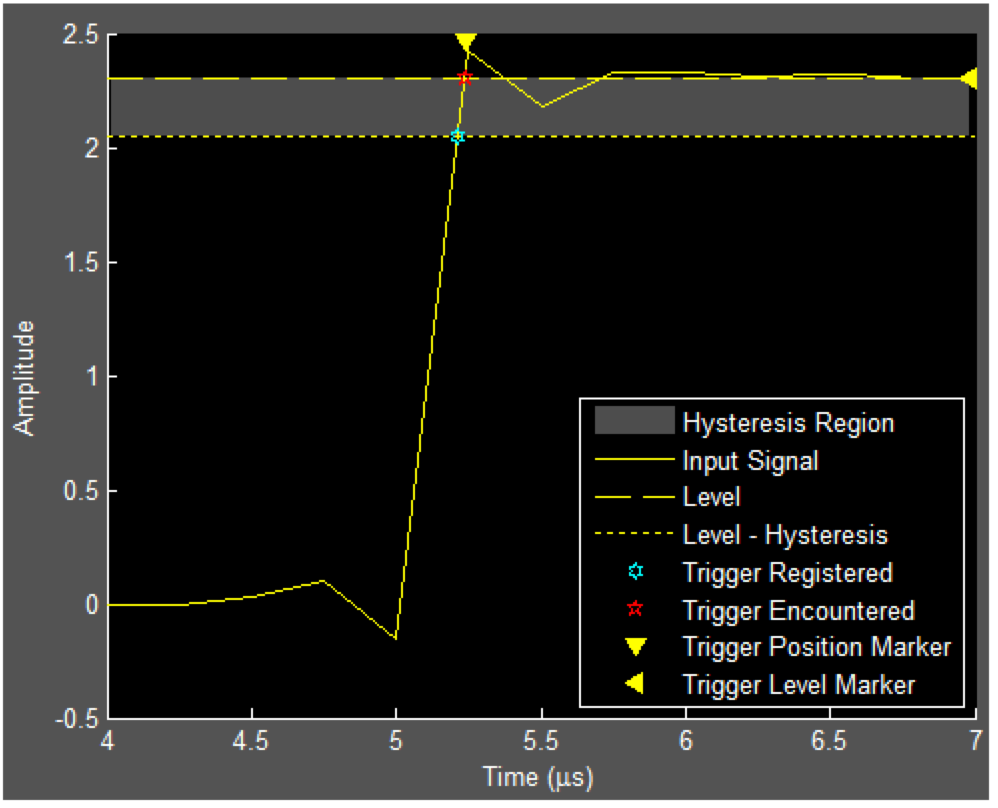
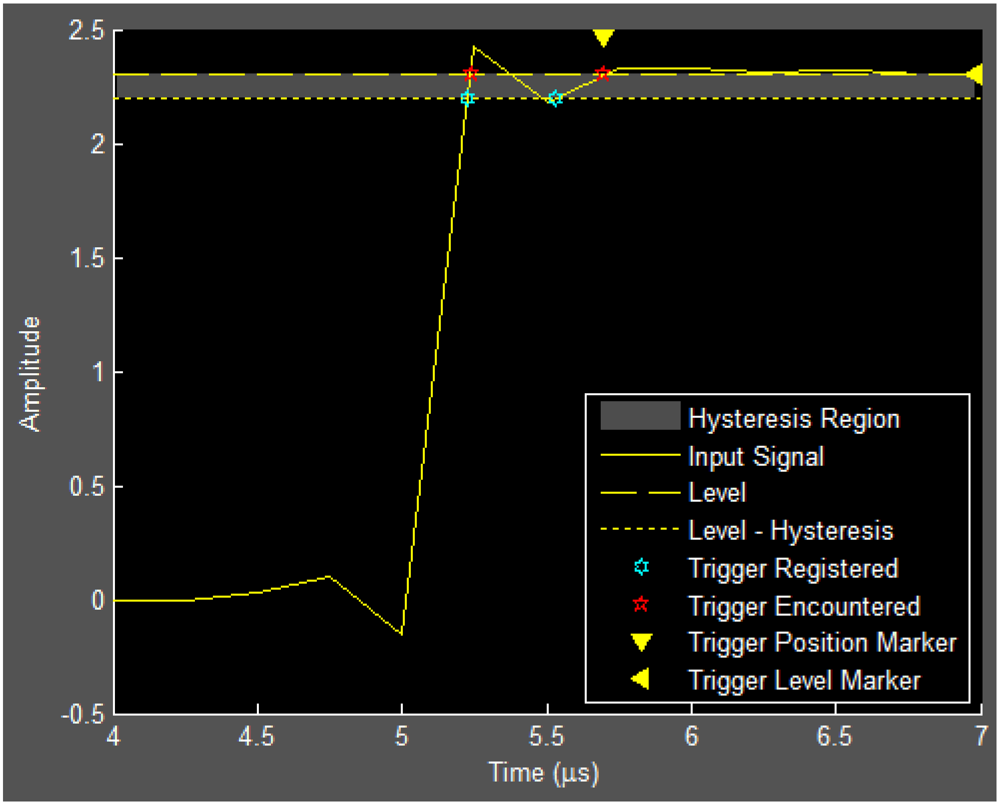
- **Auto level** — Enable the Triggers panel to choose automatically the level parameters. If you set the trigger type to **Edge**, this option sets the **Level** parameter to 50% of the range of the source signal. If you set the trigger **Type** to `Timeout`, the Triggers panel does not show this option. Setting the trigger **Type** to other menu choices results in **High** and **Low** parameter adjustment. **Auto level** sets the **High** parameter to 90% of the range of the source signal and the **Low** parameter to 10% of the range of the source signal.
- **Level (V)** — Specify, in volts, the trigger level. This parameter is visible when you set **Type** to `Edge` or `Timeout`.
- **Hysteresis (V)** — Specify the hysteresis or noise reject value in volts. This parameter is visible when you set **Type** to `Edge` or `Timeout`. If the signal jitters inside this range and briefly crosses the trigger level, the scope does not register an event. For an edge trigger with rising polarity, the scope ignores any times that the signal crosses the trigger level within the hysteresis region. You can reduce the hysteresis region by decreasing the hysteresis value. If the signal then hysteresis level a second time and rises to the trigger level, a second trigger event occurs. See the following figures.

Hysteresis Plots





- **High (V)** — Specify, in volts, the value that denotes a positive polarity, or high-state level. This parameter is visible when you set **Type** to `Pulse Width`, `Transition`, `Runt`, or `Window`.
- **Low (V)** — Specify, in volts, the value that denotes a negative polarity, or low-state level. This parameter is visible when you set **Type** to `Pulse Width`, `Transition`, `Runt`, or `Window`.
- **Min Width (s)** — Specify, in seconds, the minimum pulse width. This parameter is visible when you set **Type** to `Pulse Width` or `Runt`.
- **Max Width (s)** — Specify, in seconds, the maximum pulse width. This parameter is visible when you set **Type** to `Pulse Width` or `Runt`.
- **Min Time (s)** — Specify, in seconds, the minimum duration. This parameter is visible when you set **Type** to `Transition` or `Window`.

- **Max Time (s)** — Specify, in seconds, the maximum duration. This parameter is visible when you set **Type** to `Transition` or `Window`.
- **Timeout (s)** — Specify, in seconds, the timeout duration. This parameter is visible when you set **Type** to `Timeout`.

The **Delay / Holdoff** pane enables you to offset the trigger position by a fixed delay or set the minimum possible time between trigger events.

- **Delay (s)** — Specify, in seconds, the fixed delay time by which to offset the trigger position. This parameter controls the amount of time the scope waits after a trigger event occurs before displaying a signal.
- **Holdoff (s)** — Specify, in seconds, the minimum possible time between trigger events. This amount of time is used to suppress data acquisition after a valid trigger event is encountered. A trigger holdoff prevents repeated occurrences of a trigger from occurring during the portion of a burst that is of interest.

Cursor Measurements Panel

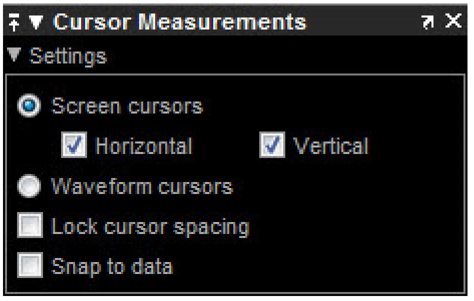
The **Cursor Measurements** panel displays screen cursors. The panel provides two types of cursors for measuring signals. Waveform cursors are vertical cursors that track along the signal. Screen cursors are both horizontal and vertical cursors that you can place anywhere in the display.

Note: If a data point in your signal has more than one value, the cursor measurement at that point is undefined and no cursor value is displayed.

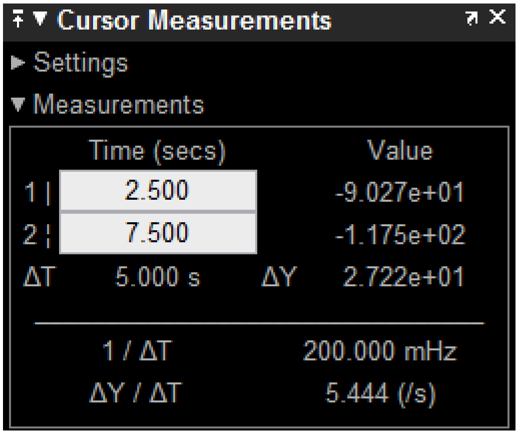
In the Scope menu, select **Tools** > **Measurements** > **Cursor Measurements**.

Alternatively, in the Scope toolbar, click the Cursor Measurements  button.

The **Settings** pane enables you to modify the type of screen cursors used for calculating measurements. When more than one signal is displayed, you can assign cursors to each trace individually.



- **Screen Cursors** — Shows screen cursors.
- **Horizontal** — Shows horizontal screen cursors.
- **Vertical** — Shows vertical screen cursors.
- **Waveform Cursors** — Shows cursors that attach to the input signals.
- **Lock Cursor Spacing** — Locks the frequency difference between the two cursors.
- **Snap to Data** — Positions the cursors on signal data points.



You can use the mouse or the left and right arrow keys to move vertical or waveform cursors and the up and down arrow keys for horizontal cursors.

The **Measurements** pane shows the time and value measurements.

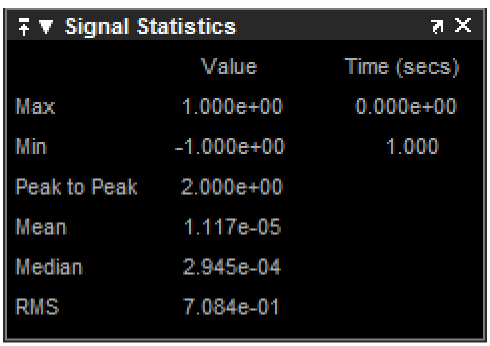
- **1 |** — Shows or enables you to modify the time or value at cursor number one, or both.

- **2 :**— Shows or enables you to modify the time or value at cursor number two, or both.
- **Δt**— Shows the absolute value of the difference in the times between cursor number one and cursor number two.
- **ΔV**— Shows the absolute value of the difference in signal amplitudes between cursor number one and cursor number two.
- **1/Δt**— Shows the rate, the reciprocal of the absolute value of the difference in the times between cursor number one and cursor number two.
- **ΔV/Δt**— Shows the scope, the ratio of the absolute value of the difference in signal amplitudes between cursors to the absolute value of the difference in the times between cursors.

Signal Statistics Panel

Note: The **Signal Statistics** panel requires a DSP System Toolbox or Simscape™ license.

The **Signal Statistics** panel displays the maximum, minimum, peak-to-peak difference, mean, median, and RMS values of a selected signal. It also shows the *x*-axis indices at which the maximum and minimum values occur. In the Scope menu, select **Tools** > **Measurements** > **Signal Statistics**. Alternatively, in the scope toolbar, click the Signal Statistics  button.



The statistics shown are:

- **Max** — The maximum or largest value within the displayed portion of the input signal. For more information on the algorithm this measurement uses, see the MATLAB `max` function reference.
- **Min** — The minimum or smallest value within the displayed portion of the input signal. For more information on the algorithm this measurement uses, see the MATLAB `min` function reference.
- **Peak to Peak** — The difference between the maximum and minimum values within the displayed portion of the input signal. For more information on the algorithm this measurement uses, see the Signal Processing Toolbox `peak2peak` function reference.
- **Mean** —The average or mean of all the values within the displayed portion of the input signal. For more information on the algorithm this measurement uses, see the MATLAB `mean` function reference.
- **Median** — The median value within the displayed portion of the input signal. For more information on the algorithm this measurement uses, see the MATLAB `median` function reference.
- **RMS** — Shows the difference between the maximum and minimum values within the displayed portion of the input signal. For more information on the algorithm this measurement uses, see the Signal Processing Toolbox `rms` function reference.

When you use the zoom options in the Scope, the Signal Statistics measurements automatically adjust to the time range shown in the display. For example, you can zoom in on one pulse to make the **Signal Statistics** panel display information about only that particular pulse.

The Signal Statistics measurements are valid for any units of the input signal. The letter after the value associated with each measurement represents the appropriate International System of Units (SI) prefix, such as *m* for *milli-*. For example, if the input signal is measured in volts, an *m* next to a measurement value indicates that this value is in units of millivolts.

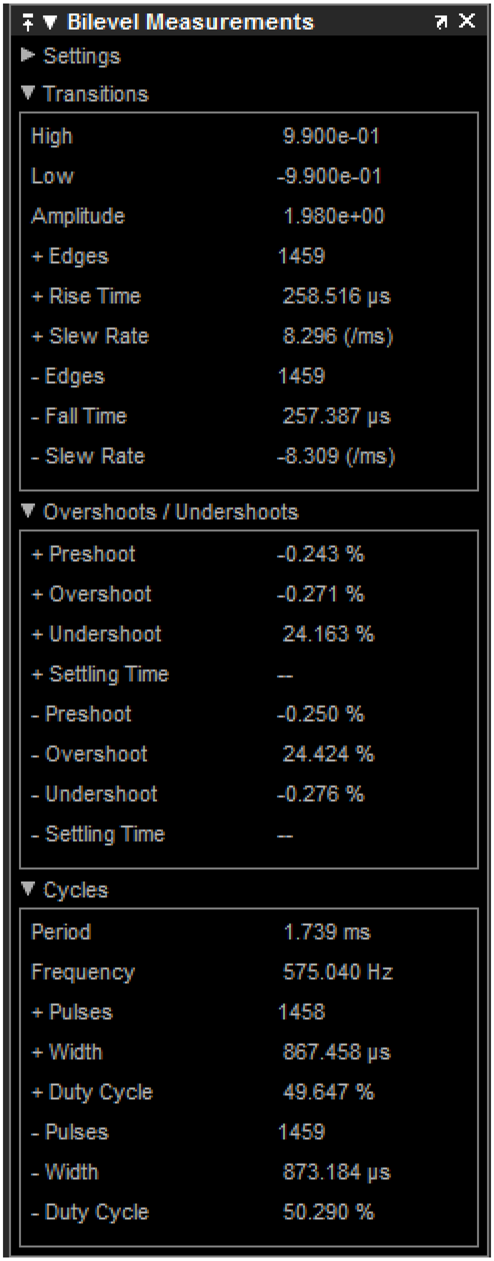
Bilevel Measurements Panel

Note: The **Bilevel Measurements** panel requires a DSP System Toolbox or Simscape license.

The **Bilevel Measurements** panel shows information about transitions, overshoots, undershoots, and cycles for a selected signal. You can choose to hide or display the

Bilevel Measurements panel. In the scope menu, select **Tools** > **Measurements** > **Bilevel Measurements**. Alternatively, in the scope toolbar, you can select the Bilevel Measurements  button.

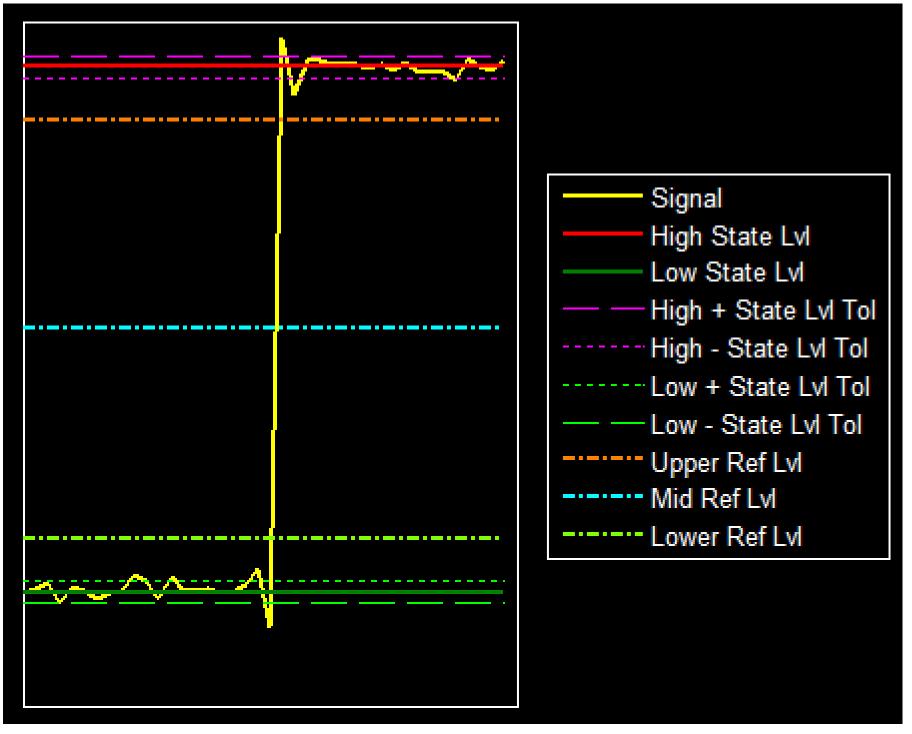
When you use the zoom options in the Scope, the bilevel measurements automatically adjust to the time range shown in the display. For example, you can zoom in on one rising edge to make the **Bilevel Measurements** panel display information about only that particular rising edge. This feature does not apply to the **High** and **Low** measurements.



Bilevel Measurements
Settings
Transitions
High 9.900e-01
Low -9.900e-01
Amplitude 1.980e+00
+ Edges 1459
+ Rise Time 258.516 μs
+ Slew Rate 8.296 (/ms)
- Edges 1459
- Fall Time 257.387 μs
- Slew Rate -8.309 (/ms)
Overshoots / Undershoots
+ Preshoot -0.243 %
+ Overshoot -0.271 %
+ Undershoot 24.163 %
+ Settling Time --
- Preshoot -0.250 %
- Overshoot 24.424 %
- Undershoot -0.276 %
- Settling Time --
Cycles
Period 1.739 ms
Frequency 575.040 Hz
+ Pulses 1458
+ Width 867.458 μs
+ Duty Cycle 49.647 %
- Pulses 1459
- Width 873.184 μs
- Duty Cycle 50.290 %

The **Bilevel Measurements** panel is separated into four panes, labeled **Settings**, **Transitions**, **Overshoots/Undershoots**, and **Cycles**. You can expand each pane to see the available options.

Bilevel Measurements Plot



Note: Opening the **Overshoots/Undershoots** pane may reduce the number of available edges by 1 if the last edge of the pulse is not within the **Settle Seek** time of the end of the plot. This reduction in the number of edges changes the values of **Edges**, **Fall Time**, and **Slew Rate** in the **Transitions** pane.

The **Settings** pane enables you to modify the properties used to calculate various measurements involving transitions, overshoots, undershoots, and cycles. You can modify the high-state level, low-state level, state-level tolerance, upper-reference level, mid-reference level, and lower-reference level, as shown in the following figure.

- **Auto State Level** — When this check box is selected, the Bilevel measurements panel autodetects the high- and low- state levels of a bilevel waveform. For more information on the algorithm this option uses, see the Signal Processing Toolbox `statelevels` function reference. When this check box is cleared, you can enter in values for the high- and low- state levels manually.
  - **High** — Manually specify the value for a positive polarity or high-state level.
  - **Low** — Manually specify the value for a negative polarity or low-state level.
- **State Level Tolerance** — Tolerance within which the initial and final levels of each transition must be within their respective state levels. This value is expressed as a percentage of the difference between the high- and low-state levels.
- **Upper Ref Level** — Used to compute the end of the rise-time measurement or the start of the fall time measurement. This value is expressed as a percentage of the difference between the high- and low-state levels.
- **Mid Ref Level** — Used to determine when a transition occurs. This value is expressed as a percentage of the difference between the high- and low- state levels. The mid-reference level is shown as a horizontal line, and its corresponding mid-reference level instant is shown as a vertical line.
- **Lower Ref Level** — Used to compute the end of the fall-time measurement or the start of the rise-time measurement. This value is expressed as a percentage of the difference between the high- and low-state levels.
- **Settle Seek** — The duration after the mid-reference level instant when each transition occurs used for computing a valid settling time. This value is equivalent to the input parameter, `D`, which you can set when you run the `settlingtime` function. The settling time is displayed in the **Overshoots/Undershoots** pane.

The **Transitions** pane displays calculated measurements associated with the input signal changing between its two possible state level values, high and low. The Transition measurements assume that the amplitude of the input signal is in units of volts. Convert all input signals to volts for the Transition measurements to be valid.

A positive-going transition, or *rising edge*, in a bilevel waveform is a transition from the low-state level to the high-state level. A positive-going transition has a slope value greater than zero. Whenever there is a plus sign (+) next to a text label, this symbol refers to measurement associated with a rising edge, a transition from a low-state level to a high-state level.

A negative-going transition, or falling edge, in a bilevel waveform is a transition from the high-state level to the low-state level. A negative-going transition has a slope value less than zero. Whenever there is a minus sign (–) next to a text label, this symbol refers to measurement associated with a falling edge, a transition from a high-state level to a low-state level.

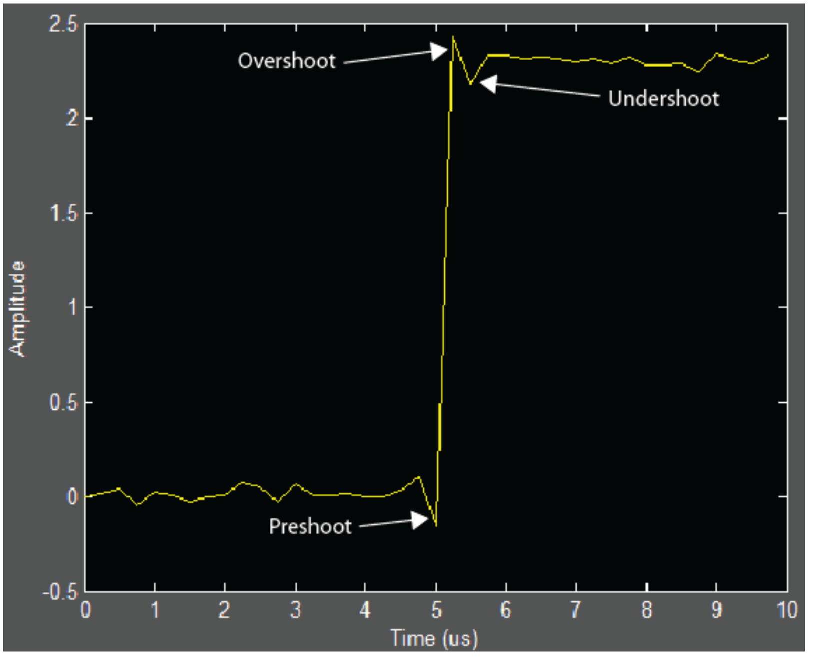
- **High** — The high-amplitude state level of the input signal over the duration of the **Time Span** parameter. You can set **Time Span** in the **Main** or**Time** tab of the Visuals—Time Domain Properties dialog box. For more information on the algorithm this measurement uses, see the Signal Processing Toolbox `statelevels` function reference.
- **Low** — The low-amplitude state level of the input signal over the duration of the **Time Span** parameter. You can set **Time Span** in the **Main** or **Time** tab of the Visuals—Time Domain Properties dialog box. The tab in which **Time Span** appears depends on whether you launched the scope from a from a MATLAB System object or from a Simulink block, respectively. For more information on the algorithm this measurement uses, see the Signal Processing Toolbox `statelevels` function reference.
- **Amplitude** — Difference in amplitude between the high-state level and the low-state level.
- **+ Edges** — Total number of positive-polarity, or rising, edges counted within the displayed portion of the input signal.
- **+ Rise Time** — Average amount of time required for each rising edge to cross from the lower-reference level to the upper-reference level. For more information on the algorithm this measurement uses, see the Signal Processing Toolbox `risetime` function reference.
- **+ Slew Rate** — Average slope of each rising-edge transition line within the upper- and lower-percent reference levels in the displayed portion of the input signal. The region in which the slew rate is calculated appears in gray.

  For more information on the algorithm this measurement uses, see the Signal Processing Toolbox `slewrate` function reference.
- **– Edges** — Total number of negative-polarity or falling edges counted within the displayed portion of the input signal.
- **– Fall Time** — Average amount of time required for each falling edge to cross from the upper-reference level to the lower-reference level. For more information on the algorithm this measurement uses, see the Signal Processing Toolbox `falltime` function reference.
- **– Slew Rate** — Average slope of each falling edge transition line within the upper- and lower-percent reference levels in the displayed portion of the input signal. For

more information on the algorithm this measurement uses, see the Signal Processing Toolbox `slewrate` function reference.

The **Overshoots/Undershoots** pane displays calculated measurements involving the distortion and damping of the input signal. *Overshoot* and *undershoot* refer to the amount that a signal, respectively, exceeds and falls below its final steady-state value. *Preshoot* refers to the amount before a transition that a signal varies from its initial steady-state value. This figure shows preshoot, overshoot, and undershoot for a rising-edge transition.

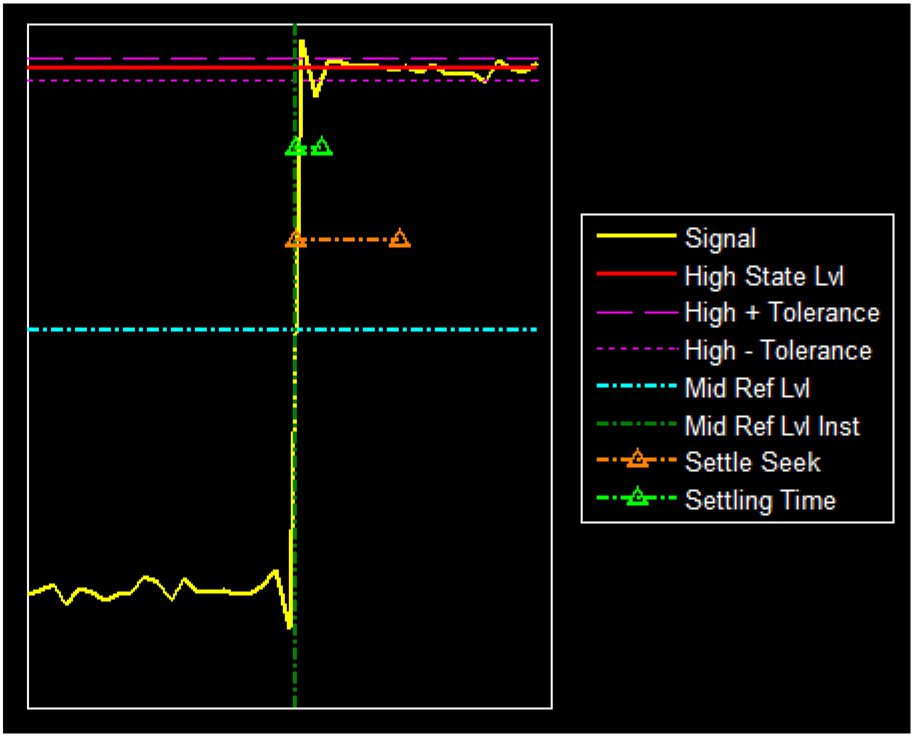
Overshoot/Undershoot Plot



- + *Preshoot* — Average lowest aberration in the region immediately preceding each rising transition.
- + *Overshoot* — Average highest aberration in the region immediately following each rising transition. For more information on the algorithm this measurement uses, see the Signal Processing Toolbox `overshoot` function reference.
- + *Undershoot* — Average lowest aberration in the region immediately following each rising transition. For more information on the algorithm this measurement uses, see the Signal Processing Toolbox `undershoot` function reference.

- + *Settling Time* — Average time required for each rising edge to enter and remain within the tolerance of the high-state level for the remainder of the settle seek duration. The settling time is the time after the mid-reference level instant when the signal crosses into and remains in the tolerance region around the high-state level. This crossing is illustrated in the following figure.

Settling Time Plot



You can modify the settle seek duration parameter in the **Settings** pane. For more information on the algorithm this measurement uses, see the Signal Processing Toolbox `settlingtime` function reference.

- – *Preshoot* — Average highest aberration in the region immediately preceding each falling transition.

- – *Overshoot* — Average highest aberration in the region immediately following each falling transition. For more information on the algorithm this measurement uses, see the Signal Processing Toolbox `overshoot` function reference.
- – *Undershoot* — Average lowest aberration in the region immediately following each falling transition. For more information on the algorithm this measurement uses, see the Signal Processing Toolbox `undershoot` function reference.
- – *Settling Time* — Average time required for each falling edge to enter and remain within the tolerance of the low-state level for the remainder of the settle seek duration. The settling time is the time after the mid-reference level instant when the signal crosses into and remains in the tolerance region around the low-state level. You can modify the settle seek duration parameter in the **Settings** pane. For more information on the algorithm this measurement uses, see the Signal Processing Toolbox `settlingtime` function reference.

The **Cycles** pane displays calculated measurements of to repetitions or trends in the displayed portion of the input signal.

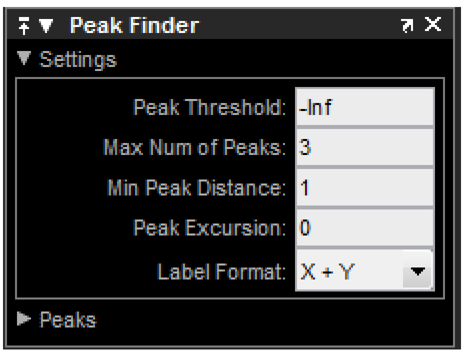
- **Period** — Average duration between adjacent edges of identical polarity within the displayed portion of the input signal. The Bilevel measurements panel calculates period as follows. It takes the difference between the mid-reference level instants of the initial transition of each positive-polarity pulse and the next positive-going transition. These mid-reference level instants appear as red dots.

  For more information on the algorithm this measurement uses, see the Signal Processing Toolbox `pulseperiod` function reference.
- **Frequency** — Reciprocal of the average period. Whereas period is typically measured in some metric form of seconds, or seconds per cycle, frequency is typically measured in hertz or cycles per second.
- **+ Pulses** — Number of positive-polarity pulses counted.
- **+ Width** — Average duration between rising and falling edges of each positive-polarity pulse within the displayed portion of the input signal. For more information on the algorithm this measurement uses, see the Signal Processing Toolbox `pulsewidth` function reference.
- **+ Duty Cycle** — Average ratio of pulse width to pulse period for each positive-polarity pulse within the displayed portion of the input signal. For more information on the algorithm this measurement uses, see the Signal Processing Toolbox `dutycycle` function reference.
- **– Pulses** — Number of negative-polarity pulses counted.

- – **Width** — Average duration between rising and falling edges of each negative-polarity pulse within the displayed portion of the input signal. For more information on the algorithm this measurement uses, see the Signal Processing Toolbox `pulsewidth` function reference.
- – **Duty Cycle** — Average ratio of pulse width to pulse period for each negative-polarity pulse within the displayed portion of the input signal. For more information on the algorithm this measurement uses, see the Signal Processing Toolbox `dutycycle` function reference.

Peak Finder Panel

The **Peak Finder** panel displays the maxima, showing the *x*-axis values at which they occur. Peaks are defined as a local maximum where lower values are present on both sides of a peak. Endpoints are not considered to be peaks. This panel allows you to modify the settings for peak threshold, maximum number of peaks, and peak excursion. You can choose to hide or display the **Peak Finder** panel. In the scope menu, select **Tools** > **Measurements** > **Peak Finder**. Alternatively, in the scope toolbar, select the Peak Finder  button.



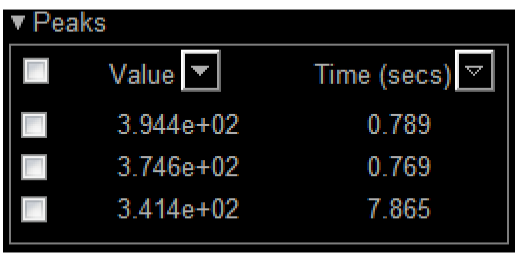
The **Peak finder** panel is separated into two panes, labeled **Settings** and **Peaks**. You can expand each pane to see the available options.

The **Settings** pane enables you to modify the parameters used to calculate the peak values within the displayed portion of the input signal. For more information on the algorithms this pane uses, see the Signal Processing Toolbox `findpeaks` function reference.

- **Peak Threshold** — The level above which peaks are detected. This setting is equivalent to the `MINPEAKHEIGHT` parameter, which you can set when you run the `findpeaks` function.
- **Max Num of Peaks** — The maximum number of peaks to show. The value you enter must be a scalar integer from 1 through 99. This setting is equivalent to the `NPEAKS` parameter, which you can set when you run the `findpeaks` function.
- **Min Peaks Distance** — The minimum number of samples between adjacent peaks. This setting is equivalent to the `MINPEAKDISTANCE` parameter, which you can set when you run the `findpeaks` function.
- **Peak Excursion** — The minimum height difference between a peak and its neighboring samples The peak excursion setting is equivalent to the `THRESHOLD` parameter, which you can set when you run the `findpeaks` function.
- **Label Format** — The coordinates to display next to the calculated peak values on the plot. To see peak values, expand the **Peaks** pane and select the check boxes associated with individual peaks of interest. By default, both *x*-axis and *y*-axis values are displayed on the plot. Select which axes values you want to display next to each peak symbol on the display.

  - `X+Y` — Display both *x*-axis and *y*-axis values.
  - `X` — Display only *x*-axis values.
  - `Y` — Display only *y*-axis values.

The **Peaks** pane displays all of the largest calculated peak values. It also shows the coordinates at which the peaks occur, using the parameters you define in the **Settings** pane. You set the **Max Num of Peaks** parameter to specify the number of peaks shown in the list.



The numerical values displayed in the **Value** column are equivalent to the `pks` output argument returned when you run the `findpeaks` function. The numerical values

displayed in the second column are similar to the `locs` output argument returned when you run the `findpeaks` function.

The Peak Finder displays the peak values in the **Peaks** pane. By default, the **Peak Finder** panel displays the largest calculated peak values in the **Peaks** pane in decreasing order of peak height. Use the sort descending button () to rearrange the category and order by which Peak Finder displays peak values. Click this button again to sort the peaks in ascending order instead. When you do so, the arrow changes direction to become the sort ascending button (). A filled sort button indicates that the peak values are currently sorted in the direction of the button arrow. If the sort button is not filled (), then the peak values are sorted in the opposite direction of the button arrow. The **Max Num of Peaks** parameter still controls the number of peaks listed.

Use the check boxes to control which peak values are shown on the display. By default, all check boxes are cleared and the **Peak Finder** panel hides all the peak values. To show all the peak values on the display, select the check box in the top-left corner of the **Peaks** pane. To hide all the peak values on the display, clear this check box. To show an individual peak, select the check box directly to the left of its **Value** listing. To hide an individual peak, clear the check box directly to the left of its **Value** listing.

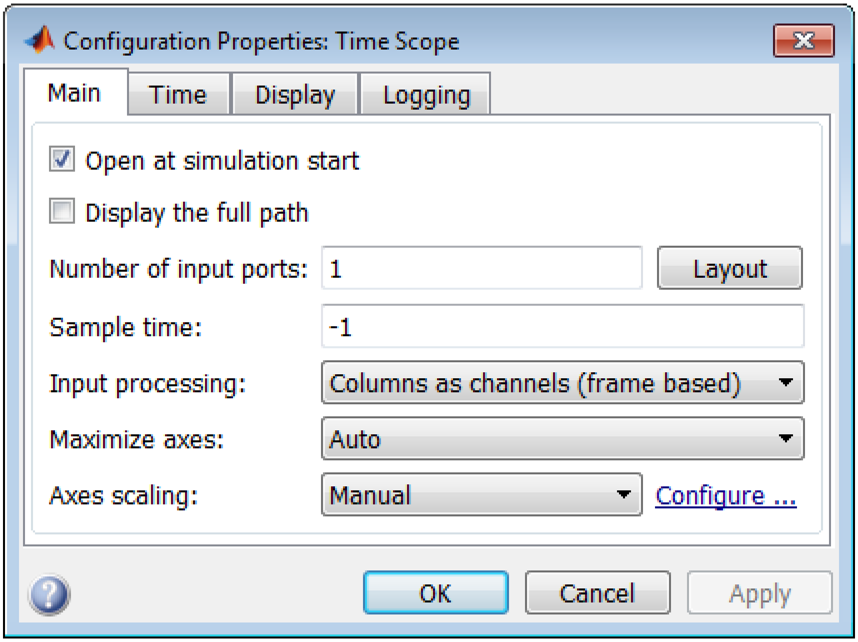
The Peaks are valid for any units of the input signal. The letter after the value associated with each measurement indicates the abbreviation for the appropriate International System of Units (SI) prefix, such as *m* for *milli-*. For example, if the input signal is measured in volts, an *m* next to a measurement value indicates that this value is in units of millivolts.

Configuration Properties Dialog Box

The Configuration Properties dialog box controls various properties about the Time Scope displays. From the Time Scope menu, select **View** > **Configuration Properties** to open this dialog box. Alternatively, in the Time Scope toolbar, click the Configuration Properties  button.

Main Pane

The **Main** pane of the Configuration Properties dialog box appears as follows.



Open at simulation start

Select this check box to ensure that the scope opens when the simulation starts. The following table summarizes the interaction between the **Open at simulation start** check box and the Scope figure.

Open at simulation start	Scope figure status when model saved	Scope figure opens
Checked	Closed	At simulation start
Checked	Open	At model loading
Not checked	Closed	Only if you double-click the Scope block icon in the model
Not checked	Open	At model loading

Display the full path

Select this check box to display in the title bar the path of this scope in this model.

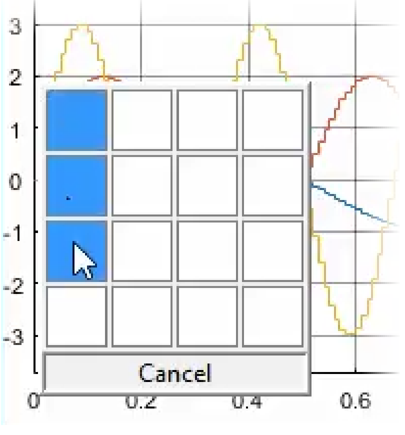
Number of input ports

Specify the number of input ports to show on the left side of the scope block. You can also specify the number of input ports using **File** > **Number of input ports**.

Layout

Specify number and arrangement of displays. The maximum layout is 16 rows by 16 columns.

To expand the layout grid beyond 4 by 4, click within the dialog box and drag. Maximum of 16 rows by 16 columns.



- If the number of displays are equal to the number of ports, signals from each port appear on separate displays.
- If the number of displays are less than the number of ports, signals from additional ports appear on the last display.
- For layouts with multiple columns and rows, ports are mapped down then across.

Sample time

Specify the sample time in seconds, as a scalar value. If you enter -1, the sample time is inherited. For information on sample time, see “What Is Sample Time?” (Simulink) and “Types of Sample Time” (Simulink).

Input processing

Specify whether the Time Scope treats the input signal as `Columns as channels (frame based)` or `Elements as channels (sample based)`.

Frame-based processing is only available for discrete input signals. For more information about frame-based input channels, see “What Is Frame-Based Processing?”. For an example that uses the Time Scope block and frame-based input signals, see “Display Time-Domain Data”.

Maximize axes

Specify whether to display the scope in maximized axes mode. In this mode, each of the axes is expanded to fit into the entire display. To conserve space, labels do not appear in each display. Instead, tick-mark values appear on top of the plotted data. You can select one of the following options:

- `Auto` — In this mode, the axes appear maximized in all displays only if the `Title` and `YLabel` properties are empty for every display. If you enter any value in any display for either of these properties, the axes are not maximized.
- `On` — In this mode, the axes appear maximized in all displays. Any values entered into the `Title` and `YLabel` properties are hidden.
- `Off` — In this mode, none of the axes appear maximized.

This property is Tunable (Simulink).

The default setting is `Auto`.

Axes scaling

Specify when the scope automatically scales the axes. You can select one of the following options:

- `Manual` — When you select this option, the scope does not automatically scale the axes. You can manually scale the axes in any of the following ways:
  - Select **Tools** > **Axes Scaling Properties**.
  - Press one of the **Scale Axis Limits** toolbar buttons.
  - When the scope figure is the active window, press **Ctrl** and **A** simultaneously.
- `Auto` — When you select this option, the scope scales the axes as needed, both during and after simulation. Selecting this option shows the **Do not allow Y-axis limits to shrink** check box.

- `After N Updates` — Selecting this option causes the scope to scale the axes after a specified number of updates. This option is useful and more efficient when your scope display starts with one axis scale, but quickly reaches a different steady state axis scale. Selecting this option shows the **Number of updates** edit box.

By default, this property is set to `Auto`. This property is Tunable (Simulink).

Axes scaling - Configure — (Available only on the **Configuration Properties Main** tab) Click the **Configure** link to the right of the **Axes scaling** property to see additional axes scaling properties. After you click this button, its label changes to **Hide**.

By default, this property is set to `Auto`. This property is Tunable (Simulink).

Number of updates

Specify as a positive integer the number of updates after which to scale the axes. This property appears only when you select `After N Updates` for the **Axes scaling** property. Tunable (Simulink).

Do not allow Y-axis limits to shrink

When you select this property, the *y*-axis is allowed only to grow during axes scaling operations. If you clear this check box, the *y*-axis or color limits may shrink during axes scaling operations.

This property appears only when you select `Auto` for the **Axis scaling** property. When you set the **Axes scaling** property to `Manual` or `After N Updates`, the *y*-axis or color limits are allowed to shrink. Tunable (Simulink).

Scale axes limits at stop

Select this check box to scale the axes when the simulation stops. The *y*-axis is always scaled. The *x*-axis limits are only scaled if you also select the **Scale X-axis limits** check box.

Y-axis Data range (%)

Set the percentage of the *y*-axis that the scope uses to display the data when scaling the axes. Valid values are from 1 through 100. For example, if you set this property to `100`, the Scope scales the *y*-axis limits such that your data uses the entire *y*-axis range. If you then set this property to `30`, the scope increases the *y*-axis range such that your data uses only 30% of the *y*-axis range. Tunable (Simulink).

Y-axis Align

Specify where the scope aligns your data along the *y*-axis when it scales the axes. You can select `Top`, `Center`, or `Bottom`. Tunable (Simulink).

Autoscale X-axis limits

Check this box to allow the scope to scale the *x*-axis limits when it scales the axes. If **Axes scaling** is set to `Auto`, checking **Autoscale X-axis limits** only scales the data currently within the axes, not the entire signal in the data buffer. If **Autoscale X-axis limits** is on and the resulting axis is greater than the span of the scope, trigger position markers will not be displayed. Triggers are controlled using the Trigger Measurements panel. Tunable (Simulink).

X-axis Data range (%)

Set the percentage of the *x*-axis that the scope uses to display the data when scaling the axes. Valid values are from 1 through 100. For example, if you set this property to `100`, the scope scales the *x*-axis limits such that your data uses the entire*x*-axis range. If you then set this property to `30`, the scope increases the *x*-axis range such that your data uses only 30% of the *x*-axis range. Use the *x*-axis **Align** property to specify data placement along the *x*-axis.

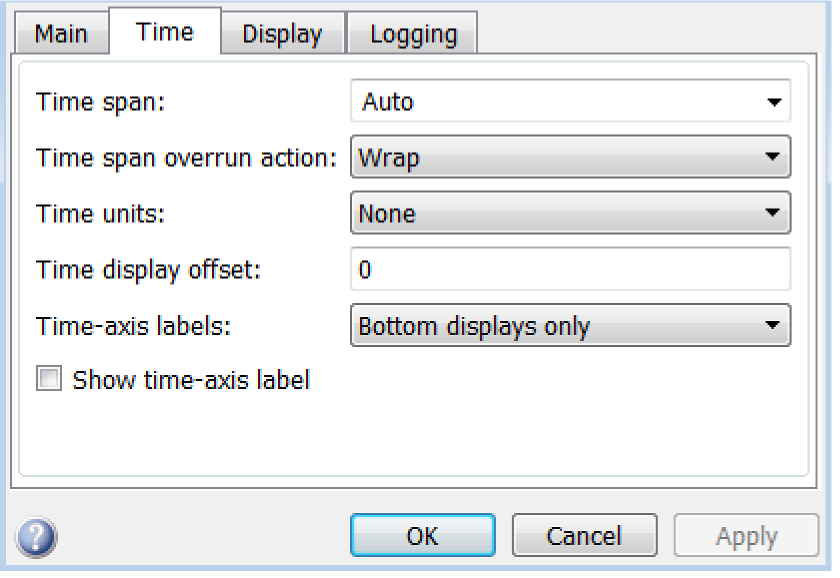
This property appears only when you select the **Scale X-axis limits** check box. Tunable (Simulink).

X-axis Align

Specify how the scope aligns your data along the *x*-axis: `Left`, `Center`, or `Right`. This property appears only when you select the **Scale X-axis limits** check box. Tunable (Simulink).

Time Pane

The **Time** pane of the Configuration Properties dialog box appears as follows.



Time span

Specify the time span, either by selecting a predefined option or by entering a numeric value in seconds. You can select one of the following options:

- `Auto` — Time Scope automatically calculates the minimum and maximum time-axis limits for time span.

  - Minimum time-axis limit = Simulation “Start time” (Simulink)
  - Maximum time-axis limit = Simulation “Stop time” (Simulink) + max(*FrameRate* * (*FrameSize*–1) / *FrameSize*)

  FrameSize is a vector equal to the number of rows in each input signal. *FrameRate* is the reciprocal of the sample time for each frame. The Time Scope System object calculates the minimum and maximum time-axis limits as follows:

  - Minimum time-axis limit = min(`TimeDisplayOffset`)
  - Maximum time-axis limit = max(`TimeDisplayOffset`) + max(1/`SampleRate`.**FrameSize*)

  where `TimeDisplayOffset` on page 4-1707 and `SampleRate` on page 4-1706 are the values of their respective properties. This property is Tunable (Simulink).

- `One frame period` — In this mode, the Time Scope uses the frame period of the input signal to the Time Scope block. This option is only available when the **Input processing** parameter is set to `Columns as channels (frame based)`. This option is not available when you set the **Input processing** parameter to `Elements as channels (sample based)`.
- `<user defined>` — In this mode, you specify the time span by replacing the text `<user defined>` with a numeric value in seconds.

The scope sets the time-axis limits using the value of this property and the value of the **Time display offset** property. Tunable (Simulink)

Time span overrun action

Specify how the scope displays new data beyond the visible time span. You can select one of the following options:

- `Wrap` — In this mode, the scope displays new data until the data reaches the maximum time-axis limit. When the data reaches the maximum time-axis limit of the scope window, the scope clears the display. The scope then updates the time offset value and begins displaying subsequent data points starting from the minimum time-axis limit.
- `Scroll` — In this mode, the scope scrolls old data to the left to make room for new data on the right side of the scope display. This mode is graphically intensive and can affect run-time performance. However, it is beneficial for debugging and monitoring time-varying signals.

This property is Tunable (Simulink).

The default setting is `Wrap`.

Time units

Specify the units used to describe the time axis. You can select one of the following options:

- `Metric` — In this mode, the scope converts the times on the time axis to the most appropriate measurement units. These units include milliseconds, microseconds, nanoseconds, minutes, days, etc. The scope chooses the appropriate measurement units based on the minimum time-axis limit and the maximum time-axis limit of the scope window.
- `Seconds` — In this mode, the scope always displays the units on the time axis as seconds.

- `None` — In this mode, the scope does not display any units on the time axis. The scope only shows the word `Time` on the time axis.

This property is Tunable (Simulink).

The default setting is `Metric`.

Time display offset

You use this property to offset the values displayed on the time axis by a specified number of seconds. When you specify a scalar value, the scope offsets all channels equally. When you specify a vector of offset values, the scope offsets each channel independently. Tunable (Simulink).

When you specify a **Time display offset** vector of length *N*, the scope offsets the input channels as follows:

- When *N* is equal to the number of input channels, the scope offsets each channel according to its corresponding value in the offset vector.
- When *N* is less than the number of input channels, the scope applies the values you specify in the offset vector to the first *N* input channels. The scope does not offset the remaining channels.
- When *N* is greater than the number of input channels, the scope offsets each input channel according to the corresponding value in the offset vector. The scope ignores all values in the offset vector that do not correspond to a channel of the input.

The scope computes the time-axis range using the values of the **Time display offset** and **Time span** properties. For example, if you set the **Time display offset** to `5e-6` and the **Time span** to `25e-6`, the scope sets the time-axis minimum to 5 seconds and the maximum to 30 seconds.

Similarly, when you specify a vector of values, the scope sets the minimum time-axis limit using the smallest value in the vector. To set the maximum time-axis limit, the scope sums the largest value in the vector with the value of the **Time span** property. For more information, see "Signal Display" on page 2-1650.

Time-axis labels

Specify how to display the time units used to describe the time axis. The default setting is `All`. You can select one of the following options:

- `All` — The time-axis labels appear in all displays.
- `None` — The time-axis labels do not appear in the displays.

- `Bottom Displays Only` — The time-axis labels appear in only the bottom row of the displays.

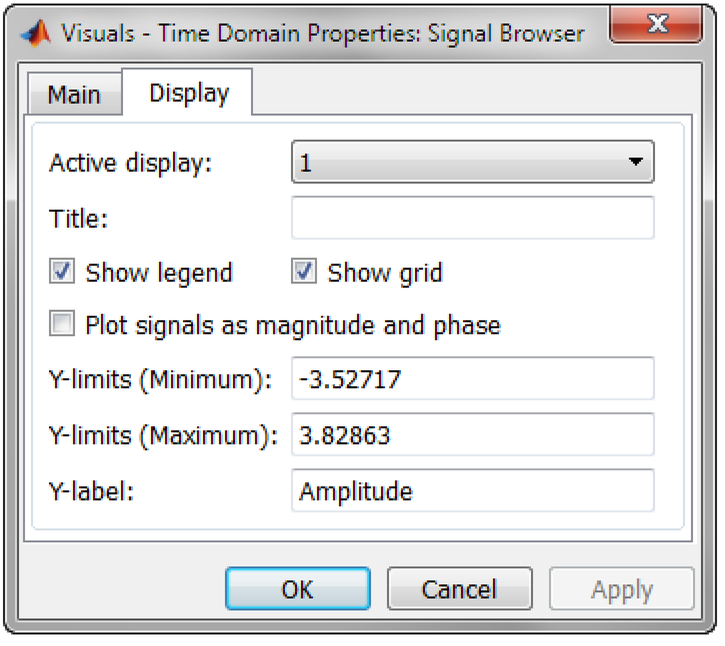
Tunable (Simulink).

Show time-axis label

Select this check box to show the time-axis label on the scope display. If this box is not checked, the scope does not display the time-axis label, but still displays tick marks and other time-axis items. This check box is not available if **Time-axis labels** is `None`.

Display Pane

The **Display** pane of the Configuration Properties dialog box appears as follows.



Active display

Specify the active display as an integer to get and set relevant properties. The number of a display corresponds to its column-wise placement index. Set this property to control which display has its axes colors, line properties, marker properties, and visibility changed. Tunable (Simulink)

When you use the Layout option to tile the window into multiple displays, the display highlighted in blue is referred to as the *active display*. The default setting is `1`.

Title

Specify the active display title as a character vector. Enter `%<SignalLabel>` to use the signal labels in the Simulink Model as the axes titles. By default, the active display has no title. Tunable (Simulink).

Show legend

Select this check box to show the legend in the display. The channel legend displays a name for each channel of each input signal. When the legend appears, you can place it anywhere inside of the scope window. To turn off the legend, clear the **Show legend** check box. This parameter applies only when the **View Type** is `Spectrum` or `Spectrum and spectrogram`.

You can edit the name of any channel in the legend. To do so, double-click the current name, and enter a new channel name. By default, the scope names each channel according to either its signal name or the name of the block from which it comes. If the signal has multiple channels, the scope uses an index number to identify each channel of that signal.

Time Scope does not display signal names that were labeled within an unmasked subsystem. You must label all input signals to the scope block that originate from an unmasked subsystem.

The legend lets you modify what signals are shown. To show only one signal, click the signal name. To toggle a signal on/off, right-click the signal name.

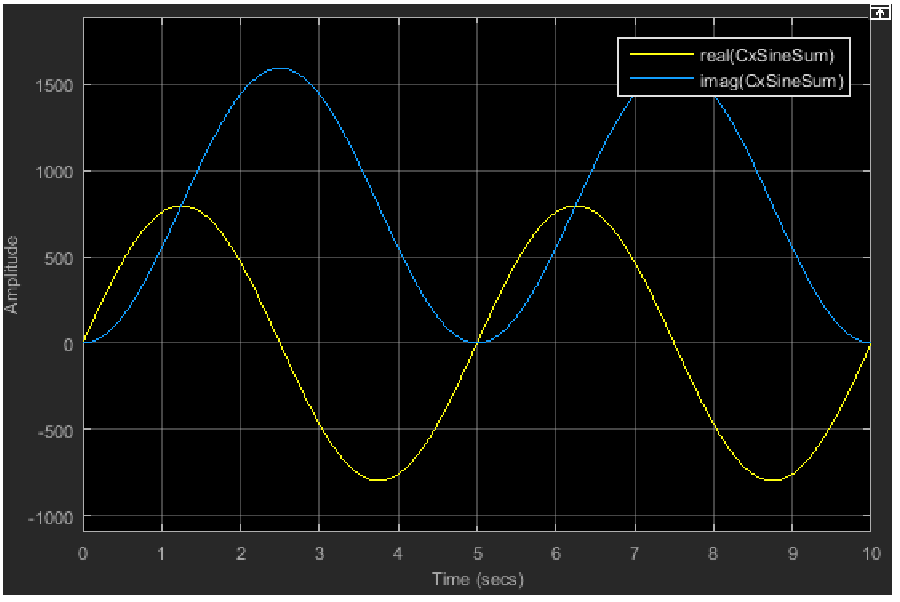
To change the appearance of any channel of any input signal in the scope window, from the menu, select **View > Style**.

Show grid

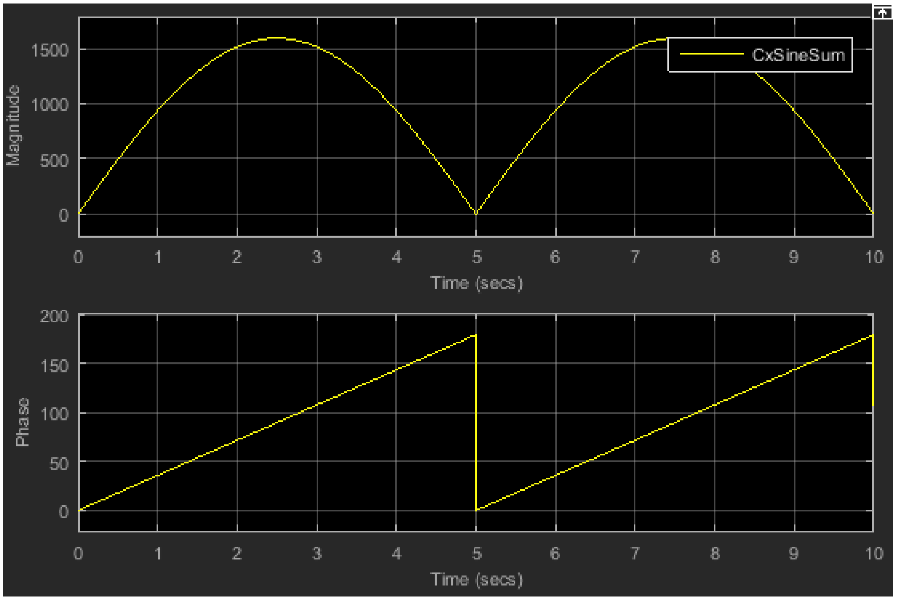
When you select this check box, a grid appears in the display of the scope figure. To hide the grid, clear this check box. Tunable (Simulink)

Plot signals as magnitude and phase

When you select this check box, the scope splits the display into a magnitude plot and a phase plot. By default, this check box is cleared. If the input signal has complex values, the scope plots the real and imaginary portions on the same axes. These real and imaginary portions appear as different-colored lines on the same axes, as shown in the following figure.



Selecting this check box and clicking the **Apply** or **OK** button changes the display. The magnitude of the input signal appears on the top axes and its phase, in degrees, appears on the bottom axes. See the following figure.



This feature is useful for complex-valued input signals. If the input is a real-valued signal, selecting this check box returns the absolute value of the signal for the magnitude. The phase is 0 degrees for nonnegative input and 180 degrees for negative input. Tunable (Simulink)

Y-limits (Minimum)

Specify the minimum value of the *y*-axis. Tunable (Simulink)

When you select the **Plot signal(s) as magnitude and phase** check box, the value of this property always applies to the magnitude plot on the top axes. The phase plot on the bottom axes is always limited to a minimum value of -180 degrees.

Y-limits (Maximum)

Specify the maximum value of the *y*-axis. Tunable (Simulink)

When you select the **Plot signal(s) as magnitude and phase** check box, the value of this property always applies to the magnitude plot on the top axes. The phase plot on the bottom axes is always limited to a maximum value of 180 degrees.

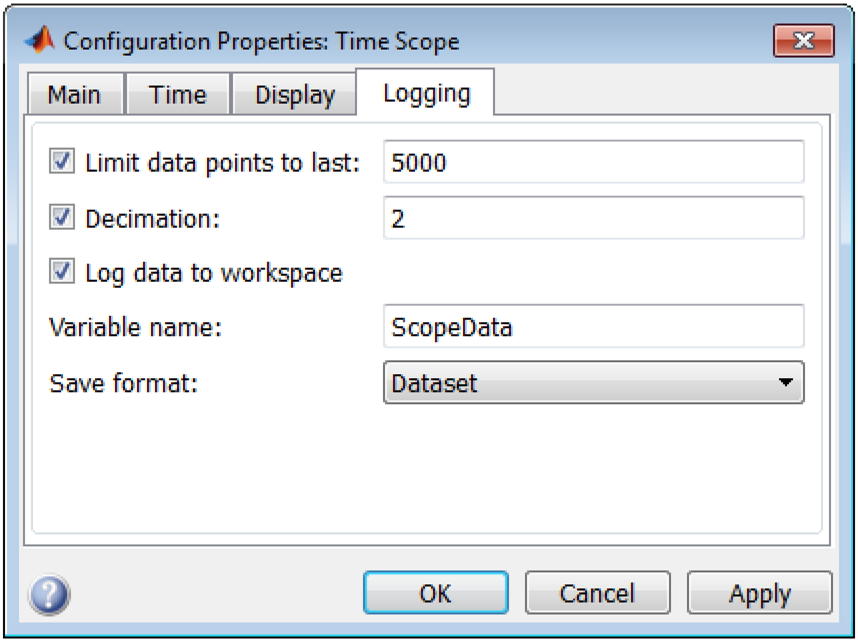
Y-label

Specify the text for the scope to display to the left of the *y*-axis. Tunable (Simulink)

This property becomes invisible when you select the **Plot signal(s) as magnitude and phase** check box. When you enable that property, the *y*-axis label always appears as `Magnitude` on the top axes and `Phase` on the bottom axes.

Logging Pane

The **Logging** pane of the Configuration Properties dialog box appears as follows.



Limit data points to last

Specify the number of data points a scope collects. The scope relies on its data history for zooming and auto-scaling operations. If the number of data points is limited to 1,000 and the simulation generates 2,000 data points, only the last 1,000 are available for regenerating the display.

Note: If you do not select the **Limit data points to last** check box, the memory consumed by MATLAB steadily increases as the simulation stores the entire simulation history. An out of memory error can occur. Memory is limited by available memory on your system.

For simulations with the **Stop time** set to `inf`, always select the **Limit data points to last** check box and enter a value.

The default setting is unchecked, so that all data is saved. When checked, the default is the last `5000` data points.

Decimation

When you select this check box, the scope logs every N^{th} data point, where N is the decimation factor you specify.

The default setting is unchecked, so that logged data is not decimated. When checked, the default decimation rate is `2`.

Log data to workspace

When you select this check box, the scope logs data in the format you select in **Save format**.

The default setting is unchecked and no data is logged.

Variable name

Specify as a character vector the name of the variable in the MATLAB workspace to which the scope logs data. Any existing variable is overwritten.

Save format

Select the format in which to save logged data. Unless otherwise noted, you can save logged data for single- and multi-port data, sample-based and frame-based data, variable-size data, MAT-file logging, and external mode archiving.

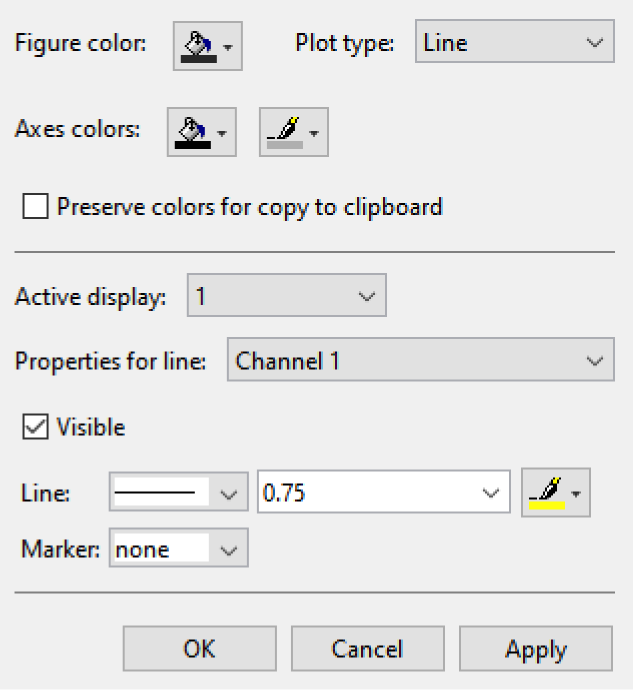
Note: If a Scope is in a disabled subsystem, you may see discontinuities in the Scope display. Data logged to the workspace does not include any of these discontinuity values.

Valid values for **Save format** are:

- `Structure With Time` — Save logged data as a structure with associated time information to the MATLAB workspace. Structure With Time format does not support multirate data.
- `Structure` — Save logged data as a structure to the MATLAB workspace. Structure format does not support multirate data.
- `Array` — Save logged data as an array with associated time information to the MATLAB workspace. Array format does not support multiport sample-based data, single port or multiport frame-based data, variable-size data, or multirate data.
- `Dataset` — Save logged data as a dataset object to the MATLAB workspace. Dataset format does not support variable-size data, MAT-file logging, or external mode archiving. See Simulink.SimulationData.Dataset for information.

Style Dialog Box

Select **View** > **Style** or the Style button () in the dropdown below the Configuration Properties button to open the Style dialog box. In this dialog box, you can change the figure colors, background axes colors, foreground axes colors, and properties of lines in a display.



