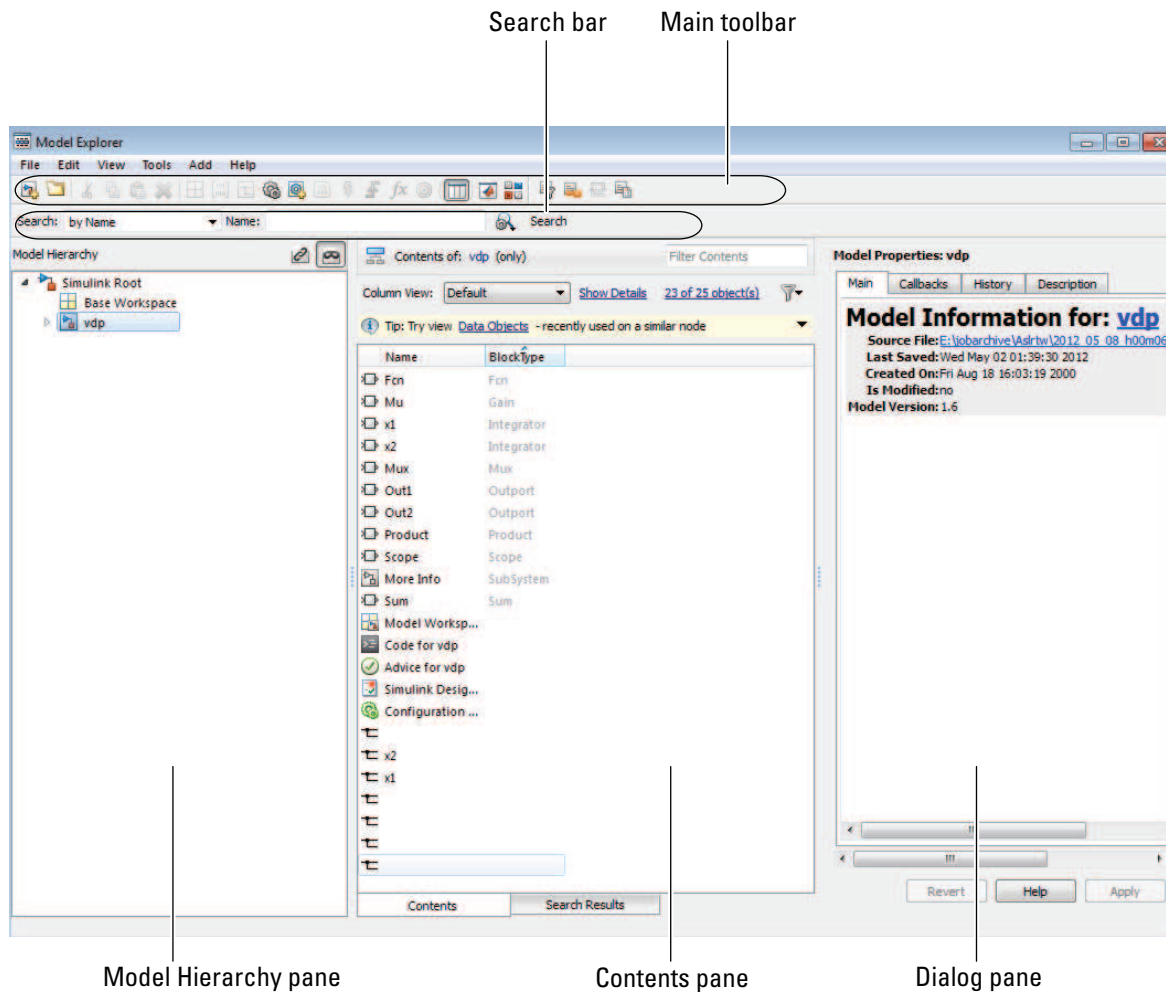

Use the Model Explorer to perform a wide range of activities relating to viewing and changing model and chart elements. You can perform activities in any order, using panes in the order you choose. Your actions in one pane often affect other panes.

For example, if you want to edit properties of objects in a model, you might use a general workflow such as:

- 1 Open a model.
- 2 Open the Model Explorer.
- 3 Select the model in the **Model Hierarchy** pane, specifying whether the Model Explorer displays only the current system or the whole system hierarchy of the current system
- 4 Control the model information the **Contents** pane displays, and how it displays that information, by using a combination of:
 - The **View > Column View** option to control which property columns to display
 - The **View > Row Filter** option to control which types of objects to display
 - Techniques to directly manipulate column headings
- 5 Identify model elements with specific values, using the search bar.
- 6 Edit the values for model elements, in either the **Contents** pane or the **Dialog** pane. To edit workspace variables, you can use the Variable Editor.

Model Explorer Components

By default, the Model Explorer opens with three panes (**Model Hierarchy**, **Contents**, and **Dialog**), a main toolbar, and a search bar.

Component	Purpose	Documentation
Main toolbar	Execute Model Explorer commands	“The Main Toolbar” on page 12-5
Search bar	Perform a search within the context of the selected node in Model Hierarchy pane.	“Search Bar Controls” on page 12-7

Component	Purpose	Documentation
Model Hierarchy pane	Navigate and explore model, chart, and workspace nodes	“Model Explorer: Model Hierarchy Pane” on page 12-12
Contents pane	Display and modify model or chart objects	“Model Explorer: Contents Pane” on page 12-22
Dialog pane	View and change the details of object properties	“Model Explorer: Property Dialog Pane” on page 12-54

The Main Toolbar

The main toolbar at the top of the Model Explorer provides buttons you click to perform Model Explorer operations. Most of the toolbar buttons perform actions that you can also perform using Model Explorer menu items.

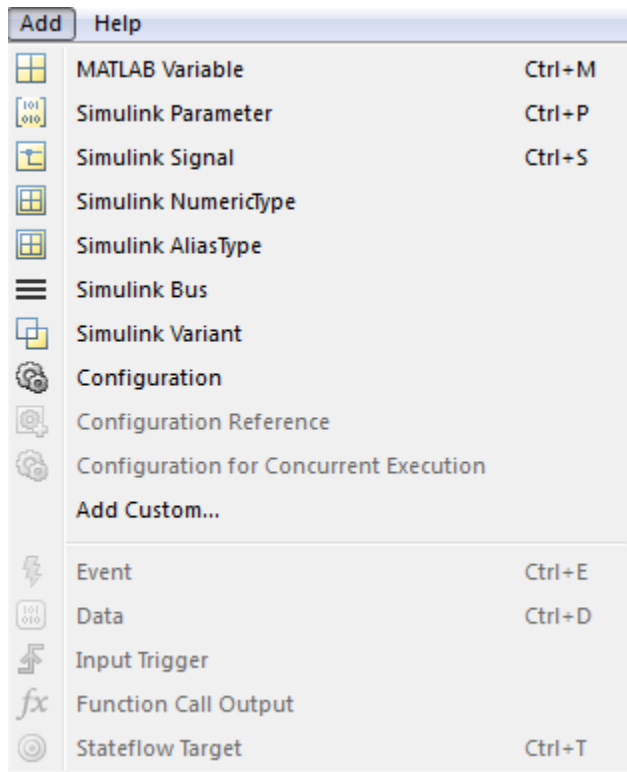

The toolbar buttons in the following table perform actions that you cannot perform using Model Explorer menus:

Button	Usage
	Bring the MATLAB window to the front.
	Display the Simulink Library Browser.

If you have Simulink Verification and Validation installed, you can use additional toolbar buttons relating to requirements links.

Adding Objects

You can use the Model Explorer to add many kinds of objects to a model, chart, or workspace. The types of objects that you can add depend on the node you select in the **Model Hierarchy** pane. Use toolbar buttons or the **Add** menu to add objects. The **Add** menu lists the types of objects you can add.

Customizing the Model Explorer Interface

You can customize the Model Explorer interface in several ways. This section describes how to show or hide the toolbars and how to control the font size.

Other ways you can customize the Model Explorer interface include:

- “Marking Nonexistent Properties” on page 12-46
- “Showing and Hiding the Dialog Pane” on page 12-54

Showing and Hiding Toolbars

To show or hide toolbars, in the Model Explorer select **View > Toolbars**, and then select the toolbar you want to hide from the menu.

Controlling the Font Size

You can change the font size in the Model Explorer panes:

- To increase the font size, press the **Ctrl + Plus Sign (+)**.

Alternatively, from the Model Explorer **View** menu, select **Increase Font Size**.

- To decrease the font size, press the **Ctrl + Minus Sign (-)**.

Alternatively, from the Model Explorer **View** menu, select **Decrease Font Size**.

Note The changes remain in effect for the Model Explorer and in the Simulink dialog boxes across Simulink sessions.

Search Bar Controls

The search bar includes these controls:

Search Type

Use the **Search Type** control to specify the type of objects or properties to include in the search.

Search Type Option	Description
by Name	Searches a model or chart for all objects that have the specified string in the name of the object. See “Search Strings” on page 12-9.
by Property Name	Searches for objects that have a specified property. Specify the target property name from a list of properties that objects in the search domain can have.
by Property Value	Searches for objects with a property value that matches the value you specify. Specify the name of

Search Type Option	Description
	the property, the value to be matched, and the type of match (for example, equals, less than, or greater than). See “Search Strings” on page 12-9.
by Block Type	Searches for blocks of a specified block type. Select the target block type from the list of types contained in the currently selected model.
by Stateflow Type	Searches for Stateflow objects of a specified type.
for Variable Usage	Searches for blocks that use variables defined in a workspace. Select the base workspace or a model workspace (model name) and, optionally, the name of a variable. See “Search Strings” on page 12-9.
for Referenced Variables	Searches for variables that a model or block uses. Specify the name of the model or block in the by System field. The model or block must be in the Model Hierarchy pane.
for Unused Variables	Searches for variables that are defined in a workspace but not used by any model or block. Select the name of the workspace from the drop-down list for the in Workspace field.
for Library Links	Searches for library links in the current model.
by Class	Searches for Simulink objects of a specified class.
for Fixed Point Capable	Searches a model for all blocks that support fixed-point computations.
for Model References	Searches a model for references to other models.
by Dialog Prompt	Searches a model for all objects whose dialogs contain the prompt you specify. See “Search Strings” on page 12-9.
by String	Searches a model for all objects in which the string you specify occurs. See “Search Strings” on page 12-9.

Search Options

Use the **Search Options** control to specify the scope and how to apply search strings.

Search Option	Description
Match Whole String	Do not allow partial string matches (for example, do not allow <code>sub</code> to match <code>substring</code>).
Match Case	Considers case when matching strings (for example, <code>Gain</code> does not match <code>gain</code>).
Regular Expression	Considers a string to be matched as a regular expression.
Evaluate Property Values During Search	Applies only for searches by property value. If enabled, Model Explorer evaluates the value of each property as a MATLAB expression and compares the result to the search value. If this option is disabled (the default), the Model Explorer compares the unevaluated property value to the search value.
Refine Search	Initiates a secondary search that provides additional search criteria to refine the initial search results. The second search operation searches for objects that meet both the original and the new search criteria.

Search Strings

By default, search strings are case-insensitive and are treated as regular expressions.

By default, the search allows partial string matches. You cannot use wildcard characters in search strings. For example, if you enter `*1` as a name search string, you get no search results unless there is an item whose name starts with the two characters `*1`. If there is an `out1` item, the search results do not include that item.

Focusing on Specific Elements of a Model or Chart

As you explore a model or chart, you might want to narrow the contents that you see in the Model Explorer to particular elements of a model or chart. You can use several different techniques. The table summarizes techniques for controlling the content the Model Explorer displays and how the contents appear.

Technique	When to Use	Documentation
Show partial or whole model hierarchy contents	To control how much of a hierarchical model to display	“Displaying Partial or Whole Model Hierarchy Contents” on page 12-14
Use the Row Filter option	To focus on, or hide, a specific kind of a model object, such as signals	“Using the Row Filter Option” on page 12-48
Search	To find objects that might not be currently displayed	“Search Using Model Explorer” on page 12-60
Filter contents	To focus on specific objects in the Contents pane, based on a search string	“Filtering Contents” on page 12-50

Once you have the general set of data that you are interested in, you can use the following techniques to organize the display of contents.

Technique	When to Use	Documentation
Sort	To quickly organize data for a property in ascending or descending order	“Sorting Column Contents” on page 12-38
Group by property column	To logically group data based on values for a property	“How to Group by a Property Column” on page 12-40
Use column views	To display a named subset of property columns to apply to different kinds of nodes in the Model Hierarchy pane	“Control Model Explorer Contents Using Views” on page 12-29
Add, delete, or rearrange property table columns	To customize property columns	“Organize Data Display in Model Explorer” on page 12-38

What You Can Do with the Model Hierarchy Pane

The **Model Hierarchy** pane displays a tree-structured view of the Simulink model and Stateflow chart hierarchy. Use the **Model Hierarchy** pane to navigate to the part of the model and chart hierarchy that you want to explore.

Simulink Root

The first node in the hierarchy represents the Simulink root. Expand the root node to display nodes representing the MATLAB workspace, Simulink models, and Stateflow charts that are in the current session.

Base Workspace

This node represents the MATLAB workspace. The MATLAB workspace is the base workspace for Simulink models and Stateflow charts. Variables defined in this workspace are visible to all open models and charts.

For information about exporting and importing workspace variables, see “Export Workspace Variables” on page 57-99 and “Importing Workspace Variables” on page 57-101.

Model Nodes

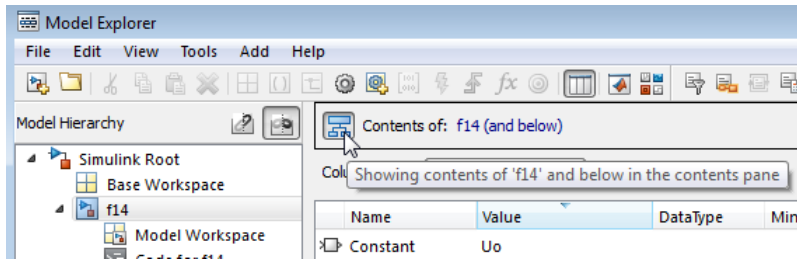

Expanding a model or chart node in the **Model Hierarchy** pane displays nodes representing the following elements, as applicable for the models and charts you have open.

Node	Description
Model workspace	For information about how to use the Model Explorer to work with model workspace variables, see the following sections: <ul style="list-style-type: none"> • “Finding Variables That Are Used by a Model or Block” on page 57-88 • “Finding Blocks That Use a Specific Variable” on page 57-91 • “Editing Workspace Variables” on page 57-94 • “Export Workspace Variables” on page 57-99 • “Importing Workspace Variables” on page 57-101 • “Model Workspaces” on page 4-71
Configuration sets	For information about adding, deleting, saving, and moving configuration sets, see “Manage a Configuration Set” on page 13-11.
Top-level subsystems	Expand a node representing a subsystem to display underlying subsystems, if any.
Model blocks	Expand model blocks to show contents of referenced models (see “Expanding Model References” on page 12-17).
Stateflow charts	<ul style="list-style-type: none"> • Expand a node representing a Stateflow chart to display the top-level states of the chart. • Expand a node representing a state to display its substates.

Displaying Partial or Whole Model Hierarchy Contents

By default, the Model Explorer displays objects for the system that you select in the **Model Hierarchy** pane. It does not display data for child systems. You can override that default, so that the Model Explorer displays objects for the whole hierarchy of the currently selected system. To toggle between displaying only the current system and displaying the whole system hierarchy of the current system, use one of these techniques:

- Select **View > Show Current System and Below**.
- Click the **Show Current System and Below** button () at the top of the **Contents** pane.

When you select the **Show Current System and Below** option:

- The **Model Hierarchy** pane highlights in pale blue the current system and its child systems.
- After the path in the **Contents of** field, the text (and below) appears.
- The appearance of the **Show Current System and Below** button at the top of the **Contents** pane and in the **View** menu changes.
- The status bar indicates the scope of the displayed objects when you hover over the **Show Current System and Below** button.

Loading very large models for the current system and below can be slow. To stop the loading process at any time, either click the **Show Current System and Below** button or click another node in the tree hierarchy.

If you show the current system and below, you might want to change the view to better reflect the displayed system contents. For details about views, see “Control Model Explorer Contents Using Views” on page 12-29.

The setting for the **Show Current System and Below** option is persistent across Simulink sessions.

Displaying Linked Library Subsystems

By default, the Model Explorer does not display the contents of linked library subsystems in the **Model Hierarchy** pane. To display the contents of linked library subsystems, use one of these approaches:

- At the top of the **Model Hierarchy** pane, click the **Show/Hide Library Links** button () .
- From the **View** menu, select **Show Library Links**.

Library-linked subsystems are visible in the **Contents** pane, regardless of how you configure the **Model Hierarchy** pane.

Note: Search does not find elements in linked library or masked subsystems that are not displayed in the **Model Hierarchy** pane.

Displaying Masked Subsystems

By default, the Model Explorer does not display the contents of masked subsystems in the **Model Hierarchy** pane. To display the contents of masked subsystems, use one of these approaches:

- At the top of the **Model Hierarchy** pane, click the **Show/Hide Masked Subsystems** button () .
- From the **View** menu, select **Show Masked Subsystems**.

Masked subsystems are visible in the **Contents** pane, regardless of how you configure the **Model Hierarchy** pane.

Linked Library and Masked Subsystems

For subsystems that are both library-linked and masked, how you set the linked library subsystems and masked subsystems options affects which subsystems appear in the **Model Hierarchy** pane, as described in the following table.

Settings	Subsystems Displayed in the Model Hierarchy Pane
Show Library Links	Only library-linked, unmasked subsystems
Hide Masked Subsystems	
Hide Library Links	Only masked subsystems that are not library-linked subsystems

Settings	Subsystems Displayed in the Model Hierarchy Pane
Show Masked Subsystems	
Show Library Links	All library-linked or masked subsystems
Show Masked Subsystems	

Displaying Node Contents

Select the object in the **Model Hierarchy** pane whose contents you want to display in the **Contents** pane.

Navigating to the Block Diagram

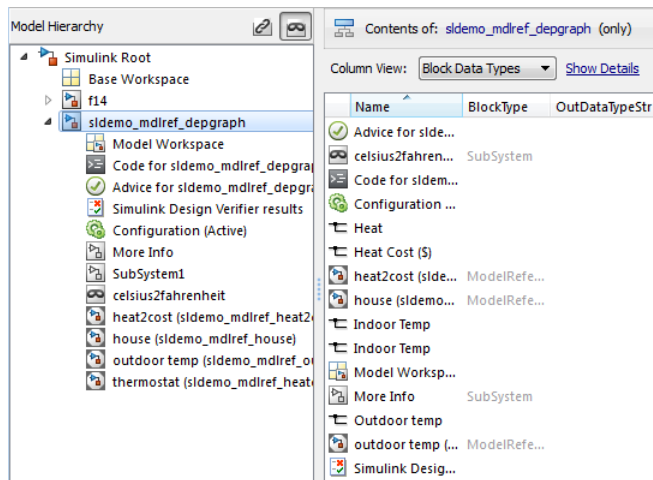

To open a graphical object (for example, a model, subsystem, or chart) in an editor window, right-click the object in the **Model Hierarchy** pane. From the context menu, select **Open**.

Working with Configuration Sets

See “Manage a Configuration Set” on page 13-11 for information about using the **Model Hierarchy** pane to perform tasks such as adding, deleting, saving, and moving configuration sets.

Expanding Model References

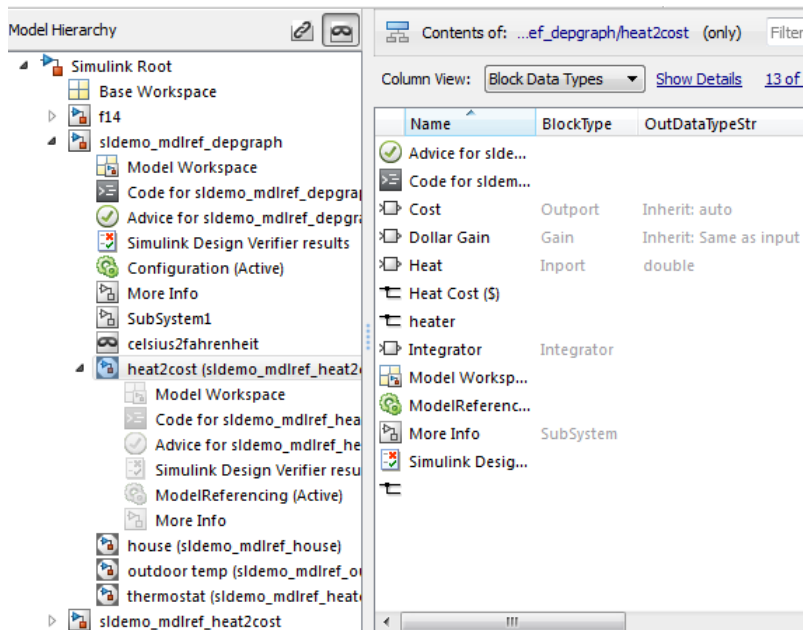

To browse a model that includes Model blocks, you can expand the **Model Hierarchy** pane nodes of the Model blocks. For example, the `sldemo_md1ref_depgraph` model includes Model blocks that reference other models. If you open the `sldemo_md1ref_depgraph` model and expand that model node in the **Model Hierarchy** pane, you see that the model contains several Model blocks, including `heat2cost`.

To browse a model referenced by a Model block:

- 1 Right-click the referenced model node in the **Model Hierarchy** pane.
- 2 From the context menu, choose **Open Model**.
 - The referenced model opens.
 - The **Model Hierarchy** pane indicates that you can expand the Model block node.
 - The **Model Hierarchy** pane displays a separate expandable node for the referenced model (read-only).
 - The **Contents** pane displays objects corresponding to the Model block node (read-only).

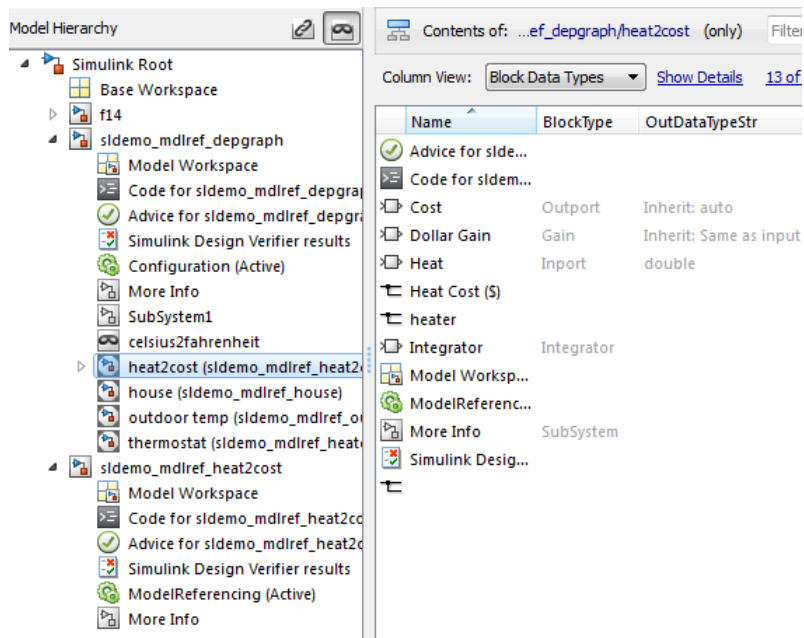

For example, if you right-click the `heat2cost` Model block node and select the **Open Model** option, the **Contents** pane displays the objects corresponding to the `heat2cost` Model block. You can expand the `heat2cost` node.

You can browse the contents of the referenced model, but you cannot edit the model objects that are underneath the Model block.

Editing the Referenced Model

To edit the referenced model, expand the referenced model node in the **Model Hierarchy** pane. For example, expand the `sldemo_md1ref_heat2cost` node:

You can now edit the properties of object in the referenced model.

For information about referenced models, see “Model Referencing”.

Cutting, Copying, and Pasting Objects

To cut, copy, and paste workspace objects from one workspace into another workspace:

- 1 In the **Contents** pane, right-click on the workspace object you want to cut or copy.
- 2 From the context menu, select **Cut** or **Copy**.
 - You can also cut a workspace object by selecting in the **Contents** pane **Edit** > **Cut** or by clicking the **Cut** button (.
 - You can also copy a workspace object by selecting **Edit** > **Copy** or by clicking the **Copy** button (.
- 3 If you want to paste the workspace object that you cut or copied, in the **Model Hierarchy** pane, right-click the workspace into which you want to paste the object, and select **Paste**.

- You can also paste the object by selecting **Edit > Paste** or by clicking the **Paste** button ()

You can also perform cut, copy, and paste operations by selecting an object and performing drag and drop operations.

Model Explorer: Contents Pane

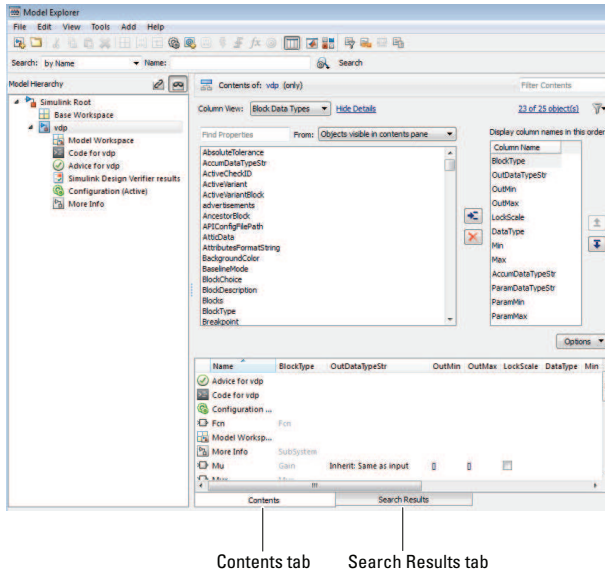

In this section...
“Contents Pane Tabs” on page 12-22
“Data Displayed in the Contents Pane” on page 12-24
“Link to the Currently Selected Node” on page 12-25
“Horizontal Scrolling in the Object Property Table” on page 12-25
“Working with the Contents Pane” on page 12-26
“Editing Object Properties” on page 12-27

Contents Pane Tabs

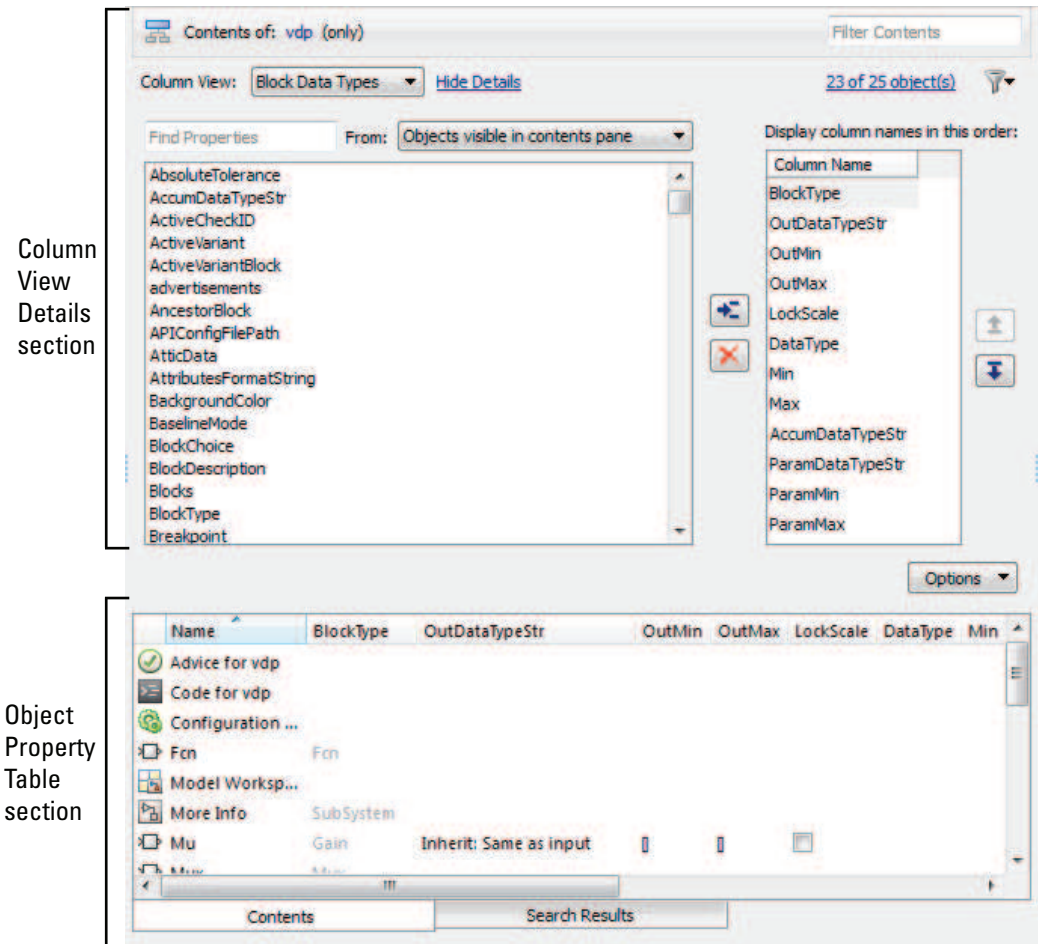

The **Contents** pane displays one of two tables containing information about models and charts, depending on the tab that you select:

- The **Contents** tab displays an object property table for the node that you select in the **Model Hierarchy** pane.
- The **Search Results** tab displays the search results table (see “Search Using Model Explorer” on page 12-60).

Optionally, you can also open a column view details section in the **Contents** pane. The following graphic shows the **Contents** pane with the column view details section opened.

To open the column view details section, click **Show Details**, at the top of the **Contents** pane.

The **Column view details** section provides an interface for customizing the column view (hidden by default).

The **Object property table** section displays a table of model and chart object data (open by default).

Data Displayed in the Contents Pane

In the object property table section of the **Contents** tab and in the **Search Results** tab:

- Table columns correspond to object properties (for example, Name and BlockType).
- Table rows correspond to objects (for example, blocks, and states).

The objects and properties displayed in the **Contents** pane depend on:

- The column view that you select in the **Contents** pane
- The node that you select in the **Model Hierarchy** pane
- The kind of object (for example, subsystem, chart, or configuration set) that you select in the **Model Hierarchy** pane
- The **View > Row Filter** options that you select

For more information about controlling which objects and properties to display in the **Contents** pane, see:

- “Control Model Explorer Contents Using Views” on page 12-29
- “Organize Data Display in Model Explorer” on page 12-38
- “Filter Objects in the Model Explorer” on page 12-48

Link to the Currently Selected Node

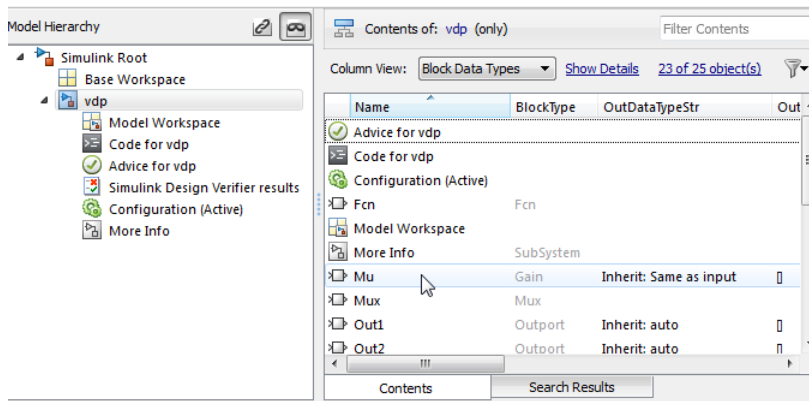

The **Contents of** link at the top left side of the **Contents** pane links to the currently selected node in the **Model Hierarchy** pane. The model data displayed in the Contents pane reflects the setting of the **Current System and Below** option. In the following example, **Contents of** links to the vdp model, which is the currently selected node.

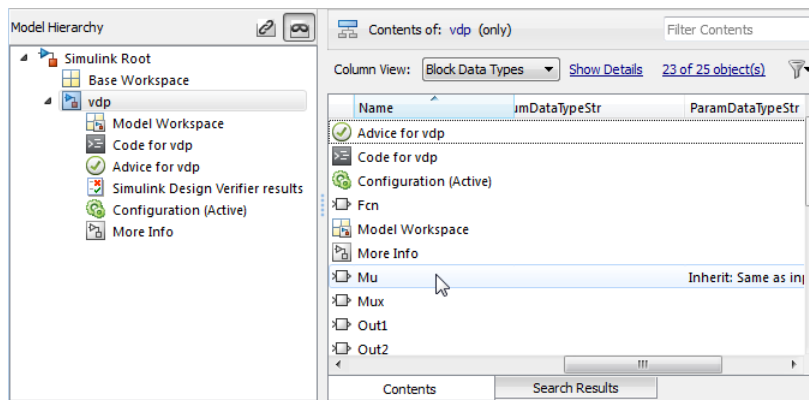

Horizontal Scrolling in the Object Property Table

The object property table displays the first two columns (the object icon and the Name property) persistently. These columns remain visible, regardless of how far you scroll to the right.

For example, the following image shows the initial display of the object property table for the vdp model. The ParamDataTypeStr column is too far to the right to be displayed.

The next image shows the results of scrolling to the right. The icon and Name columns remain visible, but now you can see the ParamDataTypeStr column.

Working with the Contents Pane

The following table summarizes the key tasks to control what is displayed in the Contents.

Task	Documentation
Control which kinds of objects to display.	“Using the Row Filter Option” on page 12-48

Task	Documentation
Search within the selected set of objects.	“Search Using Model Explorer” on page 12-60
Specify a set of properties to display based on the kind of node.	“Control Model Explorer Contents Using Views” on page 12-29
Group data based on unique values in a property column.	“Grouping by a Property” on page 12-39
Manage views (for example, save and export a view).	“Managing Views” on page 12-33
Add, remove, or rearrange columns.	“Organize Data Display in Model Explorer” on page 12-38
Edit object property values.	“Editing Object Properties” on page 12-27

Editing Object Properties

To open a properties dialog box for an object in the **Model Hierarchy** pane, right-click the object, and from the context menu, select **Properties**. Alternatively, click an object and from the **Edit** menu, select **Properties**.

You can change modifiable properties in the **Contents** pane (for example, a block name) by editing the displayed value. To edit a value, first select the row that contains the value, and then click the value. An edit control replaces the value (for example, an edit field for text values or a list for a range of values). For workspace variables that are arrays or structures, you can use the Variable Editor. Use the edit control to change the value of the selected property.

To assign the same property value to multiple objects in the **Contents** pane, select the objects and then change one of the selected objects to have the new property value. An edit control replaces the value with `<edit>`, indicating that you are doing batch editing. The Model Explorer assigns the new property value to the other selected objects, as well.

You can also change property values using the **Dialog** pane. See “Model Explorer: Property Dialog Pane” on page 12-54.

Control Model Explorer Contents Using Views

In this section...

“Using Views” on page 12-29

“Customizing Views” on page 12-32

“Managing Views” on page 12-33

Using Views

What Is a Column View?

A view in the Model Explorer is a named set of properties.

The Model Explorer uses views to specify sets of property columns to display in the **Contents** pane.

For each kind of node in the **Model Hierarchy** pane, certain properties are most relevant for the objects displayed in the **Contents** pane. For example, for a Simulink model node, such as a model or subsystem, some properties that are useful to display include:

- **BlockType** (block type)
- **OutDataTypeStr** (output data type)
- **OutMin** (minimum value for the block output)

Generally, a column view does not contain the total set of properties for all the objects in a node. Specifying a subset of properties to display can streamline the task of exploring and editing model and chart object properties and increase the density of the data displayed in the **Contents** pane.

What You Can Capture in a View

You can use a view to capture the following characteristics of the model information to show in the Model Explorer:

- Properties that you want to display in the **Contents** pane (see “Customizing Views” on page 12-32)
- Layout of the **Contents** pane (for example, grouping by property, the order of property columns, and sorting), as described in “Organize Data Display in Model Explorer” on page 12-38.

Use Standard Views or Customized Views

You can use views in the following ways:

- Use the standard views shipped with the Model Explorer
- Customize the standard views
- Create your own views

Automatically Applied Views

The first time you open the Model Explorer, the software automatically applies one of the standard views to the node you select in the **Model Hierarchy** pane. The Model Explorer applies a view based on the kind of node you select.

The Model Explorer assigns one of four categories of nodes in the **Model Hierarchy** pane. The Model Explorer initially associates a default view with each node category. The four node categories are:

Node Category	Kinds of Hierarchy Nodes Included	Initial Associated View
Simulink	Models, subsystems, and root level models	Block Data Types
Workspace	Base and model workspace objects	Data Objects
Stateflow	Stateflow charts and states	Stateflow
Other	Objects that do not fit into one of the first three categories; for example, configuration sets	Default

The **Column View** field at the top of the **Contents** pane displays the view that the Model Explorer is currently using.

If you select a view

In the **Contents** pane, from the **Column View** list, you can select a different view. If you select a different view, then the Model Explorer associates that view with the category of the current node. For example, suppose the selected node in the **Model Hierarchy** pane is a Simulink model, and the current view is **Data Objects**. If you change the view to **Signals**, then when you select another Simulink model node, the

Model Explorer uses the **Signals** view. See “Selecting a View Manually” on page 12-31.

Selecting a View Manually

By default, the Model Explorer automatically applies a view, based on the category of node that you select and the last view used for that node. You can manually select a view from the **Column View** list that better meets your current task.

You can shift from the default mode of having the Model Explorer automatically apply views to a mode in which you must manually select a view to change views.

To enable the manual view selection mode:

- 1 Select **View > Column View > Manage Views**.

The View Manager dialog box opens.

- 2 In the View Manager dialog box, click the **Options** button and clear **Change View Automatically**.

In the manual view selection mode, if you switch to a different kind of node in the **Model Hierarchy** pane that has a different view associated with it, the **Contents** pane displays a yellow informational bar suggesting a view to use.

Tip interface

The tip interface appears immediately above the object property table.

The tip does not appear if you use automatic view selection.

To hide the currently displayed tip, from the menu button on the right-hand side of the tip bar, select **Hide This Tip**.

The tip interface displays a link for changing the current view to a suggested view. To choose the suggested view displayed in the tip bar, click the link.

Initially, the suggested view is the default view associated with a node. If you associate a different view with a node category, then the tip suggests the most recently selected view when you select similar nodes.

To change from manual specification of views to automatic specification, from the tip interface, select the down arrow and then the **Change View Automatically** menu item.

Customizing Views

If a standard view does not meet your needs, you can either modify the view or create a new view.

You can customize the object property table represented by the current view in several ways, as described in these sections:

- “Adding Property Columns” on page 12-43
- “Hiding or Removing Property Columns” on page 12-44
- “Changing the Order of Property Columns” on page 12-42

How the Model Explorer Saves Your Customizations

As you modify the object property table, you change the current view definition.

The Model Explorer saves the following changes to the object property table as part of the column view definition:

- Grouping by property
- Sorting in a column
- Changing the order of property columns
- Adding a property column
- Hiding and removing property columns

When you change from one view to another view, the Model Explorer saves any customizations that you have made to the previous view.

For example, suppose you use the **Block Data Types** view and you remove the **LockScale** property column. If you then switch to use the **Data Objects** view, and later use the **Block Data Types** view again, the **Block Data Types** view no longer includes the **LockScale** column that you deleted.

At the end of a Simulink session, the Model Explorer saves the view customizations that you made during that session. When you reopen the Model Explorer, Simulink uses the customized view, reflecting any changes that you made to the view in the previous session.

Managing Views

If a standard view does not meet your needs, you can either modify the view or create a new view. See “Customizing Views” on page 12-32.

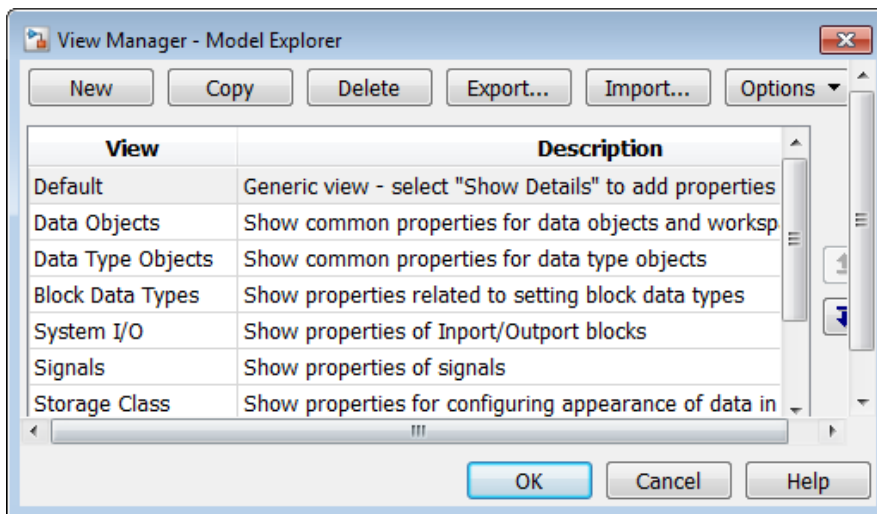

You can manage views (for example, create a new view or export a view) using the View Manager dialog box.

Opening the View Manager Dialog Box

To open the View Manager dialog box, select the **Manage Views** option from either:

- The **View > Column View** menu
- The options listed when you click the **Options** button in the column view details section

The View Manager dialog box displays a list of defined views and provides tools for you to manage views.

You can manage views in several ways, including:

- “Creating a New View” on page 12-34
- “Deleting Views” on page 12-35
- “Reordering Views” on page 12-35
- “Exporting Views” on page 12-35
- “Importing Views” on page 12-36
- “Resetting Views to Factory Settings” on page 12-36

Creating a New View

To create a new view that has a new name, you can use one of these approaches:

- Copy an existing view, rename it, and customize the view.
- Create a completely new view.

After you create a new view, you can customize the view as described in “Customizing Views” on page 12-32.

Copying and renaming an existing view

You can build a new view by copying an existing view, renaming it, and optionally customizing the renamed view. In the View Manager dialog box:

- 1 Select the view that you want to use as the starting point for your new view.
- 2 Click the **Copy** button.

A new row appears at the bottom of the View Manager table of views. The new row contains the name of the view you copied, followed by a number in parentheses.

For example, if you copy the **Stateflow** view, the initial name of the copied view is **Stateflow (1)**.

Creating a completely new view

To create a completely view, in the View Manager dialog box, click the **New** button. A new view row appears at the bottom of the View Manager dialog box list of views.

Naming and describing a new view

Once you create a view, you can name the view and provide a description of the view:

- 1 Double-click **New View** in the left column of the table of views and replace the text with a name for the view.
- 2 Double-click **Description** in the table and replace the text with a description of the view.
- 3 Click **OK**.

Deleting Views

To delete a view from the **Column View** list of views:

- 1 In the View Manager dialog box, select one or more views that you want to remove from the list.
- 2 Click the **Delete** button or the **Delete** key.
- 3 Click **OK**.

Deleting a view using the View Manager dialog box permanently deletes that view from the Model Explorer interface.

If you think you or someone else might want to use a view again, consider exporting the view before you delete it (see “Exporting Views” on page 12-35).

Reordering Views

To change the position of a view in the **Column View** list, in the View Manager dialog box:

- 1 Select one or more views that you wish to move up or down one row in the table of views.
- 2 Click the up or down arrow buttons to the right of the table of views. Repeat this step until the view appears where you want it to be in the table.
- 3 Click **OK**.

Exporting Views

To export views that you or others can then import, in the View Manager dialog box:

- 1 In the View Manager dialog box, select one or more views that you want to export.
- 2 Click the **Export** button.

An Export Views dialog box opens, with check marks next to the views that you selected.

- 3 Click **OK**.

An Export to File Name dialog box opens.

- 4 Navigate to the folder to which you want to export the view.

By default, the Model Explorer exports views to the MATLAB current folder.

- 5 Specify the file name for the exported view.

The file format is `.mat`.

- 6 Click **OK**.

Importing Views

To import view files from another location for use by the Model Explorer:

- 1 In the View Manager dialog box, click the **Import** button.

The Select `.mat` File to Import dialog box opens.

- 2 Navigate to the folder from which you want to import the view.

- 3 Select the MAT-file containing the view that you want to import and then click **Open**.

A confirmation dialog box opens. Click **OK** to import the view.

The imported view appears at the bottom of the **Column View** list of views.

The Model Explorer automatically renames the view if a name conflict occurs.

Resetting Views to Factory Settings

You can reset (restore) the original definition of a specific standard view (that is, a view shipped with the Model Explorer) if that view is the current view. To do so, click the **Options** button in the column view details section and select **Reset This View to Factory Settings**.

To reset the factory settings for *all* standard views in one step, in the View Manager dialog box, click the **Options** button and select **Reset All Views to Factory Settings**.

Note: When you reset all views, the Model Explorer removes all the custom views you have created. Before you reset views to factory settings, export any views that you will want to use in the future.

“Sorting Column Contents” on page 12-38

“Grouping by a Property” on page 12-39

“Changing the Order of Property Columns” on page 12-42

“Adding Property Columns” on page 12-43

“Hiding or Removing Property Columns” on page 12-44

“Marking Nonexistent Properties” on page 12-46

Layout Options

You can control how the object property table and **Search Results** pane organize the layout of property information by:

- Sorting column contents
- Grouping by a property
- Changing the order of property columns
- Adding a property column
- Hiding and removing property columns

Sorting Column Contents

To sort the column contents in ascending order, click the heading of the property column. A triangle pointing up appears in the column heading. To change the order from ascending to descending, or from descending to ascending, click the heading of the column again.

For example, if properties are in ascending order, based on the **Name** property (the default), click the heading of the **Name** column to display objects by name, in descending order.

By default, the **Contents** pane displays its contents in ascending order, based on the name of the object. Objects that have no values in any property columns appear at the end of the object property table.

Note: When you group by property, the Model Explorer applies sorting of column contents within each group.

Grouping by a Property

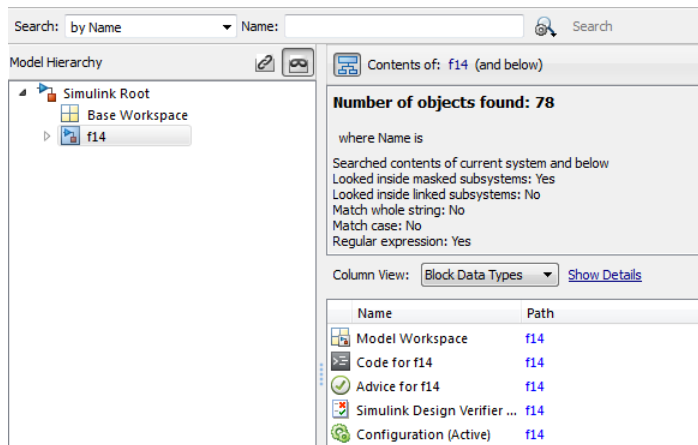

Organizing Contents by Property Values

When you explore a model, you might want to focus on all objects with the same property value. One approach is to group data by a property column.

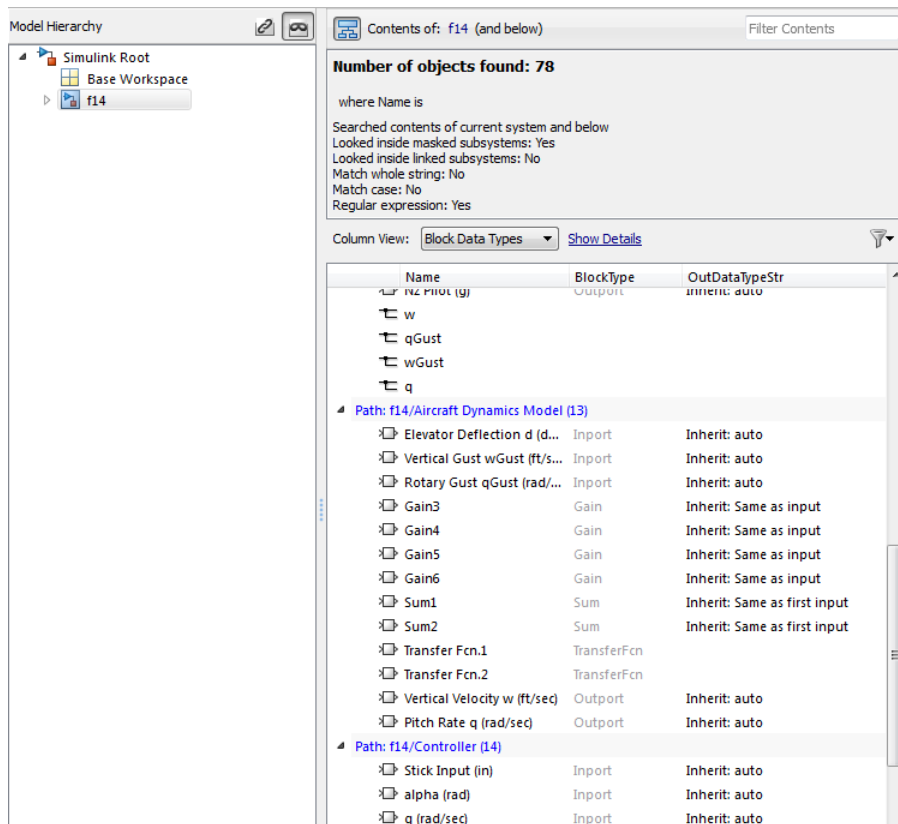

For example, suppose that you want to see all of the blocks in the **f14** model. You could perform the following search.

The search results obscure the whole path name for lower-level nodes:

By grouping on the **Path** property column, you see the whole path for lower-level nodes.

You can also collapse groups to focus on specific portions of a model.

How to Group by a Property Column

To group by a property:

- 1 In the object property table, right-click the column heading of the property by which you want to group contents.

You can group by object icons, such as a block icon (📦), which represents a type of object. Right-click the empty column heading in the first column.

- 2 From the context menu, select the **Group By This Column** menu item.

Sorting with Grouped Data

When you group by property, the Model Explorer applies sorting of column contents within each group.

Expanding and Collapsing Grouped Data

By default, Model Explorer displays groups in expanded form. That is, all the objects in each group are visible. You can collapse and expand groups.

- To collapse the contents of a group, click the minus sign icon for that group.
- To expand a group, click the plus sign.
- To collapse or expand all the groups, right-click anywhere in the object property table and select either the **Collapse All Groups** menu item (**Shift+C**) or **Expand All Groups** menu item (**Shift+E**).

Hiding the Group Column

By default, the property column that you use for grouping appears in the property table. That property also appears in the top row for each group.

To hide the group column in the property table, use one of the following approaches:

- From the **View** menu, clear the **Show Group Column** check box.
- Right-click a column heading in the property table and clear the **Show Group Column** check box.

Persistence of Grouped Data Settings

If you group by a property, that grouping is saved as part of the view definition.

When you select a different node in the **Model Hierarchy** pane, the contents for the new node are grouped by that same property. However, all groups are expanded, even if you had collapsed all groups before switching nodes.

Grouping Search Results

You can use grouping to organize the **Search Results** pane. The grouping that you apply to the **Search Results** pane also applies to the object property table, if that property is in the table. If the search results include a property that is not in the object property

table, and you group on that property, then the Model Explorer removes the grouping setting that was in effect in the object property table.

Changing the Order of Property Columns

Object Icon and Name Columns Are Always First

The first two columns of every object property table are the object icon column (the column with a blank column heading) and the **Name** property column. You cannot hide, remove, or change the location of the first two columns.

How to Change the Order of Property Columns

To change the order of property columns in the object property table, use one of these approaches:

- In the object property table, select a column heading and drag it to a new location in the table.

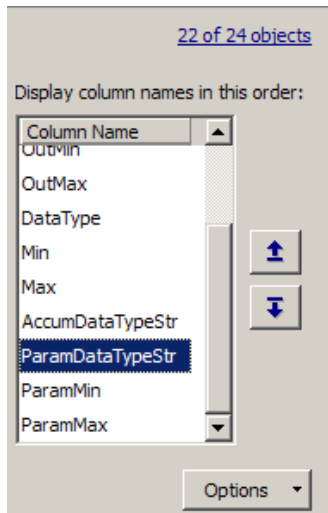

This approach avoids opening the column view details section and makes it easier to move a column a short distance to the right or left.

- In the column view details section, select one or more property columns and move them up or down in the list, using the arrow buttons to the right of the list.

This approach allows you to move several property columns in one step, but it moves the selected columns right or left by only one column at a time.

To move a property column by using the view details interface:

- 1 In the **Display column names in this order** list on the right side of the column view details section, select one or more property columns that you want to move.

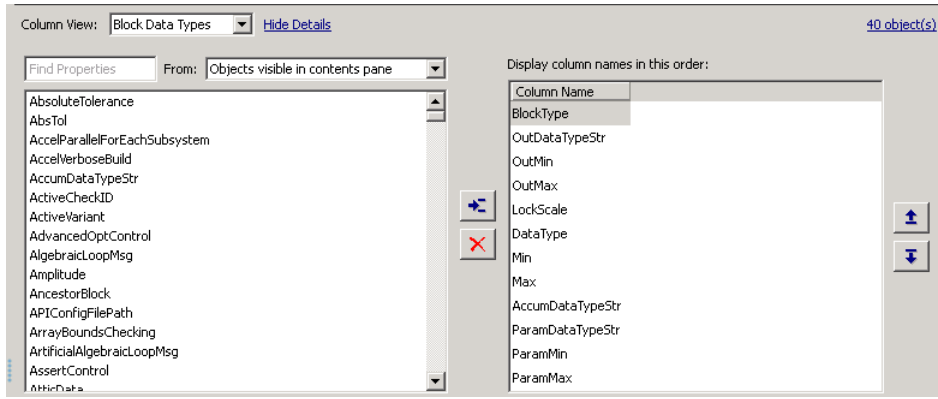

- 2 Click the **Move column left in view** button () or the **Move column right in view** button ()

Adding Property Columns

To add property columns to a view:

- 1 If you do not have the column view details section of the **Contents** pane already open, then at the top of the **Contents** pane, select **Show Details**.

- 2 In the list of properties on left side of the column view details section, select one or more properties that you want to add.
 - The list displays property names in alphabetical order. You can use the **Find Properties** search box in the column view details section to search for properties that contain the text string that you enter. You can specify the scope of the search with the **From** list to the right of the search box.
- 3 In the list of column names on the right side, select the property column that you want to be to the left of the property columns you insert.
- 4 Click the **Display property as column in view** button ()

Adding a Path Property Column

The Model Explorer provides a shortcut for adding a **Path** property column to a view. To add a **Path** property column:

- 1 Right-click the column heading in the object property table to the right of which you want to insert a **Path** column.
- 2 From the context menu, select **Insert Path**.

Hiding or Removing Property Columns

You can choose between two approaches to hide (remove) a property column from the object property table. Hiding and removing a column both have the same result. You can:

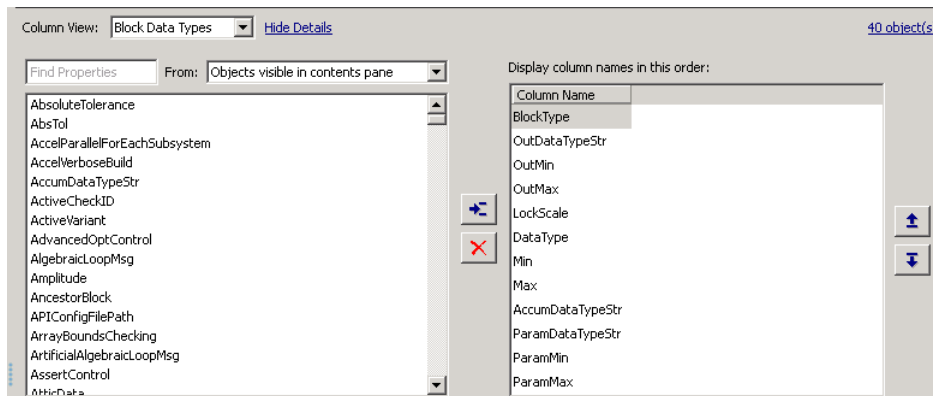

- Hide a column using the context menu for a column heading. This approach avoids needing to open the column view details section.
- Remove a column using the column view details interface. This approach allows you to delete several properties in one step.

Hiding a Column Using the Column Heading Context Menu

- 1 Right-click the column heading of the column that you want to remove.
- 2 From the context menu, select **Hide**.

Removing a Column Using the Column View Details Interface

- 1 If you do not have the column view details section of the **Contents** pane already open, then at the top of the **Contents** pane, select **Show Details**.

- 2 In the column view details section of the **Contents** pane, in the **Display column names in this order** list, select one or more properties that you want to remove.
- 3 Click the **Remove column from view** button () or the **Delete** key.

Inserting Recently Hidden or Removed Columns

The Model Explorer maintains a list of columns you hide or remove for each view during a Simulink session.

To add a recently hidden or removed column back into a view:

- 1 Right-click the column heading of the column to the right of which you want to insert a recently hidden column.

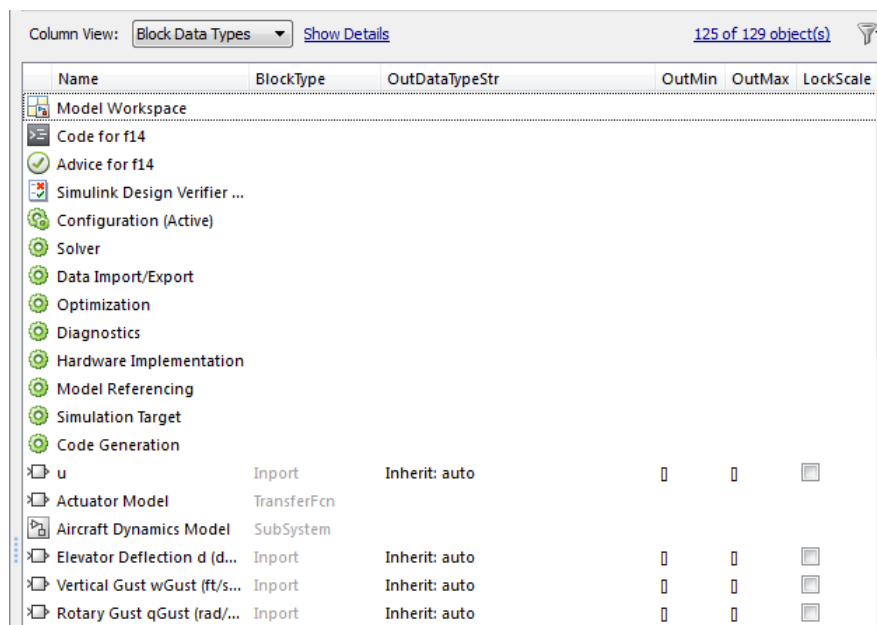

- 2 From the context menu, select **Insert Recently Hidden Columns**.
- 3 Select the column that you want to insert.

See “Hiding or Removing Property Columns” on page 12-44.

Marking Nonexistent Properties

Usually, some of the properties that the **Contents** pane displays do not apply to all the displayed objects (in other words, some objects do not have values set). By default, the Model Explorer displays a dash (–) to mark properties that do not have a value.

If you want the Model Explorer to display a blank (instead of the default dash) in property cells that have no values, clear the **View > Show Nonexistent Properties as “–”** option. The **Contents** pane looks similar to the following graphic:

- “Model Explorer: Property Dialog Pane” on page 12-54

Filter Objects in the Model Explorer

In this section...

“Controlling the Set of Objects to Display” on page 12-48

“Using the Row Filter Option” on page 12-48

“Filtering Contents” on page 12-50

Controlling the Set of Objects to Display

Two techniques that you can use to control the set of objects that the **Contents** pane displays are:

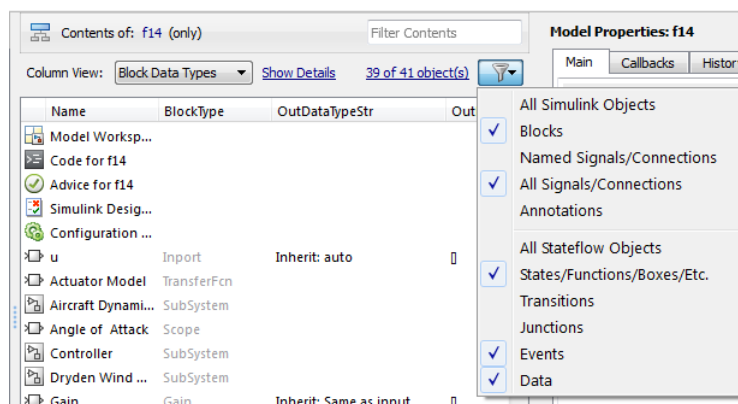

- Using the Row Filter option
- Filtering contents

For a summary of other techniques, see “Focusing on Specific Elements of a Model or Chart” on page 12-9.

Using the Row Filter Option

You can filter the kinds of objects that the **Contents** pane displays:

- 1 Open the **Row Filter** options menu. In the Model Explorer, at the top-right corner of the **Contents** pane, click the **Row Filter** button.

An alternative way to open the Row Filter menu is to select **View > Row Filter**.

By default, the **Contents** pane displays these kinds of objects for the selected node:

- Blocks
 - Signals and connections
 - Stateflow states, functions, and boxes
 - Stateflow events
 - Stateflow data
- 2 Clear the kinds of objects that you do not want to display in the **Contents** pane, or enable any cleared options to display more kinds of objects. For example, clear **All Signals/Connections** to prevent the display of signal and connection objects in the **Contents** pane.

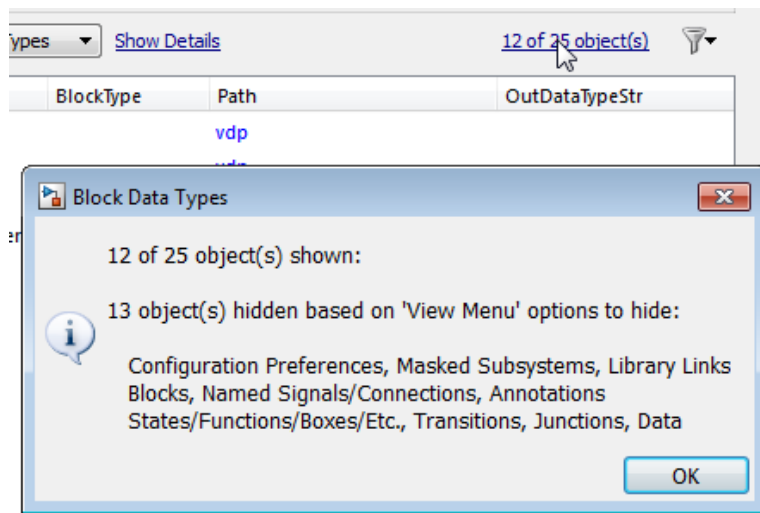

Object Count

The top-right portion of the **Contents** pane includes an object counter, indicating how many objects the **Contents** pane is displaying.

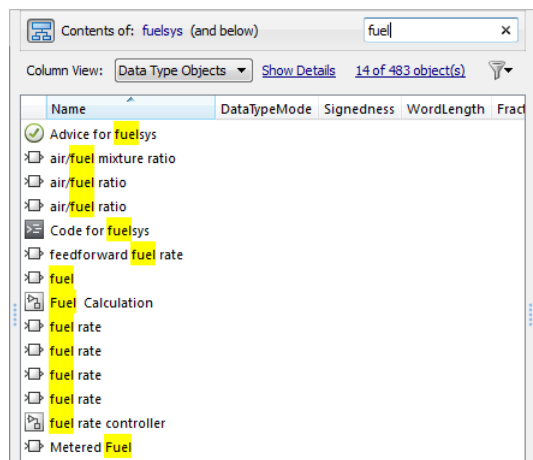

When you use the **Row Filter** option to filter objects, the object count indicator reflects that the **Contents** pane displays a subset of all the model and chart objects.

To view an explanation of the current object count, click the object count link (for example, 12 of 25 objects). That link displays a pop-up information box:

Filtering Contents

To refine the display of objects that are currently displayed in the **Contents** pane, you can use the **Filter Contents** text box at the top of the **Contents** pane to specify search strings for filtering a subset of objects.

Using the **Filter Contents** text box can help you to find specific objects within the set of objects, based on a particular object name, property value, or property that is of interest to you. For example, if you enter the text string `fuel` in the **Filter Contents** edit box, the Model Explorer displays results similar to those shown above. The results highlight the text string that you specified.

Specifying Filter Text Strings

As you enter text in the **Filter Contents** text box, the Model Explorer performs a dynamic search, displaying results that reflect the text as you enter it.

The text strings you enter must be in the format consistent with the guidelines described in the following sections.

Case Sensitivity

By default, the Model Explorer ignores case as it performs the filtering.

To specify that you want the Model Explorer to respect case sensitivity for a text string that you enter, put that text string in quotation marks. For example, if you want to restrict the filtering to display only objects that include the text `Fuel` (with a capital F), enter `"Fuel"` (with quotation marks).

Specifying Properties and Property Values

To restrict the filtering to apply to objects with a specific property, specify the property name followed by a colon (:). The **Contents** pane displays objects that have that property.

To filter for a objects for which a specific property has a specific value, specify the property name followed by a colon (:) and then the value. For example, to filter the contents to display only objects whose `OutDataTypeStr` property has a value that includes `Inherit`, enter `OutDataTypeStr: Inherit` (alternatively, you could put the whole string in quotation marks to enforce case sensitivity):

Name	BlockType	OutDataTypeStr
Constant2	Constant	Inherit: Inherit from 'Constant v
Constant3	Constant	Inherit: Inherit from 'Constant v
Constant4	Constant	Inherit: Inherit from 'Constant v
Constant5	Constant	Inherit: Inherit from 'Constant v
High Speed (rad./Sec.)	Constant	Inherit: Inherit from 'Constant v
Nominal Speed	Constant	Inherit: Inherit from 'Constant v
engine speed	Inport	Inherit: auto
throttle angle	Inport	Inherit: auto
fuel	Inport	Inherit: auto

Wildcards and MATLAB Expressions Not Supported

The Model Explorer does not recognize wildcard characters, such as an asterisk (*), as having any special meaning. For example, if you enter `fuel*` in the **Filter Contents** text box, you get no results, even if several objects contain the text string `fuel`.

Also, if you specify a MATLAB expression, in the **Filter Contents** text box, the Model Explorer interprets that string as literal text, not as a MATLAB expression.

Clearing the Filtered Contents

To redisplay the object property table as it appeared before you filtered the contents, click the **X** in the **Filter Contents** text box.

Filtering Removes Grouping

If you have set up grouping on a column, then when you filtering contents, the Model Explorer does not retain that grouping.

Model Explorer: Property Dialog Pane

In this section...

“What You Can Do with the Dialog Pane” on page 12-54

“Showing and Hiding the Dialog Pane” on page 12-54

“Editing Properties in the Dialog Pane” on page 12-54

What You Can Do with the Dialog Pane

You can use the **Dialog** pane to view and change properties of objects that you select in the **Model Hierarchy** pane or in the **Contents** pane.

Showing and Hiding the Dialog Pane

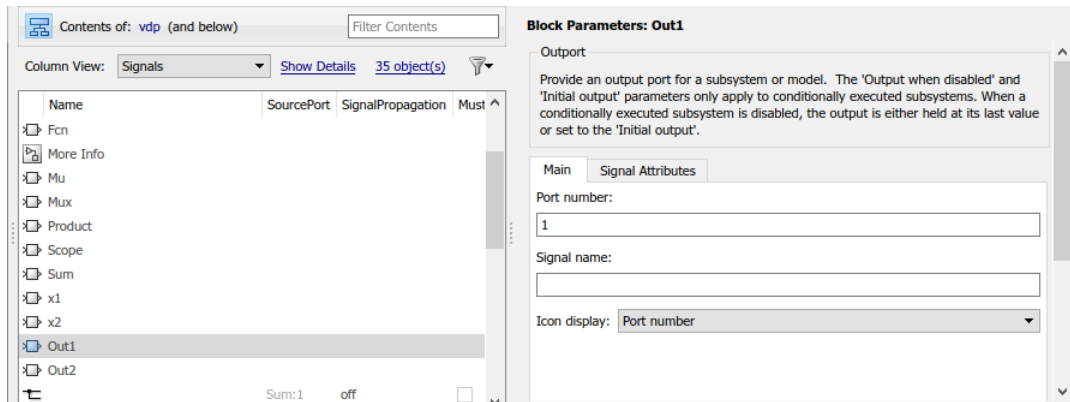

By default, the **Dialog** pane appears in the Model Explorer, to the right of the **Contents** pane. To show or hide the **Dialog** pane, use one of these approaches:

- From the **View** menu, select **Show Dialog Pane**.
- From the main toolbar, click the **Dialog View** button ()

Editing Properties in the Dialog Pane

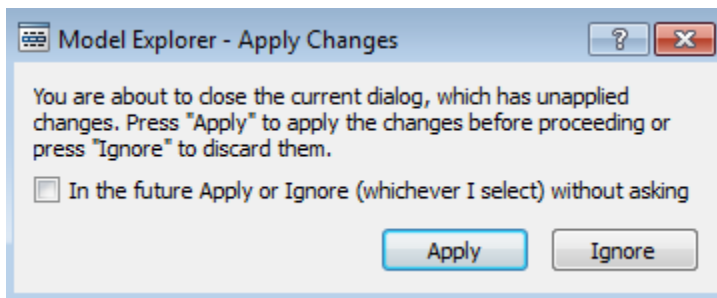

To edit property values using the **Dialog** pane:

- 1 In the **Contents** pane, select an object (such as a block or signal). The **Dialog** pane displays the properties of the object you selected.

- 2 Change a property (for example, the port number of an Outport block) in the **Dialog** pane.
- 3 Click **Apply** to accept the change, or click **Revert** to return to the original value.

By default, clicking outside a dialog box with unapplied changes causes the Apply Changes dialog box to appear:

Click **Apply** to accept the changes or **Ignore** to revert to the original settings.

To prevent display of the **Apply Changes** dialog box:

- 1 In the dialog box, click the **In the future Apply or Ignore (whichever I select) without asking** check box.
- 2 If you want Simulink to apply changes without warning you, press **Apply**. If you want Simulink to ignore changes without warning you, press **Ignore**.

To restore display of the **Apply Changes** dialog box, from the **Tools** menu, select **Prompt if dialog has unapplied changes**.

Find Model Elements in Simulink Models

When you build and modify your model, it helps to understand your model structure and locate specific model elements. Simulink Editor tools simplify these tasks. Use the tool that is appropriate for your model size and complexity.

- Use the model browser to view and navigate the structure of your model. You can find an element using the model browser by navigating to it through the model hierarchy. This approach works well for a smaller model whose structure you are familiar with. See “Explore the Model Hierarchy Using the Model Browser” on page 12-57.
- Use **Edit > Find** to locate model elements that match search criteria. You can search in a selected system and optionally include all systems below it. You can also narrow your results based on search criteria. See “Search for Model Elements Using Find” on page 12-58.
- Use the Model Explorer to search the model hierarchy using advanced criteria. You can use it to search the model hierarchy and search for variables. The Model Explorer also enables you to search in and apply a change to multiple model elements at once. See “Search Using Model Explorer” on page 12-60.
- Use project-wide search to search across all your models and supporting files in one place. You can find matches inside model files, MATLAB files, and other project files such as PDF and Microsoft Word files. See “Project-Wide Search” on page 17-4.

Explore the Model Hierarchy Using the Model Browser

Use the model browser to navigate a model hierarchy using a tree structure. The browser helps you to understand the organization of your model and explore systems within systems.

To display the model browser, in the Simulink Editor, select **View > Model Browser > Show Model Browser**. You can also use the **Hide/Show Model Browser** control on the palette to toggle the browser display.

You can use the commands on the **View > Model Browser** menu to specify whether to include in the browser blocks that are linked to a library and masked subsystems. For information on these types of blocks, see “Linked Blocks” on page 38-14 and “Masking Fundamentals” on page 36-2.

Search for Model Elements Using Find

You can search in Simulink models using **Edit > Find**. Use Find to locate, navigate to, and select any element that matches the search string that you enter. Searching can match the string anywhere in the element, such as in the name and in parameter values. You can customize the search to look only in certain types of elements or when specific parameters are set a certain way.

Default Search	Search Options
In the current system	Specify to search the current system and all systems below it in the model hierarchy.
In all model elements, including all types of Simulink and Stateflow objects	Narrow your search to include only the elements you are interested in, such as blocks, annotations, or signals.
In parameters	Specify to omit parameter values from the search.
Case-insensitive, partial matches	Search for an exact match and use regular expressions.
In referenced models but not in linked blocks or masked systems	You can turn each of these options off and on.

Perform a Basic Search

Search in the current level of the model `sldemo_fuelsys` for any model element that contains the number 2.

Tip Open the property inspector to see the properties and parameters of the current selection. Select **View > Property Inspector**.

- 1 Open the model `sldemo_fuelsys`.
- 2 Select **Edit > Find**.

- 3 In the search box, enter **2** and press **Enter**.

Nine model elements appear highlighted. The first element found, the copyright annotation, appears selected.

- 4 To move the selection to the next element found, click the search box down arrow. In this example, the selection moves to a Constant block. The block name does not appear in the model. Look in the property inspector to see the block name, Constant2.
- 5 Use the up and down arrows to scroll through the rest of the elements the search found.

Specify Search Criteria and Sort Results

You can specify criteria for your search and sort the results using the Finder interface. In this example, you search for all elements that contain the string `fuel`. You then use the Finder interface to narrow your results.

Tip Use the model browser with the Finder interface to select the starting point for your search.

- 1 Open the model `sldemo_fuelsys`.
- 2 Select **Edit > Find**. Next to the search box, click the **View in Finder** button.

- 3 To expand the scope of the search, in the Finder interface, click the **Click to search in current system and below** button .
- 4 Search for any elements that include the string `fuel`. In the search box, enter `fuel` and press **Enter**.

The model has many elements with `fuel` in the name or in a parameter or property value, including blocks, annotations, signals (data), and Stateflow charts.

Use the Finder interface to make your results more meaningful. For example, you can sort by any of the headings and double-click an item in the list to select the element in the model.

- 5 When a search returns too many results, use the advanced search settings. Next to the search box, click the **Configure advanced search settings** button .
- 6 Search only for blocks. In the Advanced Search Settings dialog box, under **Object Type**, clear the **Stateflow** check box. Expand the **Simulink** list and clear the **Annotations** and **Signals** check boxes.
- 7 Narrow the search further to look only in blocks whose description contains the word **input**. Under **Property : Value**, from the property list, select **BlockDescription**. In the value box, enter **input**, and then click the **Add property and value** button. Click **OK**.
- 8 Searching returns 11 blocks. You can add more property values to narrow the search further. For example, you can specify the type of blocks to search in. Open the Advanced Search Settings dialog box. Under **Property : Value**, add another property-value pair. Set the property to **BlockType** and the value to **MultiPortSwitch**. Click the **Add property and value** button and click **OK**.

One block appears in the list.
- 9 Clear the advanced search criteria. Click the arrow on the **Configure advanced search settings** button and select **Clear advanced settings**.

Search Using Model Explorer

Model Explorer helps you to explore and modify your model using advanced techniques. Use the Model Explorer for to search for:

- Variables in workspaces and data dictionaries
- Variable usage in a model
- Instances of a type of block
- Block parameters and parameter values

You can combine search criteria and iteratively refine the results. Search in Model Explorer for model elements, starting with the node you select in the model hierarchy. You can search the entire model, in a particular system, or in a system and all the systems below it in the hierarchy. For details on the options, see “Search Bar Controls” on page 12-7.

Using your search results, you can apply changes to multiple elements at once.

Search for a Parameter and Refine Results

In this example, you search for model elements that have an **Output minimum** parameter. You then refine the results to include only Constant blocks. You can use the search results to find out more about how these values are set or make batch changes to the model elements found by the search.

- 1 Open the model `sldemo_fuelsys`.
- 2 Open Model Explorer. Select **View > Model Explorer > Model Explorer**.

By default, the Model Explorer searches the current system and below. You can use the model hierarchy tree in combination with the **Show contents** button  to specify the scope of the search. For example, you can select a node and set the search to **current system only** to keep the search only at that level. Set the search to **current system and below** to search the current system and all the subsystems within it.

- 3 For this example, leave the search scope set to search the current system and below, starting with the top level of the model. Specify your search criteria. In the search bar, set:

- **Search to by Property Name**
- **Property to OutMin**

OutMin is the programmatic name for the **Output Minimum** parameter. For a list of these names, see “Block-Specific Parameters”.

- 4 Click **Search**. In the **Search Results** box, 126 results appear. You can go to an item by clicking the link to the path.
- 5 Refine the search. In the search bar, click **Search Options** and select **Refine Search**.

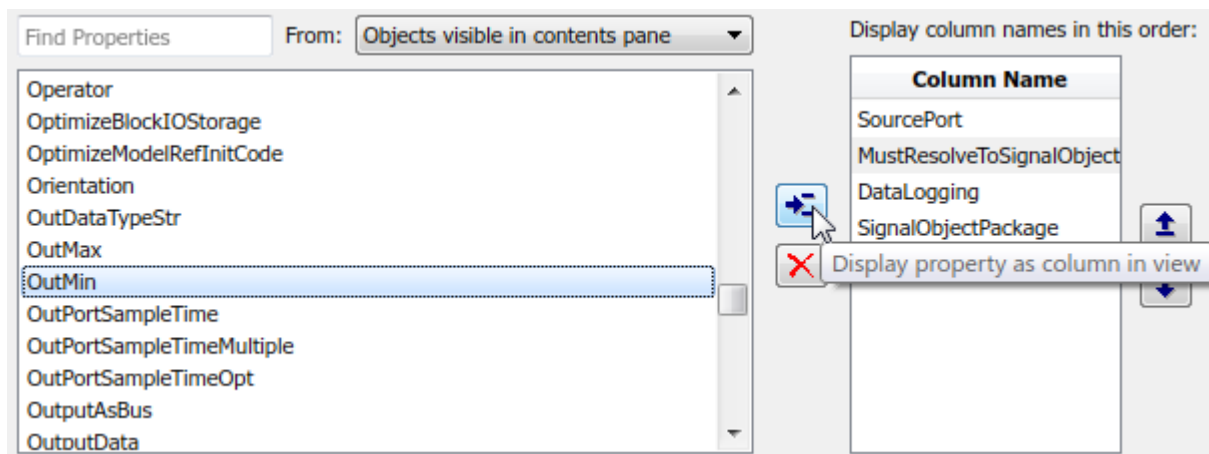

The search button label changes to **Refine**. With this label in effect, additional search criteria act on the previous set of results.

- 6 Set **Search** to by **Block Type** and set **Type** to **Constant**. Click **Refine**.

The search returns 19 items.

- 7 To work further with the values, click **Show Details**.
- 8 The property you are interested learning more about or acting on is **OutMin**. First add a column for it in the search results. Select **OutMin** from the list (you can enter it in the **Find Properties** box to locate it quickly), and click the **Display property as column in view** button.

A column for **OutMin** appears in the search results. For any parameter or property that appears in a column, you can view, sort, and change values for multiple items. For example, to change the **OutMin** values on all **Constant** blocks you find by searching, select all the items in the list. In the **OutMin** column, click one value, type the new value (for example, 0), and press **Enter**.

Tip To view a summary of the search options that you used, expand the **Number of objects found** box by clicking the **Show Search Details** button .

- To create, modify, and view the entries in a data dictionary, use the Model Explorer. See “Edit and Manage Workspace Variables Used by Models” on page 57-88 and “View and Revert Changes to Dictionary Data” on page 61-27.
- For general information about Model Explorer and its uses, see “Model Explorer Overview” on page 12-2.

Model Dependency Viewer

In this section...

“Model Dependency Views” on page 12-64

“View Model File and Library Dependencies” on page 12-67

Model Dependency Views

The Model Dependency Viewer displays a dependency view of a model. The dependency view is a graph of all the models and libraries referenced directly or indirectly by the model. You can use the dependency view to find and open referenced libraries and models. To identify and package all required files instead, see “Analyze Model Dependencies” on page 18-25.

The Model Dependency Viewer allows you to choose between the file dependency view and the model instances view.

File Dependency View

The file dependency view shows the model and library files referenced by a top model. A referenced model or library appears only once in the view even if it is referenced more than once in the model. The figure shows a dependency view. Gray blocks represent model files and blue boxes represent libraries. Arrows represent dependencies. For example, the arrows in this view indicate that the `aero_guidance` model references two libraries: `aerospace` and `simulink_need_slupdate`.

An arrow from a library that points to itself indicates that the library references itself. Blocks in the library reference other blocks in that same library. The example view shows that the `aerospace` library references itself.

A file dependency view can include a legend that identifies the model in the view and the date and time the view was created.

Model Instances View

The model instances view shows every reference to a model in a model reference hierarchy (see “Model Referencing”) with the top model at the root of the hierarchy. If a model hierarchy references the same model more than once, the referenced model appears multiple times in the instance view, once for each reference. For example, this view indicates that the model reference hierarchy for `sldemo_md1ref_depgraph` contains two references to the model `sldemo_md1ref_F2C`.

In an instance view, boxes represent a top model and model references. Boxes representing accelerated-mode instances (see “Simulate Model Referencing Models”

on page 8-31) have filled triangles in their corners; boxes representing normal-mode instances have empty triangles in their corners. For example, the previous diagram shows that one of the references to `sldemo_md1ref_F2C` operates in normal mode, and the other operates in accelerated mode.

Boxes representing protected referenced models on page 8-83 show the protected models `.slxp` extension. You cannot expand protected reference models.

An instance view displays information icons  on instance boxes to indicate an override in simulation mode for that instance. For example, if a referenced model is configured to run in normal mode and it runs in accelerator mode, its simulation mode is overridden. This override occurs because another referenced model that runs in accelerator mode directly or indirectly references it.

Processor-in-the-Loop Mode Indicator

An instance view appends PIL to the names of models that run in processor-in-the-loop mode (see “Simulate Model Referencing Models” on page 8-31). For example, this dependency instance view indicates one instance of the referenced model `ModDepViewerSub` runs in processor-in-the-loop mode.

View Model File and Library Dependencies

This example shows how to use Model Dependency Viewer to view model file and library dependencies of the model. To identify and package all required files instead, see “Analyze Model Dependencies” on page 18-25.

- 1 Open the model `sldemo_mdhref_depgraph`.
- 2 To open the Model Dependency Viewer in file dependency view, select **Analysis > Model Dependencies > Model Dependency Viewer > Models Only**.
- 3 Select the **User-Defined Libraries** check box. The viewer shows dependencies on user-defined libraries, if such dependencies exist.

You can open this view directly from the Simulink Editor by selecting **Analysis > Model Dependencies > Model Dependency Viewer > Models & Libraries**.

- 4 Select the **Built-In Libraries** check box to show dependencies on MathWorks built-in libraries.
- 5 To view the dependencies laid out horizontally, click **Options** and, under **Layout**, select **Horizontal**.
- 6 Collapse the dependencies of `sldemo_mdhref_outdoor_temp`. Click **-** on the box for `sldemo_mdhref_outdoor_temp`.
- 7 Hide the dependency viewer legend. Click **Options** and, under **Display**, select the **Legend** check box.
- 8 Click **Model Instances** to open the model instance view.

You can open this view directly from the Simulink editor by selecting **Analysis > Model Dependencies > Model Dependency Viewer > Referenced Model Instances**.

- 9 To display full paths in the boxes representing the instances, click **Options** and, under **Display**, select the **Full path** check box. Each box in the instance view displays the path of the Model block corresponding to the instance. The name of the referenced model appears in parentheses.
- 10 Select the box for `sldemo_md1ref_heat2cost` and click **Highlight Box**. The corresponding block in the `sldemo_md1ref_depgraph` model appears highlighted.
- 11 In the dependency viewer, double-click the `sldemo_md1ref_heat2cost` box to open the model in the Simulink Editor.

View Linked Requirements in Models and Blocks

In this section...

- “Requirements Traceability in Simulink” on page 12-69
- “Highlight Requirements in a Model” on page 12-69
- “View Information About a Requirements Link” on page 12-72
- “Navigate to Requirements from a Model” on page 12-73
- “Filter Requirements in a Model” on page 12-74

Requirements Traceability in Simulink

If your Simulink model has links to requirements in external documents, you can review these links. To identify which model objects satisfy certain design requirements, use the following requirements features available in Simulink software:

- Highlighting objects in your model that have links to external requirements
- Viewing information about a requirements link
- Navigating from a model object to its associated requirement
- Filtering requirements highlighting based on specified keywords

Having a Simulink Verification and Validation license enables you to perform the following additional tasks, using the Requirements Management Interface (RMI):

- Adding new requirements
- Changing existing requirements
- Deleting existing requirements
- Applying user tags to requirements
- Creating reports about requirements links in your model
- Checking the validity of the links between the model objects and the requirements documents

Highlight Requirements in a Model

You can highlight a model to identify which objects in the model have links to requirements in external documents. Both the Simulink Editor and the Model Explorer provide this capability.

- “Highlight a Model Using the Simulink Editor” on page 12-70
- “Highlight a Model Using the Model Explorer” on page 12-71

Note: If your model contains a Model block whose referenced model contains requirements, those requirements are not highlighted. If you have Simulink Verification and Validation, you can view this information only in requirements reports. To generate requirements information for referenced models and then see highlighted snapshots of those requirements, follow the steps in “Report for Requirements in Model Blocks”.

Highlight a Model Using the Simulink Editor

If you are working in the Simulink Editor and want to see which model objects in the `slvndemo_fuelsys_officereq` model have requirements, follow these steps:

- 1 Open the example model:

```
slvndemo_fuelsys_officereq
```

- 2 Select **Analysis > Requirements Traceability > Highlight Model**.

Two types of highlighting indicate model objects with requirements:

- Yellow highlighting indicates objects that have requirements links for the object itself.

- Orange outline indicates objects, such as subsystems, whose child objects have requirements links.

Objects that do not have requirements are colored gray.

- 3 To remove the highlighting from the model, select **Analysis > Requirements Traceability > Unhighlight Model**. Alternatively, you can right-click anywhere in the model, and select **Remove Highlighting**.

While a model is highlighted, you can still manage the model and its contents.

Highlight a Model Using the Model Explorer

If you are working in Model Explorer and want to see which model objects have requirements, follow these steps:

- 1 Open the example model:
`slvndemo_fuelsys_officereq`
- 2 Select **View > Model Explorer**.
- 3 To highlight all model objects with requirements, click the **Highlight items with requirements on model** icon ()

The Simulink Editor window opens, and all objects in the model with requirements are highlighted.

Note: If you are running a 64-bit version of MATLAB, when you navigate to a requirement in a PDF file, the file opens at the beginning of the document, not at the specified location.

View Information About a Requirements Link

Using Simulink, you can view detailed information about a requirements link, such as identifying the location and type of document that contains the requirement.

Note: You can only modify the requirements information if you have a Simulink Verification and Validation license.

For example, to view information about the requirements link from the MAP Sensor block in the `slvndemo_fuelsys_officereq` example model, follow these steps:

- 1 Open the example model:
`slvndemo_fuelsys_officereq`
- 2 Right-click the MAP sensor block, and select **Requirements > Edit/Add Links**.

The Requirements dialog box opens and displays the following information about the requirements link:

- The description of the link (which is the actual text of the requirement).

- The Microsoft Excel® workbook named `slvndemo_FuelSys_TestScenarios.xlsx`, which contains the linked requirement.
- The requirements text, which appears in the named cell `Simulink_requirement_item_2` in the workbook.
- The user tag `test`, which is associated with this requirement.

Navigate to Requirements from a Model

Navigate from the Model Object

You can navigate directly from a model object to that object's associated requirement. When you take these steps, the external requirements document opens in the application, with the requirements text highlighted.

- 1 Open the example model:
`slvndemo_fuelsys_officereq`
- 2 Open the fuel rate controller subsystem.
- 3 To open the linked requirement, right-click the Airflow calculation subsystem and select **Requirements Traceability > 1. “Mass airflow estimation”**.

The Microsoft Word document `slvndemo_FuelSys_DesignDescription.docx`, opens with the section **2.1 Mass airflow estimation** selected.

Note: If you are running a 64-bit version of MATLAB, when you navigate to a requirement in a PDF file, the file opens at the top of the page, not at the bookmark location.

Navigate from a System Requirements Block

Sometimes you want to see all the requirements links at a given level of the model hierarchy. In such cases, you can insert a System Requirements block to collect all requirements links in a model or subsystem. The System Requirements block lists requirements links for the model or subsystem in which it resides; it does not list requirements links for model objects inside that model or subsystem, because those are at a different level of the model hierarchy.

In the following example, you insert a System Requirements block at the top level of the `slvndemo_fuelsys_officereq` model, and navigate to the requirements using the links inside the block.

- 1 Open the example model:

`slvndemo_fuelsys_officereq`

- 2 In the Simulink Editor, select **Analysis > Requirements Traceability > Highlight Model**.
- 3 Open the fuel rate controller subsystem.

The Airflow calculation subsystem has a requirements link.

- 4 Open the Airflow calculation subsystem.
- 5 In the Simulink Editor, select **View > Library Browser**.
- 6 On the **Libraries** pane, select **Simulink Verification and Validation**.

This library contains only one block—the System Requirements block.

- 7 Drag a System Requirements block into the Airflow calculation subsystem.

The RMI software collects and displays any requirements links for that subsystem in the System Requirements block.

- 8 In the System Requirements block, double-click 1. “**Mass airflow subsystem**”.

The Microsoft Word document, `slvndemo_FuelSys_DesignDescription.docx`, opens, with the section **2.1 Mass airflow estimation** selected.

Filter Requirements in a Model

- “Filtering Requirements Highlighting by User Tag” on page 12-74
- “Filtering Options for Highlighting Requirements” on page 12-75

Filtering Requirements Highlighting by User Tag

Some requirements links in your model can have one or more associated user tags. *User tags* are keywords that you create to categorize a requirement, for example, **design** or **test**.

For example, in the `slvndemo_fuelsys_officereq` model, the requirements link from the MAP sensor block has the user tag **test**.

To highlight only all the blocks that have a requirement with the user tag `test`:

- 1 Open the example model:

`slvndemo_fuelsys_officereq`

- 2 In the Simulink Editor, select **Analysis > Requirements > Settings**.

The Requirements Settings dialog box opens. If you do not have a Simulink Verification and Validation license, the **Filters** tab is the only option available.

By default, your model has no requirements filtering enabled.

- 3 Select **Filter links by user tags when highlighting and reporting requirements**.
- 4 In the **Include links with any of these tags** text box, delete `design`, and enter `test`.
- 5 Press **Enter**.
- 6 Highlight the `slvndemo_fuelsys_officereq` model for requirements. Select **Analysis > Requirements > Highlight Model**.

In the top-level model, only the MAP sensor block and the Test inputs block are highlighted.

- 7 To disable the filtering by user tag, select **Analysis > Requirements > Settings**, and clear **Filter links by user tags when highlighting and reporting requirements**.

The model highlighting updates immediately.

Filtering Options for Highlighting Requirements

On the **Filters** tab, you select options that designate which objects with requirements are highlighted. The following table describes these settings, which apply to all requirements in your model for the duration of your MATLAB session.

Option	Description
Filter links by user tags when highlighting and reporting requirements	Enables filtering for highlighting and reporting, based on specified user tags.
Include links with any of these tags	Highlights all objects whose requirements match at least one of the specified user

Option	Description
	tags. The tag names must match exactly. Separate multiple user tags with commas or spaces.
Exclude links with any of these tags	Excludes from the highlighting all objects whose requirements match at least one of the specified user tags. The tag names must match exactly. Separate multiple user tags with commas or spaces.
Apply same filters in context menus	Disables navigation links in context menus for all objects whose requirements do not match at least one of the specified user tags.
Under Link type filters, Disable DOORS surrogate item links in context menus	Disables links to IBM® Rational® DOORS® surrogate items from the context menus when you right-click a model object. This option does not depend on current user tag filters.

Trace Connections Using Interface Display

In this section...

“How Interface Display Works” on page 12-77

“Trace Connections in a Subsystem” on page 12-77

How Interface Display Works

In the Simulink Editor, you can turn on and off the display of interfaces in a model. When you are building large, complex models, you can connect or add signal lines between blocks or buses that are at different levels. The interface view allows you to trace signals through the nested levels. This capability helps you to:

- Identify inputs and outputs.
- Trace signal lines and bus elements to sources and terminations.
- Annotate signal characteristics such as data type, dimensions, and sample time.
- View units associated with signals, where applicable.

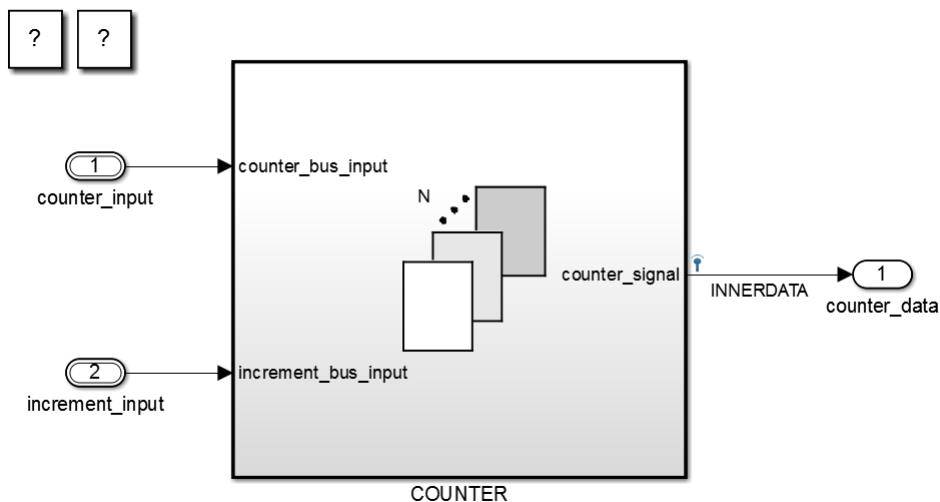

When you build a model, transition block pairs such as Inport and Outport and From and Goto help you to simplify connections of the crossovers among many signal lines. The interface view enables you to trace the hand-off and receipt between such blocks by way of colored highlights.

Trace Connections in a Subsystem

This example shows how to use the display of model interfaces to examine, trace, and understand the flow of signals and buses. This model propagates bus signals into referenced models.

- 1 Open the model `sldemo_mdhref_counter_bus`.

The `counter_bus_input` port channels the data and saturation limits of the counter to count and sets the upper and lower limit values. The `increment_bus_input` port channels a bus signal to change the increment and reset the counter.

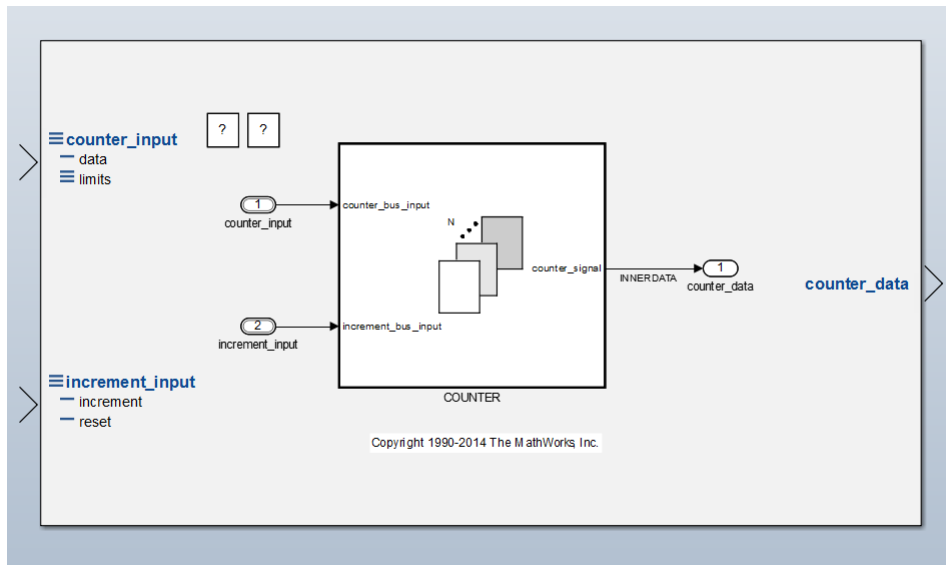

- 2 Select **Display > Interface** to enable the interface view.

Tip Use the perspectives control in the lower-right corner of the model to toggle the display of interfaces.

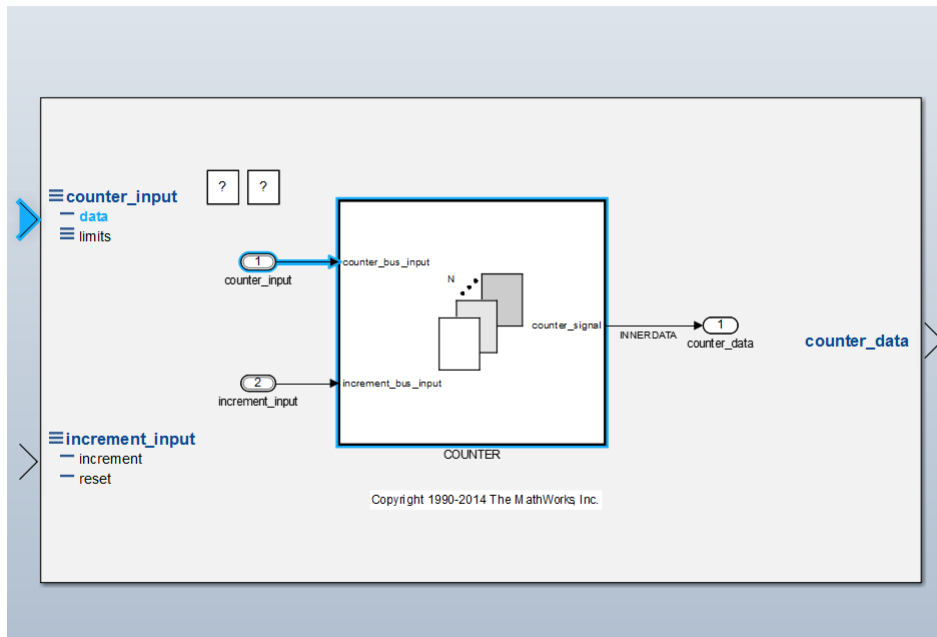

The three bars next to the `counter_input` and `increment_input` interfaces indicate the bus input signals. The single bars indicate data lines, such as counts per second, or command lines, such as reset, to start a new counting sequence. The three bars next to `limits` indicate that bus signals are nested inside the `COUNTER` subsystem.

- 3 Under `counter_input`, click `data`.

The path for the data appears in blue. The COUNTER subsystem is highlighted, indicating the path continues within it.

4 Double-click the COUNTER subsystem.

The continuation of the path for the data signal appears in blue.

5 Select **Simulation > Update Diagram**.

Note: This model requires values from a parent model to simulate completely.

The `counter_signal` interface displays these signal attributes, which help you to synchronize signals between blocks during simulation:

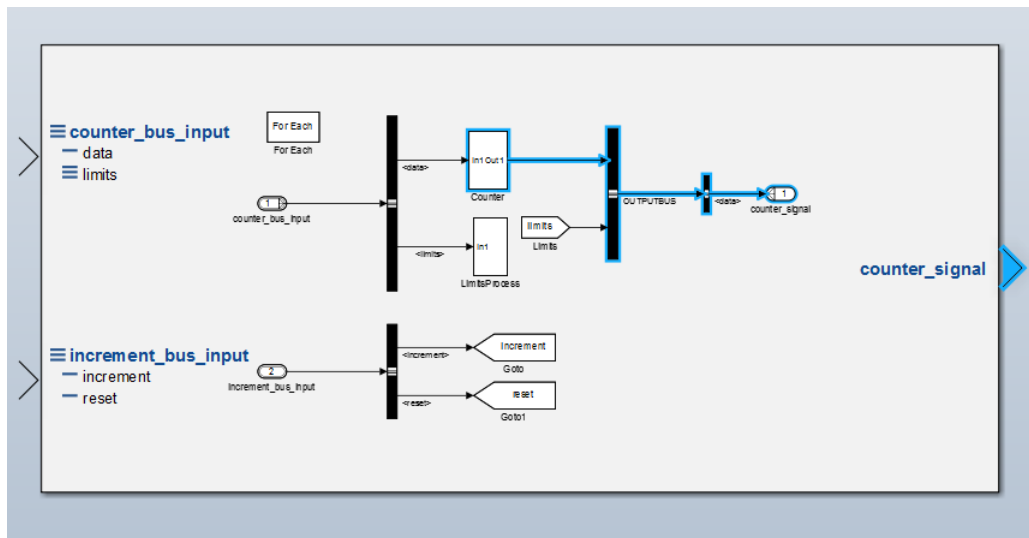

- Data type: int32 (signed 32-bit integer)
- Dimensions: (2) (a 1-D Simulink representation of a scalar)
- Sample time: Ts:D1 (a discrete sample time of D1, which is the highest speed)

In addition, when you update the diagram with interfaces displayed, the model displays the color code for sample time at each interface. For example, this model displays a red bar at each interface to indicate a sample time of D1.

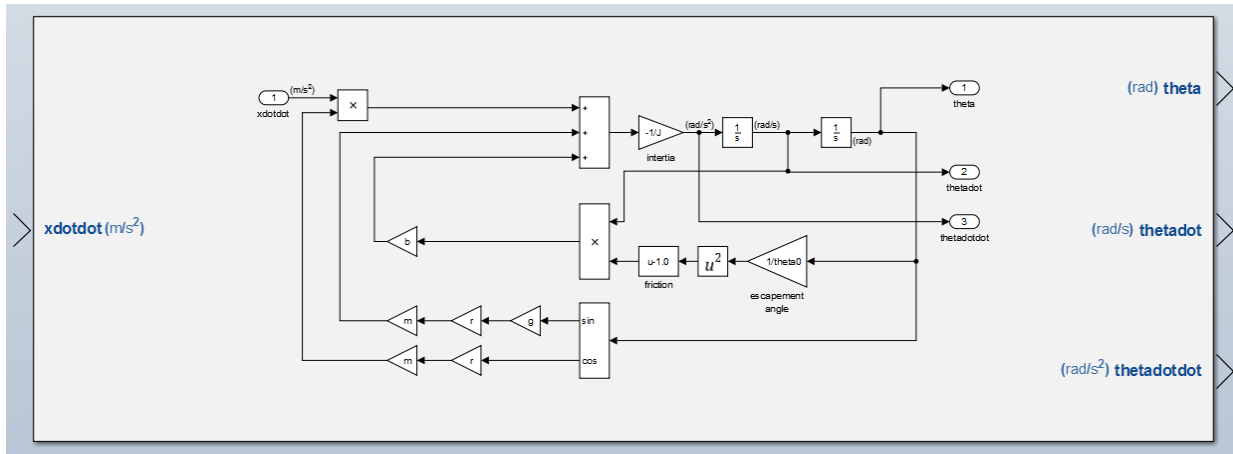

Tip To display a legend of the meaning of sample time colors, select **Display > Sample Time > Colors**.

- Click the `counter_signal` output interface to see the output of the bus outlined in blue, where the path ends.

- If you want to print this diagram with the interfaces displayed, select **File > Print > Print**.

When signals in your model have units associated with them, you see the units in the interface view. For example, in the model `sldemo_metro`, the `Metronome1` subsystem shows units for inputs and outputs of the subsystem in the interface view.

Managing Model Configurations

- “About Model Configurations” on page 13-2
- “Multiple Configuration Sets in a Model” on page 13-3
- “Share a Configuration for Multiple Models” on page 13-4
- “Share a Configuration Across Referenced Models” on page 13-6
- “Manage a Configuration Set” on page 13-11
- “Manage a Configuration Reference” on page 13-18
- “About Configuration Sets” on page 13-25
- “About Configuration References” on page 13-28
- “Model Configuration Command Line Interface” on page 13-32

About Model Configurations

A model configuration is a named set of values for the parameters of a model. It is referred to as a *configuration set*. Every new model is created with a default configuration set, called `Configuration`, that initially specifies default values for the model parameters. You can change the default values for new models by setting the Model Configuration Preferences. For more information, see “Model Configuration Pane”.

You can subsequently create and modify additional configuration sets and associate them with the model. The configuration sets associated with a model can specify different values for any or all configuration parameters. For more information, see “About Configuration Sets” on page 13-25. For examples on how to use configuration sets, see:

- “Multiple Configuration Sets in a Model” on page 13-3
- “Manage a Configuration Set” on page 13-11

By default, a configuration set resides within a single model so that only that model can use it. Alternatively, you can store a configuration set independently, so that other models can use it. A configuration set that exists outside any model is a *freestanding configuration set*. Each model that uses a freestanding configuration set defines a *configuration reference* that points to the freestanding configuration set. A freestanding configuration set allows you to single-source a configuration set for several models. For more information, see “About Configuration References” on page 13-28. For examples on how to use configuration references, see:

- “Share a Configuration for Multiple Models” on page 13-4
- “Share a Configuration Across Referenced Models” on page 13-6
- “Manage a Configuration Reference” on page 13-18

More About

- “Configuration Parameters Dialog Box Overview”
- “Solver Pane”
- “Hardware Implementation Pane”

Multiple Configuration Sets in a Model

A model can include many different configuration sets. This capability is useful if you want to compare the difference in simulation output after changing the values of several parameters. Attaching additional configuration sets allows you to quickly switch the active configuration.

- 1 To create additional configuration sets in your model, in the Model Explorer, select your model node in the Model Hierarchy pane and do one of the following:
 - Right-click the model node and select **Configuration > Add Configuration**.
 - Right-click an existing configuration set. In the context menu, select **Copy**.
- 2 To import a previously saved configuration set, right-click the model node and select **Configuration > Import**. In the Import Configuration From File dialog box, select a configuration file.
- 3 To modify the newly added configuration set, in the Model Hierarchy pane, select the configuration node. In the **Contents** pane, select a component, and then modify any parameters which are displayed in the right pane.
- 4 To make the new configuration set the active configuration, in the configuration set context menu, select **Activate**. In the Model Hierarchy pane, the new configuration set name is now displayed as **(Active)**.
- 5 To simulate your model using a different configuration set, switch the active configuration by repeating step 4.

Related Examples

- “Manage a Configuration Set” on page 13-11
- “Model Configuration Command Line Interface” on page 13-32

Share a Configuration for Multiple Models

With configuration references, multiple models can share a configuration set. To share a configuration set between models, store the configuration set as a configuration set object in the base workspace. Then create a configuration reference in your model that references the configuration set object. You can create configuration references in other models that also point to the same configuration set object.

Note: Before saving and closing your models, follow the instructions to “Save a Referenced Configuration Set” on page 13-23. If you do not save the referenced configuration set from the base workspace, when you reopen your model, the configuration reference is unresolved.

Convert an Existing Configuration Set to a Configuration Reference

To convert an existing configuration set in your model to a configuration reference:

- 1 Open the Model Explorer.
- 2 In the Model Hierarchy pane, right-click the active configuration set to share.
- 3 In the configuration set context menu, select **Convert to Configuration Reference**, which opens a dialog box. Alternatively, you can right-click the model node and select **Configuration > Convert Active Configuration to Reference**.
- 4 In the Convert Active Configuration to Reference dialog box, use the default configuration set object name, `configSetObj`, or type a name.
- 5 Click **OK**, which creates a configuration reference in the model and a configuration set object in the base workspace. The configuration reference points to the configuration set object, which has the same values as the original active configuration set. The configuration reference name in the Model Hierarchy is now marked as *(Active)*.
- 6 To change the name of the configuration reference, select it in the Model Hierarchy, and in the right pane, change the **Name** field.

Create a Configuration Reference in Another Model

To share the preceding configuration set, which is stored as `configSetObj` in the base workspace, create a configuration reference in another model:

- 1 In the Model Hierarchy pane, right-click the model node.
- 2 In the context menu, select **Configuration > Add Configuration Reference**.
- 3 The Create Configuration Reference dialog box opens. Specify the name of the configuration set object, `configSetObj`, in the base workspace.
- 4 To make the new configuration reference the active configuration, in the Model Hierarchy, right-click the configuration reference. In the context menu, select **Activate**.

Both models now contain a configuration reference that points to the same configuration set object in the base workspace. To set up your model to automatically load the configuration set object, see “Callbacks for Customized Model Behavior” on page 4-56.

More About

- “About Configuration References” on page 13-28

Share a Configuration Across Referenced Models

This example shows how to share the same configuration set for the top model and referenced models in a model reference hierarchy. You can use a configuration reference in each of the models to reference the same configuration set object in the base workspace.

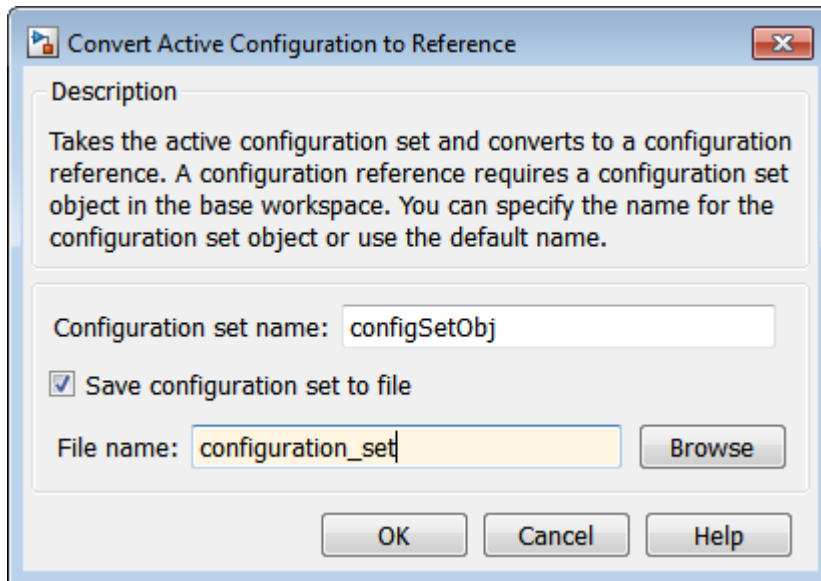

In the diagram, each model shown in the Model Dependency Viewer specifies the configuration reference, `my_configuration`, as its active configuration set. `my_configuration` points to the freestanding configuration set, `Configuration`. Therefore, the parameter values in `Configuration` apply to all four models. Any parameter change in `Configuration` applies to all four models.

Convert Configuration Set to Configuration Reference

In the top model, you must convert the active configuration set to a configuration reference:

- 1 Open the `sldemo_mdhref_depgraph` model and the Model Explorer.
- 2 In the Model Hierarchy pane, expand the top model, `sldemo_mdhref_depgraph`. In the list, right-click **Configuration (Active)**. In the context menu, select **Convert to Configuration Reference**.
- 3 In the **Configuration set name** field, specify a name for the configuration set object, or use the default name, `configSetObj`. This configuration set object is stored in the base workspace.
- 4 Optionally, you can save the configuration set to a MAT-file. Select **Save configuration set to file**. This enables the **File name** parameter.
- 5 In the **File name** field, specify a name for the MAT-file.

- 6 Click **OK**.

The original configuration set is now stored as a configuration set object, `configSetObj`, in the base workspace. The configuration set is also stored in a MAT-file, `configuration_set.mat`. The active configuration for the top model is now a

configuration reference. This configuration reference points to the configuration set object in the base workspace.

Propagate a Configuration Reference

Now that the top model contains an active configuration reference, you can propagate this configuration reference to all of the child models. Propagation creates a copy of the top model configuration reference in each referenced model. For each referenced model, the configuration reference is now the active configuration. The configuration references point to the configuration set object, `configSetObj`, in the base workspace.

- 1 In the Model Explorer, in the Model Hierarchy pane, expand the `sldemo_md1ref_depgraph` node.

- 2 Right-click the active configuration reference, **Reference (Active)**. In the context menu, select **Propagate to Referenced Models**.
- 3 In the Configuration Reference Propagation dialog box, select the check box for each referenced model. In this example, they are already selected.
- 4 Verify that your current folder is a writable folder. The propagation mechanism saves the original configuration parameters for each referenced model so that you can undo the propagation. Click **Propagate**.
- 5 In the Propagation Confirmation dialog box, click **OK**.
- 6 In the Configuration Reference Propagation dialog box, the Propagation Report is updated and the **Status** for each referenced model is marked as **Converted**.

Undo a Configuration Reference Propagation

After propagating a configuration reference from a top model to the referenced models, you can undo the propagation for all referenced models by clicking **Restore All**. If you want to undo the propagation for individual referenced models, in the **Undo/Redo** column, click the **Undo** button. The Propagation Report is updated and the **Status** for the referenced model is set to **Restored**.

Manage a Configuration Set

In this section...

- “Create a Configuration Set in a Model” on page 13-11
- “Create a Configuration Set in the Base Workspace” on page 13-11
- “Open a Configuration Set in the Configuration Parameters Dialog Box” on page 13-12
- “Activate a Configuration Set” on page 13-13
- “Set Values in a Configuration Set” on page 13-13
- “Copy, Delete, and Move a Configuration Set” on page 13-13
- “Save a Configuration Set” on page 13-14
- “Load a Saved Configuration Set” on page 13-15
- “Copy Configuration Set Components” on page 13-15
- “Compare Configuration Sets” on page 13-16

Create a Configuration Set in a Model

- 1 Open the Model Explorer.
- 2 In the Model Hierarchy pane, select the model name.
- 3 You can create a new configuration set in any of the following ways:
 - From the **Add** menu, select **Configuration**.
 - On the toolbar, click the **Add Configuration** button .
 - In the Model Hierarchy pane, right-click an existing configuration set and copy and paste the configuration set.

Create a Configuration Set in the Base Workspace

- 1 Open the Model Explorer.
- 2 In the Model Hierarchy pane, select **Base Workspace**.
- 3 You can create a new configuration set object in the following ways:
 - From the **Add** menu, select **Configuration**

- In the toolbar, click the **Add Configuration** button 
- 4 The configuration set object appears in the Contents pane, with the default name, ConfigSet.

Open a Configuration Set in the Configuration Parameters Dialog Box

In the Model Explorer, to open the Configuration Parameters dialog box for a configuration set, right-click the configuration set's node to display the context menu, then select **Open**. You can open the Configuration Parameters dialog box for any configuration set, whether or not it is active.

The title bar of the dialog box indicates whether the configuration set is active or inactive.

Note: Every configuration set has its own Configuration Parameters dialog box. As you change the state of a configuration set, the title bar of the dialog box changes to reflect the state.

Activate a Configuration Set

Only one configuration set associated with a model is active at any given time. The active set determines the current values of the model parameters. You can change the active or inactive set at any time (except when executing the model). In this way, you can quickly reconfigure a model for different purposes, for example, testing and production, or apply standard configuration settings to new models.

To activate a configuration set, right-click the configuration set node to display the context menu, then select **Activate**.

Set Values in a Configuration Set

To set the value of a parameter in a configuration set, in the Model Explorer:

- 1 In the Model Hierarchy, select the configuration set node.
- 2 In the Contents pane, select the component from where the parameter resides.
- 3 In the Dialog pane, edit the parameter value.

Copy, Delete, and Move a Configuration Set

You can use edit commands on the Model Explorer **Edit** or context menus or object drag-and-drop operations to delete, copy, and move configuration sets among models displayed in the **Model Hierarchy** pane.

For example, to copy a configuration set from one model to another:

- 1 In the **Model Hierarchy** pane, right-click the configuration set node that you want to copy.
- 2 Select **Copy** in the configuration set context menu.
- 3 Right-click the model node in which you want to create the copy.
- 4 Select **Paste** from the model context menu.

To copy the configuration set using object drag-and-drop, hold down the right mouse button and drag the configuration set node to the node of the model in which you want to create the copy.

To move a configuration set from one model to another using drag-and-drop, hold the left mouse button down and drag the configuration set node to the node of the destination model.

Note You cannot move or delete an active configuration set from a model.

Save a Configuration Set

You can save the settings of configuration sets as MATLAB functions or scripts. Using the MATLAB function or script, you can share and archive model configuration sets. You can also compare the settings in different configuration sets by comparing the MATLAB functions or scripts of the configuration sets.

To save an active or inactive configuration set from the Model Explorer:

- 1 Open the model.
- 2 Open the Model Explorer.
- 3 Save the configuration set:
 - a In the **Model Hierarchy** pane:
 - Right-click the model node and select **Configuration > Export Active Configuration Set**.
 - Right-click a configuration set and select **Export**.
 - Select the model. In the **Contents** pane, right-click a configuration set and select **Export**.
 - b In the Export Configuration Set to File dialog box, specify the name of the file and the file type. If you specify a `.m` extension, the file contains a function that creates a configuration set object. If you specify a `.mat` extension, the file contains a configuration set object.

Note: Do not specify the name of the file to be the same as a model name. If the file and model have the same name, the software cannot determine which file contains the configuration set object when loading the file.

- c Click **Save**. The Simulink software saves the configuration set.

Load a Saved Configuration Set

You can load configuration sets that you previously saved as MATLAB functions or scripts.

To load a configuration set from the Model Explorer:

- 1 Open the model.
- 2 Open the Model Explorer.
- 3 In the **Model Hierarchy** pane, right-click the model and select **Configuration > Import**.
- 4 In the Import Configuration Set From File dialog box, select the **.m** file that contains the function to create the configuration set object, or the **.mat** file that contains the configuration set object.
- 5 Click **Open**. The Simulink software loads the configuration set.

Note: If you load a configuration set object that contains an invalid custom target, the software sets the “**System target file**” parameter to `ert.tlc`.

- 6 Optionally, activate the configuration set. For more information, see “Activate a Configuration Set” on page 13-13.

Copy Configuration Set Components

To copy a configuration set component from one configuration set to another:

- 1 Select the component in the Model Explorer **Contents** pane.
- 2 From either the Model Explorer **Edit** menu or the component context menu, select **Copy**.
- 3 Select the configuration set into which you want to copy the component.

- 4 From either the Model Explorer **Edit** menu or the component context menu, select **Paste**.

Note The copy replaces the component of the same name in the destination configuration set. For example, if you copy the Solver component of configuration set A and paste it into configuration set B, the copy replaces the existing Solver component in B.

Compare Configuration Sets

You can visually compare two configuration sets using the `visdiff` function. This function opens the Comparison Tool and presents the differences between the two files. If you have Simulink Report Generator, you can select a pair of models to compare XML text files generated from them. See “Select Simulink Models for XML Comparison” and “View Changes in Model Configuration Parameters” in the Simulink Report Generator documentation.

- 1 Get the first configuration set for a model.

```
cs = getConfigSet('model_name','config_set_1_name');
```

- 2 Save the configuration set to a MAT-file.

```
save('configSet1.mat','cs');
```

- 3 Get the second configuration set for the model.

```
cs = getConfigSet('model_name','config_set_2_name');
```

- 4 Save the second configuration set to a MAT-file.

```
save('configSet2.mat','cs');
```

- 5 Compare the files.

```
visdiff('configSet1.mat','configSet2.mat');
```

For more information on using the Comparison Tool to compare MAT-files, see “Comparing MAT-Files”.

Manage a Configuration Reference

In this section...

“Create and Attach a Configuration Reference” on page 13-18

“Resolve a Configuration Reference” on page 13-19

“Activate a Configuration Reference” on page 13-21

“Manage Configuration Reference Across Referenced Models” on page 13-22

“Change Parameter Values in a Referenced Configuration Set” on page 13-23

“Save a Referenced Configuration Set” on page 13-23

“Load a Saved Referenced Configuration Set” on page 13-24

Create and Attach a Configuration Reference

To use a configuration reference, it must point to freestanding configuration set. Create a freestanding configuration set before creating a configuration reference, see “Create a Configuration Set in the Base Workspace” on page 13-11.

To create a configuration reference:

- 1 In the Model Explorer, in the Model Hierarchy pane, select the model.
- 2 Click the **Add Reference** tool  or select **Add > Configuration Reference**. The Create Configuration Reference dialog box opens.
- 3 Specify the **Configuration set name** of the configuration set object in the base workspace to be referenced.
- 4 Click **OK**. If you chose to create a configuration reference without first creating a configuration set object, a dialog box opens asking if you would like to continue. If you choose:
 - **Yes**, an unresolved configuration reference is created. For more information, see “Unresolved Configuration References” on page 13-29. Follow the instructions in “Resolve a Configuration Reference” on page 13-19.
 - **No**, then the configuration reference is not created. Follow the instructions in “Create a Configuration Set in the Base Workspace” on page 13-11, and then return to step 1 above.

- 5 A new configuration reference appears in the Model Hierarchy under the selected model. The default name of the new reference is **Reference**.

Resolve a Configuration Reference

An unresolved configuration reference is a configuration reference that is not pointing to a valid configuration set object.

To resolve a configuration reference:

- 1 In the Model Hierarchy pane, select the unresolved configuration reference or right-click the configuration reference, and select **Open** from the context menu.

The Configuration Reference dialog box opens in the Dialog pane or a separate window.

- 2 Specify the **Referenced configuration** set to be a configuration set object already in the base workspace. If one does not exist, see “Create a Configuration Set in the Base Workspace” on page 13-11.

Tip Do not specify the name of a configuration reference. If you nest a configuration reference, an error occurs.

- 3 Click **OK** or **Apply**.

If you specified a Referenced configuration that exists in the base workspace, the **Is Resolved** field in the dialog box changes to **yes**.

Activate a Configuration Reference

After you create a configuration reference and attach it to a model, you can activate it so that it is the active configuration.

- In the GUI, from the context menu of the configuration reference, select **Activate**.
- From the API, execute `setActiveConfigSet`, specifying the configuration reference as the second argument.

When a configuration reference is active, the **Is Active** field of the Configuration Reference dialog box changes to **yes**. Also, the Model Explorer shows the name of the reference with the suffix (**Active**).

The freestanding configuration set of the active reference now provides the configuration parameters for the model.

Manage Configuration Reference Across Referenced Models

In a model hierarchy, you can share a configuration reference across referenced models. Using the Configuration Reference Propagation dialog box, you can propagate a configuration reference of a top model to an individual referenced model or to all referenced models in the model hierarchy. The dialog box provides:

- A list of referenced models in the top model.
- The ability to select only specific referenced models for propagation.
- After propagation, the status for the converted configuration for each referenced model.
- A view of the changed parameters after the propagation.
- The ability to undo the configuration reference and restore the previous configuration settings for a referenced model.

To open the dialog box, in the Model Explorer, in the model hierarchy pane, right-click the configuration reference node of a model. In the context menu, select **Propagate to Referenced Models**. For an example, see “Share a Configuration Across Referenced Models” on page 13-6.

Change Parameter Values in a Referenced Configuration Set

To obtain a referenced configuration set:

- 1 In the Model Hierarchy pane, select the configuration reference, or right-click the configuration reference, and select **Open** from the context menu.

The Configuration Reference dialog box appears in the Dialog pane or in a separate window.

- 2 To the right of the **Referenced configuration** field, click **Open**. The Configuration Parameters dialog box opens. You can now change and apply parameter values as you would for any configuration set.

Save a Referenced Configuration Set

If your model uses a configuration reference to specify the model configuration, before closing your model, you need to save the referenced configuration set to a MAT-file or MATLAB script.

- 1 In the Model Explorer, in the Model Hierarchy, select **Base Workspace**.
- 2 In the Contents pane, right-click the name of the referenced configuration set object.
- 3 From the context menu, select **Export Selected**.
- 4 Specify the filename for saving the configuration set as either a MAT-file or a MATLAB script.

Tip When you reopen the model you must load the saved configuration set, otherwise, the configuration reference is unresolved. To set up your model to automatically load the configuration set object, see “Callbacks for Customized Model Behavior” on page 4-56.

Load a Saved Referenced Configuration Set

If your model uses a configuration reference to specify the model configuration, you need to load the referenced configuration set from a MAT-file or MATLAB script to the base workspace.

- 1 In the Model Explorer, in the Model Hierarchy, right-click **Base Workspace**.
- 2 From the context menu, select **Import**.
- 3 Specify the filename for the saved configuration set and select OK. The configuration set object appears in the base workspace.

Tip When you reopen the model you must load the saved configuration set, otherwise, the configuration reference is unresolved. To set up your model to automatically load the configuration set object, see “Callbacks for Customized Model Behavior” on page 4-56.

More About

- “About Configuration References” on page 13-28

About Configuration Sets

In this section...
“What Is a Configuration Set?” on page 13-25
“What Is a Freestanding Configuration Set?” on page 13-26

What Is a Configuration Set?

A configuration set comprises groups of related parameters called components. Every configuration set includes the following components:

- Solver
- Data Import/Export
- Optimization
- Diagnostics
- Hardware Implementation
- Model Referencing
- Simulation Target

Some MathWorks products that work with Simulink, such as Simulink Coder, define additional components. If such a product is installed on your system, the configuration set also contains the components that the product defines.