Properties

The **Style** dialog box allows you to modify the following properties of the scope figure:

Figure color

Specify the color that you want to apply to the background of the scope figure. By default, the figure color is gray.

Plot type

Specify the type of plot to use. The default setting is `Line`. Valid values for **Plot type** are:

- `Line` — line graph, similar to the `line` or `plot` function.
- `Stairs` — *stair-step* graph, similar to the `stairs` function. Stair-step graphs are useful for drawing time history graphs of digitally sampled data.

- `Stem` — stem graph, similar to the `stem` function.
- `Auto` — displays input signal as a line graph for a continuous signal, stair step graph for a discrete signal, and stem for Simulink message signal.

This property is Tunable (Simulink).

Active display

Specify the active display as an integer to get and set relevant properties. The number of a display corresponds to its column-wise placement index. Set this property to control which display has its axes colors, line properties, marker properties, and visibility changed. Tunable (Simulink)

When you use the Layout option to tile the window into multiple displays, the display highlighted in blue is referred to as the *active display*. The default setting is `1`.

Axes colors

Specify the color that you want to apply to the background of the axes for the active display.

Preserve colors for copy to clipboard

Specify whether or not to use the displayed color of the scope when copying.

When you select **File** > **Copy to Clipboard**, the software changes the color of the scope to be printer friendly (white background, visible lines). If you want to copy and paste the scope with the colors displayed, select this check box.

Default: Off

Properties for line

Specify the signal for which you want to modify the visibility, line properties, and marker properties.

Visible

Specify whether the selected signal on the active display is visible. If you clear this check box, the line disappears.

Line

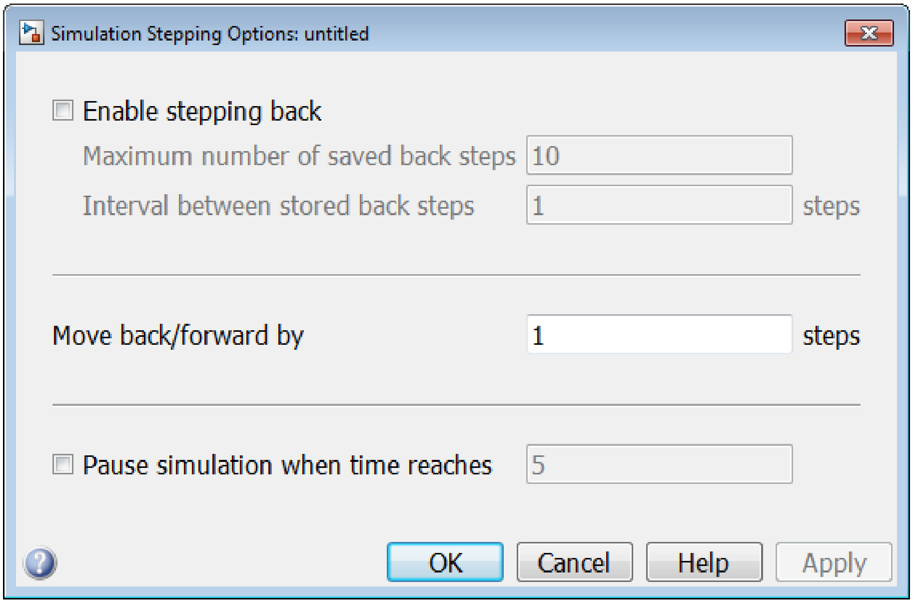
Specify the line style, line width, and line color for the selected signal on the active display.

Marker

Specify marks for the selected signal on the active display to show at data points. This property is similar to the `Marker` property for plot objects. Choose any of the marker symbols from the dropdown list.

Stepping Options

Select **Simulation** > **Stepping Options** to open the Simulation Stepping Options dialog box. If stepping back is disabled, in the Time Scope toolbar, click the step back  button. This dialog box lets you pause the simulation at a specified time, enable stepping back, and specify options for stepping back. You can also modify the number of steps by which to step forward or backward.



The Simulation Stepping Options dialog box is not unique to Time Scope; it can also be launched from any Simulink model. To open this dialog box from any Simulink model, select **Simulation** > **Stepping Options**. For more information, see "Simulation Stepping Options" (Simulink).

Enable stepping back

Select this check box to enable the scope to take steps back in time. When selected, the scope enables the step back button ( ) on the simulation toolbar.

Maximum number of saved back steps

Specify the maximum number of back steps that the scope saves in memory. To maximize simulation speed, keep the value for this property small. The default setting is 10.

Interval between stored back steps

Specify the number of steps between back steps that the scope saves in memory for stepping backward. Set this property to a larger number to increase the time span of a back step without increasing the amount of memory used. The default setting is 1.

Move back/forward by

Specify the number of steps forward or backward that the Scope progresses when you click the step forward ( ) and step back ( ) buttons. The default setting is 1.

Pause simulation when time reaches

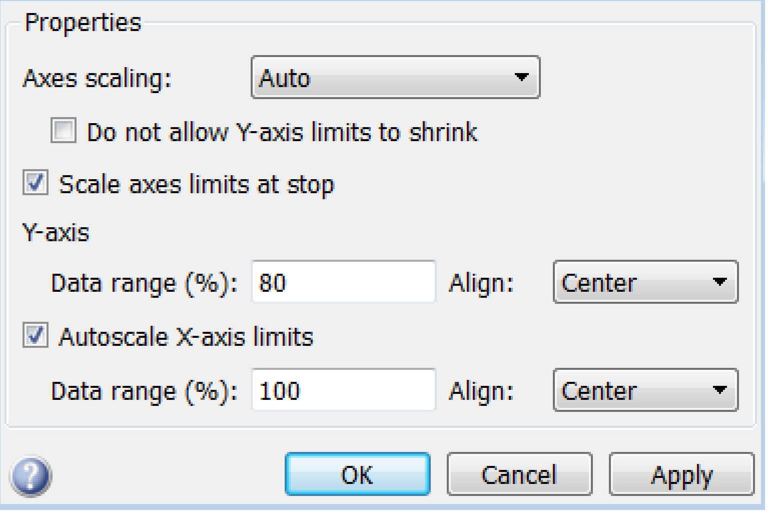
Select this check box to enable the Scope to pause the simulation when it reaches a specified time and then, specify the time at which you want the scope to pause.

Tools—Axes Scaling Properties

Select **Tools** > **Axes Scaling Properties** to open the Axes Scaling Properties dialog box. This dialog box provides you with the ability to zoom automatically in on and out of your data, and to scale the axes of the scope.

Properties

The Tools—Axes Scaling Properties dialog box appears as follows.



Axes scaling

Specify when the scope automatically scales the axes. You can select one of the following options:

- `Manual` — When you select this option, the scope does not automatically scale the axes. You can manually scale the axes in any of the following ways:
  - Select **Tools** > **Axes Scaling Properties**.
  - Press one of the **Scale Axis Limits** toolbar buttons.
  - When the scope figure is the active window, press **Ctrl** and **A** simultaneously.
- `Auto` — When you select this option, the scope scales the axes as needed, both during and after simulation. Selecting this option shows the **Do not allow Y-axis limits to shrink** check box.
- `After N Updates` — Selecting this option causes the scope to scale the axes after a specified number of updates. This option is useful and more efficient when your scope display starts with one axis scale, but quickly reaches a different steady state axis scale. Selecting this option shows the **Number of updates** edit box.

By default, this property is set to `Auto`. This property is Tunable (Simulink).

Do not allow Y-axis limits to shrink

When you select this property, the *y*-axis is allowed only to grow during axes scaling operations. If you clear this check box, the *y*-axis or color limits may shrink during axes scaling operations.

This property appears only when you select `Auto` for the **Axis scaling** property. When you set the **Axes scaling** property to `Manual` or `After N Updates`, the *y*-axis or color limits are allowed to shrink. Tunable (Simulink).

Number of updates

Specify as a positive integer the number of updates after which to scale the axes. This property appears only when you select `After N Updates` for the **Axes scaling** property. Tunable (Simulink).

Scale axes limits at stop

Select this check box to scale the axes when the simulation stops. The *y*-axis is always scaled. The *x*-axis limits are only scaled if you also select the **Scale X-axis limits** check box.

Y-axis Data range (%)

Set the percentage of the *y*-axis that the scope uses to display the data when scaling the axes. Valid values are from 1 through 100. For example, if you set this property to `100`, the Scope scales the *y*-axis limits such that your data uses the entire *y*-axis range. If you then set this property to `30`, the scope increases the *y*-axis range such that your data uses only 30% of the *y*-axis range. Tunable (Simulink).

Y-axis Align

Specify where the scope aligns your data along the *y*-axis when it scales the axes. You can select `Top`, `Center`, or `Bottom`. Tunable (Simulink).

Autoscale X-axis limits

Check this box to allow the scope to scale the *x*-axis limits when it scales the axes. If **Axes scaling** is set to `Auto`, checking **Autoscale X-axis limits** only scales the data currently within the axes, not the entire signal in the data buffer. If **Autoscale X-axis limits** is on and the resulting axis is greater than the span of the scope, trigger position markers will not be displayed. Triggers are controlled using the Trigger Measurements panel. Tunable (Simulink).

X-axis Data range (%)

Set the percentage of the *x*-axis that the scope uses to display the data when scaling the axes. Valid values are from 1 through 100. For example, if you set this property to `100`, the scope scales the *x*-axis limits such that your data uses the entire*x*-axis range. If you then set this property to `30`, the scope increases the *x*-axis range such that your data uses only 30% of the *x*-axis range. Use the *x*-axis **Align** property to specify data placement along the *x*-axis.

This property appears only when you select the **Scale X-axis limits** check box. Tunable (Simulink).

X-axis Align

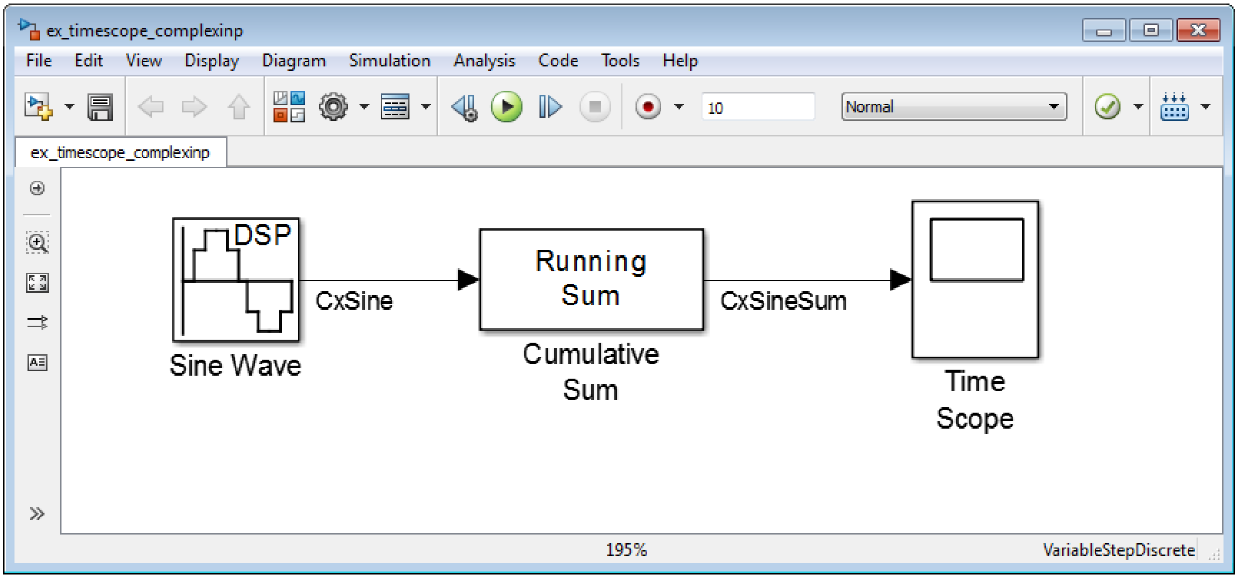
Specify how the scope aligns your data along the *x*-axis: `Left`, `Center`, or `Right`. This property appears only when you select the **Scale X-axis limits** check box. Tunable (Simulink).

Examples

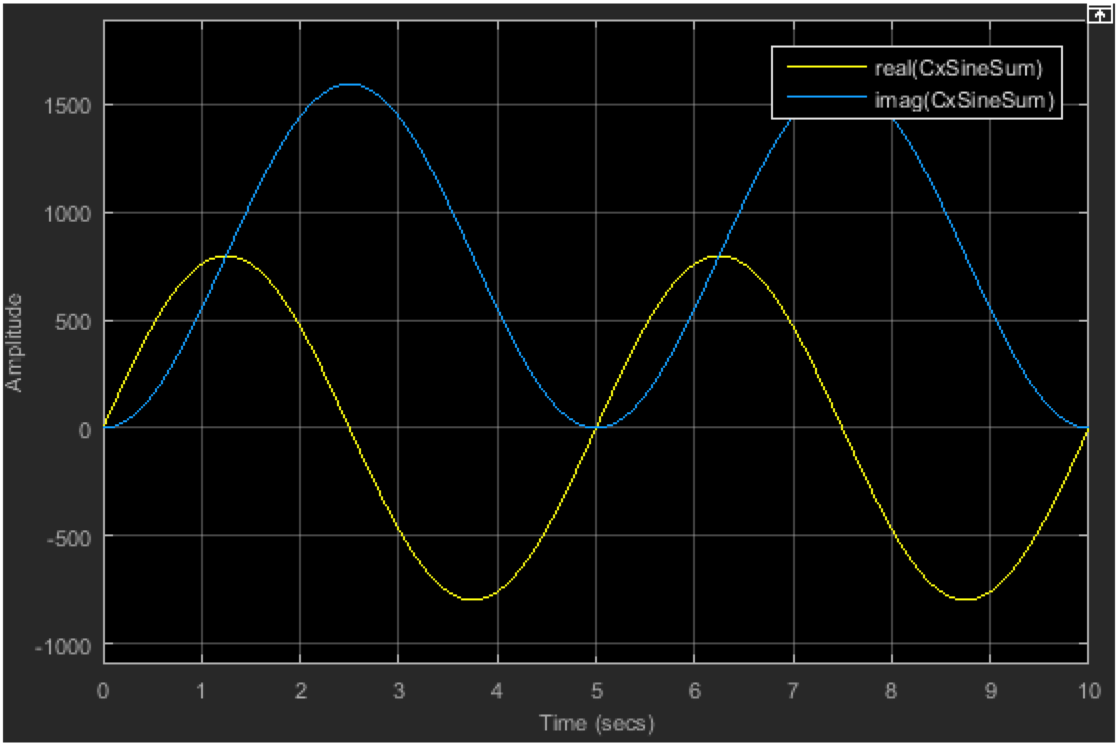
The first three examples illustrate how to use the Time Scope block to view various input signals in the time domain. The remaining examples demonstrate how to use the **Measurements Panels** in the Time Scope figure to glean information about the input signals.

Display Complex-Valued Input Signal

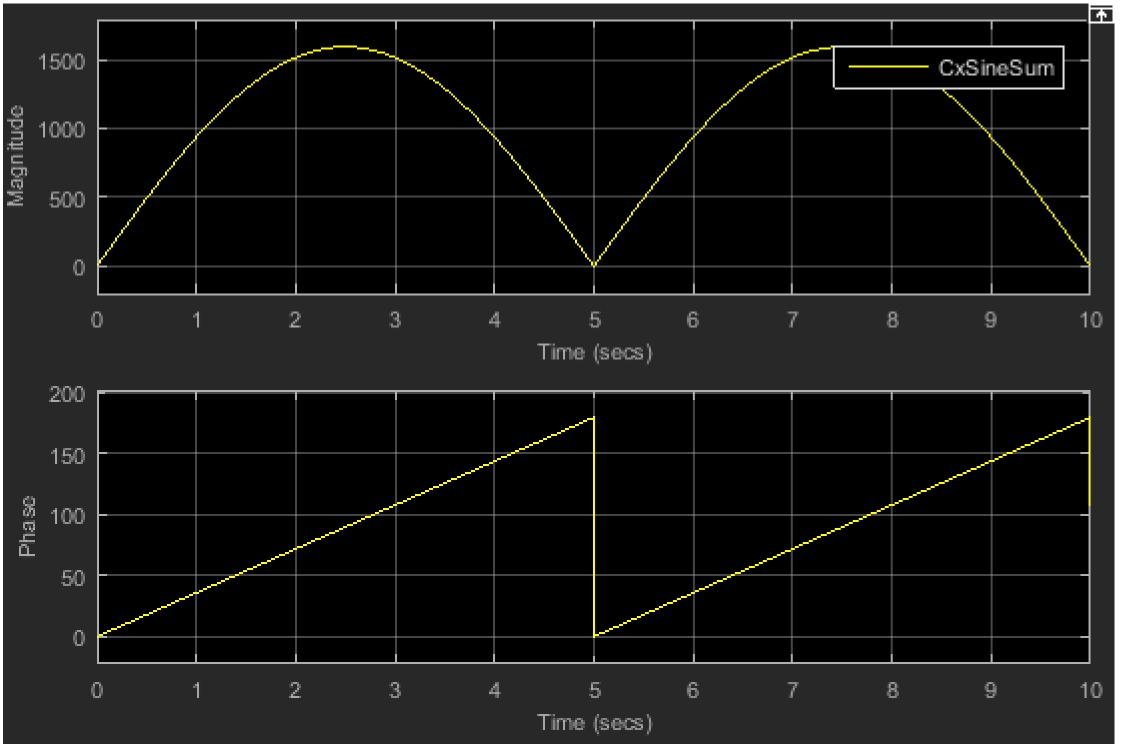
At the MATLAB® command prompt, type ex_timescope_complexinp to open the example model. The following Simulink® model appears.



By default, when the input is a complex-valued signal, Time Scope plots the real and imaginary portions on the same axes. These real and imaginary portions appear as different-colored lines on the same axes within the same active display. Run your model to see the time domain output, as shown in the following figure.

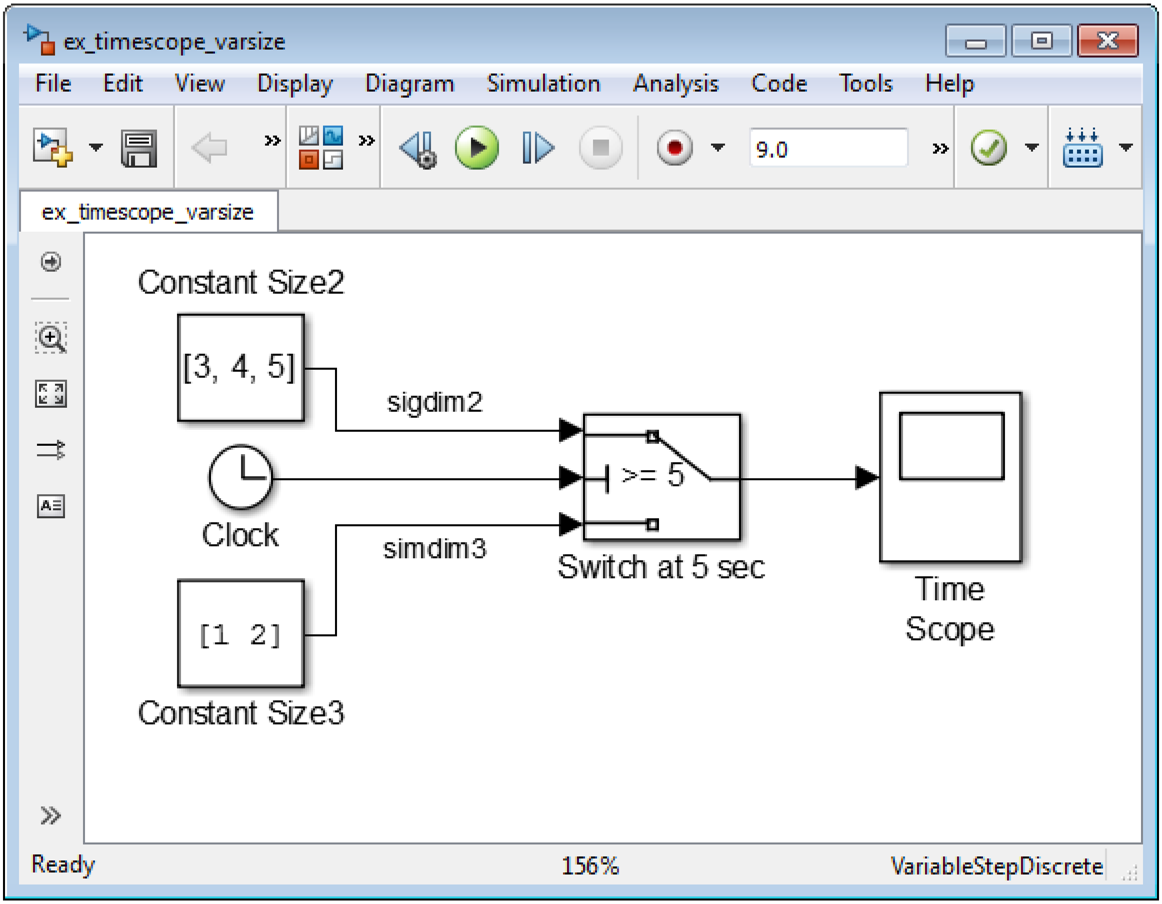


The Configuration Properties dialog box controls the visual configuration settings of the Scope displays. From the Scope menu, select **View** > **Configuration Properties** to open this dialog box. Go to the Display tab. Selecting the **Plot signal(s) as magnitude and phase** check box specifies the Scope to plot the magnitude and phase of the input signal. The magnitude and phase appear on two separate axes within the same active display. After you select this check box, click **OK**. The active display shows the magnitude of the input signal on the top axes. The signal phase, in degrees, appears on the bottom axes.

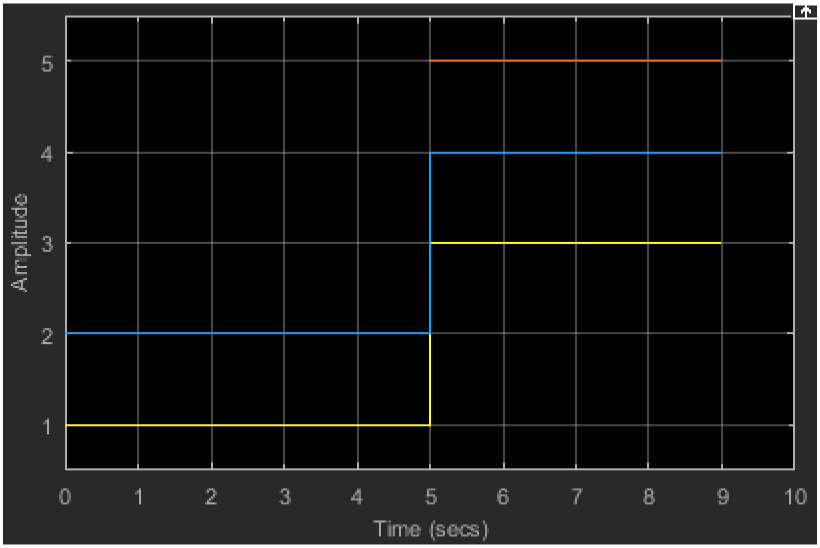


Display Input Signal of Changing Size

At the MATLAB® command prompt, type ex_timescope_varsize to open the example model. The following Simulink® model appears.



In this example, the size of the input signal to the Time Scope block changes as the simulation progresses. When the simulation time is less than 5 seconds, Time Scope plots the signal connected to the third input port of the Switch block, which has signal dimensions 1 by 2. After 5 seconds, Time Scope plots the signal connected to the first input port of the Switch block, which has signal dimensions 1 by 3. Run your model to see the time domain output.

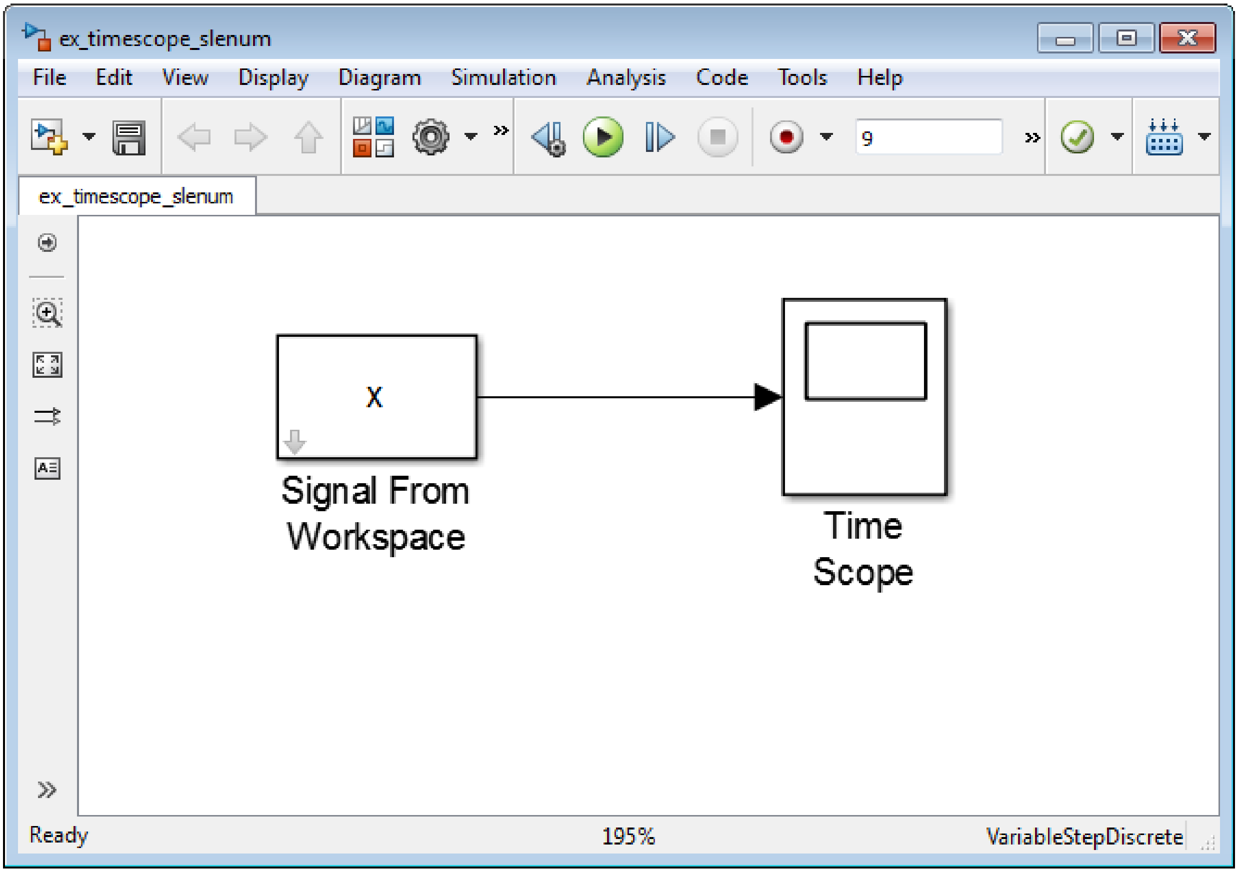


As you can see in the figure, the third line on the display, colored red, appears only after 5 seconds.

Display Simulink Enumeration Input Signal

This example shows how to use the Time Scope to display an enumerated input signal.

At the MATLAB® command prompt, type ex_timescope_slenum to open the example model. The following Simulink® model appears.

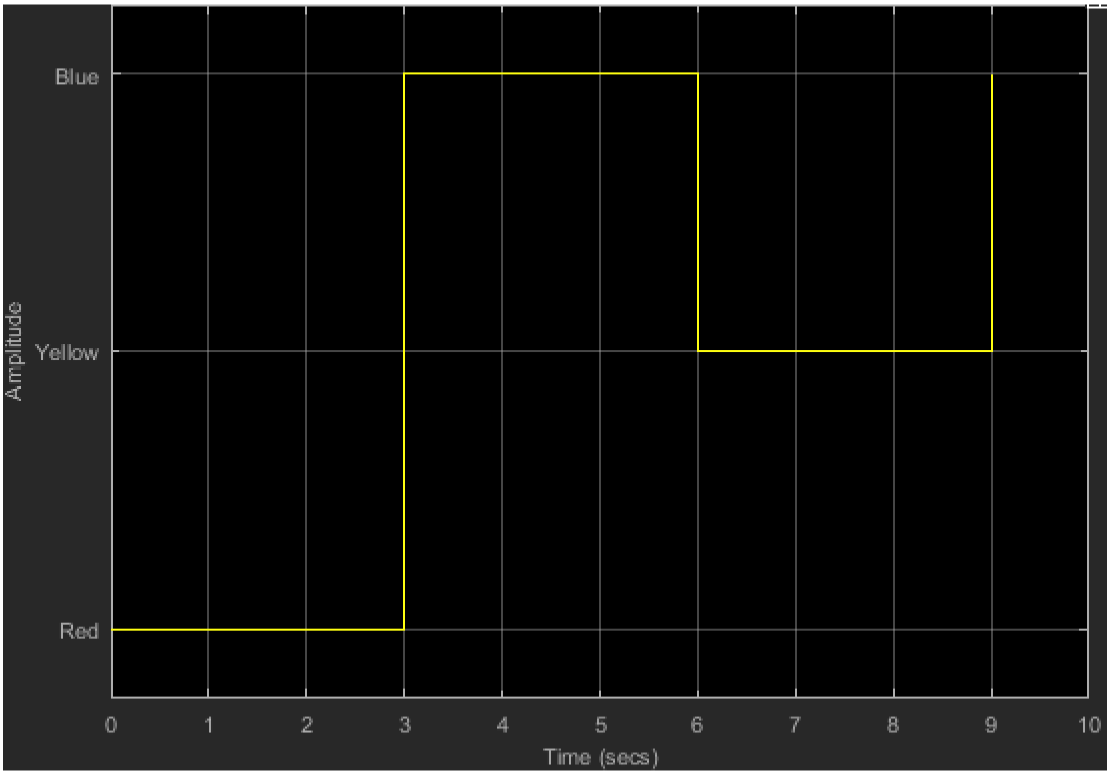


In this example, Simulink® imports the variable `x`, which is a Simulink® enumeration data type, from the MATLAB® workspace. This variable is created when the model loads because the commands that construct it reside in the model pre-load function. To view these commands, in the Simulink® menu, select `File > Model Properties > Model Properties`. The following lines of MATLAB® code appear when you click the `Callbacks` tab.

```
if ~exist('BasicColors','class')
    Simulink.defineIntEnumType('BasicColors', ...
        {'Red', 'Yellow', 'Blue'}, ...
        [0;1;2], ...
        'Description', 'Basic colors', ...
        'DefaultValue', 'Blue', ...
```

```
        'AddClassNameToEnumNames', true);
end
x = [BasicColors(0), BasicColors(2), BasicColors(1)];
```

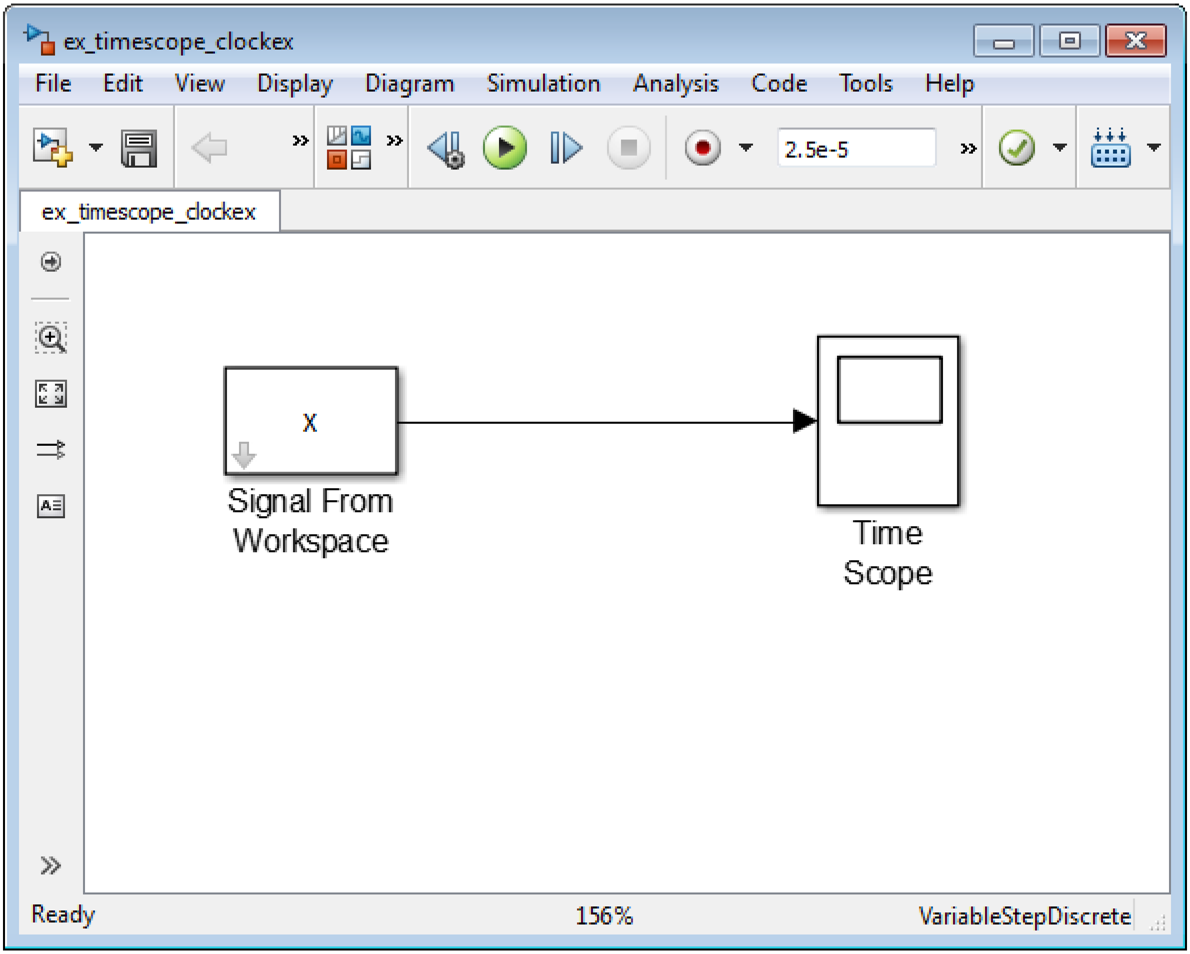
The Signal from Workspace block has a Sample time of 3 seconds. Thus, the input signal changes to the next value in vector x every 3 seconds. Run your model to see the time domain output, as shown in the following figure.



Use Bilevel Measurements Panel with Clock Input Signal

This example shows how to use the Time Scope Bilevel Measurements panel.

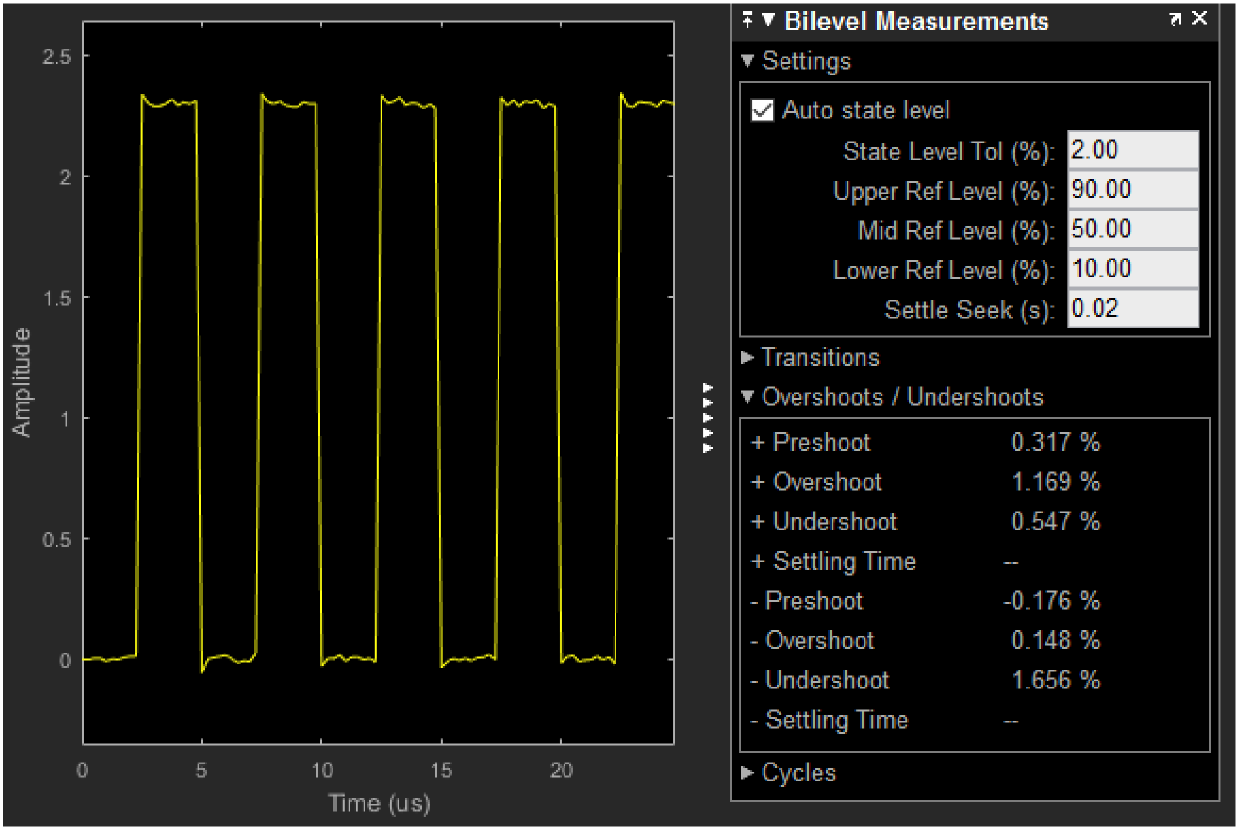
At the MATLAB® command prompt, type ex_timescope_clockex to open the example model. The following Simulink® model appears.



In this example, Simulink® imports the variable `x`, from the MATLAB® workspace. This variable is created when the model loads because the commands that construct it reside in the model Preload function. To view these commands, in the Simulink® menu, select `File > Model Properties > Model Properties`. The Model Properties dialog box appears. Click the `Callbacks` tab. The following lines of MATLAB® code appear.

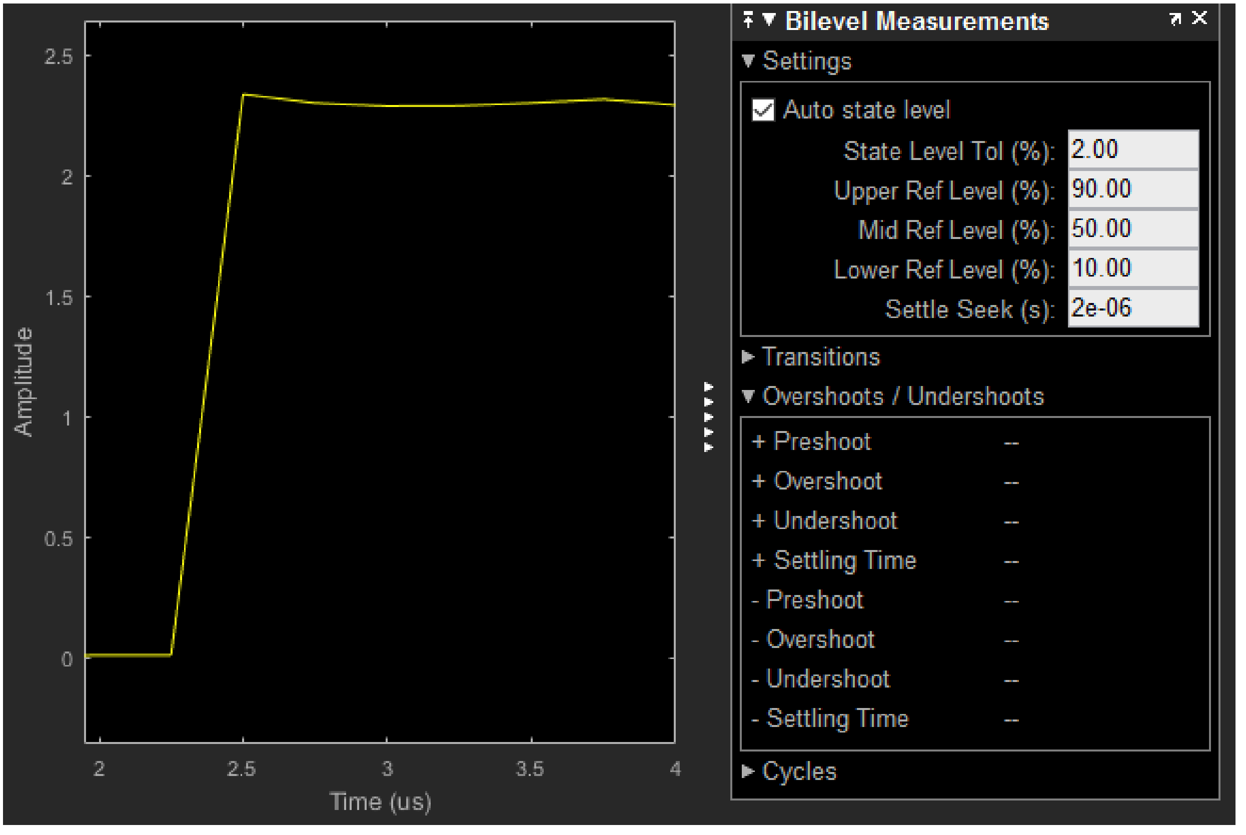
```
load clockex;
ts = t(2)-t(1);
```

Run your model to see the time domain output. To show the `Bilevel Measurements` panel, in the Time Scope menu, select `Tools > Measurements > Bilevel Measurements`. Collapse the `Transitions` section, click the arrow next to the section label. Expand the `Settings` and `Overshoots/Undershoots` sections, click the arrow next to each label. The Time Scope appears as shown in the following figure.



The value for the rising edge `Settling Time` parameter is not displayed initially because the default value for the `Settle Seek` parameter is too large for this example. Here, the settle seek time is longer than the entire simulation duration. Enter a value for `Settle seek` of 2e-6 and press the Enter key. The Time Scope now displays a rising edge settling time value of 118.392 ns.

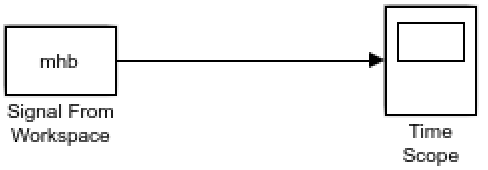
The settling time value displayed is the statistical average of the settling times for all five rising edges. To show the settling time for one rising edge, zoom in on that transition. In the Time Scope toolbar, click the Zoom X button.. Click the display near a value of 2 microseconds on the time-axis. Drag to the right and release near a value of 4 microseconds on the time-axis. The Time Scope updates the rising edge settling time value to reflect the new time window, as shown in the following figure.



Use Peak Finder to Find Heart Rate from ECG Input

This example shows how to use the Time Scope Peak Finder panel to measure the heart rate from an ECG.

This model emulates an ECG heart rate.



To emulate a heart beat, the model imports the variable `mhb` from the MATLAB® workspace. This variable is created when the model loads because the commands that construct it are in the model Preload function. To view these commands, in the Simulink® menu, select **File > Model Properties > Model Properties**. The Model Properties dialog box appears. Click the **Callbacks** tab. The following lines of MATLAB® code appear.

```
x1 = 3.5*ecg(2700);
y1 = sgolayfilt(kron(ones(1,13),x1),0,21);
n = (1:30000)';
del = round(2700*rand(1));
mhb = y1(n + del);
ts = 0.00025;
```

`ecg` is a custom fuction that helps generate the heartbeat signal.

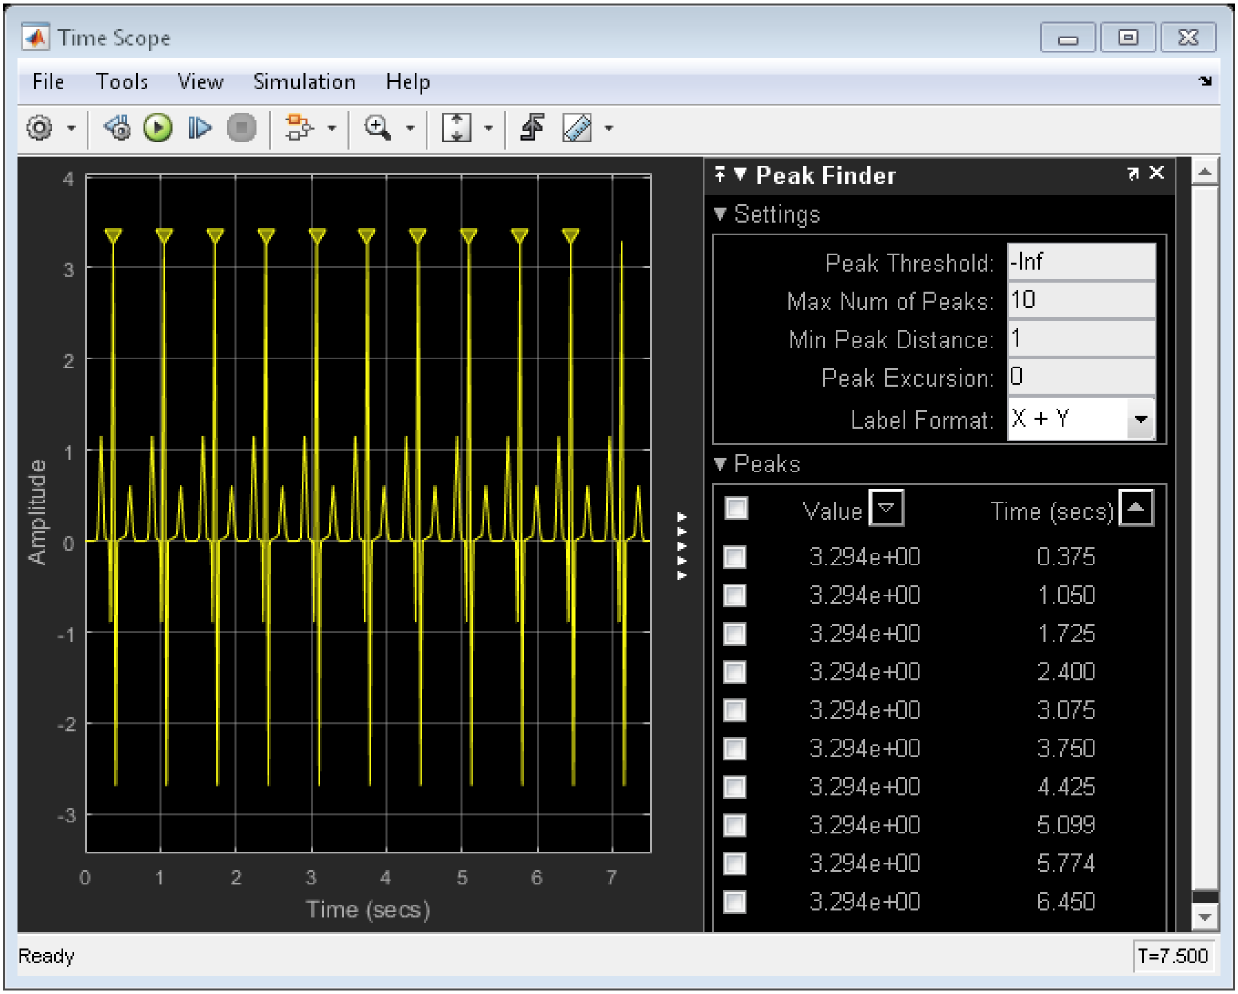
```
function x = ecg(L)
a0 = [0,  1, 40,  1,   0, -34, 118, -99,   0,   2,  21,   2,   0,   0,   0];
d0 = [0, 27, 59, 91, 131, 141, 163, 185, 195, 275, 307, 339, 357, 390, 440];
a = a0 / max(a0);
d = round(d0 * L / d0(15));
d(15) = L;
for i = 1:14
    m = d(i) : d(i+1) - 1;
    slope = (a(i+1) - a(i)) / (d(i+1) - d(i));
    x(m+1) = a(i) + slope * (m - d(i));
end
```

Run your model to see the time domain output.

1 To show the **Peak Finder** panel, in the Time Scope menu, select **Tools > Measurements > Peak Finder**.

2 To expand the **Settings** section, click the arrow next to the label.

3 Enter 10 for `Max Num of Peaks`. The Time Scope Peaks section now displays a list of 10 peak amplitude values, and the times at which they occur.



The list of peak values show a constant time difference of 0.675 seconds between each heartbeat. Therefore, the heart rate of the ECG signal is 88.89 beats per min (bpm).

Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers • Simulink enumerations

You can use nonvirtual buses and array of buses as inputs. For details, see “Bus Support” on page 2-1719.

Supported Simulation Modes

You can use the scope block in models running the following supported simulation modes.

Mode	Supported	Notes and Limitations
Normal	Yes	
Accelerator	Yes	
Rapid Accelerator	Yes	You can use Rapid Accelerator mode as a method to increase the execution speed of your Simulink model. Rapid Accelerator mode creates an executable that includes the solver and model methods. This executable resides outside MATLAB and Simulink. Rapid Accelerator mode uses External mode to communicate with Simulink. For more information about Rapid Accelerator mode, see “Acceleration” (Simulink).
PIL	No	

Mode	Supported	Notes and Limitations
SIL	No	
External	Yes	You can use External mode to tune block parameters in real time and view block outputs in many types of blocks and subsystems. External mode establishes communication between a host system, where the Simulink environment resides, and a target system, where the executable runs after code generation and the build process. For more information about External mode, see “Set Up and Use Host/Target Communication Channel” (Simulink Coder). The scope does not support data archiving. See “Set External Mode Data Archiving Parameters” (Simulink Desktop Real-Time).

For more information about these modes, see “How Acceleration Modes Work” (Simulink).

To log bus signals with a Time Scope block, set the **Save format** block parameter to `Dataset`.

Bus Support

You can connect nonvirtual bus and array of buses signals to a Time Scope block. To display the bus signals, use normal or accelerator simulation mode. The Time Scope block displays each bus element signal, in the order the elements appear in the bus, from the top to the bottom. Nested bus elements are flattened.

To log bus signals with a Time Scope block, set the **Save format** block parameter to `Dataset`.

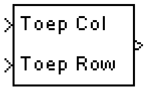
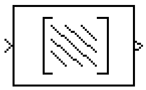
Introduced before R2006a

Toeplitz

Generate matrix with Toeplitz symmetry





Library

Math Functions / Matrices and Linear Algebra / Matrix Operations

`dspmtrx3`

Description

The Toeplitz block generates a Toeplitz matrix from inputs defining the first column and first row. The top input (`Col`) is a vector containing the values to be placed in the first *column* of the matrix, and the bottom input (`Row`) is a vector containing the values to be placed in the first *row* of the matrix.

```
y = toeplitz(Col,Row)       % Equivalent MATLAB code
```

The other elements of the matrix obey the relationship

```
y(i,j) = y(i-1,j-1)
```

and the output has dimension `[length(Col) length(Row)]`. The y(1,1) element is inherited from the `Col` input. For example, the following inputs

```
Col = [1 2 3 4 5]
Row = [7 7 3 3 2 1 3]
```

produce the Toeplitz matrix

$$\begin{bmatrix} 1 & 7 & 3 & 3 & 2 & 1 & 3 \\ 2 & 1 & 7 & 3 & 3 & 2 & 1 \\ 3 & 2 & 1 & 7 & 3 & 3 & 2 \\ 4 & 3 & 2 & 1 & 7 & 3 & 3 \\ 5 & 4 & 3 & 2 & 1 & 7 & 3 \end{bmatrix}$$

When you select the **Symmetric** check box, the block generates a symmetric (Hermitian) Toeplitz matrix from a single input, `u`, defining both the first row and first column of the matrix.

```
y = toeplitz(u)      % Equivalent MATLAB code
```

The output has dimension `[length(u) length(u)]`. For example, the Toeplitz matrix generated from the input vector `[1 2 3 4]` is

$$\begin{bmatrix} 1 & 2 & 3 & 4 \\ 2 & 1 & 2 & 3 \\ 3 & 2 & 1 & 2 \\ 4 & 3 & 2 & 1 \end{bmatrix}$$

The Toeplitz block supports real and complex floating-point and fixed-point inputs.

Parameters

Symmetric

When selected, enables the single-input configuration for symmetric Toeplitz matrix output.

Saturate on integer overflow

When you generate a symmetric Toeplitz matrix with this block, if the input vector is complex, the output is a symmetric Hermitian matrix whose elements satisfy the relationship

$$y(i,j) = \mathrm{conj}(y(j,i))$$

For fixed-point signals the conjugate operation could result in an overflow. When you select this parameter, overflows saturate. This parameter is only visible with the **Symmetric** parameter is selected. This parameter is ignored for floating-point signals.

Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers (real signals only)
Toep Col	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers
Toep Row	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers
Output	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers

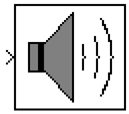
Introduced before R2006a

To Audio Device

Write audio data to computer's audio device



Note: The To Audio Device block will be removed in a future release. Existing instances of the block continue to run. For new models, use the `Audio Device Writer` block instead.

Library

Sinks

`dspsnks4`

Description

The To Audio Device block sends audio data to your computer's audio device. This block is not supported for use with the Simulink Model block.

Use the **Device** parameter to specify the device to which you want to send the audio data. This parameter is automatically populated based on the audio devices installed on your system. If you plug or unplug an audio device from your system, type `clear mex` at the MATLAB command prompt to update the list.

Select the **Inherit sample rate from input** check box if you want the block to inherit the sample rate of the audio signal from the input to the block. If you clear this check box, the **Sample rate (Hz)** parameter appears on the block. Use this parameter to specify the number of samples per second in the signal.

The range of supported audio device sample rates and data type formats, depend on both the sound card and the API which is chosen for the sound card.

Use the **Device data type** to specify the data type of the audio data that is sent to the device. You can choose:

- `8-bit integer`
- `16-bit integer`
- `24-bit integer`
- `32-bit float`
- `Determine from input data type`

If you choose `Determine from input data type`, the following table summarizes the block's behavior.

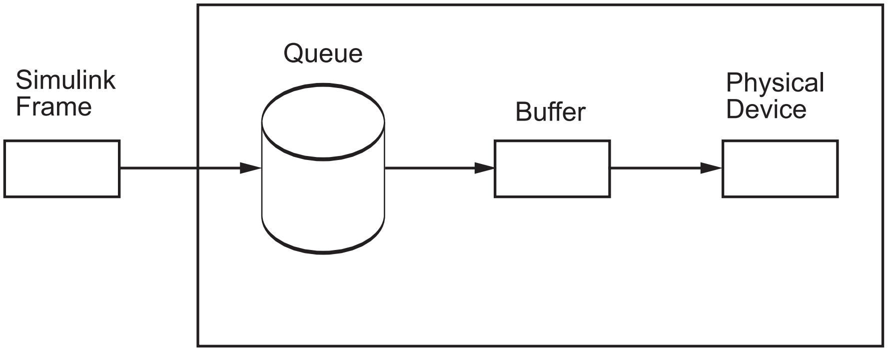
Input Data Type	Device Data Type
Double-precision floating point or single-precision floating point	32-bit floating point
32-bit integer	24-bit integer
16-bit integer	16-bit integer
8-bit integer	8-bit integer

If you choose `Determine from input data type` and the device does not support the input data type, the block uses the next lowest-precision data type supported by the device.

The generated code for this block relies on prebuilt .dll files. You can run this code outside the MATLAB environment, or redeploy it, but be sure to account for these extra .dll files when doing so. The packNGo function creates a single zip file containing all of the pieces required to run or rebuild this code. See `packNGo` for more information.

Buffering

The To Audio Device block buffers the data from a Simulink signal using the process illustrated by the following figure.



To Audio Device Block

1 At the start of the simulation, the queue is filled with silence. Specify the size of this queue using the **Queue duration (seconds)** parameter. As Simulink runs, the block appends Simulink frames to the bottom of the queue.

2 At each time step, the blocks sends a buffer of samples from the top of the queue to the audio device. Select the **Automatically determine buffer size** check box to allow the block to use a conservative buffer size. See the `From Audio Device` block reference page for the equation the block uses to calculate this buffer size. If you clear this check box, the **Buffer size (samples)** parameter appears on the block. Use this parameter to specify the size of the buffer in samples.

3 The block writes the buffer of audio data to the device. If the queue did not contain enough data to completely fill the buffer, the block fills the remaining portion of the buffer with zeros. This data has a the data type specified by the **Device data type** parameter.

When the simulation throughput rate is lower than the hardware throughput rate, the queue, which is initially full, becomes empty. If the queue is empty, the block sends zeros (silence) to the audio device. You can monitor inserted zeroes using the optional `Underrun` output port. When the simulation throughput rate is higher than the hardware throughput rate, the To Audio Device block waits to write data to the queue.

To minimize the chance of dropouts, the block checks to make sure the queue duration is at least as large as the maximum of the buffer size and the frame size. If it is not, the queue duration is automatically set to this maximum value.

Channel Mapping

The term *Channel Mapping* refers to a 1-to-1 mapping that associates channels on the selected audio device to channels of the data. When you play audio, channel mapping allows you to specify which channel of the audio device directs input to a specific channel of audio data. You can specify channel mapping as a vector of output channel indices corresponding to each output channel of data being written. The default value in the **Device Output Channels** parameter is 1:MAXOUTPUTCHANNELS. If you do not select the default mapping, you must specify the **Device Output Channels** parameter in the dialog box.

Example: The selected output audio device contains 8 channels. The data being output has dimensions N×3 (3–channel data). You want the output to be redirected as follows:

- First data channel to Audio Device channel 3
- Second data channel to Audio Device channel 1
- Third data channel to Audio Device channel 8

Thus, you would specify the **Device Output Channels** as [3 1 8].

Troubleshooting

Not Keeping Up in Real Time

When Simulink cannot keep up with an audio device that is operating in real time, the queue becomes empty and gaps occur in the audio data that the block sends to the device. Select the **Output number of samples by which the queue was underrun** check box to add an output port indicating when the queue was empty. Here are several ways to deal with this situation:

- *Increase the queue duration.*

  The **Queue duration (seconds)** parameter specifies the duration of the signal, in seconds, that can be buffered during the simulation. This is the maximum length of time that the block's data supply can lag the hardware's data demand.
- *Increase the buffer size.*

  The size of the buffer processed in each interrupt from the audio device affects the performance of your model. If the buffer is too small, a large portion of hardware resources are used to write data to the device. If the buffer is too big, Simulink must wait for the device to empty the buffer before it can write the data to the queue, which introduces latency.

- *Increase the simulation throughput rate.*

  Two useful methods for improving simulation throughput rates are increasing the signal frame size and compiling the simulation into native code:

  - Increase frame sizes and use frame-based processing throughout the model to reduce the amount of block-to-block communication overhead. This can increase throughput rates in many cases. However, larger frame sizes generally result in greater model latency due to initial buffering operations.
  - Generate executable code with Simulink Coder code generation software. Native code runs much faster than Simulink and should provide rates adequate for real-time audio processing.

Other ways to improve throughput rates include simplifying the model and running the simulation on a faster PC processor. For other ideas on improving simulation performance, see “Delay and Latency” and “Performance” (Simulink).

Running an Executable Outside MATLAB

To run your generated standalone executable application in Shell, you need to set your environment to the following:

Platform	Command

Mac	`setenv DYLD_LIBRARY_PATH $LD_LIBRARY_PATH: $MATLABROOT/bin/maci64 (csh/tcsh)`
	
	`export DYLD_LIBRARY_PATH $LD_LIBRARY_PATH: $MATLABROOT/bin/maci64 (Bash)`

Linux	`setenv LD_LIBRARY_PATH $LD_LIBRARY_PATH: $MATLABROOT/bin/glnxa64 (csh/tcsh)`
	
	`export LD_LIBRARY_PATH $LD_LIBRARY_PATH: $MATLABROOT/bin/glnxa64 (Bash)`

Platform	Command
Windows	`set PATH = $MATLABROOT\bin\win64;%PATH%`

Channel-to-Speaker Mapping on Windows Operating Systems

The To Audio Device and From Audio Device blocks can support multiple channels. On Windows operating systems, the channel-to-speaker mapping is defined as listed below. This mapping only applies when your sound card is properly configured and capable of receiving the audio data you send. If the number of channels on the card does not match the number of channels on the block, or if you specify a data type for the **Device data type** parameter that is not supported by your device, the Windows mixer intervenes to translate from one format to another. If the Windows mixer does intervene, the channel-to-speaker mapping might differ from what is specified here.

- Single channel input — Front center speaker

  On systems with two speakers, the front center channel is split between the right and left speakers.
- Multichannel input — Channels are assigned to speakers as follows:

  - One channel — Front center
  - Two channels — Front left, front right
  - Four channels — Front left, front right, rear left, rear right
  - Six channels — Front left, front right, front center, low frequency, rear left, rear right
  - Eight channels — Front left, front right, front center, low frequency, rear left, rear right, front left center, front right center
  - For all other channel combinations, the channel assignment is dictated by the audio card.

Audio Hardware API

The To Audio Device and From Audio Device blocks use the open-source PortAudio library in order to communicate with the audio hardware on a given computer. The PortAudio library supports a range of API's designed to communicate with the audio hardware on a given platform. The following API choices were made when building the PortAudio library for the DSP System Toolbox product:

- Windows: DirectSound, WDM-KS, ASIO

- Linux: ALSA, OSS
- Mac: CoreAudio

For Windows, the default is DirectSound, for Linux, the default is ALSA, and for Mac there is only one choice.

To determine the audio hardware API currently selected, type the following command in the MATLAB command prompt.

```
getpref('dsp','portaudioHostApi')
```

The output is a scalar indicating the choice of the API.

- 1 — DirectSound
- 3 — ASIO
- 7 — OSS
- 8 — ALSA
- 11 — WDM-KS

To select a particular API, type the following command in the MATLAB command prompt.

```
setpref('dsp','portaudioHostApi',N)
```

where *N* is a scalar. Choose *N* based on the API choice above.

Parameters

Device

Specify which device to send the audio data to.

Inherit sample rate from input

Select this check box if you want the block to inherit the sample rate of the audio signal from the input to the block.

Sample rate (Hz)

Specify the number of samples per second in the signal. This parameter is visible when the **Inherit sample rate from input** check box is cleared.

Device data type

Specify the data type of the audio data sent to the device.

Automatically determine buffer size

Select this check box to allow the block to calculate a conservative buffer size.

Buffer size (samples)

Specify the size of the buffer. This parameter is visible when the **Automatically determine buffer size** check box is cleared.

Queue duration (seconds)

Specify the size of the queue in seconds.

Use default mapping between Data and Device Output Channels

Select this check box to have the default mapping, where the data from the first channel of audio device is sent to the first channel of the input data, data from second channel of audio device is sent to second channel of data and so on. The maximum number of channels in the input data is determined by the **Number of channels** property.

Device Output Channels

Specify the channel mapping. This parameter is visible when the **Use default mapping between Device Input Channels and Data** check box is disabled.

Output number of samples by which the queue was underrun

Select this check box to output the number of zero samples inserted into the audio stream due to queue underrun since the last transfer of a frame to the audio device. You can use this value to debug throughput problems and adjust the queues and buffers in your model. To learn how to improve throughput, see "Troubleshooting" on page 2-1728.

Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point • 32-bit signed integers • 16-bit signed integers • 8-bit unsigned integers
Underrun	32-bit unsigned integer

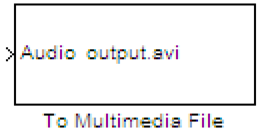
To Multimedia File

Stream video frames and audio samples to multimedia file



Library

Sinks

`dspsnks4`

Description

The To Multimedia File block writes video frames, audio samples, or both to a multimedia (`.avi, .wav, .wma, .mp4, .ogg, .flac, or .wmv`) file.

You can compress the video frames or audio samples by selecting a compression algorithm. You can connect as many of the input ports as you want. Therefore, you can control the type of video and/or audio the multimedia file receives.

Note This block supports code generation for platforms that have file I/O available. You cannot use this block with Simulink Desktop Real-Time software, because that product does not support file I/O.

This block performs best on platforms with Version 11 or later of Windows Media Player software. This block supports only uncompressed RGB24 AVI files on Linux and Mac platforms.

Windows 7 UAC (User Account Control), may require administrative privileges to encode `WMV` and `WMA` files.

The generated code for this block relies on prebuilt library files. You can run this code outside the MATLAB environment, or redeploy it, but be sure to account for these extra library files when doing so. The packNGo function creates a single zip file containing all of the pieces required to run or rebuild this code. See `packNGo` for more information.

To run an executable file that was generated from a model containing this block, you may need to add precompiled shared library files to your system path. See “Understanding C Code Generation” for details.

Cross-Platform Supported File Formats for Audio Files

Audio files can be of the following formats on all platforms:

- WAV
- FLAC
- OGG
- MPEG4 (only on Windows 7 and Mac OS X)

The default format is WAV. This block supports MPEG-4 AAC audio files on Windows 7, and Mac OS X. You can use both M4A and MP4 extensions. The following platform specific restrictions apply when writing these files:

<table>
<tr><th>Windows 7</th><th>Mac OS X</th></tr>
<tr><td>• Only sample rates of 44100 and 48000 Hz are supported.</td><td rowspan="2">• Only mono or stereo outputs are allowed for MPEG-4 AAC file format. For all other formats, more than two audio output channels are allowed.</td></tr>
<tr><td>• Only mono or stereo outputs are allowed for MPEG-4 AAC file format. For all other formats, more than two audio output channels are allowed.</td></tr>
<tr><td>• The output data is padded on both the front and back of the signal, with extra samples of silence.

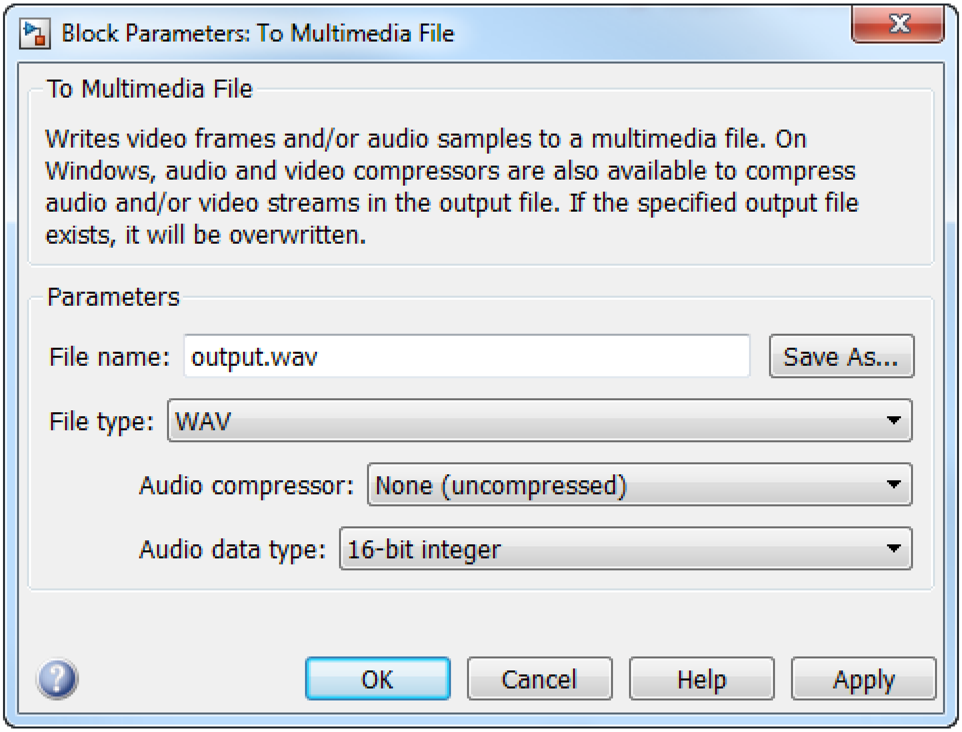
Windows AAC encoder places sharp fade-in and fade-out on audio signal, causing signal to be slightly longer in samples when written to disk.</td><td rowspan="2">• Not all sampling rates are supported, although the Mac Audio Toolbox API do not explicitly specify a restriction.</td></tr>
<tr><td>• A minimum of 1025 samples per channel must be written to the MPEG-4 AAC file.</td></tr>
</table>

Ports

Port	Description
Image	M-by-N-by-3 matrix RGB, Intensity, or YCbCr 4:2:2 signal.
R, G, B	Matrix that represents one plane of the RGB video stream. Inputs to the R, G, or B port must have the same dimensions and data type.
Audio	M-by-N matrix. M is the number of samples in each channel, and N is the number of channels.
Y, Cb, Cr	Matrix that represents one frame of the YCbCr video stream. The Y, Cb, and Cr ports use the following dimensions: Y: $M \text{ x } N$ Cb: $M \text{ x } \frac{N}{2}$ Cr: $M \text{ x } \frac{N}{2}$

Dialog Box

The **Main** pane of the To Multimedia File block dialog appears as follows.



File name

Specify the name of the multimedia file. The block saves the file in your current folder. To specify a different file or location, click the **Save As...** button.

File type

Specify the file type of the multimedia file. You can select `AVI`, `WAV`, `MJ2000`, `WMA`, `WMV`, `MPEG4`, `FLACC`, or `OGG`. By default, the **File type** is set to `WAV`.

Write

Specify whether the block writes video frames, audio samples, or both to the multimedia file. You can select `Video and audio`, `Video only`, or `Audio only`. This parameter is visible only when you set **File type** to `AVI`, `MPEG4`, or `OGG`.

Audio compressor

Select the type of compression algorithm to use to compress the audio data. This compression reduces the size of the multimedia file. Choose `None (uncompressed)` to save uncompressed audio data to the multimedia file.

Note: The other items available in this parameter list are the audio compression algorithms installed on your system. For information about a specific audio compressor, see the documentation for that compressor.

Audio data type

Select the audio data type. You can use the **Audio data type** parameter only for uncompressed wave files.

Video compressor

Select the type of compression algorithm to use to compress the video data. This compression reduces the size of the multimedia file. Choose `None (uncompressed)` to save uncompressed video data to the multimedia file.

Note: The other items available in this parameter list are the video compression algorithms installed on your system. For information about a specific video compressor, see the documentation for that compressor.

Compression Factor (>1)

Specify the compression factor as an integer scalar greater than `1`. This parameter is applicable only when the **File type** is set to `MJ2000` and **Video compressor** is set to `Lossy`. By default, this parameter is set to `10`.

File color format

Select the color format of the data stored in the file. You can select either `RGB` or `YCbCr 4:2:2`.

Image signal

Specify how the block accepts a color video signal. If you select `One multidimensional signal`, the block accepts an *M*-by-*N*-by-*P* color video signal, where *P* is the number of color planes, at one port. If you select `Separate color signals`, additional ports appear on the block. Each port accepts one *M*-by-*N* plane of an RGB video stream.

Video Quality (0-100)

Quality of the video specified as an integer scalar in the range `[0 100]`. This parameter is applicable only when **File name** is set to `MPEG4` and **Write** is set to `Video only`. By default, this parameter is set to `75`.

Troubleshooting

Running an Executable Outside MATLAB

To run your generated standalone executable application in Shell, you need to set your environment to the following:

Platform	Command

Mac	`setenv DYLD_LIBRARY_PATH "${DYLD_LIBRARY_PATH}:$MATLABROOT/bin/maci64" (csh/tcsh)`
	
	`export DYLD_LIBRARY_PATH=$LD_LIBRARY_PATH:$MATLABROOT/bin/maci64 (Bash)`

Linux	`setenv LD_LIBRARY_PATH ${LD_LIBRARY_PATH}:$MATLABROOT/bin/glnxa64 (csh/tcsh)`
	
	`export LD_LIBRARY_PATH=$LD_LIBRARY_PATH:$MATLABROOT/bin/glnxa64 (Bash)`

Windows	`set PATH=%PATH%;%MATLABROOT%\bin\win64`

Supported Data Types

For the block to display video data properly, double- and single-precision floating-point pixel values must be between 0 and 1. Any other data type requires the pixel values between the minimum and maximum values supported by their data type.

Check the specific codecs you are using for supported audio rates.

Port	Supported Data Types	Supports Complex Values?
Image	• Double-precision floating point • Single-precision floating point	No

Port	Supported Data Types	Supports Complex Values?
	• Boolean • 8-, 16- 32-bit signed integers • 8-, 16- 32-bit unsigned integers	
R, G, B	Same as Image port	No
Audio	• Double-precision floating point • Single-precision floating point • 16-bit signed integers • 32-bit signed integers • 8-bit unsigned integers	No
Y, Cb, Cr	Same as Image port	No

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Usage notes and limitations:

The executable generated from this block relies on prebuilt dynamic library files (`.dll` files) included with MATLAB. Use the `packNGo` function to package the code generated from this block and all the relevant files in a compressed zip file. Using this zip file, you can relocate, unpack, and rebuild your project in another development environment where MATLAB is not installed. For more details, see “How To Run a Generated Executable Outside MATLAB”.

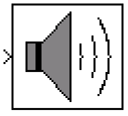
Introduced before R2006a

To Wave Device (Obsolete)

Send audio data to standard Windows audio device in real time



Library

`dspwin32`

Description

Note The To Wave Device block is still supported but is likely to be obsoleted in a future release. We strongly recommend replacing this block with the `To Audio Device` block.

The To Wave Device block sends audio data to a standard Windows audio device in real time. It is compatible with most popular Windows hardware, including Sound Blaster cards. The data is sent to the hardware in uncompressed pulse code modulation (PCM) format, and should typically be sampled at one of the standard Windows audio device rates: 8000, 11025, 22050, or 44100 Hz. Some hardware might support other rates in addition to these.

Note: Models that contain both the To Wave Device block and the From Wave Device block require a duplex-capable sound card.

The **Use default audio device** check box allows the To Wave Device block to detect and use the system's default audio hardware. You should select this option for systems that have a single sound device installed, or when the default sound device on a multiple-device system is your desired target. When the default sound device is *not* your desired output device, clear **Use default audio device**, and set the desired hardware in the **Audio device** parameter. This parameter lists the names of the installed audio devices.

The block input can contain audio data from a mono or stereo signal. A mono signal is represented as either a sample-based scalar or a frame-based length-M vector, where M is frame size. A stereo signal is represented as a sample-based length-2 vector or a frame-based M-by-2 matrix.

When the input data type is `uint8`, the block conveys the signal samples to the audio device using 8 bits. When the input data type is `double`, `single`, `int16`, or fixed point with a word length of 16 and a fraction length of 15, the block conveys the signal samples to the audio device using 16 bits by default. For inputs of data type `double` and `single`, you can also set the block to convey the signal samples using 24 bits by selecting the **Enable 24-bit output for double- and single-precision input signals** check box. The 24-bit sample width requires more memory but in general yields better fidelity.

The amplitude of the input must be in a valid range that depends on the input data type, as shown in the following table. Amplitudes outside the valid range are clipped to the nearest allowable value.

Input Data Type	Valid Input Amplitude Range
`double`	$-1 \leq amplitude < 1$
`single`	$-1 \leq amplitude < 1$
`int16`	$-32768 \leq amplitude \leq 32767$
`uint8`	$0 \leq amplitude \leq 255$
Fixed point with a word length of 16 and a fraction length of 15	$-1 \leq amplitude \leq 1 - 2^{-15}$

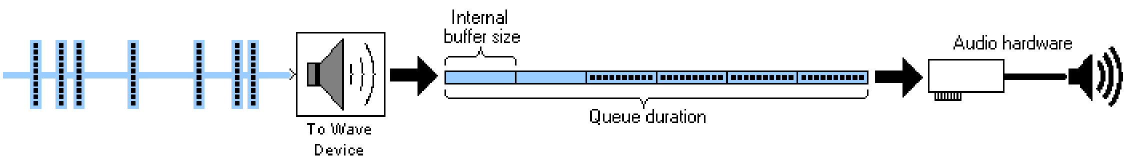
Buffering

Because audio devices generate real-time audio output, the Simulink environment must maintain a continuous flow of data to a device throughout simulation. Delays in passing data to the audio hardware can result in hardware errors or distortion of the output. This means that the To Wave Device block must in principle supply data to the audio hardware as quickly as the hardware reads the data. However, the To Wave Device block often *cannot* match the throughput rate of the audio hardware, especially when the simulation is running within Simulink rather than as generated code. Simulink execution speed can vary during the simulation as the host operating system services other processes. The block must therefore rely on a buffering strategy to ensure that signal data is available to the hardware on demand.

Note: This block requires real-time execution of the parent model for best performance.

The following block parameters control the memory management for this block:

- **Queue duration**
- **Automatically determine internal buffer size** or **User-defined internal buffer size**
- **Initial output delay**



The **Queue duration** parameter defines the overall size of the block's buffer. The block reads in chunks of data in the size of the input dimensions and stores them in the buffer. The internal buffer size defines the dimensions of the block output to the hardware. You can define the internal buffer size yourself in the **User-defined internal buffer size parameter**. If you select **Automatically determine internal buffer size** instead, the internal buffer size is calculated for you according to the following rules:

- If the input to the block has a frame size of 32 samples or larger, the internal buffer size be the same as the input frame size.
- If the input to the block has a frame size smaller than 32 samples, the internal buffer size is based on the input sample rate according to the following table, where

$$F_s = sampling\ frequency = \frac{1}{sample\ time}$$

F_s (Hz)	Internal Buffer Size (samples)
$F_s < 8000$	$\min(64, 2 * F_s)$
$8000 \le F_s < 22{,}050$	128
$22{,}050 \le F_s < 44{,}100$	256
$44{,}100 \le F_s < 96{,}000$	512
$F_s \ge 96{,}000$	1024

To minimize the chance of dropouts, the block checks to make sure that the queue duration is at least as big as twice the internal buffer size. If it is not, the queue duration is automatically set to twice the internal buffer size.

The **Initial output delay** parameter enables you to preload the buffer before the block starts to output data to the audio device, which can be helpful for models that do not run in real time. However, for real-time applications, it is best to set the initial output delay to zero (one frame of delay), or as close to zero as possible.

Troubleshooting

If you are getting undesirable audio output using the To Wave Device block, first determine whether your model can run in real time. Replace the To Wave Device block with a To Wave File block, run the model, and compare the model's simulation stop time to the elapsed time on your watch. If the model simulation stop time is less than the elapsed time on your watch, your model can probably run in real time. Then,

- If your model can run in real time,

  1. Select **Automatically determine internal buffer size**. This alone might solve the problem. If not,
  2. Try increasing the **Queue duration** parameter to a relatively large value, such as 0.5 s.

  If one or both of these options restores desirable audio output, you can try reducing the internal buffer size and/or queue duration until the quality of the audio output again degrades.
- If your model is not running in real time, try to make it run in real time by

1. Optimizing the model (using a more efficient implementation), or
2. Using a Simulink “Acceleration” (Simulink) mode, or
3. Generating stand-alone code

If none of these are possible, but the model only runs for a short period of time, set the **Queue duration** parameter to a size equal to a significant fraction of the model stop time and use a similarly large initial delay. This is not an optimal solution, but might work in some cases.

Parameters

Queue duration (seconds)

Specify the overall buffer size. To minimize the chance of dropouts, the block checks to make sure that the queue duration is as least as large as twice the internal buffer size. If it is not, the queue duration is automatically set to twice the internal buffer size.

Automatically determine internal buffer size

Select to have the block automatically select the internal buffer size for you. For details, see “Buffering” on page 2-1743.

User-defined internal buffer size (samples)

Define the internal buffer size, or the size of the chunks of data sent by the block to the audio hardware device.

This parameter is only visible when **Automatically determine internal buffer size** is not selected.

Initial output delay (seconds)

Specify the amount of time by which to delay the initial output to the audio device. During this time data accumulates in the block's buffer. Any value less than or equal to the queue duration specifies the smallest possible initial delay, which is a single frame.

Use default audio device

Select to direct audio output to the system's default audio device.

Audio device

This parameter lists the names of the installed audio devices. Specify the name of the audio device to receive the audio output. Select **Use default audio device** when the system has only a single audio card installed.

This parameter is only enabled when the **Use default audio device** check box is not selected.

Enable 24-bit output for double and single precision input signals

Select to output 24-bit data when inputs are double- or single-precision. Otherwise, the block outputs 16-bit data for double- and single-precision inputs.

Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point • Signed fixed point with a word length of 16 and a fraction length of 15 • 16-bit signed integers • 8-bit unsigned integers

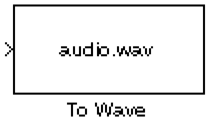
To Wave File (Obsolete)	DSP System Toolbox
`audioplayer`	MATLAB
`sound`	MATLAB

Introduced in R2008b

To Wave File (Obsolete)

Write audio data to file in Microsoft Wave (`.wav`) format



Library

`dspwin32`

Description

Note The To Wave File block is still supported but is likely to be obsoleted in a future release. We strongly recommend replacing this block with the `To Multimedia File` block.

The To Wave File block streams audio data to a Microsoft Wave (`.wav`) file in the uncompressed pulse code modulation (PCM) format. For compatibility reasons, the sample rate of the discrete-time input signal should typically be one of the standard Windows audio device rates (8000, 11025, 22050, or 44100 Hz), although the block supports arbitrary rates.

The input to the block, u, can contain audio data with one or more channels. A signal with C channels is represented as a sample-based length-C vector or a frame-based M-by-C matrix. The amplitude of the input should be in the range ±1. Values outside this range are clipped to the nearest allowable value.

```
wavwrite(u,Fs,bits,'filename')    % Equivalent MATLAB code
```

Note: AVI files are the only supported file type for non-Windows platforms.

Parameters

File name

Specify the path and name of the file to write. Paths can be relative or absolute. You do not need to specify the `.wav` extension.

Sample width (bits)

Specify the number of bits used to represent the signal samples in the file. The higher sample width settings require more memory but yield better fidelity for double- and single-precision inputs:

- `8` — Allocates 8 bits to each sample, allowing a resolution of 256 levels
- `16` — Allocates 16 bits to each sample, allowing a resolution of 65536 levels
- `24` — Allocates 24 bits to each sample, allowing a resolution of 16777216 levels
- `32` — Allocates 32 bits to each sample, allowing a resolution of 2^{32} levels ranging from -1 to 1

The 8-, 16-, and 24-bit modes output integer data, while the 32-bit mode outputs single-precision floating-point data.

Minimum number of samples for each write to file

Specify the number of consecutive samples, L, to write with each file access. To reduce the required number of file accesses, the block writes L consecutive samples to the file during each access for $L \geq M$. For $L < M$, the block instead writes M consecutive samples during each access. Larger values of L result in fewer file accesses, which reduces run-time overhead.

Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point • Signed fixed point with a word length of 16 and a fraction length of 15 • 16-bit signed integers • 8-bit unsigned integers

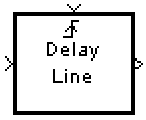
Description

The To Workspace block is an implementation of the Simulink To Workspace block. See To Workspace for more information.

Introduced in R2014b

Triggered Delay Line (Obsolete)

Buffer sequence of inputs into frame-based output



Library

dspobslib

Description

Note The Triggered Delay Line block is still supported but is likely to be obsoleted in a future release. We strongly recommend replacing this block with the `Delay Line` block.

The Triggered Delay Line block acquires a collection of M_o input samples into a frame, where you specify M_o in the **Delay line size** parameter. The block buffers a single sample from input 1 whenever it is triggered by the control signal at input 2 (⤒). When the next triggering event occurs, the newly acquired input sample is appended to the output frame so that the new output overlaps the previous output by M_o-1 samples. Between triggering events the block ignores input 1 and holds the output at its last value.

You specify the triggering event at input 2 in the **Trigger type** pop-up menu:

- `Rising edge` triggers execution of the block when the trigger input rises from a negative value to zero or a positive value, or from zero to a positive value.
- `Falling edge` triggers execution of the block when the trigger input falls from a positive value to zero or a negative value, or from zero to a negative value.
- `Either edge` triggers execution of the block when either a rising or falling edge (as described above) occurs.

The Triggered Delay Line block has zero latency, so the new input appears at the output in the same simulation time step. The output frame period is the same as the input sample period, $T_{fo}=T_{si}$.

Sample-Based Operation

In sample-based operation, the Triggered Delay Line block buffers a sequence of sample-based length-N vector inputs (1-D, row, or column) into a sequence of overlapping sample-based M_o-by-N matrix outputs, where you specify M_o in the **Delay line size** parameter (M_o>1). That is, each input vector becomes a *row* in the sample-based output matrix. When M_o=1, the input is simply passed through to the output, and retains the same dimension. Sample-based full-dimension matrix inputs are not accepted.

Frame-Based Operation

In frame-based operation, the Triggered Delay Line block rebuffers a sequence of frame-based M_i-by-N matrix inputs into an sequence of overlapping frame-based M_o-by-N matrix outputs, where M_o is the output frame size specified by the **Delay line size** parameter (that is, the number of consecutive samples from the input frame to rebuffer into the output frame). M_o can be greater or less than the input frame size, M_i. Each of the N input channels is rebuffered independently.

Initial Conditions

The Triggered Delay Line block's buffer is initialized to the value specified by the **Initial condition** parameter. The block always outputs this buffer at the first simulation step (*t*=0). When the block's output is a vector, the **Initial condition** can be a vector of the same size or a scalar value to be repeated across all elements of the initial output. When the block's output is a matrix, the **Initial condition** can be a matrix of the same size or a scalar to be repeated across all elements of the initial output.

Parameters

Trigger type

The type of event that triggers the block's execution.

Delay line size

The length of the output frame (number of rows in output matrix), M_o.

Initial condition

The value of the block's initial output, a scalar, vector, or matrix.

Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers
Trigger	• Any data type supported by the Trigger block
Output	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers

Triggered Signal From Workspace

Import signal samples from MATLAB workspace when triggered

Library

Signal Operations

`dspsigops`

Description

The Triggered Signal From Workspace block imports signal samples from the MATLAB workspace into the Simulink model when triggered by the control signal at the input port (). The **Signal** parameter specifies the name of a MATLAB workspace variable containing the signal to import, or any valid MATLAB expression defining a matrix or 3-D array.

When the **Signal** parameter specifies an M-by-N matrix (M≠1), each of the N columns is treated as a distinct channel. You specify the frame size in the **Samples per frame** parameter, M_o, and the output when triggered is an M_o-by-N matrix containing M_o consecutive samples from each signal channel. For convenience, an imported row vector (M=1) is treated as a single channel, so the output dimension is M_o-by-1.

When the **Signal** parameter specifies an M-by-N-by-P array, the block generates a single page of the array (an M-by-N matrix) at each trigger time. The **Samples per frame** parameter must be set to `1`.

Trigger Event

You specify the triggering event at the input port in the **Trigger type** pop-up menu:

- `Rising edge` triggers execution of the block when the trigger input rises from a negative value to zero or a positive value, or from zero to a positive value.

- `Falling edge` triggers execution of the block when the trigger input falls from a positive value to zero or a negative value, or from zero to a negative value.
- `Either edge` triggers execution of the block when either a rising or falling edge (as described above) occurs.

Initial and Final Conditions

The **Initial output** parameter specifies the output of the block from the start of the simulation until the first trigger event arrives. Between trigger events, the block holds the output value constant at its most recent value (that is, no linear interpolation takes place). For single-channel signals, the **Initial output** parameter value can be a vector of length M_o or a scalar to repeat across the M_o elements of the initial output frames. For matrix outputs (M_o-by-N or M-by-N), the **Initial output** parameter value can be a matrix of the same size or a scalar to be repeated across all elements of the initial output.

When the block has output all of the available signal samples, it can start again at the beginning of the signal, or simply repeat the final value or generate zeros until the end of the simulation. (The block does not extrapolate the imported signal beyond the last sample.) The **Form output after final data value by** parameter controls this behavior:

- When you specify `Setting To Zero`, the block generates zero-valued outputs for the duration of the simulation after generating the last frame of the signal.
- When you specify `Holding Final Value`, the block repeats the final sample for the duration of the simulation after generating the last frame of the signal.
- When you specify `Cyclic Repetition`, the block repeats the signal from the beginning after generating the last frame. When there are not enough samples at the end of the signal to fill the final frame, the block zero-pads the final frame as necessary to ensure that the output for each cycle is identical (for example, the *i*th frame of one cycle contains the same samples as the *i*th frame of any other cycle).

Parameters

Signal

The name of the MATLAB workspace variable from which to import the signal, or a valid MATLAB expression specifying the signal.

Trigger type

The type of event that triggers the block's execution.

Initial output

The value to output until the first trigger event is received.

Samples per frame

The number of samples, M_o, to buffer into each output frame. This value must be `1` when you specify a 3-D array in the **Signal** parameter.

Form output after final data value by

Specifies the output after all of the specified signal samples have been generated. The block can output zeros for the duration of the simulation (`Setting to zero`), repeat the final data sample (`Holding Final Value`) or repeat the entire signal from the beginning (`Cyclic Repetition`).

Supported Data Types

- Double-precision floating point
- Single-precision floating point
- Fixed point (signed and unsigned)
- 8-, 16-, and 32-bit signed integers
- 8-, 16-, and 32-bit unsigned integers

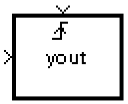
`Triggered To Workspace`	DSP System Toolbox

Introduced before R2006a

Triggered To Workspace

Write input sample to MATLAB workspace when triggered



Library

Sinks

`dspsnks4`

Description

The Triggered To Workspace block creates a matrix or array variable in the MATLAB workspace, where it stores the acquired inputs at the end of a simulation. The block overwrites an existing variable with the same name.

When you set the **Save 2-D signals as** parameter to `2-D array (concatenate along first dimension`, the block saves an *M*-by-*N* input as a *P*-by-*N* matrix, where *P* is the **Maximum number of rows** parameter. When the simulation progresses long enough for the block to acquire more than *P* samples, the block stores only the most recent *P* samples. The **Decimation factor**, *D*, allows you to store only every *D*th input matrix.

When you set the **Save 2-D signals as** parameter to `3-D array (concatenate along third dimension`, the block saves an *M*-by-*N* input as a three-dimensional array in which each *M*-by-*N* page represents a single sample from each of the *M***N* channels (the most recent input matrix occupies the last page). The maximum size of this variable is limited to *M*-by-*N*-by-*P*, where *P* is the **Maximum number of rows** parameter. When the simulation progresses long enough for the block to acquire more than *P* inputs, it stores only the last *P* inputs. The **Decimation factor**, *D*, allows you to store only every *D*th input matrix.

The block acquires and buffers a single frame from input 1 whenever it is triggered by the control signal at input 2 (). At all other times, the block ignores input 1. You specify the triggering event at input 2 in the **Trigger type** pop-up menu:

- `Rising edge` triggers execution of the block when the trigger input rises from a negative value to zero or a positive value, or from zero to a positive value.
- `Falling edge` triggers execution of the block when the trigger input falls from a positive value to zero or a negative value, or from zero to a negative value.
- `Either edge` triggers execution of the block when either a rising or falling edge (as described above) occurs.

To save a record of the sample time corresponding to each sample value, open the Configuration Parameters dialog box. In the **Select** pane, click **Data Import/Export** and select the **Time** check box.

The nontriggered version of this block is the To Workspace block.

Parameters

Trigger type

The type of event that triggers the block's execution.

Variable name

The name of the workspace variable in which to store the data.

Maximum number of rows

The maximum number of rows (one row per time step) to be saved, P.

Decimation

The decimation factor, D.

Save 2-D signals as

Specify whether the block saves 2-D signals as a 2-D or 3-D array in the MATLAB workspace:

- `2-D array (concatenate along first dimension)` — When you select this option, the block vertically concatenates each M-by-N matrix input with the previous input to produce a 2-D output array.
- `3-D array (concatenate along third dimension)` — When you select this option, the block saves an M-by-N input signal as a 3-D array. The maximum size of this 3-D array is limited to M-by-N-by-P, where P is the **Maximum number of rows** parameter. When the simulation progresses long enough for the block to acquire more than P inputs, the block stores only the last P inputs. The **Decimation factor**, D, allows you to store only every Dth input matrix.

Log fixed-point data as a fi object

Select to log fixed-point data to the MATLAB workspace as a Fixed-Point Designer `fi` object. Otherwise, fixed-point data is logged to the workspace as `double`.

Supported Data Types

Port	Supported Data Types
Input	• Any data type supported by the To Workspace block
Trigger	• Any data type supported by the Trigger block

Two-Channel Analysis Subband Filter

Decompose signal into high-frequency and low-frequency subbands

Library

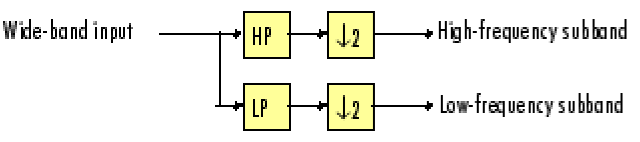
Filtering / Multirate Filters

`dspmlti4`

Description

The Two-Channel Analysis Subband Filter block decomposes the input into high-frequency and low-frequency subbands, each with half the bandwidth and half the sample rate of the input.

The block filters the input with a pair of highpass and lowpass FIR filters, and then downsamples the results by 2, as illustrated in the following figure.



The block implements the FIR filtering and downsampling steps together using a polyphase filter structure, which is more efficient than the straightforward filter-then-decimate algorithm shown in the preceding figure. Each subband is the first phase of the respective polyphase filter. You can implement a multilevel dyadic analysis filter bank by connecting multiple copies of this block or by using the `Dyadic Analysis Filter Bank` block. See “Creating Multilevel Dyadic Analysis Filter Banks” on page 2-1764 for more information.

You must provide a vector of filter coefficients for the lowpass and highpass FIR filters. Each filter should be a half-band filter that passes the frequency band that the other filter stops.

See the following topics for more information about this block:

- "Specifying the FIR Filters" on page 2-1762
- "Frame-Based Processing" on page 2-1762
- "Sample-Based Processing" on page 2-1763
- "Latency" on page 2-1763
- "Creating Multilevel Dyadic Analysis Filter Banks" on page 2-1764

Specifying the FIR Filters

You must provide the vector of numerator coefficients for the lowpass and highpass filters in the **Lowpass FIR filter coefficients** and **Highpass FIR filter coefficients** parameters.

For example, to specify a filter with the following transfer function, enter the vector `[b(1) b(2) ... b(m)]`.

$$H(z) = B(z) = b_1 + b_2 z^{-1} + \ldots + b_m z^{-(m-1)}$$

Each filter should be a half-band filter that passes the frequency band that the other filter stops. You can use the `Two-Channel Synthesis Subband Filter` block to reconstruct the input to this block. To do so, you must design perfect reconstruction filters to use in the synthesis subband filter.

The best way to design perfect reconstruction filters is to use the Wavelet Toolbox `wfilters` function in to design both the filters both in this block and in the `Two-Channel Synthesis Subband Filter` block. You can also use other DSP System Toolbox and Signal Processing Toolbox functions.

The Two-Channel Analysis Subband Filter block initializes all filter states to zero.

Frame-Based Processing

When you set the **Input processing** parameter to `Columns as channels (frame based)`, the block accepts an M-by-N matrix. The block treats each column of the input as the high- or low-frequency subbands of the corresponding output channel. You can use the **Rate options** parameter to specify how the block resamples the input:

- When you set the **Rate options** parameter to `Enforce single-rate processing`, the input to the block can be an M-by-N matrix, where M is a multiple of two. The block treats each column of the input as an independent channel and decomposes each channel over time. The block outputs two matrices, where each column of the output is the high- or low-frequency subband of the corresponding input column. To maintain the input sample rate, the block decreases the output frame size by a factor of two.

- When you set the **Rate options** parameter to `Allow multirate processing`, the block treats an M_i-by-N matrix input as N independent channels and decomposes each channel over time. The block outputs two M-by-N matrices, where each column of the output is the high- or low-frequency subband of the corresponding input column. The input and output frame *sizes* are the same, but the frame *rate* of the output is half that of the input. Thus, the overall sample rate of the output is half that of the input.

  In this mode, the block has one frame of latency, as described in the "Latency" on page 2-1763 section.

Sample-Based Processing

When you set the **Input processing** parameter to `Elements as channels (sample based)`, the block treats an M-by-N matrix input as $M \cdot N$ independent channels. The block decomposes each channel over time and outputs two M-by-N matrices whose sample rates are half the input sample rate. Each element in the output matrix is the high- or low-frequency subband output of the corresponding element of the input matrix.

Depending on the setting of your Simulink configuration parameters, the output may have one sample of latency, as described in the "Latency" on page 2-1763 section.

Latency

When you set the **Input processing** parameter to `Columns as channels (frame based)` and the **Rate options** parameter to `Enforce single-rate processing`, the Two-Channel Analysis Subband Filter block always has zero-tasking latency. *Zero-tasking latency* means that the block propagates the first input sample (received at time t=0) as the first output sample.

When you set the **Rate options** parameter to `Allow multirate processing`, the Two-Channel Analysis Subband Filter block may exhibit latency. The amount of latency depends on the setting of the **Input processing** parameter of this block, and the setting of the Simulink **Treat each discrete rate as a separate task** configuration parameter. The following table summarizes the conditions that produce latency when the block is performing multirate processing.

Input processing	Treat each discrete rate as a separate task	Latency
`Elements as channels (sample based)`	`Off`	None.
	`On`	One sample. The first output sample in each channel always has a value of `0`.
`Columns as channels (frame based)`	`On` or `Off`	One frame. All samples in the first output frame have a value of `0`.

Note: For more information on latency and the Simulink tasking modes, see "Excess Algorithmic Delay (Tasking Latency)" and "Time-Based Scheduling and Code Generation" (Simulink Coder).

Creating Multilevel Dyadic Analysis Filter Banks

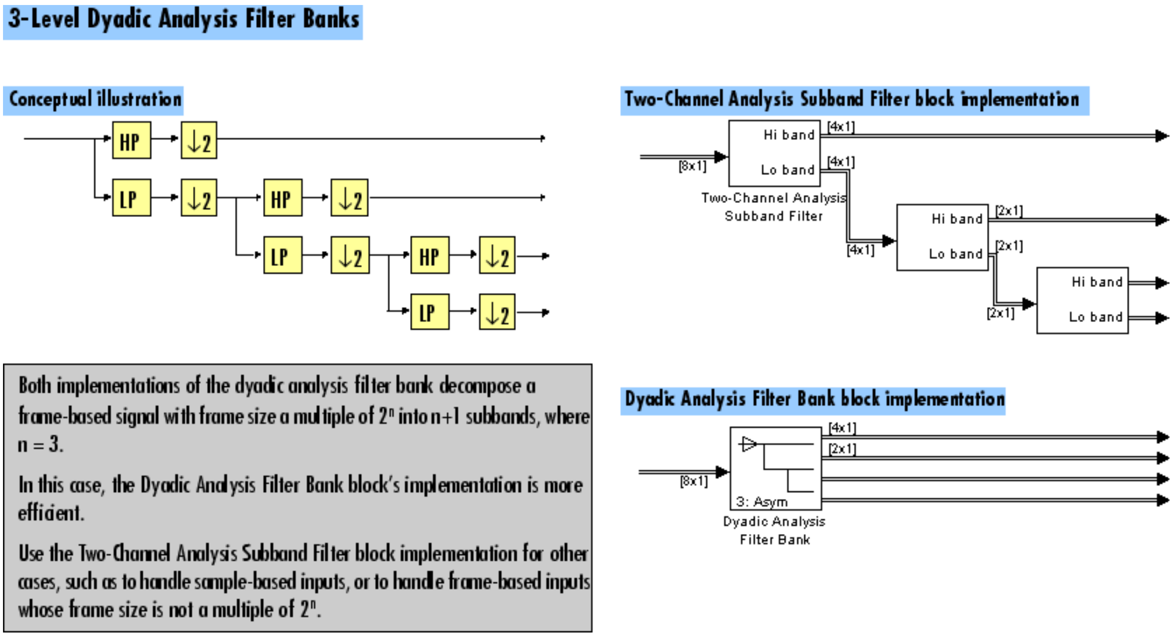
The Two-Channel Analysis Subband Filter block is the basic unit of a dyadic analysis filter bank. You can connect several of these blocks to implement an n-level filter bank, as illustrated in the following figure. For a review of dyadic analysis filter banks, see the `Dyadic Analysis Filter Bank` block reference page.

When you create a filter bank by connecting multiple copies of this block, the output values of the filter bank differ depending on whether there is latency. Though the output values differ, both sets of values are valid; the difference arises from changes in latency. See the "Latency" on page 2-1763 section for more information about when latency can occur in the Two-Channel Analysis Subband Filter block.

In some cases, rather than connecting several Two-Channel Analysis Subband Filter blocks, you can use the `Dyadic Analysis Filter Bank` block, which is faster and requires less memory. In particular, the Dyadic Analysis Filter Bank block is more efficient under the following conditions:

- The frame size of the signal you are decomposing is a multiple of 2^n.
- You are decomposing the signal into n+1 or 2^n subbands.

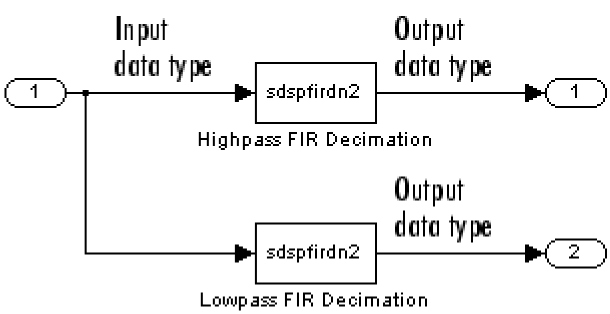
In all other cases, use Two-Channel Analysis Subband Filter blocks to implement your filter banks.



The `Dyadic Analysis Filter Bank` block allows you to specify the filter bank filters by providing vectors of filter coefficients, just as this block does. The Dyadic Analysis Filter Bank block provides an additional option of using wavelet-based filters that the block designs by using a wavelet you specify.

Fixed-Point Data Types

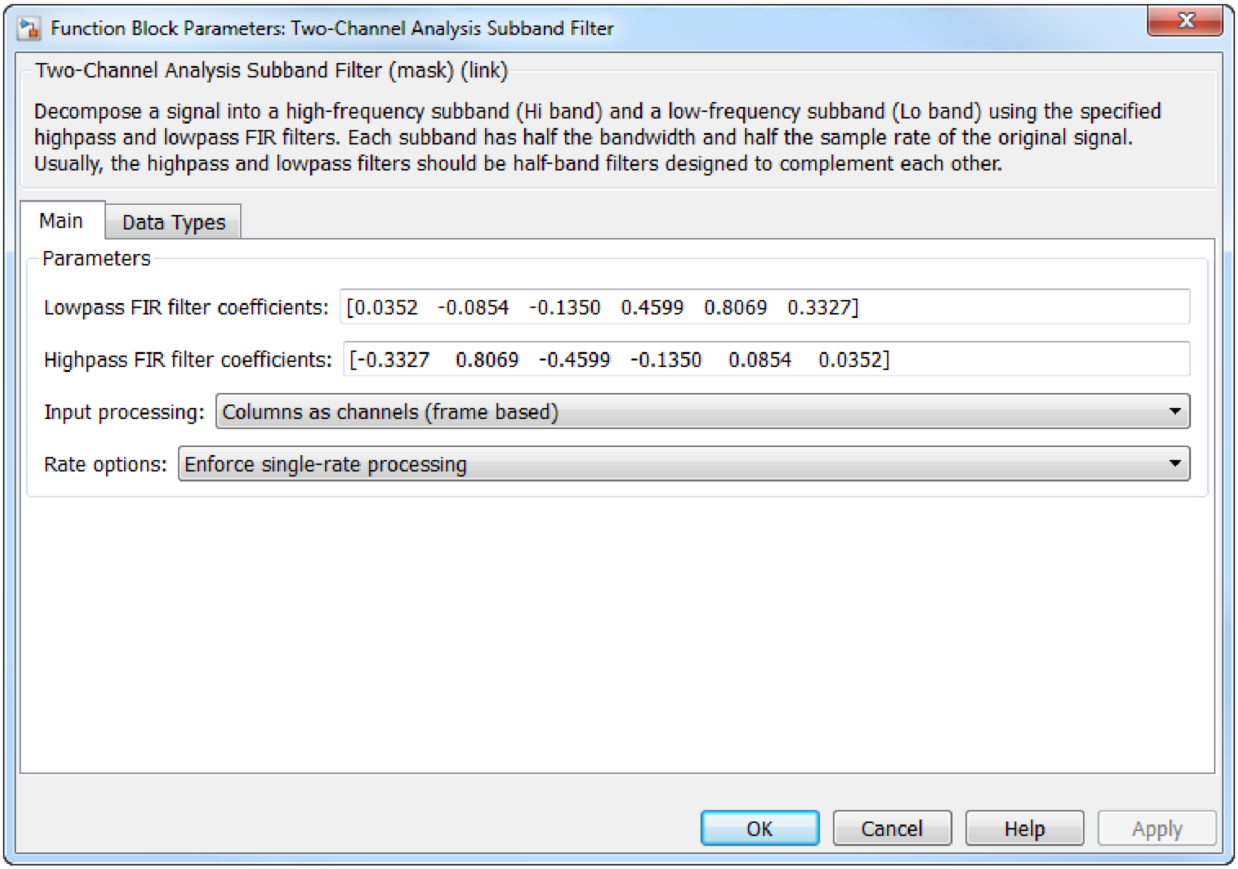
The Two-Channel Analysis Subband Filter Bank block is composed of two FIR Decimation blocks as shown in the following diagram.



For fixed-point signals, you can set the coefficient, product output, accumulator, and output data types of the FIR Decimation blocks as discussed in "Dialog Box" on page 2-1766. For a diagram showing the usage of these data types, see the `FIR Decimation` block reference page.

Dialog Box

The **Main** pane of the Two-Channel Analysis Subband Filter block dialog appears as follows.



Lowpass FIR filter coefficients

Specify a vector of lowpass FIR filter coefficients, in descending powers of *z*. The lowpass filter should be a half-band filter that passes the frequency band stopped by the filter specified in the **Highpass FIR filter coefficients** parameter. The default values of this parameter specify a filter based on a third-order Daubechies wavelet. When you use the `Two-Channel Synthesis Subband Filter` block to reconstruct the input to this block, you need to design perfect reconstruction filters to use in the synthesis subband filter. For more information, see "Specifying the FIR Filters" on page 2-1762.

Highpass FIR filter coefficients

Specify a vector of highpass FIR filter coefficients, in descending powers of *z*. The highpass filter should be a half-band filter that passes the frequency band stopped by the filter specified in the **Lowpass FIR filter coefficients** parameter. The default values of this parameter specify a filter based on a third-order Daubechies wavelet. When you use the `Two-Channel Synthesis Subband Filter` block to reconstruct the input to this block, you need to design perfect reconstruction filters to use in the synthesis subband filter. For more information, see "Specifying the FIR Filters" on page 2-1762.

Input processing

Specify how the block should process the input. You can set this parameter to one of the following options:

- `Columns as channels (frame based)` (default) — When you select this option, the block treats each column of the input as a separate channel.
- `Elements as channels (sample based)` — When you select this option, the block treats each element of the input as a separate channel.

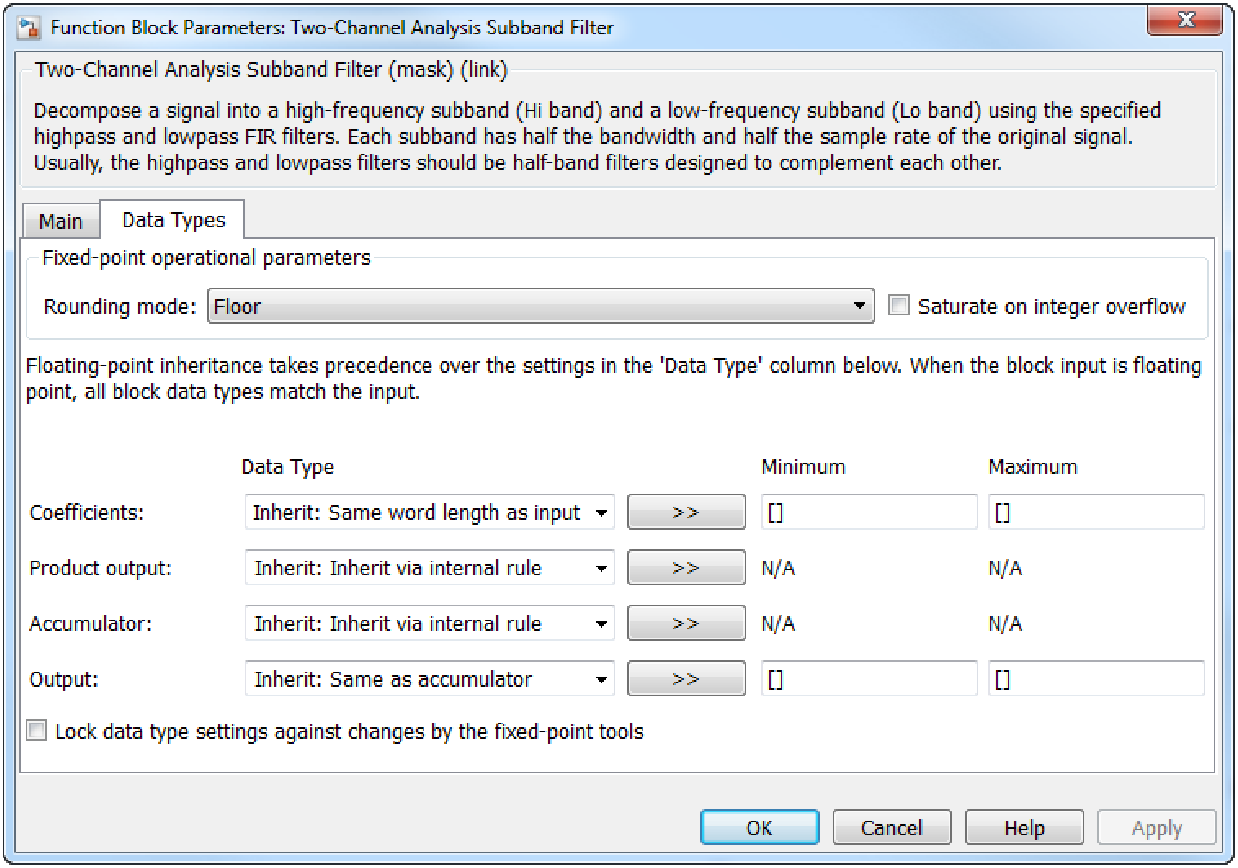
Rate options

Specify the rate processing rule for the block. You can set this parameter to one of the following options:

- `Enforce single-rate processing` — When you select this option, the block treats each column of the input as an independent channel and decomposes each channel over time. The output has the same sample rate as the input, but the output frame size is half that of the input frame size. To select this option, you must set the **Input processing** parameter to `Columns as channels (frame based)`.
- `Allow multirate processing` — When you select this option, the input and output of the block are the same size, but the sample rate of the output is half that of the input.

Some settings of this parameter cause the block to have nonzero latency. See “Latency” on page 2-1763 for more information.

The **Data Types** pane of the Two-Channel Analysis Subband Filter block dialog appears as follows.



Rounding mode

Select the rounding mode for fixed-point operations. The filter coefficients do not obey this parameter; they are always rounded to `Nearest`.

Note: The **Rounding mode** and **Saturate on integer overflow** settings have no effect on numerical results when all the following conditions exist:

- **Product output data type** is `Inherit: Inherit via internal rule`
- **Accumulator data type** is `Inherit: Inherit via internal rule`
- **Output data type** is `Inherit: Same as accumulator`

With these data type settings, the block is effectively operating in full precision mode.

Saturate on integer overflow

When you select this check box, the block saturates the result of its fixed-point operation. When you clear this check box, the block wraps the result of its fixed-point operation. By default, this check box is cleared. For details on `saturate` and `wrap`, see overflow mode for fixed-point operations. The filter coefficients do not obey this parameter; they are always saturated.

Coefficients data type

Specify the coefficients data type. See "Fixed-Point Data Types" on page 2-1765 and "Multiplication Data Types" for illustrations depicting the use of the coefficients data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same word length as input`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Coefficients data type** parameter.

See "Specify Data Types Using Data Type Assistant" (Simulink) in Simulink User's Guide (Simulink) for more information.

Coefficients Minimum

Specify the minimum value of the filter coefficients. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Automatic scaling of fixed-point data types

Coefficients Maximum

Specify the maximum value of the filter coefficients. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Automatic scaling of fixed-point data types

Product output data type

Specify the product output data type. See “Fixed-Point Data Types” on page 2-1765 and “Multiplication Data Types” for illustrations depicting the use of the product output data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`. For more information on this rule, see “Inherit via Internal Rule”.

Note The actual product output word length may be equal to or greater than the calculated ideal product output word length, depending on the settings on the **Hardware Implementation** pane of the Configuration Parameters dialog box.

- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button 

to display the **Data Type Assistant**, which helps you set the **Product output data type** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in Simulink User's Guide (Simulink) for more information.

Accumulator data type

Specify the accumulator data type. See “Fixed-Point Data Types” on page 2-1765 for illustrations depicting the use of the accumulator data type in this block. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`. For more information on this rule, see “Inherit via Internal Rule”.
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button 

to display the **Data Type Assistant**, which helps you set the **Accumulator data type** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in Simulink User's Guide (Simulink) for more information.

Output data type

Specify the output data type. See “Fixed-Point Data Types” on page 2-1765 for illustrations depicting the use of the output data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as accumulator`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Output data type** parameter.

See “Control Signal Data Types” (Simulink) in Simulink User's Guide (Simulink) for more information.

Output Minimum

Specify the minimum value that the block should output. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

Output Maximum

Specify the maximum value that the block should output. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

Lock data type settings against changes by the fixed-point tools

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block mask.

Supported Data Types

- Double-precision floating point
- Single-precision floating point
- Fixed point (signed only)
- 8-, 16-, and 32-bit signed integers

Two-Channel Synthesis Subband Filter

Reconstruct signal from high-frequency and low-frequency subbands

Library

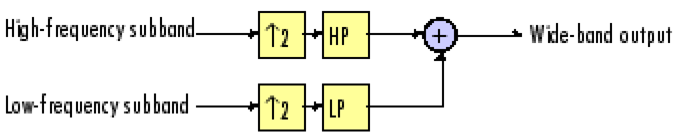
Filtering / Multirate Filters

`dspmlti4`

Description

The Two-Channel Synthesis Subband Filter block reconstructs a signal from its high-frequency and low-frequency subbands, each with half the bandwidth and half the sample rate of the original signal. Use this block to reconstruct signals decomposed by the `Two-Channel Analysis Subband Filter` block.

The block upsamples the high- and low-frequency subbands by 2, and then filters the results with a pair of highpass and lowpass FIR filters, as illustrated in the following figure.



The block implements the FIR filtering and downsampling steps together using a polyphase filter structure, which is more efficient than the straightforward interpolate-then-filter algorithm shown in the preceding figure. You can implement a multilevel dyadic synthesis filter bank by connecting multiple copies of this block or by using the `Dyadic Synthesis Filter Bank` block. For more information, see “Creating Multilevel Dyadic Synthesis Filter Banks” on page 2-1776.

You must provide a vector of filter coefficients for the lowpass and highpass FIR filters. Each filter should be a half-band filter that passes the frequency band that the other filter stops. You can use this block to reconstruct the output of a `Two-Channel Analysis Subband Filter` block. To do so, you must design the filters in this block such that they perfectly reconstruct the outputs of the analysis filters.

See the following topics for more information about this block:

- "Specifying the FIR Filters" on page 2-1774
- "Frame-Based Processing" on page 2-1774
- "Sample-Based Processing" on page 2-1775
- "Latency" on page 2-1776
- "Creating Multilevel Dyadic Synthesis Filter Banks" on page 2-1776

Specifying the FIR Filters

You must provide the vector of numerator coefficients for the lowpass and highpass filters in the **Lowpass FIR filter coefficients** and **Highpass FIR filter coefficients** parameters.

For example, to specify a filter with the following transfer function, enter the vector `[b(1) b(2) ... b(m)]`.

$$H(z) = B(z) = b_1 + b_2 z^{-1} + \ldots + b_m z^{-(m-1)}$$

Each filter should be a half-band filter that passes the frequency band that the other filter stops. You can use this block to reconstruct the output of a `Two-Channel Analysis Subband Filter` block. To do so, you must design the filters in this block such that they perfectly reconstruct the outputs of the analysis filters.

The best way to design perfect reconstruction filters is to use the Wavelet Toolbox `wfilters` function for the filters in both this block *and* in the corresponding Two-Channel Analysis Subband Filter block. You can also use DSP System Toolbox and Signal Processing Toolbox functions.

The Two-Channel Synthesis Subband Filter block initializes all filter states to zero.

Frame-Based Processing

When you set the **Input processing** parameter to `Columns as channels (frame based)`, the block accepts any two M-by-N matrices with the same frame rates. The block treats each column of the input as the high- or low-frequency subbands of the corresponding output channel. You can use the **Rate options** parameter to specify how the block resamples the input:

- When you set the **Rate options** parameter to `Enforce single-rate processing`, the input to the block can be any two *M*-by-*N* matrices with the same frame rate. The block treats each input column as the high- or low-frequency subbands of the corresponding output channel. The input to the topmost input port should contain the high-frequency subbands. The block outputs one matrix, where each column is reconstructed from the corresponding columns of each input matrix. The input and output frame *rates* are the same, but the frame *size* of the output is twice that of the input.
- When you set the **Rate options** parameter to `Allow multirate processing`, the block treats each column of the input as the high- or low-frequency subbands of the corresponding output channel. The input to the topmost input port should contain the high-frequency subbands. The block outputs one matrix, where each column is reconstructed from the corresponding columns of the input matrices. The input and output frame *sizes* are the same, but the frame *rate* of the output is twice that of the input. Thus, the overall sample rate of the output is twice that of the input sample rate.

  In this mode, the block has one frame of latency, as described in the "Latency" on page 2-1776 section.

Sample-Based Processing

When you set the **Input processing** parameter to `Elements as channels (sample based)`, the block accepts any two *M*-by-*N* matrices with the same sample rates. The block treats each *M*-by-*N* matrix as $M \cdot N$ independent subbands. Each element of the input matrices is the high- or low-frequency subband of the corresponding channel in the output matrix. The input to the topmost input port should contain the high-frequency subbands. The block outputs one matrix with the same dimensions as the input matrices, but a sample rate that is twice that of the input. The block reconstructs each element of the output from the corresponding elements in the input matrices.

Depending on the setting of your Simulink configuration parameters, the output may have one sample of latency, as described in the "Latency" on page 2-1776 section.

Latency

When you set the **Input processing** parameter to `Columns as channels (frame based)` and the **Rate options** parameter to `Enforce single-rate processing`, the Two-Channel Synthesis Subband Filter block always has zero-tasking latency. *Zero-tasking latency* means that the block propagates the first input sample (received at time t= 0) as the first output sample.

When you set the **Rate options** parameter to `Allow multirate processing`, the Two-Channel Synthesis Subband Filter block may exhibit latency. The amount of latency depends on the setting of the **Input processing** parameter of this block and the setting of the Simulink **Treat each discrete rate as a separate task** configuration parameter. The following table summarizes the conditions that produce latency when the block is performing multirate processing.

Input processing	Treat each discrete rate as a separate task	Latency
`Elements as channels (sample based)`	`Off`	None.
	`On`	One sample. The first output sample in each channel always has a value of `0`.
`Columns as channels (frame based)`	`Off` or `On`	One frame. All samples in the first output frame have a value of `0`.

Note: For more information on latency and the Simulink tasking modes, see "Excess Algorithmic Delay (Tasking Latency)" and "Time-Based Scheduling and Code Generation" (Simulink Coder).

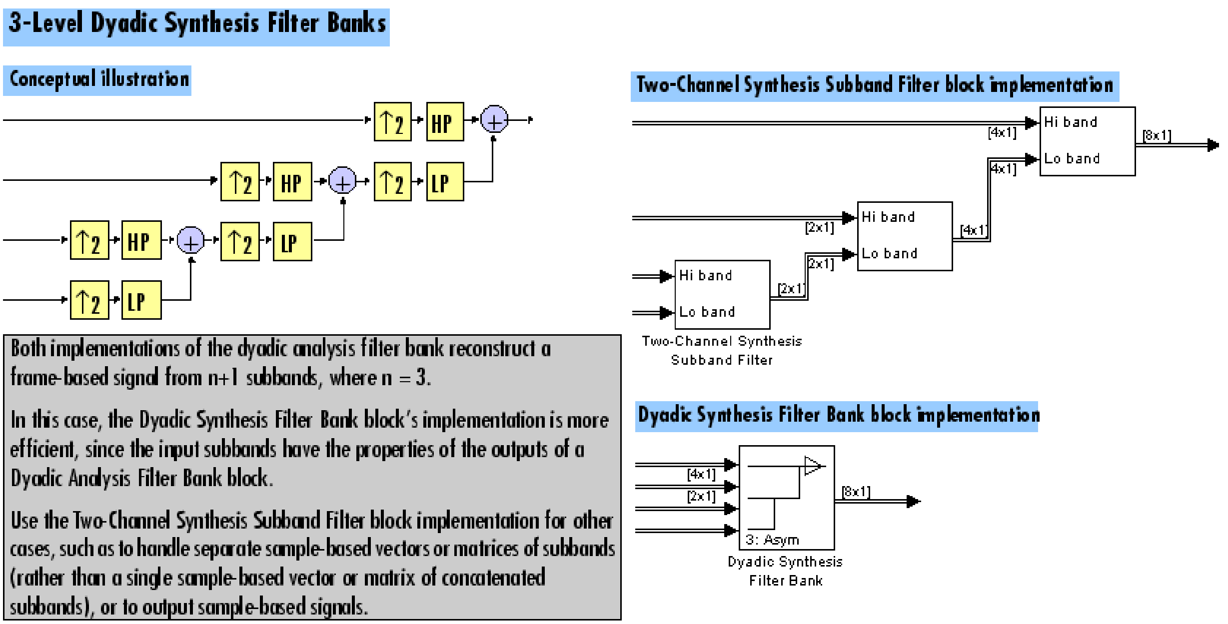
Creating Multilevel Dyadic Synthesis Filter Banks

The Two-Channel Synthesis Subband Filter block is the basic unit of a dyadic synthesis filter bank. You can connect several of these blocks to implement an n-level filter bank, as illustrated in the following figure. For a review of dyadic synthesis filter banks, see the `Dyadic Synthesis Filter Bank` block reference page.

When you create a filter bank by connecting multiple copies of this block, the output values of the filter bank differ depending on whether there is latency. Though the output values differ, both sets of values are valid; the difference arises from changes in latency. See the “Latency” on page 2-1776 section for more information about when latency can occur in the Two-Channel Analysis Subband Filter block.

In some cases, rather than connecting several Two-Channel Analysis Subband Filter blocks, you can use the `Dyadic Analysis Filter Bank` block, which is faster and requires less memory. In particular, the Dyadic Analysis Filter Bank block is more efficient under the following conditions:

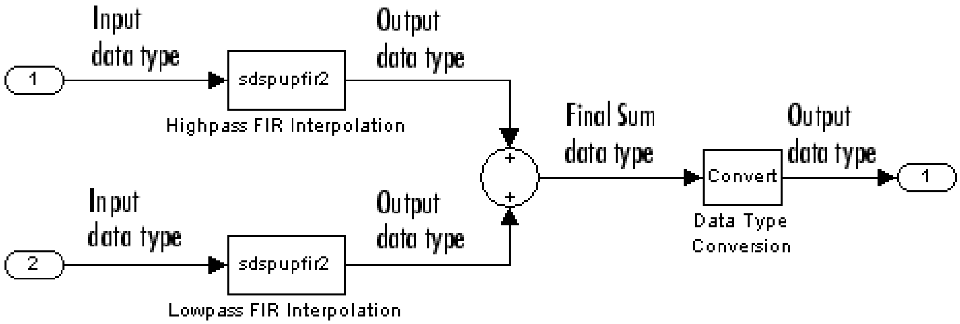
- You are reconstructing a signal from 2^n or $n+1$ subbands.
- The frame size of the signal you are reconstructing is a multiple of 2^n.
- The properties of the subbands you are working with match those of the outputs of the Dyadic Analysis Filter Bank block. These properties are described in the `Dyadic Analysis Filter Bank` reference page.



The `Dyadic Synthesis Filter Bank` block allows you to specify the filter bank filters by providing vectors of filter coefficients, just as this block does. The Dyadic Synthesis Filter Bank block provides an additional option of using wavelet-based filters that the block designs by using a wavelet you specify.

Fixed-Point Data Types

The Two-Channel Synthesis Subband Filter block is composed of two FIR Interpolation blocks as shown in the following diagram.

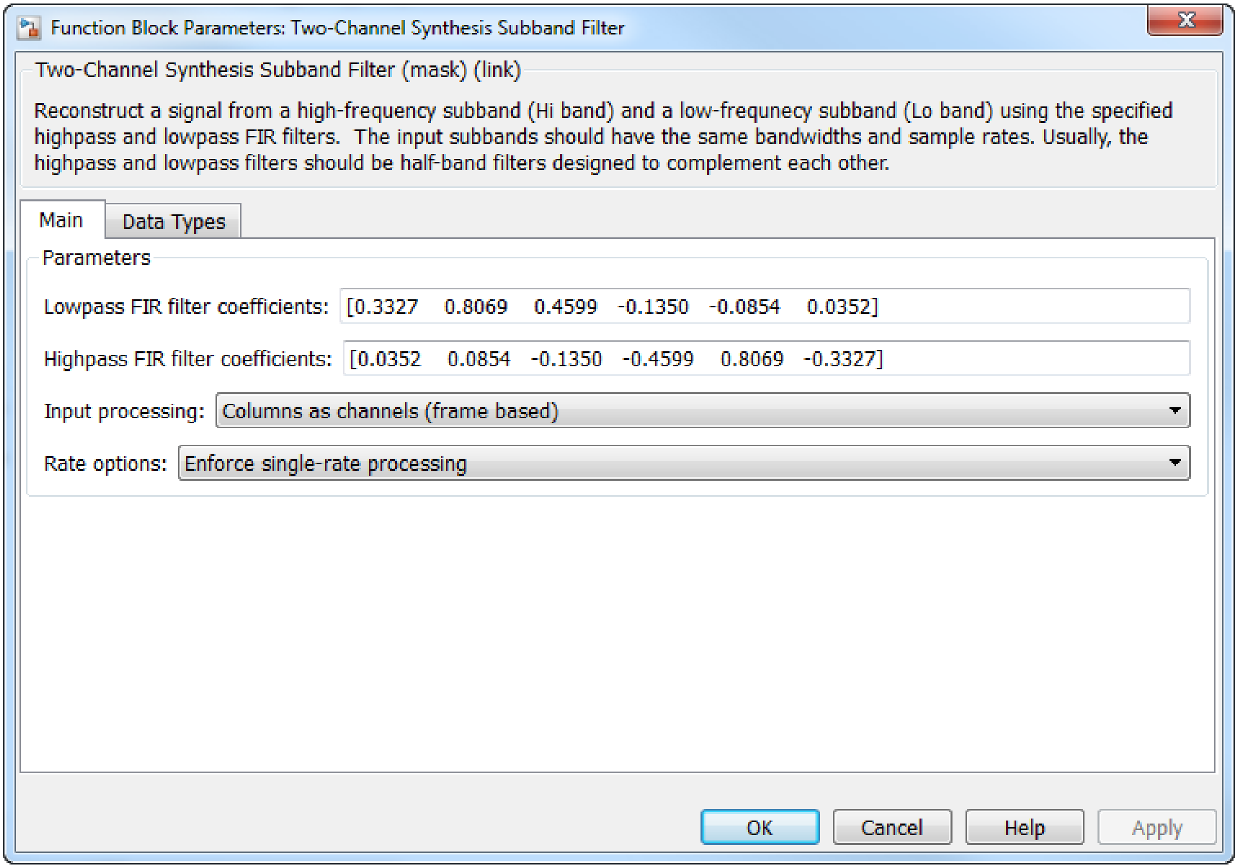


For fixed-point signals, you can set the coefficient, product output, accumulator, and output data types used in the FIR Interpolation blocks as discussed in "Dialog Box" on page 2-1778. For a diagram showing the usage of these data types within the FIR blocks, see the `FIR Interpolation` block reference page.

In addition, the inputs to the Sum block shown in the previous diagram are accumulated using the accumulator data type. The output of the Sum block is then cast from the accumulator data type to the output data type. Therefore the output of the Two-Channel Synthesis Subband Filter block is in the output data type. You also set these data types in the block dialog box as discussed in the "Dialog Box" on page 2-1778 section.

Dialog Box

The **Main** pane of the Two-Channel Synthesis Subband Filter block dialog appears as follows.



Lowpass FIR filter coefficients

A vector of lowpass FIR filter coefficients, in descending powers of z. The lowpass filter should be a half-band filter that passes the frequency band stopped by the filter specified in the **Highpass FIR filter coefficients** parameter. To use this block to reconstruct the output of a `Two-Channel Analysis Subband Filter` block, you must design the filters in this block to perfectly reconstruct the outputs of the analysis filters. For more information, see "Specifying the FIR Filters" on page 2-1774.

Highpass FIR filter coefficients

A vector of highpass FIR filter coefficients, in descending powers of z. The highpass filter should be a half-band filter that passes the frequency band stopped by the filter specified in the **Lowpass FIR filter coefficients** parameter. To use this block to reconstruct the output of a `Two-Channel Analysis Subband Filter` block, you must design the filters in this block to perfectly reconstruct the outputs of the analysis filters. For more information, see "Specifying the FIR Filters" on page 2-1774.

Input processing

Specify how the block should process the input. You can set this parameter to one of the following options:

- `Columns as channels (frame based)` (default) — When you select this option, the block treats each column of the input as a separate channel.
- `Elements as channels (sample based)` — When you select this option, the block treats each element of the input as a separate channel.

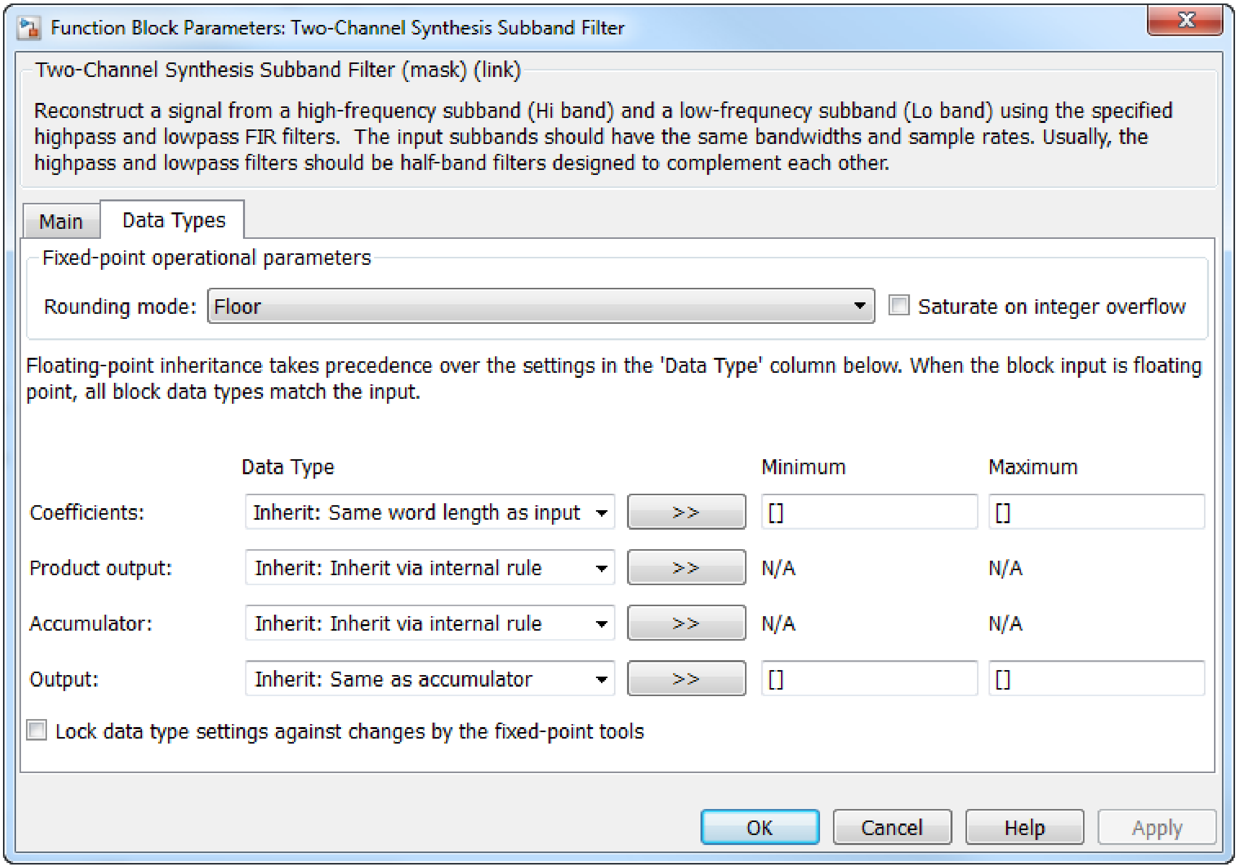
Rate options

Specify the rate processing rule for the block. You can set this parameter to one of the following options:

- `Enforce single-rate processing` — When you select this option, the block treats each column of the input as an independent channel and reconstructs each channel over time. The output has the same sample rate as the input, but the output frame size is twice that of the input frame size. To select this option, you must set the **Input processing** parameter to `Columns as channels (frame based)`.
- `Allow multirate processing` — When you select this option, the input and output of the block are the same size, but the sample rate of the output is twice that of the input.

Some settings of this parameter cause the block to have nonzero latency. See "Latency" on page 2-1776 for more information.

The **Data Types** pane of the Two-Channel Synthesis Subband Filter block dialog appears as follows.



Rounding mode

Select the rounding mode for fixed-point operations. The filter coefficients do not obey this parameter; they always round to `Nearest`.

Note: The **Rounding mode** and **Saturate on integer overflow** settings have no effect on numerical results when all the following conditions exist:

- **Product output data type** is `Inherit: Inherit via internal rule`
- **Accumulator data type** is `Inherit: Inherit via internal rule`
- **Output data type** is `Inherit: Same as accumulator`

With these data type settings, the block is effectively operating in full precision mode.

Saturate on integer overflow

When you select this check box, the block saturates the result of its fixed-point operation. When you clear this check box, the block wraps the result of its fixed-point operation. By default, this check box is cleared. For details on `saturate` and `wrap`, see overflow mode for fixed-point operations. The filter coefficients do not obey this parameter; they are always saturated.

Coefficients data type

Specify the coefficients data type. See “Fixed-Point Data Types” on page 2-1778 and “Multiplication Data Types” for illustrations depicting the use of the coefficients data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same word length as input`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Coefficients data type** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in Simulink User's Guide (Simulink) for more information.

Coefficients Minimum

Specify the minimum value of the filter coefficients. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Automatic scaling of fixed-point data types

Coefficients Maximum

Specify the maximum value of the filter coefficients. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Automatic scaling of fixed-point data types

Product output data type

Specify the product output data type. See “Fixed-Point Data Types” on page 2-1778 and “Multiplication Data Types” for illustrations depicting the use of the product output data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`. For more information on this rule, see “Inherit via Internal Rule”.

Note The actual product output word length may be equal to or greater than the calculated ideal product output word length, depending on the settings on the **Hardware Implementation** pane of the Configuration Parameters dialog box.

- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Product output data type** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in Simulink User's Guide (Simulink) for more information.

Accumulator data type

Specify the accumulator data type. See “Fixed-Point Data Types” on page 2-1778 for illustrations depicting the use of the accumulator data type in this block. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`. For more information on this rule, see “Inherit via Internal Rule”.
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Accumulator data type** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in Simulink User's Guide (Simulink) for more information.

Output data type

Specify the output data type. See “Fixed-Point Data Types” on page 2-1778 for illustrations depicting the use of the output data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as accumulator`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button to display the **Data Type Assistant**, which helps you set the **Output data type** parameter.

See “Control Signal Data Types” (Simulink) in Simulink User's Guide (Simulink) for more information.

Output Minimum

Specify the minimum value that the block should output. The default value is [ ] (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

Output Maximum

Specify the maximum value that the block should output. The default value is [ ] (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

Lock data type settings against changes by the fixed-point tools

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block mask.

Supported Data Types

- Double-precision floating point
- Single-precision floating point
- Fixed point (signed only)
- 8-, 16-, and 32-bit signed integers

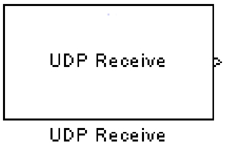
UDP Receive

Receive `uint8` vector as UDP message



Library

Sources

`dspsrcs4`

Description

The UDP Receive block receives UDP packets from an IP network port and saves them to its buffer. With each sample, the block outputs the contents of a single UDP packet as a data vector. The local IP port number on which the block receives the UDP packets is tunable in the C/C++ generated code.

The generated code for this block relies on prebuilt `.dll` files. You can run this code outside the MATLAB environment, or redeploy it, but you must account for these extra `.dll` files when doing so. The `packNGo` function creates a single zip file containing all of the pieces required to run or rebuild this code. For more details, see "How To Run a Generated Executable Outside MATLAB".

Parameters

Local IP port

Specify the IP port number on which to receive UDP packets. This parameter is tunable in the C/C++ generated code but not tunable during simulation. The default is `25000`. The value can be in the range [1 65535].

Note: On Linux, to set the IP port number below 1024, run MATLAB with root privileges. For example, at the Linux command line, enter:

```
sudo matlab
```

Remote IP address ('0.0.0.0' to accept all)

Specify the IP address from which to accept packets. Entering a specific IP address blocks UDP packets from other addresses. To accept packets from any IP address, enter `'0.0.0.0'`. This value defaults to `'0.0.0.0'`.

Receive buffer size (bytes)

Make the receive buffer large enough to avoid data loss caused by buffer overflows. This value defaults to `8192`.

Maximum length for Message

Specify the maximum length, in vector elements, of the data output vector. Set this parameter to a value equal or greater than the data size of a UDP packet. The system truncates data that exceeds this length. This value defaults to `255`.

If you disable **Output variable-size signal**, the block outputs a fixed-length output the same length as the **Maximum length for Message**.

Data type for Message

Set the data type of the vector elements in the Message output. Match the data type with the data input used to create the UDP packets. This option defaults to `uint8`.

Output variable-size signal

If your model supports signals of varying length, enable the **Output variable-size signal** parameter. This checkbox defaults to selected (enabled). In that case:

- The output vector varies in length, depending on the amount of data in the UDP packet.
- The block emits the data vector from a single unlabeled output.

If your model does not support signals of varying length, disable the **Output variable-size signal** parameter. In that case:

- The block emits a fixed-length output the same length as the **Maximum length for Message**.
- If the UDP packet contains less data than the fixed-length output, the difference contains invalid data.

- The block emits the data vector from the **Message** output.
- The block emits the length of the valid data from the **Length** output.
- The block dialog box displays the **Data type for Length** parameter.

In both cases, the block truncates data that exceeds the **Maximum length for Message**.

Data type for Length

Set the data type of the Length output. This option defaults to `double`.

Blocking time (seconds)

For each sample, wait this length of time for a UDP packet before returning control to the scheduler. This value defaults to `inf`, which indicates to wait indefinitely.

Note: This parameter appears only in the Embedded Coder® UDP Receive block.

Sample time (seconds)

Specify how often the scheduler runs this block. Enter a value greater than zero. In real-time operation, setting this option to a large value reduces the likelihood of dropped UDP messages. This value defaults to a sample time of 0.01 s.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Usage notes and limitations:

- The executable generated from this block relies on prebuilt dynamic library files (`.dll` files) included with MATLAB. Use the `packNGo` function to package the code generated from this block and all the relevant files in a compressed zip file. Using this zip file, you can relocate, unpack, and rebuild your project in another development environment where MATLAB is not installed. For more details, see “How To Run a Generated Executable Outside MATLAB”.
- The **Local IP port** parameter is tunable in the generated code, but not tunable during simulation. You can control the parameter tunability in the generated code

through several ways. One of the ways is to configure the parameter as a tunable field of a global structure in the generated code. Other ways include applying a built-in storage class or custom storage class to a `Simulink.Parameter` object and using this object to set the value of the block parameter. For details, see “Block Parameter Representation in the Generated Code” (Simulink Coder).

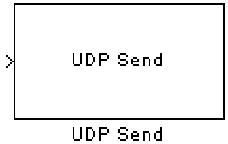
Blocks
`UDP Send`

Introduced in R2010a

UDP Send

Send UDP message



Library

Sinks

`dspsnks4`

Description

The UDP Send block transmits an input vector as a UDP message over an IP network port. The remote IP port number to which the block sends the UDP packets is tunable in the C/C++ generated code.

Note: Some Simulink blocks and `.exe` files built from models that contain those blocks require shared libraries, such as `.dll` files on Windows. The UDP Send block requires the `networkdevice.dll` library file. To meet this requirement, follow the example on the `packNGo` function page to package the code files for your model. The resulting compressed folder contains the `.dll` files that the model requires, including `networkdevice.dll`. To run this type of `.exe` file outside a MATLAB environment, place the required `.dll` files in the same folder as the `.exe` file, or place them in a folder on the Windows system path. For more details, see “How To Run a Generated Executable Outside MATLAB”.

Parameters

IP address ('255.255.255.255' for broadcast)

Specify the IP address or hostname to which the block sends the message. To broadcast the UDP message, retain the default value, `'255.255.255.255'`.

Remote IP port

Specify the port to which the block sends the message. This parameter is tunable in the C/C++ generated code but not tunable during simulation. The default is `25000`. The value can be in the range [1 65535].

Note: On Linux, to set the IP port number below 1024, run MATLAB with root privileges. For example, at the Linux command line, enter:

```
sudo matlab
```

Local IP port source

To let the system automatically assign the port number, select `Assign automatically`. To specify the IP port number using the **Local IP port** parameter, select `Specify`.

Local IP port

Specify the IP port number from which the block sends the message.

If the receiving address expects messages from a particular port number, enter that number here.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Usage notes and limitations:

- The executable generated from this block relies on prebuilt dynamic library files (`.dll` files) included with MATLAB. Use the `packNGo` function to package the code generated from this block and all the relevant files in a compressed zip file. Using this zip file, you can relocate, unpack, and rebuild your project in another development environment where MATLAB is not installed. For more details, see "How To Run a Generated Executable Outside MATLAB".

- The **Remote IP port** parameter is tunable in the generated code, but not tunable during simulation. You can control the parameter tunability in the generated code through several ways. One of the ways is to configure the parameter as a tunable field of a global structure in the generated code. Other ways include applying a built-in storage class or custom storage class to a `Simulink.Parameter` object and using this object to set the value of the block parameter. Blocks
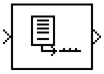
`UDP Receive`

Introduced in R2010a

Unbuffer

Unbuffer input frame into sequence of scalar outputs



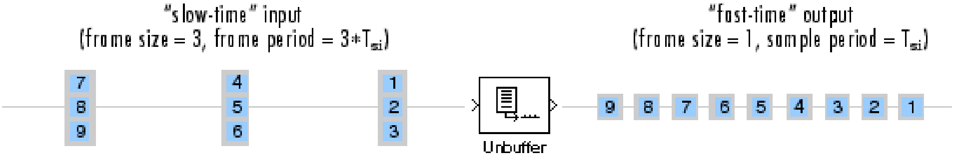
Library

Signal Management / Buffers

`dspbuff3`

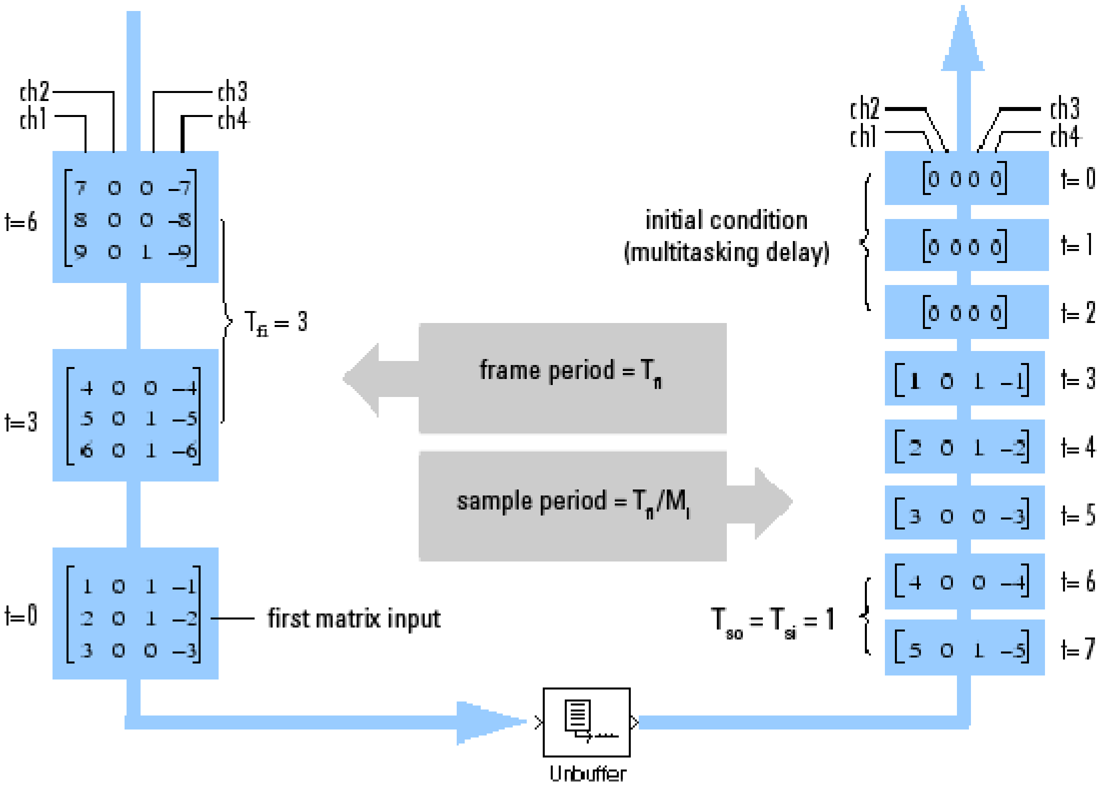
Description

The Unbuffer block unbuffers an M_i-by-N input into a 1-by-N output. That is, inputs are unbuffered *row-wise* so that each matrix row becomes an independent time-sample in the output. The rate at which the block receives inputs is generally less than the rate at which the block produces outputs.



The block adjusts the output rate so that the *sample period* is the same at both the input and output, $T_{so}=T_{si}$. Therefore, the output sample period for an input of frame size M_i and frame period T_{fi} is T_{fi}/M_i, which represents a *rate* M_i times higher than the input frame rate. In the example above, the block receives inputs only once every three sample periods, but produces an output once every sample period. To rebuffer inputs to a larger or smaller frame size, use the `Buffer` block.

In the model below, the block unbuffers a four-channel input with a frame size of three. The **Initial conditions** parameter is set to zero and the tasking mode is set to multitasking, so the first three outputs are zero vectors.



Zero Latency

The Unbuffer block has *zero-tasking latency* in Simulink single-tasking mode. Zero-tasking latency means that the first input sample (received at t=0) appears as the first output sample.

Nonzero Latency

For *multitasking* operation, the Unbuffer block's buffer is initialized with the value specified by the **Initial conditions** parameter, and the block begins unbuffering this frame at the start of the simulation. Inputs to the block are therefore delayed by one buffer length, or M_i samples.

The **Initial conditions** parameter can be one of the following:

- A scalar to be repeated for the first M_i output samples of every channel
- A length-M_i vector containing the values of the first M_i output samples for every channel
- An M_i-by-N matrix containing the values of the first M_i output samples in each of N channels

Note For more information on latency and the Simulink tasking modes, see “Excess Algorithmic Delay (Tasking Latency)” and “Time-Based Scheduling and Code Generation” (Simulink Coder).

Parameters

Initial conditions

The value of the block's initial output for cases of nonzero latency. You can specify a scalar, vector, or matrix.

Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers
Output	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers

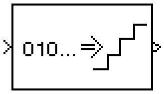
Uniform Decoder

Decode integer input into floating-point output



Library

Quantizers

`dspquant2`

Description

The Uniform Decoder block performs the inverse operation of the Uniform Encoder block, and reconstructs quantized floating-point values from encoded integer input. The block adheres to the definition for uniform decoding specified in ITU-T Recommendation G.701.

Inputs can be real or complex values of the following six integer data types: `uint8`, `uint16`, `uint32`, `int8`, `int16`, or `int32`.

The block first casts the integer input values to floating-point values, and then uniquely maps (decodes) them to one of 2^B uniformly spaced floating-point values in the range [-V, $(1-2^{1-B})$V], where you specify B in the **Bits** parameter (as an integer between 2 and 32) and V is a floating-point value specified by the **Peak** parameter. The smallest input value representable by B bits (0 for an unsigned input data type; -2^{B-1} for a signed input data type) is mapped to the value -V. The largest input value representable by B bits (2^B-1 for an unsigned input data type; 2^{B-1}-1 for a signed input data type) is mapped to the value $(1-2^{1-B})$V. Intermediate input values are linearly mapped to the intermediate values in the range [-V, $(1-2^{1-B})$V].

To correctly decode values encoded by the Uniform Encoder block, the **Bits** and **Peak** parameters of the Uniform Decoder block should be set to the same values as the **Bits** and **Peak** parameters of the Uniform Encoder block. The **Overflow mode** parameter specifies the Uniform Decoder block's behavior when the integer input is outside the range representable by B bits. When you select **Saturate**, *unsigned* input values greater than 2^B-1 saturate at 2^B-1; *signed* input values greater than 2^{B-1}-1 or less than -2^{B-1} saturate at those limits. The real and imaginary components of complex inputs saturate independently.

When you select **Wrap**, *unsigned* input values, `u`, greater than 2^B-1 are wrapped back into the range [0, 2^B-1] using mod-2^B arithmetic.

```
u = mod(u,2^B)
```

Signed input values, `u`, greater than 2^{B-1}-1 or less than -2^{B-1} are wrapped back into that range using mod-2^B arithmetic.

```
u = (mod(u+2^B/2,2^B)-(2^B/2))
```

The real and imaginary components of complex inputs wrap independently.

The **Output type** parameter specifies whether the decoded floating-point output is single or double precision. Either level of output precision can be used with any of the six integer input data types.

Examples

See example model ex_uniform_decoder.

In this example, the input to the block is the `uint8` output of a Uniform Encoder block. This block has comparable settings: **Peak** = `2`, **Bits** = `3`, and **Output type** = `Unsigned`. (Comparable settings ensure that inputs to the Uniform Decoder block do not saturate or wrap. See the example on the Uniform Encoder block reference page for more about these settings.)

The real and complex components of each input are independently mapped to one of 2^3 distinct levels in the range `[-2.0,1.5]`.

```
0  is mapped to  -2.0
1  is mapped to  -1.5
2  is mapped to  -1.0
3  is mapped to  -0.5
4  is mapped to   0.0
5  is mapped to   0.5
```

```
6  is mapped to   1.0
7  is mapped to   1.5
```

Parameters

Peak

Specify the largest amplitude represented in the encoded input. To correctly decode values encoded with the Uniform Encoder block, set the **Peak** parameters in both blocks to the same value.

Bits

Specify the number of input bits, B, used to encode the data. (This can be less than the total number of bits supplied by the input data type.) To correctly decode values encoded with the Uniform Encoder block, set the **Bits** parameters in both blocks to the same value.

Overflow mode

Specify the block's behavior when the integer input is outside the range representable by B bits. Out-of-range inputs can either saturate at the extreme value, or wrap back into range.

Output type

Specify the precision of the floating-point output, `single` or `double`.

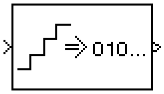
Uniform Encoder

Quantize and encode floating-point input into integer output



Library

Quantizers

`dspquant2`

Description

The Uniform Encoder block performs the following two operations on each floating-point sample in the input vector or matrix:

1. Quantizes the value using the same precision
2. Encodes the quantized floating-point value to an integer value

In the first step, the block quantizes an input value to one of 2^B uniformly spaced levels in the range $[-V, (1-2^{1-B})V]$, where you specify B in the **Bits** parameter and you specify V in the **Peak** parameter. The quantization process rounds both positive and negative inputs *downward* to the nearest quantization level, with the exception of those that fall exactly on a quantization boundary. The real and imaginary components of complex inputs are quantized independently.

The number of bits, B, can be any integer value between 2 and 32, inclusive. Inputs greater than $(1-2^{1-B})V$ or less than $-V$ saturate at those respective values. The real and imaginary components of complex inputs saturate independently.

In the second step, the quantized floating-point value is uniquely mapped (encoded) to one of 2^B integer values. When the **Output type** is set to `Unsigned integer`, the smallest quantized floating-point value, $-V$, is mapped to the integer 0, and the largest quantized floating-point value, $(1-2^{1-B})V$, is mapped to the integer 2^B-1. Intermediate quantized floating-point values are linearly (uniformly) mapped to the intermediate integers in the range $[0, 2^B\text{-}1]$. For efficiency, the block automatically selects an *unsigned* output data type (`uint8`, `uint16`, or `uint32`) with the minimum number of bits equal to or greater than B.

When the **Output type** is set to `Signed integer`, the smallest quantized floating-point value, $-V$, is mapped to the integer $-2^{B\text{-}1}$, and the largest quantized floating-point value, $(1\text{-}2^{1\text{-}B})V$, is mapped to the integer $2^{B\text{-}1}\text{-}1$. Intermediate quantized floating-point values are linearly mapped to the intermediate integers in the range $[-2^{B\text{-}1}, 2^{B\text{-}1}\text{-}1]$. The block automatically selects a *signed* output data type (`int8`, `int16`, or `int32`) with the minimum number of bits equal to or greater than B.

Inputs can be real or complex, double or single precision. The output data types that the block uses are shown in the table below. Note that most of the DSP System Toolbox blocks accept only double-precision inputs. Use the Simulink Data Type Conversion block to convert integer data types to double precision. See "About Data Types in Simulink" (Simulink) for a complete discussion of data types, as well as a list of Simulink blocks capable of reduced-precision operations.

Bits	Unsigned Integer	Signed Integer
2 to 8	`uint8`	`int8`
9 to 16	`uint16`	`int16`
17 to 32	`uint32`	`int32`

The Uniform Encoder block operations adhere to the definition for uniform encoding specified in ITU-T Recommendation G.701.

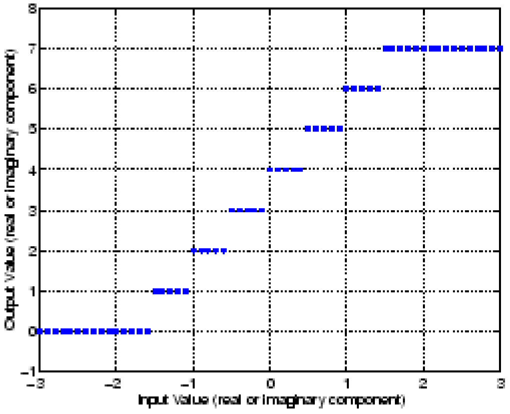
Examples

See example model ex_uniform_encoder.

In this example, the following parameters are set:

- **Peak** = 2
- **Bits** = 3
- **Output type** = `Unsigned`

The following figure illustrates uniform encoding.



The real and complex components of each input (horizontal axis) are independently quantized to one of 2^3 distinct levels in the range `[-2,1.5]`. These components are then mapped to one of 2^3 integer values in the range `[0,7]`.

```
-2.0  is mapped to  0
-1.5  is mapped to  1
-1.0  is mapped to  2
-0.5  is mapped to  3
 0.0  is mapped to  4
 0.5  is mapped to  5
 1.0  is mapped to  6
 1.5  is mapped to  7
```

This table shows the results for a few particular inputs.

Input	Quantized Input	Output	Notes
1.6	1.5+0.0i	7+4i	
-0.4	-0.5+0.0i	3+4i	
-3.2	-2.0+0.0i	4i	Saturation (real)
0.4-1.2i	0.0-1.5i	4+i	
0.4-6.0i	0.0-2.0i	4	Saturation (imaginary)

Input	Quantized Input	Output	Notes
`-4.2+3.5i`	`-2.0+2.0i`	`7i`	Saturation (real and imaginary)

The output data type is automatically set to `uint8`, the most efficient format for this input range.

Parameters

Peak

The largest input amplitude to be encoded, V. Real or imaginary input values greater than $(1\text{-}2^{1-B})V$ or less than $-V$ saturate (independently for complex inputs) at those limits.

Bits

Specify the number of bits, B, needed to represent the integer output. The number of levels at which the block quantizes the floating-point input is 2^B.

Output type

The data type of the block's output, `Unsigned integer` or `Signed integer`. Unsigned outputs are `uint8`, `uint16`, or `uint32`, while signed outputs are `int8`, `int16`, or `int32`.

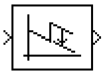
Unwrap

Unwrap signal phase



Library

Signal Operations

`dspsigops`

Description

The Unwrap block unwraps each channel of the input by adding or subtracting appropriate multiples of 2π to each channel element. The input can be a vector or matrix, and must have radian phase entries. The block recognizes phase discontinuities larger than the **Tolerance** parameter setting. For more information about phase unwrapping, see the “Definition of Phase Unwrap” on page 2-1810.

The block preserves the input size and dimension, and the output port rate equals the input port rate.

Unwrap Method

The Unwrap block unwraps each channel of its input matrix or input vector by adding 2π*k* to each successive channel element, and updating *k* at each *phase jump*. A phase jump occurs when the difference between two adjacent phase value entries exceeds the value of the **Tolerance** parameter.

The following code illustrates how the block unwraps the data in a given input channel `u`.

```
k=0;    % initialize k to 0
i=1;    % initialize the counter to 1
alpha=pi;   % set alpha to the desired Tolerance. In this case, pi
```

```
for i = 1:(size(u)-1)
    yout(i,:)=u(i)+(2*pi*k); % add 2*pi*k to ui
    if((abs(u(i+1)-u(i)))>(abs(alpha)))  %if diff is greater than alpha, increment or d

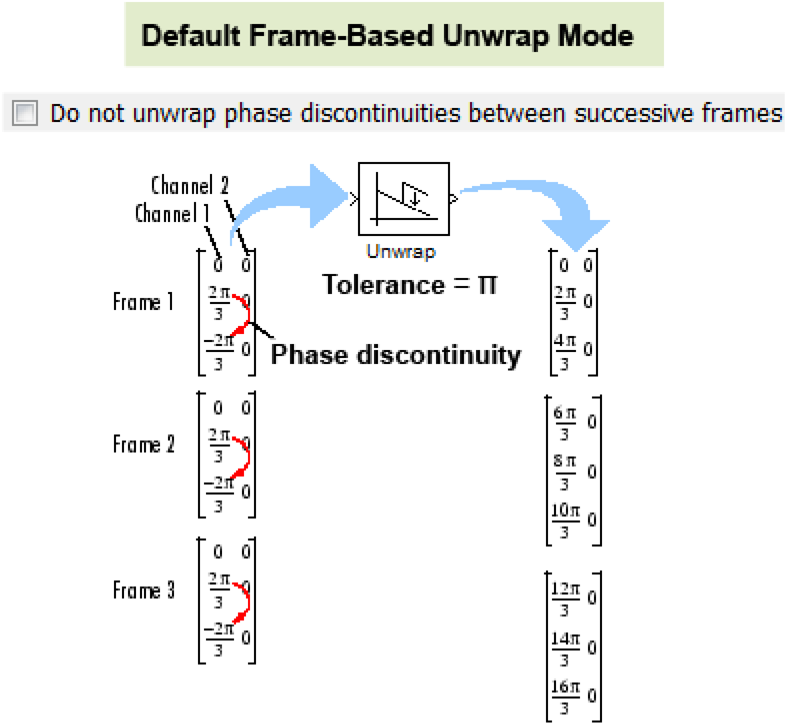
        if u(i+1)<u(i)   % if the phase jump is negative, increment k
            k=k+1;
        else             % if the phase jump is positive, decrement k
            k=k-1;
        end
    end
end
yout((i+1),:)=u(i+1)+(2*pi*k); % add 2*pi*k to the last element of the input
```

Frame-Based Processing

When you configure the block to perform frame-based processing, the block supports two different unwrap modes. In both modes, the block adds $2\pi k$ to each input channel's elements, and updates k at each phase discontinuity. The difference between the two modes is how often the block resets the initial phase value (k) to zero. You can choose to unwrap data across frame boundaries (default), or to unwrap only within input frames, by resetting the initial phase value each time a new input frame is received.

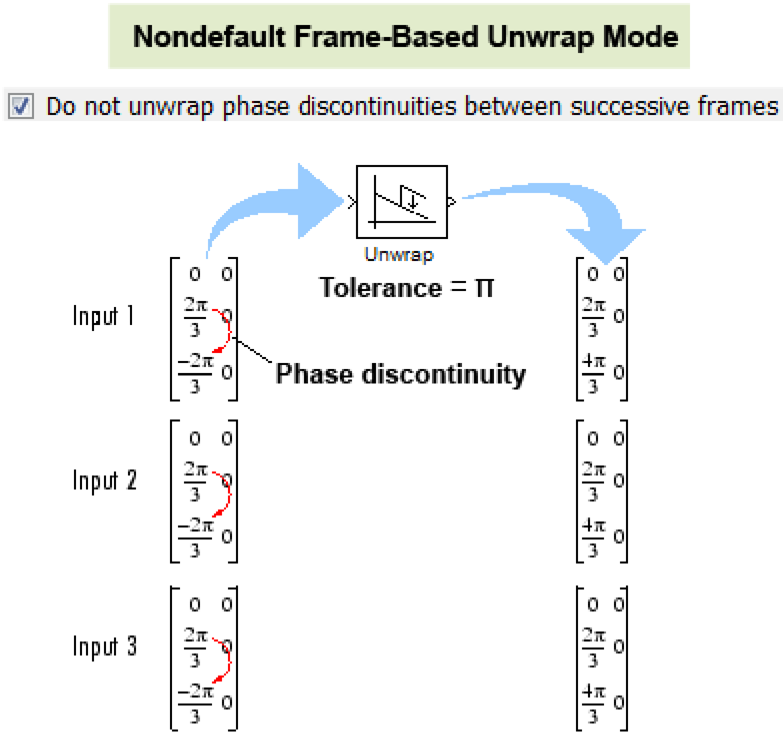
Unwrapping Across Frame Boundaries

In the default mode, the block ignores boundaries between input frames, and continues to unwrap the data in each channel without resetting the initial phase value to zero. To specify this mode, clear the **Do not unwrap phase discontinuities between successive frames** check box. The following figure illustrates how the block unwraps data in this mode.



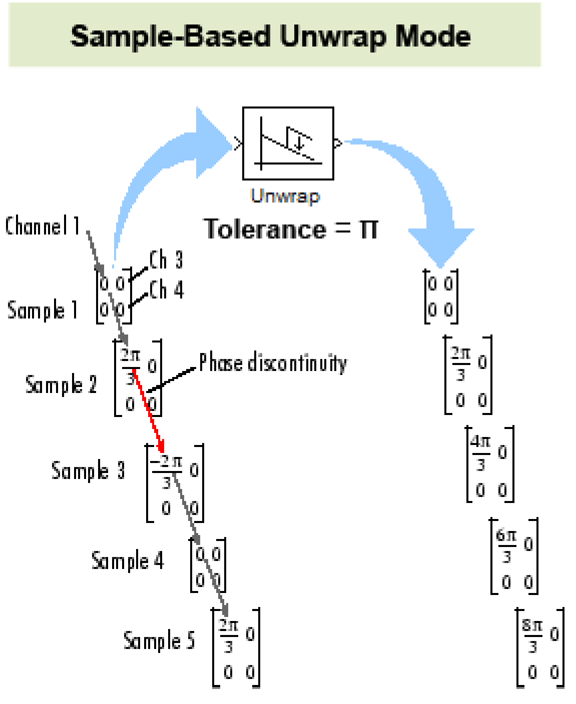
Unwrapping Within Frames

When you select the **Do not unwrap phase discontinuities between successive frames** check box, the block treats each frame of input data independently. In this mode, the block resets the initial phase value to zero each time a new input frame is received. The following figure illustrates how the block unwraps data in this mode.



Sample-Based Processing

When you configure the block to perform sample-based processing, the block treats each element of the input as an individual channel. The block unwraps the data in each channel of the input, and does not reset the initial phase to zero each time a new input is received. The following figure illustrates how the block unwraps data when performing sample-based processing.

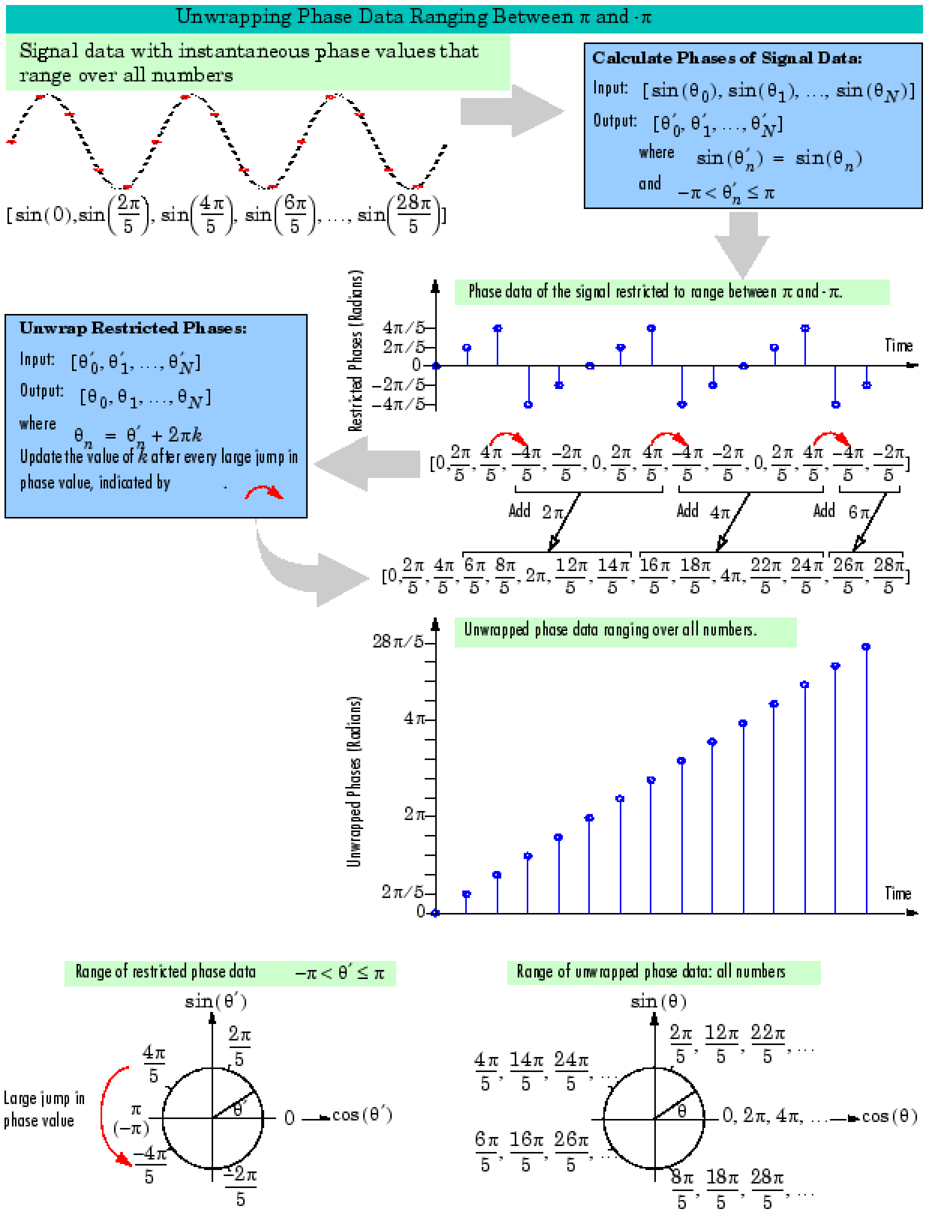


Definition of Phase Unwrap

Algorithms that compute the phase of a signal often only output phases between –π and π. For instance, such algorithms compute the phase of sin(2π + 3) to be 3, since sin(3) = sin(2π + 3), and since the actual phase, 2π + 3, is not between –π and π. Such algorithms compute the phases of sin(–4π + 3) and sin(16π + 3) to be 3 as well.

Phase unwrap or unwrap is a process often used to reconstruct a signal's original phase. Unwrap algorithms add appropriate multiples of 2π to each phase input to restore original phase values, as illustrated in the following diagram. See “Unwrap Method” on page 2-1806 for more information on the unwrap algorithm used by this block.

The following figure illustrates the concept of phase unwrapping.



Unwrapping Phase Data Ranging Between π and -π
Signal data with instantaneous phase values that range over all numbers
[sin(0), sin(2π/5), sin(4π/5), sin(6π/5), ..., sin(28π/5)]
Calculate Phases of Signal Data:
Input: [sin(θ0), sin(θ1), ..., sin(θN)]
Output: [θ'0, θ'1, ..., θ'N]
where sin(θ'n) = sin(θn)
and −π < θ'n ≤ π
Phase data of the signal restricted to range between π and -π.

Output: [θ0, θ1, ..., θN]
where θn = θ'n + 2πk
Update the value of k after every large jump in phase value, indicated by
Add 2π
Add 4π
Add 6π
Unwrapped phase data ranging over all numbers.
Unwrapped Phases (Radians)
Range of restricted phase data −π < θ' ≤ π
Large jump in phase value
Range of unwrapped phase data: all numbers

Parameters

Tolerance

The jump size that the block recognizes as a true phase discontinuity. The default is set to π (rather than a smaller value) to avoid altering legitimate signal features. To increase the block's sensitivity, set the **Tolerance** to a value slightly less than π.

Input processing

Specify how the block should process the input. You can set this parameter to one of the following options:

- `Columns as channels (frame based)` (default) — When you select this option, the block treats each column of the input as a separate channel.
- `Elements as channels (sample based)` — When you select this option, the block treats each element of the input as a separate channel.

Do not unwrap phase discontinuities between successive frames

When you clear this check box, the block ignores boundaries between input frames and does not reset the initial phase value to zero each time a new input is received. In this mode, the block continuously unwraps the data in each column of the input. When you select this check box, the block treats each frame of input data independently, and resets the initial phase value for each new input frame. See the "Frame-Based Processing" on page 2-1807 section for more information.

This parameter is available only when you configure the block to perform frame-based processing. In sample-based processing mode, the block does not reset the initial phase value to zero for each new input. See "Sample-Based Processing" on page 2-1809 for more information.

Supported Data Types

- Double-precision floating point
- Single-precision floating point

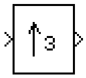
Upsample

Resample input at higher rate by inserting zeros



Library

Signal Operations

`dspsigops`

Description

The Upsample block resamples each channel of the M_i-by-N input at a rate L times higher than the input sample rate by inserting L-1 zeros between consecutive samples. You specify the integer L in the **Upsample factor** parameter. The **Sample offset** parameter, D, allows you to delay the output samples by an integer number of sample periods. Doing so enables you to select any of the L possible output phases. The value you specify for the **Sample offset** parameter must be in the range $0 \leq D < (L-1)$.

You can use this block inside of triggered subsystems when you set the **Rate options** parameter to `Enforce single-rate processing`.

Frame-Based Processing

When you set the **Input processing** parameter to `Columns as channels (frame based)`, the block upsamples each column of the input over time. In this mode, the block can perform either single-rate or multirate processing. You can use the **Rate options** parameter to specify how the block upsamples the input:

- When you set the **Rate options** parameter to `Enforce single-rate processing`, the input and output of the block have the same sample rate. In this mode, the block outputs a signal with a proportionally larger frame *size* than the input. For upsampling by a factor of L, the output frame size is L times larger than the input frame size ($M_o = M_i*L$), but the input and output frame rates are equal.

For an example of single-rate upsampling, see Example: Single-Rate Processing.

- When you set the **Rate options** parameter to `Allow multirate processing`, the block treats an M_i-by-N matrix input as N independent channels. The block upsamples each column of the input over time by keeping the frame size constant (M_i=M_o), and making the output frame period (T_{fo}) L times shorter than the input frame period ($T_{fo} = T_{fi}/L$).

  See Example: Multirate, Frame-Based Processing for an example that uses the Upsample block in this mode.

Sample-Based Processing

When you set the **Input processing** parameter to `Elements as channels (sample based)`, the block treats an M-by-N matrix input as $M*N$ independent channels, and upsamples each channel over time. In this mode, the block always performs multirate processing. The output sample rate is L times higher than the input sample rate ($T_{so} = T_{si}/L$), and the input and output sizes are identical.

Zero Latency

The Upsample block has *zero-tasking latency* for all single-rate operations. The block is in a single-rate mode if you set the **Upsample factor** parameter to `1` or if you set the **Input processing** parameter to `Columns as channels (frame based)` and the **Rate options** parameter to `Enforce single-rate processing`.

The Upsample block also has zero-tasking latency for multirate operations if you run your model in Simulink single-tasking mode.

Zero-tasking latency means that the block propagates the first input (received at t=0) immediately following the D consecutive zeros specified by the **Sample offset** parameter. This output (D+1) is followed in turn by the L-1 inserted zeros and the next input sample.

Nonzero Latency

The Upsample block has tasking latency for multirate, multitasking operation:

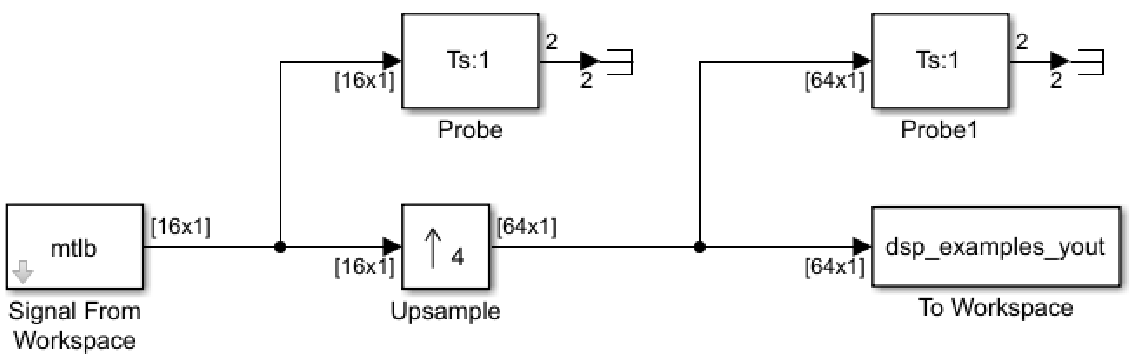
- In multirate, sample-based processing mode, the initial condition for each channel appears as output sample D+1, and is followed by L-1 inserted zeros. The channel's first input appears as output sample D+L+1. The **Initial conditions** parameter can be an M_i-by-N matrix containing one value for each channel, or a scalar to be applied to all signal channels.
- In multirate, frame-based processing mode, the first row of the initial condition matrix appears as output sample D+1, and is followed by L-1 inserted rows of zeros, the second row of the initial condition matrix, and so on. The first row of the first input matrix appears in the output as sample M_iL+D+1. The **Initial conditions** parameter can be an M_i-by-N matrix, or a scalar to be repeated across all elements of the input matrix.

Note: For more information on latency and the Simulink tasking modes, see "Excess Algorithmic Delay (Tasking Latency)" and "Time-Based Scheduling and Code Generation" (Simulink Coder).

Examples

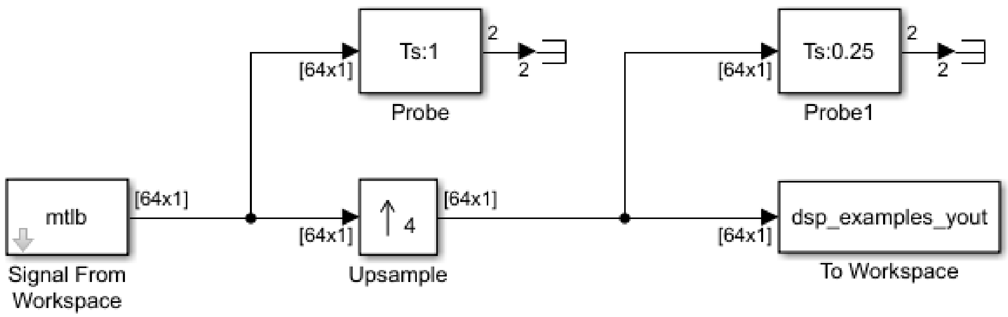
Example: Single-Rate Processing

In the ex_upsample_ref2 model, the Upsample block resamples a single-channel input with a frame size of 16. The block upsamples the input by a factor of 4. Thus, the output of the block has a frame size of 64. Because the block is in single-rate processing mode, the input and output frame rates are identical.



Example: Multirate, Frame-Based Processing

In the ex_upsample_ref1 model, the Upsample block resamples a single-channel input with a frame period of 1 second. The block upsamples the input by a factor of 4. Thus, the output of the block has a frame period of 0.25 seconds. Because the block is in multirate processing mode, the input and output frame sizes are identical.



Parameters

Upsample factor

The integer factor, L, by which to increase the input sample rate.

Sample offset

The sample offset, D, which must be an integer in the range [0,L-1].

Input processing

Specify how the block should process the input. You can set this parameter to one of the following options:

- `Columns as channels (frame based)` — When you select this option, the block treats each column of the input as a separate channel. In this mode, the block can perform single-rate or multirate processing.
- `Elements as channels (sample based)` — When you select this option, the block treats each element of the input as a separate channel. In this mode, the block always performs multirate processing.

Rate options

Specify the method by which the block upsamples the input. You can select one of the following options:

- `Enforce single-rate processing` — When you select this option, the block maintains the input sample rate by increasing the output frame size by a factor of *L*. To select this option, you must set the **Input processing** parameter to `Columns as channels (frame based)`.
- `Allow multirate processing` — When you select this option, the block resamples the signal such that the output sample rate is *L* times faster than the input sample rate.

Initial conditions

The value with which the block is initialized for cases of nonzero latency, a scalar or matrix. This value appears in the output as sample *D*+1. This parameter appears only when you configure the block to perform multirate processing.

HDL Code Generation

This block supports HDL code generation using HDL Coder. HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic. For more information on implementations, properties, and restrictions for HDL code generation, see Upsample.

Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers

Port	Supported Data Types
Output	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers

Variable Bandwidth FIR Filter

Design tunable bandwidth FIR filter

Library

Filtering / Filter Designs

`dspfdesign`

Description

The Variable Bandwidth FIR Filter block filters each channel of the input signal over time using specified FIR filter specifications. This block offers tunable filter design parameters, which enable you to tune the filter characteristics while the simulation is running.

The block designs the FIR filter according to the filter parameters set in the block dialog box. The output port properties, such as datatype, complexity, and dimension, are identical to the input port properties.

Each column of the input signal is treated as a separate channel. If the input is a two-dimensional signal, the first dimension represents the channel length (or frame size) and the second dimension represents the number of channels. If the input is a one-dimensional signal, then it is interpreted as a single channel.

This block supports variable-size input, enabling you to change the channel length during simulation. To enable variable-size input, clear the **Inherit sample rate from input** check box. The number of channels must remain constant.

Algorithms

This block brings the capabilities of dsp.VariableBandwidthFIRFilter System object to the Simulink environment.

The FIR filter is designed using the window method. For information on the algorithms used by the Variable Bandwidth FIR Filter block, see the "Algorithms" on page 4-1853 section of `dsp.VariableBandwidthFIRFilter`.

Examples

- "System Identification Using RLS Adaptive Filtering"

Parameters

FIR filter order

Order of the FIR filter, specified as a positive integer scalar. The default is `30`. This parameter is nontunable.

Filter type

Type of FIR filter. You can set this parameter to:

- `Lowpass` (default)
- `Highpass`
- `Bandpass`
- `Bandstop`

This parameter is nontunable.

Filter Cutoff frequency (Hz)

Cutoff frequency of the FIR filter, specified as a real positive scalar that is less than half the sample rate of the input signal. This parameter applies when you set **Filter type** to `Lowpass` or `Highpass`. The default is `1000`. This parameter is tunable.

Filter center frequency (Hz)

Center frequency of the FIR filter, specified as a real positive scalar that is less than half the sample rate of the input signal. This parameter applies when you set **Filter type** to `Bandpass` or `Bandstop`. The default is `10000`. This parameter is tunable.

Filter bandwidth (Hz)

Bandwidth of the FIR filter, specified as a real positive scalar that is less than half the sample rate of the input signal. This parameter applies when you set **Filter type** to `Bandpass` or `Bandstop`. The default is `2000`. This parameter is tunable.

Window function

Window function used to design the FIR filter. You can set this parameter to:

- `Hann` (default)
- `Hamming`
- `Chebyshev`
- `Kaiser`

This parameter is nontunable.

Chebyshev window sidelobe attenuation (dB)

Sidelobe attenuation of chebyshev window, specified as a real positive scalar. This parameter applies when you set **Window function** to `Chebyshev`. The default is `60`. This parameter is nontunable.

Kaiser window parameter

Kaiser window parameter, specified as a real scalar. This parameter applies when you set **Window function** to `Kaiser`. The default is `0.5`. This parameter is nontunable.

Inherit sample rate from input

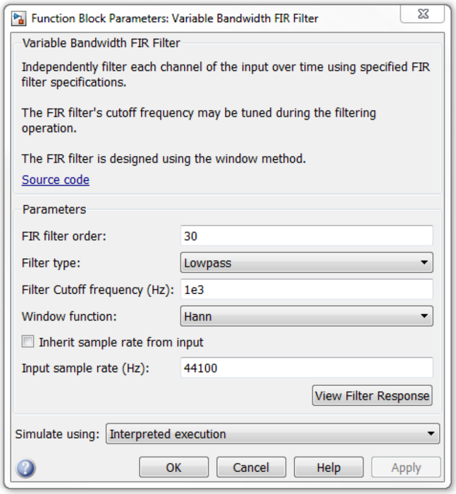
When you select this check box, the block's sample rate is computed as N / Ts, where N is the frame size of the input signal and Ts is the sample time of the input signal. When you clear this check box, the block's sample rate is the value specified in **Input sample rate (Hz)**. By default, this check box is selected.

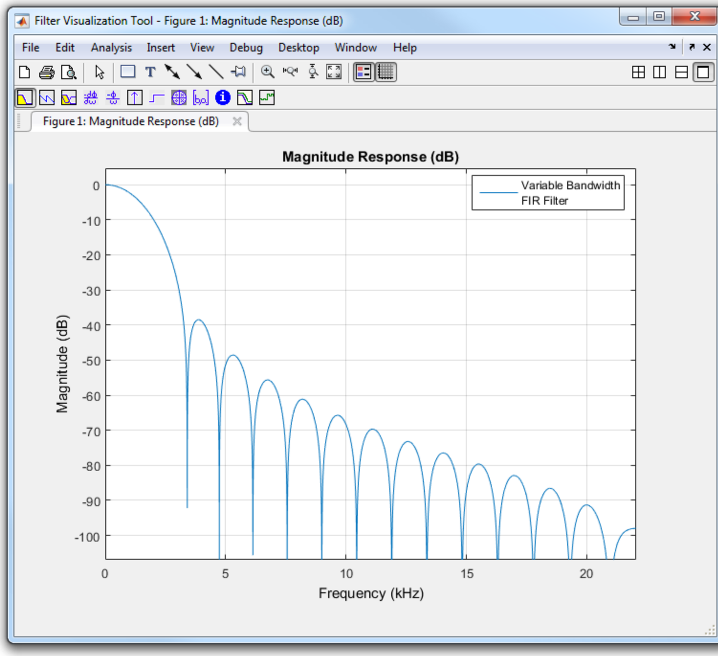
Input sample rate (Hz)

Sample rate of the input signal, specified as a positive scalar. The default is `44100`. This parameter applies when you clear the **Inherit sample rate from input** check box. This parameter is nontunable.

View Filter Response

Opens the Filter Visualization Tool FVTool and displays the magnitude/phase response of the Variable Bandwidth FIR Filter. The response is based on the block dialog box parameters. Changes made to these parameters update FVTool.





To update the magnitude response while FVTool is running, modify the dialog box parameters and click **Apply**.

Simulate using

Type of simulation to run. You can set this parameter to:

- `Interpreted execution` (default)

  Simulate model using the MATLAB interpreter. This option has faster simulation speed compared to `Code generation`.

- `Code generation`

  Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time compared to `Interpreted execution`.

Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point
Output	• Double-precision floating point • Single-precision floating point

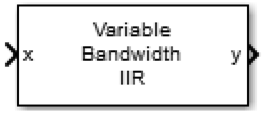
Variable Bandwidth IIR Filter

Design tunable bandwidth IIR filter



Library

Filtering / Filter Designs

`dspfdesign`

Description

The Variable Bandwidth IIR Filter block filters each channel of the input signal over time using specified IIR filter specifications. This block offers tunable filter design parameters, which enable you to tune the filter characteristics while the simulation is running.

The block designs the IIR filter according to the filter parameters set in the block dialog box. The output port properties, such as datatype, complexity, and dimension, are identical to the input port properties.

Each column of the input signal is treated as a separate channel. If the input is a two-dimensional signal, the first dimension represents the channel length (or frame size) and the second dimension represents the number of channels. If the input is a one-dimensional signal, then it is interpreted as a single channel.

This block supports variable-size input, enabling you to change the channel length during simulation. To enable variable-size input, clear the **Inherit sample rate from input** check box. The number of channels must remain constant.

Algorithms

This block brings the capabilities of dsp.VariableBandwidthIIRFilter System object to the Simulink environment.

The IIR filter is designed using the elliptical method. The IIR filter is tuned using IIR spectral transformations based on allpass filters. For more information on the algorithms used by the Variable Bandwidth IIR Filter block, see the “Algorithms” on page 4-1863 section of `dsp.VariableBandwidthIIRFilter`.

Examples

- “Tunable Lowpass Filtering of Noisy Input in Simulink”

Parameters

Filter type

Type of IIR filter. You can set this parameter to:

- `Lowpass` (default)
- `Highpass`
- `Bandpass`
- `Bandstop`

This parameter is nontunable.

IIR filter order

Order of the IIR filter, specified as a positive integer scalar. The default is `8`. This parameter is nontunable.

Filter passband frequency (Hz)

Passband frequency of the IIR filter, specified as a real positive scalar that is less than half the sample rate of the input signal. This parameter applies when you set **Filter type** to `Lowpass` or `Highpass`. The default is `1000`. This parameter is tunable.

Filter center frequency (Hz)

Center frequency of the IIR filter, specified as a real positive scalar that is less than half the sample rate of the input signal. This parameter applies when you set **Filter type** to `Bandpass` or `Bandstop`. The default is `10000`. This parameter is tunable.

Filter bandwidth (Hz)

Bandwidth of the IIR filter, specified as a real positive scalar that is less than half the sample rate of the input signal. This parameter applies when you set **Filter type** to `Bandpass` or `Bandstop`. The default is `2000`. This parameter is tunable.

Filter passband ripple (dB)

Passband ripple of the IIR filter, specified as a real positive scalar. The default is `1`. This parameter is nontunable.

Filter Stopband attenuation (dB)

Stopband attenuation of the IIR filter, specified as a real positive scalar. The default is `60`. This parameter is nontunable.

Inherit sample rate from input

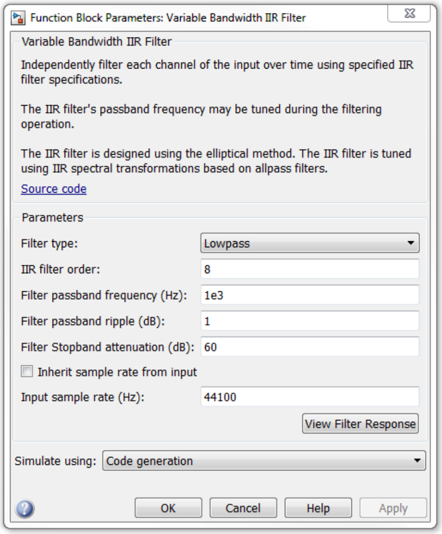
When you select this check box, the block's sample rate is computed as N / Ts, where N is the frame size of the input signal and Ts is the sample time of the input signal. When you clear this check box, the block's sample rate is the value specified in **Input sample rate (Hz)**. By default, this check box is selected.

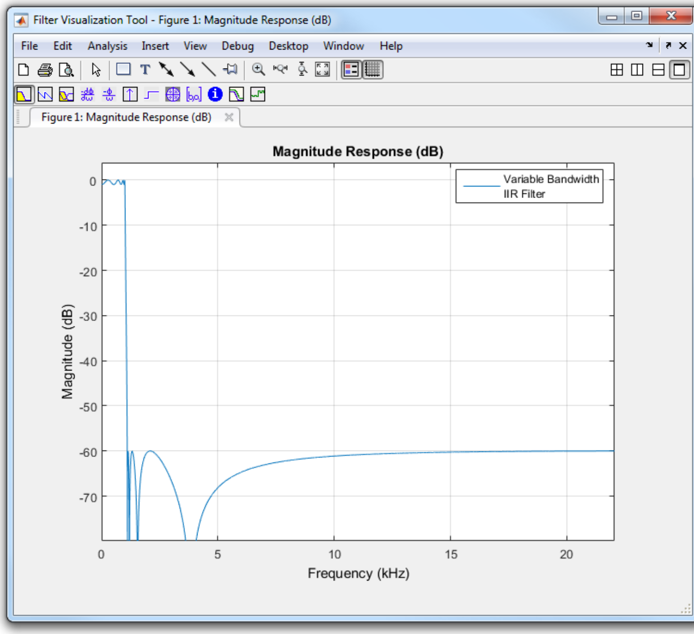
Input sample rate (Hz)

Sample rate of the input signal, specified as a positive scalar. The default is `44100`. This parameter applies when you clear the **Inherit sample rate from input** check box. This parameter is nontunable.