When you select any model configuration, the Model Configuration dialog appears in the Model Explorer **Dialog** pane. In this location, you can edit the name and description of your configuration.

Tip If you want to reuse the same configuration settings in new models, use a model template. See “Use Customized Settings When Creating New Models” on page 1-8.

What Is a Freestanding Configuration Set?

A freestanding configuration set is a configuration set object, `Simulink.ConfigSet`, stored in the base workspace. To use a freestanding configuration set as the configuration for a model, you must create a configuration reference in the model that references it. You can create a freestanding configuration set in the base workspace in these ways:

- Create a new configuration set object.

- Copy a configuration set that resides within a model to the base workspace.
- Load a configuration set from a MAT-file.

You can store any number of configuration sets in the base workspace by assigning each set to a different MATLAB variable.

Note: Although you can store a configuration set in a model and point to it with a base workspace variable, such a configuration set is not freestanding. Using it in a configuration reference causes an error.

About Configuration References

In this section...

“What Is a Configuration Reference?” on page 13-28

“Why Use Configuration References?” on page 13-28

“Unresolved Configuration References” on page 13-29

“Configuration Reference Limitations” on page 13-29

“Configuration References for Models with Older Simulation Target Settings” on page 13-30

What Is a Configuration Reference?

A configuration reference in a model is a reference to a configuration set object in the base workspace. A model that has a configuration reference that points to a freestanding configuration set uses that configuration set when configuration reference is active. The model then has the same configuration parameters as if the referenced configuration set resides directly in the model.

You can attach any number of configuration references to a model. Each reference must have a unique name. For more information, see “Why Use Configuration References?” on page 13-28. For an example on how to use configuration references, see “Share a Configuration for Multiple Models” on page 13-4 or “Create and Attach a Configuration Reference” on page 13-18.

Tip Save or export the configuration set object. Otherwise, when you reopen your model the configuration reference is unresolved. To set up your model to automatically load the configuration set object, see “Callbacks for Customized Model Behavior” on page 4-56.

Why Use Configuration References?

You can use configuration references and freestanding configuration sets to:

- **Assign the same configuration set to any number of models**

Each model that uses a given configuration set contains a configuration reference that points to a MATLAB variable. The value of that variable is a freestanding

configuration set. All the models share that configuration set. Changing the value of any parameter in the set changes it for every model that uses the set. Use this feature to reconfigure many referenced models quickly and ensure consistent configuration of parent models and referenced models.

- **Replace the configuration sets of any number of models without changing the model files**

When multiple models use configuration references to access a freestanding configuration set, assigning a different set to the MATLAB variable assigns that set to all models. Use this feature to maintain a library of configuration sets and assign them to any number of models in a single operation.

- **Use different configuration sets for a referenced model used in different contexts without changing the model file**

A referenced model that uses different configuration sets in different contexts contains a configuration reference that specifies the referenced model configuration set as a variable. When you call an instance of the referenced model, Simulink software assigns that variable a freestanding configuration set for the current context.

Unresolved Configuration References

When a configuration reference does not reference a valid configuration set, the **Is Resolved** field of the Configuration Reference dialog box has the value **no**. If you activate an unresolved configuration reference, no warning or error occurs. However, an unresolved configuration reference that is active provides no configuration parameter values to the model. Therefore:

- Fields that display values known only by accessing a configuration parameter, like Stop Time in the model window, are blank.
- Trying to build the model, simulate it, generate code for it, or otherwise require it to access configuration parameter values, causes an error.

For more information, see “Resolve a Configuration Reference” on page 13-19.

Configuration Reference Limitations

- You cannot nest configuration references. Only one level of indirection is available, so a configuration reference cannot link to another configuration reference. Each reference must specify a freestanding configuration set.

- If you activate a configuration reference when using a custom target, the `ActivateCallback` function does not trigger to notify the corresponding freestanding configuration set. Likewise, if a freestanding configuration set switches from one target to another, the `ActivateCallback` function does not trigger to notify the new target. This behavior occurs, even if an active configuration reference points to that target. For more information about `ActivateCallback` functions, see “`rtwgensettings Structure`” in the Simulink Coder documentation.

Configuration References for Models with Older Simulation Target Settings

Suppose that you have a nonlibrary model that contains one of these blocks:

- MATLAB Function
- Stateflow chart
- Truth Table
- Attribute Function

In R2008a and earlier, this type of nonlibrary model does not store simulation target (or `Sfun`) settings in the configuration parameters. Instead, the model stores the settings outside any configuration set.

When you load this older type of model, the simulation target settings migrate to parameters in the active configuration set.

- If the active configuration set resides internally with the model, the migration happens automatically.
- If the model uses an active configuration reference to point to a configuration set in the base workspace, the migration process is different.

The following sections describe the two types of migration for nonlibrary models that use an active configuration reference.

Default Migration Process That Disables the Configuration Reference

Because multiple models can share a configuration set in the base workspace, loading a nonlibrary model cannot automatically change any parameter values in that configuration set. By default, these actions occur during loading of a model to ensure that simulation results are the same, no matter which version of the software that you use:

- A copy of the configuration set in the base workspace attaches to the model.
- The simulation target settings migrate to the corresponding parameters in this new configuration set.
- The new configuration set becomes active.
- The old configuration reference becomes inactive.

A warning message appears in the MATLAB Command Window to describe those actions. Although this process ensures consistent simulation results for the model, it disables the configuration reference that links to the configuration set in the base workspace.

“Change Values in a Referenced Configuration Set” on page 13-37

“Obtain a Configuration Reference Handle” on page 13-38

Overview

An application programming interface (API) lets you create and manipulate configuration sets at the command line or in a script. The API includes the `Simulink.ConfigSet` and `Simulink.ConfigSetRef` classes and the following functions:

- `attachConfigSet`
- `attachConfigSetCopy`
- `detachConfigSet`
- `getConfigSet`
- `getConfigSets`
- `setActiveConfigSet`
- `getActiveConfigSet`
- `openDialog`
- `closeDialog`
- `Simulink.BlockDiagram.saveActiveConfigSet`
- `Simulink.BlockDiagram.loadActiveConfigSet`

These functions, along with the methods and properties of `Simulink.ConfigSet` class, allow you to create a script to:

- Create and modify configuration sets.
- Attach configuration sets to a model.
- Set the active configuration set for a model.
- Open and close configuration sets.
- Detach configuration sets from a model.
- Save configuration sets.
- Load configuration sets.

For examples using the preceding functions and the `Simulink.ConfigSet` class, see the function and class reference pages.

Load and Activate a Configuration Set at the Command Line

To load a configuration set from a MATLAB function or script:

- 1 Use the `getActiveConfigSet` or `getConfigSet` function to get a handle to the configuration set that you want to update.
- 2 Call the MATLAB function or execute the MATLAB script to load the saved configuration set.
- 3 Optionally, use the `attachConfigSet` function to attach the configuration set to the model. To avoid configuration set naming conflicts, set `allowRename` to `true`.
- 4 Optionally, use the `setActiveConfigSet` function to activate the configuration set.

Alternatively, to load a configuration set at the command line and make it the active configuration set:

- 1 Open the model.
- 2 Use the `Simulink.BlockDiagram.loadActiveConfigSet` function to load the configuration set and make it active.

Note: If you load a configuration set with the same name as the:

- Active configuration set, the software overwrites the active configuration set.

- Inactive configuration set that is associated with the model, the software detaches the inactive configuration from the model.
-

Save a Configuration Set at the Command Line

To save an active or inactive configuration set as a MATLAB function or script:

- 1 Use the `getActiveConfigSet` or `getConfigSet` function to get a handle to the configuration set.
- 2 Use the `saveAs` method of the `Simulink.Configset` class to save the configuration set as a function or script.

Alternatively, to save the active configuration set:

- 1 Open the model.
- 2 Use the `Simulink.BlockDiagram.saveActiveConfigSet` function to save the active configuration set.

Create a Freestanding Configuration Set at the Command Line

Copy a Configuration Set Stored in a Model

Create a freestanding configuration set to be referenced by a configuration reference in several models. You must copy any configuration set obtained from an existing model, otherwise, `cset` refers to the existing configuration set stored in the model, rather than a new freestanding configuration set in the base workspace. For example, use one of the following:

- `cset = copy (getActiveConfigSet(model))`
- `cset = copy (getConfigSet(model, ConfigSetName))`

model is any open model, and *ConfigSetName* is the name of any configuration set attached to the model.

Read a Configuration Set from a MAT-File

To use a freestanding configuration set across multiple MATLAB sessions, you can save it to a MAT-file. To create the MAT-file, you first copy the configuration set to a base workspace variable, then save the variable to the MAT-file:

```
save (workfolder/ConfigSetName.mat, cset)
```

workfolder is a working folder, *ConfigSetName.mat* is the MAT-file name, and *cset* is a base workspace variable whose value is the configuration set to save. When you later reopen your model, you can reload the configuration set into the variable:

```
load (workfolder/ConfigSetName.mat)
```

To execute code that reads configuration sets from MAT-files, use one of these techniques:

- The preload function of a top model
- The MATLAB startup script
- Interactive entry of load statements

Create and Attach a Configuration Reference at the Command Line

To create and populate a configuration reference, `Simulink.ConfigSetRef`, using the API:

- 1 Create the reference:

```
cref = Simulink.ConfigSetRef
```

- 2 Change the default name if desired:

```
cref.Name = 'ConfigSetRefName'
```

- 3 Specify the referenced configuration set:

```
cref.SourceName = 'cset'
```

Tip Do not specify the name of a configuration reference. If you nest a configuration reference, an error occurs.

- 4 Attach the reference to a model:

```
attachConfigSet(model, cref, true)
```

The third argument is optional and authorizes renaming to avoid a name conflict.

Using a configuration reference with an invalid configuration set, `SourceName`, generates an error and is called an unresolved configuration reference. The GUI

equivalent of `SourceName` is **Referenced configuration**. You can later use the API or GUI to provide the name of a freestanding configuration set. For more information, see “Unresolved Configuration References” on page 13-29.

Note: A `Simulink.ConfigSetRef` object cannot be saved to a MATLAB file. To save the configuration, call the `Simulink.ConfigSetRef.getRefConfigSet` method. Then save the `Simulink.ConfigSet` object that the method returns. For more information, see “Save a Configuration Set at the Command Line” on page 13-34.

Attach a Configuration Reference to Multiple Models at the Command Line

After you create a configuration reference and attach it to a model, you can attach copies of the reference to any other models. Each model has its own copy of any configuration reference attached to it, just as each model has its own copy of any attached configuration set.

If you use the GUI, attaching an existing configuration reference to another model automatically attaches a distinct copy to the model. If necessary to prevent name conflict, the GUI adds or increments a digit at the end of the name of the copied reference. If you use the API, be sure to copy the configuration reference explicitly before attaching it, with statements like:

```
cref = copy (getConfigSet(model, ConfigSetRefName))  
attachConfigSet (model, cref, true)
```

If you omit the `copy` operation, `cref` becomes a handle to the original configuration reference, rather than a copy of the reference. Any attempt to use `cref` causes an error. If you omit the argument `true` to `attachConfigSet`, the operation fails if a name conflict exists.

The following example shows code for obtaining a freestanding configuration set and attaching references to it from two models. After the code executes, one of the models contains an internal configuration set and a configuration reference that points to a freestanding copy of that set. If the internal copy is an extra copy, you can remove it with `detachConfigSet`, as shown in the last line of the example.

```
open_system('model1')  
% Get handle to local cset
```

```

cset = getConfigSet('model1', 'Configuration')

% Create freestanding copy; original remains in model
cset1 = copy(cset)

% In the original model, create a configuration
% reference to the cset copy
cref1 = Simulink.ConfigSetRef
cref1.SourceName = 'cset1'

% Attach the configuration reference to the model
attachConfigSet('model1', cref1, true)

% In a second model, create a configuration
% reference to the same cset
open_system('model2')
% Rename if name conflict occurs
attachConfigSetCopy('model2', cref1, true)

% Delete original cset from first model
detachConfigSet('model1', 'Configuration')

```

Get Values from a Referenced Configuration Set

You can use `get_param` on a configuration reference to obtain parameter values from the linked configuration set, as if the reference object were the configuration set itself. Simulink software retrieves the referenced configuration set and performs the indicated `get_param` on it.

For example, if configuration reference *cref* links to configuration set *cset*, the following operations give identical results:

```

get_param (cset, 'StopTime')
get_param (cref, 'StopTime')

```

Change Values in a Referenced Configuration Set

By operating on only a configuration reference, you cannot change the referenced configuration set parameter values. If you execute:

```

set_param (cset, 'StopTime', '300')
set_param (cref, 'StopTime', '300')           % ILLEGAL

```

the first operation succeeds, but the second causes an error. Instead, you must obtain the configuration set itself and change it directly, using the GUI or the API.

To obtain a referenced configuration set using the API:

- 1 Follow the instructions in “Obtain a Configuration Reference Handle” on page 13-38.
- 2 Obtain the configuration set *cset* from the configuration reference *cref*:

```
cset = cref.getRefConfigSet
```

You can now use `set_param` on *cset* to change parameter values. For example:

```
set_param (cset, 'StopTime', '300')
```

Tip If you want to change parameter values through the GUI, execute:

```
cset.openDialog
```

The Configuration Parameters dialog box opens on the specified configuration set.

Obtain a Configuration Reference Handle

Most functions and methods that operate on a configuration reference take a handle to the reference. When you create a configuration reference:

```
cref = Simulink.ConfigSetRef
```

the variable *cref* contains a handle to the reference. If you do not already have a handle, you can obtain one by executing:

```
cref = getConfigSet(model, 'ConfigSetRefName')
```

ConfigSetRefName is the name of the configuration reference as it appears in the Model Explorer, for example, **Reference**. You specify this name by setting the **Name** field in the Configuration Reference dialog box or executing:

```
cref.Name = 'ConfigSetRefName'
```

The technique for obtaining a configuration reference handle is the same technique you use to obtain a configuration set handle. Wherever the same operation applies to both configuration sets and configuration references, applicable functions and methods overload to perform correctly with either class.

Concepts in Multicore Programming

In this section...

“Basics of Multicore Programming” on page 14-2

“Types of Parallelism” on page 14-3

“System Partitioning for Parallelism” on page 14-6

“Challenges in Multicore Programming” on page 14-7

Basics of Multicore Programming

Multicore programming helps you create concurrent systems for deployment on multicore processor and multiprocessor systems. A *multicore processor system* is a single processor with multiple execution cores in one chip. By contrast, a *multiprocessor system* has multiple processors on the motherboard or chip. A multiprocessor system might include a Field-Programmable Gate Array (FPGA). An FPGA is an integrated circuit containing an array of programmable logic blocks and a hierarchy of reconfigurable interconnects. A *processing node* processes input data to produce outputs. It can be a processor in a multicore or multiprocessor system, or an FPGA.

The multicore programming approach can help when:

- You want to take advantage of multicore and FPGA processing to increase the performance of an embedded system.
- You want to achieve scalability so your deployed system can take advantage of increasing numbers of cores and FPGA processing power over time.

Concurrent systems that you create using multicore programming have multiple tasks executing in parallel. This is known as *concurrent execution*. When a processor executes multiple parallel tasks, it is known as *multitasking*. A CPU has firmware called a scheduler, which handles the tasks that execute in parallel. The CPU implements tasks using operating system threads. Your tasks can execute independently but have some data transfer between them, such as data transfer between a data acquisition module and controller for the system. Data transfer between tasks means that there is a *data dependency*.

Multicore programming is commonly used in signal processing and plant-control systems. In signal processing, you can have a concurrent system that processes multiple frames

in parallel. In plant-control systems, the controller and the plant can execute as two separate tasks. Using multicore programming helps to split your system into multiple parallel tasks, which run simultaneously, speeding up the overall execution time.

To model a concurrently executing system, see “Partitioning Guidelines” on page 14-37.

Types of Parallelism

The concept of multicore programming is to have multiple system tasks executing in parallel. Types of parallelism include:

- Data parallelism
- Task parallelism
- Pipelining

Data Parallelism

Data parallelism involves processing multiple pieces of data independently in parallel. The processor performs the same operation $F()$ on each piece of data. You achieve parallelism by feeding the data in parallel.

The figure shows the timing diagram for this parallelism. The input is divided into four chunks, A, B, C, and D. The same operation $F()$ is applied to each of these pieces and the output is O_A , O_B , O_C , and O_D respectively. All four tasks are identical, and they run in parallel.

The time taken per processor cycle, known as cycle time, is

$$t = tF.$$

The total processing time is also tF , since all four tasks run simultaneously. In the absence of parallelism, all four pieces of data are processed by one processing node. The cycle time is tF for each task but the total processing time is $4 * tF$, since the pieces are processed in succession.

You can use data parallelism in scenarios where it is possible to process each piece of input data independently. For example, a web database with independent data sets for processing or processing frames of a video independently are good candidates for data parallelism.

Task Parallelism

In contrast to data parallelism, task parallelism doesn't split up the input data. Instead, it achieves parallelism by splitting up an application into multiple tasks. Task parallelism involves distributing tasks within an application across multiple processing nodes. Some tasks can have data dependency on others, so all tasks do not run at exactly the same time.

Consider a system that involves four functions. Functions F2a() and F2b() are in parallel, that is, they can run simultaneously. In task parallelism, you can divide your computation into two tasks. Function F2b() runs on a separate processing node after it gets data Out1 from Task 1, and it outputs back to F3() in Task 1.

The figure shows the timing diagram for this parallelism. Task 2 does not run until it gets data Out1 from Task 1. Hence, these tasks do not run completely in parallel. The time taken per processor cycle, known as cycle time, is

$$t = tF1 + \max(tF2a, tF2b) + tF3.$$

You can use task parallelism in scenarios such as a factory where the plant and controller run in parallel.

Model Pipeline Execution (Pipelining)

Use model pipeline execution, or pipelining, to work around the problem of task parallelism where threads do not run completely in parallel. This approach involves modifying your system model to introduce delays between tasks where there is a data dependency.

In this figure, the system is divided into three tasks to run on three different processing nodes, with delays introduced between functions. At each time step, each task takes in the value from the previous time step by way of the delay.

Each task can start processing at the same time, as this timing diagram shows. These tasks are truly parallel and they are no longer serially dependent on each other in one processor cycle. The cycle time does not have any additions but is the maximum processing time of all the tasks.

$$t = \max(\text{Task1}, \text{Task2}, \text{Task3}) = \max(t_{F1}, t_{F2a}, t_{F2b}, t_{F3}).$$

You can use pipelining wherever you can introduce delays artificially in your concurrently executing system. The resulting overhead due to this introduction must not exceed the time saved by pipelining.

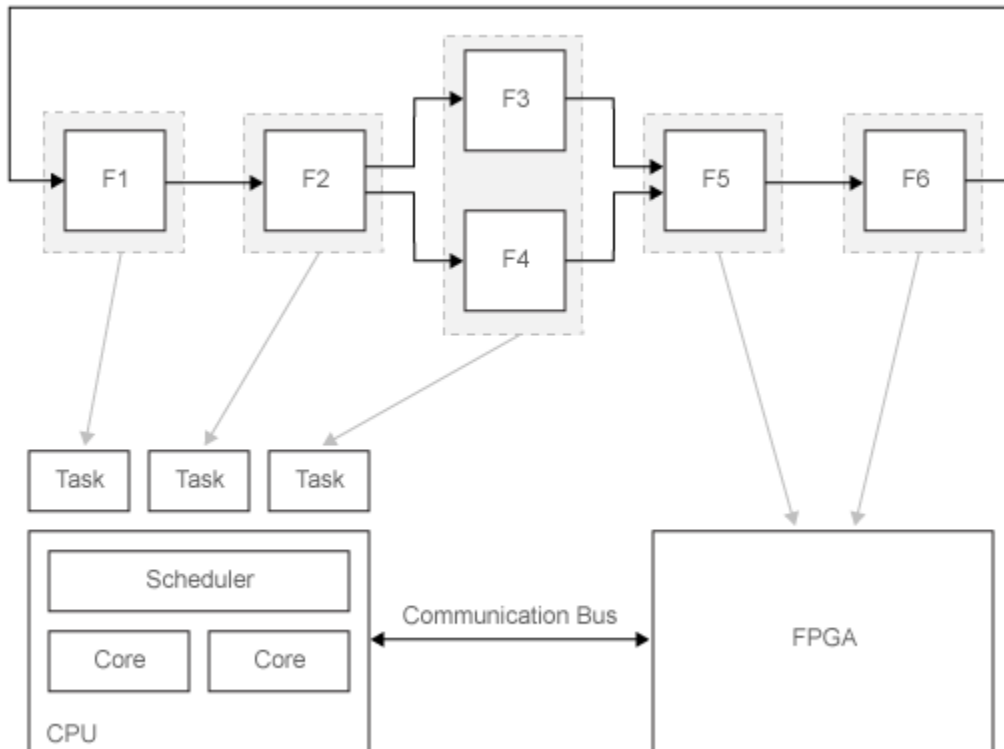

System Partitioning for Parallelism

Partitioning methods help you to designate areas of your system for concurrent execution. Partitioning allows you to create tasks independently of the specifics of the target system on which the application is deployed.

Consider this system. F1–F6 are functions of the system that can be executed independently. An arrow between two functions indicates a data dependency. For example, the execution of F5 has a data dependency on F3.

Execution of these functions is assigned to the different processor nodes in the target system. The grey arrows indicate assignment of the functions to be deployed on the CPU

or the FPGA. The CPU scheduler determines when individual tasks run. The CPU and FPGA communicate via a common communication bus.

The figure shows one possible configuration for partitioning. In general, you test different configurations and iteratively improve until you get the optimal distribution of tasks for your application.

Challenges in Multicore Programming

Manually coding your application onto a multicore processor or an FPGA poses challenges beyond the problems caused by manual coding. In concurrent execution, you must track:

- Scheduling of the tasks that execute on the embedded processing system multicore processor

- Data transfers to and from the different processing nodes

Simulink manages the implementation of tasks and data transfer between tasks. It also generates the code that is deployed for the application. For more information, see “Multicore Programming with Simulink” on page 14-10.

In addition to these challenges, there are challenges when you want to deploy your application to different architectures and when you want to improve the performance of the deployed application.

Portability: Deployment to Different Architectures

The hardware configuration that runs the deployed application is known as the architecture. It can contain multicore processors, multiprocessor systems, FPGAs, or a combination of these. Deployment of the same application to different architectures can require effort due to:

- Different number and types of processor nodes on the architecture
- Communication and data transfer standards for the architecture
- Standards for certain events, synchronization, and data protection in each architecture

To deploy the application manually, you must reassign tasks to different processing nodes for each architecture. You might also need to reimplement your application if each architecture uses different standards.

Simulink helps overcome these problems by offering portability across architectures. For more information, see “How Simulink Helps You to Overcome Challenges in Multicore Programming” on page 14-11.

Deployment Efficiency

You can improve the performance of your deployed application by balancing the load of the different processing nodes in the multicore processing environment. You must iterate and improve upon your distribution of tasks during partitioning, as mentioned in “System Partitioning for Parallelism” on page 14-6. This process involves moving tasks between different processing nodes and testing the resulting performance. Since it is an iterative process, it takes time to find the most efficient distribution.

Simulink helps you to overcome these problems using profiling. For more information, see “How Simulink Helps You to Overcome Challenges in Multicore Programming” on page 14-11.

Cyclic Data Dependency

Some tasks of a system depend on the output of other tasks. The data dependency between tasks determines their processing order. Two or more partitions containing data dependencies in a cycle creates a data dependency loop, also known as an *algebraic loop*.

Simulink identifies loops in your system before deployment. For more information, see “How Simulink Helps You to Overcome Challenges in Multicore Programming” on page 14-11.

Multicore Programming with Simulink

In this section...
“Basic Workflow” on page 14-10
“How Simulink Helps You to Overcome Challenges in Multicore Programming” on page 14-11

Using the process of partitioning, mapping, and profiling in Simulink, you can address common challenges of designing systems for concurrent execution.

Partitioning enables you to designate regions of your model as tasks, independent of the details of the embedded multicore processing hardware. This independence enables you to arrange the content and hierarchy of your model to best suit the needs of your application.

In a partitioned system, mapping enables you to assign partitions to processing elements in your embedded processing system. Use the Simulink mapping tool to represent and manage the details of executing threads, HDL code on FPGAs, and the work that these threads or FPGAs perform. While creating your model, you do not need to track the partitions or data transfer between them because the tool does this work. Also, you can reuse your model across multiple architectures.

Profiling simulates deployment of your application under typical computational loads. It enables you to determine the partitioning and mapping for your model that gives the best performance, before you deploy to your hardware.

Basic Workflow

To deploy your model to the target.

- 1 Set up your model for concurrent execution.
 - If you are using a desktop target, you need to configure your model. For more information, see “Configure Your Model for Concurrent Execution” on page 14-24.
 - If you are not using a desktop target, you need to configure your model, specify a target, and explicitly partition your model. Additionally, you may want to change the default mapping of blocks to tasks in explicit partitioning. To set up your model for concurrent execution, see “Configure Your Model for Concurrent Execution” on page 14-24. To specify the target architecture, see “Specify a

Target Architecture” on page 14-25. For explicit partitioning of a model, see “Partition Your Model Using Explicit Partitioning” on page 14-31

- 2 Generate code and deploy it to your target. You can choose to deploy onto multiple targets.
 - To build and deploy on a desktop target, see “Build on Desktop” on page 14-45.
 - To deploy onto embedded targets using Embedded Coder, see “Deployment”.
 - To deploy onto FPGAs using HDL Coder™, see “Deployment”.
 - To build and deploy on a real-time target using Simulink Real-Time™, see “Standalone Operation”.
- 3 Optimize your design. This step is optional, and includes iterating over the design of your model and mapping to get the best performance, based on your metrics. One way to evaluate your model is to profile it and get execution times.

Product	Information
Desktop target	“Profile and Evaluate on a Desktop” on page 14-47
Simulink Real-Time	“Execution Profiling for Real-Time Applications”
Embedded Coder	“Perform Execution-Time Profiling for IDE and Toolchain Targets”
HDL Coder	“Speed and Area Optimization”

How Simulink Helps You to Overcome Challenges in Multicore Programming

Manually programming your application for concurrent execution poses challenges beyond the typical challenges with manual coding. With Simulink, you can overcome the challenges of portability across multiple architectures, efficiency of deployment for an architecture, and cyclic data dependencies between application components. For more information on these challenges, see “Challenges in Multicore Programming” on page 14-7

Portability

Simulink enables you to determine the content and hierarchical needs of the modeled system without considering the target system. While creating model content, you do not

need to keep track of the number of cores in your target system. Instead, you select the partitioning methods that enable you to create model content. Simulink generates code for the architecture you specify.

You can select an architecture from the available supported architectures or add a custom architecture. When you change your architecture, Simulink generates only the code that needs to change for the second architecture. The new architecture reuses blocks and functions. For more information, see “Supported Targets For Multicore Programming” on page 14-55 and “Specify a Target Architecture” on page 14-25.

Deployment Efficiency

To improve the performance of the deployed application, Simulink allows you to simulate it under typical computational loads and try multiple configurations of partitioning and mapping the application. Simulink compares the performance of each of these configurations to provide the optimal configuration for deployment. This is known as profiling. Profiling helps you to determine the optimum partition configuration before you deploy your system to the desired hardware.

You can create a mapping for your application in which Simulink maps the application components across different processing nodes. You can also manually assign components to processing nodes. For any mapping, you can see the data dependencies between components and remap accordingly. You can also introduce and remove data dependencies between different components.

Cyclic Data Dependency

Some tasks of a system depend on the output of other tasks. The data dependency between tasks determines their processing order. Two or more partitions containing data dependencies in a cycle creates a data dependency loop, also known as an *algebraic loop*. Simulink does not allow algebraic loops to occur across potentially parallel partitions because of the high cost of solving the loop using parallel algorithms.

In some cases, the algebraic loop is artificial. For example, you can have an artificial algebraic loop because of Model-block-based partitioning. An algebraic loop involving Model blocks is artificial if removing the use of Model partitioning eliminates the loop. You can minimize the occurrence of artificial loops. In the Configuration Parameter dialog boxes for the models involved in the algebraic loop, select **Model Referencing > Minimize algebraic loop occurrences**.

Additionally, if the model is configured for the Generic Real-Time target (`grt.tlc`) or the Embedded Real-Time target (`ert.tlc`) in the Configuration Parameters dialog box, clear the **All Parameters > Single output/update function** check box.

If the algebraic loop is a true algebraic condition, you must either contain all the blocks in the loop in one `Model` partition, or eliminate the loop by introducing a delay element in the loop.

The following examples show how to implement different types of parallelism in Simulink. These examples contain models that are partitioned and mapped to a simple architecture with one CPU and one FPGA.

Implement Data Parallelism in Simulink

This example shows how to implement data parallelism for a system in a Simulink model. The model consists of an input, a functional component that applies to each input, and a concatenated output. For more information on data parallelism, see “Types of Parallelism” on page 14-3.

Set up this model for concurrent execution. To see the completed model, open `ex_data_parallelism_top`.

- 1 Convert areas in this model to referenced models. Use the same referenced model to replace each of the functional components that process the input. The figure shows a sample configuration.

- 2 Open the Model Explorer.
- 3 Expand the options for the top-level model and right-click the **Configuration (Active)**, the active configuration set. Select **Show Concurrent Execution options** to see how the options for concurrent execution are set in the model configuration parameters.
- 4 Close the Model Explorer and open the model configuration parameters. In the **All Parameters** tab, clear the **MAT-file logging** check box.
- 5 On the **Solver** pane, set **Type** to **Fixed-step** and click **Apply**. Under **Additional options**, click **Configure Tasks**.
- 6 In the Concurrent Execution dialog box, in the right pane, select the **Enable explicit model partitioning for concurrent behavior** check box. With explicit partitioning, you can partition your model manually.
- 7 In the selection pane, select **CPU**. Click **Add task**  four times to add four new tasks.
- 8 In the selection pane, select **Tasks and Mapping**. On the **Map block to tasks** pane:
 - Under **Block: Input**, click **select task** and select **Periodic: Task**.
 - Under **Block: Function 1**, select **Periodic: Task1**.
 - Under **Block: Function 2**, select **Periodic: Task2**.
 - Under **Block: Function 3**, select **Periodic: Task3**.

- Under **Block: Output**, select **Periodic: Task**.

This maps your partitions to the tasks you created. The Input and Output model blocks are on one task. Each functional component is assigned a separate task.

- 9 In the selection pane, select **Data transfer**. In the **Data Transfer Options** pane, set the parameter **Periodic signals** to **Ensure deterministic transfer (minimum delay)**. Click **Apply** and close the Concurrent Execution dialog box.
- 10 Apply these configuration parameters to all referenced models. For more information, see “Share a Configuration for Multiple Models” on page 13-4.

Update your model to see the tasks mapped to individual model blocks.

Configure Your Model for Concurrent Execution

Follow these steps to configure your Simulink model to take advantage of concurrent execution.

- 1 Open your model.
- 2 Open Model Explorer and expand the node for the model. Under the model, right-click **Configuration**, then select **Show Concurrent Execution options**.
- 3 Select the **Allow tasks to execute concurrently on target** check box in the **Solver** pane of the Configuration Parameters dialog box. Selection of this check box is optional for models referenced in the model hierarchy. When you select this option for a referenced model, Simulink allows each rate in the referenced model to execute as an independent concurrent task on the target processor.
- 4 Clear the **MAT-file logging** check box in the **All Parameters** tab.
- 5 Choose **Fixed-step** for the **Type** and **auto (Automatic solver selection)** for the **Solver** in **Configuration Parameters > Solver > Solver options**.

Once you have a model that executes concurrently on your computer, you can further configure your model in the following ways.

- “Specify a Target Architecture” on page 14-25
- Explicitly map blocks to tasks. For more information, see “Partition Your Model Using Explicit Partitioning” on page 14-31.
- “Configure Data Transfer Settings Between Concurrent Tasks” on page 14-40

Specify a Target Architecture

In this section...

“Choose from Predefined Architectures” on page 14-25

“Define a Custom Architecture File” on page 14-27

For models configured for concurrent execution, you can choose the architecture to which you want to deploy your model. Choose from a set of predefined architectures in Simulink, or you can create an interface for a custom architecture. After selecting your architecture, you can use explicit partitioning to specify which tasks run on it. For more information, see “Partition Your Model Using Explicit Partitioning” on page 14-31.

Choose from Predefined Architectures

You can choose from the predefined architectures available in Simulink, or you can download support packages for different available architectures.

- 1 In the Concurrent Execution dialog box, in the **Concurrent Execution** pane, click **Select**. The concurrent execution target architecture selector appears.

- 2 Select your target.

Property	Description
Multicore	Single CPU with multiple cores.
Sample Architecture	Single CPU with multiple cores and two FPGAs.
Simulink Real-Time	Simulink Real-Time target.
Get more ...	Click OK to start the Support Package Installer. From the list, select the target and follow the instructions.

- 3 In the Target architecture window, clear the **Preserve compatible properties** check box to reset existing target property settings to their default. Alternatively, select the **Preserve compatible properties** check box to preserve existing target property settings.
- 4 Click **OK**.

Simulink adds the corresponding software and hardware nodes to the configuration tree hierarchy. For example, the following illustrates one software node and two hardware nodes added to the configuration tree when you select **Sample architecture** as the target architecture.

Define a Custom Architecture File

A custom architecture file is an XML file that allows you to define custom target properties for tasks and triggers. For example, you may want to define custom properties to represent threading APIs. Threading APIs are necessary to take advantage of concurrency on your target processor.

The following is an example custom architecture file:

```
<architecture brief="Multicore with custom threading API"
  format="1.1" revision="1.1"
```

```

        uuid="MulticoreCustomAPI" name="MulticoreCustomAPI">
<configurationSet>
  <parameter name="SystemTargetFile" value="ert.tlc"/>
  <parameter name="SystemTargetFile" value="grt.tlc"/>
</configurationSet>
<node name="MulticoreProcessor" type="SoftwareNode" uuid="MulticoreProcessor"/>
<template name="CustomTask" type="Task" uuid="CustomTask">
  <property name="affinity" prompt="Affinity:" value="1" evaluate="true"/>
  <property name="schedulingPolicy" prompt="Scheduling policy:" value="Rate-monotonic">
    <allowedValue>Rate-monotonic</allowedValue>
    <allowedValue>Round-robin</allowedValue>
  </property>
</template>
</architecture>

```

An architecture file must contain:

- The architecture element that defines basic information used by Simulink to identify the architecture.
- A `configurationSet` element that lists the system target files for which this architecture is valid.
- One node element that Simulink uses to identify the multicore processing element.

Note: The architecture must contain exactly one node element that identifies a multicore processing element. You cannot create multiple nodes identifying multiple processing elements or an architecture with no multicore processing element.

- One or more template elements that list custom properties for tasks and triggers.
 - The type attribute can be `Task`, `PeriodicTrigger`, or `AperiodicTrigger`.
 - Each property is editable and has the default value specified in the `value` attribute.
 - Each property can be a text box, check box, or combo box. A check box is one where you can set the `value` attribute to `on` or `off`. A combo box is one where you can optionally list `allowedValue` elements as part of the property.
 - Each text box property can also optionally define an `evaluate` attribute. This lets you place MATLAB variable names as the value of the property.

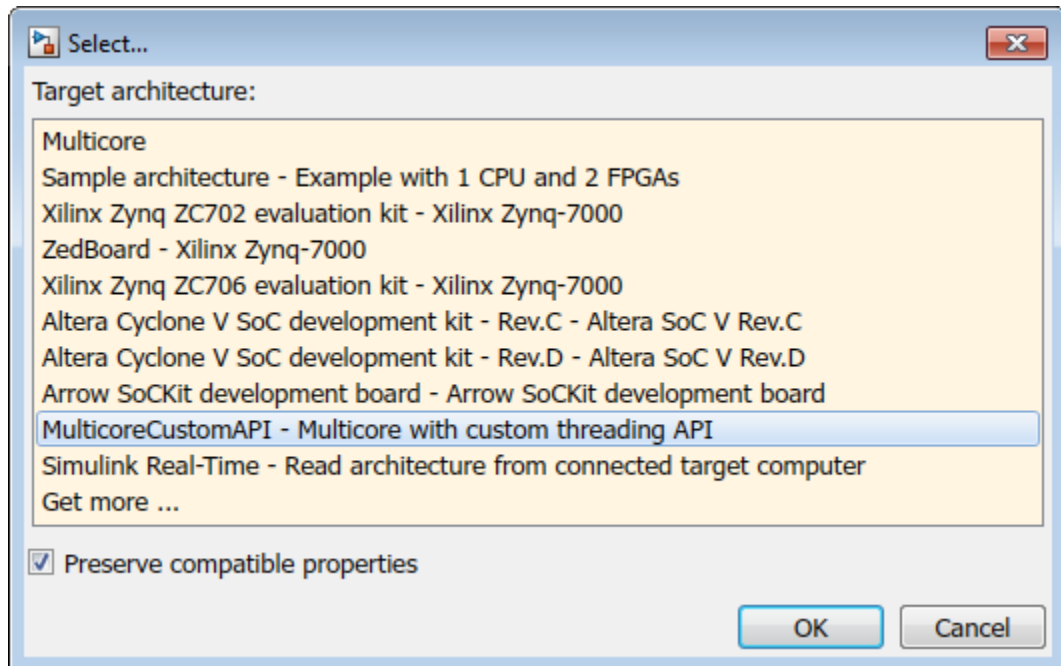

Assuming that you have saved the custom target architecture file in `C:\custom_arch.xml`, register this file with Simulink using the `Simulink.architecture.register` function.

For example:

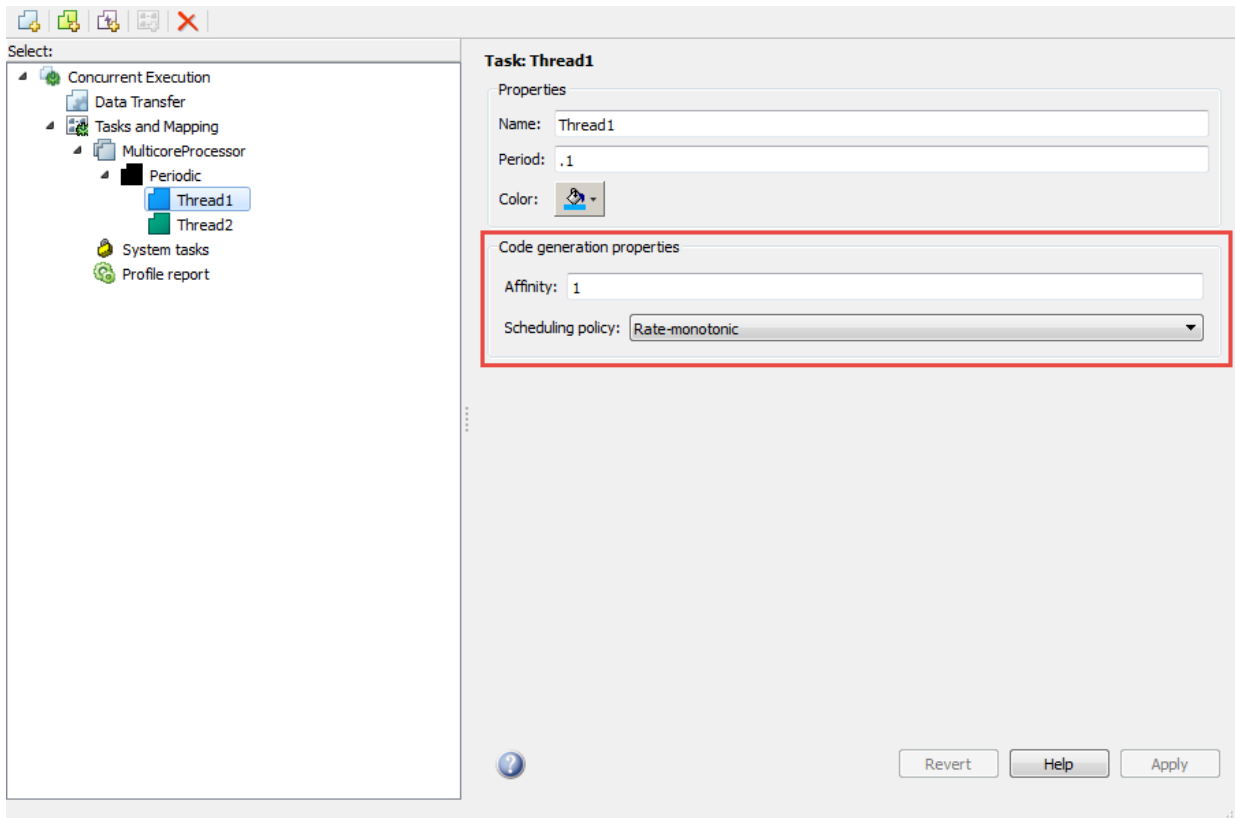

- 1 Save the contents of the listed XML file in `custom_arch.xml`.
- 2 In the MATLAB Command Window, type:

```
Simulink.architecture.register('custom_arch.xml')
```
- 3 In the MATLAB Command Window, type:

```
slexMulticoreSolverExample
```
- 4 In the Simulink editor, open the **Configuration Parameters** > **Solver** pane and click **Configure Tasks**. The Concurrent Execution dialog box displays.
- 5 In the **Concurrent Execution** pane, click **Select...** under **Target Architecture**. The Target architecture window displays.
- 6 Select `MulticoreCustomAPI` and click **OK**.

Your Concurrent Execution dialog box updates to contain Code Generation properties for the tasks as shown. These are the properties defined in the XML file.

Partition Your Model Using Explicit Partitioning

When you have a model that is configured for concurrent execution, you can add tasks, create partitions, and map individual tasks to partitions using explicit partitioning. This enables you to execute different parts of your model to different parts of your architecture. For more information, see “Implicit and Explicit Partitioning of Models” on page 14-37.

In this section...

“Prerequisites for Explicit Partitioning” on page 14-31

“Add Periodic Triggers and Tasks” on page 14-31

“Add Aperiodic Triggers and Tasks” on page 14-32

“Map Blocks to Tasks, Triggers, and Nodes” on page 14-34

Prerequisites for Explicit Partitioning

To use explicit partitioning, you must meet the following prerequisites:

- 1 Set up your model for concurrent execution. For more information, see “Configure Your Model for Concurrent Execution” on page 14-24.
- 2 Convert all blocks at the root level of your model into MATLAB System blocks or models that are referenced using Model blocks. For more information, see “Implicit and Explicit Partitioning of Models” on page 14-37.

Note: When using referenced models, replicate the model configuration parameters of the top model to the referenced models. Consider using a single configuration reference to use for all of your referenced models. For more information, see “Configuration Reuse”.

- 3 Select the target architecture on which to deploy your model. For more information, see “Specify a Target Architecture” on page 14-25.

Add Periodic Triggers and Tasks

Add periodic tasks for components in your model that you want to execute periodically. To add aperiodic tasks whose execution is trigger based, see “Add Aperiodic Triggers and Tasks” on page 14-32.

If you want to explore the effects of increasing the concurrency on your model execution, you can create additional periodic tasks in your model.

- 1 In the Concurrent Execution dialog box, right-click the **Periodic** node and select **Add task**.

A task node appears in the Configuration Execution hierarchy.

- 2 Select the task node and enter a name and period for the task, then click **Apply**.

The task node is renamed to the name you enter.

- 3 Optionally, specify a color for the task. The color illustrates the block-to-task mapping. If you do not assign a color, Simulink chooses a default color. If you enable sample time colors for your model, the software honors the setting.
- 4 Click **Apply** as necessary.

To create more periodic triggers, click the **Add periodic trigger** symbol. You can also create multiple periodic triggers with their own trigger sources.

Note: Periodic triggers let you represent multiple periodic interrupt sources such as multiple timers. The periodicity of the trigger is either the base rate of the tasks that the trigger schedules, or the period of the trigger. Data transfers between triggers can only be **Ensure Data Integrity Only** types. With blocks mapped to periodic triggers, you can only generate code for `ert.tlc` and `grt.tlc` system target files.

To delete tasks and triggers, right-click them in the pane and select **Delete**.

When the periodic tasks and trigger configurations are complete, configure the aperiodic (interrupt) tasks as necessary. If you do not need aperiodic tasks, continue to “Map Blocks to Tasks, Triggers, and Nodes” on page 14-34.

Add Aperiodic Triggers and Tasks

Add aperiodic tasks for components in your model whose execution is interrupt-based. To add periodic tasks whose execution is periodic, see “Add Periodic Triggers and Tasks” on page 14-31.

- 1 To create an aperiodic trigger, in the Concurrent Execution dialog box, right-click the **Concurrent Execution** node and click the **Add aperiodic trigger** symbol.

A node named **Interrupt N** appears in the configuration tree hierarchy, where N is an integer.

2 Select **Interrupt**.

This node represents an aperiodic trigger for your system.

3 Specify the name of the trigger and configure the aperiodic trigger source. Depending on your deployment target, choose either **Posix Signal (Linux/VxWorks 6.x)** or **Event (Windows)**. For POSIX[®] signals, specify the signal number to use for delivering the aperiodic event. For Windows events, specify the name of the event.

4 Click **Apply**.

The software services aperiodic triggers as soon as possible. If you want to process the trigger response using a task:

1 Right-click the **Interrupt** node and select **Add task**.

A new task node appears under the **Interrupt** node.

2 Specify the name of the new task node.

- 3 Optionally, specify a color for the task. The color illustrates the block-to-task mapping. If you do not assign a color, Simulink chooses a default color.
- 4 Click **Apply**.

To delete tasks and triggers, right-click them in the pane and select **Delete**.

Once you have created your tasks and triggers, map your execution components to these tasks. For more information, see “Map Blocks to Tasks, Triggers, and Nodes” on page 14-34.

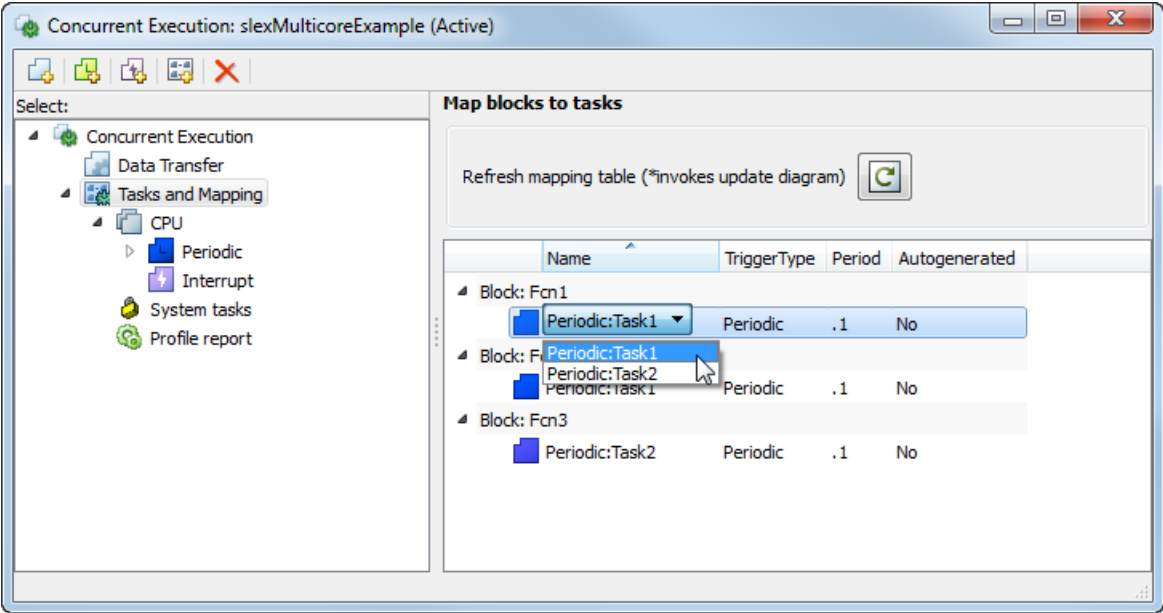

Map Blocks to Tasks, Triggers, and Nodes

After you create the tasks and triggers, you can explicitly assign partitions to these execution elements.

- 1 In the Concurrent Execution dialog box, click the **Tasks and Mapping** node.

The **Tasks and Mapping** pane appears. If you add a Model block to your model, the new block appears in the table with a **select task** entry under it.

- 2 If you want to add a task to a block, in the **Name** column, right-click a task under the block and select **Add new entry**.
- 3 To assign a task for the entry, click the box in the **Name** column and select an entry from the list. For example:

The block-to-task mapping symbol appears on the top-left corner of the Model block. For example:

If you assign a Model block to multiple tasks, multiple task symbols are displayed in the top-left corner.

To display the Concurrent Execution dialog box from the block, click the block-to-task mapping symbol.

- 4 Click **Apply**.

Note:

- System tasks allow you to perform mapping incrementally. This means that if there is only one periodic trigger, Simulink assigns any Model blocks or MATLAB System blocks that you have not explicitly mapped to a task, trigger, or hardware node to a task created by the system. Simulink creates at most one system task for each rate in the model. If there are multiple periodic triggers created, explicitly map the Model block partitions or MATLAB System blocks to a task, trigger, or hardware node.
 - Map Model block partitions that contain continuous blocks to the same periodic trigger.
 - You can map only Model blocks to hardware nodes. Also, if you map the Model block to a hardware node, and the Model block contains multiple periodic sample times, clear the **Allow tasks to execute concurrently on target** check box in the **Solver** pane of the Configuration Parameters dialog box.
-

When the mapping is complete, simulate the model again.

- “Multicore Programming with Simulink” on page 14-10
- “Implicit and Explicit Partitioning of Models” on page 14-37

Implicit and Explicit Partitioning of Models

When implementing multicore programming for your application in Simulink, there are two ways to partition your model for running on individual processing nodes. If you are new to multicore programming in Simulink, use the default (implicit partitioning) for your first iteration of implementing multicore programming.

The automated way of creating tasks and mapping them to your processing nodes is called *implicit partitioning*. Simulink partitions your model based on the sample time of blocks at the root level. Each sample time in your model corresponds to a partition, and all blocks of a single rate or sample time belong to the same partition. Simulink maps these partitions to tasks that run on your processor. Implicit partitioning assumes your architecture to be a single multicore CPU. The CPU task scheduler handles all the partitioned tasks.

If you want to specify how to partition your model, use *explicit partitioning*. In explicit partitioning, you create partitions in the root-level model by using referenced models, MATLAB system blocks, and so on. For example, if your model has data acquisition and a controller, partition your model by putting these components in two referenced models at the model root-level. Each sample time in a referenced model or a system block is a partition. You can add tasks to run on processing nodes in the Concurrent Execution dialog box and assign your partitions to these tasks. If some partitions are left unassigned, Simulink automatically assigns them to tasks.

In explicit partitioning, you can specify your own architecture. The default architecture is a multicore CPU, the same as the assumed architecture in implicit partitioning. Explicit partitioning has more restrictions on your root-level model than implicit partitioning. For more information, see “Limitations with Multicore Programming in Simulink” on page 14-57.

Partitioning Guidelines

There are multiple ways to partition your model for concurrent execution in Simulink. Rate-based and model-based approaches give you primarily graphical means to represent concurrency for systems that are represented using Simulink and Stateflow blocks. You can partition MATLAB code using the **MATLAB System** block. You can also partition models of physical systems using multisolver methods.

Each method has additional considerations to help you decide which to use.

Goal	Valid Partitioning Methods	Considerations
Increase the performance of a simulation on the host computer.	No partitioning method	Simulink tries to optimize the host computer performance regardless of the modeling method you use. For more information on the ways that Simulink helps you to improve performance, see “Performance”.
Increase the performance of a plant simulation in a multicore HIL (hardware-in-the-loop) system.	You can use any of the partitioning methods and their combinations.	The processing characteristics of the HIL system and the embedded processing system can vary greatly. Consider partitioning your system into more units of work than there are number of processing elements in the HIL or embedded system. This convention allows flexibility in the mapping process.
Create a valid model of a multirate concurrent system to take advantage of a multicore processing system.	You can use any of the partitioning methods and their combinations.	Partitioning can introduce signal delays to represent the data transfer requirements for concurrent execution. For more information, see “Configure Data Transfer Settings Between Concurrent Tasks” on page 14-40.
Create a valid model of a heterogeneous system to take advantage of multicore and FPGA processing.	<ul style="list-style-type: none"> • Multicore processing: Use any of the partitioning methods. • FPGA processing: Partition your model using Model blocks. 	Consider partitioning for FPGA processing where your computations have bottlenecks that could be reduced using fine-grained hardware parallelism.

Configure Data Transfer Settings Between Concurrent Tasks

Data dependencies arise when a signal originates from one block in one partition and is connected to a block in another partition. To create opportunities for parallelism, Simulink provides multiple options for handling data transfers between concurrently executing partitions. These options help you trade off computational latency for numerical signal delays.

Use the **Data Transfer Options** pane to define communications between tasks. Set the values for the `Use global setting` option of the Data Transfer tab in the Signal Properties dialog box. The table provides the model-level options that you can apply to each signal that requires data transfer in the system.

Data Transfer Options

Goal	Data Transfer Type	Simulation	Deployment
<ul style="list-style-type: none"> • Create opportunity for parallelism. • Reduce signal latency. 	Ensure data integrity only.	Data transfer is simulated using a one-step delay.	<p>Simulink Coder ensures data integrity during data transfer. Simulink generates code to operate with maximum responsiveness and data integrity. However, the implementation is interruptible, which can lead to loss of data during data transfer.</p> <p>Use a deterministic execution schedule to achieve determinism in the deployment environment.</p>
<ul style="list-style-type: none"> • Create opportunity for parallelism. 	Ensure deterministic transfer (maximum delay).	Data transfer is simulated using a one-step delay,	Simulink Coder ensures data integrity during data

Goal	Data Transfer Type	Simulation	Deployment
<ul style="list-style-type: none"> Produce numeric results that are repeatable with each run of the generated code. 		<p>which can have impact on the numeric results. To compensate, you might need to specify an initial condition for these delay elements.</p>	<p>transfer. In addition, Simulink Coder ensures that data transfer is identical with simulation.</p>
<ul style="list-style-type: none"> Enforce data dependency. Produce numeric results that are repeatable with each run of the generated code. 	<p>Ensure deterministic transfer (minimum delay).</p>	<p>Data transfer occurs within the same step.</p>	

You can also override these options for each signal from the **Data Transfer** pane of the Signal Properties dialog box. For more information, see “Data Transfer Options for Concurrent Execution”.

For example, consider a control application in which a controller that reads sensory data at time T must produce the control signals to the actuator at time $T+\Delta$.

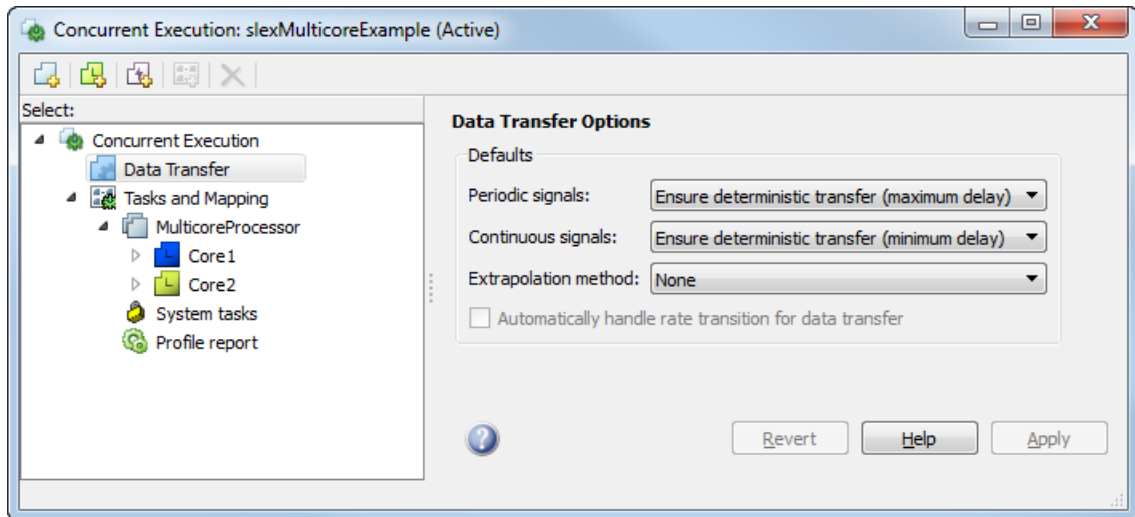

- If the sequential algorithm meets the timing deadlines, consider using option 3.
- If the embedded system provides deterministic scheduling, consider using option 2.
- Otherwise, use option 1 to create opportunities for parallelism by introducing signal delays.

For continuous signals, Simulink uses extrapolation methods to compensate for numerical errors that were introduced due to delays and discontinuities in data transfer.

To avoid numerical errors in signals configured for **Ensure Data Integrity Only** and **Ensure deterministic transfer (maximum delay)** data transfers, you may need to provide an initial condition. You can specify this initial condition in the **Data Transfer** tab of the Signal Properties dialog box. To access this dialog box, right-click the signal line and select **Properties** from the context menu. A dialog box like the following is displayed.

- 1 From the Data Transfer Options table, determine how you want your tasks to communicate.
- 2 In the Concurrent Execution dialog box, select Data Transfer defaults and apply the settings from step 1.

3 Apply your changes.

Optimize and Deploy on a Multicore Target

In this section...

“Generate Code” on page 14-44

“Build on Desktop” on page 14-45

“Profile and Evaluate on a Desktop” on page 14-47

“Customize the Generated C Code” on page 14-51

This topic shows you how to use a model that is configured for concurrent execution using explicit partitioning and deploy it onto a target. To set up your model for concurrent execution, see “Configure Your Model for Concurrent Execution” on page 14-24. To specify the target architecture, see “Specify a Target Architecture” on page 14-25. To use explicit partitioning in a model that is set up for concurrent execution, see “Partition Your Model Using Explicit Partitioning” on page 14-31.

Generate Code

To generate code for a model that is configured for concurrent execution, in the Simulink editor window, select **Code > C/C++ Code > Build Model**. The resulting code includes:

- C code for parts of the model that are mapped to tasks and triggers in the Concurrent Execution dialog box. C code generation requires a Simulink Coder license. For more information, see “Code Generation” in the Simulink Coder documentation and “Code Generation from Simulink Models” in the Embedded Coder documentation.
- HDL code for parts of the model that are mapped to hardware nodes in the Concurrent Execution dialog box. HDL code generation requires an HDL Coder license. For more information, see “HDL Code Generation from Simulink”.
- Code to handle data transfer between the concurrent tasks and triggers and to interface with the hardware and software components.

The generated C code contains one function for each task or trigger defined in the system. The task and trigger determines the name of the function:

```
void <TriggerName>_TaskName(void);
```

The content for each such function consists of target-independent C code, except for:

- Code corresponding to blocks that implement target-specific functionality

- Customizations, including those derived from “Custom Storage Classes” or “Code Replacement Libraries”
- Code that is generated to handle how data is transferred between tasks. In particular, Simulink Coder uses target-specific implementations of mutual exclusion primitives and data synchronization semaphores to implement the data transfer as described in the following table of pseudocode.

Data Transfer	Initialization	Reader	Writer
Data Integrity Only	BufferIndex = 0; Initialize Buffer[1] with IC	Begin mutual exclusion Tmp = 1 - BufferIndex; End mutual exclusion Read Buffer[Tmp];	Write Buffer[BufferIndex]; Begin mutual exclusion BufferIndex = 1 - BufferIndex; End mutual exclusion
Ensure Determinism (Maximum Delay)	WriterIndex = 0; ReaderIndex = 1; Initialize Buffer[1] with IC	Read Buffer[ReaderIndex]; ReaderIndex = 1 - ReaderIndex;	Write Buffer[WriterIndex]; WriterIndex = 1 - WriterIndex;
Ensure Determinism (Minimum Delay)	N/A	Wait dataReady; Read data; Post readDone;	Wait readDone; Write data; Post dataReady;
Data Integrity Only C-HDL interface	The Simulink Coder and HDL Coder products both take advantage of target-specific communication implementations and devices to handle the data transfer between hardware and software components.		

The generated HDL code contains one HDL project for each hardware node.

Build on Desktop

Simulink Coder and Embedded Coder targets provide an example target to generate code for Windows, Linux and Mac OS operating systems. It is known as the *native threads example*, which is used to deploy your model to a desktop target. The desktop may not be your final target, but can help to profile and optimize your model before you deploy it on another target.

If you have specified an Embedded Coder target, make the following changes in the Configuration Parameters dialog box.

- 1 Select the **Code Generation > Templates > Generate an example main program** check box.
- 2 From the **Code Generation > Templates > Target Operating System** list, select **NativeThreadsExample**.
- 3 Click **OK** to save your changes and close the Configuration Parameters dialog box.
- 4 Apply these settings to all referenced models in your model.

Once you have set up your model, press **Ctrl-B** to build and deploy it to your desktop. The native threads example illustrates how Simulink Coder and Embedded Coder use target-specific threading APIs and data management primitives, as shown in “Threading APIs Used by Native Threads Example” on page 14-46. The data transfer between concurrently executing tasks behaves as described in Data Transfer Options. The coder products use the APIs on supported targets for this behavior, as described in “Data Protection and Synchronization APIs Used by Native Threads Example” on page 14-47.

Threading APIs Used by Native Threads Example

Aspect of Concurrent Execution	Linux Implementation	Windows Implementation	Mac OS Implementation
Periodic triggering event	POSIX timer	Windows timer	Not applicable
Aperiodic triggering event	POSIX real-time signal	Windows event	POSIX non-real-time signal
Aperiodic trigger	For blocks mapped to an aperiodic task: thread waiting for a signal For blocks mapped to an aperiodic trigger: signal action	Thread waiting for an event	For blocks mapped to an aperiodic task: thread waiting for a signal For blocks mapped to an aperiodic trigger: signal action
Threads	POSIX	Windows	POSIX
Threads priority	Assigned based on sample time: fastest task has highest priority	Priority class inherited from the parent process.	Assigned based on sample time: fastest task has highest priority

Aspect of Concurrent Execution	Linux Implementation	Windows Implementation	Mac OS Implementation
		Assigned based on sample time; fastest task has highest priority for the first three fastest tasks. The rest of the tasks share the lowest priority.	
Example of overrun detection	Yes	Yes	No

Data Protection and Synchronization APIs Used by Native Threads Example

API	Linux Implementation	Windows Implementation	Mac OS Implementation
Data protection API	<ul style="list-style-type: none"> • pthread_mutex_init • pthread_mutex_ - destroy • pthread_mutex_lock • pthread_mutex_ - unlock 	<ul style="list-style-type: none"> • CreateMutex • CloseHandle • WaitForSingleObject • ReleaseMutex 	<ul style="list-style-type: none"> • pthread_mutex_init • pthread_mutex_ - destroy • pthread_mutex_lock • pthread_mutex_ - unlock
Synchronization API	<ul style="list-style-type: none"> • sem_init • sem_destroy • sem_wait • sem_post 	<ul style="list-style-type: none"> • CreateSemaphore • CloseHandle • WaitForSingle-Object • ReleaseSemaphore 	<ul style="list-style-type: none"> • sem_open • sem_unlink • sem_wait • sem_post

Profile and Evaluate on a Desktop

Profile the execution of your code on the multicore target using the **Profile Report** pane of the Concurrent Execution dialog box. You can profile using Simulink Coder (GRT) and Embedded Coder (ERT) targets. Profiling helps you identify the areas in your model that are execution bottlenecks. You can analyze the execution time of each task and find the task that takes most of the execution time. For example, you can compare the average

execution times of the tasks. If a task is computation intensive, or does not satisfy real-time requirements and overruns, you can break it into tasks that are less computation intensive and that can run concurrently.

When you generate a profile report, the software:

- 1 Builds the model.
- 2 Generates code for the model.
- 3 Adds tooling to the generated code to collect data.
- 4 Executes the generated code on the target and collects data.
- 5 Collates the data, generates an HTML file (*model_name_ProfileReport.html*) in the current folder, and displays that HTML file in the **Profile Report** pane of the Concurrent Execution dialog box.

Note: If an HTML profile report exists for the model, the **Profile Report** pane

displays that file. To generate a new profile report, click .

Section	Description
Summary	Summarizes model execution statistics, such as total execution time and profile report creation time. It also lists the total number of cores on the host machine.
Task Execution Time	Displays the execution time, in microseconds, for each task in a pie chart color coded by task. Visible for Windows, Linux, and Mac OS platforms.
Task Affinitization to Processor Cores	Platform-dependent. For each time step and task, Simulink displays the processor core number the task started executing on at that time step, color coded by processor. If there is no task scheduled for a particular time step, NR is displayed. Visible for Windows and Linux platforms.

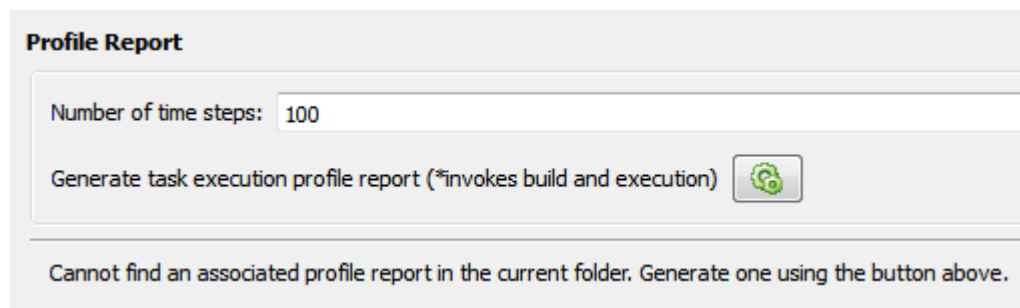

After you analyze the profile report, consider changing the mapping of Model blocks to efficiently use the concurrency available on your multicore system (see “Map Blocks to Tasks, Triggers, and Nodes” on page 14-34).

Generate Profile Report

This topic assumes a previously configured model ready to be profiled for concurrent execution. For more information, see “Configure Your Model for Concurrent Execution” on page 14-24.

- 1 In the Concurrent Execution dialog box, click the **Profile report** node.

The profile tool looks for a file named *model_name_ProfileReport.html*. If such a file does not exist for the current model, the **Profile Report** pane displays the following.

Note: If an HTML profile report exists for the model, the **Profile Report** pane displays that file. To generate a new profile report, click .

- 2 Enter the number of time steps for which you want the profiler to collect data for the model execution.
- 3 Click the **Generate task execution profile report** button.

This action builds the model, generates code, adds data collection tooling to the code, and executes it on the target, which also generates an HTML profile report. This process can take several minutes. When the process is complete, the contents of the profile report appear in the **Profile Report** pane. For example:

Generate Profile Report at Command Line

Alternatively, you can generate a profile report for a model configured for concurrent execution at the command line. Use the `Simulink.architecture.profile` function.

For example, to create a profile report for the model `slexMulticoreSolverExample`:

```
Simulink.architecture.profile('slexMulticoreSolverExample');
```

To create a profile report with a specific number of samples (100) for the model `slexMulticoreSolverExample`:

```
Simulink.architecture.profile('slexMulticoreSolverExample',120);
```

The function creates a profile report named `slexMulticoreSolverExample_ProfileReport.html` in your current folder.

Customize the Generated C Code

The generated code is suitable for many different applications and development environments. To meet your needs, you can customize the generated C code as described in “Target Development”. In addition to those customization capabilities, for multicore and heterogeneous targets you can further customize the generated code as follows:

- You can register your preferred implementation of mutual exclusion and data synchronization primitives using the code replacement library.
- You can define a custom target architecture file that allows you to specify target specific properties for tasks and triggers in the Concurrent Execution dialog box. For more information, see “Define a Custom Architecture File” on page 14-27.

- “Implicit and Explicit Partitioning of Models” on page 14-37

Programmatic Interface for Concurrent Execution

Use these functions to configure models for concurrent execution.

To	Use
Create or convert configuration for concurrent execution.	<code>Simulink.architecture.config</code>
Add triggers to the software node or add tasks to triggers.	<code>Simulink.architecture.add</code>
Delete triggers or tasks.	<code>Simulink.architecture.delete</code>
Find objects with specified parameter values.	<code>Simulink.architecture.find_system</code>
Get configuration parameters for target architecture.	<code>Simulink.architecture.get_param</code>
Import and select architecture.	<code>Simulink.architecture.importAndSelect</code>
Generate profile report for model configured for concurrent execution.	<code>Simulink.architecture.profile</code>
Add custom target architecture.	<code>Simulink.architecture.register</code>
Set properties for a concurrent execution object (such as task, trigger, or hardware node).	<code>Simulink.architecture.set_param</code>
Configure concurrent execution data transfers.	<code>Simulink.GlobalDataTransfer</code>

Map Blocks to Tasks

To map blocks to tasks, use the `set_param` function.

Map a block to one task:

```
set_param(block, 'TargetArchitectureMapping', [bdroot 'CPU/PeriodicTrigger1/Task1']);
```

Map a block to multiple tasks:

```
set_param(block, 'TargetArchitectureMapping', ...  
{{bdroot 'CPU/PeriodicTrigger1/Task1'}; ...  
[bdroot 'CPU/PeriodicTrigger1/Task2']});
```

Get the current mapping of a block:

```
get_param(block, 'TargetArchitectureMapping');
```

Supported Targets For Multicore Programming

Supported Multicore Targets

You can build and download concurrent execution models for the following multicore targets using system target files:

- Linux, Windows, and Mac OS using `ert.tlc` and `grt.tlc`
- Simulink Real-Time using `slrt.tlc` and `slrtert.tlc`
- `idelink_ert.tlc`, `idelink_grt.tlc`, and `ert.tlc`, if it is supported for your hardware board.

Note:

- To build and download your model, you must have Simulink Coder software installed.
 - To build and download your model to a Simulink Real-Time system, you must have Simulink Real-Time software installed. You must also have a multicore target system supported by the Simulink Real-Time product.
 - Deploying to an embedded processor that runs Linux and VxWorks® operating systems requires the Embedded Coder product.
-

Supported Heterogeneous Targets

In addition to multicore targets, Simulink also supports building and downloading partitions of a model to heterogeneous targets that contain a multicore target and one or more field-programmable gate arrays (FPGAs).

Select the heterogeneous architecture using the Target architecture option in the Concurrent Execution dialog box **Concurrent Execution** pane:

Item	Description
Sample Architecture	Example architecture consisting of single CPU with multiple cores and two FPGAs. You can use this architecture to model for concurrent execution.

Item	Description
Simulink Real-Time	Simulink Real-Time target containing FPGA boards.
Xilinx Zynq ZC702 evaluation kit	Xilinx® Zynq® ZC702 evaluation kit target.
Xilinx Zynq ZC706 evaluation kit	Xilinx Zynq ZC706 evaluation kit target.
Xilinx Zynq Zedboard	Xilinx Zynq ZedBoard™ target.
Altera Cyclone V SoC development kit Rev. C	Altera® Cyclone® SoC Rev. C development kit target.
Altera Cyclone V SoC development kit Rev. D	Altera Cyclone SoC Rev. D development kit target.
Arrow SoCKit development board	Arrow® SoCKit development board target.

Note: Building HDL code and downloading it to FPGAs requires the HDL Coder product. You can generate HDL code if:

- You have an HDL Coder license
- You are building on Windows or Linux operating systems

You cannot generate HDL code on Macintosh systems.

More About

Limitations with Multicore Programming in Simulink

The following limitations apply when partitioning a model for concurrent execution.

- Configure the model to use the fixed-step solver.
- Do not use the following modes of simulation for models in the concurrent execution environment:
 - External mode
 - Logging to MAT-files (**All Parameters > MAT-file logging** check box selected). However, you can use the **To Workspace** and **To File** blocks.
 - If you are simulating your model using Rapid Accelerator mode, the top-level model cannot contain a root level **Inport** block that outputs function calls.
 - In the Configuration Parameters dialog box, set the **Diagnostics > Sample Time > Multitask conditionally executed subsystem** and **Diagnostics > Data Validity > Multitask data store** parameters to **error**.
 - In addition, use the model-level control to handle data transfer for rate transition or if you use **Rate Transition** blocks, then:
 - Select the **Ensure data integrity during data transfer** check box.
 - Clear the **Ensure deterministic data transfer (maximum delay)** check box.
- If you want to use explicit partitioning, your model must consist entirely of **Model** blocks, **MATLAB System** blocks, and virtual connectivity blocks at the root-level. The following are valid virtual connectivity blocks:
 - **Goto** and **From** blocks
 - **Ground** and **Terminator** blocks
 - **Inport** and **Outport** blocks
 - Virtual subsystem blocks that contain permitted blocks

General Considerations when Building Simulink Models

In this section...

“Avoiding Invalid Loops” on page 15-2

“Shadowed Files” on page 15-4

“Model Building Tips” on page 15-6

Avoiding Invalid Loops

You can connect the output of a block directly or indirectly (i.e., via other blocks) to its input, thereby, creating a loop. Loops can be very useful. For example, you can use loops to solve differential equations diagrammatically (see “Model a Continuous System” on page 15-8) or model feedback control systems. However, it is also possible to create loops that cannot be simulated. Common types of invalid loops include:

- Loops that create invalid function-call connections or an attempt to modify the input/output arguments of a function call (see “Create a Function-Call Subsystem” on page 10-54 for a description of function-call subsystems)
- Self-triggering subsystems and loops containing non-latched triggered subsystems (see “Create a Triggered Subsystem” on page 10-40 in the Using Simulink documentation for a description of triggered subsystems and **Import** in the Simulink reference documentation for a description of latched input)
- Loops containing action subsystems

The Subsystem Examples block library in the Ports & Subsystems library contains models that illustrates examples of valid and invalid loops involving triggered and function-call subsystems. Examples of invalid loops include the following models:

- `simulink/Ports&Subsystems/sl_subsys_semantics/Triggered subsystem/sl_subsys_trigerr1 (sl_subsys_trigerr1)`
- `simulink/Ports&Subsystems/sl_subsys_semantics/Triggered subsystem/sl_subsys_trigerr2 (sl_subsys_trigerr2)`
- `simulink/Ports&Subsystems/sl_subsys_semantics/Function-call systems/sl_subsys_fcncallerr3 (sl_subsys_fcncallerr3)`

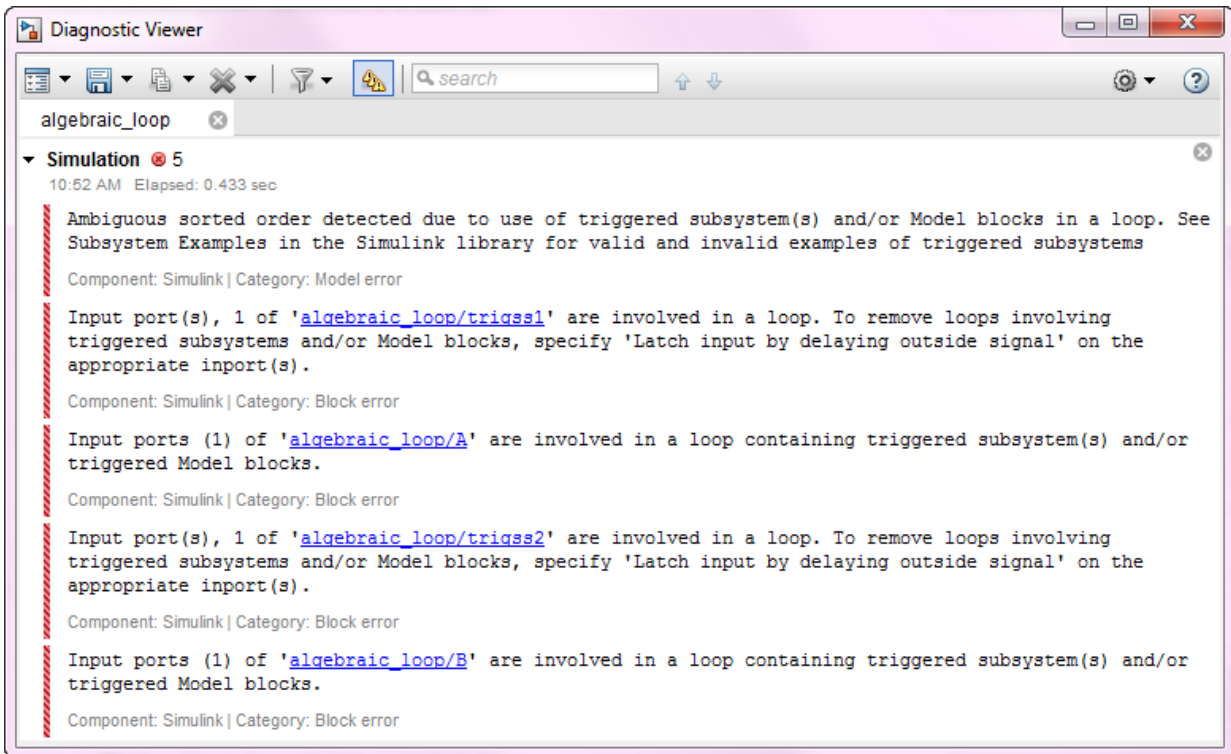

You might find it useful to study these examples to avoid creating invalid loops in your own models.

Detecting Invalid Loops

To detect whether your model contains invalid loops, select **Update Diagram** from the model's **Simulation** menu. If the model contains invalid loops, the invalid loops are highlighted. This is illustrated in the following model ,

and displays an error message in the Diagnostic Viewer.

Shadowed Files

If there are two Model files with the same name (e.g. `mylibrary.slx`) on the MATLAB path, the one higher on the path is loaded, and the one lower on the path is said to be "shadowed".

Tip To help avoid problems with shadowed files, turn on the Simulink preference **Do not load models that are shadowed on the MATLAB path**. See “Do not load models that are shadowed on the MATLAB path”.

The rules Simulink software uses to find Model files are similar to those used by MATLAB software. See “What Is the MATLAB Search Path?” in the MATLAB documentation. However, there is an important difference between how Simulink

block diagrams and MATLAB functions are handled: a loaded block diagram takes precedence over any unloaded ones, regardless of its position on the MATLAB path. This is done for performance reasons, as part of the Simulink software's incremental loading methodology.

The precedence of a loaded block diagram over any others can have important implications, particularly since a block diagram can be loaded without the corresponding Simulink window being visible.

Making Sure the Correct Block Diagram Is Loaded

When using libraries and referenced models, you can load a block diagram without showing its window. If the MATLAB path or the current MATLAB folder changes while block diagrams are in memory, these block diagrams can interfere with the use of other files of the same name.

For example, open a model with a library called `mylib`, change to another folder, and then open another model with a library also called `mylib`. When you run the first model, it uses the library associated with the second model.

This can lead to problems including:

- Simulation errors
- "Unresolved Link" icons on blocks that are library links
- Wrong results

Detecting and Fixing Problems

To help avoid problems with shadowed files, you can turn on the Simulink preference **Do not load models that are shadowed on the MATLAB path**. See “Do not load models that are shadowed on the MATLAB path”.

When updating a block diagram, the Simulink software checks the position of its file on the MATLAB path and will issue a warning if it detects that another file of the same name exists and is higher on the MATLAB path. The warning reads:

```
The file containing block diagram 'mylibrary' is shadowed  
by a file of the same name higher on the MATLAB path.
```

```
This may indicate that the wrong file called mylibrary.slx is being used. To see which  
file called mylibrary.slx is loaded into memory, enter:
```

```
which mylibrary
```

```
C:\work\Model1\mylibrary.slx
```

To see all the files called `mylibrary` which are on the MATLAB path, including MATLAB scripts, enter:

```
which -all mylibrary
```

```
C:\work\Model1\mylibrary.slx
```

```
C:\work\Model2\mylibrary.slx % Shadowed
```

To close the block diagram called `mylibrary` and let the Simulink software load the file which is highest on the MATLAB path, enter:

```
close_system('mylibrary')
```

Model Building Tips

Here are some model-building hints you might find useful:

- Memory issues

In general, more memory will increase performance.

- Using hierarchy

More complex models often benefit from adding the hierarchy of subsystems to the model. Grouping blocks simplifies the top level of the model and can make it easier to read and understand the model. For more information, see “Create a Subsystem” on page 4-28. The Model Browser provides useful information about complex models (see “Explore the Model Hierarchy Using the Model Browser” on page 12-57).

- Cleaning up models

Well organized and documented models are easier to read and understand. Signal labels and model annotations can help describe what is happening in a model. For more information, see “Signal Names and Labels” on page 62-4 and “Describe Models Using Annotations” on page 4-13.

- Modeling strategies

If several of your models tend to use the same blocks, you might find it easier to save these blocks in a model. Then, when you build new models, just open this model and copy the commonly used blocks from it. You can create a block library by placing a collection of blocks into a system and saving the system. You can then access the system by typing its name in the MATLAB Command Window.

Generally, when building a model, design it first on paper, then build it using the computer. Then, when you start putting the blocks together into a model, add the blocks to the model window before adding the lines that connect them. This way, you can reduce how often you need to open block libraries.

Model a Continuous System

To model the differential equation

$$x' = -2x(t) + u(t),$$

where $u(t)$ is a square wave with an amplitude of 1 and a frequency of 1 rad/sec, use an integrator block and a gain block. The Integrator block integrates its input x' to produce x . Other blocks needed in this model include a Gain block and a Sum block. To generate a square wave, use a Signal Generator block and select the Square Wave form but change the default units to radians/sec. Again, view the output using a Scope block. Gather the blocks and define the gain.

In this model, to reverse the direction of the Gain block, select the block, then use the **Diagram > Rotate & Flip > Flip Block** command. To create the branch line from the output of the Integrator block to the Gain block, hold down the **Ctrl** key while drawing the line. For more information, see “Draw a Branch Line” on page 4-7.

Now you can connect all the blocks.

An important concept in this model is the loop that includes the Sum block, the Integrator block, and the Gain block. In this equation, x is the output of the Integrator block. It is also the input to the blocks that compute x' , on which it is based. This relationship is implemented using a loop.

The Scope displays x at each time step. For a simulation lasting 10 seconds, the output looks like this:

The equation you modeled in this example can also be expressed as a transfer function. The model uses the Transfer Fcn block, which accepts u as input and outputs x . So, the block implements x/u . If you substitute sx for x' in the above equation, you get $sx = -2x + u$.

Solving for x gives

$$x = u/(s + 2)$$

or,

$$x/u = 1/(s + 2).$$

The Transfer Fcn block uses parameters to specify the numerator and denominator coefficients. In this case, the numerator is 1 and the denominator is $s+2$. Specify both terms as vectors of coefficients of successively decreasing powers of s .

In this case the numerator is [1] (or just 1) and the denominator is [1 2].

The results of this simulation are identical to those of the previous model.

Best-Form Mathematical Models

In this section...

“Series RLC Example” on page 15-11

“Solving Series RLC Using Resistor Voltage” on page 15-12

“Solving Series RLC Using Inductor Voltage” on page 15-13

Series RLC Example

You can often formulate the mathematical system you are modeling in several ways. Choosing the best-form mathematical model allows the simulation to execute faster and more accurately. For example, consider a simple series RLC circuit.

According to Kirchoff's voltage law, the voltage drop across this circuit is equal to the sum of the voltage drop across each element of the circuit.

$$V_{AC} = V_R + V_L + V_C$$

Using Ohm's law to solve for the voltage across each element of the circuit, the equation for this circuit can be written as

$$V_{AC} = Ri + L \frac{di}{dt} + \frac{1}{C} \int_{-\infty}^t i(t) dt$$

You can model this system in Simulink by solving for either the resistor voltage or inductor voltage. Which you choose to solve for affects the structure of the model and its performance.

Solving Series RLC Using Resistor Voltage

Solving the RLC circuit for the resistor voltage yields

$$V_R = Ri$$

$$Ri = V_{AC} - L \frac{di}{dt} - \frac{1}{C} \int_{-\infty}^t i(t) dt$$

Circuit Model

The following diagram shows this equation modeled in Simulink where R is 70, C is 0.00003, and L is 0.04. The resistor voltage is the sum of the voltage source, the capacitor voltage, and the inductor voltage. You need the current in the circuit to calculate the capacitor and inductor voltages. To calculate the current, multiply the resistor voltage by a gain of $1/R$. Calculate the capacitor voltage by integrating the current and multiplying by a gain of $1/C$. Calculate the inductor voltage by taking the derivative of the current and multiplying by a gain of L .

Series RLC Circuit: Formulated to solve for resistor current

This formulation contains a Derivative block associated with the inductor. Whenever possible, you should avoid mathematical formulations that require Derivative blocks as they introduce discontinuities into your system. Numerical integration is used to solve the model dynamics through time. These integration solvers take small steps through

time to satisfy an accuracy constraint on the solution. If the discontinuity introduced by the Derivative block is too large, it is not possible for the solver to step across it.

In addition, in this model the Derivative, Sum, and two Gain blocks create an algebraic loop. Algebraic loops slow down the model's execution and can produce less accurate simulation results. See “Algebraic Loops” on page 3-38 for more information.

Solving Series RLC Using Inductor Voltage

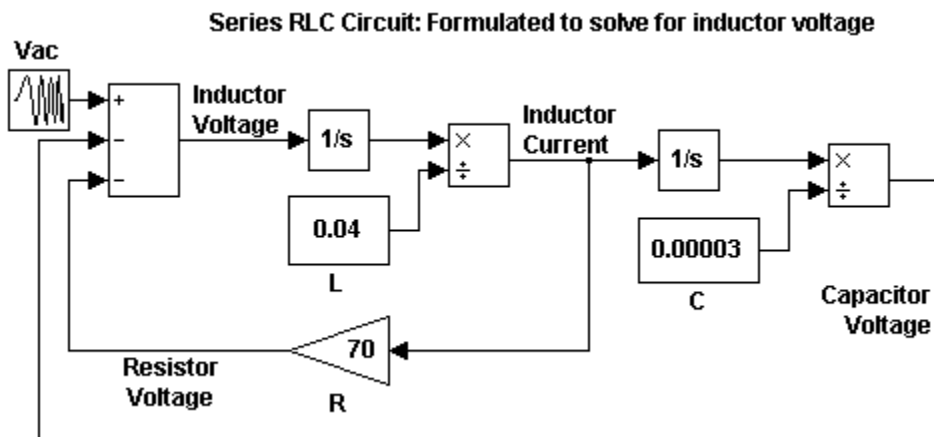

To avoid using a Derivative block, formulate the equation to solve for the inductor voltage.

$$V_L = L \frac{di}{dt}$$

$$L \frac{di}{dt} = V_{AC} - Ri - \frac{1}{C} \int_{-\infty}^t i(t) dt$$

Circuit Model

The following diagram shows this equation modeled in Simulink. The inductor voltage is the sum of the voltage source, the resistor voltage, and the capacitor voltage. You need the current in the circuit to calculate the resistor and capacitor voltages. To calculate the current, integrate the inductor voltage and divide by L . Calculate the capacitor voltage by integrating the current and dividing by C . Calculate the resistor voltage by multiplying the current by a gain of R .

This model contains only integrator blocks and no algebraic loops. As a result, the model simulates faster and more accurately.

Model a Simple Equation

To model the equation that converts Celsius temperature to Fahrenheit

$$T_F = 9/5(T_C) + 32$$

First, consider the blocks needed to build the model:

- A Ramp block to input the temperature signal, from the Sources library
- A Constant block to define a constant of 32, also from the Sources library
- A Gain block to multiply the input signal by 9/5, from the Math Operations library
- A Sum block to add the two quantities, also from the Math Operations library
- A Scope block to display the output, from the Sinks library

Next, gather the blocks into your model window.

Assign parameter values to the Gain and Constant blocks by opening (double-clicking) each block and entering the appropriate value. Then, click the **OK** button to apply the value and close the dialog box.

Now, connect the blocks.

The Ramp block inputs Celsius temperature. Open that block and change the **Initial output** parameter to 0. The Gain block multiplies that temperature by the constant $9/5$. The Sum block adds the value 32 to the result and outputs the Fahrenheit temperature.

Open the Scope block to view the output. Now, choose **Run** from the **Simulation** menu to run the simulation. The simulation runs for 10 seconds.

Model Differential Algebraic Equations

In this section...

“Overview of Robertson Reaction Example” on page 15-17

“Simulink Model from ODE Equations” on page 15-17

“Simulink Model from DAE Equations” on page 15-20

“Simulink Model from DAE Equations Using Algebraic Constraint Block” on page 15-23

Overview of Robertson Reaction Example

Robertson [1] created a system of autocatalytic chemical reactions to test and compare numerical solvers for stiff systems. The reactions, rate constants (k), and reaction rates (V) for the system are given as follows:

Because there are large differences between the reaction rates, the numerical solvers see the differential equations as stiff. For stiff differential equations, some numerical solvers cannot converge on a solution unless the step size is extremely small. If the step size is extremely small, the simulation time can be unacceptably long. In this case, you need to use a numerical solver designed to solve stiff equations.

Simulink Model from ODE Equations

A system of ordinary differential equations (ODE) has the following characteristics:

- All of the equations are ordinary differential equations.
- Each equation is the derivative of a dependent variable with respect to one independent variable, usually time.
- The number of equations is equal to the number of dependent variables in the system.

Using the reaction rates, you can create a set of differential equations describing the rate of change for each chemical species. Since there are three species, there are three differential equations in the mathematical model.

$$A' = -0.04A + 1 \cdot 10^4 BC$$

$$B' = 0.04A - 1 \cdot 10^4 BC - 3 \cdot 10^7 B^2$$

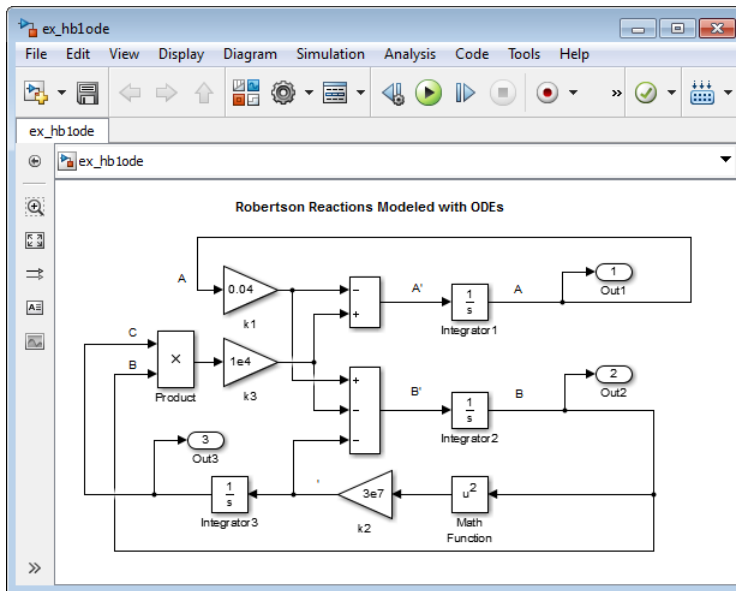

$$C' = 3 \cdot 10^7 B^2$$

Initial conditions: $A = 1$, $B = 0$, and $C = 0$.

Build the Model

Create a model, or open the model `ex_hb1ode`.

- 1 Add three Integrator blocks to your model. Label the inputs A' , B' , and C' , and the outputs A , B , and C respectively.
- 2 Add Sum, Product, and Gain blocks to solve each differential variable. For example, to model the signal C' ,
 - a Add a Math Function block and connect the input to signal B . Set the **Function** parameter to **square**.
 - b Connect the output from the Math Function block to a Gain block. Set the **Gain** parameter to $3e7$.
 - c Continue to add the remaining differential equation terms to your model.
- 3 Model the initial condition of A by setting the **Initial condition** parameter for the A Integrator block to 1.
- 4 Add Out blocks to save the signals A , B , and C to the MATLAB variable `yout`.

Simulate the Model

Create a script that uses the `sim` command to simulate your model. This script saves the simulation results in the MATLAB variable `yout`. Since the simulation has a long time interval and `B` initially changes very fast, plotting values on a logarithmic scale helps to visually compare the results. Also, since the value of `B` is small relative to the values of `A` and `C`, multiply `B` by $1 \cdot 10^4$ before plotting the values.

- 1 Enter the following statements in a MATLAB script. If you built your own model, replace `ex_hb1ode` with the name of your model.

```
sim('ex_hb1ode')
yout(:,2) = 1e4*yout(:,2);
figure;
semilogx(tout,yout);
xlabel('Time');
ylabel('Concentration');
title('Robertson Reactions Modeled with ODEs')
```

- 2 From the Simulink Editor menu, select **Simulation > Model Configuration Parameters**:

- In the Solver pane, set the **Stop time** to $4e5$ and the **Solver** to `ode15s` (`stiff/NDF`).
 - In the Data Import pane, select the **Time** and **Output** check boxes.
- 3 Run the script. Observe that all of A is converted to C.

Simulink Model from DAE Equations

A system of differential algebraic equations (DAE) has the following characteristics:

- It contains both ordinary differential equations and algebraic equations. Algebraic equations do not have any derivatives.
- Only some of the equations are differential equations defining the derivatives of some of the dependent variables. The other dependent variables are defined with algebraic equations.
- The number of equations is equal to the number of dependent variables in the system.

Some systems contain constraints due to conservation laws, such as conservation of mass and energy. If you set the initial concentrations to $A = 1$, $B = 0$, and $C = 0$, the total concentration of the three species is always equal to 1 since $A + B + C = 1$. You can replace the differential equation for C' with the following algebraic equation to create a set of differential algebraic equations (DAEs).

$$C = 1 - A - B$$

The differential variables A and B uniquely determine the algebraic variable C .

$$A' = -0.04A + 1 \cdot 10^4 BC$$

$$B' = 0.04A - 1 \cdot 10^4 BC - 3 \cdot 10^7 B^2$$

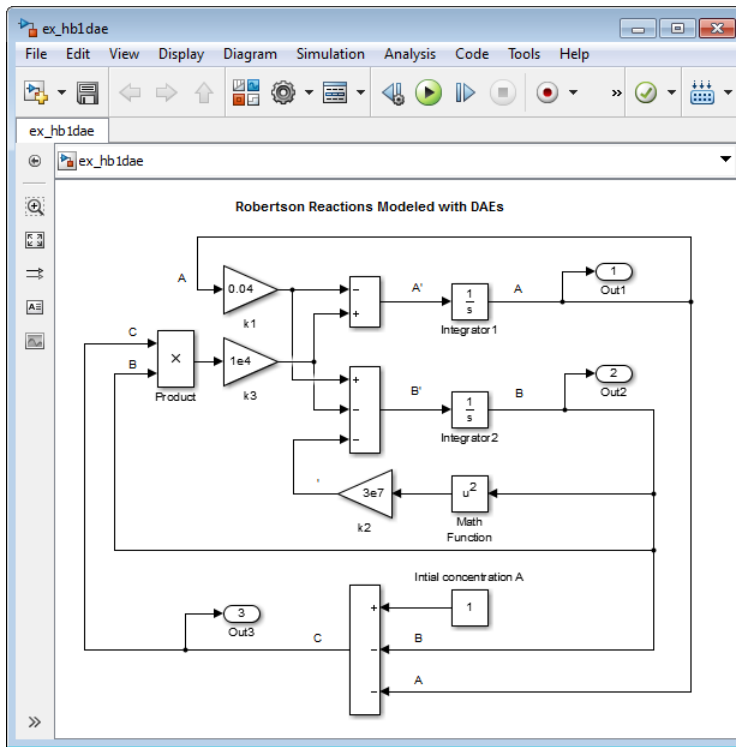

$$C = 1 - A - B$$

Initial conditions: $A = 1$ and $B = 0$.

Build the Model

Make these changes to your model or to the model `ex_hb1ode`, or open the model `ex_hb1dae`.

- 1 Delete the Integrator block for calculating C .
- 2 Add a Sum block and set the **List of signs** parameter to $+--$.
- 3 Connect the signals A and B to the minus inputs of the Sum block.
- 4 Model the initial concentration of A with a Constant block connected to the plus input of the Sum block. Set the **Constant value** parameter to 1.
- 5 Connect the output of the Sum block to the branched line connected to the Product and Out blocks.

Simulate the Model

Create a script that uses the `sim` command to simulate your model.

- 1 Enter the following statements in a MATLAB script. If you built your own model, replace `ex_hb1dae` with the name of your model.

```
sim('ex_hb1dae')
yout(:,2) = 1e4*yout(:,2);
figure;
semilogx(tout,yout);
xlabel('Time');
ylabel('Concentration');
title('Robertson Reactions Modeled with DAEs')
```

- 2 From the Simulink Editor menu, select **Simulation > Model Configuration Parameters**:

- In the Solver pane, set the **Stop time** to $4e5$ and the **Solver** to ode15s (stiff/NDF).
 - In the Data Import pane, select the **Time** and **Output** check boxes.
- 3** Run the script. The simulation results when you use an algebraic equation are the same as for the model simulation using only differential equations.

Simulink Model from DAE Equations Using Algebraic Constraint Block

Some systems contain constraints due to conservation laws, such as conservation of mass and energy. If you set the initial concentrations to $A = 1$, $B = 0$, and $C = 0$, the total concentration of the three species is always equal to 1 since $A + B + C = 1$.

You can replace the differential equation for C' with an algebraic equation modeled using an Algebraic Constraint block and a Sum block. The Algebraic Constraint block constrains its input signal $F(z)$ to zero and outputs an algebraic state z . In other words, the block output is a value needed to produce a zero at the input. Use the following algebraic equation for input to the block.

$$0 = A + B + C - 1$$

The differential variables A and B uniquely determine the algebraic variable C .

$$A' = -0.04A + 1 \cdot 10^4 BC$$

$$B' = 0.04A - 1 \cdot 10^4 BC - 3 \cdot 10^7 B^2$$

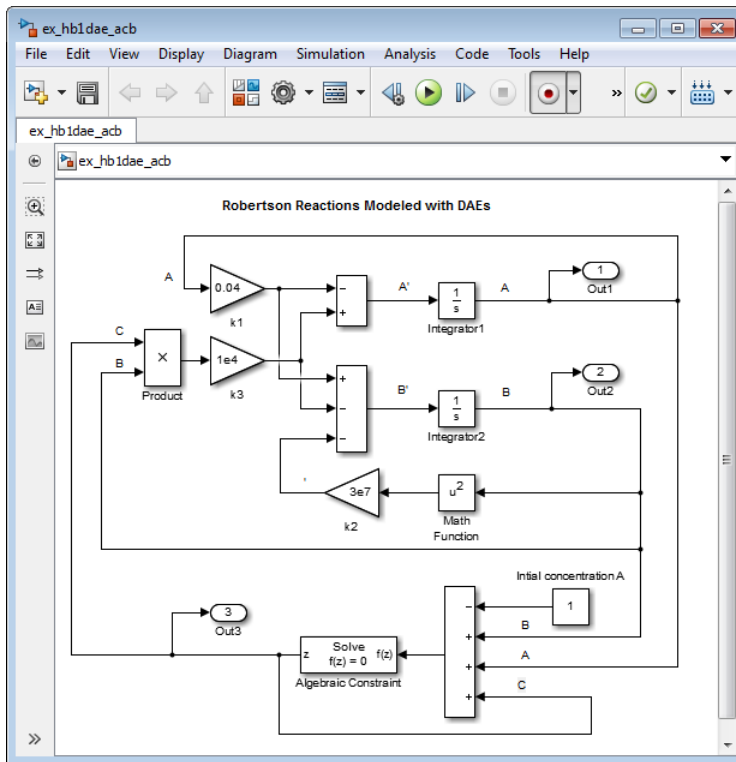

$$C = 1 - A - B$$

Initial conditions: $A = 1$, $B = 0$, and $C = 1 \cdot 10^{-3}$.

Build the Model

Make these changes to your model or to the model `ex_hb1ode`, or open the model `ex_hb1dae_acb`.

- 1 Delete the Integrator block for calculating C .
- 2 Add an Algebraic Constraint block. Set the **Initial guess** parameter to `1e-3`.
- 3 Add a Sum block. Set the **List of signs** parameter to `-+++`.
- 4 Connect the signals A and B to plus inputs of the Sum block.
- 5 Model the initial concentration of A with a Constant block connected to the minus input of the Sum block. Set the **Constant value** parameter to `1`.
- 6 Connect the output of the Algebraic Constraint block to the branched line connected to the Product and Out block inputs.
- 7 Create a branch line from the output of the Algebraic Constraint block to the final plus input of the Sum block.

Simulate the Model

Create a script that uses the `sim` command to simulate your model.

- 1 Enter the following statements in a MATLAB script. If you built your own model, replace `ex_hb1_acb` with the name of your model.

```
sim('ex_hb1dae_acb')
yout(:,2) = 1e4*yout(:,2);
figure;
semilogx(tout,yout);
xlabel('Time');
ylabel('Concentration');
title('Robertson Reactions Modeled with DAEs and Algebraic Constraint Block')
```

- 2 From the Simulink Editor menu, select **Simulation > Model Configuration Parameters**:

- In the Solver pane, set the **Stop time** to $4e5$ and the **Solver** to `ode15s` (stiff/NDF).
 - In the Data Import pane, select the **Time** and **Output** check boxes.
- 3 Run the script. The simulation results when you use an Algebraic Constraint block are the same as for the model simulation using only differential equations.

Using an Algebraic Constraint block creates an algebraic loop in a model, If you set the **Algebraic Loop** parameter to `warning` (**Simulation > Model Configuration Parameters > Diagnostics > Algebraic Loop**), the following message displays in the Diagnostic Viewer during simulation.

For this model, the algebraic loop solver was able to find a solution for the simulation, but algebraic loops don't always have a solution, and they are not supported for code generation. For more information about algebraic loops in Simulink models and how to remove them, see “Algebraic Loops” on page 3-38.

Componentization Guidelines

Componentization

A component is a piece of your design, a unit level item, or a subassembly, that you can work on without needing the higher level parts of the model.

Componentization involves organizing your model into components. Componentization provides many benefits for organizations that develop large Simulink models that consist of many functional pieces. The benefits include:

- Meeting development process requirements, such as:
 - Component reuse
 - Team-based development
 - Intellectual property protection
 - Unit testing
- Improving performance for:
 - Model loading
 - Simulation speed
 - Memory usage

Componentization Techniques

Key componentization techniques that you can use with Simulink include:

- Subsystems
- Libraries
- Model referencing

These componentization techniques support a wide range of modeling requirements for models that vary in size and complexity. Most large models use a combination of componentization techniques. For example, you can include subsystems in referenced models, and include referenced models in subsystems. As another example, a large model might use model reference Accelerator blocks at the top level component partitions and blend model reference Accelerator and atomic subsystem libraries at lower levels.

Simulink provides tools to convert from subsystems to model referencing. Because of the differences between subsystems and model referencing, switching from subsystems to model referencing can involve several steps (see *Converting a Subsystem to a Referenced Model* on page 8-17). Consider scalability and support for anticipated future modeling requirements, such as how a model is likely to grow in size and complexity and possible code generation requirements. Designing a scalable architecture can avoid later conversion costs.

General Componentization Guidelines

This table provides high-level guidelines about the kinds of modeling goals and models for which subsystems, libraries, and model referencing are each particularly well suited.

Componentization Technique	Modeling Goals for Which the Technique Is Well Suited
Subsystems	<ul style="list-style-type: none"> • Add hierarchy to organize and visually simplify a model. • Maximize design reuse with inherited attributes for context-dependent behavior.
Libraries	<ul style="list-style-type: none"> • Provide a frequently used, and infrequently changed, modeling utility. • Reuse components repeatedly in a model or in multiple models.
Model referencing	<ul style="list-style-type: none"> • Develop a referenced model independently from the models that use it. • Obscure the contents of a referenced model, allowing you to distribute it without revealing the intellectual property that it embodies. • Reference a model multiple times without having to make redundant copies. • Facilitate changes by multiple people, with defined interfaces for top-level components. • Improve the overall performance by using incremental model loading, update diagram, simulation, and code generation for large models (for example, a model with 10,000 blocks). • Perform unit testing.

Componentization Technique	Modeling Goals for Which the Technique Is Well Suited
	<ul style="list-style-type: none"> • Simplify debugging for large models. • Generate code that reflects the model structure.

For a more detailed comparison of these modeling techniques, see “Summary of Componentization Techniques” on page 15-31.

Summary of Componentization Techniques

This section compares subsystems, libraries, and model referencing. The table includes recommendations and notes about a range of modeling requirements and features.

To see more information about a specific requirement or feature, click a link in a table cell.

Modeling Requirement or Feature	Subsystems	Libraries	Model Referencing
Development Process

For each modeling technique, you can see a summary table that includes the more detailed information included in the links in the above summary table of componentization techniques:

- “Subsystems Summary” on page 15-32
- “Libraries Summary” on page 15-36
- “Model Referencing Summary” on page 15-39

Subsystems Summary

This section provides guidelines for using subsystems for each of the modeling requirements and features highlighted in the “Summary of Componentization Techniques” on page 15-31.

For additional information about subsystems, see:

- Creating Subsystems on page 4-28
- “Conditional Subsystems”

Modeling Requirement or Feature	Guidelines for Subsystems
Development Process	
Component reuse	<p>Not supported</p> <ul style="list-style-type: none"> • Copy a subsystem to reuse it in a model. • Subsystem copies are independent of each other. • Save a subsystem by saving the model that contains the subsystem. • Configuration management for subsystems is difficult.
Team-based development	<p>Not supported</p> <ul style="list-style-type: none"> • For subsystems in a model, Simulink provides no direct interface with source control tools. • To create or change a subsystem, you need to open the parent model’s file. This can lead to file contention when multiple people want to work on multiple subsystems in a model.
Intellectual property protection	<p>Not supported</p> <p>Use model referencing protected models instead.</p>
Unit testing	<p>Supported, with limitations</p> <ul style="list-style-type: none"> • For coverage testing, use Signal Builder and source blocks. • Each time a subsystem changes, you need to copy the subsystem to a harness model. • The test harness may have different Simulink sort orders, due to virtual boundaries. • Test harness files require configuration management overhead.
Performance	

Modeling Requirement or Feature	Guidelines for Subsystems
Model loading speed	<p>Supported, with limitations</p> <p>Loading a model loads all subsystems at one time. There is no incremental loading.</p>
Simulation speed for large models	<p>Supported, with limitations</p> <ul style="list-style-type: none"> • To speed simulation, use Accelerator or Rapid Accelerator simulation mode. • Simulation mode applies to the whole model. Model referencing provides a finer level of control for simulation modes.
Memory	<p>Supported, with limitations</p> <p>Memory use for simulation and code generation is comparable for subsystems and libraries. For models with over 500 blocks, model reference Accelerator mode can significantly reduce memory usage for simulation and code generation.</p>
Artificial algebraic loop avoidance	<p>Well suited</p> <ul style="list-style-type: none"> • Virtual subsystems avoid artificial algebraic loops. • For nonvirtual subsystems, consider enabling the Subsystem block parameter Minimize algebraic loop occurrences.
Features	
Signal property inheritance	<p>Well suited</p> <ul style="list-style-type: none"> • Inheriting signal properties from outside of the subsystem boundary avoids your having to specify properties for every signal. • Propagation of signal properties can lead to Simulink using signal properties that you did not anticipate.
State initialization	<p>Well suited</p> <p>You can initialize states of subsystems.</p>

Modeling Requirement or Feature	Guidelines for Subsystems
Tunability	<p>Well suited</p> <ul style="list-style-type: none"> • Tune subsystems using a block parameterization or masked subsystems. • Control tunability in generated code using Configuration Parameters > Optimization > Signals and Parameters > Default parameter behavior.
Buses	<p>Well suited</p> <p>Subsystems do not require the use of bus objects for virtual buses.</p>
S-functions	<p>Well suited</p> <p>Subsystems support inlined or noninlined S-functions.</p>
Model configuration settings	<p>Well suited</p> <p>A subsystem uses the model configuration settings of the model that contains the subsystem.</p>
Tools	<p>Well suited</p> <p>Subsystems provide extensive support for Simulink tools.</p>
Code generation	<p>Supported, with limitations</p> <ul style="list-style-type: none"> • To generate code for a subsystem by itself, right-click the Subsystem block and select a code generation option. • As an optimization, Simulink attempts to recognize identical subsystems. For detected identical subsystems, the generated code includes only one copy of code for the multiple subsystems. • For virtual subsystems, you cannot specify file or function code partitions for code generation.

Libraries Summary

This section provides guidelines for using libraries for each of the modeling requirements and features highlighted in the “Summary of Componentization Techniques” on page 15-31.

For additional information about libraries, see “Libraries”.

Modeling Requirement or Feature	Guidelines for Libraries
Development Process	
Component reuse	<p>Well suited</p> <ul style="list-style-type: none"> • Access a collection of well-defined utility blocks. • Create a component once and reuse it in models. • Link to the same library block multiple times without creating multiple copies. • Link to the same library block from multiple models. • Restrict write access to library components. • Maintain one truth: propagate changes from a single library block to all blocks that link to that library. • Disable a link to allow independent changes to a linked block. • Managing library links adds some overhead. • Save library in a file similar to a Simulink model, but you cannot simulate the file contents.
Team-based development	<p>Supported, with limitations</p> <ul style="list-style-type: none"> • Place library files in source control for version control and configuration management. • Maintain one truth: propagate changes from a single library block to all blocks that link to that library. • To reduce file contention, use one subsystem per library. • Link to the same library block from multiple models. • Restrict write access to library component.

Modeling Requirement or Feature	Guidelines for Libraries
	<ul style="list-style-type: none"> • See General Reusability Limitations on page 8-94.
Intellectual property protection	<p>Not supported</p> <p>Use model referencing protected models instead.</p>
Unit testing	<p>Supported, with limitations</p> <ul style="list-style-type: none"> • For coverage testing, use Signal Builder and source blocks. • Test harness may have different Simulink sort orders, due to virtual boundaries. • Test harness files require configuration management overhead.
Performance	
Model loading speed	<p>Well suited</p> <p>Simulink incrementally loads a library at the point needed during editing, updating a diagram, or simulating a model.</p>
Simulation speed for large models	<p>Supported, with limitations</p> <ul style="list-style-type: none"> • To speed simulation, use Accelerator or Rapid Accelerator simulation mode. • Simulation mode applies to the whole model. Model referencing provides a finer level of control for simulation modes.
Memory	<p>Supported, with limitations</p> <ul style="list-style-type: none"> • Simulink incrementally loads libraries at the point needed during editing, updating a diagram, or simulating a model. • Simulink duplicates library block instances during block update. • Memory usage for simulation and code generation is comparable for subsystems and libraries. For models with over 500 blocks, model reference Accelerator mode can significantly reduce memory usage for simulation and code generation.

Modeling Requirement or Feature	Guidelines for Libraries
Artificial algebraic loop avoidance	<p>Well suited</p> <ul style="list-style-type: none"> • Virtual subsystems avoid artificial algebraic loops. • For nonvirtual subsystems, consider enabling the Subsystem block parameter Minimize algebraic loop occurrences.
Features	
Signal property inheritance	<p>Well suited</p> <ul style="list-style-type: none"> • Inheriting signal properties from outside of the library block boundary avoids your having to specify properties for every signal. • Propagation of signal properties can lead to Simulink using signal properties that you did not anticipate.
State initialization	<p>Well suited</p> <p>You can initialize states of library blocks.</p>
Tunability	<p>Well suited</p> <ul style="list-style-type: none"> • Tune library blocks using block parameterization or masked subsystems. • Control tunability in generated code using Configuration Parameters > Optimization > Signals and Parameters > Default parameter behavior.
Buses	<p>Well suited</p> <p>Libraries do not require the use of bus objects for virtual buses.</p>
S-functions	<p>Well suited</p> <p>Libraries support inlined and noninlined S-functions.</p>

Modeling Requirement or Feature	Guidelines for Libraries
Model configuration settings	<p>Well suited</p> <ul style="list-style-type: none"> • Library models do not have model configuration settings. • A referenced library block uses the model configuration setting of the model that contains that block.
Tools	<p>Supported, with limitations</p> <p>There are some limitations for using some Simulink tools, such as the Model Advisor, with libraries.</p>
Code generation	<p>Supported, with limitations</p> <ul style="list-style-type: none"> • As an optimization, Simulink attempts to recognize identical subsystems. For detected identical subsystems, the generated code includes only one copy of code for the multiple subsystems. • For virtual subsystems, you cannot specify file or function code partitions for code generation.

Model Referencing Summary

This section provides guidelines for using model referencing for each of the modeling requirements and features highlighted in the “Summary of Componentization Techniques” on page 15-31.

For additional information about model referencing, see:

- “Model Referencing”
- Simulink Model Referencing Requirements on page 8-55
- Model Referencing Limitations on page 8-93

Modeling Requirement or Feature	Guidelines for Model Referencing
Development Process Requirements	
Component reuse	Well suited

Modeling Requirement or Feature	Guidelines for Model Referencing
	<ul style="list-style-type: none"> • Create a standalone component once and reuse it in multiple models. • Reference the same model multiple times without creating multiple copies. • Reference the same model from multiple models. • Model referencing uses specified boundaries for preserving component integrity.
Team-based development	<p>Well suited</p> <ul style="list-style-type: none"> • For version control and configuration management, you can place model reference files in a source control system. • Design, create, simulate, and test a referenced model independently from the model that references it. • Link to the same model reference from multiple models. • Changes made to a referenced model apply to all instances of that referenced model. • Simulink does not limit access for changing a model reference. • You save a referenced model in a separate file from the model that references it. Using separate files helps to avoid file contention.
Intellectual property protection	<p>Well suited</p> <ul style="list-style-type: none"> • Use the protected model feature to obscure contents of a referenced model in a distributed model. • Creating a protected model feature requires a Simulink Coder license. Using a protected model does <i>not</i> require a Simulink Coder license.

Modeling Requirement or Feature	Guidelines for Model Referencing
Unit testing	<p>Well suited</p> <ul style="list-style-type: none"> • Test components independently to isolate behaviors, by simulating them standalone. • You can eliminate unit retest for unchanged components. • Use a data-defined test harness, with MATLAB test vectors and direct coverage collection. • For coverage testing, use root inports and outports.
Performance	
Model loading speed	<p>Well suited</p> <ul style="list-style-type: none"> • Simulink incrementally loads a referenced model at the point needed during editing, updating a diagram, or simulating a model. • If a simulation target build is required, first-time loading can be slow.
Simulation speed for large models	<p>Well suited</p> <ul style="list-style-type: none"> • Simulate a referenced model standalone. • The Model block has an option for specifying the simulation mode. • You can improve rebuild performance by selecting the appropriate setting for the Configuration Parameters > Model Referencing > Rebuild parameter. • Simulation through code generation can have a slow start-up time, which might be undesirable during prototyping. • See “Limitations on Normal Mode Referenced Models” on page 8-96, “Limitations on Accelerator Mode Referenced Models” on page 8-96, and “Limitations on SIL and PIL Mode Referenced Models” on page 8-100.

Modeling Requirement or Feature	Guidelines for Model Referencing
Memory	<p>Well suited</p> <ul style="list-style-type: none"> • Simulink loads a referenced model at the point that model is needed for navigation during editing, updating a diagram, or simulating a model. • Use model reference Accelerator mode to reduce memory usage, incrementally loading a compiled version of a referenced model.
Artificial algebraic loop avoidance	<p>Supported, with limitations</p> <p>Consider enabling Configuration Parameters > Model Referencing > Minimize algebraic loop occurrences.</p>
Features	
Signal property inheritance	<p>Supported, with limitations</p> <ul style="list-style-type: none"> • Inherit sample time when the referenced model is sample-time independent. You cannot propagate a continuous sample time to a Model block that is sample-time independent. • Model block is context-independent, so it cannot inherit signal properties. Explicitly set input and output signal properties. • Use a bus object to define the signal data type of a bus signal that is passed into a referenced model. • Goto and From block lines cannot cross model referencing boundaries. • See Index Base Limitations on page 8-93.

Modeling Requirement or Feature	Guidelines for Model Referencing
State initialization	<p>Supported, with limitations</p> <ul style="list-style-type: none"> • You can initialize states from the top model. • Use either the structure format or structure with time format to initialize the states of a top model and the models that it references. • To use the <code>SimState</code> (simulation state) feature with model referencing, simulate all Model blocks in Normal mode. • See “State Information for Referenced Models” on page 59-235.
Tunability	<p>Supported, with limitations</p> <ul style="list-style-type: none"> • To have each instance of a referenced model use different values, use model arguments in the Model block. • To have each instance of a referenced model use the same values, use <code>Simulink.Parameter</code> objects. • By default, all other parameters are inlined in generated code.
Buses	<p>Supported, with limitations</p> <p>You must use bus objects for bus signals that cross referenced model boundaries (for example, global data stores, root inports, root outports).</p>
S-functions	<p>Supported, with limitations</p> <p>Model referencing generally supports inlined or noninlined S-functions. See “S-Function Limitations” on page 8-98.</p>

Modeling Requirement or Feature	Guidelines for Model Referencing
Model configuration settings	<p>Supported, with limitations</p> <ul style="list-style-type: none"> • To apply the same model configuration settings to all models in a model hierarchy, use a referenced configuration set. • Configuration settings for the root model and referenced models must be consistent. However, not all configuration settings need to be the same across the model hierarchy.
Tools	<p>Supported, with limitations</p> <ul style="list-style-type: none"> • There are some limitations for using some Simulink tools, such as the Simulink Debugger, with model referencing. • For details, see “Simulink Tool Limitations” on page 8-94.
Code generation	<p>Well suited</p> <ul style="list-style-type: none"> • By default, model referencing generates code incrementally. • You can improve rebuild performance by selecting the appropriate setting for the Configuration Parameters > Model Referencing > Rebuild parameter. • Model referencing requires the use of bus objects. For information, see “Bus Data Crossing Model Reference Boundaries” on page 63-123.

Model Complex Logic

To model complex logic in a Simulink model, consider using Stateflow software.

Stateflow extends Simulink with a design environment for developing state transition diagrams and flow charts. Stateflow provides the language elements required to describe complex logic in a natural, readable, and understandable form. It is tightly integrated with MATLAB and Simulink products, providing an efficient environment for designing embedded systems that contain control, supervisory, and mode logic.

For more information on Stateflow software, see “Stateflow”.

Model Physical Systems

To model physical systems in the Simulink environment, consider using Simscape software.

Simscape extends Simulink with tools for modeling systems spanning mechanical, electrical, hydraulic, and other physical domains as physical networks. It provides fundamental building blocks from these domains to let you create models of custom components. The MATLAB based Simscape language enables text-based authoring of physical modeling components, domains, and libraries.

For more information on Simscape software, see “Simscape”.

Model Signal Processing Systems

To model signal processing systems in the Simulink environment, consider using DSP System Toolbox™ software.

DSP System Toolbox provides algorithms and tools for the design and simulation of signal processing systems. These capabilities are provided as MATLAB functions, MATLAB System objects, and Simulink blocks. The system toolbox includes design methods for specialized FIR and IIR filters, FFTs, multirate processing, and DSP techniques for processing streaming data and creating real-time prototypes. You can design adaptive and multirate filters, implement filters using computationally efficient architectures, and simulate floating-point digital filters. Tools for signal I/O from files and devices, signal generation, spectral analysis, and interactive visualization enable you to analyze system behavior and performance. For rapid prototyping and embedded system design, the system toolbox supports fixed-point arithmetic and C or HDL code generation.

For more information on DSP System Toolbox software, see “DSP System Toolbox”.

Organize Large Modeling Projects

You can use Simulink Projects to help you organize your work. To get started with managing your files in a project:

- 1** Try an example project to see how the tools can help you organize your work. See “Explore Simulink Project Tools with the Airframe Project” on page 16-5.
- 2** Create a new project. See “Create a New Project to Manage Existing Files” on page 16-20.
- 3** Use the Dependency Analysis view to analyze your project and check required files. See “Run Dependency Analysis” on page 18-4.
- 4** Explore views of your files. See “Work with Project Files” on page 17-8.
- 5** Create shortcuts to save and run frequent tasks. See “Use Shortcuts to Find and Run Frequent Tasks” on page 16-41.
- 6** Run operations on batches of files. See “Run a Simulink Project Batch Job and Publish Report” on page 17-42.
- 7** If you use a source control integration, you can use the **Modified Files** view to review changes, compare revisions, and commit modified files. If you want to use source control with your project, see “About Source Control with Projects” on page 19-2.

For guidelines on structuring projects, see “Componentization Guidelines” on page 15-29.

What Are Simulink Projects?

You can use Simulink Projects to help you organize your work. Find all your required files; manage and share files, settings, and user-defined tasks; and interact with source control.

If your work involves any of the following:

- More than one model file
- More than one model developer
- More than one model version

— then Simulink Projects can help you organize your work. You can manage all the files you need in one place — all MATLAB and Simulink files, and any other file types you need such as data, requirements, reports, spreadsheets, tests, or generated files.

Projects can promote more efficient team work and individual productivity by helping you:

- Find all the files that belong with your project.
- Create standard ways to initialize and shut down a project.
- Create, store, and easily access common operations.
- View and label modified files for peer review workflows.
- Share projects using built-in integration with Subversion[®] (SVN) or Git[™], external source control tools.

See the Web page <http://www.mathworks.com/discovery/simulink-projects.html> for the latest information, downloads, and videos.

To get started with managing your files in a project:

- 1** Try an example project to see how the tools can help you organize your work. See “Explore Simulink Project Tools with the Airframe Project” on page 16-5.
- 2** Create a new project. See “Create a New Project to Manage Existing Files” on page 16-20.
- 3** Analyze your project and check required files by using the Dependency Analysis view. See “Run Dependency Analysis” on page 18-4.
- 4** Explore views of your files. See “Work with Project Files” on page 17-8.

- 5 Create shortcuts to save and run frequent tasks. See “Use Shortcuts to Find and Run Frequent Tasks” on page 16-41.
- 6 Run operations on batches of files. See “Run a Simulink Project Batch Job and Publish Report” on page 17-42.
- 7 If you use a source control integration, you can use the **Modified Files** view to review changes, compare revisions, and commit modified files. If you want to use source control with your project, see “About Source Control with Projects” on page 19-2.

For guidelines on structuring projects, see “Large-Scale Modeling”.

Explore Simulink Project Tools with the Airframe Project

In this section...

- “Explore the Airframe Project” on page 16-5
- “Set Up Project Files and Open Simulink Project” on page 16-6
- “View, Search, and Sort Project Files” on page 16-6
- “Understand Project Startup and Shutdown Tasks” on page 16-8
- “Create a Startup Shortcut” on page 16-9
- “Open and Run Frequently Used Files” on page 16-9
- “Review Changes in Modified Files” on page 16-10
- “Run Project Integrity Checks” on page 16-12
- “Run Dependency Analysis” on page 16-12
- “Commit Modified Files” on page 16-15
- “View Project and Source Control Information” on page 16-15

Explore the Airframe Project

Try an example Simulink project to see how the tools can help you organize your work. Projects can help you manage:

- Your design (model and library files, .m, .mat, and other files, source code for S-functions, data)
- A set of actions to use with your project (run setup code, open models, simulate, build, run shutdown code)
- Working with files under source control (check out, compare revisions, tag or label, check in)

The Airframe example shows how to:

- 1 Set up and browse some example project files under source control.
- 2 Examine project shortcuts to run setup and shutdown tasks and access frequently used files and tasks.
- 3 Analyze dependencies in the example project and locate required files that are not yet in the project.

- 4 Modify some project files, find and review modified files, compare to an ancestor version, and commit modified files to source control.
- 5 Explore views of project files only, modified files, and all files under the project root folder.