View Filter Response

Opens the Filter Visualization Tool FVTool and displays the magnitude/phase response of the Variable Bandwidth IIR Filter. The response is based on the block dialog box parameters. Changes made to these parameters update FVTool.





To update the magnitude response while FVTool is running, modify the dialog box parameters and click **Apply**.

Simulate using

Type of simulation to run. You can set this parameter to:

- `Code generation` (default)

  Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time but provides faster simulation speed than `Interpreted execution`.

- `Interpreted execution`

  Simulate model using the MATLAB interpreter. This option shortens startup time but has slower simulation speed than `Code generation`.

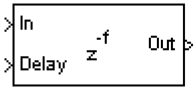
Variable Fractional Delay

Delay input by time-varying fractional number of sample periods



Library

Signal Operations

`dspsigops`

Description

The Variable Fractional Delay block delays each element of the discrete-time N-D input array, u, by a variable number of sample intervals. The input delay values can be integer or noninteger values. The block provides three different interpolation modes: `Linear`, `FIR`, and `Farrow`.

The block computes the value for each channel of the output based on the stored samples in memory most closely indexed by the `Delay` input, v, and the interpolation method specified by the **Interpolation mode** parameter.

- In `Linear` interpolation mode, the block stores the D_{max}+1 most recent samples received at the In port for each channel, where D_{max} is the value you specify for the **Maximum delay (Dmax) in samples** parameter.
- In `FIR` interpolation mode, the block stores the D_{max}+P+1 most recent samples received at the In port for each channel, where P is the value you specify for the **Interpolation filter half-length (P)** parameter.
- In `Farrow` interpolation mode, the block stores the $D_{max}+\frac{N}{2}+1$ most recent samples received at the In port for each channel, where N is the value you specify for the **Farrow filter length (N)** parameter.

The Variable Fractional Delay block assumes that the input values at the `Delay` port are between D_{min} and D_{max}, where D_{min} appears in the `Valid delay range` section on the

Main pane of the block mask, and D_{max} is the value of the **Maximum delay (Dmax) in samples** parameter. The block clips delay values less than D_{min} to D_{min} and delay values greater than D_{max} to D_{max}.

You must consider additional factors when selecting valid `Delay` values for the `FIR` and `Farrow` interpolation modes. For more information about these considerations, refer to or , respectively.

The Variable Fractional Delay block is similar to the Variable Integer Delay block, in that they both store a minimum of D_{max}+1 past samples in memory. The Variable Fractional Delay block differs only in the way that these stored samples are accessed; a fractional delay requires the computation of a value by interpolation from the nearby samples in memory.

Sample-Based Processing

When you set the **Input processing** parameter to `Elements as channels (sample based)`, the block treats each element of the N-D input array, u, as an independent channel. The input to the Delay port, v, must either be an N-D array of the same size and dimension as the input u, or be a scalar value, such that $D_{min} \leq v \leq D_{max}$.

For example, consider an M-by-N input matrix. The block treats each of the M*N matrix elements as independent channels. The input to the Delay port can be an M-by-N matrix of floating-point values in the range $D_{min} \leq v \leq D_{max}$ that specifies the number of sample intervals to delay each channel of the input, or it can be a scalar floating-point value, $D_{min} \leq v \leq D_{max}$, by which to equally delay all channels.

In sample-based processing mode, the block treats an unoriented vector input as an M-by-1 matrix. In this mode, the output is also an unoriented vector.

The **Initial conditions** parameter specifies the values in the block's memory at the start of the simulation in the same manner as the Variable Integer Delay block. See the Variable Integer Delay block reference page for more information.

Frame-Based Processing

When you set the **Input processing** parameter to `Columns as channels (frame based)`, the block treats each of the N input columns as an independent channel containing M_i sequential time samples.

The input to the Delay port, v, contains floating-point values that specify the number of sample intervals to delay the current input.

The input to the Delay port can be a scalar value to uniformly delay every sample in every channel. It can also be a length-M column vector, containing one delay for each sample in the input frame. The block applies the set of delays contained in the vector identically to every channel of a multichannel input. The Delay port entry can also be a length-N row vector, containing one delay for each channel. Finally, the Delay port entry can be an M-by-N matrix, containing a different delay for each corresponding element of the input.

For example, if v is the M_i-by-1 matrix `[v(1) v(2) ... v(Mi)]'`, the earliest sample in the current frame is delayed by `v(1)` fractional sample intervals, the following sample in the frame is delayed by `v(2)` fractional sample intervals, and so on. The block applies the set of fractional delays contained in v identically to every channel of a multichannel input.

The **Initial conditions** parameter specifies the values in the block's memory at the start of the simulation in the same manner as the Variable Integer Delay block. See the Variable Integer Delay block reference page for more information.

Interpolation Modes

The delay value specified at the Delay port serves as an index into the block's memory, `U`, which stores, at a minimum, the D_{max}+1 most recent samples received at the In port for each channel. For example, an integer delay of `5` on a scalar input sequence retrieves and outputs the fifth most recent input sample from the block's memory, `U(6)`. The block computes fractional delays by interpolating between stored samples; the three available interpolation modes are `Linear`, `FIR` and `Farrow`.

Linear Interpolation Mode

For noninteger delays, at each sample time, the `Linear Interpolation` mode uses the two samples in memory nearest to the specified delay to compute a value for the sample at that time. If v is the specified fractional delay for a scalar input, the output sample, y, is computed as follows.

```
vi = floor(v)     % vi = integer delay
vf = v-vi     % vf = fractional delay
y = (1-vf)*U(vi+1) + vf*U(vi)
```

FIR Interpolation Mode

In `FIR Interpolation` mode, the block provides a discrete set of fractional delays described by:

$$v + \frac{i}{L}, \qquad v \geq P - 1, \;\; i = 0, 1, \ldots, L-1$$

If v is less than P-1, the block's behavior depends on the setting of the **For small input delay values** parameter. You can specify the block's behavior when the input delay value is too small to center the kernel (less than P-1), by setting the **For small input delay values** parameter:

- If you select `Clip to the minimum value necessary for centered kernel`, the block remains in `FIR` interpolation mode by clipping small input delay values to the smallest value necessary to center the kernel.

  To determine the minimum delay value, select `Clip to the minimum value necessary for centered kernel`, and click **Apply** on the block mask. All input delay values less than the value displayed for D_{min} will be clipped to D_{min}.
- If you select `Switch to linear interpolation if kernel cannot be centered`, the block computes fractional delays using linear interpolation when the input delay value is less than P-1.

To add an extra delay to the minimum possible delay value, select the **Disable direct feedthrough by increasing minimum possible delay by one** check box. Checking this box prevents algebraic loops from occurring when you use the block inside a feedback loop.

In `FIR Interpolation` mode, the block implements a polyphase structure to compute a value for each sample at the desired delay. Each arm of the structure corresponds to a different delay value and the output computed for each sample corresponds to the output of the arm with a delay value nearest to the desired input delay. Thus, only a discrete set of delays is actually possible. The number of coefficients in each of the L filter arms of the polyphase structure is $2P$. In most cases, using values of P between 4 and 6 will provide you with reasonably accurate interpolation values.

In this mode, the Signal Processing Toolbox `intfilt` function computes an FIR filter for interpolation.

For example, when you set the parameters on the block mask to the following values:

- Interpolation filter half-length (P): 4
- Interpolation points per input sample: 10
- Normalized input bandwidth: 1

The filter coefficients are given by:

```
b = intfilt(10,4,1);
```

The block then implements this filter as a polyphase structure, as described previously.

Increasing the **Interpolation filter half length (P)** increases the accuracy of the interpolation, but also increases the number of computations performed per input sample, as well as the amount of memory needed to store the filter coefficients. Increasing the **Interpolation points per input sample** (L) increases the number of representable discrete delay points, but also increases the simulation's memory requirements and does not affect the computational load per sample.

The **Normalized input bandwidth (0 to 1)** parameter allows you to take advantage of the bandlimited frequency content of the input. For example, if you know that the input signal does not have frequency content above $F_s/4$, you can specify a value of `0.5` for the **Normalized input bandwidth (0 to 1)** to constrain the frequency content of the output to that range.

Note You can consider each of the L interpolation filters to correspond to one output phase of an "upsample-by-L" FIR filter. Thus, the **Normalized input bandwidth (0 to 1)** value improves the stopband in critical regions, and relaxes the stopband requirements in frequency regions where there is no signal energy.

Farrow Interpolation Mode

In `Farrow` interpolation mode, the block uses the LaGrange method to interpolate values.

To increase the minimum possible delay value, select the **Disable direct feedthrough by increasing minimum possible delay by one** check box. Checking this box prevents algebraic loops from occurring when you use the block inside a feedback loop.

To specify the block's behavior when the input delay value is too small to center the kernel (less than $\frac{N}{2}$-1), set the **For small input delay values** parameter:

- If you select `Clip to the minimum value necessary for centered kernel`, the block clips small input delay values to the smallest value necessary to keep the kernel centered. This increases D_{min} but yields more accurate interpolation values.

  To determine the minimum delay value, select `Clip to the minimum value necessary for centered kernel`, and click **Apply** on the block mask. All input delay values less than the value displayed for D_{min} will be clipped to D_{min}.
- If you select `Use off-centered kernel`, the block computes fractional delays using a Farrow filter with an off-centered kernel. This mode does not increase D_{min}, but if there are input delay values less than $\frac{N}{2}$-1, the results are less accurate than the results achieved by keeping the kernel centered.

Fixed-Point Data Types

The diagrams in the following sections show the data types used within the Variable Fractional Delay block for fixed-point signals.

Although you can specify most of these data types on the **Data Types** pane of the block mask, the following data types are computed internally by the block and cannot be directly specified on the block mask.

Data Type	Word Length	Fraction Length
vf data type	Same word length as the **Coefficients**	Same as the word length
HoldInteger data type	Same word length as the input delay value	0 bits
Integer data type	32 bits	0 bits

Note: When the block input is fixed point, all internal data types are signed fixed point.

To compute the integer (v_i) and fractional (v_f) parts of the input delay value (v), the Variable Fractional Delay block uses the following equations:

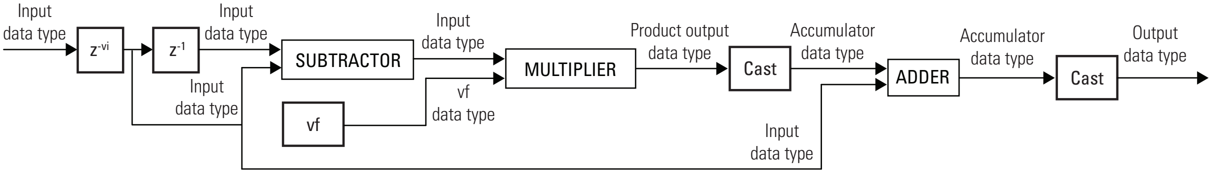
$$D_{min} < v < D_{max} \Rightarrow \begin{cases} v_i = \text{floor}(v) \\ v_f = v - vi \end{cases}$$

$$v \leq D_{min} \Rightarrow \begin{cases} v_i = D_{min} \\ v_f = 0 \end{cases}$$

$$v \geq D_{max} \Rightarrow \begin{cases} v_i = D_{max} \\ v_f = 0 \end{cases}$$

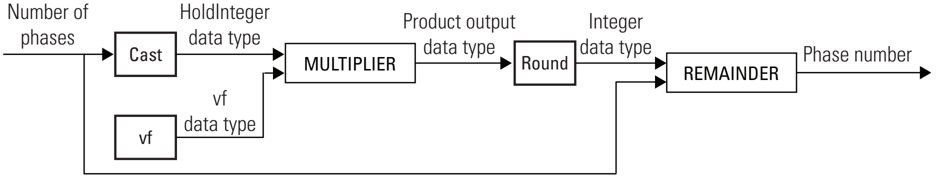
Linear Interpolation Mode

The following diagram shows the fixed-point data types used by the `Linear` interpolation mode of the Variable Fractional Delay block.



FIR Interpolation Mode

The following diagram illustrates how the Variable Fractional Delay block selects the arm of the polyphase filter structure that most closely matches the fractional delay value (v_f).

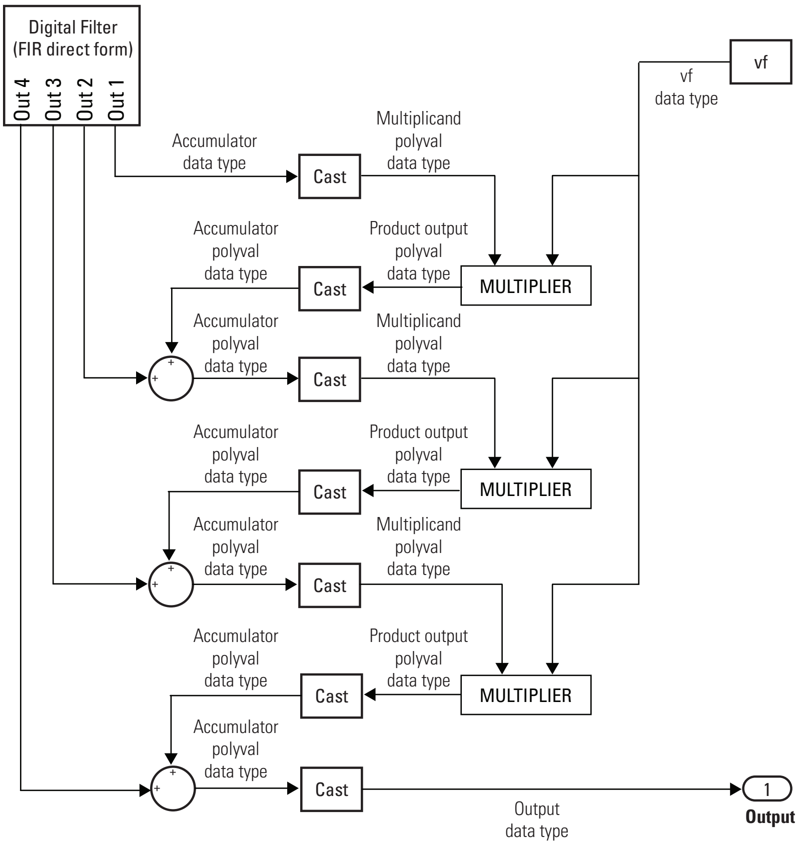


See the "Fixed-Point Data Types" on page 2-723 section of the FIR Interpolation reference page for a diagram showing the fixed-point data types used by the Variable Fractional Delay block in `FIR` interpolation mode.

Farrow Interpolation Mode

The following diagram shows the fixed-point data types used by the `Farrow` interpolation mode of the Variable Fractional Delay block where:

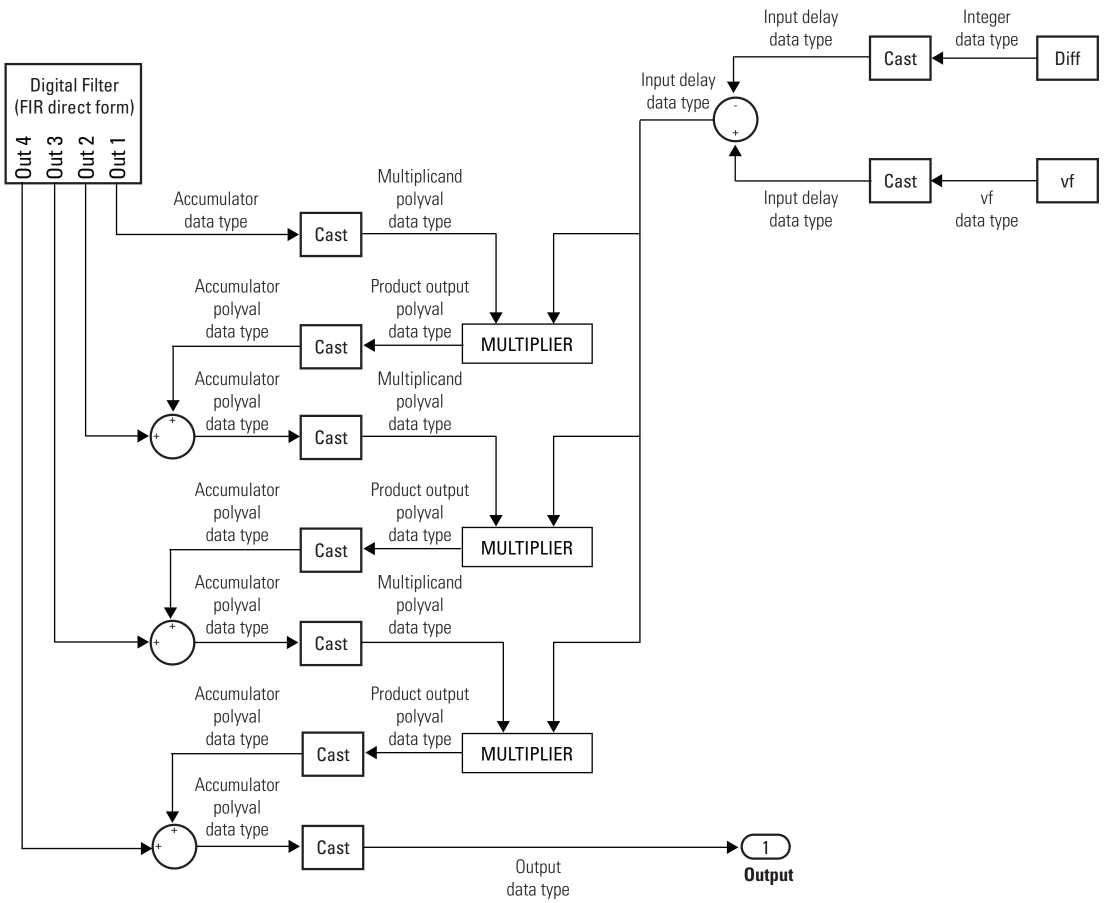
- **Farrow filter length (N)** = 4
- **For small input delay values** = `Clip to the minimum value necessary to for centered kernel`



The following diagram shows the fixed-point data types used by the `Farrow` interpolation mode of the Variable Fractional Delay block where:

- **Farrow filter length (N)** = 4

- **For small input delay values** = `Use off-centered kernel`



`Diff` is computed from the integer part of the delay value (v_i) and the **Farrow filter length (N)** according to the following equation:

$$Diff = v_i - \left(\frac{N-1}{2}\right)$$
$$Diff \geq 0 \Rightarrow Diff = 0$$
$$Diff < 0 \Rightarrow Diff = -Diff$$

The following diagram shows the fixed-point data types used by the Digital Filter block's FIR direct form filter.

Interpolation mode

The method by which to interpolate between adjacent stored samples to obtain a value for the sample indexed by the input at the Delay port.

Interpolation filter half-length (P)

Half the number of input samples to use in the FIR interpolation filter. This parameter is only visible when the **Interpolation mode** is set to `FIR`.

Farrow filter length (N)

The number of input samples to use in the Farrow interpolation filter. This parameter is only visible when the **Interpolation mode** is set to `Farrow`.

Interpolation points per input sample

The number of points per input sample, L, at which a unique FIR interpolation filter is computed. This parameter is only visible when the **Interpolation mode** is set to `FIR`.

Normalized input bandwidth (0 to 1)

The bandwidth to which the interpolated output samples should be constrained. The value must be a real scalar between `0` and `1`. A value of `1` specifies half the sample frequency. This parameter is only visible when the **Interpolation mode** is set to `FIR`.

Maximum delay (Dmax) in samples

The maximum delay that the block can produce, D_{max}. Input delay values exceeding this maximum are clipped to D_{max}.

Input processing

Specify how the block should process the input. You can set this parameter to one of the following options:

- `Columns as channels (frame based)` (default) — When you select this option, the block treats each column of the input as a separate channel.
- `Elements as channels (sample based)` — When you select this option, the block treats each element of the input as a separate channel.

Initial conditions

The values with which the block's memory is initialized. See the Variable Integer Delay block for more information.

Disable direct feedthrough by increasing minimum possible delay by one

Select this box to disable direct feedthrough by increasing the minimum possible delay value. When you set the **Input processing** parameter to `Columns as channels (frame based)`, the block increases the minimum possible delay value by *`frame size`* -1. Similarly, when you set the **Input processing** parameter to `Elements as channels (sample based)`, the block increases the minimum possible delay value by one sample.

Checking this box allows you to use the Variable Fractional Delay block in feedback loops.

For small input delay values

Specify the block's behavior when the input delay values are too small to center the kernel. This parameter is only visible when the **Interpolation mode** is set to `FIR` or `Farrow`.

You can specify how the block handles input delay values that are too small for the kernel to be centered using one of the following choices:

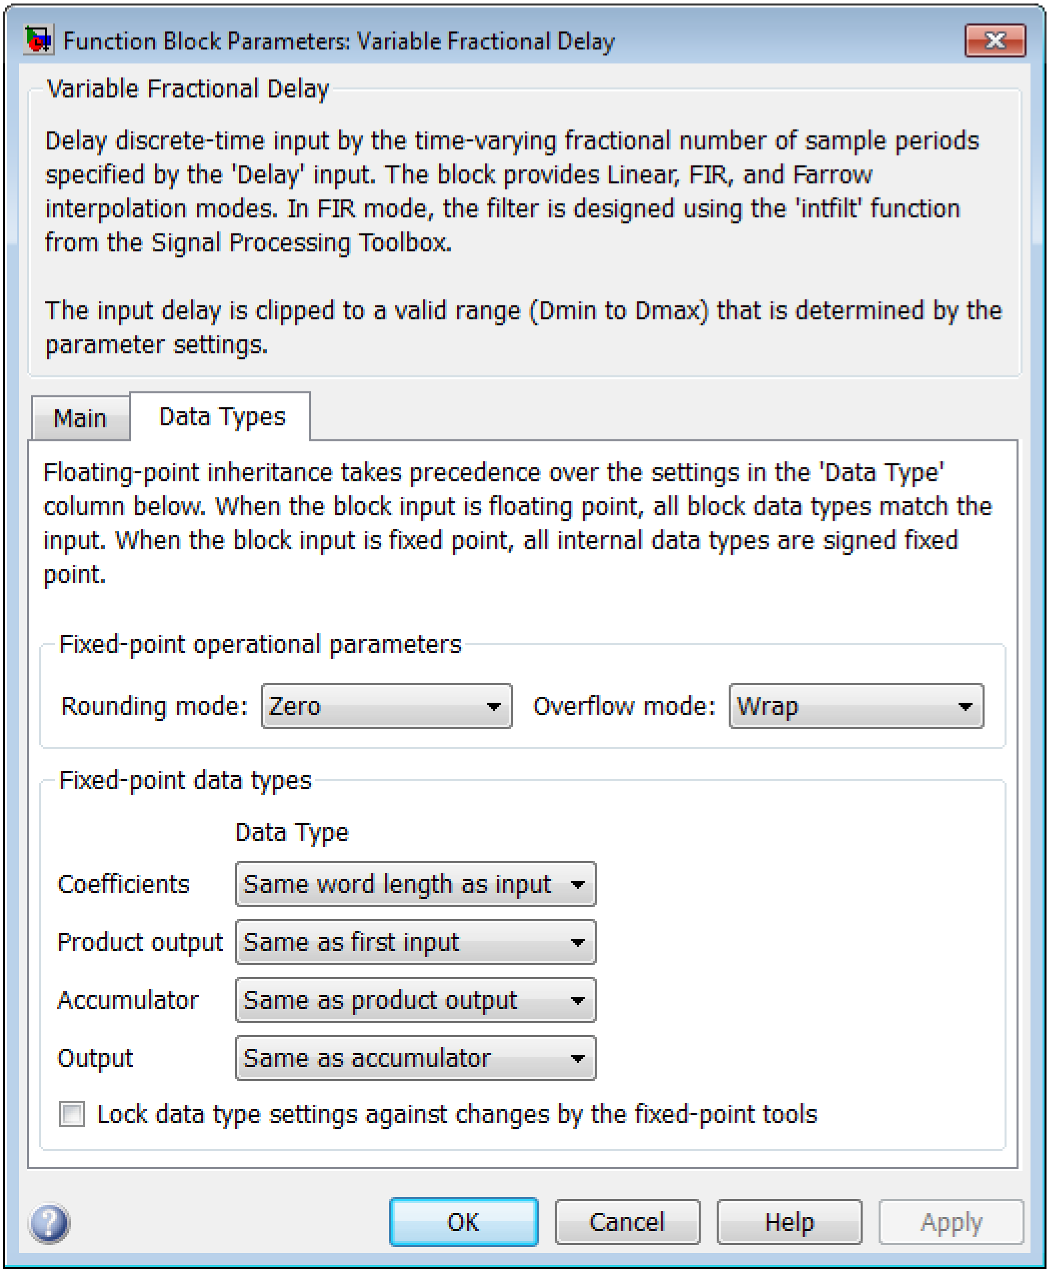
- In both `FIR` and `Farrow` interpolation modes, you can select `Clip to the minimum value necessary for centered kernel`. This option forces the block to increase D_{min} to the smallest value necessary to keep the kernel centered.
- In `FIR` interpolation mode, you can select `Switch to linear interpolation if kernel cannot be centered`. This option forces the block to preserve the value of D_{min} and compute all interpolated values using `Linear` interpolation.
- In `Farrow` interpolation mode, you can select `Use off-centered kernel`. This option forces the block to preserve the value of D_{min} and compute the interpolated values using a farrow filter with an off-centered kernel.

Valid delay range

The values displayed in this section of the **Main** pane are calculated (in samples) by the block based on the current parameter settings.

- `Dmin` is the smallest possible valid delay value (in samples) based on the current settings of the block parameters. The block clips all input delay values less than `Dmin` to `Dmin`.
- `Dmax` is the maximum valid delay value (in samples) based on the current settings of the block parameters. The block clips all input delay values greater than `Dmax` to `Dmax`.

The **Data Types** pane of the Variable Fractional Delay block dialog appears as follows.



Function Block Parameters: Variable Fractional Delay
Variable Fractional Delay
Delay discrete-time input by the time-varying fractional number of sample periods specified by the 'Delay' input. The block provides Linear, FIR, and Farrow interpolation modes. In FIR mode, the filter is designed using the 'intfilt' function from the Signal Processing Toolbox.
The input delay is clipped to a valid range (Dmin to Dmax) that is determined by the parameter settings.
Main
Data Types
Floating-point inheritance takes precedence over the settings in the 'Data Type' column below. When the block input is floating point, all block data types match the input. When the block input is fixed point, all internal data types are signed fixed point.

Rounding mode

Select the rounding mode for fixed-point operations.

Overflow mode

Select the overflow mode for fixed-point operations.

Coefficients

Choose how you specify the word length and fraction length of the filter coefficients.

- When you select `Same word length as input`, the word length of the filter coefficients match that of the input to the block. In this mode, the fraction length of the coefficients is automatically set to the binary-point only scaling that provides you with the best precision possible given the value and word length of the coefficients.
- When you select `Specify word length`, you can enter the word length of the coefficients, in bits. In this mode, the fraction length of the coefficients is automatically set to the binary-point only scaling that provides you with the best precision possible given the value and word length of the coefficients.

Product output

Use this parameter to specify how you would like to designate the product output word and fraction lengths. See "Fixed-Point Data Types" on page 2-1835 and "Multiplication Data Types" for illustrations depicting the use of the product output data type in this block.

- When you select `Same as first input`, these characteristics match those of the first input to the block.
- When you select `Binary point scaling`, you can enter the word length and the fraction length of the product output, in bits.
- When you select `Slope and bias scaling`, you can enter the word length, in bits, and the slope of the product output. This block requires power-of-two slope and a bias of zero.

Accumulator

Use this parameter to specify how you would like to designate the accumulator word and fraction lengths. See "Fixed-Point Data Types" on page 2-1835 and "Multiplication Data Types" for illustrations depicting the use of the accumulator data type in this block:

- When you select `Same as product output`, these characteristics match those of the product output.

- When you select `Same as first input`, these characteristics match those of the first input to the block.
- When you select `Binary point scaling`, you can enter the word length and the fraction length of the accumulator, in bits.
- When you select `Slope and bias scaling`, you can enter the word length, in bits, and the slope of the accumulator. This block requires power-of-two slope and a bias of zero.

Product output polyval

Choose how you specify the word length and fraction length of the product output polyval data type. This parameter is only visible when the **Interpolation mode** is set to `Farrow`.

- When you select `Same as first input`, these characteristics match those of the first input to the block.
- When you select `Binary point scaling`, you can enter the word length and the fraction length of the product output polyval in bits.
- When you select `Slope and bias scaling`, you can enter the word length, in bits, and the slope of the product output polyval. This block requires power-of-two slope and a bias of zero.

Accumulator polyval

Choose how you specify the word length and fraction length of the accumulator polyval data type. This parameter is only visible when the **Interpolation mode** is set to `Farrow`.

- When you select `Same as first input`, these characteristics match those of the first input to the block.
- When you select `Binary point scaling`, you can enter the word length and the fraction length of the accumulator polyval in bits.
- When you select `Slope and bias scaling`, you can enter the word length, in bits, and the slope of the accumulator polyval. This block requires power-of-two slope and a bias of zero.

Multiplicand polyval

Choose how you specify the word length and fraction length of the multiplicand polyval data type. This parameter is only visible when the **Interpolation mode** is set to `Farrow`.

- When you select `Same as first input`, these characteristics match those of the first input to the block.
- When you select `Binary point scaling`, you can enter the word length and the fraction length of the multiplicand polyval, in bits.
- When you select `Slope and bias scaling`, you can enter the word length, in bits, and the slope of the multiplicand polyval. This block requires power-of-two slope and a bias of zero.

Output

Choose how you specify the output word length and fraction length:

- When you select `Same as accumulator`, these characteristics match those of the accumulator.
- When you select `Same as first input`, these characteristics match those of the first input to the block.
- When you select `Binary point scaling`, you can enter the word length and the fraction length of the output, in bits.
- When you select `Slope and bias scaling`, you can enter the word length, in bits, and the slope of the output. This block requires power-of-two slope and a bias of zero.

Lock data type settings against changes by the fixed-point tools

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block mask.

Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers
Delay	• Double-precision floating point • Single-precision floating point

Port	Supported Data Types
	• Fixed point (signed and unsigned) • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers
Output	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers

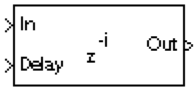
Description

The Variable Integer Delay block is an implementation of the Simulink Delay block. See Delay for more information.

Introduced before R2006a

Variable Integer Delay (Obsolete)

Delay input by time-varying integer number of sample periods



Library

`dspobslib`

Description

Note: The Variable Integer Delay block has been replaced with the Simulink Variable Integer Delay block. Existing instances of the DSP block will continue to operate, but certain functionality will be disabled in future releases. See "Functionality being removed or replaced for blocks and System objects".

The Variable Integer Delay block delays the discrete-time input at the In port by the integer number of sample intervals specified by the input to the Delay port. The sample rate of the input signal at the Delay port must be the same as the sample rate of the input signal at the In port. When these sample rates are not the same, you need to insert a Zero-Order Hold or Rate Transition block in order to make the sample rates identical. When you set the **Input processing** parameter to `Elements as channels (sample based)`, the delay for an N-D input can be a scalar value to uniformly delay every sample in every channel, or a matrix containing one delay value for each channel of the input. When you set the **Input processing** parameter to `Columns as channels (frame based)`, the delay can be a scalar value to uniformly delay every sample in every channel, a vector containing one delay value for each sample in the input frame, or a vector containing one delay value for each channel in the input frame.

The delay values should be in the range of 0 to *D*, where *D* is the **Maximum delay**. Delay values greater than *D* or less than 0 are clipped to those respective values and noninteger delays are rounded to the nearest integer value.

The Variable Integer Delay block differs from the Delay block in the following ways.

Variable Integer Delay Block	Delay Block
The delay is provided as an input to the Delay port.	You specify the delay as a parameter setting in the dialog box.
Delay can vary with time; for example, when the block performs frame-based processing, the *n*th element's delay in the first input frame can differ from the *n*th element's delay in the second input frame.	Delay cannot vary with time; for example, when the block performs frame-based processing, the *n*th element's delay is the same for every input frame.
When you use the Variable Integer Delay block in a feedback loop, you must check the **Disable direct feedthrough by increasing minimum possible delay by one** check box. This prevents the occurrence of an algebraic loop when the delay of the Variable Integer Delay block is driven to zero.	You can use the Delay block to break an algebraic loop.

Sample-Based Processing

When you set the **Input processing** parameter to `Elements as channels (sample based)`, the Variable Integer Delay block supports N-D input arrays. When the input is an *M*-by-*N*-by-*P* array, the block treats each of the *M***N***P* elements as independent channels, and applies the delay at the Delay port to each channel.

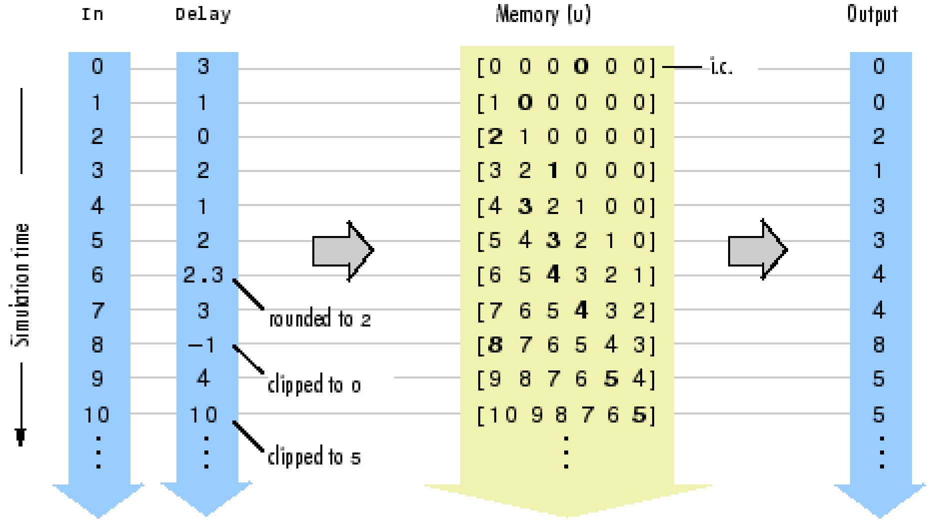
The Variable Integer Delay block stores the D+1 most recent samples received at the In port for each channel. At each sample time the block outputs the stored sample(s) indexed by the input to the Delay port.

For example, when the input to the In port, `u`, is a scalar signal, the block stores a vector, `U`, of the D+1 most recent signal samples. When the current input sample is `U(1)`, the previous input sample is `U(2)`, and so on, then the block's output is

```
y = U(v+1);     % Equivalent MATLAB code
```

where `v` is the input to the Delay port. A delay value of 0 (`v`=0) causes the block to pass through the sample at the In port in the same simulation step that it is received. The block's memory is initialized to the **Initial conditions** value at the start of the simulation (see below).

The next figure shows the block output for a scalar ramp sequence at the In port, a **Maximum delay** of 5, an **Initial conditions** of 0, and a variety of different delays at the Delay port.



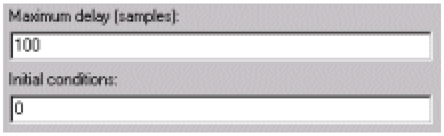
The current input at each time step is immediately stored in memory as `U(1)`. This allows the current input to be available at the output for a delay of 0 (v=0).

The **Initial conditions** parameter specifies the values in the block's memory at the start of the simulation. Unlike the Delay block, the Variable Integer Delay block does not have a fixed initial delay period during which the initial conditions appear at the output. Instead, the initial conditions are propagated to the output only when they are indexed in memory by the value at the Delay port. Both fixed and time-varying initial conditions can be specified in a variety of ways to suit the dimensions of the input sequence.

Fixed Initial Conditions

The settings in this section specify fixed initial conditions. For a fixed initial condition, the block initializes each of D samples in memory to the value entered in the **Initial conditions** parameter. A fixed initial condition in sample-based mode can be specified in one of the following ways:

- Scalar value with which to initialize every sample of every channel in memory. For a general M-by-N input and the parameter settings in this figure,



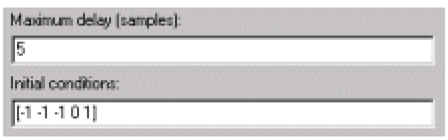
the block initializes 100 *M*-by-*N* matrices in memory with zeros.

- Array of size *M*-by-*N*-by-*D*. In this case, you can specify different fixed initial conditions for each channel. See the Array bullet in "Time-Varying Initial Conditions" on page 2-1852 below for details.

Time-Varying Initial Conditions

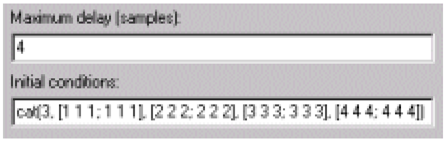
The following settings specify time-varying initial conditions. For a time-varying initial condition, the block initializes each of *D* samples in memory to one of the values entered in the **Initial conditions** parameter. This allows you to specify a unique output value for each sample in memory. A time-varying initial condition in sample-based mode can be specified in one of the following ways:

- Vector containing *D* elements with which to initialize memory samples `U(2:D+1)`, where *D* is the **Maximum delay**. For a scalar input and the parameters in the next figure, the block initializes `U(2:6)` with values `[-1, -1, -1, 0, 1]`.



- Array of dimension *M*-by-*N*-by-*D* with which to initialize memory samples `U(2:D+1)`, where *D* is the **Maximum delay** and *M* and *N* are the number of rows and columns, respectively, in the input matrix. For a 2-by-3 input and the following parameters, the block initializes memory locations `U(2:5)` with values

$$\mathbf{U}(2)=\begin{bmatrix}1&1&1\\1&1&1\end{bmatrix},\ \mathbf{U}(3)=\begin{bmatrix}2&2&2\\2&2&2\end{bmatrix},\ \mathbf{U}(4)=\begin{bmatrix}3&3&3\\3&3&3\end{bmatrix},\ \mathbf{U}(5)=\begin{bmatrix}4&4&4\\4&4&4\end{bmatrix}$$



An *M*-by-*N*-by-*P*-by-*D* array can be entered for the **Initial Conditions** parameter when the input is an *M*-by-*N*-by-*P* array. The (*M*,*N*,*P*,*T*)th sample of the **Initial Conditions** matrix provides the initial condition value for the (*M*,*N*,*P*)th channel of the input matrix at delay = *D*–*t*+1 samples.

Frame-Based Processing

When you set the **Input processing** parameter to `Columns as channels (frame based)`, the input can be an *M*-by-*N* matrix. The block treats each of the *N* input columns as independent channels containing *M* sequential time samples.

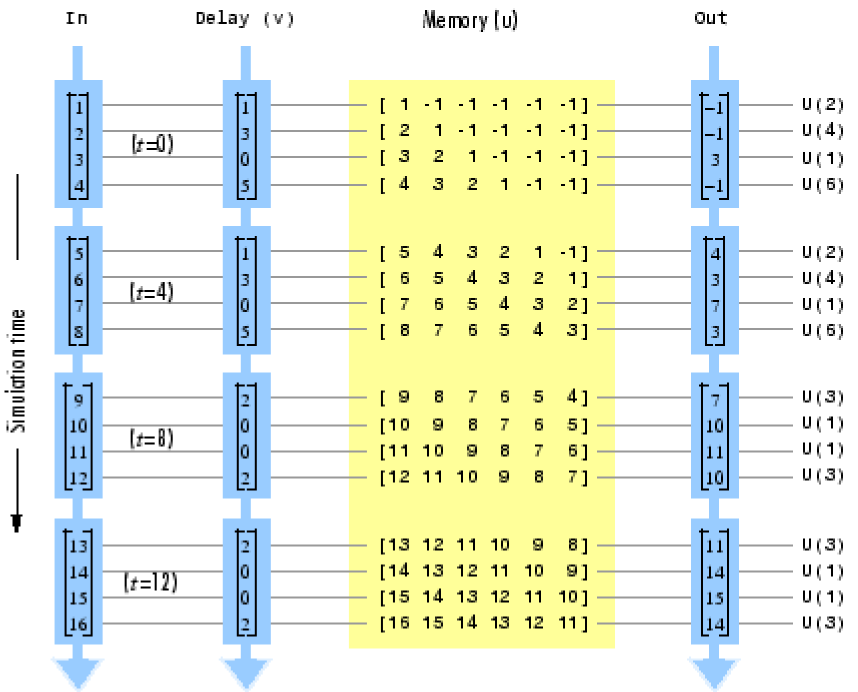
In this mode, the input at the Delay port can be a scalar value to uniformly delay every sample in every channel. It can also be a length-*M* column vector containing one delay value for each sample in the input frame(s). The set of delays contained in the vector is applied identically to every channel of a multichannel input. The Delay port entry can also be a length-*N* row vector, containing one delay for each channel. Finally, the Delay port entry can be an *M*-by-*N* matrix, containing a different delay for each corresponding element of the input.

Vector `v` does not specify when the samples in the current input frame will appear in the output. Rather, `v` indicates which previous input samples (stored in memory) should be included in the current output frame. The first sample in the current output frame is the input sample `v(1)` intervals earlier in the sequence, the second sample in the current output frame is the input sample `v(2)` intervals earlier in the sequence, and so on.

The illustration below shows how this works for an input with a sample period of 1 and frame size of 4. The **Maximum delay** (`Dmax`) is `5`, and the **Initial conditions** parameter is set to `-1`. The delay input changes from `[1 3 0 5]` to `[2 0 0 2]` after the second input frame. The samples in each output frame are the values in memory indexed by the elements of `v`:

```
y(1) = U(v(1)+1)
y(2) = U(v(2)+1)
y(3) = U(v(3)+1)
```

```
y(4) = U(v(4)+1)
```

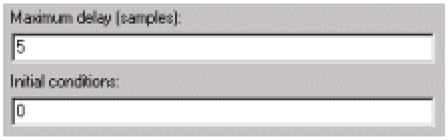


The **Initial conditions** parameter specifies the values in the block's memory at the start of the simulation. Both fixed and time-varying initial conditions can be specified.

Fixed Initial Conditions

The settings shown in this section specify fixed initial conditions. For a fixed initial condition, the block initializes each of D samples in memory to the value entered in the **Initial conditions** parameter. A fixed initial condition in frame-based mode can be one of the following:

- Scalar value with which to initialize every sample of every channel in memory. For a general M-by-N input with the parameter settings below, the block initializes five samples in memory with zeros.



- Array of size 1-by-N-by-D. In this case, you can specify different fixed initial conditions for each channel. See the Array bullet in "Time-Varying Initial Conditions" on page 2-1855 below for details.

Time-Varying Initial Conditions

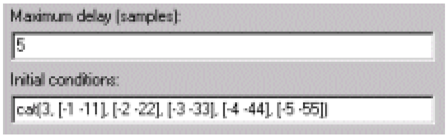
The following setting specifies a time-varying initial condition. For a time-varying initial condition, the block initializes each of D samples in memory to one of the values entered in the **Initial conditions** parameter. This allows you to specify a unique output value for each sample in memory. When the block is performing frame-based processing, you can specify a time-varying initial condition in the following ways:

- Vector containing D elements. In this case, all channels have the same set of time-varying initial conditions specified by the entries of the vector. For the ramp input `[1:100; 1:100]'` with a frame size of `4`, delay of `5`, and the following parameter settings, the block outputs the following sequence of frames at the start of the simulation:

$$\begin{bmatrix} -1 & -1 \\ -2 & -2 \\ -3 & -3 \\ -4 & -4 \end{bmatrix}, \begin{bmatrix} -5 & -5 \\ 1 & 1 \\ 2 & 2 \\ 3 & 3 \end{bmatrix}, \begin{bmatrix} 4 & 4 \\ 5 & 5 \\ 6 & 6 \\ 7 & 7 \end{bmatrix}, \ldots$$

- Array of size 1-by-N-by-D. In this case, you can specify different time-varying initial conditions for each channel. For the ramp input `[1:100; 1:100]'` with a frame size of `4`, delay of `5`, and the following parameter settings, the block outputs the following sequence of frames at the start of the simulation:

$$\begin{bmatrix} -1 & -11 \\ -2 & -22 \\ -3 & -33 \\ -4 & -44 \end{bmatrix}, \begin{bmatrix} -5 & -55 \\ 1 & 1 \\ 2 & 2 \\ 3 & 3 \end{bmatrix}, \begin{bmatrix} 4 & 4 \\ 5 & 5 \\ 6 & 6 \\ 7 & 7 \end{bmatrix}, \ldots$$



By specifying a 1-by-*N*-by-*D* initial condition array such that each 1-by-*N* vector entry is identical, you can implement different fixed initial conditions for each channel.

Examples

See “Basic Algorithmic Delay” in the *DSP System Toolbox User's Guide*.

Parameters

Maximum delay

The maximum delay that the block can produce for any sample. Delay input values exceeding this maximum are clipped at the maximum.

Initial conditions

The values with which the block's memory is initialized.

Input processing

Specify how the block should process the input. You can set this parameter to one of the following options:

- `Columns as channels (frame based)` — When you select this option, the block treats each column of the input as a separate channel.
- `Elements as channels (sample based)` — When you select this option, the block treats each element of the input as a separate channel.

Note: The `Inherited (this choice will be removed - see release notes)` option will be removed in a future release. See "Frame-Based Processing" in the *DSP System Toolbox Release Notes* for more information.

Disable direct feedthrough by increasing minimum possible delay by one

Select this box to disable direct feedthrough by adding one to the minimum possible delay value. When you set the **Input processing** parameter to `Columns as channels (frame based)`, the block increases the minimum possible delay value by *`frame size`* – 1. Similarly, when you set the **Input processing** parameter to `Elements as channels (sample based)`, the block increases the minimum possible delay value by one sample.

Checking this box allows you to use the Variable Integer Delay block in feedback loops.

Supported Data Types

Port	Supported Data Types
In	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers
Delay	• Double-precision floating point • Single-precision floating point • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers
Out	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers

`dspindex`

Description

The Variable Selector block extracts a subset of rows or columns from the M-by-N input matrix `u` at each input port. You specify the number of input and output ports in the **Number of input signals** parameter.

When the **Select** parameter is set to `Rows`, the Variable Selector block extracts rows from each input matrix, while if the **Select** parameter is set to `Columns`, the block extracts columns.

When the **Selector mode** parameter is set to `Variable`, the length-L vector input to the Idx port selects L rows or columns of each input to pass through to the output. The elements of the indexing vector can be updated at each sample time, but the vector length must remain the same throughout the simulation.

When the **Selector mode** parameter is set to `Fixed`, the Idx port is disabled, and the length-L vector specified in the **Elements** parameter selects L rows or columns of each input to pass through to the output. The **Elements** parameter is tunable, so you can change the values of the indexing vector elements at any time during the simulation; however, the vector length must remain the same.

For both variable and fixed indexing modes, the row selection operation is equivalent to

```
y = u(idx,:)      % Equivalent MATLAB code
```

and the column selection operation is equivalent to

```
y = u(:,idx)      % Equivalent MATLAB code
```

where `idx` is the length-L indexing vector. The row selection output size is L-by-N and the column selection output size is M-by-L. Input rows or columns can appear any number of times in the output, or not at all.

When the input is an unoriented vector, the **Select** parameter is ignored; the output is a unoriented vector of length L containing those elements specified by the length-L indexing vector.

When an element of the indexing vector references a nonexistent row or column of the input, the block reacts with the action you specify using the **Invalid index** parameter.

When the indexing vector elements are of Boolean data type, the block performs logical indexing. Select **Fill empty spaces in outputs (for logical indexing)** to access the **Fill values** parameter. These values are appended to the output to make it as long as the input elements.

Note The Variable Selector block always copies the selected input rows to a contiguous block of memory (unlike the Simulink Selector block).

Parameters

Number of input signals

Specify the number of input signals. An input port is created on the block for each input signal.

Select

Specify the dimension of the input to select, `Rows` or `Columns`.

Selector mode

Specify the type of indexing operation to perform, `Variable` or `Fixed`. Variable indexing uses the input at the Idx port to select rows or columns from the input at the `In` port. Fixed indexing uses the **Elements** parameter value to select rows from the input at the In port, and disables the Idx port.

Elements

Specify a vector containing the indices of the input rows or columns that will appear in the output matrix. This parameter appears only when you set the **Selector mode** to `Fixed`.

Index mode

When set to `One-based`, an index value of `1` refers to the first row or column of the input. When set to `Zero-based`, an index value of `0` refers to the first row or column of the input.

Invalid index

Specify how the block handles an invalid index value. You can select one of the following options:

- `Clip index` — Clip the index to the nearest valid value, and do not issue an alert.

  For example, if the block receives a `64`-by-`4` input and the **Select** parameter is set to `Rows`, the block clips an index of `72` to `64`. For the same input, if the **Select** parameter is set to `Columns`, the block clips an index of `72` to `4`. In both cases, the block clips an index of `-2` to `1`.
- `Clip and warn` — Clip the index to the nearest valid value and display a warning message at the MATLAB command line.
- `Generate error` — Display an error dialog box and terminate the simulation.

This parameter is tunable (Simulink).

Fill empty spaces in outputs (for logical indexing)

When the indexing vector elements are of Boolean data type, the block performs logical indexing. This can cause empty spaces in the output. Select this parameter to designate values to be appended to the output in the **Fill values** parameter.

Fill values

Specify the fill values when the block performs logical indexing. This parameter appears only when you select the **Fill empty spaces in outputs (for logical indexing)** check box.

HDL Code Generation

This block supports HDL code generation using HDL Coder. HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

For more information on implementations, properties, and restrictions for HDL code generation, see Variable Selector.

Supported Data Types

Port	Supported Data Types
In	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers • Enumerated
Idx	• Double-precision floating point • Single-precision floating point • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers • Enumerated
Out	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers • Enumerated

Variance

Variance of input or sequence of inputs
Library: DSP System Toolbox / Statistics

Description

The Variance block computes the unbiased variance of each row or column of the input, or along vectors of a specified dimension of the input. It can also compute the variance of the entire input. You can specify the dimension using the **Find the variance value over** parameter. The Variance block can also track the variance in a sequence of inputs over a period of time. To track the variance in a sequence of inputs, select the **Running variance** parameter.

Note: The **Running** mode in the Variance block will be removed in a future release. To compute the running variance in Simulink, use the `Moving Variance` block instead.

Ports

Input

`In` — Data input

vector | matrix | *N*-D array

The block accepts real-valued or complex-valued multichannel and multidimensional inputs.

This port is unnamed until you select the **Running variance** parameter and set the **Reset port** parameter to any option other than `None`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed_point`
Complex Number Support: Yes

`Rst` — Reset port

scalar

Specify the reset event that causes the block to reset the running variance. The sample time of the **Rst** input must be a positive integer multiple of the input sample time.

Dependencies

To enable this port, select the **Running variance** parameter and set the **Reset port** parameter to any option other than `None`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean`

Output

`Port_1` — Variance along the specified dimension

scalar | vector | matrix | *N*-D array

The data type of the output matches the data type of the input.

When you do not select the **Running variance** parameter, the block computes the variance in each row or column of the input, or along vectors of a specified dimension of the input. It can also compute the variance of the entire input at each individual sample time. Each element in the output array `y` is the variance of the corresponding column, row, or entire input. The output array `y` depends on the setting of the **Find the variance value over** parameter. Consider a three-dimensional input signal of size *M*-by-*N*-by-*P*. When you set **Find the variance value over** to:

- `Entire input` — The output at each sample time is a scalar that contains the variance of the *M*-by-*N*-by-*P* input matrix.
- `Each row` — The output at each sample time consists of an *M*-by-1-by-*P* array, where each element contains the variance of each vector over the second dimension of the input. For an *M*-by-*N* matrix input, the output at each sample time is an *M*-by-1 column vector.
- `Each column` — The output at each sample time consists of a 1-by-*N*-by-*P* array, where each element contains the variance of each vector over the first dimension of the input. For an *M*-by-*N* matrix input, the output at each sample time is a 1-by-*N* row vector.

In this mode, the block treats length-M unoriented vector inputs as M-by-1 column vectors.

- `Specified dimension` — The output at each sample time depends on the value of the **Dimension** parameter. If you set the **Dimension** to `1`, the output is the same as when you select `Each column`. If you set the **Dimension** to `2`, the output is the same as when you select `Each row`. If you set the **Dimension** to `3`, the output at each sample time is an M-by-N matrix containing the variance of each vector over the third dimension of the input.

When you select **Running variance**, the block tracks the variance of each channel in a time sequence of inputs. In this mode, you must also specify a value for the **Input processing** parameter.

- `Elements as channels (sample based)` — The block treats each element of the input as a separate channel. For a three-dimensional input signal of size M-by-N-by-P, the block outputs an M-by-N-by-P array. Each element y_{ijk} of the output contains the variance of the element u_{ijk} for all inputs since the last reset.

  When a reset event occurs, the running variance y_{ijk} in the current frame is reset to the element u_{ijk}.
- `Columns as channels (frame based)` — The block treats each column of the input as a separate channel. This option does not support input signals with more than two dimensions. For a two-dimensional input signal of size M-by-N, the block outputs an M-by-N matrix. Each element y_{ij} of the output contains the variance of the elements in the jth column of all inputs since the last reset, up to and including the element u_{ij} of the current input.

  When a reset event occurs, the running variance for each channel becomes the variance of all the samples in the current input frame, up to and including the current input sample.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed_point`

Parameters

Main Tab

`Running variance` — Option to select running variance

off (default) | on

When you select the **Running variance** parameter, the block tracks the variance value of each channel in a time sequence of inputs.

`Find the variance value over` — Dimension over which the block computes the variance

`Each column` (default) | `Entire input` | `Each row` | `Specified dimension`

- `Each column` — The block outputs the variance over each column.
- `Each row` — The block outputs the variance over each row.
- `Entire input` — The block outputs the variance over the entire input.
- `Specified dimension` — The block outputs the variance over the dimension specified in the **Dimension** parameter.

Dependencies

To enable this parameter, clear the **Running variance** parameter.

`Dimension` — Custom dimension

`1` (default) | scalar

Specify the dimension (one-based value) of the input signal over which the variance is computed. The value of this parameter must be greater than 0 and less than the number of dimensions in the input signal.

Dependencies

To enable this parameter, set **Find the variance value over** to `Specified dimension`.

`Input processing` — Method to process the input in running mode
`Columns as channels (frame based)` (default) | `Elements as channels (sample based)`

- `Columns as channels (frame based)` — The block treats each column of the input as a separate channel. This option does not support input signals with more than two dimensions. For a two-dimensional input signal of size *M*-by-*N*, the block outputs an *M*-by-*N* matrix. Each element y_{ij} of the output contains the variance of the elements in the *j*th column of all inputs since the last reset, up to and including the element u_{ij} of the current input.

  When a reset event occurs, the running variance for each channel becomes the variance of all the samples in the current input frame, up to and including the current input sample.
- `Elements as channels (sample based)` — The block treats each element of the input as a separate channel. For a three-dimensional input signal of size *M*-by-*N*-by-*P*, the block outputs an *M*-by-*N*-by-*P* array. Each element y_{ijk} of the output contains the variance of the element u_{ijk} for all inputs since the last reset.

  When a reset event occurs, the running variance y_{ijk} in the current frame is reset to the element u_{ijk}.

  Variable-Size Inputs

  When your inputs are of variable size, and you select the **Running variance** parameter, then:

  - If you set the **Input processing** parameter to `Elements as channels (sample based)`, the state is reset.
  - If you set the **Input processing** parameter to `Columns as channels (frame based)`, then:

    - When the input size difference is in the number of channels (number of columns), the state is reset.
    - When the input size difference is in the length of channels (number of rows), no reset occurs and the running operation is carried out as usual.

Dependencies

To enable this parameter, select the **Running variance** parameter.

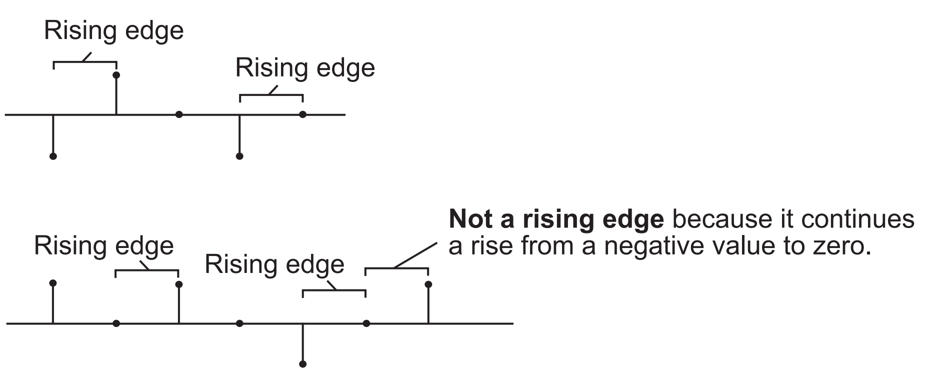
`Reset port` — Reset event
`None` (default) | `Rising edge` | `Falling edge` | `Either edge` | `Non-zero sample`

The block resets the running variance whenever a reset event is detected at the optional **Rst** port. The reset sample time must be a positive integer multiple of the input sample time.

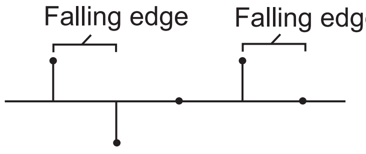
When a reset event occurs while the **Input processing** parameter is set to `Elements as channels (sample based)`, the running variance for each channel is initialized to the value in the corresponding channel of the current input. Similarly, when the **Input processing** parameter is set to `Columns as channels (frame based)`, the running variance for each channel becomes the variance of all the samples in the current input frame, up to and including the current input sample.

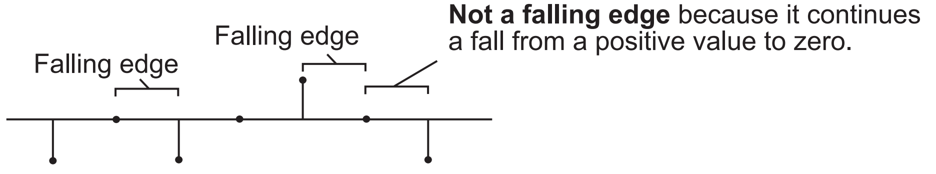
Use this parameter to specify the reset event.

- `None` — Disables the **Rst** port.
- `Rising edge` — Triggers a reset operation when the **Rst** input does one of the following:
  - Rises from a negative value to either a positive value or zero.
  - Rises from zero to a positive value, where the rise is not a continuation of a rise from a negative value to zero.



- `Falling edge` — Triggers a reset operation when the **Rst** input does one of the following:
  - Falls from a positive value to a negative value or zero.
  - Falls from zero to a negative value, where the fall is not a continuation of a fall from a positive value to zero.





- `Either edge` — Triggers a reset operation when the **Rst** input is a `Rising edge` or `Falling edge`.
- `Non-zero sample` — Triggers a reset operation at each sample time, when the **Rst** input is not zero.

Note: When running simulations in the Simulink multitasking mode, reset signals have a one-sample latency. Therefore, when the block detects a reset event, there is a one-sample delay at the reset port rate before the block applies the reset. For more information on latency and the Simulink tasking modes, see “Excess Algorithmic Delay (Tasking Latency)” and “Time-Based Scheduling and Code Generation” (Simulink Coder).

Dependencies

To enable this parameter, select the **Running variance** parameter.

Data Types Tab

Note: To use these parameters, the data input must be fixed point. For all other inputs, the parameters on the **Data Types** tab are ignored.

`Rounding mode` — Method of rounding operation

`Floor` (default) | `Ceiling` | `Convergent` | `Nearest` | `Round` | `Simplest` | `Zero`

Select the rounding mode for fixed-point operations.

`Overflow mode` — Method of overflow action

`Wrap` (default) | `Saturate`

Select the overflow mode for fixed-point operations.

`Input-squared product` — Data type that stores the input-squared term

`Same as input` (default) | `Binary point scaling` | `Slope and bias scaling`

The squares of the input elements are stored in the **Input-squared product** data type. If the input is complex, the squares of the real and imaginary parts of the input are stored in this data type. For more details, see “Fixed Point” on page 2- .

You can set this parameter to:

- `Inherit: Same as input` — The block specifies this data type to be the same as the input data type.
- `Binary point scaling` — The **Input-squared product** data type uses binary point scaling. If you select this option, the block displays the fields to specify the **Word length** and **Fraction length**. The **Signedness** is inherited from the input.
- `Slope and bias scaling` — The **Input-squared product** data type uses slope and bias scaling. If you select this option, the block displays the fields to specify the **Word length** and **Slope**. The **Signedness** is inherited from the input and **Bias** is specified to be `0`.

`Input-sum-squared product` — Data type that stores the input-sum-squared term

`Same as input-squared product` (default) | `Binary point scaling` | `Slope and bias scaling`

The squares of the sum of the input elements are stored in the **Input-sum-squared product** data type. If the input is complex, the squares of the sum of the real parts and the squares of the sum of the imaginary parts are stored in this data type. For more details, see “Fixed Point” on page 2- .

You can set this parameter to:

- `Same as input-squared product` — The block specifies this data type to be the same as the input squared-product data type.
- `Binary point scaling` — The **Input-sum-squared product** data type uses binary point scaling. If you select this option, the block displays the fields to specify the **Word length** and **Fraction length**. The **Signedness** is inherited from the input.
- `Slope and bias scaling` — The **Input-sum-squared product** data type uses slope and bias scaling. If you select this option, the block displays the fields to specify the **Word length** and **Slope**. The **Signedness** is inherited from the input and **Bias** is specified to be `0`.

`Accumulator` — Accumulator data type

`Same as input-squared product` (default) | `Same as input` | `Binary point scaling` | `Slope and bias scaling`

Accumulator specifies the data type of the output of an accumulation operation in the Variance block. See “Fixed Point” on page 2- for illustrations depicting the use of the accumulator data type in this block.

You can set this parameter to:

- `Same as input-squared product` — The block specifies the accumulator data type to be the same as the input-squared product data type.
- `Same as input` — The block specifies the accumulator data type to be the same as the input data type.
- `Binary point scaling` — The **Accumulator** data type uses binary point scaling. If you select this option, the block displays the fields to specify the **Word length** and **Fraction length**. The **Signedness** is inherited from the input.
- `Slope and bias scaling` — The **Accumulator** data type uses slope and bias scaling. If you select this option, the block displays the fields to specify the **Word length** and **Slope**. The **Signedness** is inherited from the input and **Bias** is specified to be `0`.

`Output` — Output data type

`Same as input-squared product` (default) | `Same as accumulator` | `Same as input` | `Binary point scaling` | `Slope and bias scaling`

Output specifies the data type of the output of the Variance block. See "Fixed Point" on page 2- for illustrations depicting the use of the output data type in this block. You can set it to:

- `Same as input-squared product` — The block specifies the output data type to be the same as the input-squared product data type.
- `Same as accumulator` — The block specifies the output data type to be the same as the accumulator data type.
- `Same as input` — The block specifies the output data type to be the same as the input data type.
- `Binary point scaling` — The **Output** data type uses binary point scaling. If you select this option, the block displays the fields to specify the **Word length** and **Fraction length**. The **Signedness** is inherited from the input.
- `Slope and bias scaling` — The **Output** data type uses slope and bias scaling. If you select this option, the block displays the fields to specify the **Word length** and **Slope**. The **Signedness** is inherited from the input and **Bias** is specified to be `0`.