Set Up Project Files and Open Simulink Project

Run this command to create a working copy of the project files and open the project:

```
sldemo_slproject_airframe_svn
```

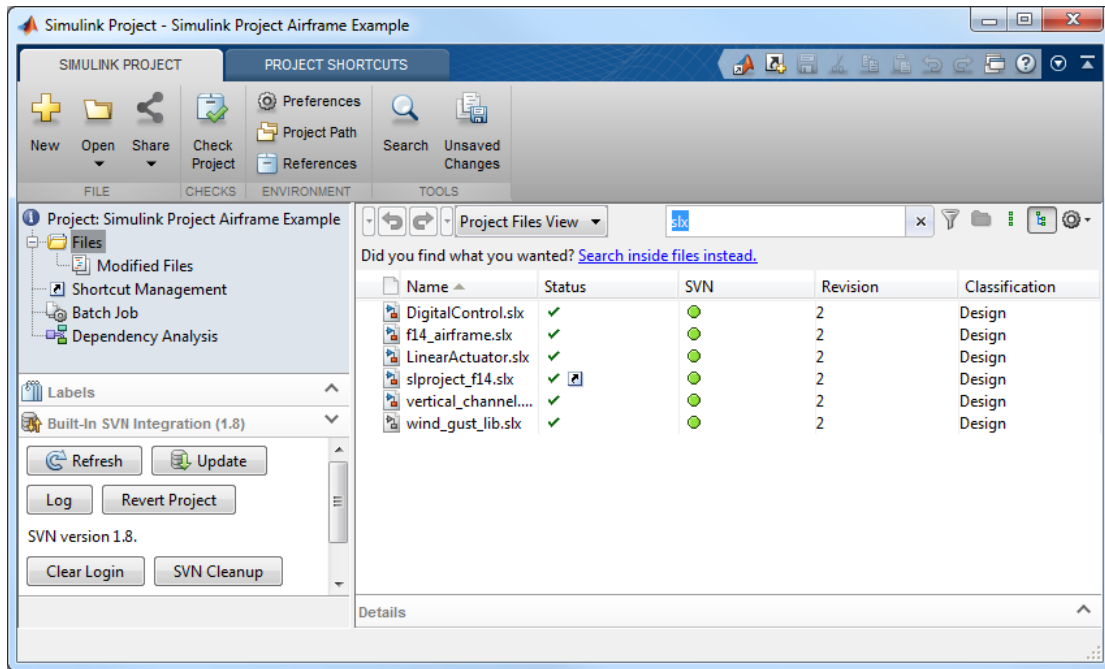

The project example copies files to your temporary folder so that you can edit them and put them under SVN source control.

The Simulink Project opens and loads the project. The project is configured to run some startup tasks, including changing the current working folder to the project root folder.

Note: Alternatively, you can try this example project using Git source control, by specifying `sldemo_slproject_airframe_git`. The following example shows the options when using SVN.

View, Search, and Sort Project Files

- 1 From the Simulink Project tree, select the **Files** node to manage the files within your project. When **Project Files View** is selected, only the files in your project are shown.
- 2 To see all the files in your sandbox, click the **Project Files View** button and select **All Files View**. This view shows all the files that are under the project root, not just the files that are in the project. This view is useful for adding files to the project from your sandbox.
- 3 To find particular files or file types, in any file view, type in the search box or click the Filter button. You can also search inside files.

Click the x to clear the search.

- 4 To view files as a list instead of a tree, click the List view button.

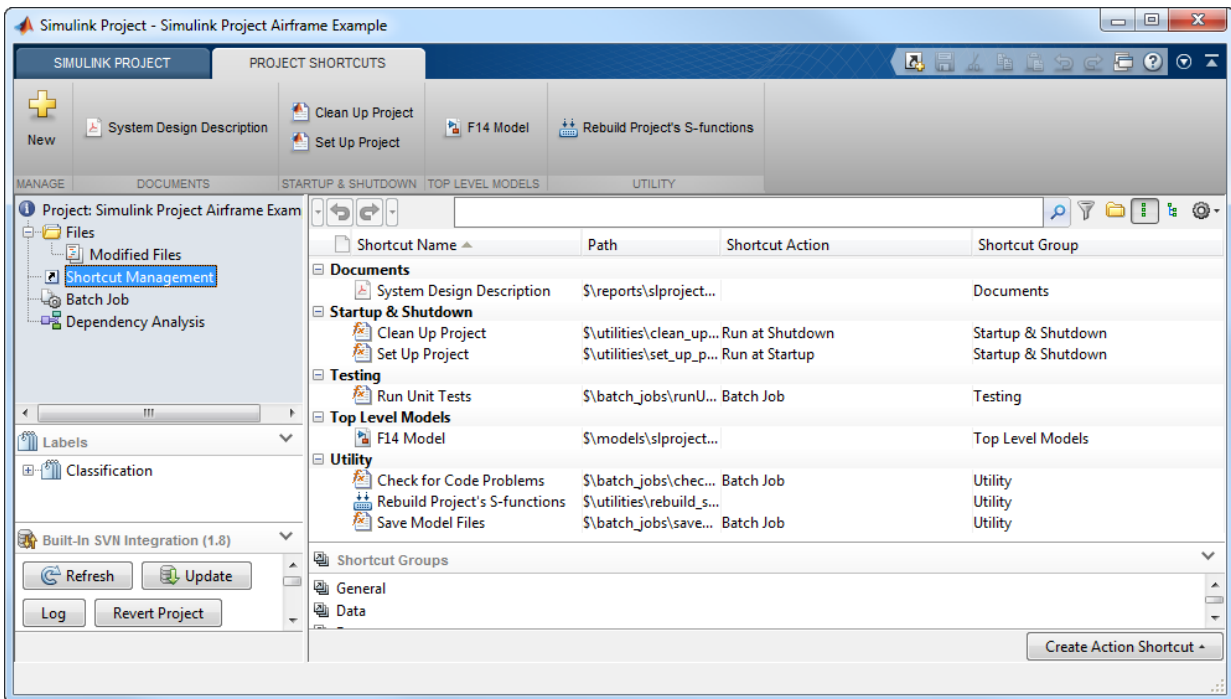

- 5 To sort files and to customize the columns, click the Actions button at the far right of the search box.
- 6 You can dock and undock the Simulink Project into the MATLAB Desktop. If you want to maximize space for viewing your project files, undock the Simulink Project. Drag the title bar to undock it.

Understand Project Startup and Shutdown Tasks

You can use shortcuts to run automatically startup or shutdown tasks, and to find files within a large project.

You can view and run shortcuts on the Project Shortcuts toolbar. The shortcuts are organized into groups that you specify through the **Shortcut Management** view.

In this example, you can see that some files are set as **Run at Startup** shortcuts. Startup shortcut files automatically run, load, or open when you open the project. You can use these shortcuts to set up the environment for your project. The file `set_up_project.m` defines where to create the `slprj` folder.

- Open the Set Up Project shortcut to understand how it works. In the **Shortcut Management** view, double-click the shortcut, or right-click and select **Open**. The file `set_up_project.m` opens in the Editor. The following lines use the project API to get the current project and the root folder:

```
project = simulinkproject;
projectRoot = project.RootFolder;
```

- The shortcut **Clean Up Project** is set as a **Run at Shutdown** shortcut. This type of shortcut runs before the current project closes. In this example, `clean_up_project.m` resets the environment changes made by `set_up_project.m`.

Create a Startup Shortcut

- 1 From the Simulink Project tree, select the **Files** node and select **Project Files View**.
- 2 Right-click a file, and select **Add Shortcut to > General**.
- 3 In the **Shortcut Management** view, right-click the shortcut you created and select **Set Shortcut Action > Startup** to make the file run, load, or open at startup.

When you open the project, the project performs the default action for startup shortcut files depending on their type:

- Run `.m` files.
- Load `.mat` files.
- Open Simulink models.

For details on shortcuts, see “Automate Startup Tasks with Shortcuts” on page 16-33.

Open and Run Frequently Used Files

You can use shortcuts to make scripts easier to find in a large project. In this example, the script that regenerates S-functions is set as a shortcut so that a new user of the project can easily find it. You can also make the top-level model, or models, within a project easier to find. In this example, the top-level model, `slproject_f14.mdl`, is a shortcut.

Regenerate the S-functions.

- 1 On the Project Shortcuts tab in the toolstrip, click the shortcut **Rebuild Project's S-functions**.

The shortcut file builds a MEX-file. If you do not have a compiler set up, follow the instructions to choose a compiler.

- 2 Open the `rebuild_s_functions.m` file to explore how it works.

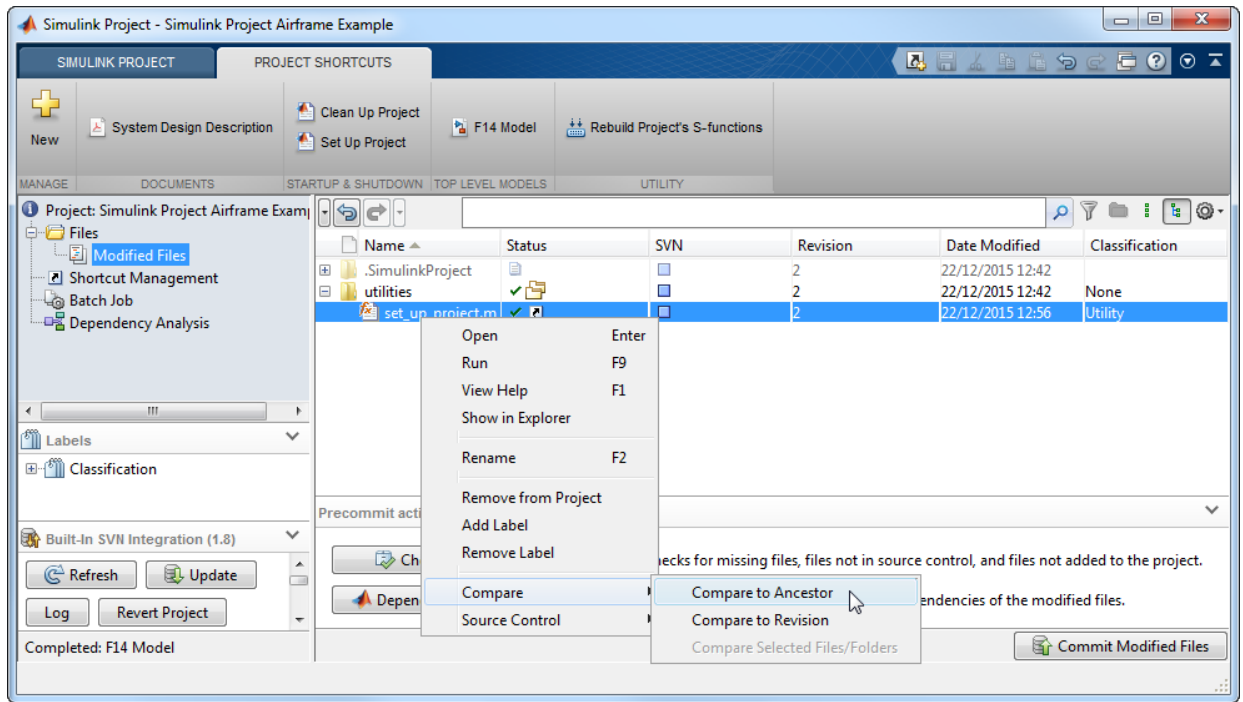

Open the top model.

- On the Project Shortcuts tab, click the shortcut **F14 Model** to open the root model for this project. This model runs only after you compile the required S-function.
- To create shortcuts to access frequently used files, select the **Project > Files** node, right-click a file, and select **Add Shortcut to > General** or any other *shortcutGroupName*. This action creates a basic shortcut with no startup or shutdown action.

Review Changes in Modified Files

Open and make changes to files and review changes.

- 1 Select **Project Files View**. View folders using the tree view button, and then expand the `utilities` folder.
- 2 Either double-click to open the `set_up_project` file for editing from the Simulink Project, or right-click and select **Open**.
- 3 Make a change in the Editor, such as adding a comment, and save the file.
- 4 Under **Files**, select the **Modified Files** node. The files you changed appear in the list.
- 5 To review changes, right-click the `set_up_project` file in the **Modified Files** view and select **Compare > Compare to Ancestor**.

The MATLAB Comparison Tool opens a report comparing the modified version of the file in your sandbox against its ancestor stored in the version control tool. The comparison report type can differ depending on the file you select.

If you select a Simulink model to **Compare > Compare to Ancestor**, and you have Simulink Report Generator installed, this command runs a Simulink XML comparison.

If you have Simulink Report Generator, try the following example.

- 1 Select the **Files** node and expand the **models** folder.
- 2 Either double-click to open the **AnalogControl** file for editing from the Simulink Project, or right-click and select **Open**.
- 3 Make a change in the model, such as opening a block and changing some parameters, and then save the model.

- 4 To review changes, right-click the file in the **Modified Files** view and select **Compare > Compare to Ancestor**.

The Comparison Tool opens a report.

Run Project Integrity Checks

In the **Modified Files** view, under **Precommit actions**, click **Check Project** to run the project integrity checks. The checks look for missing files, files to add to source control or retrieve from source control, and other issues. The checks dialog box can offer automatic fixes to problems found.

When you click a **Fix** button in the Checks dialog box, you can view recommended actions and decide whether to make the changes.

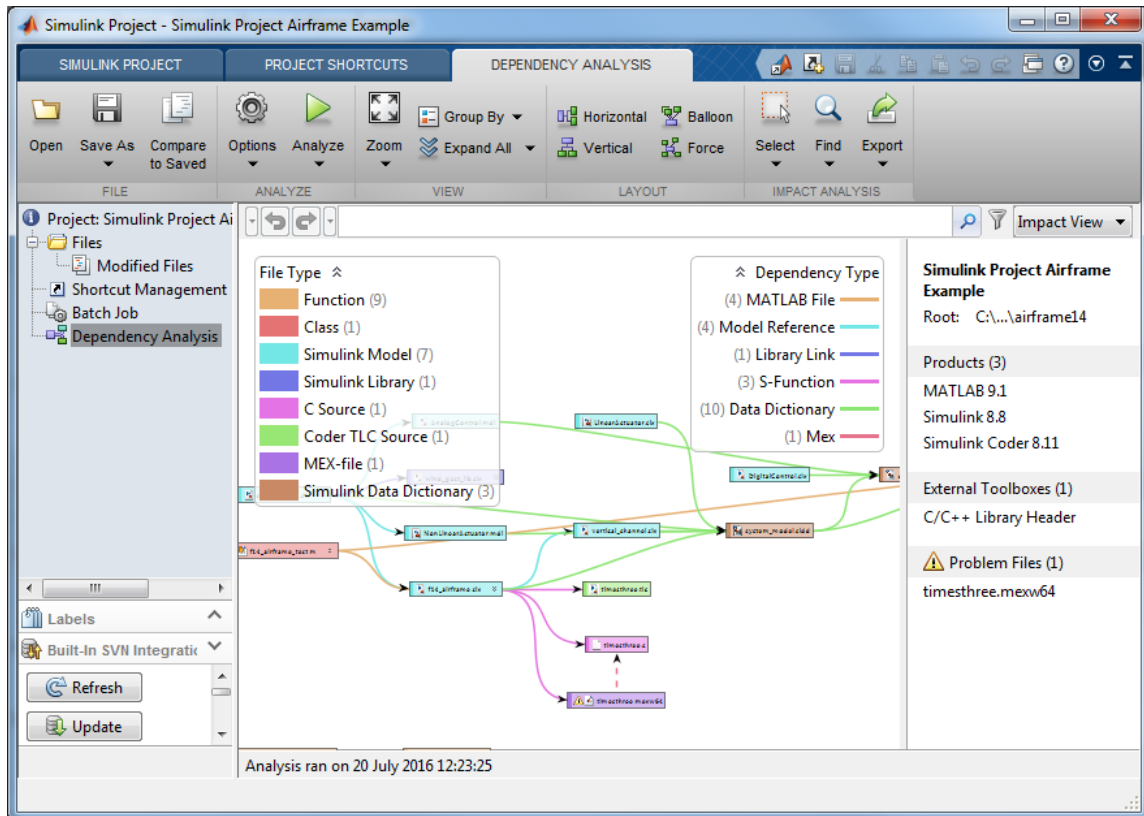

For an example using the project checks to fix issues, see “Upgrade Model Files to SLX and Preserve Revision History” on page 17-19.

Run Dependency Analysis

To check that all required files are in the project, run a file dependency analysis on the modified files in your project.

- 1 From the Simulink Project tree, select **Dependency Analysis**.
- 2 Click **Analyze**.

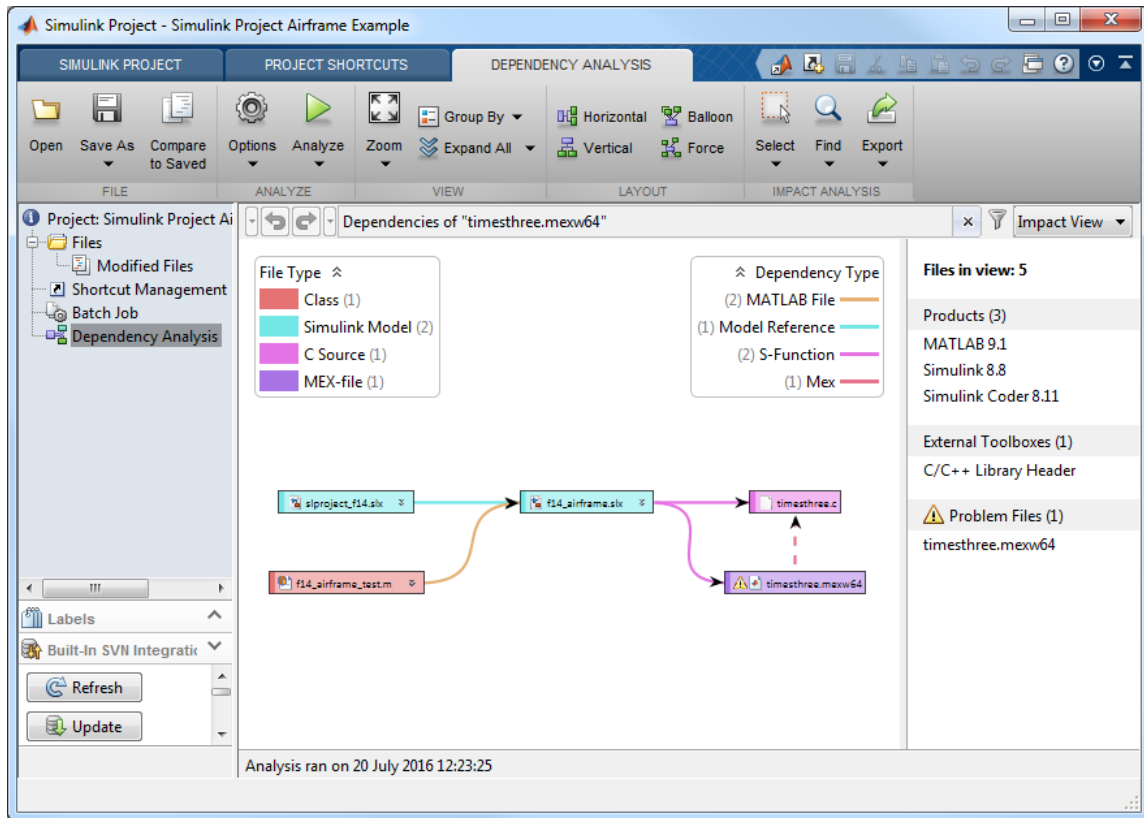

The Impact graph displays the structure of all analyzed dependencies in the project. The right pane lists required toolboxes and any problem files.

- 3 To view the files that use a problem file, hover over the problem file `timesthree.mexw64` and click Find Dependencies.

The graph updates to display only the problem file and its dependencies, and the problem message in the right panel. The file is not in the project.

- 4 Observe that `timesthree.mexw64` is an S-function binary file required by `f14_airframe.slx`. You can add binary files to your project or, as in this project, provide a utility script that regenerates them from the source code that is part of the project.

- 5 To remove the file from the problem files list, right-click the file and select **Add External File**. The next time you run a dependency analysis, the file does not appear as a problem file.

In this example, you do not want to add the binary file to the project, but instead use the script to regenerate the binary file from the source code in the project. Use **Add External File** to stop such files being marked as problems.

- 6 In the **Impact View**, on the **Dependency Analysis** tab, select **Find > All Files**.
- 7 In the **Impact Analysis** section, choose **Select > Modified Files**.
- 8 To view dependencies of the modified files, in the **Impact Analysis** section, select **Find > All Dependencies of Selection**.

Commit Modified Files

After you modify files and you are satisfied with the results of the checks, you can commit your changes to the source control repository.

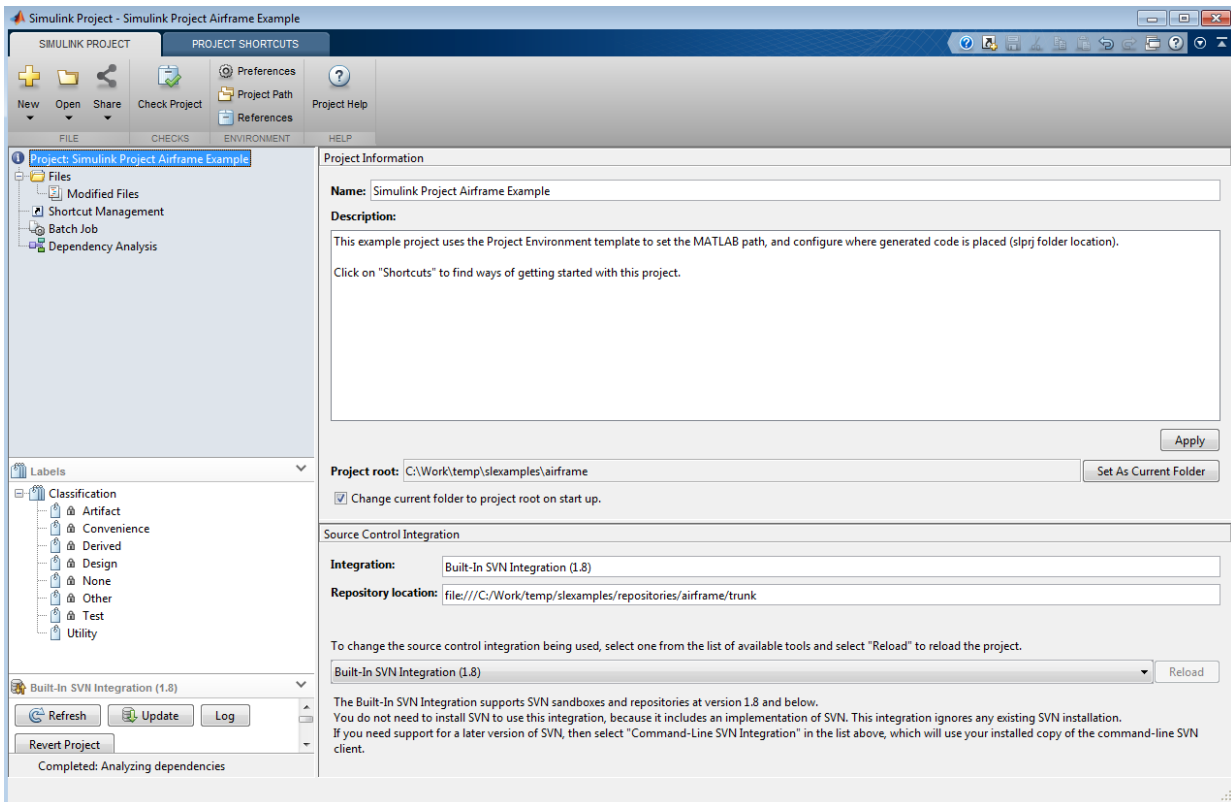

- 1 In the **Modified Files** view, under **Precommit actions**, click **Check Project** to make sure that your changes are ready to commit.
- 2 Observe that the Modified Files list includes a **.SimulinkProject** folder. The files stored in the **.SimulinkProject** folder are internal project definition files generated by your changes. These definition files allow you to add a label to a file without checking it out. You do not need to view the definition files directly unless you need to merge them, but they are listed so you know about all the files being committed to the source control system. See “Project Definition Files” on page 19-42.
- 3 To commit your changes to source control, click **Commit Modified Files**.
- 4 Enter a comment for your submission, and click **Submit**.

Watch the messages as the example source control commits your changes.

View Project and Source Control Information

Click the root tree node **Project: Simulink Project Airframe Example** to see information about:

- The open project, which includes a description and the location of the project root folder.
- The source control tool used by the current project.

This Airframe example project is under the control of the SVN source control tool.

For next steps, see “Project Management”.

- “About Source Control with Projects” on page 19-2

Create a Project from a Model

Create a project to organize your model and any dependent files. Simulink projects can help you organize your work and collaborate in teams. The project can help you to:

- Find all your required files
- Manage and share files, settings, and user-defined tasks
- Interact with source control.

- 1 In a Simulink model, select **File > Simulink Project > Create Project from Model**.

Simulink runs dependency analysis on your model to identify required files and a project root location that contains all dependencies.

- 2 In the New Simulink Project dialog box, edit any settings you want to change:
 - **Project name** — By default, the name of the suggested project root folder. Edit if desired.
 - **Project folder** — A folder that dependency analysis identified to contain all dependencies. If you want, click to select a different folder in the file system hierarchy between the file system root and the model folder.
 - **Files to include** — Files to include in the project. Files with selected check boxes are identified by dependency analysis. Select check boxes to specify all the files you want to include.

Any external dependencies are listed. If required files are outside your project root, then you cannot add these files to your project. An external dependency might not indicate a problem if the file is on your path and is a utility or other resource that is not part of your project.

- If you do not want to make a shortcut to the top-level file, or add all the folders to the project path, under **More Options**, clear the check boxes. Alternatively, you can edit these project settings later.
- 3 Click **Create** to create the Simulink project containing your model and any other specified files.

For an example showing what you can do with projects, see “Explore Simulink Project Tools with the Airframe Project” on page 16-5.

Related Examples

- “Sharing Simulink Projects” on page 17-45
- “About Source Control with Projects” on page 19-2

Create a New Project to Manage Existing Files

If you have many files that you want to organize into a project, with or without source control, use the following steps for a new project.

Note: If you have a model (with or without other dependent files) that you want to put in a project, see instead “Create a Project from a Model” on page 16-18.

If you want to retrieve a project from a source control repository, see instead “Retrieve a Working Copy of a Project from Source Control” on page 19-29.

To create a new project to manage your files:

- On the MATLAB **Home** tab, click **Simulink** or select **New > Simulink Project**.
 - From the Model Editor, select **File > New > Project**.
 - From the Simulink Project, on the **Simulink Project** tab, click **New**.
- 1 In the Simulink start page, click a template in the list to read the description. If you selected a new project option to open the start page, the list shows only project templates, or you can filter the list for Project Templates using the list next to the Search box.
 - Select the **Blank Project** template if you are creating a project in a folder with existing files. The **Blank Project** template creates a Simulink project in your selected folder and leaves any other files untouched. The project helps you manage all your files as a unit.
 - Try the **Simple Project** template if you are creating a project in a new folder and want a blank model. The **Simple Project** template creates a simple Simulink project containing a blank model and some utilities. The model is a shortcut so you can open it from the toolbar. The project manages your path and the location of the temporary files (slprj folder) with startup and shutdown shortcuts when you open and close the project. You can modify any of these files, folders, and settings later. As your project grows, the project helps you manage all your files as a unit.
 - You can create your own templates. See “Using Templates to Create Standard Project Settings” on page 16-44.
 - 2 In the start page, select a template and click **Create Project**.

- 3 In the Create Project dialog box, specify your project folder and edit the project name, and click **Create Project**.

The Simulink Project displays the Project Files view for the specified project root.

You can control the default folder for new projects using the project preferences.

For next steps, see “Add a Project to Source Control” on page 19-6 or “Add Files to the Project” on page 16-22.

More About

- “What Can You Do With Project Shortcuts?” on page 16-32

Add Files to the Project

After creating a new Simulink Project, unless you created the project from a model, then the **Files** node in the **Project** tree shows the empty Project Files view. Files under your chosen project root are not included in your project until you add them. If you created your project from a model, you already specified initial files to include in the project.

To display all files in your project folder (or `projectroot`), in the **Files** view, click the **Project Files View** button and select **All Files View**. You might not want to include all files in your project. For example, you might want to exclude some files under `projectroot` from your project, such as SVN or CVS source control folders.

To add existing files to your project, use any of these methods:

- In **All Files View**, select files or folders, right-click, and select **Add to Project** or **Add to Project (including child files)**.
- To add files to your project, cut and paste or drag and drop files from a file browser or the Current Folder browser onto the **Project Files** view. If you drag a file from outside the project root, this moves the file and adds it to your project. You can drag files within project root to move them.
- Add and remove project files at the command line using `addFile`.

To create new files or folders in the project, right-click a white space in the **Files** view and select **New Folder** or **New File**. The new files are added to the project.

To learn how to set up your project with all required files, see “Run Dependency Analysis” on page 18-4.

To add or remove project folders from the MATLAB search path, see “Specify Project Path” on page 16-30.

To configure your project to automatically run startup and shutdown tasks, see “Automate Startup Tasks with Shortcuts” on page 16-33.

You can access your recent projects direct from MATLAB. See “Open Recent Projects” on page 16-26.

If you want to add source control, see “Add a Project to Source Control” on page 19-6.

More About

- “What Can You Do With Project Shortcuts?” on page 16-32

Create a New Project from an Archived Project

To create a new project from an archived project:

- 1** From MATLAB, on the **Home** tab, in the **File** section, select **New > Simulink Project**.
- 2** In the start page, under **Projects** in the left list, click **Archive**.
- 3** In the Extract Project from Zip File dialog box, specify:
 - In the **Zip file** field, the location of the archived project.
 - In the **Project folder** field, the location of the new project. For example, `C:\myNewProject`.
- 4** Click **Extract**.

The new project opens. The current working folder, for example, `C:\myNewProject`, contains the imported project folders.

If the archived project contains referenced projects, Simulink Project imports files into two subfolders, `main` and `refs`. The current working folder, for example, `C:\myNewProject\main` contains the project folders and `C:\myNewProject\refs` contains the referenced project folders.

Related Examples

- “Archive Projects in Zip Files” on page 17-51

More About

- “Sharing Simulink Projects” on page 17-45

Create a New Project Using Templates

In Simulink Project, you can use templates to create and reuse a standard project structure.

- 1 To browse for templates, on the Simulink Project tab, click **New**.
- 2 In the Simulink start page, click a template in the list to read the description. For example, click **Simple Project**.
- 3 The start page shows all project templates (*.sltx) on the MATLAB path. If your templates do not appear, locate them by clicking **Open**. In the Open dialog box, make *.sltx files visible by changing the file type list **Model Files** to **All MATLAB files**, and browse to your template.
- 4 In the start page, select a template and click **Create Project**.
- 5 In the Create Project dialog box, specify your project folder and edit the project name, and click **Create Project**.

Use Project Templates from R2014a or Before

To use project templates created in R2014a or earlier (.zip files), upgrade them to .sltx files using `Simulink.exportToTemplate`.

After you upgrade the templates to .sltx and put them on the MATLAB path, you can use the templates from the start page.

- “Create a Template from a Model” on page 4-2

More About

- “Using Templates to Create Standard Project Settings” on page 16-44

Open Recent Projects

Note: You can have one project open at a time, to avoid conflicts. If you open another project, any currently open project closes.

You can use any of these methods to open recent Simulink projects:

- On the MATLAB **Home** tab, click **Simulink**, and select your project in the recent projects list.

If you select a recent model that is part of a project, you can choose to also open the project.

- On the MATLAB **Home** tab, click the **Open** arrow and select your project under the **Recent Simulink Projects** list.
- From the Current Folder browser, double-click the `.prj` file.
- In the Simulink Editor, if an open model, library, or chart belongs to a project, you can select **File > Simulink Project > Open Project**.

Alternatively, open Simulink Project by entering `simulinkproject`, or in the Simulink Editor, select **View > Simulink Project**. When Simulink Project is open, you can open projects with these methods:

- On the **Simulink Project** tab, click the **Open** arrow and select your project under the **Recent** list.
- For projects created or saved in Release 2012b or later, select **Open > Open Project File**. Browse and select your project `.prj` file.
- For projects saved in Release 2012a or earlier, select **Open > Open Project by Folder**. Navigate to the folder containing the `.SimulinkProject` folder, and click **OK** to load the project. After you load this project once, then you can use **Open Project File** to open the project.

Tip Create a MATLAB shortcut for opening or giving focus to the Simulink Project by dragging this command to the toolstrip from the Command History or Command Window:

`simulinkproject`

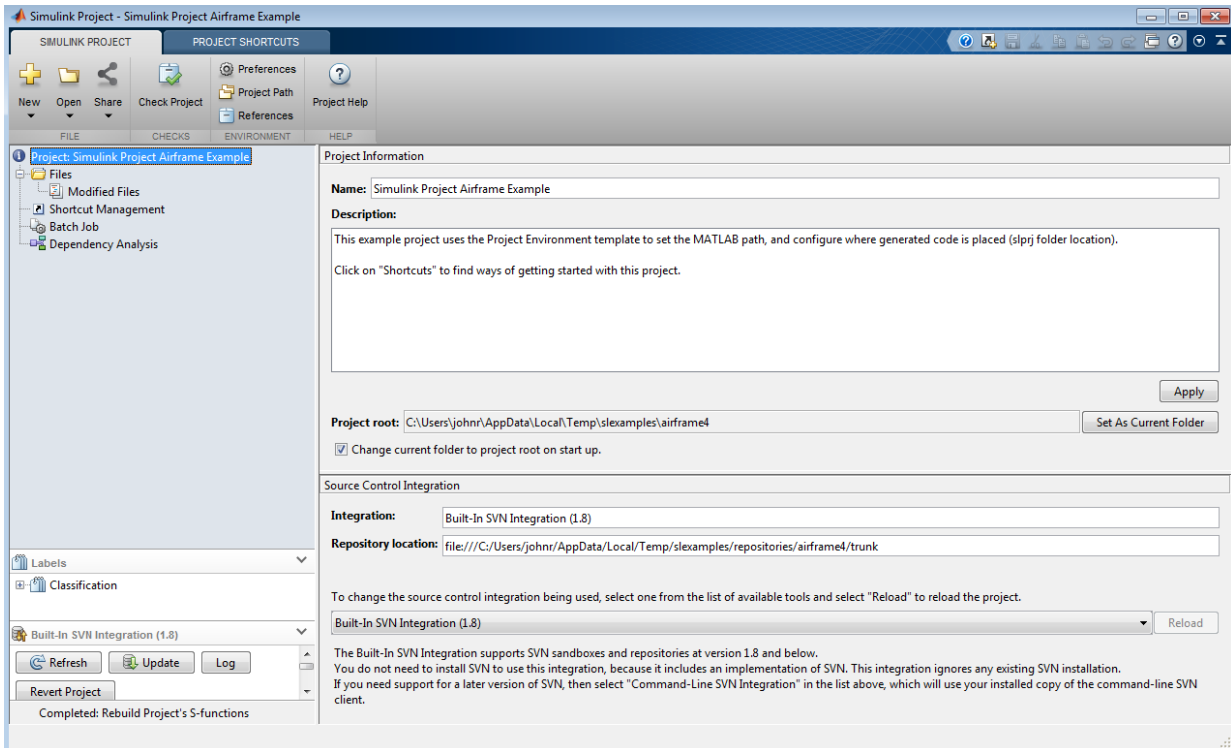

When you open a project, you are prompted if loaded files shadow your project model files. To avoid working on the wrong files, close the shadowing files. See “Manage Shadowed and Dirty Model Files” on page 17-11.

Related Examples

- “Work with Project Files” on page 17-8

Change the Project Name, Root, Description, and Startup Folder

In Simulink Project, use the Project root tree node to edit the project name or add a description. If you edit the name or description, click **Apply** to save your changes.

You can view the project root folder, and click **Set as Current Folder** to change the current working folder to your project root. You can change your project root by moving your entire project on your file system, and reopening your project in its new location. All project file paths are stored as relative paths.

The check box option **Change current folder to project root on start up** is selected by default. Clear the check box if you do not want to change to the project root folder on startup.

You can also configure startup shortcut scripts that set the current folder and perform other setup tasks. If you configure startup shortcuts to set the current folder, your

shortcut setting takes precedence over the check box at the Project node. To set up shortcuts, see “Automate Startup Tasks with Shortcuts” on page 16-33.

If your project is under source control, you can view source control information at the root node. See “Add a Project to Source Control” on page 19-6.

Related Examples

- “Automate Startup Tasks with Shortcuts” on page 16-33
- “Add a Project to Source Control” on page 19-6

Specify Project Path

When Simulink Project:

- Opens your project, it adds the project path to the MATLAB search path before applying startup shortcuts.
- Closes your project, it removes the project path from the MATLAB search path after applying shutdown shortcuts.

You can add or remove folders from the project path. Add project folders to ensure dependency analysis detects project files. On the **Simulink Project** tab, in the **Environment** section, click **Project Path**:

- To add a folder (without subfolders) to the project path, click **Add Folder**. If you want to add a folder and its subfolders, click **Add with Subfolders** instead. Then use the Open dialog box to add the new folder.
- To remove a folder from the project path, from the display list, select the folder. Then click **Remove**.

In the **Project > Files** view, you can use the context menu to add or remove folders from the project path. Right-click a folder and select **Project Path > Add to Project Path**, or **Add to the Project Path (Including Subfolders)**, or one of the options to remove the folder from the path.

Folders on the project path display the project path icon in the **Status** column.

Name ^	Status	SVN	Revision	Type	Classification
batch_jobs			2	Folder	None
data			2	Folder	None
models			2	Folder	None
reports			2	Folder	None
src			2	Folder	None
tests			2	Folder	None
utilities			2	Folder	None
work			2	Folder	None

src (Folder)

If you want to set the startup folder, see the check box option at the root project node:
Change current folder to project root on start up.

Related Examples

- “Change the Project Name, Root, Description, and Startup Folder” on page 16-28

More About

- “What Is the MATLAB Search Path?”
- “What Can You Do With Project Shortcuts?” on page 16-32

What Can You Do With Project Shortcuts?

In Simulink Project, use shortcuts to make it easy for any project user to find and access important files and operations. You can use shortcuts to make top models or scripts easier to find in a large project. You can group shortcuts to organize them by type and annotate them to use meaningful names instead of cryptic file names.

You can automate shortcuts to perform startup and shutdown tasks. Startup shortcuts help you set up the environment for your project. Shutdown shortcuts help you clean up the environment for the current project when you close it.

In the Shortcut Management view, you can execute, group, annotate, or automate shortcuts. You can specify Startup, Shutdown, or basic shortcuts.

- Startup shortcuts run when you open your project.
- Shutdown shortcuts run when you close your project.
- Basic shortcuts run when you execute them manually from the context menu or Project Shortcuts tab in the toolstrip.

Related Examples

- “Automate Startup Tasks with Shortcuts” on page 16-33
- “Automate Shutdown Tasks with Shortcuts” on page 16-35
- “Create Shortcuts to Frequent Tasks” on page 16-37
- “Use Shortcuts to Find and Run Frequent Tasks” on page 16-41
- “Specify Project Path” on page 16-30

Automate Startup Tasks with Shortcuts

In Simulink Project, startup shortcuts help you set up the environment for your project.

Startup shortcut files are automatically run (.m and .p files), loaded (.mat files), and opened (Simulink models) when you open the project.

Note: Files named `startup.m` on the MATLAB path run when you start MATLAB. If your `startup.m` file calls the project with `simulinkproject`, an error appears because no project is loaded yet. To avoid the error, rename `startup.m` and use it as a project startup shortcut instead.

Projects warn if you have more than one startup shortcut. Startup shortcuts run in alphabetical order. If execution order is important, consider creating one script that calls all the others, and use that script as your only startup shortcut.

Configure an existing file as a shortcut to run when you open your project.

- 1 In the **Files** view, right-click the project file and select **Add Shortcut to > General**, or if you have created a shortcut group you want to use, then select **Add Shortcut to > GroupName**. You can change shortcut group later.
- 2 Select **Shortcuts Management**.
- 3 Right-click the shortcut file and select **Set Shortcut Action > Startup**.

The **Shortcut Action** column displays **Run at Startup**.

Create a new startup shortcut file.

- 1 In the **Shortcut Management** view, click **Create Action Shortcut > Startup Script**.
- 2 Name and save the file. Startup shortcut scripts can have any name. You do not need to use `startup.m`.

The tool adds the new file to the project and sets it to **Run at Startup**.

- 3 Right-click the file and select **Open**.
- 4 Write the shortcut script using the Editor.
- 5 Click **Save**.

Note: Shortcuts are included when you commit modified files to source control. Any startup shortcuts you create run for all other project users.

To stop a shortcut running at startup, change back to a basic shortcut using **Set Shortcut Action > None**.

If you want to set the start up folder, see the check box option at the root project node: **Change current folder to project root on start up**. See “Change the Project Name, Root, Description, and Startup Folder” on page 16-28.

More About

- “What Can You Do With Project Shortcuts?” on page 16-32

Automate Shutdown Tasks with Shortcuts

In Simulink Project, shutdown shortcuts help you clean up the environment for the current project when you close it. Shutdown shortcuts should undo the settings applied in startup shortcuts. You can view an example in the `sldemo_slproject_airframe` project.

Configure an existing file as a shortcut to run when you close your project.

- 1 Right-click the file in the **Project Files View** and select **Add Shortcut to > General**, or if you have created a shortcut group you want to use, then select **Add Shortcut to > GroupName**. You can change shortcut group later.
- 2 Click the Shortcut Management node.
- 3 Right-click the shortcut file and select **Set Shortcut Action > Shutdown**.

The Action column displays `Run at Shutdown`.

Create a new shutdown shortcut file.

- 1 In the Shortcut Management view, click **Create Action Shortcut > Shutdown Script**.
- 2 Name and save the file.

The tool adds the new file to the project and sets it to `Run at Shutdown`.

- 3 Right-click the file and select **Open**.
- 4 Write the shortcut script using the Editor.
- 5 Click **Save**.

Note: Shortcuts are included when you commit modified files to source control. Any shutdown shortcuts you create run for all other project users.

To stop a shortcut running at shutdown, change back to a basic shortcut using **Set Shortcut Action > None**.

- “Use Shortcuts to Find and Run Frequent Tasks” on page 16-41

More About

- “What Can You Do With Project Shortcuts?” on page 16-32

Create Shortcuts to Frequent Tasks

In this section...

“Create Shortcuts” on page 16-37

“Group Shortcuts” on page 16-38

“Annotate Shortcuts to Use Meaningful Names” on page 16-39

“Customize Shortcut Icons” on page 16-40

Create Shortcuts

In Simulink Project, create shortcuts for common project tasks and to make it easy to find and access important files and operations. For example, find and open top models, run startup code (for example, to load data), simulate models, or run shutdown code.

To create a shortcut to an existing project file, use any of the following methods:

- Right-click the file in the **Project Files View** and select **Add Shortcut to > General**, or **ShortcutGroupName**.
- Click **New** on the Project Shortcuts tab on the toolstrip and browse to select a file.

The shortcut appears on the Project Shortcuts tab on the toolstrip.

You can create new shortcuts interactively only in the Simulink Project, but you can get and view your shortcuts at the command line. For details, see “Query Shortcuts” on page 17-35.

Note: Shortcuts are included when you commit your modified files to source control, so you can share shortcuts with other project users.

Group Shortcuts

You can group shortcuts to organize them by type. For example, you can group shortcuts for loading data, opening models, generating code, and running tests.

By default, new shortcuts appear in the General group on the Project Shortcuts toolstrip tab and in the Shortcut Management view.

Create new shortcut groups to organize your shortcuts:

- Right-click in the Shortcut Groups pane and select **Create New Shortcut Group**. Enter a name for the group and click **OK**.

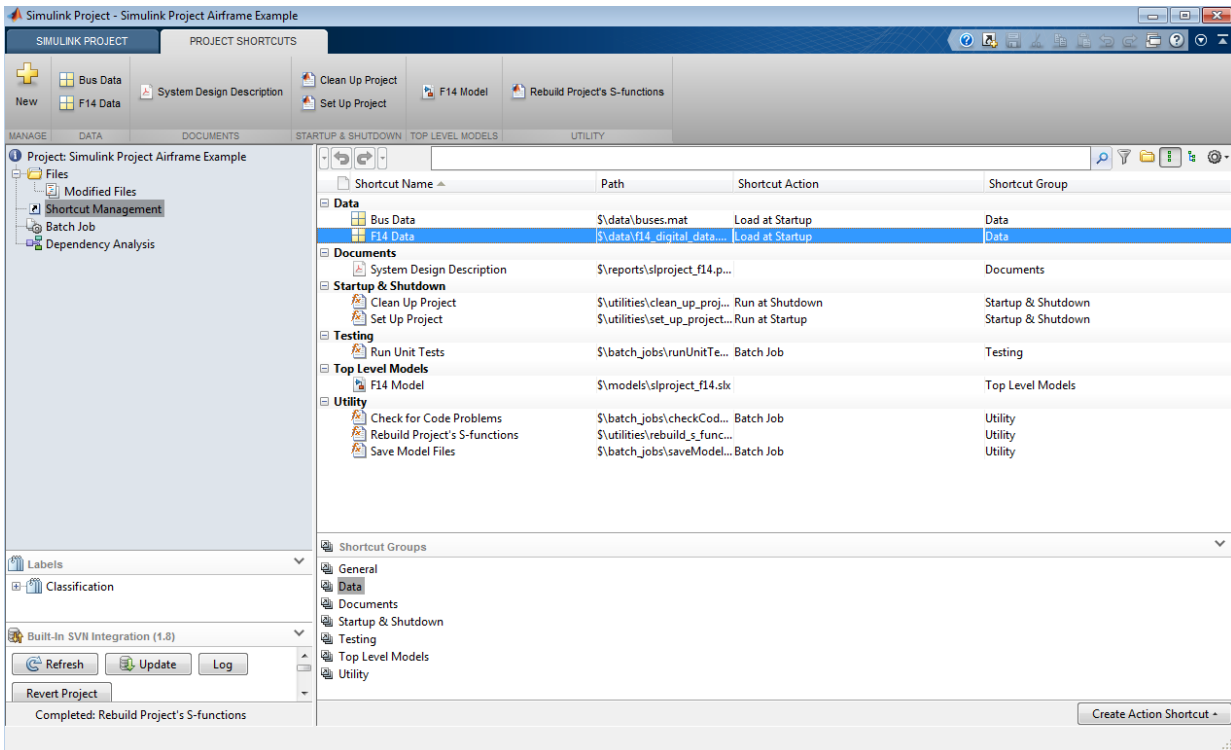

The new shortcut group appears in the Shortcut Groups pane.

- Alternatively, click **New** in the Project Shortcuts tab. Right-click in the Select a Shortcut Group pane to create a new group.

To organize your shortcuts by group, either:

- In the **Project Files View**, right-click a file and select **Add Shortcut to > ShortcutGroupName**.
- In the Shortcut Management view, drag a shortcut group onto a file from the Shortcut Groups pane, or right-click a file and select **Set Shortcut Group > ShortcutGroupName**.

The shortcuts are organized by group in the Project Shortcuts tab and in the Shortcut Management view.

To change shortcut group, in the Shortcut Management view, drag a different group onto the file, or right-click and select **Set Shortcut Group > GroupName**.

Annotate Shortcuts to Use Meaningful Names

Annotating shortcuts makes their purpose visible, without changing the file name or location of the script or model the shortcut points to. For example, you can change a cryptic file name to a descriptive name for the shortcut. To put shortcuts in a workflow order on the toolbar, prefix the shortcut names with numbers.

In the Shortcut Management view, right-click and select **Rename** to edit the **Shortcut Name** column. The **Shortcut Name** does not affect the file name or location.

Your specified **Shortcut Name** appears on the Project Shortcuts tab, to make it easier to find your shortcuts.

Customize Shortcut Icons

You can specify an icon to use for your shortcut buttons on the Project Shortcuts tab. Icons such as "build" can aid other project users to recognize frequent tasks.

- 1 In the Shortcut Management view, right-click a shortcut and select **Set Custom Icon**.
- 2 Select an image file. Images must be exactly 16 pixels square, and a png or a gif file.

Related Examples

- “Use Shortcuts to Find and Run Frequent Tasks” on page 16-41
- “Automate Startup Tasks with Shortcuts” on page 16-33

More About

- “What Can You Do With Project Shortcuts?” on page 16-32

Use Shortcuts to Find and Run Frequent Tasks

In Simulink Project, use shortcuts to make it easy for any project user to find and access important files and operations. You can use shortcuts to make top models or scripts easier to find in a large project. Shortcuts are available from any file view via the toolstrip.

If your project does not yet contain any shortcuts, see “Create Shortcuts to Frequent Tasks” on page 16-37.

To use shortcuts:

- In the Project Shortcuts toolstrip tab, click the shortcut. Clicking a shortcut in the toolstrip performs the default action for the file type, for example, run `.m` files, load `.mat` files, and open models. Hover over a shortcut to view the full path.
- Alternatively, select the Shortcut Management view, right-click the shortcut file, and select an action, such as **Open** or **Run**.

- To make a shortcut available in the Batch Job list without browsing for the file, select **Set Shortcut Action > Batch Job**.

Choose which behavior you want when running shortcuts:

- If the script is not on the path, and you want to switch to the parent folder and run the script without being prompted, then right-click and select **Run Shortcut** in the Shortcut Management view or click the shortcut in the Project Shortcuts toolbar. If you use this option, the result of `pwd` in the script is the parent folder of the script.
- If you select **Run** in the **Files** view context menu, and the script is not on the path, then MATLAB asks if you want to change folder or add the folder to the path. This is the same behavior as running from the Current Folder browser. If you use this option, the result of `pwd` in the script is the current folder when you run the script.

- “What Can You Do With Project Shortcuts?” on page 16-32

Using Templates to Create Standard Project Settings

In Simulink Project, use templates to create and reuse a standard project structure. Templates help you make consistent projects across teams. You can use templates to create new projects that:

- Use a standard folder structure.
- Set up a company standard environment, for example, with company libraries on the path.
- Have access to tools such as company Model Advisor checks.
- Use company standard startup and shutdown scripts.
- Share labels and categories.

You can use templates to share information and best practices. You or your colleagues can create templates.

Create a template from a project when it is useful to reuse or share with others. You can use the template when creating new projects.

Related Examples

- “Create a New Project Using Templates” on page 16-25
- “Create a Template from the Current Project” on page 16-45
- “Create a Template from a Project Under Version Control” on page 16-46
- “Edit a Template” on page 16-47
- “Explore the Example Templates” on page 16-48
- “Compare Project or Model Templates”

Create a Template from the Current Project

In Simulink Project, when you create a template, it contains the structure and all the contents of the current project, enabling you to reuse scripts and other files for your standard project setup. Simulink Project does not include the contents of referenced projects in the template.

- 1 Before creating the template, create a copy of the project, and edit the copy to contain only the files you want to reuse. Use the copy as the basis for the template.

Note: If the project is under version control, see instead “Create a Template from a Project Under Version Control” on page 16-46.

- 2 On the **Simulink Project** tab, in the **File** section, select **Share > Template**.
- 3 On the Create Template dialog box, edit the name, add a description to help template users, then click **Save As**. Choose a file location and click **Save**.

More About

- “Using Templates to Create Standard Project Settings” on page 16-44

Create a Template from a Project Under Version Control

- 1 Get a new working copy of the project. See “Retrieve a Working Copy of a Project from Source Control” on page 19-29.
- 2 To avoid accidentally committing changes to your project meant only for the template, stop using source control with this sandbox as you work on the template. In the Source Control view, under **Available Source Control Integrations**, select **No Source Control Integration** and click **Reload**.
- 3 Remove the files that you do not want in the template. For example, you might want to reuse only the utility functions, startup and shutdown scripts, and labels. In the **Files** view, right-click unwanted files and select **Remove from Project**.
- 4 On the **Simulink Project** tab, in the **File** section, select **Share > Template** and use the dialog box to name and save the file.

To verify that your template behaves as you expect, create a new project that uses your new template. See “Create a New Project Using Templates” on page 16-25.

More About

- “Using Templates to Create Standard Project Settings” on page 16-44

Edit a Template

- 1 Create a new project that uses the template you want to modify. See “Create a New Project Using Templates” on page 16-25.
- 2 Make the changes.
- 3 On the **Simulink Project** tab, in the **File** section, select **Share > Template**.

Use the dialog box to create a new template or overwrite the existing one.

More About

- “Using Templates to Create Standard Project Settings” on page 16-44

Explore the Example Templates

Example templates are supplied with Simulink Project. You can use these templates as example structures for a new project. The templates include:

- The **Blank Project** template, which creates an empty project. Use this to manage existing files. As your project grows, the project helps you manage all your files as a unit. For example, the project can keep track of files as you add them, manage the path, provide shortcuts, run startup and shutdown scripts, help you rename and move files, warn you about shadowed files and unsaved changes, and optionally, add source control.
- The **Simple Project** template, which creates a simple project containing a blank model. After you use the template to create the project, the model has a shortcut so that you can open it from the toolstrip. The project manages your path and the location of the temporary files (slprj folder) when you open and close the project. As your project grows, the project helps you manage all your files as a unit.
- The **Code Generation** template, which shows how to get started with production code generation using plant and controller models. The controller settings are optimized for code efficiency. After you create the project, run the project shortcut "Generate Controller Code" to generate code and display a report.

Tip If you want model templates suitable for code generation instead of the project template, try entering "code generation" in the start page search box.

This template requires Simulink Coder and Embedded Coder.

You can explore the templates using the Simulink start page. See "Create a New Project Using Templates" on page 16-25.

Group and Sort File Views

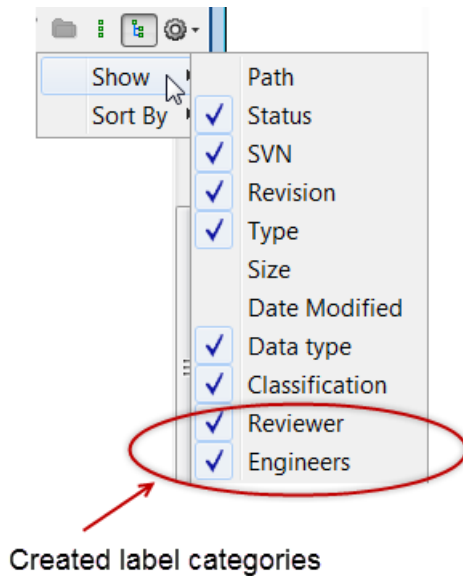

In Simulink Project, to group and sort the views in the Files view:

- Use the List view or Tree view buttons to switch between a flat list of files and a hierarchical tree of files.

In a list view, you can click the **Hide Folders** button if you want to view only files.

- Click the Actions button  to specify display columns and sort order. For example, you can display columns for label categories that you created and sort files by label category.

Related Examples

- “Search Inside Project Files and Filter File Views” on page 17-4

Search Inside Project Files and Filter File Views

In this section...

“Project-Wide Search” on page 17-4

“Filter Project File Views” on page 17-6

“More Ways to Search” on page 17-7

Project-Wide Search

In Simulink Project, you can search inside all your models and supporting files. You can find matches inside model files, MATLAB files, and other project files such as PDF and Microsoft Word files. You search only the current project. If you want to search referenced project files, open the referenced project.

- 1 On the Simulink Project tab, click **Search**. Alternatively, type in the file filter box, and the project provides a link to try searching inside files instead.

- 2 In the Search Inside Simulink Project Files dialog box, enter some characters to search for. Do not use quotes around phrases, or hyphens.
- 3 Expand files in the list to see results inside the file. Double-click results to locate specific items, e.g., highlight blocks in Simulink models, or highlight specific lines in MATLAB files.

Filter Project File Views

In the Simulink Project Files, Batch Job, and Dependency Analysis views, you can use the search box and filtering tools to specify file display.

- To view files, select the **Files** node. When **Project Files View** is selected, only the files in your project are shown. To see all the files in your sandbox, click the **Project Files View** button and select **All Files View**. This view shows all the files that are under the project root, not just the files that are in the project.
- To search, type a search term in the search box, for example, part of a file name or a file extension. You can use wildcards, for example, `*.m`, or `*.m*`.

Click **X** to clear the search.

- To build a filter for the current view, click the filter button .

In the Filter Builder dialog box you can select multiple filter criteria to apply using names, file types, project status, and labels.

The dialog box reports the resulting filter at the bottom, for example:

Filter = file type is 'Model files (*.slx, *.mdl)' AND project status is 'In project' AND has label 'Engine Type:Diesel'

When you click **Apply**, the search box shows the filter that you are applying.

More Ways to Search

You can also search:

- Model contents without loading the models into memory. On the MATLAB **Home** tab, in the **File** section, click **Find Files**. You can search a folder or the entire path. However, you cannot highlight results in models from the results in the Find Files dialog box the same way you do with project search. See “Advanced Search for Files”.
- A model hierarchy. In the Simulink Editor, select **Edit > Find**. Select options to look inside masks, links, and references. This search loads the models into memory. See “Find Model Elements in Simulink Models” on page 12-57
- For variables, block parameter values, or search a model hierarchy and contents using more options, using the Model Explorer. This search loads the models into memory. Use the Model Explorer to search for variables in workspaces and data dictionaries, and variable usage in a model. See “Edit and Manage Workspace Variables Used by Models” on page 57-88

Related Examples

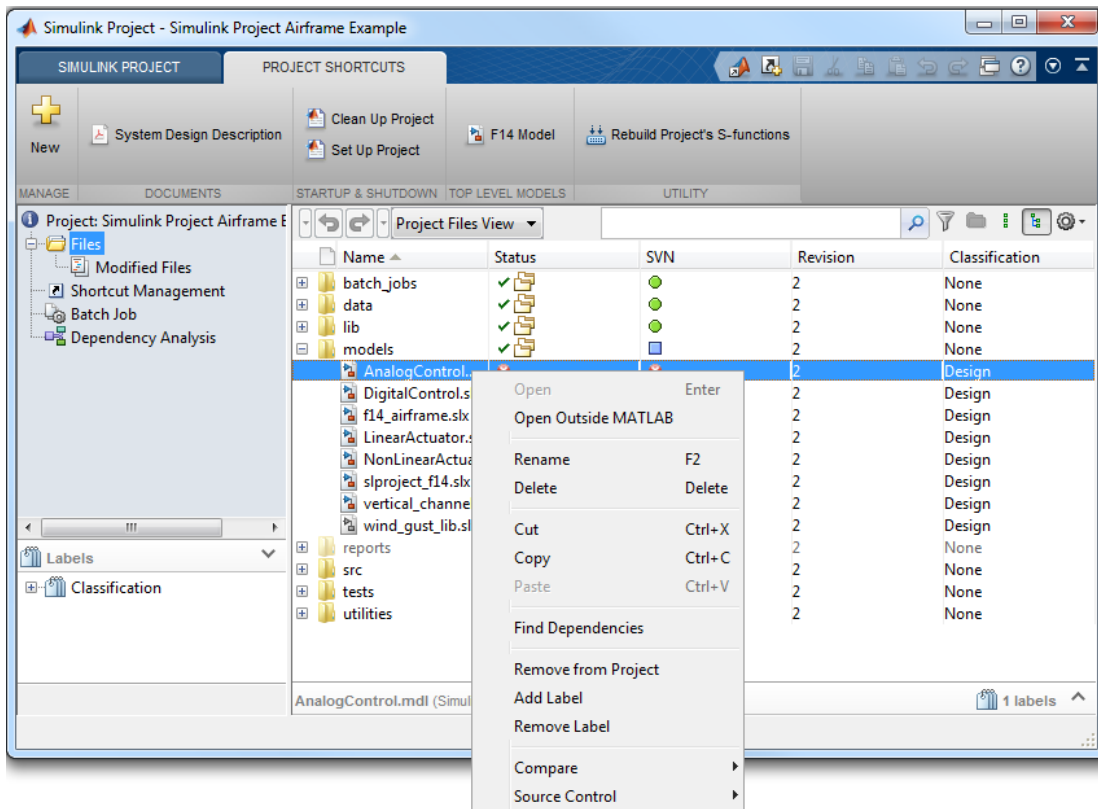

- “Group and Sort File Views” on page 17-2

- “Edit and Manage Workspace Variables Used by Models” on page 57-88

Work with Project Files

In Simulink Project, in the **Files** view, use the context menus to perform actions on the files that you are viewing. Right-click a file (or selected multiple files) to perform project options such as:

- Open files.
- Add and remove files from the project.
- Add, change, and remove labels. See “Add Labels to Files” on page 17-26.
- Create entry point shortcuts (for example, code to run at startup or shutdown, open models, simulate, or generate code). See “Create Shortcuts to Frequent Tasks” on page 16-37.
- If a source control interface is enabled, you can also:
 - Refresh source control status.
 - Update from source control.
 - Check for modifications.
 - Revert.
 - Compare against revision (select a version to compare).

See “About Source Control with Projects” on page 19-2.

In the **Files** view, if you select, for example a model file, the bottom right-hand pane displays file information, a model preview, and file labels.

Manage Shadowed and Dirty Model Files

In this section...

“Identify Shadowed Project Files When Opening a Project” on page 17-11

“Find Models and MATLAB Files With Unsaved Changes” on page 17-12

“Manage Open Models When Closing a Project” on page 17-12

Identify Shadowed Project Files When Opening a Project

If there are two model files with the same name on the MATLAB path, then the one higher on the path is loaded, and the one lower on the path is shadowed. This shadowing applies to all models and libraries (SLX and MDL files).

A loaded model always takes precedence over unloaded ones, regardless of its position on the MATLAB path. Loaded models can interfere when you try to use other files of the same name, especially when models are loaded but not visible. Simulink warns when you try to load a shadowed model, because the other model is already loaded and can cause conflicts. Simulink Project checks for shadowed files when you open a project.

- 1 When you open a Simulink project, it warns you if any models of the same names as your project models are already loaded. This check enables you to find and avoid shadowed files before opening any project models.

The Configuring Project Environment dialog box reports the **Identify shadowed project files** check fails. Click **Details**.

- 2 In the dialog box, you can choose to show or close individual files, or close all potentially shadowing files, by clicking the hyperlinks. To avoid working on the wrong files, close the loaded models.
- 3 After deciding whether to show or close the loaded models, click **OK** to return to the Configuring Project Environment dialog box.
- 4 Inspect the other project loading tasks, then click **Continue** to view the project.

Tip To help avoid problems with shadowed files, turn on the Simulink preference **Do not load models that are shadowed on the MATLAB path**. See “Do not load models that are shadowed on the MATLAB path”.

To learn more about shadowed files, see “Shadowed Files” on page 15-4.

Find Models and MATLAB Files With Unsaved Changes

You can check your project for models and MATLAB files with unsaved changes. On the **Simulink Project** tab, in the **Tools** section, click **Unsaved Changes**.

In the Unsaved Changes dialog box, you can see all dirty project models and MATLAB files. If you have referenced projects, files are grouped by project. You can save or discard all changes.

Manage Open Models When Closing a Project

When you close a project, it closes any project models that are open, unless they are dirty.

When you close a project, if there are model files with unsaved changes, a message prompts you to save or discard changes. You can see all dirty files, grouped by project if you have referenced projects. To avoid losing work, you can save or discard changes by file, by project, or globally.

Control this behavior using the Simulink project shutdown preferences.

Move, Rename, Copy, or Delete Project Files

In this section...

“Move or Add Files” on page 17-13

“Automatic Updates When Renaming, Deleting, or Removing Files” on page 17-13

Move or Add Files

To move or add project files, you can drag them to Simulink Project, or use clipboard operations.

- To add files to your project, you can paste files or drag them from your operating system file browser or the MATLAB Current Folder browser onto the Project Files View in Simulink Project. When you drag a file to the Project Files View, you add the file to the project. For projects under source control, you also add the file to source control.
- To move files within your project, cut and paste or drag files in the Simulink Project.

See also “Add Files to the Project” on page 16-22.

Automatic Updates When Renaming, Deleting, or Removing Files

When you rename, delete, or remove files or folders in a Simulink project, the project checks for impact in other project files. You can find and fix impacts such as changed library links, model references, and model callbacks. You can avoid refactoring pain tracking down other affected files. Automatic renaming helps to prevent errors that result from changing names or paths manually and overlooking or mistyping one or more instances of the name.

For example:

- When renaming a library, the project offers to automatically update all library links to the renamed library.
- When renaming a class, the project offers to automatically update all classes that inherit from it. If you rename a `.m` or `.mlx` file, the project offers to automatically update any files and callbacks that call it.
- When deleting files or removing them from the project, the project prompts you if other files refer to them. You must decide how to fix the affected files manually.

- When renaming a C file, the project prompts you to update the S-function that uses it.

To use automatic updates:

- 1 Rename a model, library, or MATLAB file in a Simulink project.

The project runs a dependency analysis to look for impacts in other files.

- 2 In the Rename dialog box, you can examine impacted files, choose to rename and update, just rename, or cancel renaming the file.
- 3 If you choose automatic updates, you can examine the results in updated files.

Automatic Renaming Using the Power Window Project

- 1 Open the power window example project by entering in MATLAB:

```
slexPowerWindowStart
```

The project opens the top model, some scopes, and an animation window.

- 2 In Simulink Project, expand the `model` folder, and rename the `slexPowerWindowControl.slx` model to `slexPowerWindowControlSystem.slx`.

The project runs a dependency analysis to look for impacts in other files, and then the Rename dialog box reports impacted files.

- 3 In the Rename dialog box, click **Show impacted files**. Expand the last impacted file to view the dependency, which is a model reference.

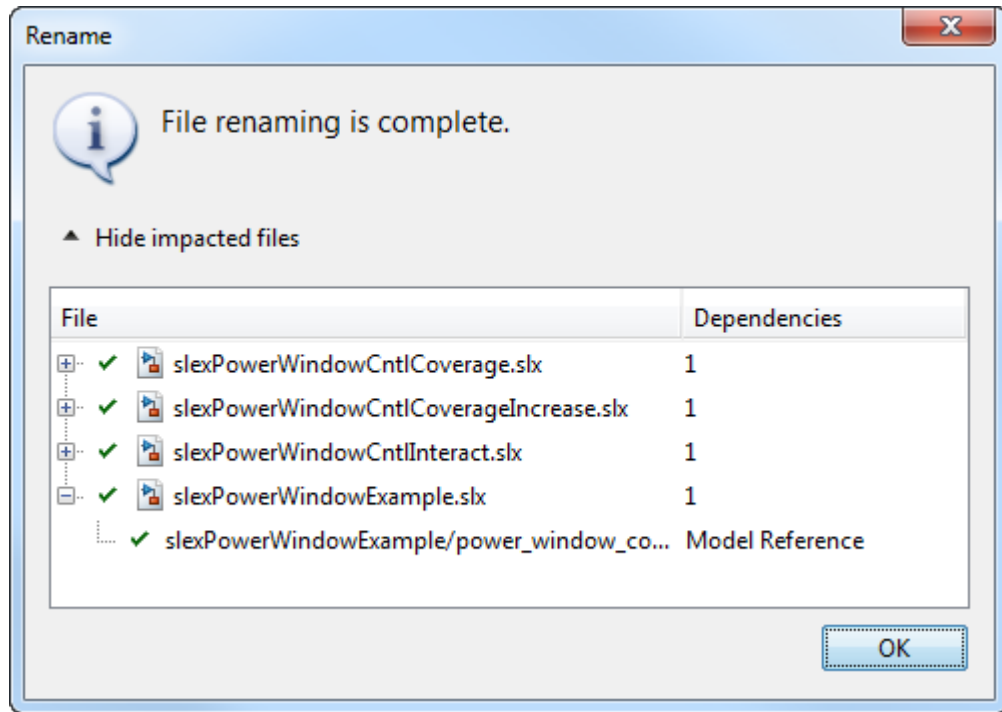

- 4 To view the dependency highlighted in the model, double-click the last **Model Reference** line in the Rename dialog box. Observe the model name on the highlighted control block, `slexPowerWindowControl`.

- 5 In the Rename dialog box, click **Rename and Update**.

The project updates the impact files to use the new model name in model references. When the project can automatically rename items, it reports success with a check mark. With some impacts, you must decide how to fix the affected files manually.

- 6 Examine the results by double-clicking items in the Rename dialog box. Double-click the last **Model Reference** line. Check if the model name on the highlighted control block is updated to `slxPowerWindowControlSystem`.

Related Examples

- “Work with Project Files” on page 17-8

Back Out Changes

Similar to many applications, Simulink Project enables you to Undo and Redo, to back out recent changes.

- 1 Click the arrow next to the Undo or Redo button.
- 2 Select the actions you want to undo or redo. You can select multiple actions. Hover over each action to view details in a tooltip.

If you are using source control, you can revert to particular versions of files or projects. See “Revert Changes” on page 19-49.

Related Examples

- “Revert Changes” on page 19-49

Upgrade Model Files to SLX and Preserve Revision History

In this section...

“Project Tools for Migrating Model Files to SLX” on page 17-19

“Upgrade the Model and Commit the Changes” on page 17-19

“Verify Changes After Upgrade to SLX” on page 17-22

Project Tools for Migrating Model Files to SLX

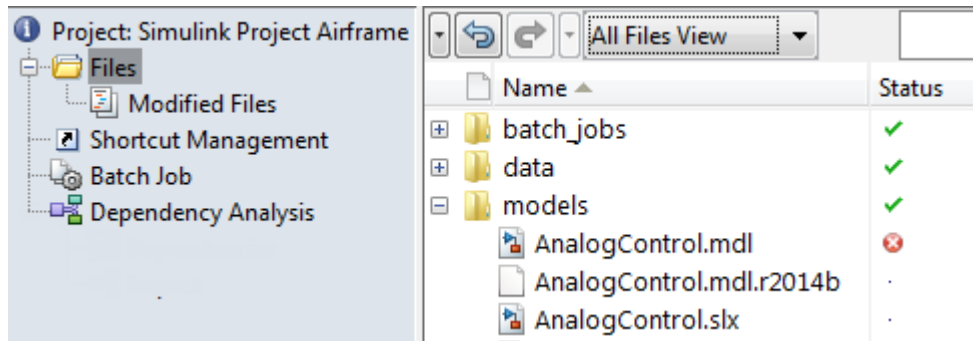

Simulink Project helps you upgrade model files from MDL format to SLX format. You can use the project integrity checks to automatically add the new SLX file to your project, remove the MDL file from the project, and preserve the revision history of your MDL file with the new SLX file. You can then commit your changes to source control and maintain the continuity of your model file history.

The following example shows how to use project checks to fix your project after manually saving a model as SLX.

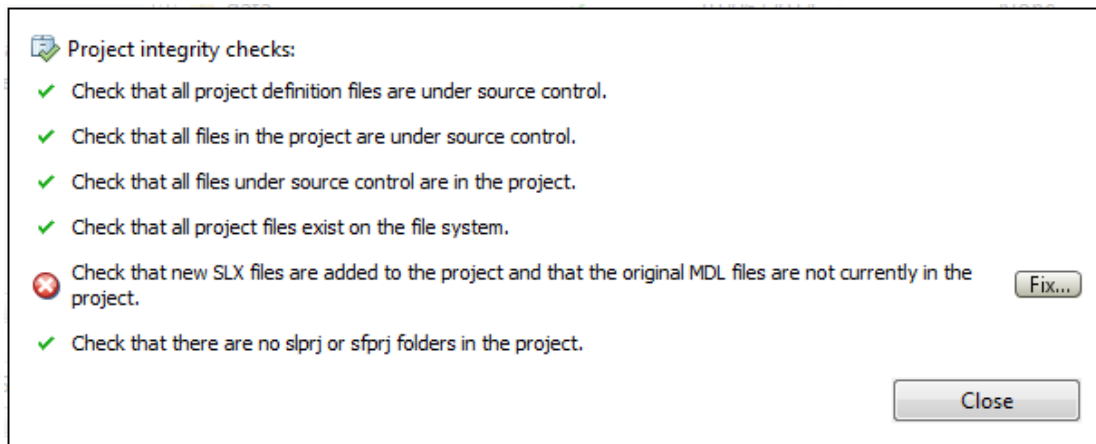

Upgrade the Model and Commit the Changes

- 1 Open a new copy of the `airframe` project.
`sldemo_slproject_airframe`
- 2 In the Project Files View, right-click the model file `AnalogControl.mdl`, and select **Open**.
- 3 Select **File > Save As**.
- 4 Ensure that **Save as type** is SLX, and click **Save**. SLX is the default unless you change your preferences.
- 5 To see the results, in the Files view, click the **Project Files View** button and change the selection to the **All Files View**. Expand the `models` folder.

Simulink saves the model in SLX format, and creates a backup file by renaming the MDL file to `AnalogControl.mdl.releasename`. The project also reports the original name of the MDL file as missing.

- 6 To resolve these issues, on the Simulink Project tab, click **Check Project** to run the project integrity checks. The checks look for MDL files converted to SLX, and offer automatic fixes if that check fails.
- 7 Click the **Fix** button to view recommended actions and decide whether to make the changes.

When you click **Fix**, the Missing Files dialog box offers to remove the missing MDL file from the project and add the new SLX file to the project.

- 8 Click **Yes** to perform the fix.

Project checks rerun after you click **Yes** to perform the fix.

Close the Project Integrity Checks dialog box.

- 9 Select the Modified Files view. Expand the `models` folder and check the Modifications column to see that the newly created SLX file has been added to the project, and the original MDL file is scheduled for removal.

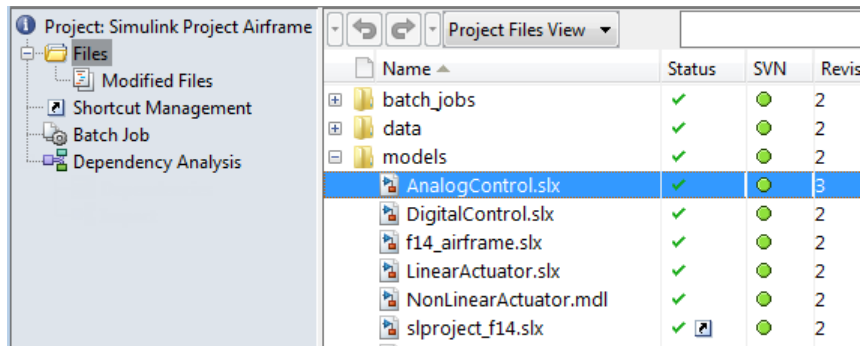

- 10 Click **Commit Modified Files**. Enter a comment for your submission in the dialog box, for example, Convert to SLX, and click **Submit**.

Verify Changes After Upgrade to SLX

- 1 In the Files view, ensure the **All Files View** is selected. Check that the backup file `AnalogControl.mdl.r2012b` is still present, along with the new SLX file. Click the Actions button  to customize the columns to show, such as **Date Modified**.

- 2 In the Files view, click the **All Files View** button and change the selection to the **Project Files View**. Check that only the new SLX file is included in the project, and the backup file is not included in the project.

- 3 Right-click the model file `AnalogControl.slx` and select **Show Revisions**.
- 4 In the File Revisions dialog box, verify that the previous revision is `AnalogControl.mdl`. The revision history of the previous model file is preserved with the new SLX file.

For an example showing commands to find and upgrade all model files in the project to SLX, see [Converting from MDL to SLX Model File Format in a Simulink Project](#).

Note: For an example showing how to programmatically upgrade a whole project using `upgradeadvisor`, see instead:

`sldemo_slproject_upgrade`

Create Labels

In Simulink Project, use labels to organize files and communicate information to project users. You can create these types of label categories:

- Single-valued — You can attach only one label from the category to a file.
- Multi-valued — You can attach multiple labels from the category to a file.

The **Labels** tree has built-in labels in the single-valued **Classification** category:

- You cannot rename or delete **Artifact**, **Convenience**, **Derived**, **Design**, **None**, **Test**, and **Other**.
- You can rename or delete **Utility**.
- You cannot annotate built-in labels.

To create a label category:

- 1 In Simulink Project, right-click the **Labels** pane. Then select **Create New Category**.
- 2 In the Create Category dialog box, enter a name for the new category.
- 3 If you require a single-valued label category, select the **Single Valued** check box. The default is multi-valued.
- 4 If you want to specify a data type for the label other than **String**, from the **Type** list, select **Double**, **Integer**, **Logical**, or **None**.
- 5 Click **Create**.

To create a label in a category:

- 1 In the **Labels** pane, right-click the label category and select **Create New Label**.
- 2 In the Create Label dialog box, enter a name for the new label and click **OK**.

To rename or delete a category or label, right-click it and select **Rename** or **Remove**.

To create new labels at the command line, see “Automate Project Management Tasks” on page 17-29.

Related Examples

- “Add Labels to Files” on page 17-26

- “View and Edit Label Data” on page 17-27

Add Labels to Files

In Simulink Project, use labels to organize files and communicate information to project users.

To add a label to a file, use one of these methods:

- Drag the label from the **Labels** pane onto the file.
- In the Files view, select the file. Then, drag the label from the **Labels** pane into the label editor.

To add a label to multiple files, in the Files view or Impact graph, select the files that require the label. Then right-click and select **Add Label**. Use the dialog box to specify the label.

To add labels programmatically, for example, in batch job functions, see “Automate Project Management Tasks” on page 17-29.

Note: After you add a label to a file, the label persists across file revisions.

After you add labels, you can organize files by label in the Files view and Impact graph. See “Group and Sort File Views” on page 17-2 and “Perform Impact Analysis” on page 18-7.

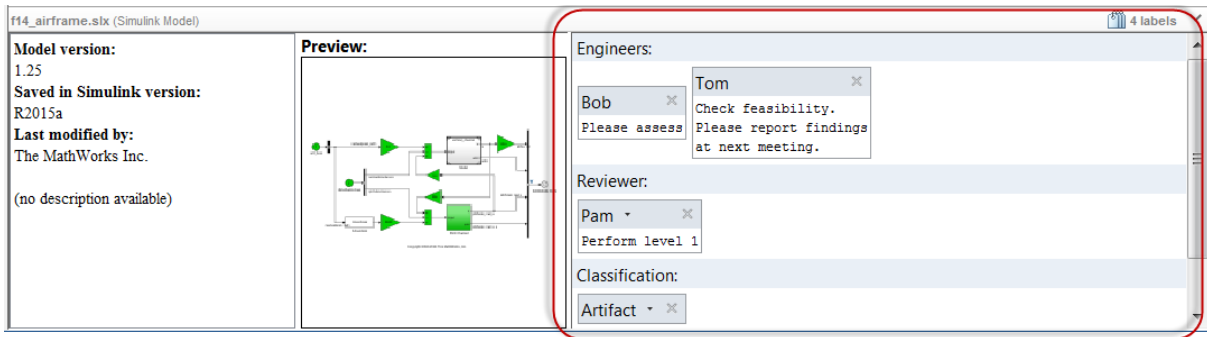

If the project is under SVN source control, adding tags to all your project files enables you to mark versions. See “Tag and Retrieve Versions of Project Files” on page 19-34.

Related Examples

- “Create Labels” on page 17-24
- “View and Edit Label Data” on page 17-27

View and Edit Label Data

When you select a file in the Simulink Project Files view, the file labels appear in the label editor view.

To change a label that belongs to a single-valued category, select the new value from the label list.

You can annotate labels from categories that you create. In the label, insert or modify text. Then, click **Apply**.

“Query Shortcuts” on page 17-35

“Label Files” on page 17-37

“Close Project” on page 17-39

“More Project API Examples Including Source Control” on page 17-39

Manipulate a Simulink Project at the Command Line

You can automate some Simulink project tasks using scripts. You can manipulate project files and labels and use commands for scripting operations on project files. This example shows how to use commands to automate Simulink project tasks with files, including working with modified files, dependencies, shortcuts, and labels.

To automate *startup* and *shutdown* tasks, see “Automate Startup Tasks with Shortcuts” on page 16-33.

Get Simulink Project at the Command Line

This example shows how to open the Airframe project and use `simulinkproject` to get a project object to manipulate the project at the command line. You must open a project in Simulink Project to perform command-line operations on the project.

```
sldemo_slproject_airframe
```

```
proj = simulinkproject
```

```
proj =
```

```
    ProjectManager with properties:
```

```
        Information: [1×1 slproject.Information]
```

```
Dependencies: [1x1 slproject.Dependencies]
Shortcuts: [1x9 slproject.Shortcut]
ProjectPath: [1x7 slproject.PathFolder]
ProjectReferences: [1x0 slproject.ProjectReference]
Categories: [1x1 slproject.Category]
Files: [1x33 slproject.ProjectFile]
RootFolder: 'C:\slexamples\airframe'
```

Find Project Commands

This example shows how to find out what you can do with your project.

Examine project commands.

```
methods(proj)
```

```
Methods for class slproject.ProjectManager:
```

```
addFile                createCategory
addFolderIncludingChildFiles  export
close                  findCategory

findFile              refreshSourceControl
isLoaded              reload
listModifiedFiles    removeCategory

removeFile
```

Examine Project Files

After you get a project object, you can examine project properties.

1 Examine the project files.

```
files = proj.Files
```

```
files =
```

```
1x33 ProjectFile array with properties:
```

```
Path
Labels
Revision
```

```
SourceControlStatus
```

- 2** Use indexing to access files in this list. The following command gets file number 13. Each file has two properties describing its path and attached labels.

```
proj.Files(14)
```

```
ans =
```

```
ProjectFile with properties:
```

```
Path: 'C:\slexamples\airframe\models\AnalogControl.mdl'
Labels: [1x1 slproject.Label]
Revision: '2'
SourceControlStatus: Unmodified
```

- 3** Examine the labels of the 13th file.

```
proj.Files(14).Labels
```

```
ans =
```

```
Label with properties:
```

```
File: 'C:\slexamples\airframe\models\AnalogControl.mdl'
DataType: 'none'
Data: []
Name: 'Design'
CategoryName: 'Classification'
```

- 4** Get a particular file by name.

```
myfile = findFile(proj, 'models/AnalogControl.mdl')
```

```
myfile =
```

```
ProjectFile with properties:
```

```
Path: 'C:\slexamples\airframe\models\AnalogControl.mdl'
Labels: [1x1 slproject.Label]
Revision: '2'
SourceControlStatus: Unmodified
```

- 5** Find out what you can do with the file.

```
methods(myfile)
```

```
Methods for class slproject.ProjectFile:
```

```
addLabel    findLabel    removeLabel
```

Get a List of Modified Files

- 1 Modify a project model file by adding an arbitrary block.

```
open_system('AnalogControl')
add_block('built-in/SubSystem', 'AnalogControl/test')
save_system('AnalogControl')
```

- 2 Get all the modified files in the project.

```
modifiedfiles = listModifiedFiles(proj)
```

```
modifiedfiles =
```

```
1x2 ProjectFile array with properties:
```

```
    Path
    Labels
    Revision
    SourceControlStatus
```

Observe two modified files. Compare with the Modified Files view in Simulink Project, where you can see a modified model file, and the corresponding `.SimulinkProject` definition file.

- 3 Get the second modified file.

```
modifiedfiles(2)
```

```
ans =
```

```
ProjectFile with properties:
```

```
    Path: 'C:\slexamples\airframe\models\AnalogControl.mdl'
    Labels: [1x1 slproject.Label]
    Revision: '2'
    SourceControlStatus: Modified
```

Observe the file `SourceControlStatus` property is `Modified`. Similarly, `listModifiedFiles` returns any files that are added, conflicted, deleted, etc., that show up in the Modified Files view in Simulink Project.

- 4 Get all the project files with a particular source control status. For example, get the files that are `Unmodified`.

```
proj.Files(ismember([proj.Files.SourceControlStatus], matlab.sourcecontrol.Status.L
ans =
    1x32 ProjectFile array with properties:
        Path
        Labels
        Revision

```

Get File Dependencies

- 1 Update the file dependencies.

```
update(proj.Dependencies)
```

The project runs a dependency analysis to update the known dependencies between project files.

- 2 Examine the dependencies in the project object.

```
proj.Dependencies
```

```
ans =
```

```
Dependencies with properties:
```

```
Graph: [1×1 digraph]
```

The dependencies property of the project object contains the graph of dependencies between project files in a MATLAB digraph object. You can view the same dependency analysis graph in the **Impact** view of Simulink Project. If you want to plot the graph, instead of working with the digraph object, save the impact view to an image file. See “Perform Impact Analysis” on page 18-7.

- 3 Get the graph dependencies.

```
g = proj.Dependencies.Graph
```

```
g =
```

```
digraph with properties:
```

```
Edges: [22×1 table]
```

```
Nodes: [24x1 table]
```

- You can use digraph methods to get information from the graph.
- 4** Get the files required by a model.

```
requiredFiles = bfsearch(g, which('AnalogControl'))

requiredFiles =

    3x1 cell array

    'C:\slexamples\airframe11\models\AnalogControl.mdl'
    'C:\slexamples\airframe11\data\controller.sldd'
    'C:\slexamples\airframe11\data\buses.sldd'
```

- 5** Get the top-level files of all types in the graph.

```
top = g.Nodes.Name(indegree(g)==0);
```

- 6** Get the top-level files that have dependencies.

```
top = g.Nodes.Name(indegree(g)==0 & outdegree(g)>0)
```

```
top =
```

```
    5x1 cell array
```

```
    'C:\slexamples\airframe11\models\DigitalControl.slx'
    'C:\slexamples\airframe11\models\LinearActuator.slx'
    'C:\slexamples\airframe11\models\slproject_f14.slx'
    'C:\slexamples\airframe11\tests\f14_airframe_test.m'
    'C:\slexamples\airframe11\utilities\upgrade_project.m'
```

- 7** Find impacted (or “upstream”) files by creating a graph from the transposed adjacency matrix.

```
transposed = digraph(adjacency(g)', g.Nodes.Name);
impacted = bfsearch(transposed, which('vertical_channel'))
```

```
impacted =
```

```
    4x1 cell array
```

```
    'C:\slexamples\airframe11\models\vertical_channel.slx'
    'C:\slexamples\airframe11\models\f14_airframe.slx'
    'C:\slexamples\airframe11\models\slproject_f14.slx'
    'C:\slexamples\airframe11\tests\f14_airframe_test.m'
```

- 8** Get information on your files, such as the number of dependencies and orphans.

```
averageNumDependencies = mean(outdegree(g));
numberOfOrphans = sum(indegree(g)+outdegree(g)==0);
```

- 9** If you want to make changes to a model hierarchy, starting from the bottom up, find the topological order.

```
ordered = g.Nodes.Name(flip(toposort(g)));
```

Query Shortcuts

- 1** Examine the project's `Shortcuts` property.

```
shortcuts = proj.Shortcuts
```

```
shortcuts =
```

```
1x9 Shortcut array with properties:
```

```
File
RunAtStartup
RunAtShutdown
```

- 2** Examine the 8th shortcut in the array.

```
shortcuts(9)
```

```
ans =
```

```
Shortcut with properties:
```

```
File: 'C:\slexamples\airframe\utilities\set_up_project.m'
RunAtStartup: 1
RunAtShutdown: 0
```

The `RunAtStartup` property is set to 1, so this shortcut file is set to run at project startup. At the command line, you can view but not change the `RunAtStartup` and `RunAtShutdown` properties. To set these properties, use the `Shortcut Management` node in the Simulink Project.

- 3** Get the file path of a shortcut.

```
shortcuts(6).File
```

```
ans =
```

```
C:\slexamples\airframe\reports\slproject_f14.pdf
```

- 4 Examine all the files in the `shortcuts` cell array.

```
{shortcuts.File}'

ans =

    'C:\slexamples\airframe\batch_jobs\billOfMaterials.m'
    'C:\slexamples\airframe\batch_jobs\checkCodeProblems.m'
    'C:\slexamples\airframe\batch_jobs\runUnitTest.m'
    'C:\slexamples\airframe\batch_jobs\saveModelFiles.m'
    'C:\slexamples\airframe\models\slproject_f14.slx'
    'C:\slexamples\airframe\reports\slproject_f14.pdf'
    'C:\slexamples\airframe\utilities\clean_up_project.m'
    'C:\slexamples\airframe\utilities\rebuild_s_functions.m'
    'C:\slexamples\airframe\utilities\set_up_project.m'
```

- 5 Create a logical array that shows the shortcuts set to run at startup.

```
idx = [shortcuts.RunAtStartup]

idx =
    0  0  0  0  0  0  0  0  1
```

- 6 Use the logical array to get only the startup shortcuts.

```
startupshortcuts = shortcuts(idx)

startupshortcuts =

    Shortcut with properties:

        File: 'C:\slexamples\airframe\utilities\set_up_project.m'
    RunAtStartup: 1
    RunAtShutdown: 0
```

- 7 Get the path of the startup shortcut by accessing the File property.

```
startupshortcuts.File

ans =

    1×51 char array

    C:\slexamples\airframe\utilities\set_up_project.m
```

Label Files

Create New Category of Project Labels

- 1 Create a new category of labels, of type char.

```
createCategory(proj, 'Engineers', 'char')

ans =

    Category with properties:
        Name: 'Engineers'
        SingleValued: 0
        DataType: 'char'
        LabelDefinitions: [1x0 slproject.LabelDefinition]
```

- 2 In Simulink Project, the new **Engineers** category appears in the **Labels** pane. Find out what you can do with the new category.

```
category = findCategory(proj, 'Engineers');
methods(category)

Methods for class slproject.Category:

createLabel  findLabel  removeLabel
```

Define a New Label

- 1 Define a new label in the new category.

```
createLabel(category, 'Bob');
```

- 2 Get a label definition.

```
ld = findLabel(category, 'Bob')

ld =

    LabelDefinition with properties:
        Name: 'Bob'
        CategoryName: 'Engineers'
```

Label a Project File

- Attach a label to the retrieved file, myfile.

```
addLabel(myfile, 'Engineers', 'Bob');
```

If you select the file in Simulink Project, you can see this label in the label editor pane.

Attach Data to a Label

- Get a particular label and attach data to it, for example, the text Please assess.

```
label = findLabel(myfile, 'Engineers', 'Bob');  
label.Data = 'Please assess'
```

```
label =
```

```
Label with properties:
```

```
File: 'C:\slexamples\airframe\models\AnalogControl.mdl'  
DataType: 'char'  
Data: 'Please assess'  
Name: 'Bob'  
CategoryName: 'Engineers'
```

You can specify a variable for the label data: `mydata = label.Data`.

Attach New Label with Numeric Data Type

- 1 Create label category with numeric data type.

```
createCategory(proj, 'Assessors', 'double');  
category = findCategory(proj, 'Assessors');
```

- 2 Create new label.

```
createLabel(category, 'Sam');
```

- 3 Specify project file.

```
myfile = proj.Files(14);
```

- 4 Attach label to file and assign data value 2 to the label.

```
addLabel(myfile, 'Assessors', 'Sam', 2)
```

```
ans =
```

Label with properties:

```
File: 'C:\slexamples\airframe\models\AnalogControl.mdl'  
DataType: 'double'  
Data: 2  
Name: 'Sam'  
CategoryName: 'Assessors'
```

Close Project

- `close(proj)`

Closing the project at the command line is the same as closing the project using the Simulink Project tool. For example, the project runs shutdown scripts.

More Project API Examples Including Source Control

For more examples, see:

- Automate Label Management in a Simulink Project
- Examples on specific function pages, for example, `simulinkproject`, `listModifiedFiles`, `refreshSourceControl`, `addLabel`, `createLabel`, `createCategory`.

Related Examples

- “Create Labels” on page 17-24

- “View and Edit Label Data” on page 17-27
- “View Modified Files” on page 19-41

Create a Batch Function

In Simulink Project, in the Batch Job view, you can create functions and run them on selected project files.

For example batch jobs, see [Running Batch Jobs with a Simulink Project](#).

To create a batch function:

- 1** In the Simulink Project Batch Job view, click **Create**.
- 2** Name and save the file on your MATLAB path. Simulink Project adds the file to the project and makes it a batch job shortcut so it is easy to reuse.
- 3** The MATLAB Editor opens the new file containing a simple example batch job for you to edit. Edit the function to perform the desired action on each file. The instructions guide you to create a batch job with the correct function signature.
- 4** In the Batch Job view, click **Select** to choose your new batch job function from the list.

Similarly, you can create a batch job at the Shortcut Management node by selecting **Create Action Shortcut > Batch Job Function**.

To make existing batch functions into shortcuts, see “Create Shortcuts to Batch Job Functions” on page 17-41.

Related Examples

- “Run a Simulink Project Batch Job and Publish Report” on page 17-42

Create Shortcuts to Batch Job Functions

You can make existing batch functions in the project easier to find and reuse by making them shortcuts. These shortcuts are available in the Batch Job list without browsing for the file.

- 1 In the Project Files view, right-click the batch function and select **Create Shortcut**.
- 2 In the Shortcut Management view, right-click the batch function and select **Set Shortcut Action > Batch Job**.
- 3 In the Batch Job view, click **Select** to choose from a list of batch job shortcuts and recently used shortcuts.

Related Examples

- “Create a Batch Function” on page 17-40
- “Run a Simulink Project Batch Job and Publish Report” on page 17-42

Run a Simulink Project Batch Job and Publish Report

- 1 In Simulink Project, in the Batch Job view, select the check boxes of project files you want to include in the batch job.

Tip If the batch function can identify the files to operate on, include all files. For example, the batch job function `saveModelFiles` in the `airframe` project checks that the file is a Simulink model and does nothing if it is not.

To select multiple files, **Shift** or **Ctrl**+click, and then right-click a file and select **Include** or **Exclude**.

- 2 Specify the batch function to run in the Batch function box. Enter the name, or click **Select** to browse or choose from a list of Batch Job shortcuts and recently used shortcuts.

If your project does not yet contain any batch functions, see “Create a Batch Function” on page 17-40.

- 3 Click **Run Batch Job**.

Simulink Project displays the results in the Batch Job Results column.

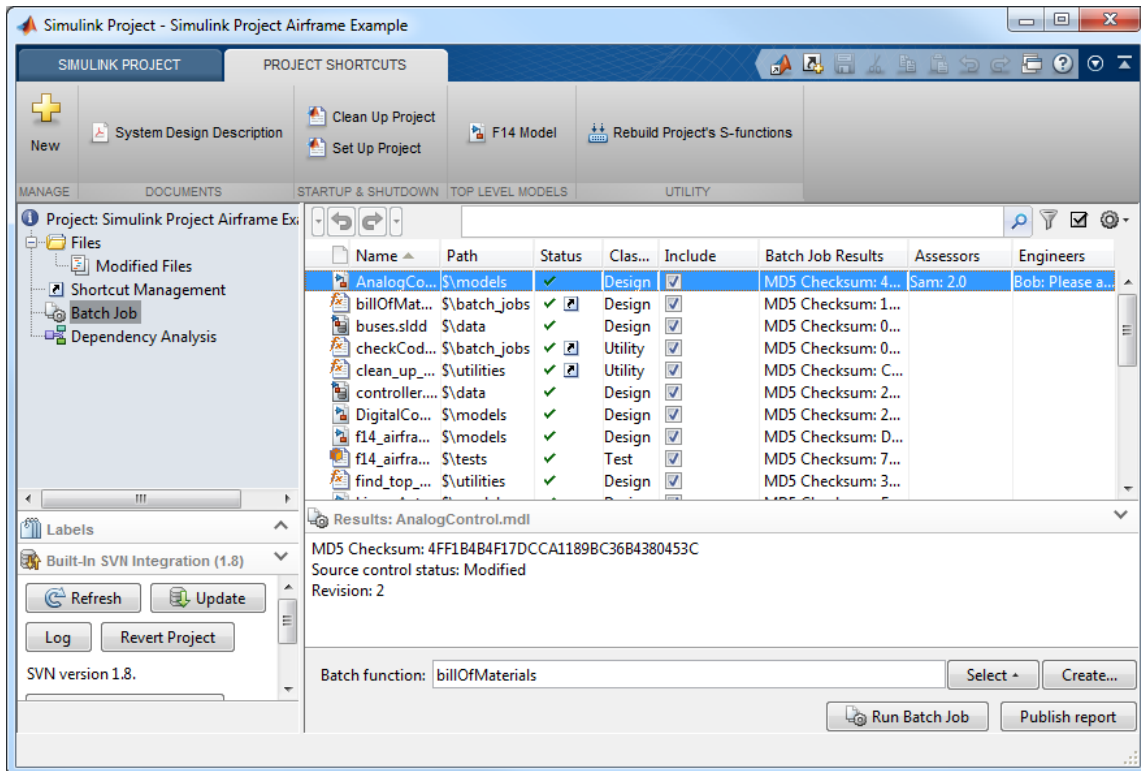

- 4 Expand the Results pane to view details of results for the currently selected file.

You can publish a report of your batch job results. For example, try this batch job:

- 1 Open an example project by entering `sldemo_slproject_batchjobs`.
- 2 In the Batch Job view, click **Select** to choose from a list of batch job shortcuts and recently used shortcuts. Choose **Select > Utility > Generate Bill of Materials Report**.
- 3 Click **Run Batch Job**. Results appear.
- 4 Click **Publish Report**.
- 5 In the file browser, specify a name and location for the report, and choose a file type from HTML or Microsoft Word. If you have MATLAB Report Generator, on Windows, you can also choose PDF.
- 6 View the results in the report.

The example batch job function **Generate Bill of Materials Report** creates a list of project files, their source control status, revision numbers, and MD5 checksums. You can view the code for this batch job in the file `billOfMaterials.m`.

- To see the report file and add it to your project, switch to the **All Files View**.

Tip To try example batch jobs in a project, see the example [Running Batch Jobs with a Simulink Project](#).

Sharing Simulink Projects

Simulink projects help you collaborate. Use the **Share** menu to share your project in these ways:

- Archive your project in a zip file.
- Share your project by email (Windows only).
- Create a template from your project.
- Package your project as a MATLAB toolbox.
- Make your project publicly available on GitHub.

You can also collaborate by using source control within Simulink projects.

Related Examples

- “Archive Projects in Zip Files” on page 17-51
- “Create a Template from the Current Project” on page 16-45
- “Share Project by Email” on page 17-47

- “Share Project as a MATLAB Toolbox” on page 17-48
- “Share Project on GitHub” on page 17-49

More About

- “About Source Control with Projects” on page 19-2

Share Project by Email

To package and share Simulink project files on Windows, you can email your project as a zip file attachment. For example, you can share the project with people who do not have access to the connected source control tool.

- 1 With a project loaded, on the **Simulink Project** tab, select **Share > Email**.

The project opens a new email in your default email client with the project attached as a zip file.

- 2 Edit and send the email.

Related Examples

- “Create a New Project from an Archived Project” on page 16-24
- “Archive Projects in Zip Files” on page 17-51

More About

- “Sharing Simulink Projects” on page 17-45

Share Project as a MATLAB Toolbox

To package and share Simulink project files, you can create a MATLAB toolbox from your project.

- 1 With a project loaded, on the **Simulink Project** tab, select **Share > Toolbox**.

The packager adds all project files to the toolbox and opens the Package a Toolbox dialog box.

- 2 The **Toolbox Information** fields are populated with the project name, author, and description. Edit the information if needed.
- 3 If you want to include files not already included in the project files, edit the excluded files and folders.
- 4 Click **Package**.

Related Examples

- “Create and Share Toolboxes”

More About

- “Sharing Simulink Projects” on page 17-45

Share Project on GitHub

To share your Simulink project, you can make your project publicly available on GitHub. First, create a login on GitHub.

You can share any project. Sharing adds Git source control to the open project. If your project is already under source control, sharing replaces the source control configuration with Git, and the project's remote repository is GitHub.

Note: If you do not want to change your current source control in the open project, share a copy of the project instead. To create a copy to share, see “Archive Projects in Zip Files” on page 17-51.

- 1 With a project loaded, on the **Simulink Project** tab, select **Share > Get More**.
- 2 Add the **GitHub** option to your **Share** menu. In the Manage Sharing dialog box, select **GitHub** and click **Close**.
- 3 Select **Share > GitHub**.
- 4 In the Create GitHub Repository dialog box, enter your GitHub user name and password, and edit the name for the new repository. Click **Create**.

A warning prompts you to confirm that you want to create a public repository and modify the current project's remote repository location. To continue, click **Yes**.

- 5 The Create GitHub Repository dialog box displays the URL address for your new repository. Click the link to view the new repository on the GitHub website. The repository contains the initial check-in of your project files.
- 6 The source control in your current project now references the new repository on GitHub as the remote repository. To use the project with the new repository, in the Create GitHub Repository dialog box, click **Reload Project**.

In the project, you can find the URL address for your remote repository at the top project node, under **Source Control**, in the **Repository location** field.

If you have not already set up Git, you need some additional setup steps before you can merge branches. You can use other Git functionality without any additional installation. See “Set Up Git Source Control” on page 19-20.

Related Examples

- “Archive Projects in Zip Files” on page 17-51
- “Set Up Git Source Control” on page 19-20

More About

- “Sharing Simulink Projects” on page 17-45

Archive Projects in Zip Files

To package and share project files, you can export all project files to a zip file. For example, you can share a zipped project with people who do not have access to the connected source control tool.

- 1 With a project loaded, on the **Simulink Project** tab, select **Share > Zip Archive**.
- 2 Use the file browser to specify a file path in the **Zip file** field. By default, the file *myProjectName.zip* is created in the current working folder.
- 3 If you have referenced projects and want to export the referenced project files, then select the **Copy referenced projects into archive** check box.
- 4 Click **Archive**.

If you want to exclude files from the archive, create an export profile to exclude files with particular labels.

- 1 Create labels and add them to the project files you want to exclude. See “Create Labels” on page 17-24.
- 2 Specify an export profile. On the **Simulink Project** tab, select **Share > Manage Export Profiles**.
 - a Click **+** and specify a name for the export profile.
 - b In the Files pane, click **+** and select the labels for the files you do not want to export, and click **OK**. You can also choose not to export custom labels.
 - c Click **Apply** and close the Manage Export Profiles dialog box.
- 3 When you share the project to an archive, in the **Export** list, select the name of your export profile to export only the specified files.

Before sharing projects with other users, it can be useful to examine the required toolboxes for your project. See “Find Required Toolboxes” on page 18-9.

Simulink Project Dependency Analysis

- “What Is Dependency Analysis?” on page 18-2
- “Run Dependency Analysis” on page 18-4
- “Perform Impact Analysis” on page 18-7
- “Check Dependency Results and Resolve Problems” on page 18-17
- “Find Requirements Documents in a Project” on page 18-22
- “Save, Open, and Compare Dependency Analysis Results” on page 18-23
- “Analyze Model Dependencies” on page 18-25

What Is Dependency Analysis?

Project Dependency Analysis

In Simulink Project, you can analyze project structure and discover files required by your project in the Dependency Analysis view.

- To help you set up your project with all required files, you can use dependency analysis.

In a Simulink model, select **File > Simulink Project > Create Project from Model**.

Simulink runs dependency analysis on your model to identify required files and a project root location that contains all dependencies. See “Create a Project from a Model” on page 16-18.

Alternatively, you can manually add models to your project, analyze the model dependencies, and then add all dependent files to your project. See “Run Dependency Analysis” on page 18-4.

- You can use the Impact graph view of a dependency analysis to analyze the structure of a project visually. You can perform impact analysis to find the impact of changing particular files. In the graph, you can examine your project structure; find required toolboxes for the whole project or for selected files; open, edit, and run files; add labels and export files. See “Perform Impact Analysis” on page 18-7.

Impact analysis can show you how a change affects other files before you make the change. For example:

- Investigate the potential impact of a change in requirements by finding the design files linked to the requirements document.
- Investigate change set impact by finding upstream and downstream dependencies of modified files before committing the changes. Finding these dependencies can help you identify design and test files that need modification and help you find the tests you need to run.
- You can run dependency analysis at any point in your workflow when you want to check that the project has all required files. For example, check dependencies before submitting a version of your project to source control. To work with results, see “Check Dependency Results and Resolve Problems” on page 18-17.

- You can search for requirements documents in a project. See “Find Requirements Documents in a Project” on page 18-22.
- After performing dependency analysis, you can open or label the files, export the results as workspace variables, images, or reloadable files, or send files for batch processing. Exporting the results enables further processing or archiving of impact analysis results. You can add the exported list of files to reports or artifacts that describe the impact of a change. See “Save, Open, and Compare Dependency Analysis Results” on page 18-23.

Tip For an example showing how to perform file-level impact analysis to find and run the tests affected by modified files, see Perform Impact Analysis with a Simulink Project.

Model Dependency Analysis

Simulink Project can analyze file dependencies for your entire project. For detailed dependency analysis of a *specific* model, use the manifest tools to control more options. Use the manifest tools if you want to:

- Analyze a model that is not in a project.
- Save the list of the model dependencies to a manifest file.
- Create a report to identify where dependencies arise.
- Control the scope of dependency analysis.

See “Analyze Model Dependencies” on page 18-25.

Related Examples

- “Run Dependency Analysis” on page 18-4
- “Check Dependency Results and Resolve Problems” on page 18-17
- “Perform Impact Analysis” on page 18-7
- “Find Requirements Documents in a Project” on page 18-22
- “Analyze Model Dependencies” on page 18-25

Run Dependency Analysis

Note: You can analyze only files that are in your Simulink project. If your project is new, add files to the project before running a dependency analysis. See “Add Files to the Project” on page 16-22.

- 1 In the Simulink Project tree, select **Dependency Analysis**.
- 2 If you want to analyze the dependencies of external toolboxes, select **Options > Analyze External Toolboxes**.

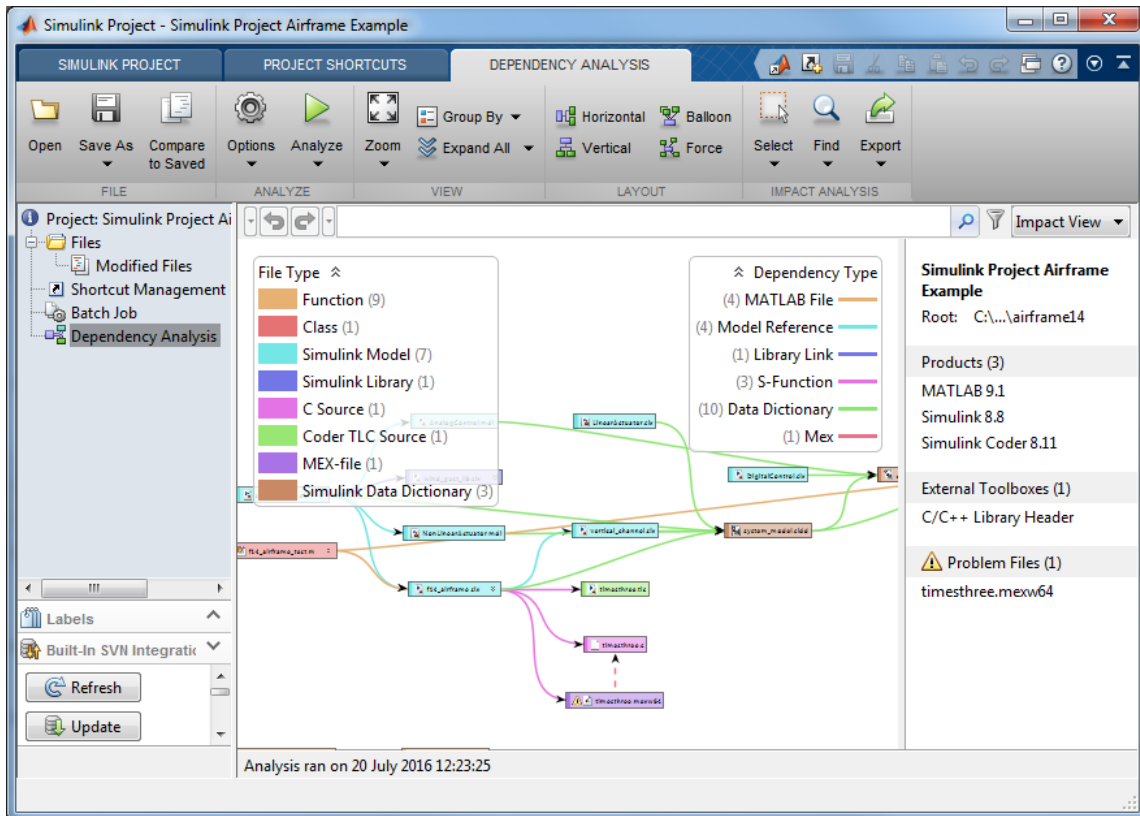

After you run the first dependency analysis of your project, subsequent analyses are incremental updates. However, if you update external toolboxes and want to discover dependency changes in them, you must perform a complete analysis. In this case, turn off **Options > Perform Incremental Updates** before running the dependency analysis.

- 3 To analyze all files in your project, on the **Dependency Analysis** tab or view, select **Analyze**.

If you want to analyze specific files, on the **Dependency Analysis** tab, click **Analyze > Select Files to Analyze**. In the Dependency Analysis dialog box, select files for analysis, and click **Analyze**.

Note: In the Simulink Editor, if an open model, library, or chart belongs to a project, you can find file dependencies. Select **File > Simulink Project > Find Dependencies**. Simulink Project analyzes the whole project and shows upstream and downstream dependencies for the file.

For next steps, see:

- “Find Required Toolboxes” on page 18-9
- “Find Dependencies of Selected Files” on page 18-12
- “Select, Edit, and Export File Dependencies” on page 18-13
- “Check Dependency Results and Resolve Problems” on page 18-17

Tip To try a dependency analysis on example files, see Perform Impact Analysis with a Simulink Project.

Related Examples

- “Check Dependency Results and Resolve Problems” on page 18-17

- “Save, Open, and Compare Dependency Analysis Results” on page 18-23
- “Find Requirements Documents in a Project” on page 18-22

Perform Impact Analysis

In this section...

“About Impact Analysis” on page 18-7

“Run Dependency Analysis” on page 18-7

“Find Required Toolboxes” on page 18-9

“Find Dependencies of Selected Files” on page 18-12

“Select, Edit, and Export File Dependencies” on page 18-13

About Impact Analysis

In Simulink Project, you can use impact analysis to find out the impact of changing particular files. Investigate dependencies visually and explore the structure of your project. Analyze selected or modified files to find their required files and the files they affect. Impact analysis can show you how a change affects other files before you make the change. For example, you can:

- Investigate the potential impact of a change in requirements by finding the design files linked to the requirements document.
- Investigate change set impact by finding upstream and downstream dependencies of modified files before committing the changes. Finding these dependencies can help you identify design and test files that need modification, and help you find the tests you need to run.

After performing dependency analysis, you can open or label the files, export the results as workspace variables, images, or reloadable files, or send files for batch processing. Exporting the results enables further processing or archiving of impact analysis results. You can add the exported list of files to reports or artifacts that describe the impact of a change.

Tip For an example showing how to perform file-level impact analysis to find and run the tests affected by modified files, see Perform Impact Analysis with a Simulink Project.

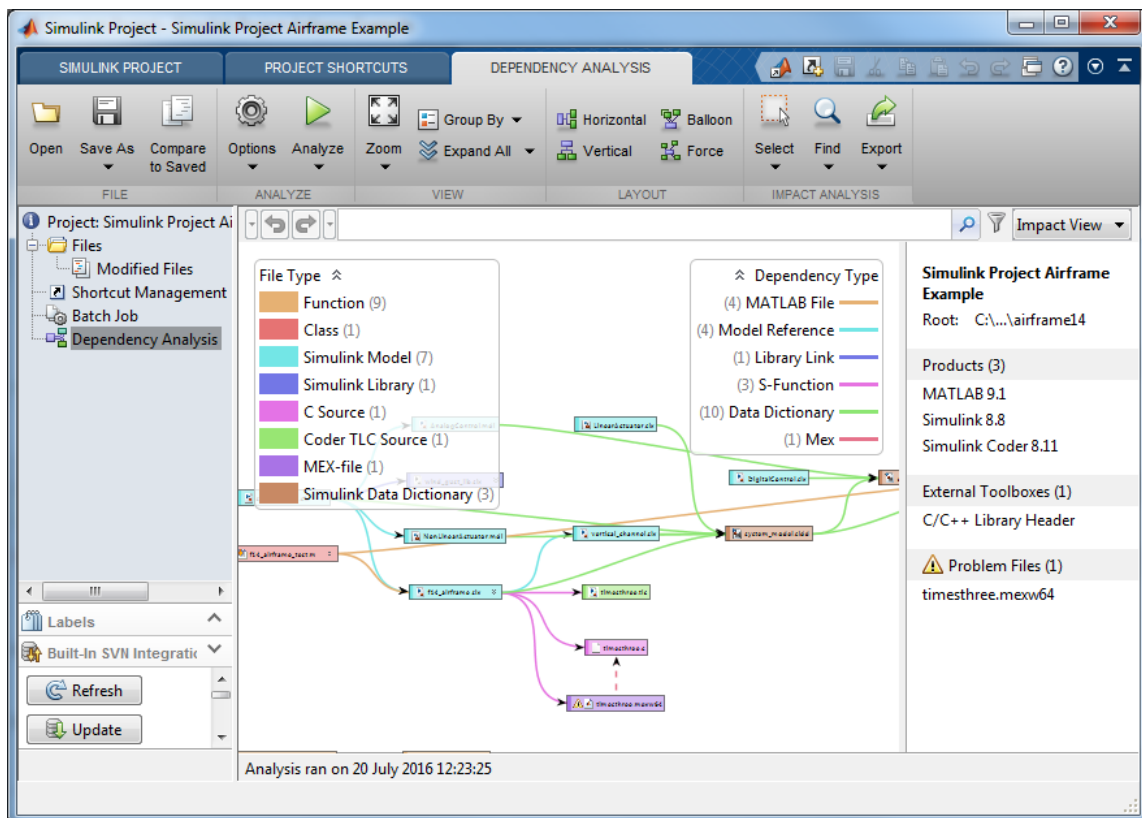

Run Dependency Analysis

To investigate dependencies, run a dependency analysis on your project.

- 1 In the Simulink Project tree, select **Dependency Analysis**. If you want to analyze the dependencies of external toolboxes, select **Options > Analyze External Toolboxes**.
- 2 Click **Analyze**.

The **Impact View** graph displays the structure of all analyzed dependencies in the project. Project files that are not detectable dependencies of the analyzed files do not appear on the graph.

After you run the first dependency analysis of your project, clicking **Analyze** again produces incremental updates. If you want to analyze changes in external toolboxes, turn off the incremental update option.

After performing dependency analysis, the Impact view shows:

- A graph of your project structure and its file dependencies, showing how files such as models, libraries, functions, data files, and source and derived files relate to each other.
- Required products and toolboxes.
- Relationships between source and derived files (such as `.m` and `.p` files, `.slx` and `.slxp`, `.ssc` and `.sscp`, `.c` and `.mex` files), and between C/C++ source and header files.
- Warnings about problem files, such as missing files, files not in the project, unsaved changes, and out-of-date derived files.

For next steps:

- “Find Required Toolboxes” on page 18-9
- “Find Dependencies of Selected Files” on page 18-12
- “Select, Edit, and Export File Dependencies” on page 18-13
- “Check Dependency Results and Resolve Problems” on page 18-17

Tip To try a dependency analysis on example files, see Perform Impact Analysis with a Simulink Project.

Find Required Toolboxes

After running dependency analysis in a Simulink project, the Impact view shows the required toolboxes for the whole project or for selected files. You can see which products a new team member requires to use the project, or find which file is introducing a product dependency.

- 1 After running dependency analysis, view the required products for the whole project listed in the right pane.
- 2 To find which file is introducing a product dependency, hover over the product name and click **Find Usages**.

Simulink Project Airframe Example

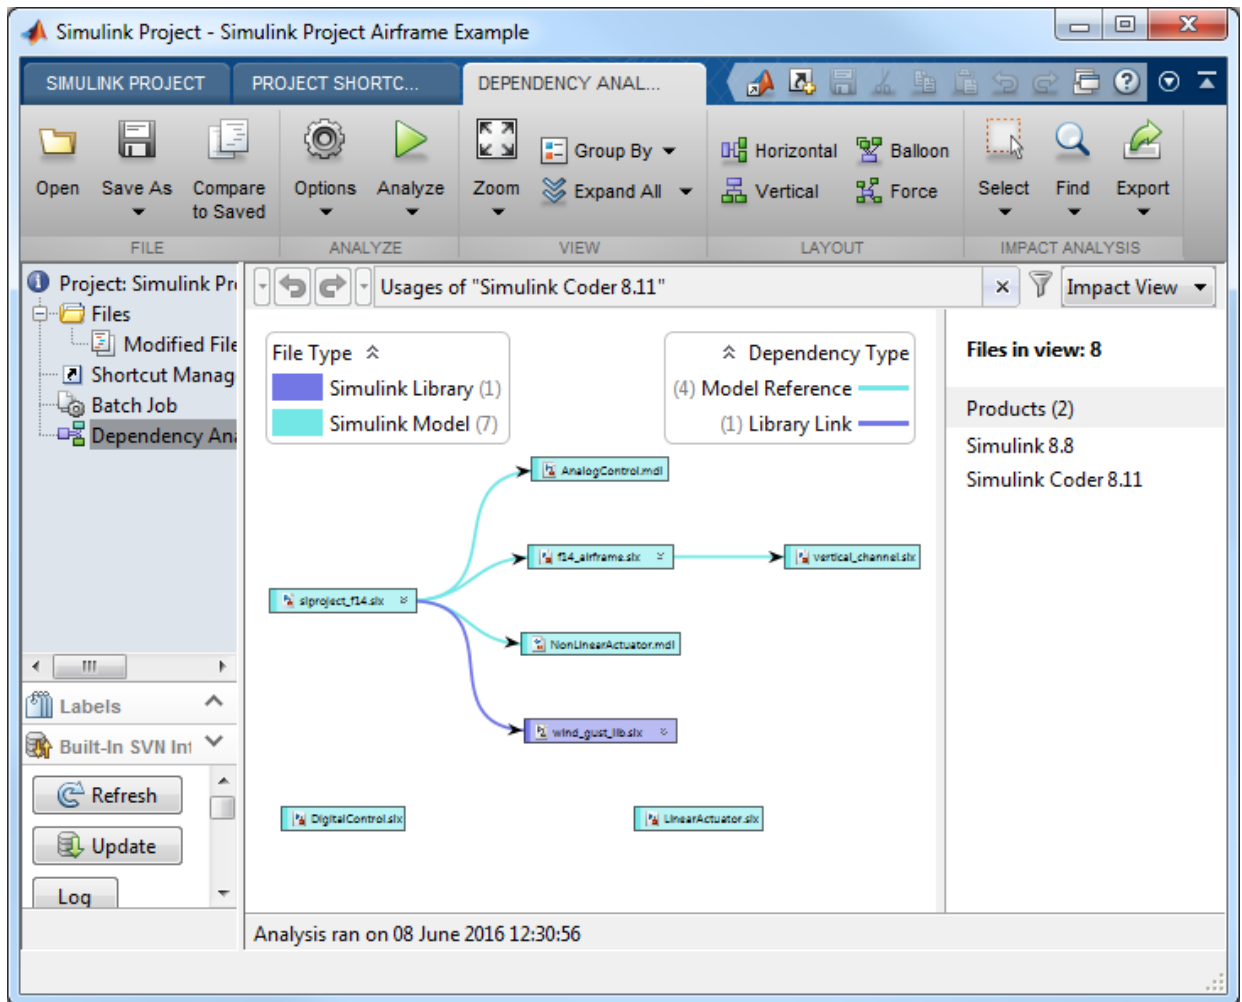

Root: C:\slexamples\airframe8

Products (3)
MATLAB 9.1
Simulink 8.8
Simulink Coder 8... Find Usages →

External Toolboxes (1)
C/C++ Library Header

⚠ Problem Files (1)
timesthree

The graph updates to show only the files using the selected product.

To return to the full project view, clear the filter in the search box (e.g., Usages of “*productname*”).

- 3 To view required products of selected files, select some files by clicking the graph or a legend.

Find Dependencies of Selected Files

After a dependency analysis, to find out the impact of particular files, in the **Impact View** use controls in the **View** and **Impact Analysis** sections of the **Dependency Analysis** tab.

- 1 Select files to investigate using one of these methods:
 - Select files in the graph or select groups of files by clicking the legend. For example, select all model files by clicking **Simulink Model** in the **File Type** legend. Change the legend, in the **View** section of the toolbar, using the **Group By** menu, for example to show problem types, status, or labels.
 - To select modified files, problem files or external files, use the **Select** menu in the **Impact Analysis** section of the toolbar.
- 2 In the **Impact Analysis** section, select **Find** and then specify the range of dependencies you want to display: **All Dependencies of Selection**, **Files Impacted by Selection**, or **Files Required by Selection**.

The graph shows the selected files and their file dependencies.

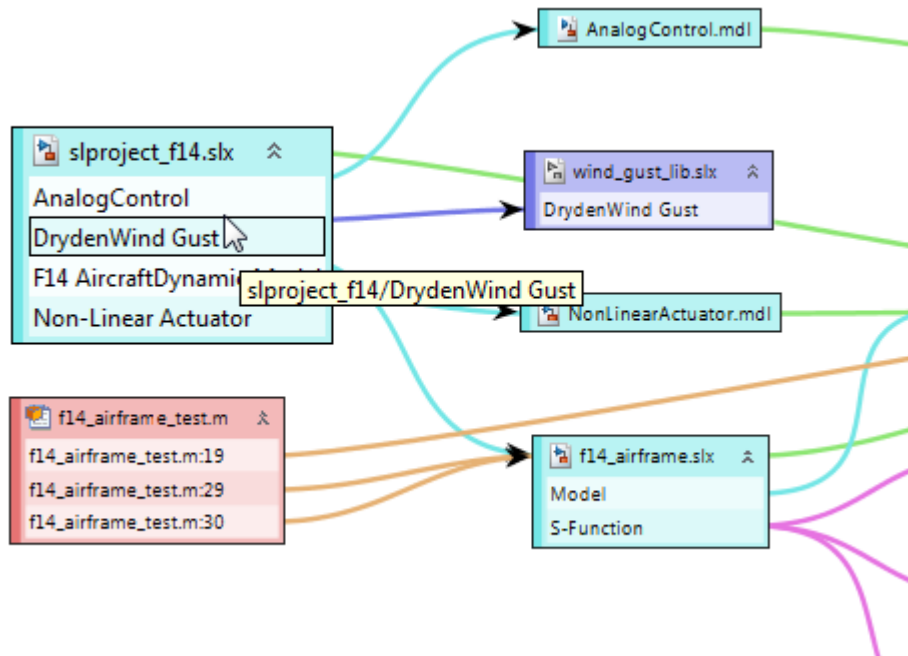

- 3 To see the blocks that have dependencies, expand individual files in the graph by clicking the arrows next to the file names.

The Impact graph expands the dependent file. You can see the subsystems that have dependencies. You can view dependent blocks, models, libraries, and library blocks.

To highlight a dependent block in the model, double-click the block name in the expanded file.

To expand all files in the graph, in the **View** section, click **Expand All**.

- 4 To investigate changes in modified files, right-click and select **Compare to Ancestor** or **Compare to Revision**. See “Compare Revisions” on page 19-43.

Tip To reset the graph to show all analyzed dependencies in the project, on the **Dependency Analysis** tab, in the **Impact Analysis** section, select **Find > All Files**.

Select, Edit, and Export File Dependencies

To highlight or select groups of files:

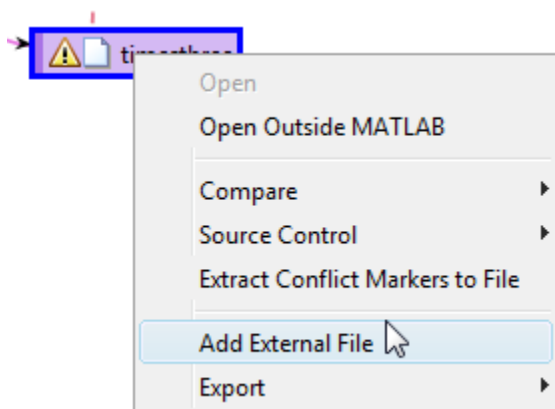

- Click a legend item to select all files of that type. For example, to select all model files, in the **File Type** legend, click **Simulink Model**. Selected files display a blue box.
- To choose a legend, on the **Dependency Analysis** tab, in the **View** section, use the **Group By** control. Choose a category such as file type, project status, source control status, labels, project, and problem type. Files in the graph are colored to indicate the legend category on each file.

For example:

- If your project is under source control, to show modified files, select **Group By > SVN** (or **Git**).
- To identify whether files are in your project or a referenced project, select **Group By > Project**.

To perform file operations:

- Take actions to resolve problem files. For example, right-click a problem file and select **Add to Project** or **Add External File**. For advice on resolving problem files, see “Check Dependency Results and Resolve Problems” on page 18-17.

- Hover over a file to read the file name in the tooltip at any zoom level. Double-click to open the file. Expand or collapse files in the graph by clicking the arrows next to the file names. View dependent blocks under an expanded file, and double-click a dependent block to highlight it in the model.
- Right-click files in the graph to use commands such as **Open**, **Compare**, or **Source Control** operations.

You can perform file operations on multiple files. To fit the view to the currently selected files, press **F**.

- Export selected files using the **Export** menu. You can switch to the files or batch views with the files selected, or send the file paths to a workspace variable. You can also save and reload graph layouts, and save the graph as an image file, using **Save As**. Your graph layout is saved with the project. See “Save, Open, and Compare Dependency Analysis Results” on page 18-23.

Alternatively, you can work with the graph information programmatically. See “Automate Project Management Tasks” on page 17-29.

- Perform Impact Analysis with a Simulink Project

Check Dependency Results and Resolve Problems

In the Simulink Project tree, select **Dependency Analysis**. If you have not yet run an analysis, click **Analyze**. After you run a dependency analysis, you see the Impact graph for the whole project in **Impact View**. The project dependency analysis identifies problem files, such as missing files, files not in the project, unsaved changes, and out-of-date derived files. You can examine problem files and resolve issues using the **Impact View** or the **Table View**.

Problem Message	Description	Fix
Not in project	The file is not in the project.	Add it to the project. You do not need to add all required files to the project. For example, you can exclude derived S-Function binary files that the source code in your project generates. See “Work with Derived Files in Projects” on page 19-66. To remove a file from the problem list without adding it to the project, right-click the file and select Add External File .
Missing	The file is in the project but does not exist on disk.	Create the file, or recover it using source control.
Outside project root	The file is outside the project root folder.	If this is OK, set the file as an external file. Otherwise move it under the project root. If you need a file that is outside the project root to be in your project,

Problem Message	Description	Fix
		<p>copy or move the file within the project root, and add it to the project and the path. Remove the original file location from the path.</p> <p>If required files are outside your project root, you cannot add these files to your project. This dependency might not indicate a problem if the file is on your path and is a utility or resource that is not part of your project. Use dependency analysis to ensure that you understand the design dependencies.</p>
In unreferenced project	The file is within a project that is not referenced by the current project.	Add the project containing the file as a project reference.
Missing variable or file not on MATLAB path	The file or variable could not be found.	If this status is acceptable, set the file as an external file.
Unsaved changes	The file has unsaved changes in the MATLAB or Simulink editors	Save the file.

Problem Message	Description	Fix
Derived file out of date	The derived file is older than the source file it was derived from.	<p>Regenerate the derived file. If it is a P-file, you can regenerate automatically by running the project checks.</p> <p>On the Simulink Project tab, click Check Project and follow prompts to rebuild files.</p> <p>If you rename a source file, the project detects impact in the derived file and prompts you to update it.</p>

Investigate Problem Files in Impact View

Use the **Impact View** to investigate your project dependencies graphically.

- 1 In the Impact view, to see problem files for the whole project, clear any file selections by clicking a blank area of the graph. View any problem files listed in the right panel.
- 2 To view the files that use a problem file, hover over the problem file and click **Find Dependencies**.

The graph updates to display only the problem file and its dependencies, and the problem message in the right panel.

- 3 Take actions to resolve the problem file. For example, right-click the file and select **Add to Project** or **Add External File**.
- 4 Click a problem file and check the path shown on the right. Check if required files are outside your project root.
- 5 Examine or edit dependencies by opening referencing components (such as a block or line of MATLAB code that references a problem file). To open a referencing component, expand a file in the graph, and double-click an item in the list.

MATLAB files open in the MATLAB Editor, and Simulink models open in the Simulink Editor with the referencing component block highlighted.

- 6 To return to the full project view, clear the filter in the search box (e.g., **Dependencies of "filename"**).

For more ways to work with the Impact view, see “Perform Impact Analysis” on page 18-7.

Investigate Problem Files in Table View

- 1 Select **Table View** and sort by the Problem Description column.
- 2 Click each file in the problem list.

The lower pane, under **Upstream Dependencies: *filename***, displays the files that use the selected file.

Check the message in the **Problem Description** column.

- 3 In the dependencies table, check the problem description and project status of dependent files.
- 4 To open the referencing component for editing, right-click a file **Upstream Dependencies: *filename*** table and select **Open**.
- 5 Check the path, where \$ indicates the project root. Check if required files are outside your project root.
- 6 To remove a file from the problem list without adding it to the project, right-click the file and select **Add External File**. The file disappears from the problem list. The next time you run a dependency analysis, this file does not appear in the problem list.
- 7 Clear the search box to view all identified dependencies, not just problem files.

Related Examples

Find Requirements Documents in a Project

In Simulink Project, a dependency analysis finds requirements documents linked using the Requirements Management Interface.

- You can view and navigate to and from the linked requirements documents.
 - You can create or edit Requirements Management links only if you have Simulink Verification and Validation.
- 1 From the Simulink Project tree, select **Dependency Analysis**.
 - 2 Click the **Analyze** button.

The Impact graph displays the structure of all analyzed dependencies in the project. Project files that are not detectable dependencies of the analyzed files are not visible in the graph.

- 3 To highlight requirements documents in the graph, in the Dependency Type legend, click **Requirements Link**. Arrows connect requirements documents to the files with the requirement links.
- 4 To find the specific block containing a requirement link, expand the model file in the graph. Click **Expand All** or click the arrows next to the file name. View the arrow connecting the block containing the requirement link to the requirements document file.
- 5 To open a requirements document, double-click the document in the graph.

Related Examples

- “Save, Open, and Compare Dependency Analysis Results” on page 18-23
- “View Linked Requirements in Models and Blocks” on page 12-69

Save, Open, and Compare Dependency Analysis Results

In Simulink Project, you can save the results of a dependency analysis. You can view the saved results later, without having to repeat the analysis. You can also save results separately in named files and reload them.

Save, open, and compare dependency analysis results from the **File** section of the **Dependency Analysis** tab.

- To save your results as a `.graphml` file, click **Save As** and choose a file name and location.
- To open saved dependency analysis results, click **Open**.
- To compare results with previously saved results, click **Compare to Saved**. Select a `.graphml` file. Inspect the differences in the comparison report.

You can save reports that include more detailed results by using model dependency analysis. For more information about choosing model or project dependency analysis, see “What Is Dependency Analysis?” on page 18-2.

Export Impact Graph Results to Files or Images

To export impact analysis results, on the **Dependency Analysis** tab, in the **Impact Analysis** section, use the **Export** controls, or use the **Export** context menu on selected files.

Select Files to Export

To export all the files in the current view, check that no files are selected. (Click the graph background to clear the selection on all files.) Click **Export** to display **Files in view: *number of files***.

Select a subset of files in the graph to export. Click **Export** to see how many files are selected: **Selected files: *number of files***.

Export Files

- To save the selected file paths to a variable, select **Export > Save to Workspace**.
- To switch to the Batch Job view with the batch job files selected, select **Export > Send to Batch Job**.

- To switch to the Files view with the files selected, select **Export > Show in Files View**.

Export Graph to Image File

To export the Impact graph as an image file for sharing or archiving, you can either:

- Save an image file. On the **Dependency Analysis** tab, in the **File** section, select **Save As > Save As Image**. Use the Save dialog box to specify the name, file type, and location. The default file type is SVG, which supports image scaling.
- Copy the image to the clipboard using the keyboard. You can paste the clipboard contents into other documents.

Export Reloadable Results

To export the impact results to a `.graphml` file that you can reload in Simulink Project, click **Save As** and choose a file name and location..

- “Command-Line Dependency Analysis” on page 18-31
- “Edit Manifests” on page 18-34
- “Compare Manifests” on page 18-37
- “Export Files in a Manifest” on page 18-38
- “Scope of Dependency Analysis” on page 18-40
- “Best Practices for Dependency Analysis” on page 18-43
- “Use the Model Manifest Report” on page 18-44

What Are Model Dependencies?

Each Simulink model requires a set of files to run successfully. These files can include referenced models, data files, S-functions, and other files the model cannot run without. These required files are called *model dependencies*.

Dependency Analysis Requirements	Tools to Choose
Find required files for an entire project.	Use dependency analysis from the Simulink Project. See “Dependency Analysis”.
Perform dependency analysis of a specific model with control of more options.	<p>Use the manifest tools from your model. See “Generate Manifests” on page 18-26.</p> <p>Generate a manifest if you want to:</p> <ul style="list-style-type: none"> • Analyze a model that is not in a project. • Save the list of the model dependencies to a manifest file. • Create a report to identify where dependencies arise.

Dependency Analysis Requirements	Tools to Choose
	<ul style="list-style-type: none"> Control the scope of dependency analysis.

After you generate a manifest for a model to determine its dependencies, you can:

- View the files required by your model in a manifest file.
- Trace dependencies using the report to understand why a particular file or toolbox is required by a model.
- Package the model with its required files into a zip file to send to another Simulink user.
- Compare older and newer manifests for the same model.
- Save a specific version of the model and its required files in a revision control system.

You can also view the libraries and models referenced by your model in a graphical format using the Model Dependency Viewer. See “Model Dependency Viewer” on page 12-64.

Generate Manifests

Generating a manifest performs the dependency analysis and saves the list of model dependencies to a manifest file. You must generate the manifest before using any of the other Simulink Manifest Tools.

Note: The model dependencies identified in a manifest depend upon the **Analysis Scope** options you specify. For example, performing an analysis without selecting **Find Library Links** might not find all the Simulink blocksets that your model requires, because they are often included in a model as library links. See “Manifest Analysis Scope Options” on page 18-29.

To generate a manifest:

- 1 Select **Analysis > Model Dependencies > Generate Manifest**.

The Generate Model Manifest dialog box appears.

- 2 Click **OK** to generate a manifest and report using the default settings.

Alternatively you can first change the following settings:

- Select the **Analysis scope** check boxes to specify the type of dependencies you want to detect (see “Manifest Analysis Scope Options” on page 18-29).
- Control whether to report file dependency locations by selecting **Report file dependency locations for:**
 - **User files only** (default) — only report locations where dependencies are upon user files. Use this option if you want to understand the interdependencies of your own code and do not care about the locations of dependencies on MathWorks products. This option speeds up report creation and streamlines the report.
 - **All files** — report all locations where dependencies are introduced, including all dependencies on MathWorks products. This is the slowest option and the most verbose report. Use this option if you need to trace all dependencies to understand why a particular file or toolbox is required by a model. If you need to analyze many references, it can be helpful to sort the results by clicking the report column headers.
 - **None** — do not report any dependency locations. This is the fastest option and the most streamlined report. Use this option if you want to discover and package required files and do not require all the information about file references.
- If desired, change the **Project Root Location**. If the model is in a project, you can select **Current Simulink Project root folder**. Other check box options are: **Folder containing root model file** (the default), **Common root folder of required files**, or **User-defined location** — for this option, enter a path in the edit box, or browse to a location.
- If desired, edit the **Manifest file name** and location in which to save the file.
- Use the check box **View HTML report on completion** to specify if you want to generate a report when you generate the manifest. You can edit the **Report file name** or leave the default, *mymodelname_manifest_report.html*. You can set the **Report style** to Plain HTML or HTML with Hyperlinks.

When you click **OK** Simulink generates a manifest file containing a list of the model dependencies. If you selected **View HTML report on completion**, the Model Manifest Report appears after Simulink generates the manifest. See “Use the Model Manifest Report” on page 18-44 for an example.

The manifest is an XML file with the extension `.smf` located (by default) in the same folder as the model itself.

Manifest Analysis Scope Options

The Simulink Manifest Tools allow you to specify the scope of analysis when generating the manifest. The dependencies identified by the analysis depend upon the scope you specify.

Tip You can select analysis options that perform a Model Update. If Model Update fails you see an error message. Either clear those analysis options to generate a manifest without a Model Update, or try a manual Model Update to find out more about the problem. For example your model might require variables that are not present in the workspace (for example, if a block parameter defines a variable that you forgot to load manually).

The following table describes the Analysis Scope options.

Check Box Option	Description
Find orphaned base workspace data (performs a Model Update)	Searches for base workspace variables the model requires, that are not defined in any file in this Manifest.
Find enumeration definition files (performs a Model Update)	Searches for enumeration definition files. Turn on this option to detect enumerated datatypes used as part of a bus object definition.
Find and analyze model references	Searches for <code>Model</code> blocks in the model, and identifies any referenced models as dependencies.
Find and analyze linked libraries	Searches for links to library blocks in the model, and identifies any library links as dependencies.
Allow models with unsaved changes to be analyzed	Select this check box only if you want to allow analysis of unsaved changes.
Find requirements documents	Searches for requirements documents linked using the Requirements Management Interface. Note that requirements links created with IBM Rational DOORS software are not included in manifests. For more information, see “Find Requirements Documents in a Project” on page

Check Box Option	Description
	18-22 and “Requirements Management Interface Setup” in the Simulink Verification and Validation documentation.
Click the >> button on the right to show the following advanced analysis options.	
Find S-functions	Searches for S-Function blocks in the model, and identifies S-function files (MATLAB code and C) as dependencies. See the source code item in “Special Cases” on page 18-42.
Analyze model and block callbacks (including Interpreted MATLAB Function blocks)	Searches for file dependencies introduced by the code in Interpreted MATLAB Function blocks, block callbacks, and model callbacks. For more detail on how callbacks are analyzed, see “Code Analysis” on page 18-41.
Find files required for code generation	Searches for file dependencies introduced by Simulink Coder custom code, and Embedded Coder templates. If you do not have a code generation product, this check is off by default, and produces a warning if you select it. This includes analysis of all configuration sets (not just the Active set) and <i>STF_make_rtw_hook</i> functions, and locates system target files and Code Replacement Library definition files (.m or .mat). See also “Required Toolboxes” on page 18-45, and the source code item in “Special Cases” on page 18-42.
Find data files (e.g. in “From File” blocks)	Searches for explicitly referenced data files, such as those in From File blocks, and identifies those files as dependencies. See “Special Cases” on page 18-42.
Analyze Stateflow charts	Searches for file dependencies introduced by using syntax such as <code>ml.mymean(myvariable)</code> in models that use Stateflow.

Check Box Option	Description
Analyze code in MATLAB Functions blocks	Searches for MATLAB Function blocks in the model, and identifies any file dependencies (outside toolboxes) introduced in the code. Toolbox dependencies introduced by a MATLAB Function block are not detected.
Analyze files in “user toolboxes”	Searches for file dependencies introduced by files in user-defined toolboxes. See “Special Cases” on page 18-42.
Analyze MATLAB files	Searches for file dependencies introduced by MATLAB files called from the model. For example, if this option is selected and you have a callback to <code>mycallback.m</code> , then the referenced file <code>mycallback.m</code> is also analyzed for further dependencies. See “Code Analysis” on page 18-41.
Store MATLAB code analysis warnings in manifest	Saves any warnings in the manifest.

See also “Scope of Dependency Analysis” on page 18-40 for more information.

Command-Line Dependency Analysis

- “Check File Dependencies” on page 18-31
- “Check Toolbox Dependencies” on page 18-32

Check File Dependencies

To programmatically check for file dependencies, use the function `dependencies.fileDependencyAnalysis` as follows.

```
[files, missing, depfile, manifestfile] =
dependencies.fileDependencyAnalysis('modelName', 'manifestfile')
```

This returns the following:

- *files* — a cell array of character vectors containing the full-paths of all existing files referenced by the model *modelName*.
- *missing* — a cell array of character vectors containing the names all files that are referenced by the model *modelName*, but cannot be found.

- *depfile* — returns the full path of the user dependencies (.smd) file, if it exists, that stores the names of any files you manually added or excluded. Simulink uses the .smd file to remember your changes the next time you generate a manifest. See “Edit Manifests” on page 18-34.
- *manifestfile* — (optional input) specify the name of the manifest file to create. The suffix .smf is always added to the user-specified name.

If you specify the optional input, *manifestfile*, then the command creates a manifest file with the specified name and path *manifestfile*. *manifestfile* can be a full-path or just a file name (in which case the file is created in the current folder).

If you try this analysis on an example model, it returns an empty list of required files because the standard MathWorks installation includes all the files required for the example models.

Check Toolbox Dependencies

To check which toolboxes are required, use the function `dependencies.toolboxDependencyAnalysis` as follows:

```
[names,dirs] = dependencies.toolboxDependencyAnalysis(files_in)
```

files_in must be a cell array of character vectors containing .m or model files on the MATLAB path. Simulink model names (without file extension) are also allowed.

This returns the following:

- *names* — a cell-array of toolbox names required by the files in *files_in*.
- *dirs* — a cell-array of the toolbox folders.

Note: The method `toolboxDependencyAnalysis` looks for toolbox dependencies of the files in *files_in* but does *not* analyze any subsequent dependencies.

If you want to find all detectable toolbox dependencies of your model *and* the files it depends on:

- 1 Call `fileDependencyAnalysis` on your model.

For example:

```
[files, missing, depfile, manifestfile] = dependencies.fileDependencyAnalysis('mymodel')

files =
    'C:\Work\manifest\foo.m'
    'C:\Work\manifest\mymodel'
missing =
    []
depfile =
    []
manifestfile =
    []
```

- 2 Call `toolboxDependencyAnalysis` on the `files` output of step 1.

For example:

```
tbxes = dependencies.toolboxDependencyAnalysis(files)

tbxes =
[1x24 char]    'MATLAB'    'Simulink Coder'    'Simulink'
```

To view long product names examine the `tbxes` cell array as follows:

```
tbxes{:}

ans =
Image Processing Toolbox

ans =
MATLAB

ans =
Simulink Coder

ans =

Simulink
```

For command-line dependency analysis, the analysis uses the default settings for analysis scope to determine required toolboxes. For example, if you have code generation products, then the check **Find files required for code generation** is on by default and Simulink Coder is always reported as required. See “Required Toolboxes” on page 18-45 for more examples of how your installed products and analysis scope settings can affect reported toolbox requirements.

Edit Manifests

After you generate a manifest, you can view the list of files identified as dependencies, and manually add or delete files from the list.

To edit the list of required files in a manifest:

- 1 Select **Analysis > Model Dependencies > Edit Manifest Contents**.

Alternatively, if you are viewing a manifest report you can click **Edit** in the top **Actions** box, or you can click **View and Edit Manifest** in the Export Manifest dialog box.

The View and Edit Manifest dialog box appears, showing the latest manifest for the current model.

Note: You can open a different manifest by clicking the Browse for manifest file

button . If you have not generated a manifest, select **Generate Manifest** to open the Generate Model Manifest dialog box (see “Generate Manifests” on page 18-26).

- 2 Examine the **Files to be exported** list on the left side of the dialog box. This list shows the files identified as dependencies.
- 3 To add a file to the manifest:

- a Click **Add Files**.

The Add Files to Manifest dialog box opens.

- b Select the file you want to add, then click **Open**.

The selected file is added to the **Files to be exported** list.

- 4 To remove a file from the manifest:

- a Select the file you want to remove from the **Files to be exported** list.

- b

Click the Exclude selected files button .

The selected file is moved to the **Excluded files** list.

Note: If you add a file to the manifest and then exclude it, that file is removed from the dialog box (it is not added to the **Excluded files** list). Only files detected by the Simulink Manifest Tools are included in the Excluded files list.

- 5 If desired, change the **Project Root Location**.
- 6 Click **Save** to save your changes to the manifest file.

Simulink saves the manifest (.smf) file, and creates a user dependencies (.smd) file that stores the names of any files you manually added or excluded. Simulink uses the .smd file to remember your changes the next time you generate a manifest, so you do not need to repeat manual editing. For example, you might want to exclude source code or include a copyright document every time you generate a manifest for exporting to a customer. The user dependencies (.smd) file has the same name and folder as the model. By default, the user dependencies (.smd) file is also included in the manifest.

Note: If the user dependencies (.smd) file is read-only, a warning is displayed when you save the manifest.

- 7 To view the Model Manifest Report for the updated manifest, click **Show Report**.

An updated Model Manifest Report appears, listing the required files and toolboxes, and details of references to other files. See “Use the Model Manifest Report” on page 18-44 for an example.

- 8 When you are finished editing the manifest, click **OK**.

Compare Manifests

You can compare two manifests to see how the list of model dependencies differs between two models, or between two versions of the same model. You can also compare a manifest with a folder or a ZIP file.

To compare manifests:

- 1 From the Current Folder browser, right-click a manifest file and select **Compare Against > Choose**.

Alternatively, from your model, select **Analysis > Model Dependencies > Compare Manifests**.

The dialog box Select Files or Folders for Comparison appears.

- 2 In the dialog box Select Files or Folders for Comparison, select files to compare, and the comparison type.
 - a Use the drop-down lists or browse to select manifest files to compare.
 - b Select the **Comparison type**. For two manifests you can select:
 - **Simulink manifest comparison** — Select for a manifest file list comparison reporting new, removed, and changed files. The report contains links to open files and compare files that differ. You can use a similar file **List comparison** for comparing a manifest to a folder or a ZIP file.
 - **Simulink manifest comparison (printable)** — Select for a printable Model Manifest Differences Report without links. The report provides details about each manifest file, and lists the differences between the files.
- 3 View the report in the Comparison Tool comparing the file names, dates, and sizes stored in the manifests.

Be aware the details stored in the manifest might differ from the files on disc. If you click a “compare” link in the report, you see warnings if there are problems such as size mismatches, or if the tool cannot find those files on disc.

For more information on the Comparison Tool, see “Comparing Files and Folders” in the MATLAB Data and File Management documentation.

Export Files in a Manifest

You can export copies of the files listed in the manifest to a ZIP file. Exporting the files allows you to package the model with its required files into a single ZIP file, so you can easily send it to another user or save it in a revision control system.

To export your model with its required files:

- 1** Select **Analysis > Model Dependencies > Export Files in Manifest**.

Alternatively, if you are viewing a manifest report you can click **Export** in the top **Actions** box.

The Export Files in Manifest dialog box appears, showing the latest manifest for the current model.

Note: You can export a different manifest by clicking the Browse for manifest file button . If you have not generated a manifest, select **Generate Manifest** to open the Generate Model Manifest dialog box (see “Generate Manifests” on page 18-26).

- 2 If you want to view or edit the manifest before exporting it, click **View and Edit Manifest** to view or change the list of required files. See “Edit Manifests” on page 18-34. When you close the View and Edit Manifest dialog box, you return to the Export Files in Manifest dialog box.
- 3 Click **Validate** to check the manifest. Validation reports information about possible problems such as missing files, warnings, and orphaned base workspace data.
- 4 Enter the ZIP file name to which you want to export the model.

- 5 Select **Preserve folder hierarchy when exporting** if you want to keep folder structure for your exported model and files. Then, select the root folder to use for this structure (usually the same as the **Project Root Location** on the Generate Manifest dialog box).

Note: You must select **Preserve folder hierarchy** if you are exporting a model that uses an `.m` file inside a MATLAB class (to maintain the folder structure of the class), or if the model refers to files in other folders (to ensure the exported files maintain the same relative paths).

- 6 Click **OK**.

The model and its file dependencies are exported to the specified ZIP file.

Scope of Dependency Analysis

The Simulink Manifest Tools identify required files and list them in an XML file called a *manifest*. When Simulink generates a manifest file, it performs a static analysis on your model, which means that the model does not need to be capable of performing an “update diagram” operation (see “Update Diagram and Run Simulation” on page 1-64). The only exception to this is when you select the analysis option **Find orphaned base workspace data (performs a Model Update)**.

You can specify the type of dependencies you want to detect when you generate the manifest. See “Manifest Analysis Scope Options” on page 18-29.

For more information on what the tool analyzes, refer to the following sections:

- “Analysis Limitations” on page 18-40
- “Code Analysis” on page 18-41
- “Special Cases” on page 18-42

Analysis Limitations

The analysis might not find all files required by your model (for examples, see “Code Analysis” on page 18-41).

The analysis might not report certain blocksets or toolboxes required by a model. You should be aware of this limitation when sending a model to another user. Blocksets that do not introduce dependence on any files (such as Fixed-Point Designer™) cannot

be detected. Some SimEvents blocks do not introduce a detectable dependence on SimEvents.

To include dependencies that the analysis cannot detect, you can add additional file dependencies to a manifest file using the View/Edit Manifest Contents option (see “Edit Manifests” on page 18-34).

Code Analysis

When the Simulink dependency analysis encounters MATLAB code, for example in a model or block callback, or in a `.m` file S-function, the analysis attempts to identify the files it references. If those files contain MATLAB code, *and* the analysis scope option **Analyze MATLAB files** is selected, the referenced files are also analyzed. This function is similar to `matlab.codetools.requiredFilesAndProducts` but with some enhancements:

- Character vectors passed into calls to `eval`, `evalc`, and `evalin` are analyzed.
- File names passed to `load`, `fopen`, `xlsread`, `importdata`, `dlmread`, and `imread` are identified.

Files that are in MathWorks toolboxes are not analyzed.

File names passed to `load`, etc., are identified only if they are literal character vectors, for example:

```
load('mydatafile')
load mydatafile
```

If you define a file name as a variable and pass that to a function, the file is a hidden dependency. The following example, and anything more complicated, does not identify the dependency because the file name is inside a variable:

```
str = 'mydatafile';
load(str);
```

Similarly, arguments to `eval`, etc., are analyzed only if they are literal character vectors.

The Simulink dependency analysis looks inside MAT-files to find the names of variables to be loaded. This enables them to distinguish reliably between variable names and function names in block callbacks.

If a model depends upon a file for which both `.m` and `.p` files exist, then the manifest reports both, and, if the **Analyze MATLAB files** option is selected, the `.m` file is analyzed.

Special Cases

The following list contains more information about specific cases:

- If your model references a data class created using MATLAB syntax, for example called *MyPackage.MyClass*, all files inside the folder *MyPackage* and its subfolders are added to the manifest.

Warning The analysis adds all files in the class, which includes any source control files such as `.svn` or `.cvs`. You might want to edit the manifest to remove these files.

- A user-defined toolbox must have a properly configured `Contents.m` file. The Simulink Manifest Tools search user-defined toolboxes as follows:
 - If you have a `Contents.m` file in folder X, any file inside a subfolder of X is considered part of your toolbox.
 - If you have a `Contents.m` file in folder X/X, any file inside all subfolders of the “outer” folder X is considered part of your toolbox.

For more information on the format of a `Contents.m` file, see `ver`.

- If your S-functions require TLC files, these are detected.
- If you have Simscape, your Simscape components are analyzed. See also “Required Toolboxes” on page 18-45 for other effects of your installed products on manifests.
- If you create a UI using GUIDE and add this to a model callback, then the dependency analysis detects the `.m` and `.fig` file dependencies.
- If you have a dependence on source code, such as `.c`, `.h` files, these files are not analyzed at all to find any files that they depend upon. For example, subsequent `#include` calls inside `.h` files are not detected. To make such files detectable, you can add them as dependent files to the “header file” section of the Custom Code pane of the Simulink Coder section of the Configuration Parameters dialog box (or specify them with `rtwmakecfg`). Alternatively, to include dependencies that the analysis cannot detect, you can add additional file dependencies to a manifest file using the View/Edit Manifest Contents option (see “Edit Manifests” on page 18-34).
- Various blocksets and toolboxes can introduce a dependence on a file through their additional source blocks. If the analysis scope option **Find data files (e.g. in “From File” blocks)** is selected, the analysis detects file dependencies introduced by the following blocks:

Product	Blocks
DSP System Toolbox	From Wave File (Obsolete) block (Microsoft Windows operating system only) From Multimedia File block (Windows only)
Computer Vision System Toolbox™	Image From File block Read Binary File block
Simulink 3D Animation™	VR Sink block

The option **Find data files** also detects dependencies introduced by setting a "Model Workspace" for a model to either **MAT-File** or **MATLAB Code**, and model dependencies specified on the Model Referencing pane of the Configuration Parameters dialog box.

Best Practices for Dependency Analysis

The starting point for dependency analysis is the model itself. Make sure that the model refers to any data files it needs, even if you would normally load these manually. For example, add code to the model's `PreLoadFcn` to load them automatically, like this example:

```
load mydatafile
load('my_other_data_file.mat')
```

This way, the Simulink Manifest Tools can add them to the manifest. For more detail on callback analysis, see the notes on code analysis (see "Code Analysis" on page 18-41).

More generally, ensure that the model creates or loads any variables it uses, either in model callbacks or in scripts called from model callbacks. This reduces the possibility of the Simulink Manifest Tools confusing variable names with function names when analyzing block callbacks.

If you plan to export the manifest after creating it, ensure that the model does not refer to any files by their absolute paths, for example:

```
load C:\mymodel\mydata\mydatafile.mat
```

Absolute paths can become invalid when you export the model to another machine. If referring to files in other folders, do it by relative path, for example:

```
load mydata\mydatafile.mat
```

Select **Preserve folder hierarchy** when exporting, so that the exported files are in the same locations relative to each other. Also, choose a root folder so that all the files listed in the manifest are inside it. Otherwise, any files outside the root are copied into a new folder called **external** underneath the root, and relative paths to those files become invalid.

If you are exporting a model that uses a `.m` file inside a MATLAB class (in a folder called `@myclass`, for example), you must select the **Preserve folder hierarchy** check box when exporting, to maintain the folder structure of the class.

Always test exported ZIP files by extracting the contents to a new location on your computer and testing the model. Be aware that in some cases required files might be on your path but not in the ZIP file, if your path contains references to folders other than MathWorks toolboxes.

Use the Model Manifest Report

- “Report Sections” on page 18-44
- “Required Toolboxes” on page 18-45
- “Example Model Manifest Report” on page 18-46

Report Sections

If you selected **View HTML report on completion** in the Generate Model Manifest dialog box, the Model Manifest Report appears after Simulink generates the manifest. The report shows:

- Analysis date
- **Actions** pane — Provides links to regenerate, edit, or compare the manifest, and export the files in the manifest to a ZIP file.
- **Model Reference and Library Link Hierarchy** — Links you can click to open models.
- **Files used by this model** — Required files, with paths relative to the `projectroot`.

You can sort the results by clicking the report column headers.

- **Toolboxes required by this model.** For details, see “Required Toolboxes” on page 18-45.
- **References in this model** — This section provides details of references to other files so you can identify where dependencies arise. You control the scope of this section with the **Report file dependency locations** options on the Generate Manifest dialog box. You can choose to include references to user files only, all files, or no files. See “Generate Manifests” on page 18-26. Use this section of the report to trace dependencies to understand why a particular file or toolbox is required by a model. If you need to analyze many references, it can be helpful to sort the results by clicking the report column headers.
- **Folders referenced by this model**
- **Orphaned base workspace variables** — If you selected the analysis option **Find orphaned base workspace data**, this section reports any base workspace variables the model requires that are not defined in a file in this manifest.
- **Warnings generated while analyzing MATLAB code** — You can opt out of this section by clearing the **Store MATLAB code analysis warnings in manifest** analysis option.
- **Dependency analysis settings** — Records the details of the analysis scope options.

See the examples shown in “Example Model Manifest Report” on page 18-46.

Required Toolboxes

In the report, the “Toolboxes required by this model” section lists all products required by the model *that the analysis can detect*. Be aware that the analysis might not report certain blocksets or toolboxes required by a model, e.g., blocksets that do not introduce dependence on any files (such as Fixed-Point Designer) cannot be detected. Some MathWorks files under toolbox/shared can report only requiring MATLAB instead of their associated toolbox.

The results reported can be affected by your analysis scope settings and your installed products. For example:

- If you have code generation products and select the scope option “**Find files required for code generation**”, then:
 - Simulink Coder software is always reported as required.
 - If you also have an `.ert` system target file selected, then Embedded Coder software is always reported as required.

- If you clear the **Find library links** option, then the analysis cannot find a dependence on, for example, *someBlockSet*, and so no dependence is reported upon the block set.
- If you clear the **Analyze MATLAB files** option, then the analysis cannot find a dependence upon *fuzzy.m*, and so no dependence is reported upon the Fuzzy Logic Toolbox™.

Example Model Manifest Report

You should always check the **Dependency analysis settings** section in the Model Manifest Report to see the scope of analysis settings used to generate it.

Following are portions of a sample report.

Model Manifest Report:mpowertrain

Orphaned base workspace variables

Use the table below to determine what base workspace variables the model requires, that are not defined in a file in this Manifest

Click on a column header to sort the table

Variable Name	Class	Reference Location
manual	logical	mpowertrain/Model Variants (show)
trans_type_auto	Simulink.Variant	mpowertrain/Model Variants (show)
trans_type_manual	Simulink.Variant	mpowertrain/Model Variants (show)

Warnings generated while analyzing MATLAB code

(No warnings were generated)

Dependency analysis settings:

- Detect orphaned workspace variables: **true**
- Find model references: **true**
- Find library links: **true**
- Allow models with unsaved changes to be analyzed: **false**
- Find S-functions: **true**
- Analyze model and block callbacks: **true**
- Find code-generation files: **true**
- Find data files: **true**
- Analyze Stateflow charts: **true**
- Analyze Embedded MATLAB code: **true**
- Find Requirements documents: **false**
- Analyze files in user-defined toolboxes: **true**
- Analyze MATLAB files: **true**
- Reporting of file dependence locations: **user files only**
- Store warnings: **true**

About Source Control with Projects

You can use Simulink Project to work with source control. You can perform operations such as update, commit, merge changes, and view revision history directly from the Simulink Project environment.

Simulink Project has interfaces to:

- Subversion (SVN) — See “Set Up SVN Source Control” on page 19-11.
- Git— See “Set Up Git Source Control” on page 19-20.
- Software Development Kit (SDK) — You can use the SDK to integrate Simulink Projects with third-party source control tools. See “Write a Source Control Integration with the SDK” on page 19-28.

To use source control in your project, use any of the following workflows:

- Add source control to a project. See “Add a Project to Source Control” on page 19-6.
- Retrieve files from an existing repository and create a new project. See “Retrieve a Working Copy of a Project from Source Control” on page 19-29.
- Create a new project in a folder already under source control and click **Detect**. See “Create a New Project to Manage Existing Files” on page 16-20.
- Make your project publicly available on GitHub. See “Share Project on GitHub” on page 17-49.

When your project is under source control, you can:

- “Retrieve a Working Copy of a Project from Source Control” on page 19-29
- “Compare Revisions” on page 19-43
- “Commit Modified Files to Source Control” on page 19-47

Caution Before using source control, you must register model files with your source control tools to avoid corrupting models. See “Register Model Files with Source Control Tools” on page 19-10.

To view an example project under source control, see “Explore Simulink Project Tools with the Airframe Project” on page 16-5.

Classic and Distributed Source Control

This diagram represents the classic source control workflow (for example, using SVN).

Benefits of classic source control:

- Locking and user permissions on a per-file basis (e.g., you can enforce locking of model files)
- Central server, reducing local storage needs
- Simple and easy to learn

This diagram represents the distributed source control workflow (for example, using Git).

Benefits of distributed source control:

- Offline working
- Local repository, which provides full history
- Branching
- Multiple remote repositories, enabling large-scale hierarchical access control

To choose classic or distributed source control, consider these tips.

Classic source control can be helpful if:

- You need file locks.
- You are new to source control.

Distributed source control can be helpful if:

- You need to work offline, commit regularly, and need access to the full repository history.
- You need to branch locally.

Related Examples

Add a Project to Source Control

In this section...
“Add a Project to Git Source Control” on page 19-6
“Add a Project to SVN Source Control” on page 19-7

Add a Project to Git Source Control

If you want to add version control to your Simulink project files without sharing with another user, it is quickest to create a local Git repository in your sandbox.

- 1 Select the top Project node in the project tree.
- 2 Under **Source Control**, click **Add project to source control**.
- 3 In the Add to Source Control dialog box, in the **Source control integration** list, select **Git** to use the Git source control integration provided by Simulink Project.
- 4 Click **Convert** to finish adding the project to source control.

Git creates a local repository in your sandbox project root folder. The project runs integrity checks.

- 5 Click **Open Project** to return to your project.

The Project node displays the source control name **Git** and the repository location **Local Repository: *yoursandboxpath***.

- 6 Select the Modified Files view and click **Commit Modified Files** to commit the first version of your files to the new repository.

In the dialog box, enter a comment if you want, and click **Submit**.

You need some additional setup steps only if you want to merge branches with Git. See “Install Command-Line Git Client” on page 19-22.

Tip If you want to use Git and share with other users:

- To clone an existing remote Git repository, see “Retrieve a Working Copy of a Project from Source Control” on page 19-29.
 - To make your project publicly available on GitHub, see “Share Project on GitHub” on page 17-49.
-

Add a Project to SVN Source Control

Caution Before you start, check that your sandbox folder is on a local hard disc. Using a network folder with SVN is slow and unreliable.

This procedure adds a project to the built-in SVN integration that comes with Simulink Project. If you want to use a different version of SVN, see “Set Up SVN Source Control” on page 19-11.

- 1 Select the top Project node in the project tree.
- 2 Under **Source Control**, click **Add project to source control**.
- 3 In the Add to Source Control dialog box, leave the default **Source control integration** selected to use **Built-In SVN Integration**.
- 4 Next to **Repository path**, click **Change**.
- 5 In the Specify SVN Repository URL dialog box, select an existing repository or create a new one.

- To specify an existing repository, click Generate URL from folder  to browse for your repository, paste a URL into the box, or use the list to select a recent repository.
- To create a new repository, click Create an SVN repository in a folder . Using the file browser, create a folder where you want to create the new repository and click **Select Folder**. Do not place the new repository inside the existing project folder.

Simulink Project creates a repository in your folder, and you return to the Specify SVN Repository URL dialog box. The URL of the new repository is in the **Repository URL** box, and the project automatically selects the **trunk** folder.

Caution Specify `file://` URLs and create new repositories for single users only. For multiple users, see “Share a Subversion Repository” on page 19-17.

- 6 Click **Validate** to check the path to the selected repository.

When the path is valid, you can browse the repository folders. For example, select the `trunk` folder, and verify the selected URL at the bottom of the dialog box, as shown.

- 7 Click **OK** to return to the Add to Source Control dialog box.

If your repository has a file URL, a warning appears that file URLs are for single users. Click **OK** to continue.

- 8 Click **Convert** to finish adding the project to source control.

The project runs integrity checks.

- 9 After the integrity checks run, click **Open Project** to return to your project.

The Project node displays details of the current source control tool and the repository location.

- 10 If you created a new repository, select the Modified Files view and click **Commit Modified Files** to commit the first version of your files to the new repository. In the dialog box, enter a comment if you want, and click **Submit**.

Caution Before using source control, you must register model files with your source control tools to avoid corrupting models. See “Register Model Files with Subversion” on page 19-13.

More About

- “About Source Control with Projects” on page 19-2

Register Model Files with Source Control Tools

If you use third-party source control tools, you must register your model file extensions (.mdl and .slx) as binary formats. If you do not, these third-party tools can corrupt your model files when you submit them, by changing end-of-line characters, expanding tokens, substituting keywords, or attempting to automerge. Corruption can occur whether you use the source control tools outside of Simulink or if you try submitting files from Simulink Project without first registering your file formats.

Also check that other file extensions are registered as binary to avoid corruption at check-in for files such as .mat, .mlx, .mdl, .slxp, .sldd, .p, MEX-files, .xlsx, .jpg, .pdf, .docx, etc.

For instructions with SVN, see “Register Model Files with Subversion” on page 19-13. You must register model files if you use SVN, including the Built-In SVN Integration provided by Simulink Project.

For instructions with Git, see “Register Model Files with Git” on page 19-23.

- “Register Model Files with Subversion” on page 19-13
- “Register Model Files with Git” on page 19-23

Set Up SVN Source Control

In this section...

“Set Up SVN Integration Provided with Simulink Project” on page 19-11

“Set Up SVN Integration for SVN Version Already Installed” on page 19-12

“Set Up SVN Integration for SVN Version Not Yet Provided with Simulink Project” on page 19-12

“Register Model Files with Subversion” on page 19-13

“Enforce SVN Locking Model Files Before Editing” on page 19-16

“Share a Subversion Repository” on page 19-17

“Manage SVN Externals” on page 19-18

Set Up SVN Integration Provided with Simulink Project

Simulink Project provides **Built-In SVN Integration** for use with Subversion (SVN) sandboxes and repositories at version 1.8. You do not need to install SVN to use this integration because it includes an implementation of SVN.

Note: This integration ignores any existing SVN installation.

The **Built-In SVN Integration** supports secure logins.

To use the version of SVN provided with Simulink Project, when you add a project to source control or retrieve from source control, select **Built-In SVN Integration** in the **Source control integration** list. For instructions, see

- “Add a Project to Source Control” on page 19-6, or
- “Retrieve a Working Copy of a Project from Source Control” on page 19-29.

Caution Place your project sandbox folder on a local hard disc. Using a network folder with SVN is slow and unreliable. If you use a Windows network drive, SVN move operations can result in incorrect "not existing" status for files visible in file browsers.

When you create a new sandbox using the Simulink Project **Built-In SVN Integration**, the new sandbox uses the latest version of SVN provided by Simulink Project.

When your project is under source control, you can use these project features:

- “Retrieve a Working Copy of a Project from Source Control” on page 19-29
- “Compare Revisions” on page 19-43
- “Commit Modified Files to Source Control” on page 19-47

You can check out from a branch, but the project **Built-In SVN Integration** does not support branch merging. Use an external tool such as TortoiseSVN to perform branch merging. You can use the project tools for comparing and merging by configuring TortoiseSVN to generate an XML comparison report when you perform a diff on model files. See “Compare XML from Models Managed with Subversion”.

Set Up SVN Integration for SVN Version Already Installed

If you want to use Simulink Project with an earlier SVN version you already have installed, create a new project in a folder already under SVN source control. The project detects SVN.

For example:

- 1 Create the sandbox using TortoiseSVN from Windows Explorer.
- 2 Use Simulink Project to create a new project in that folder. The project detects the existing source control. If the sandbox is version 1.6, for example, it remains a version 1.6 sandbox.

Note: Before using source control, you must register model files with the tools. See “Register Model Files with Subversion” on page 19-13.

Set Up SVN Integration for SVN Version Not Yet Provided with Simulink Project

If you need to use a later version of SVN than 1.8, you can use **Command-Line SVN Integration (compatibility mode)**, but you must also install a command-line SVN client.

Note: Select **Command-Line SVN Integration (compatibility mode)** only if you need to use a later version of SVN than 1.8. Otherwise, use **Built-In SVN Integration** instead, for more features, improved performance, and no need to install an additional command-line SVN client.

Command-line SVN integration communicates with any Subversion (SVN) client that supports the command-line interface.

- 1 Install an SVN client that supports the command-line interface.

Note: TortoiseSVN does not support the command-line interface. However, you can continue to use TortoiseSVN from Windows Explorer after installing another SVN client that supports the command-line interface. Ensure that the major version numbers match, for example, both clients are SVN 1.7.

You can find Subversion clients on this Web page:

<http://subversion.apache.org/packages.html>

- 2 In Simulink Project, select **Command-Line SVN Integration (compatibility mode)**.

With **Command-Line SVN Integration (compatibility mode)**, if you try to rename a file in a project and the folder name contains an @ character, an error appears because command-line SVN treats all characters after the @ symbol as a peg revision value.

Tip You can check for updated source control integration downloads on the Simulink Projects Web page: <http://www.mathworks.com/products/simulink/simulink-projects/>

Register Model Files with Subversion

You must register model files if you use SVN, including the **Built-In SVN Integration** provided by Simulink Project.

If you do not register your model file extension as binary, SVN might add annotations to conflicted Simulink files and attempt automerger. This corrupts model files so you cannot load the models in Simulink.

To avoid this problem when using SVN, register file extensions.

- 1 Locate your SVN config file. Look for the file in these locations:
 - C:\Users\myusername\AppData\Roaming\Subversion\config or C:\Documents and Settings\myusername\Application Data\Subversion\config on Windows
 - In ~/.subversion on Linux or Mac OS X
- 2 If you do not find a config file, create a new one. See “Create SVN Config File” on page 19-14.
- 3 If you find an existing config file, you have previously installed SVN. Edit the config file. See “Update Existing SVN Config File” on page 19-15.

Create SVN Config File

- 1 If you do not find an SVN config file, create a text file containing these lines:

```
[miscellany]
enable-auto-props = yes
[auto-props]
*.mdl = svn:mime-type=application/octet-stream
*.mat = svn:mime-type=application/octet-stream
*.slx = svn:mime-type= application/octet-stream
*.mlx = svn:mime-type=application/octet-stream
```
- 2 Check for other file types you use in your projects that you also need to register as binary to avoid corruption at check-in. Check for files such as .mat, .mdl, .slx, .p, MEX-files (.mexa64, .mexmaci64, .mexw64), .xlsx, .jpg, .pdf, .docx, etc. Add a line to the attributes file for each file type you need. Examples:

```
*.mdl = svn:mime-type=application/octet-stream
*.slx = svn:mime-type=application/octet-stream
*.sldd = svn:mime-type=application/octet-stream
*.p = svn:mime-type=application/octet-stream
*.mexa64 = svn:mime-type=application/octet-stream
*.mexw64 = svn:mime-type=application/octet-stream
*.mexmaci64 = svn:mime-type=application/octet-stream
*.xlsx = svn:mime-type=application/octet-stream
*.docx = svn:mime-type=application/octet-stream
```

```
*.pdf = svn:mime-type=application/octet-stream
*.jpg = svn:mime-type=application/octet-stream
*.png = svn:mime-type=application/octet-stream
```

3 Name the file `config` and save it in the appropriate location:

- `C:\Users\myusername\AppData\Roaming\Subversion\config` or `C:\Documents and Settings\myusername\Application Data\Subversion\config` on Windows
- `~/.subversion` on Linux or Mac OS X

After you create the SVN config file, SVN treats new model files as binary.

If you already have models in repositories, see “Register Models Already in Repositories” on page 19-16.

Update Existing SVN Config File

If you find an existing `config` file, you have previously installed SVN. Edit the `config` file to register files as binary.

- 1** Edit the `config` file in a text editor.
- 2** Locate the `[miscellany]` section, and verify the following line enables `auto-props` with `yes`:

```
enable-auto-props = yes
```

Ensure that this line is not commented (that is, that it does not start with a `#`).

Config files can contain example lines that are commented out. If there is a `#` character at the beginning of the line, delete it.

- 3** Locate the `[auto-props]` section. Ensure that `[auto-props]` is not commented. If there is a `#` character at the beginning, delete it.
- 4** Add the following lines at the end of the `[auto-props]` section:

```
*.mdl = svn:mime-type= application/octet-stream
*.mat = svn:mime-type=application/octet-stream
*.slx = svn:mime-type= application/octet-stream
*.mlx = svn:mime-type=application/octet-stream
```

These lines prevent SVN from adding annotations to MATLAB and Simulink files on conflict and from automerging.

- 5** Check for other file types you use in your projects that you also need to register as binary to avoid corruption at check-in. Check for files such as `.mat`, `.mdl`, `.slx`,

.p, MEX-files (.mexa64, .mexmaci64, .mexw64), .xlsx, .jpg, .pdf, .docx, etc. Add a line to the config file for each file type you need.

Examples:

```
*.mdl  = svn:mime-type=application/octet-stream
*.slxp = svn:mime-type=application/octet-stream
*.sldd = svn:mime-type=application/octet-stream
*.p    = svn:mime-type=application/octet-stream
*.mexa64 = svn:mime-type=application/octet-stream
*.mexw64 = svn:mime-type=application/octet-stream
*.mexmaci64 = svn:mime-type=application/octet-stream
*.xlsx  = svn:mime-type=application/octet-stream
*.docx  = svn:mime-type=application/octet-stream
*.pdf   = svn:mime-type=application/octet-stream
*.jpg   = svn:mime-type=application/octet-stream
*.png   = svn:mime-type=application/octet-stream
```

6 Save the config file.

After you create or update the SVN config file, SVN treats new model files as binary.

If you already have models in repositories, register them as described next.

Register Models Already in Repositories

Caution Changing your SVN config file does not affect model files already committed to an SVN repository. If a model is not registered as binary, use `svn propset` to manually register models as binary.

To manually register a file in a repository as binary, use the following command with command-line SVN:

```
svn propset svn:mime-type application/octet-stream modelfilename
```

If you need to install a command-line SVN client, see “Set Up SVN Integration for SVN Version Not Yet Provided with Simulink Project” on page 19-12.

Enforce SVN Locking Model Files Before Editing

To ensure users remember to get a lock on model files before editing, you can configure SVN to make specified file extensions read only. To locate your SVN config file, see “Register Model Files with Subversion” on page 19-13.

After this setup, SVN sets model files to read only when you open the project, so you need to select **Source Control > Get File Lock** before you can edit them. Doing so helps prevent editing of models without getting the file lock. When the file has a lock, other users know the file is being edited, and you can avoid merge issues.

- 1 To make SLX files read only, add a property to your SVN config file. Find this line in the [auto-props] section that registers slx files as binary:

```
*.slx = svn:mime-type= application/octet-stream
```
- 2 Add the `needs-lock` property to the end of the existing `slx` line, separated by a semicolon, so the line looks like this:

```
*.slx = svn:mime-type=application/octet-stream;svn:needs-lock=yes
```

You can combine properties in any order, but multiple entries (e.g., for `slx`) must be on a single line separated by semicolons.
- 3 Recreate the sandbox for the config to take effect.
- 4 You need to select **Get File Lock** before you can edit model files. See “Get SVN File Locks” on page 19-40.

If you need to resolve merge issues, see “Resolve Conflicts” on page 19-61.

Share a Subversion Repository

You can specify a repository location using the `file://` protocol. However, Subversion documentation strongly recommends only single users access a repository directly via `file://` URLs. See the Web page:

<http://svnbook.red-bean.com/en/1.7/svn-book.html#svn.serverconfig.choosing.recommendations>

Caution Do not allow multiple users to access a repository directly via `file://` URLs or you risk corrupting the repository. Use `file://` URLs only for single-user repositories.

Be aware of this caution with these workflows:

- If you specify a repository with a `file://` URL, or
- If you use Simulink Projects to create a repository, this uses the `file://` protocol. Creating new repositories is provided for local single-user access only, for testing and debugging.

Also, accessing a repository via `file://` URLs is slower than using a server.

When you want to share a repository, you need to set up a server. You can use `svnserve` or the Apache™ SVN module. See the Web page references:

<http://svnbook.red-bean.com/en/1.7/svn-book.html#svn.serverconfig.svnserve>
<http://svnbook.red-bean.com/en/1.7/svn-book.html#svn.serverconfig.httpd>

Standard Repository Structure

Create your repository with the standard `tags`, `trunk`, and `branches` folders, and check out files from `trunk`. The Subversion project recommends this structure. See the Web page:

<http://svn.apache.org/repos/asf/subversion/trunk/doc/user/svn-best-practices.html>

If you use Simulink Project to create an SVN repository, it creates the standard repository structure. To enable tagging, the repository must have `trunk/` and `tags/` folders.

After you create a repository with this structure, you can click **Tag** in the SVN pane to add tags to all your project files. See “Tag and Retrieve Versions of Project Files” on page 19-34.

Manage SVN Externals

To get files into your project from another repository or from a different part of the same repository, use SVN externals.

- 1** In Simulink Project, right-click a project folder and select **Source Control > Manage Externals**.
- 2** In the Manage Externals dialog box, click **Add entry**. You can browse to and validate a repository location, specify the relative reference format, specify the subfolder, choose the revision, e.g., the `HEAD` node, etc.
- 3** After specifying the externals, click **OK**. The project displays the externals definition in the Manage Externals dialog box.

Alternatively, enter or paste an `svn:external` definition in the Manage Externals dialog box. The project applies an SVN version 1.6 compliant externals definition.

- 4** Click **Set** to validate and apply your changes.
- 5** To retrieve the external files, click **Update** to update the sandbox.

If two users modify the `svn:external` for a folder, you can get a conflict. To resolve the conflict, in the All Files View, locate the `.prej` file and examine the conflict details. Open the Manage Externals dialog box and specify the desired `svn:external`, mark the folder conflict resolved, and then commit the changes.

Set Up Git Source Control

In this section...

“About Git Source Control” on page 19-20

“Use Git Source Control in Simulink Project” on page 19-21

“Install Command-Line Git Client” on page 19-22

“Register Model Files with Git” on page 19-23

“Add Git Submodules” on page 19-24

About Git Source Control

If you want to manage your models and source code using Git, you can integrate with Simulink Project.

Git integration with Simulink Project provides distributed source control with support for creating and merging branches. Git is a distributed source control tool, so you can commit changes to a local repository and later synchronize with other remote repositories.

Git supports distributed development because every sandbox contains a complete repository. The full revision history of every file is saved locally. This enables working offline, because you do not need to contact remote repositories for every local edit and commit, only when pushing batches of changes. In addition, you can create your own branches and commit local edits. Doing so is fast, and you do not need to merge with other changes on each commit.

Capabilities of Git source control:

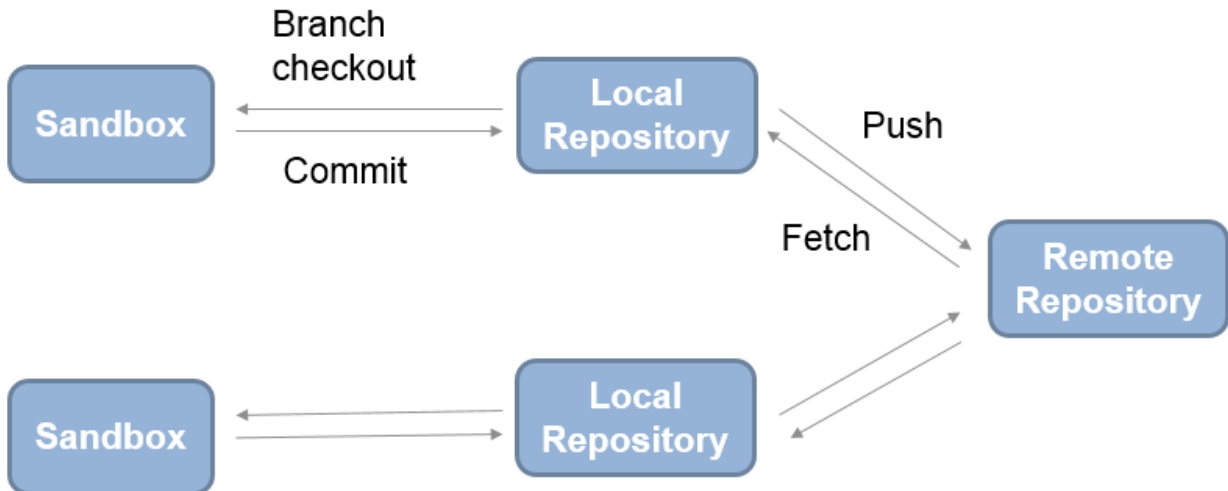

- Branch management
- Local full revision history
- Local access that is quicker than remote access
- Offline working
- Tracking of file names and contents separately
- Enforcing of change logs for tracing accountability
- Integration of batches of changes when ready

These capabilities do not suit every situation. If your project is not appropriate for offline working or your repository is too large for a full local revision history, for example, Git is not the ideal source control. In addition, if you need to enforce locking of files before editing, Git does not have this ability. In that situation, SVN is the better choice.

When you use Git in Simulink Project, you can:

- Create local Git repositories.
- Fetch files from remote Git repositories.
- Create and switch branches.
- Merge branches locally.
- Commit locally.
- Push files to remote Git repositories.

This diagram represents the distributed Git workflow.

Use Git Source Control in Simulink Project

To use the version of Git provided with Simulink Project, when you add a project to source control or retrieve from source control, select **Git** in the **Source control integration** list.

- If you add an existing project to Git source control, you create a local Git repository in that sandbox. You cannot connect to a remote repository using this workflow. See “Add a Project to Source Control” on page 19-6
- If you want to clone a remote Git repository to create a project, select **New > Simulink Project** on the MATLAB Home tab, and then in the start page, click **Source Control**. After you specify a remote repository to retrieve from, a local repository is created. You can also fetch and push changes to the remote repository. See “Retrieve a Working Copy of a Project from Source Control” on page 19-29.

Note: You cannot add empty folders to Git source control. Use **Check Project** instead. See “Push and Fetch Files with Git” on page 19-52.

To use a Git server for your remote repository, you can set up your own Apache Git server or use a Git server hosting solution. If you cannot set up a server and must use a remote repository via the file system using the `file:///` protocol, make sure that it is a bare repository with no checked out working copy.

- To make your project publicly available on GitHub, see “Share Project on GitHub” on page 17-49. Sharing adds Git source control to the open project and the project’s remote repository is GitHub.

Install Command-Line Git Client

If you want to use Git to merge branches in Simulink Project, you must also install a command-line Git client that is available systemwide. You can use other Git functionality without any additional installation.

Some clients are not available systemwide, including the `mingw32` environment provided by GitHub (**Git Shell** on the **Start** menu). Installing command-line Git makes it available systemwide, and then Simulink Project can locate standard `ssh` keys.

Check if Git is available by using the command `!git` in MATLAB. If Git is not available, install it.

On Windows:

- 1 Download the Git installer and run it. You can find command-line Git at:

<http://msysgit.github.io/>

- 2 In the section on adjusting your PATH, choose the install option to **Use Git from the Windows Command Prompt**. This option adds Git to your PATH variable, so that the Simulink Project can communicate with Git.
- 3 In the section on configuring the line-ending conversions, choose the option **Checkout as-is, commit as-is** to avoid converting any line endings in files.

On Linux, Git is available for most distributions. Install Git for your distribution. For example, on Debian[®], install Git by entering:

```
sudo apt-get install git
```

On Mac, on Mavericks (10.9) or above, try to run `git` from the Terminal. If you do not have Git installed already, it will prompt you to install Xcode Command Line Tools. For more options, see <http://git-scm.com/doc>.

Caution To avoid corrupting models, before using Git to merge branches, register model files. See “Register Model Files with Git” on page 19-23.

Register Model Files with Git

After you install a command-line Git client, you can prevent Git from corrupting your Simulink models by inserting conflict markers. To do so, edit your `.gitattributes` file to register model files as binary. For details, see:

<http://git-scm.com/docs/gitattributes>

- 1 If you do not already have a `.gitattributes` file in your project root folder, create one by entering in MATLAB:

```
edit .gitattributes
```

- 2 Add these lines to the `.gitattributes` file:

```
*.slx -crlf -diff -merge  
*.mdl -crlf -diff -merge  
*.mat -crlf -diff -merge  
*.mlx -crlf -diff -merge
```

These lines specify not to try automatic line feed, diff, and merge attempts for MATLAB and Simulink files.

- 3 Check for other file types you use in your projects that you also need to register as binary to avoid corruption at check-in. Check for files such as `.mat`, `.mdl`, `.slx`,

.p, MEX-files (.mexa64, .mexmaci64, .mexw64), .xlsx, .jpg, .pdf, .docx, etc. Add a line to the attributes file for each file type you need.

Examples:

```
*.mdl -crlf -diff -merge
*.slxp -crlf -diff -merge
*.sldd -crlf -diff -merge
*.p -crlf -diff -merge
*.mexa64 -crlf -diff -merge
*.mexw64 -crlf -diff -merge
*.mexmaci64 -crlf -diff -merge
*.xlsx -crlf -diff -merge
*.docx -crlf -diff -merge
*.pdf -crlf -diff -merge
*.jpg -crlf -diff -merge
*.png -crlf -diff -merge
```

- 4 Restart MATLAB so you can start using the Git client with Simulink Project.

After you have installed a command-line Git client and registered your model files as binary, you can use the merging features of Git in Simulink Project.

Add Git Submodules

To reuse code from another repository, you can specify Git submodules to include in your project.

To clone an external Git repository as a submodule:

- 1 In Simulink Project, in the Git pane, click **Submodules**.
- 2 In the Submodules dialog box, click the **+** button.
- 3 In the Add Submodule dialog box, in the **Remote** box, specify a repository location. Optionally, click **Validate**.
- 4 In the **Path** box, specify a location for the submodule in your project and click **OK**. The Submodules dialog box displays the status and details of the submodule.
- 5 Check the status message, and click **Close** to return to your project.

Use Fetch to Get Latest Submodule Version

When you want to manage the added submodule, open the Submodules dialog box.

- 1 To get the latest version of a submodule, in the Submodules dialog box, click **Fetch**.
- 2 After fetching, you must merge. Check the **Status** message in the Submodules dialog box for information about your current branch relative to the remote tracking branch in the repository. When you see the message **Behind**, you need to merge in changes from the repository to your local branch.
- 3 Click **Branches** and merge in the origin changes to your local branch using the Branches dialog box. See “Fetch and Merge” on page 19-53.

Use Push to Send Changes to the Submodule Repository

If you make changes in your submodule and want to send changes back to the repository:

- 1 Perform a local commit in the parent project.
- 2 Open the Submodules dialog box and click **Push**.

If you want other project users to obtain your changes in the submodule when they clone the parent project, make sure the index and head match.

- 1 In the Submodules dialog box, check the index and head values. The index points to the head commit at the time you first cloned the submodule, or when you last committed the parent project repository. If the index and head do not match, you must update the index.
- 2 To update the index, commit your changes in the parent project, and then click **Push** in the Submodules dialog box. This action makes the index and head the same.

Related Examples

- “Branch and Merge Files with Git” on page 19-57

Disable Source Control

Disabling source control is useful when you are preparing a project to create a template from it, and you want to avoid accidentally committing unwanted changes.

- 1 Select the top Project node in the project tree.
- 2 Under **Source Control**, change the selection from the current source control to **No source control integration**.
- 3 Click **Reload**.

Note: Source control tools create files in the project folders (for example, SVN creates an `.svn` folder), so you can put the project back under the same source control only by selecting your previous source control from the list.

Related Examples

- “Change Source Control” on page 19-27
- “Create a Template from a Project Under Version Control” on page 16-46
- “Add a Project to Source Control” on page 19-6

Change Source Control

Changing source control is useful when you want to create a new local repository for testing and debugging.

- 1 Prepare your project by checking for any updates from the existing source control tool repository and committing any local changes.
- 2 On the **Simulink Project** tab, click **Share > Zip Archive** to save a zip file containing the project without any source control information.
- 3 On the **Simulink Project** tab, click **New**, and then in the start page, click **Archive** to create a new project from the archived project.
- 4 In the top Project node, under **Source Control**, click **Add project to source control** to select a new source control. For details, see “Add a Project to Source Control” on page 19-6.

Tip To avoid accidentally committing changes to the previous source control, delete the original sandbox.

Related Examples

- “Disable Source Control” on page 19-26
- “Add a Project to Source Control” on page 19-6

Write a Source Control Integration with the SDK

Simulink provides a Software Development Kit (SDK) that you can use to integrate Simulink Projects with third-party source control tools.

The SDK provides instructions for writing an integration to a source control tool that has a published API you can call from Java[®].

You must create a `.jar` file that implements a collection of Java interfaces and a Java Manifest file, that defines a set of required properties.

The SDK provides example source code, Javadoc, and files for validating, building, and testing your source control integration. Build and test your own interfaces using the example as a guide. Then you can use your source control integration with Simulink Projects.

- 1 Extract the contents of the SDK.

```
run(fullfile(matlabroot, 'toolbox', 'shared', 'cmlink', 'adapterSDK', 'extractSDK'))
```

Select a folder to place the `cm_adapter_SDK` folder and files in, and click **OK**.

- 2 Locate the new folder `cm_adapter_SDK`, and open the file `cm_adapter_SDK_guide.pdf` for instructions.

After you write a source control integration, see “Add a Project to Source Control” on page 19-6.

More About

- “About Source Control with Projects” on page 19-2

Retrieve a Working Copy of a Project from Source Control

Create a new local copy of a project by retrieving files from source control.

- 1 From MATLAB, on the **Home** tab, click **Simulink**, or select **New > Simulink Project**.

Alternatively, on the **Simulink Project** tab, in the **File** section, click **New**.

- 2 In the Start Page, under **Projects** in the left list, click **Source Control**.
- 3 In the Project Retriever dialog box, select the source control interface from the **Source control integration** list.
 - To use SVN, leave the default **Built-In SVN Integration**.
 - To use Git, select **Git**.
- 4 If you know your repository location, you can paste it into the **Repository Path** box and proceed to step 8. Click **Change** to browse for and validate the repository path to retrieve files from.
- 5 In the dialog box, specify the repository URL by entering or pasting a URL in the box, using the list of recent repositories, or by using the **Generate URL from folder** button .

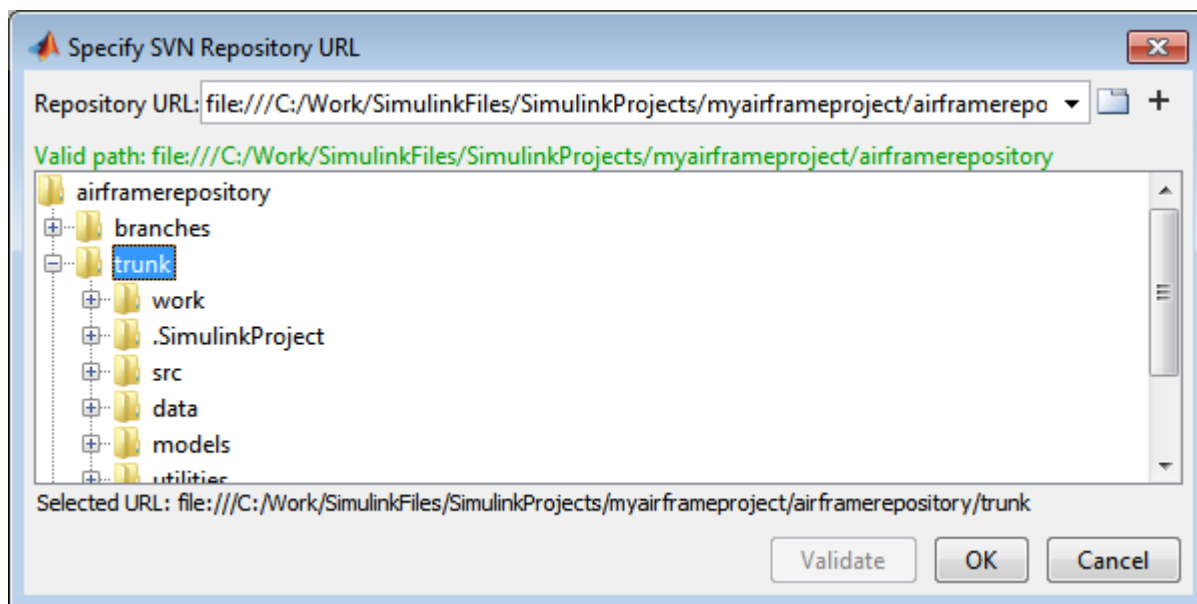

Caution Use `file://` URLs only for single-user repositories. For more information, see “Share a Subversion Repository” on page 19-17.

- 6 Click **Validate** to check the repository path.

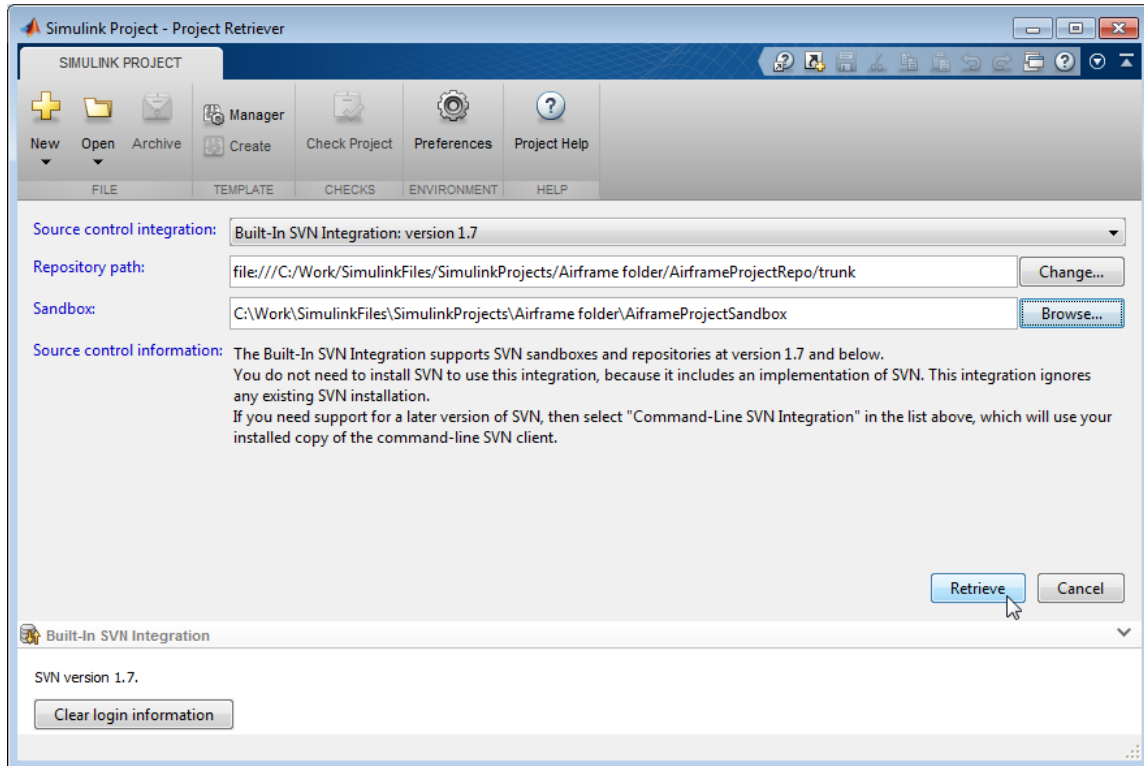

If the path is invalid, check the URL against your source control repository browser.

- 7 If you see an authentication dialog box for your repository, enter login information to continue.
- 8 If necessary, select a deeper folder in the repository tree. You might want to check out from `trunk` or from a branch folder under `tags`, if your repository contains tagged versions of files. The example shows `trunk` selected, and the **Selected URL** displays at the bottom of the dialog box. The retriever uses this URL when you click **OK**.

- 9 When you have finished specifying the URL path you want to retrieve, click **OK**.
- 10 In the Project Retriever, select the sandbox folder where you want to put the retrieved files for your new project, and click **Retrieve**.

Caution Use local sandbox folders. Using a network folder with SVN is slow.

The source control pane (for example, **Built-In SVN Integration** or **Git**) displays messages as the project retrieves the files from source control.

If your repository already contains a Simulink project, the project is ready when the tool finishes retrieving files to your selected sandbox folder.

- 11 If your sandbox does not yet contain a Simulink project, then a dialog box prompts you to check whether you want to create a project in the folder. Click **Yes** to continue creating the project.

The new project controls appear.

- a** In the new project controls, enter a project name.
- b** Click **Create** to finish creating the new project in your new sandbox.

Simulink Project displays the empty Project Files list for the chosen project root. The project does not yet contain any files. For next steps, see “Add Files to the Project” on page 16-22.

Note: To update an existing project sandbox from source control, see “Update Revisions of Project Files” on page 19-38.

Troubleshooting

If you encounter errors like `OutOfMemoryError: Java heap space`, for example when cloning big Git repositories, then edit your MATLAB preferences to increase the heap size.

- 1** On the **Home** tab, in the **Environment** section, click **Preferences**.
- 2** Select **MATLAB > General > Java Heap Memory**.
- 3** Move the slider to increase the heap size, and then click **OK**.
- 4** Restart MATLAB.

- “Commit Modified Files to Source Control” on page 19-47

More About

- “About Source Control with Projects” on page 19-2

Tag and Retrieve Versions of Project Files

With SVN, you can use tags to identify specific revisions of all project files. Not every source control has the concept of tags. To use tags with SVN, you need the standard folder structure in your repository and you need to check out your files from `trunk`. See “Standard Repository Structure” on page 19-18.

- 1 In the SVN pane, click **Tag**.
- 2 Specify the tag text and click **OK**. The tag is added to every project file.

Errors appear if you do not have a `tags` folder in your repository.

Note: You can retrieve a tagged version of your project files from source control, but you cannot tag them again with a new tag. You must check out from `trunk` to create new tags.

To retrieve the tagged version of your project files from source control:

- 1 On the **Simulink Project** tab, click **New**, and then in the start page, click **Source Control**.
- 2 Click **Change** to select the Repository Path that you want to retrieve files from.

The Specify Repository URL dialog box opens.

- a Select a recent repository from the **Repository URL** list, or click the **Generate URL from folder** button  to browse for the repository location.
 - b Click **Validate** to show the repository browser.
 - c Expand the `tags` folder in the repository tree, and select the tag version you want. Verify there is a `.SimulinkProject` folder under the chosen tag subfolder.
 - d Click **OK** to continue and return to the Project Retriever.
- 3 Select the sandbox folder to receive the tagged files. You must use an empty sandbox folder. (If you try to retrieve tagged files into an existing sandbox, an error appears.)
 - 4 Click **Retrieve**.

Alternatively, you can use labels to apply any metadata to files and manage configurations. You can group and sort by labels, and create batch jobs to export files by label. See “Add Labels to Files” on page 17-26.

With Git, you can switch branches. See “Branch and Merge Files with Git” on page 19-57.

Related Examples

- “Standard Repository Structure” on page 19-18
- “Add Labels to Files” on page 17-26
- “Branch and Merge Files with Git” on page 19-57

Refresh Status of Project Files

To check for locally modified project files, click **Refresh** in the source control pane.

Refresh queries the local sandbox state and checks for changes made with another tool outside of MATLAB.

Note: For SVN, **Refresh** does not contact the repository. To check the repository for later revisions, use **Check for Modifications** instead. To get the latest revisions, use **Update** instead. See “Check for Modifications” on page 19-37 and “Update Revisions of Project Files” on page 19-38.

The source control pane title depends on your source control, for example, **Built-In SVN Integration**. The source control pane reports source control messages, and the buttons in the pane apply to the whole project.

Refresh refreshes the view of the source control status for all files under `projectroot`. Clicking **Refresh** updates the information shown in the **Revision** column and the source control status column (for example, **SVN**, or **Git** columns). Hover over the icon to see the tooltip showing the source control status of a file, e.g., **Modified**.

Related Examples

- “Check for Modifications” on page 19-37
- “Update Revisions of Project Files” on page 19-38
- “Revert Changes” on page 19-49

Check for Modifications

To check the status of individual files for modifications, right-click files in Simulink Project and select **Source Control > Check for Modifications**. Use this to find out if the repository version has moved ahead.

With SVN, this option contacts the repository to check for external modifications. Simulink Project compares the revision numbers of the local file and the repository version. If the revision number in the repository is larger than that in the local sandbox folder, then Simulink Project displays (**not latest**) next to the revision number of the local file.

If your local file is not the latest version, get the latest revisions from the repository by clicking **Update**. See “Update Revisions of Project Files” on page 19-38. You might need to resolve conflicts after updating. See “Resolve Conflicts” on page 19-61 and “Compare Revisions” on page 19-43.

To check for locally modified files, use **Refresh** instead. See “Refresh Status of Project Files” on page 19-36.

Related Examples

- “Refresh Status of Project Files” on page 19-36
- “Update Revisions of Project Files” on page 19-38
- “Compare Revisions” on page 19-43
- “Revert Changes” on page 19-49

Update Revisions of Project Files

In this section...
“Update Revisions with SVN” on page 19-38
“Update Revisions with Git” on page 19-39
“Update Selected Files” on page 19-39

Update Revisions with SVN

In Simulink Project, to get the latest revisions of all project files from the source control repository, click **Update** in the source control pane.

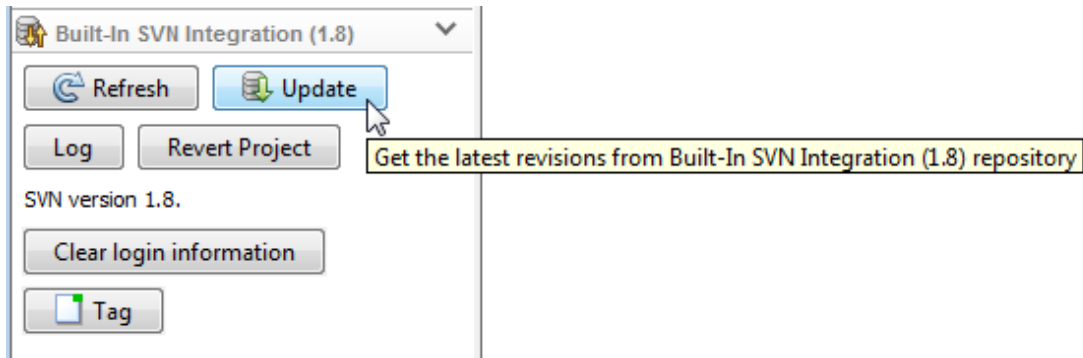

Use **Update** to get other people’s changes from the repository and find out about any conflicts. If you want to back out local changes, use **Revert** instead. See “Discard Local Changes” on page 19-49.

After you update, the project displays a dialog box listing all the files that have changed on disk. You can control this behavior using the project preference **Show changes on source control update**.

When your project uses SVN source control, **Update** calls `svn update` to bring changes from the repository into your working copy. If there are other people’s changes in your modified files, SVN adds conflict markers to the file. SVN preserves your modifications.

Caution Ensure you have registered SLX files as binary with SVN before using **Update**. If you do not, SVN conflict markers can corrupt your SLX file. Simulink Project warns you about this when you first click **Update** to ensure you protect your model files. See “Register Model Files with Subversion” on page 19-13.

You must resolve any conflicts before you can commit. See “Resolve Conflicts” on page 19-61.

Update Revisions with Git

If you are using Git source control, click **Fetch** in the source control pane.

Caution Ensure you have registered SLX files as binary with Git before using **Fetch**. If you do not, conflict markers can corrupt your SLX file. See “Set Up Git Source Control” on page 19-20.

After clicking **Fetch**, you need to merge in the origin changes to your local branches. For next steps, see “Fetch and Merge” on page 19-53.

Update Selected Files

To update selected files, right-click and select the **Update** command for the source control system you are using. For example, if you are using SVN, select **Source Control > Update from SVN** to get fresh local copies of the selected files from the repository.

Related Examples

- “Register Model Files with Source Control Tools” on page 19-10
- “Resolve Conflicts” on page 19-61
- “Discard Local Changes” on page 19-49

Get SVN File Locks

To ensure users remember to get a lock on model files before editing, you can configure SVN to make model files read only. Follow the steps in “Enforce SVN Locking Model Files Before Editing” on page 19-16. After you configure SVN to make files with certain extensions read only, then users must get a lock on these read-only files before editing.

- 1 In Simulink Project, in any Files view, select the files you want to check out.
- 2 Right-click the selected files and select **Source Control > Get File Lock**.

Get File Lock is for SVN. This option does not modify the file in your local sandbox. Git does not have locks.

A lock symbol appears in the SVN source control column. Other users cannot see the lock symbol in their sandboxes, but they cannot get a file lock or check in a change when you have the lock.

Note: To get a fresh local copy of the file from the repository, select **Update from SVN**.

In the Simulink Editor, if an open model belongs to a project under SVN, you can get a lock by selecting **File > Simulink Project > Get File Lock**.

If you see an SVN message reporting a **working copy locked** error, remove stale locks by clicking **SVN Cleanup** in the SVN pane. SVN uses working copy locks internally and they are not the file locks you control using **Get File Lock**.

Related Examples

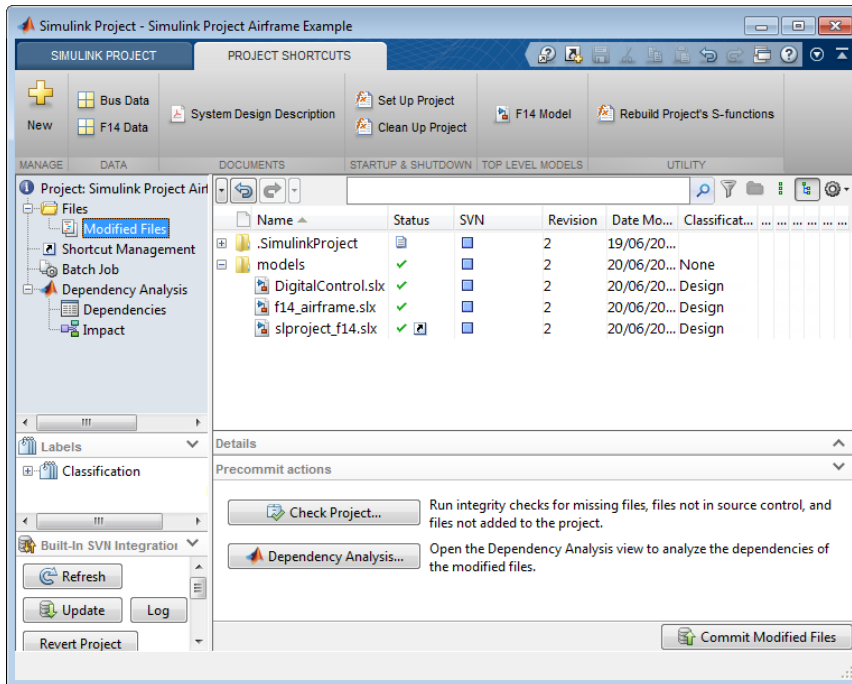

- “Work with Project Files” on page 17-8
- “Enforce SVN Locking Model Files Before Editing” on page 19-16
- “View Modified Files” on page 19-41
- “Commit Modified Files to Source Control” on page 19-47

More About

- “About Source Control with Projects” on page 19-2

View Modified Files

In Simulink Project, select the Modified Files view. The Modified Files node is visible only if you are using source control integration with your project.

If you need to update the modified files list, click **Refresh** in the source control pane.

Use the Modified Files view to review, analyze, label, and commit modified files. Lists of modified files are sometimes called changesets. You can perform the same operations in the Modified Files view as you can in other file views.

Tip In the Modified Files view, it can be useful to switch to List view by clicking the List button 

You can identify modified or conflicted folder contents using the source control summary status. In the Files views, folders display rolled-up source control status. This makes

it easier to locate changes in files, particularly conflicted files. You can hover over the source control status (e.g., the **SVN** or **Git** column) for a folder to view a tooltip displaying how many files inside are modified, conflicted, added or deleted.

Project Definition Files

The files in `.SimulinkProject` are project definition files generated by your changes. The project definition files allow you to add metadata to files without checking them out, for example, by creating shortcuts, adding labels, and adding a project description. Project definition files also define the files that are added to your project.

Any changes you make to your project (for example, to shortcuts, labels, categories, or files in the project) generate changes in the `.SimulinkProject` folder. These files store the definition of your project in XML files whose format is subject to change.

You do not need to view project definition files directly, except when the source control tool requires a merge. The files are shown so that you know about all the files being committed to the source control system. See “Resolve Conflicts” on page 19-61.

If you want to change project definition file from the type used when the project was created, see `export`.

If you want to use projects with configurations that do not allow folder names to start with “.”, then you can choose an underscore instead. Use the project preferences to change the project definition folder for new projects to `_SimulinkProject`.

- “Resolve Conflicts” on page 19-61
- “Discard Local Changes” on page 19-49
- “Commit Modified Files to Source Control” on page 19-47

More About

- “About Source Control with Projects” on page 19-2

Compare Revisions

To review changes in modified files in Simulink Project, select the Modified Files view.

If you need to update the modified files list, click **Refresh** in the source control pane.

To review changes in modified files, right-click selected files in any view in Simulink Project and:

- Select **Compare > Compare to Ancestor** to run a comparison with the last checked-out version in the sandbox (SVN) or against the local repository (Git). The Comparison Tool displays a report.
- To compare other revisions of a file, select **Compare > Compare to Revision**. In the Compare to Revisions dialog box, you can view information about who previously committed the file, when they committed it, and the log messages. To view a comparison report, select the revisions you want to compare. You can either:
 - Select a revision and click **Compare to Local**.

- Select two revisions and click **Compare Selected**.
- To browse the revision history of a file, select **Source Control > Show Revisions**. In the File Revisions dialog box, view information about who previously committed the file, when they committed it, and the log messages.

Note: In the Simulink Editor, if an open model, library, or chart belongs to a project under source control, you can view changes by selecting **File > Simulink Project > Compare to Ancestor** or **Compare to Revision**.

When you compare to a revision or ancestor, the MATLAB Comparison Tool opens a report comparing the modified version of the file in your sandbox with the selected revision or against its ancestor stored in the version control tool.

Comparison type depends on the file you select. If you select a Simulink model, and you have Simulink Report Generator installed, this command runs a Simulink XML comparison.

When reviewing changes, you can merge Simulink models from the Comparison Tool report (requires Simulink Report Generator). See “Merge Text Files” on page 19-63 and “Merge Models” on page 19-64.

To examine the dependencies of modified files, see “Perform Impact Analysis” on page 18-7.

Run Project Checks

In Simulink Project, you can run checks from any project view by clicking **Check Project** on the **Simulink Project** tab. The project checks can find problems with project integrity such as missing files, unsaved files, or files not under source control.

For details on problems the checks can fix, see “Work with Derived Files in Projects” on page 19-66, “Upgrade Model Files to SLX and Preserve Revision History” on page 17-19, and “Check Dependency Results and Resolve Problems” on page 18-17.

The Precommit actions pane in the Modified Files view contains tools to use before committing your changes to source control, including **Check Project**.

- Click **Check Project** to check the integrity of the project. For example, is everything under source control in the project? Are all project files under source control? A dialog box reports results. You can click for details and follow prompts to fix problems.

For an example showing how the checks can help you, see “Upgrade Model Files to SLX and Preserve Revision History” on page 17-19.

- If you want to check for required files, click **Dependency Analysis** to open the Dependency Analysis view. The modified files are automatically selected for analysis. (You can select more or fewer files to analyze by selecting and clearing the check boxes in the Include column.) Click **Analyze** when you are ready to run the analysis.

You can use the dependency tools to analyze the structure of your project. See “What Is Dependency Analysis?” on page 18-2.

Note: The files in `.SimulinkProject` are project definition files generated by your changes. See “Project Definition Files” on page 19-42.

Commit Modified Files to Source Control

Before you commit modified files, review changes and consider precommit actions. See “Compare Revisions” on page 19-43 and “Run Project Checks” on page 19-45.

- 1 In Simulink Project, select the Modified Files view.

If you need to update the modified files list, click **Refresh** in the source control pane.

- 2 Click **Commit Modified Files** to check in all files in the modified files list.

If you are using SVN source control, this commits changes to your repository.

If you are using Git source control, this commits to your local repository. To commit to the remote repository, see “Push” on page 19-52.

- 3 Enter comments in the dialog box if you want, and click **Submit**.
- 4 A message appears if you cannot commit because the repository has moved ahead. Before you can commit the file, you must update its revision up to the current HEAD revision. If you are using SVN source control, click **Update**. If you are using Git source control, click **Fetch**. Resolve any conflicts before you commit.

Note: You can commit individual files using the context menu, by selecting **Source Control > Commit**. However if you commit individual files, you risk not committing the related project definition files that keep track of your files. Instead, use the Modified Files view to commit all related changes.

- “Resolve Conflicts” on page 19-61
- “Revert Changes” on page 19-49

More About

- “About Source Control with Projects” on page 19-2

Revert Changes

In this section...

“Discard Local Changes” on page 19-49

“Revert a File to a Specified Revision” on page 19-49

“Revert the Project to a Specified Revision” on page 19-50

Discard Local Changes

With SVN, if you want to roll back local changes in a particular file, in Simulink Project, right-click the file and select **Source Control > Discard Local Changes and Release Locks** to release locks and revert to the version in the last sandbox update (that is, the last version you synchronized or retrieved from the repository).

In the Simulink Editor, if an open model belongs to a project under source control, you can revert changes by selecting **File > Simulink Project > Discard Local Changes and Release Locks**.

To abandon all local changes, in Simulink Project select all the files in the Modified Files list, then right-click and select **Discard Local Changes and Release Locks**.

With Git, right-click a file and select **Source Control > Revert Local Changes**. Git does not have locks. To remove all local changes, click **Branches** in the **Git** pane and click **Revert to Head**.

Revert a File to a Specified Revision

- 1 Right-click a file and select **Source Control > Revert using SVN** or **Source Control > Revert using Git**.
- 2 In the Revert Files dialog box, choose a revision to revert to. Select a revision to view information about the change such as the author, date, log message, and the list of modified files also in the change set.
- 3 Click **Revert**.

Simulink Project reverts the selected file.

- 4 If you revert a file to an earlier revision and then make changes, you cannot commit the file until you resolve the conflict with the repository history.

With SVN, if you try to commit the file, you see a message that it is out of date. Before you can commit the file, you must update its revision up to the current HEAD revision. click **Update** in the SVN source control pane.

The project marks the file as conflicted because you have made changes to an earlier version of the file than the version in the repository.

- 5 With either SVN or Git, to examine conflicts, right-click and select **View Conflicts**.

Decide how to resolve the conflict or to keep your changes to the reverted file. See “Resolve Conflicts” on page 19-61.

- 6 After you have resolved the conflict, mark the conflict resolved, either by using the merge tool or manually by right-clicking the file and selecting **Source Control > Mark Conflict Resolved**.
- 7 Select the Modified Files view and click **Commit Modified Files**.

Revert the Project to a Specified Revision

With SVN, inspect the project revision information by clicking **Log** in the Built-In SVN Integration pane. In the Log dialog box, each revision in the list is a change set of modified files. Select a revision to view information about the change such as the author, date, log message and the list of modified files.

To revert the project:

- 1 Click **Revert Project** in the Built-In SVN Integration pane.
- 2 In the Revert Files dialog box, choose a revision to revert to.

Each revision in the list is a change set of modified files. Select a revision to view information about the change such as the author, date, log message and the list of modified files.

- 3 Click **Revert**.

Simulink Project displays progress messages in the SVN pane as it restores the project to the state it was in when the selected revision was committed. Depending on the change set you selected, all files do not necessarily have a particular revision number or matching revision numbers. For example, if you revert a project to revision 20, all files will show their revision numbers when revision 20 was committed (20 or lower).

With Git, you can switch branches. See “Branch and Merge Files with Git” on page 19-57.

Related Examples

- “Resolve Conflicts” on page 19-61

Push and Fetch Files with Git

In this section...

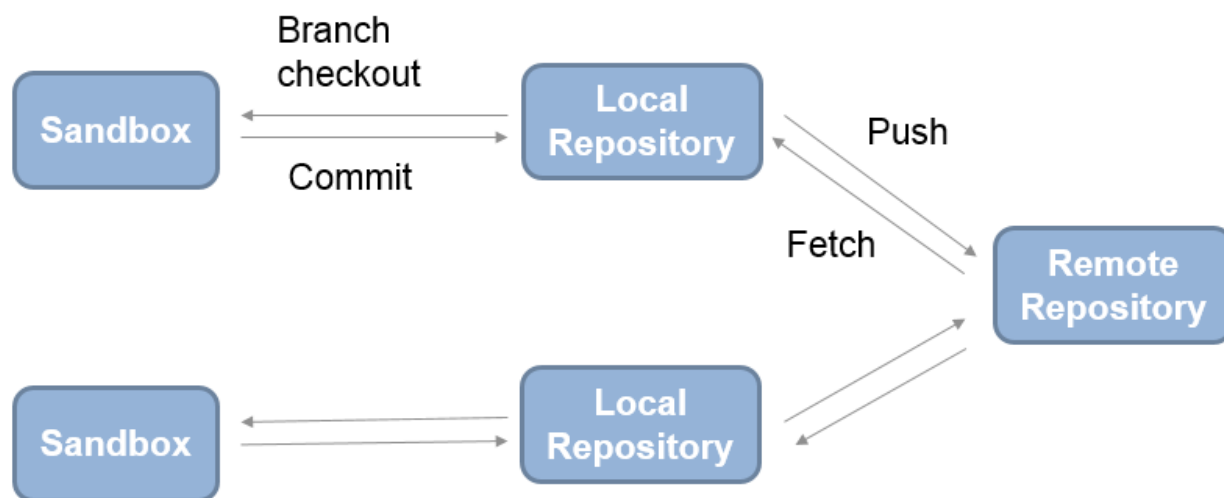

“Push” on page 19-52

“Fetch and Merge” on page 19-53

“Push Empty Folders” on page 19-56

Push

Use this workflow to work with a Git project connected to a remote repository. With Git, there is a two-step workflow: commit local changes, and then push to the remote repository. In Simulink Project, the only access to the remote repository is through the **Push** and **Fetch** buttons. All other actions use the local repository (such as **Check for Modifications**, **Compare to Ancestor**, and **Commit**). This diagram represents the Git workflow.

- 1 Click **Branches** in the **Git** pane. Create branches to work on using the Branches dialog box, as described in “Branch and Merge Files with Git” on page 19-57.
- 2 When you want to commit changes, select the Modified Files view and click **Commit Modified Files**. The changes are committed to your current branch in your local repository. Check the **Git** pane for information about the current branch. You see

the message **Ahead** when you commit local changes that have moved ahead of the remote tracking branch.

```
Current branch: master  
Branch status: SAFE  
Ahead of /origin/master
```

- 3 To send your local commits to the remote repository, click **Push** in the **Git** pane.
- 4 A message appears if you cannot push your changes directly because the repository has moved on. Click **Fetch** in the **Git** pane to fetch changes from the remote repository. Merge branches and resolve conflicts, and then you can push your changes. See “Fetch and Merge” on page 19-53.

Fetch and Merge

Note: After fetching you must merge. Before you can merge branches, you must install command-line Git on your system path and register model files as binary to prevent Git from inserting conflict markers. See “Install Command-Line Git Client” on page 19-22.

To fetch changes from the remote repository, click **Fetch** in the **Git** pane.

Fetch updates all of the origin branches in the local repository.

Note: When you click **Fetch**, your sandbox files are not changed. To see others’ changes, you need to merge in the origin changes to your local branches.

Check the Git pane for information about your current branch relative to the remote tracking branch in the repository. When you see the message **Behind**, you need to merge in changes from the repository to your local branch.

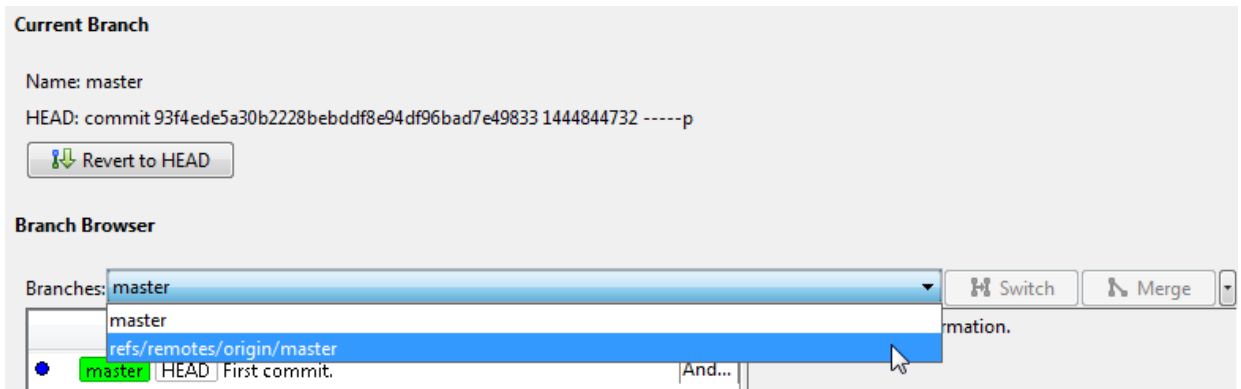

For example, if you are on the master branch and want to get changes from the master branch in the remote repository:

- 1 Click **Fetch** in the **Git** source control pane.

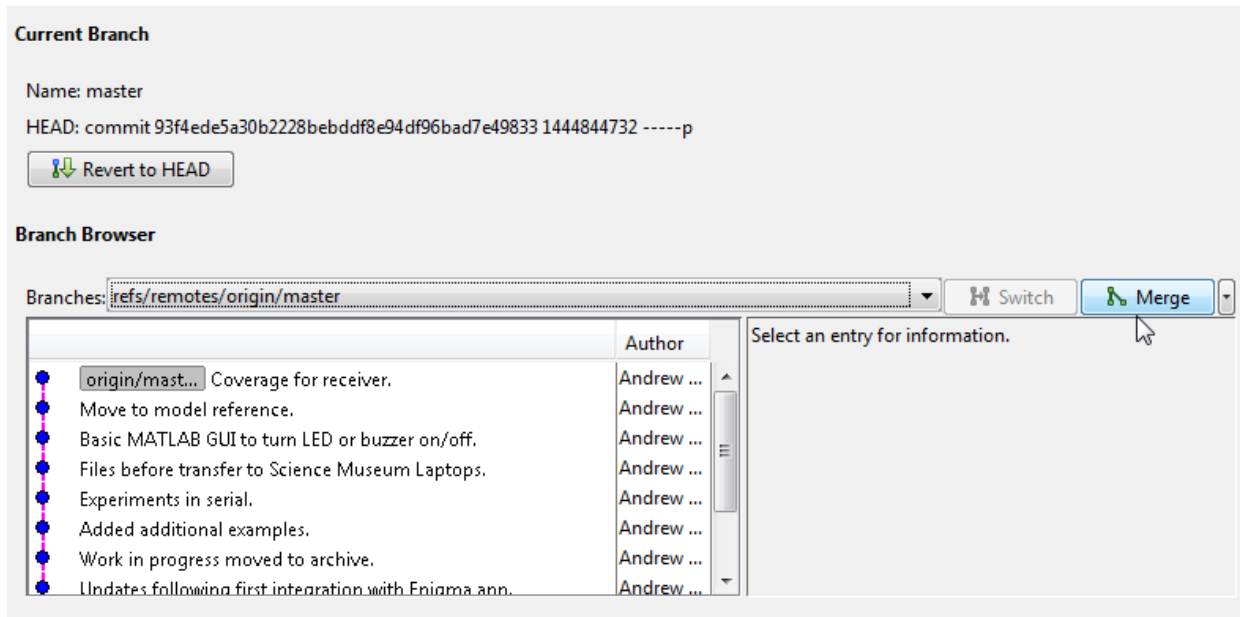

Observe the message in the Git pane, **Behind /origin/master**. You need to merge in the changes from the repository to your local branch, using **Branches**.

Current branch: master
Branch status: SAFE
Behind /origin/master

- 2 Click **Branches**.
- 3 In the Branches dialog box, in the **Branches** list, select **origin/master**.

- 4 Click **Merge**. This merges the origin branch changes into the master branch in your sandbox.

- Close the Branches dialog box. Observe the message in the Git pane now says **Coincident with /origin/master**. You can now view the changes fetched and merged from the remote repository in your local sandbox files.

When you fetch and merge, you might need to resolve conflicting changes. If the branch merge causes a conflict that Git cannot resolve automatically, an error dialog box reports

that automatic merge failed. Resolve the conflicts before proceeding. See “Resolve Conflicts” on page 19-61.

Push Empty Folders

Using Git, you cannot add empty folders to source control, so you cannot select **Push** and then clone an empty folder. You can create an empty folder in Simulink Project, but if you push changes and then sync a new sandbox, then the empty folder does not appear in the new sandbox. You can instead run **Check Project** which creates the empty folder for you.

Alternatively, to push empty folders to the repository for other users to sync, create a `gitignore` file in the folder and then push your changes.

Branch and Merge Files with Git

In this section...

“Create a Branch” on page 19-57

“Switch Branch” on page 19-59

“Merge Branches” on page 19-59

“Revert to Head” on page 19-60

“Delete Branches” on page 19-60

Create a Branch

- 1 In Simulink Project, click **Branches** in the **Git** pane. The Branches dialog box appears, where you can view, switch, create, and merge branches.

Tip You can inspect information about each commit node. Select a node in the Branch Browser diagram to view the author, date, commit message, and changed files.

The **Branches** pane in this figure shows an example branch history.

- 2 Select a source for the new branch. Click a node in the Branch Browser diagram, or enter a unique identifier in the Source text box. You can enter a tag, branch name, or a unique prefix of the SHA1 hash (for example, 73c637 to identify a specific commit). Leave the default to create a branch from the head of the current branch.
- 3 Enter a name in the **Branch name** text box and click **Create**.
- 4 To work on the files on your new branch, switch your project to the branch.

In the **Branches** drop-down list, select the branch you want to switch to and click **Switch**.

- 5 Close the Branches dialog box to return to Simulink Project and work on the files on your branch.

For next steps, see “Push and Fetch Files with Git” on page 19-52.

Switch Branch

- 1 In Simulink Project, click **Branches** in the **Git** pane.
- 2 In the Branches dialog box, select the branch you want to switch to in the **Branches** list and click **Switch**.
- 3 Close the Branches dialog box to return to Simulink Project and work on the files on the selected branch.

Merge Branches

Before you can merge branches, you must install command-line Git on your system path and register model files as binary to prevent Git from inserting conflict markers. See “Install Command-Line Git Client” on page 19-22.

Tip After you use **Fetch**, you must merge. See “Fetch and Merge” on page 19-53.

To merge any branches:

- 1 In Simulink Project, click **Branches** in the Git pane.
- 2 In the Branches dialog box, from the **Branches** drop-down list, select a branch you want to merge into the current branch, and click **Merge**.
- 3 Close the Branches dialog box to return to Simulink Project and work on the files on the current branch.

If the branch merge causes a conflict that Git cannot resolve automatically, an error dialog box reports that automatic merge failed. The Branch status in the **Git** pane displays **MERGING**. Resolve the conflicts before proceeding.

Caution Do not move or delete files outside of MATLAB because this can cause errors on merge.

Keep Your Version

- 1 To keep your version of the file, right-click the file and select **Mark Conflict Resolved**. The Branch status in **Git** pane displays `MERGE_RESOLVED`. The Modified Files list is empty, because you have not changed any file contents. The local repository index version and your branch version are identical.
- 2 Click **Commit Modified Files** to commit your change that marks the conflict resolved.

Compare Branch Versions

If you merge a branch and there is a conflict in a model file, Git marks the file as conflicted and does not modify the contents. Right-click the file and select **View Conflicts**. Simulink Project opens a comparison report showing the differences between the file on your branch and the branch you want to merge into. Decide how to resolve the conflict. See “Resolve Conflicts” on page 19-61.

Revert to Head

To remove all local changes, in the Branches dialog box, click **Revert to Head**.

Delete Branches

- 1 In the Branches dialog box, from the **Branches** drop-down list, select a branch you want to delete. You cannot delete the current branch.
- 2 On the far right, click the down arrow and select **Delete Branch**.

Caution You cannot undo deleting a branch.

Related Examples

- “Resolve Conflicts” on page 19-61

More About

- “About Source Control with Projects” on page 19-2

Resolve Conflicts

In this section...

- “Resolve Conflicts” on page 19-61
- “Merge Text Files” on page 19-63
- “Merge Models” on page 19-64
- “Extract Conflict Markers” on page 19-64

Resolve Conflicts

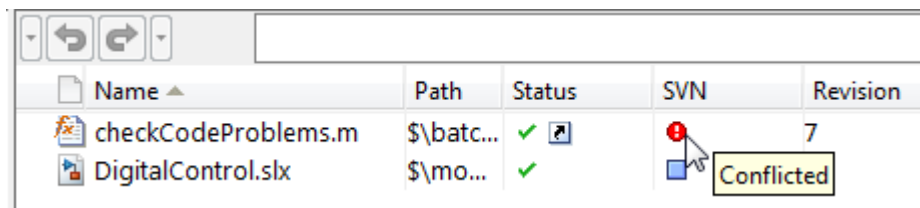

If you and another user change the same file in different sandboxes or on different branches, a conflict message appears when you try to commit your modified files. Extract conflict markers if necessary, compare the differences causing the conflict, and resolve the conflict.

- 1 Look for conflicted files in the Modified Files view.

Identify conflicted folder contents using source control summary status. Folders display rolled-up source control status. This makes it easier to locate changes in files, particularly conflicted files. You can hover over the source control status for a folder to view a tooltip displaying how many files inside are modified, conflicted, added or deleted.

Tip Use the List view  to view files without needing to expand folders.

- 2 Check the source control status column (**SVN** or **Git**) for files with a red warning symbol, which indicates a conflict.

Name	Path	Status	SVN	Revision
checkCodeProblems.m	\$.batc...	✓	⚠	7
DigitalControl.slx	\$.mo...	✓	✓	

- 3 Right-click the conflicted file and select **View Conflicts** to compare versions.
- 4 Examine the conflict. Simulink Project opens a comparison report showing the differences between the conflicted files.
 - For SVN, the comparison shows the differences between the file and the version of the file in conflict.
 - For Git, the comparison shows the differences between the file on your branch and the branch you want to merge into.
 - For model files, see “Merge Models” on page 19-64.
- 5 Use the comparison report to determine how to resolve the conflict.

To resolve conflicts you can:

- Use the report to merge changes between revisions.
- Decide to overwrite one set of changes with the other.
- Make changes manually from the project by editing files, changing labels, or editing the project description.

For details on using the Comparison Tool to merge changes between revisions, see “Merge Text Files” on page 19-63 and “Merge Models” on page 19-64.

- 6 When you have resolved the changes and want to commit the version in your sandbox, in Simulink Project, right-click the file and select **Source Control > Mark Conflict Resolved**. You can use the merge tool to mark the conflict resolved, or you can choose to manually mark the conflict resolved in the project.

For Git, the Branch status in the **Git** pane changes from MERGING to SAFE.

- 7 Select the Modified Files view and click **Commit Modified Files**.

Merge Text Files

When comparing text files, you can merge changes from one file to the other. Merging changes is useful when resolving conflicts between different versions of files.

Conflict markers appear in a text comparison report like this:

```
<<<<<<< .mine
```

If your comparison report contains conflict markers, extract them before merging, as described in “Extract Conflict Markers” on page 19-64.

Tip You can merge only from left to right. When comparing to another version in source control, the right file is the version in your sandbox. The left file is either a temporary copy of the previous version or another version causing a conflict (e.g., *filename_theirs*). Observe the file paths of the left and right file at the top of the comparison report. Merge differences from the left (temporary copy) file to the right file to resolve conflicts.

- 1 In the Comparison Tool report, select a difference in the report and click **Merge**. The selected difference is copied from the left file to the right file.

Merged differences display gray row highlighting and a green merge arrow.

```
1 function [len,dims] = lengthofline(hline)      function [len,dims] = lengthofline(hline)  i →
```

The merged file name at the top of the report displays the dirty flag (*filename.m**) to show you that the file contains unsaved changes.

- 2 Click **Save Merged File** to save the file on the right. Check the file path of the right file in the comparison report. (To save to a different file, select **Save Merged File > Save Merged File As**). To resolve conflicts, save the merged file over the conflicted file.
- 3 If you want to inspect the files in the editor, click the line number links in the report.

Note: If you make any further changes in the editor, the comparison report does not update to reflect changes and report links can become incorrect.

- 4 After merging to resolve conflicts, mark the conflict resolved and commit the changes, as described in “Resolve Conflicts” on page 19-61.

Merge Models

In the Comparison Tool report, you can merge changes between revisions. To use this capability on models, you must have Simulink Report Generator installed. For details, see “Merge Simulink Models from the Comparison Report” in the Simulink Report Generator documentation.

After merging to resolve conflicts, the merge tool can mark the conflict resolved for you, or you can choose to manually mark the conflict resolved. Then commit the changes, as described in “Resolve Conflicts” on page 19-61.

Extract Conflict Markers

- “What Are Conflict Markers?” on page 19-64
- “Extract Conflict Markers” on page 19-65

What Are Conflict Markers?

Source control tools can insert conflict markers in files that you have not registered as binary (e.g., text files). You can use Simulink Project tools to extract the conflict markers and compare the files causing the conflict. This process helps you to decide how to resolve the conflict.

Caution Register model files with source control tools to prevent them from inserting conflict markers and corrupting models. See “Register Model Files with Source Control Tools” on page 19-10. If your model already contains conflict markers, the project tools can help you to resolve the conflict, but only if you open the model from the project. Opening a model that contains conflict markers from the Current Folder or from a file explorer can fail because Simulink does not recognize conflict markers.

Conflict markers have the following form:

```
<<<<<<<["mine" file descriptor]
["mine" file content]
=====
["theirs" file content]
<<<<<<<["theirs" file descriptor]
```

If you try to open a file marked conflicted that contains conflict markers, the Conflict Markers Found dialog box opens. Follow the prompts to fix the file by extracting the conflict markers. After you extract the conflict markers, resolve the conflicts as described in “Resolve Conflicts” on page 19-61.

To view the conflict markers, in the Conflict Markers Found dialog box, click **Load File**. Do not try to load model files, because Simulink does not recognize conflict markers. Instead, click **Fix File** to extract the conflict markers.

By default, the project checks only conflicted files for conflict markers. You can change this preference to check all files or no files. Click **Preferences** in the Simulink Project tab to change the setting.

Extract Conflict Markers

When you open a conflicted file or select **View Conflicts**, the project checks files for conflict markers and offers to extract the conflict markers. The project checks only conflicted files for conflict markers unless you change your preferences setting.

However, some files that are not marked conflicted can still contain conflict markers. This can happen if you or another user marked a conflict resolved without removing the conflict markers and then committed the file. If you see conflict markers in a file that is not marked conflicted, you can remove the conflict markers.

- 1 In Simulink Project, right-click the file and select **Source Control > Extract Conflict Markers to File**.
- 2 Leave the default option to copy the “mine” revision over the conflicted file. Leave the **Compare** check box selected. Click **Extract**.
- 3 Use the Comparison Tool report as usual to continue to resolve the conflict.

Work with Derived Files in Projects

Best practice is to omit derived and temporary files from your project or exclude them from source control. Use **Check Project** in the Precommit Actions pane or the **Simulink Project** tab to check the integrity of the project. If you add the `slprj` folder to a project, the project checks advise you to remove this from the project and offer to make the fix.

Best practice is to exclude derived files, such as `.mex*`, the contents of the `slprj` folder, `sccprj` folder, or other code generation folders from source control, because they can cause problems. For example:

- With a source control that can do file locking, you can encounter conflicts. If `slprj` is under source control and you generate code, most of the files under `slprj` change and become locked. Other users cannot generate code because of file permission errors. The `slprj` folder is also used for simulation via code generation (for example, with model reference or Stateflow), so locking these files can have an impact on a team. The same problems arise with binaries, such as `.mex*`.
- Deleting `slprj` is often required. However, deleting `slprj` causes problems such as “not a working copy” errors if the folder is under some source control tools (for example, SVN).
- If you want to check in the generated code as an artifact of the process, it is common to copy some of the files out of the `slprj` cache folder and into a separate location that is part of the project. That way, you can delete the temporary cache folder when you need to. See `packNGo` to discover the list of generated code files, and use the project API to add to the project with appropriate metadata.
- The `slprj` folder can contain many small files. This can affect performance with some source control tools when each of those files is checked to see if it is up-to-date.

Customize External Source Control to Use MATLAB for Diff and Merge

You can customize external source control tools to use the MATLAB Comparison Tool for diff and merge. If you want to compare MATLAB files such as live scripts, MAT, SLX, or MDL files from your source control tool, then you can configure your source control tool to open the MATLAB Comparison Tool.

MATLAB Comparison Tool provides useful merge tools for MathWorks files and is compatible with all popular software configuration management and version control systems.

Set up your source control tool to use MATLAB as the application for diff and merge for the file extensions you want, for example, `.mlx`, `.mat`, `.slx`, or `.mdl`, by following these steps:

- 1 To get the required file paths and set the preference to reuse open MATLAB sessions, run this command in MATLAB:

```
comparisons.ExternalSCMLink.setup()
```

This command sets the MATLAB preference, under **Comparison**, called **Allow external source control tools to use open MATLAB sessions for diffs and merges**.

The command also displays the file paths you will copy and paste into your source control tool setup:

- On Windows:

```
matlabroot\bin\win64\mlDiff.exe
```

```
matlabroot\bin\win64\mlMerge.exe
```

- On Linux:

```
matlabroot/bin/glnxa64/mlDiff
```

```
matlabroot/bin/glnxa64/mlMerge
```

On Mac:

```
matlabroot/bin/maci64/mlDiff
```

```
matlabroot/bin/maci64/mlMerge
```

Where *matlabroot* is replaced with the full path to your installation, for example, `C:\Program Files\MATLAB\R2016b`.

2 Set up diff.

- a In the MATLAB Command Window, copy the file path to `m1Diff`, for example, `C:\Program Files\MATLAB\R2016b\bin\win64\m1Diff.exe`.
- b In your source control tool, locate the diff setting, and add an entry to specify what to do with a particular file extension (for example, `.slx`). Paste in the file path to `m1Diff` that you copied from the MATLAB Command Window.
- c After the path to the script, or in the arguments box, add arguments to specify the input files. Look up the argument names specific to your source control tool. Specify the inputs for diffs, in this order: *leftFile*, *rightFile*.

For example, for Tortoise SVN:

```
"C:\Program Files\MATLAB\R2016b\bin\win64\m1Diff.exe" %base %mine
```

For Perforce® P4V:

```
"C:\Program Files\MATLAB\R2016b\bin\win64\m1Diff.exe" %1 %2
```

3 Set up merge.

- a In the MATLAB Command Window, copy the file path to `m1Merge`.
- b In your source control tool, locate the merge setting, and add an entry to specify what to do with a particular file extension (for example, `.slx`). Paste in the file path to `m1Merge` that you copied from the MATLAB Command Window.
- c After the path to the script, or in the arguments box, add arguments to specify the input files. Look up the argument names specific to your source control tool. Specify the inputs for merges, in this order: *base*, *mine*, *theirs*, and *merged* target file.

For example, for Tortoise SVN:

```
"C:\Program Files\MATLAB\R2016b\bin\win64\m1Merge.exe" %base %mine %theirs %merged
```

For Perforce P4V:

```
"C:\Program Files\MATLAB\R2016b\bin\win64\m1Merge.exe" %b %2 %1 %r
```

- 4 After this setup, when you use diff or merge, your external source control tool opens a report in MATLAB Comparison Tool. Use the report to view changes and resolve merges.

Your diff and merge operations use open MATLAB sessions if available, and only open MATLAB when necessary. The comparison only uses the specified MATLAB installation.

Componentization Using Referenced Projects

For a large modeling project, organizing the project into components facilitates:

- Component reuse
- Modular, team-based development
- Unit testing
- Independent release of components

Simulink Project supports large-scale project componentization by allowing you to reference other projects from a parent project. A collection of parent and referenced projects constitutes a project reference hierarchy. Project referencing provides these benefits:

- A parent project has access to a referenced project's project paths, entry-point shortcuts, and source control information. For example, from a parent project, you can use referenced project shortcuts to view and run files that belong to the referenced project.
- Through a referenced project, your team can develop a component independent of other components.
- In a referenced project, you can test the component separately.

This project hierarchy illustrates the use of parent and referenced projects as components of a large project.

Through the Transistor Development project, a team independently creates and tests a library of blocks. The team makes the library available to other developers by exporting release versions, for example, version 2.3.

Through the Radio Development project, another team develops and tests the Radio system. This team requires:

- Version 2.3 of the Transistor component. The team sets up the Radio Development project to reference the Transistor Release V2.3 project.
- Tools to plot signals, for example, MATLAB files that are not distributed to customers. The team sets up the Radio Development project to reference the Plotting Tools Development project.

When the Radio system is ready for customers, the team exports a release version, for example, version 4.1.

Add or Remove a Reference to Another Project

Add new components to your project by referencing other projects. The addition of referenced projects creates a project hierarchy. When Simulink Project loads a referenced project in a project hierarchy, it:

- Adds project paths from the referenced project to the MATLAB search path.
- Runs startup shortcuts from the referenced project.

To reference a project:

- 1 On the Simulink Project tab, in the **Environment** section, click **References**.
- 2 In the Referenced Projects dialog box, click the **Add a reference to another project** button .

- If your project hierarchy has a well-defined root relative to your project root, for example, a folder under source control, select **Add Relative Reference**.
- If the project you want to reference is in a location accessible to your computers, for example, a network drive, select **Add Absolute Reference**.

- 3 Using the Open dialog box, navigate to the project location and select the project folder.

On the **Project Shortcuts** tab, the **Referenced Projects** section displays the newly added project.

To remove a referenced project from your project hierarchy:

- 1 On the Simulink Project tab, in the **Environment** section, click **References**.
- 2 In the Referenced Projects dialog box, select the project that you want to remove and click the **Remove reference to selected project** button .

View or Run Referenced Project Files

In a Simulink Project hierarchy, from a parent project, use referenced project shortcuts to view and run files that belong to the referenced project.

- 1 Within the referenced project, create shortcuts for the files that you want to view or run from the parent project.
- 2 From the parent project, on the **Project Shortcuts** tab, in the **Referenced Projects** section, click the referenced project button arrow.

- 3 From the list, select the file that you want to view or run.

More About

- “Componentization Using Referenced Projects” on page 20-2

Open a Referenced Project

In Simulink Project, you can open a referenced project from a parent project.

Note: Opening a referenced project closes the parent project.

- 1 On the **Project Shortcuts** tab, in the **Referenced Projects** section, click the referenced project button arrow.

- 2 From the list, select **Open**.
- 3 In the Warning dialog box, click **Continue**.

More About

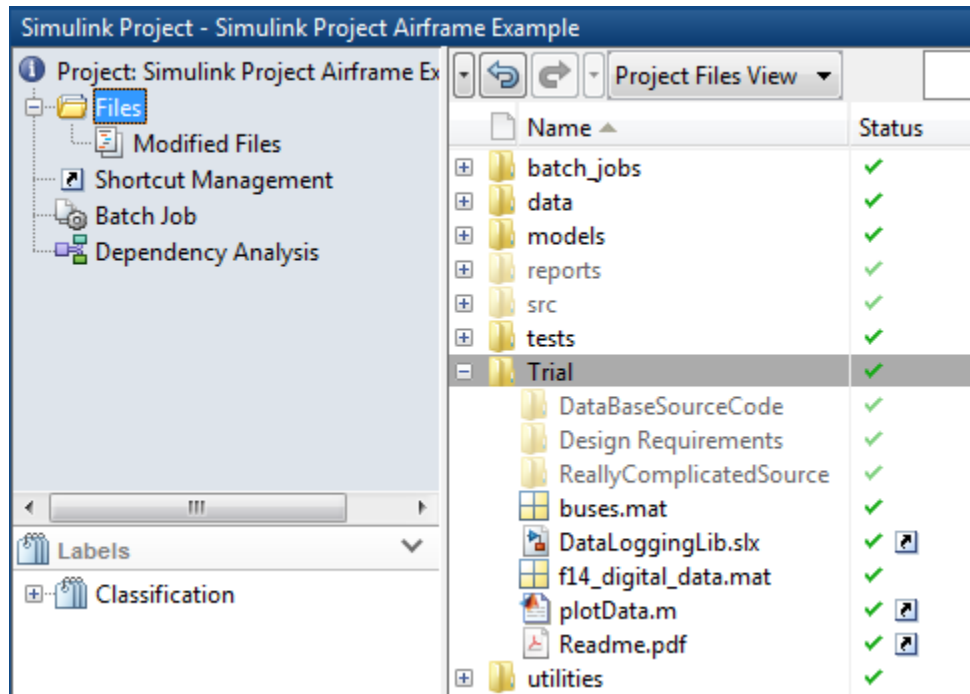

- “Componentization Using Referenced Projects” on page 20-2

Extract a Folder to Create a Referenced Project

In Simulink Project, you can partition a large project into components through the use of project references.

Consider the Airframe example project. Suppose you create a folder `Trial` and carry out development work within the folder. You produce:

- Shortcuts to a Simulink library, a MATLAB file, and a `Readme` document
- Design and source code folders
- Data files

For easier management, you want to convert the `Trial` folder into a separate component. In addition, you want access to the folder contents, for example, shortcuts to key files. To fulfill these requirements, extract the folder from the project and convert the folder into a referenced project.

- 1 With **Project Files View** selected, right-click the **Trial** folder and select **Extract to Referenced Project**.
- 2 In the **Extract Folder to New Project** dialog box, specify these options:
 - **New Project Name** — For example, **DataLogging**.
 - **New Project Location** – For example, **C:\Work\DataLogging**.
 - **Reference Type** – The default is **Relative reference**. Use the default if you specify the new project location with reference to the current project root. If you specify the full path for the new location, which is, for example, on a network drive, select **Absolute reference**.
- 3 Click **More Options**. If you want to disable any of the default content migration actions, clear the corresponding check box.
- 4 Click **Extract**.
- 5 In the **Warning** dialog box, click **Continue**.

The folder **Trial** and its contents are removed from the project. On the **Project Shortcuts** tab, the **Referenced Projects** section displays a new **DataLogging** button.

- “Partition an Existing Design” on page 21-10
- “Manage Components Using Libraries” on page 21-11

When to Partition a Design

Partition a design when it becomes too complex for one person to know all of the details. Complexity increases with design size and team size, for example,

- Design size and complexity:
 - Thousands of blocks
 - Hundreds of logical decisions
 - Hundreds of inputs and outputs
 - Hundreds of times larger industry examples in some cases
 - Multiple variant configurations of the same functionality
- Team integration:
 - Multiple people working on the design
 - People located in different places
 - People from different companies

Partitioning your design into components helps you to work with large-scale designs. Partitioning a design into components gives modularity to help you reduce complexity, collaborate on development, test and reuse components, and to succeed with large-scale model-based design. Component-based modeling helps:

- Enable efficient and robust system development.

- Reduce overall design complexity by solving smaller problems.
- Gain performance benefits that scale.
- Reuse components across multiple projects.
- Facilitate collaboration
 - Partition algorithms, physical models, and tests. Define architecture in terms of structural and functional partitioning of the design using defined interfaces.
 - Collaborate with teams across organizational boundaries on product development. Teams can elaborate individual components independently to do plant modeling, algorithm design, and developing of test harnesses.
 - Manage design with source control tools.
- Improved iteration, elaboration, and verification workflows
 - Iterate faster via more efficient testing and reuse.
 - Eliminate retesting for unchanged components.
 - Reuse environment models and algorithm designs in different projects.
 - Create variants of designs.
 - Elaborate components independently through well-defined interfaces.
 - Manage design evolution with configuration management tools.

Component-based modeling requires:

- Mechanisms for partitioning models and specifying interfaces
- Tools and processes for managing data, models, and environment

Use the following techniques for component-based modeling.

When Not to Partition a Design

Componentization provides benefits for large-scale designs, but is not needed for small designs. Partitioning your design into components requires design work and can increase time taken to update diagrams. Use separate components only when your design is large enough to benefit from componentization.

To decide whether your design needs partitioning, see the recommendations in “Guidelines for Component Size and Functionality” on page 21-4.

Plan for Componentization in Model Design

After models grow large and complex over time, it is difficult to split them into components to allow multiple engineers to work on them in parallel. Splitting a Simulink model into components is easier if the model is designed for componentization from the start. Designing for componentization in the first place can help you avoid these difficulties:

- If a single engineer develops a model from the bottom up, adding blocks and grouping them into subsystems as the model complexity increases, it is hard to later split the model into components. The subsystems within the model are often “virtual” and nonatomic. When you convert these to atomic subsystems and then to model reference components, you can introduce unwanted algebraic loops that are hard to diagnose and solve.
- Subsystems grown over time do not always represent the best way to partition the model. “Best” here might mean the most useful structure for reusable components in other models, or for generating code that integrates with legacy functionality, or for performing Hardware-in-the-Loop tests, etc.
- If you try to expand to parallel development without componentizing models, it is difficult to share work in teams without time-consuming and error-prone merging of subsystems.

These problems are analogous to taking a large piece of code (C, Java, or MATLAB code) and trying to break it down into a number of separate functions. Significant effort is required and can require extensive modifications to some parts of the code, if the code was not designed to be modular in the first place. The same is true for Simulink models.

Lack of componentization causes common failure modes when trying to place Simulink models into configuration management as they grow and you want more than one engineer to work on it in parallel. The best way to avoid these issues is to design for components from the start. You can use the following features of Simulink to design a model suitable for componentization.

If you already have a design that you want to divide into components, see “Partition an Existing Design” on page 21-10.

Guidelines for Component Size and Functionality

To set up your project for a team to work on, consider the following model architecture guidelines for components. Useful components:

- Have well-defined interface I/O boundaries.
- Perform a defined set of functions (actions), defined by requirements.
- Form part of a larger system.
- Have the “right” size:
 - Large enough to be reusable
 - Small enough to be tested
 - Only one engineer is likely to want to edit each model at a time

The right size can depend on team size. You can have larger components if only one person is working on each, but if you need to share components between several people, you probably need to divide the design into smaller logical pieces. This aids two goals: understanding the design, and reducing file contention and time spent on merging.

Recommendations:

- In most cases, if you have fewer than 100 blocks, do not divide the design into components. Instead, use subsystems if you want to create a visual hierarchy. For example, the example model `vdp` is not large enough to benefit from componentization.
- If you have 500–1000 blocks, consider creating a model reference to contain that component in a separate file. The cost of verification can reduce the size for components. For example, if you have a small component of 100 blocks with high testing costs and frequent changes, consider separating that component into a separate file to make verification easier.

Consider dividing the model based on:

- Physical components (e.g., plant and controller, for code generation)
- Algorithm logic
- Reusability in other models
- Testability, for example, for performing Hardware-in-the-Loop tests
- Sample rate; consider grouping components that have the same sample rate
- Simulation speed; using different solvers for components with different numerical properties can increase simulation speed
- Accessibility to other teams or others on your team.

While you cannot always plan on model size, if you expect multiple people to work on the design, you can benefit from componentization techniques. Consider controlling

configuration management using Simulink Project and partitioning the design using Model Reference so that the team can work on separate files concurrently.

Component Size	Recommended Componentization Techniques	Notes
Small <500 blocks	Create visual hierarchy using subsystems.	Small designs do not benefit from dividing into separate files. However, larger teams that cause file contention or high cost of verification can make it worth partitioning smaller components into separate files instead of using subsystems.
Large >500 blocks	Separate components into separate files using Model Reference or Libraries.	For multiple engineers or teams working on a design, best practice is one file per component. To reduce file contention, aim for components in which only one engineer needs to edit each model at a time.
Small <500 blocks, but expected to grow over time	Use atomic subsystems for functional block grouping instead of virtual subsystems. Atomic subsystems are easier to migrate to separate file components later.	If possible, plan your components from the start to avoid migration pain.