`Lock data type settings against changes by the fixed-point tools` — Prevent fixed-point tools from overriding data types

off (default) | on

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block.

Definitions

Variance

The variance of a discrete-time signal is the square of the standard deviation of the signal.

Variance gives a measure of deviation of the signal from its mean value.

For purely real or imaginary input, u, of size M-by-N, the variance is given by the following equation:

$$y = \sigma^2 = \frac{\sum_{i=1}^{M}\sum_{j=1}^{N}\left|u_{ij}\right|^2 - \frac{\left|\sum_{i=1}^{M}\sum_{j=1}^{N}u_{ij}\right|^2}{M*N}}{M*N-1}$$

- u_{ij} is the input data element at indices i, j.
- M is the length of the jth column.
- N is the number of columns.

For complex inputs, the variance is given by the following equation:

$$\sigma^2 = \sigma_{\mathrm{Re}}{}^2 + \sigma_{\mathrm{Im}}{}^2$$

- $\sigma_{Re}{}^2$ is the variance of the real part of the complex input.
- $\sigma_{Im}{}^2$ is the variance of the imaginary part of the complex input.

Algorithms

Variance

When you clear the **Running variance** parameter in the block and specify a dimension, the block produces results identical to the MATLAB `var` function, when it is called as `y = var(u,0,D)`.

- `u` is the data input.
- `D` is the dimension.
- `y` is the variance along the specified dimension.

The variance along the entire input is identical to calling the `var` function as `y = var(u(:))`.

For a complex input signal, the variance is the sum of the variances of the real and imaginary parts.

$$\sigma^2 = \sigma_{\mathrm{Re}}{}^2 + \sigma_{\mathrm{Im}}{}^2$$

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

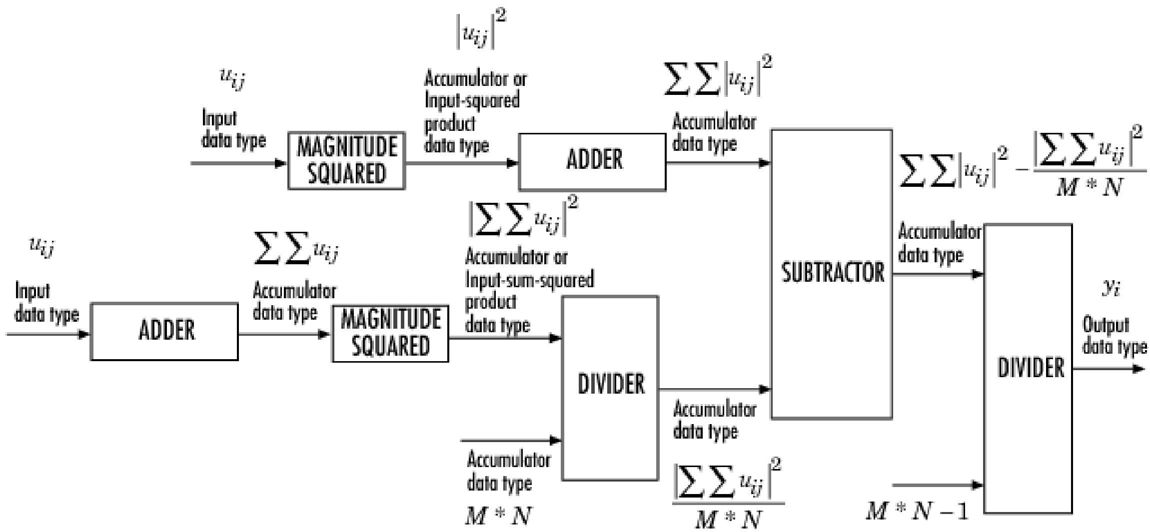
Fixed-Point Conversion

Design and simulate fixed-point algorithms using Fixed-Point Designer™.

For purely real or imaginary input, *u* of size *M*-by-*N*, the variance is given by the following equation.

$$y = \sigma^2 = \frac{\sum_{i=1}^{M}\sum_{j=1}^{N}\left|u_{ij}\right|^2 - \frac{\left|\sum_{i=1}^{M}\sum_{j=1}^{N}u_{ij}\right|^2}{M*N}}{M*N-1}$$

The following diagram shows the data types used within the Variance block when the input is fixed-point.



For complex inputs, the variance is given by the following equation:

$$\sigma^2 = \sigma_{\mathrm{Re}}{}^2 + \sigma_{\mathrm{Im}}{}^2$$

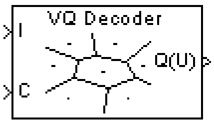
Vector Quantizer Decoder

Find vector quantizer codeword that corresponds to given, zero-based index value



Vector Quantizer
Decoder

Library

Quantizers

`dspquant2`

Description

The Vector Quantizer Decoder block associates each input index value with a codeword, a column vector of quantized output values defined in the **Codebook values** parameter. When you input multiple index values into this block, the block outputs a matrix of quantized output vectors. This matrix is created by horizontally concatenating the codeword vectors that correspond to each index value.

You can select how you want to enter the codebook values using the **Source of codebook** parameter. When you select `Specify via dialog`, you can type the codebook values into the block parameters dialog box. Select `Input port` and port C appears on the block. The block uses the input to port C as the **Codebook values** parameter.

The **Codebook values** parameter is a k-by-N matrix of values, where $k \geq 1$ and $N \geq 1$. Each column of this matrix is a codeword vector, and each codeword vector corresponds to an index value. The index values are zero based; therefore, the first codeword vector corresponds to an index value of 0, the second codeword vector corresponds to an index value of 1, and so on.

The input to this block is a vector of index values, where $0 \leq index < N$ and N is the number of columns of the codebook matrix. Use the **Action for out of range index**

value parameter to determine how the block behaves when an input index value is out of this range. When you want any index values less than 0 to be set to 0 and any index values greater than or equal to *N* to be set to *N*-1, select `Clip`. When you want to be warned when any index values less than 0 are set to 0 and any index values greater than or equal to *N* are set to *N*-1, select `Clip and warn`. When you want the simulation to stop and display an error when the index values are out of range, select `Error`.

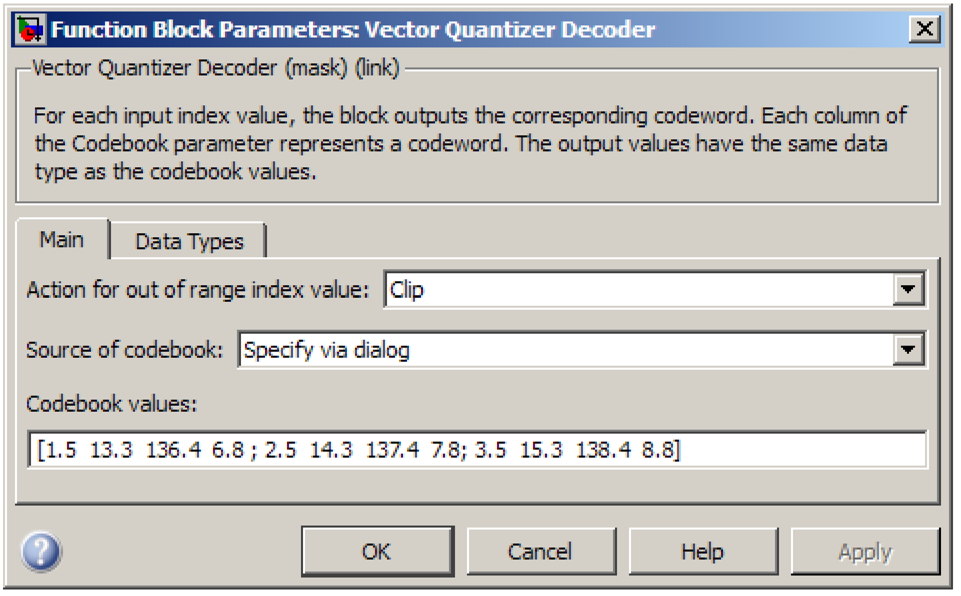
Data Type Support

The input to the block can be the index values and the codebook values. The data type of the index input to the block at port I can be `uint8`, `uint16`, `uint32`, `int8`, `int16`, or `int32`. The data type of the codebook values can be `double`, `single`, or Fixed-point.

The output of the block is the quantized output values. These quantized output values always have the same data type as the codebook values. When the codebook values are specified via an input port, the block assigns the same data type to the Q(U) output port. When the codebook values are specified via the dialog, use the **Codebook and output data type** parameter to specify the data type of the Q(U) output port. The data type of the codebook and quantized output can be `Same as input`, `double`, `single`, `Fixed-point`, `User-defined`, or `Inherit via back propagation`.

Dialog Box

The **Main** pane of the Vector Quantizer Decoder block dialog appears as follows.



Action for out of range index value

Choose the behavior of the block when an input index value is out of range, where $0 \leq index < N$ and N is the length of the codebook vector. Select `Clip` when you want any index values less than 0 to be set to 0 and any index values greater than or equal to N to be set to N-1. Select `Clip and warn` when you want to be warned when any index values less than 0 are set to 0 and any index values greater than or equal to N are set to N-1. Select `Error` when you want the simulation to stop and display an error when the index values are out of range.

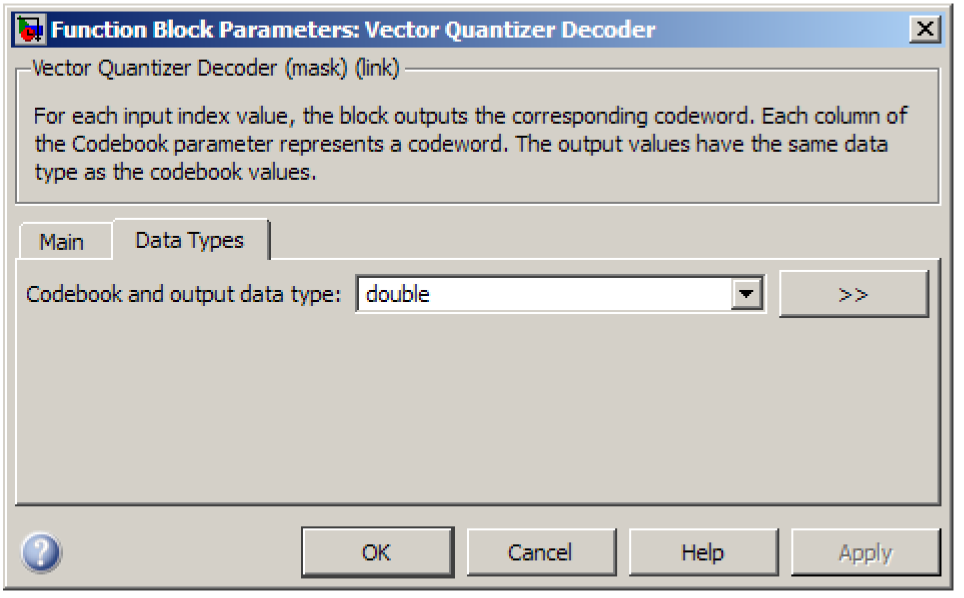
Source of codebook

Choose `Specify via dialog` to type the codebook values into the block parameters dialog box. Select `Input port` to specify the codebook values using the block's input port, C.

Codebook values

Enter a k-by-N matrix of quantized output values, where $1 \leq k$ and $1 \leq N$. Each column of your matrix corresponds to an index value. This parameter is visible if, from the **Source of codebook** list, you select `Specify via dialog`.

The **Data Types** pane of the Vector Quantizer Decoder block dialog appears as follows.



Codebook and output data type

Specify the data type of the codebook and quantized output values. You can select one of the following:

- A rule that inherits a data type, for example, `Inherit: Same as input`.
- A built in data type, such as `double`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16)`

Click the **Show data type assistant** button 

to display the **Data Type Assistant**, which helps you set the **Output data type** parameter.

See “Control Signal Data Types” (Simulink) in Simulink User's Guide (Simulink) for more information.

This parameter is available only when you set the **Source of codebook** parameter to `Specify via dialog`. If you set the **Source of codebook** parameter to `Input port`, the output values have the same data type as the input codebook values.

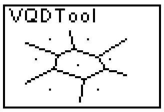
Vector Quantizer Design

Design vector quantizer using Vector Quantizer Design Tool (VQDTool)



Vector Quantizer
Design

Library

Quantizers

`dspquant2`

Description

Double-click on the Vector Quantizer Design block to start VQDTool, a GUI that allows you to design and implement a vector quantizer. You can also start VQDTool by typing `vqdtool` at the MATLAB command prompt. Based on your specifications, VQDTool iteratively calculates the codebook values that minimize the mean squared error between the training set and the codebook until the stopping criteria for the design process is satisfied. The block uses the resulting codebook values to implement your vector quantizer.

For the **Training Set** parameter, enter a k-by-M matrix of values you want to use to train the quantizer codebook. The variable k, where $k \geq 1$, is the length of each training vector. It also represents the dimension of your quantizer. The variable M, where $M \geq 2$, is the number of training vectors. This data can be created using a MATLAB function, such as the default value `randn(10,1000)`, or it can be any variable defined in the MATLAB workspace.

You have two choices for the **Source of initial codebook** parameter. Select `Auto-generate` to have the block choose the values of the initial codebook. In this case, the block picks N random training vectors as the initial codebook, where N is the **Number of levels** parameter and $N \geq 2$. When you select `User defined`, enter the initial codebook values in the **Initial codebook** field. The initial codebook matrix must have the same number of rows as the training set. Each column of the codebook is a codeword, and your codebook must have at least two codewords.

For the given training set and initial codebook, the block performs an iterative process, using the Generalized Lloyd Algorithm (GLA), to design a final codebook. For each iteration of the GLA, the block first associates each training vector with its nearest codeword by calculating the distortion. You can specify one of the two possible methods for calculating distortion using the **Distortion measure** parameter.

When you select `Squared error` for the **Distortion measure** parameter, the block finds the nearest codeword by calculating the squared error (unweighted). Consider the codebook $CB = [CW_1 \quad CW_2 \quad ... \quad CW_N]$. This codebook has N codewords; each codeword has k elements. The i-th codeword is defined as $CW_i = [a_{1i} \quad a_{2i} \quad \cdots \quad a_{ki}]$. The training set has M columns and is defined as $U = [U_1 \quad U_2 \quad ... \quad U_M]$, where the p-th training vector is $U_p = [u_{1p} \quad u_{2p} \quad \cdots \quad u_{kp}]'$. The squared error (unweighted) is calculated using the equation

$$D = \sum_{j=1}^{k} \left(a_{ji} - u_{jp}\right)^2$$

When you select `Weighted squared error` for the **Distortion measure** parameter, enter a vector or matrix for the **Weighting factor** parameter. When the weighting factor is a vector, its length must be equal to the number of rows in the training set. This weighting factor is used for each training vector. When the weighting factor is a matrix, it must be the same size as the training set matrix. The block finds the nearest codeword by calculating the weighted squared error. If the weighting factor for the p-th column of the training vector, U_p, is defined as $Wp = [w_{1p} \quad w_{2p} \quad \cdots \quad w_{kp}]'$, then the weighted squared error is defined by the equation

$$D = \sum_{j=1}^{k} w_{jp} \left(a_{ji} - u_{jp}\right)^2$$

Once the block has associated all the training vectors with their nearest codeword vectors, the block calculates the mean squared error for the codebook and checks to see if the stopping criteria for the process has been satisfied.

The two possible options for the **Stopping criteria** parameter are `Relative threshold` and `Maximum iteration`. When you want the design process to stop when the fractional drop in the squared error is below a certain value, select `Relative threshold`. Then, type the maximum acceptable fractional drop in the **Relative threshold** field. The fraction drop in the squared error is defined as

$$\frac{\text{error at previous iteration} - \text{error at current iteration}}{\text{error at previous iteration}}$$

When you want the design process to stop after a certain number of iterations, choose `Maximum iteration`. Then, enter the maximum number of iterations you want the block to perform in the **Maximum iteration** field. For **Stopping criteria**, you can also choose `Whichever comes first` and enter **Relative threshold** and **Maximum iteration** values. The block stops iterating as soon as one of these conditions is satisfied.

When a training vector has the same distortion for two different codeword vectors, the algorithm uses the **Tie-breaking rule** parameter to determine which codeword vector the training vector is associated with. When you want the training vector to be associated with the lower indexed codeword, select `Lower indexed codeword`. To associate the training vector with the higher indexed codeword, select `Higher indexed codeword`.

With each iteration, the block updates the codeword values in order to minimize the distortion. The **Codebook update method** parameter defines the way the block calculates these new codebook values.

Note If, for the **Distortion measure** parameter, you choose `Squared error`, the **Codebook update method** parameter is set to `Mean`.

If, for the **Distortion measure** parameter, you choose `Weighted squared error` and you choose `Mean` for the **Codebook update method** parameter, the new codeword vector is found as follows. Suppose there are three training vectors associated with one codeword vector. The training vectors are

$$TS_1 = \begin{bmatrix} 1 \\ 2 \end{bmatrix},\ TS_3 = \begin{bmatrix} 10 \\ 12 \end{bmatrix},\ \text{and } TS_7 = \begin{bmatrix} 11 \\ 12 \end{bmatrix}.$$

The new codeword vector is calculated as

$$CW_{new} = \begin{bmatrix} \frac{1+10+11}{3} \\ \frac{2+12+12}{3} \end{bmatrix}$$

where the denominator is the number of training vectors associated with this codeword. If, for the **Codebook update method** parameter, you choose `Centroid` and you specify the weighting factors $W_1 = \begin{bmatrix} 0.1 \\ 0.2 \end{bmatrix}$, $W_3 = \begin{bmatrix} 1 \\ 0.6 \end{bmatrix}$, and $W_7 = \begin{bmatrix} 0.3 \\ 0.4 \end{bmatrix}$, the new codeword vector is calculated as

$$CW_{new} = \begin{bmatrix} \frac{(0.1)(1)+(1)(10)+(0.3)(11)}{0.1+1+0.3} \\ \frac{(0.2)(2)+(0.6)(12)+(0.4)(12)}{0.2+0.6+0.4} \end{bmatrix}$$

Click **Design and Plot** to design the quantizer with the parameter values specified on the left side of the GUI. The performance curve and the entropy of the quantizer are updated and displayed in the figures on the right side of the GUI.

Note You must click **Design and Plot** to apply any changes you make to the parameter values in the VQDTool dialog box.

The following is an example of how the block calculates the entropy of the quantizer at each iteration. Suppose you have a codebook with four codewords and a training set with 200 training vectors. Also suppose that, at the i-th iteration, 40 training vectors are associated with the first codeword, 60 training vectors are associated with the second codeword, 20 training vectors are associated with the third codeword, and 80 training vectors are associated with the fourth codeword. The probability that a training vector is associated with the first codeword is $\frac{40}{200}$. The probabilities that training vectors are associated with the second, third, and fourth codewords are $\frac{60}{200}$, $\frac{20}{200}$, and $\frac{80}{200}$, respectively. The GUI uses these probabilities to calculate the entropy according to the equation

$$H = \sum_{i=1}^{N} -p_i \log_2 p_i$$

where N is the number of codewords. Based on these probabilities, the GUI calculates the entropy of the quantizer at the i-th iteration as

$$H = -\left(\frac{40}{200}\log_2 \frac{40}{200} + \frac{60}{200}\log_2 \frac{60}{200} + \frac{20}{200}\log_2 \frac{20}{200} + \frac{80}{200}\log_2 \frac{80}{200} \right)$$
$$H = 1.8464$$

VQDTool can export parameter values that correspond to the figures displayed in the GUI. Click the **Export Outputs** button, or press **Ctrl+E**, to export the **Final Codebook**, **Mean Square Error**, and **Entropy** values to the workspace, a text file, or a MAT-file.

In the **Model** section of the GUI, specify the destination of the block that will contain the parameters of your quantizer. For **Destination**, select `Current model` to create a block with your parameters in the model you most recently selected. Type `gcs` in the MATLAB Command Window to display the name of your current model. Select `New model` to create a block in a new model file.

From the **Block type** list, select `Encoder` to design a Vector Quantizer Encoder block. Select `Decoder` to design a Vector Quantizer Decoder block. Select `Both` to design a Vector Quantizer Encoder block and a Vector Quantizer Decoder block.

In the **Encoder block name** field, enter a name for the Vector Quantizer Encoder block. In the **Decoder block name** field, enter a name for the Vector Quantizer Decoder block. When you have a Vector Quantizer Encoder and/or Decoder block in your destination model with the same name, select the **Overwrite target block** check box to replace the block's parameters with the current parameters. When you do not select this check box, a new Vector Quantizer Encoder and/or Decoder block is created in your destination model.

Click **Generate Model**. VQDTool uses the parameters that correspond to the current plots to set the parameters of the Vector Quantizer Encoder and/or Decoder blocks.

Parameters

Training Set

Enter the samples of the signal you would like to quantize. This data set can be a MATLAB function or a variable defined in the MATLAB workspace. The typical length of this data vector is `1e5`.

Source of initial codebook

Select `Auto-generate` to have the block choose the initial codebook values. Choose `User defined` to enter your own initial codebook values.

Number of levels

Enter the number of codeword vectors, N, in your codebook matrix, where $N \geq 2$.

Initial codebook

Enter your initial codebook values. From the **Source of initial codebook** list, select `User defined` in order to activate this parameter. The codebook must have the same number of rows as the training set. You must provide at least two codeword vectors.

Distortion measure

When you select `Squared error`, the block finds the nearest codeword by calculating the squared error (unweighted). When you select `Weighted squared error`, the block finds the nearest codeword by calculating the weighted squared error.

Weighting factor

Enter a vector or matrix. The block uses these values to compute the weighted squared error. When the weighting factor is a vector, its length must be equal to the number of rows in the training set. This weighting factor is used for each training vector. When the weighting factor is a matrix, it must be the same size as the training set matrix. The individual weighting factors cannot be negative. The weighting factor vector or matrix cannot contain all zeros.

Stopping criteria

Choose `Relative threshold` to enter the maximum acceptable fractional drop in the squared quantization error. Choose `Maximum iteration` to specify the number of iterations at which to stop. Choose `Whichever comes first` and the block stops the iteration process as soon as the relative threshold or maximum iteration value is attained.

Relative threshold

This parameter is available when you choose `Relative threshold` or `Whichever comes first` for the **Stopping criteria** parameter. Enter the value that is the maximum acceptable fractional drop in the squared quantization error.

Maximum iteration

This parameter is available when you choose `Maximum iteration` or `Whichever comes first` for the **Stopping criteria** parameter. Enter the maximum number of iterations you want the block to perform.

Tie-breaking rules

When a training vector has the same distortion for two different codeword vectors, select `Lower indexed codeword` to associate the training vector with the lower indexed codeword. Select `Higher indexed codeword` to associate the training vector with the lower indexed codeword.

Codebook update method

When you choose `Mean`, the new codeword vector is calculated by taking the average of all the training vector values that were associated with the original codeword vector. When you choose `Centroid`, the block calculates the new codeword vector by taking the weighted average of all the training vector values that were associated with the original codeword vector Note that if, for the **Distortion measure** parameter, you choose `Squared error`, the **Codebook update method** parameter is set to `Mean`.

Destination

Choose `Current model` to create a Vector Quantizer block in the model you most recently selected. Type `gcs` in the MATLAB Command Window to display the name of your current model. Choose `New model` to create a block in a new model file.

Block type

Select `Encoder` to design a Vector Quantizer Encoder block. Select `Decoder` to design a Vector Quantizer Decoder block. Select `Both` to design a Vector Quantizer Encoder block and a Vector Quantizer Decoder block.

Encoder block name

Enter a name for the Vector Quantizer Encoder block.

Decoder block name

Enter a name for the Vector Quantizer Decoder block.

Overwrite target block

When you do not select this check box and a Vector Quantizer Encoder and/or Decoder block with the same block name exists in the destination model, a new Vector Quantizer Encoder and/or Decoder block is created in the destination model. When you select this check box and a Vector Quantizer Encoder and/or Decoder block with the same block name exists in the destination model, the parameters of these blocks are overwritten by new parameters.

Generate Model

Click this button and VQDTool uses the parameters that correspond to the current plots to set the parameters of the Vector Quantizer Encoder and/or Decoder blocks.

Design and Plot

Click this button to design a quantizer using the parameters on the left side of the GUI and to update the performance curve and entropy plots on the right side of the GUI.

You must click **Design and Plot** to apply any changes you make to the parameter values in the VQDTool GUI.

Export Outputs

Click this button, or press **Ctrl+E**, to export the **Final Codebook**, **Mean Squared Error**, and **Entropy** values to the workspace, a text file, or a MAT-file.

Supported Data Types

- Double-precision floating point

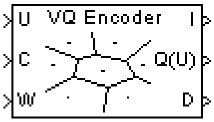
Vector Quantizer Encoder

For given input, find index of nearest codeword based on Euclidean or weighted Euclidean distance measure



Vector Quantizer Encoder

Library

Quantizers

`dspquant2`

Description

The Vector Quantizer Encoder block compares each input column vector to the codeword vectors in the codebook matrix. Each column of this codebook matrix is a codeword. The block finds the codeword vector nearest to the input column vector and returns its zero-based index. This block supports real floating-point and fixed-point signals on all input ports.

The block finds the nearest codeword by calculating the distortion. The block uses two methods for calculating distortion: Euclidean squared error (unweighted) and weighted Euclidean squared error. Consider the codebook, $CB = [CW_1 \quad CW_2 \quad \ldots \quad CW_N]$. This codebook has N codewords; each codeword has k elements. The i-th codeword is defined as a column vector, $CW_i = [a_{1i} \quad a_{2i} \quad \ldots \quad a_{ki}]$. The multichannel input has M columns and is defined as $U = [U_1 \quad U_2 \quad \ldots \quad U_M]$, where the p-th input column vector is $U_p = [u_{1p} \quad u_{2p} \quad \ldots \quad u_{kp}]'$. The squared error (unweighted) is calculated using the equation

$$D = \sum_{j=1}^{k} \left(a_{ji} - u_{jp}\right)^2$$

The weighted squared error is calculated using the equation

$$D = \sum_{j=1}^{k} w_j \left(a_{ji} - u_{jp}\right)^2$$

where the weighting factor is defined as $W = [w_1 \quad w_2 \quad \ldots \quad w_k]$. The index of the codeword that is associated with the minimum distortion is assigned to the input column vector.

You can select how you want to enter the codebook values using the **Source of codebook** parameter. When you select `Specify via dialog`, you can type the codebook values into the block parameters dialog box. Select `Input port` and port C appears on the block. The block uses the input to port C as the **Codebook** parameter.

The **Codebook** parameter is an k-by-N matrix of values, where $k \geq 1$ and $N \geq 1$. Each input column vector is compared to this codebook. Each column of the codebook matrix is a codeword, and each codeword has an index value. The first codeword vector corresponds to an index value of 0, the second codeword vector corresponds to an index value of 1, and so on. The codeword vectors must have the same number of rows as the input, U.

For the **Distortion measure** parameter, select `Squared error` when you want the block to calculate the distortion by evaluating the Euclidean distance between the input column vector and each codeword in the codebook. Select `Weighted squared error` when you want to use a weighting factor to emphasize or deemphasize certain input values.

For the **Source of weighting factor** parameter, select `Specify via dialog` to enter a weighting factor vector in the dialog box. Choose `Input port` to specify the weighting factor using port W.

Use the **Weighting factor** parameter to emphasize or deemphasize certain input values when calculating the distortion measure. For example, consider the p-th input column vector, U_p, as previously defined. When you want to neglect the effect of the first element of this vector, enter `[0 1 1 ... 1]` as the **Weighting factor** parameter. This weighting factor is used to calculate the weighted squared error using the equation

$$D = \sum_{j=1}^{k} w_j \left(a_{ji} - u_{jp}\right)^2$$

Because of the weighting factor used in this example, the weighted squared error is not affected by the first element of the input matrix. Therefore, the first element of the input column vector no longer impacts the choice of index value output by the Vector Quantizer Encoder block.

Use the **Index output data type** parameter to specify the data type of the index values output at port I. The data type of the index values can be `int8`, `uint8`, `int16`, `uint16`, `int32`, or `uint32`.

When an input vector is equidistant from two codewords, the block uses the **Tie-breaking rule** parameter to determine which index value the block chooses. When you want the input vector to be represented by the lower index valued codeword, select `Choose the lower index`. To represent the input column vector by the higher index valued codeword, select `Choose the higher index`.

Select the **Output codeword** check box to output at port Q(U) the codeword vectors that correspond to each index value. When the input is a matrix, the corresponding codeword vectors are horizontally concatenated into a matrix.

Select the **Output quantization error** check box to output at port D the quantization error that results when the block represents the input column vector by its nearest codeword. When the input is a matrix, the quantization error values are horizontally concatenated.

The Vector Quantizer Encoder block accepts real floating-point and fixed-point inputs. For more information on the data types accepted by each port, see “Data Type Support” on page 2-1892 or “Supported Data Types” on page 2-1898.

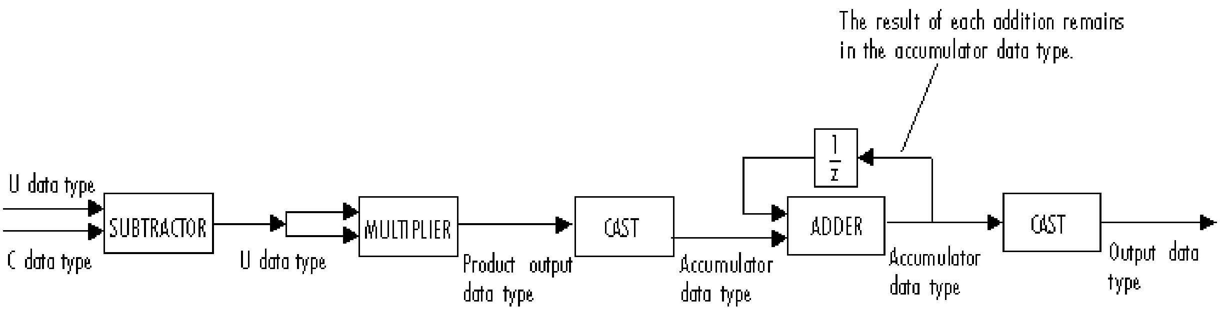
Data Type Support

The input data values, codebook values, and weighting factor values are input to the block at ports U, C, and W, respectively. The data type of the input data values, codebook values, and weighting factor values can be `double`, `single`, or Fixed-point. The input data, codebook values, and weighting factor must be the same data type.

The outputs of the block are the index values, output codewords, and quantization error. Use the **Index output data type** parameter to specify the data type of the index output from the block at port I. The data type of the index can be `int8`, `uint8`, `int16`, `uint16`, `int32`, or `uint32`. The data type of the output codewords and the quantization error can be `double`, `single`, or Fixed-point. The block assigns the data type of the output codewords and the quantization error based on the data type of the input data.

Fixed-Point Data Types

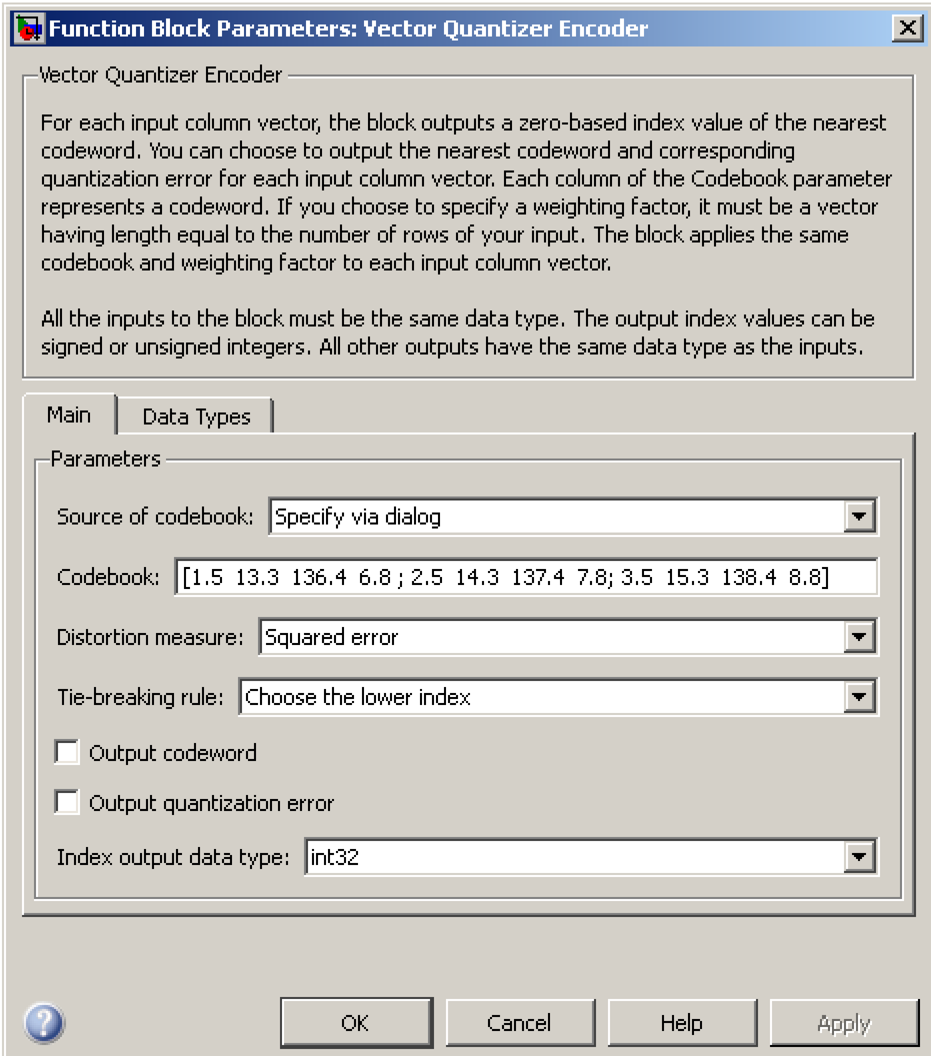
The following diagram shows the data types used within the Vector Quantizer Encoder block for fixed-point signals.



You can set the product output, accumulator, and index output data types in the block dialog as discussed below.

Dialog Box

The **Main** pane of the Vector Quantizer Encoder block dialog appears as follows.



Source of codebook

Choose `Specify via dialog` to type the codebook values into the block parameters dialog box. Select `Input port` to specify the codebook values using the block's input port, C.

Codebook

Enter a k-by-N matrix of values, where $1 \leq k$ and $1 \leq N$, to which your input column vector or matrix is compared. This parameter is visible if, from the **Source of codebook** list, you select `Specify via dialog`.

Distortion measure

Select `Squared error` when you want the block to calculate the distortion by evaluating the Euclidean distance between the input column vector and each codeword in the codebook. Select `Weighted squared error` when you want the block to calculate the distortion by evaluating a weighted Euclidean distance using a weighting factor to emphasize or deemphasize certain input values.

Source of weighting factor

Select `Specify via dialog` to enter a value for the weighting factor in the dialog box. Choose `Input port` and specify the weighting factor using port W on the block. This parameter is visible if, for the **Distortion measure** parameter, you select `Weighted squared error`.

Weighting factor

Enter a vector of values. This vector must have length equal to the number of rows of the input, U. This parameter is visible if, for the **Source of weighting factor** parameter, you select `Specify via dialog`.

Tie-breaking rule

Set this parameter to determine the behavior of the block when an input column vector is equidistant from two codewords. When you want the input column vector to be represented by the lower index valued codeword, select `Choose the lower index`. To represent the input column vector by the higher index valued codeword, select `Choose the higher index`.

Output codeword

Select this check box to output the codeword vectors nearest to the input column vectors.

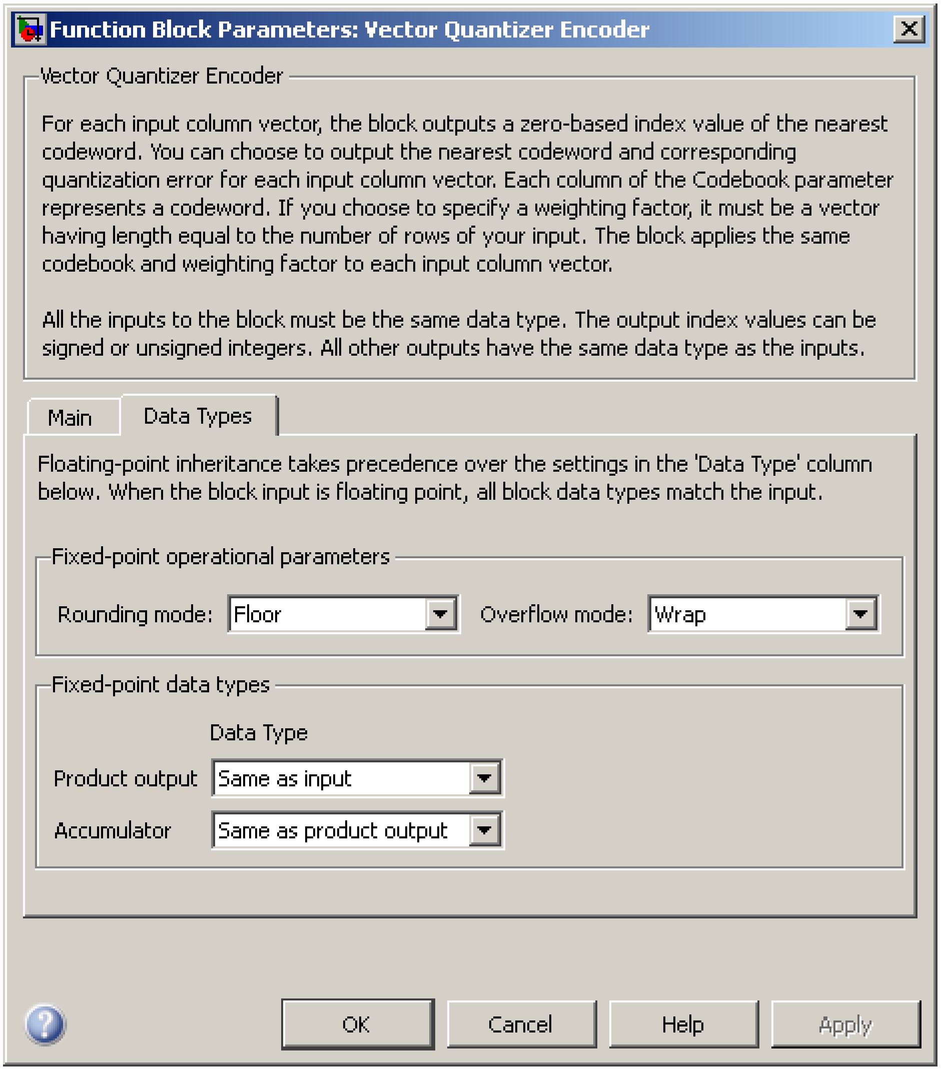
Output quantization error

Select this check box to output the quantization error value that results when the block represents the input column vector by the nearest codeword.

Index output data type

Select `int8`, `uint8`, `int16`, `uint16`, `int32`, or `uint32` as the data type of the index output at port I.

The **Data Types** pane of the Vector Quantizer Encoder block dialog appears as follows.



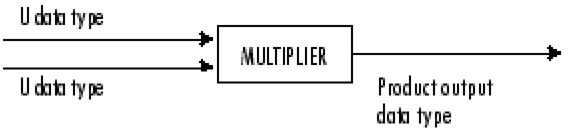
Rounding mode

Select the rounding mode for fixed-point operations.

Overflow mode

Select the overflow mode to be used when block inputs are fixed point.

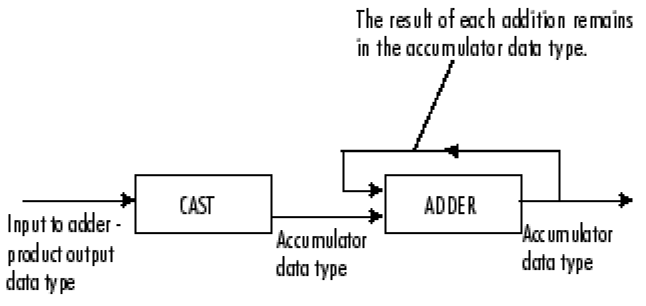
Product output



As depicted above, the output of the multiplier is placed into the product output data type and scaling. Use this parameter to specify how you would like to designate this product output word and fraction lengths.

- When you select `Same as input`, these characteristics match those of the input to the block.
- When you select `Binary point scaling`, you can enter the word length and the fraction length of the product output, in bits.
- When you select `Slope and bias scaling`, you can enter the word length, in bits, and the slope of the product output. This block requires power-of-two slope and zero bias.

Accumulator



As depicted above, inputs to the accumulator are cast to the accumulator data type. The output of the adder remains in the accumulator data type as each element of the input is added to it. Use this parameter to specify how you would like to designate the accumulator word and fraction lengths.

- When you select `Same as product output`, these characteristics match those of the product output.
- When you select `Same as input`, these characteristics match those of the input to the block.
- When you select `Binary point scaling`, you can enter the word length and the fraction length of the accumulator, in bits.

- When you select `Slope and bias scaling`, you can enter the word length, in bits, and the slope of the accumulator. This block requires power-of-two slope and zero bias.

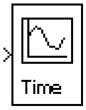
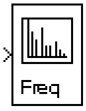
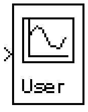
Vector Scope

Display vector or matrix of time-domain, frequency-domain, or user-defined data







Library

Sinks

`dspsnks4`

Description

Note: Consider using the `Array Plot` block, which offers more features than the Vector Scope. Additional features supported by the Array Plot are:

- Multiple inputs
- Cursors, Signal Statistics, and Peak Finder measurements
- Magnitude-phase plot
- Log *x*-axis scaling
- Advanced panning, zooming, and autoscaling
- Ability to customize the plot appearance, such as, figure and axes colors, line width, and legend text

---

The Vector Scope block is a comprehensive display tool similar to a digital oscilloscope. The block can display time-domain, frequency-domain, or user-defined signals. You can use the Vector Scope block to plot consecutive time samples from a vector, or to plot vectors containing data such as filter coefficients or spectral magnitudes. To compute and plot the periodogram of a signal with a single block, use the `Spectrum Analyzer` block.

The input to the Vector Scope block can be any real-valued matrix or vector. The block treats each column of an *M*-by-*N* matrix input as an independent channel of data with *M* consecutive samples.

The block plots each sample of each input channel sequentially across the horizontal axis of the plot.

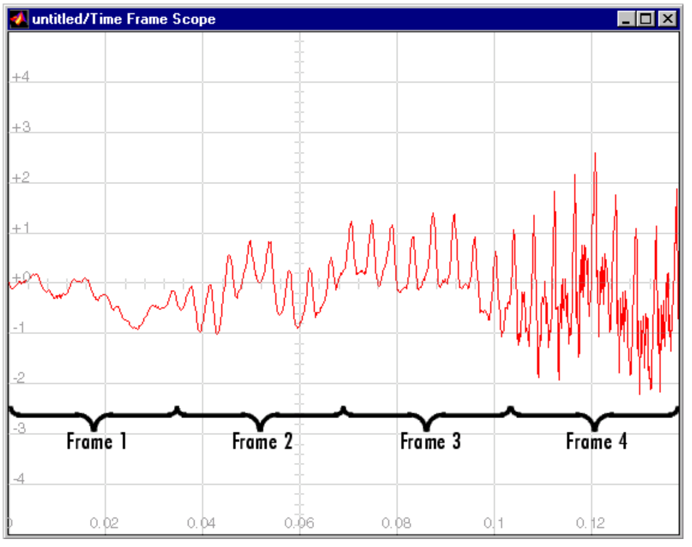
Scope Properties Pane

The **Scope Properties** pane enables you to plot time-domain, frequency-domain, or user-defined data, and adjust the horizontal display span of the plot. The scope displays frames of data, and updates the display for each new input frame.

The **Input domain** parameter specifies the domain of the input data. If you select `Time`, for *M*-by-*N* inputs containing time-domain data, the block treats each of the *N* input frames (columns) as a succession of *M* consecutive samples taken from a time series. That is, each data point in the input frame is assumed to correspond to a unique time value. Also, the **Time display span (number of frames)** parameter appears on the pane. Enter a scalar value greater than or equal to one that corresponds to the number of frames to be displayed across the width of the scope window.

If you select `Frequency` for the **Input domain** parameter, for *M*-by-*N* inputs containing frequency-domain data, the block treats each of the *N* input frames (columns) as a vector of spectral magnitude data corresponding to *M* consecutive ascending frequency indices. That is, when the input is a single column vector, u, each value in the input frame, `u(i)`, is assumed to correspond to a unique frequency value, `f(i)`, where `f(i+1)>f(i)`.

If you select `User-defined` for the **Input domain** parameter, the block does not assume that the input frame data is time-domain or frequency-domain data. You can plot the data in the appropriate manner. Also, the **Horizontal display span (number of frames)** parameter appears on the pane. Enter a scalar value greater than or equal to one that corresponds to the number of frames to be displayed across the width of the scope window.



Display Properties Pane

The **Display Properties** pane enables you to control how the block displays your data.

The **Show grid** parameter toggles the background grid on and off.

If you select the **Frame number** check box, the block displays the number of the current frame in the input sequence on the scope window, and the block increments the count as each new input is received. Counting starts at 1 with the first input frame, and continues until the simulation stops.

If you select the **Channel legend** check box, a legend indicating the line color, style, and marker of each channel's data is added. When the input signal is labeled, that label appears in the channel legend. When the input signal is not labeled, but comes from a Concatenate block or a Mux block with labeled inputs, those labels appear in the channel legend. Otherwise, each channel in the legend is labeled with the channel number (`CH 1`, `CH 2`, etc.). Click and drag the legend to reposition it in the scope window; double-click on the line label to edit the text. If you rerun the simulation, the labels revert to the defaults.

If you select the **Compact display** check box, the scope completely fills the figure window. The scope does not display menus and axis titles, but it does show the numerical axis labels within the axes. If you clear the **Compact display** check box, the scope displays the axis labels and titles in a gray border surrounding the scope axes, and the window's menus and toolbar become visible.

If you select the **Open scope at start of simulation** check box, the scope opens at the start of the simulation. If you clear this parameter, the scope does not open automatically during the simulation. You can use this feature when you have several scope blocks in a model, and you do not want to view all the associated scopes during the simulation.

Note: Before running a model that contains a Vector Scope block in Accelerator, Rapid Accelerator, or External mode, you must select the **Open scope at start of simulation** check box. If you do not select this check box before running your model for the first time, the scope will not display your simulation data.

If you want to view a scope window that is not open during simulation, click **Open scope immediately** on the **Display Properties** pane of the desired Scope block.

The **Scope position** parameter specifies a four-element vector of the form

```
[left bottom width height]
```

specifying the position of the scope window on the screen, where (0,0) is the lower-left corner of the display. See the MATLAB `figure` function for more information.

Axis Properties Pane

The parameters that are available on the **Axis Properties** pane depend on the setting of the **Input domain** parameter on the **Scope Properties** pane.

Time Domain Inputs

When **Time display limits** is set to `Auto`, the block scales the horizontal axis of time-domain signals automatically. The range of the time axis is $[0, S * T_{fi}]$, where T_{fi} is the input frame period, and S is the **Time display span (number of frames)** parameter on the **Scope Properties** pane. The spacing between time points is $T_{fi}/(M-1)$, where M is the number of samples in each consecutive input frame.

When **Time display limits** is set to `User-defined`, the **Minimum X-limit (s)** and **Maximum X-limit (s)** parameters set the range of the horizontal axis.

Minimum Y-limit and **Maximum Y-limit** parameters set the range of the vertical axis. Setting these parameters is analogous to setting the `ymin` and `ymax` values of the MATLAB axis function.

The **Y-axis label** is the text displayed to the left of the *y*-axis.

Frequency Domain Inputs

The **Frequency units** parameter specifies whether the frequency axis values should be in units of Hertz or rad/sec. When the **Frequency units** parameter is set to `Hertz`, the spacing between frequency points is $1/(M * T_s)$, where T_s is the sample time of the original time-domain signal. When the **Frequency units** parameter is set to `rad/sec`, the spacing between frequency points is $2\pi/(M * T_s)$.

The **Frequency range** parameter specifies the range of frequencies over which the magnitudes in the input should be plotted. The available options are `[0..Fs/2]`, `[-Fs/2..Fs/2]`, and `[0..Fs]`, where `Fs` is the original time-domain signal's sample frequency. The Vector Scope block assumes that the input data spans the range $[0, F_s)$, which is the same as the output from an FFT. To plot over the range `[0..Fs/2]` the scope truncates the input vector, leaving only the first half of the data, then plots these remaining samples over half the frequency range. To plot over the range `[-Fs/2..Fs/2]`, the scope reorders the input vector elements such that the last half of the data becomes the first half, and vice versa; then it relabels the *x*-axis accordingly.

If you select the **Inherit sample time from input** check box for frequency domain inputs, the block scales the frequency axis by reconstructing the frequency data from the frame-period of the frequency-domain input. This is valid when the following conditions hold:

- Each frame of frequency-domain data shares the same length as the frame of time-domain data from which it was generated; for example, when the FFT is computed on the same number of points as are contained in the time-domain input.
- The sample period of the time-domain signal in the simulation is equal to the period with which the physical signal was originally sampled.
- Consecutive frames containing the time-domain signal do not overlap each other; that is, a particular signal sample does not appear in more than one sequential frame.

In cases where not all of these conditions hold, specify the appropriate value for the **Sample time of original time series** parameter.

When **Frequency display limits** is set to `Auto`, the block scales the horizontal axis of frequency-domain signals automatically. To do this, the Vector Scope block needs to know the sample period of the original time-domain sequence represented by the frequency-domain data. Specify this period by entering a value for the **Sample time of original time series** parameter.

When **Frequency display limits** is set to `User-defined`, the **Minimum frequency** and **Maximum frequency** parameters set the range of the horizontal axis.

The **Y-axis scaling** parameter allows you to select `Magnitude` or `dB` scaling along the *y*-axis.

Minimum Y-limit and **Maximum Y-limit** parameters set the range of the vertical axis. Setting these parameters is analogous to setting the `ymin` and `ymax` values of the MATLAB axis function.

The **Y-axis label** is the text displayed to the left of the *y*-axis.

User-Defined Inputs

If you select the **Inherit sample increment from input** check box for user-defined input domains, the block scales the horizontal axis by computing the horizontal interval between samples in the input frame from the frame period of the input. For example, when the input frame period is 1, and there are 64 samples per input frame, the interval between samples is computed to be 1/64. Computing the interval this way is usually only valid when the following conditions hold:

- The input is a nonoverlapping time series; the *x*-axis on the scope represents time.
- The input sample period (1/64 in the above example) is equal to the period with which the physical signal was originally sampled.

In cases where not all of these conditions hold, use the **X display offset (samples)** and **Increment per sample in input** parameters.

The **X-axis title** is the text displayed below the *x*-axis.

When **X display limits** is set to `Auto`, the block scales the horizontal axis of user-defined domain signals automatically. To do this, the Vector Scope block needs to know the spacing of the input data. Specify this spacing using the **Increment per sample in input** parameter, I_s. This parameter represents the numerical interval between adjacent *x*-axis points corresponding to the input data. The range of the horizontal axis is $[0, M * I_s * S]$, where M is the number of samples in each consecutive input frame, and S is the **Horizontal display span (number of frames)** parameter that you specify in the **Scope Properties** pane.

When **X display limits** is set to `User-defined`, the **Minimum X-limit (samples)** and **Maximum X-limit (samples)** parameters set the range of the horizontal axis.

Minimum Y-limit and **Maximum Y-limit** parameters set the range of the vertical axis. Setting these parameters is analogous to setting the `ymin` and `ymax` values of the MATLAB `axis` function.

The **Y-axis label** is the text displayed to the left of the *y*-axis.

Line Properties Pane

Use the parameters on the **Line Properties** pane to help you distinguish between two or more independent channels of data on the scope.

The **Line visibilities** parameter specifies which channel's data is displayed on the scope, and which is hidden. The syntax specifies the visibilities in list form, where the term `on` or `off` as a list entry specifies the visibility of the corresponding channel's data. The list entries are separated by the pipe symbol, `|`.

For example, a five-channel signal would ordinarily generate five distinct plots on the scope. To disable plotting of the third and fifth lines, enter the following visibility specification in the **Line visibilities** parameter.

```
 on | on | off | on | off
ch 1 ch 2 ch 3  ch 4 ch 5
```

Note that the first (leftmost) list item corresponds to the first signal channel (leftmost column of the input matrix).

The **Line styles** parameter specifies the line style with which each channel's data is displayed on the scope. The syntax specifies the channel line styles in list form, with each list entry specifying a style for the corresponding channel's data. The list entries are separated by the pipe symbol, `|`.

For example, a five-channel signal would ordinarily generate all five plots with a solid line style. To plot each line with a different style, enter

```
   - | -- | : | -. | -
ch 1 ch 2 ch 3 ch 4 ch 5
```

These settings plot the signal channels with the following styles.

Line Style	Command to Type in Line Style Parameter	Appearance
Solid	-	

Line Style	Command to Type in Line Style Parameter	Appearance
Dashed	`--`	
Dotted	`:`	
Dash-dot	`-.`	
No line	`none`	No line appears

Note that the first (leftmost) list item, `'-'`, corresponds to the first signal channel (leftmost column of the input matrix). See the LineStyle property of the MATLAB `line` function for more information about the style syntax.

The **Line markers** parameter specifies the marker style with which each channel's samples are represented on the scope. The syntax specifies the channels' marker styles in list form, with each list entry specifying a marker for the corresponding channel's data. The list entries are separated by the pipe symbol, `|`.

For example, a five-channel signal would ordinarily generate all five plots with no marker symbol (that is, the individual sample points are not marked on the scope). To instead plot each line with a different marker style, you could enter

```
  * | . | x | s | d
ch 1 ch 2 ch 3 ch 4 ch 5
```

These settings plot the signal channels with the following styles.

Marker Style	Command to Type in Marker Style Parameter	Appearance
Asterisk	`*`	
Point	`.`	
Cross	`x`	
Square	`s`	
Diamond	`d`	

Note that the leftmost list item, `'*'`, corresponds to the first signal channel or leftmost column of the input matrix. See the LineSpec (Line Specification) (MATLAB) property of the MATLAB `line` function for more information about the available markers.

To produce a stem plot for the data in a particular channel, type the word `stem` instead of one of the basic marker shapes.

The **Line colors** parameter specifies the color in which each channel's data is displayed on the scope. The syntax specifies the channel colors in list form, with each list entry specifying a color (in one of the MATLAB `ColorSpec` formats) for the corresponding channel's data. The list entries are separated by the pipe symbol, `|`.

For example, a five-channel signal would ordinarily generate all five plots in the color black. To instead plot the lines with the color order below, enter

```
[0 0 0] | [0 0 1] | [1 0 0 ] | [0 1 0] | [.7529 0 .7529]
 ch 1      ch 2      ch 3       ch 4          ch 5
```

or

```
'k' | 'b' | 'r' | 'g' | [.7529 0 .7529]
ch 1  ch 2  ch 3  ch 4      ch 5
```

These settings plot the signal channels in the following colors (8-bit RGB equivalents shown in the center column).

Color	RGB Equivalent	Appearance
Black	(0,0,0)	
Blue	(0,0,255)	
Red	(255,0,0)	
Green	(0,255,0)	
Dark purple	(192,0,192)	

Note that the leftmost list item, `'k'`, corresponds to the first signal channel or leftmost column of the input matrix. See the MATLAB function `ColorSpec` for more information about the color syntax.

Vector Scope Window

The title that appears in the title bar of the scope window is the same as the block title. In addition to the standard MATLAB figure window menus such as **File**, **Window**, and **Help**, the Vector Scope window contains **View**, **Axes**, and **Channels** menus.

The options in the **View** menu allow you to zoom in and out of the scope window:

- To zoom in on the scope window, you must first select **View** > **Zoom In** or click the corresponding `Zoom In` toolbar button ( ). You can then zoom in by clicking in the center of your area of interest, or by clicking and dragging your cursor to draw a rectangular area of interest inside of the scope window.
- To zoom in on the *x*-axis of the scope window, you must first select **View** > **Zoom X**, or click the corresponding `Zoom X-Axis` toolbar button ( ) on the scope window. You can then zoom in on the *x*-axis with a single click inside the scope window or by clicking and dragging the cursor along the *x*-axis over your area of interest.
- To zoom in on the *y*-axis of the scope window, you must first select **View** > **Zoom Y** or click the corresponding `Zoom Y-Axis` toolbar button ( ). You can then zoom in on the *y*-axis with a single click inside the scope window or by clicking and dragging the cursor along the *y*-axis over your area of interest.
- To return to the original view of the scope window, you have the following options:
  - Select **Full View** from the **View** menu .
  - Click the `Restore default view` toolbar button ( ) on the Vector Scope window.
  - Right-click inside the scope window, and select `Reset to Original View`.

Note: To zoom out in smaller increments, you can right-click inside of the scope window and select `Zoom Out`. You can also zoom out by holding down the **Shift** key and clicking the left mouse button inside the scope window.

The parameters that you set using the **Axes** menu apply to all channels. Many of the parameters in this menu are also accessible through the block parameters dialog box. For descriptions of these parameters, see “Display Properties Pane” on page 2-1902. Below are descriptions of other parameters in the **Axes** menu:

- **Refresh** erases all data on the scope display, except for the most recent trace.
- **Autoscale** resizes the *y*-axis to best fit the vertical range of the data.

Note: The **Minimum Y-limit** and **Maximum Y-limit** parameters on the **Axis properties** pane of the block dialog are not updated to display the numerical limits selected by the autoscale feature.

- **Save Axes Settings** allows you to save the current axes settings. When you select this option, the **Minimum Y-limit** and **Maximum Y-limit** parameters of the **Axes Properties** pane update with the current *y*-axes limits. The **Time display limits** (or **Frequency display limits**) parameter is set to `User-defined`, and the current *x*-axes limits are saved in the **Minimum X-limit** and **Maximum X-limit** (or **Minimum Frequency** and **Maximum Frequency**) parameters. To save these axes settings for your next MATLAB session, you need to resave your model.
- **Save Scope Position** updates the **Scope position** parameter on the **Display Properties** pane of the block dialog to reflect the scope window's current position and size. To make the scope window open at a particular location on the screen when the simulation runs, drag the window to the desired location, resize it, and select **Save Scope Position** from the **Axes** menu.

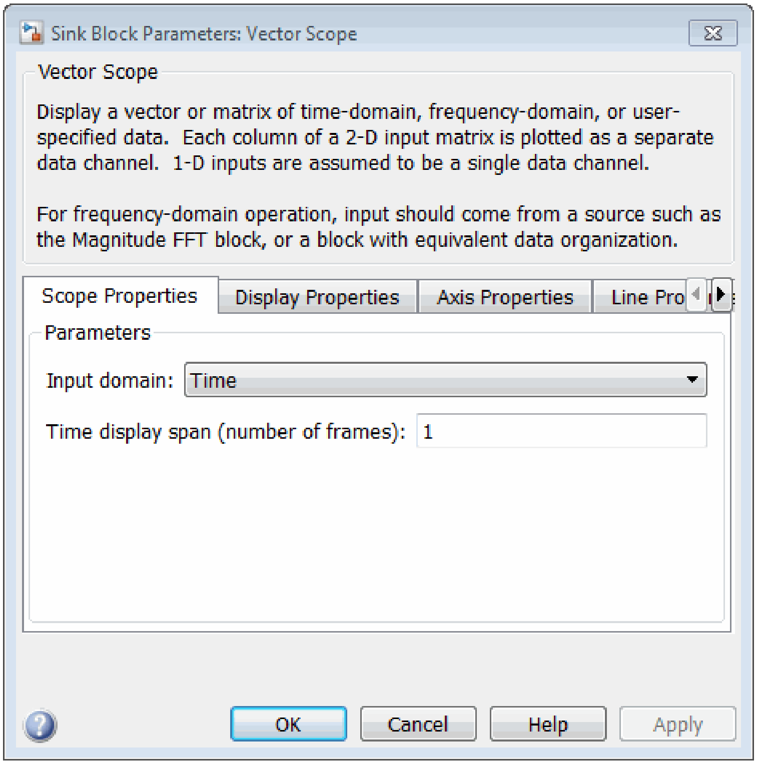
The properties listed in the **Channels** menu apply to a particular channel. All of the parameters in this menu are also accessible through the block parameters dialog box. For descriptions of these parameters, see “Line Properties Pane” on page 2-1907.

Many of these options can also be accessed by right-clicking with the mouse anywhere on the scope display. The menu that is displayed contains a combination of the options available in the **View**, **Axes** and **Channels** menus.

Note When you select **Compact Display** from the **Axes** menu, the scope window menus are no longer visible. Right-click in the Vector Scope window and click **Compact Display** in order to make the menus reappear.

Dialog Box

Scope Properties Pane



Input domain

Select the domain of the input. Your choices are `Time`, `Frequency`, or `User-defined`. Tunable (Simulink).

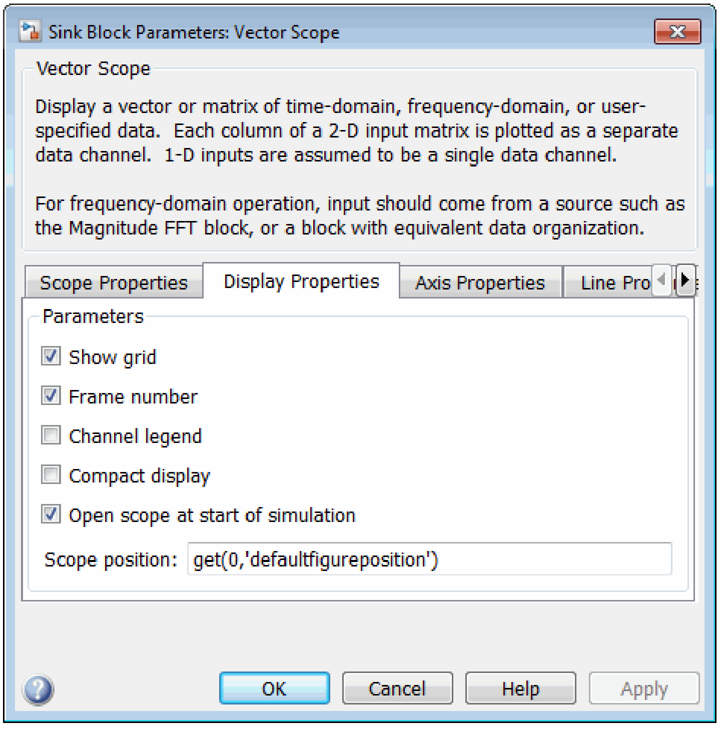
Time display span (number of frames)

The number of consecutive frames to display (horizontally) on the scope at any one time. This parameter is visible when the **Input domain** parameter is set to `Time`.

Horizontal display span (number of frames)

The number of consecutive frames to display (horizontally) on the scope at any one time. This parameter is visible when the **Input domain** parameter is set to `User-defined`.

Display Properties Pane



Show grid

Toggle the scope grid on and off.Tunable (Simulink).

Frame number

If you select this check box, the number of the current frame in the input sequence appears in the Vector Scope window. Tunable (Simulink).

Channel legend

Toggles the legend on and off. Tunable (Simulink).

Compact display

Resizes the scope to fill the window. Tunable (Simulink).

Open scope at start of simulation

Select this check box to open the scope at the start of the simulation. When this parameter is cleared, the scope does not open automatically during the simulation. Tunable (Simulink).