If your design or team is large enough to benefit from separating components into separate files, this table summarizes when to apply each technique.

Component Characteristics	Technique	Benefits	Costs
Small, low-level utility functions, reused in	Library model containing a single reusable	<ul style="list-style-type: none"> Context-dependent: can adapt to various interfaces with different data types, sample time, and dimensions, 	<ul style="list-style-type: none"> Cannot use independently to simulate or generate code. Requires a parent model.

Component Characteristics	Technique	Benefits	Costs
many places in a design	atomic subsystem	<p>in different contexts, without changing the design.</p> <ul style="list-style-type: none"> • Can be reused in other models • Stored as a separate file, can apply version control, but each instance adapts to context of parent model, so generated code can differ in each instance. 	<ul style="list-style-type: none"> • Context adaptation not desirable for big components in large-scale models where interfaces are managed and locked down to specific data type and dimension. In these cases, you might not want code generated for the library block to differ in each instance. • Requires link management to avoid problems with broken, disabled, or parameterized links. See “Manage Components Using Libraries” on page 21-11.
Groups of blocks for sharing among users	<p>Library for grouping and storing Simulink blocks</p> <p>Library <i>palette</i> of links to components</p>	<ul style="list-style-type: none"> • Libraries are useful for storing blocks to share among a number of users • To reduce file contention, use library palettes of links to individual components in separate files. Store each component in a model reference file or a single subsystem in a separate library. 	<ul style="list-style-type: none"> • Causes file contention if multiple components reside in a single library file. File contention is a problem only if blocks need frequent updates or multi-user access. Palettes can help. • Requires link management to avoid problems with broken, disabled, or parameterized links. See “Manage Components Using Libraries” on page 21-11.

Component Characteristics	Technique	Benefits	Costs
<p>Top-level components for large-scale models: >500 blocks</p> <p>Large components: starting at ~ 500–5000 blocks for one or a few reusable instances, or smaller if many instances</p> <p>Components at any level of model hierarchy where teams need to work independently</p>	<p>Model Referencing</p>	<ul style="list-style-type: none"> • Components are independent model files and part of a larger model. You can simulate and generate code in the component. • Independent of context—good for large-scale model components where interfaces are managed and locked down. • Stored as a separate file—can apply version control to a component independently of the models that use it. • Possible to use Accelerator mode generated code to reduce memory requirements when loading models and increase simulation speed, compared to subsystems or libraries. Useful for top-level component partitions. 	<p>Performance can reduce slightly when updating a model (update diagram) because each reference model is checked for changes to enable incremental builds. When components are large enough (>500 blocks), update diagram is faster in most cases.</p> <p>See “Partition a Design Using Model Reference” on page 21-10.</p>

Choose Components for Team-Based Development

To perform parallel development, you need component-based modeling. Best practice for successful team-based development is to partition the models within the project so that only one user works on each part at a time. Componentization enables you to avoid or minimize time-consuming merging. To set up your project for work by a team, consider the following model architecture guidelines.

This table compares subsystems, libraries, and model referencing for team-based development.

Modeling Development Process	Subsystems	Libraries	Model Referencing
Team-based development	<p>Not supported</p> <p>For subsystems in a model, Simulink provides no direct interface with source control tools.</p> <p>To create or change a subsystem, you need to open the parent model's file. This can lead to file contention when multiple people want to work on multiple subsystems in a model.</p> <p>Merging subsystems is slow and errorprone, so best avoided as a workflow process. However, Simulink Report Generator provides tools to help you merge subsystems. See "Merge Simulink Models from the Comparison Report".</p>	<p>Supported, with limitations</p> <p>You can place library files in source control for version control and configuration management. You can use Simulink Project to interact with source control.</p> <p>You can maintain one truth, by propagating changes from a single library block to all blocks that link to that library.</p> <p>To reduce file contention, use one subsystem per library.</p> <p>You can link to the same library block from multiple models.</p> <p>You can restrict write access to library components.</p>	<p>Well suited</p> <p>You can place model reference files in source control for version control and configuration management. You can use Simulink Project to interact with source control.</p> <p>You save a referenced model in a separate file from the model that references it. Using separate files helps to avoid file contention.</p> <p>You can design, create, simulate, and test a referenced model independently from the model that references it.</p> <p>Simulink does not limit access for changing a model reference.</p>

Most large models use a combination of componentization techniques. No single approach is suitable for the wide range of users of Simulink. The following advice describes some

typical processes to show what you can do with MathWorks tools to perform team-based development.

One File Per Component for Parallel Development

To perform efficient parallel development, break a large model into a number of individual files, so that team members can work independently and you can place each file under revision control. Componentization enables you to avoid or minimize time-consuming merging. To set up your project for work by a team, consider the advice in “Guidelines for Component Size and Functionality” on page 21-4.

A key goal of component-based modeling is to allow parallel development, where different engineers can work on components of a larger system in parallel. You can achieve this if each component is a single file. You can then control and trace the changes in each component using source control in Simulink Project. See “Configuration Management” on page 21-18.

Partition an Existing Design

If you already have a design that you want to divide into components, first decide where to partition the model. Existing subsystems that grow over time are not always the best way to partition the model. Consider dividing the model based on the advice in “Guidelines for Component Size and Functionality” on page 21-4.

Agreeing on an interface is a useful first step in deciding how to break down the functionality of a large system into subcomponents. You can group signals and partition data. See “Interface Design” on page 21-13.

After you decide how to partition your design, Simulink tools can help you divide an existing model into components.

Simulink can help you partition models by converting subsystems to files. You can convert to files using Model Reference or Libraries. See “Guidelines for Component Size and Functionality” on page 21-4 for suggestions on when to apply each technique.

Partition a Design Using Model Reference

Use Model Reference to divide the components into separate files so that the team can work on separate files concurrently. You can also reuse the models in other models. To partition a model using model reference, see “Create a Referenced Model” on page 8-9 or “Convert a Subsystem to a Referenced Model” on page 8-17.

Manage Components Using Libraries

- Use Libraries containing a single subsystem to contain a component in a single file. Use libraries to store blocks you can reuse in models. The linked blocks inherit attributes from the surrounding models, such as data types and sample rate. Using this technique for componentization has the management overhead of library links, described below.
- Use Libraries to reuse blocks in multiple models. Libraries work well for grouping and storing Simulink blocks to share. Best practice for libraries is to use them for storing blocks to share with multiple users, and blocks that are updated infrequently. As a rough guideline, it is appropriate to use a Simulink library if its contents are updated once every few months. If you update it more frequently, then the library is probably being used to perform configuration management. In this case, take care to avoid the common problems described in “Library Link Management” on page 21-11.
- To make library blocks available for reuse while reducing file contention and applying revision control, use library palettes. A palette is a library containing links to other components. If each component is a single subsystem in a separate library, or a model reference file, you can achieve the one-file-per-component best practice for component-based modeling. You can use separate version control for each component, and you can also control the palette.

When you drag a block from the library palette into your model, Simulink follows the link back to the file where the subsystem or model reference is implemented. The models that use the component contain a link to the component and not to the palette.

Library Link Management

Library links can introduce management overhead if you use them for configuration management. Take care to manage:

- Disabled links — Can cause merge conflicts, and failure to update all instances of the same model component. In a hierarchy of links, you can accidentally disable all links without being aware of it, and only restore one link while leaving others disabled.
- Broken links — Accidentally broken links are a hard problem to solve, because, by design, you cannot detect what the broken link linked to previously.
- Parameterized link data — It can be useful to change the value of parameter data, such as the value of a gain within a gain block, without disabling the library link. This generates “link data” for that instance only. However for configuration management this can cause a problem, if you assume all instances are identical, as one now has different properties.

Simulink tools help you manage library links to avoid problems:

- Lock links to prevent editing. See “Lock Links to Blocks in a Library” on page 38-24.
- Use diagnostic options to check library link integrity whenever you save a model. You can set the checks to warn, error, or ignore that a model has disabled or parameterized library links. You select these settings per model. In the Configuration Parameters dialog box, see **Diagnostics > Saving**.

See the diagnostic settings “Block diagram contains disabled library links” and “Block diagram contains parameterized library links”.

- Use Model Advisor checks to report on library link integrity. The advisor checks for disabled and parameterized links within a model. You can use the resulting report as an artifact to check into a configuration management system.

See the Model Advisor checks:

- “Identify disabled library links”
- “Identify parameterized library links”
- “Identify unresolved library links”
- Use the Links Tool to view and restore disabled and edited links. See “Restore Disabled or Parameterized Links” on page 38-26.

Caution These link management tools can detect link problems but cannot prevent editing the wrong files. If this is a problem, then use Model Reference as the partitioning mechanism to avoid the risks associated with disabled, broken, and parameterized links.

Interface Design

In this section...

“Why Interface Definitions Are Important” on page 21-13

“Recommendations for Interface Design” on page 21-13

“Partitioning Data” on page 21-15

“Configure Data Interface for Component” on page 21-15

Why Interface Definitions Are Important

Defining the “interface” of a software component, such as a C or MATLAB code function or a Simulink subsystem, is a key first step before others can use it, for these reasons:

- Agreeing on an interface is a useful first step in deciding how to break down the functionality of a large system into subcomponents.
- After you define interfaces between a number of components, you can develop the components in parallel. If the interface remains stable, then it is easy to integrate those components into a larger system.
- Changing the interface between components is expensive. It requires changes to at least two components (the source and any sinks) and to any test harnesses. It also makes all previous versions of those components incompatible with the current and future versions.

When you need to change an interface, doing so is much easier if the components are stored under configuration management. You can track configurations of compatible component versions to prevent incompatible combinations of components.

Recommendations for Interface Design

Suggestions for defining the interfaces of components for a new project:

- Base the boundaries of the components upon those of the corresponding real systems. This is especially useful when the model contains:
 - Both physical (plant and environment) and control systems
 - Algorithms that run at different rates

- Consider future model elaboration. If you intend to add models of sensors, then put them in from the start as an empty subsystem that passes signals straight through or performs a unit delay and/or name conversion.
- Consider future component reuse.
- Consider using a signal naming convention.
- Use data objects for :
 - Defining component interfaces
 - Precise control over data attributes
- Simplify interface design by grouping signals into buses. Signal buses are well suited for use at the high levels of models, where components often have a large number of signals going in and out, and do not use all the signals available. Using buses can simplify modifying the interface to a component. For example, if you need to add or remove signals used by a component, it can be simpler to modify a bus than to add or remove inports or outports to that component. However, using a bus that crosses model reference boundaries requires using a bus object.

Best practices for using Simulink bus signals and bus objects:

- Make buses virtual, except for model reference component boundaries.
- Use nonvirtual buses when defining interfaces between components. However, this requires associating the bus with a bus object. Bus objects completely define the properties of the signals on a bus, giving an unambiguous interface definition.

Include bus objects in a data dictionary, or save bus objects as a `.mat` or `.m` file, in order to place them under revision control.

- Pass only required signals to each component to reduce costly passing of unnecessary data. Signal buses allow the full set of input and output signals to be defined, but not necessarily used or created.
- Make sure that the interface specifies exactly what the component uses.
- Use a rigorous naming convention for bus objects. Unless you use a data dictionary, bus objects are stored in the base workspace.
- At the lower levels of a model, consider using inports and outports for each signal. At lower levels of a model, where components typically implement algorithms rather than serve as containers for other components, it can increase readability if you use individual inports and outports for components, instead of using signal buses. However, creating interfaces in this way has a greater risk of connection

problems, because it is difficult to check the validity of connections, other than their data type, size, etc.

Partitioning Data

Explicitly control the scope of data for your components. Some techniques:

- Global parameters — A common approach in the automotive world is to completely separate the problem of parameter storage from model storage. The parameters for a model come from a database of calibration data, and the specific calibration file used becomes part of the configuration. The calibration data is treated as global data, and resides in the base MATLAB workspace. You can migrate base workspace data to a data dictionary for more control.
- Nonglobal parameters — Combining a number of components that somehow store their own parameter data has the risk of parameter name collisions. If you do not use a naming convention for parameters or, alternatively, a list of unique parameter names and definitions, then there is the risk that two components use a parameter with the same name but with different meanings.

Methods for storing local parameter data include:

- Partition data into reference dictionaries for each component.
- With Model Reference, you can use model workspaces.
- Use parameter files (.m or .mat) and callbacks of the individual Simulink models (e.g., `preload` function).

You can also automatically load required data using Simulink Project shortcuts.

- Mask workspaces, with or without the use of mask initialization functions.
- For subsystems, you can control the scope of data for a subsystem using the Subsystem Parameters, Permit Hierarchical Resolution dialog box.

Configure Data Interface for Component

Whether you use referenced models or subsystems to break a large system into components, the components can exchange signal data through Inport and Output blocks. You can explicitly configure design attributes (such as data type and numeric complexity) of the interface to prevent modeling errors and make integrating the components easier.

After you create the Inport and Outport blocks, you can use the Model Data Editor and the interface display to configure the design attributes (such as data type and numeric complexity) of the blocks. Use this technique to view the component interface in its entirety at once and to trace the pieces of the interface to usage points in the internal block algorithm. You can also use this technique to configure the interface of a component before you develop the internal algorithm, in which case the component contains unconnected Inport and Outport blocks.

The example model `sldemo_fuelsys_dd` contains two components which are referenced models:

- A plant component, `sldemo_fuelsys_dd_plant`.
- A controller component, `sldemo_fuelsys_dd_controller`.

Use the Model Data Editor and the interface display to examine and configure the interface of the plant component.

- 1 Open the plant component.

`sldemo_fuelsys_dd_plant`

- 2 Select **Display > Interface**.
- 3 Select **View > Model Data**.

By default, in the Model Data Editor, the **Inports/Outports** tab is selected. Each row in the table represents an Inport or Outport block. By default, the **Change View** drop-down list is set to **Design**.

Tip To view only the Inport and Outport blocks at the root level of the model (by excluding the blocks inside the subsystems), deactivate the **Change Scope** button.

- 4 Use the columns in the Model Data Editor to explicitly configure the design attributes of the interface. For example, specify minimum and maximum values for each Inport and Outport block by using the **Min** and **Max** columns.

To configure code generation settings for the interface of a controller component, in the Model Data Editor, set the **Change View** drop-down list to **Code**.

For more information about using the interface display, see “Trace Connections Using Interface Display” on page 12-77. For more information about the Model Data Editor, see “Configure Data Properties by Using a Table” on page 57-103.

Configuration Management

In this section...

“Manage Designs Using Source Control” on page 21-18

“Determine the Files Used by a Component” on page 21-19

“Manage Model Versions” on page 21-19

“Create Configurations” on page 21-20

Manage Designs Using Source Control

Simulink projects can help you work with configuration management tools for team collaboration. You can use projects to help you manage all the models and associated files for model-based design.

You can control and trace the changes in each component using source control in Simulink Project. Using source control directly from Simulink Project provides these benefits:

- Engineers do not have to remember to use two separate tools, avoiding the common mistake of beginning work in Simulink without checking out the required files first.
- You can perform analysis within MATLAB and Simulink to determine the dependencies of files upon each other. Third-party tools are unlikely to understand such dependencies.
- You can compare revisions and use tools to merge models (requires Simulink Report Generator).

If each component is a single file, you can achieve efficient parallel development, where different engineers can work on the different components of a larger system in parallel. Componentization enables you to avoid or minimize time-consuming merging. See “One File Per Component for Parallel Development” on page 21-10. One file per component is not strictly necessary to perform configuration management, but it makes parallel development much easier.

If you break down a model into a number of components, it is easier to reuse those components in different projects. If the components are kept under revision control and configuration management, then you can reuse components in a number of projects simultaneously.

To find out about source control support in Simulink, see “Source Control in Simulink Project”.

Determine the Files Used by a Component

You can use Simulink Project to determine the set of files you need to place under configuration management. You can analyze the set of files that are required for the model to run, such as model references, library links, block and model callbacks (`preload` functions, `init` functions, etc.), S-functions, From Workspace blocks, etc. Any MATLAB code found is also analyzed to determine additional file dependencies. You can use the Simulink manifest tools to report which toolboxes are required by a model, which can be a useful artifact to store.

You can also perform a file dependency analysis of a model programmatically from MATLAB using `dependencies.fileDependencyAnalysis` to get a cell array of paths to required files.

For more information, see “Dependency Analysis”.

Manage Model Versions

Simulink can help you to manage multiple versions of a model.

- Use Simulink Projects to manage your project files, connect to source control, review modified files, and compare revisions. See “Project Management”.
- Simulink notifies you if a model has changed on disk when updating, simulating, editing, or saving the model. Models can change on disk, for example, with source control operations and multiple users. Control this notification with the Model File Change Notification preference. See “Model File Change Notification” on page 4-87.
- As you edit a model, Simulink generates version information about the model, including a version number, who created and last updated the model, and an optional comments history log. Simulink saves these version properties with the model.
 - Use the Model Properties dialog box to view and edit some of the version information stored in the model and specify history logging.
 - The `Model Info` block lets you display version information as an annotation block in a model diagram.
- Use `Simulink.MDLInfo` class to extract information from a model file without loading the block diagram into memory. You can use `MDLInfo` to query model version and

Simulink version, find the names of referenced models without loading the model into memory, and attach arbitrary metadata to your model file.

Create Configurations

You can use Simulink Project to work with the revision control parts of the workflow: retrieving files, adding files to source control, checking out files, and committing edited files to source control.

To define configurations of files, you can label a number of files as a new mutually consistent configuration. Other users can get this set of files from the revision control system.

Configurations are different from revisions. Individual components can have revisions that work together only in particular configurations.

Tools for creating configurations in Simulink:

- Variant modeling. See “Variant Systems”.
- Tools in Simulink Project:
 - Label — Label project files. Use labels to apply metadata to files. You can group and sort by labels, label folders for adding to the path using shortcut functions, or create batch jobs to export files by label, for example, to manage files with the label **Diesel**. You cannot retrieve from source control by label, and labels persist across revisions.
 - Revision Log — Use Revert Project to choose a revision to revert to (SVN source control only).
 - Branch — Create branches of file versions, and switch to any branch in the repository (Git source control only).
 - Tag — You can tag all project files (SVN source control only) to identify a particular configuration of a project, and retrieve tagged versions from source control. However, continued development is limited. That is, you cannot tag again, and you must check out from `trunk` to apply tags.
 - Archive — Package all project files in a Zip file that you can create a new project from. However, this packaging removes all source control information, because archiving is for exporting, sharing, and changing to another source control. You can commit the new Zip file to source control.

Study Power Windows

Automobiles use electronics for control operations such as:

- Opening and closing windows and sunroof
- Adjusting mirrors and headlights
- Locking and unlocking doors

These systems are subject to stringent operation constraints. Failures can cause dangerous and possibly life-threatening situations. As a result, careful design and analysis are needed before deployment.

This example focuses on the design of a power window system of an automobile, in particular, the passenger-side window. A critical aspect of this system is that it cannot exert a force of more than 100 N on an object when the window closes. When the system detects such an object, it must lower the window by about 10 cm.

As part of the design process, the example considers:

- Quantitative requirements for the window control system, such as timing and force requirements
- System requirements, captured in activity diagrams
- Data definitions for the signals used in activity diagrams

Other aspects of the design process that this example contains are:

- Managing the components of the system
- Building the model
- Validating the results of system simulation
- Generating code

MathWorks Software Used in This Example

In addition to Simulink, this example uses these additional MathWorks products:

- DSP System Toolbox
- Fixed-Point Designer
- Simscape Multibody
- Simscape Power Systems™

- Simscape
- Simulink 3D Animation
- Simulink Real-Time
- Simulink Verification and Validation
- Stateflow

Quantitative Requirements

Quantitative requirements for the control are:

- The window must fully open and fully close within 4 s.
- If the up is issued for between 200 ms and 1 s, the window must fully open. If the down command is issued for between 200 ms and 1 s, the window must fully close.
- The window must start moving 200 ms after the command is issued.
- The force to detect when an object is present is less than 100 N.
- When closing the window, if an object is in the way, stop closing the window and lower the window by approximately 10 cm.

Capturing Requirements in Activity and Context Diagrams

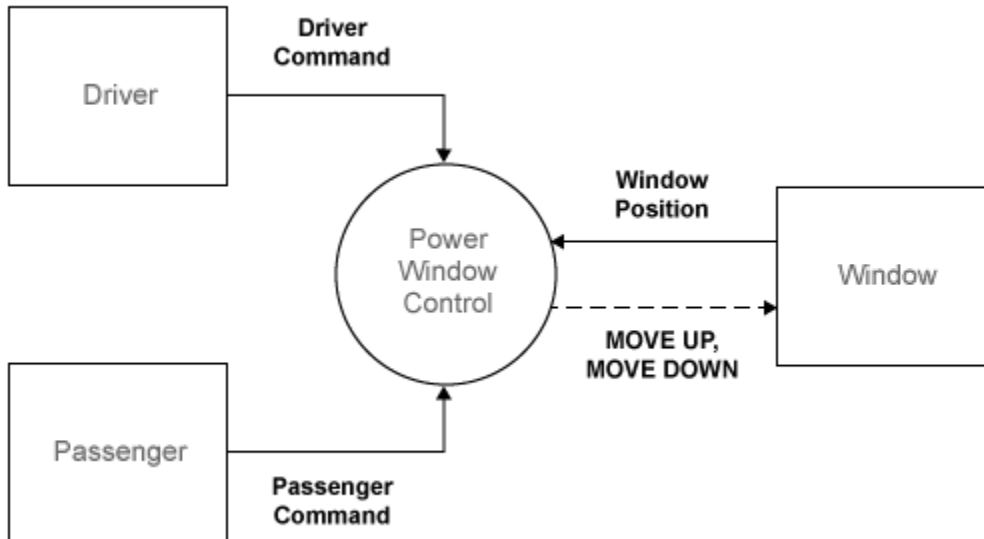

Activity diagrams help you graphically capture the specification and understand how the system operates. A hierarchical structure helps with analyzing even large systems. At the top level, a context diagram describes the system environment and its interaction with the system under study in terms of data exchange and control operations. Then you can decompose the system into an activity diagram with processes and control specifications (CSPEC).

The processes guide the hierarchical decomposition. You specify each process using another activity diagram or a primitive specification (PSPEC). You can specify a PSPEC in a number of representations with a formal semantic, such as a Simulink block diagram. In addition, context diagrams graphically capture the context of system operation.

Context Diagram: Power Window System

The figure represents the context diagram of a power window system. The square boxes capture the environment, in this case, the driver, passenger, and window. Both the driver and passenger can send commands to the window to move it up and down. The controller infers the correct command to send to the window actuator (e.g., the driver command has

priority over the passenger command). In addition, diagram monitors the state of the window system to establish when the window is fully opened and closed and to detect if there is an object between the window and frame.

The circle (also known as a bubble) represents the power window controller. The circle is the graphical notation for a process. Processes capture the transformation of input data into output data. Primitive process might also generate. CSPECs typically consist of combinational or sequential logic to infer output control signals from input control.

For implementation in the Simulink environment, see “Implementation of Context Diagram: Power Window System” on page 22-35.

Activity Diagram: Power Window Control

The power window control consists of three processes and a CSPEC. Two processes validate the driver and passenger input to ensure that their input is meaningful given the state of the system. For example, if the window is completely opened, the MOVE DOWN command does not make sense. The remaining process detects if the window is completely opened or completely closed and if an object is present. The CSPEC takes the control signals and infers whether to move the window up or down (e.g., if an object is present, the window moves down for about one second or until it reaches an endstop).

For implementation in the Simulink environment, see “Implementation of Activity Diagram: Power Window Control” on page 22-15.

Activity Diagram: Validate Driver

Each process in the VALIDATE DRIVER activity chart is primitive and specified by the following PSPEC. In the MAKE EXCLUSIVE PSPEC, for safety reasons the DOWN command takes precedence over the UP command.

PSPEC 1.1.1: CHECK DOWN

CHECKED_DOWN = DOWN and not RESET

PSPEC 1.1.2: CHECK UP

CHECKED_UP = UP and not RESET

PSPEC 1.1.3: MAKE EXCLUSIVE

VALIDATED_DOWN = CHECKED_DOWN

VALIDATED_UP = CHECKED_UP and not CHECKED_DOWN

VALIDATED_NEUTRAL = (NEUTRAL and not (CHECKED_UP and not CHECKED_DOWN))
or not (CHECKED_UP or CHECKED_DOWN)

For implementation in the Simulink environment, see “Implementation of Activity Diagram: Validate” on page 22-36.

Activity Diagram: Validate Passenger

The internals of the VALIDATE PASSENGER process are the same as the VALIDATE DRIVER process. The only difference is the different input and output.

PSPEC 1.2.1: CHECK DOWN
 CHECKED_DOWN = DOWN and not RESET

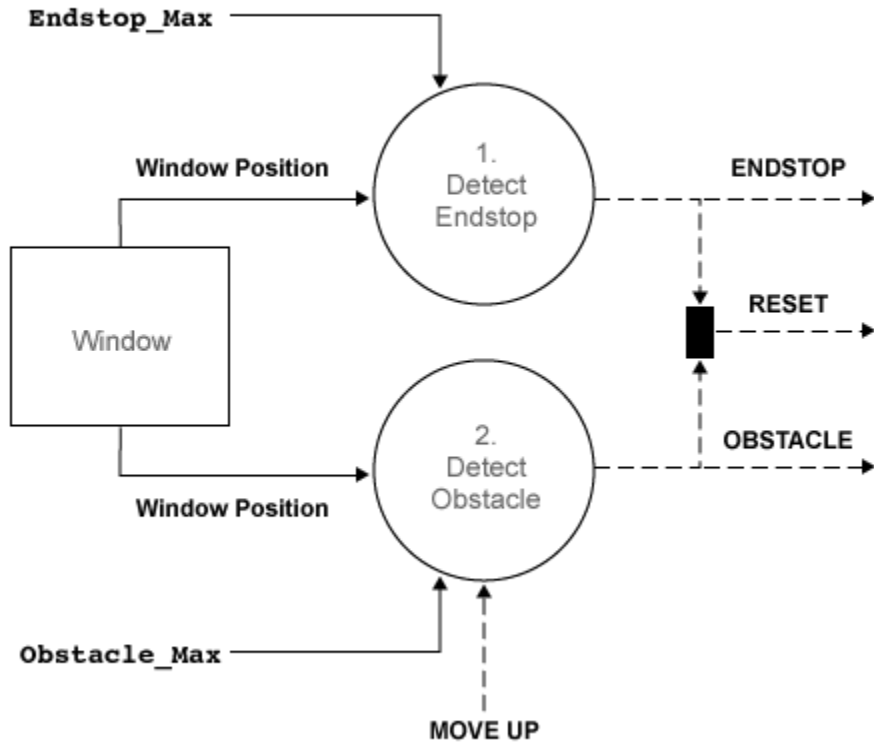

PSPEC 1.2.2: CHECK UP
CHECKED_UP = UP and not RESET

PSPEC 1.2.3: MAKE EXCLUSIVE
VALIDATED_DOWN = CHECKED_DOWN
VALIDATED_UP = CHECKED_UP and not CHECKED_DOWN
VALIDATED_NEUTRAL = (NEUTRAL and not (CHECKED_UP and not CHECKED_DOWN))
or not (CHECKED_UP or CHECKED_DOWN)

For implementation in the Simulink environment, see “Activity Diagram: Validate Passenger” on page 22-8.

Activity Diagram: Detect Obstacle Endstop

The third process in the POWER WINDOW CONTROL activity diagram detects the presence of an obstacle or when the window reaches its top or bottom (ENDSTOP). The detection mechanism is based on the armature current of the window actuator. During normal operation, this current is within certain bounds. When the window reaches its top or bottom, the electromotor draws a large current (more than 15 A or less than -15 A) to try and sustain its angular velocity. Similarly, during normal operation the current is about 2 A or -2 A (depending on whether the window is opening or closing). When there is an object, there is a slight deviation from this value. To keep the window force on the object less than 100 N, the control switches to its emergency operation when it detects a current that is less than -2.5 A. This operations is necessary only when the window is rolling up, which corresponds to a negative current in the particular wiring of this model. The DETECT OBSTACLE ENDSTOP activity diagram embodies this functionality.

CSPEC 1.3: DETECT OBSTACLE ENDSTOP
 RESET = OBSTACLE or ENDSTOP

PSPEC 1.3.1: DETECT ENDSTOP
 ENDSTOP = WINDOW_POSITION > ENDSTOP_MAX

PSPEC 1.3.2: DETECT OBSTACLE
 OBSTACLE = (WINDOW_POSITION > OBSTACLE_MAX) and MOVE_UP for 500 ms

For implementation in the Simulink environment, see “Activity Diagram: Detect Obstacle Endstop” on page 22-9.

Data Definitions

The functional decomposition unambiguously specifies each process by its decomposition or primitive specification (PSPEC). In addition, it must also formally specify the signals in the activity diagrams. Use data definitions for these specifications.

The following tables are data definitions for the signals used in the activity diagrams.

For the associated activity diagram, see “Context Diagram: Power Window System” on page 22-4.

Context Diagram: Power Window System Data Definitions

Signal	Information Type	Continuous/ Discrete	Data Type	Values
DRIVER_COMMAND	Data	Discrete	Aggregate	Neutral, up, down
PASSENGER_COMMAND	Data	Discrete	Aggregate	Neutral, up, down
WINDOW_POSITION	Data	Continuous	Real	0 to 0.4 m
MOVE_UP	Control	Discrete	Boolean	'True', 'False'
MOVE_DOWN	Control	Discrete	Boolean	'True', 'False'

For the associated activity diagram, see “Activity Diagram: Power Window Control” on page 22-5.

Activity Diagram: Power Window Control Data Definitions

Signal	Information Type	Continuous/ Discrete	Data Type	Values
DRIVER_COMMAND	Data	Discrete	Aggregate	Neutral, up, down
PASSENGER_COMMAND	Data	Discrete	Aggregate	Neutral, up, down
WINDOW_POSITION	Data	Continuous	Real	0 to 0.4 m
MOVE_UP	Control	Discrete	Boolean	'True', 'False'

Signal	Information Type	Continuous/ Discrete	Data Type	Values
MOVE_DOWN	Control	Discrete	Boolean	'True', 'False'

For the associated activity diagram, see “Activity Diagram: Validate Driver” on page 22-6.

Activity Diagram: Validate Driver Data Definitions

Signal	Information Type	Continuous/ Discrete	Data Type	Values
DRIVER_COMMAND	Data	Discrete	Aggregate	Neutral, up, down
PASSENGER_COMMAND	Data	Discrete	Aggregate	Neutral, up, down
WINDOW_POSITION	Data	Continuous	Real	0 to 0.4 m
MOVE_UP	Control	Discrete	Boolean	'True', 'False'
MOVE_DOWN	Control	Discrete	Boolean	'True', 'False'

For the associated activity diagram, see “Activity Diagram: Validate Passenger” on page 22-8.

Activity Diagram: Validate Passenger Data Definitions

Signal	Information Type	Continuous/ Discrete	Data Type	Values
NEUTRAL	Data	Discrete	Boolean	'True', 'False'
UP	Data	Discrete	Boolean	'True', 'False'
DOWN	Data	Discrete	Boolean	'True', 'False'
CHECKED_UP	Data	Discrete	Boolean	'True', 'False'

Signal	Information Type	Continuous/ Discrete	Data Type	Values
CHECKED_DOWN	Data	Discrete	Boolean	'True', 'False'

For the associated activity diagram, see “Activity Diagram: Detect Obstacle Endstop” on page 22-9.

Activity Diagram: Detect Obstacle Endstop Data Definitions

Signal	Information Type	Continuous/ Discrete	Data Type	Values
ENDSTOP_MIN	Data	Constant	Real	0.0 m
ENDSTOP_MAX	Data	Constant	Real	0.4 m
OBSTACLE_MAX	Data	Constant	Real	0.3 m

The model design iterates as we examine more detailed implementations. For information about how the model design iterates as you introduce more detail, see “Iterate on the Design” on page 22-46.

Simulink Power Window Controller in Simulink Project

MATLAB and Simulink support Model-Based Design for embedded control design, from initial specification to code generation. To organize large projects and share your work with others, use Simulink Projects.

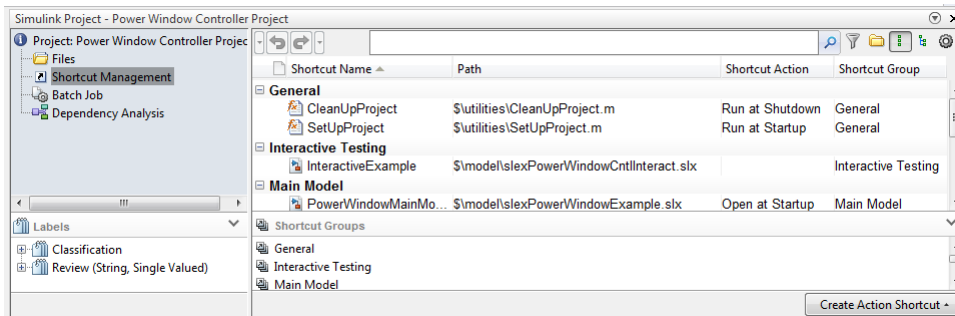

The Power Window Control Project example shows how you can use MathWorks tools and the Model-Based Design process to go from concept through implementation for an automobile power window system. It uses Simulink Projects to organize the files and other model components.

In addition, this example shows how to link models to system documentation.

Explore the Power Window Controller Project

- 1 To open the Power Window Controller project, in the MATLAB Command Window, type:

```
slexPowerWindowStart
```

2 Explore the project folders. In particular, note the **task** folders. This folder contains scripts that run frequent tasks for a model. For the Power Window Controller Project, these scripts:

- Set up the model to control window movement on a controller area network (CAN).
- Set up the model to use the Stateflow and Simulink software to model discrete-event reactive behavior and continuous time behavior, with a low-order plant model.
- Set up the model with a more detailed plant model that includes power effects in the electrical and mechanical domains. The plant model validates the force exerted by the window on a trapped object.
- Set up the model with a model that includes other effects that may change the model, such as quantization of the measurements.

Note: These scripts also simulate the model. To only configure the model, see the scripts in the **configureModel** folder.

3 The **Shortcut Management** section contains quick-access commands that you can double-click to perform common tasks such as:

- Set up and clean up projects.
- Add projects to MATLAB paths.
- Perform interactive testing.
- Validate model testing with model coverage.

- Open the main model.
- Simulate the model with various configurations.
- Generate a model coverage report for increased coverage of the model.
- Open the model used for increasing model coverage.

Simulink Power Window Controller

- “Implementation of Activity Diagram: Power Window Control” on page 22-15

- “Model Coverage” on page 22-29

Implementation of Activity Diagram: Power Window Control

This topic describes the high-level discrete-event control specification for a power window control.

You can model the discrete-event control of the window with a Stateflow chart. A Stateflow chart is a finite state machine with hierarchy and parallelism. This state machine contains the basic states of the power window system: up, auto-up, down, auto-down, rest, and emergency. It models the state transitions and accounts for the precedence of driver commands over the passenger commands. It also includes emergency behavior that activates when the software detects an object between the window and the frame while moving up.

The initial Simulink model for the power window control, `slexPowerWindowControl`, is a discrete-event controller that runs at a given sample rate.

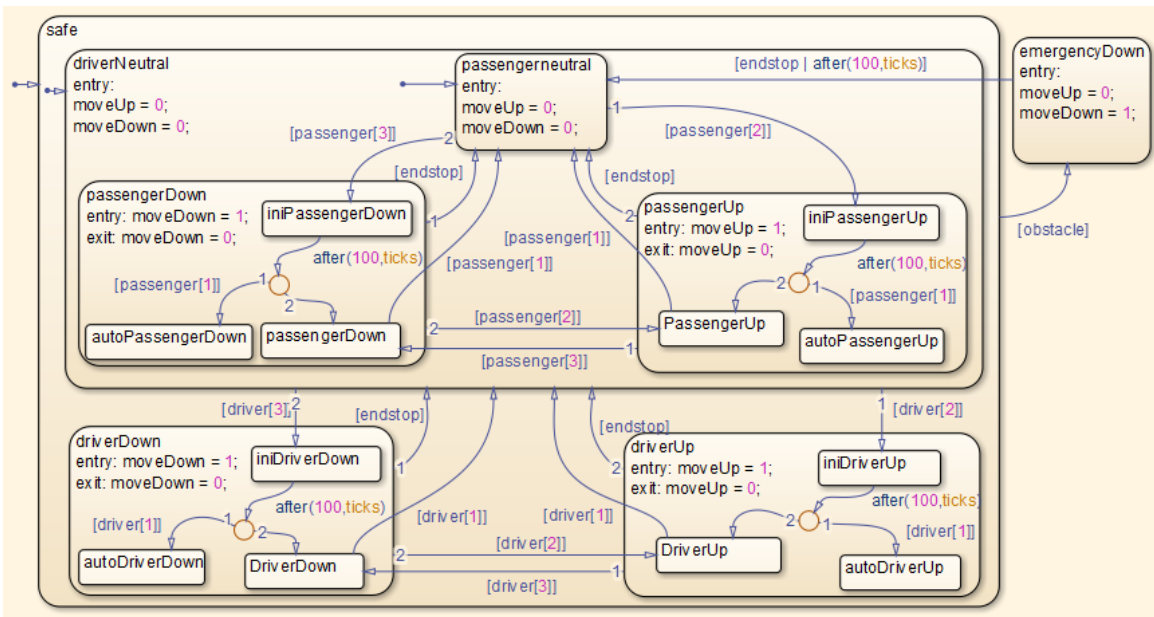

In this implementation, open the power window control subsystem and observe that the Stateflow chart with the discrete-event control forms the CSPEC, represented by the tilted thick bar in the bottom right corner. The `detect_obstacle_endstop` subsystem encapsulate the threshold detection mechanisms.

The discrete-event control is a Stateflow model that extends the state transition diagram notion with hierarchy and parallelism. State changes because of passenger commands are encapsulated in a *super state* that does not correspond to an active driver command.

Consider the control of the passenger window. The passenger or driver can move this window up and down.

This state machine contains the basic states of the power window system: up, auto-up, down, auto-down, rest, and emergency.

Interactive Testing

Control Input

The `slexPowerWindowCntlInteract` model includes this control input as switches. Double-click these switches to manually operate them.

Test the state machine that controls a power window by running the input test vectors and checking that it reaches the desired internal state and generates output. The power window has the following external inputs:

- Passenger input
- Driver input
- Window up or down
- Obstacle in window

Each input consists of a vector with these inputs.

Passenger Input

Element	Description
neutral	Passenger control switch is not depressed.
up	Passenger control switch generates the up signal.
down	Passenger control switch generates the down signal.

Driver Input

Element	Description
neutral	Driver control switch is not depressed.
up	Driver control switch generates the up signal.
down	Driver control switch generates the down signal.

Window Up or Down

Element	Description
0	Window moves freely between top or bottom.
1	Window is stuck at the top or bottom because of physical limitations.

Obstacle in Window

Element	Description
0	Window moves freely between top or bottom.
1	Window has obstacle in the frame.

Generate the passenger and driver input signals by mapping the up and down signals according to this table:

Inputs		Outputs		
up	down	up	down	neutral
0	0	0	0	1
0	1	0	1	0
1	0	1	0	0
1	1	0	0	1

The inputs explicitly generate the **neutral** event from the **up** and **down** events, generated by pressing a power window control switch. The inputs are entered as a truth table in the passenger neutral, up, down map and the driver neutral, up, down map.

Experimental Results from Interactive Testing

Case 1: Window Up

To observe the state machine behavior:

- 1 Open the `slexPowerWindowCntlInteract` model.
- 2 Run the simulation and then double-click the passenger up switch.

If you press the physical window switch for more than one second, the window moves up until the up switch is released (or the top of the window frame is reached and the endstop event is generated).

- 3 Double-click the selected passenger up switch to release it.

4 Simulate the model.

Setting the endstop switch generates the endstop event.

Case 2: Window Auto-Up

If you press the physical passenger window up switch for a short period of time (less than a second), the software activates auto-up behavior and the window continues to move up.

- 1 Press the physical passenger window up switch for a short period of time (less than a second).

Ultimately, the window reaches the top of the frame and the software generates the `endstop` event. This event moves the state machine back to its neutral state.

2 Simulate the model.

Case 3: Driver-Side Precedence

The driver switch for the passenger window takes precedence over the driver commands. To observe the state machine behavior in this case:

- 1 Run the simulation, and then move the system to the **passenger up** state by double-clicking the passenger window up switch.

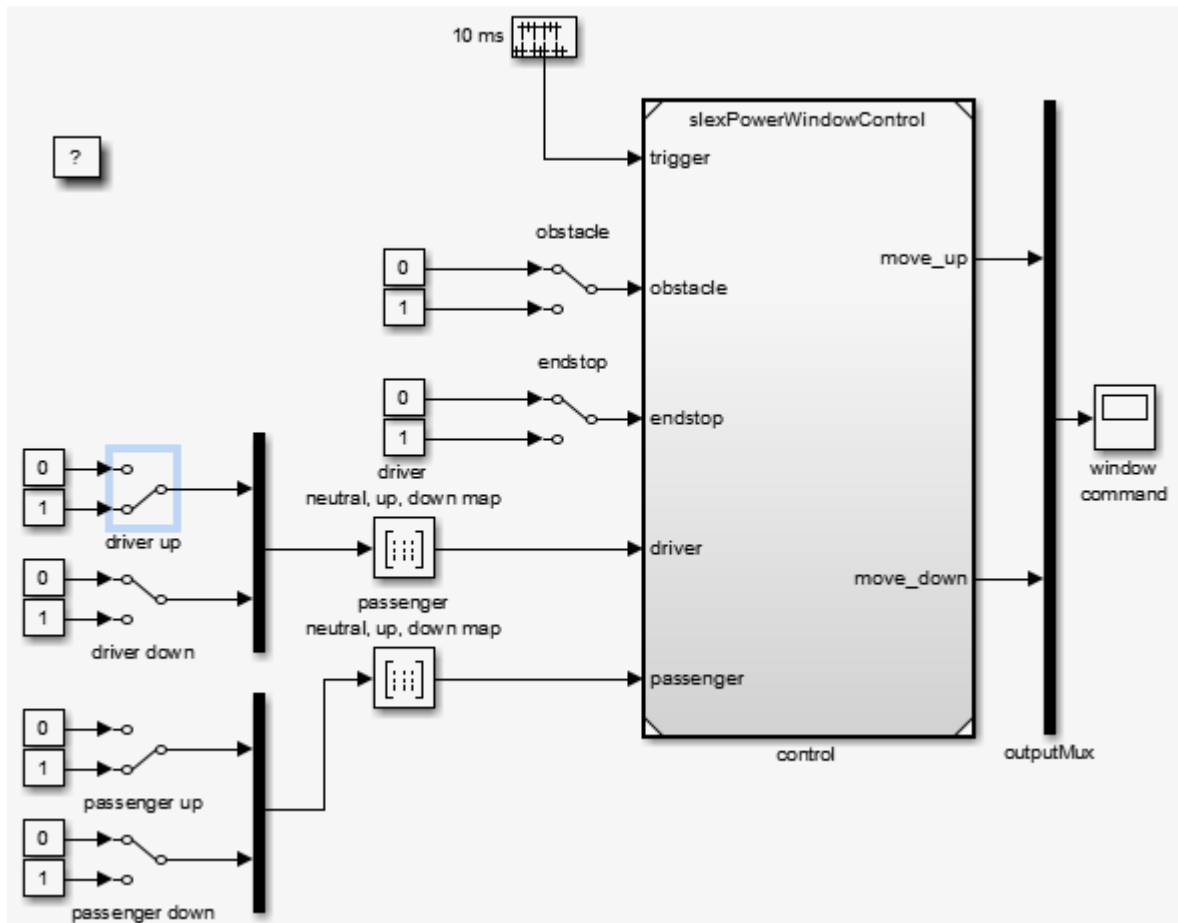

2 Double-click the driver down switch.

- 3 Simulate the model.
- 4 Notice how the state machine moves to the driver control part to generate the window down output instead of the window up output.
- 5 Double-click the driver control to driver up. Double-click the driver down switch.

The driver window up state is reached, which generates the window up output again, i.e., $windowUp = 1$.

- 6 To observe state behavior when an object is between the window and the frame, double-click the obstacle switch.

7 Simulate the model.

On the next sample time, the state machine moves to its **emergencyDown** state to lower the window a few inches. How far the software lowers the window depends on how long the state machine is in the **emergencyDown** state. This behavior is part of the next analysis phase.

If a driver or passenger window switch is still active, the state machine moves into the up or down states upon the next sample time after leaving the emergency state.

If the obstacle switch is also still active, the software again activates the emergency state at the next sample time.

Model Coverage

Validation of the Control Subsystem

Validate the discrete-event control of the window using the model coverage tool. This tool helps you determine the extent to which a model test case exercises the conditional branches of the controller. It helps evaluate whether all transitions in the discrete-event control are taken, given the test case, and whether all clauses in a condition that enables a particular transition have become true. Multiple clauses can enable one transition, e.g., the transition from emergency back to neutral occurs when either 100 ticks have occurred or if the endstop is reached.

To achieve full coverage, each clause evaluates to true and false for the test cases used. The percentage of transitions that a test case exercises is called its *model coverage*. Model coverage is a measure of how thoroughly a test exercises a model.

Using Simulink Verification and Validation software, you can apply the following test to the power window controller.

Position	Step						
	0	1	2	3	4	5	6
Passenger up	0	0	0	0	0	0	0
Passenger down	0	0	0	1	0	1	1
Driver up	0	0	1	0	1	0	1
Driver down	0	1	0	0	1	1	0

With this test, all switches are inactive at time 0. At regular 1 s steps, the state of one or more switches changes. For example, after 1 s, the driver down switch becomes active. To automatically run these input vectors, replace the manual switches by prescribed sequences of input. To see the preconstructed model:

- 1 In the MATLAB Command Window, type:

```
slexPowerWindowCntlCoverage
```

- 2 Simulate the model to generate the Simulink Verification and Validation coverage report.

For the `slexPowerWindowCntrlCoverage` model, the report reveals that this test handles 100% of the decision outcomes from the driver neutral, up, down map. However, the test achieves only 50% coverage for the passenger neutral, up, down map block. This coverage means the overall coverage for `slexPowerWindowCntrlCoverage` is 45% while the overall coverage for the `slexPowerWindowControl` model is 42%. A few of the contributing factors for the coverage levels are:

- Passenger up block does not change.

- Endstop and obstacle blocks do not change.

Increase Model Coverage

To increase total coverage to 100%, you need to take into account all possible combinations of driver, passenger, obstacle, and endstop settings. When you are satisfied with the control behavior, you can create the power window system. For more information, see “Create Model Using Model-Based Design” on page 22-34.

This example increases the model coverage for the validation of the discrete-event control of the window. To start, the example uses inputs from `slexPowerWindowCntlCoverage` as a baseline for the model coverage. Next, to further exercise the discrete-event control of the window, it creates more input sets. The spreadsheet file, `inputCntlCoverageIncrease.xlsx`, contains these input sets using one input set per sheet.

In the example, the `slexPowerWindowSpreadsheetGeneration` utility function, which creates a spreadsheet template from the controller model, `slexPowerWindowControl`, creates the `inputCntlCoverageIncrease.xlsx`. In `inputCntlCoverageIncrease.xlsx`, the function uses the block names in the controller model as signal names. `slexPowerWindowSpreadsheetGeneration` defines the sheet names. The `slexWindowSpreadsheetAddInput` utility function populates `inputCntlCoverageIncrease.xlsx` with signal data.

The sheet names of these input sets and their descriptions are:

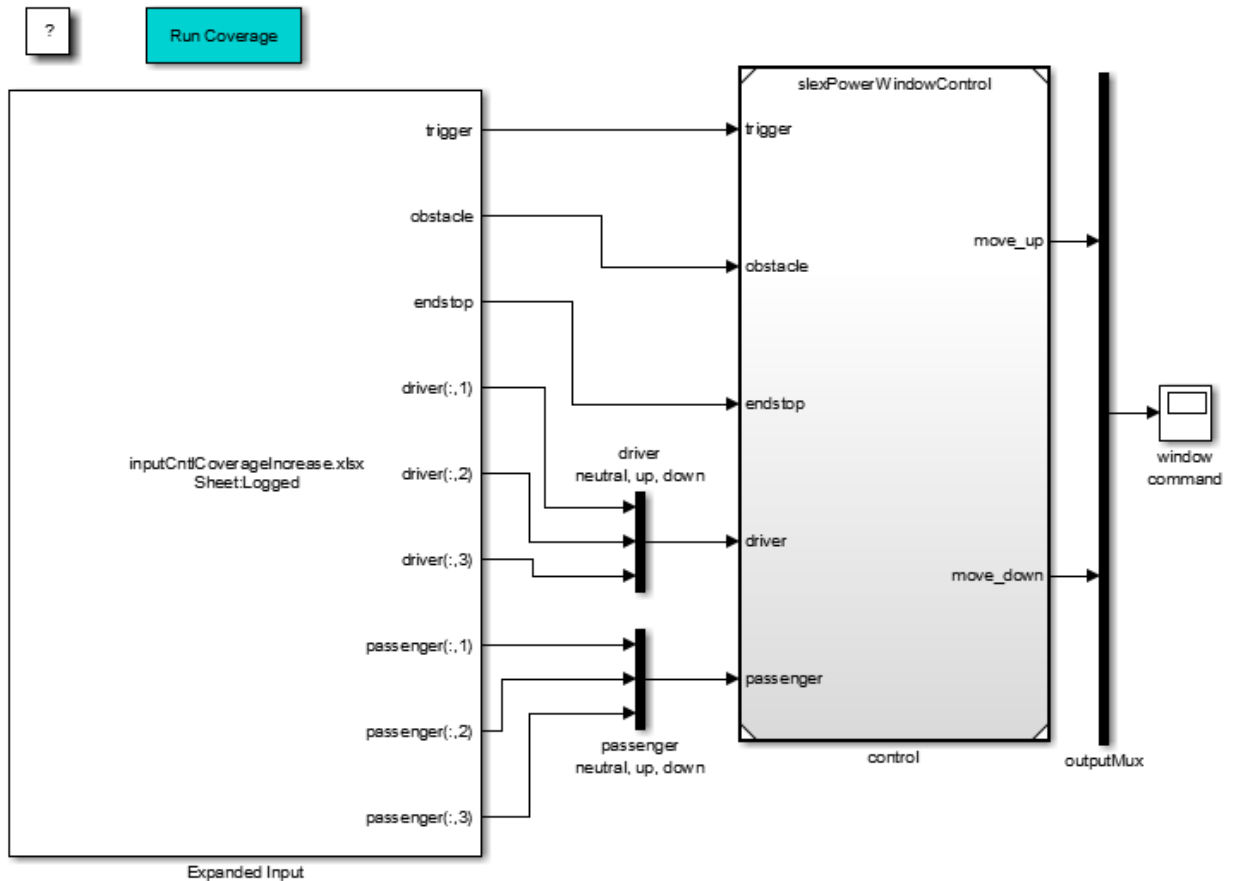

Sheet Name	Description
Logged	Inputs logged from <code>slexPowerWindowCntlCoverage</code>
LoggedObstacleOffEndStopOn	Inputs logged from <code>slexPowerWindowCntlCoverage</code> with ability to hit endstop
LoggedObstacleOnEndStopOff	Inputs logged from <code>slexPowerWindowCntlCoverage</code> with obstacle in window
LoggedObstacleOnEndStopOn	Inputs logged from <code>slexPowerWindowCntlCoverage</code> with obstacle in window and ability to hit endstop
DriverLoggedPassengerNeutral	Inputs logged from <code>slexPowerWindowCntlCoverage</code> for driver only and passenger takes no action
DriverDownPassengerNeutral	Driver is putting down window and passenger takes no action

Sheet Name	Description
DriverUpPassengerNeutral	Driver is putting up window and passenger takes no action
DriverAutoDownPassengerNeutral	Driver is putting down window for one second (auto-down) and passenger takes no action
DriverAutoUpPassengerNeutral	Driver is putting up window for one second (auto-up) and passenger takes no action
PassengerAutoDownDriverNeutral	Passenger is putting down window for one second (auto-down) and driver takes no action
PassengerAutoUpDriverNeutral	Passenger is putting up window for one second (auto-up) and driver takes no action

To automatically run these input vectors, replace the inputs to the discrete-event control with the From Spreadsheet block using the file, `inputCntlCoverageIncrease.xlsx`. This file contains the multiple input sets. To see the preconstructed model:

- 1 In the MATLAB Command Window, type:

```
slexPowerWindowCntlCoverageIncrease
```

- 2 To generate the Simulink Verification and Validation coverage report for multiple input set, double click the Run Coverage subsystem in the model.

For the `slxPowerWindowCtrlCoverageIncrease` model, the report reveals that using multiple input sets has successfully raised the overall coverage for the `slxPowerWindowControl` model from 42% to 78%. Coverage levels are less than 100% because of missing input sets for:

- Passenger up state
- Driver up and down states

- Passenger automatic down and automatic up states

Why Use Model-Based Design?

In Model-Based Design, a system model is at the center of the development process, from requirements development, through design, implementation, and testing. Use Model-Based Design to:

- Use a common design environment across project teams.
- Link designs directly to requirements.
- Integrate testing with design to continuously identify and correct errors.
- Refine algorithms through multidomain simulation.
- Automatically generate embedded software code.
- Develop and reuse test suites.
- Automatically generate documentation for the model.
- Reuse designs to deploy systems across multiple processors and hardware targets.

For more information, see “Model-Based Design”.

context diagram into parts. This diagram shows the input and output signals present in the context diagram for easier tracing to their origins.

Implement Power Window Control System

To satisfy full requirements, the power window control must work with the validation of the driver and passenger inputs and detect the endstop.

For requirements presented as an activity diagram, see “Activity Diagram: Power Window Control” on page 22-5.

Double-click the slxPowerWindowExample/power_window_control_system block to open the following subsystem:

Implementation of Activity Diagram: Validate

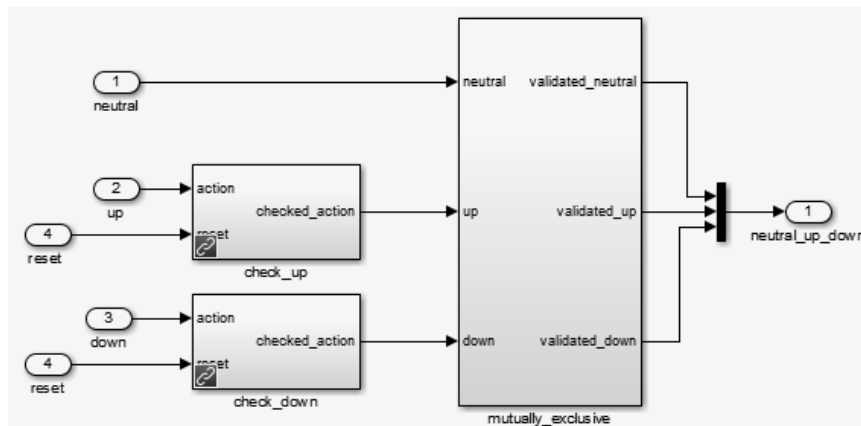

For requirements presented as activity diagrams, see “Activity Diagram: Validate Driver” on page 22-6 and “Activity Diagram: Validate Passenger” on page 22-8.

The activity diagram adds data validation functionality for the driver and passenger commands to ensure correct operation. For example, when the window reaches the top, the software blocks the up command. The implementation decomposes each validation process in new subsystems. Consider the validation of the driver commands (validation of the passenger commands is similar). Check if the model can execute the up or down commands, according to the following:

- The model allows the **down** command only when the window is not completely opened.
- The model allows the **up** command only when the window is not completely closed and no object is detected.

The third activity diagram process checks that the software sends only one of the three commands (**neutral**, **up**, **down**) to the controller. In an actual implementation, both **up** and **down** can be simultaneously true (for example, because of switch bouncing effects).

From the `power_window_control_system` subsystem, this is the `validate_driver_state` subsystem:

From the `power_window_control_system` subsystem, this is the `validate_passenger_state` subsystem:

Implementation of Activity Diagram: Detect Obstacle Endstop

For requirements presented as an activity diagram, see “Activity Diagram: Detect Obstacle Endstop” on page 22-9.

In the `slexPowerWindowExample` model, the `power_window_control_system/detect_obstacle_endstop` block implements this activity diagram in the continuous variant of the Variant Subsystem block. During design iterations, you can add additional variants.

Double-click the `slexPowerWindowExample` model `power_window_control_system/detect_obstacle_endstop/Continuous/verify_position` block:

Hybrid Dynamic System: Combine Discrete-Event Control and Continuous Plant

After you have designed and verified the discrete-event control, integrate it with the continuous-time plant behavior. This step is the first iteration of the design with the simplest version of the plant.

In Simulink Project, navigate to **Files** and click **Project Files**. In the **configureModel** folder, run the **slexPowerWindowContinuous** utility to open and initialize the model.

The window_system block uses the Variant Subsystem block to allow for varying levels of fidelity in the plant modeling. Double-click the window_system/Continuous/2nd_order_window_system block to see the continuous variant.

The plant is modeled as a second-order differential equation with step-wise changes in its input:

- When the Stateflow chart generates `windowUp`, the input is 1.
- When the Stateflow chart generates `windowDown`, the input is -1 .
- Otherwise, the input is 0.

This phase allows analysis of the interaction between the discrete-event state behavior, its sample rate, and the continuous behavior of the window movement. There are threshold values to generate the window frame top and bottom:

- `endStop`
- Event when an obstacle is present, that is, `obstacle`
- Other events

Double-click the `slexPowerWindowExample` model `power_window_control_system/-detect_obstacle_endstop/Continuous/verify_position` block to see the continuous variant.

When you run the `slexPowerWindowContinuous` `configureModel` utility, the model uses the continuous time solver `ode23` (Bogacki-Shampine).

A structure analysis of a system results in:

- A functional decomposition of the system
- Data definitions with the specifics of the system signals

- Timing constraints

A structure analysis can also include the implementation architecture (outside the scope of this discussion).

The implementation also adds a control mechanism to conveniently switch between the presence and absence of the object.

Expected Controller Response

To view the window movement, in Simulink Project in the **Shortcut Management** section, right-click `SimHybridPlantLowOrder`, and select **Run**. Alternatively, you can run the task `slexPowerWindowContinuousSim`.

The position scope shows the expected result from the controller. After 30 cm, the model generates the `obstacle` event and the Stateflow chart moves into its `emergencyDown` state. In this state, `windowDown` is output until the window lowers by about 10 cm. Because the passenger window up switch is still on, the window starts moving up again and this process repeats. Stop the simulation and open the position scope to observe the oscillating process. In case of an emergency, the discrete-event control rolls down the window approximately 10 cm.

Detailed Modeling of Power Effects

After an initial analysis of the discrete-event control and continuous dynamics, you can use a detailed plant model to evaluate performance in a more realistic situation. It is best to design models at such a level of detail in the power domain, in other words, as energy flows. Several domain-specific MathWorks blocksets can help with this.

To take into account energy flows, add a more detailed variant consisting of power electronics and a multibody system to the `window_system` variant subsystem.

To open the model and explore the more detailed plant variant, in Simulink Project, run `configureModel slxPowerWindowPowerEffects`.

Double-click the `slxPowerWindowExample` model `window_system/Power Effects - Visualization/detailed_window_system` block.

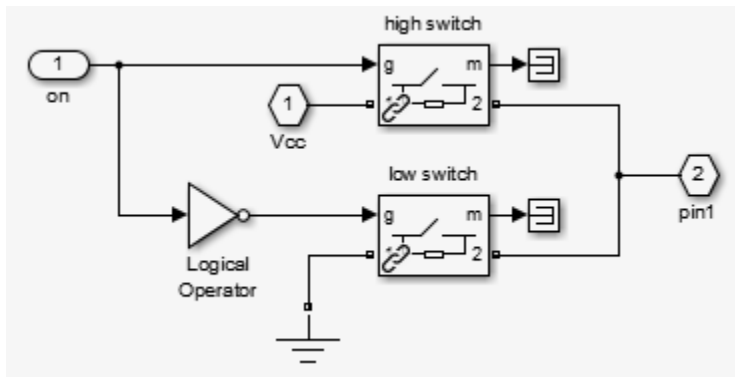

Power Electronics Subsystem

The model must amplify the control signals generated by the discrete-event controller to be powerful enough to drive the DC motor that moves the window.

The amplification modules model this behavior. They show that a switch either connects the DC motor to the battery voltage or ground. By connecting the battery in reverse, the system generates a negative voltage and the window can move up, down, or remain still. The window is always driven at maximum power. In other words, no DC motor controller applies a prescribed velocity.

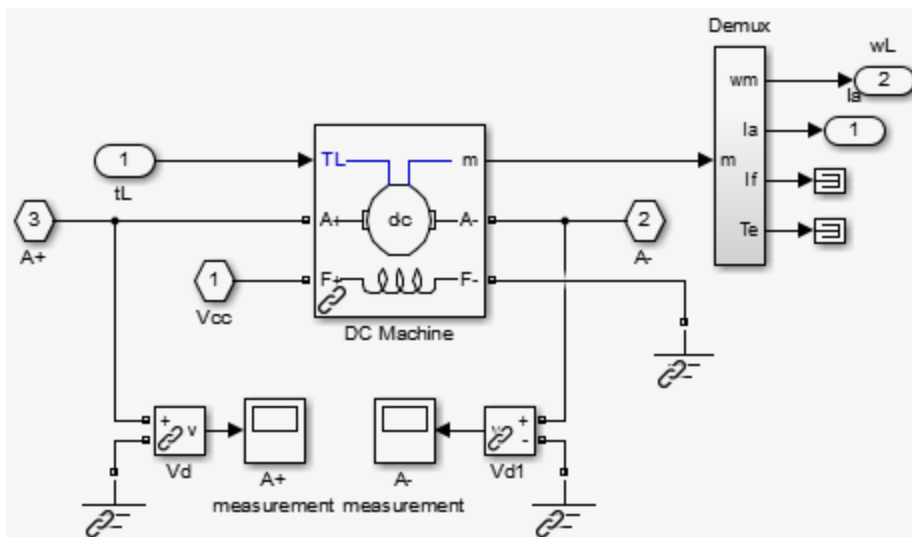

To see the implementation, double-click the `slxPowerWindowExample` model `window_system/Power Effects - Visualization/detailed_window_system/amplification_up` block.

Multibody System

This implementation models the window using Simscape Multibody multibody blocks.

To see the actuator implementation, double-click the `slexPowerWindowExample` model `window_system/Power Effects - Visualization/detailed_window_system/actuator` block.

To see the window implementation, double-click the `slexPowerWindowExample` model `window_system/Power Effects - Visualization/detailed_window_system/plant` block.

This implementation uses Simscape Multibody multibody blocks for bodies, joints, and actuators. The window model consists of:

- A worm gear
- A lever to move the window holder in the vertical direction

The figure shows how the mechanical parts move.

Iterate on the Design

An important effect of the more detailed implementation is that there is no window position measurement available. Instead, the model measures the DC motor current and uses it to detect the endstops and to see if an obstacle is present. The next stage of the

system design analyzes the control to make sure that it does not cause excessive force when an obstacle is present.

In the original system, the design removes the obstacle and endstop detection based on the window position and replaces it with a current-based implementation. It also connects the process to the controller and position and force measurements. To reflect the different signals used, you must modify the data definition. In addition, observe that, because of power effects, the units are now amps.

PSPEC 1.3.1: DETECT ENDSTOP
 $\text{ENDSTOP} = \text{ARMATURE_CURRENT} > \text{ENDSTOP_MAX}$

PSPEC 1.3.2: DETECT OBSTACLE
 $\text{OBSTACLE} = (\text{ARMATURE_CURRENT} > \text{OBSTACLE_MAX})$ and MOVE_UP for 500 ms

PSPEC 1.3.3: ABSOLUTE VALUE
 $\text{ABSOLUTE_ARMATURE_CURRENT} = \text{abs}(\text{ARMATURE_CURRENT})$

This table lists the additional signal for the Context Diagram: Power Window System data definitions.

Context Diagram: Power Window System Data Definition Changes

Signal	Information Type	Continuous/ Discrete	Data Type	Values
ARMATURE_CURRENT	Data	Continuous	Real	-20 to 20 A

This table lists the changed signals for the Activity Diagram: Detect Obstacle Endstop data definitions.

Activity Diagram: Detect Obstacle Endstop Data Definition Changes

Signal	Information Type	Continuous/ Constant	Data Type	Values
ABSOLUTE_ARMATURE_CURRENT	Data	Continuous	Real	0 to 20 A
ENDSTOP_MAX	Data	Constant	Real	15 A
OBSTACLE_MAX	Data	Constant	Real	2.5 A

To see the window subsystem, double-click the `slexPowerWindowExample` model `window_system/Power Effects - Visualization/detailed_window_system/plant/window` block.

Control Law Evaluation

The idealized continuous plant allows access to the window position for `endStop` and `obstacle` event generation. In the more realistic implementation, the model must generate these events from accessible physical variables. For power window systems, this physical variable is typically the armature current, I_a , of the DC motor that drives the worm gear.

When the window is moving, this current has an approximate value of 2 A. When you switch the window on, the model draws a transient current that can reach a value

of approximately 10 A. When the current exceeds 15 A, the model activates endstop detection. The model draws this current when the angular velocity of the motor is kept at almost 0 despite a positive or negative input voltage.

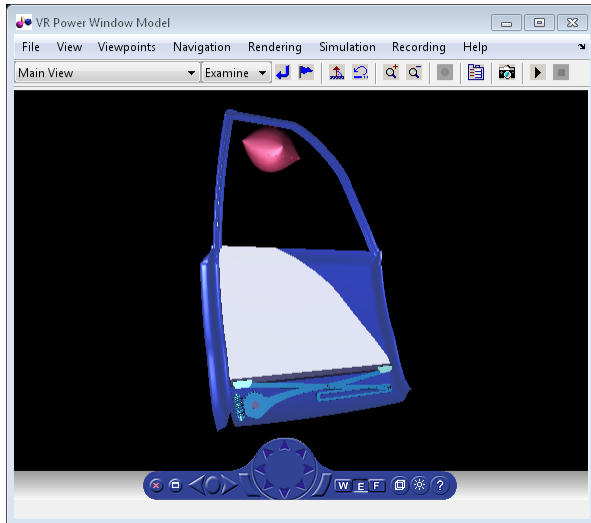

Detecting the presence of an object is more difficult in this setup. Because safety concerns restrict the window force to no more than 100 N, an armature current much less than 10 A should detect an object. However, this behavior conflicts with the transient values achieved during normal operation.

Implement a control law that disables object detection during achieved transient values. Now, when the system detects an armature current more than 2 A, it considers an object to be present and enters the **emergencyDown** state of the discrete-event control. Open the force scope window (measurements are in newtons) to check that the force exerted remains less than 100 N when an object is present and the window reverses its velocity.

In reality, far more sophisticated control laws are possible and implemented. For example, you can implement neural-network-based learning feedforward control techniques to emulate the friction characteristic of each individual vehicle and changes over time.

Visualization of the System in Motion

If you have Simulink 3D Animation software installed, you can view the geometrics of the system in motion via a virtual reality world. If the VR Sink block is not yet open, in the `slexPowerWindowExample/window_world/Simulink_3D_Animation View` model, double-click the VR Sink block.

To simulate the model with a stiff solver:

- 1 In Simulink Project, run the task, `slexPowerWindowPowerEffectsSim`. This batch job sets the solver to `ode23tb` (stiff/TR-BDF2).
- 2 In the `slexPowerWindowExample` model `passenger_switch/Normal` block, set the passenger up switch to on.
- 3 In the `slexPowerWindowExample` model `driver_switch/Normal` block, set the driver up switch to off.
- 4 Simulate the model.
- 5 Between 10 ms and 1 s in simulation time, switch off the `slexPowerWindowExample/passenger_switch/Normal` block passenger up switch to initiate the auto-up behavior.

- 6 Observe how the window holder starts to move vertically to close the window. When the model encounters the object, it rolls the window down.
- 7 Double-click the `slexPowerWindowExample` model `passenger_switch/Normal` block driver down switch to roll down the window completely and then simulate the model. In this block, at less than one second simulation time, switch off the driver down switch to initiate the auto-down behavior.

- 8 When the window reaches the bottom of the frame, stop the simulation.
- 9 Look at the position measurement (in meters) and at the armature current (I_a) measurement (in amps).

Note: The absolute value of the armature current transient during normal behavior does not exceed 10 A. The model detects the obstacle when the absolute value of the armature current required to move the window up exceeds 2.5 A (in fact, it is less than -2.5 A). During normal operation, this is about 2 A. You might have to zoom into the scope to see this measurement. The model detects the window endstop when the absolute value of the armature current exceeds 15 A.

Variation in the armature current during normal operation is due to friction that is included by sensing joint velocities and positions and applying window specific coefficients.

Realistic Armature Measurement

The armature current as used in the power window control is an ideal value that is accessible because of the use of an actuator model. In a more realistic situation, data acquisition components must measure this current value.

To include data acquisition components, add the more realistic measurement variant to the window_system variant subsystem. This realistic measurement variant contains a signal conditioning block in which the current is derived based on a voltage measurement.

To open a model and configure the realistic measurement, in Simulink Project, run the configureModel task `slexPowerWindowRealisticArmature`.

To view the contents of the Realistic Armature - Communications Protocol block, double-click the `SlexPowerWindowExample` model `window_system/Realistic Armature - Communications Protocol/detailed_window_system_with_DAQ`.

The measurement voltage is within the range of an analog-to-digital converter (ADC) that discretizes based on a given number of bits. You must scale the resulting value based on the value of the resistor and the range of the ADC.

Include these operations as fixed-point computations. To achieve the necessary resolution with the given range, 16 bits are required instead of 8.

Study the same scenario:

- 1 In the `slexPowerWindowExample/passenger_switch/Normal` block, set the passenger up switch.

- 2 Run the simulation.
- 3 After some time, in the `slexPowerWindowExample/passenger_switch/Normal` block, switch off the passenger up switch.
- 4 When the window has been rolled down, click the `slexPowerWindowExample/passenger_switch/Normal` block driver down switch.
- 5 After some time, switch off the `slexPowerWindowExample/passenger_switch/Normal` block driver down switch.
- 6 When the window reaches the bottom of the frame, stop the simulation.
- 7 Zoom into the `armature_current` scope window and notice the discretized appearance.

Communication Protocols

Similar to the power window output control, hardware must generate the input events. In this case, the hardware is the window control switches in the door and center control panels. Local processors generate these events and then communicate them to the window controller via a CAN bus.

To include these events, add a variant containing input from a CAN bus and switch components that generate the events delivered on the CAN bus to the driver switch and passenger switch variant subsystems. To open the model and configure the CAN communication protocols, run the `configureModel` task, `slexPowerWindowCommunicationProtocolsSim`.

To see the implementation of the switch subsystem, double-click the `slexPowerWindowExample/driver_switch/Communication Protocol/driver window control switch` block.

Observe a structure that is very similar to the window control system. This structure contains a:

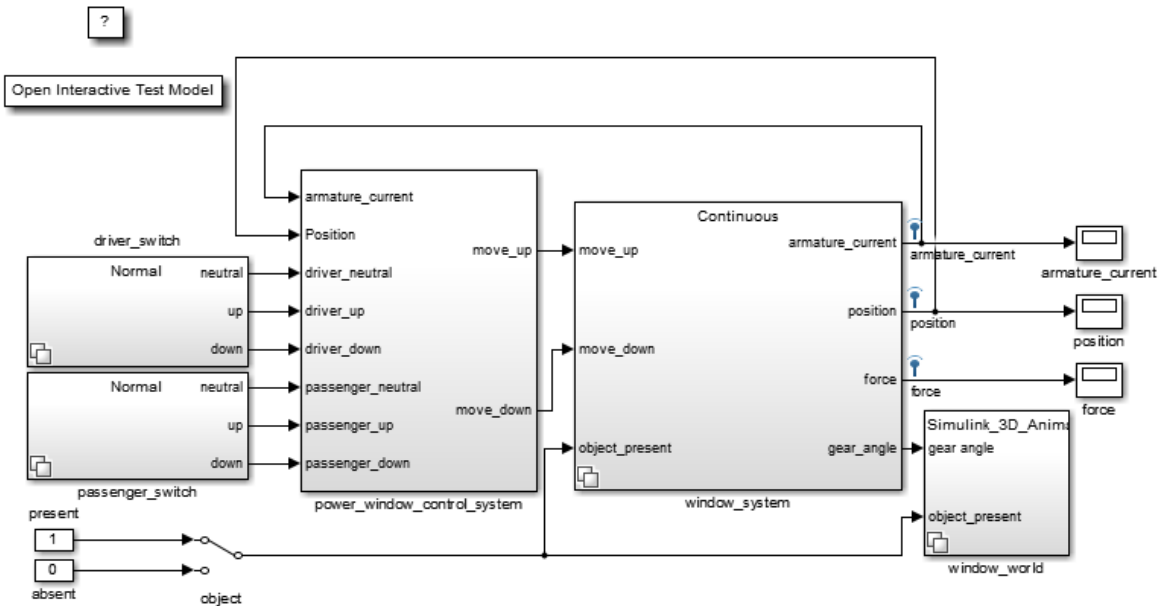

- Plant model that represents the control switch

- Data acquisition subsystem that includes, among other things, signal conditioning components
- Control module to map the commands from the physical switch to logical commands
- CAN module to post the events to the vehicle data bus

You can add communication effects, such as other systems using the CAN bus, and more realism similar to the described phases. Each phase allows analysis of the discrete-event controller in an increasingly realistic situation. When you have enough detail, you can automatically generate controller code for any specific target platform.

Automatic Code Generation for Control Subsystem

You can generate code for the designed control model, `slexPowerWindowExample`.

- 1 Display the sample rates of the controller. In the Simulink Editor, select **Display > Sample Time > Colors**. Observe that the controller runs at a uniform sample rate.

- 2 Right-click the `power_window_control_system` block and select **C/C++ Code > Build This Subsystem**.

Simulate a Model Interactively

Simulation Basics

You can simulate a model in the Simulink Editor using **Simulation > Run** or the **Run** button  on the toolbar. The **Run** button also appears in tools within the Simulink Editor. You can simulate from any tool that includes the button, such as the Scope viewer.

Before you start a simulation, you can specify options like simulation start time, stop time, and the solver for solving the model. (See “Solvers” on page 23-7) You specify these options in the Configuration Parameters dialog box, which you can open from the **Simulation** menu or using the **Model Configuration Parameters** button  on the toolbar. These settings are saved with the model in a *configuration set*. You can create multiple configuration sets for each model and switch between them to see the effects of different settings. See “Configuration Reuse”.

After you set your model configuration parameters, you can start the simulation. You can pause, resume, and stop simulation using toolbar controls. You can also simulate more than one model at a time, so you can start another simulation while one is running.

During simulation, you cannot make changes to the structure of the model, such as adding or deleting lines or blocks. However, you can make these changes while a simulation is running:

- Modify some configuration parameters, including the stop time and the maximum step size.
- Modify the parameters of a block, as long as you do not cause a change in:
 - Number of states, inputs, or outputs
 - Sample time
 - Number of zero crossings
 - Vector length of any block parameters
 - Length of the internal block work vectors
 - Dimension of any signals

You can also examine the model visually as it simulates. For example, you can click a line to see the signal carried on that line on a Floating Scope or Display block. You can

also display port values as a model simulates. See “Display Port Values for Debugging” on page 33-15.

Run, Pause, and Stop a Simulation

To start simulating your model, click the **Run** button . You can pause, resume, or stop a simulation using the corresponding controls on the toolbar.

The model starts simulating at the specified start time and runs until the specified end time. While the simulation is running, information at the bottom of the editor shows the percentage of simulation completed and the current simulation time.

- If an error occurs, simulation stops and a message appears. If a warning condition occurs, simulation completes. In both cases, click the diagnostics link at the bottom of the editor to see the message, which helps you to locate errors.
- Pausing takes effect after the current time step finishes executing. Resuming a paused simulation occurs at the next time step.
- If you stop a simulation, the current time step completes, and then simulation stops.
- If the model outputs to a file or to the workspace, stopping or pausing simulation writes the data.

Use Blocks to Stop or Pause a Simulation

Stop Simulation Using Stop Simulation Blocks

You can use the **Stop Simulation** block to stop a simulation when the input to the block is nonzero. If the block input is a vector, any nonzero element stops the simulation.

- 1 Add a **Stop Simulation** block to your model.
- 2 Connect the **Stop Simulation** block to a signal whose value becomes nonzero at the specified stop time.

For example, this model stops the simulation when the simulation time reaches 10.

Pause Simulation Using Assertion Blocks

You can use an Assertion block to pause the simulation when the input signal to the block is zero. The Assertion block uses the `set_param` command to pause the simulation. See “Control Simulations Programmatically” on page 24-10 for more information on using the `set_param` command to control the execution of a Simulink model.

- 1 Add an Assertion block to your model.
- 2 Connect the Assertion block to a signal whose value becomes zero at the desired pause time.
- 3 In the Assertion block dialog box, clear the **Stop simulation when assertion fails** check box. Enter this command as the value of **Simulation callback when assertion fails**:

```
set_param(bdroot, 'SimulationCommand', 'pause'),
disp(sprintf('\nSimulation paused.'))
```

This model uses an Assertion block with these settings to pause the simulation when the simulation time reaches 5.

When the simulation pauses, a message appears that shows the time the block paused the simulation.

You can resume the simulation using **Continue** as you can for any paused simulation.

Specify Simulation Start and Stop Time

By default, simulations start at 0.0 s and end at 10.0 s.

Note: In the Simulink software, time and all related parameters (such as sample times) are implicitly in seconds. If you choose to use a different time unit, scale all parameters accordingly.

The **Solver** configuration pane allows you to specify other start and stop times for the currently selected simulation configuration. See “Solver Pane” for more information. On computers running the Microsoft Windows operating system, you can also specify the simulation stop time in the **Simulation** menu.

Note Simulation time and actual clock time are not the same. For example, if running a simulation for 10 s usually does not take 10 s as measured on a clock. The amount of time it actually takes to run a simulation depends on many factors including the complexity of the model, the step sizes, and the computer speed.

- “Solvers” on page 23-7

Solvers

You simulate a dynamic system by computing its states at successive time steps over a specified time span. This computation uses information provided by a model of the system. The time steps are time intervals when the computation happens. The size of this time interval is called the *step size*. The process of computing the states of a model in this manner is known as solving the model. No single method of solving a model applies to all systems. Simulink provides a set of programs called *solvers*. Each solver embodies a particular approach to solving a model.

A solver applies a numerical method to solve the set of ordinary differential equations that represent the model. Through this computation, it determines the time of the next simulation step. In the process of solving this initial value problem, the solver also satisfies the accuracy requirements that you specify.

Solvers are broadly classified using these criteria:

- The type of step size used in the computation
 - Fixed-step solvers solve the model at step sizes from the beginning to the end of the simulation. You can specify the step size or let the solver choose the step size. Generally, decreasing the step size increases the accuracy of the results and increases the time required to simulate the system.
 - Variable-step solvers vary the step size during the simulation. They reduce the step size to increase accuracy when the states of a model change rapidly and during zero-crossing events. They increase the step size to avoid taking unnecessary steps when the states of a model change slowly. Computing the step size adds to the computational overhead at each step. However, it can reduce the total number of steps, and hence the simulation time required to maintain a specified level of accuracy for models with piecewise continuous or rapidly changing states.
- The nature of states in the model
 - Continuous solvers use numerical integration to compute continuous states of a model at the current time step based on the states at previous time steps and the state derivatives. Continuous solvers rely on individual blocks to compute the values of the discrete states of the model at each time step.
 - Discrete solvers are primarily for solving purely discrete models. They compute only the next simulation time step for a model. When they perform this

computation, they rely on each block in the model to update its individual discrete state. They do not compute continuous states.

When you choose a solver for simulating a model, consider:

- The dynamics of the system
- The stability of the solution
- The speed of computation
- The robustness of the solver

A solver might not completely satisfy all of your requirements, so use an iterative approach when choosing one. Compare simulation results from several solvers and select one that offers the best performance with minimal tradeoffs.

There are two ways to select a solver for your model:

- Use auto solver. New models have their solver selection set to auto solver by default. Auto solver recommends a fixed-step or variable-step solver for your model as well as maximum step size.
- If you are not satisfied with simulation results using auto solver, select a solver in the **Solver** pane in the model configuration parameters.

Choose a Solver

In this section...

“Solver Classification Criteria” on page 23-11

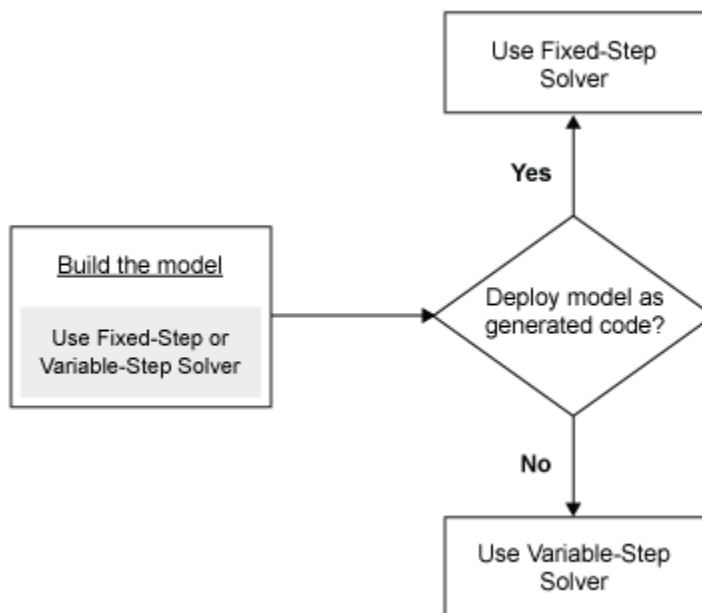

“Choose a Fixed-Step Solver” on page 23-15

“Choose a Variable-Step Solver” on page 23-20

“Choose a Jacobian Method for an Implicit Solver” on page 23-27

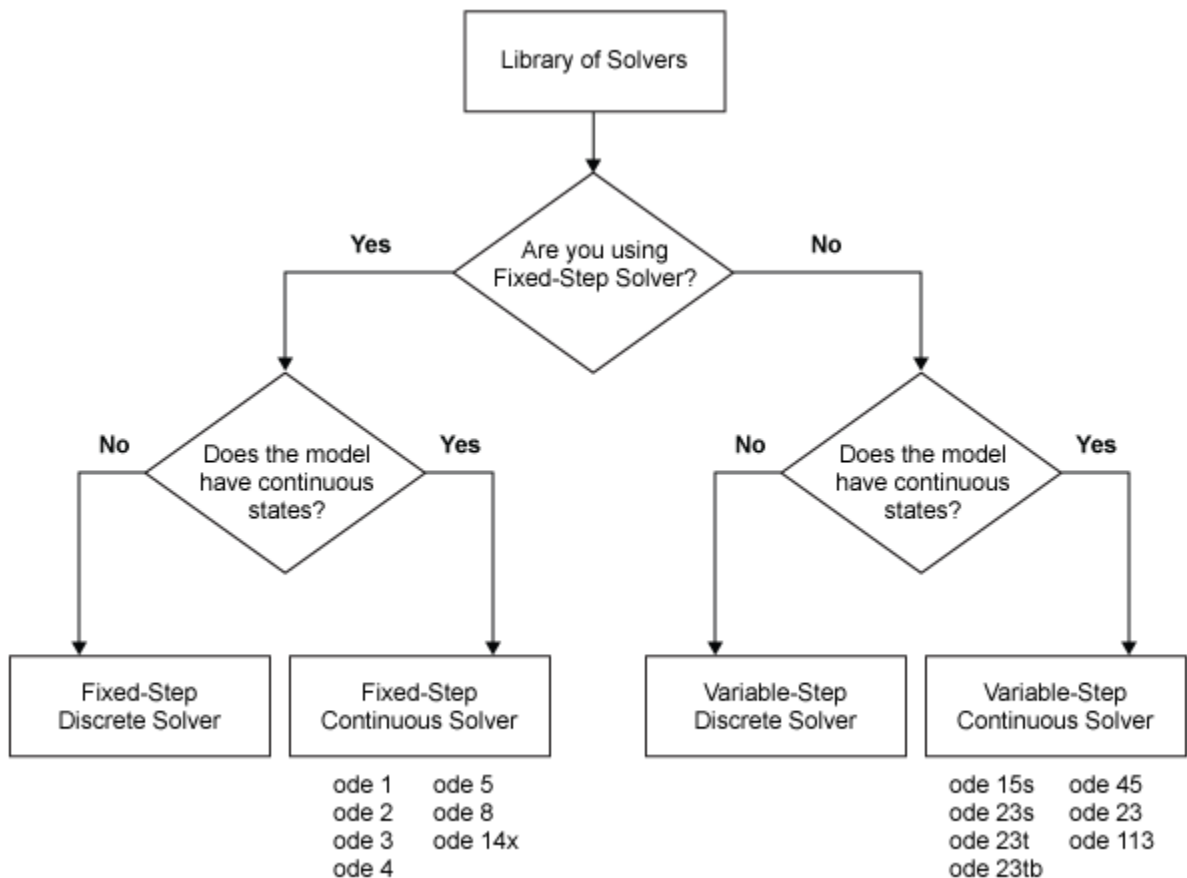

The Simulink library of solvers has two main types—fixed-step and variable-step solvers. You can see the solvers under each type in the **Solver** pane of model configuration parameters.

When you build and simulate a model, you can choose either type of solver based on the dynamics of the model. A model that contains several switches, like an inverter power system, needs a fixed-step solver. A variable-step solver is better suited for purely continuous models, like the dynamics of a mass spring damper system.

When you deploy a model as generated code, you can use only a fixed-step solver. If you selected a variable-step solver during simulation, use it to calculate the step size required for the fixed-step solver that you need at deployment.

This chart provides a broad classification of solvers in the Simulink library.

You can use auto solver to select a solver for a model. Auto solver can pick a fixed-step or variable-step solver for your model and also suggest the maximum step size to use. For more information, see “Use Auto Solver to Select a Solver” on page 23-34.

To tailor the selected solver to your model, see “Check and Improve Simulation Accuracy” on page 28-11.

Ideally, the solver you select should:

- Solve the model successfully.
- Provide a solution within the tolerance limits you specify.
- Solve the model in a reasonable duration.

A single solver might not meet all of these requirements. Try simulating with several solvers before making a selection.

Solver Classification Criteria

The Simulink library provides several solvers, all of which can work with the algebraic loop solver.

		Discrete	Continuous	Variable-Order
Fixed-Step	Explicit	Not Applicable	“Fixed-Step Continuous Explicit Solvers” on page 23-17	Not Applicable
	Implicit	Not Applicable	“Fixed-Step Continuous Implicit Solvers” on page 23-19	Not Applicable
Variable-Step	Explicit	“Choose a Variable-Step Solver” on page 23-20	“Variable-Step Continuous Explicit Solvers” on page 23-21	“Single-Order Versus Variable-Order Continuous Solvers” on page 23-15
	Implicit		“Variable-Step Continuous Implicit Solvers” on page 23-22	“Single-Order Versus Variable-Order Continuous Solvers” on page 23-15

In the **Solver** pane of model configuration parameters, the Simulink library of solvers is divided into two major types. See “Fixed-Step Versus Variable-Step Solvers” on page 23-12.

You can further categorize the solvers of each type:

- “Discrete Versus Continuous Solvers” on page 23-13
- “Explicit Versus Implicit Continuous Solvers” on page 23-13
- “One-Step Versus Multistep Continuous Solvers” on page 23-14

- “Single-Order Versus Variable-Order Continuous Solvers” on page 23-15

Fixed-Step Versus Variable-Step Solvers

Fixed-step and variable-step solvers compute the next simulation time as the sum of the current simulation time and a quantity known as the *step size*. The **Type** control on the **Solver** configuration pane allows you to select the type of solver. With a fixed-step solver, the step size remains constant throughout the simulation. With a variable-step solver, the step size can vary from step to step, depending on the model dynamics. In particular, a variable-step solver increases or reduces the step size to meet the error tolerances that you specify.

The choice between these types depends on how you plan to deploy your model and the model dynamics. If you plan to generate code from your model and run the code on a real-time computer system, choose a fixed-step solver to simulate the model. You cannot map the variable-step size to the real-time clock.

If you do not plan to deploy your model as generated code, the choice between a variable-step and a fixed-step solver depends on the dynamics of your model. A variable-step solver might shorten the simulation time of your model significantly. A variable-step solver allows this saving because, for a given level of accuracy, the solver can dynamically adjust the step size as necessary. This approach reduces the number of steps required. The fixed-step solver must use a single step size throughout the simulation, based on the accuracy requirements. To satisfy these requirements throughout the simulation, the fixed-step solver typically requires a small step.

This model shows how a variable-step solver can shorten simulation time for a multirate discrete model.

The model generates outputs at two different rates: every 0.5 s and every 0.75 s. To capture both outputs, the fixed-step solver must take a time step every 0.25 s (the *fundamental sample time* for the model).

[0.0 0.25 0.5 0.75 1.0 1.25 1.5 ...]

By contrast, the variable-step solver has to take a step only when the model generates an output.

[0.0 0.5 0.75 1.0 1.5 ...]

This scheme significantly reduces the number of time steps required to simulate the model.

Discrete Versus Continuous Solvers

When you select a solver type, you can also select a specific solver. Both sets of solvers include two types: discrete and continuous. Discrete and continuous solvers rely on the model blocks to compute the values of any discrete states. Blocks that define discrete states are responsible for computing the values of those states at each time step. However, unlike discrete solvers, continuous solvers use numerical integration to compute the continuous states that the blocks define. When choosing a solver, determine first whether to use a discrete solver or a continuous solver.

If your model has no continuous states, then Simulink switches to either the fixed-step discrete solver or the variable-step discrete solver. If your model has only continuous states or a mix of continuous and discrete states, choose a continuous solver from the remaining solver choices based on the dynamics of your model. Otherwise, an error occurs.

The solver library contains two discrete solvers—a fixed-step discrete solver and a variable-step discrete solver. The fixed-step solver by default chooses a step size and simulation rate fast enough to track state changes in the fastest block in your model. The variable-step solver adjusts the simulation step size to keep pace with the actual rate of discrete state changes in your model. This adjustment can avoid unnecessary steps and shorten simulation time for multirate models (see “Sample Times in Systems” on page 7-28 for more information.)

Note: The fixed-step discrete solvers do not solve for discrete states. Each block calculates its discrete states independent of the solver.

Explicit Versus Implicit Continuous Solvers

You represent an explicit system by the system of equation

$$\dot{x} = f(x)$$

. For any given value of x , you can compute \dot{x} by substituting x in $f(x)$ and evaluating the equation.

Equations of the form

$$F(\dot{x}, x) = 0$$

are considered to be implicit. For any given value of x , you must solve this equation to calculate \dot{x} .

A linearly implicit system can be represented by the equation

$$M(x).\dot{x} = f(x)$$

. $M(x)$ is called the mass matrix and $f(x)$ is the forcing function. A system becomes linearly implicit when you use physical modeling blocks in the model.

While you can apply an implicit or explicit continuous solver to solve all these systems, implicit solvers are designed specifically for solving stiff problems. Explicit solvers solve nonstiff problems. An ordinary differential equation problem is said to be stiff if the desired solution varies slowly, but there are closer solutions that vary rapidly. The numerical method must then take small time steps to solve the system. Stiffness is an efficiency issue. The more stiff a system, the longer it takes for the explicit solver to perform a computation. A stiff system has both slowly and quickly varying continuous dynamics.

When compared to explicit solvers, implicit solvers provide greater stability for oscillatory behavior. However, implicit solvers are also computationally more expensive. They generate the Jacobian matrix and solve the set of algebraic equations at every time step using a Newton-like method. To reduce this extra cost, the implicit solvers offer a `Solver Jacobian method` parameter that allows you to improve the simulation performance of implicit solvers. See “Choose a Jacobian Method for an Implicit Solver” on page 23-27 for more information. Implicit solvers are more efficient than explicit solvers when you solve a linearly implicit system.

One-Step Versus Multistep Continuous Solvers

The Simulink solver library provides both one-step and multistep solvers. The one-step solvers estimate $y(t_n)$ using the solution at the immediately preceding time point,

$y(t_{n-1})$, and the values of the derivative at multiple points between t_n and t_{n-1} . These points are minor steps.

The multistep solvers use the results at several preceding time steps to compute the current solution. Simulink provides one explicit multistep solver, `ode113`, and one implicit multistep solver, `ode15s`. Both are variable-step solvers.

Single-Order Versus Variable-Order Continuous Solvers

This distinction is based on the number of orders that the solver uses to solve the system of equation. Two variable-order solvers, `ode15s` and `ode113`, are part of the solver library. They use multiple orders to solve the system of equations. Specifically, the implicit, variable-step `ode15s` solver uses first-order through fifth-order equations while the explicit, variable-step `ode113` solver uses first-order through thirteenth-order. For `ode15s`, you can limit the highest order applied via the `Maximum Order` parameter. For more information, see “Maximum Order” on page 23-23.

Choose a Fixed-Step Solver

The Fixed-Step Discrete Solver

The fixed-step discrete solver computes the time of the next simulation step by adding a fixed step size to the current time. The accuracy and the length of time of the resulting simulation depends on the size of the steps taken by the simulation: the smaller the step size, the more accurate the results are but the longer the simulation takes. By default, Simulink chooses the step size or you can choose the step size yourself. If you choose the default setting of `auto`, and if the model has discrete sample times, then Simulink sets the step size to the fundamental sample time of the model. Otherwise, if no discrete rates exist, Simulink sets the size to the result of dividing the difference between the simulation start and stop times by 50.

Note If you try to use the fixed-step discrete solver to update or simulate a model that has continuous states, an error message appears. Thus, selecting a fixed-step solver and then updating or simulating a model is a quick way to determine whether the model has continuous states.

Fixed-Step Continuous Solvers

The fixed-step continuous solvers, like the fixed-step discrete solver, compute the next simulation time by adding a fixed-size time step to the current time. For each of these steps, the continuous solvers use numerical integration to compute the values of the continuous states for the model. These values are calculated using the continuous states at the previous time step and the state derivatives at intermediate points (minor steps) between the current and the previous time step. The fixed-step continuous solvers can, therefore, handle models that contain both continuous and discrete states.

Note In theory, a fixed-step continuous solver can handle models that contain no continuous states. However, that would impose an unnecessary computational burden on the simulation. Consequently, Simulink uses the fixed-step discrete solver for a model that contains no states or only discrete states, even if you specify a fixed-step continuous solver for the model.

Simulink provides two types of fixed-step continuous solvers — explicit and implicit.

The difference between these two types lies in the speed and the stability. An implicit solver requires more computation per step than an explicit solver but is more stable. Therefore, the implicit fixed-step solver that Simulink provides is more adept at solving a stiff system than the fixed-step explicit solvers. For more information, see “Explicit Versus Implicit Continuous Solvers” on page 23-13.

Fixed-Step Continuous Explicit Solvers

Explicit solvers compute the value of a state at the next time step as an explicit function of the current values of both the state and the state derivative. A fixed-step explicit solver is expressed mathematically as:

$$x(n+1) = x(n) + h * Dx(n)$$

where x is the state, Dx is a solver-dependent function that estimates the state derivative, h is the step size, and n indicates the current time step.

Simulink provides a set of fixed-step continuous explicit solvers. The solvers differ in the specific numerical integration technique that they use to compute the state derivatives of the model. This table lists each solver and the integration technique it uses. The table lists the solvers in order of the computational complexity of the integration methods they use, from the least complex (ode1) to the most complex (ode8).

Solver	Integration Technique	Order of Accuracy
ode1	Euler's Method	First
ode2	Heun's Method	Second
ode3	Bogacki-Shampine Formula	Third
ode4	Fourth-Order Runge-Kutta (RK4) Formula	Fourth
ode5	Dormand-Prince (RK5) Formula	Fifth
ode8	Dormand-Prince RK8(7) Formula	Eighth

None of these solvers has an error control mechanism. Therefore, the accuracy and the duration of a simulation depend directly on the size of the steps taken by the solver. As you decrease the step size, the results become more accurate, but the simulation takes longer. Also, for any given step size, the more computationally complex the solver is, the more accurate are the simulation results.

If you specify a fixed-step solver type for a model, then by default, Simulink selects the `FixedStepAuto` solver. Auto solver then selects an appropriate fixed-step solver that can handle both continuous and discrete states with moderate computational effort. As with the discrete solver, if the model has discrete rates (sample times), then Simulink sets the step size to the fundamental sample time of the model by default. If the model has no discrete rates, Simulink automatically uses the result of dividing the simulation total duration by 50. Consequently, the solver takes a step at each simulation time at which Simulink must update the discrete states of the model at its specified sample rates. However, it does not guarantee that the default solver accurately computes the continuous states of a model. Therefore, you may need to choose another solver, a different fixed step size, or both to achieve acceptable accuracy and an acceptable simulation time.

Fixed-Step Continuous Implicit Solvers

An implicit solver computes the state at the next time step as an implicit function of the state at the current time step and the state derivative at the next time step. In other words:

$$x(n+1) - x(n) - h * Dx(n+1) = 0$$

Simulink provides one fixed-step implicit solver: `ode14x`. This solver uses a combination of Newton's method and extrapolation from the current value to compute the value of a state at the next time step. You can specify the number of Newton's method iterations and the extrapolation order that the solver uses to compute the next value of a model state (see “Fixed-step size (fundamental sample time)”). The more iterations and the higher the extrapolation order that you select, the greater the accuracy you obtain. However, you simultaneously create a greater computational burden per step size.

How to Choose a Fixed-Step Continuous Solver

Any of the fixed-step continuous solvers in the Simulink product can simulate a model to any desired level of accuracy, given a small enough step size. Unfortunately, it is not possible or practical to decide without trial, the combination of solver and step size that will yield acceptable results for the continuous states in the shortest time. Determining the best solver for a particular model generally requires experimentation.

To select a fixed-step continuous solver,

- 1 Choose error tolerances. For more information, see “Error Tolerances for Variable-Step Solvers” on page 23-24.
- 2 Use one of the variable-step solvers to simulate your model to the level of accuracy that you want. Start with `ode45`. If your model runs slowly, your problem may be stiff and need an implicit solver. The results of this step give a good approximation of the correct simulation results and the appropriate fixed step size.
- 3 Use `ode1` to simulate your model at the default step size for your model. Compare the simulation results for `ode1` with the simulation for the variable-step solver. If the results are the same for the specified level of accuracy, you have found the best fixed-step solver for your model, namely `ode1`. You arrive at this conclusion because `ode1` is the simplest of the fixed-step solvers and hence yields the shortest simulation time for the current step size.
- 4 If `ode1` does not give satisfactory results, repeat the preceding steps with the other fixed-step solvers until you find one that gives accurate results with the least

computational effort. The most efficient way to perform this task is to use a binary search technique:

- a** Try `ode3`.
- b** If `ode3` gives accurate results, try `ode2`. If `ode2` gives accurate results, it is the best solver for your model; otherwise, `ode3` is the best.
- c** If `ode3` does not give accurate results, try `ode5`. If `ode5` gives accurate results, try `ode4`. If `ode4` gives accurate results, select it as the solver for your model; otherwise, select `ode5`.
- d** If `ode5` does not give accurate results, reduce the simulation step size and repeat the preceding process. Continue in this way until you find a solver that solves your model accurately with the least computational effort.

Choose a Variable-Step Solver

When you set the **Type** control of the **Solver** configuration pane to **Variable-step**, the **Solver** control allows you to choose one of the variable-step solvers. As with fixed-step solvers, the set of variable-step solvers comprises a discrete solver and a subset of continuous solvers. However, unlike the fixed-step solvers, the step size varies dynamically based on the local error.

The choice between the two types of variable-step solvers depends on whether the blocks in your model define states and, if so, the type of states that they define. If your model defines no states or defines only discrete states, select the discrete solver. If a model has no states or only discrete states, Simulink uses the discrete solver to simulate the model even if you specify a continuous solver. If the model has continuous states, the continuous solvers use numerical integration to compute the values of the continuous states at the next time step.

Variable-Step Continuous Solvers

Variable-step solvers dynamically vary the step size during the simulation. Each of these solvers increases or reduces the step size using its local error control to achieve the tolerances that you specify. Computing the step size at each time step adds to the computational overhead. However, it can reduce the total number of steps, and the simulation time required to maintain a specified level of accuracy.

You can further categorize the variable-step continuous solvers as: one-step or multistep, single-order or variable-order, and explicit or implicit. (See “Solver Classification Criteria” on page 23-11 for more information.)

Variable-Step Continuous Explicit Solvers

The variable-step explicit solvers are designed for nonstiff problems. Simulink provides three such solvers:

- ode45
- ode23
- ode113

ODE Solver	One-Step Method	Multistep Method	Order of Accuracy	Method
ode45	X		Medium	Runge-Kutta, Dormand-Prince (4,5) pair
ode23	X		Low	Runge-Kutta (2,3) pair of Bogacki & Shampine
ode113		X	Variable, Low to High	PECE Implementation of Adams-Bashforth-Moulton

ODE Solver	Tips on When to Use
ode45	<p>In general, the <code>ode45</code> solver is the best to apply as a first try for most problems. For this reason, <code>ode45</code> is the default solver for models with continuous states. This Runge-Kutta (4,5) solver is a fifth-order method that performs a fourth-order estimate of the error. This solver also uses a fourth-order “free” interpolant, which allows for event location and smoother plots.</p> <p>The <code>ode45</code> is more accurate and faster than <code>ode23</code>. If the <code>ode45</code> is computationally slow, your problem may be stiff and thus in need of an implicit solver.</p>
ode23	<p>The <code>ode23</code> can be more efficient than the <code>ode45</code> solver at crude error tolerances and in the presence of mild stiffness. This solver provides accurate solutions for “free” by applying a cubic Hermite interpolation to the values and slopes computed at the ends of a step.</p>
ode113	<p>For problems with stringent error tolerances or for computationally intensive problems, the Adams-Bashforth-Moulton PECE solver can be more efficient than <code>ode45</code>.</p>

Variable-Step Continuous Implicit Solvers

If your problem is stiff, try using one of the variable-step implicit solvers:

- `ode15s`
- `ode23s`
- `ode23t`
- `ode23tb`

ODE Solver	One-Step Method	Multistep Method	Order of Accuracy	Solver Reset Method	Max. Order	Method
ode15s		X	Variable, Low to Medium	X	X	Numerical Differentiation Formulas (NDFs)
ode23s	X		Low			Second-order, modified Rosenbrock formula
ode23t	X		Low	X		Trapezoidal rule using a “free” interpolant
ode23tb	X		Low	X		TR-BDF2

Solver Reset Method

For three of the stiff solvers — `ode15s`, `ode23t`, and `ode23tb`— a drop-down menu for the **Solver reset method** appears on the **Solver Configuration** pane. This parameter controls how the solver treats a reset caused, for example, by a zero-crossing detection. The options allowed are **Fast** and **Robust**. **Fast** specifies that the solver does not recompute the Jacobian for a solver reset, whereas **Robust** specifies that the solver does. Consequently, the **Fast** setting is computationally faster but it may use a small step size in certain cases. To test for such cases, run the simulation with each setting and compare the results. If there is no difference, you can safely use the **Fast** setting and save time. If the results differ significantly, try reducing the step size for the fast simulation.

Maximum Order

For the `ode15s` solver, you can choose the maximum order of the numerical differentiation formulas (NDFs) that the solver applies. Since the `ode15s` uses first-through fifth-order formulas, the **Maximum order** parameter allows you to choose 1 through 5. For a stiff problem, you may want to start with order 2.

Tips for Choosing a Variable-Step Implicit Solver

The following table provides tips relating to the application of variable-step implicit solvers. For an example comparing the behavior of these solvers, see `sldemo_solvers`.

ODE Solver	Tips on When to Use
ode15s	<code>ode15s</code> is a variable-order solver based on the numerical differentiation formulas (NDFs). NDFs are related to, but are more efficient than the backward differentiation formulas (BDFs), which are also known as Gear's method. The <code>ode15s</code> solver numerically generates the Jacobian matrices.

ODE Solver	Tips on When to Use
	If you suspect that a problem is stiff, or if <code>ode45</code> failed or was highly inefficient, try <code>ode15s</code> . As a rule, start by limiting the maximum order of the NDFs to 2.
<code>ode23s</code>	<code>ode23s</code> is based on a modified Rosenbrock formula of order 2. Because it is a one-step solver, it can be more efficient than <code>ode15s</code> at crude tolerances. Like <code>ode15s</code> , <code>ode23s</code> numerically generates the Jacobian matrix for you. However, it can solve certain kinds of stiff problems for which <code>ode15s</code> is not effective.
<code>ode23t</code>	The <code>ode23t</code> solver is an implementation of the trapezoidal rule using a “free” interpolant. Use this solver if your model is only moderately stiff and you need a solution without numerical damping. (Energy is not dissipated when you model oscillatory motion.)
<code>ode23tb</code>	<code>ode23tb</code> is an implementation of TR-BDF2, an implicit Runge-Kutta formula with two stages. The first stage is a trapezoidal rule step while the second stage uses a backward differentiation formula of order 2. By construction, the method uses the same iteration matrix in evaluating both stages. Like <code>ode23s</code> , this solver can be more efficient than <code>ode15s</code> at crude tolerances.

Note For a *stiff* problem, solutions can change on a time scale that is very small as compared to the interval of integration, while the solution of interest changes on a much longer time scale. Methods that are not designed for stiff problems are ineffective on intervals where the solution changes slowly because these methods use time steps small enough to resolve the fastest possible change. For more information, see Shampine, L. F., *Numerical Solution of Ordinary Differential Equations*, Chapman & Hall, 1994.

Support for Zero-Crossing Detection

The variable-step discrete and continuous solvers use zero-crossing detection (see “Zero-Crossing Detection” on page 3-24) to handle continuous signals.

Error Tolerances for Variable-Step Solvers

Local Error

The variable-step solvers use standard control techniques to monitor the local error at each time step. During each time step, the solvers compute the state values at the end

of the step and determine the *local error*—the estimated error of these state values. They then compare the local error to the *acceptable error*, which is a function of both the relative tolerance (*rtol*) and the absolute tolerance (*atol*). If the local error is greater than the acceptable error for *any one* state, the solver reduces the step size and tries again.

- The *Relative tolerance* measures the error relative to the size of each state. The relative tolerance represents a percentage of the state value. The default, 1e-3, means that the computed state is accurate to within 0.1%.
- *Absolute tolerance* is a threshold error value. This tolerance represents the acceptable error as the value of the measured state approaches zero.

The solvers require the error for the *i*th state, e_i , to satisfy:

$$e_i \leq \max(\text{rtol} \times |x_i|, \text{atol}_i).$$

The following figure shows a plot of a state and the regions in which the relative tolerance and the absolute tolerance determine the acceptable error.

Absolute Tolerances

Your model has a global absolute tolerance that you can set on the Solver pane of the Configuration Parameters dialog box. This tolerance applies to all states in the model. You can specify `auto` or a real scalar. If you specify `auto` (the default), Simulink initially sets the absolute tolerance for each state to 1e-6. As the simulation progresses, the absolute tolerance for each state resets to the maximum value that the state has assumed so far, times the relative tolerance for that state. Thus, if a state changes from 0 to 1 and `reltol` is 1e-3, then by the end of the simulation, `abstol` becomes 1e-3 also. If a state goes from 0 to 1000, then `abstol` changes to 1.

If the computed setting is not suitable, you can determine an appropriate setting yourself. You might have to run a simulation more than once to determine an appropriate value for the absolute tolerance.

Several blocks allow you to specify absolute tolerance values for solving the model states that they compute or that determine their output:

- Integrator
- Second-Order Integrator, Second-Order Integrator Limited
- Variable Transport Delay
- Transfer Fcn
- State-Space
- Zero-Pole

The absolute tolerance values that you specify for these blocks override the global settings in the Configuration Parameters dialog box. You might want to override the global setting if, for example, the global setting does not provide sufficient error control for all of your model states because they vary widely in magnitude. You can set the block absolute tolerance to:

- `auto`
- `-1` (same as `auto`)
- `positive scalar`
- `real vector` (having a dimension equal to the number of corresponding continuous states in the block)

Tips

If you do choose to set the absolute tolerance, keep in mind that too low of a value causes the solver to take too many steps in the vicinity of near-zero state values. As a result, the simulation is slower.

On the other hand, if you set the absolute tolerance too high, your results can be inaccurate as one or more continuous states in your model approach zero.

Once the simulation is complete, you can verify the accuracy of your results by reducing the absolute tolerance and running the simulation again. If the results of these two simulations are satisfactorily close, then you can feel confident about their accuracy.

Choose a Jacobian Method for an Implicit Solver

The Solver Jacobian

For implicit solvers, Simulink must compute the *solver Jacobian*, which is a submatrix of the Jacobian matrix associated with the continuous representation of a Simulink model. In general, this continuous representation is of the form:

$$\begin{aligned}\dot{x} &= f(x, t, u) \\ y &= g(x, t, u).\end{aligned}$$

The Jacobian, J , formed from this system of equations is:

$$J = \begin{pmatrix} \frac{\partial f}{\partial x} & \frac{\partial f}{\partial u} \\ \frac{\partial g}{\partial x} & \frac{\partial g}{\partial u} \end{pmatrix} = \begin{pmatrix} A & B \\ C & D \end{pmatrix}.$$

In turn, the solver Jacobian is the submatrix, J_x .

$$J_x = A = \frac{\partial f}{\partial x}.$$

Sparsity of Jacobian

For many physical systems, the solver Jacobian J_x is *sparse*, meaning that many of the elements of J_x are zero.

Consider the following system of equations:

$$\begin{aligned}\dot{x}_1 &= f_1(x_1, x_3) \\ \dot{x}_2 &= f_2(x_2) \\ \dot{x}_3 &= f_3(x_2).\end{aligned}$$

From this system, you can derive a sparsity pattern that reflects the structure of the equations. The pattern, a Boolean matrix, has a 1 for each x_i that appears explicitly on the right-hand side of an equation. Therefore, you attain:

$$J_{x,pattern} = \begin{pmatrix} 1 & 0 & 1 \\ 0 & 1 & 0 \\ 0 & 1 & 0 \end{pmatrix}$$

As discussed in “Full and Sparse Perturbation Methods” on page 23-31 and “Full and Sparse Analytical Methods” on page 23-32 respectively, the Sparse Perturbation Method and the Sparse Analytical Method may be able to take advantage of this sparsity pattern to reduce the number of computations necessary and improve performance.

Solver Jacobian Methods

When you choose an implicit solver from the **Solver** pane of the configuration parameters dialog box, a parameter called **Solver Jacobian method** and a drop-down menu appear. This menu has five options for computing the solver Jacobian:

- **auto**
- **Sparse perturbation**
- **Full perturbation**
- **Sparse analytical**
- **Full analytical**

Note: If you set **Automatic solver parameter selection** to **warning** or **error** in the Solver Diagnostics pane, and you choose a different solver method than Simulink, you may receive a warning or an error.

Limitations

The solver Jacobian methods have the following limitations associated with them.

- If you select an analytical Jacobian method, but one or more blocks in the model do not have an analytical Jacobian, then Simulink applies a perturbation method.

- If you select sparse perturbation and your model contains data store blocks, Simulink applies the full perturbation method.

Heuristic 'auto' Method

The default setting for the Solver Jacobian method is auto. Selecting this choice causes Simulink to perform a heuristic to determine which of the remaining four methods best suits your model. This algorithm is depicted in the following flow chart.

Because sparse methods are beneficial for models having a large number of states, if 50 or more states exist in your model, the heuristic chooses a sparse method. The logic also

leads to a sparse method if you specify `ode23s` because, unlike other implicit solvers, `ode23s` generates a new Jacobian at every time step. A sparse analytical or a sparse perturbation method is, therefore, highly advantageous. The heuristic also ensures that the analytical methods are used only if every block in your model can generate an analytical Jacobian.

Full and Sparse Perturbation Methods

The full perturbation method was the standard numerical method that Simulink used to solve a system. For this method, Simulink solves the full set of perturbation equations and uses LAPACK for linear algebraic operations. This method is costly from a computational standpoint, but it remains the recommended method for establishing baseline results.

The sparse perturbation method attempts to improve the run-time performance by taking mathematical advantage of the sparse Jacobian pattern. Returning to the sample system of three equations and three states,

$$\begin{aligned}\dot{x}_1 &= f_1(x_1, x_3) \\ \dot{x}_2 &= f_2(x_2) \\ \dot{x}_3 &= f_3(x_2).\end{aligned}$$

The solver Jacobian is:

$$J_x = \begin{pmatrix} \frac{\partial f_1}{\partial x_1} & \frac{\partial f_1}{\partial x_2} & \frac{\partial f_1}{\partial x_3} \\ \frac{\partial f_2}{\partial x_1} & \frac{\partial f_2}{\partial x_2} & \frac{\partial f_2}{\partial x_3} \\ \frac{\partial f_3}{\partial x_1} & \frac{\partial f_3}{\partial x_2} & \frac{\partial f_3}{\partial x_3} \end{pmatrix} = \begin{pmatrix} \frac{f_1(x_1 + \Delta x_1, x_2, x_3) - f_1}{\Delta x_1} & \frac{f_1(x_1, x_2 + \Delta x_2, x_3) - f_1}{\Delta x_2} & \frac{f_1(x_1, x_2, x_3 + \Delta x_3) - f_1}{\Delta x_3} \\ \frac{f_2(x_1 + \Delta x_1, x_2, x_3) - f_2}{\Delta x_1} & \frac{f_2(x_1, x_2 + \Delta x_2, x_3) - f_2}{\Delta x_2} & \frac{f_2(x_1, x_2, x_3 + \Delta x_3) - f_2}{\Delta x_3} \\ \frac{f_3(x_1 + \Delta x_1, x_2, x_3) - f_3}{\Delta x_1} & \frac{f_3(x_1, x_2 + \Delta x_2, x_3) - f_3}{\Delta x_2} & \frac{f_3(x_1, x_2, x_3 + \Delta x_3) - f_3}{\Delta x_3} \end{pmatrix}$$

It is, therefore, necessary to perturb each of the three states three times and to evaluate the derivative function three times. For a system with n states, this method perturbs the states n times.

By applying the sparsity pattern and perturbing states x_1 and x_2 together, this matrix reduces to:

$$J_x = \begin{pmatrix} \frac{f_1(x_1 + \Delta x_1, x_2 + \Delta x_2, x_3) - f_1}{\Delta x_1} & 0 & \frac{f_1(x_1, x_2, x_3 + \Delta x_3) - f_1}{\Delta x_3} \\ 0 & \frac{f_2(x_1 + \Delta x_1, x_2 + \Delta x_2, x_3) - f_2}{\Delta x_2} & 0 \\ 0 & \frac{f_3(x_1 + \Delta x_1, x_2 + \Delta x_2, x_3) - f_3}{\Delta x_2} & 0 \end{pmatrix}$$

The solver can now solve columns 1 and 2 in one sweep. While the sparse perturbation method saves significant computation, it also adds overhead to compilation. It might even slow down the simulation if the system does not have a large number of continuous states. A tipping point exists for which you obtain increased performance by applying this method. In general, systems having a large number of continuous states are usually sparse and benefit from the sparse method.

The sparse perturbation method, like the sparse analytical method, uses UMFPACK to perform linear algebraic operations. Also, the sparse perturbation method supports both RSim and Rapid Accelerator mode.

Full and Sparse Analytical Methods

The full and sparse analytical methods attempt to improve performance by calculating the Jacobian using analytical equations rather than the perturbation equations. The sparse analytical method, also uses the sparsity information to accelerate the linear algebraic operations required to solve the ordinary differential equations.

Sparsity Pattern

For details on how to access and interpret the sparsity pattern in MATLAB, see `sldemo_metro`.

Support for Code Generation

While the sparse perturbation method supports RSim, the sparse analytical method does not. Consequently, regardless of which sparse method you select, any generated code uses the sparse perturbation method. This limitation applies to Rapid Accelerator mode as well.

Use Auto Solver to Select a Solver

In this section...

“Use Auto Solver with vdp Model” on page 23-34

“Auto Solver Heuristics” on page 23-35

When you want Simulink to select a solver for simulating the model, use auto solver. Auto solver chooses a suitable solver and sets the maximum step size of the simulation.

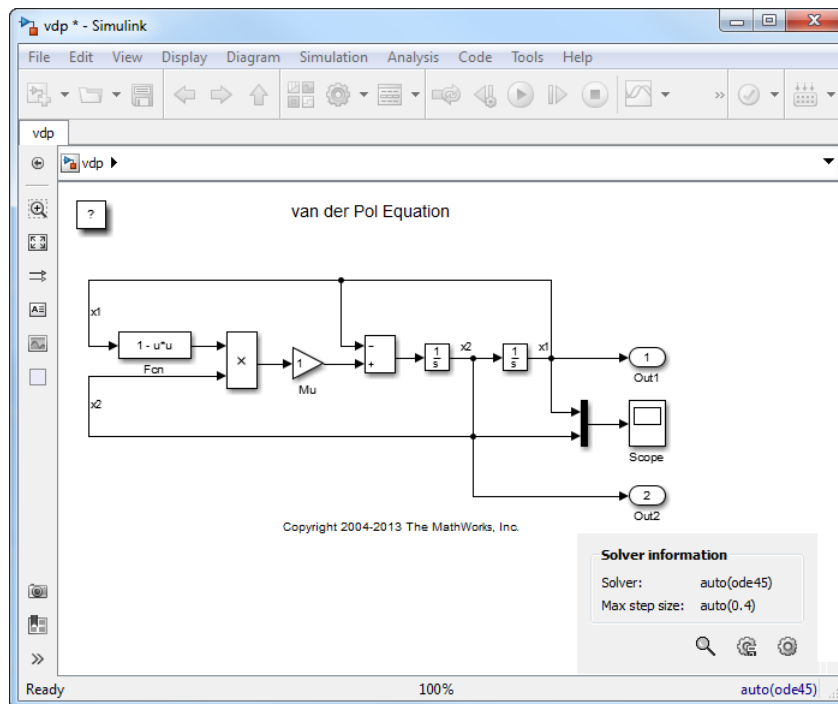

For new models, Simulink selects auto solver and sets the type to variable-step by default. For an existing model, you can use auto solver to select a solver.

Use Auto Solver with vdp Model

- 1 Open vdp and click the solver link in the lower-right corner. The **Solver information** pane opens.

- 2 In the pane, click the **View solver settings** button  to open the **Solver** pane of the model configuration parameters.
- 3 Under **Solver options**, set **Type** to fixed or variable-step according to your preference and set **Solver** to auto.
- 4 When you simulate the model, auto solver selects a fixed-step or variable-step solver according to your preference and calculates the maximum step size it recommends. To see the results, open the **Solver information** pane.

- 5 Click the **Accept suggested settings** button  to apply the recommendations of auto solver. To select different settings, click the **View solver settings** button and make changes in the configuration parameters **Solver** pane.

Auto Solver Heuristics

This chart describes the heuristics of auto solver.

Auto Solver Heuristics

The system has The solver type is		Only discrete states	Continuous states		
			The system is an ordinary differential equation (ODE)	The system has differential algebraic equations (DAE)	
Fixed-Step	FixedStepDiscrete		ode3	ode14x	
			<table border="1"> <tr> <th>The model is stiff</th> <th>The model is non-stiff</th> </tr> <tr> <td>ode15s</td> <td>ode45</td> </tr> </table>	The model is stiff	The model is non-stiff
The model is stiff	The model is non-stiff				
ode15s	ode45				

- For Simscape Power Systems models, auto solver selects `ode23tb`. These systems can have circuits with nonlinear models, especially circuit breakers and power electronics. Such nonlinear models require a stiff solver.
- If the number of continuous states in the model exceeds the `NumStatesForStiffnessChecking` value, auto solver uses `ode15s`. It does not calculate the stiffness of the model. The default value for this parameter is 1000. You can change this value using `set_param`.
- If the number of continuous states in the model is less than the `NumStatesForStiffnessChecking` value, auto solver calculates the stiffness of the model. A model is stiff if the stiffness exceeds the `StiffnessThreshold` value. The default value for this parameter is 1000. You can change this value using `set_param`.

- “Model Changes and SimState” on page 23-41
- “Limitations of SimState” on page 23-42

SimState and Repetitive Simulations

When designing a system, you simulate a model repeatedly to analyze the behavior of a system for different inputs, boundary conditions, or operating conditions. In many applications, a startup phase with significant dynamic behavior is common to multiple simulations. For example, the cold start takeoff of a gas turbine engine occurs before each set of aircraft maneuvers. Ideally, you:

- 1 Simulate the startup phase once.
- 2 Save the simulation state at the end of the start-up phase.
- 3 Use this state as the initial state for each set of conditions or maneuvers.

In this type of situation, use SimState to save the state of a simulation. For future simulations, you can restore the SimState and use it to set initial conditions for simulations going forward.

A SimState includes both the logged and internal states of every block (e.g., continuous states, discrete states, work vectors, zero-crossing states) and the internal state of the Simulink engine (e.g., the data of the ODE solver).

Note: You can also use the **Final states** option in the Configuration Parameters **Data Import/Export** pane to save a simulation state. However, this option saves only *logged*

states—the continuous and discrete states of blocks. These states are only subsets of the complete simulation state of the model. They do not include information about hidden states of certain blocks — information that is not included in logged states but is still required for the proper execution of the block. Hence you cannot use **Final states** to save and restore the complete simulation state as the initial state of a new simulation.

Information Saved in a SimState

A `SimState` contains information about:

- Logged states
- State of the solver and execution engine
- Zero-crossing signals for blocks that register zero crossings
- Output values of certain blocks in the model

Simulink analyzes block connections and other information to determine whether it is using the output values effectively as state information.

`SimState` also stores the hidden states of these blocks:

- Transport Delay
- Variable Transport Delay
- From Workspace
- For Each subsystem
- Conditionally executed subsystems
- Stateflow
- MATLAB System
- Simscape Multibody Second Generation

By storing this information, `SimState` ensures that the result of a simulation that starts from `SimState` is the same as a simulation that runs from the beginning.

Benefits of Using SimState

- When `SimState` saves the state of a simulation, it saves information in addition to the logged states in the model. You need to restore all of this information to ensure

that the simulation matches the uninterrupted simulation. For example, if solver information affected the simulation, then changing the state of a block without using `SimState` can produce different results.

- You can save several `SimStates` during a simulation. You can then resume a simulation from any of those states.
- `SimState` can help to restore the state of blocks such as the Transport Delay block, which is typically difficult to restore to a particular state. The state of the Transport Delay block is not saved in the structure format or the array format when you log data using the **Final states** configuration parameter without using `Simstate`. The blocks with hidden states are particularly difficult to restore, and `SimState` enables you to do so.

When You Can Save a SimState

You can save a `SimState`:

- At the final **Stop time**
- When you interrupt a simulation with the **Pause** or **Stop** button
- When you use `get_param` or a block, like the Stop block, to stop a simulation

Save SimState

Save a `SimState` at the beginning of the final step using one of these options.

Interactive

- 1 In the Configuration Parameters dialog box, in the **Data Import/Export** pane, select the **Final states** check box. The **Save complete SimState in final state** check box becomes available.
- 2 Select the **Save complete SimState in final state** check box.
- 3 In the **Final states** text box, enter a variable name for the `SimState`.
- 4 Simulate the model.

From the MATLAB Command Prompt

Use the `sim` command with `set_param`. Set the `SaveCompleteFinalSimState` parameter to `on`.

```
set_param mdl, 'SaveFinalState', 'on', 'FinalStateName', ...  
    [mdl 'SimState'], 'SaveCompleteFinalSimState', 'on')  
simOut = sim(mdl, 'StopTime', tstop)  
set_param(mdl, 'SaveFinalState', 'off')
```

Restore SimState

The **Start time** does not change from the value in the simulation that generated `SimState`. It is a reference value for all time and time-dependent variables in both the original and the current simulation. For example, a block can save and restore the number of sample time hits that occurred since the beginning of simulation as its `SimState`.

Consider a model that you ran from 0–100 s and that you now want to run from 100–200 s. The **Start time** is 0 s for both the original simulation (0–100 s) and for the current simulation (100–200 s). The initial time of the current simulation is 100 s. Also, if the block had 10 sample time hits during the original simulation, Simulink recognizes that the next sample time hit is the 11th, relative to 0, not 100 s.

Note: If you change **Start time** before restoring a `SimState`, Simulink overwrites the **Start time** with the value saved in the `SimState`.

Restore a `SimState` using one of these options.

Interactive

- 1 In the Configuration Parameters dialog box, in the **Data Import/Export** pane, under **Load from workspace**, select the **Initial state** check box. The text box becomes available.
- 2 Enter the name of the variable containing the `SimState` in the text box.
- 3 Set **Stop time** to a value greater than the time at which the `SimState` was saved.

From the MATLAB Command Prompt

Use `set_param` to specify the initial condition as the `SimState`.

```
set_param(mdl, 'LoadInitialState', 'on', 'InitialState', ...  
    [mdl 'xFinal']);  
simOut.get([mdl 'SimState']);
```

Restore SimState Saved in an Earlier Version of Simulink

You can use `SimState` objects saved in releases starting with R2010a to restore the `SimState` of a model. However, this option restores only the logged states of the model. To see the version of Simulink used to save the `SimState`, examine the **version** parameter of the `SimState` object.

Simulink detects if the `SimState` object you provided as the initial state was saved in the current release. By default, Simulink displays an error message if the `SimState` was not saved in the current release. You can configure the diagnostic to allow Simulink to display the message as a warning and try to restore as many of the values as possible.

To enable this best-effort restoration, in the Configuration Parameters dialog box, in the **All Parameters** pane, set the message for **SimState object from earlier release** to warning.

Change the States of a Block Within SimState

- Use `loggedStates` to get or set the states of blocks. If `xout` is the state log that Simulink exports to the workspace, then the `loggedStates` field has the same structure as `xout.signals`.
- You cannot change the states that are not logged. Simulink does not allow this modification as it could cause the state to be inconsistent with the simulation.

S-Functions

You can use APIs for C and Level-2 MATLAB S-functions to enable S-functions to work with `SimState`. For information on how to implement these APIs within S-functions, see “S-Function Compliance with the `SimState`”.

S-functions that have P-work vectors but do not declare their `SimState` compliance level or declare it to be unknown or disallowed do not support `SimState`. For more information, see “S-Function Compliance with the `SimState`”.

Model Changes and SimState

- You cannot make any structural changes to the model between the time you save the `SimState` and the time you restore the simulation using the `SimState`. For example, you cannot add or remove a block after saving the `SimState` without repeating the simulation and saving the new `SimState`.

- The `SimState` interface checksum is primarily based on the configuration settings in a model. You can make some nonstructural changes to the model between saving and restoring a `SimState`. In the Configuration Parameters dialog box, in the **Diagnostics** pane, use the **SimState interface checksum mismatch** diagnostic to track such changes. You can then find out if the interface checksum of the restored `SimState` matches the current interface checksum.

Mismatches can occur when you try to simulate using a solver that is different from the one that generated the saved `SimState`. Simulink permits solver changes. For example, you can use the `ode15s` solver to solve the initial stiff portion of a simulation and save the final `SimState`. You can then continue the simulation with the restored `SimState` using `ode45`. In other words, this diagnostic helps you see the solver changes but does not signal a problem with the simulation.

- When you use a variable-step solver with the maximum step size set to `auto`, Simulink uses the maximum step size from the restored `SimState` for the new simulation. To ensure that the concatenated `SimState` trajectory of two simulations matches that of an uninterrupted simulation, specify a value for the maximum step size.

Limitations of SimState

Note: In some cases, saving partial state information avoids some of the limitations of using `SimState`. For a comparison of the two ways to save state data, see “Comparison of `SimState` and Final State Logging” on page 59-232.

Block Support

The following blocks do not support `SimState`:

- In the Stack and Queue blocks, the default setting for the **Push full stack** option is **Dynamic reallocation**. This default setting does not support `SimState`. Other settings (**Ignore**, **Warning** and **Error**) support `SimState`.
- Simscape Multibody First Generation blocks
- `SimEvents` blocks

Simulink tries to save the output of a block as part of a `SimState`. For S-functions, this happens even if the functions declare that no `SimState` is required. If the block output

is of custom type, Simulink cannot save the `SimState` and displays an error. For more information about `SimState` use with S-functions, see “S-Functions” on page 23-41.

Model reference offers partial support for `SimState`. For details, see “Model Referencing” on page 23-43.

Simulation

- You can save `SimState` only at the final stop time or at the execution time at which you pause or stop the simulation.
- You can use only the Normal or the Accelerator simulation mode.
- You cannot save `SimState` in Normal mode and restore it in Accelerator mode, or vice versa.
- You cannot change the states of certain blocks that are not logged. For more information, see “Change the States of a Block Within `SimState`” on page 23-41.

Code Generation

The `SimState` feature does not support Simulink Coder or Embedded Coder code generation.

Model Referencing

- You cannot modify logged states of blocks that are inside a referenced model in Accelerator mode.
- The following blocks do not support `SimState` when included in a model referenced in Accelerator mode:
 - Level 2 MATLAB S-Function
 - MATLAB System
 - n-D Lookup Table
 - S-Function (with custom `SimState` or `PWork` vectors)
 - To File
 - Simscape blocks
- For additional information, see “State Information for Referenced Models” on page 59-235.

Model Function

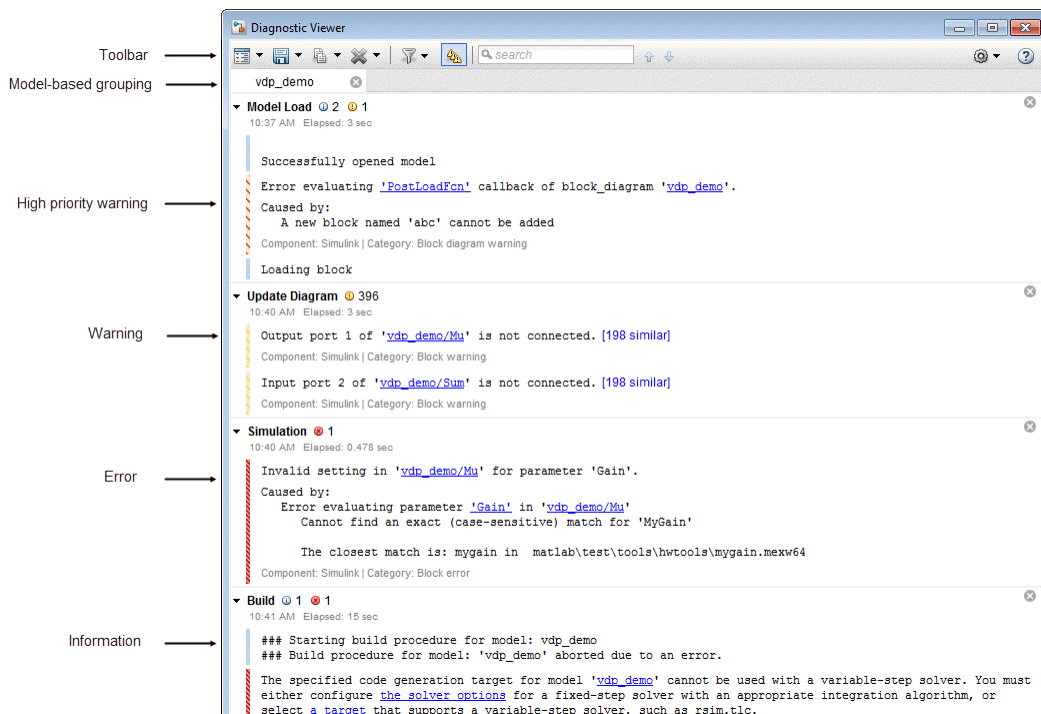

You cannot input the `SimState` to the `model` function.

More About

- “Benefits of Using SimState” on page 23-38

- “Limitations of SimState” on page 23-42

View Diagnostics

You can view and diagnose errors and warnings generated by your model using the **Diagnostic Viewer**. The **Diagnostic Viewer** displays three types of diagnostic messages: errors, warnings, and information. A model generates these messages during a runtime operation, like model load, simulation, or update diagram.

The diagnostic viewer window is divided into:

- **Toolbar menu:** Displays various commands to help you manage the diagnostic messages. For more information, see “Toolbar” on page 23-46.
- **Diagnostic Message pane:** Displays the error, warning, and information messages. For more information, see “Diagnostic Message Pane” on page 23-46.
- **Suggested Actions:** Displays suggestions and fixes to correct the diagnostic errors and warnings. For more information, see. “Suggested Actions” on page 23-48.

Toolbar

To manage the diagnostic messages, use the **Diagnostic Viewer** toolbar.

Button	Action
	Expand or collapse messages
	Save all or latest messages in a log file
	Copy all or latest messages
	Clear all or all but latest messages
	Filter out errors, warning, and information messages
	Group similar type of messages
	Search messages for specific keywords and navigate between messages
	Set maximum number of models to display in tabbed panes and the maximum number of events to display per model

Diagnostic Message Pane

The diagnostic message pane displays the error, warning, and information messages in a tabbed format. These messages are color-coded for distinction and are hierarchical.

A new stage is generated for each successive event, you can save or clear stage. Each stage represents a single event such as model load, update diagram, or simulation.

Different types of diagnostic messages are:

- Information message: Displays the information related to a model load. Information messages are marked as .

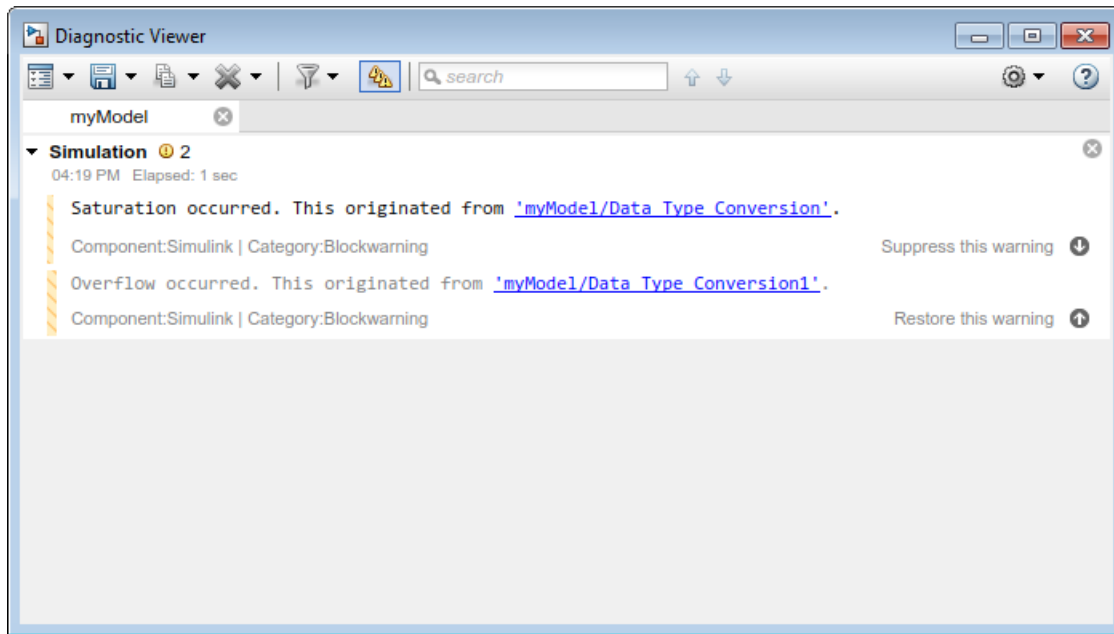

- High priority warning: Displays the errors encountered during model load as a high priority warning. Any subsequent operation, like update on the model without rectifying the high priority warning messages are marked as errors. High priority warnings are marked as .
- Warning: Displays the warnings associated during an operation on a model. Warnings are marked as .
- Error: Displays the errors associated during an operation on a model. Errors are marked as .

Tip To locate the source of error, click the hyperlink in the message. The source of error in the model is highlighted.

Suppress Warnings

The Diagnostic viewer provides a **Suppress** button for certain diagnostics. This button allows you to suppress certain numerical warnings (for example, overflow, saturation, precision loss) for specific objects in your model. Click the **Suppress** button next to the warning in the Diagnostic viewer to suppress the warning from the specified source. You can restore the warning from the source by clicking **Restore**. Diagnostic suppressions are saved with the model and persist across sessions.

You can also control the suppression of warnings from the command line. For more information, see “Suppress Diagnostic Messages Programmatically” on page 23-56.

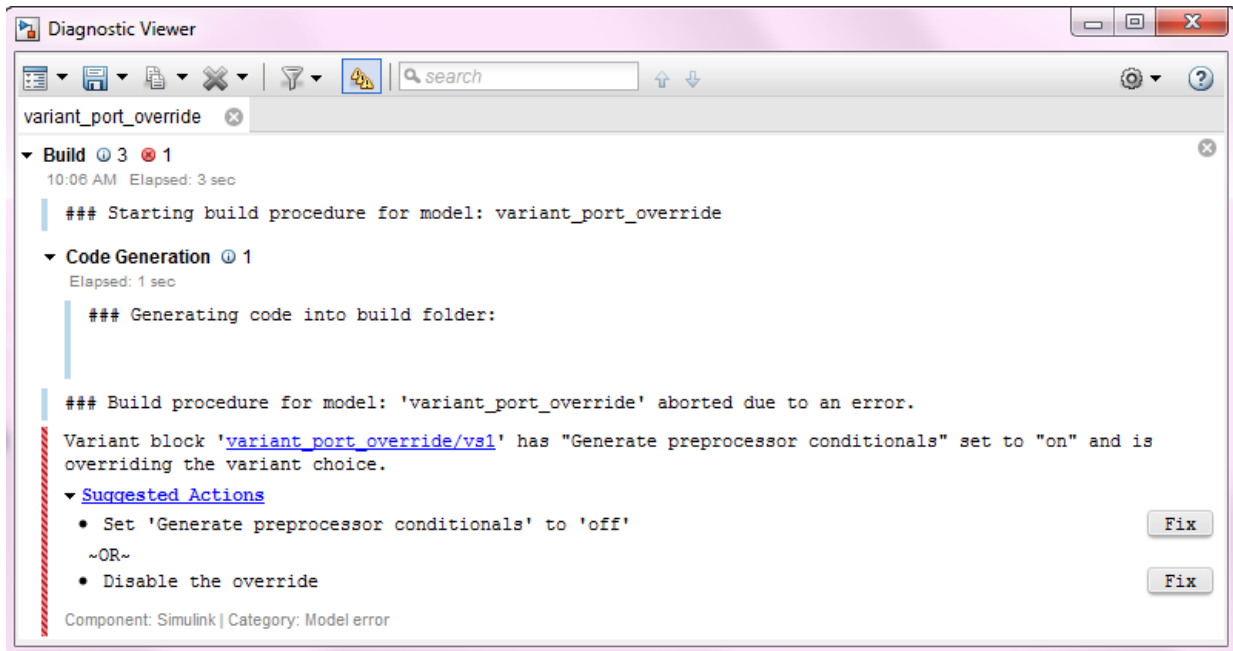

Note: To suppress a warning that originates from a model reference block, you must suppress the diagnostic on the referenced model.

Suggested Actions

Diagnostic viewer provides suggestions and fixes for diagnostic error and warning messages. These suggestions and fixes are provided in the **Suggested Actions** section of diagnostic message pane.

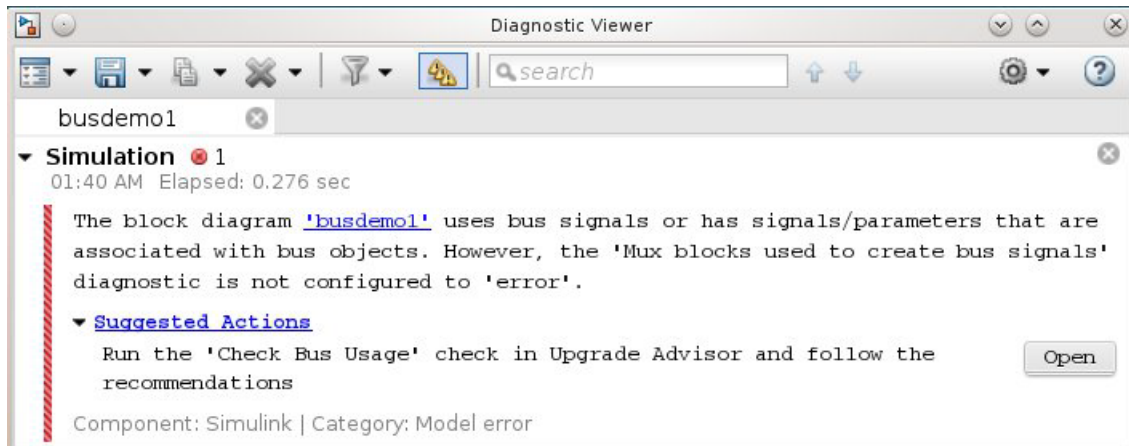

A diagnostic error or warning can have multiple fixes and suggestions. Each fix is associated with a **Fix** button.

You can click the **Fix** button for the most suitable fix to rectify the error automatically.

The **Fix** buttons for a diagnostic error or warning are no longer available after a fix is successfully applied. If a fix was unsuccessful, a failure message is displayed in the **Suggested Actions** section.

Suggestions are provided for errors and warnings that cannot be fixed automatically.

Note: The **Suggested Actions** section is available only for the diagnostic errors or warnings that have a predefined fix.

Related Examples

- “Systematic Diagnosis of Errors and Warnings” on page 23-51
- “Customize Diagnostic Messages” on page 23-61
- “Report Diagnostic Messages Programmatically” on page 23-64

Systematic Diagnosis of Errors and Warnings

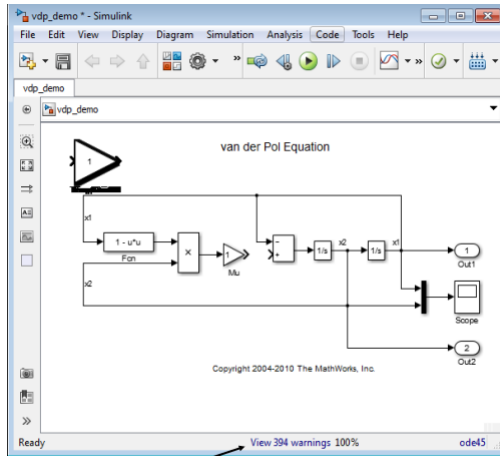

This example shows how to use the Diagnostic Viewer to identify and locate simulation errors and warnings systematically.

- 1 Open your model.

If your model contains errors related to callback functions, the **Diagnostic Viewer** opens and displays the following errors in **Model Load** stage.

Tip To open the **Diagnostic Viewer** window, click **View > Diagnostic Viewer** or click **View warnings** in the Simulink Editor.

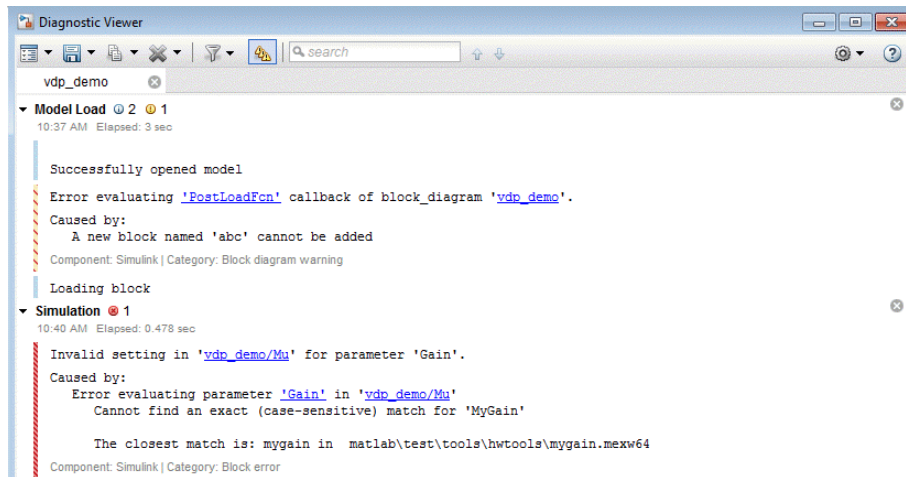

- 2 In the Simulink Editor, click **File > Model Properties > Model Properties**, and examine the callback error.

- 3 After fixing any callback errors, simulate the model to diagnose simulation errors and warnings.

Diagnostic Viewer lists errors and warnings in stages. Each stage in **Diagnostic Viewer** represents a single event such as model load, update diagram, simulation, or build.

- 4 Filter out warnings by clicking  so that you can address errors first.
- 5 To locate the source of the error, click the hyperlink in the message. The model in the source is highlighted. If a block has multiple ports, you can hover over each port to see the port number.

- 6 After fixing all errors, simulate your model again and view the **Diagnostic Viewer** to identify remaining problems.

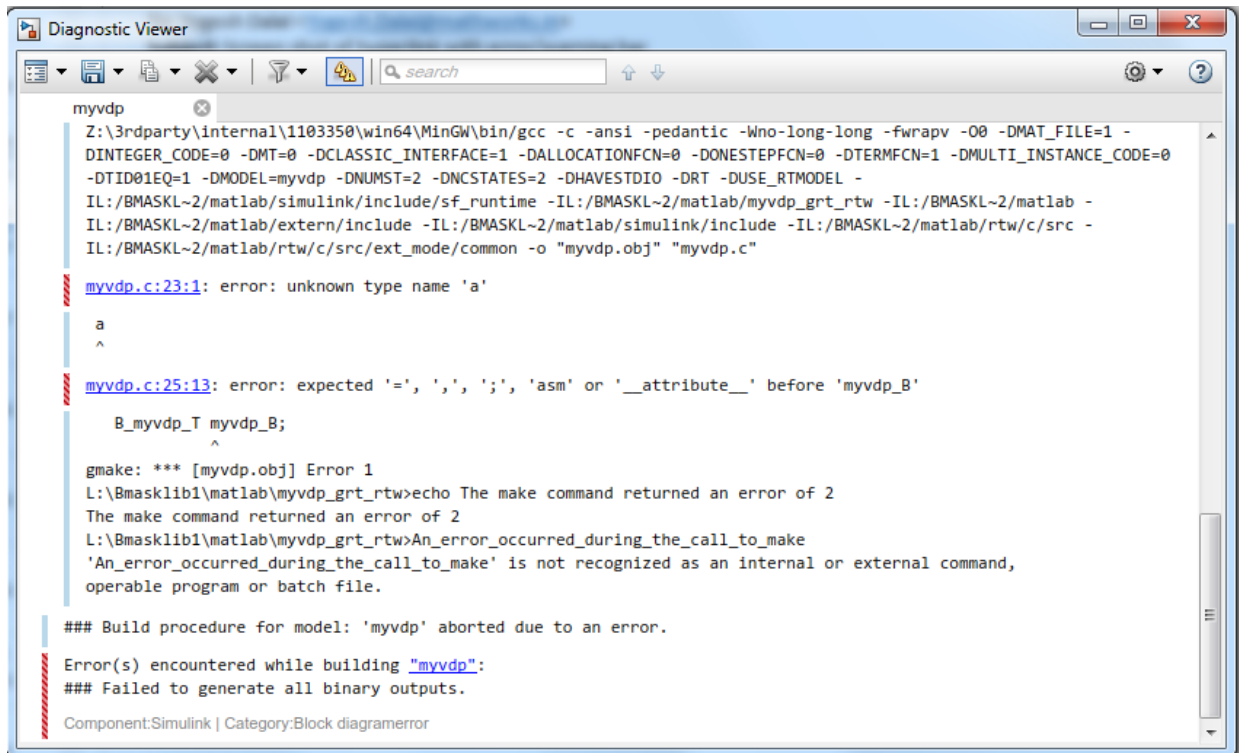

Note: If an error or warning has a predefined fix, the diagnostic message pane displays a **Suggested Actions** section. You can use the **Fix** button provided in this section to rectify the related error or warning. For more information see, “Suggested Actions” on page 23-48.

- 7 If an object in your model generates a warning that you do not want to be notified of, sometimes, you can suppress the warning from the specified source using the **Suppress** button. You can restore the warning from that source using the **Restore**

button. For example, if a Counter Free-Running block generates an overflow warning that is intentional in your design, you can suppress only overflow warnings from this particular block, without sacrificing notification of other overflows in your model.

- 8 To generate code for your model, click **Code** > **C/C++ Code** > **Build Model**.

Note: If there is a failure during code generation, Diagnostic Viewer provides hyperlinks for easy navigation to the source of the error or warning message.

Related Examples

- “Customize Diagnostic Messages” on page 23-61
- “Report Diagnostic Messages Programmatically” on page 23-64

Suppress Diagnostic Messages Programmatically

This example shows how to access simulation metadata to manage diagnostic suppressions and to restore diagnostic messages programmatically.

Create a New Folder and Copy Relevant Files

- 1 Create a local working folder, for example, `c:\diadnostic_suppressor_demo`.
- 2 Change to the `docroot\toolbox\simulink\examples` folder. At the MATLAB command line, enter:

```
cd(fullfile(docroot, 'toolbox', 'simulink', 'examples'))
```

- 3 Copy the `getDiagnosticObjects.m`, `suppressor_script.m`, and `Suppressor_CLI_Demo.slx` files to your local working folder.

The `getDiagnosticObjects.m` function queries the simulation metadata to access diagnostics that were thrown during simulation. The `suppressor_script.m` script contains the commands for suppressing and restoring diagnostics to the `Suppressor_CLI_Demo` model.

`getDiagnosticObjects.m`

```
function y = getDiagnosticObjects(in)
Warningdata = in.getSimulationMetadata.ExecutionInfo.WarningDiagnostics;
Errordata = in.getSimulationMetadata.ExecutionInfo.ErrorDiagnostic;

index = 1;

for i = 1 : numel(Warningdata)
    y(index) = Warningdata(i).Diagnostic;
    index = index + 1;
end

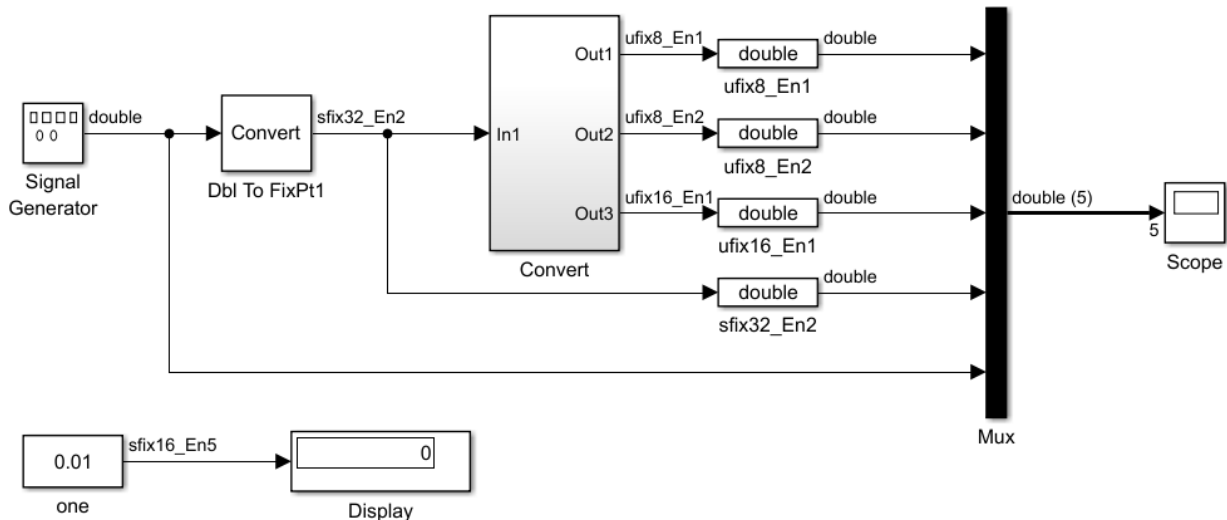

for i = 1 : numel(Errordata)
    y(index) = Errordata(i).Diagnostic;
    index = index + 1;
end
```

Open and Simulate the Model

Open the model. To access `Simulink.SimulationMetadata`, set the `ReturnWorkspaceOutputs` parameter value to `'on'`. Simulate the model.

```
model = 'Suppressor_CLI_Demo';
open_system(model);
set_param(model, 'ReturnWorkspaceOutputs', 'on');
out = sim(model);
```

Fixed-Point to Fixed-Point Conversion

Get Message Identifiers from Simulation Metadata

Find the names of diagnostic message identifiers using the simulation meta data stored in the `MSLDiagnostic` object.

```
if (exist('out', 'var'))
    diag_objects = getDiagnosticObjects(out);
end
```

Several warnings were generated during simulation, including a saturation of the Data Type Converter block. Query the `diag_objects` variable to get more information on the identifiers.

```
diag_objects(5)

ans =

  MSLDiagnostic with properties:

    identifier: 'SimulinkFixedPoint:util:Saturationoccurred'
    message: 'Saturation occurred. This originated from 'Suppressor_CLI_Demo/Con...'
    paths: {'Suppressor_CLI_Demo/Convert/FixPt To FixPt3'}
    cause: {}
    stack: [0x1 struct]
```

Suppress Saturation Diagnostic on a Block

Use the `Simulink.suppressDiagnostic` function to suppress the saturation diagnostic on the data type conversion block only. Simulate the model.

```
Simulink.suppressDiagnostic('Suppressor_CLI_Demo/Convert/FixPt To FixPt3', 'SimulinkFixedPoint:util:Saturationoccurred');
set_param(model, 'SimulationCommand', 'start');
```

Restore the Saturation Diagnostic

Use the `Simulink.restoreDiagnostic` function to restore the saturation diagnostic of the same block.

```
Simulink.restoreDiagnostic('Suppressor_CLI_Demo/Convert/FixPt To FixPt3', 'SimulinkFixedPoint:util:Saturationoccurred');
set_param(model, 'SimulationCommand', 'start');
```

Suppress Multiple Diagnostics on a Source

You can suppress multiple warnings on a single source by creating a cell array of message identifiers. Suppress the precision loss and parameter underflow warnings of the Constant block, `one`, in the model.

```
diags = {'SimulinkFixedPoint:util:fxpParameterPrecisionLoss', 'SimulinkFixedPoint:util:fxpParameterUnderflowWarning'};
Simulink.suppressDiagnostic('Suppressor_CLI_Demo/one', diags);
set_param(model, 'SimulationCommand', 'start');
```

Restore All Diagnostics on a Block

Restore all diagnostics on a specified block using the `Simulink.restoreDiagnostic` function.

```
Simulink.restoreDiagnostic('Suppressor_CLI_Demo/one');
set_param(model, 'SimulationCommand', 'start');
```

Suppress a Diagnostic on Many Blocks

You can suppress one or more diagnostics on many blocks. For example, use the `find_system` function to create a cell array of all Data Type Converter blocks in a system, and suppress all saturation warnings on the specified blocks.

```
dtc_blocks = find_system('Suppressor_CLI_Demo/Convert', 'BlockType', 'DataTypeConversion');
Simulink.suppressDiagnostic(dtc_blocks, 'SimulinkFixedPoint:util:Saturationoccurred');
set_param(model, 'SimulationCommand', 'start');
```

Restore All Diagnostics Inside a Subsystem

You can also use the `Simulink.restoreDiagnostic` function to restore all diagnostics inside a specified subsystem.

```
Simulink.restoreDiagnostic('Suppressor_CLI_Demo/Convert', 'FindAll', 'On');
set_param(model, 'SimulationCommand', 'start');
```

Add Comments and User Information to a Suppression

A `SuppressedDiagnostic` object contains information on the source of the suppression and the suppressed diagnostic message identifier. You can also include comments, and the name of the user who last modified the suppression.

```
Object = Simulink.SuppressedDiagnostic('Suppressor_CLI_Demo/Convert/FixPt To FixPt1',
Object.Comments = 'Reviewed: John Doe';
Object.LastModifiedBy = 'Joe Schmoe';
set_param(model, 'SimulationCommand', 'start');
```

```
Object =
```

```
SuppressedDiagnostic with properties:
```

```
Source: 'Suppressor_CLI_Demo/Convert/FixPt To FixPt1'
Id: 'SimulinkFixedPoint:util:Saturationoccurred'
LastModifiedBy: 'Joe Schmoe'
Comments: 'Reviewed: John Doe'
LastModified: '2016-Jun-21 18:23:01'
```

Get Suppression Data

To get suppression data for a certain subsystem or block, use the `Simulink.getSuppressedDiagnostics` function.

```
Object = Simulink.getSuppressedDiagnostics('Suppressor_CLI_Demo/Convert/FixPt To FixPt1');
```

```
set_param(model, 'SimulationCommand', 'start');
```

Restore All Diagnostics on a Model

When a model contains many diagnostic suppressions, and you want to restore all diagnostics to a model, use the `Simulink.getSuppressedDiagnostics` function to return an array `Simulink.SuppressedDiagnostic` objects. Then use the `Simulink.SuppressedDiagnostic.restore` method as you iterate through the array.

```
Objects = Simulink.getSuppressedDiagnostics('Suppressor_CLI_Demo');  
for iter = 1:numel(Objects)  
    restore(Objects(iter));  
end  
set_param(model, 'SimulationCommand', 'start');
```

Customize Diagnostic Messages

In this section...

“Display Custom Text” on page 23-61

“Create Hyperlinks to Files, Folders, or Blocks” on page 23-62

“Create Programmatic Hyperlinks” on page 23-62

The **Diagnostic Viewer** displays the output of MATLAB error functions executed during simulation.

You can customize simulation error messages in the following ways by using MATLAB error functions in callbacks, S-functions, or MATLAB Function blocks.

Display Custom Text

This example shows how to can customize the MATLAB function `check_signal` to display the text `Signal is negative`.

- 1 Open the MATLAB Function for editing.

- 2 In the MATLAB Editor, create a function to display custom text.

```

function y = check_signal(x)
    if x < 0
        error('Signal is negative');
    else
        y = x;
    end
  
```

- 3 Simulate the model.

A runtime error appears and you are prompted to start the debugger. Click **OK**.

- 4 To view the following error in **Diagnostic Viewer**, close the debugger.

Create Hyperlinks to Files, Folders, or Blocks

To create hyperlinks to files, folders, or blocks in an error message, include the path to these items within customized text.

Example error message	Hyperlink
<code>error('Error reading data from "C:/Work/designData.mat"')</code>	Opens <code>designData.data</code> in the MATLAB Editor.
<code>error('Could not find data in folder "C:/Work"')</code>	Opens a Command Window and sets <code>C:\Work</code> as the working folder.
<code>error('Error evaluating parameter in block "myModel/Mu"')</code>	Displays the block <code>Mu</code> in model <code>myModel</code> .

Create Programmatic Hyperlinks

This example shows how to can customize the MATLAB function `check_signal` to display a hyperlink to the documentation for `find_system`.

- 1 Open the MATLAB Function for editing.

- 2 In the MATLAB Editor, create a function to display custom text.

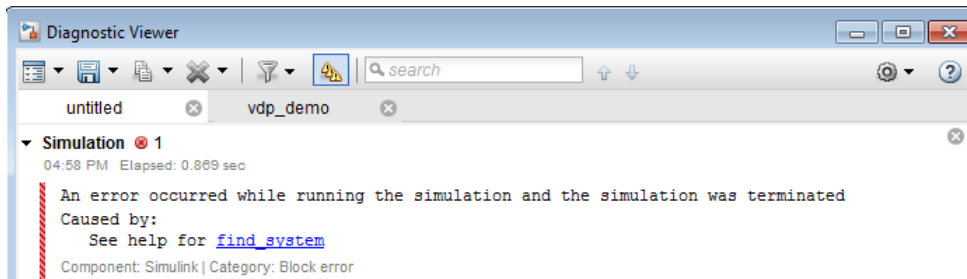

```
function y = check_signal(x)
    if x < 0
```

```
    error('See help for <a href="matlab:doc find_system">find_system</a>');  
else  
    y = x;  
end
```

- 3 Simulate the model.

A runtime error appears and you are prompted to start the debugger. Click **OK**.

- 4 To view the following error in **Diagnostic Viewer**, close the debugger.

Related Examples

- “Systematic Diagnosis of Errors and Warnings” on page 23-51
- “Report Diagnostic Messages Programmatically” on page 23-64

Report Diagnostic Messages Programmatically

The `sldiagviewer` functions enable you to generate, display, and log diagnostic messages in the Diagnostic Viewer.

You can use these functions to report the diagnostic messages programmatically:

- Function to create a stage: `sldiagviewer.createStage`
- Functions to report diagnostic messages:
 - `sldiagviewer.reportError`
 - `sldiagviewer.reportWarning`
 - `sldiagviewer.reportInfo`
- Function to log the diagnostics: `sldiagviewer.diary`

Create Diagnostic Stages

In the Diagnostic Viewer, errors, warnings, and information messages are displayed in groups based on the operation, such as model load, simulation, and build. These groups are called stages. The `sldiagviewer.createStage` function enables you to create stages. You can also create child stages for a stage object. A parent stage object must be active to create a child stage. When you create a stage object, Simulink initializes a stage. When you close the stage object, Simulink ends the stage. If you delete a parent stage object, the corresponding parent and its child stage close in the Diagnostic Viewer. The syntax for creating a stage is:

```
stageObject =  
sldiagviewer.createStage(StageName, 'ModelName', ModelNameValue)
```

In this syntax,

- `StageName` specifies the name of a stage and is a required argument, for example, 'Analysis'.
- Use the 'ModelName', `ModelNameValue` pair to specify the model name of a stage, for example 'ModelName', 'vdp'. All the child stages inherit the model name from their parent.

Example to Create Stage

```
my_stage = sldiagviewer.createStage('Analysis', 'ModelName', 'vdp');
```

Report Diagnostic Messages

You can use the `sldiagviewer` functions to report error, warning, or information messages in the Diagnostic Viewer. The syntaxes for reporting diagnostic messages are:

- `sldiagviewer.reportError(Message)`: Reports the error messages.
- `sldiagviewer.reportWarning(Message)`: Reports the warnings.
- `sldiagviewer.reportInfo(Message)`: Reports the information messages.

`Message` describes the error, warning, or build information and is a required argument. `Message` can have values in these formats:

- String
- `MSLException` or `MException` object

Optionally, you can use the '`Component`' argument and its corresponding value in the syntax to specify the component or product that generates the message, for example, '`Simulink`' and '`Stateflow`'.

Example to Report Diagnostics

```
% Create a Stage to display all the messages

my_stage = sldiagviewer.createStage('Analysis', 'modelName', 'vdp');

% Catch the error introduced in vdp as an exception.

try
sim('vdp');
catch error
end

% Report the caught exception as warning

sldiagviewer.reportWarning(error);

% Report a custom info message to Diagnostic Viewer

sldiagviewer.reportInfo('My Info message');
```

Log Diagnostic Messages

You can use the `sldiagviewer.diary` function to log the simulation warning, error, and build information to a file. The syntaxes for generating log files are:

- `sldiagviewer.diary`: Intercepts the build information, warnings, and errors transmitted to the Diagnostic Viewer and logs them to a text file `diary.txt` in the current directory.
- `sldiagviewer.diary(filename)`: Toggles the logging state of the text file specified by `filename`.
- `sldiagviewer.diary(toggle)`: Toggles the logging ability. Valid values are 'on' and 'off'. If you have not specified a log file name, the toggle setting applies to the last file name that you specified for logging or to the `diary.txt` file.
- `sldiagviewer.diary(filename, 'UTF-8')`: Specifies the character encoding for the log file.

In this syntax,

- `filename` specifies the file to log the data to.
- `toggle` specifies the logging state 'on' or 'off'.

Example to Log Diagnostic Messages

```
% Log messages using sldiagviewer.diary

sldiagviewer.diary
open_system('vdp')
rtwbuild('vdp')

% Open diary.txt to view logs.

### Starting build procedure for model: vdp
### Build procedure for model: 'vdp' aborted due to an error.
...
% Log messages using sldiagviewer.diary(filename)

sldiagviewer.diary('C:\MyLogs\log1.txt')

% Log messages using sldiagviewer.diary(toggle)

sldiagviewer.diary('C:\MyLogs\log1.txt') % Start logging
open_system('vdp')
```

```
rtwbuild('vdp')

sldiagviewer.diary('off') % Switch off logging
open_system('sldemo_fuelsys')
rtwbuild('sldemo_fuelsys')

sldiagviewer.diary('on') % Resume logging

% Log messages using sldiagviewer.diary(filename,'UTF-8')

sldiagviewer.diary('C:\MyLogs\log1.txt','UTF-8')
```

Run Simulations Programmatically

You can programmatically simulate a model with the `sim` function, using various techniques to specify parameter values. In addition to simulation using the `sim` function, these examples show you how to enable simulation timeouts, capture simulation errors, and access simulation metadata when your simulation is complete.

In this section...

“Specify Parameter Name-Value Pairs” on page 24-2
 “Specify a Parameter Structure and Perform a Parameter Sweep” on page 24-4
 “Specify a Configuration Set” on page 24-5
 “Enable Simulation Timeouts” on page 24-6
 “Capture Simulation Errors” on page 24-6
 “Access Simulation Metadata” on page 24-7

Specify Parameter Name-Value Pairs

This example shows how to programmatically simulate a model, specifying parameters as name-value pairs.

Simulate the `vdp` model with parameter values specified as consecutive name-value pairs.

```
simOut = sim('vdp','SimulationMode','normal','AbsTol','1e-5',...
            'SaveState','on','StateSaveName','xout',...
            'SaveOutput','on','OutputSaveName','yout',...
            'SaveFormat','Dataset');
outputs = simOut.get('yout')
```

```
outputs =

    Simulink.SimulationData.Dataset
    Package: Simulink.SimulationData

    Characteristics:
        Name: 'yout'
        Total Elements: 2
```

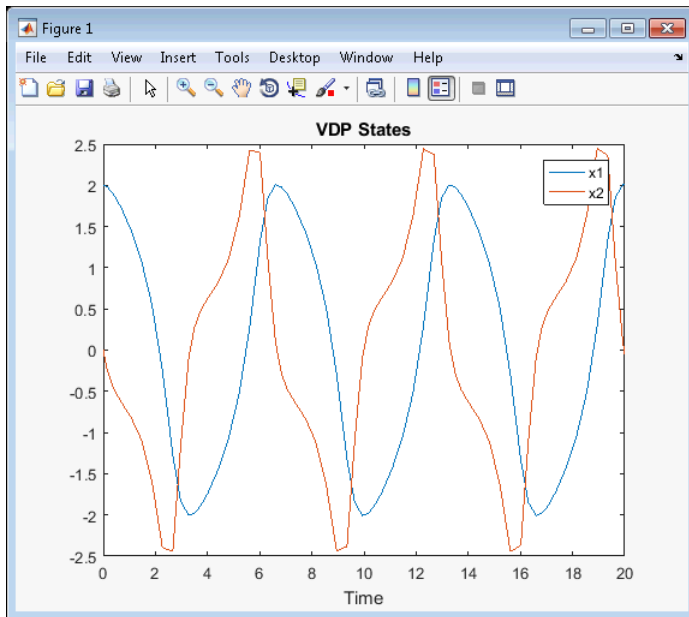

```
Elements:  
 1 : 'x1'  
 2 : 'x2'
```

- Use `get` or `getElement` to access elements by index or name.
- Use `addElement` or `setElement` to add or modify elements.

You simulate the model in **Normal** mode, specifying an absolute tolerance for solver error. The `sim` function returns `SimOut`, a single `Simulink.SimulationOutput` object that contains all of the simulation outputs (logged time, states, and signals). The `sim` function *does not* return simulation values to the workspace.

Plot the output signal values against time.

```
x1=(outputs.get('x1').Values);  
x2=(outputs.get('x2').Values);  
plot(x1); hold on;  
plot(x2);  
title('VDP States')  
xlabel('Time'); legend('x1','x2')
```

Specify a Parameter Structure and Perform a Parameter Sweep

This example shows how to programmatically simulate a model, specifying parameters values in a structure. You also perform a parameter sweep of the model, simulating the model each time you change parameter values and plotting the results.

Specify parameter values in a structure.

```
paramNameValStruct.SimulationMode = 'normal';
paramNameValStruct.AbsTol         = '1e-5';
paramNameValStruct.SaveState     = 'on';
paramNameValStruct.StateSaveName = 'xout';
paramNameValStruct.SaveOutput    = 'on';
paramNameValStruct.OutputSaveName = 'yout';
paramNameValStruct.SaveFormat    = 'Dataset';
```

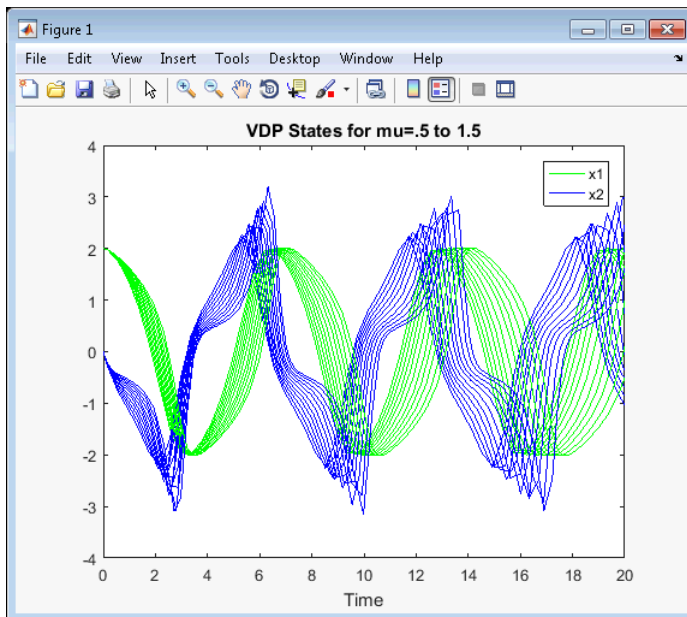

Simulate the model while performing a parameter sweep for the Gain parameter of the Mu block. Plot the results.

```
open_system('vdp');
muSweep = .5:.1:1.5;
```

```

for i = 1:length(muSweep)
    set_param('vdp/Mu', 'Gain', 'muSweep(i)');
    simOut = sim('vdp',paramNameValStruct);
    outputs = simOut.get('yout');
    x1 =(outputs.get('x1').Values);
    x2 =(outputs.get('x2').Values);
    h1 = plot(x1); hold on;
    h2 = plot(x2);
    set(h1,'color',[0 1 0]);
    set(h2,'color',[0 0 1]);
    legend('x1', 'x2');
end
title('VDP States for mu=.5 to 1.5')
xlabel('Time');

```

Specify a Configuration Set

This example shows how to specify parameter values in a new configuration set.

Create a new configuration set by copying the active configuration set and changing it using `set_param`. Then, use `sim` to simulate the model with the new configuration set.

```
model = 'vdp';
load_system(model)
cs = getActiveConfigSet(model);
model_cs = cs.copy;
set_param(model_cs, 'AbsTol', '1e-5', ...
            'SaveState', 'on', 'StateSaveName', 'xout', ...
            'SaveOutput', 'on', 'OutputSaveName', 'yout')
simOut = sim(model, model_cs);
```

Enable Simulation Timeouts

If you are running multiple simulations in a loop and are using a variable-step solver, consider using `sim` with the `timeout` parameter. If, for some reason, a simulation hangs or begins to take unexpectedly small time steps, it will time out. Then, the next simulation can run. Example syntax is shown below.

```
N = 100;
simOut = repmat(Simulink.SimulationOutput, N, 1);
for i = 1:N
    simOut(i) = sim('vdp', 'timeout', 1000);
end
```

Capture Simulation Errors

If an error causes your simulation to stop, you can see the error in the simulation metadata. In this case, `sim` captures simulation data in the simulation output object up to the time it encounters the error, enabling you to do some debugging of the simulation without rerunning it. To enable this feature, use the `CaptureErrors` parameter with the `sim` function.

Example syntax and resulting output for capturing errors with `sim` is:

```
simOut = sim('my_model', 'CaptureErrors', 'on');
simOut.getSimulationMetadata.ExecutionInfo

ans =

    struct with fields:

        StopEvent: 'DiagnosticError'
        StopEventSource: []
        StopEventDescription: 'Division by zero in 'my_model/Divide''
        ErrorDiagnostic: [1×1 struct]
```

```
WarningDiagnostics: [0x1 struct]
```

Another advantage of this approach is that the simulation error does not also cause `sim` to stop. Therefore, if you are using `sim` in a `for` loop for example, subsequent iterations of the loop will still run.

Access Simulation Metadata

This example shows you how to access simulation metadata once your simulation is complete.

Run the simulation as described in “Specify Parameter Name-Value Pairs” on page 24-2.

```
simOut = sim('vdp','SimulationMode','normal','AbsTol','1e-5',...
            'SaveState','on','StateSaveName','xoutNew',...
            'SaveOutput','on','OutputSaveName','youtNew',...
            'SaveFormat','StructureWithTime');
```

Access the `ModelInfo` property, which has some basic information about the model and solver.

```
simOut.getSimulationMetadata.ModelInfo
```

```
ans =
```

```
struct with fields:
```

```
    ModelName: 'vdp'
    ModelVersion: '1.6'
    ModelFilePath: 'C:\MyWork'
    UserID: 'User'
    MachineName: 'MyMachine'
    Platform: 'PCWIN64'
    ModelStructuralChecksum: [4x1 uint32]
    SimulationMode: 'normal'
    StartTime: 0
    StopTime: 20
    SolverInfo: [1x1 struct]
    SimulinkVersion: [1x1 struct]
    LoggingInfo: [1x1 struct]
```

Inspect the solver information.

```
simOut.getSimulationMetadata.ModelInfo.SolverInfo
```

```
ans =  
  
  struct with fields:  
  
    Type: 'Variable-Step'  
    Solver: 'ode45'  
    MaxStepSize: 0.4000
```

Review timing information for your simulation, such as when your simulation started and finished, and the time the simulation took to initialize, execute, and terminate.

```
simOut.getSimulationMetadata.TimingInfo
```

```
ans =  
  
  struct with fields:  
  
    WallClockTimestampStart: '2016-06-17 10:26:58.433686'  
    WallClockTimestampStop: '2016-06-17 10:26:58.620687'  
    InitializationElapsedWallTime: 0.1830  
    ExecutionElapsedWallTime: 1.0000e-03  
    TerminationElapsedWallTime: 0.0030  
    TotalElapsedWallTime: 0.1870
```

Add notes to your simulation.

```
simOut=simOut.setUserString('Results from simulation 1 of 10');  
simOut.getSimulationMetadata
```

```
ans =  
  
  SimulationMetadata with properties:  
  
    ModelInfo: [1x1 struct]  
    TimingInfo: [1x1 struct]  
    ExecutionInfo: [1x1 struct]  
    UserString: 'Results from simulation 1 of 10'  
    UserData: []
```

You can also add your own custom data using the `UserData` property.

Control Simulations Programmatically

These examples show you how to use `set_param` and `get_param` to programmatically control a model simulation, check the status of a running simulation, and control simulations using block callbacks.

In this section...

“Control and Check Status of Simulation” on page 24-10

“Automate Simulation Tasks Using Block Callbacks” on page 24-11

Control and Check Status of Simulation

This example shows how to use `set_param` to control and check the status of your simulation.

Start a simulation.

```
set_param('vdp', 'SimulationCommand', 'start')
```

When you start a simulation using `set_param` and the `'start'` argument, you must use the `'stop'` argument to stop it.

Pause, continue, and stop a simulation.

```
set_param('vdp', 'SimulationCommand', 'pause')
set_param('vdp', 'SimulationCommand', 'continue')
set_param('vdp', 'SimulationCommand', 'stop')
```

When you use `set_param` to start, pause, continue or stop a simulation, the commands are requests for such actions and the simulation doesn't execute them immediately. Simulink first completes uninterruptable work, such as solver steps and other commands that preceded the `set_param` command. Then, simulation starts, pauses, continues or stops as specified by the `set_param` command.

Check the status of a simulation.

```
get_param('vdp', 'SimulationStatus')
```

The software returns `'stopped'`, `'initializing'`, `'running'`, `'paused'`, `'compiled'`, `'updating'`, `'terminating'`, or `'external'` (used with the Simulink Coder product).

Update changed workspace variables dynamically while a simulation is running.

```
set_param('vdp','SimulationCommand','update')
```

Write all data-logging variables to the base workspace.

```
set_param('vdp','SimulationCommand','WriteDataLogs')
```

Automate Simulation Tasks Using Block Callbacks

A callback executes when you perform various actions on your model, such as starting, pausing, or stopping a simulation. You can use callbacks to execute a MATLAB script or other MATLAB commands. For more information, see “Callbacks for Customized Model Behavior” on page 4-56 and “Block Callback Parameters” on page 4-62.

This example shows how to use the model `StartFcn` callback to automatically execute MATLAB code before the simulation starts.

Write a MATLAB script that finds Scope blocks in your model and opens them in the foreground when you simulate the model.

```
% openscopes.m
% Brings scopes to forefront at beginning of simulation.

blocks = find_system(bdroot,'BlockType','Scope');

% Finds all of the scope blocks in the top level of your
% model. To find scopes in subsystems, provide the subsystem
% names. Type help find_system for more on this command.

for i = 1:length(blocks)
    set_param(blocks{i},'Open','on')
end

% Loops through all of the scope blocks and brings them
% to the forefront.
```

Set the `StartFcn` parameter for the model to call the script.

```
set_param('my_model','StartFcn','openscopes')
```

Overview of Calling `sim` from Within `parfor`

The `parfor` command allows you to run parallel (simultaneous) Simulink simulations of your model (design). In this context, parallel runs mean multiple model simulations at the same time on different workers. Calling `sim` from within a `parfor` loop often helps for performing multiple simulation runs of the same model for different inputs or for different parameter settings. For example, you can save simulation time performing parameter sweeps and Monte Carlo analyses by running them in parallel. Note that running parallel simulations using `parfor` does not currently support decomposing your model into smaller connected pieces and running the individual pieces simultaneously on multiple workers.

Normal, Accelerator, and Rapid Accelerator simulation modes are supported by `sim` in `parfor`. (See “Choosing a Simulation Mode” on page 32-12 for details on selecting a simulation mode and “Design Your Model for Effective Acceleration” on page 32-18 for optimizing simulation run times.) For other simulation modes, you need to address any workspace access issues and data concurrency issues to produce useful results. Specifically, the simulations need to create separately named output files and workspace variables. Otherwise, each simulation overwrites the same workspace variables and files, or can have collisions trying to write variables and files simultaneously.

For information on code regeneration and parameter handling in Rapid Accelerator mode, see “Parameter Tuning in Rapid Accelerator Mode” on page 32-9.

Also, see `parfor`.

Note: If you open models inside a `parfor` statement, close them again using `bdclose all` to avoid leaving temporary files behind.

The following examples show how to use `sim` in `parfor` using the `sldemo_suspn_3dof` model. To access these examples, from Simulink Documentation Center, click **Examples** > **Modeling Features** and navigate to **Simulation Performance**:

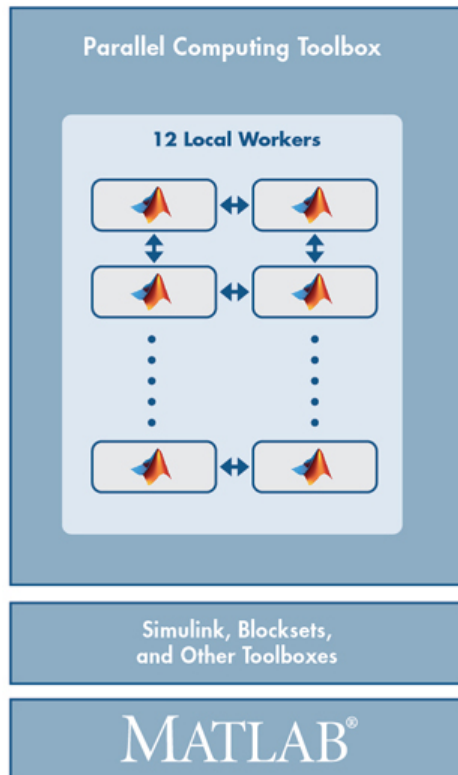

- Parallel Simulations Using Parfor: Test-Case Sweep
- Parallel Simulations Using Parfor: Parameter Sweep in Normal Mode
- Parallel Simulations Using Parfor: Parameter Sweep in Rapid Accelerator Mode

Computationally Intensive Simulations

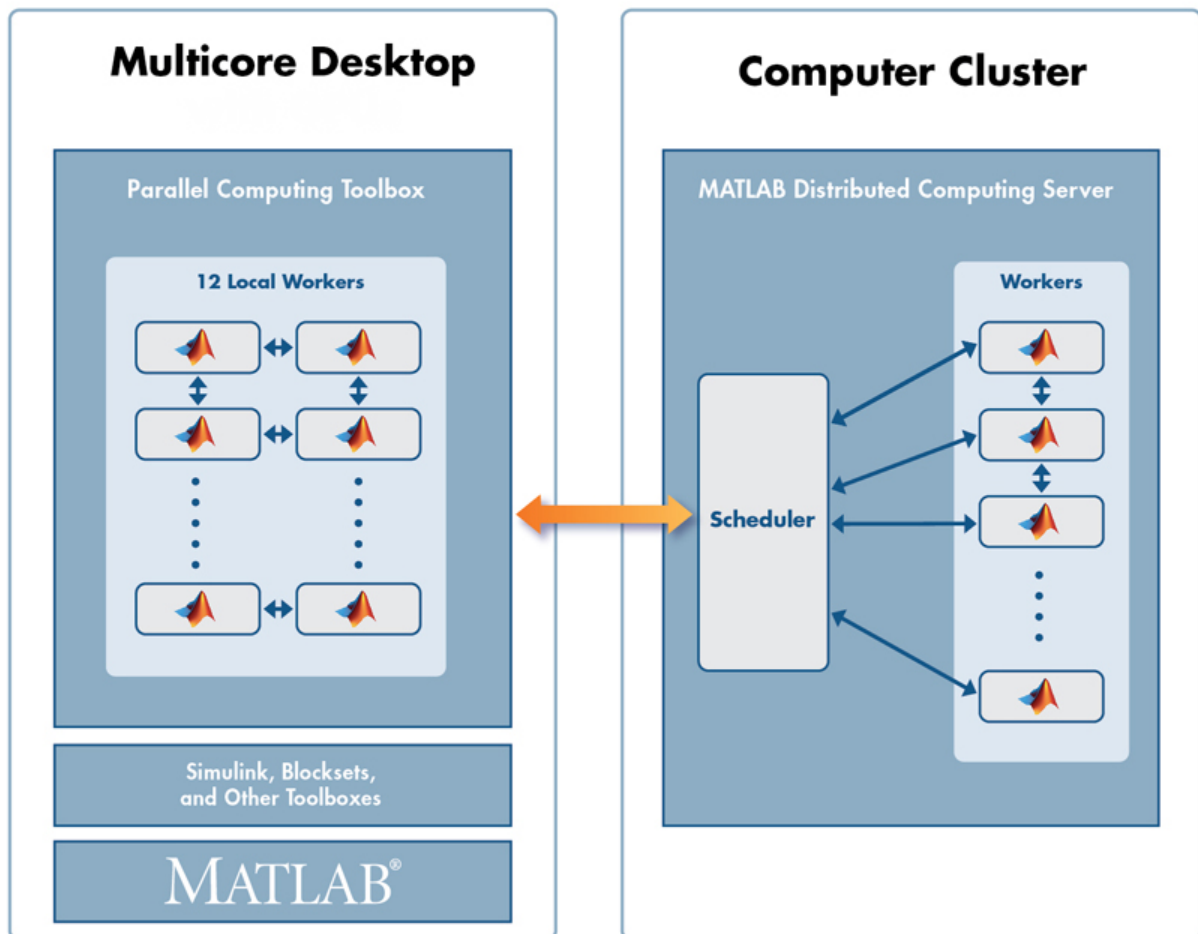

To further improve the performance of multiple simulations of the same model, you can use:

- Multiple designated workers (MATLAB computational engines) using the Parallel Computing Toolbox software

Multicore Desktop

- Multiple computer clusters, clouds, and grids using the MATLAB Distributed Computing Server software

To take advantage of these environments, you can:

- 1 Simulate your model on a single computer.
- 2 When satisfied with single simulation, run multiple simulations in parallel on multiple designated workers on a local multicore desktop.
- 3 When satisfied with multiple simulations on local multicore desktop, run simulations in parallel remotely on computer clusters, clouds, and grids.

Consider the following:

Action	Required Software*			
	MATLAB	Simulink	Parallel Computing Toolbox	MATLAB Distributed Computing Server
Run a single simulation.	✓	✓		
Run multiple simulations simultaneously on your computer.	✓	✓	✓	
Run multiple simulations remotely on a server.	✓	✓	✓	✓

* And other required and optional software

Simulink and Parallel Computing Toolbox Software

Before you run simulations in the Parallel Computing Toolbox environment, see “Parallel Computing Toolbox”. You can use the Parallel Computing Toolbox software to run simulations on a local multicore computer or on multiple remote computers.

- 1 Have a Parallel Computing Toolbox license.
- 2 Run `sim` in `parfor` for your model.

For an example of using `sim` in `parfor` using Normal mode, see “`sim` in `parfor` with Normal Mode” on page 24-18.

For an example of using `sim` in `parfor` using Rapid Accelerator, see “`sim` in `parfor` with Rapid Accelerator Mode” on page 24-21.

Note: Code generation operations for the same model overwrite each other. If you want each worker to generate its own copy of code, attach and distribute the folder to each worker.

You can also use Parallel Computing Toolbox software to run simulations on multiple remote computers or in a nonhomogeneous environment. For these cases, you can use the Parallel Computing Toolbox software with the MATLAB Distributed Computing Server software.

Simulink and MATLAB Distributed Computing Server Software

Before you run simulations in the MATLAB Distributed Computing Server environment, see “MATLAB Distributed Computing Server”.

- 1 Have Parallel Computing Toolbox and MATLAB Distributed Computing Server licenses.
- 2 Select and configure your cluster configuration.
- 3 Use the “Parallel Computing Toolbox” software to create, import, and select a default parallel cluster profile.
- 4 Use the Parallel Computing Toolbox software to run `sim` in `parfor` for your model.

For an example of `sim` in `parfor` with Normal mode using MATLAB Distributed Computing Server software, see “`sim` in `parfor` with Normal Mode and MATLAB Distributed Computing Server Software” on page 24-20.

You can also use `sim` in `parfor` with Rapid Accelerator and MATLAB Distributed Computing Server software (see “`sim` in `parfor` with Rapid Accelerator Mode” on page 24-21). In that example, you build the code once and distribute that generated code to the other local workers. You can adapt “`sim` in `parfor` with Rapid Accelerator Mode” on page 24-21 example for a remote cluster environment by:

- Calling `parpool` with a cluster name as input
- Attaching required files

For an example of how to adapt to a remote cluster environment, see “`sim` in `parfor` with Normal Mode and MATLAB Distributed Computing Server Software” on page 24-20.

`sim` in `parfor` with Normal Mode

This code fragment shows how you can use `sim` and `parfor` in Normal mode. Save changes to your model before simulating in `parfor`. The saved copy of your model is distributed to parallel workers when simulating in `parfor`.

```
% 1) Load model and initialize the pool.  
model = 'sldemo_suspn_3dof';
```

```
load_system(model);
parpool;

% 2) Set up the iterations that we want to compute.
Cf = evalin('base', 'Cf');
Cf_sweep = Cf*(0.05:0.1:0.95);
iterations = length(Cf_sweep);
simout(iterations) = Simulink.SimulationOutput;

% 3) Need to switch all workers to a separate tempdir in case
% any code is generated for instance for StateFlow, or any other
% file artifacts are created by the model.
spmd
    % Setup tempdir and cd into it
    currDir = pwd;
    addpath(currDir);
    tmpDir = tempname;
    mkdir(tmpDir);
    cd(tmpDir);
    % Load the model on the worker
    load_system(model);
end

% 4) Loop over the number of iterations and perform the
% computation for different parameter values.
parfor idx=1:iterations
    set_param([model ' /Road-Suspension Interaction'], 'MaskValues', ...
        {'Kf', num2str(Cf_sweep(idx)), 'Kr', 'Cr'});
    simout(idx) = sim(model, 'SimulationMode', 'normal');
end

% 5) Switch all of the workers back to their original folder.
spmd
    cd(currDir);
    rmdir(tmpDir, 's');
    rmpath(currDir);
    close_system(model, 0);
end

close_system(model, 0);
delete(gcf('ncreate'));
```

sim in parfor with Normal Mode and MATLAB Distributed Computing Server Software

This code fragment is identical to the one in “sim in parfor with Normal Mode” on page 24-18

. Modify it as follows for using `sim` and `parfor` in Normal mode:

- In item 1, modify the `parpool` command as follows to create an object and use it to call a cluster name.

```
p = parpool('clusterProfile');  
% 'clusterProfile' is the name of the distributed cluster
```

- In item 1, find files on which the model depends and attach those files to the model for distribution to cluster workers on remote machines.

```
files = dependencies.fileDependencyAnalysis(modelName);  
p.addAttachedFiles(files);
```

- If you do not have a MATLAB Distributed Computing Server cluster, use your local cluster. For more information, see “Clusters and Cluster Profiles”.

Start your cluster before running the code.

```
% 1) Load model and initialize the pool.
```

```
model = 'sldemo_suspn_3dof';  
load_system(model);  
parpool;
```

```
% 2) Set up the iterations that we want to compute.
```

```
Cf = evalin('base', 'Cf');  
Cf_sweep = Cf*(0.05:0.1:0.95);  
iterations = length(Cf_sweep);  
simout(iterations) = Simulink.SimulationOutput;
```

```
% 3) Need to switch all workers to a separate tempdir in case  
% any code is generated for instance for StateFlow, or any other  
% file artifacts are created by the model.
```

```
spmd  
    % Setup tempdir and cd into it  
    addpath(pwd);  
    currDir = pwd;  
    addpath(currDir);
```

```

    tmpDir = tempname;
    mkdir(tmpDir);
    cd(tmpDir);
    % Load the model on the worker
    load_system(model);
end

% 4) Loop over the number of iterations and perform the
% computation for different parameter values.
parfor idx=1:iterations
    set_param([model '/Road-Suspension Interaction'],'MaskValues',...
        {'Kf',num2str(Cf_sweep(idx)),'Kr','Cr'});
    simout(idx) = sim(model, 'SimulationMode', 'normal');
end

% 5) Switch all of the workers back to their original folder.
spmd
    cd(currDir);
    rmdir(tmpDir,'s');
    rmpath(currDir);
    close_system(model, 0);
end

close_system(model, 0);
delete(gcp('ncreate'));

```

sim in parfor with Rapid Accelerator Mode

Running Rapid Accelerator simulations in `parfor` combines speed with automatic distribution of a prebuilt executable to the `parfor` workers. As a result, this mode eliminates duplication of the update diagram phase.

To run parallel simulations in Rapid Accelerator simulation mode using the `sim` and `parfor` commands:

- Configure the model to run in Rapid Accelerator simulation mode.
- Save changes to your model before simulating in `parfor`. The saved copy of your model is distributed to parallel workers when simulating in `parfor`.
- Ensure that the Rapid Accelerator target is already built and up to date.
- Disable the Rapid Accelerator target up-to-date check by setting the `sim` command option `RapidAcceleratorUpToDateCheck` to `'off'`.

To satisfy the second condition, you can change parameters only between simulations that do not require a model rebuild. In other words, the structural checksum of the model must remain the same. Hence, you can change only tunable block diagram parameters and tunable run-time block parameters between simulations. For a discussion on tunable parameters that do not require a rebuild subsequent to their modifications, see “Determine If the Simulation Will Rebuild” on page 32-9.

To disable the Rapid Accelerator target up-to-date check, use the `sim` command, as shown in this sample.

```
parpool;
% Load the model and set parameters
model = 'vdp';
load_system(model);
% Build the Rapid Accelerator target
rtp = Simulink.BlockDiagram.buildRapidAcceleratorTarget(model);
% Run parallel simulations
parfor i=1:4
    simOut{i} = sim(model,'SimulationMode', 'rapid',...
        'RapidAcceleratorUpToDateCheck', 'off',...
        'SaveTime', 'on',...
        'StopTime', num2str(10*i));
    close_system(model, 0);
end

close_system(model, 0);
delete(gcp('nocreate'));
```

In this example, the call to the `buildRapidAcceleratorTarget` function generates code once. Subsequent calls to `sim` with the `RapidAcceleratorUpToDateCheck` option `off` guarantees that code is not regenerated. Data concurrency issues are thus resolved.

When you set `RapidAcceleratorUpToDateCheck` to `'off'`, changes that you make to block parameter values in the model (for example, by using block dialog boxes, by using the `set_param` function, or by changing the values of MATLAB variables) do not affect the simulation. Instead, use `RapidAcceleratorParameterSets` to pass new parameter values directly to the simulation.

For a detailed example of this method of running parallel simulations, refer to the Rapid Accelerator Simulations Using PARFOR.

Workspace Access Issues

Workspace Access for MATLAB worker sessions

By default, to run `sim` in `parfor`, a parallel pool opens automatically, enabling the code to run in parallel. Alternatively, you can also first open MATLAB workers using the `parpool` command. The `parfor` command then runs the code within the `parfor` loop in these MATLAB worker sessions. The MATLAB workers, however, do not have access to the workspace of the MATLAB client session where the model and its associated workspace variables have been loaded. Hence, if you load a model and define its associated workspace variables outside of and before a `parfor` loop, then neither is the model loaded, nor are the workspace variables defined in the MATLAB worker sessions where the `parfor` iterations are executed. This is typically the case when you define model parameters or external inputs in the base workspace of the client session. These scenarios constitute workspace access issues.

Transparency Violation

When you run `sim` in `parfor` with `srcWorkspace` set to `current`, Simulink uses the `parfor` workspace, which is a transparent workspace. Simulink then displays an error for transparency violation. For more information on transparent workspaces, see “Specify Variables in `parfor`-Loops”.

Resolving Workspace Access Issues

When a Simulink model is loaded into memory in a MATLAB client session, it is only visible and accessible in that MATLAB session; it is not accessible in the memory of the MATLAB worker sessions. Similarly, the workspace variables associated with a model that are defined in a MATLAB client session (such as parameters and external inputs) are not automatically available in the worker sessions. You must therefore ensure that the model is loaded and that the workspace variables referenced in the model are defined in the MATLAB worker session by using the following two methods.

- In the `parfor` loop, use the `sim` command to load the model and to set parameters that change with each iteration. (Alternative: load the model and then use the `g(s)et_param` command(s) to set the parameters in the `parfor` loop)
- In the `parfor` loop, use the MATLAB `evalin` and `assignin` commands to assign data values to variables.

Alternatively, you can simplify the management of workspace variables by defining them in the model workspace. These variables will then be automatically loaded when the

model is loaded into the worker sessions. There are, however, limitations to this method. For example, you cannot store parameter objects that use a storage class other than `Auto` in a model workspace. For a detailed discussion on the model workspace, see “Model Workspaces” on page 4-71.

Specifying Parameter Values Using the `sim` Command

Use the `sim` command in the `parfor` loop to set parameters that change with each iteration.

`%Specifying Parameter Values Using the sim Command`

```
model = 'vdp';
load_system(model)

%Specifying parameter values.
paramName = 'StopTime';
paramValue = {'10', '20', '30', '40'};

% Run parallel simulations
parfor i=1:4
    simOut{i} = sim(model, ...
                    paramName, paramValue{i}, ...
                    'SaveTime', 'on'); %#ok
end

close_system(model, 0);
```

An equivalent method is to load the model and then use the `set_param` command to set the `paramName` in the `parfor` loop.

Specifying Variable Values Using the `assignin` Command

You can pass the values of model or simulation variables to the MATLAB workers by using the `assignin` or the `evalin` command. The following example illustrates how to use this method to load variable values into the appropriate workspace of the MATLAB workers.

```
parfor i = 1:4
    assignin('base', 'extInp', paramValue{i})%#ok
    % 'extInp' is the name of the variable in the base
    % workspace which contains the External Input data
    simOut{i} = sim(model, 'ExternalInput', 'extInp'); %#ok
```

end

For further details, see the Rapid Accelerator Simulations Using PARFOR example.

Data Concurrency Issues

Data concurrency issues refer to scenarios for which software makes simultaneous attempts to access the same file for data input or output. In Simulink, they primarily occur as a result of the nonsequential nature of the `parfor` loop during simultaneous execution of Simulink models. The most common incidences arise when code is generated or updated for a simulation target of a Stateflow, Model block or MATLAB Function block during parallel computing. The cause, in this case, is that Simulink tries to concurrently access target data from multiple worker sessions. Similarly, To File blocks may simultaneously attempt to log data to the same files during parallel simulations and thus cause I/O errors. Or a third-party blockset or user-written S-function may cause a data concurrency issue while simultaneously generating code or files.

A secondary cause of data concurrency is due to the unprotected access of network ports. This type of error occurs, for example, when a Simulink product provides blocks that communicate via TCP/IP with other applications during simulation. One such product is the HDL Verifier™ for use with the Mentor Graphics® ModelSim® HDL simulator.

Resolving Data Concurrency Issues

The core requirement of `parfor` is the independence of the different iterations of the `parfor` body. This restriction is not compatible with the core requirement of simulation via incremental code generation, for which the simulation target from a prior simulation is reused or updated for the current simulation. Hence during the parallel simulation of a model that involves code generation (such as Accelerator mode simulation), Simulink makes concurrent attempts to access (update) the simulation target. However, you can avoid such data concurrency issues by creating a temporary folder within the `parfor` loop and then adding several lines of MATLAB code to the loop to perform the following steps:

- 1 Change the current folder to the temporary, writable folder.
- 2 In the temporary folder, load the model, set parameters and input vectors, and simulate the model.
- 3 Return to the original, current folder.

4 Remove the temporary folder and temporary path.

In this manner, you avoid concurrency issues by loading and simulating the model within a separate temporary folder. Following are examples that use this method to resolve common concurrency issues.

A Model with Stateflow, MATLAB Function Block, or Model Block

In this example, either the model is configured to simulate in Accelerator mode or it contains a Stateflow, a MATLAB Function block, or a Model block (for example, `sf_bounce`, `sldemo_autotrans`, or `sldemo_mdhref_basic`). For these cases, Simulink generates code during the initialization phase of simulation. Simulating such a model in `parfor` would cause code to be generated to the same files, while the initialization phase is running on the worker sessions. As illustrated below, you can avoid such data concurrency issues by running each iteration of the `parfor` body in a different temporary folder.

```
parfor i=1:4
    cwd = pwd;
    addpath(cwd)
    tmpdir = tempname;
    mkdir(tmpdir)
    cd(tmpdir)
    load_system(model)
    % set the block parameters, e.g., filename of To File block
    set_param(someBlkInMdl, blkParamName, blkParamValue{i})
    % set the model parameters by passing them to the sim command
    out{i} = sim(model, mdlParamName, mdlParamValue{i});
    close_system(model,0);
    cd(cwd)
    rmdir(tmpdir, 's')
    rmpath(cwd)
end
```

Note the following:

- You can also avoid other concurrency issues due to file I/O errors by using a temporary folder for each iteration of the `parfor` body.
- On Windows platforms, consider inserting the `evalin('base', 'clear mex');` command before `rmdir(tmpdir, 's')`. This sequence closes MEX-files first before calling `rmdir` to remove `tmpdir`.

```
evalin('base', 'clear mex');
```

```
rmdir(tmpdir, 's')
```

A Model with To File Blocks

If you simulate a model with To File blocks from inside of a `parfor` loop, the nonsequential nature of the loop may cause file I/O errors. To avoid such errors during parallel simulations, you can either use the temporary folder idea above or use the `sim` command in Rapid Accelerator mode with the option to append a suffix to the file names specified in the model To File blocks. By providing a unique suffix for each iteration of the `parfor` body, you can avoid the concurrency issue.

```
rtp = Simulink.BlockDiagram.buildRapidAcceleratorTarget(model);  
    parfor idx=1:4  
        sim(model, ...  
            'ConcurrencyResolvingToFileSuffix', num2str(idx),...  
            'SimulationMode', 'rapid',...  
            'RapidAcceleratorUpToDateCheck', 'off');  
    end
```

Error Handling in Simulink Using MSLException

Error Reporting in a Simulink Application

Simulink allows you to report an error by throwing an exception using the `MSLException` object, which is a subclass of the MATLAB `MException` class. As with the MATLAB `MException` object, you can use a `try-catch` block with a `MSLException` object construct to capture information about the error. The primary distinction between the `MSLException` and the `MException` objects is that the `MSLException` object has the additional property of `handles`. These handles allow you to identify the object associated with the error.

The MSLException Class

The `MSLException` class has five properties: `identifier`, `message`, `stack`, `cause`, and `handles`. The first four of these properties are identical to those of `MException`. For detailed information about them, see “Properties of the `MException` Class”. The fifth property, `handles`, is a cell array with elements that are double array. These elements contain the handles to the Simulink objects (blocks or block diagrams) associated with the error.

Methods of the MSLException Class

The methods for the `MSLException` class are identical to those of the `MException` class. For details of these methods, see `MException`.

Capturing Information about the Error

The structure of the Simulink `try-catch` block for capturing an exception is:

```
try
    Perform one or more operations
catch E
    if isa(E, 'MSLException')
    ...
end
```

If an operation within the `try` statement causes an error, the `catch` statement catches the exception (*E*). Next, an `if isa` conditional statement tests to determine if the

exception is Simulink specific, i.e., an `MSLEException`. In other words, an `MSLEException` is a type of `MException`.

The following code example shows how to get the handles associated with an error.

```
errHndls = [];
try
    sim('ModelName', ParamStruct);
catch e
    if isa(e,'MSLEException')
        errHndls = e.handles{1}
    end
end
```

You can see the results by examining `e`. They will be similar to the following output:

```
e =
MSLEException

Properties:
    handles: {[7.0010]}
    identifier: 'Simulink:Parameters:BlkParamUndefined'
    message: [1x87 char]
    cause: {0x1 cell}
    stack: [0x1 struct]

Methods, Superclasses
```

To identify the name of the block that threw the error, use the `getfullname` command. For the present example, enter the following command at the MATLAB command line:

```
getfullname(errHndls)
```

If a block named `Mu` threw an error from a model named `vdp`, MATLAB would respond to the `getfullname` command with:

```
ans =
vdp/Mu
```

Prototype and Debug Models with Scopes

Simulink Scope blocks and Scope viewers offer a quick and lightweight way to visualize your simulation data over time. If you are prototyping a model design, you can attach signals to a Scope block. After simulating the model, you can use the results to validate your design. See “Scope Blocks and Scope Viewer Overview” on page 25-8 and “Integrate a House Heating Model”.

A Scope block or Scope viewer opens to a Scope window where you can display and evaluate simulation data.

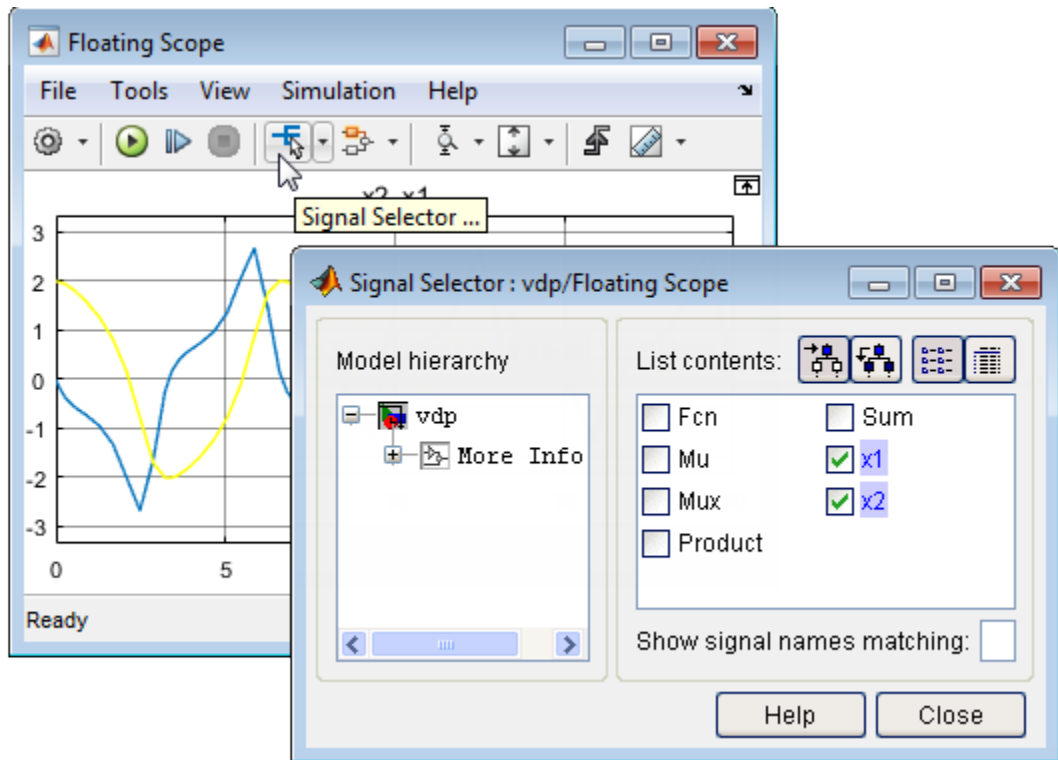

The toolbar contains controls for starting, stopping, and stepping forward through a simulation . You can use these controls to debug a model by viewing signal data at each time interval. See “How Stepping Through a Simulation Works” on page 2-3.

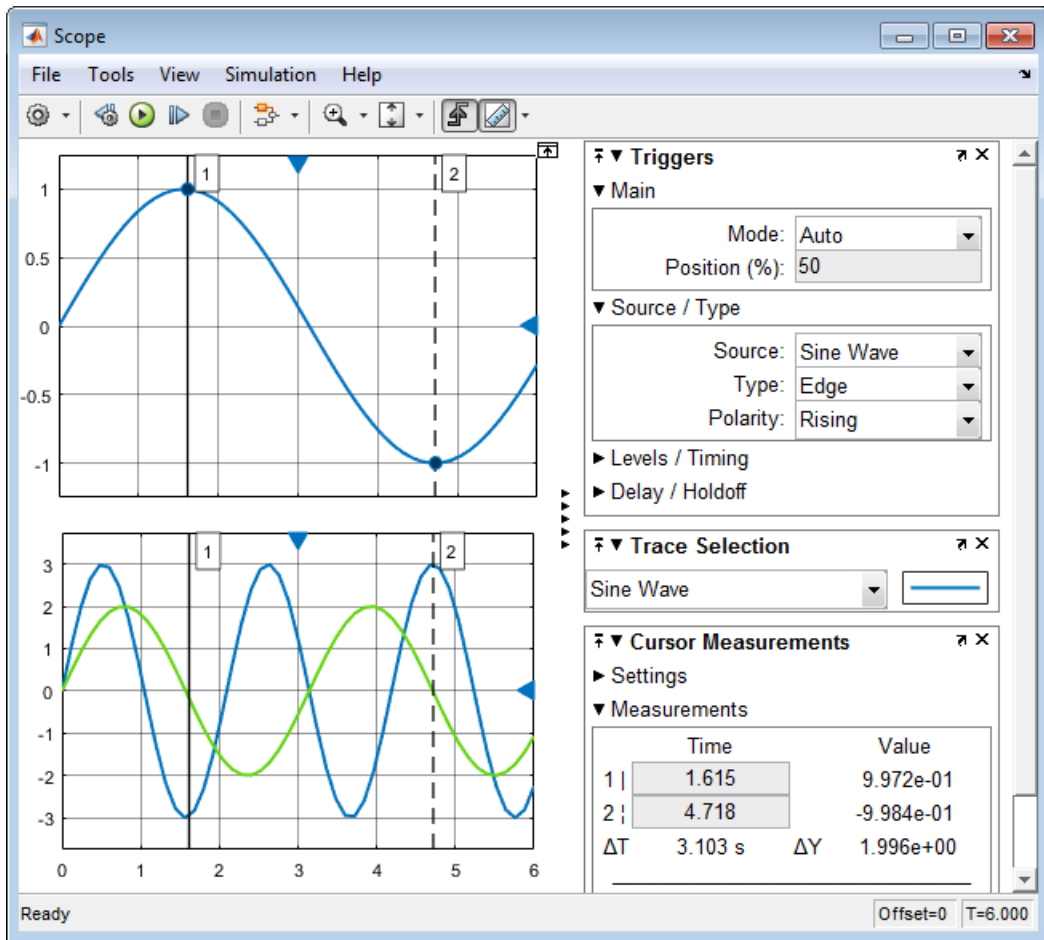

Connect signal lines to a Scope block using multiple input ports. See “Number of input ports” in Scope block reference.

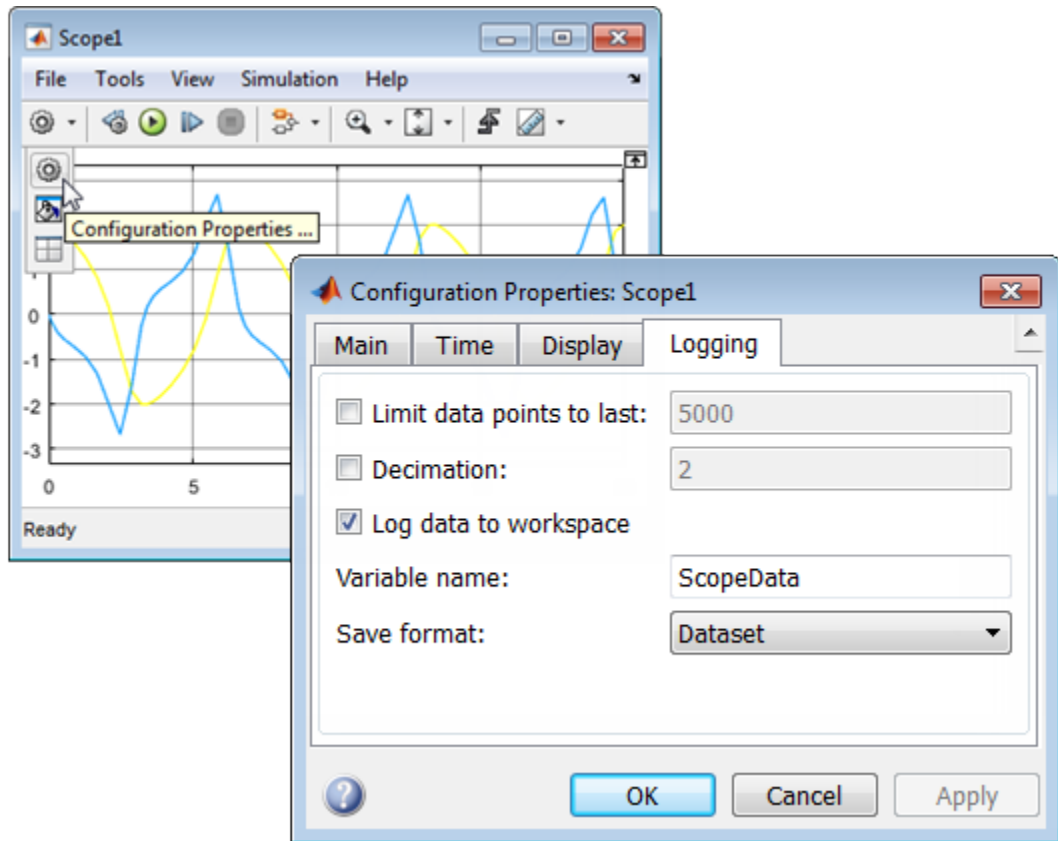

Attach signals to a Floating Scope block or signal viewer using a signal selector tool that hierarchically displays all signals in a model. See “Signal Selector” on page 25-77.

Use the oscilloscope-like tools available with a scope to debug your model. Set triggers to capture events, use interactive cursors to measure signal values at various points, and review signal statistics such as maximum and mean values. See “Scope Triggers Panel” on page 25-16 and “Scope Cursor Measurements Panel” on page 25-30.

Save or log signal data to the MATLAB workspace, and then plot data in a MATLAB figure window. Use MATLAB functions or your own scripts to analyze the data. See “Save Simulation Data Using Floating Scope Block” on page 25-67.

Scope Blocks and Scope Viewer Overview

In this section...

“Overview of Methods” on page 25-8

“Simulink Scope Versus Floating Scope” on page 25-9

“Simulink Scope Versus DSP System Toolbox Time Scope” on page 25-11

Overview of Methods

Simulink scopes provide several methods for displaying simulation data and capturing the data for later analysis. Symbols on your block diagram represent the various data display and data capture methods.

For more information about these methods:

- Scope and Floating Scope blocks — Scope, Floating Scope, “Scope Tasks” on page 25-54, “Floating Scope and Scope Viewer Tasks” on page 25-65.
- Scope Viewer — “Signal and Scope Manager” on page 25-73, “Floating Scope and Scope Viewer Tasks” on page 25-65.
- Signal Logging — “Save Simulation Data Using Floating Scope Block” on page 25-67.
- Signal Test Point — “Test Points” on page 62-55.

Simulink Scope Versus Floating Scope

Scope blocks and Floating Scope blocks both display simulation results, but they differ in how you attach signals and save data. Simulation behavior for a Floating Scope and a Scope Viewer is identical, but you manage them differently in your model.

Capability	Simulink Scope	Simulink Floating Scope	Simulink Scope Viewer
Attaching signals	Connect signal lines to a Scope block using input ports.	Attach signals using the Signal Selector. See “Signal Selector” on page 25-77. Attach signals interactively from the model before and during a simulation. See “View Signals on a Floating Scope Quickly” on page 25-69.	Attach signals using the Signal Selector or signal line context menu.
Access to signals	Because signals lines are connected to a Scope block, access signals at different levels of a model hierarchy using GoTo blocks.	Because signals are attached without signal lines, you do not have to route lines to a Floating Scope block. You can access most signals inside the model hierarchy, including referenced models and Stateflow charts. You cannot access optimized signals.	Scope viewers are attached to signal lines.
Data logging	Save data to a MATLAB variable as	Save data to a MATLAB variable as an object.	

Capability	Simulink Scope	Simulink Floating Scope	Simulink Scope Viewer
	an array, structure, or object.		
Simulation control	Run, forward, and back toolbar buttons.	Run and forward toolbar buttons. A Floating Scope window does not have a toolbar Back button. If you use the Back button from your model, stepping back appears to work due to the data buffer, but it does not work in all cases.	Run, forward, and back toolbar buttons.
Scale axes after simulation	Toolbar buttons to Scale X-axis and Y-axis limits Axes scaling set to Auto for the X-axis and Y-axis.	Toolbar button to scale only the Y-axis limits, and Axes scaling set to Auto for only the Y-axis.	Toolbar buttons to Scale X-axis and Y-axis limits Axes scaling set to Auto for the X-axis and Y-axis.
Add to model	Add block from Simulink sinks library.	Add block from Simulink sinks library.	Add using Signal & Scope Manager. See “Signal and Scope Manager” on page 25-73.
Visual indication in model		Floating Scope block not attached to any signal lines.	Viewer icons located above signal lines for all attached signals.
Manage scopes centrally	No.	No.	Use the Signal & Scope Manager to add or delete viewers, and attach or remove signals.

Capability	Simulink Scope	Simulink Floating Scope	Simulink Scope Viewer
Manage scopes locally	Attach signal lines to Scope block in ports.	Attach signals from the Floating Scope window.	Add viewers and attach additional signals within a model hierarchy using the context menus.
Simulink Report Generator support	Yes.	Yes.	No.
Connecting Constant block with Sample time set to <code>inf</code> (constant sample time)		Plots all data values.	Plots the data value at the first time step and anytime you tune a parameter.

Simulink Scope Versus DSP System Toolbox Time Scope

If you have Simulink and a DSP System Toolbox license, you can use either the Simulink Scope or DSP System Toolbox Time Scope. Choose the scope based on your application requirements, how the blocks work, and the default values of each block.

If you have a DSP System Toolbox license and you have been using Time Scopes, continue to do so in your applications. Using the Time Scope block requires a DSP System Toolbox license.

Feature	Scope	Time Scope
Location in block library	Simulink Sinks library	DSP System Toolbox Sinks library
Trigger and measurement panels	With Simulink only: <ul style="list-style-type: none"> • Trigger • Cursor Measurement With DSP System Toolbox or Simscape license: <ul style="list-style-type: none"> • Signal Statistics 	<ul style="list-style-type: none"> • Trigger • Cursor Measurements • Signal Statistics • Bilevel Measurements • Peak Finder

Feature	Scope	Time Scope
	<ul style="list-style-type: none"> • Bilevel Measurements • Peak Finder

Debugging a Model with Scope Blocks

There are different types of triggering techniques available in with a Scope block. You can choose one over the other depending on your application. Some of the important triggering techniques available in with a Scope include:

- **Edge Trigger:** Use edge triggering to stabilize a repetitive waveform and search for a occurrence of a particular pattern in the signal. Using the edge triggering technique, one can stabilize a repetitive signal based on occurrence of edge in a signal and then measure important attributes of a signal like Rise Time, Fall Time, Peak to peak voltage, RMS voltage etc.
- **Pulse width triggering:** Using this technique, you can set the Scope to trigger, for example, on the occurrence of a glitch – a pulse which is faster / slower than the reference pulse. This ability can help one investigate the properties of the glitch and do some investigation on the root cause of the glitch
- **Runt triggering:** Using the Runt Triggering, one can set the Scope to trigger for pulses whose amplitude crosses one of the two voltage threshold but not both and whose pulse width lies in a specific predefined time range. This is very useful in debugging the Runt Signals frequently encountered in troubleshooting Digital integrated Circuits.

Runt signals are the signals which typically cross a voltage threshold level but fail to cross a second threshold before re-crossing the first threshold level. Runt signals are frequently encountered in digital circuits.

To look for Runt signals, enable the Trigger, set the Trigger Mode to Normal, set the trigger type as Runt, adjust the voltage threshold and then view if the Scope detects and displays the presence of any runt signals in the incoming data stream.

“Main Pane” on page 25-17

“Source/Type and Levels/Timing Panes” on page 25-17

“Hysteresis of Trigger Signals” on page 25-27

“Delay/Holdoff Pane” on page 25-28

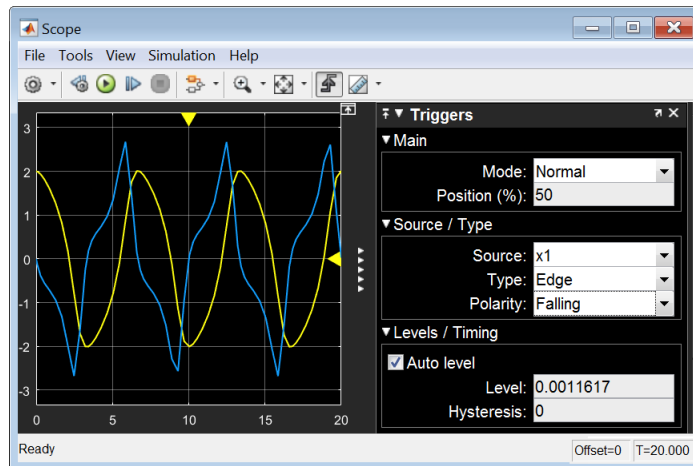

What Is the Trigger Panel

The Trigger panel defines a trigger event to synchronize simulation time with input signals. You can use trigger events to stabilize periodic signals such as a sine wave or capture non-periodic signals such as a pulse that occurs intermittently.

To open the Trigger panel:

- 1 Open a Scope block window.
- 2 On the toolbar, click the Triggers button .
- 3 Run a simulation.

Triangle trigger pointers indicate the trigger time ▼ and trigger level ◀ of an event. The marker color corresponds to the color of the source signal.

Main Pane

Mode — Specify when the display updates.

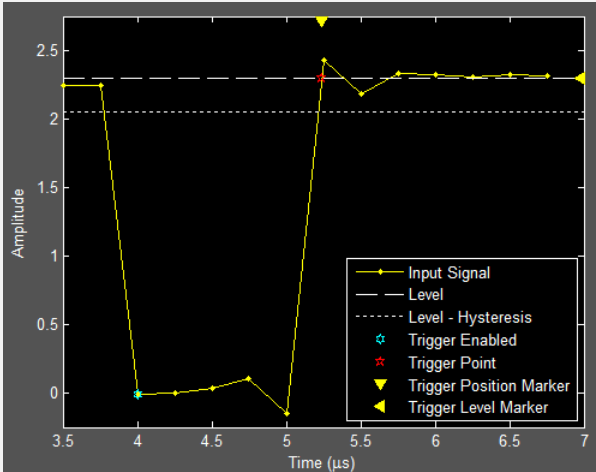

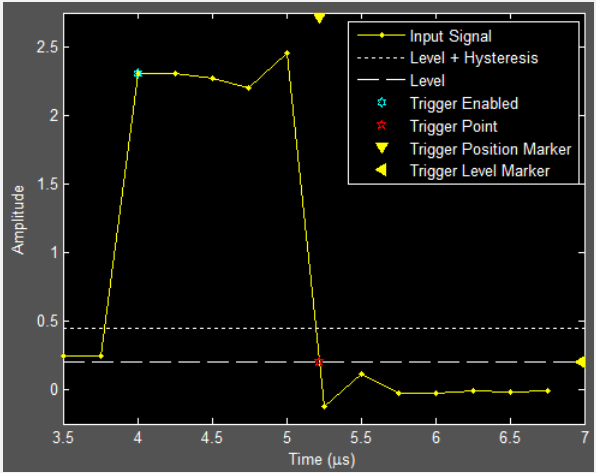

- **Auto** — Display data from the last trigger event. If no event occurs after one time span, display the last available data.
- **Normal** — Display data from the last trigger event. If no event occurs, the display remains blank.
- **Once** — Display data from the last trigger event and freeze the display. If no event occurs, the display remains blank. Click the **Rearm** button to look for the next trigger event.
- **Off** — Disable triggering.

Position (%) — Specify the position of the time pointer along the y-axis. You can also drag the time pointer to the left or right to adjust its position.

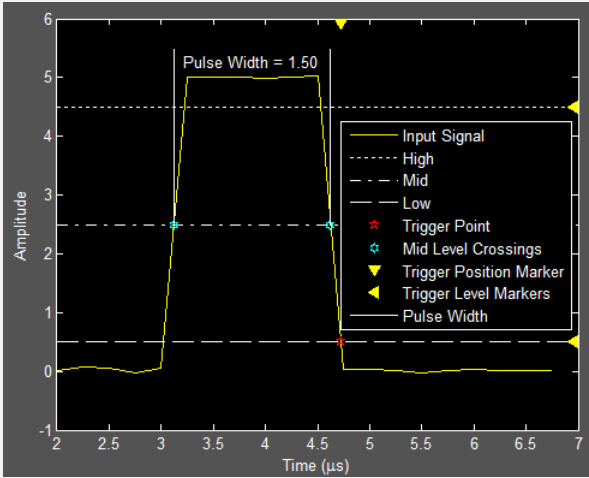

Source/Type and Levels/Timing Panes

Source — Select a trigger signal. For magnitude and phase plots, select either the magnitude or the phase.

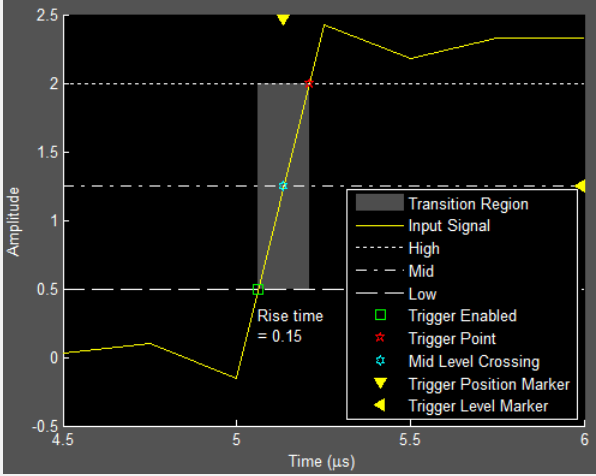

Type — Select the type of trigger.

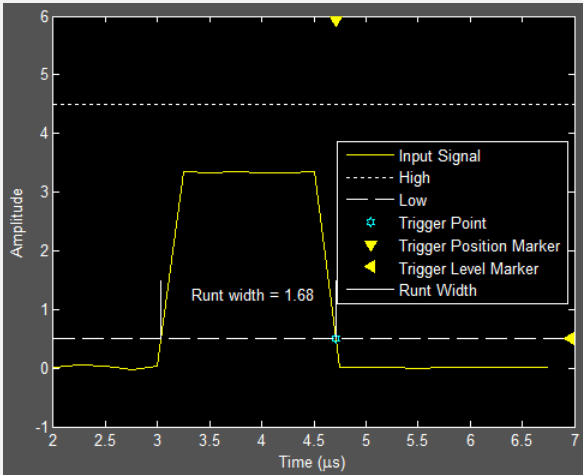

Trigger Type	Trigger Parameters
<p>Edge — Trigger when the signal crosses a threshold.</p>	<p>Polarity — Select the polarity for an edge-triggered signal.</p> <ul style="list-style-type: none"> • Rising — Trigger when the signal is increasing.  <ul style="list-style-type: none"> • Falling — Trigger when the signal value is decreasing.  <ul style="list-style-type: none"> • Either — Trigger when the signal is increasing or decreasing.

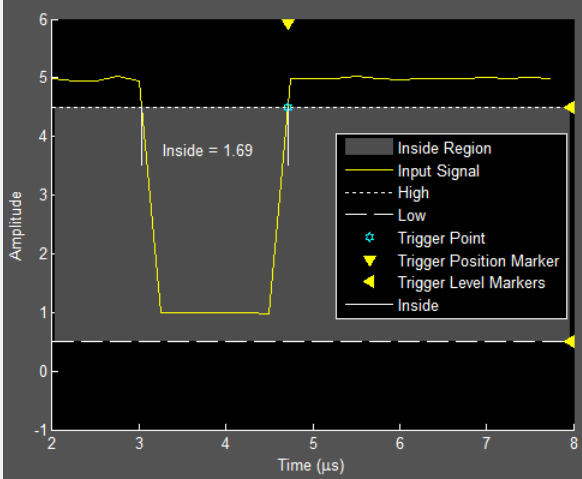

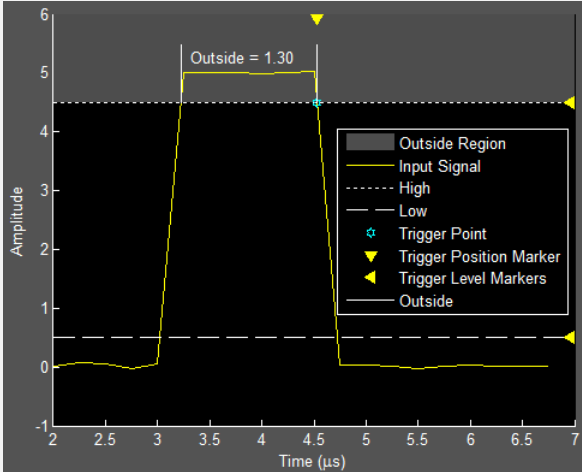

Trigger Type	Trigger Parameters
	<p data-bbox="541 303 1302 361">Level — Enter a threshold value for an edge triggered signal. Auto level is 50%</p> <p data-bbox="541 390 1302 453">Hysteresis — Enter a value for an edge-triggered signal. See “Hysteresis of Trigger Signals” on page 25-27</p>

Trigger Type	Trigger Parameters
<p>Pulse Width — Trigger when the signal crosses a low threshold and a high threshold twice within a specified time.</p>	<p>Polarity — Select the polarity for a pulse width-triggered signal.</p> <ul style="list-style-type: none"> • Positive — Trigger on a positive-polarity pulse when the pulse crosses the low threshold for a second time.  <ul style="list-style-type: none"> • Negative — Trigger on a negative-polarity pulse when the pulse crosses the high threshold for a second time. • Either — Trigger on both positive-polarity and negative-polarity pulses.
	<p>Note: A glitch-trigger is a special type of a pulse width-trigger. A glitch-Trigger occurs for a pulse or spike whose duration is less than a specified amount. You can implement a glitch trigger by using a pulse width-trigger and setting the Max Width parameter to a small value.</p>
	<p>High — Enter a high value for a pulse width-triggered signal. Auto level is 90%.</p>

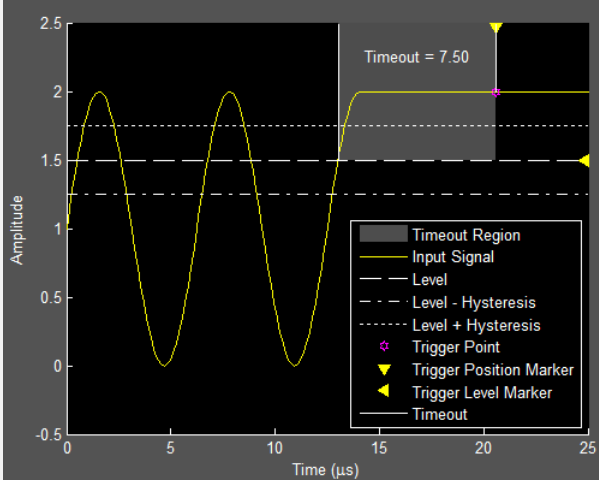

Trigger Type	Trigger Parameters
	<p data-bbox="541 303 1283 355">Low — Enter a low value for a pulse width-triggered signal. Auto level is 10%.</p> <p data-bbox="541 390 1283 477">Min Width — Enter the minimum pulse-width for a pulse width triggered signal. Pulse width is measured between the first and second crossings of the middle threshold.</p> <p data-bbox="541 512 1283 564">Max Width — Enter the maximum pulse width for a pulse width triggered signal.</p>

Trigger Type	Trigger Parameters
<p>Transition — Trigger on the rising or falling edge of a signal that crosses the high and low levels within a specified time range.</p>	<p>Polarity — Select the polarity for a transition-triggered signal.</p> <ul style="list-style-type: none"> • Rise Time — Trigger on an increasing signal when the signal crosses the high threshold.  <ul style="list-style-type: none"> • Fall Time — Trigger on a decreasing signal when the signal crosses the low threshold. • Either — Trigger on an increasing or decreasing signal. <p>High — Enter a high value for a transition-triggered signal. Auto level is 90%.</p> <p>Low — Enter a low value for a transition-triggered signal. Auto level is 10%.</p> <p>Min Time — Enter a minimum time duration for a transition-triggered signal.</p> <p>Max Time — Enter a maximum time duration for a transition-triggered signal.</p>

Trigger Type	Trigger Parameters
<p>Runt— Trigger when a signal crosses a low threshold or a high threshold twice within a specified time.</p>	<p>Polarity — Select the polarity for a runt-triggered signal.</p> <ul style="list-style-type: none"> • Positive — Trigger on a positive-polarity pulse when the signal crosses the low threshold a second time, without crossing the high threshold.  <ul style="list-style-type: none"> • Negative — Trigger on a negative-polarity pulse. • Either — Trigger on both positive-polarity and negative-polarity pulses. <p>High — Enter a high value for a runt-triggered signal. Auto level is 90%.</p> <p>Low — Enter a low value for a runt-triggered signal. Auto level is 10%.</p> <p>Min Width — Enter a minimum width for a runt-triggered signal. Pulse width is measured between the first and second crossing of a threshold.</p> <p>Max Width — Enter a maximum pulse width for a runt-triggered signal.</p>

Trigger Type	Trigger Parameters
<p>Window — Trigger when a signal stays within or outside a region defined by the high and low thresholds for a specified time.</p>	<p>Polarity — Select the region for a window-triggered signal.</p> <ul style="list-style-type: none"> <p>Inside — Trigger when a signal leaves a region between the low and high levels.</p>  <p>Outside — Trigger when a signal enters a region between the low and high levels.</p> 

Trigger Type	Trigger Parameters
	<ul style="list-style-type: none"><li data-bbox="543 305 1297 357">• Either — Trigger when a signal leaves or enters a region between the low and high levels. <p data-bbox="543 392 1326 444">High — Enter a high value for a window-triggered signal. Auto level is 90%.</p> <p data-bbox="543 479 1282 531">Low — Enter a low value for a window-trigger signal. Auto level is 10%.</p> <p data-bbox="543 565 1311 618">Min Time — Enter the minimum time duration for a window-triggered signal.</p> <p data-bbox="543 652 1320 704">Max Time — Enter the maximum time duration for a window-triggered signal.</p>

Trigger Type	Trigger Parameters
<p>Timeout — Trigger when a signal stays above or below a threshold longer than a specified time</p>	<p>Polarity — Select the polarity for a timeout-triggered signal.</p> <ul style="list-style-type: none"> • Rising — Trigger when the signal does not cross the threshold from below. For example, if you set Timeout to 7.50 seconds, the scope triggers 7.50 seconds after the signal crosses the threshold.  <ul style="list-style-type: none"> • Falling — Trigger when the signal does not cross the threshold from above. • Either — Trigger when the signal does not cross the threshold from either direction <p>Level — Enter a threshold value for a timeout-triggered signal.</p> <p>Hysteresis — Enter a value for a timeout-triggered signal. See “Hysteresis of Trigger Signals” on page 25-27.</p> <p>Timeout — Enter a time duration for a timeout-triggered signal.</p> <p>Alternatively, a trigger event can occur when the signal stays within the boundaries defined by the hysteresis for 7.50 seconds after the signal crosses the threshold.</p>

Hysteresis of Trigger Signals

Hysteresis (V) — Specify the hysteresis or noise reject value. This parameter is visible when you set **Type** to **Edge** or **Timeout**. If the signal jitters inside this range and briefly crosses the trigger level, the scope does not register an event. In the case of an edge trigger with rising polarity, the scope ignores the times that a signal crosses the trigger level within the hysteresis region.

You can reduce the hysteresis region size by decreasing the hysteresis value. If you set the hysteresis value to 0.07 in this example, then the scope also considers the second rising edge to be a trigger event, as shown in the following figure.

Delay/Holdoff Pane

Offset the trigger position by a fixed delay, or set the minimum possible time between trigger events.

- **Delay (s)** — Specify the fixed delay time by which to offset the trigger position. This parameter controls the amount of time the scope waits after a trigger event occurs before displaying a signal.
- **Holdoff (s)** — Specify the minimum possible time between trigger events. This amount of time is used to suppress data acquisition after a valid trigger event has occurred. A trigger holdoff prevents repeated occurrences of a trigger from occurring during the relevant portion of a burst.

- **Waveform Cursors** — Select vertical cursors attached to input signals.
- **1** — From the drop-down list, select an input signal for first waveform cursor.

- **2** — From the drop-down list, select an input signal for second waveform cursor.
- **Lock Cursor Spacing** — Lock the time and value difference between the two cursors.
- **Snap to Data** — Position waveform cursors on signal data points.

Measurements Pane

The Measurements pane is part of the Cursor Measurements panel.

The Measurements pane is part of the Cursor Measurements panel.

The screenshot shows a window titled "Cursor Measurements" with a "Settings" button and a "Measurements" section. The "Measurements" section contains a table with two columns: "Time" and "Value". The table has two rows for cursors 1 and 2, and a row for the difference between them. Below the table, there are two rows of calculated values: "1 / ΔT" and "ΔV / ΔT".

	Time	Value
1	5.000	-838.389 m
2	15.000	852.448 m
ΔT	10.000 s	ΔV 1.691
<hr/>		
	1 / ΔT	100.000 mHz
	ΔV / ΔT	169.084 V/ks

Display time and value measurements.

- **1 |**— Shows or enables you to modify the time or value at cursor number one, or both.
- **2 |**— Shows or enables you to modify the time or value at cursor number two, or both.
- **Δt**— Shows the absolute value of the difference in the times between cursor number one and cursor number two.
- **ΔV**— Shows the absolute value of the difference in signal amplitudes between cursor number one and cursor number two.
- **1/Δt**— Shows the rate, the reciprocal of the absolute value of the difference in the times between cursor number one and cursor number two.
- **ΔV/Δt**— Shows the slope, the ratio of the absolute value of the difference in signal amplitudes between cursors to the absolute value of the difference in the times between cursors.

Scope Signal Statistics Panel

Note: The Signal Statistics panel requires a DSP System Toolbox or Simscape license.

Display signal statistics for the signal selected in the **Trace Selection** panel. To open the Signal Statistics panel:

- From the menu, select **Tools > Measurements > Signal Statistics**.
- On the toolbar, click the Signal Statistics  button.

Signal Statistics		
	Value	Time
Max	2.011	20.000
Min	-2.008	16.596
Peak to Peak	4.019	
Mean	182.407 m	
Median	401.438 m	
RMS	1.568	

The statistics shown are:

- **Max** — Shows the maximum or largest value within the displayed portion of the input signal.
- **Min** — Shows the minimum or smallest value within the displayed portion of the input signal.
- **Peak to Peak** — Shows the difference between the maximum and minimum values within the displayed portion of the input signal.
- **Mean** — Shows the average or mean of all the values within the displayed portion of the input signal.
- **Median** — Shows the median value within the displayed portion of the input signal.
- **RMS** — Shows the difference between the maximum and minimum values within the displayed portion of the input signal.

When you use the zoom options in the Scope, the Signal Statistics measurements automatically adjust to the time range shown in the display. In the Scope toolbar, click

the **Zoom In** or **Zoom X** button to constrict the x -axis range of the display, and the statistics shown reflect this time range. For example, you can zoom in on one pulse to make the **Signal Statistics** panel display information about only that particular pulse.

The Signal Statistics measurements are valid for any units of the input signal. The letter after the value associated with each measurement represents the appropriate International System of Units (SI) prefix, such as m for *milli*-. For example, if the input signal is measured in volts, an m next to a measurement value indicates that this value is in units of millivolts. The SI prefixes are shown in the following table:

Scope Bilevel Measurements Panel

In this section...

“Settings” on page 25-35

“Transitions Pane” on page 25-38

“Overshoots / Undershoots Pane” on page 25-42

“Cycles Pane” on page 25-45

Note: The Bilevel Measurements panel requires a DSP System Toolbox or Simscape license.

Display information about signal transitions, overshoots, undershoots, and cycles. To open the Bilevel Measurements panel:

- From the menu, select **Tools > Measurements > Bilevel Measurements**.
- On the toolbar, click the Bilevel Measurements  button.

Settings

The **Settings** pane enables you to modify the properties used to calculate various measurements involving transitions, overshoots, undershoots, and cycles. You can modify the high-state level, low-state level, state-level tolerance, upper-reference level, mid-reference level, and lower-reference level.

- **Auto State Level** — When this check box is selected, the Bilevel measurements panel detects the high- and low- state levels of a bilevel waveform. When this check box is cleared, you can enter in values for the high- and low- state levels manually.
- **High** — Used to specify manually the value that denotes a positive polarity, or high-state level, as shown in the following figure.

- **Low** — Used to specify manually the value that denotes a negative polarity, or low-state level, as shown in the following figure.

- **State Level Tolerance** — Tolerance within which the initial and final levels of each transition must be within their respective state levels. This value is expressed as a percentage of the difference between the high- and low-state levels.
- **Upper Ref Level** — Used to compute the end of the rise-time measurement or the start of the fall time measurement. This value is expressed as a percentage of the difference between the high- and low-state levels.
- **Mid Ref Level** — Used to determine when a transition occurs. This value is expressed as a percentage of the difference between the high- and low- state levels. In the following figure, the mid-reference level is shown as the horizontal line, and its corresponding mid-reference level instant is shown as the vertical line.

- **Lower Ref Level** — Used to compute the end of the fall-time measurement or the start of the rise-time measurement. This value is expressed as a percentage of the difference between the high- and low-state levels.
- **Settle Seek** — The duration after the mid-reference level instant when each transition occurs used for computing a valid settling time. This value is equivalent to the input parameter, D, which you can set when you run the `settlingtime` function. The settling time is displayed in the **Overshoots/Undershoots** pane.

Transitions Pane

Display calculated measurements associated with the input signal changing between its two possible state level values, high and low.

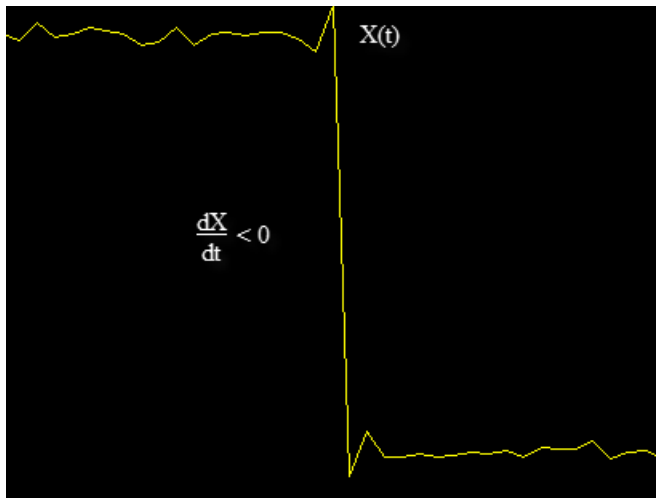

Bilevel Measurements	
Settings	
Transitions	
High	1.991 V
Low	-1.988 V
Amplitude	3.979 V
+ Edges	3
+ Rise Time	2.314 secs
+ Slew Rate	1.376 V/s
- Edges	2
- Fall Time	2.315 secs
- Slew Rate	-1.375 V/s
Overshoots / Undershoots	
Cycles	

A positive-going transition, or *rising edge*, in a bilevel waveform is a transition from the low-state level to the high-state level. A positive-going transition has a slope value greater than zero. The following figure shows a positive-going transition.

Whenever there is a plus sign (+) next to a text label, this symbol refers to measurement associated with a rising edge, a transition from a low-state level to a high-state level.

A negative-going transition, or falling edge, in a bilevel waveform is a transition from the high-state level to the low-state level. A negative-going transition has a slope value less than zero. The following figure shows a negative-going transition.

Whenever there is a minus sign (–) next to a text label, this symbol refers to measurement associated with a falling edge, a transition from a high-state level to a low-state level.

The Transition measurements assume that the amplitude of the input signal is in units of volts. You must convert all input signals to volts for the Transition measurements to be valid.

- **High** — The high-amplitude state level of the input signal over the duration of the **Time Span** parameter. You can set **Time Span** in the **Main** pane of the Visuals—Time Domain Properties dialog box.
- **Low** — The low-amplitude state level of the input signal over the duration of the **Time Span** parameter. You can set **Time Span** in the **Main** pane of the Visuals—Time Domain Properties dialog box.
- **Amplitude** — Difference in amplitude between the high-state level and the low-state level.

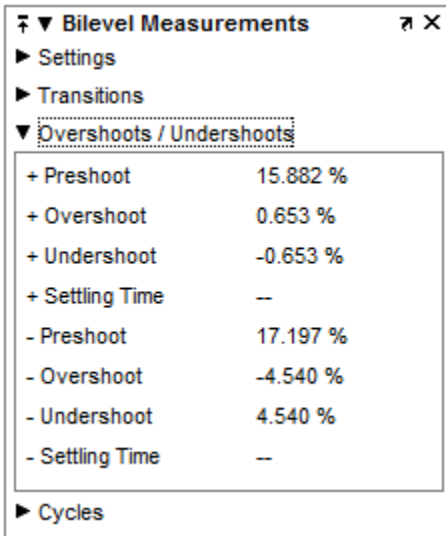

- **+ Edges** — Total number of positive-polarity, or rising, edges counted within the displayed portion of the input signal.
- **+ Rise Time** — Average amount of time required for each rising edge to cross from the lower-reference level to the upper-reference level.
- **+ Slew Rate** — Average slope of each rising-edge transition line within the upper- and lower-percent reference levels in the displayed portion of the input signal. The region in which the slew rate is calculated appears in gray in the following figure.

- **- Edges** — Total number of negative-polarity or falling edges counted within the displayed portion of the input signal.
- **- Fall Time** — Average amount of time required for each falling edge to cross from the upper-reference level to the lower-reference level.
- **- Slew Rate** — Average slope of each falling edge transition line within the upper- and lower-percent reference levels in the displayed portion of the input signal.

Overshoots / Undershoots Pane

The **Overshoots/Undershoots** pane displays calculated measurements involving the distortion and damping of the input signal. *Overshoot* and *undershoot* refer to the amount that a signal respectively exceeds and falls below its final steady-state value. *Preshoot* refers to the amount before a transition that a signal varies from its initial steady-state value.

The screenshot shows a software interface window titled "Bilevel Measurements". It contains a tree view with the following items: "Settings", "Transitions", "Overshoots / Undershoots" (expanded), and "Cycles". The "Overshoots / Undershoots" section is expanded to show a table of measurements for a rising-edge transition.

+ Preshoot	15.882 %
+ Overshoot	0.653 %
+ Undershoot	-0.653 %
+ Settling Time	--
- Preshoot	17.197 %
- Overshoot	-4.540 %
- Undershoot	4.540 %
- Settling Time	--

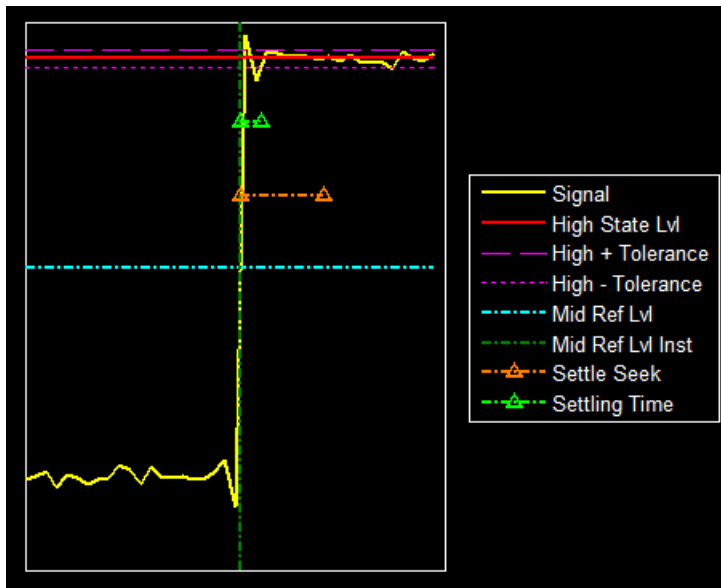

This figure shows preshoot, overshoot, and undershoot for a rising-edge transition.

The next figure shows preshoot, overshoot, and undershoot for a falling-edge transition.

- **+ Preshoot** — Average lowest aberration in the region immediately preceding each rising transition.
- **+ Overshoot** — Average highest aberration in the region immediately following each rising transition.
- **+ Undershoot** — Average lowest aberration in the region immediately following each rising transition.
- **+ Settling Time** — Average time required for each rising edge to enter and remain within the tolerance of the high-state level for the remainder of the settle seek duration. The settling time is the time after the mid-reference level instant when the signal crosses into and remains in the tolerance region around the high-state level. This crossing is illustrated in the following figure.

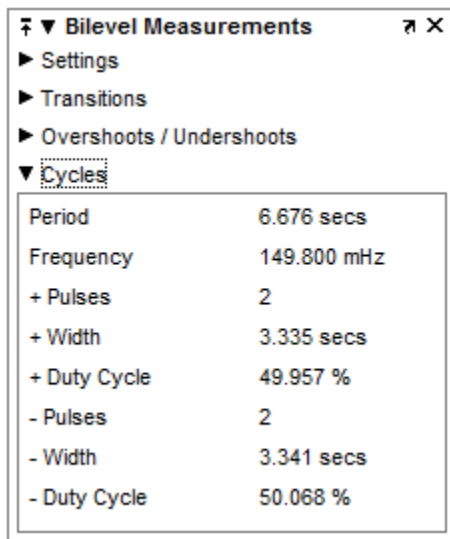

You can modify the settle seek duration parameter in the **Settings** pane.

- – **Preshoot** — Average highest aberration in the region immediately preceding each falling transition.
- – **Overshoot** — Average highest aberration in the region immediately following each falling transition.
- – **Undershoot** — Average lowest aberration in the region immediately following each falling transition.
- – **Settling Time** — Average time required for each falling edge to enter and remain within the tolerance of the low-state level for the remainder of the settle seek duration. The settling time is the time after the mid-reference level instant when the signal crosses into and remains in the tolerance region around the low-state level. You can modify the settle seek duration parameter in the **Settings** pane.

Cycles Pane

The **Cycles** pane displays calculated measurements pertaining to repetitions or trends in the displayed portion of the input signal.