Note: Before running a model that contains a Vector Scope block in Accelerator, Rapid Accelerator, or External mode, you must select the **Open scope at start of simulation** check box. If you do not select this check box before running your model for the first time, the scope will not display your simulation data.

Open scope immediately

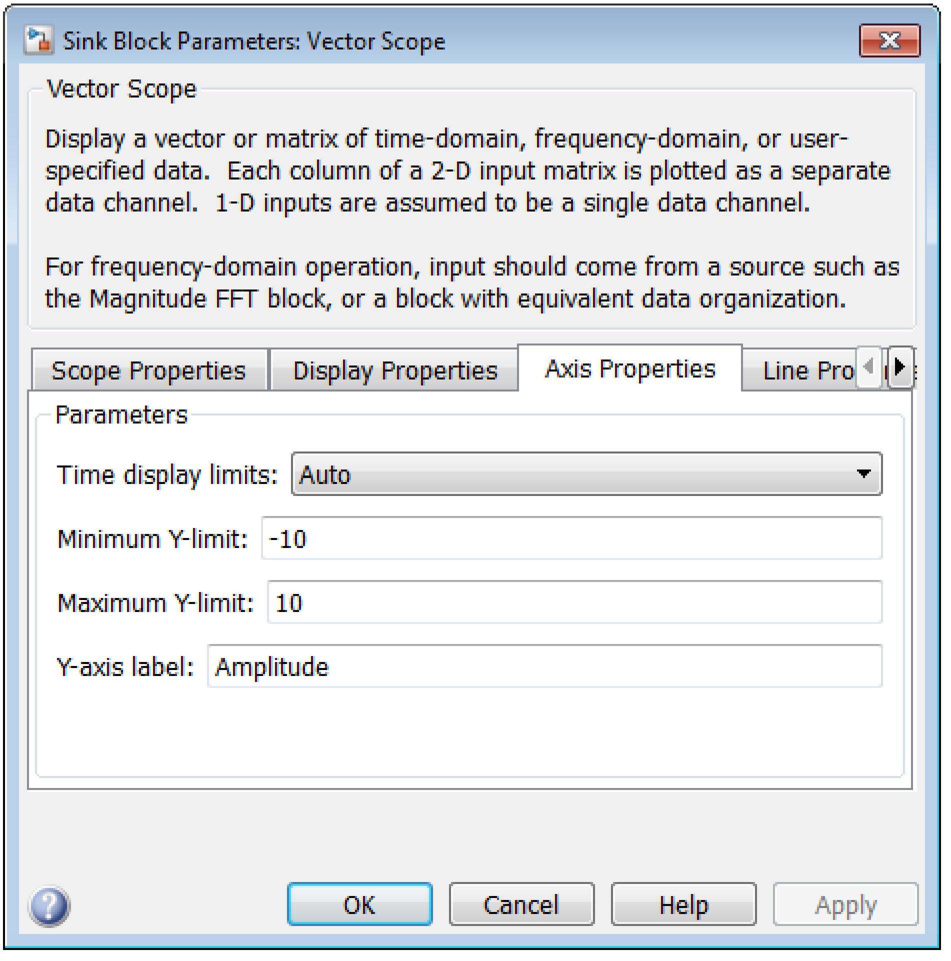
If the scope is not open during simulation, select this check box to open it. This parameter is visible only while the simulation is running.

Scope position

A four-element vector of the form `[left bottom width height]` specifying the position of the scope window. `(0,0)` is the lower-left corner of the display. Tunable (Simulink).

Axis Properties Pane

The parameters that are available on the **Axis Properties** pane depend on the setting of the **Input domain** parameter on the **Scope Properties** pane. When `Time` is selected for the **Input domain** parameter, the following parameters are available on the **Axis Properties** pane:



Time display limits

Select `Auto` to have the limits of the *x*-axis set for you automatically, or `User-defined` to set the limits yourself in the **Minimum X-limit (s)** and **Maximum X-limit (s)** parameters.

Minimum X-limit (s)

Specify the minimum value of the *x*-axis in seconds. This parameter is only visible if the **Time display limits** parameter is set to `User-defined`. Tunable (Simulink).

Maximum X-limit (s)

Specify the maximum value of the *x*-axis in seconds. This parameter is only visible if the **Time display limits** parameter is set to `User-defined`. Tunable (Simulink).

Minimum Y-limit

Specify the minimum value of the *y*-axis. Setting this parameter is analogous to setting the `ymin` value of the MATLAB `axis` function. Tunable (Simulink).

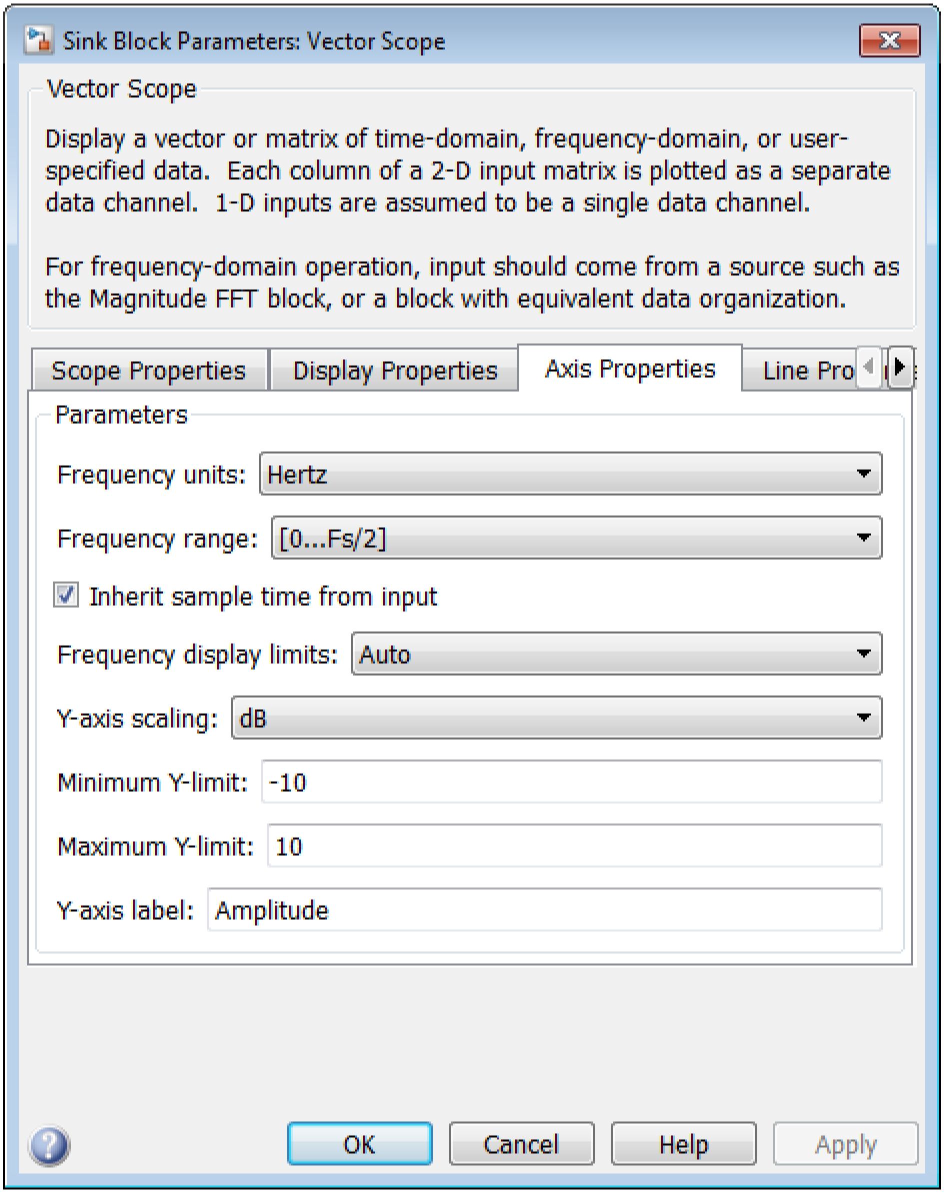
Maximum Y-limit

Specify the maximum value of the *y*-axis. Setting this parameter is analogous to setting the `ymax` value of the MATLAB `axis` function. Tunable (Simulink).

Y-axis label

Specify text to be displayed to the left of the *y*-axis. Tunable (Simulink).

When `Frequency` is selected for the **Input domain** parameter, the following parameters are available on the **Axis Properties** pane:



Frequency units

Choose the frequency units for the x-axis, `Hertz` or `rad/sec`. Tunable (Simulink).

Frequency range

Specify the frequency range over which to plot the data. Tunable (Simulink).

Inherit sample time from input

If you select this check box, the block computes the time-domain sample period from the frame period and frame size of the frequency-domain input. Use this parameter only when the length of the each frame of frequency-domain data is the same as the length of the frame of time-domain data from which it was generated. Tunable (Simulink).

Sample time of original time series

Enter the sample period, T_s, of the original time-domain signal. This parameter is only visible when the **Inherit sample time from input** check box is not selected. Tunable (Simulink).

Frequency display limits

Select `Auto` to have the limits of the *x*-axis set for you automatically, or `User-defined` to set the limits yourself in the **Minimum frequency** and **Maximum frequency** parameters.

Minimum frequency

Specify the minimum frequency value of the *x*-axis in Hertz or rad/sec. This parameter is only visible if the **Frequency display limits** parameter is set to `User-defined`. Tunable (Simulink).

Maximum frequency

Specify the maximum frequency value of the *x*-axis in Hertz or rad/sec. This parameter is only visible if the **Frequency display limits** parameter is set to `User-defined`. Tunable (Simulink).

Y-axis scaling

Choose either `dB` (decibel) or `Magnitude` scaling for the *y*-axis. Tunable (Simulink).

Minimum Y-limit

Specify the minimum value of the *y*-axis. Setting this parameter is analogous to setting the `ymin` value of the MATLAB `axis` function. Tunable (Simulink).

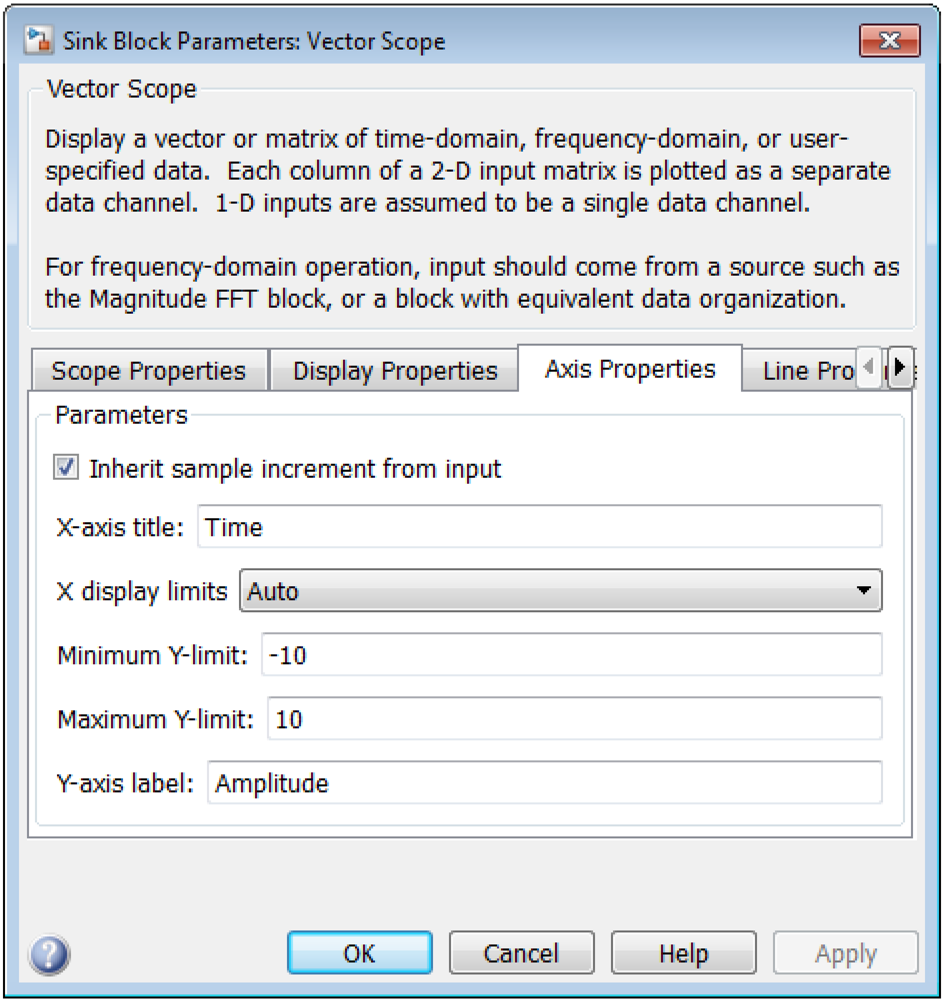
Maximum Y-limit

Specify the maximum value of the *y*-axis. Setting this parameter is analogous to setting the `ymax` value of the MATLAB `axis` function. Tunable (Simulink).

Y-axis label

Specify text to be displayed to the left of the *y*-axis. Tunable (Simulink).

When `User-defined` is selected for the **Input domain** parameter, the following parameters are available on the **Axis Properties** pane:



Inherit sample increment from input

When you select this check box, the block scales the horizontal axis by computing the horizontal interval between samples in the input frame from the frame period of the input. Use this parameter only when the input's sample period is equal to the period with which the physical signal was originally sampled. Tunable (Simulink).

Increment per sample in input

Enter the numerical interval between adjacent *x*-axis points corresponding to the user-defined input data. This parameter is only visible when the **Inherit sample increment from input** check box is not selected. Tunable (Simulink).

X display offset (samples)

Specify an offset for the *x*-axis display in samples. This parameter is only visible when the **Inherit sample increment from input** check box is not selected. Tunable (Simulink).

X-axis title

Enter the text to be displayed below the *x*-axis. Tunable (Simulink).

X display limits

Select `Auto` to have the limits of the *x*-axis set for you automatically, or `User-defined` to set the limits yourself in the **Minimum X-limit (samples)** and **Maximum X-limit (samples)** parameters.

Minimum X-limit (samples)

Specify the minimum value of the *x*-axis in samples. This parameter is only visible if the **X display limits** parameter is set to `User-defined`. Tunable (Simulink).

Maximum X-limit (samples)

Specify the maximum value of the *x*-axis in samples. This parameter is only visible if the **X display limits** parameter is set to `User-defined`. Tunable (Simulink).

Minimum Y-limit

Specify the minimum value of the *y*-axis. Setting this parameter is analogous to setting the `ymin` value of the MATLAB `axis` function. Tunable (Simulink).

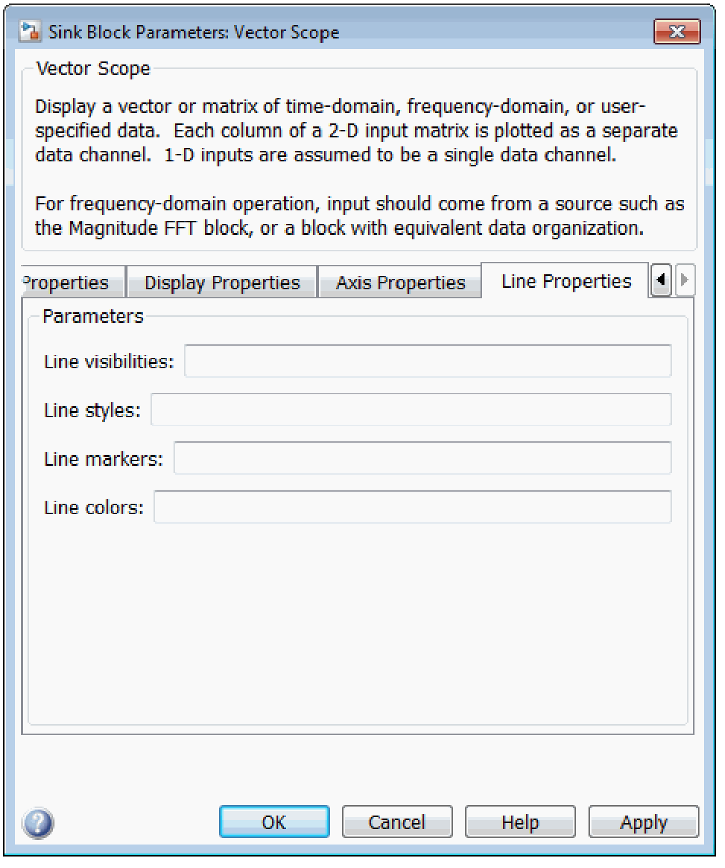
Maximum Y-limit

Specify the maximum value of the *y*-axis. Setting this parameter is analogous to setting the `ymax` value of the MATLAB `axis` function. Tunable (Simulink).

Y-axis label

Specify text to be displayed to the left of the *y*-axis. Tunable (Simulink).

Line Properties Pane



Line visibilities

Enter `on` or `off` to specify the visibility of the various channels' scope traces. Separate your choices for each channel with by a pipe (|) symbol. Tunable (Simulink).

Line styles

Enter the line styles of the various channels' scope traces. Separate your choices for each channel with by a pipe (|) symbol. Tunable (Simulink).

Line markers

Enter the line markers of the various channels' scope traces. Separate your choices for each channel with by a pipe (|) symbol. Tunable (Simulink).

Line colors

Enter the colors of the various channels' scope traces using the `ColorSpec` formats. Separate your choices for each channel with by a pipe (|) symbol. Tunable (Simulink).

Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers

Description

The Waterfall block displays multiple vectors of data at one time. These vectors represent the input data at consecutive sample times. The input to the block can be real or complex-valued data vectors of any data type including fixed-point data types. However, the input is converted to double-precision before the block processes the data. The Waterfall block displays only real-valued, double-precision vectors of data.

The data is displayed in a three-dimensional axis in the Waterfall window. By default, the x-axis represents amplitude, the y-axis represents samples, and the z-axis represents time. You can adjust the number of sample vectors that the block displays, move and resize the Waterfall window, and modify block parameter values during the simulation. The Waterfall window has toolbar buttons that enable you to zoom in on displayed data, suspend data capture, freeze the scope's display, save the scope position, and export data to the workspace. The toolbar buttons are labeled in the following figure, which shows the Waterfall window as it appears when you double-click a Waterfall block.

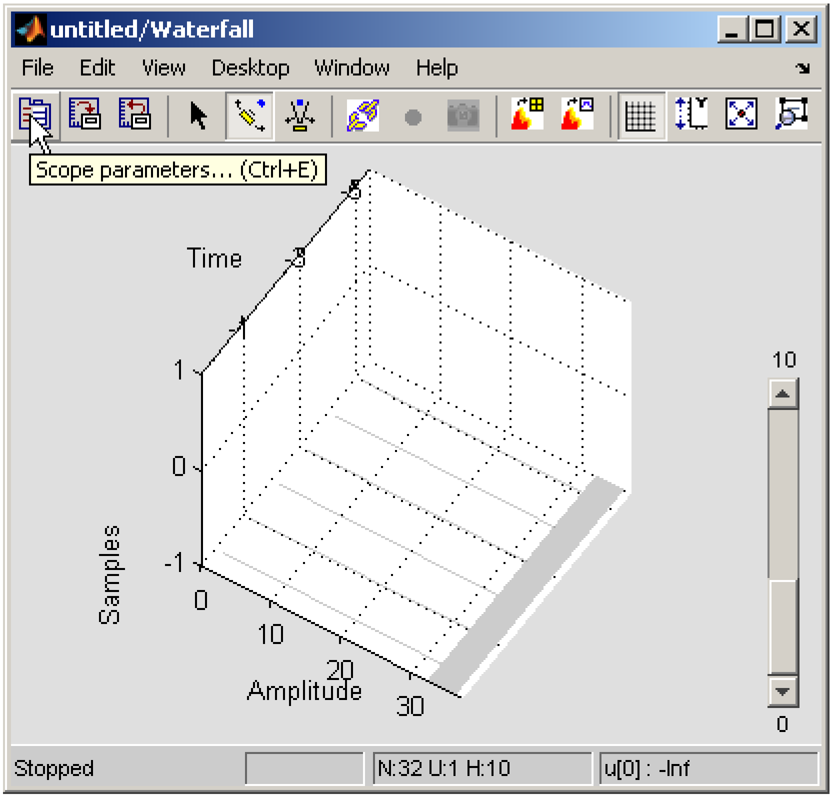
Waterfall Parameters

You can control the display and behavior of the Waterfall window using the Parameters dialog box.

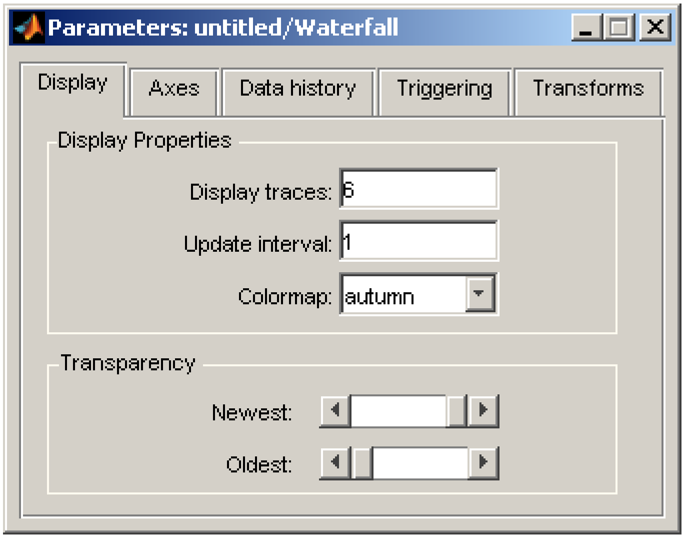
Note You can alter the Waterfall parameters while the simulation is running. However, when you make changes to values in text boxes, you must click **Enter** or click outside the text box before the block accepts your changes.

---

1 To open the Parameters dialog box, click the **Scope parameters** button.



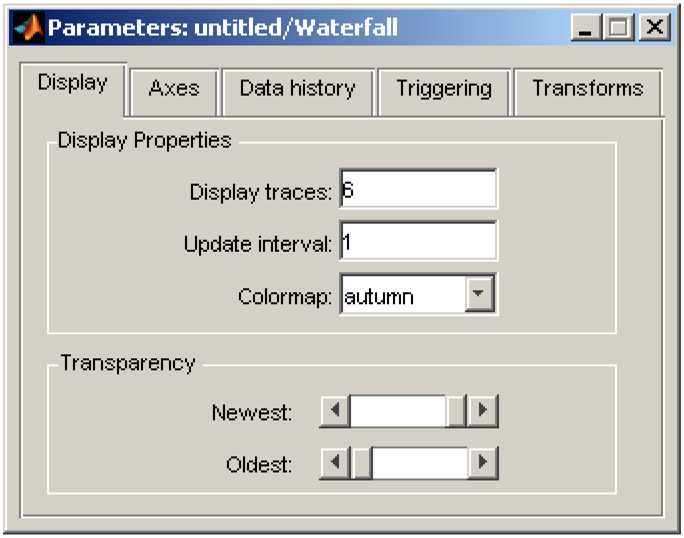
The Parameters dialog box appears.



2 Click on the different panes to enter parameter settings.

Display Parameters

The following parameters control the Waterfall window's display.



Display traces

Enter the number of vectors of data to be displayed in the Waterfall window.

Update interval

Enter the number of vectors the block should store before it displays them to the window.

Colormap

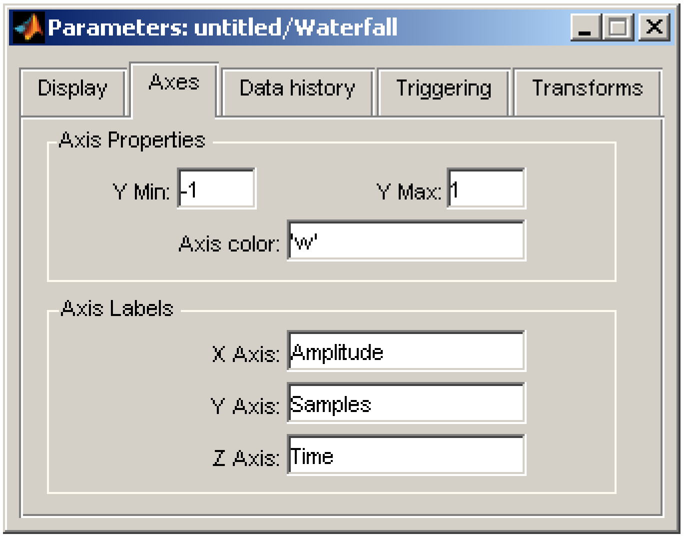
Choose a colormap for the displayed data.

Transparency

Specify the transparency of the newest and oldest data vectors. Placing the slider in the left-most position tells the block to make the data vector transparent. Placing the slider in the right-most position tells the block to make the data vector opaque. The intermediate data vectors transition between the two chosen transparency values.

Axes Parameters

The following parameters control the axes in the Waterfall window.



Y Min

Enter the minimum value of the *y*-axis.

Y Max

Enter the maximum value of the *y*-axis.

Axis color

Enter a background color for the axes. Specify the color using a character vector. For example, to specify black, enter `'k'`.

X Axis

Enter the *x*-axis label.

Y Axis

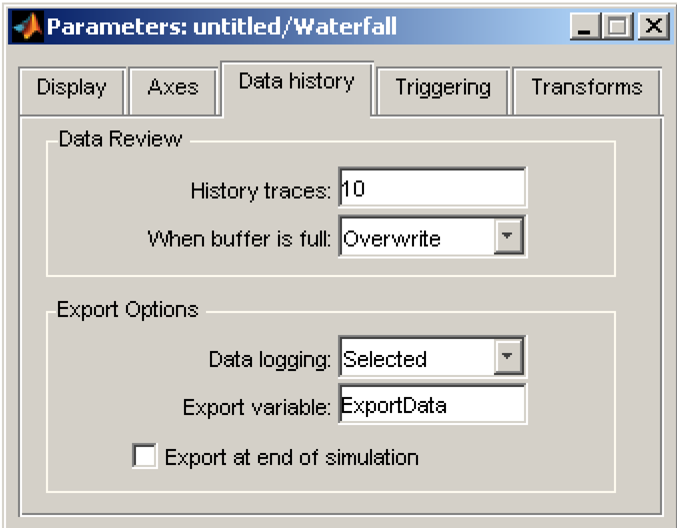
Enter the *y*-axis label.

Z Axis

Enter the *z*-axis label.

Data History Parameters

The following parameters control how many input data vectors the Waterfall block stores. They also control how the data is exported to the MATLAB workspace or SPTool.



History traces

Enter the number of vectors (traces) that you want the block to store.

When the buffer is full

Use this parameter to control the behavior of the block when the buffer is filled:

- `Overwrite` — The old data is replaced with the new data.
- `Suspend` — The block stops storing data in the buffer; however, the simulation continues to run.
- `Extend` — The block extends the buffer so that it can continue to store all the input data.

Data logging

Use this parameter to control which data is exported from the block:

- `Selected` — The selected data vector is exported.
- `All visible` — All of the data vectors displayed in the Waterfall window are exported.
- `All history` — All of the data vectors stored in the block's history buffer are exported.

Export variable

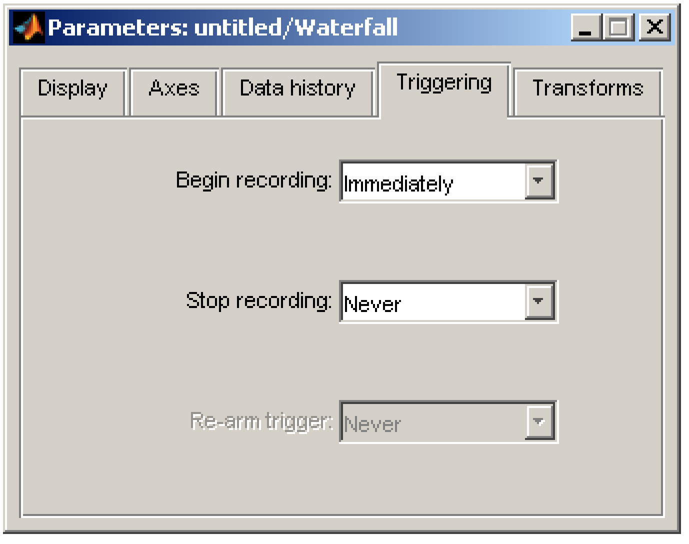
Enter the name of the variable that represents your data in the MATLAB workspace or SPTool. The default variable name is `ExportData`.

Export at end of simulation

Select this check box to automatically export the data to the MATLAB workspace when the simulation stops.

Triggering Parameters

The following parameters control when the Waterfall block starts and stops capturing data.



Begin recording

This parameter controls when the Waterfall block starts capturing data:

- `Immediately` — The Waterfall window captures the input data as soon as the simulation starts.
- `After T seconds` — The **Time, T** parameter appears in the dialog box. Enter the number of seconds the block should wait before it begins capturing data.
- `After N inputs` — The **Count, N** parameter appears in the dialog box. Enter the number of inputs the block should receive before it begins capturing data.

- `User-defined` — The **Function name** parameter appears in the dialog box. Enter the name of a MATLAB function that defines when the block should begin capturing data. For more information about how you define this function, see "Scope Trigger Function" on page 2-1933.

Stop recording

This parameter controls when the Waterfall block stops capturing data:

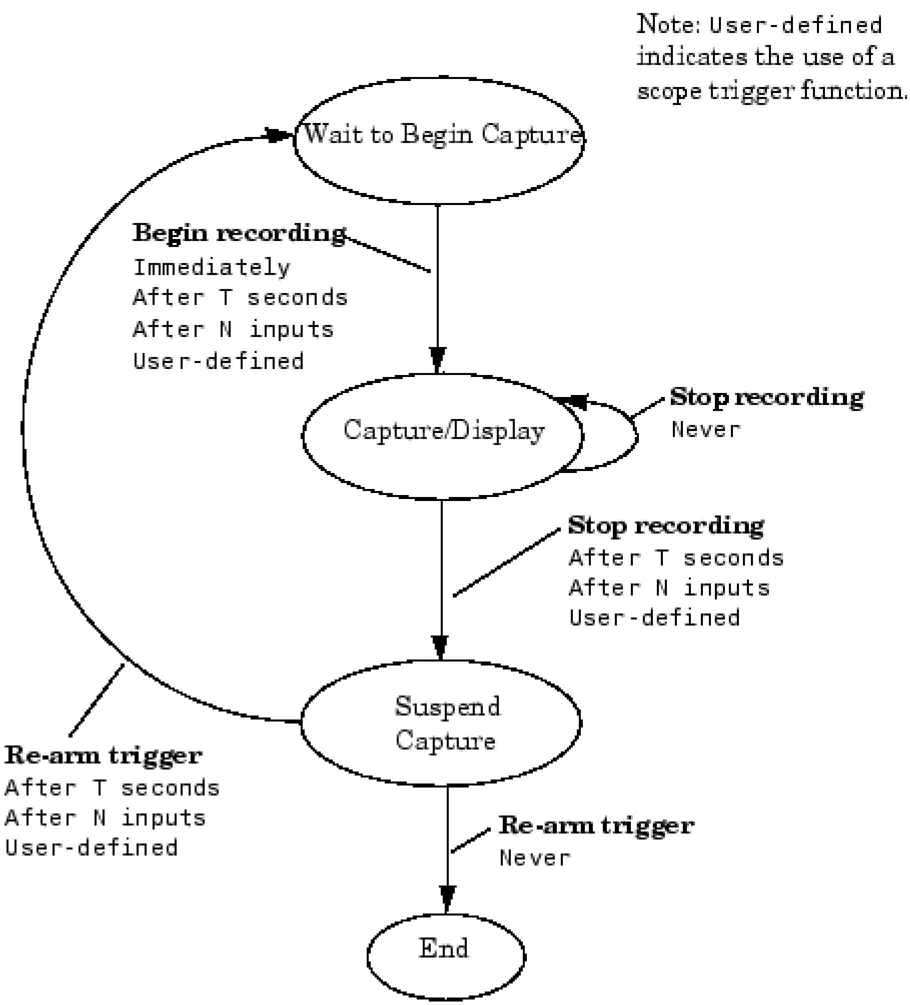
- `Never` — The block captures the input data as long as the simulation is running.
- `After T seconds` — The **Time, T** parameter appears in the dialog box. Enter the number of seconds the block should wait before it stops capturing data.
- `After N inputs` —The **Count, N** parameter appears in the dialog box. Enter the number of inputs the block should receive before it stops capturing data.
- `User-defined` — The **Function name** parameter appears in the dialog box. Enter the name of a MATLAB function that defines when the block should stop capturing data. For more information about how you define this function, see "Scope Trigger Function" on page 2-1933.

Re-arm trigger

This parameter controls when the Waterfall block begins waiting to capture data. It is available only when you select `After T seconds`, `After N inputs`, or `User-defined` for the **Stop recording** parameter:

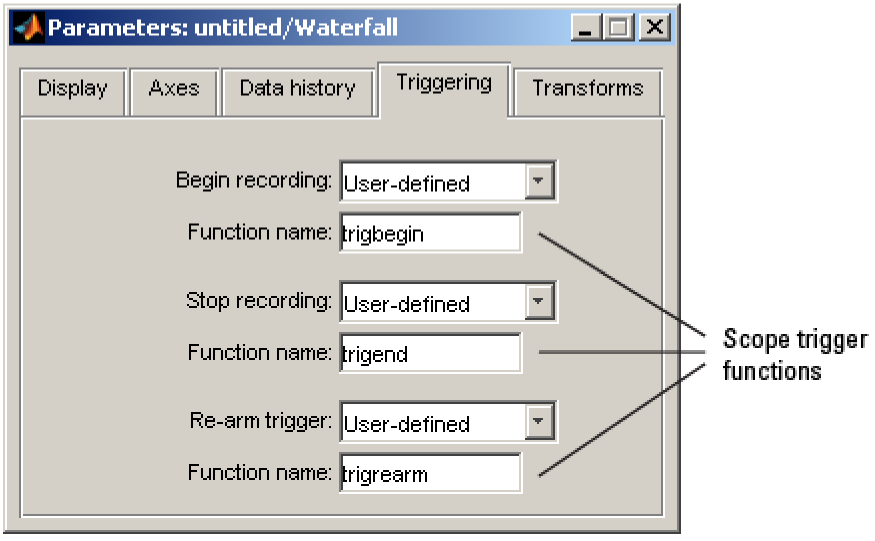
- `Never` — The Waterfall Scope block starts and stops capturing data as defined by the **Begin recording** and **Stop recording** parameters.
- `After T seconds` — The **Time, T** parameter appears in the dialog box. Enter the number of seconds the block should wait before it begins waiting to capture data.
- `After N inputs` — The **Count, N** parameter appears in the dialog box. Enter the number of inputs the block should receive before it begins waiting to capture data.
- `User-defined` — The **Function name** parameter appears in the dialog box. Enter the name of a MATLAB function that defines when the block should begin waiting to capture data. For more information about how you define this function, see "Scope Trigger Function" on page 2-1933.

The triggering process is illustrated in the state diagram below.



Scope Trigger Function

You can create custom scope trigger functions to control when the scope starts, stops, or begins waiting to capture data.



These functions must be valid MATLAB functions and be located either in the current folder or on the MATLAB path.

Each scope trigger function must have the following form

`y = functionname(blk,t,u),`

where `functionname` refers to the name you give your scope trigger function. The variable `blk` is the Simulink block handle. When the scope trigger function is called by the block, Simulink automatically populates this variable with the handle of the Waterfall block. The variable `t` is the current simulation time, represented by a real, double-precision, scalar value. The variable `u` is the vector input to the block. The output of the scope trigger function, `y`, is interpreted as a logical signal. It is either true or false:

- Begin recording scope trigger function
  - When the output of this scope trigger function is true, the Waterfall block starts capturing data.
  - When the output is false, the block remains in its current state.
- Stop recording scope trigger function
  - When the output of this scope trigger function is true, the block stops capturing data.

  - When the output is false, the block remains in its current state.
- Re-arm trigger scope trigger function
  - When the output of this scope trigger function is true, the block waits for a begin recording event.
  - When the output is false, the block remains in its current state.

Note The Waterfall block passes its input data directly to the scope trigger functions. These functions do not use the transformed data defined by the Transform parameters.

The following is an example of a scope trigger function. This function, called `trigPower` detects when the energy in u exceeds a certain threshold.

```
function y = trigPower(blk, t, u)

y = (u'*u > 2300);
```

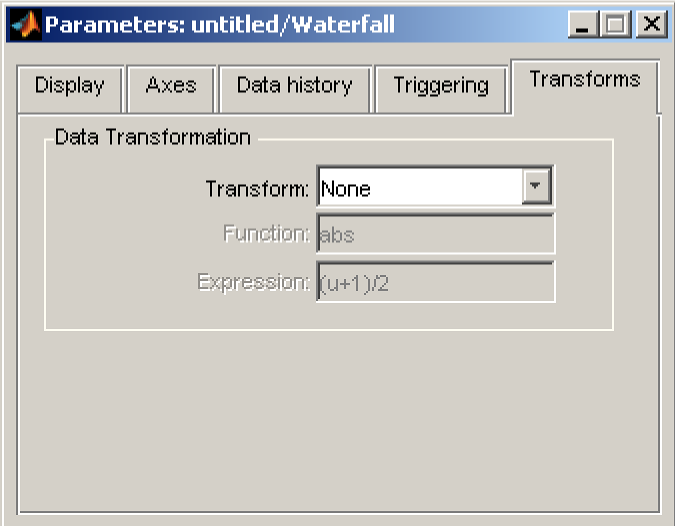
The following is another example of a scope trigger function. This function, called `count3`, triggers the scope once three vectors with positive means are input to the block. Then, the function resets itself and begins searching for the next three input vectors with positive means. This scope trigger function is valid only when one Waterfall block is present in your model.

```
function y = count3(blk, t, u)

persistent state;
if isempty(state); state = 0; end
if mean(u)>0; state = state+1; end
y = (state>=3);
if y; state = 0; end
```

Transform Parameters

The following parameters transform the input data to the Waterfall block. The result of the transform is displayed in the Waterfall window.



Note The block assumes that the input to the block corresponds to the **Transform** parameter you select. For example, when you choose `Complex-> Angle`, the block assumes that the input is complex. The block does not produce an error when the input is not complex. Therefore, you must verify the format of your input data to guarantee that a meaningful result is displayed in the Waterfall window.

Transform

Choose a transform that you would like to apply to the input of the Waterfall block:

- `None` — The input is displayed as it is received by the block.
- `Amplitude-> dB` — The block converts the input amplitude into decibels.
- `Complex-> Mag Lin` — The block converts the complex input into linear magnitude.
- `Complex-> Mag dB` — The block converts the complex input into magnitude in decibels.
- `Complex-> Angle` — The block converts the complex input into phase.
- `FFT-> Mag Lin Fs/2` — The block takes the linear magnitude of the FFT input and plots it from 0 to the Nyquist frequency.

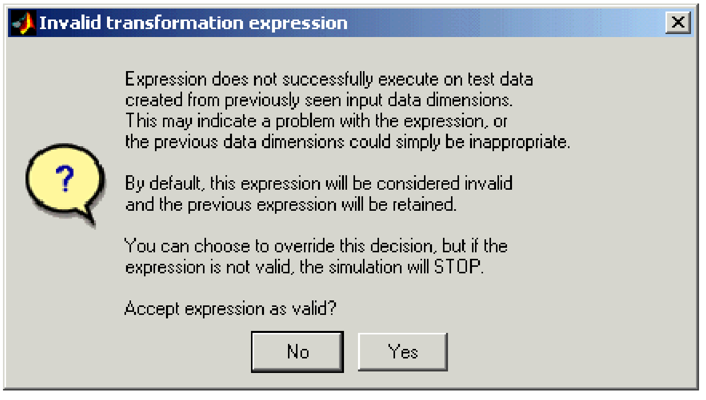
- `FFT-> Mag dB Fs/2` — The block takes the magnitude of the FFT input, converts it to decibels, and plots it from 0 to the Nyquist frequency.
- `FFT-> Angle Fs/2` — The block converts the FFT input into phase and plots it from 0 to the Nyquist frequency.
- `Power-> dB` — The block converts the input power into decibels.

Function

This parameter is only available when you select `User-defined fcn` for the **Transform** parameter. Enter a function that you would like to apply to the input of the Waterfall block. For more information about how you define this function, see "Scope Transform Function" on page 2-1938.

Expression

This parameter is only available when you select `User-defined expr` for the **Transform** parameter. Enter an expression that you would like to apply to the input of the Waterfall block. The result of this expression must be real-valued. When you write the expression, be sure to include only one unknown variable. The block assumes this unknown variable represents the input to the block. When the block believes your expression is invalid, the following window appears.



When you click **No**, your expression is not applied to the input. When you click **Yes** and your expression is invalid, your simulation stops and Simulink displays an error.

Scope Transform Function

You can create a scope transform function to control how the Waterfall block transforms your input data. This function must have a valid MATLAB function name and be located either in the current folder or on the MATLAB path.

Your scope transform function must have the following form

```
y = functionname(u),
```

where `functionname` refers to the name you give your function. The variable `u` is the real or complex vector input to the block. The output of the scope transform function, `y`, must be a double-precision, real-valued vector. When it is not, the simulation stops and Simulink displays an error. Note that the output vector does not need to be the same size as the input vector.

Examples

The following examples illustrate some capabilities of the Waterfall block.

- "Exporting Data" on page 2-1938
- "Capturing Data" on page 2-1939
- "Linking Scopes" on page 2-1939
- "Selecting Data" on page 2-1941
- "Zooming" on page 2-1943
- "Rotating the Display" on page 2-1943
- "Scaling the Axes" on page 2-1943
- "Saving Scope Settings" on page 2-1943

Exporting Data

You can use the Waterfall block to export data to the MATLAB workspace or to SPTool:

1. Open and run the `dspanc` example.
2. While the simulation is running, click the **Export to Workspace** button.
3. Type `whos` at the MATLAB command line.

The variable `ExportData` appears in your MATLAB workspace. `ExportData` is a 40-by-6 matrix. This matrix represents the six data vectors that were present in the Waterfall window at the time you clicked the **Export to Workspace** button. Each column of this matrix contains 40 filter coefficients. The columns of data were captured at six consecutive instants in time.

You can control what data is exported using the **Data logging** parameter in **Data history** pane of the Parameters dialog box. For more information, see "Data History Parameters" on page 2-1929.

4. While the simulation is running, click the **Export to SPTool** button.

   The SPTool GUI opens and the variable `ExportData` is displayed in the **Signals** list.

For more information about SPTool, see the Signal Processing Toolbox documentation.

Capturing Data

You can use the Waterfall block to interact with your data while it is being captured:

1. Open and run the `dspanc` example.
2. While the simulation is running, click the **Suspend data capture** button.

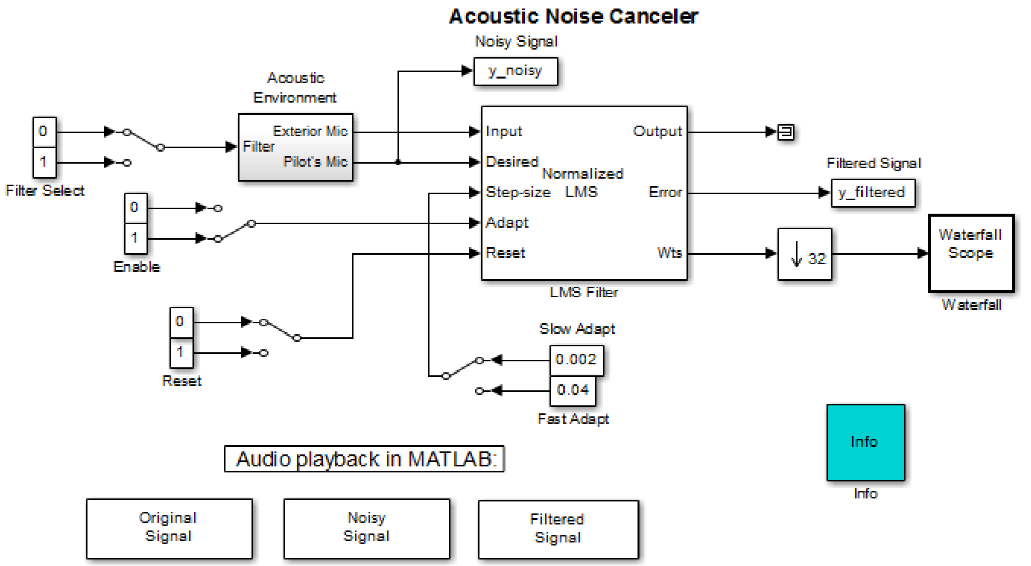
   The Waterfall block no longer captures or displays the data coming from the Downsample block.
3. To continue capturing data, click the **Resume data capture** button.
4. To freeze the data display while continuing to capture data, click the **Snapshot display** button.
5. To view the Waterfall block that the data is coming from, click the **Go to scope block** button.

   In the Simulink model window, the Waterfall block that corresponds to the active Waterfall window flashes. This feature is helpful when you have more than one Waterfall block in a model and you want to clarify which data is being displayed.

Linking Scopes

You can link several Waterfall blocks together in order to capture the effect of a model event in all of the Waterfall windows in the model:

1 Open the `dspanc` example.
2 Drag a second Waterfall block into the example model.
3 Connect this block to the Output port of the LMS Filter block as shown in the figure below.



4 Run the model and view the model behavior in both Waterfall windows.
5 In the dspanc/Waterfall window, click the **Link scopes** button.
6 In the same window, click the **Suspend data capture** button.

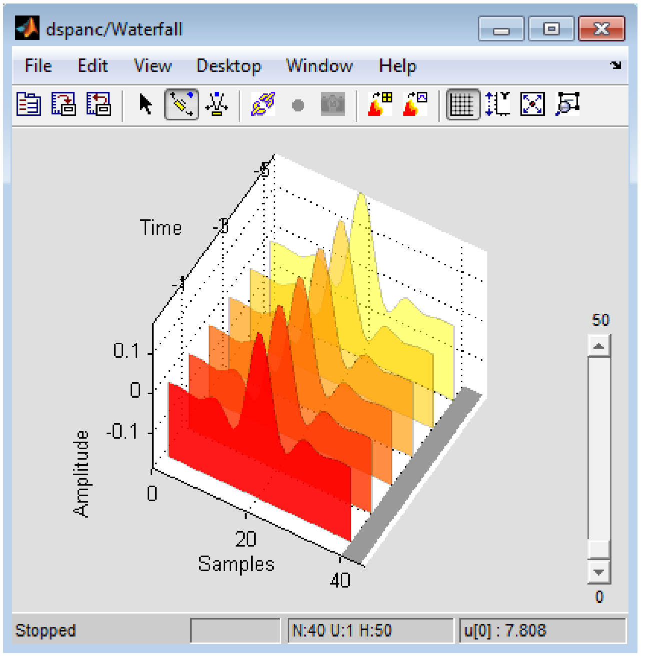
   The data capture is suspended in both scope windows.
7 Click the **Resume data capture** button.

   The data capture resumes in both scope windows.
8 In the dspanc/Waterfall window, click the **Snapshot display** button.

   In both scope windows, the data display freezes while the block continues to capture data.
9 To continue displaying the captured data, click the **Resume display** button.

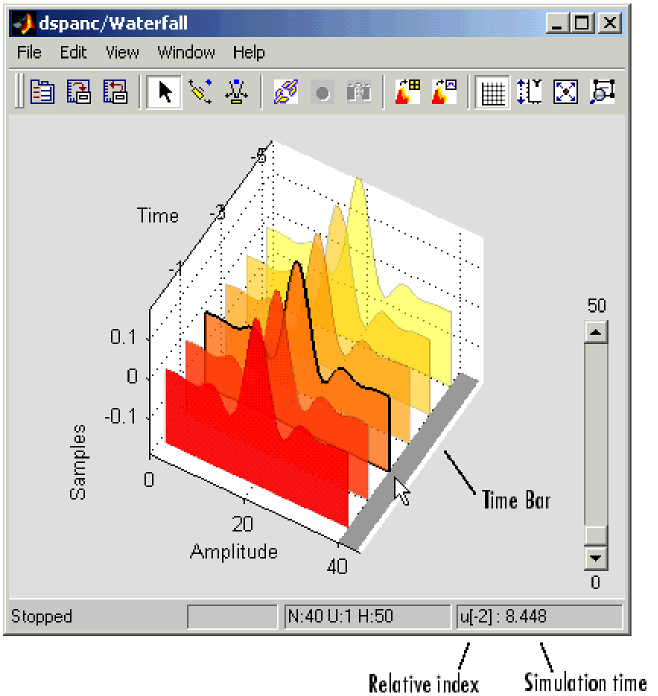
Selecting Data

The following figure shows the Waterfall window displaying the output of the `dspanc` example:



1. To select a particular set of data, click the **Select** button.
2. Click on the Time Bar at the bottom right of the axes to select a vector of data.

   The Waterfall block highlights the selected trace.



While the simulation is running, in the bottom right corner, the Waterfall window displays the relative index of the selected trace. For example, in the previous figure, the selected vector is two sample times away from the most current data vector. When the simulation is stopped, the Waterfall window displays both the relative index and the simulation time associated with the selected trace.

3 To deselect the data vector, click it again.

4 Click-and-drag along the Time Bar.

Your selection follows the movement of the pointer.

You can use this feature to choose a particular vector to export to the MATLAB workspace or SPTool. For more information, see "Data History Parameters" on page 2-1929.

Zooming

You can use the Waterfall window to zoom in on data:

1. Click the **Zoom camera** button.
2. In the Waterfall window, click and hold down the left mouse button.
3. Move the mouse up and down and side-to-side to move closer and farther away from the axes.
4. To resize the axes to fit the Waterfall window, click the **Fit to view** button.

Rotating the Display

You can rotate the data displayed in the Waterfall window:

1. Click on the **Orbit camera** button.
2. In the Waterfall window, click and hold down the left mouse button.
3. Move the mouse in a circular motion to rotate the axes.
4. To return to the position of the original axes, click the **Restore scope position and view** button.

Scaling the Axes

You can use the Waterfall window to rescale the *y*-axis values:

1. Open and run the `dspanc` example.
2. Click the **Rescale amplitude** button.

   The *y*-axis changes so that its minimum value is zero. The maximum value is scaled to fit the data displayed.

Alternatively, you can scale the *y*-axis using the **Y Min** and **Y Max** parameters in the **Axes** pane of the Parameters dialog box. This is helpful when you want to undo the effects of rescaling the amplitude. For more information, see “Axes Parameters” on page 2-1928.

Saving Scope Settings

The Waterfall block can save the screen position and viewpoint of the Waterfall window:

1 Click the **Save scope position and view** button.
2 Close the Waterfall window.
3 Reopen the Waterfall window.

It reopens at the same place on your screen. The viewpoint of the axes also remains the same.

Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers

The Waterfall block accepts any of these data types as input. However, the input is converted to double-precision before the block processes the data. The Waterfall block displays only real-valued, double-precision vectors of data.

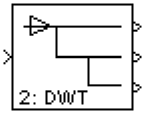
Wavelet Analysis (Obsolete)

Decompose signal into components of logarithmically decreasing frequency intervals and sample rates (requires the Wavelet Toolbox product)



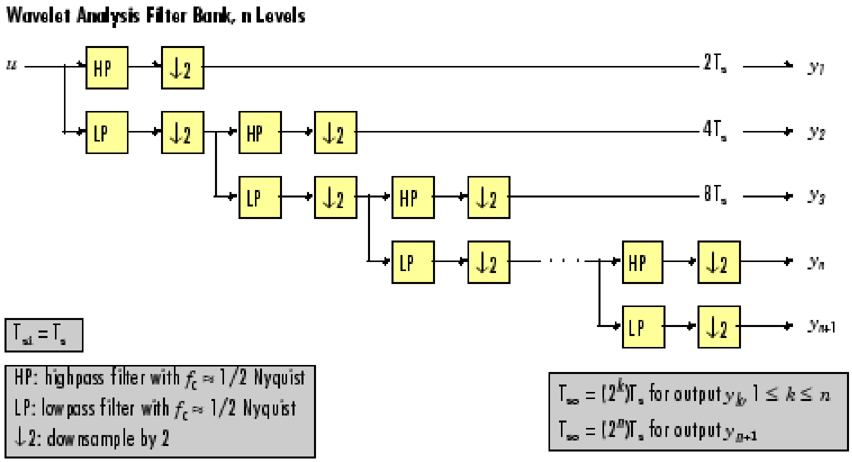
Library

dspobslib

Description

Note: The Wavelet Analysis block will be removed from the product in a future release. We strongly recommend replacing this block with the DWT block.

The Wavelet Analysis block uses the Wavelet Toolbox `wfilters` function to construct a dyadic analysis filter bank that decomposes a broadband signal into a collection of successively more bandlimited components. An *n*-level filter bank structure is shown below, where *n* is specified by the **Number of levels** parameter.



At each level, the low-frequency output of the previous level is decomposed into adjacent high- and low-frequency subbands by a highpass (HP) and lowpass (LP) filter pair. Each of the two output subbands is half the bandwidth of the input to that level. The bandlimited output of each filter is maximally decimated by a factor of 2 to preserve the bit rate of the original signal.

Filter Coefficients

The filter coefficients for the highpass and lowpass filters are computed by the Wavelet Toolbox function `wfilters`, based on the wavelet specified in the **Wavelet name** parameter. The table below lists the available options.

Wavelet Name	Sample Wavelet Function Syntax
Haar	`wfilters('haar')`
Daubechies	`wfilters('db4')`
Symlets	`wfilters('sym3')`
Coiflets	`wfilters('coif1')`
Biorthogonal	`wfilters('bior3.1')`
Reverse Biorthogonal	`wfilters('rbio3.1')`
Discrete Meyer	`wfilters('dmey')`

The **Daubechies**, **Symlets**, and **Coiflets** options enable a secondary **Wavelet order** parameter that allows you to specify the wavelet order. For example, if you specify a **Daubechies** wavelet with **Wavelet order** equal to `6`, the Wavelet Analysis block calls the `wfilters` function with input argument `'db6'`.

The **Biorthogonal** and **Reverse Biorthogonal** options enable a secondary **Filter order [synthesis / analysis]** parameter that allows you to independently specify the wavelet order for the analysis and synthesis filter stages. For example, if you specify a **Biorthogonal** wavelet with **Filter order [synthesis / analysis]** equal to `[2 / 6]`, the Wavelet Analysis block calls the `wfilters` function with input argument `'bior2.6'`.

See the Wavelet Toolbox documentation for more information about the `wfilters` function. If you want to explicitly specify the FIR coefficients for the analysis filter bank, use the `Dyadic Analysis Filter bank` block.

Tree Structure

The wavelet tree structure has n+1 outputs, where n is the number of levels. The sample rate and bandwidth of the top output are half the input sample rate and bandwidth. The sample rate and bandwidth of each additional output (except the last) are half that of the output from the previous level. In general, for an input with sample period $T_{si} = T_s$, and bandwidth BW, output y_k has sample period $T_{so,k}$ and bandwidth BW_k.

$$T_{so,k} = \begin{cases} \left(2^k\right)T_s & (1 \le k \le n) \\ \left(2^n\right)T_s & (k = n+1) \end{cases}$$

$$BW_k = \begin{cases} \dfrac{BW}{2^k} & (1 \le k \le n) \\ \dfrac{BW}{2^n} & (k = n+1) \end{cases}$$

Note that in frame-based mode, the change in the sample period of output y_k is reflected by its frame size $M_{o,k}$, rather than by its frame rate.

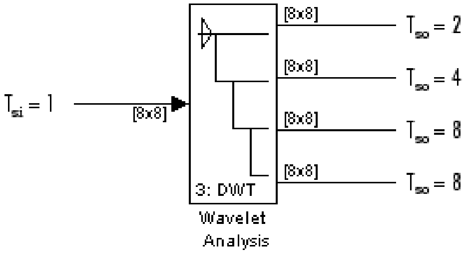
$$M_{o,k} = \begin{cases} \dfrac{M_i}{2^k} & (1 \le k \le n) \\ \dfrac{M_i}{2^n} & (k = n+1) \end{cases}$$

The bottom two outputs (y_n and y_{n+1}) share the same sample period, bandwidth, and frame size because they originate at the same tree level.

Sample-Based Operation

An M-by-N sample-based matrix input is treated as $M*N$ independent channels, and the block filters each channel independently over time. The output at each port is the same size as the input, one output channel for each input channel. As described earlier, each output port has a different sample period.

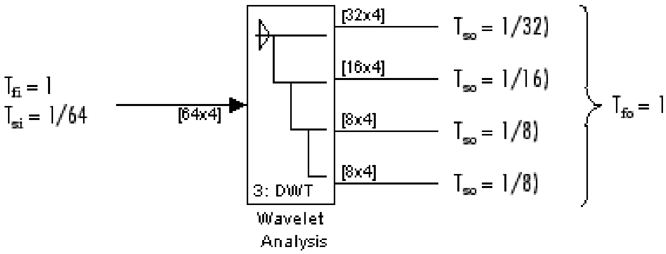
The figure below shows the input and output sample periods for a 64-channel sample-based input to a three-level filter bank. The input has a period of 1, so the fastest output has a period of 2.



Frame-Based Operation

An M_i-by-N frame-based matrix input is treated as N independent channels, and the block filters each channel independently over time. The input frame size M_i must be a multiple of 2^n, and n is the number of filter bank levels. For example, a frame size of 8 would be appropriate for a three-level tree (2^3=8). The number of columns in each output is the same as the number of columns in the input.

Each output port has the same frame period as the input. The reduction in the output sample rates results from the smaller output frame sizes, as shown in the example below for a four-channel input to a three-level filter bank.



Zero Latency

The Wavelet Analysis block has no tasking latency for frame-based operation, which is always single-rate. The block therefore analyzes the first input sample (received at *t*=0) to produce the first output sample at each port.

Nonzero Latency

For sample-based operation, the Wavelet Analysis block is multirate and has 2^{n-1} samples of latency in both Simulink tasking modes. As a result, the block repeats a zero initial condition in each channel for the first 2^{n-1} output samples, before propagating the first analyzed input sample (computed from the input received at *t*=0).

Note For more information on latency and the Simulink tasking modes, see "Excess Algorithmic Delay (Tasking Latency)" and "Time-Based Scheduling and Code Generation" (Simulink Coder).

Parameters

Wavelet name

The wavelet used in the analysis.

Wavelet order

The order for the **Daubechies**, **Symlets**, and **Coiflets** wavelets. This parameter is available only when one of these wavelets is selected in the **Wavelet name** menu.

Filter order [synthesis / analysis]

The filter orders for the synthesis and analysis stages of the **Biorthogonal** and **Reverse Biorthogonal** wavelets. For example, `[2 / 6]` selects a second-order synthesis stage and a sixth-order analysis stage. The **Filter order** parameter is available only when one of the above wavelets is selected in the **Wavelet name** menu.

Number of levels

The number of filter bank levels. An *n*-level structure has *n*+1 outputs.

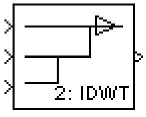
Wavelet Synthesis (Obsolete)

Reconstruct signal from its multirate bandlimited components (requires the Wavelet Toolbox product)



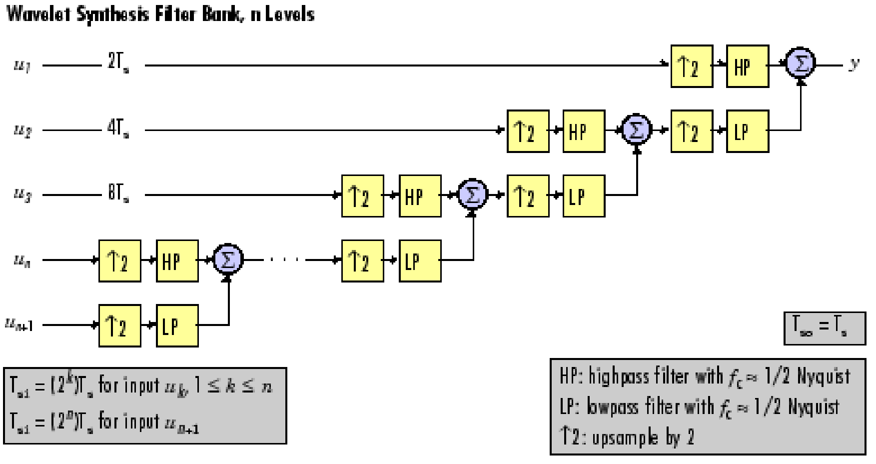
Library

`dspobslib`

Description

Note: The Wavelet Synthesis block will be removed from the product in a future release. We strongly recommend replacing this block with the `IDWT` block.

The Wavelet Synthesis block uses the Wavelet Toolbox `wfilters` function to reconstruct a signal that was decomposed by the Wavelet Analysis (Obsolete) block. The reconstruction or synthesis process is the inverse of the analysis process, and restores the original signal by upsampling, filtering, and summing the bandlimited inputs in stages corresponding to the analysis process. An n-level synthesis filter bank structure is shown below, where n is specified by the **Number of levels** parameter.



At each level, the two bandlimited inputs (one low-frequency, one high-frequency, both with the same sample rate) are upsampled by a factor of 2 to match the sample rate of the input to the next stage. They are then filtered by a highpass (HP) and lowpass (LP) filter pair with coefficients calculated to cancel (in the subsequent summation) the aliasing introduced in the corresponding analysis filter stage. The output from each (upsample-filter-sum) level has twice the bandwidth and twice the sample rate of the input to that level.

For perfect reconstruction, the Wavelet Synthesis and Wavelet Analysis blocks must have the same parameter settings.

Filter Coefficients

The filter coefficients for the highpass and lowpass filters are computed by the Wavelet Toolbox function `wfilters`, based on the wavelet specified in the **Wavelet name** parameter. The table below lists the available options.

Wavelet Name	Sample Wavelet Function Syntax
Haar	`wfilters('haar')`
Daubechies	`wfilters('db4')`
Symlets	`wfilters('sym3')`
Coiflets	`wfilters('coif1')`
Biorthogonal	`wfilters('bior3.1')`

Wavelet Name	Sample Wavelet Function Syntax
Reverse Biorthogonal	`wfilters('rbio3.1')`
Discrete Meyer	`wfilters('dmey')`

The **Daubechies**, **Symlets**, and **Coiflets** options enable a secondary **Wavelet order** parameter that allows you to specify the wavelet order. For example, if you specify a **Daubechies** wavelet with **Wavelet order** equal to `6`, the Wavelet Synthesis block calls the `wfilters` function with input argument `'db6'`.

The **Biorthogonal** and **Reverse Biorthogonal** options enable a secondary **Filter order [synthesis / analysis]** parameter that allows you to independently specify the wavelet order for the analysis and synthesis filter stages. For example, if you specify a **Biorthogonal** wavelet with **Filter order [synthesis / analysis]** equal to `[2 / 6]`, the Wavelet Synthesis block calls the `wfilters` function with input argument `'bior2.6'`.

See the Wavelet Toolbox documentation for more information about the `wfilters` function. If you want to explicitly specify the FIR coefficients for the synthesis filter bank, use the `Dyadic Synthesis Filter bank` block.

Tree Structure

The wavelet tree structure has n+1 inputs, where n is the number of levels. The sample rate and bandwidth of the output are twice the sample rate and bandwidth of the top input. The sample rate and bandwidth of each additional input (except the last) are half that of the input to the previous level.

$$T_{si,k+1} = 2T_{si,k} \quad 1 \le k < n$$

$$BW_{k+1} = \frac{BW_k}{2} \quad 1 \le k < n$$

The bottom two inputs (u_n and u_{n+1}) should have the same sample rate and bandwidth since they are processed by the same level.

$$T_{si,n+1} = T_{si,n}$$

$$BW_{n+1} = BW_n$$

Note that in frame-based mode, the sample period of input u_k is reflected by its frame size$M_{i,k}$, rather than by its frame rate.