The image shows a software interface window titled "Bilevel Measurements". It has a close button (X) and a maximize button (rectangle with a diagonal line) in the top right corner. The window contains a tree view with the following items: "Settings", "Transitions", "Overshoots / Undershoots", and "Cycles". The "Cycles" item is expanded, showing a list of properties and their values:

Period	6.676 secs
Frequency	149.800 mHz
+ Pulses	2
+ Width	3.335 secs
+ Duty Cycle	49.957 %
- Pulses	2
- Width	3.341 secs
- Duty Cycle	50.068 %

Properties to set:

- **Period** — Average duration between adjacent edges of identical polarity within the displayed portion of the input signal. The Bilevel measurements panel calculates period as follows. It takes the difference between the mid-reference level instants of the initial transition of each positive-polarity pulse and the next positive-going transition. These mid-reference level instants appear as red dots in the following figure.

- **Frequency** — Reciprocal of the average period. Whereas period is typically measured in some metric form of seconds, or seconds per cycle, frequency is typically measured in hertz or cycles per second.
- **+ Pulses** — Number of positive-polarity pulses counted.
- **+ Width** — Average duration between rising and falling edges of each positive-polarity pulse within the displayed portion of the input signal.
- **+ Duty Cycle** — Average ratio of pulse width to pulse period for each positive-polarity pulse within the displayed portion of the input signal.
- **- Pulses** — Number of negative-polarity pulses counted.
- **- Width** — Average duration between rising and falling edges of each negative-polarity pulse within the displayed portion of the input signal.
- **- Duty Cycle** — Average ratio of pulse width to pulse period for each negative-polarity pulse within the displayed portion of the input signal.

When you use the zoom options in the Scope, the bilevel measurements automatically adjust to the time range shown in the display. In the Scope toolbar, click the **Zoom In** or **Zoom X** button to constrict the *x*-axis range of the display, and the statistics shown reflect this time range. For example, you can zoom in on one rising edge to make the

Bilevel Measurements panel display information about only that particular rising edge. However, this feature does not apply to the **High** and **Low** measurements.

Scope Peak Finder Panel

In this section...

“Settings Pane” on page 25-49

“Peaks Pane” on page 25-51

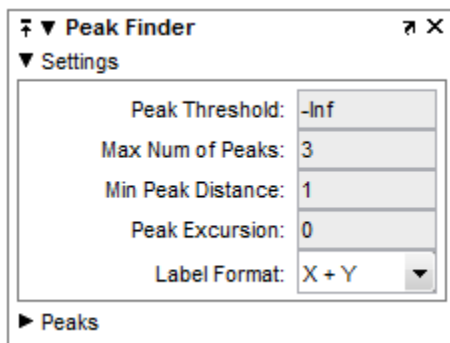

Note: The Peak Finder panel requires a DSP System Toolbox or Simscape license.

The **Peak Finder** panel displays the maxima, showing the x -axis values at which they occur. This panel allows you to modify the settings for peak threshold, maximum number of peaks, and peak excursion.

- From the menu, select **Tools > Measurements > Peak Finder**.
- On the toolbar, click the Peak Finder  button.

Settings Pane

The **Settings** pane enables you to modify the parameters used to calculate the peak values within the displayed portion of the input signal.

Properties to set:

- **Peak Threshold** — The level above which peaks are detected. This setting is equivalent to the MINPEAKHEIGHT parameter, which you can set when you run the `findpeaks` function.

- **Max Num of Peaks** — The maximum number of peaks to show. The value you enter must be a scalar integer from 1 through 99. This setting is equivalent to the `NPEAKS` parameter, which you can set when you run the `findpeaks` function.
- **Min Peaks Distance** — The minimum number of samples between adjacent peaks. This setting is equivalent to the `MINPEAKDISTANCE` parameter, which you can set when you run the `findpeaks` function.
- **Peak Excursion** — The minimum height difference between a peak and its neighboring samples. Peak excursion is illustrated alongside peak threshold in the following figure.

The *peak threshold* is a minimum value necessary for a sample value to be a peak. The *peak excursion* is the minimum difference between a peak sample and the samples to its left and right in the time domain. In the figure, the green vertical line illustrates the lesser of the two height differences between the labeled peak and its neighboring samples. This height difference must be greater than the **Peak Excursion** value for the labeled peak to be classified as a peak. Compare this setting to peak threshold, which is illustrated by the red horizontal line. The amplitude must be above this horizontal line for the labeled peak to be classified as a peak.

The peak excursion setting is equivalent to the **THRESHOLD** parameter, which you can set when you run the `findpeaks` function.

- **Label Format** — The coordinates to display next to the calculated peak values on the plot. To see peak values, you must first expand the **Peaks** pane and select the check boxes associated with individual peaks of interest. By default, both *x*-axis and *y*-axis values are displayed on the plot. Select which axes values you want to display next to each peak symbol on the display.
 - **X+Y** — Display both *x*-axis and *y*-axis values.
 - **X** — Display only *x*-axis values.
 - **Y** — Display only *y*-axis values.

Peaks Pane

The **Peaks** pane displays all of the largest calculated peak values. It also shows the coordinates at which the peaks occur, using the parameters you define in the **Settings** pane. You set the **Max Num of Peaks** parameter to specify the number of peaks shown in the list.

The numerical values displayed in the **Value** column are equivalent to the `pks` output argument returned when you run the `findpeaks` function. The numerical values displayed in the second column are similar to the `locs` output argument returned when you run the `findpeaks` function.

The Peak Finder displays the peak values in the **Peaks** pane. By default, the **Peak Finder** panel displays the largest calculated peak values in the **Peaks** pane in decreasing order of peak height. Use the sort descending button () to rearrange the

category and order by which Peak Finder displays peak values. Click this button again to sort the peaks in ascending order instead. When you do so, the arrow changes direction to become the sort ascending button (). A filled sort button indicates that the peak values are currently sorted in the direction of the button arrow. If the sort button is not filled () , then the peak values are sorted in the opposite direction of the button arrow. The **Max Num of Peaks** parameter still controls the number of peaks listed.

Use the check boxes to control which peak values are shown on the display. By default, all check boxes are cleared and the **Peak Finder** panel hides all the peak values. To show all the peak values on the display, select the check box in the top-left corner of the **Peaks** pane. To hide all the peak values on the display, clear this check box. To show an individual peak, select the check box directly to the left of its **Value** listing. To hide an individual peak, clear the check box directly to the left of its **Value** listing.

The Peaks are valid for any units of the input signal. The letter after the value associated with each measurement indicates the abbreviation for the appropriate International System of Units (SI) prefix, such as *m* for *milli*-. For example, if the input signal is measured in volts, an *m* next to a measurement value indicates that this value is in units of millivolts.

Abbreviation	Name	Multiplier
a	atto	10^{-18}
f	femto	10^{-15}
p	pico	10^{-12}
n	nano	10^{-9}
u	micro	10^{-6}
m	milli	10^{-3}
		10^0
k	kilo	10^3
M	mega	10^6
G	giga	10^9
T	tera	10^{12}
P	peta	10^{15}
E	exa	10^{18}

“Select Number of Displays and Layout” on page 25-62

“Dock and Undock Scope Window to MATLAB Desktop” on page 25-63

Add Scope Block to Model

To add a Scope block from the Simulink block library:

- 1 From the Simulink Editor menu, select **View > Library Browser**, or on the toolbar, click the Library Browser button .
- 2 From the Simulink Sinks library, drag a copy of the Scope block to the Simulink Editor.

To add a Scope block by searching from the model diagram:

- 1 In the Simulink Editor, click the model diagram.
- 2 Start typing **scope**, and then from the list, select **Scope Simulink/Sinks**.

Connect Signals to Scope Block

To specify the number of input ports and the display layout:

- 1 Open a Scope window.
- 2 On the Scope toolbar, click the Configuration Properties button .
- 3 Click the **Main** tab. In the **Number of input ports** box, enter the number of signal lines you want to connect.

- 4 Connect signals from block output ports to the scope.

Save Simulation Data Using a Scope Block

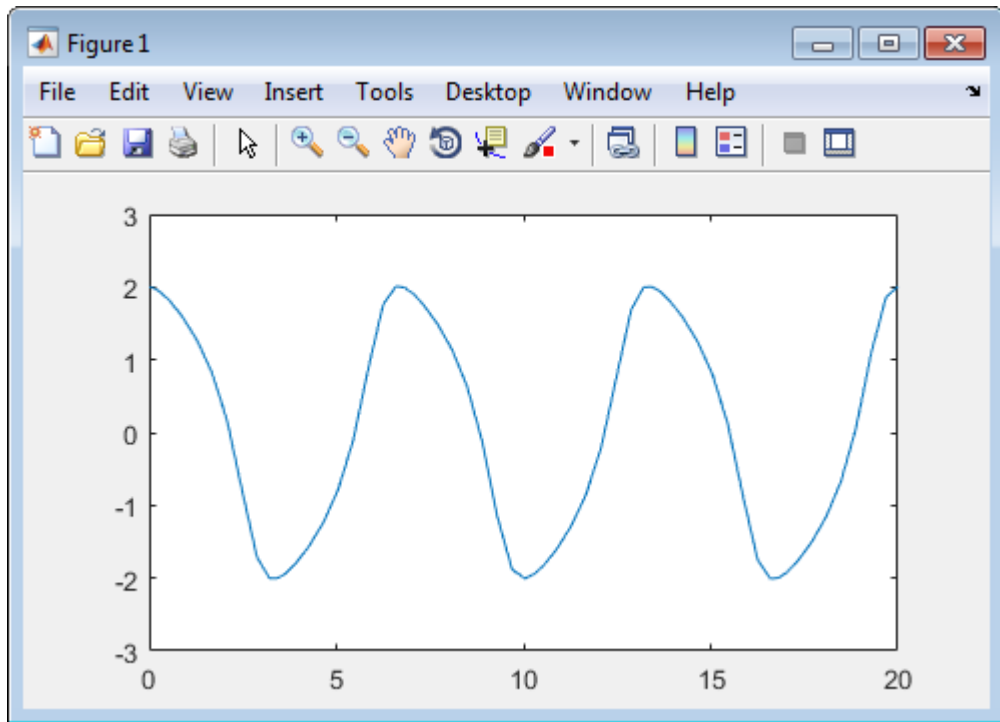

This procedure uses the model `vdp` to demonstrate saving signals to the MATLAB Workspace.

- 1 Add a Scope block to your model. See “Add Scope Block to Model” on page 25-54.
- 2 Connect signals to scope input ports. See “Connect Signals to Scope Block” on page 25-54. For example, connect the signals `x1` and `x2` to a scope.
- 3 Open the Scope window. From the toolbar, click the Parameters button .
- 4 Click the **Logging** tab, and then select the **Log data to workspace** check box. In the **Variable name** box, enter a variable name for saving the data or use the default name `ScopeData`. From the **Save format** list, select **Dataset**. Click **OK**.

Note: When saving data from a Scope block, you do not have to select the **Log signal data** property for a signal or the **Signal logging** parameter on the **Model Configuration Parameters > Data Import/Export** pane.

- 5 Run a simulation. Simulink saves data to the MATLAB Workspace in a Dataset object with two elements, one element for each signal.
- 6 In the MATLAB Command Window, enter these commands to view the logged data from `ScopeData`, where `x1` is the name of a signal:

```
x1_data = ScopeData.getElement('x1').Values.Data
x1_time = ScopeData.getElement('x1').Values.Time
plot(x1_time,x1_data)
```

For information about the `Dataset` object, see `Simulink.SimulationData.Dataset`.

Plot an Array of Signals

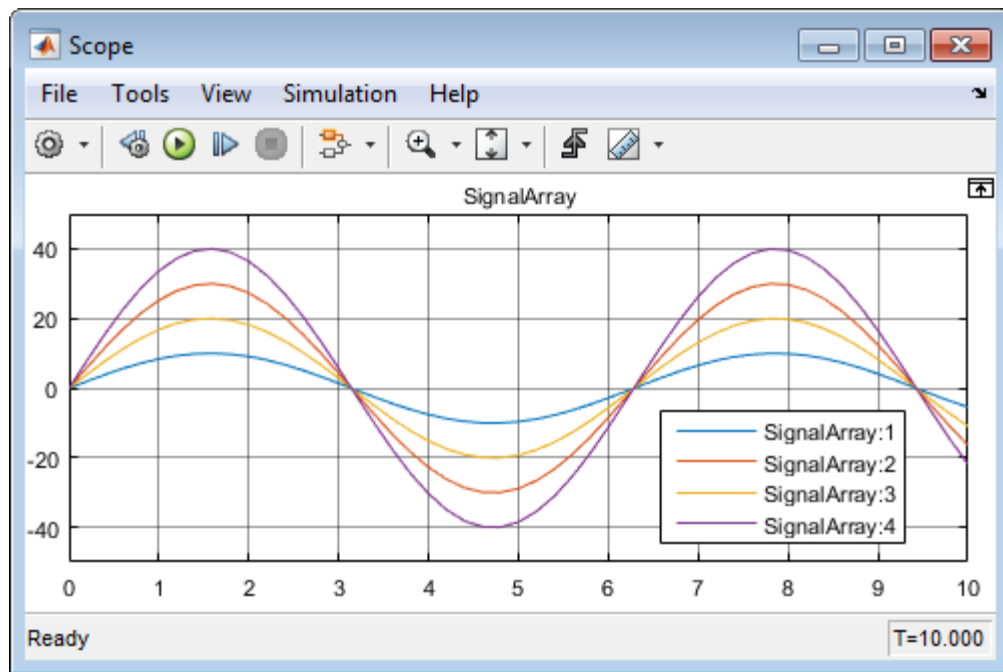

This example takes an array of four-sine wave signals and plots them on a Scope display.

- 1 Connect a Sine Wave block to a Scope block.
- 2 Open the Scope Configuration Properties dialog box. On the Display pane, select the **Legends** check box.
- 3 Set the **Amplitude** parameter for the Sine Wave block to `[10 20;30 40]`.
- 4 Set the **Signal name** property for the signal to `SignalArray`.

- 5 Simulate the model.

The Scope window displays the four signals in the matrix order (1,1), (2,1), (1,2), (2,2).

Scopes Within an Enabled Subsystem

When placed within an Enabled Subsystem block, Scope blocks and Scope Viewers behave differently depending on the simulation mode:

- Normal mode — Scope plots data when the subsystem is enabled. The display plot shows gaps when the subsystem is disabled.

- External, Accelerator, and Rapid modes — Scope plots data when the subsystem is enabled. The display shows draw lines to connect the gaps.

Show Signal Units on a Scope Display

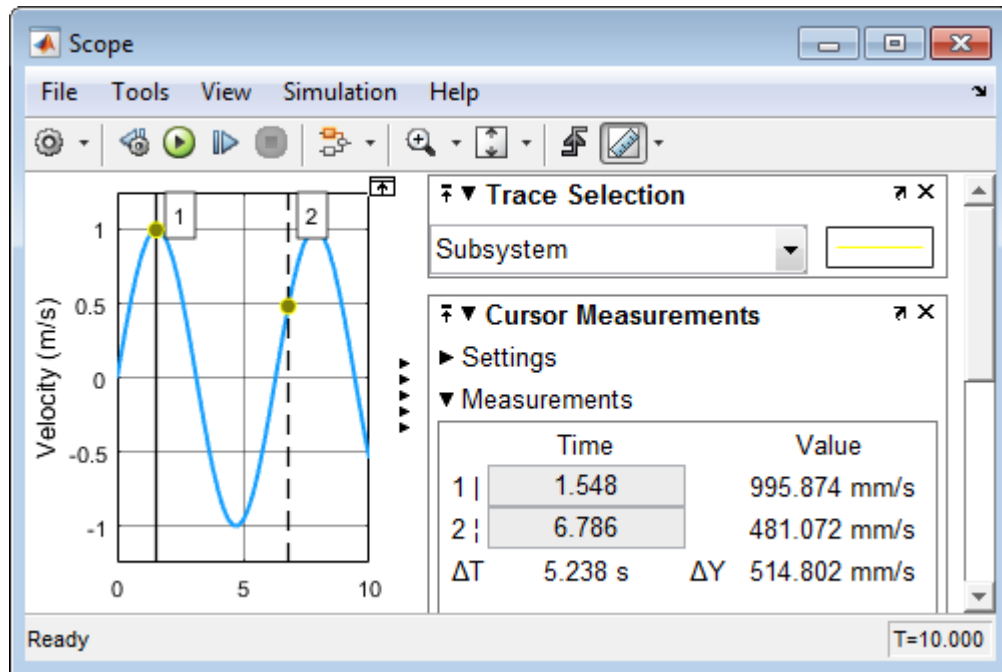

You can specify signal units at a model component boundary (Subsystem and Model blocks) using Inport and Outport blocks. See “Unit Specification in Simulink Models” on page 9-2 . You can then connect a Scope block to an Outport block or a signal originating from an Outport block. This example, the **Unit** property for the Out1 block was set to m/s.

Show Units on a Scope Display

- 1 From the Scope window toolbar, select the Configuration Properties button .
- 2 In the Configuration Properties: Scope dialog box, select the **Display** tab.
- 3 In the **Y-label** box, enter a title for the y-axis followed by (%<SignalUnits>). For example, enter
Velocity (%<SignalUnits>)
- 4 Click **OK** or **Apply**.

Signal units display in the y-axis label as meters per second (m/s) and in the Cursor Measurements panel as millimeters per second (mm/s).

You can also select **Display > Signals & Ports > Ports Units**. You do not have to enter (%<SignalUnits>) in the **Y-Label** property.

Show Units on a Scope Display Programmatically

- 1 Get the scope properties. In the MATLAB Command Window, enter

```
load_system('my_model')
s = get_param('my_model/Scope', 'ScopeConfiguration');
```

- 2 Add a y-axis label to the first display.

```
s.ActiveDisplay = 1
s.YLabel = 'Velocity (%<SignalUnits>);'
```

You can also set the model parameter **ShowPortUnits** to 'on'. All scopes in your model, with and without (%<SignalUnits>) in the **Y-Label** property, show units on the displays.

```
load_system('my_model')
```

```

get_param('my_model', 'ShowPortUnits')

ans =
off

set_param('my_model', 'ShowPortUnits', 'on')

ans =
on

```

Determine Units from Logged Data Object

When saving simulation data from a scope with the `Dataset` format, you can find unit information in the `DataInfo` field of the timeseries object.

Note: Scope support for signal units is only for the `Dataset` logging format and not for the legacy logging formats `Array`, `Structure`, and `Structure With Time`.

- 1 From the Scope window toolbar, select the Configuration Properties button .
- 2 In the Configuration Properties: Scope dialog box, select the **Logging** tab.
- 3 Select the **Log data to workspace** check box. In the text box, enter a variable name for saving simulation data. For example, enter `ScopeData`.
- 4 From the Scope window toolbar, select the Run button .
- 5 In the MATLAB Command Window, enter

```

ScopeData.getElement(1).Values.DataInfo

Package: tsdata
Common Properties:
    Units: m/s (Simulink.SimulationData.Unit)
    Interpolation: linear (tsdata.interpolation)

```

Connect Signals with Different Units to a Scope

When there are multiple ports on a scope, Simulink ensures that each port receives data with only one unit. If you try to combine signals with different units, such as by using a Bus Creator block, Simulink returns an error.

Scopes show units depending on the number of ports and displays:

- **Number of ports equal to the number of displays** — One port is assigned to one display with units for the port signal shown on the *y-axis* label.
- **Greater than the number of displays** — One port is assigned to one display, with the last display assigned the remaining signals. Different units are shown on the last *y-axis* label as a comma-separated list.

Select Number of Displays and Layout

- 1 From a Scope window toolbar, select the Configuration Properties button .
- 2 In the Configuration Properties dialog box, select the **Main** tab, and then Select the **Layout** button.
- 3 Move your mouse pointer to select the number of displays and the layout you want. For example, select three displays in one column.

You can select more than four displays in a row or column. Click within the layout, and then drag your mouse pointer to expand the layout to a maximum of 16 rows by 16 columns. For example, click and drag down to select six displays in one column.

- 4 Click the left mouse button to apply the selected layout to the Scope window.

Dock and Undock Scope Window to MATLAB Desktop

- 1 In the right corner of a Scope window, click the Dock Scope button.

The Scope window is placed above the Command Window in the MATLAB desktop.

- 2 Click the Show Scope Actions button, and then click **Undock Scope**.

Floating Scope and Scope Viewer Tasks

In this section...

- “Add Floating Scope Block to Model” on page 25-65
- “Add Scope Viewer with Signal & Scope Manager” on page 25-65
- “Connect Signals to Floating Scope Block or Scope Viewer” on page 25-66
- “Save Simulation Data Using Floating Scope Block” on page 25-67
- “Run Simulation from Floating Scope Window” on page 25-69
- “Delete Scope Viewer” on page 25-69
- “View Signals on a Floating Scope Quickly” on page 25-69
- “Connect Scope Viewers Without Using Signal Selector” on page 25-69

Add Floating Scope Block to Model

To add a Floating Scope block from the Simulink block library:

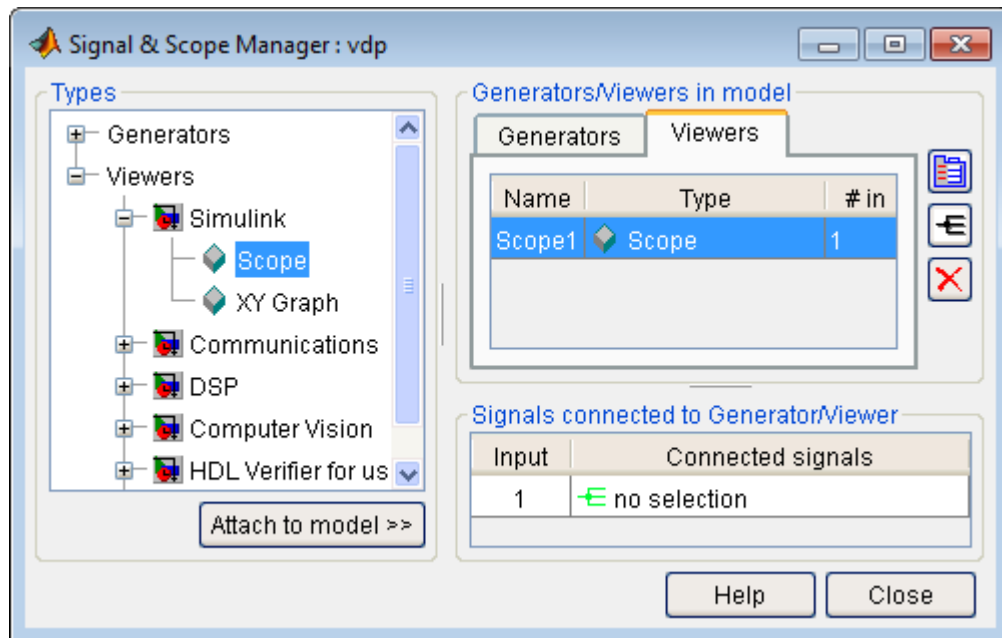

- 1 From the Simulink Editor menu, click the Library Browser button .
- 2 From the Simulink Sinks library, drag a copy of the Floating Scope block to the Simulink Editor.

To add a Floating Scope block by searching from the model diagram:

- 1 In the Simulink Editor, click the model diagram, and then start typing `floating scope`.
- 2 From the list, select `Floating Scope Simulink/Sinks`.

Add Scope Viewer with Signal & Scope Manager

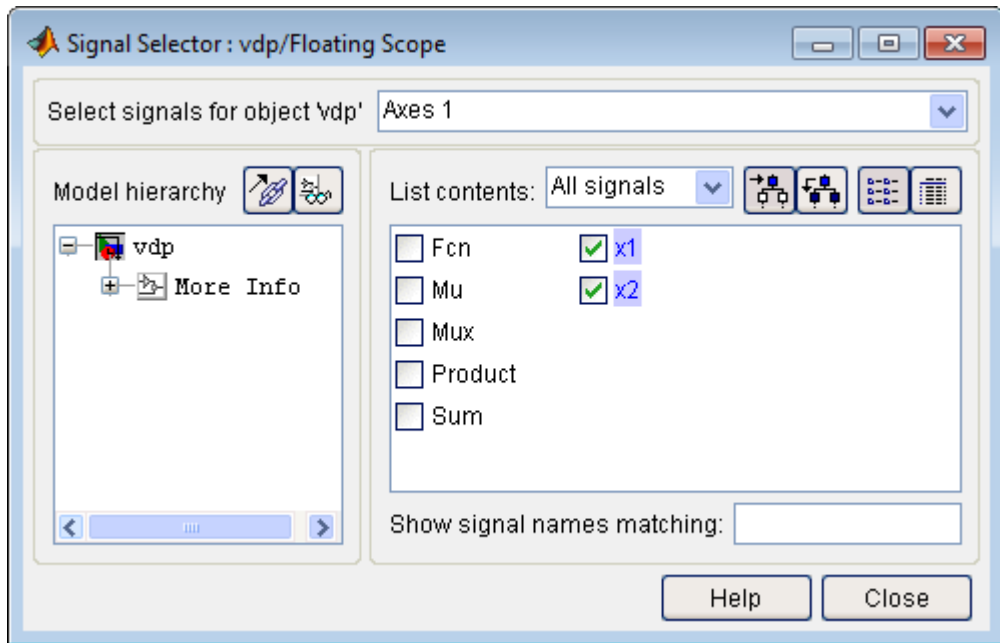

- 1 From the Simulink Editor menu, select **Diagram > Signals & Ports > Signal & Scope Manager**.
- 2 In the Signal & Scope Manager, in the **Types** pane and under the **Viewers** node, expand a product node to show the available viewers.
- 3 Select a **Scope**, and then click **Attach to model**. The viewer is added to a table on the **Viewers** tab in the **Generators/Viewers in model** pane.

Connect Signals to Floating Scope Block or Scope Viewer

Use the Signal Selector to connect signals to a Floating Scope block or Scope viewer.

- 1 Open a Scope window. In a Simulink model, double-click a Floating Scope block or Scope viewer icon .
- 2 Open the Signal Selector. On the Scope window toolbar, click the Signal Selector button .
- 3 For Scopes with multiple displays, select a display. In the Signal Selector dialog box, select a display from the **Select signals for object** drop-down list.
- 4 Select check boxes for the signals you want to view.

- 5 Click **Close** and then run a simulation.

Save Simulation Data Using Floating Scope Block

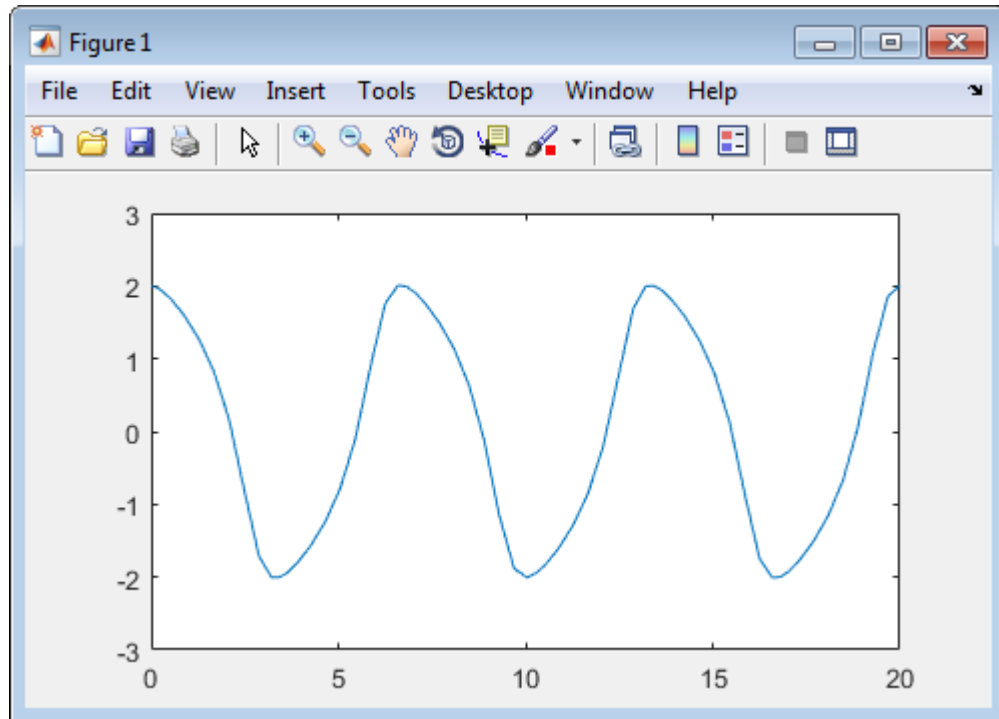

This procedure uses the model vdp to demonstrate saving signals to the MATLAB Workspace.

- 1 Add a Floating Scope or Scope Viewer to your model. See “Add Floating Scope Block to Model” on page 25-65 or “Add Scope Viewer with Signal & Scope Manager” on page 25-65.
- 2 Connect signals using the Signal Selector. See “Connect Signals to Floating Scope Block or Scope Viewer” on page 25-66. For example, select the signals x1 and x2.
- 3 Open a Floating Scope or Scope Viewer window. From the toolbar, click the Parameters button .
- 4 Click the **Logging** tab, and then select the **Log/Unlog Viewed Signals to Workspace** button.

This selection also sets the **Log signal data** parameter check box for the connected signals. The Simulink Editor places logging symbols  on the signals.

- 5 Open the **Configuration Parameters** dialog box. From the Simulink Editor menu, select **Simulation > Model Configuration Parameters > Data Import/Export**.
- 6 Select the **Signal logging** check box. Use the default Dataset object name `logsout` or enter your own name. Click **OK**.
- 7 Run a simulation. Simulink saves data to the MATLAB Workspace in a Dataset object with two elements, one element for each signal.
- 8 In the MATLAB Command Window, enter these commands to view the logged data from `logsout`, where `x1` is the name of a signal:

```
x1_data = logsout.get('x1').Values.Data  
x1_time = logsout.get('x1').Values.Time  
plot(x1_time,x1_data)
```

Run Simulation from Floating Scope Window

- 1 From a Simulink model, double-click a Floating Scope block.
- 2 From the toolbar, click the **Run** button .

For information on using toolbar buttons to control a simulation, see “Step Through a Simulation” on page 2-15.

Delete Scope Viewer

- 1 Right-click any signal line with a viewer attached or click the viewer symbol  attached to a signal line.
- 2 Select **Delete Viewer**, and then select a viewer name.

View Signals on a Floating Scope Quickly

- 1 Open a Floating Scope window.
- 2 On the toolbar, click the Lock button  to unlock  the Floating Scope.

Signals that you connected to this scope using the Signal Selector are removed.

- 3 On the model, click a signal line to select and highlight the signal line. To select multiple signals, hold down the **Shift** key while selecting signals.

- 4 Run a simulation.

Connect Scope Viewers Without Using Signal Selector

- 1 Right-click a signal line.
- 2 Select **Create & Connect Viewer > Simulink > Scope**.

The selected signal connects to the Scope Viewer, and a viewer symbol  is added to the signal line.

Connect additional signals using the Signal Selector.

Signal Generator Tasks

In this section...

“Attach Signal Generator” on page 25-71

“Attach and Remove Signal Generator” on page 25-71

Attach Signal Generator

Using the Context Menu

- 1 In the Simulink Editor, right-click the input to a block.
- 2 From the context menu, select **Create & Connect Generator**, the product, and then the generator you want as input to the block.

The name of the generator you choose appears in a box connected to the block input.

- 3 Right-click the generator name and select **Generator Parameters**. In the Generator Parameters dialog box, enter values for parameters that are specific to this generator.

Using the Signal and Scope Manager

- 1 Right-click the input to a block and select **Signal & Scope Manager**.
- 2 In the **Types** pane and under the Generators node, expand a product node to show the available generators.
- 3 Select a generator and click **Attach to model**.

The generator is added to a table in the **Generators** tab in the **Generators/Viewers in model** section. The table lists the generators in your model.

Attach and Remove Signal Generator

- 1 Right-click a generator icon on a signal line.
- 2 From the context menu, select **Disconnect Generator**.

Signal and Scope Manager

In this section...

“About the Signal & Scope Manager” on page 25-73

“Change Scope Viewer Parameters” on page 25-74

“Connect Viewers and Generators” on page 25-74

“View Test Point Data” on page 25-74

“Customize Signal & Scope Manager” on page 25-75

About the Signal & Scope Manager

Using the Signal & Scope Manager you can manage viewers and generators from a central point.

Note: The Signal and Scope Manager requires that you have Java enabled when you start MATLAB.

Viewer and Generator

Symbols identify a viewer attached to a signal line and signal names identify generators. Manage viewers and generators using the Signal & Scope Manager.

Viewers and generators are not blocks. Blocks are dragged from the Library browser and managed with block dialog boxes.

Change Scope Viewer Parameters

- 1 Open the Signal & Scope Manager. Right-click the input to a block and select **Signal & Scope Manager**.
- 2 To the right side of the **Generators** and **Viewers** pane, click the Parameters button .
 - For a generator, the Generator Parameters dialog box opens.
 - For a viewer, a Viewer opens. From the viewer toolbar, select the parameters button . The Viewer parameters dialog box opens.
- 3 Review and change parameters.

Connect Viewers and Generators

Connect signals to new viewer or generator using the Signal & Scope Manager.

- 1 Open the Signal & Scope Manager window. Right-click a signal line, and then select **Signal & Scope Manager**.
- 2 From the **Types** pane, select a viewer or generator.
- 3 Click **Attach to model**.
- 4 Use the Signal Selector (see “Signal Selector” on page 25-77) to connect the viewer or generator to a signal.

View Test Point Data

Use a Scope viewer available from the Signal and Scope Manager to view any signal that is defined as a test point in a referenced model. A test point is a signal that you can always see when using a Scope viewer in a model.

Note: With some viewers (for example, XY Graph, To Video Display, Matrix Viewer, Spectrum Scope, and Vector Scope), you cannot use the Signal Selector to select signals with test points in referenced models.

For more information, see “Test Points” on page 62-55.

Customize Signal & Scope Manager

You can add custom signal viewers or generators so that they appear in the Signal & Scope Manager. The following procedure assumes that you have a custom viewer named `newviewer` that you want to add.

- 1 Open a new Simulink library.

For example, open the Simulink browser and select **File > New > Library**.

- 2 Save the library.

For example, save it as `newlib`.

- 3 In the MATLAB Command Window, set the library type for the library.

For example, to set the library type of `newviewer` to `viewer`,

```
set_param('newlib','LibraryType','SSMgrViewerLibrary')
```

To set library type for generators, use the type `'SSMgrGenLibrary'`.

For example,

```
set_param('newlib','LibraryType','SSMgrGenLibrary')
```

- 4 Set the display name of the library.

For example,

```
set_param('newlib','SSMgrDisplayString','My Custom Library')
```

- 5 Add the viewer or generator to the library.

Note: If the viewer is a compound viewer, such as a subsystem with multiple blocks, make the top-level subsystem an atomic one.

- 6 Set the `ioType` of the viewer.

For example,

```
set_param('newlib/newviewer','ioType','viewer')
```

- 7 Save the library `newlib`. In the Simulink window, select **File > Save**.

- 8 Using the MATLAB editor, create a file named `sl_customization.m`. In this file, enter a directive to incorporate the new library as a viewer library.

For example, to save `newLib` as a viewer library, add the following lines:

```
function sl_customization(cm)
cm.addSigScopeMgrViewerLibrary('newLib')
%end function
```

To add a library as a generator library, add a line like the following:

```
cm.addSigScopeMgrGeneratorLibrary('newLib')
```

- 9** Add a corresponding `cm.addSigScope` line for each viewer or generator library you want to add.
- 10** Save the `sl_customization.m` file on your MATLAB path. Edit this file to add new viewer or generator libraries.
- 11** To see the new custom libraries, restart MATLAB and start the Signal & Scope Manager.

Signal Selector

In this section...

“About the Signal Selector” on page 25-77

“Select Signals” on page 25-78

“Model Hierarchy” on page 25-78

“Inputs/Signals List” on page 25-78

About the Signal Selector

Use the Signal Selector to add signals to a Floating Scope or Scope viewer. See “Add Scope Viewer with Signal & Scope Manager” on page 25-65 . To open the Signal Selector,

- Open a Floating Scope. From the menu, select **Simulation > Signal Selector**, or on the toolbar, click the Signal Selector button .
- Open a model. From the menu, select **Diagram > Signal & Ports > Signal & Scope Manager**. On the right side of the Signal & Scope Manager, click the Signal Selector button .

The Signal Selector that appears when you click the **Edit signal selection** button applies only to the currently selected generator or viewer. If you want to connect blocks to another generator or viewer object, select the object in the Signal & Scope Manager and then open another instance of the Signal Selector.

Select Signals

This list box allows you to select the owner output port (in the case of signal generators) or display axis (in the case of viewers) to which you want to connect blocks in your model.

The list box is enabled only if the signal generator has multiple outputs or the viewer has multiple axes.

Model Hierarchy

This tree-structured list lets you select any subsystem in your model.

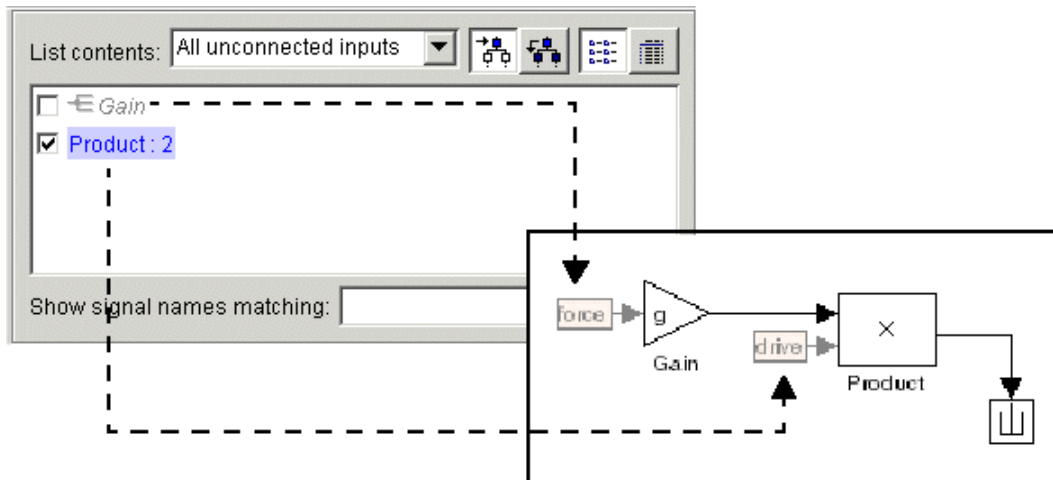

Selecting a subsystem causes the adjacent port list to display the ports available for connection in the selected subsystem. To display subsystems included as library links in your model, click the **Follow links** button at the top of the **Model hierarchy** control. To display subsystems contained by masked subsystems, click the **Look under masks** button at the top of the panel.

Inputs/Signals List

The contents of this panel displays input ports available for connection to the Signal Selector owner if the owner is a signal generator or signals available for connection to the owner if the owner is a viewer.

If the Signal Selector owner is a signal generator, the inputs/signals list by default lists each input port in the system selected in the model hierarchy tree that is either unconnected or connected to a signal generator.

The label for each entry indicates the name of the block of which the port is an input. If the block has more than one input, the label indicates the number of the displayed port. A greyed label indicates that the port is connected to a signal generator other than the Signal Selector owner. Selecting the check box next to a port entry in the list connects the Signal Selector owner to the port, replacing, if necessary, the signal generator previously connected to the port.

To display more information on each signal, click the **Detailed view** button at the top of the pane. The detailed view shows the path and data type of each signal and whether the signal is a test point. The controls at the top and bottom of the panel let you restrict the amount of information shown in the ports list.

- To show named signals only, select **Named signals only** from the **List contents** control at the top of the pane.
- To show only signals selected in the Signal Selector, select **Selected signals only** from the **List contents** control.
- To show test point signals only, select **Testpointed/Logged signals only** from the **List contents** control.
- To show only signals whose signals match a specified string of characters, enter the characters in the **Show signals matching** control at the bottom of the **Signals** pane and press the **Enter** key.

- To show the selected types of signals for all subsystems below the currently selected subsystem in the model hierarchy, click the **Current and Below** button at the top of the **Signals** pane.

To select or clear a signal in the **Signals** pane, click its entry or use the arrow keys to move the selection highlight to the signal entry and press the **Enter** key. You can also move the selection highlight to a signal entry by typing the first few characters of its name (enough to identify it uniquely).

Note You can continue to select and clear signals on the block diagram with the Signal Selector open. For example, shift-clicking a line in the block diagram adds the corresponding signal to the set of signals that you previously selected with the Signal Selector. If the Signal Selector owner is a Floating Scope block and a simulation is running when you open the Signal Selector, Simulink updates the Signal Selector to reflect signal selection changes you have made on the block diagram. However, the changes do not appear until you select the Signal Selector window itself. You can also use the Signal Selector before running a model. If no simulation is running, selecting a signal in the model does not change the Signal Selector.

Control Scopes Programmatically

In this section...

“Use Simulink Configuration Object” on page 25-81

“Scope Configuration Properties” on page 25-83

Use Simulink Configuration Object

Use a Scope Configuration object for programmatic access to scope parameters.

- Modify the title, axis labels, and axis limits
- Turn on or off the legend or grid
- Control the number of inputs
- Change the number of displays and which display is active

In this example, the variable `myConfiguration` stores the mask object obtained using `get_param`. The example also shows how to change the value of a Scope parameter.

Create a New Model

```
mdl='myModel';
new_system(mdl);
```

Add Scope and Time Scope Blocks to Model

```
add_block('Simulink/Sinks/Scope', [mdl '/myScope']);
add_block('dspnks4/Time Scope', [mdl '/myTimeScope']);
```

Get a Scope Configuration Object

Many of the scope configuration properties correspond to Scope block parameters.

```
myConfiguration = get_param([mdl '/myScope'],'ScopeConfiguration')
```

```
myConfiguration =
```

```
Scope Configuration with properties:
```

```
    Name: 'myScope'
  Position: [680 390 560 420]
    Visible: 0
```

```
OpenAtSimulationStart: 0
  NumInputPorts: '1'
  LayoutDimensions: [1 1]
  SampleTime: '-1'
  MaximizeAxes: 'Off'
  MinimizeControls: 0
  AxesScaling: 'Manual'
  TimeSpan: 'Auto'
  TimeSpanOverrunAction: 'Wrap'
  TimeUnits: 'none'
  TimeDisplayOffset: '0'
  TimeAxisLabels: 'Bottom'
  ShowTimeAxisLabel: 0
  ActiveDisplay: 1
  Title: '%<SignalLabel>'
  ShowLegend: 0
  ShowGrid: 1
  PlotAsMagnitudePhase: 0
  YLimits: [-10 10]
  YLabel: ''
  DataLogging: 0
  DataLoggingVariableName: 'ScopeData'
  DataLoggingLimitDataPoints: 0
  DataLoggingMaxPoints: '5000'
  DataLoggingDecimateData: 0
  DataLoggingDecimation: '1'
  DataLoggingSaveFormat: 'Dataset'
```

Set a Property

```
myConfiguration.DataLoggingMaxPoints = '10000';
```

Find Scope and Time Scope Blocks

```
find_system mdl, 'LookUnderMasks', 'on', 'IncludeCommented', 'on', ...
'AllBlocks', 'on', 'BlockType', 'Scope')
```

```
ans =
  'myModel/myScope'
  'myModel/myTimeScope'
```

Find Only Simulink Scope Blocks

```
find_system mdl, 'LookUnderMasks', 'on', 'IncludeCommented', 'on', ...
```

```
'AllBlocks', 'on', 'BlockType', 'Scope', 'DefaultConfigurationName', ...  
'Simulink.scopes.TimeScopeBlockCfg')
```

```
ans =  
    'myModel/myScope'
```

Find Only DSP System Toolbox Time Scope Blocks

```
find_system mdl, 'LookUnderMasks', 'on', 'IncludeCommented', 'on', ...  
'AllBlocks', 'on', 'BlockType', 'Scope', 'DefaultConfigurationName', ...  
'spbscopes.TimeScopeBlockCfg')
```

```
ans =  
    'myModel/myScope'
```

Inspect Signal Data with Simulation Data Inspector

The Simulation Data Inspector software provides the capability to inspect and compare time series data at several stages of your workflow:

- Model design: Inspect and compare simulation data after making changes to the model diagram or its configuration
- Testing your model: Compare simulation data with different input data
- Code generation: Compare simulation data and generated code output of your model

You can compare variable-step data, fixed-step solver data from Simulink and Simulink Coder, and fixed-step output with external data. “How the Simulation Data Inspector Compares Time Series Data” on page 26-43 describes how aligned signal data are compared. “How the Simulation Data Inspector Aligns Signals” on page 26-44 describes how signals are aligned between compared runs.

A typical workflow for inspecting and comparing signal data is:

- 1 Set up your model to send data to the Simulation Data Inspector, as in “Stream Data to the Simulation Data Inspector” on page 26-6 or “Record Logged Simulation

Data” on page 26-12. If you are sending logged data, configure your model to log signals as in “Export Signal Data Using Signal Logging” on page 59-57.

- 2** Open the Simulation Data Inspector, as described in “Open the Simulation Data Inspector” on page 26-4.
- 3** Simulate your model or import signal data from the base workspace or a MAT-file, as described in and “Import Signal Data” on page 26-15.
- 4** Configure the runs appearance and specify how you want to plot the data, as described in “Customize the Simulation Data Inspector Interface” on page 26-48.
- 5** Inspect signals using data cursors to quickly determine if the run satisfies requirements, as described in “Inspect Signal Data” on page 26-25.
- 6** If the run is unsatisfactory, delete it. Repeat steps 3 and 4 to collect the desired simulation runs for comparing data.
- 7** Compare two signals or all of the signal data from multiple runs, as described in “Compare Signal Data from Multiple Simulations” on page 26-36.
- 8** Optionally assign tolerances to signals and graphically inspect the applied tolerances.
- 9** Determine which signals have discrepancies within the specified tolerances. Plot and analyze the discrepancies of any two signals.
- 10** Save the signal data and comparison results.

The Simulation Data Inspector software provides a command-line interface. For more information, see “Inspect and Compare Signal Data Programmatically” on page 26-63.

Related Examples

- “Stream Data to the Simulation Data Inspector” on page 26-6

Open the Simulation Data Inspector

To open the Simulation Data Inspector, choose one of the following methods:

- **Simulink Editor:** Click the **Simulation Data Inspector** button.

- **Simulink Editor:** Click the **Simulation Data Inspector** button arrow, and select **Simulation Data Inspector** from the menu.

- Right-click the badge above a signal marked for streaming  and select **Open Data Inspector**.
- **MATLAB Command Window:** Enter

```
Simulink.sdi.view
```

Why Is the Simulation Data Inspector Empty?

There are several methods for populating the Simulation Data Inspector with data.

- “Stream Data to the Simulation Data Inspector” on page 26-6
- “Record Logged Simulation Data” on page 26-12. If you want to view logged data, configure your model to log signals. For more information, see:
 - “Export Simulation Data” on page 59-3

- “Export Signal Data Using Signal Logging” on page 59-57
- “Import Signal Data” on page 26-15 to view signal data stored in the base workspace or a MAT-file.

For a list of Simulink data export formats that are not supported in the Simulation Data Inspector, see “Limitations of the Simulation Data Inspector” on page 26-62.

Related Examples

- “Inspect Signal Data” on page 26-25

Stream Data to the Simulation Data Inspector

You can stream data from your model into the Simulation Data Inspector during simulation. Streaming is useful for iteratively debugging and optimizing a model. Streaming does not store data in memory, and thus reduces the demand on computer memory. You can stream signals from the top model or within reference models only if the simulation mode is set to `Normal`.

If you have a model with logged signals and only want to stream them, convert the logged signals to streamed signals using the `Simulink.sdi.changeLoggedToStreamed` function.

- 1 Select one or more signals in the model.
- 2 On the Simulink Editor toolbar, click the **Simulation Data Inspector** button arrow and select **Stream Selected Signals to Data Inspector** to mark the signal for streaming.

The streaming badge shows signals in the model marked for streaming.

- 3 Click the **Simulation Data Inspector** button to open the Simulation Data Inspector.
- 4 Simulate the model.

A new simulation run appears in the **Runs** pane of the Simulation Data Inspector. During simulation, the **Simulation Data Inspector** button appears highlighted to indicate that new simulation output is available in the Simulation Data Inspector.

- 5 In the Simulation Data Inspector **Runs** pane, expand the new run and select the check box next to the signal you want to stream in the plot. The figure shows the plot for the signal `ego` from the `sldemo_fuelsys` model.

If you also set the Simulation Data Inspector to send logged signals from the workspace to the Simulation Data Inspector, then the logged signals also appear in the **Runs** pane when the simulation is paused or has finished.

- 6 To stop streaming a signal, select it and then select **Stop Streaming Selected Signals** on the Simulink Editor toolbar.

The badge disappears from the signal that you stopped streaming.

Use Signal Streaming to Iterate Model Design

You can use the Simulation Data Inspector to stream data from your model during simulation, which helps you quickly optimize model parameters. The run overwrite mode

replaces a run at the start of a new simulation and reduces the accumulation of runs in the **Runs** pane.

- 1 To enable overwrite mode for a run in the **Runs** pane, right-click the run and select **Overwrite Run**.

An overwrite symbol appears next to the run to indicate that overwrite mode is on for that run.

- 2 Simulate the model.

The new run replaces the existing run in the **Runs** pane, and the new run remains in overwrite mode. Signals selected for plotting are plotted again when the new run starts simulating.

- 3 To inspect a signal value at a time point, add a data cursor to the plot during simulation, while simulation is paused, or after simulation has finished. On the **Visualize** tab, click **Data Cursors**.
- 4 Drag the data cursor to the point you want to inspect.

- 5 To turn off overwrite mode, right-click the overwritten run in the **Runs** pane and select **Overwrite Run**.

Configure Signals for Streaming by Using Model Data Editor

To configure signals for streaming, instead of locating the signals in your model and selecting **Stream Selected Signals to Data Inspector**, you can use the Model Data Editor. The Model Data Editor enables you to view a flat list of signals in your model. You can sort, group, and filter the list. Use this technique to configure streaming for:

- Many signals at once, especially when the signals are not close to each other in the block diagram.
- Signals that are difficult to locate in a large model or hierarchy of subsystems.

To open the Model Data Editor, in a model, select **View > Model Data**. In the Model Data Editor, on the **Signals** tab, set the **Change View** drop-down list to **Instrumentation** and use the **Stream** column. For information about the Model Data Editor, see “Configure Data Properties by Using a Table” on page 57-103.

Related Examples

- “Inspect Signal Data” on page 26-25
- “Record Logged Simulation Data” on page 26-12

Requirements for Recording Data

The Simulation Data Inspector records the following data configured on the “Model Configuration Parameters: Data Import/Export” of the Configuration Parameters dialog:

- **States** and **Output**, if **Format** is **Structure with time**, or if **Format** is **Array or Structure** and **Time** is logged.
- **Signal logging**
- **Data stores**

The Simulation Data Inspector supports the following data imported from MAT-files and the MATLAB base workspace:

- `Simulink.Timeseries` and MATLAB timeseries objects
- `Simulink.SimulationData.Dataset` or `Simulink.ModelDataLogs` objects
- Data in **Structure with time** format

The Simulation Data Inspector supports output from the following blocks:

- **Scope** (**Structure with time** and **Array** format)
- **To File** (**Timeseries** format)
- **To Workspace** (**Timeseries** or **Structure With Time** format)

Related Examples

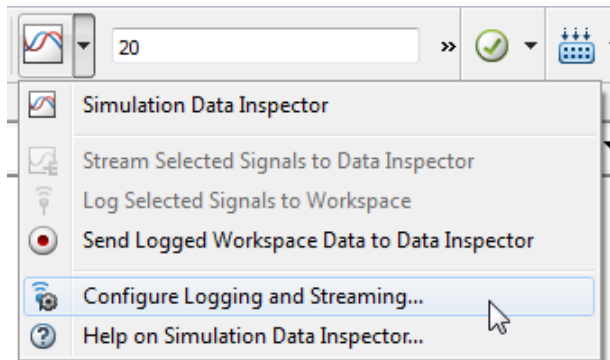

- “Stream Data to the Simulation Data Inspector” on page 26-6
- “Record Logged Simulation Data” on page 26-12

Record Logged Simulation Data

You can configure your model and the Simulation Data Inspector to record logged signal data from a simulation run. Logged signals are marked with a logging badge  in the model.

Configure Model for Recording Logged Data

- 1 Set up your model to log signal data, as in “Export Signal Data Using Signal Logging” on page 59-57.
- 2 On the Simulink Editor toolbar, click the **Simulation Data Inspector** button arrow and select **Configure Logging and Streaming** to open the **Data Import/Export** pane of the Configuration Parameters dialog box.

- 3 In the **Data Import/Export** pane:
 - Select the **Signal logging** check box.
 - Select the **Record logged workspace data in Simulation Data Inspector** check box.

Note: Alternatively, you can turn on record in the Simulation Data Inspector menu. Click the **Simulation Data Inspector** button arrow and select **Send Logged Workspace Data to Data Inspector** to turn on record.

- 4 Click **OK**.

- To log a particular signal, select the signal in the model, click the **Simulation Data Inspector** button arrow, and then select **Log Selected Signals to Workspace**.

The signal logging badge  appears on the signal marked for logging.

Simulate Model and Record a Run

- Open the Simulation Data Inspector by clicking the **Simulation Data Inspector** button on the Simulink Editor toolbar.

- To send logged data to the Simulation Data Inspector, simulate the model.

Note: If recording is off, logged data is not sent to the Simulation Data Inspector. To turn on recording, see “Configure Model for Recording Logged Data” on page 26-12.

- When the simulation is done, the **Simulation Data Inspector** button appears highlighted to indicate that new simulation output is available in the Simulation Data Inspector.

The logged data appears in the **Runs** pane of the Simulation Data Inspector.

- To record another simulation run, simulate the model again. When the simulation is done, the data appears as a new run.

To configure the Simulation Data Inspector to overwrite a run, see “Overwrite a Run” on page 26-47.

- When you are done importing logged data for your simulations, click the **Simulation Data Inspector** button arrow and select **Send Logged Workspace Data to Data Inspector** to turn recording off.

Related Examples

Import Signal Data

To import data into the Simulation Data Inspector, you must have timeseries or logged signal data in the base workspace or in a MAT-file. For information on how to log signal data to the base workspace, see “Export Signal Data Using Signal Logging” on page 59-57. If you have a Simulink Design Verifier license, then you can also import test cases.

Import Signal Data from the Base Workspace

You can import data from the base workspace into the Simulation Data Inspector.

- 1 Click **Import** on the **Visualize** tab to open the Import dialog.
- 2 Select **Base workspace**. Data from the base workspace populates the table.

- 3 Select the corresponding signal check box in the table to import a signal. Clear the signal check box for signals that you do not want to import.
- 4 For **Import to**, select **New run** or **Existing run**. If you select **Existing run**, select a run from the list.
- 5 Click **Import**.

The imported signals appear in the **Runs** pane.

Import Signal Data from a MAT-File

You can select a subset of signals from a MAT-file to import into the Simulation Data Inspector.

- 1 Click **Import** on the **Visualize** tab to open the Import dialog.
- 2 For **Import from**, select **MAT-file**.

- 3 Click the **Browse** button and select the MAT-file you want to import from.

The data from the MAT-file populates the table.

- 4 For **Import to**, select **New run** or **Existing run**. If you select **Existing run**, select a run from the list.
- 5 Select the corresponding signal check box in the table to import a signal. Clear the signal check box for signals that you do not want to import.
- 6 Click **Import**.

The imported signals appear in the **Runs** pane.

Related Examples

- “Inspect Signal Data” on page 26-25

Share Simulation Data Inspector Data and Views

In this section...

- “Save and Load a Simulation Data Inspector Session” on page 26-18
- “Export Signal Data from the Simulation Data Inspector” on page 26-19
- “Share Simulation Data Inspector Data Views” on page 26-20
- “Create Images of Plots” on page 26-23
- “Create MATLAB Plots” on page 26-23

After you have inspected, analyzed, or compared data in the Simulation Data Inspector, you might want to share it with others. You can share information from the Simulation Data Inspector in multiple ways:

- Export runs or comparisons data to a MAT-file
- Save all runs data, comparisons data, and plot states to a session MAT-file
- Share the Simulation Data Inspector view so that others can view data using the same layout
- Create and copy images of plots
- Send plots to a MATLAB figure

Save and Load a Simulation Data Inspector Session

If you have signal data in the Simulation Data Inspector and you want to archive or share the data, save the Simulation Data Inspector session. When you save a Simulation Data Inspector session, the MAT-file contains:

- All runs, signal data, and properties from the **Runs** and **Comparisons** panes
- Check box selection state for signals in the **Runs** pane (the view is not saved)

Save Session to a MAT-File

- 1 On the **Visualize** tab, click **Save**.
- 2 Browse to where you want to save the MAT-file to, name the file, and click **Save**.

Load a Saved Simulation Data Inspector Session

- 1 On the **Visualize** tab, click **Open**.

- 2 Browse, select the MAT-file saved from the Simulation Data Inspector, and click **Open**.

Data stored in the MAT-file appears in the **Runs** pane of the Simulation Data Inspector.

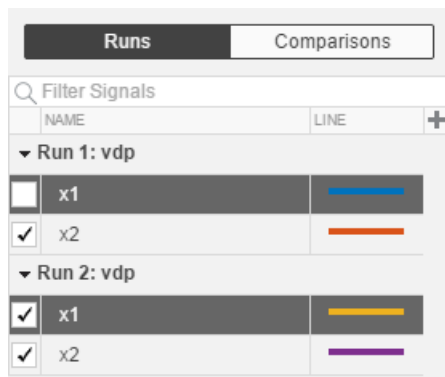

- 3 If signal data in the session is plotted on multiple subplots, on the **Visualize** tab, click **Subplots** and select the subplot layout.

Export Signal Data from the Simulation Data Inspector

You can use the Simulation Data Inspector to export data from the **Runs** or **Comparisons** pane to the base workspace or a MAT-file. When you export data from the Simulation Data Inspector, the MAT-file contains:

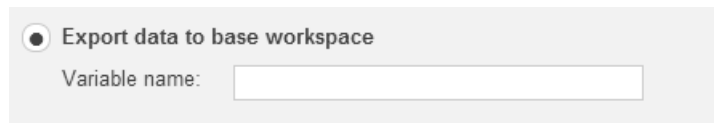

- Signal data
- Signal names
- Units of measure (supported by Simscape)
- Interpolation method
- Block path (when you export multiple signals)
- Port index (when you export multiple signals)

Only highlighted runs and signals from the **Runs** or **Comparisons** panes are exported. For example, in the figure, only **x1** from Run 1 and Run 2 are exported because they are both highlighted. The check box selection does not affect whether signal data is exported.

Export Data to the Base Workspace

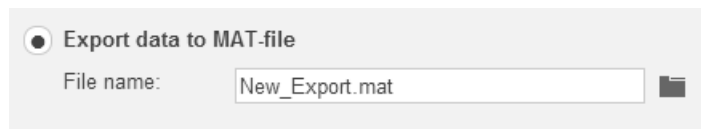

- 1 Highlight the signals or runs you want to export from the **Runs** or **Comparisons** panes. Use **Ctrl+Click** to select more than one item.
- 2 On the **Visualize** tab, click **Export**.
- 3 Select **Export data to base workspace**, and specify the variable name.

- 4 Click **Export**.

Export Data to a MAT-File

- 1 Highlight the signals or runs you want to export from the **Runs** or **Comparisons** panes. Use **Ctrl+Click** to select more than one item.
- 2 On the **Visualize** tab, click **Export**.
- 3 Select **Export data to MAT-file**.

- 4 Browse to a file location, specify the file name, and click **Save**.
- 5 Click **Export**.

Share Simulation Data Inspector Data Views

If you have different data sets from a model, but you want to visualize them in the same way, then you can use views. A view saves the layout of the Simulation Data Inspector. However, a view does not save signal data contained in the Simulation Data Inspector. Specifically, a view saves:

- Number of plots, axis ranges, linked plots, normalized axis, signal marker selection
- Location of signals in the plots
- Signal grouping and columns on display in the Runs pane

- Signal color and line styling

You can control views from the **Saved Views** button in the Simulation Data Inspector **Visualize** tab. As an example, here is a layout of the Simulation Data Inspector with signal data plotted.

If you want to share how the data appears with someone who has different signal data from the model, then save the view and share it. To save the view, click the **Saved Views** button arrow on the toolbar, and select **Save View**. Save the view to a .mldatx file.

Here is different layout with different signal data that someone else generated, which is from the same model, but you want to view it as it appears in the saved view.

To load the saved view, click the **Saved Views** button. Select the saved view and open it. Now the new data appears in the same way as the original layout.

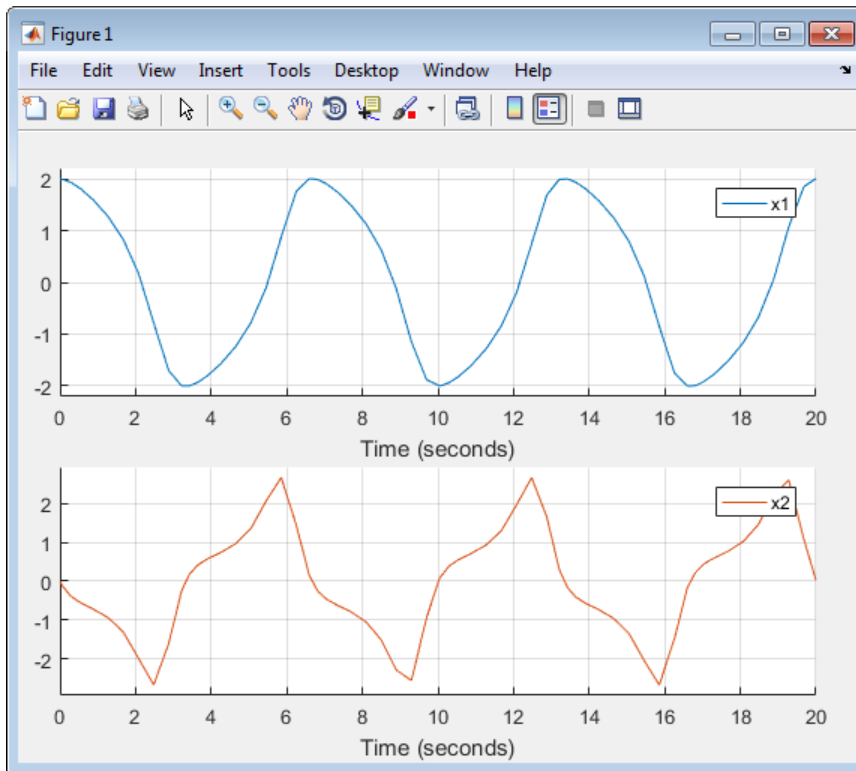

Create Images of Plots

If you want to share an image of all the plots in the Simulation Data Inspector, then you can use the **Copy All Plots** button on the **Visualize** or the **Copy Plot** button on the **Compare** tab.

When you click the button, an image of the plot is copied to your clipboard, and you can paste the image into a program, such as Microsoft PowerPoint® or Microsoft Word. If you want to copy a single plot image to the clipboard, then right-click the plot and select **Copy Plot**.

Create MATLAB Plots

If you need to plot Simulation Data Inspector data in a MATLAB figure, then you can use the **Send to Figure** button. On the **Visualize** or **Compare** tab, click **Send to Figure**. All of the plots in the current plot area are sent to the figure.

For more information on plotting and customizing your MATLAB data plots, see “Types of MATLAB Plots”.

Related Examples

- “Create Simulation Data Inspector Report” on page 26-41

Inspect Signal Data

Using the Simulation Data Inspector, you can view and inspect signal data from simulations or from imported data. The Simulation Data Inspector allows you to group data from multiple simulations on multiple plots, which gives you a comprehensive view of your data. You can also use data cursors in the plots for close examination of signal values.

These examples show you how to view and inspect signal data using the Simulation Data Inspector using the `slexAircraftExample` model as an example.

- “View Signal Data” on page 26-25
- “Explore Signal Data” on page 26-27
- “View Signals on Multiple Plots” on page 26-29
- “Filter Runs and Signals” on page 26-32
- “Inspect Event-Based Data” on page 26-34

View Signal Data

This example uses signal streaming to send data to the Simulation Data Inspector. You can also “Record Logged Simulation Data” on page 26-12 or you can “Import Signal Data” on page 26-15 from the base workspace or a MAT-file.

- 1 In the MATLAB Command Window, enter `slexAircraftExample` to open the model.
- 2 To stream signals `q`, `rad/sec`, `Stick`, and `alpha`, `rad` from the model to the Simulation Data Inspector, select each signal, click the **Simulation Data Inspector** button arrow, and select **Stream Selected Signals to Data Inspector**.

The streaming badge appears above each signal marked for streaming.

- 3 Double-click the Pilot signal generator block. Set **Wave form** to **sine**, and click **OK**.
- 4 In the Simulink Editor, click the **Simulation Data Inspector** button to open the Simulation Data Inspector.
- 5 Simulate the model. A new run appears in the Simulation Data Inspector.

By default, the **Runs** pane contains a row for each signal, organized by simulation runs. You can expand or collapse any of the runs to view the signals in a run. For more information on signal grouping, see “Customize the Simulation Data Inspector Interface” on page 26-48.

- 6 To plot the signals, select the check box next to the q , rad/sec , Stick , and alpha , rad signals. The signal data appears in the plot.

Explore Signal Data

In the Simulation Data Inspector, you can inspect signal values at any point of the simulation using data cursors.

- 1 On the **Visualize** tab, click **Data Cursors** to add one data cursor to the plot.

- 2 Drag the data cursor left or right to a point of interest, or you can use the arrow keys to move the data cursor.
- 3 You can move a data cursor to a specific point without dragging it. Click the data cursor time field and enter the time value 40.33.

If an asterisk appears in the data cursor label, then it means the value is interpolated. The Simulation Data Inspector linearly interpolates the value if the signal was not sampled at a point of interest.

4

Click the **Data Cursors** arrow  and select **Hide**.

View Signals on Multiple Plots

You can use subplot layouts to group signals on different subplots. For example, you can group the same signal from different simulation runs, group signals with a similar range of values, or normalize a subset of your signal data.

- 1 In the model, double-click the Pilot signal generator block. Set **Wave form** to square, and click **OK**.
- 2 Simulate the model.

A new run appears in the Simulation Data Inspector.

- 3 In the Simulation Data Inspector, on the **Visualize** tab, click **Subplots** and select 3x1.
- 4 Click the middle subplot. In the **Runs** pane, from Run 2, select the **q, rad/sec**, **Stick**, and **alpha, rad** signal check boxes.

The signal check boxes show the signals that are plotted in the selected subplot, which is outlined in blue.

Move Signals Between Plots in a View

- 1 Select the signal you want to move.
- 2 Drag the signal to the plot you want to move it to.

For more information on working with plots, see “Modify a Plot in the Simulation Data Inspector” on page 26-59.

Linked Subplots

Subplots are linked together by default so that plots stay in sync when you pan and zoom. These operations synchronize across linked plots:

- Pan by clicking on the plot and dragging
- Zoom in, zoom out, zoom on the time axis, and zoom on the Y-axis
- Fit data to view

To pan and zoom independently in a subplot, unlink the subplot.

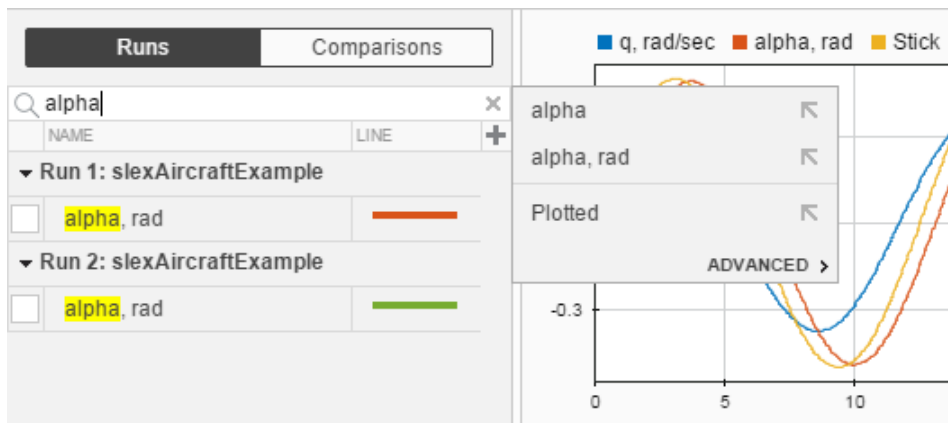

- 1 Select the subplot you want to unlink.
- 2 On the **Format** tab, click the **Unlink a Subplot** button on.

The broken link symbol  appears on the unlinked subplot.

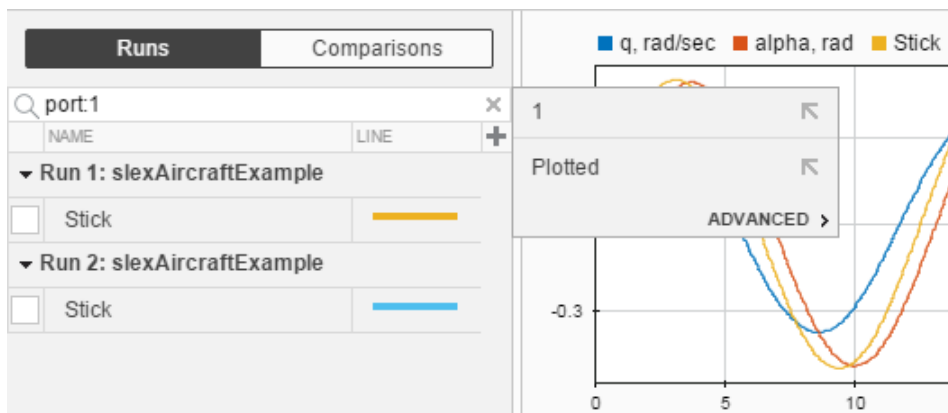

Filter Runs and Signals

To help search through a large amount of data in the **Runs** and **Comparisons** panes, you can filter runs and signals by text contained in the run or signal name and properties. The properties are also found in the **Runs** and **Comparisons** pane columns.

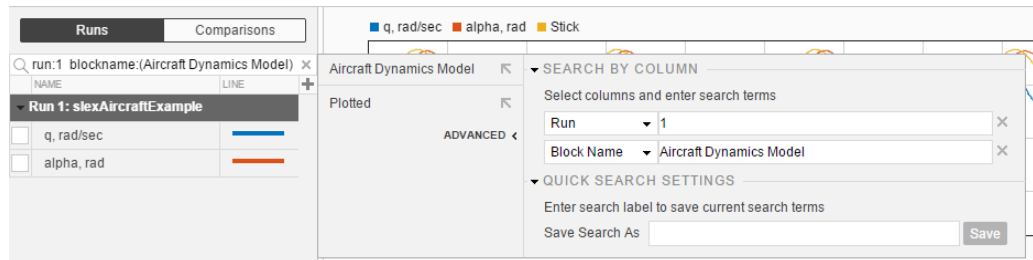

- 1 To show signals only with the name alpha, type alpha into the Filter Signals text box. The matches are highlighted in the filter results.

- 2 To filter for a signal or run property, you can use colons. For example, port:1 filters for signals that use port 1 in the model. Since the column is not visible in the **Runs** pane, the result is not highlighted.

- 3 To save multiple filter terms to a filter name, open the **Advanced** section of the filter dialog box.
- 4 Select a column filter criteria, and enter the filter value. This example uses the Run and Block Name columns as filter criteria.

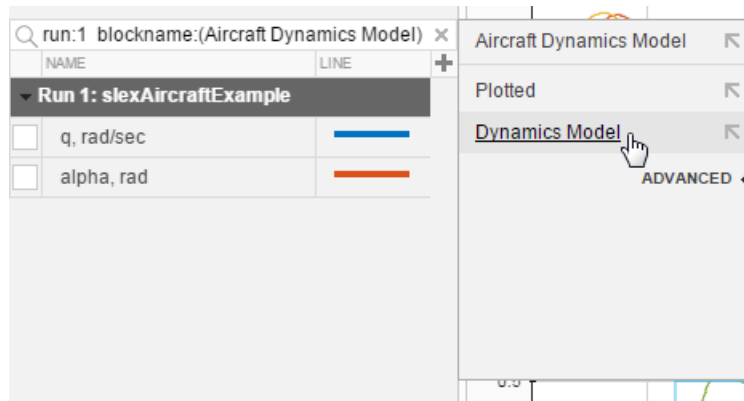

Note: The filter matches text. For example, if you want to filter for absolute tolerance values of 0.1, then a filter of 00.1 will not return any filter results.

- 5 To save the filter, enter a name in the **Save Search As** box. Click **Save**.

The saved filter shows in the filter list.

Inspect Event-Based Data

You can visualize and inspect event-based data in the Simulation Data Inspector with stem plots. To visualize event-based or message data, mark the signal for streaming. When you simulate the model, the data appears in the Simulation Data Inspector as a stem plot for each event.

- “Overwrite a Run” on page 26-47

Compare Signal Data from Multiple Simulations

In this section...

“Compare Two Signals” on page 26-36

“Compare Two Runs” on page 26-37

In the Simulation Data Inspector, you can use the **Compare** tab to compare two signals or all signal data from two different simulation runs. This example is a continuation of “Inspect Signal Data” on page 26-25.

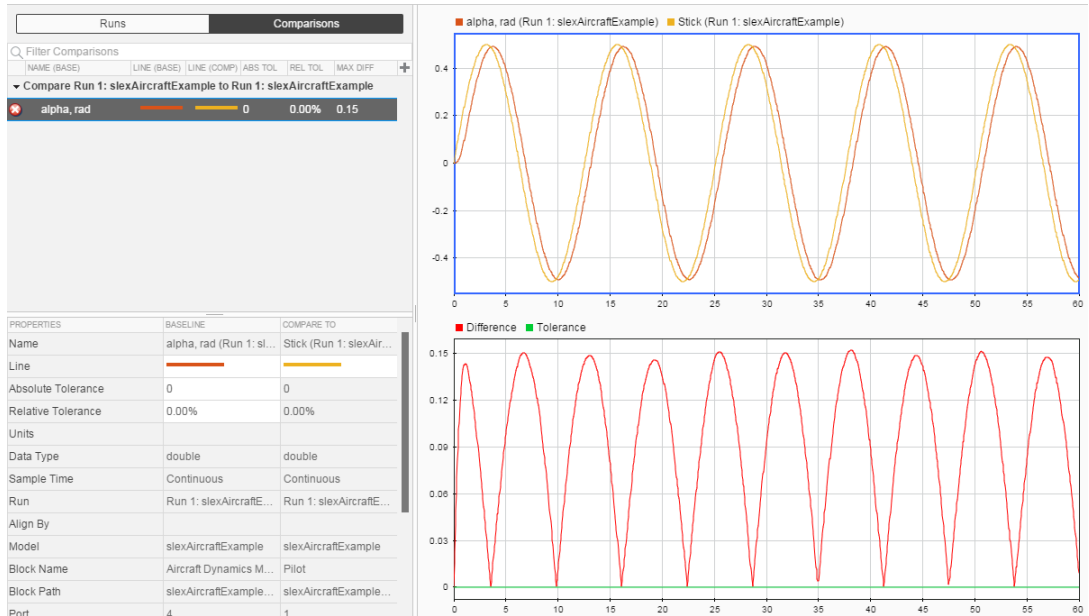

Compare Two Signals

- 1 In the **Runs** pane, right-click a baseline signal and select **Compare Signals > Set as Baseline**.
- 2 Right-click another signal that you want to compare to that baseline and select **Compare Signals > Set as Compare To**.

- 3 In the **Compare** tab, click **Compare**.

Here, the `alpha, rad` and `Stick` signals are compared from Run 1. In this example, the comparison fails because the signals do not match within the default relative and absolute tolerance.

Compare Two Runs

- 1 Click the **Compare** tab.
- 2 Select the **Runs** option button.

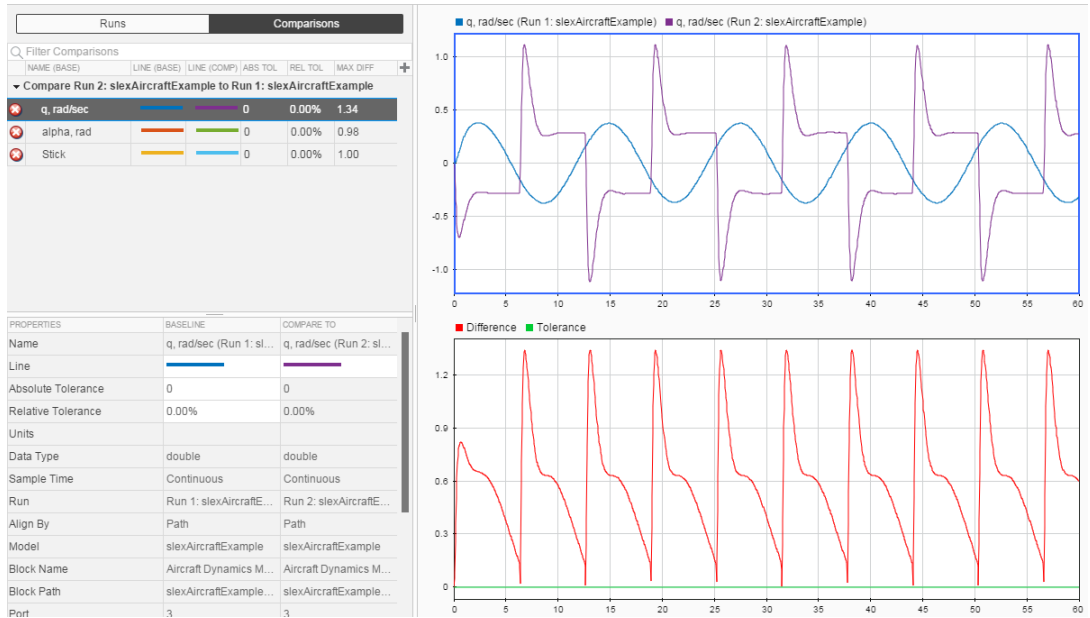

- 3 From the **Baseline** and **Compare To** lists, select two different runs. These runs correspond to runs located in the **Runs** pane.
- 4 Click **Compare**. The **Comparisons** pane lists all signals from each run with a result. In this example, the comparison results of the aligned signals do not match because the signal differences are not within the absolute tolerance or relative tolerance.

Runs		Comparisons			
Filter Comparisons					
NAME (BASE)	LINE (BASE)	LINE (COMP)	ABS TOL	REL TOL	MAX DIFF
Compare Run 2: slxAircraftExample to Run 1: slxAircraftExample					
⊗ q, rad/sec			0	0.00%	1.34
⊗ alpha, rad			0	0.00%	0.98
⊗ Stick			0	0.00%	1.00

Note: The Simulation Data Inspector only compares signals from **Baseline** that are aligned with a signal from **Compare To**. If a signal from **Baseline** does not align with a signal from **Compare To**, then the signal is listed with a warning . For more information on signal alignment, see “How the Simulation Data Inspector Aligns Signals” on page 26-44.

- 5 To plot a comparison, in the **Plot** column select the option button for a signal, in the example it is **q, rad/sec**. The top plot shows the **q, rad/sec** signals from the **Baseline** and **Compare To** runs. The bottom plot shows the difference between the signals and the tolerance. For information on manipulating the plot, see “Customize the Simulation Data Inspector Interface” on page 26-48.

Note: Even though relative and absolute tolerances can be specified, the only tolerance that shows in the Difference and Tolerance plot is the more lenient tolerance. For more information on tolerances, see “How the Simulation Data Inspector Applies Tolerances” on page 26-43.

- 6 To modify the relative tolerance or absolute tolerance, double-click the **Abs Tol** or **Rel Tol** field for a signal and type in a value. In this example, the signal comparison of q , rad/sec passes using an absolute tolerance of 1.5.

Runs		Comparisons			
Filter Comparisons					
NAME (BASE)	LINE (BASE)	LINE (COMP)	ABS TOL	REL TOL	MAX DIFF
▼ Compare Run 2: slexAircraftExample to Run 1: slexAircraftExample					
✓ q, rad/sec			1.5	0.00%	1.34
✗ alpha, rad			0	0.00%	0.98
✗ Stick			0	0.00%	1.00

- To create a report of the comparison results, see “Create Simulation Data Inspector Report” on page 26-41.

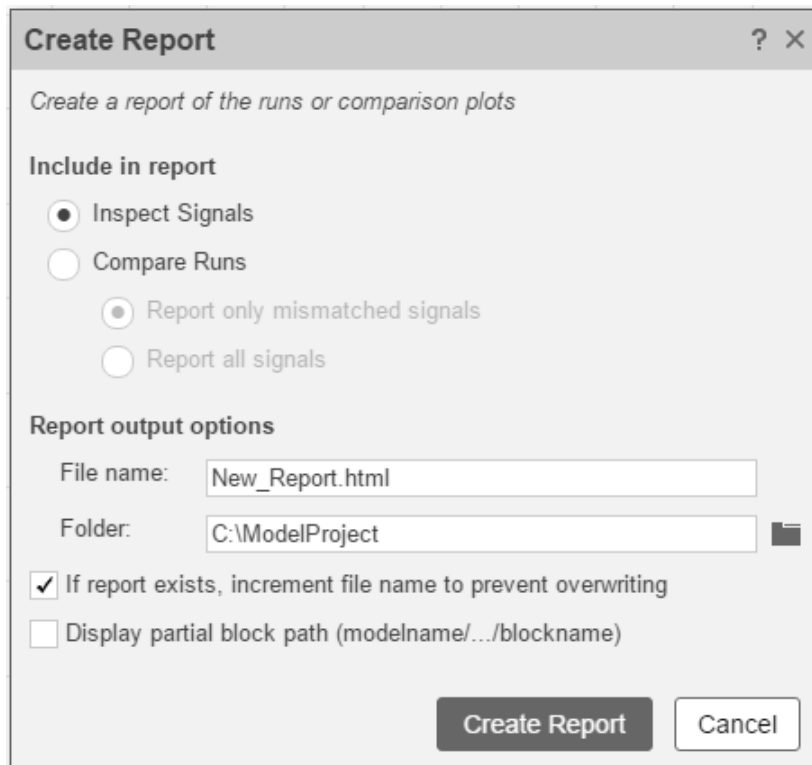

Related Examples

- “Inspect Signal Data” on page 26-25
- “Create Simulation Data Inspector Report” on page 26-41

Create Simulation Data Inspector Report

You can create a Simulation Data Inspector report that shows the plots in the **Runs** or **Comparisons** panes.

- 1 In the Simulation Data Inspector, on the **Visualize** or **Compare** tab, click **Create Report**.

- 2 Under **Include in report**, specify the plots to include in the report. Select **Inspect Signals** to include the plots from the **Runs** pane. Select **Compare Runs** to include the plots from the **Comparisons** pane. If you select **Compare Runs**, you can select **Report only mismatched signals**, which show only signal comparisons that are not within the specified tolerances. Or you can select **Report all signals** to include all signal comparisons.
- 3 Specify the **File name** and **Folder**.

- 4 Select the file and block naming options you want, and then click **Create Report**.

The report opens when it is completed.

Related Examples

- “Share Simulation Data Inspector Data and Views” on page 26-18

How the Simulation Data Inspector Compares Time Series Data

To compare time series data, the Simulation Data Inspector:

- 1 Converts Simulink time series data to MATLAB time series data.
- 2 Aligns the time vectors using the default synchronization method `union`. (You can change the synchronization method for a signal: add the **Sync Method** column to the Navigation pane table and choose a method.)
- 3 Aligns the data vectors using the default interpolation method, `zoh` (zero-order hold). (You can change the interpolation method for a signal: add the **Interpolation Method** column to the Navigation pane table and choose a method.)
- 4 Differences the data.
- 5 Applies the specified tolerances for plotting the difference. For more information, see “How the Simulation Data Inspector Applies Tolerances” on page 26-43.

After it aligns signals from **Baseline** with signals from **Compare To**, the Simulation Data Inspector compares only the aligned signals. The **Comparisons** pane displays the results of all signal comparisons using these symbols.

Status	Comparison Result
	<ul style="list-style-type: none"> • Signal aligns. • Signal data from two runs matches within the tolerance.
	<ul style="list-style-type: none"> • Signal aligns. • Signal data from two runs does not match within the tolerance.
	Signal from Baseline does not align with a signal from Compare To .

How the Simulation Data Inspector Applies Tolerances

The default value for the relative tolerance and absolute tolerance for a signal is zero. If you specify tolerances, then the Simulation Data Inspector calculates the tolerances as follows:

```
tolerance = max(absoluteTolerance, relativeTolerance*abs(baselineData));
```

If you want to change the relative tolerance or absolute tolerance, select the **Rel Tol** or **Abs Tol** column of a signal in the **Comparisons** pane and type a value. Values for the tolerances must be positive, scalar values of double-precision.

How the Simulation Data Inspector Aligns Signals

When the Simulation Data Inspector aligns signals across simulation runs, it attempts to match signals between runs using signal properties. On the **Compare** tab, click **Comparison Options**. In the dialog box, you can specify the signal properties to use to align signals, as shown in the table.

Property	Description
Data Source	Path of the variable in the MATLAB workspace (streamed signals do not have a data source because they do not come from the workspace)
Path	Block path of the source signal that produced the data
SID	“Locate Diagram Components Using Simulink Identifiers” on page 1-18
Signal Name	Name of the signal in the model

By default, the Simulation Data Inspector is configured to first align signals by data source, then by path, then by SID, and then by signal name. For more information on how to change alignment settings, see “Modify Signal Alignment for Comparisons” on page 26-56.

An instance where a comparison of signals does not align is if a signal name is different between two runs and the Comparison Options alignment properties are set to align by signal name only. In this case, the signal comparison does not align.

Related Examples

- “Compare Signal Data from Multiple Simulations” on page 26-36

Run Management Configuration

The Simulation Data Inspector loads new simulation runs into the **Runs** pane. You can configure how new runs are loaded into the Simulation Data Inspector.

- “Append New Runs” on page 26-46
- “Specify a Run Naming Rule” on page 26-46
- “Overwrite a Run” on page 26-47

Append New Runs

You can specify whether to add new runs in the **Runs** pane at the top or bottom of the runs list. From the **Visualize** tab, click **Run Options** to open the Run Options dialog.

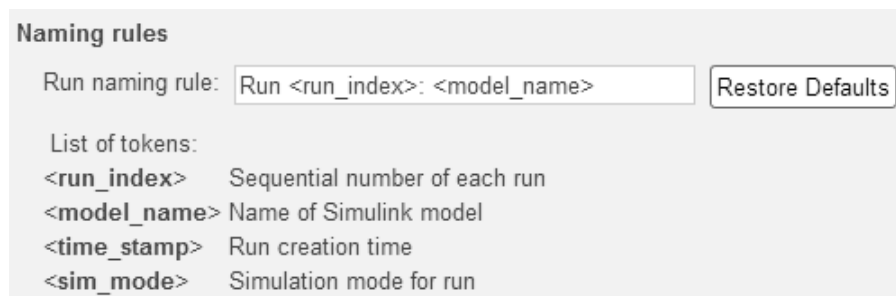

In the Run Options dialog box, the default is set to add new runs to the bottom of the runs list.

To append new runs at the top of the list, click **Add new runs at top**.

Specify a Run Naming Rule

To specify run naming rules, click **Run Options** on the **Visualize** tab. In the Run Options dialog box, the default value for the **Run naming rule** is `Run <run_index>: <model_name>`.

To change the run name, enter available tokens from the list and any other regular characters. For example, to include all four tokens, enter the following in the **Run naming rule** box:

```
Run <run_index>: <model_name>: <time_stamp>: <sim_mode>
```

For model `slexAircraftExample`, the run name appears as follows:

```
Run 1: slexAircraftExample: 31-May-2014 10:50:18: normal
```

Overwrite a Run

You can overwrite an existing run in the **Runs** pane with the next simulation run.

- 1 In the **Runs** pane, right-click the run name you want to overwrite and select **Overwrite Run**.

The overwrite symbol appears on the run to be overwritten.

- 2 Simulate the model.

The data for the selected run is replaced with the new simulation run.

See “Use Signal Streaming to Iterate Model Design” on page 26-7 for more information on how run overwrite can be used in combination with signal streaming.

- “Stream Data to the Simulation Data Inspector” on page 26-6
- “Customize the Simulation Data Inspector Interface” on page 26-48

Customize the Simulation Data Inspector Interface

You can customize the information displayed in the **Runs** and **Comparisons** panes by performing the following tasks:

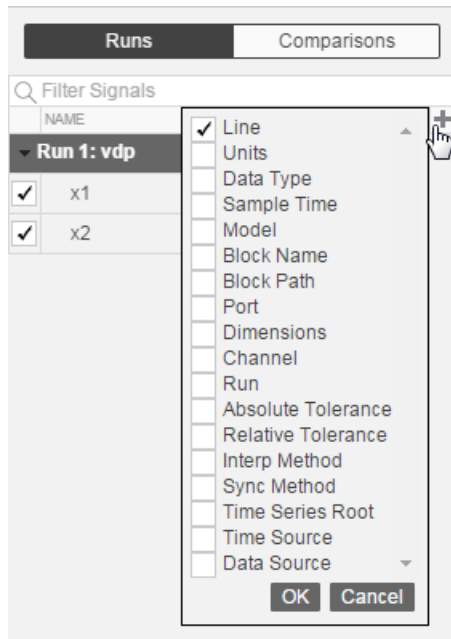

- “Add or Remove a Column in the Runs or Comparisons Pane” on page 26-48
- “Rename a Run” on page 26-53
- “Modify Grouping in Runs Pane” on page 26-54
- “View Signal and Run Properties” on page 26-51
- “Modify Signal Alignment for Comparisons” on page 26-56

You can also modify how signals appear in a plot by performing the following tasks:

- “Specify the Line Color and Style” on page 26-57
- “Modify Streamed Signal Properties” on page 26-58
- “Modify a Plot in the Simulation Data Inspector” on page 26-59

Add or Remove a Column in the Runs or Comparisons Pane

Columns in the **Runs** and **Comparisons** panes display plot configuration and signal properties. To add or remove a column, click the column selector button. From the list, select the columns that you want to display in the pane and click **OK**. After you select a column, the new column is added to the table in the order that it appears in the column selection list.

Column Options for Runs Pane

Column Option	Value
Line	Signal line style and color
Units	Signal measurement units
Data Type	Signal data type
Sample Time	Sample time used during model simulation
Model	Model name for the signal data
Block Name	Name of the source block
Block Path	Path to the source block for the signal
Port	Index of the signal output port
Dimensions	Number of dimensions of the signal
Channel	Channel of matrix data
Run	Name of a simulation run
Absolute Tolerance	Positive number (user-specified)

Column Option	Value
Relative Tolerance	Positive number (user-specified)
Interp Method	Interpolation method to plot data: zoh , linear (user-specified)
Sync Method	Synchronization method to align time vector: union , intersection , uniform (user-specified)
Time Series Root	Name of the Simulink.Timeseries object
Time Source	Name of array containing the time data
Data Source	The path of the variable in the MATLAB workspace (streamed signals do not have a data source because they do not come from the workspace)

Each column in the **Comparisons** pane has a Baseline and Compare To component corresponding to the Baseline or Compare To run selected on the **Compare** tab.

Column Options for Comparisons Pane

Column Option	Value
Line	Signal line style and color
Absolute Tolerance	Positive number (user-specified)
Relative Tolerance	Positive number (user-specified)
Max Difference	The maximum difference between the Baseline and Compare To signal selected in the Comparisons pane
Name	Name of Compare To signal (Baseline signal name is displayed by default)
Units	Signal measurement units
Data Type	Signal data type
Sample Time	Sample time used during model simulation
Run	Name of the simulation run
Align By	Signal alignment specified in Comparison Options

Column Option	Value
Model	Model name
Block Name	Name of the source block
Block Path	Path to the source block for the signal
Port	Index of the signal output port
Dimensions	Dimensionality of the signal
Channel	Channel of matrix data
Interp Method	Interpolation method to plot data: <code>zoh</code> , <code>linear</code> (user-specified)
Sync Method	Synchronization method to align time vector: <code>union</code> , <code>intersection</code> , <code>uniform</code> (user-specified)
Time Series Root	Name of the Simulink.Timeseries object
Time Source	Name of array containing the time data
Data Source	Path of the variable in the MATLAB workspace (streamed signals do not have a data source because they do not come from the workspace)

View Signal and Run Properties

To view the properties of a signal, highlight a signal in the **Runs** or **Comparisons** pane. The properties pane displays the signal information.

Runs

Comparisons

	NAME	LINE
▼ Run 1: vdp		
<input checked="" type="checkbox"/>	x1	
<input checked="" type="checkbox"/>	x2	

PROPERTIES	VALUES
Name	x1

Block Name	x1
Block Path	vdp/x1
Port	1
Dimensions	[1]
Channel	
Run	Run 1: vdp
Absolute Tolerance	0
Relative Tolerance	0.00%
Interp Method	linear
Sync Method	union
Time Series Root	
Time Source	
Data Source	

To view the properties of a run, highlight the run in the **Runs** or **Comparisons** pane. The properties pane displays the run information.

The screenshot shows the Simulation Data Inspector interface. At the top, there are two tabs: "Runs" (selected) and "Comparisons". Below the tabs is a search bar labeled "Filter Signals". Underneath is a table with columns "NAME" and "LINE", and a "+" icon on the right. A dropdown menu is open, showing "Run 1: vdp". Below this, there are two rows in the table:

NAME	LINE
<input checked="" type="checkbox"/> x1	
<input checked="" type="checkbox"/> x2	

Below the table is a "PROPERTIES" section with a table of run details:

PROPERTIES	VALUES
Name	Run 1: vdp
Description	
Tag	
Date	22-Dec-2015 15:46:27
Model	vdp
Simulation Mode	normal
Start Time	0
Stop Time	20
Simulink Version	
Model Version	
User ID	
Machine Name	
Solver Type	
Solver Name	
Initialization Time	
Execution Time	
Termination Time	
Total Elapsed Time	

Rename a Run

To rename a run name, you can:

- Double-click the run row, type the new run name, and press **Enter**.

- Click the Name row in the properties pane, type the new run name, and press **Enter**.

To specify a new run naming rule for subsequent simulation runs, see “Specify a Run Naming Rule” on page 26-46.

Modify Grouping in Runs Pane

You can customize the organizational hierarchy of your data in the **Runs** pane. The data is first grouped by run name, which cannot be modified. You can then group your data by data hierarchy, model hierarchy, or without further hierarchy. Changes to signal grouping apply only to the **Runs** pane, not the **Comparisons** pane. If you have a Simscape license, then you can group your data by physical system data hierarchy.

If your model contains referenced models to view, you can group your data by model hierarchy and then by data hierarchy. As an example, change the grouping in the **Runs** pane to group by run name, then by model hierarchy, and then by data hierarchy.

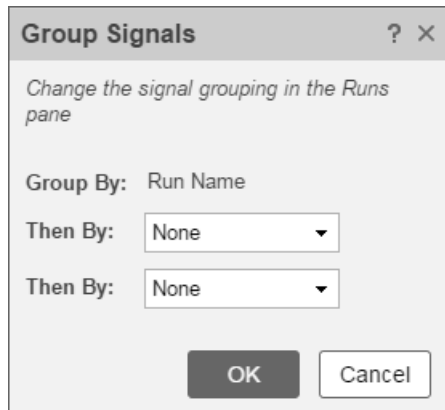

- 1 On the **Visualize** tab, click **Group Signals**.
- 2 In the Group Signals dialog box, in the first **Then By** list, select **Model Hierarchy**.
- 3 In the second **Then By** list, select **Data Hierarchy**.

- 4 Click **OK**. The **Runs** pane groups the signal data by run name, then by model, and then by the data.

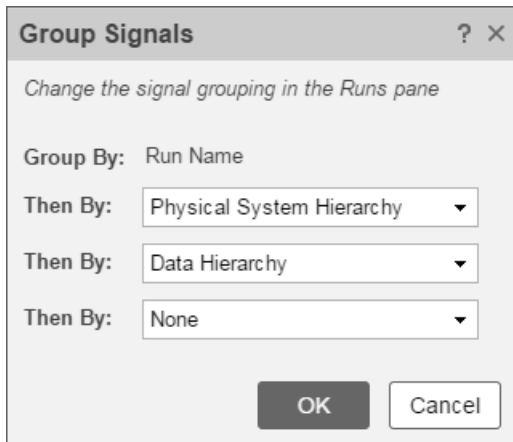

To remove the hierarchy and display a simple list of signals, select **None** from both Group Signals dialog box lists, and click **OK**.

Runs		Comparisons	
Filter Signals			
NAME	LINE	BLOCK PATH	
▼ Run 1: sldemo_mdref_dsm			
<input type="checkbox"/> A1:1		sldemo_mdref_dsm/A1	
<input type="checkbox"/> A:1		sldemo_mdref_dsm/A	
<input type="checkbox"/> Data Store Read:1		sldemo_mdref_dsm/Data Store Read	
<input type="checkbox"/> Mux:1[1]		sldemo_mdref_dsm/Mux	
<input type="checkbox"/> Mux:1[2]		sldemo_mdref_dsm/Mux	
<input type="checkbox"/> Sine Wave:1		sldemo_mdref_dsm/Sine Wave	
<input type="checkbox"/> Switch:1		sldemo_mdref_dsm/Switch	

If you have a Simscape license, then you can group your data by physical system data hierarchy using the default settings.

Modify Signal Alignment for Comparisons

When the Simulation Data Inspector aligns signals across simulation runs, it attempts to match signals between runs using signal properties. For more information on the properties used for alignment, see “How the Simulation Data Inspector Aligns Signals” on page 26-44. To modify how signals are aligned for run comparisons:

- 1 On the **Compare** tab, select **Comparison Options**.

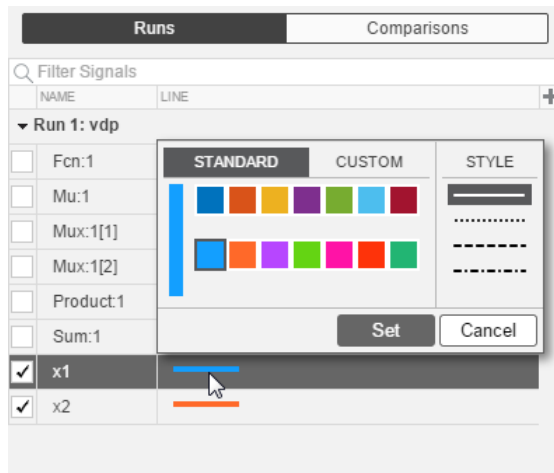

- 2 Select the **Align By** and **Then By** signal properties, and click **OK**.
- 3 Click **Compare** to align the signal data and compare the aligned signal data.

The default alignment options are by **Data Source**, then by **Path**, then by **SID**, and then by **Signal Name**.

Specify the Line Color and Style

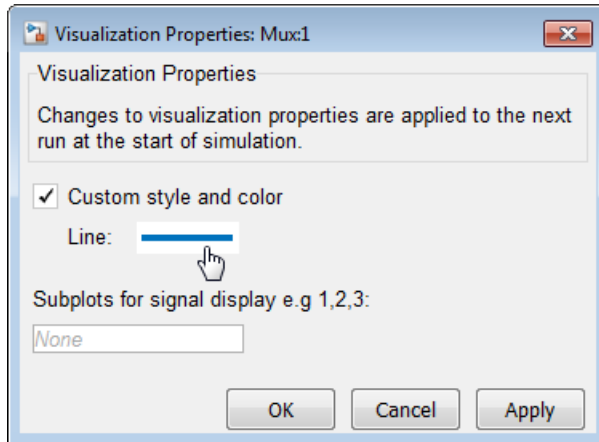

To specify the line style and color, click in the **Line** column of a signal. If the line column is not shown, add the column using the column selector button **+**. Select a color from the palette and a line style.

Modify Streamed Signal Properties

You can modify the line color, line style, and the subplot arrangement of a streaming signal from the model. Changes you make in this dialog are applied to the next run in the Simulation Data Inspector at the start of simulation.

- 1 In the model, right-click the streaming badge  and select **Properties** to open the properties dialog box.
- 2 To specify the line style and color, select the **Custom style and color** check box, and then select the style and color.

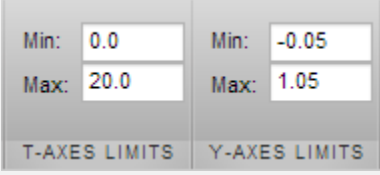

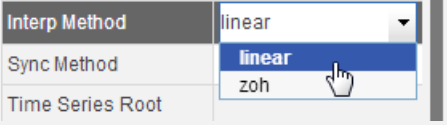

- 3 To specify where a streamed signal is plotted at the start of simulation, enter a subplot number in the **Subplots for signal display** box. The number refers to the subplot number in column-major order.
- 4 Click **OK**, and save the model.

For information on how to stream signals, see “Stream Data to the Simulation Data Inspector” on page 26-6.

Modify a Plot in the Simulation Data Inspector

Goal	Action
Normalize the data for each signal from 0 to 1 along the y-axis of a plot.	On the Format tab, select Normalize Y Axis .
Show markers at each sample point on a signal.	On the Format tab, select Show Markers .
Set the plot axes minimum and maximum values.	On the Format tab, enter the axes limit values.

Goal	Action
	
<p>Zoom and pan to inspect the data.</p>	<p>On the Visualize tab, select one of the zoom actions.</p> 
<p>Send all the plots to a separate MATLAB figure window.</p>	<p>On the Visualize or Compare tab, click Send to Figure.</p> <p>For more information on plotting and customizing your MATLAB data plots, see “Types of MATLAB Plots”.</p>
<p>Set the interpolation method used for plotting a signal to zero-order-hold or linear.</p>	<p>Select a signal in the Runs or Comparisons pane. In the properties table, select an interpolation method from the Interp Method list.</p> 
<p>Unlink or link a subplot.</p>	<p>Select a subplot. On the Format tab, select Unlink a Subplot.</p> <p>For more details, see “Linked Subplots” on page 26-31.</p>

Related Examples

- “Run Management Configuration” on page 26-46

Limitations of the Simulation Data Inspector

- The following Simulink data export formats are not supported if the time is not logged:
 - Structure: If the structure format does not contain sample time information, then structure format signals in the Simulation Data Inspector display using ZOH interpolation.
 - Array
- If you simulate a model with the simulation mode set to Rapid Accelerator, then the following cannot be streamed into the Simulation Data Inspector:
 - Multi-instance model reference signals
 - Nonvirtual bus signals
- When you simulate and stream data from the Simulink Editor or send logged data from the base workspace, after you open the Simulation Data Inspector, the simulation data appears in the **Runs** pane. However, when you simulate a model at the command line using `sim`, use the `Simulink.sdi.createRun` function to view the simulation data in the Simulation Data Inspector. For more information, see “Create a Run in the Simulation Data Inspector” on page 26-66.
- The Simulation Data Inspector allows up to 8000 channels per signal in a run created from imported workspace data.

Related Examples

- “Inspect Signal Data with Simulation Data Inspector” on page 26-2

Inspect and Compare Signal Data Programmatically

Overview

Using the Simulation Data Inspector API, you can plot signal data, compare two signals, and compare data from two simulation runs. You can use the `Simulink.sdi.createRun` function to add simulation output data to the Simulation Data Inspector. Once the Simulation Data Inspector contains signal data, you can perform the following tasks:

Goal	Use
View signal data, open the Simulation Data Inspector	<code>Simulink.sdi.view</code>
Compare the data of two signals	<code>Simulink.sdi.compareSignals</code>
Compare the output of two simulation runs	<code>Simulink.sdi.compareRuns</code>

Run Management

Simulation Data Inspector software creates and manages a list of simulation runs. Each run is an instance of a `Simulink.sdi.Run` object. This object contains all of the simulation data and metadata for that simulation run.

Goal	Use
Get the number of runs currently in the Simulation Data Inspector	<code>Simulink.sdi.getRunCount</code>
Get the run ID from the list of simulation runs in the Simulation Data Inspector	<code>Simulink.sdi.getRunIDByIndex</code>
Determine if a run ID corresponds to a run currently in the Simulation Data Inspector	<code>Simulink.sdi.isValidRunID</code>
Add more data to a run currently in the Simulation Data Inspector	<code>Simulink.sdi.addToRun</code>
Make a copy of a run currently in the Simulation Data Inspector	<code>Simulink.sdi.copyRun</code>
Delete a run from the Simulation Data Inspector	<code>Simulink.sdi.deleteRun</code>

Goal	Use
Get simulation data for a run in the Simulation Data Inspector	<code>Simulink.sdi.getRun</code>
Specify a run naming rule using tokens and regular characters as a template	<code>Simulink.sdi.setRunNamingRule</code>
Mark a run in the Simulation Data Inspector for overwriting on the next simulation	<code>Simulink.sdi.setRunOverwrite</code>
Change signal grouping hierarchy of Runs pane	<code>Simulink.sdi.setTableGrouping</code>
Manage output signal data and metadata of a simulation run	<code>Simulink.sdi.Run</code> class
Get the <code>Simulink.sdi.Signal</code> object corresponding to the given signal ID	<code>Simulink.sdi.Run.getSignal</code> method
Get the <code>Simulink.sdi.Signal</code> object corresponding to the index into the array signals in the run	<code>Simulink.sdi.Run.getSignalByIndex</code> method
Get the signal ID corresponding to the index into the array signals in the run	<code>Simulink.sdi.Run.getSignalIDByIndex</code> method
Determine if a signal ID corresponds to a signal currently in the run	<code>Simulink.sdi.Run.isValidSignalID</code> method

Signal Management

Each `Simulink.sdi.Run` object contains a `Simulink.sdi.Signal` object for each output signal data. This object contains all of the simulation data for the signal and its metadata.

Goal	Use
Get the simulation data and metadata for a signal from one simulation run.	<code>Simulink.sdi.getSignal</code>
Copy signal line style and color from one run to another	<code>Simulink.sdi.copyRunViewSettings</code>
Set number of subplots	<code>Simulink.sdi.setSubPlotLayout</code>

Goal	Use
Delete a signal from the Simulation Data Inspector	<code>Simulink.sdi.deleteSignal</code>
Manages a signal's time series data and metadata for one simulation run.	<code>Simulink.sdi.Signal</code> class
Turn streaming on or off for a signal	<code>Simulink.sdi.markSignalForStreaming</code>
Change signals marked for logging to streaming	<code>Simulink.sdi.changeLoggedToStreamed</code>
Change signals marked for streaming to logging	<code>Simulink.sdi.changeStreamedToLogged</code>

Import/Export Data

Goal	Use
Save signal data currently in the Simulation Data Inspector	<code>Simulink.sdi.save</code>
Load previously saved Simulation Data Inspector session	<code>Simulink.sdi.load</code>
Clear all data from the Simulation Data Inspector	<code>Simulink.sdi.clear</code>
Close the Simulation Data Inspector and save data	<code>Simulink.sdi.close</code>
Generate report from Simulation Data Inspector	<code>Simulink.sdi.report</code>
Create run from simulation output results	<code>Simulink.sdi.createRunsFromSimulationOutput</code>
Import Simulink Design Verifier test case inputs	<code>Simulink.sdi.createRunsFromSLDV</code>

Comparison Results

Goal	Use
Manage the results of comparing two runs (<code>Simulink.sdi.compareRuns</code> creates the <code>Simulink.sdi.DiffRunResult</code> object)	<code>Simulink.sdi.DiffRunResult</code> class

Goal	Use
Manage the results of comparing two signals (<code>Simulink.sdi.compareSignals</code> creates the <code>Simulink.sdi.DiffSignalResult</code> object)	<code>Simulink.sdi.DiffSignalResult</code> class

Create a Run in the Simulation Data Inspector

To populate the Simulation Data Inspector with runs of simulation data, you must first simulate your model and then call `Simulink.sdi.createRun`. When using the `sim` function, logged workspace data is not automatically sent to the Simulation Data Inspector. To create a run of simulation data, you can use the following code:

```
% Open model and stream logged signals
% to Simulation Data Inspector
load_system('sldemo_absbrake');
Simulink.sdi.changeLoggedToStreamed('sldemo_absbrake');

% Simulate model
sim('sldemo_absbrake');

% Open Simulation Data Inspector
Simulink.sdi.view;
```

Create a Run from Workspace Variables

To create a run in the Simulation Data Inspector from variables in the base workspace, you can use the following code:

```
% Create timeseries data
t = (0:0.1:2*pi)';
ts1 = timeseries(sin(t),t,'Name','sine');
ts2 = timeseries(cos(t),t,'Name','cosine');

% Import timeseries into Simulation Data Inspector
runID = Simulink.sdi.createRun('My Run','vars',ts1,ts2);
run = Simulink.sdi.getRun(runID);

% Plot signals
sig1 = getSignalByIndex(run,1);
sig2 = getSignalByIndex(run,2);
```

```
sig1.checked = true;
sig2.checked = true;

% Open Simulation Data Inspector
Simulink.sdi.view
```

Stream Data and Send to Base Workspace

If you stream data into the Simulation Data Inspector, then you can send it to the base workspace using the following code:

```
% Open model
load_system('sldemo_absbrake');

% Streamed logged signals directly to
% Simulation Data Inspector and automatically
% export them at end of simulation
Simulink.sdi.changeLoggedToStreamed('sldemo_absbrake');
set_param('sldemo_absbrake', 'StreamToWorkspace', 'on');

% Simulate model and stream data to base workspace
out = sim('sldemo_absbrake', 'ReturnWorkspaceOutputs', 'on');
```

Compare Signal Data

To compare the simulation data for two signals, you can use the following code:

```
% Open model and stream logged signals
% to Simulation Data Inspector
load_system('sldemo_absbrake');
Simulink.sdi.changeLoggedToStreamed('sldemo_absbrake');

% Simulate model
sim('sldemo_absbrake');

% Create a Simulation Data Inspector run
runID = Simulink.sdi.getRunIDByIndex(1);
run = Simulink.sdi.getRun(runID);

sig1 = getSignalIDByIndex(run, 1);
sig2 = getSignalIDByIndex(run, 2);
```

```
% Compare two signals
diff = Simulink.sdi.compareSignals(sig1,sig2);

% Find if signal data match
Match = diff.Match;

% Get tolerance used when comparing signals
tolerance = diff.Tol;
```

Compare Runs of Simulation Data

To compare the signal data between two simulation runs, you can use the following code. At the end of this example, the difference between the Ww signal from each run is plotted in a MATLAB figure.

```
% Open model and stream logged signals
% to Simulation Data Inspector
load_system('sldemo_absbrake');
Simulink.sdi.changeLoggedToStreamed('sldemo_absbrake');

% Simulate model using 0.24 desired slip
set_param('sldemo_absbrake/Desired relative slip','Value','0.24')
sim('sldemo_absbrake');

% Simulate model using 0.25 desired slip
set_param('sldemo_absbrake/Desired relative slip','Value','0.25')
sim('sldemo_absbrake');

% Compare runs
run1 = Simulink.sdi.getRunIDByIndex(1);
run2 = Simulink.sdi.getRunIDByIndex(2);
runResult = Simulink.sdi.compareRuns(run1,run2);

% Plot 'Ww' signal difference between runs
signalResult = getResultByIndex(runResult,1);
plot(signalResult.Diff);
```

Generate a Report from Simulation Data Inspector

To create a report from a run comparison, you can use the following code:

```
% Open model and stream logged signals
% to Simulation Data Inspector
```

```

load_system('sldemo_absbrake');
Simulink.sdi.changeLoggedToStreamed('sldemo_absbrake');

% Simulate model twice
set_param('sldemo_absbrake/Desired relative slip','Value','0.22')
sim('sldemo_absbrake');

set_param('sldemo_absbrake/Desired relative slip','Value','0.25')
sim('sldemo_absbrake');

% Compare two runs
runID1 = Simulink.sdi.getRunIDByIndex(1);
runID2 = Simulink.sdi.getRunIDByIndex(2);
Simulink.sdi.compareRuns(runID1,runID2);

% Create report
Simulink.sdi.report('ReportToCreate','Compare Runs');

```

Record Data During Parallel Simulations

This example shows how to run parallel simulations using a `parfor` loop and record each run in the Simulation Data Inspector.

```

% Open Simulation Data Inspector
Simulink.sdi.view;

% Load model
mdl = 'sldemo mdlref_bus';
load_system(mdl);

% Start parallel pool with four workers
myPool = parpool(4);

% Run simulation in parfor loop
out = cell(1,4);
parfor idx = 1:4
    % Run simulation
    out{idx} = sim(mdl,'ReturnWorkspaceOutputs','on');

    % Create a simulation run in
    % Simulation Data Inspector
    runName = sprintf('Run %d',idx);
    Simulink.sdi.createRun(runName,'vars',out{idx});
end

```

```
% Delete current parallel
% pool and close model
delete(myPool);
close_system mdl);

% Import data from parallel pool
% into Simulation Data Inspector
Simulink.sdi.importDataFromWorkers;
```

Keyboard Shortcuts for the Simulation Data Inspector

In the table, if the shortcut is called **Ctrl+N**, for example, it means to hold down the **Ctrl** key and press the **N** key.

Note: On Macintosh platforms, use the **command** key instead of **Ctrl**.

General Actions

Task	Shortcut
Start a new session	Ctrl+N
Open a session	Ctrl+O
Save a session	Ctrl+S
Compare	Ctrl+E
Link/Unlink a subplot	Ctrl+U
Delete a run or signal	Delete

Plot Zooming

Task	Shortcut
Zoom in T (time)	Ctrl+Shift+T
Zoom in Y	Ctrl+Shift+Y
Zoom in T and Y	Ctrl++ (numeric keypad only)
Zoom out	Ctrl+- (numeric keypad only)
Fit to view	Spacebar
Cancel out of zoom operation or signal dragging	Esc

Data Cursors

Task	Shortcut
Show a data cursor	Ctrl+I
Hide all data cursors	Shift+Del
Move a selected data cursor to next data point	Right arrow
Move a selected data cursor to previous data point	Left arrow
Activate first (left) cursor	Ctrl+1
Activate second (right) cursor	Ctrl+2

Tune and Visualize Your Model with Dashboard Blocks

In this section...

“Dashboard Blocks” on page 26-73

“Open the Model and Dashboard Library” on page 26-73

“Connect Parameter to a Knob” on page 26-73

“View Signal Data” on page 26-74

“Tune Parameters During Simulation” on page 26-75

“Visualize Signal Data” on page 26-75

Dashboard Blocks

The blocks in the Dashboard library help you to control and visualize your Simulink model during simulation or while the simulation is paused. The Dashboard blocks are located in the Dashboard block library under **Simulink > Dashboard**. The types of blocks available in the library are:

- Knobs
- Gauges
- Switches
- Lamp
- Dashboard scope

Open the Model and Dashboard Library

This example uses the Fault-Tolerant Fuel Control System model.

- 1 To open the model, enter `sldemo_fuel_sys` into the MATLAB command window.
- 2 Open the **Simulink Library Browser**.
- 3 Select **Simulink > Dashboard** in the library browser to view the Dashboard library.

Connect Parameter to a Knob

You can adjust model parameters and tunable variables after you connect them to knobs and switches from the Dashboard block library. You can change the parameters and

tunable variables before simulation, during simulation, and while simulation is paused by using these blocks.

- 1 Add a Knob block from the Dashboard library to the model.
- 2 Double-click the Knob block to open the block dialog box.
- 3 In the model, select the Nominal Speed block. Nominal Speed is a Constant block whose **Constant value** parameter you can tune with the Knob block.

When you select Nominal Speed, the name of the block and the parameter you can tune appear in the connections table in the Knob block dialog box.

Note: You cannot connect to a block that is commented out.

- 4 Select the option button next to **Nominal Speed:Value** in the connections table.
- 5 After you have connected the parameter you want to tune with the knob, you can set the tick range for the knob to values that make sense for your simulation. In this example, set **Minimum** to 75, **Maximum** to 750, and **Tick Interval** to 75.
- 6 Click **OK** to connect the **Nominal Speed:Value** parameter to the knob.

View Signal Data

You can view signal data using gauges, lamps, or strip charts from the Dashboard block library. In this example, connect a gauge so you can view the value of the `air_fuel_ratio` signal, which changes according to the value of the Nominal Speed block controlled by the knob.

- 1 Add a Gauge block from the Dashboard library to the model.
- 2 Double-click the Gauge block to open the block dialog box.
- 3 In the model, select the `air_fuel_ratio` signal. The signal name appears in the connections table in the Gauge block dialog box.

- 4 Select the option button next to `air_fuel_ratio` in the connections table.
- 5 To better see the results on the gauge, enter **50** for the **Maximum** tick mark value.
- 6 Click **OK** to connect the `air_fuel_ratio` signal to the Gauge block.

Note: If you turn off streaming for a signal connected to any dashboard gauge, then the connection shows as broken. Signal data does not stream to the block. To view signal data again, double-click the gauge and reconnect the signal.

Tune Parameters During Simulation

Simulate the model and tune the parameter.

- 1 Start the simulation.
- 2 As the simulation runs, drag the knob pointer to adjust the value of the parameter.

Notice as you use the knob to adjust the value of the Nominal Speed block between 75 and 750, the `air_fuel_ratio` value displayed on the gauge changes.

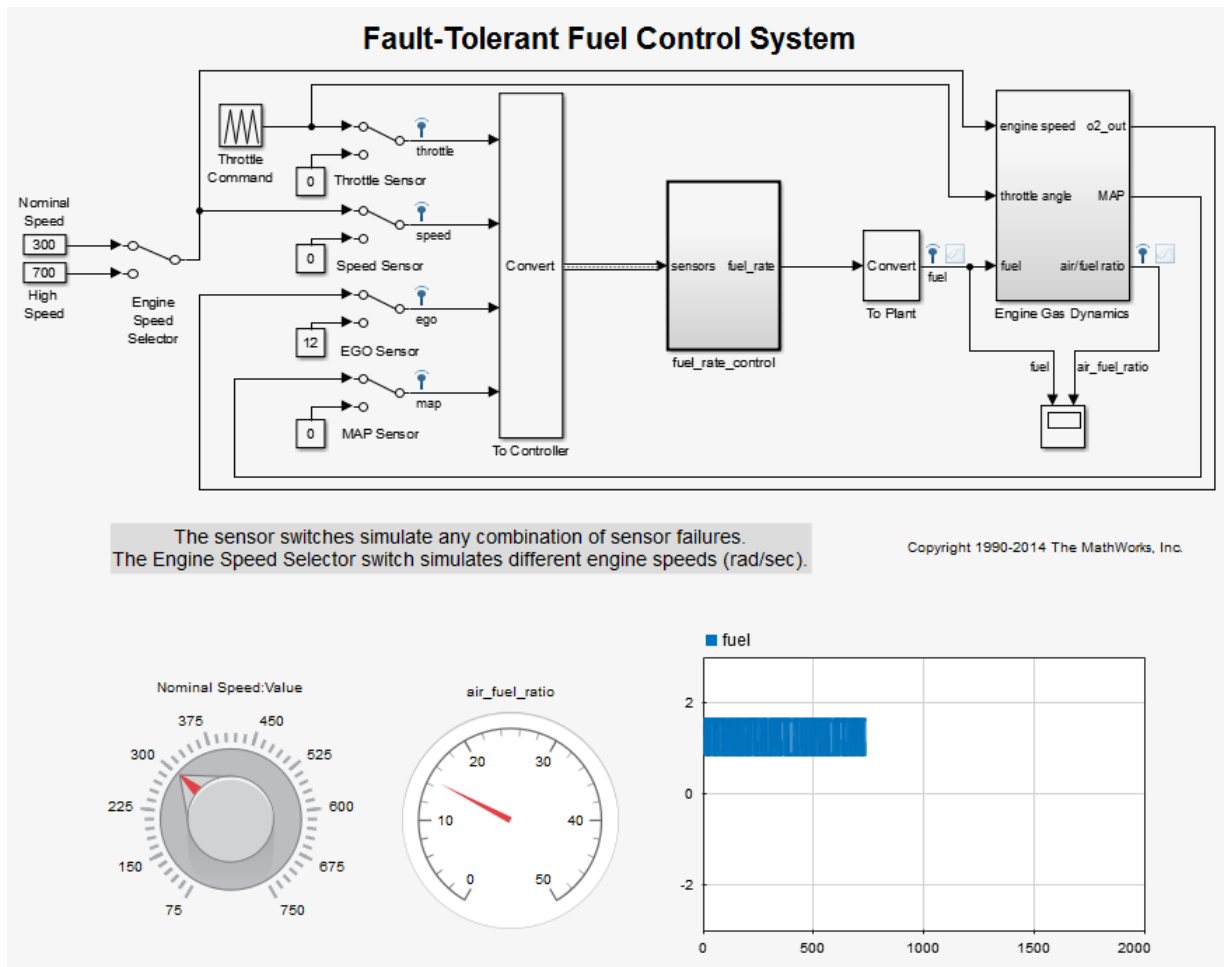

- 3 Stop the simulation when you are finished tuning parameters.

Visualize Signal Data

If you want to view signal data on a streaming plot during simulation, you can use the Dashboard Scope in the model.

- 1 Add a Dashboard Scope block from the Dashboard library to the model.

- 2 Double-click the Dashboard Scope block to open the block dialog box.
- 3 In the model, select the `fuel` signal. The signal name appears in the connections table in the Dashboard Scope block dialog box.
- 4 Select the checkbox next to the signal name.
- 5 Click **OK**.
- 6 Simulate the model. The fuel signal streams to the Dashboard Scope block.

- 7 To add a data cursor to the Dashboard Scope plot, right-click the plot area and select **Data Cursors > One**.
- 8 To inspect signal data, drag the cursor along the time axis.

Visualizing Simulation Data

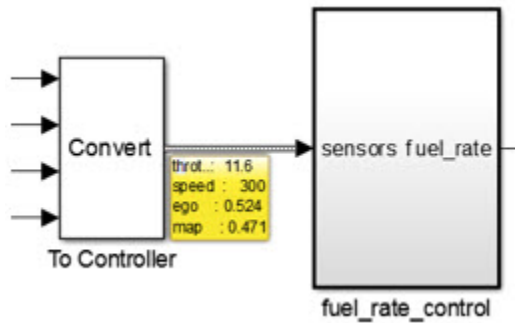

During the modeling process, you run simulations to learn about the behavior of your model. To observe that behavior, view and plot signal values during and after a simulation. Some common modeling tasks that include simulations are:

- Prototype — Quickly model a design and compare design alternatives.
- Validate — Compare simulated data with functional requirements to validate that you built your model correctly.
- Optimize — Compare simulated data between simulations to check if changes to your model remain within a specified design tolerance.
- Verify — Compare simulated data from a model with measured data from the modeled system to verify that your model gives the correct answer.

In Simulink you can view simulation data using several approaches. Some approaches display signal data during a simulation. Other approaches save signal data to the MATLAB workspace where you can post process the data. Learn about each of these approaches so you can choose one suitable for your application.

Port Value Displays

When debugging a model to isolate a particular issue, a common task is to observe signal values at each time step during a simulation. To observe a signal value, right-click a signal line, and then select **Show Value Label of Selected Port**.

Displaying port values for a bus signal allows you to monitor the signal values at each time step during a simulation.

Scope Blocks and Scope Viewers

Scope blocks and scope viewers offer a way to visualize your simulation data over time. If you are prototyping a model design, you can attach signals to a Scope block, and then simulate your model to test and validate the design. Use the oscilloscope-like tools (triggers and measurements) available with a scope to debug your model.

A Scope block or scope viewer opens to a scope window where you can display and evaluate simulation data. In the Scope window, you can:

- Select signals — Connect signal lines to a Scope block using input ports. Attach signals to a Floating Scope block using the signal selector tool that hierarchically displays all signals in a model.
- View signals — Compare selected signals by grouping them on multiple displays.
- Prototype and debug — Set triggers to capture events, use interactive cursors to measure signal values at various points, and review signal statistics such as maximum and mean values. Also, control simulations and step through simulations to validate a design.
- Save signal data — Save signal data to the MATLAB workspace using a dataset object, array, or structure format.

- Supported data types — All data types supported by Simulink including variable-size, fixed-point, sample-based, and frame-based signals.

For more information, see “Scope Blocks and Scope Viewer Overview” on page 25-8.

Simulation Data Inspector

If you run your simulation more than once and want to inspect or compare signal data between simulations, then you can use the Simulation Data Inspector. You can stream and store signal data from the model and compare data between multiple simulations.

For example, you can check to see if the difference between two signals is within a certain design tolerance. In the Simulation Data Inspector, you can:

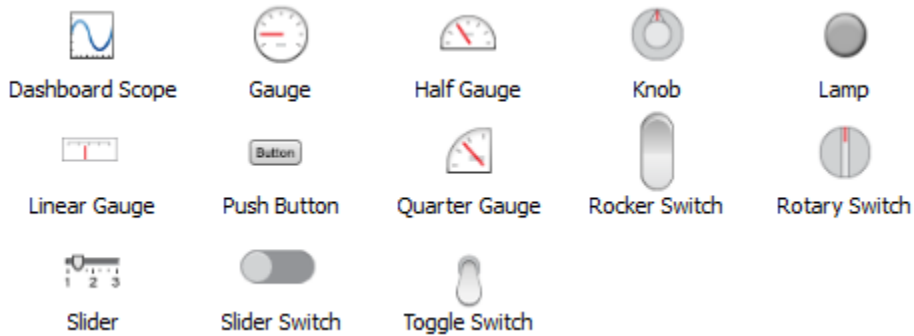

- View signals — Inspect signal data while your model is simulating.
- Import data — Import time series data from MAT-files or the base workspace.
- Compare signal data — Compare multiple simulations to check the difference between runs.
- Export data and generate reports — Export plots and comparison data to share or archive results.

For more information, see “Inspect Signal Data with Simulation Data Inspector” on page 26-2.

Dashboard Controls and Displays

Create an interactive display of controls and displays within your model diagram using blocks from the Dashboard library. Connect block parameters to control blocks (Knobs, Buttons, and Switches) and signals to displays blocks. (Scopes and Gauges).

While a simulation is running, you can change parameter values using the controls. Signal values are updated continuously in the displays.

For more information, see “Tune and Visualize Your Model with Dashboard Blocks” on page 26-73.

Output Block

Use **Output** blocks to save simulation data from the top-level of your model to the MATLAB workspace. Select and define the variables for saving data in the **Data Import/Export** pane of the Configuration Parameters dialog box. For example, select the **Time** and **Output** check boxes.

After running a simulation, you can use MATLAB plotting commands to display the simulation results. The variables `tout` and `yout` are the default variables returned by the solver after a simulation.

```
plot(tout,yout)
```

For more information, see “Model Configuration Parameters: Data Import/Export”.

To Workspace Block

Use **To Workspace** blocks to save simulation data from anywhere in your model to the MATLAB workspace. Store a time vector by connecting a Clock block to a To Workspace block. You can also get a time vector using the `sim` command.

During a simulation, the blocks write data to an internal buffer. When you pause the simulation or it reaches the end time, data is written to the workspace and saved in the variables `y` and `t`.

For more information, see “Model Configuration Parameters: Data Import/Export”.

Signal Logging Without Blocks

You can save simulation data to the MATLAB workspace without using blocks.

- 1 Select signals for logging. Right-click a signal line, select **Properties**, and then select the **Log signal data** check box.
- 2 Enable signal logging during a simulation. In the **Data Import/Export** pane of the Configuration Parameters dialog box, select the **Signal logging** check box and enter a variable name.

For more information, see Export Signal Data Using Signal Logging on page 59-57.

Linearizing Models

In this section...

“About Linearizing Models” on page 27-9

“Linearization with Referenced Models” on page 27-11

“Linearization Using the 'v5' Algorithm” on page 27-13

About Linearizing Models

The Simulink product provides the `linmod`, `linmod2`, and `dlinmod` functions to extract linear models in the form of the state-space matrices A , B , C , and D . State-space matrices describe the linear input-output relationship as

$$\begin{aligned}\dot{x} &= Ax + Bu \\ y &= Cx + Du,\end{aligned}$$

where x , u , and y are state, input, and output vectors, respectively. For example, the following model is called `lmod`.

To extract the linear model of this system, enter this command.

```
[A,B,C,D] = linmod('lmod')
```

```
A =
    -2    -1    -1
```

```
      1      0      0
      0      1     -1
B =
      1
      0
      0
C =
      0      1      0
      0      0     -1
D =
      0
      1
```

Inputs and outputs must be defined using Inport and Outport blocks from the Ports & Subsystems library. Source and sink blocks do not act as inputs and outputs. Inport blocks can be used in conjunction with source blocks, using a Sum block. Once the data is in the state-space form or converted to an LTI object, you can apply functions in the Control System Toolbox product for further analysis:

- Conversion to an LTI object
`sys = ss(A,B,C,D);`
- Bode phase and magnitude frequency plot
`bode(A,B,C,D)` or `bode(sys)`
- Linearized time response
`step(A,B,C,D)` or `step(sys)`
`impulse(A,B,C,D)` or `impulse(sys)`
`lsim(A,B,C,D,u,t)` or `lsim(sys,u,t)`

You can use other functions in the Control System Toolbox and the Robust Control Toolbox™ products for linear control system design.

When the model is nonlinear, an operating point can be chosen at which to extract the linearized model. Extra arguments to `linmod` specify the operating point.

```
[A,B,C,D] = linmod('sys', x, u)
```

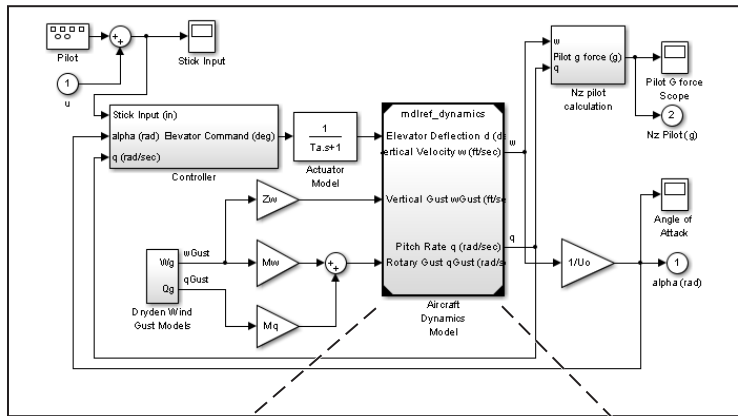

For discrete systems or mixed continuous and discrete systems, use the function `dlinmod` for linearization. This function has the same calling syntax as `linmod` except that the second right-hand argument must contain a sample time at which to perform the linearization.

Linearization with Referenced Models

You can use `linmod` to extract a linear model from a Simulink environment that contains Model blocks.

Note In Normal mode, the `linmod` command applies the block-by-block linearization algorithm on blocks inside the referenced model. If the Model block is in Accelerator mode, the `linmod` command uses numerical perturbation to linearize the referenced model. Due to limitations on linearizing multirate Model blocks in Accelerator mode, you should use Normal mode simulation for all models referenced by Model blocks when linearizing with referenced models. For an explanation of the block-by-block linearization algorithm, see the Simulink Control Design™ documentation.

For example, consider the f14 model `mdlref_f14`. The Aircraft Dynamics Model block refers to the model `mdlref_dynamics`.

To linearize the mdlref_f14 model, call the linmod command on the top mdlref_f14 model as follows.

```
[A,B,C,D] = linmod('mdlref_f14')
```

The resulting state-space model corresponds to the complete f14 model, including the referenced model.

You can call linmod with a state and input operating point for models that contain Model blocks. When using operating points, the state vector x refers to the total state vector for the top model and any referenced models. You must enter the state vector using the structure format. To get the complete state vector, call

```
x = Simulink.BlockDiagram.getInitialState(topModelName)
```

Linearization Using the 'v5' Algorithm

Calling the `linmod` command with the 'v5' argument invokes the perturbation algorithm created prior to MATLAB software version 5.3. This algorithm also allows you to specify the perturbation values used to perform the perturbation of all the states and inputs of the model.

```
[A,B,C,D]=linmod('sys',x,u,para,xpert,upert,'v5')
```

Using `linmod` with the 'v5' option to linearize a model that contains Derivative or Transport Delay blocks can be troublesome. Before linearizing, replace these blocks with specially designed blocks that avoid the problems. These blocks are in the Simulink Extras library in the Linearization sublibrary.

You access the Extras library by opening the Blocksets & Toolboxes icon:

- For the Derivative block, use the Switched derivative for linearization.
- For the Transport Delay block, use the Switched transport delay for linearization. (Using this block requires that you have the Control System Toolbox product.)

When using a Derivative block, you can also try to incorporate the derivative term in other blocks. For example, if you have a Derivative block in series with a Transfer Fcn block, it is better implemented (although this is not always possible) with a single Transfer Fcn block of the form

$$\frac{s}{s+a}$$

In this example, the blocks on the left of this figure can be replaced by the block on the right.

`dlinmod` | `linmod`

Finding Steady-State Points

The Simulink `trim` function uses a model to determine steady-state points of a dynamic system that satisfy input, output, and state conditions that you specify. Consider, for example, this model, called `ex_lmod`.

You can use the `trim` function to find the values of the input and the states that set both outputs to 1. First, make initial guesses for the state variables (`x`) and input values (`u`), then set the desired value for the output (`y`).

```
x = [0; 0; 0];
u = 0;
y = [1; 1];
```

Use index variables to indicate which variables are fixed and which can vary.

```
ix = [];      % Don't fix any of the states
iu = [];      % Don't fix the input
iy = [1;2];   % Fix both output 1 and output 2
```

Invoking `trim` returns the solution. Your results might differ because of roundoff error.

```
[x,u,y,dx] = trim('lmod',x,u,y,ix,iu,iy)
```

```
x =
    0.0000
    1.0000
    1.0000
u =
     2
y =
```

```
1.0000
1.0000
dx =
1.0e-015 *
-0.2220
-0.0227
0.3331
```

Note that there might be no solution to equilibrium point problems. If that is the case, `trim` returns a solution that minimizes the maximum deviation from the desired result after first trying to set the derivatives to zero. For a description of the `trim` syntax, see `trim`.

How Optimization Techniques Improve Performance and Accuracy

The design of a model and choice of configuration parameters can affect simulation performance and accuracy. Solvers handle most model simulations accurately and efficiently with default parameter values. However, some models yield better results when you adjust solver parameters. Information about the behavior of a model can help you improve simulation performance, particularly when you provide this information to the solver. Use optimization techniques to better understand the behavior of your model and modify the model settings to improve performance and accuracy.

To optimize your model and achieve faster simulation automatically using Performance Advisor, see “Automated Performance Optimization”.

To learn more about accelerator modes for faster simulation, see “Acceleration”.

More About

- “Modeling Techniques That Improve Performance” on page 28-13

Speed Up Simulation

Several factors can slow simulation. Check your model for some of these conditions.

- Your model includes an Interpreted MATLAB Function block. When a model includes an Interpreted MATLAB Function block, the MATLAB execution engine is called at each time step, drastically slowing down the simulation. Use the built-in Fcn block or the Math Function block whenever possible.
- Your model includes a MATLAB file S-function. MATLAB file S-functions also call the MATLAB execution engine at each time step. Consider converting the S-function either to a subsystem or to a C-MEX file S-function.
- Your model includes a Memory block. Using a Memory block causes the variable-order solvers (ode15s and ode113) to reset back to order 1 at each time step.
- The maximum step size is too small. If you changed the maximum step size, try running the simulation again with the default value (auto).
- Your accuracy requirements are too high. The default relative tolerance (0.1% accuracy) is usually sufficient. For models with states that go to zero, if the absolute tolerance parameter is too small, the simulation can take too many steps around the near-zero state values. See the discussion of this error in “Maximum order” “Maximum order” in the online documentation.
- The time scale is too long. Reduce the time interval.
- The problem is stiff, but you are using a nonstiff solver. Try using ode15s. For more information, see “Stiffness of System” on page 28-17.
- The model uses sample times that are not multiples of each other. Mixing sample times that are not multiples of each other causes the solver to take small enough steps to ensure sample time hits for all sample times.
- The model contains an algebraic loop. The solutions to algebraic loops are iteratively computed at every time step. Therefore, they severely degrade performance. For more information, see “Algebraic Loops” on page 3-38.
- Your model feeds a Random Number block into an Integrator block. For continuous systems, use the Band-Limited White Noise block in the Sources library.
- Your model contains a scope viewer that displays too many data points. Try adjusting the viewer property settings that can affect performance. For more information, see Scope Viewer.
- You need to simulate your model iteratively. You change tunable parameters between iterations but do not make structural changes to the model. Every iteration requires

the model to compile again, thus increasing overall simulation time. Use fast restart to perform iterative simulations. In this workflow, the model compiles only once and iterative simulations are tied to a single compile phase. See “How Fast Restart Improves Iterative Simulations” on page 68-2 for more information.

How Profiler Captures Performance Data

In this section...

“How Profiler Works” on page 28-5

“Start Profiler” on page 28-7

“Save Profiler Results” on page 28-10

How Profiler Works

Profiler captures performance data while your model simulates. It identifies the parts of your model that require the most time to simulate. Use the profiling information to decide where to focus your model optimization efforts.

Note: You cannot use Profiler in Rapid Accelerator mode.

Simulink stores performance data in the *simulation profile report*. The data shows the time spent executing each function in your model.

The basis for Profiler is an execution model that this pseudocode summarizes.

```

Sim()
  ModelInitialize().
  ModelExecute()
    for t = tStart to tEnd
      Output()
      Update()
      Integrate()
        Compute states from derivs by repeatedly calling:
          MinorOutput()
          MinorDeriv()
        Locate any zero crossings by repeatedly calling:
          MinorOutput()
          MinorZeroCrossings()
      EndIntegrate
    Set time t = tNew.
  EndModelExecute
ModelTerminate

```

EndSim

According to this conceptual model, Simulink runs a model by invoking the following functions zero, one, or many times, depending on the function and the model.

Function	Purpose	Level
sim	Simulate the model. This top-level function invokes the other functions required to simulate the model. The time spent in this function is the total time required to simulate the model.	System
ModelInitialize	Set up the model for simulation.	System
ModelExecute	Execute the model by invoking the output, update, integrate, etc., functions for each block at each time step from the start to the end of simulation.	System
Output	Compute the outputs of a block at the current time step.	Block
Update	Update the state of a block at the current time step.	Block
Integrate	Compute the continuous states of a block by integrating the state derivatives at the current time step.	Block
MinorOutput	Compute block output at a minor time step.	Block
MinorDeriv	Compute the state derivatives of a block at a minor time step.	Block
MinorZeroCrossings	Compute zero-crossing values of a block at a minor time step.	Block
ModelTerminate	Free memory and perform any other end-of-simulation cleanup.	System
Nonvirtual Subsystem	Compute the output of a nonvirtual subsystem at the current time step by invoking the output, update, integrate, etc., functions for each block that	Block

Function	Purpose	Level
	it contains. The time spent in this function is the time required to execute the nonvirtual subsystem.	

Profiler measures the time required to execute each invocation of these functions. After the model simulates, Profiler generates a report that describes the amount of simulation time spent on each function.

Start Profiler

- 1 Open the model.
- 2 Select **Analysis > Performance Tools > Show Profiler Report**.
- 3 Simulate the model.

When simulation is complete, Simulink generates and displays the simulation profile for the model in a MATLAB web browser.

Summary Section

The summary file displays the following performance totals.

Item	Description
Total Recorded Time	Total time required to simulate the model
Number of Block Methods	Total number of invocations of block-level functions (e.g., <code>Output()</code>)
Number of Internal Methods	Total number of invocations of system-level functions (e.g., <code>ModelExecute</code>)
Number of Model Methods	Number of methods called by the model

Item	Description
Number of Nonvirtual Subsystem Methods	Total number of invocations of nonvirtual subsystem functions
Clock Precision	Precision of the profiler's time measurement
Clock Speed	Speed of the profiler's time measurement

The function list shows summary profiles for each function invoked to simulate the model. For each function listed, the summary profile specifies this information.

Item	Description
Name	Name of function. This item is a hyperlink. Click it to display a detailed profile of this function.
Time	Total time spent executing all invocations of this function as an absolute value and as a percentage of the total simulation time.
Calls	Number of times this function was invoked.
Time/Call	Average time required for each invocation of this function, including the time spent in functions invoked by this function.
Self Time	Total time required to execute this function, excluding time spent in functions called by this function.
Location	Specifies the block or model executed for which this function is invoked. This item is a hyperlink. Click it to highlight the corresponding element in the model diagram.

Detailed Profile Section

This section of the report contains detailed profiles for each function that Simulink invoked to simulate the model. In addition to the information in the summary profile for the function, the detailed profile displays the function (parent function) that invoked the profiled function and the functions (child functions) invoked by the profiled function. Click the name of the parent or a child function to see the detailed profile for that function.

Note: Enabling Profiler on a parent model does not enable profiling for referenced models. You must enable profiling separately for each referenced model. Profiling occurs only if the referenced model executes in Normal mode. See “Normal Mode” on page 32-4 for more information.

Save Profiler Results

You can save the Profiler report to a variable in the MATLAB workspace, and after that, to a `mat` file. At a later time, you can regenerate and review the report.

Save the Profiler report for a model `vdp` to the variable `profile1` and to the data file `report1.mat`.

1 In the **Simulink Profiler Report** window, in the **Summary** section, click **click here** link. Simulink saves the report data to the variable `vdpProfileData`.

2 Review the report. At the MATLAB command prompt, enter:

```
slprofreport(vdpProfileData)
```

3 Save the data to a variable named `profile1` in the base workspace.

```
profile1 = vdpProfileData;
```

4 Save the data to a `mat` file named `report1`.

```
save report1 profile1
```

To view the report later, at the MATLAB command prompt, enter:

```
load report1  
slprofreport(profile1);
```

Check and Improve Simulation Accuracy

Check Simulation Accuracy

- 1 Simulate the model over a reasonable time span.
- 2 Reduce either the relative tolerance to $1e-4$ (the default is $1e-3$) or the absolute tolerance.
- 3 Simulate the model again.
- 4 Compare the results from both simulations.

If the results are not significantly different, the solution has converged.

If the simulation misses significant behavior at the start, reduce the initial step size to ensure that the simulation does not step over that behavior.

Unstable Simulation Results

When simulation results become unstable over time,

- The system can be unstable.
- If you are using the `ode15s` solver, try restricting the maximum order to 2 (the maximum order for which the solver is A-stable). You can also try using the `ode23s` solver.

Inaccurate Simulation Results

If simulation results are not accurate:

- For a model that has states whose values approach zero, if the absolute tolerance parameter is too large, the simulation takes too few steps around areas of near-zero state values. Reduce this parameter value in the **Solver pane** of model configuration parameters or adjust it for individual states in the function block parameters of the Integrator block.
- If reducing the absolute tolerances does not improve simulation accuracy enough, reduce the size of the relative tolerance parameter. This change reduces the acceptable error and forces smaller step sizes and more steps.

Certain modeling constructs can also produce unexpected or inaccurate simulation results.

- A Source block that inherits sample time can produce different simulation results if, for example, the sample times of the downstream blocks are modified (see “How Propagation Affects Inherited Sample Times” on page 7-38).
- A Derivative block found in an algebraic loop can result in a loss in solver accuracy.

Modeling Techniques That Improve Performance

In this section...

“Accelerate the Initialization Phase” on page 28-13

“Reduce Model Interactivity” on page 28-14

“Reduce Model Complexity” on page 28-15

“Choose and Configure a Solver” on page 28-16

“Save the Simulation State” on page 28-18

Accelerate the Initialization Phase

Speed up a simulation by accelerating the initialization phase, using these techniques.

Simplify Graphics Using Mask Editor

Complex graphics and large images take a long time to load and render. Masked blocks that contain such images can make your model less responsive. Where possible, remove complex drawings and images from masked blocks.

If you want to keep the image, replace it with a smaller, low-resolution version. Use mask editor and edit the icon drawing commands to keep the image that is loaded by the call to `image()`.

For more information on mask editor, see “Mask Editor Overview”.

Consolidate Function Calls

When you open or update a model, Simulink runs the mask initialization code. If your model contains complicated mask initialization commands that contain many calls to `set_param`, consolidate consecutive calls into a single call with multiple argument pairs. Consolidating the calls can reduce the overhead associated with these function calls.

To learn more, see “Mask Callback Code” on page 36-18.

Load Data Using MAT-file

If you use MATLAB scripts to load and initialize data, you can improve performance by loading MAT-files instead. The data in a MAT-file is in binary and can be more difficult to work with than a script. However, the load operation typically initializes data more quickly than the equivalent MATLAB script.

For more information, see “Import/Export Data” on page 26-65.

Reduce Model Interactivity

In general, the more interactive a model is, the longer it takes to simulate. Use these techniques to reduce the interactivity of your model.

Disable Debugging Diagnostics

Some enabled diagnostic features can slow simulations considerably. Consider disabling them in the model configuration parameters **Diagnostics** pane and in the **Diagnostics** category of the **All Parameters** tab.

Note: Running **Array bounds exceeded** and **Solver data inconsistency** can slow down model runtime performance. For more information, see “Array bounds exceeded” and “Solver data inconsistency”.

Disable MATLAB Debugging

After verifying that your MATLAB code works correctly, disable these checks in the model configuration parameters **Simulation Target** pane.

- **Enable debugging/animation**
- **Detect wrap on overflow (with debugging)**
- **Echo expressions without semicolons**

For more information, see “Model Configuration Parameters: Simulation Target”.

Use BLAS Library Support

If your simulation involves low-level MATLAB matrix operations, use the Basic Linear Algebra Subprograms (BLAS) libraries to make use of highly optimized external linear algebra routines.

Disable Stateflow Animations

By default, Stateflow charts highlight the current active states in a model and animate the state transitions that take place as the model simulates. This feature is useful for debugging, but it slows the simulation.

To accelerate simulations, either close all Stateflow charts or disable the animation. Similarly, consider disabling animation or reducing scene fidelity when you use:

- Simulink 3D Animation
- Simscape Multibody visualization
- FlightGear
- Any other 3D animation package

To learn more, see “Speed Up Simulation”.

Adjust Scope Viewer Properties

If your model contains a scope viewer that displays a high rate of logging and you cannot remove the scope, adjust the viewer properties to trade off fidelity for rendering speed.

However, when you use decimation to reduce the number of plotted data points, you can miss short transients and other phenomena that you can see with more data points. To have more precise control over enabling visualizations, place viewers in enabled subsystems.

For more information, see [Scope Viewer](#).

Reduce Model Complexity

Use these techniques to improve simulation performance by simplifying a model without sacrificing fidelity.

Replace Subsystems with Lower-Fidelity Alternatives

Replace a complex subsystem with one of these alternatives:

- A linear or nonlinear dynamic model that was created from measured input-output data using the System Identification Toolbox™.
- A high-fidelity, nonlinear statistical model that was created using the Model-Based Calibration Toolbox™.
- A linear model that was created using Simulink Control Design.
- A lookup table. For more information, see [A lookup table](#).

You can maintain both representations of the subsystem in a library and use variant subsystems to manage them. Depending on the model, you can make this replacement

without affecting the overall result. For more information, see “Optimize Generated Code for Lookup Table Blocks” on page 35-44.

Reduce Number of Blocks

When you reduce the number of blocks in your model, fewer blocks require updates during simulations and simulation is faster.

- Vectorization is one way to reduce your block count. For example, if you have several parallel signals that undergo a similar set of computations, try to combine them into a vector using a Mux block and perform a single computation.
- You can also enable the **Block Reduction** parameter in the **Configuration Parameters > All Parameters** tab.

Use Frame-Based Processing

In frame-based processing, Simulink processes samples in batches instead of one at a time. If a model includes an analog-to-digital converter, for example, you can collect output samples in a buffer. Process the buffer in a single operation, such as a fast Fourier transform. Processing data in chunks this way reduces the number of times that the simulation needs to invoke blocks in your model.

In general, the scheduling overhead decreases as frame size increases. However, larger frames consume more memory, and memory limitations can adversely affect the performance of complex models. Experiment with different frame sizes to find one that maximizes the performance benefit of frame-based processing without causing memory issues.

Choose and Configure a Solver

Simulink provides a comprehensive library of solvers, including fixed-step and variable-step solvers, to handle stiff and nonstiff systems. Each solver determines the time of the next simulation step. A solver applies a numerical method to solve ordinary differential equations that represent the model.

The solver you choose and the solver options you select can affect simulation speed. Select and configure a solver that helps boost the performance of your model using these criteria. For more information, see “Choose a Solver”.

Stiffness of System

A stiff system has continuous dynamics that vary slowly and quickly. Implicit solvers are particularly useful for stiff problems. Explicit solvers are better suited for nonstiff systems. Using an explicit solver to solve a stiff system can lead to incorrect results. If a nonstiff solver uses a very small step size to solve a model, this is a sign that your system is stiff.

Model Step Size and Dynamics

When you are deciding between using a variable-step or fixed-step solver, keep in mind the step size and dynamics of your model. Select a solver that uses time steps to capture only the dynamics that are important to you. Choose a solver that performs only the calculations needed to work out the next time step.

You use fixed-step solvers when the step size is less than or equal to the fundamental sample time of the model. With a variable-step solver, the step size can vary because variable-step solvers dynamically adjust the step size. As a result, the step size for some time steps is larger than the fundamental sample time, reducing the number of steps required to complete the simulation. In general, simulations with variable-step solvers run faster than those that run with fixed-step solvers.

Choose a fixed-step solver when the fundamental sample time of your model is equal to one of the sample rates. Choose a variable-step solver when the fundamental sample time of your model is less than the fastest sample rate. You can also use variable-step solvers to capture continuous dynamics.

Decrease Solver Order

When you decrease the solver order, you reduce the number of calculations that Simulink performs to determine state outputs, which improves simulation speed. However, the results become less accurate as the solver order decreases. Choose the lowest solver order that produces results with acceptable accuracy.

Increase Solver Step Size or Error Tolerance

Increasing the solver step size or error tolerance usually increases simulation speed at the expense of accuracy. Make these changes with care because they can cause Simulink to miss potentially important dynamics during simulations.

Disable Zero-Crossing Detection

Variable-step solvers dynamically adjust the step size, increasing it when a variable changes slowly and decreasing it when a variable changes rapidly. This behavior causes the solver to take many small steps near a discontinuity because this is when a variable changes rapidly. Accuracy improves, but often at the expense of long simulation times.

To avoid the small time steps and long simulations associated with these situations, Simulink uses zero-crossing detection to locate such discontinuities accurately. For systems that exhibit frequent fluctuations between modes of operation—a phenomenon known as chattering—this zero-crossing detection can have the opposite effect and thus slow down simulations. In these situations, you can disable zero-crossing detection to improve performance.

You can enable or disable zero-crossing detection for specific blocks in a model. To improve performance, consider disabling zero-crossing detection for blocks that do not affect the accuracy of the simulation.

For more information, see “When to Enable Zero-Crossing Detection”.

Save the Simulation State

In the classic workflow, a Simulink model simulates repeatedly for different inputs, boundary conditions, and operating conditions. In many situations, these simulations share a common startup phase in which the model transitions from the initial state to another state. For example, you can bring an electric motor up to speed before you test various control sequences.

Using `SimState`, you can save the simulation state at the end of the startup phase and then restore it for use as the initial state for future simulations. This technique does not improve simulation speed, but it can reduce total simulation time for consecutive runs because the startup phase needs to be simulated only once.

See “Save and Restore Simulation State as `SimState`” on page 23-37 for more information.

How Parallel Simulations Reduce Simulation Time

When you use Simulink and Parallel Computing Toolbox to distribute simulation tasks among multiple processing cores, you reduce the total amount of time required to run multiple independent simulations. You can further reduce overall simulation time by using MATLAB Distributed Computing Server to run the simulations on a computer cluster.

Common use cases for running simulations in parallel include Monte Carlo analysis and design optimization. For example, if you have a Monte Carlo simulation in which you vary the value of a parameter across a predetermined range, you can perform simulations for each parameter value independently and in parallel on multiple cores. You can parallelize many of the tasks involved in design optimization like:

- Estimating model parameters from test data
- Tuning controller gains to achieve a desired response
- Optimizing design parameters
- Performing sensitivity analysis
- Performing robustness analysis

The total simulation time decreases as the number of processors in use increases.

In many cases, you can convert a sequential algorithm to a parallel algorithm by simply changing a `for`-loop to a `parfor`-loop. The `parfor` construct in Parallel Computing Toolbox is similar to a standard `for`-loop. The key difference is that `parfor` distributes the computations performed within the loop to worker processors.

Improve Simulation Performance Using Performance Advisor

In this section...

“Performance Advisor Workflow” on page 29-2

“Prepare Your Model” on page 29-3

“Create a Performance Advisor Baseline Measurement” on page 29-5

“Run Performance Advisor Checks” on page 29-6

“View and Respond to Results” on page 29-8

“View and Save Performance Advisor Reports” on page 29-11

Whatever the level of complexity of your model, you can make systematic changes that improve simulation performance. Performance Advisor checks for configuration settings that slow down your model simulations. It produces a report that lists the suboptimal conditions or settings it finds and suggests better configuration settings where appropriate.

You can use the Performance Advisor to fix some of these suboptimal conditions automatically or you can fix them manually.

Note: Use Performance Advisor on top models. Performance Advisor does not traverse referenced models or library links.

To learn about faster simulation using acceleration modes, see “Acceleration”.

Performance Advisor Workflow

When the performance of a model is slower than expected, use Performance Advisor to help identify and resolve bottlenecks.

- 1 Prepare your model.
- 2 Create a baseline to compare measurements against.
- 3 Select the checks you want to run.
- 4 Run Performance Advisor with the selected checks and see recommended changes.
- 5 Make changes to the model. You can either:

- Automatically apply changes.
 - Generate advice, and review and apply changes manually.
- 6** After applying changes, Performance Advisor performs a final validation of the model to see how performance has improved.
- If the performance improves, the selected checks were successful. The performance check is complete.
 - If the performance is worse than the baseline, Performance Advisor reinstates the previous settings of the model.
- 7** Save your model.

Caution Performance Advisor does not automatically save your model after it makes changes. When you are satisfied with the changes to the model from Performance Advisor, save the model.

Prepare Your Model

Before running checks using Performance Advisor, complete the following steps:

- “Start Performance Advisor” on page 29-3
- “Enable Data Logging for the Model” on page 29-4
- “Select How Performance Advisor Applies Advice” on page 29-4
- “Select Validation Actions for the Advice” on page 29-4
- “Specify Runtime for Performance Advisor” on page 29-5

Start Performance Advisor

To get started with Performance Advisor:

- 1** Make a backup of the model.
- 2** Verify that the model can simulate without error.
- 3** Close all applications, including web browsers. Leave only the MATLAB Command Window, the model you want to analyze, and Performance Advisor running.

Running other applications can hinder the performance of model simulation and the ability of Performance Advisor to measure accurately.

- 4 Open Performance Advisor. In the Simulink Editor, select **Analysis > Performance Tools > Performance Advisor**.

Enable Data Logging for the Model

Make sure the model configuration parameters are set to enable data logging.

- 1 In the model, select **Simulation > Model Configuration Parameters**.
- 2 In the Configuration Parameters dialog box, click **Data Import/Export** in the left pane.
- 3 Set up signal logging. The model must log at least one signal for Performance Advisor to work. For example, select the **States** or **Output** check box.
- 4 Click **Configure Signals to Log** and select the signals to log.

Note: Select only the signals you are most interested in. Minimizing the number of signals to log can help performance. Selecting too many signals can cause Performance Advisor to run for a longer time.

- 5 Click **OK** in the Configuration Parameters dialog box.
- 6 Run the model once to make sure that the simulation is successful.

Select How Performance Advisor Applies Advice

Choose from these options to apply advice to the model:

- **Use check parameters.** Select the checks for which you want Performance Advisor to automatically apply advice. You can review the remaining checks and apply advice manually.
- **Automatically for all checks.** Performance Advisor automatically applies advice to all selected checks.
- **Generate advice only.** Review advice for each check and apply changes manually.

Select Validation Actions for the Advice

For the checks you want to run, validate an improvement in simulation time and accuracy by comparing against a baseline measurement. Each validation action requires the model to simulate. Use these validation options as global settings for the checks you select:

- **Use check parameters.** From the checks you want to run, select the ones for which you want to validate an improvement in performance. Specify validation action for fixes using individual settings for these checks.
- **For all checks.** Performance Advisor automatically validates an improvement in performance for the checks you select.
- **Do not validate.** Performance Advisor does not validate an improvement in performance. Instead, you can validate manually. When you select this option and also specify for Performance Advisor to apply advice automatically, a warning appears before Performance Advisor applies changes without validation.

These global settings for validation apply to all checks in the left pane except the Final Validation check. The Final Validation check validates the overall performance improvement in a model after you have applied changes. In case you do not want to validate changes resulting from other check results, you can run the Final Validation check to validate model changes for simulation time and accuracy.

Specify Runtime for Performance Advisor

You can specify a **Time Out** value in minutes if you want to limit the runtime duration of Performance Advisor. Use this option when running Performance Advisor on models with long simulation times.

If Performance Advisor times out before completing the checks you specify, in the left pane you can see the checks that failed.

Create a Performance Advisor Baseline Measurement

A baseline measurement is a set of simulation measurements that Performance Advisor measures check results against.

Note: Before creating a baseline measurement, set the model configuration parameters to enable data logging. For more information, see “Enable Data Logging for the Model” on page 29-16.

- 1 In the model, select **Analysis > Performance Tools > Performance Advisor** to start Performance Advisor.
- 2 In the left pane, in the Baseline folder, select **Create Baseline**.

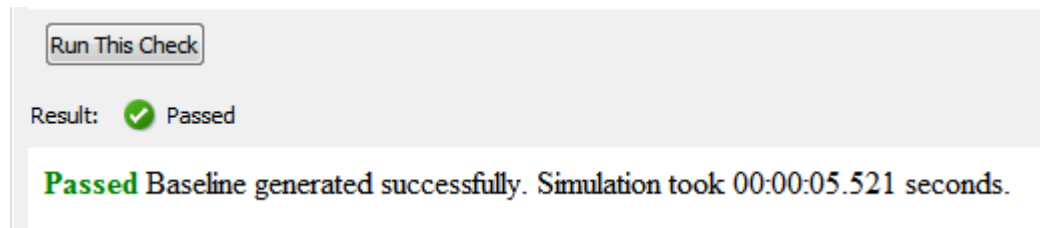

- 3 In the right pane, under **Input Parameters**, enter a value in the **Stop Time** field for the baseline.

When you enter a Stop Time value in Performance Advisor, this overrides the value set in the model. A large stop time can create a simulation that runs longer.

If you do not enter a value, Performance Advisor uses values from the model. Performance Advisor uses values from the model that are less than 10. Performance Advisor rounds values from the model larger than 10 to 10.

- 4 Select the **Check to view baseline signals and set their tolerances** check box to start the Signal Data Inspector after Performance Advisor runs a check. Using the Signal Data Inspector, you can compare signals and adjust tolerance levels.
- 5 Click **Run This Check**.

When a baseline has been created, a message like the following appears under **Analysis**:

After the baseline has been created, you can run Performance Advisor checks.

Run Performance Advisor Checks

- 1 After you have created a baseline measurement, select checks to run.
 - In the left pane of Performance Advisor, expand a folder, such as **Simulation** or **Simulation Targets**, to display checks related to specific tasks.
 - In the folder, select the checks you want to run using the check boxes.

Tip If you are unsure of which checks apply, you can select and run all checks. After you see the results, clear the checks you are not interested in.

- 2 Specify input parameters for selected checks. Use one of these methods:

- Apply global settings to all checks to take action, validate simulation time and validate simulation accuracy.
- Alternatively, for each check, in the right pane, specify input parameters.

Input Parameter	Description
Take action based on advice	<p>automatically — Allow Performance Advisor to automatically make the change for you.</p> <p>manually — Review the change first. Then manually make the change or accept Performance Advisor recommendations.</p>
Validate and revert changes if time of simulation increases	Select this check box to have Performance Advisor rerun the simulation and verify that the change made based on the advice improves simulation time. If the change does not improve simulation time, Performance Advisor reverts the changes.
Validate and revert changes if degree of accuracy is greater than tolerance	Select this check box to have Performance Advisor rerun the simulation and verify that, after the change, the model results are still within tolerance. If the result is outside tolerance, Performance Advisor reverts the changes.
Quick estimation of model build time	Select this check box to have Performance Advisor use the number of blocks of a referenced model to estimate model build time.

- 3 To run a single check, click **Run This Check** from the settings for the check. Performance Advisor displays the results in the right pane.

You can also select multiple checks from the left pane and click **Run Selected Checks** from the right pane. Select **Show report after run** to display the results of the checks after they run.

- 4 To limit the run time of Performance Advisor, specify a **Time Out** value in minutes. Use this option for models with long simulation times. The default setting for this option is 60 minutes.

Note: The **Time Out** setting does not apply to a Quick Scan diagnosis.

Performance Advisor also generates an HTML report of the current check results and actions in a file with a name in the form *model_name\report_#.html*

To view this report in a separate window, click the **Report** link in the right pane.

Note: If you rename a system, you must restart Performance Advisor to check that system.

View and Respond to Results

After you run checks with Performance Advisor, the right pane shows the results:

Identify simulation target settings

Analysis

Disabling simulation target settings, such as 'Echo expression without semicolons', can improve simulation speed.

Input Parameters

Take action based on advice:

Validate and revert changes if time of simulation increases

Validate and revert changes if degree of accuracy is greater than tolerance

Result: Warning

The simulation target setting 'Echo expressions without semicolons' is enabled. Disabling this setting might improve simulation speed. Review the following settings in the Model Configuration of model 'vdp'.

Performance Advisor has taken the necessary actions. For details, see the Action Results section.

Severity	Diagnostics checked	Original Value	New Value
	Simulation Target > Echo expressions without semicolons	on	off

Action

Review the action results

Result:

Summary of performance validations			
	Before this check	After this check	Improvement
Performance			
Accuracy	Within given tolerance	Within given tolerance Click to view	
Simulation Time	00:00:34.970	00:00:02.036	94.18%

Analysis →

Action →

To view the results of a check, in the left pane, select the check you ran. The right pane updates with the results of the check. This pane has two sections.

The **Analysis** section contains:

- Information about the check
- Option to run the simulation
- Settings to take action based on advice from Performance Advisor
- Result of the check (Passed, Failed or Warning)

The **Action** section contains:

- A setting to manually accept all recommendations for the check
- Summary of actions taken based on the recommendations for the check

Respond to Results

Use the **Take action based on advice** parameter in the **Analysis** section to select how to respond to changes that Performance Advisor suggests.

Value	Response
automatically	<ul style="list-style-type: none"> Performance Advisor makes the change for you. You can evaluate the changes using the links in the summary table. The Modify All button in the Action section is grayed out since Performance Advisor has already made all recommended changes for you.
manually	<ul style="list-style-type: none"> Performance Advisor does not make the change for you. The links in the summary table show recommendations. Use the Modify All button in the Action section to implement all recommendations after reviewing them. Depending on how you set your validation input parameters before you ran the check, the button label can change to Modify All and Validate.

Review Actions

The **Action** section contains a summary of the actions that Performance Advisor took based on the **Input Parameters** setting. If the tool also performed validation actions, this section lists the results in a summary table. If performance has not improved, Performance Advisor reports that it reinstated the model to the settings it had before the check ran.

Summary of performance validations

	Before this check	After this check	Improvement
Performance			✓
Accuracy	Within given tolerance	Within given tolerance Click to view	✓
Simulation Time	00:00:04.276	00:00:02.412	43.59%

Summary of actions

Actions:

Severity	Description
✓	The actions succeeded. The table lists the percentage of improvement.

Severity	Description
	The actions failed. For example, if Performance Advisor cannot make a recommended change, it flags it as failed. It also flags a check as failed if performance did not improve and reinstates the model to the settings it had before the check ran.

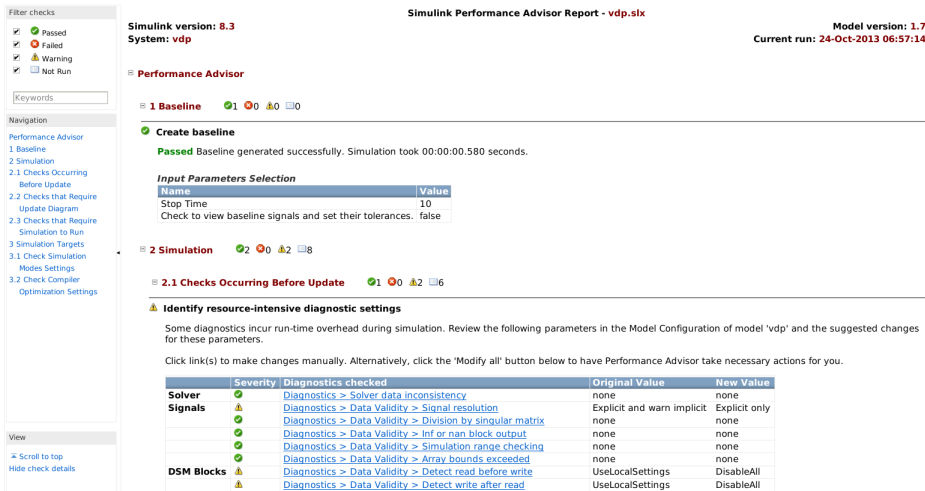

Caution Performance Advisor does not automatically save your model after it makes changes. When you are satisfied with the changes to the model from Performance Advisor, save the model.

View and Save Performance Advisor Reports

When Performance Advisor runs checks, it generates HTML reports of the results. To view a report, select a folder in the left pane and click the link in the **Report** box in the right pane.

As you run checks, Performance Advisor updates the reports with the latest information for each check in the folder. Time stamps indicate when checks ran.

In the pane for global settings, when you select **Show report after run**, Performance Advisor displays a consolidated set of check results in the report.

Simulink Performance Advisor Report - vdp.slx

Simulink version: 8.3
System: vdp

Model version: 1.7
Current run: 24-Oct-2013 06:57:14

Performance Advisor

1 Baseline 01 00 00 00

Create baseline

Passed Baseline generated successfully. Simulation took 00:00:00.580 seconds.

Input Parameters Selection

Name	Value
Stop Time	10

Check to view baseline signals and set their tolerances. false

2 Simulation 02 00 02 08

2.1 Checks Occurring Before Update 01 00 02 06

Identify resource-intensive diagnostic settings

Some diagnostics incur run-time overhead during simulation. Review the following parameters in the Model Configuration of model 'vdp' and the suggested changes for these parameters.

Click link(s) to make changes manually. Alternatively, click the 'Modify all' button below to have Performance Advisor take necessary actions for you.

Severity	Diagnostics checked	Original Value	New Value
	Diagnostics > Solver data inconsistency	none	none
	Diagnostics > Data Validity > Signal resolution	Explicit and warn implicit	Explicit only
	Diagnostics > Data Validity > Division by singular matrix	none	none
	Diagnostics > Data Validity > Inf or nan block output	none	none
	Diagnostics > Data Validity > Simulation range checking	none	none
	Diagnostics > Data Validity > Array bounds exceeded	none	none
	Diagnostics > Data Validity > Detect read before write	UseLocalSettings	DisableAll
	Diagnostics > Data Validity > Detect write after read	UseLocalSettings	DisableAll

You can perform these actions using the Performance Advisor report:

- Use the check boxes under **Filter checks** to view only the checks with the status that you are interested in viewing. For example, to see only the checks that failed or gave warnings, clear the **Passed** and **Not Run** check boxes.
- Perform a keyword search using the search box under **Filter checks**.
- Use the tree of checks under **Navigation** to jump to the category of checks or a specific check result that interests you.
- Expand and collapse content in the right pane of the report to view or hide check results.

Some checks have input parameters that you specify in the right pane of Performance Advisor. For example, **Identify resource intensive diagnostic settings** has several input parameters. When you run checks that have input parameters, Performance Advisor displays the values of the input parameters in the report.

Identify resource-intensive diagnostic settings

Some diagnostics incur run-time overhead during simulation. Review the following parameters in the Model Configuration of model 'vdp' and the suggested changes for these parameters.

Performance Advisor has taken the necessary actions. For details, see the Action Results section.

Severity	Diagnostics checked	Original Value	New Value

Validate and revert changes if time of simulation increases	true
Validate and revert changes if degree of accuracy is greater than tolerance	true

Save Performance Advisor Reports

You can archive a Performance Advisor report by saving it to a new location. Performance Advisor does not update the saved version of a report when you run checks again. Archived reports serve as good points of comparison when you run checks again.

- 1 In the left pane of the Performance Advisor window, select the folder of checks for the report you want to save.
- 2 In the **Report** box, click **Save As**.
- 3 In the **Save As** dialog box, navigate to where you want to save the report, and click **Save**. Performance Advisor saves the report to the new location.

Perform a Quick Scan Diagnosis

Quick Scan is a fast method to diagnose settings in a model and deliver an approximate analysis of performance. A model can compile and simulate several times during a normal run in Performance Advisor. Quick Scan enables you to review performance issues without compiling or changing the model or validating any fixes. In models with long compile times, use Quick Scan to get a rapid analysis of possible improvements.

When you perform a Quick Scan diagnosis, Performance Advisor

- Does not perform a baseline measurement.
- Does not automatically apply advice to the model.
- Does not validate any changes you make to the model.
- Does not time out if the Quick Scan diagnosis takes longer than the **Time Out** duration you specify.

Run Quick Scan on a Model

- 1 Select checks to run.

Tip If you are unsure of which checks apply, you can select and run all checks. After you see the results, clear the checks you are not interested in.

- In the left pane of Performance Advisor, expand a folder, such as **Simulation** or **Simulation Targets**, to display checks related to specific tasks.
 - In the folder, select the checks you want to run using the check boxes.
- 2 Select the **Show report after run** checkbox to display the results of the checks after they run.
 - 3 Click **Quick Scan** on the right pane.

Checks in Quick Scan Mode

- “Identify resource-intensive diagnostic settings”
- “Check optimization settings”
- “Identify inefficient lookup table blocks”

- “Check MATLAB System block simulation mode”
- “Identify Interpreted MATLAB Function blocks”
- “Identify simulation target settings”

Improve vdp Model Performance

In this section...

- “Enable Data Logging for the Model” on page 29-16
- “Create Baseline” on page 29-16
- “Select Checks and Run” on page 29-17
- “Review Results” on page 29-18
- “Apply Advice and Validate Manually” on page 29-20

This example shows you how to run Performance Advisor on the vdp model, review advice, and make changes to improve performance.

Enable Data Logging for the Model

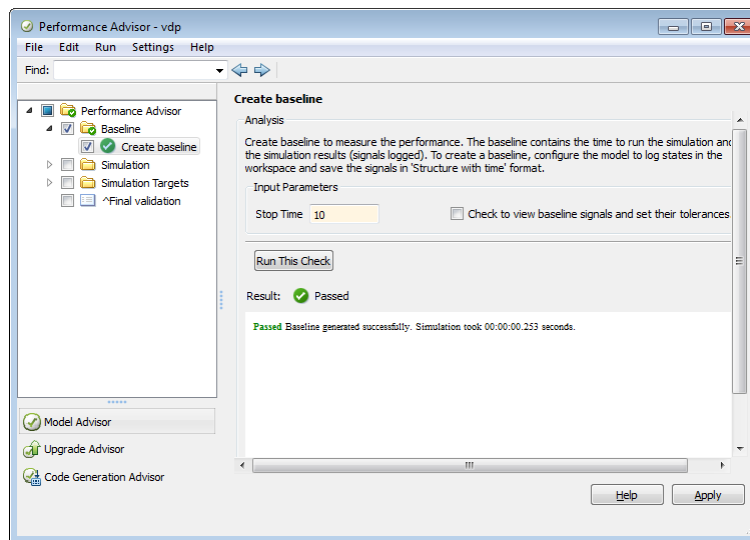

- 1 In the vdpmodel, select **Simulation > Model Configuration Parameters**.
- 2 In the Configuration Parameters dialog box, click **Data Import/Export** in the left pane.
- 3 Set up signal logging. The model must log at least one signal for Performance Advisor to work. For example, select the **States** or **Output** check box.
- 4 Click **Configure Signals to Log**.
- 5 To select signals to log, select a signal in vdp. Right click and select **Properties**.
- 6 In the Signal Properties dialog box, check the **Log signal data** option and click **OK**.
- 7 Click **OK** in the Configuration Parameters dialog box.
- 8 Run the model once to make sure that the simulation is successful.

Create Baseline

- 1 Open Performance Advisor. In the vdpmodel, select **Analysis > Performance Tools > Performance Advisor**.
- 2 In the right pane, under **Set Up**, select a global setting for **Take Action**. To automatically apply advice to the model, select **automatically for all checks**.
- 3 Select global settings to validate any improvements in simulation time and accuracy after applying advice. To select the default setting for validation, for **Validate simulation time** and **Validate simulation accuracy**, select **use check parameters**.

Note: To validate any improvements automatically, change the global settings to **For all checks**. However, this can increase simulation time as validating all checks requires more simulation runs.

- 4 Select **Show report after run**. This opens an HTML report of check results.
- 5 In the left pane, select the **Create baseline** check. Clear the other checks.
- 6 In the **Create baseline** pane, set **Stop Time** to 10. Click **Apply**.
- 7 Click **Run This Check**. The right pane updates to show that the baseline was created successfully.

Select Checks and Run

Note: The global input parameters to take action and validate improvement apply to all the checks you select.

- 1 In the left pane, clear the baseline check. Select these checks:

- In **Simulation > Checks Occurring Before Update**, select **Identify resource-intensive diagnostic settings**.
 - In **Simulation > Checks that Require Update Diagram**, select **Check model reference parallel build**.
 - In **Simulation Targets > Check Compiler Optimization Settings**, select **Select compiler optimizations on or off**.
 - Select **Final validation**.
- 2** For every check that you have selected in the left pane, select options in the right pane to validate any improvements in simulation time and accuracy. Note that **Take Action based on advice** is set to **automatically**, a result of **Take Action** being set to **automatically** for all checks.
 - 3** Select a value for **Time Out** if you want to limit the runtime duration of Performance Advisor.
 - 4** Click **Run Selected Checks**.

Performance Advisor runs the checks you selected and opens an HTML report with check results.

Review Results

- 1** In the HTML report, filter the results to see only the checks that passed.

Simulink Performance Advisor Report - vdp.slx

Simulink version: 8.3
 System: vdp
 Treat as Referenced Model: off

Performance Advisor

- 1 Baseline: 0 Passed, 0 Failed, 0 Warning, 1 Not Run
- 2 Simulation: 1 Passed, 0 Failed, 1 Warning, 10 Not Run
 - 2.1 Checks Occurring Before Update: 0 Passed, 0 Failed, 1 Warning, 8 Not Run
 - 2.2 Checks that Require Update Diagram: 1 Passed, 0 Failed, 0 Warning, 1 Not Run
 - 2.3 Checks that Require Simulation to Run: 0 Passed, 0 Failed, 0 Warning, 1 Not Run
- 3 Simulation Targets: 1 Passed, 0 Failed, 0 Warning, 1 Not Run
 - 3.1 Check Simulation Modes Settings: 0 Passed, 0 Failed, 0 Warning, 1 Not Run
 - 3.2 Check Compiler Optimization Settings: 1 Passed, 0 Failed, 0 Warning, 0 Not Run

Final validation: 0 Passed, 0 Failed, 0 Warning, 0 Not Run

All of the selected checks passed successfully.

- 2 Navigate to the results for a particular check, for example **Check model reference parallel build**. Use the navigation tree in the left pane or scroll to the results for this check in the right pane.
- 3 Performance Advisor gives you information about this check, advice for performance improvement, as well as a list of related model configuration parameters.

Check model reference parallel build

Passed

There are less than two reference models in your model. Parallel building is unnecessary. However, consider using model reference for large models. Use more than one model reference to take advantage of parallel building.

Input Parameters Selection

Name	Value
Quick estimation of model build time	true
Parallel build overhead time estimation factor	0.5

- 4 Filter the results to display warnings. See results for the **Identify resource-intensive diagnostic settings** check.

Performance Advisor identified diagnostic settings that incur runtime overhead during simulation. It modified values for some of these diagnostics. A table in the report shows the diagnostics checked and whether Performance Advisor suggested a change to the value.

If the performance of the model improved, the HTML report gives you information about this improvement. If the performance has deteriorated, Performance Advisor discards all changes and reinstates the original settings in the model.

5 See details for the **Final Validation** check.

✔ Final validation

Summary of performance validations			
	Before this check	After this check	Improvement
Performance			✔
Accuracy	Within given tolerance	Within given tolerance Click to view	✔
Simulation Time	00:00:00.253	00:00:00.100	60.38%

Passed

Overall, Performance advisor has improved the performance of the model.

Input Parameters Selection

Name	Value
Take action based on advice	automatically
Validate and revert changes if time of simulation increases	true
Validate and revert changes if degree of accuracy is greater than tolerance	true

This check validates the overall performance improvement in the model. The check results show changes in simulation time and accuracy, depending on whether performance improved or degraded.

Apply Advice and Validate Manually

Generate advice for a check, apply it, and validate any improvements manually.

- In the left pane, click **Performance Advisor**. Select these settings and click **Apply**:
 - Set **Take Action** to generate advice only.
 - Set **Validate simulation time** to use check parameters.
 - Set **Validate simulation accuracy** to use check parameters.
- For every check that you have selected in the left pane, select options in the right pane to validate any improvements in simulation time and accuracy. Note that **Take**

Action based on advice is set to **manually**, a result of **Take Action** being set to **generate advice only**.

- 3** Select **Performance Advisor** in the left pane. Click **Run Selected Checks** in the Performance Advisor pane.

If the performance of the model has improved, the **Final Validation** check results show the overall performance improvement.

- 4** In the results for **Identify resource-intensive diagnostic settings**, Performance Advisor suggests new values for the diagnostics it checked. Review these results to accept or reject the values it suggests.

Alternatively, click **Modify all and Validate** to accept all changes and validate any improvement in performance.

Performance Advisor Window

When you open Performance Advisor, it displays two panes.

In the left pane, the performance checks you can run are stored in folders. Expand the folders to see the checks within and select checks to run. You can search for folders and checks using **Find** above the pane.

Use the right pane to:

- Understand the Performance Advisor workflow
- Set up the model to run checks
- Select actions to apply generated advice and validate check results
- Learn more about each check
- Specify input parameters
- Run checks
- View and save reports
- View Performance Advisor results

After you run a check, Performance Advisor displays the results in the right pane. The right pane changes depending on the check you have selected.

Selection	Right Pane Display
Folder	<p>Analysis pane, containing:</p> <ul style="list-style-type: none"> • Run Selected Checks button — Click to run the selected checks in the folder and its subfolders. • Show report after run check box — Select to display an HTML report of the check results in a separate window. <p>Report pane, containing:</p> <ul style="list-style-type: none"> • Link to HTML report of check results • Save As button — Click to export the HTML report to a specific location <p>Tips and Legend panes, containing brief descriptions on using the checks.</p>

Selection	Right Pane Display
Check	<p data-bbox="497 303 832 331">Analysis pane, containing:</p> <ul data-bbox="497 361 1277 496" style="list-style-type: none"> <li data-bbox="497 361 1277 453">• Input Parameters section — Before running checks, specify how you want checks to run (for more information, see “Run Performance Advisor Checks” on page 29-6). <li data-bbox="497 465 1173 496">• Result section — Display results after a check runs. <p data-bbox="497 522 807 550">Action pane, containing:</p> <ul data-bbox="497 579 1329 743" style="list-style-type: none"> <li data-bbox="497 579 1329 671">• Modify button — After the check runs, Performance Advisor suggests actions to take to improve performance. Click here to accept the recommendations and modify the model. <li data-bbox="497 683 1329 743">• Result section — Display results after performing recommended actions.

From Performance Advisor, you can also run:

- **Model Advisor** — Check a model or subsystem for conditions that result in inaccurate or inefficient simulation of the system. See “Run Model Checks”.
- **Upgrade Advisor** — Upgrade and improve models with the current release. See “Consult the Upgrade Advisor” on page 6-2.
- **Code Generation Advisor** — Configure the model to meet code generation objectives. See “Application Objectives Using Code Generation Advisor”.

Examine Model Dynamics Using Solver Profiler

When model simulation slows down or stops responding, a close examination of the dynamics of the model can help you identify the factors affecting the simulation.

Understanding solver behavior enables you to interpret how the model simulates and what causes the solver to take small steps.

The Solver Profiler, a tool for variable-step solvers, analyzes a model for patterns that affect its simulation. The Solver Profiler presents graphical and statistical information about the simulation, solver settings, events, and errors. You can use this data to identify locations in the model that caused simulation bottlenecks.

In addition, in simulations that use variable-step solvers, the size of the step can be limited due to various reasons. The Solver Profiler logs and reports all the events when the solver tries to take too large steps:

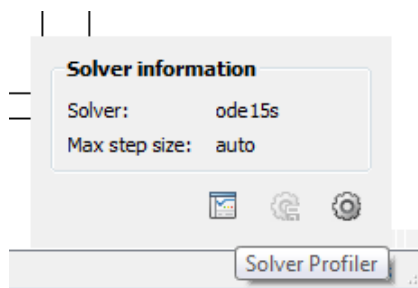

- Zero-crossing event
- Error control exception
- Newton iteration exception
- Differential algebraic equation (DAE) Newton iteration exception
- Infinite state exception

To examine model dynamics and identify causes that affect the simulation:

- 1 Open the model that is simulating slowly or unsuccessfully.

- Open the Solver Profiler by clicking the hyperlink in the lower-right corner of the Simulink Editor.

- 3 To log model states that have solver errors or exception events, select the **Continuous States** or **Simscape States** option before a run. Disable these options only if you are running out of memory. After the run, access the States Explorer or Simscape Explorer to examine those states.
- 4 Click **Run**. The profiler simulates the model and starts capturing solver performance data.

When the simulation ends, the profiler displays the statistics and exceptions it captured over the duration of the simulation.

Tip You can pause or stop the simulation at any time to view the information captured until that point.

- 5 Use the profiler plot to highlight the parts of the model that caused generate the most events.
- 6 Click **Save** to capture your profiling session, or exit without saving.

Understand Profiling Results

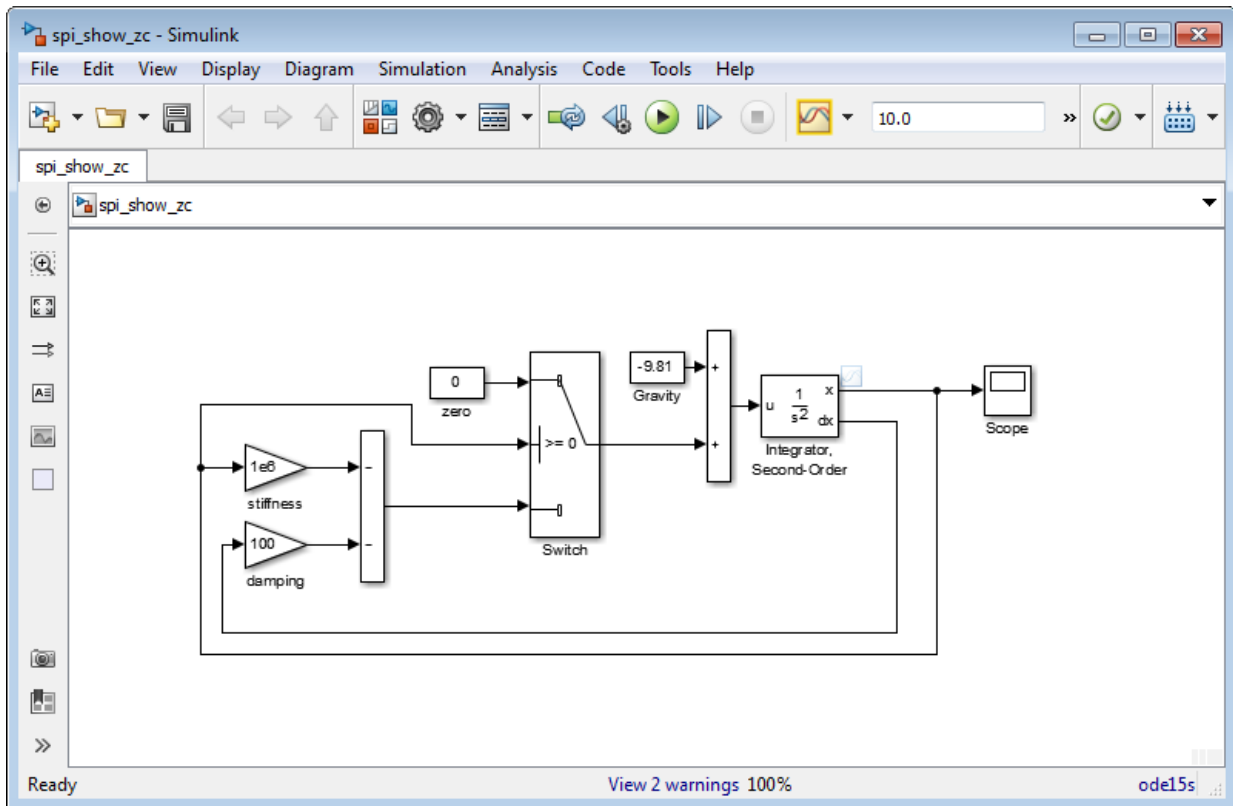

In this section...
“Zero-Crossing Events” on page 30-6
“Tolerance-Exceeding Events” on page 30-9
“Newton Iteration Failures” on page 30-12
“Differential Algebraic Equation Failures” on page 30-14
“Jacobian Logging and Analysis” on page 30-17

If you have a large model, it can be challenging to identify which parts of your model cause the solver to take small steps. The Solver Profiler logs and reports events when the solver attempts to take large steps. This report of events helps you identify which parts of your model to focus on to improve solver performance.

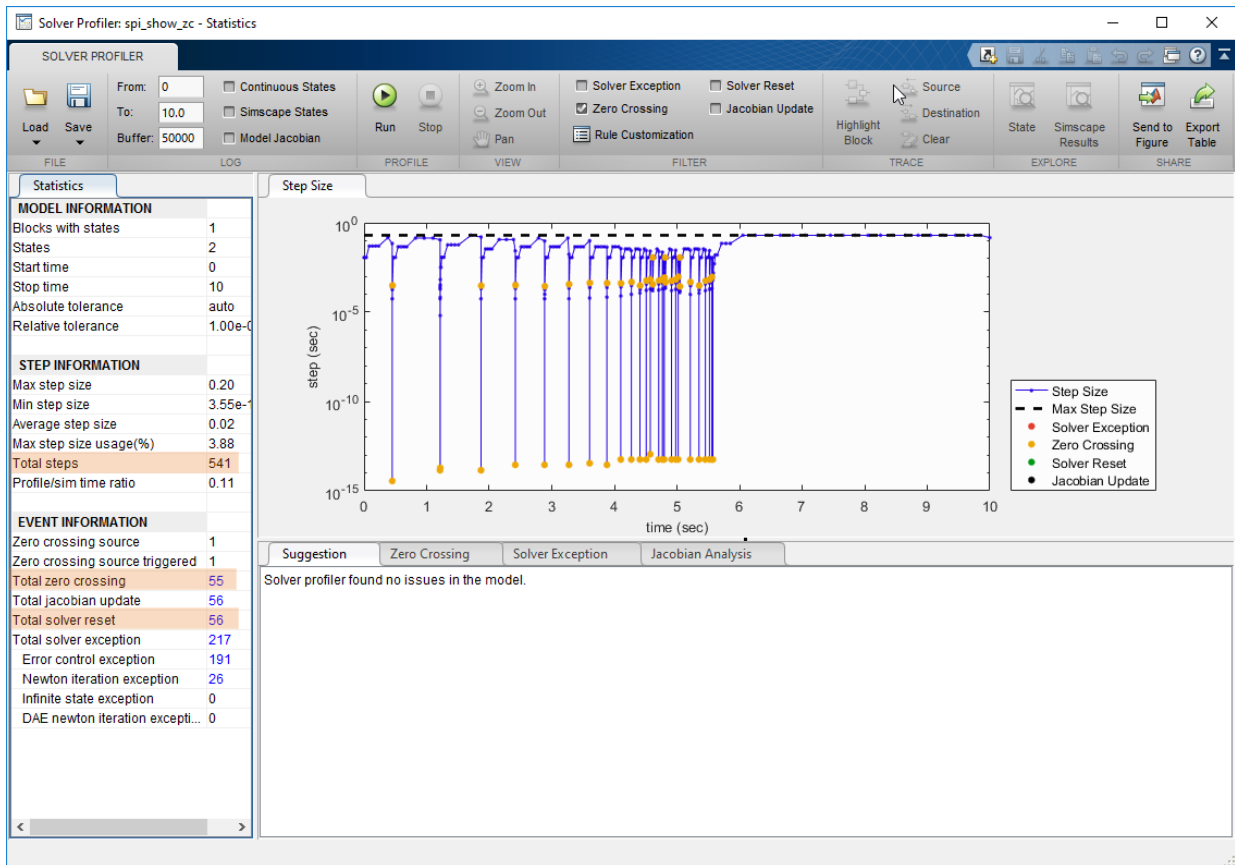

This topic presents simple examples that illustrate various events that the profiler reports.

Zero-Crossing Events

This example simulates a ball bouncing on a hard surface.

When you run the Solver Profiler on this model, the model simulates in 541 steps and that it triggers 55 zero-crossing events. To highlight the zero-crossing events on the step size plot, click the **Zero Crossing** tab and select the block that is causing the event.

The result indicates that when the ball drops on the hard surface, it bounces 55 times before coming to a stop. The solver resets after each bounce, increasing the computational load. Having many resets improves accuracy at the cost of computation load. Therefore, it is important to be cognizant of this trade-off when modeling.

If this modeling construct belonged to a larger model, the Solver Profiler would help you locate it. You could then modify the model to improve solver performance. For example, you can decide to reduce the accuracy of the contact dynamic by increasing the damping factor, which would reduce the number of bounce events. Increasing the damping from 100 to 500 makes the ball bounce only 9 times, allowing the simulation to complete in only 137 steps.

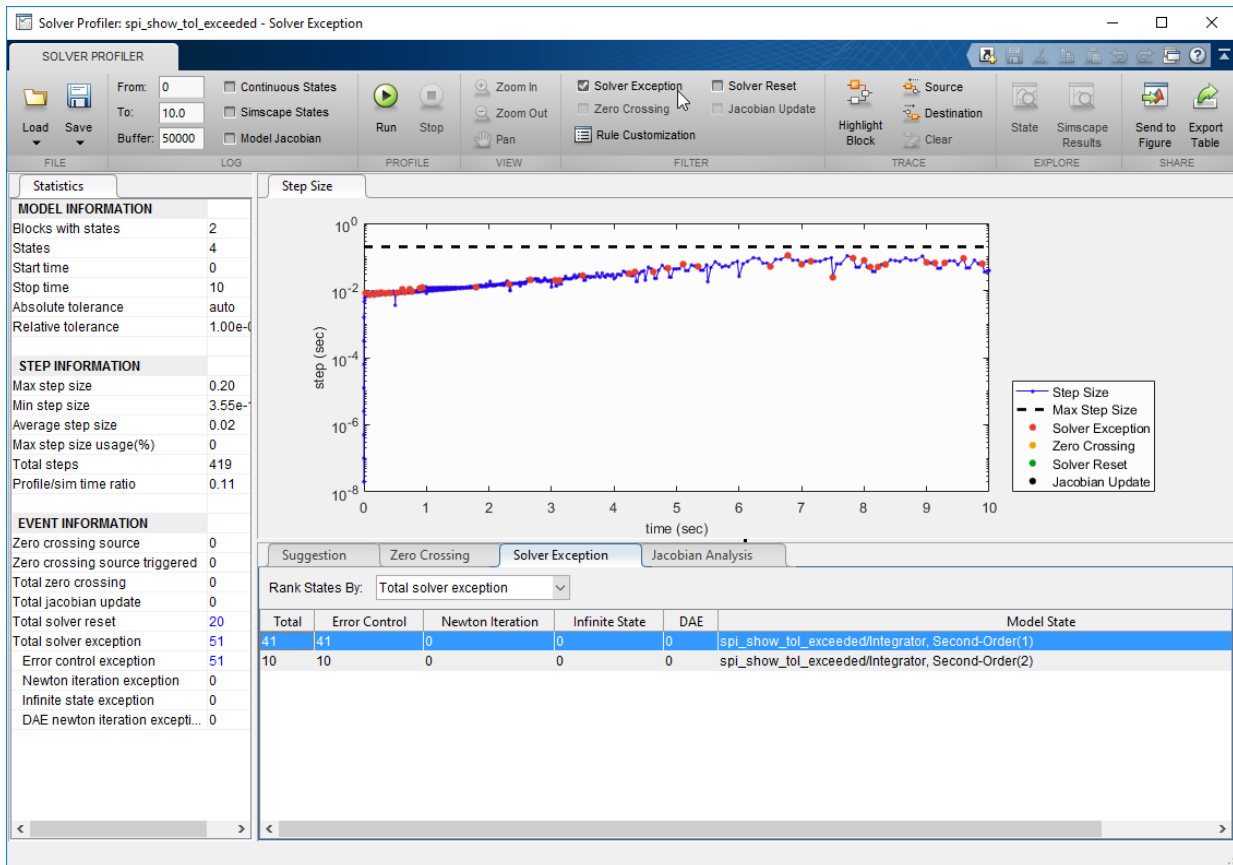

Tolerance-Exceeding Events

This example simulates two identical nonlinear spring-damping systems. The two systems have different spring stiffnesses.

When you run the Solver Profiler on this model, you can see the tolerance exceeding events in the **Solver Exception** tab.

The result indicates that the stiffer spring causes the solver tolerance to exceed the limit. Typically, model states that change the fastest tend to be closest to the solver tolerance limit.

The solver attempts to take the largest possible steps while optimally trading off between speed and accuracy. Occasionally, this trade-off causes the solver to take steps that exceed the tolerance limit and forces it to reduce the step size. Exceeding the tolerance limit is not a poor modeling practice in itself. This profiler statistic is not meant to help you reduce tolerance exceeding events to zero.

This statistic can help you identify parts of your model that are close to exceeding the tolerance limit. You can identify model components that change the fastest or are the

stiffest. You can decide to retain this model dynamic in the simulation or simplify it to speed up simulation.

The tolerance-exceeding statistic can also help you identify modeling errors. If you do not expect the highlighted states to change as fast, you can examine your model for errors. In this example, the modeling error could be the stiffness of the stiffer spring is specified as N/m instead of the N/mm. This error makes the spring 1000 times stiffer than expected.

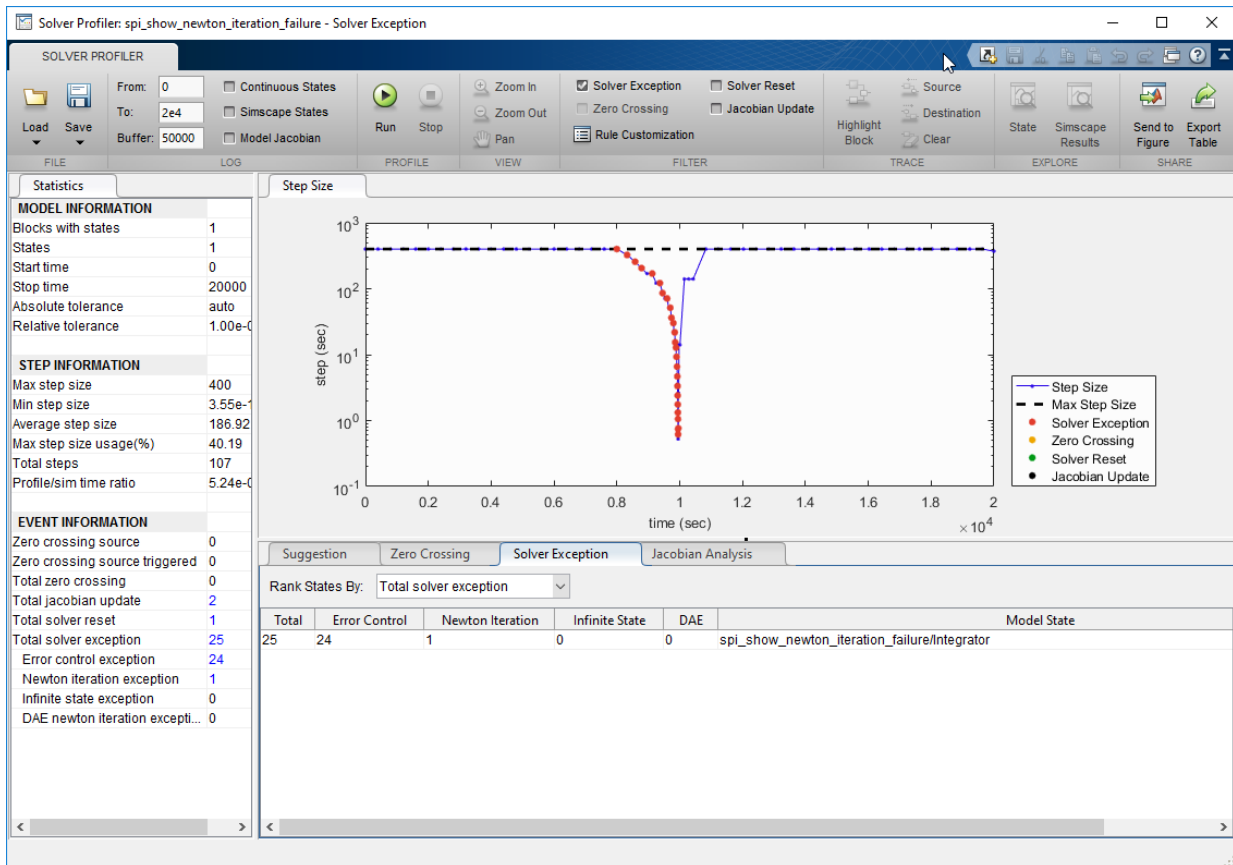

Newton Iteration Failures

Newton iteration failures are specific to implicit solvers like `ode15s` and `ode23t`, and they result from Newton iterations not converging after a few trials. Similar to tolerance-exceeding events, these failures tend to occur when a system changes quickly.

This example simulates how the radius of a ball of flame changes when you strike a match. The ball of flame grows rapidly until it reaches a critical size, when the amount of oxygen consumed balances the growth in ball surface.

When you run the Solver Profiler on this model, you can see the Newton iteration failures in the **Solver Exception** tab.

The result indicates that when the combustion begins, the solver tolerance is exceeded multiple times. When equilibrium is attained, the system appears different, and a Newton iteration failure occurs. The Jacobian of the system is recomputed, and the solver continues to move forward.

Newton failures are not indicative of poor modeling practices. This profiler statistic is not meant to help you reduce these failures to zero. In this example, you can reduce the solver tolerance to prevent this failure. But the solver then takes small steps unnecessarily, which is counterproductive. Therefore, in this example, this failure is acceptable.

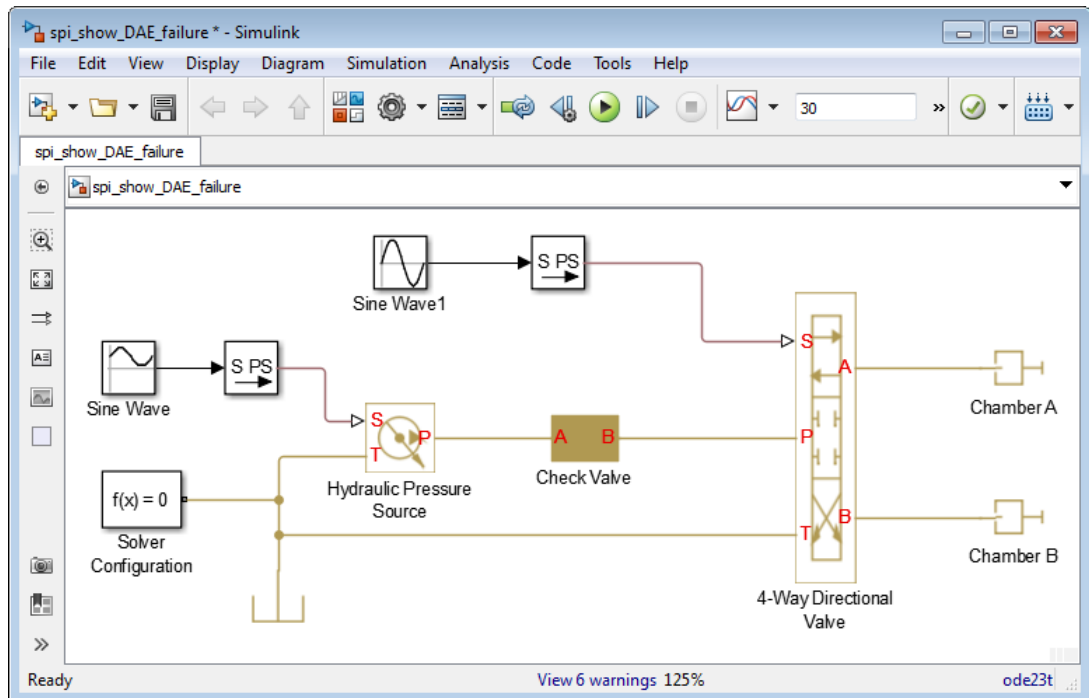

This type of failure becomes problematic when it occurs in large numbers over a short period, especially in Simscape models. Dense failures indicate that your model is not robust numerically. One way to improve numerical robustness is to tighten the solver tolerance. Another way is to modify the model to avoid rapid changes.

Differential Algebraic Equation Failures

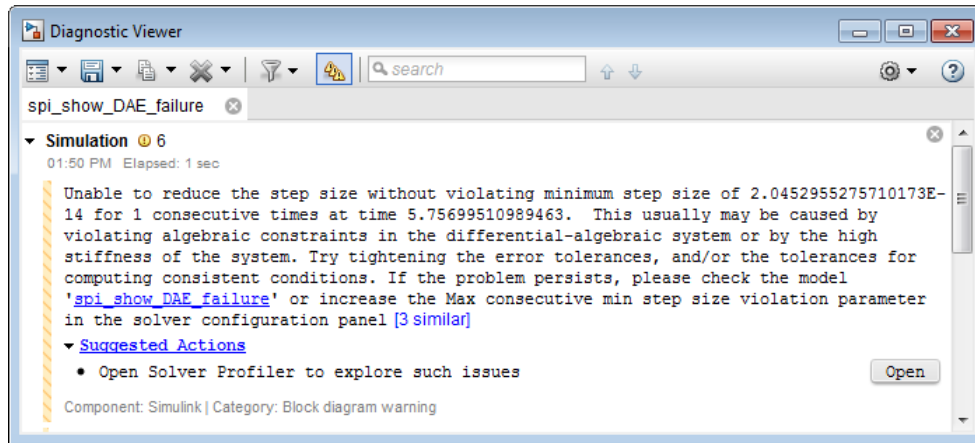

Most Simscape models are implemented using differential algebraic equations (DAEs), in contrast to Simulink models, which use ordinary differential equations.

The use of DAEs adds complexity to Simscape models. Solvers like `ode15s` and `ode23t` can handle many types of DAEs. However, when the algebraic constraints between Simscape components are complex and changing fast, the Newton iteration process fails to resolve to those constraints.

This example simulates a pressure source that can be directed toward one of two hydraulic chambers.

When you simulate this model, Simulink displays several warnings.

Typically, small models can handle such warnings and simulate to completion. However, this warning indicates that the model is not robust numerically. Minor changes to the model, or integration into a larger model, can result in errors.

When you run the Solver Profiler on this model, you can see the DAE failures in the **Solver Exception** tab.

In this case, the exception results from large solver tolerance. Tightening the solver tolerance forces the solver to take smaller steps and better capture the changes in algebraic constraints.

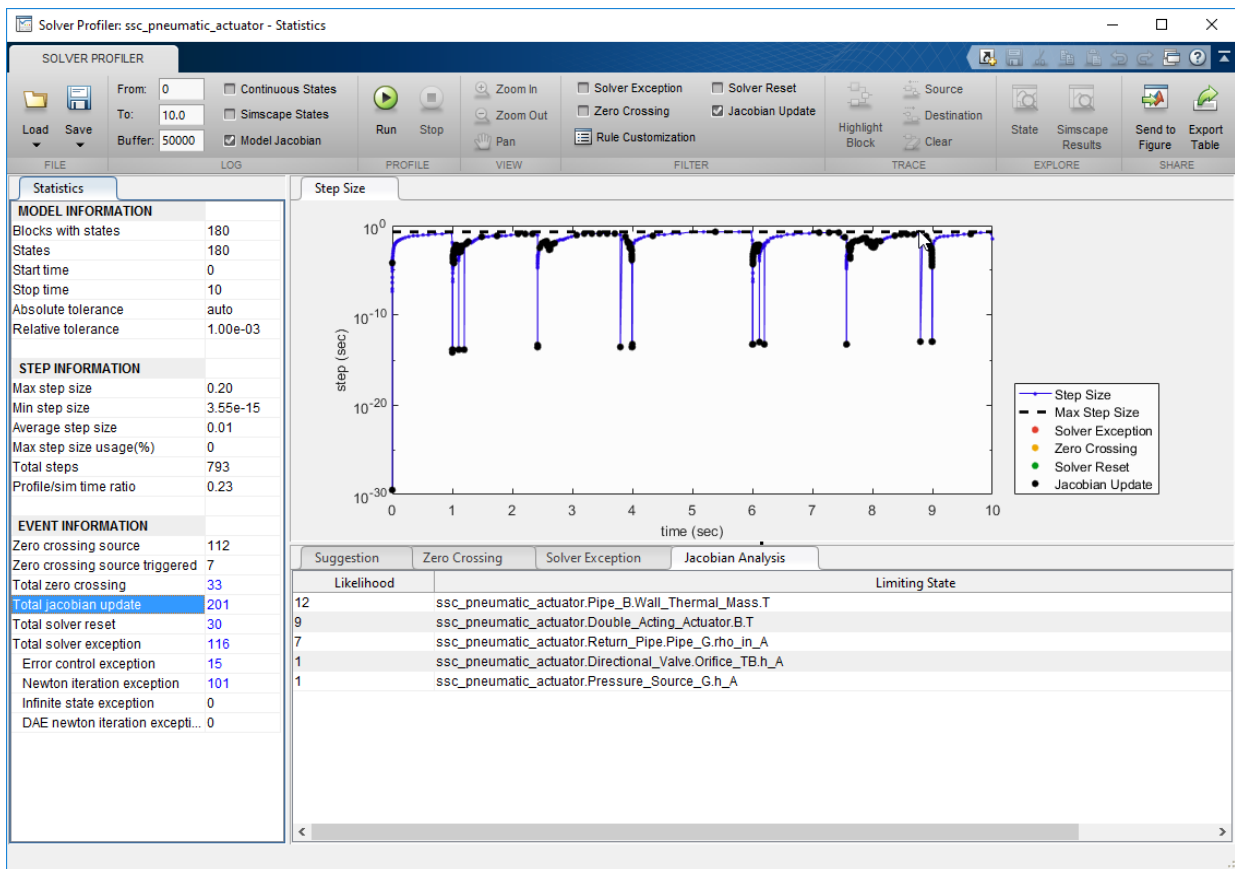

Alternatively, this exception can be avoided by removing the algebraic constraint. In this example, the **Check Valve** and the **4-Way Directional Valve** are directly connected. When their pressure–flow relationship changes rapidly, the solver is unable to capture the changes. Inserting a **Hydraulic Chamber** between those two components makes them compliant. To learn more about dry nodes, see Simscape documentation.

Jacobian Logging and Analysis

The Solver Profiler supports Jacobian logging and analysis for ode15s and ode23t solvers only.

You can select the **Model Jacobian** checkbox in the Solver Profiler to log updates to the Jacobian matrix for the model. When you run the Solver Profiler on a model, you can see the logs in the **Jacobian Analysis** tab.

The **Jacobian Analysis** tab indicates the states in the model that are likely slowing down the solver.

To investigate the cause of each limiting state, select a row in the **Jacobian Analysis** tab and click **Highlight Block**.

Related Examples

- “Examine Model Dynamics Using Solver Profiler” on page 30-2

Modify Solver Profiler Rules

You can customize the suggestions that appear in the Solver Profiler in these ways:

- Change the thresholds of the Solver Profiler rules that detect failure patterns.
- Select which rules to apply during a profiling run.
- Author your own rule set as a MATLAB script.

Change Thresholds of Profiler Rules

Click **Rule Customization** in the Solver Profiler to access the rule set. You can change the thresholds for most of these rules and also select which rules you want to apply selectively during a simulation run.

Rule Set: ssc_pneumatic_actuator

Restore to Default

If simulation hangs or pauses, show suggestions when:

<input checked="" type="checkbox"/>	Ratio of solver exceptions to number of steps exceeds	30	%
<input checked="" type="checkbox"/>	Ratio of zero crossing events to number of steps exceeds	30	%
<input checked="" type="checkbox"/>	Ratio of solver reset events to number of steps exceeds	30	%

Over the entire simulation, show suggestions when:

<input checked="" type="checkbox"/>	There are any DAE newton iteration exceptions during simulation		
<input checked="" type="checkbox"/>	There is coupling between continuous and discrete rates		
<input checked="" type="checkbox"/>	Ratio of solver reset events to number of steps exceeds	50	%
<input checked="" type="checkbox"/>	Number of solver exception in one second simulation time exceeds	100	
<input checked="" type="checkbox"/>	Number of zero crossing in one second simulation time exceeds	100	
<input checked="" type="checkbox"/>	Percentage of steps with max step size exceeds	35	%

Custom Rule Set

...

Develop Profiler Rule Set

You can override the settings on the **Rule Set** dialog box by specifying a custom rule set.

Create a rule set as a MATLAB script and specify the path to the script in the **Custom Rule Set** section of the **Rule Set** dialog box.

A simple rule set example looks as follows:

```
function diagnosticsString = customRule(profilerData)
    if isempty(profilerData.zcEvents)
        diagnosticsString{1} = 'No zero-crossing event detected.';
    else
        diagnosticsString{1} = 'Zero-crossing events detected.';
    end
end
```

The input to the function is an array of structures called `profilerData`. This array of structures organizes all the information that the Solver Profiler collects during a profiling run. It contains the following substructures.

Substructure	Fields
stateInfo : Stores information on block states	<ul style="list-style-type: none"> • name: Block name • value: State values • blockIdx: Block ID
blockInfo : Cross-reference of blocks and state IDs	<ul style="list-style-type: none"> • name: Block name • stateIdx: State ID
zcSrcInfo : Stores information on blocks causing zero-crossing events	<ul style="list-style-type: none"> • name: Block name • blockIdx: Block ID
zcEvents : Cross-reference of the time stamps of zero-crossing events and the corresponding state IDs	<ul style="list-style-type: none"> • t: Event timestamp • srcIdx: Block ID
exceptionEvents : Cross-reference of exception event timestamps, the ID of the corresponding state that caused the event, and the cause.	<ul style="list-style-type: none"> • t: Event timestamp • stateIdx: State ID • cause: Cause of exception
resetTime : Stores timestamps of solver resets.	None

Substructure	Fields
tout: Stores simulation times.	None

Customize State Ranking

If you log continuous states in the Solver Profiler, you can open the State Explorer to investigate each continuous state. The State Explorer ranks continuous states by the following metrics:

- State Derivative
- Newton/DAE Exception
- State Value
- Error Control Exception
- State Name
- State Chatter

In addition to these ranking metrics, you can write and upload your own algorithm to determine how continuous states are ranked in the State Explorer.

- 1 Click the edit button next to the **Rank States By** dropdown.

```
index = 1:nStates;
score = zeros(nStates,1);

% Loop through each state to calculate score
for i = 1:nStates
    x = sd.stateInfo(i).value;
    % apply time range constraints
    x = x(sd.tout>=tl & sd.tout<=tr);
    if max(x) > 1
        score(i) = 1;
    else
        score(i) = 0;
    end
end

% Rank the states
[score, order] = sort(score, 'descend');
index = index(order);

end
```

Solver Profiler Interface

The Solver Profiler enables you to:

- Start a profiling session, save a session, or open a saved session.
- Customize and filter the results displayed.
- Interact with the model and trace and highlight the states that contain exceptions.
- Open Simscape Explorer or States Explorer to analyze simulation data further.
- Customize profiler suggestions using your own rules.

Statistics Pane

The statistics pane displays information on model parameters, including:

- **Average step size** — A measure of how fast the solver advances. It is calculated as the total simulation time divided by the number of steps the solver used. It is bounded by the model configuration parameters **Max step size** and **Min step size**.
- **Max step size usage** — The percentage of maximum step sizes used by the solver among all step sizes.
- **Zero crossing** — A solver-specific event that affects model dynamics. During simulation, the solver detects zero crossing. Zero crossing detection incurs computation cost. For more information, see “Zero-Crossing Detection” on page 3-24.
- **Solver reset** — An event that causes the solver to reset its parameters. Solver reset detection incurs computation cost.
- **Solver exception** — An event that renders the solver unable to solve model states to meet accuracy specifications. To solve model states accurately, the solver has to run a few adjusted trials, which incur computation cost.
- **Error control exception** — An event where a solution obtained by the solver has an error that is greater than the tolerance specification.
- **Newton iteration exception** — An event specific to implicit solvers. Newton iterations do not converge after a few trials.
- **Infinite state exception** — An event where one or more states solved by the solver are infinite.
- **DAE newton iteration exception** — An event specific to implicit solvers for Simscape models. The Newton iteration does not converge even though the solver violates the minimum step size constraint.

Suggestions and Exceptions Pane

The suggestions and exceptions pane displays information on exceptions, including:

- **Solver exception** — An event that renders the solver unable to solve model states to meet accuracy specifications. To solve model states accurately, the solver has to run a few adjusted trials, which incur computation cost.
- **Error control exception** — An event where a solution obtained by the solver has an error that is greater than the tolerance specification.

- **Newton iteration exception** — An event specific to implicit solvers. Newton iterations do not converge after a few trials.
- **Infinite state exception** — An event where one or more states solved by the solver are infinite.
- **DAE newton iteration exception** — An event specific to implicit solvers for Simscape models. The Newton iteration does not converge even though the solver violates the minimum step size constraint.

Introduction to the Debugger

With the debugger, you run your simulation method by method. You can stop after each method to examine the execution results. In this way, you can pinpoint problems in your model to specific blocks, parameters, or interconnections.

Note Methods are functions that the Simulink software uses to solve a model at each time step during the simulation. Blocks are made up of multiple methods. “Block execution” in this documentation is shorthand for “block methods execution.” Block diagram execution is a multi-step operation that requires execution of the different block methods in all the blocks in a diagram at various points during the process of solving a model at each time step during simulation, as specified by the simulation loop.

The debugger has both a graphical and a command-line user interface. The graphical interface allows you to access the most commonly used features of the debugger. The command-line interface gives you access to all of the capabilities in the debugger. If you can use either to perform a task, the documentation shows you first how to use the graphical interface, “Debugger Graphical User Interface” on page 31-3, and then the command-line interface, “Debugger Command-Line Interface” on page 31-10.

All functions such as `atrace` and `ashow` can only be used within the debugger.

Debugger Graphical User Interface

In this section...

“Displaying the Graphical Interface” on page 31-3

“Toolbar” on page 31-4

“Breakpoints Pane” on page 31-5

“Simulation Loop Pane” on page 31-5

“Outputs Pane” on page 31-7

“Sorted List Pane” on page 31-7

“Status Pane” on page 31-8

Displaying the Graphical Interface

Select **Debug Model** from a model window **Simulation > Debug** menu to display the debugger graphical interface.

Note: The debugger graphical user interface does not display state or solver information. The command line interface does provide this information. See “Display System States” on page 31-31 and “Display Solver Information” on page 31-32.

Toolbar

The debugger toolbar appears at the top of the debugger window.

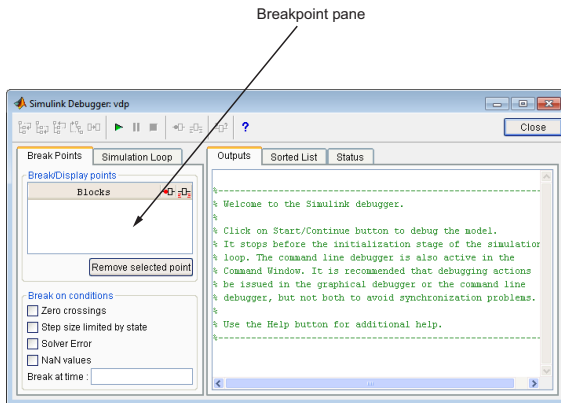

From left to right, the toolbar contains the following command buttons:

Button	Purpose
	Step into the next method (see “Stepping Commands” on page 31-20 for more information on this command, and the following stepping commands).
	Step over the next method.
	Step out of the current method.
	Step to the first method at the start of next time step.
	Step to the next block method.
	Start or continue the simulation.
	Pause the simulation.
	Stop the simulation.
	Break before the selected block.

Button	Purpose
	Display inputs and outputs of the selected block when executed (same as trace gcb).
	Display the current inputs and outputs of selected block (same as probe gcb).
	Display help for the debugger.
	Close the debugger.

Breakpoints Pane

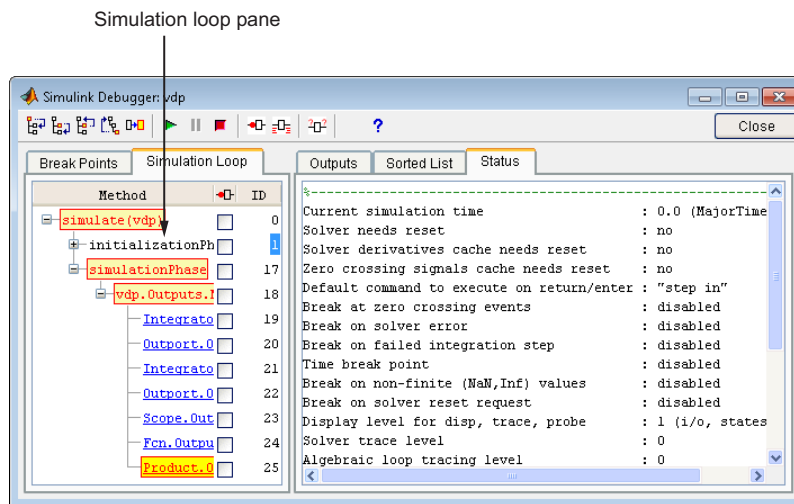

To display the **Breakpoints** pane, select the **Break Points** tab on the debugger window.

The **Breakpoints** pane allows you to specify block methods or conditions at which to stop a simulation. See “Set Breakpoints” on page 31-23 for more information.

Simulation Loop Pane

To display the **Simulation Loop** pane, select the **Simulation Loop** tab on the debugger window.

The **Simulation Loop** pane contains three columns:

- Method
- Breakpoints
- ID

Method Column

The **Method** column lists the methods that have been called thus far in the simulation as a method tree with expandable/collapsible nodes. Each node of the tree represents a method that calls other methods. Expanding a node shows the methods that the block method calls. Clicking a block method name highlights the corresponding block in the model diagram.

Whenever the simulation stops, the debugger highlights the name of the method where the simulation has stopped as well as the methods that invoked it. The highlighted method names indicate the current state of the method call stack.

Breakpoints Column

The breakpoints column consists of check boxes. Selecting a check box sets a breakpoint at the method whose name appears to the left of the check box. See “Setting Breakpoints from the Simulation Loop Pane” on page 31-25 for more information.

ID Column

The ID column lists the IDs of the methods listed in the **Methods** column. See “Method ID” on page 31-10 for more information.

Outputs Pane

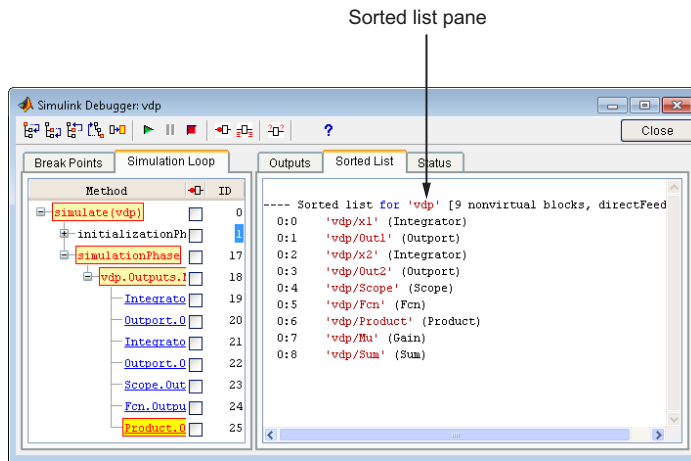

To display the **Outputs** pane, select the **Outputs** tab on the debugger window.

The Outputs pane displays the same debugger output that would appear in the MATLAB command window if the debugger were running in command-line mode. The output includes the debugger command prompt and the inputs, outputs, and states of the block at whose method the simulation is currently paused (see “Block Data Output” on page 31-19). The command prompt displays current simulation time and the name and index of the method in which the debugger is currently stopped (see “Block ID” on page 31-10).

Sorted List Pane

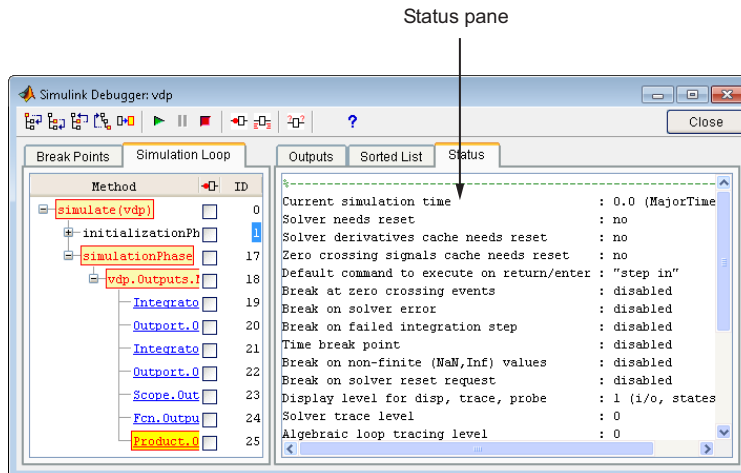

To display the **Sorted List** pane, select the **Sorted List** tab on the debugger window.

The **Sorted List** pane displays the sorted lists for the model being debugged. See “Display Model’s Sorted Lists” on page 31-34 for more information.

Status Pane

To display the **Status** pane, select the **Status** tab on the debugger window.

The **Status** pane displays the values of various debugger options and other status information.

Debugger Command-Line Interface

In this section...

“Controlling the Debugger” on page 31-10

“Method ID” on page 31-10

“Block ID” on page 31-10

“Accessing the MATLAB Workspace” on page 31-11

Controlling the Debugger

In command-line mode, you control the debugger by entering commands at the debugger command line in the MATLAB Command Window. To enter commands at the debugger command line, you must start the debugger programmatically and not through the GUI. Use `sldebug` for this purpose. The debugger accepts abbreviations for debugger commands. For more information on debugger commands, see “Simulink Debugger”.

Note: You can repeat some commands by entering an empty command (i.e., by pressing the **Enter** key) at the command line.

Method ID

Some of the Simulink software commands and messages use method IDs to refer to methods. A method ID is an integer assigned to a method the first time the method is invoked. The debugger assigns method indexes sequentially, starting with 0.

Block ID

Some of the debugger commands and messages use block IDs to refer to blocks. Block IDs are assigned to blocks while generating the model's sorted lists during the compilation phase of the simulation. A block ID has the form `sysIdx:blkIdx`, where `sysIdx` is an integer identifying the system that contains the block (either the root system or a nonvirtual subsystem) and `blkIdx` is the position of the block in the system's sorted list. For example, the block `ID0:1` refers to the first block in the model's root system. The `slist` command shows the block ID for each debugged block in the model.

Accessing the MATLAB Workspace

You can enter any MATLAB expression at the `sldebug` prompt. For example, suppose you are at a breakpoint and you are logging time and output of your model as `tout` and `yout`. The following command creates a plot.

```
(sldebug ...) plot(tout, yout)
```

You cannot display the value of a workspace variable whose name is partially or entirely the same as that of a debugger command by entering it at the debugger command prompt. You can, however, use the `eval` command to work around this problem. For example, use `eval('s')` to determine the value of `s` rather than `s(tep)` the simulation.

Debugger Online Help

You can get online help on using the debugger by clicking the **Help** button on the debugger toolbar. Clicking the **Help** button displays help for the debugger in the MATLAB product Help browser.

In command-line mode, you can get a brief description of the debugger commands by typing `help` at the debug prompt.

More About

- “Debugger Graphical User Interface” on page 31-3
- “Debugger Command-Line Interface” on page 31-10

Start the Simulink Debugger

You can start the debugger from either a Simulink model window or from the MATLAB Command Window.

In this section...

“Starting from a Model Window” on page 31-13

“Starting from the Command Window” on page 31-13

Starting from a Model Window

- 1 In a model window, select **Simulation > Debug > Debug Model**.

The debugger graphical user interface opens. See “Debugger Graphical User Interface” on page 31-3.

- 2 Continue selecting toolbar buttons.

Note: When running the debugger in graphical user interface (GUI) mode, you must explicitly start the simulation. For more information, see “Start a Simulation” on page 31-15.

Note: When starting the debugger from the GUI, you cannot enter debugger commands in the MATLAB command window. For this, you must start the debugger from the command window using the `sim` or `sldebug` commands.

Starting from the Command Window

- 1 In the MATLAB Command Window, enter either
 - the `sim` command. For example, enter

```
sim('vdp', 'StopTime', '10', 'debug', 'on')
```
 - or the `sldebug` command. For example, enter

```
sldebug 'vdp'
```

In both cases, the example model vdp loads into memory, starts the simulation, and stops the simulation at the first block in the model execution list.

- 2 The debugger opens and a debugger command prompt appears within the MATLAB command window. Continue entering debugger commands at this debugger prompt.

Start a Simulation

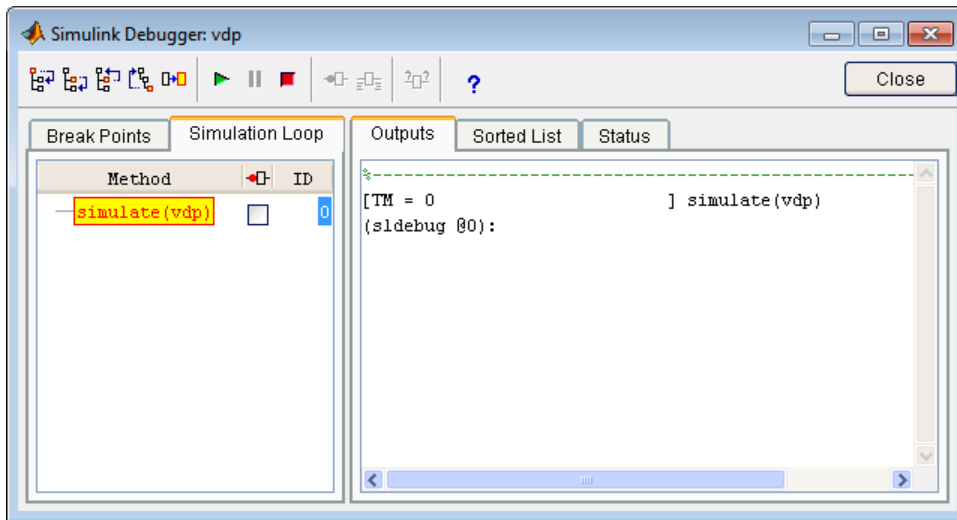

To start the simulation, click the **Start/Continue** button on the debugger toolbar.

The simulation starts and stops at the first simulation method that is to be executed. It displays the name of the method in its **Simulation Loop** pane. At this point, you can

- Set breakpoints.
- Run the simulation step by step.
- Continue the simulation to the next breakpoint or end.
- Examine data.
- Perform other debugging tasks.

The debugger displays the name of the method in the Simulation Loop pane, as shown in the following figure:

The following sections explain how to use the debugger controls to perform these debugging tasks.

Note When you start the debugger in GUI mode, the debugger command-line interface is also active in the MATLAB Command Window. However, to prevent synchronization errors between the graphical and command-line interfaces, you should avoid using the command-line interface.

Run a Simulation Step by Step

In this section...

- “Introduction” on page 31-18
- “Block Data Output” on page 31-19
- “Stepping Commands” on page 31-20
- “Continuing a Simulation” on page 31-21
- “Running a Simulation Nonstop” on page 31-21

Introduction

The debugger provides various commands that let you advance a simulation from the method where it is currently suspended (the next method) by various increments (see “Stepping Commands” on page 31-20). For example, you can advance the simulation

- Into or over the next method
- Out of the current method
- To the top of the simulation loop.

After each advance, the debugger displays information that enables you to determine the point to which the simulation has advanced and the results of advancing the simulation to that point.

For example, in GUI mode, after each step command, the debugger highlights the current method call stack in the **Simulation Loop** pane. The call stack comprises the next method and the methods that invoked the next method either directly or indirectly. The debugger highlights the call stack by highlighting the names of the methods that make up the call stack in the **Simulation Loop** pane.

In command-line mode, you can use the `where` command to display the method call stack.

Block Data Output

After executing a block method, the debugger prints any or all of the following block data in the debugger **Output** panel (in GUI mode) or, if in command line mode, the MATLAB Command Window:

- $Un = v$
where v is the current value of the block's n th input.
- $Yn = v$
where v is the current value of the block's n th output.
- $CSTATE = v$
where v is the value of the block's continuous state vector.
- $DSTATE = v$

where v is the value of the block's discrete state vector.

The debugger also displays the current time, the ID and name of the next method to be executed, and the name of the block to which the method applies in the MATLAB Command Window. The following example illustrates typical debugger outputs after a step command.

```

          Current time                Next method
          |                            |
          v                            v
-----*-----*-----*-----*-----*-----*-----*-----*-----*-----*
[Tm = 2.009509145207664e-05 ] 0:2 Integrator.Derivatives 'vdp/x2'
(sldebug @49):
Data of 0:2 Integrator block 'vdp/x2':
U1    = [-1.9998794294512876]
Y1    = [-4.0190182904153282e-05]
CSTATE = [-4.0190182904153282e-05]
-----*-----*-----*-----*-----*-----*-----*-----*-----*-----*
[Tm = 3.014263717811496e-05 ] vdp.Outputs.Minor

```

Stepping Commands

Command-line mode provides the following commands for advancing a simulation incrementally:

This command...	Advances the simulation...
<code>step [in into]</code>	Into the next method, stopping at the first method in the next method or, if the next method does not contain any methods, at the end of the next method
<code>step over</code>	To the method that follows the next method, executing all methods invoked directly or indirectly by the next method
<code>step out</code>	To the end of the current method, executing any remaining methods invoked by the current method
<code>step top</code>	To the first method of the next time step (i.e., the top of the simulation loop)
<code>step blockmth</code>	To the next block method to be executed, executing all intervening model- and system-level methods

This command...	Advances the simulation...
next	Same as <code>step over</code>

Buttons in the debugger toolbar allow you to access these commands in GUI mode.

Clicking a button has the same effect as entering the corresponding command at the debugger command line.

Continuing a Simulation

In GUI mode, the **Stop** button turns red when the debugger suspends the simulation for any reason. To continue the simulation, click the **Start/Continue** button. In command-line mode, enter `continue` to continue the simulation. By default, the debugger runs the simulation to the next breakpoint (see “Set Breakpoints” on page 31-23) or to the end of the simulation, whichever comes first.

Running a Simulation Nonstop

The `run` command lets you run a simulation to the end of the simulation, skipping any intervening breakpoints. At the end of the simulation, the debugger returns you to the command line. To continue debugging a model, you must restart the debugger.

Note The GUI mode does not provide a graphical version of the `run` command. To run the simulation to the end, you must first clear all breakpoints and then click the **Start/Continue** button.

Set Breakpoints

In this section...

“About Breakpoints” on page 31-23

“Setting Unconditional Breakpoints” on page 31-23

“Setting Conditional Breakpoints” on page 31-25

About Breakpoints

The debugger allows you to define stopping points called breakpoints in a simulation. You can then run a simulation from breakpoint to breakpoint, using the debugger `continue` command. The debugger lets you define two types of breakpoints: unconditional and conditional. An unconditional breakpoint occurs whenever a simulation reaches a method that you specified previously. A conditional breakpoint occurs when a condition that you specified in advance arises in the simulation.

Breakpoints are useful when you know that a problem occurs at a certain point in your program or when a certain condition occurs. By defining an appropriate breakpoint and running the simulation via the `continue` command, you can skip immediately to the point in the simulation where the problem occurs.

Note: When you stop a simulation at a breakpoint of a MATLAB S-function in the debugger, to exit MATLAB, you must first quit the debugger.

Setting Unconditional Breakpoints

You can set unconditional breakpoints from the:

- Debugger toolbar
- **Simulation Loop** pane
- MATLAB product Command Window (command-line mode only)

Setting Breakpoints from the Debugger Toolbar

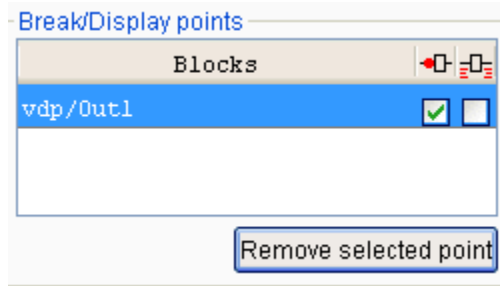

To enable the **Breakpoint** button,

- 1 Simulate the model.

- 2 Click the **Step over current method** button until `simulationPhase` is highlighted.
- 3 Click the **Step into current method** button.

The debugger displays the name of the selected block in the **Break/Display points** panel of the **Breakpoints** pane.

Note Clicking the **Breakpoint** button on the toolbar sets breakpoints on the invocations of a block's methods in major time steps.

You can temporarily disable the breakpoints on a block by deselecting the check box in the breakpoints column of the panel. To clear the breakpoints on a block and remove its entry from the panel,

- 1 Select the entry.
- 2 Click the **Remove selected point** button on the panel.

Note You cannot set a breakpoint on a virtual block. A virtual block is purely graphical: it indicates a grouping or relationship among a model's computational blocks. The debugger warns you if you try to set a breakpoint on a virtual block. You can get a listing

of a model's nonvirtual blocks, using the `slist` command (see “Displaying a Model's Nonvirtual Blocks” on page 31-35).

Setting Breakpoints from the Simulation Loop Pane

To set a breakpoint at a particular invocation of a method displayed in the Simulation Loop pane, select the check box next to the method's name in the breakpoint column of the pane.

To clear the breakpoint, deselect the check box.

Setting Breakpoints from the Command Window

In command-line mode, use the `break` and `bafter` commands to set breakpoints before or after a specified method, respectively. Use the `clear` command to clear breakpoints.

Setting Conditional Breakpoints

You can use either the **Break on conditions** controls group on the debugger **Breakpoints** pane

or the following commands (in command-line mode) to set conditional breakpoints.

This command...	Causes the Simulation to Stop...
<code>tbreak [t]</code>	At a simulation time step
<code>ebreak</code>	At a recoverable error in the model
<code>nanbreak</code>	At the occurrence of an underflow or overflow (NaN) or infinite (Inf) value
<code>xbreak</code>	When the simulation reaches the state that determines the simulation step size
<code>zcbreak</code>	When a zero crossing occurs between simulation time steps

Setting Breakpoints at Time Steps

To set a breakpoint at a time step, enter a time in the debugger **Break at time** field (GUI mode) or enter the time using the `tbreak` command. This causes the debugger to stop the simulation at the `Outputs.Major` method of the model at the first time step that follows the specified time. For example, starting `vdp` in debug mode and entering the commands

```
tbreak 2
continue
```

causes the debugger to halt the simulation at the `vdp.Outputs.Major` method of time step 2.078 as indicated by the output of the `continue` command.

```
%-----%
[Tm = 2.034340153847549      ] vdp.Outputs.Minor
(sldebug @37):
```

Breaking on Nonfinite Values

Selecting the debugger **NaN values** option or entering the **nanbreak** command causes the simulation to stop when a computed value is infinite or outside the range of values that is supported by the machine running the simulation. This option is useful for pinpointing computational errors in a model.

Breaking on Step-Size Limiting Steps

Selecting the **Step size limited by state** option or entering the **xbreak** command causes the debugger to stop the simulation when the model uses a variable-step solver and the solver encounters a state that limits the size of the steps that it can take. This command is useful in debugging models that appear to require an excessive number of simulation time steps to solve.

Breaking at Zero Crossings

Selecting the **Zero crossings** option or entering the **zcbreak** command causes the simulation to halt when a nonsampled zero crossing is detected in a model that includes blocks where zero crossings can arise. After halting, the ID, type, and name of the block in which the zero crossing was detected is displayed. The block ID (**s:b:p**) consists of a system index **s**, block index **b**, and port index **p** separated by colons (see “Block ID” on page 31-10).

For example, setting a zero-crossing break at the start of execution of the **zeroxing** example model,

```
>> sldebug zeroxing
%-----
%
[TM = 0 ] zeroxing.Simulate
(sldebug @0): >> zcbreak
Break at zero crossing events : enabled
```

and continuing the simulation

```
(sldebug @0): >> continue
```

results in a zero-crossing break at

```
Interrupting model execution before running mdlOutputs at the left post of
(major time step just before) zero crossing event detected at the following location:
 6[-0] 0:5:2 Saturate 'zeroxing/Saturation'
%-----%
```

```
[TzL= 0.3435011087932808      ] zeroxing.Outputs.Major  
(sldebug @16): >>
```

If a model does not include blocks capable of producing nonsampled zero crossings, the command prints a message advising you of this fact.

Breaking on Solver Errors

Selecting the debugger **Solver Errors** option or entering the `ebreak` command causes the simulation to stop if the solver detects a recoverable error in the model. If you do not set or disable this breakpoint, the solver recovers from the error and proceeds with the simulation without notifying you.

Display Information About the Simulation

In this section...

“Display Block I/O” on page 31-29

“Display Algebraic Loop Information” on page 31-31

“Display System States” on page 31-31

“Display Solver Information” on page 31-32

Display Block I/O

The debugger allows you to display block I/O by clicking the appropriate buttons on the debugger toolbar

or by entering the appropriate debugger command.

This command...	Displays a Blocks I/O...
probe	Immediately
disp	At every breakpoint any time execution stops
trace	Whenever the block executes

Note: The two debugger toolbar buttons, Watch Block I/O (🔴🟦) and Display Block I/O (🔴?) correspond, respectively, to `trace gcb` and `probe gcb`. The `probe` and `disp` commands do not have a one-to-one correspondence with the debugger toolbar buttons.

Displaying I/O of a Selected Block

To display the I/O of a block, select the block and click  in GUI mode or enter the `probe` command in command-line mode. In the following table, the `probe gcb` command has a corresponding toolbar button. The other commands do not.

Command	Description
<code>probe</code>	Enter or exit <code>probe</code> mode. Typing any command causes the debugger to exit <code>probe</code> mode.
<code>probe gcb</code>	Display I/O of selected block. Same as  .
<code>probe s:b</code>	Print the I/O of the block specified by system number <code>s</code> and block number <code>b</code> .

The debugger prints the current inputs, outputs, and states of the selected block in the debugger **Outputs** pane (GUI mode) or the Command Window of the MATLAB product.

The `probe` command is useful when you need to examine the I/O of a block whose I/O is not otherwise displayed. For example, suppose you are using the `step` command to run a model method by method. Each time you step the simulation, the debugger displays the inputs and outputs of the current block. The `probe` command lets you examine the I/O of other blocks as well.

Displaying Block I/O Automatically at Breakpoints

The `disp` command causes the debugger to display a specified block's inputs and outputs whenever it halts the simulation. You can specify a block by entering its block index and entering `gcb` as the `disp` command argument. You can remove any block from the debugger list of display points, using the `undisp` command. For example, to remove block `0:0`, enter `undisp 0:0`.

Note Automatic display of block I/O at breakpoints is not available in the debugger GUI mode.

The `disp` command is useful when you need to monitor the I/O of a specific block or set of blocks as you step through a simulation. Using the `disp` command, you can specify the blocks you want to monitor and the debugger will then redisplay the I/O of those blocks

on every step. Note that the debugger always displays the I/O of the current block when you step through a model block by block, using the `step` command. You do not need to use the `disp` command if you are interested in watching only the I/O of the current block.

Watching Block I/O

To watch a block, select the block and click  in the debugger toolbar or enter the `trace` command. In GUI mode, if a breakpoint exists on the block, you can set a watch on it as well by selecting the check box for the block in the watch column  of the **Break/Display points** pane. In command-line mode, you can also specify the block by specifying its block index in the `trace` command. You can remove a block from the debugger list of trace points using the `untrace` command.

The debugger displays a watched block's I/O whenever the block executes. Watching a block allows you obtain a complete record of the block's I/O without having to stop the simulation.

Display Algebraic Loop Information

The `atrace` command causes the debugger to display information about a model's algebraic loops (see “Algebraic Loops” on page 3-38) each time they are solved. The command takes a single argument that specifies the amount of information to display.

This command...	Displays for each algebraic loop...
<code>atrace 0</code>	No information
<code>atrace 1</code>	The loop variable solution, the number of iterations required to solve the loop, and the estimated solution error
<code>atrace 2</code>	Same as level 1
<code>atrace 3</code>	Level 2 plus the Jacobian matrix used to solve the loop
<code>atrace 4</code>	Level 3 plus intermediate solutions of the loop variable

Display System States

The `states` debug command lists the current values of the system states in the MATLAB Command Window. For example, the following sequence of commands shows the states of the bouncing ball example (`sldemo_bounce`) after its first, second, and

third time steps. However, before entering the debugger, open the Configuration Parameters dialog box, clear the **Block reduction** and **Signal storage reuse** check boxes on the **All Parameters** tab.

```

sldebug sldemo_bounce
%-----%
[TM = 0                               ] simulate(sldemo_bounce)
(sldebug @0): >> step top

Display Solver Information

The `strace` command allows you to pinpoint problems in solving a models differential equations that can slow down simulation performance. Executing this command causes the debugger to display solver-related information at the command line of the MATLAB product when you run or step through a simulation. The information includes the sizes of the steps taken by the solver, the estimated integration error resulting from the step size, whether a step size succeeded (i.e., met the accuracy requirements that the model specifies), the times at which solver resets occur, etc. If you are concerned about the time required to simulate your model, this information can help you to decide whether the

solver you have chosen is the culprit and hence whether choosing another solver might shorten the time required to solve the model.

Display Information About the Model

In this section...

“Display Model’s Sorted Lists” on page 31-34

“Display a Block” on page 31-35

Display Model’s Sorted Lists

In GUI mode, the debugger **Sorted List** pane displays lists of blocks for a model’s root system and each nonvirtual subsystem. Each list lists the blocks that the subsystems contains sorted according to their computational dependencies, alphabetical order, and other block sorting rules. In command-line mode, you can use the `slist` command to display a model’s sorted lists.

```

---- Sorted list for 'vdp' [9 nonvirtual blocks, directFeed=0]
 0:0   'vdp/x1' (Integrator)
 0:1   'vdp/Out1' (Output)
 0:2   'vdp/x2' (Integrator)
 0:3   'vdp/Out2' (Output)
 0:4   'vdp/Scope' (Scope)
 0:5   'vdp/Fcn' (Fcn)
 0:6   'vdp/Product' (Product)
 0:7   'vdp/Mu' (Gain)
 0:8   'vdp/Sum' (Sum)

```

These displays include the block index for each command. You can use them to determine the block IDs of the model’s blocks. Some debugger commands accept block IDs as arguments.

Identifying Blocks in Algebraic Loops

If a block belongs to an algebraic list, the `slist` command displays an algebraic loop identifier in the entry for the block in the sorted list. The identifier has the form

```
algId=s#n
```

where `s` is the index of the subsystem containing the algebraic loop and `n` is the index of the algebraic loop in the subsystem. For example, the following entry for an Integrator block indicates that it participates in the first algebraic loop at the root level of the model.

```
0:1 'test/ss/I1' (Integrator, tid=0) [algId=0#1, discontinuity]
```

You can use the debugger `ashow` command to highlight the blocks and lines that make up an algebraic loop. See “Displaying Algebraic Loops” on page 31-36 for more information.

Display a Block

To determine the block in a models diagram that corresponds to a particular index, enter `bshow s:b` at the command prompt, where `s:b` is the block index. The `bshow` command opens the system containing the block (if necessary) and selects the block in the systems window.

Displaying a Model's Nonvirtual Systems

The `systems` command displays a list of the nonvirtual systems in the model that you are debugging. For example, the `sldemo_clutch` model contains the following systems:

```
open_system('sldemo_clutch')
set_param(gcs, 'OptimizeBlockIOStorage','off')
sldebug sldemo_clutch
(sldebug @0): %-----%
[TM = 0 ] simulate(sldemo_clutch)
(sldebug @0): >> systems
0 'sldemo_clutch'
1 'sldemo_clutch/Locked'
2 'sldemo_clutch/Unlocked'
```

Note The `systems` command does not list subsystems that are purely graphical. That is, subsystems that the model diagram represents as Subsystem blocks but that are solved as part of a parent system. are not listed. In Simulink models, the root system and triggered or enabled subsystems are true systems. All other subsystems are virtual (that is, graphical) and do not appear in the listing from the `systems` command.

Displaying a Model's Nonvirtual Blocks

The `slist` command displays a list of the nonvirtual blocks in a model. The listing groups the blocks by system. For example, the following sequence of commands produces a list of the nonvirtual blocks in the Van der Pol (`vdp`) example model.

```
sldebug vdp
```

```

%-----%
[TM = 0                               ] simulate(vdp)
sldebug @0): >> slist

---- Sorted list for 'vdp' [9 nonvirtual blocks, directFeed=0]
 0:0   'vdp/x1' (Integrator)
 0:1   'vdp/Out1' (Outport)
 0:2   'vdp/x2' (Integrator)
 0:3   'vdp/Out2' (Outport)
 0:4   'vdp/Scope' (Scope)
 0:5   'vdp/Fcn' (Fcn)
 0:6   'vdp/Product' (Product)
 0:7   'vdp/Mu' (Gain)
 0:8   'vdp/Sum' (Sum)

```

Note The `slist` command does not list blocks that are purely graphical. That is, blocks that indicate relationships between or groupings among computational blocks.

Displaying Blocks with Potential Zero Crossings

The `zclist` command displays a list of blocks in which nonsampled zero crossings can occur during a simulation. For example, `zclist` displays the following list for the clutch sample model:

```

(sldebug @0): >> zclist
 0 0:4:0   F HitCross 'sldemo_clutch/Friction Mode Logic/Lockup
Detection/Velocities Match'
 1 0:4:1   F
 2 0:10:0  F Abs 'sldemo_clutch/Friction Mode Logic/Lockup
Detection/Required Friction for Lockup/Abs'
 3 0:12:0  F RelationalOperator 'sldemo_clutch/Friction Mode
Logic/Lockup Detection/Required Friction for Lockup/Relational Operator'
 4 0:19:0  F Abs 'sldemo_clutch/Friction Mode Logic/Break Apart
Detection/Abs'
 5 0:20:0  F RelationalOperator 'sldemo_clutch/Friction Mode
Logic/Break Apart Detection/Relational Operator'
 6 2:3:0   F Signum 'sldemo_clutch/Unlocked/slip direction'

```

Displaying Algebraic Loops

The `ashow` command highlights a specified algebraic loop or the algebraic loop that contains a specified block. To highlight a specified algebraic loop, enter `ashow s#n`, where `s` is the index of the system (see “Identifying Blocks in Algebraic Loops” on page 31-34) that contains the loop and `n` is the index of the loop in the system. To display the loop that contains the currently selected block, enter `ashow gcb`. To show a loop that

contains a specified block, enter `ashow s:b`, where `s:b` is the block's index. To clear algebraic-loop highlighting from the model diagram, enter `ashow clear`.

Displaying Debugger Status

In GUI mode, the debugger displays the settings of various debug options, such as conditional breakpoints, in its **Status** panel. In command-line mode, the `status` command displays debugger settings. For example, the following sequence of commands displays the initial debug settings for the `vdp` model:

```
sim('vdp', 'StopTime', '10', 'debug', 'on')
%-----%
[TM = 0                               ] simulate(vdp)
(sldebug @0): >> status
%-----%
Current simulation time                : 0.0 (MajorTimeStep)
Solver needs reset                     : no
Solver derivatives cache needs reset   : no
Zero crossing signals cache needs reset : no
Default command to execute on return/enter : ""
Break at zero crossing events          : disabled
Break on solver error                  : disabled
Break on failed integration step       : disabled
Time break point                       : disabled
Break on non-finite (NaN,Inf) values   : disabled
Break on solver reset request          : disabled
Display level for disp, trace, probe   : 1 (i/o, states)
Solver trace level                     : 0
Algebraic loop tracing level          : 0
Animation Mode                         : off
Execution Mode                         : Normal
Display level for etrace               : 0 (disabled)
Break points                           : none installed
Display points                         : none installed
Trace points                           : none installed
```

What Is Acceleration?

Acceleration is a mode of operation in the Simulink product that you can use to speed up the execution of your model. The Simulink software includes two modes of acceleration: accelerator mode and the rapid accelerator mode. Both modes replace the normal interpreted code with compiled target code. Using compiled code speeds up simulation of many models, especially those where run time is long compared to the time associated with compilation and checking to see if the target is up to date.