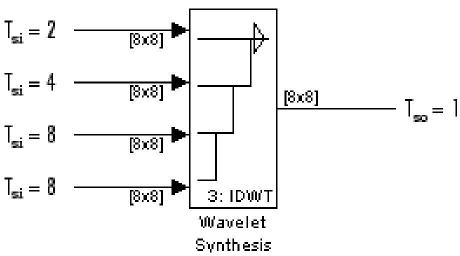
$$M_{i,k+1} = \frac{M_{i,k}}{2} \qquad 1 \le k < n$$

$$M_{i,n+1} = M_{i,n}$$

Sample-Based Operation

An M-by-N sample-based matrix input is treated as $M*N$ independent channels, and the block filters each channel independently over time. The output is the same size as the input at each port, one output channel for each input channel. As described earlier, each input port has a different sample period.

The figure below shows the input and output sample periods for the four 64-channel sample-based inputs to a three-level filter bank. The fastest input has a period of 2, so the output period is 1.

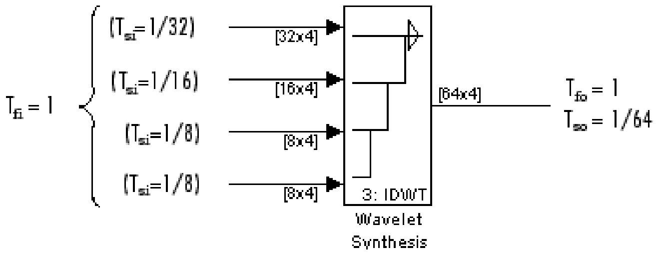


Frame-Based Operation

An M_i-by-N frame-based matrix input is treated as N independent channels, and the block filters each channel independently over time. The number of columns in the output is the same as the number of columns in the input.

All inputs must have the same frame period, which is also the output frame period. The different input sample rates should be represented by the input frame sizes: If the input to the top port has frame size M_i, the input to the second-from-top port should have frame size $M_i/2$, the input to the third-from-top port should have frame size $M_i/4$, and so on. The input to the bottom port should have the same frame size as the second-from-bottom port. The increase in the sample rate of the output is also represented by its frame size, which is twice the largest input frame size.

The relationship between sample periods, frame periods, and frame sizes is shown below for a four-channel frame-based input to a 3-level filter bank.



Zero Latency

The Wavelet Synthesis block has no tasking latency for frame-based operation, which is always single-rate. The block therefore uses the first input samples (received at t=0) to synthesize the first output sample.

Nonzero Latency

For sample-based operation, the Wavelet Synthesis block is multirate and has the following tasking latencies:

- 2^n-2 samples in Simulink's single-tasking mode
- 2^n samples in Simulink's multitasking mode

In the above cases, the block repeats a zero initial condition in each channel for the first D output samples, where D is the latency shown above. For example, in single-tasking mode the block generates 2^n-2 zero-valued output samples in each channel before propagating the first synthesized output sample (computed from the inputs received at t=0).

Note For more information on latency and the Simulink tasking modes, see “Excess Algorithmic Delay (Tasking Latency)” and “Time-Based Scheduling and Code Generation” (Simulink Coder).

Parameters

Wavelet name

The wavelet used in the synthesis.

Wavelet order

The order for the **Daubechies**, **Symlets**, and **Coiflets** wavelets. This parameter is available only when one of these wavelets is selected in the **Wavelet name** menu.

Filter order [synthesis / analysis]

The filter orders for the synthesis and analysis stages of the **Biorthogonal** and **Reverse Biorthogonal** wavelets. For example, `[2 / 6]` selects a second-order synthesis stage and a sixth-order analysis stage. The **Filter order** parameter is available only when one of the above wavelets is selected in the **Wavelet name** menu.

Number of levels

The number of filter bank levels. An n-level structure has n+1 outputs.

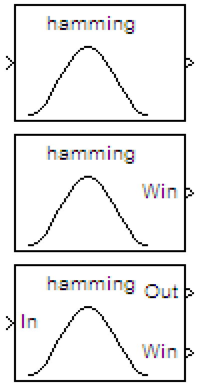
Introduced in R2008b

Window Function

Compute and/or apply window to input signal



Library

Signal Operations

`dspsigops`

Description

The Window Function block computes a window and/or applies a window to an input signal. The input signal can be a matrix or an N-D array.

Operation Modes

The Window Function block has three modes of operation that you can select via the **Operation** parameter. In each mode, the block first creates a window vector w by sampling the window specified in the **Window type** parameter at M discrete points. The operation modes are:

- `Apply window to input`

In this mode, the block computes an M-by-1 window vector w and applies it to the input. The output y always has the same dimension as the input.

When the input is an M-by-N matrix u, the window is multiplied element-wise with each of the N channels in the input matrix u. This is equivalent to the following MATLAB code:

```
y = repmat(w,1,N) .* u        % Equivalent MATLAB code
```

The window is always applied to the first dimension:

$$y(i,j,\ldots,k) = w(i) * u(i,j,\ldots,k) \qquad i = 1,\ldots,M, \;\; j = 1,\ldots,N, \;\; \ldots, \;\; k = 1,\ldots,P$$

A length-M unoriented vector input is treated as an M-by-1 matrix.

- `Generate window`

  In this mode, the block generates an unoriented window vector w with length M specified by the **Window length** parameter. The In port is disabled for this mode.

- `Generate and apply window`

  In this mode, the block generates an M-by-1 window vector w and applies it to the input. The block produces two outputs:

  - At the Out port, the block produces the result of the multiplication y, which has the same dimension as the input.
  - At the Win port, the block produces the M-by-1 window vector w.

  When the input is an M-by-N matrix u, the window is multiplied element-wise with each of the N channels in the input matrix u. This is equivalent to the following MATLAB code:

```
y = repmat(w,1,N) .* u        % Equivalent MATLAB code
```

The window is always applied to the first dimension:

$$y(i,j,\ldots,k) = w(i) * u(i,j,\ldots,k) \qquad i = 1,\ldots,M, \;\; j = 1,\ldots,N, \;\; \ldots, \;\; k = 1,\ldots,P$$

A length-M 1-D vector input is treated as an M-by-1 matrix.

Window Type

The following table lists the available window types. For complete information about the window functions, consult the Signal Processing Toolbox documentation.

Window Type	Description
Bartlett	Computes a Bartlett window. `w = bartlett(M)`
Blackman	Computes a Blackman window. `w = blackman(M)`
Boxcar	Computes a rectangular window. `w = rectwin(M)`
Chebyshev	Computes a Chebyshev window with stopband ripple `R`. `w = chebwin(M,R)`
Hamming	Computes a Hamming window. `w = hamming(M)`
Hann	Computes a Hann window (also known as a Hanning window). `w = hann(M)`
Hanning	Obsolete. This window type is included only for compatibility with older models. Use the `Hann` **Window type** instead of `Hanning` whenever possible.
Kaiser	Computes a Kaiser window with the Kaiser parameter `beta`. `w = kaiser(M,beta)`
Taylor	Computes a Taylor window. `w = taylorwin(M)`
Triang	Computes a triangular window. `w = triang(M)`
User Defined	Computes the user-defined window function specified by the entry in the **Window function name** parameter, `usrwin`.

Window Type	Description
	`w = usrwin(M) % Window takes no extra parameters` `w = usrwin(M,x1,...,xn) % Window takes extra parameters {x1 ... xn}`

Window Sampling

For the generalized-cosine windows (`Blackman`, `Hamming`, `Hann`, and `Hanning`), the **Sampling** parameter determines whether the window samples are computed in a periodic or a symmetric manner. For example, when **Sampling** is set to `Symmetric`, a Hamming window of length M is computed as

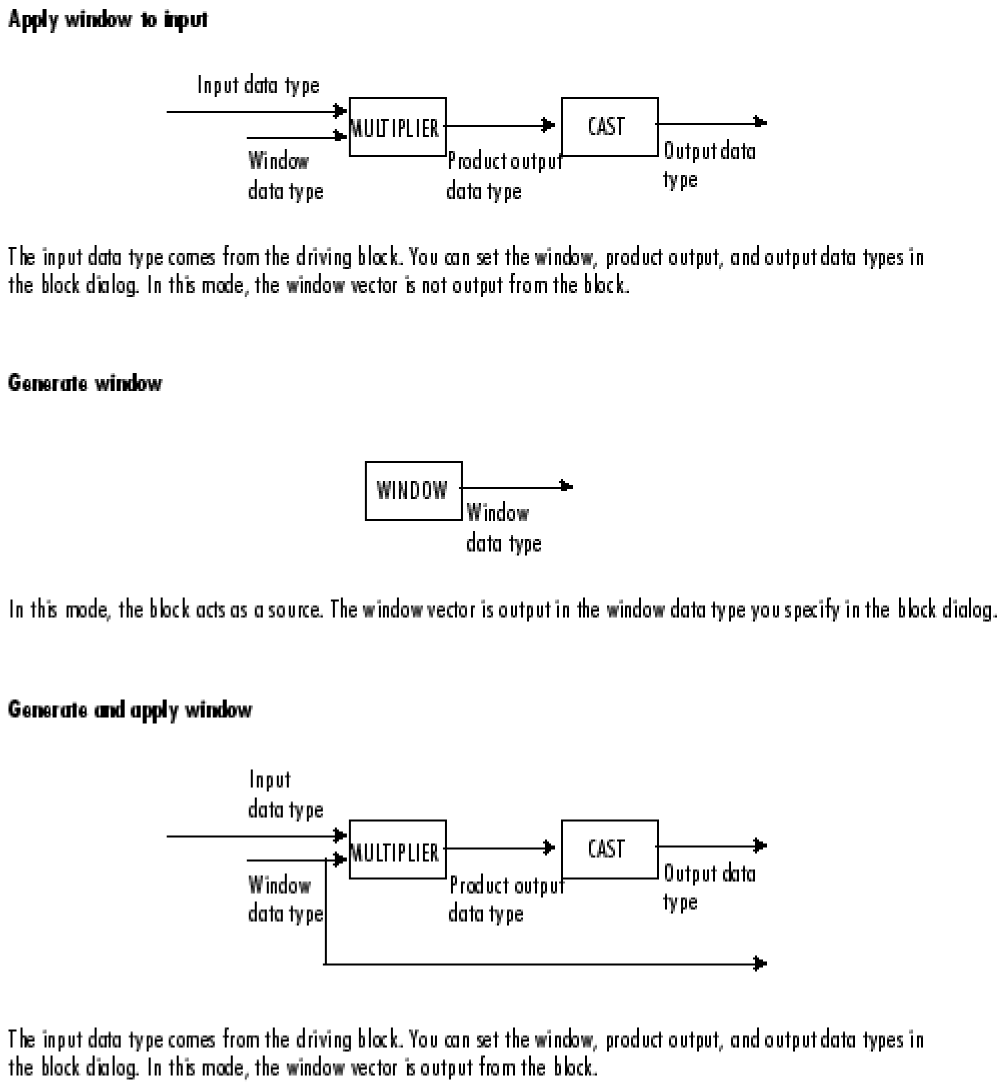
```
w = hamming(M)     % Symmetric (aperiodic) window
```

When **Sampling** is set to `Periodic`, the same window is computed as

```
w = hamming(M+1)     % Periodic (asymmetric) window
w = w(1:M)
```

Fixed-Point Data Types

The following diagram shows the data types used within the Window Function block for fixed-point signals for each of the three operating modes.



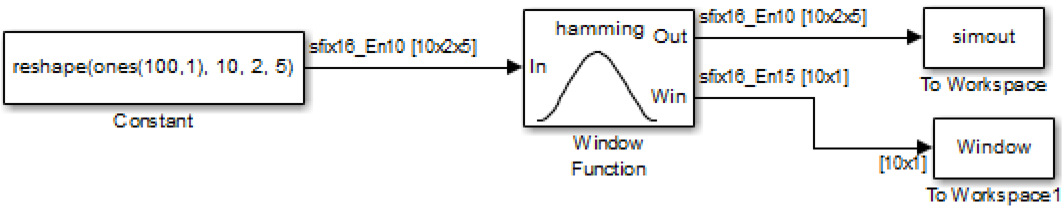
You can set the window, product output, and output data types in the block dialog box. For more information see the “Dialog Box” on page 2-1963 section.

Examples

The following model uses the Window Function block to generate and apply a Hamming window to a 3-dimensional input array.

In this example, set the **Operation** mode of the Window Function block to `Generate and apply window`, so the block provides two outputs: the window vector *Window* at the Win port, and the result of the multiplication *simout* at the Out port.

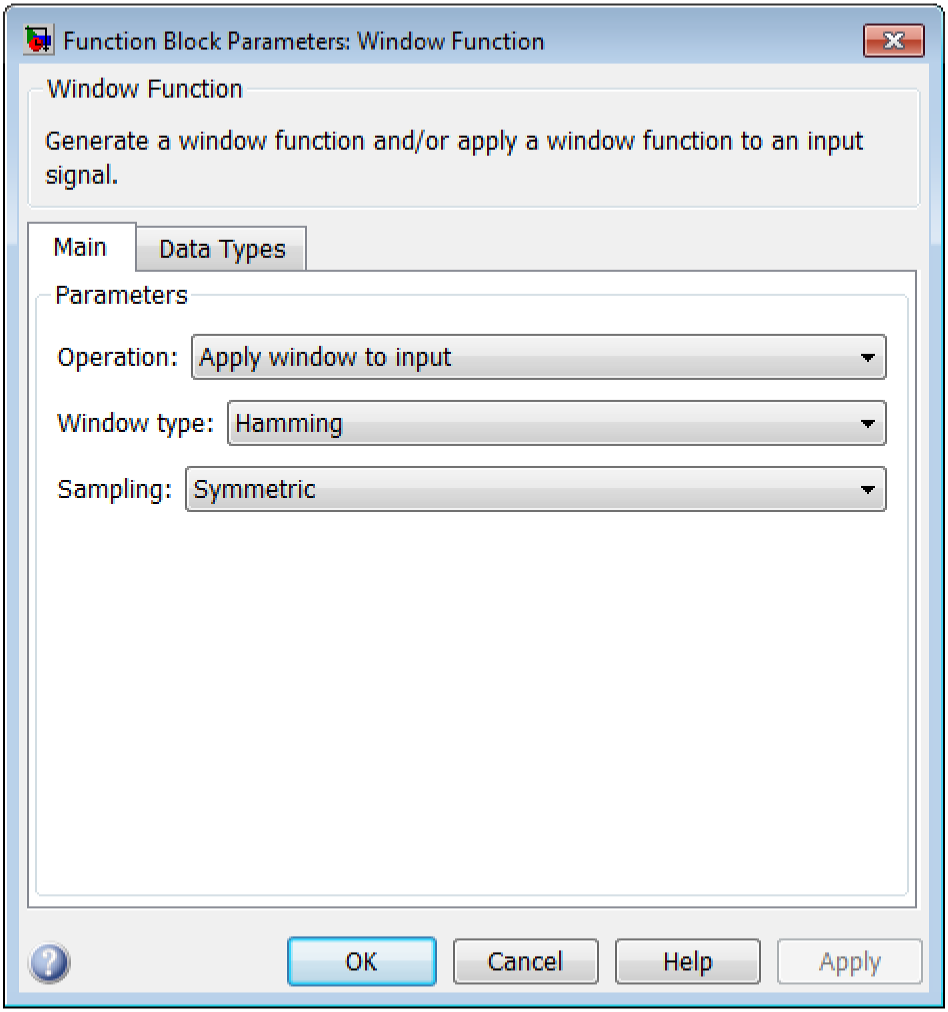
Open the model by typing `ex_windowfunction_ref` at the MATLAB command line, and run it.



- The length of the first dimension of the input array is 10, so the Window Function block generates and outputs a Hamming window vector of length 10. To see the window vector generated by the Window Function block, type `Window` at the MATLAB command line.
- To see the result of the multiplication, type `simout` at the MATLAB command line.

Dialog Box

The **Main** pane of the Window Function block dialog appears as follows.



Operation

Specify the block's operation, as discussed in "Operation Modes" on page 2-1958. The port configuration of the block is updated to match the setting of this parameter.

Window type

Specify the window type to apply, as listed in "Window Type" on page 2-1960. Tunable (Simulink) in simulation only.

Sampling

Specify the window sampling for generalized-cosine windows. This parameter is only visible when you select `Blackman`, `Hamming`, `Hann`, or `Hanning` for the **Window type** parameter. Tunable (Simulink) in simulation only.

Sample Mode

Specify the sample mode for the block, `Continuous` or `Discrete`, when it is in `Generate Window` mode. In the `Apply window to output` and `Generate and apply window` modes, the block inherits the sample time from its driving block. Therefore, this parameter is only visible when you select `Generate window` for the **Operation** parameter.

Sample time

Specify the sample time for the block when it is in `Generate window` and `Discrete` modes. In `Apply window to output` and `Generate and apply window` modes, the block inherits the sample time from its driving block. This parameter is only visible when you select `Discrete` for the **Sample Mode** parameter.

Window length

Specify the length of the window to apply. This parameter is only visible when you select `Generate window` for the **Operation** parameter. Otherwise, the window vector length is computed to match the length of the first dimension of the input.

Stopband attenuation in dB

Specify the level of stopband attenuation, R_s, in decibels. This parameter is only visible when you select `Chebyshev` for the **Window type** parameter. Tunable (Simulink) in simulation only.

Beta

Specify the `Kaiser` window β parameter. Increasing β widens the mainlobe and decreases the amplitude of the window sidelobes in the window's frequency magnitude response. This parameter is only visible when you select `Kaiser` for the **Window type** parameter. Tunable (Simulink) in simulation only.

Number of sidelobes

Specify the number of sidelobes as a scalar integer value greater than zero. This parameter is only visible when you select `Taylor` for the **Window type** parameter.

Maximum sidelobe level relative to mainlobe (dB)

Specify, in decibels, the maximum sidelobe level relative to the mainlobe. This parameter must be a scalar less than or equal to zero. The default value of –30 produces sidelobes with peaks 30 dB down from the mainlobe peak. This parameter is only visible when you select `Taylor` for the **Window type** parameter.

Window function name

Specify the name of the user-defined window function to be calculated by the block. This parameter is only visible when you select `User defined` for the **Window type** parameter.

Specify additional arguments to the hamming function

Select to enable the **Cell array of additional arguments** parameter, when the user-defined window requires parameters other than the window length. This parameter is only visible when you select `User defined` for the **Window type** parameter.

Cell array of additional arguments

Specify the extra parameters required by the user-defined window function, besides the window length. This parameter is only available when you select the **Specify additional arguments to the hamming function** parameter. The entry must be a cell array.

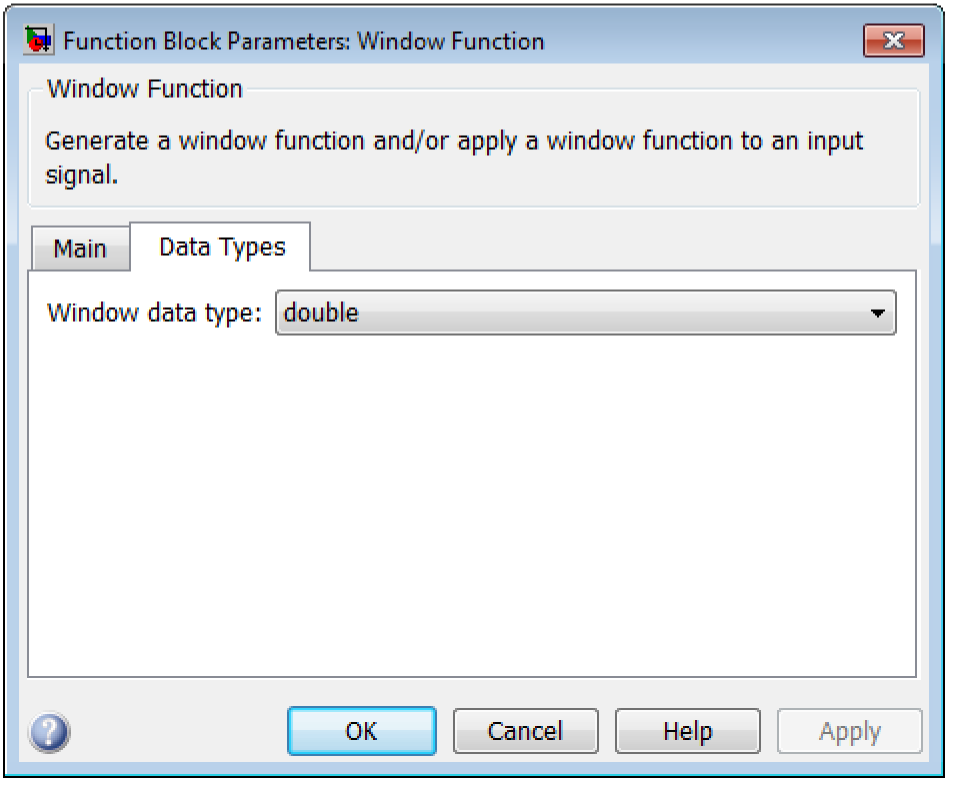
The **Data Types** pane of the Window Function block dialog is discussed in the following sections:

“Parameters for Generate Window Only Mode” on page 2-1966

“Parameters for Apply Window Modes” on page 2-1968

Parameters for Generate Window Only Mode

The **Data Types** pane of the Window Function block dialog appears as follows when the **Operation** parameter is set to `Generate window`.



Window data type

Specify the window data type in one of the following ways:

- Choose `double` or `single` from the list.
- Choose `Fixed-point` to specify the window data type and scaling in the **Signed**, **Word length**, **Set fraction length in output to**, and **Fraction length** parameters.
- Choose `User-defined` to specify the window data type and scaling in the **User-defined data type**, **Set fraction length in output to**, and **Fraction length** parameters.
- Choose `Inherit via back propagation` to set the window data type and scaling to match the following block.

Signed

Select to output a signed fixed-point signal. Otherwise, the signal is unsigned.

Word length

Specify the word length, in bits, of the fixed-point window data type. This parameter is only visible when you select `Fixed-point` for the **Window data type** parameter.

User-defined data type

Specify any built-in or fixed-point data type. You can specify fixed-point data types using the Fixed-Point Designer functions `sfix`, `ufix`, `sint`, `uint`, `sfrac`, and `ufrac`. This parameter is only visible when you select `User-defined` for the **Window data type** parameter.

Set fraction length in output to

Specify the scaling of the fixed-point window data type by either of the following two methods:

- Choose `Best precision` to have the window data type scaling automatically set such that the output signal has the best possible precision.
- Choose `User-defined` to specify the window data type scaling in the **Fraction length** parameter.

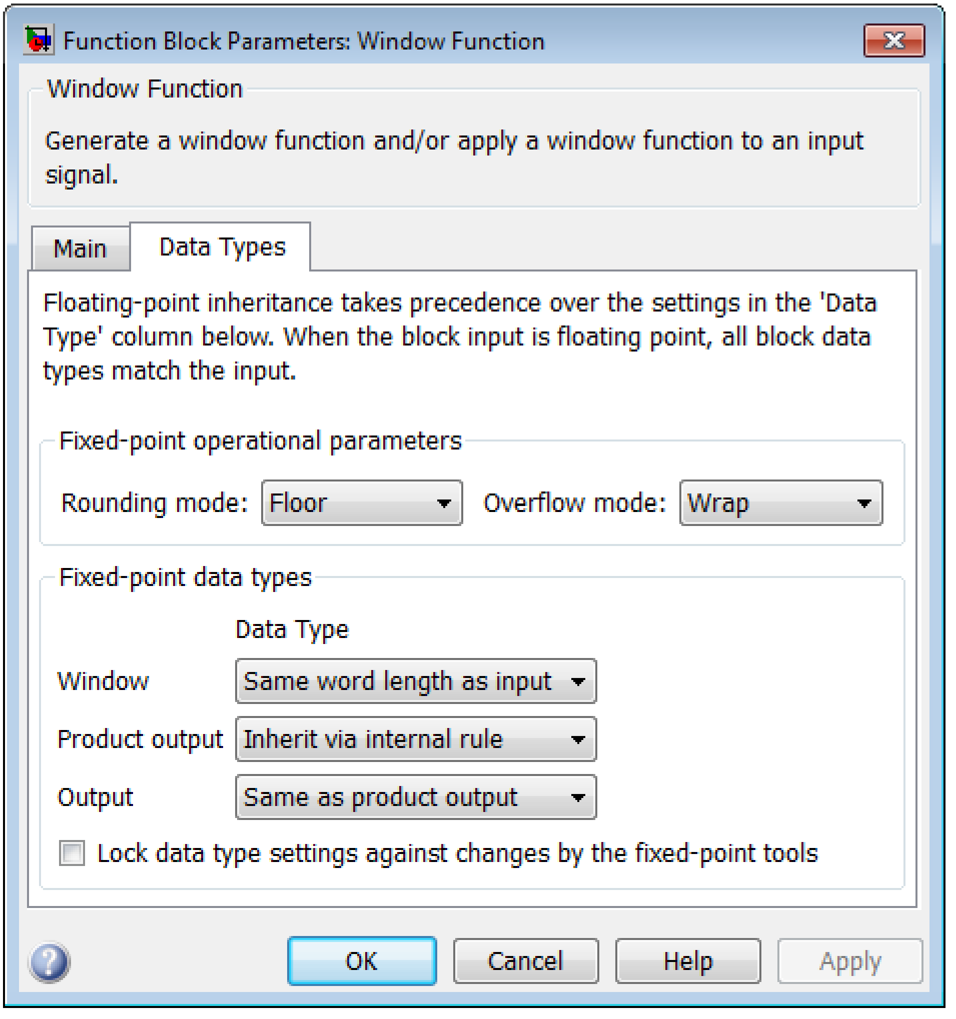
This parameter is only visible when you select `Fixed-point` or `User-defined` for the **Window data type** parameter, and when the specified window data type is a fixed-point data type.

Fraction length

Specify the fraction length, in bits, of the fixed-point window data type. This parameter is only visible when you select `Fixed-point` or `User-defined` for the **Window data type** parameter and `User-defined` for the **Set fraction length in output to** parameter.

Parameters for Apply Window Modes

The **Data Types** pane of the Window Function block dialog appears as follows when the **Operation** parameter is set to either `Apply window to input` or `Generate and apply window`.



Rounding mode

Select the rounding mode for fixed-point operations.

The window vector w does not obey this parameter; it always rounds to `Nearest`.

Note: The **Rounding mode** and **Overflow mode** settings have no effect on numerical results when both of the following conditions exist:

- **Product output data type** is `Inherit via internal rule`
- **Output data type** is `Same as product output`

With these data type settings, the block is effectively operating in full precision mode.

Overflow mode

Select the overflow mode for fixed-point operations.

The window vector *w* does not obey this parameter; it is always saturated.

Window

Choose how you specify the word length and fraction length of the window vector *w*.

When you select `Same word length as input`, the word length of the window vector elements is the same as the word length of the input. The fraction length is automatically set to the best precision possible.

When you select `Specify word length`, you can enter the word length of the window vector elements in bits. The fraction length is automatically set to the best precision possible.

When you select `Binary point scaling`, you can enter the word length and the fraction length of the window vector elements in bits.

When you select `Slope and bias scaling`, you can enter the word length, in bits, and the slope of the window vector elements. This block requires power-of-two slope and a bias of zero.

The window vector does not obey the **Rounding mode** and **Overflow mode** parameters; it is always saturated and rounded to `Nearest`.

Product output

Use this parameter to specify how you want to designate the product output word and fraction lengths.

- When you select `Inherit via internal rule`, the product output word length and fraction length are calculated automatically. For information about how the product output word and fraction lengths are calculated when an internal rule is used, see “Inherit via Internal Rule”.
- When you select `Same as input`, these characteristics match those of the input to the block.

- When you select `Binary point scaling`, you can enter the word length and the fraction length of the product output, in bits.
- When you select `Slope and bias scaling`, you can enter the word length, in bits, and the slope of the product output. This block requires power-of-two slope and a bias of zero.

Output

Choose how you specify the word length and fraction length of the output of the block:

- When you select `Same as product output`, these characteristics match those of the product output.
- When you select `Same as input`, these characteristics match those of the input to the block.
- When you select `Binary point scaling`, you can enter the word length and the fraction length of the output, in bits.
- When you select `Slope and bias scaling`, you can enter the word length, in bits, and the slope of the output. This block requires power-of-two slope and a bias of zero.

Lock data type settings against changes by the fixed-point tools

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block mask.

Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point • Fixed point (signed only) • 8-, 16-, and 32-bit signed integers
Output	• Double-precision floating point • Single-precision floating point • Fixed point (signed only) • 8-, 16-, and 32-bit signed integers

Port	Supported Data Types
Win	• Double-precision floating point • Single-precision floating point • Fixed point • 8-, 16-, and 32-bit integers

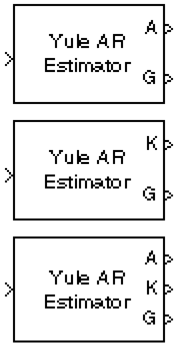
Yule-Walker AR Estimator

Compute estimate of autoregressive (AR) model parameters using Yule-Walker method



Library

Estimation / Parametric Estimation

`dspparest3`

Description

The Yule-Walker AR Estimator block uses the Yule-Walker AR method, also called the autocorrelation method, to fit an autoregressive (AR) model to the windowed input data by minimizing the forward prediction error in the least squares sense. This formulation leads to the Yule-Walker equations, which are solved by the Levinson-Durbin recursion. Block outputs are always nonsingular.

The Yule-Walker AR Estimator block can output the AR model coefficients as polynomial coefficients, reflection coefficients, or both. The input can be a row vector, a column vector, or an unoriented vector which is assumed to be the output of an AR system driven by white noise. The block accepts matrices, and treats each column of the matrix as a channel. If the input is a row vector of length N, the input is treated as N different channels. If the input is an unoriented vector, the input is treated as a single channel. The block computes the normalized estimate of the AR system parameters, $A(z)$, independently for each successive input frame.

$$H(z) = \frac{\sqrt{G}}{A(z)} = \frac{\sqrt{G}}{1 + a(2)z^{-1} + \ldots + a(p+1)z^{-p}}$$

When you select **Inherit estimation order from input dimensions**, the order *p* of the all-pole model is one less than the length of each input channel. Otherwise, the order is the value specified by the **Estimation order** parameter. To guarantee a valid output, you must set the **Estimation order** parameter to be a scalar less than or equal to half the input channel length. The Yule-Walker AR Estimator and Burg AR Estimator blocks return similar results for large frame sizes.

When **Output(s)** is set to `A`, port A is enabled. For each channel, port A outputs a column of length *p*+1 that contains the normalized estimate of the AR model coefficients in descending powers of *z*

```
[1 a(2) ... a(p+1)]
```

When **Output(s)** is set to `K`, port K is enabled. For each channel, port K outputs a length-*p* column whose elements are the AR model reflection coefficients. When **Output(s)** is set to `A and K`, both port A and K are enabled, and each port outputs the respective AR model coefficients for each channel.

The square of the model gain, *G*, is provided at port G. *G* is a scalar for each channel.

See the Burg AR Estimator block reference page for a comparison of the Burg AR Estimator, Covariance AR Estimator, Modified Covariance AR Estimator, and Yule-Walker AR Estimator blocks.

Parameters

Output(s)

The type of AR model coefficients output by the block. The block can output polynomial coefficients (`A`), reflection coefficients (`K`), or both (`A and K`).

Inherit estimation order from input dimensions

When selected, sets the estimation order *p* to one less than the length of each input channel.

Estimation order

The order of the AR model, *p*. This parameter is enabled when you do not select **Inherit estimation order from input dimensions**.

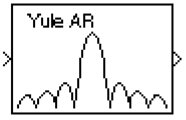
Yule-Walker Method

Power spectral density estimate using Yule-Walker method



Library

Estimation / Power Spectrum Estimation

`dspspect3`

Description

The Yule-Walker Method block estimates the power spectral density (PSD) of the input using the Yule-Walker AR method. This method, also called the *autocorrelation method*, fits an autoregressive (AR) model to the windowed input data. It does so by minimizing the forward prediction error in the least squares sense. This formulation leads to the Yule-Walker equations, which the Levinson-Durbin recursion solves. Block outputs are always nonsingular.

The input must be a column vector. This input represents a frame of consecutive time samples from a single-channel signal. The block outputs a column vector containing the estimate of the power spectral density of the signal at N_{fft} equally spaced frequency points. The frequency points are in the range $[0,F_s)$, where F_s is the sampling frequency of the signal.

When you select **Inherit estimation order from input dimensions**, the order of the all-pole model is one less that the input frame size. Otherwise, the **Estimation order** parameter value specifies the order. To guarantee a valid output, the **Estimation order** parameter must be less than or equal to half the input vector length. The block computes the spectrum from the FFT of the estimated AR model parameters.

Selecting the **Inherit FFT length from estimation order** parameter specifies that N_{fft} is one greater than the estimation order. Clearing the **Inherit FFT length from**

estimation order check box allows you to use the **FFT length** parameter to specify N_{fft} as a power of 2. The block zero-pads or wraps the input to N_{fft} before computing the FFT.

When you select the **Inherit sample time from input** check box, the block computes the frequency data from the sample period of the input signal. For the block to produce valid output, the following conditions must hold:

- The input to the block is the original signal, with no samples added or deleted (by insertion of zeros, for example).
- The sample period of the time-domain signal in the simulation equals the sample period of the original time series.

If these conditions do not hold, clear the **Inherit sample time from input** check box. You can then specify a sample time using the **Sample time of original time series** parameter.

See the Burg Method block reference for a comparison of the Burg Method, Covariance Method, Modified Covariance Method, and Yule-Walker AR Estimator blocks. The Yule-Walker AR Estimator and Burg Method blocks return similar results for large buffer lengths.

Parameters

Inherit estimation order from input dimensions

When you select this option, it sets the estimation order to one less than the length of the input vector.

Estimation order

Specify the order of the AR model. This parameter is only visible when you clear the **Inherit estimation order from input dimensions** check box.

Inherit FFT length from estimation order

When you select the **Inherit FFT length from estimation order** check box, the FFT length is one greater than the estimation order. To specify the number of points on which to perform the FFT, clear the **Inherit FFT length from estimation order** check box. You can then specify a power-of-two FFT length using the **FFT length** parameter.

FFT length

Enter the number of data points on which to perform the FFT, N_{fft}. When N_{fft} is larger than the input frame size, the block zero-pads each frame as needed. When

N_{fft} is smaller than the input frame size, the block wraps each frame as needed. This parameter becomes visible only when you clear the **Inherit FFT length from input dimensions** check box.

Inherit sample time from input

When you select the **Inherit sample time from input** check box, the block computes the frequency data from the sample period of the input signal. For the block to produce valid output, the following conditions must hold:

- The input to the block is the original signal, with no samples added or deleted (by insertion of zeros, for example).
- The sample period of the time-domain signal in the simulation equals the sample period of the original time series.

If these conditions do not hold, clear the **Inherit sample time from input** check box. You can then specify a sample time using the **Sample time of original time series** parameter.

Sample time of original time series

Specify the sample time of the original time-domain signal. This parameter becomes visible only when you clear the **Inherit sample time from input** check box.

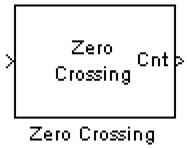
Zero Crossing

Count number of times signal crosses zero in single time step



Library

Signal Operations

`dspsigops`

Description

The Zero Crossing block concludes that a signal in a given channel has passed through zero if it meets any of the following criteria, where x_i is the current signal value, x_{i-1} is the previous signal value, and so on:

- $x_i < 0$ and $x_{i-1} > 0$
- $x_i > 0$ and $x_{i-1} < 0$
- For some positive integer L, $x_i < 0$, $x_{i-l} = 0$, and $x_{i-L-1} > 0$, where $0 \le l \le L$.
- For some positive integer L, $x_i > 0$, $x_{i-l} = 0$, and $x_{i-L-1} < 0$, where $0 \le l \le L$.

For the first input value, x_{i-1} and x_{i-2} are zero. The block outputs the number of times the signal crosses zero in a single time step at the Cnt port.

The input to this block must be a real-valued fixed-point or floating-point signal. If you set the **Input processing** parameter to `Elements as channels (sample based)`, the block treats each element of the input as a time-varying channel. If you set the **Input processing** parameter to `Columns as channels (frame based)`, the block treats each column of the input as an independent channel.

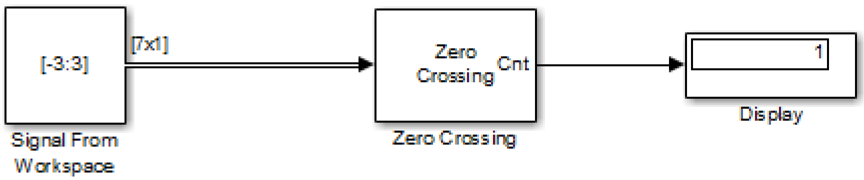
Examples

The following example, ex_zero_crossing illustrates the behavior of the Zero Crossing block.

To run the model for one time step, the **Stop time** is set to 0.

1 Run the model.

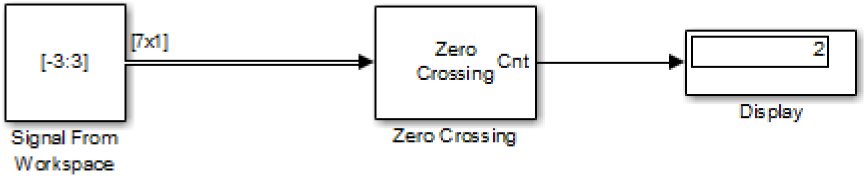
  Because the signal passes through zero once during the first time step, the Zero Crossing block finds one zero crossing. The number of detected zero crossings in the first time step is shown in the Display block in the following figure.



2 To run the model for two time steps, change the simulation **Stop time** to 1. To do so, open the Configuration Parameters dialog box by selecting **Model Configuration Parameters** from the **Simulation** menu. In the **Solver** pane, set **Stop time** to 1.

3 Run the model.

  The Zero Crossing block remembers that the last value of the last frame was 3. Therefore, the signal passes through zero twice during the second time step. It passes through zero while going from 3 to -3, and it passes through zero again while going from -3 to 3. The Zero Crossing block finds two zero crossings in the second time step as shown in the Display block in the following figure.



Parameters

Input processing

Specify how the block should process the input. You can set this parameter to one of the following options:

- `Columns as channels (frame based)` (default) — When you select this option, the block treats each column of the input as a separate channel.
- `Elements as channels (sample based)` — When you select this option, the block treats each element of the input as a separate channel.

Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating-point • Single-precision floating-point • Fixed point (signed and unsigned) • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers
Cnt	• 32-bit unsigned integers

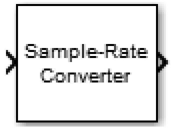
Hit Crossing   Simulink

Introduced before R2006a

Sample-Rate Converter

Multistage sample-rate conversion



Library

Signal Operations

`dspsigops`

Description

The Sample-Rate Converter block implements a multistage FIR sample-rate converter. This multistage FIR converter converts the rate of each channel of the input signal from the input sample rate to the output sample rate. Multistage implementations minimize the amount of computation required by the sample-rate conversions by first reducing the sample rate of the input signal. Next, the block determines the optimal number of decimators and interpolators required based on the parameters specified in the block dialog box. Then the block designs filters in the individual stages accordingly.

The input frame size must be a multiple of the decimation factor of the rate converter. The decimation factor depends on the parameter setting of the converter. To determine the decimation factor, in the block dialog box, click **View Info** .

Each column of a two-dimensional input signal is treated as a separate channel. If the input is a two-dimensional signal, the first dimension represents the channel length (or frame size), and the second dimension represents the number of channels. If the input is a one-dimensional signal, then it is interpreted as a single channel. The inputs to the block can be single or double, and real or complex.

Parameters

Sample rate of input signal (Hz)

Sample rate of the input signal, specified as a positive scalar in Hz. The input sample rate must be greater than the bandwidth of interest. The default is 48e3.

Sample rate of output signal (Hz)

Sample rate of the output signal, specified as a positive scalar in Hz. The output sample rate must be greater than the bandwidth of interest. The default is 96e3.

Tolerance for output sample rate

Maximum allowed tolerance for output sample rate, specified as a positive scalar in the range [0,1]. The default is 0.

The actual output sample rate varies but is within the specified range. For example, suppose that you set the **Tolerance for output sample rate**, to 0.01. Then the actual output sample rate is in the range given by sample rate of output signal ± 1%. This flexibility allows for a simpler filter design.

Two-sided bandwidth of interest (Hz)

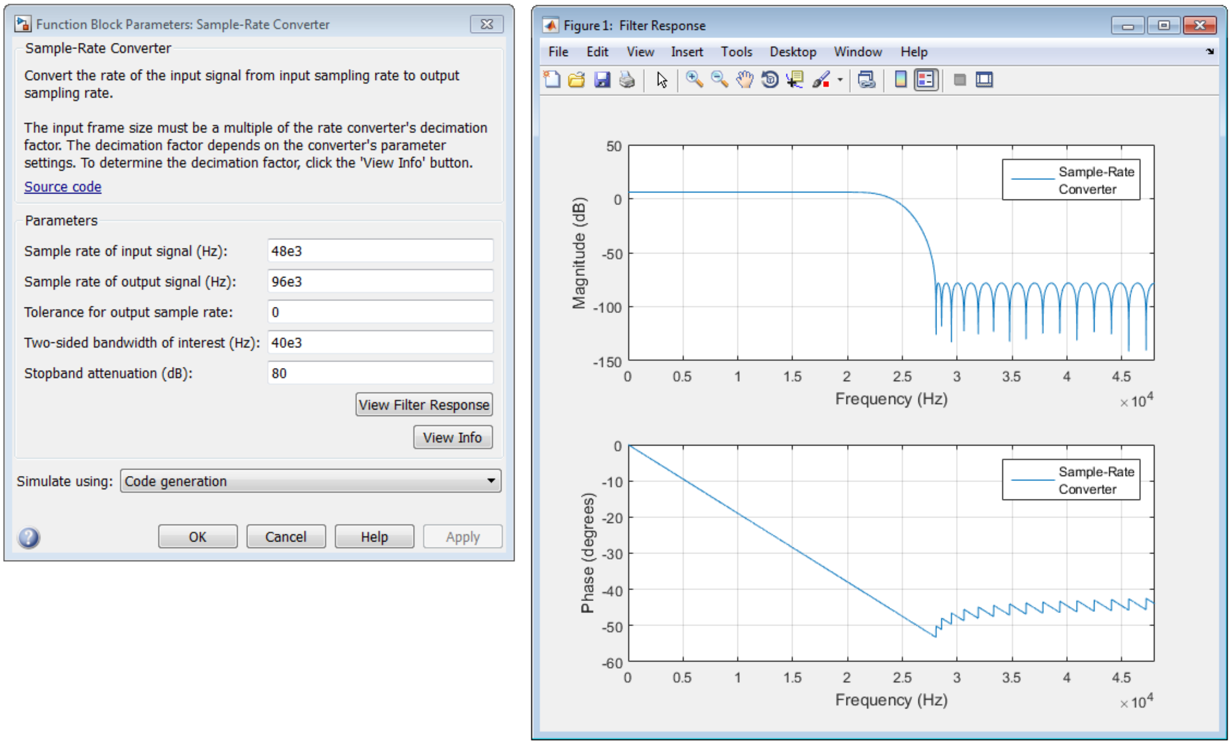
Two-sided bandwidth of interest (after the rate of conversion), specified as a positive scalar in Hz. The default is 40e3.

Stopband attenuation (dB)

Minimum amount of attenuation for aliased components in the stopband, specified as a positive scalar in dB. The default is 80. This parameter is the minimum amount by which any aliasing involved in the process is attenuated.

View Filter Response

Opens the Filter Visualization Tool FVTool and displays the magnitude/phase response of the Sample-Rate Converter. The response is based on the block dialog box parameters. Changes made to these parameters update FVTool.

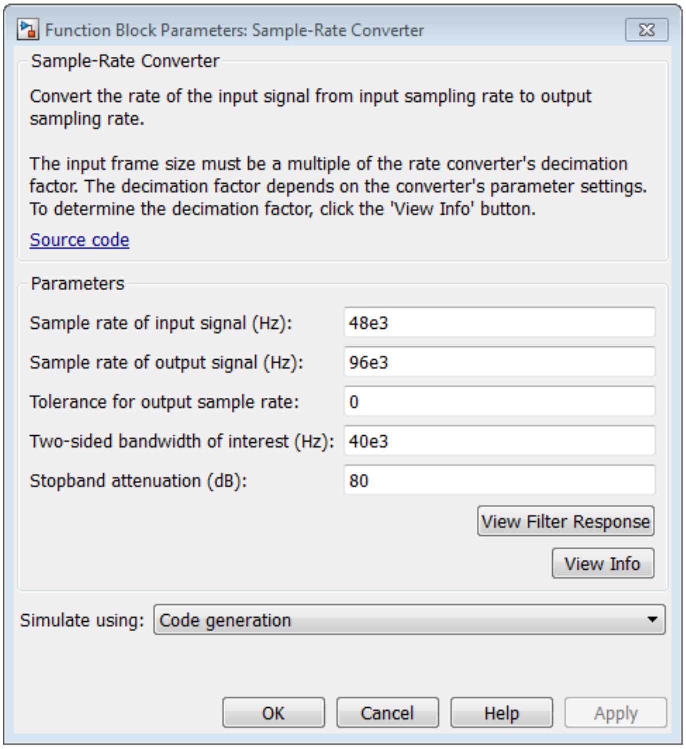


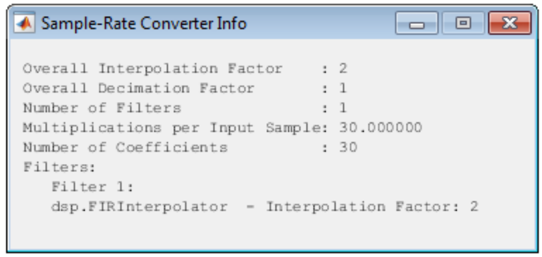
To update the magnitude response while FVTool is running, modify the dialog box parameters and click **Apply**.

View Info

Displays information about the filter system of the Sample-Rate Converter block:

- `Overall Interpolation Factor`
- `Overall Decimation Factor`
- `Number of Filters`
- `Multiplication per Input Sample`
- `Number of Coefficients`
- `Filters`





The button brings the functionality of the `dsp.SampleRateConverter.info` method into the Simulink environment.

Simulate using

Type of simulation to run. You can set this parameter to:

- `Code generation` (default)

  Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time but provides faster simulation speed than `Interpreted execution`.
- `Interpreted execution`

Simulate model using the MATLAB interpreter. This option shortens startup time but has slower simulation speed than `Code generation`.

Supported Data Types

Port	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point

`islinphase`	True for linear discrete-time filter
`ismaxphase`	True if maximum phase
`isminphase`	True if minimum phase
`isreal`	True for discrete-time filter with real coefficients
`isstable`	True if the filter is stable
`isfir`	True if the filter is FIR
`issos`	True if filter is in second order sections form
`specifyall`	Specify all fixed-point properties

System Objects — Alphabetical List

dsp.AdaptiveLatticeFilter System object

Package: dsp

Adaptive lattice filter

Description

The `dsp.AdaptiveLatticeFilter` computes output, error, and coefficients using a Lattice based FIR adaptive filter.

To implement the adaptive FIR filter object:

1. Define and set up your adaptive FIR filter object. See “Construction” on page 4-2.
2. Call step to implement the filter according to the properties of `dsp.AdaptiveLatticeFilter`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`alf = dsp.AdaptiveLatticeFilter` returns a Lattice based FIR adaptive filter System object, `alf`. This System object is used to compute the filtered output and the filter error for a given input and desired signal.

`alf = dsp.AdaptiveLatticeFilter('`*`PropertyName`*`',` *`PropertyValue`*`,...)` returns an `AdaptiveLatticeFilter` System object, `alf`, with each specified property set to the specified value.

`alf =`
`dsp.AdaptiveLatticeFilter(LEN,'`*`PropertyName`*`',`*`PropertyValue`*`,...)`

returns an `AdaptiveLatticeFilter` System object, `alf`, with the Length property set to `LEN` and other specified properties set to the specified values.

Properties

`Method`

Method to calculate filter coefficients

Specify the method used to calculate filter coefficients as one of `'Least-squares Lattice'` |`'QR-decomposition Least-squares Lattice'` |`'Gradient Adaptive Lattice'` . The default value is `'Least-squares Lattice'`. For algorithms used to implement these three different methods, refer to [1] [2]. This property is nontunable.

`Length`

Length of the filter coefficients vector

Specify the length of the FIR filter coefficients vector as a positive integer value. This property is nontunable.

The default value is 32.

`ForgettingFactor`

Least-squares lattice forgetting factor

Specify the Least-squares lattice forgetting factor as a scalar positive numeric value less than or equal to 1. Setting this value to 1 denotes infinite memory during adaptation. This property applies only if the Method property is set to `'Least-squares Lattice'` or `'QR-decomposition Least-squares Lattice'`. The default value is `1`.

This property is tunable.

`StepSize`

Joint process step size of the gradient adaptive filter

Specify the joint process step size of the gradient adaptive lattice filter as a positive numeric scalar less than or equal to 1. This property applies only if the `Method` property is set to `'Gradient Adaptive Lattice'`. The default value is `0.1`.

This property is tunable.

Offset

Offset for denominator of StepSize normalization term

Specify an offset value for the denominator of the `StepSize` normalization term as a nonnegative numeric scalar. A nonzero offset helps avoid a divide-by-near-zero condition when the input signal amplitude is very small. This property applies only if the `Method` property is set to `'Gradient Adaptive Lattice'`. The default value is `1`.

This property is tunable.

ReflectionStepSize

Reflection process step size

Specify the reflection process step size of the gradient adaptive lattice filter as a scalar numeric value between 0 and 1, both inclusive. Use this property only if the `Method` property is set to `'Gradient Adaptive Lattice'`. The default value is the `StepSize` property value.

This property is tunable.

AveragingFactor

Averaging factor of the energy estimator

Specify the averaging factor as a positive numeric scalar less than 1. Use this property to compute the exponentially windowed forward and backward prediction error powers for the coefficient updates. This property applies only if the `Method` property is set to `'Gradient Adaptive Lattice`. The default is the value of `1 - StepSize`.

This property is tunable.

InitialPredictionErrorPower

Initial prediction error power

Specify the initial values for the prediction error vectors as a scalar positive numeric value.

If the `Method` property is set to `'Least-squares Lattice'` or `'QR-decomposition Least-squares Lattice'`, the default value is `1.0`. If the `Method` property is set to `'Gradient Adaptive Lattice'`, the default value is `0.1`.

This property is tunable.

`InitialCoefficients`

Initial coefficients of the filter

Specify the initial values of the FIR adaptive filter coefficients as a scalar or a vector of length equal to the value of the `Length` property. The default value is `0`.

This property is tunable.

`LockCoefficients`

Locked status of the coefficient updates

Specify whether to lock the filter coefficient values. By default, the value of this property is `false`, and the object continuously updates the filter coefficients. If this property is set to `true`, the filter coefficients do not update and their values remain the same.

This property is applicable only if the `Method` property is set to `'Gradient Adaptive Lattice'`.

This property is tunable.

Methods

msesim	Mean-square error for Adaptive Lattice filter
reset	Reset filter states for Adaptive Lattice filter
step	Apply Adaptive Lattice filter to input

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object

Common to All System Objects	
getNumOutp	Expected number of outputs of a System object
isLocked	Check locked states of a System object (logical)
release	Allow System object property value changes

Examples

QPSK adaptive equalization Using Adaptive Lattice Filter

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

Create the QPSK signal and the noise, filter them to obtain the received signal, and delay the received signal to obtain the desired signal.

```
D = 16;
b = exp(1i*pi/4)*[-0.7 1];
a = [1 -0.7];
ntr = 1000;
s = sign(randn(1,ntr+D)) + 1i*sign(randn(1,ntr+D));
n = 0.1*(randn(1,ntr+D) + 1i*randn(1,ntr+D));
r = filter(b,a,s) + n;
x = r(1+D:ntr+D);
d = s(1:ntr);
```

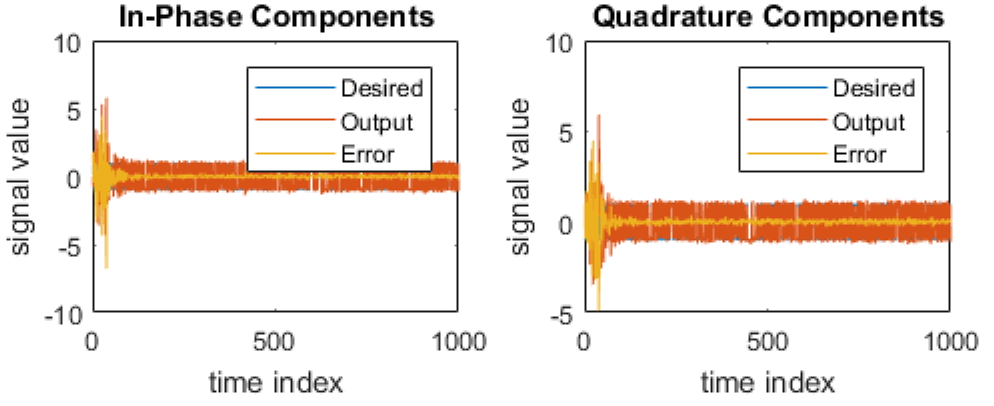
Use the Adaptive Lattice Filter to compute the filtered output and the filter error for the input and desired signal.

```
lam = 0.995;
del = 1;
alf = dsp.AdaptiveLatticeFilter('Length', 32, ...
    'ForgettingFactor', lam, 'InitialPredictionErrorPower', del);
[y,e] = alf(x,d);
```

Plot the In-Phase and the Quadrature components of the desired, output, and the error signals.

```
subplot(2,2,1); plot(1:ntr,real([d;y;e]));
title('In-Phase Components');
legend('Desired','Output','Error');
```

```
xlabel('time index'); ylabel('signal value');
subplot(2,2,2); plot(1:ntr,imag([d;y;e]));
title('Quadrature Components');
legend('Desired','Output','Error');
xlabel('time index'); ylabel('signal value');
```



Plot the received and equalized signals' scatter plots.

```
subplot(2,2,3); plot(x(ntr-100:ntr),'.'); axis([-3 3 -3 3]);
title('Received Signal Scatter Plot'); axis('square');
xlabel('Real[x]'); ylabel('Imag[x]'); grid on;
subplot(2,2,4); plot(y(ntr-100:ntr),'.'); axis([-3 3 -3 3]);
title('Equalized Signal Scatter Plot'); axis('square');
xlabel('Real[y]'); ylabel('Imag[y]'); grid on;
```

msesim

System object: dsp.AdaptiveLatticeFilter
Package: dsp

Mean-square error for Adaptive Lattice filter

Syntax

```
MSE = msesim(sysObj,X,D)
[MSE,MEANW,W,TRACEK] = msesim(sysObj,X,D)
[...] = msesim(sysObj,X,D,M)
```

Description

`MSE = msesim(sysObj,X,D)` returns a sequence of mean-square errors. This column vector contains estimates of the mean-square error of the adaptive filter at each time instant. The length of `MSE` is equal to `SIZE(X,1)`. The columns of the matrix `X` contain individual input signal sequences, and the columns of the matrix `D` contain corresponding desired response signal sequences.

`[MSE,MEANW,W,TRACEK] = msesim(sysObj,X,D)` calculates three parameters corresponding to the simulated behavior of the adaptive filter defined by `sysObj`. `MEANW` is a sequence of coefficient vector means. The columns of this matrix contain estimates of the mean values of the adaptive filter coefficients at each time instant. The dimensions of `MEANW` are `(SIZE(X,1))` by `(sysObj.length)`. `W` is an estimate of the final values of the adaptive filter coefficients for the algorithm corresponding to `sysObj`. `TRACEK` is a sequence of total coefficient error powers. This column vector contains estimates of the total coefficient error power of the adaptive filter at each time instant. The length of `TRACEK` is equal to `SIZE(X,1)`.

`[...] = msesim(sysObj,X,D,M)` specifies an optional decimation factor for computing `MSE`, `MEANW`, and `TRACEK`. If `M` > `1`, every `M`th predicted value of each of these sequences is saved. If omitted, the value of `M` is the default, which is 1.

System identification of an FIR filter Using Adaptive Lattice Filter

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

```
ha = fir1(31,0.5);
fir = dsp.FIRFilter('Numerator',ha); % FIR system to be identified
iir = dsp.IIRFilter('Numerator',sqrt(0.75),...
        'Denominator',[1 -0.5]);
x = iir(sign(randn(2000,25)));
n = 0.1*randn(size(x));            % Observation noise signal
d = fir(x)+n;                  % Desired signal
l = 32;                            % Filter length
m  = 5;                            % Decimation factor for analysis
                                   % and simulation results
ha = dsp.AdaptiveLatticeFilter(l);
[simmse,meanWsim,Wsim,traceKsim] = msesim(ha,x,d,m);
plot(m*(1:length(simmse)),10*log10(simmse));
xlabel('Iteration'); ylabel('MSE (dB)');

reset

System object: dsp.AdaptiveLatticeFilter
Package: dsp

Reset filter states for Adaptive Lattice filter

Syntax

`reset(alf)`

Description

`reset(alf)` resets the internal states of the System object,`alf`, to their initial values. The reset method is always a no-op for unlocked System objects, as the states may not be allocated when the object is not locked.

step

System object: dsp.AdaptiveLatticeFilter
Package: dsp

Apply Adaptive Lattice filter to input

Syntax

```
[Y, ERR] = step(sysObj, x, D)
Y = step(sysObj,x)
[Y1,...,YN] = step(sysObj,x)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`[Y, ERR] = step(sysObj, x, D)` filters the input `x`, using D as the desired signal, and returns the filtered output in `Y` and the filter error in `ERR`. The System object estimates the filter weights needed to minimize the error between the output signal and the desired signal.

`Y = step(sysObj,x)` processes the input data, `x`, to produce the output, `Y`, from the System object, `sysObj`. `[Y1,...,YN] = step(sysObj,x)` produces `N` outputs.

Every System object has a step method. The step method processes the input data according to the object algorithm. The number of input and output arguments depends on the algorithm, and may depend also on one or more property settings. The step method for some objects accepts fixed-point (fi) inputs.

Calling step on an object puts that object into a locked state. When locked, you cannot change nontunable properties or any input characteristics (size, data type and complexity) without reinitializing (unlocking and relocking) the object.

Note: `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.AffineProjectionFilter System object

Package: dsp

Compute output, error and coefficients using Affine Projection (AP) Algorithm

Description

The `AffineProjectionFilter` object filters each channel of the input using AP filter implementations.

To filter each channel of the input:

1. Define and set up your AP filter. See “Construction” on page 4-16.
2. Call step to filter each channel of the input according to the properties of `dsp.AffineProjectionFilter`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`apf = dsp.AffineProjectionFilter` returns an adaptive FIR filter System object, `apf`. This System object computes the filtered output and the filter error for a given input and desired signal using the Affine Projection (AP) algorithm.

`apf = dsp.AffineProjectionFilter('`*`PropertyName`*`',`*`PropertyValue`*`, ...)` returns an AP filter System object, `apf`, with each specified property set to the specified value.

`apf = dsp.AffineProjectionFilter(LEN, '`*`PropertyName`*`',` *`PropertyValue`*`, ...)` returns an AP filter System object, `apf`. This System object has the Length property set to `LEN`, and other specified properties set to the specified values.

Properties

Method

Method to calculate the filter coefficients

Specify the method used to calculate filter coefficients as one of | `Direct Matrix Inversion` | `Recursive Matrix Update` | `Block Direct Matrix Inversion`. The default value is `Direct Matrix Inversion`. This property is nontunable.

Length

Length of filter coefficients vector

Specify the length of the FIR filter coefficients vector as a scalar positive integer value. The default value is `32`. This property is nontunable.

ProjectionOrder

Projection order of the affine projection algorithm

Specify the projection order of the affine projection algorithm as a scalar positive integer value greater than or equal to 2. This property defines the size of the input signal covariance matrix. The default value is `2`. This property is nontunable.

StepSize

Affine projection step size

Specify the affine projection step size factor as a scalar non-negative numeric value between 0 and 1, both inclusive. Setting step equal to one provides the fastest convergence during adaptation. The default value is `1`. This property is tunable.

InitialCoefficients

Initial coefficients of the filter

Specify the initial values of the FIR adaptive filter coefficients as a scalar or a vector of length equal to the `Length` property value. The default value is `0`. This property is tunable.

InitialOffsetCovariance

Initial values of the offset input covariance matrix

Specify the initial values for the offset input covariance matrix. This property must be either a scalar positive numeric value or a positive-definite square matrix with each dimension equal to the `ProjectionOrder` property value. If it is a scalar value, the `OffsetCovariance` property is initialized to a diagonal matrix with the diagonal elements equal to that scalar value. If it is a square matrix, the `OffsetCovariance` property is initialized to the value of that square matrix. This property is applicable only if the Method property is set to `Direct Matrix Inversion` or `Block Direct Matrix Inversion`. The default value is `1`. This property is tunable.

InitialInverseOffsetCovariance

Initial values of the offset input covariance matrix inverse

Specify the initial values for the offset input covariance matrix inverse. This property must be either a scalar positive numeric value or a positive-definite square matrix with each dimension equal to the `ProjectionOrder` property value. If it is a scalar value, the `InverseOffsetCovariance` property is initialized to a diagonal matrix with each diagonal element equal to that scalar value. If it is a square matrix, the `InverseOffsetCovariance` property is initialized to the values of that square matrix. This property is applicable only if the `Method` property is set to `Recursive Matrix Update`. The default value is `20`. This property is tunable.

InitialCorrelationCoefficients

Initial correlation coefficients

Specify the initial values of the correlation coefficients of the FIR filter as a scalar or a vector of length equal to `ProjectionOrder` –`1`. This property is applicable only if the `Method` property is set to `Recursive Matrix Update`. The default value is `0`. This property is tunable.

LockCoefficients

Lock coefficient updates

Specify whether the filter coefficient values should be locked. When you set this property to `true`, the filter coefficients are not updated and their values remain the same. The default value is `false` (filter coefficients are continuously updated). This property is tunable.

Methods

msesim	Mean-square error for Affine Projection filter
reset	Reset the internal states of a System object
step	Process inputs using the affine projection filter algorithm

Common to All System Objects	
clone	Create System object with same property values
getNumInpu	Expected number of inputs to a System object
getNumOutp	Expected number of outputs of a System object
isLocked	Check locked states of a System object (logical)
release	Allow System object property value changes

Examples

QPSK Adaptive Equalization

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

QPSK Adaptive Equalization Using a 32-Coefficient FIR Filter (1000 Iterations)

```
D = 16;                         % Number of samples of delay
b = exp(1i*pi/4)*[-0.7 1];       % Numerator coefficients of channel
a = [1 -0.7];                   % Denominator coefficients of channel
ntr = 1000;                     % Number of iterations
s = sign(randn(1,ntr+D)) + 1i*sign(randn(1,ntr+D)); % Baseband signal
n = 0.1*(randn(1,ntr+D) + 1i*randn(1,ntr+D));       % Noise signal
r = filter(b,a,s)+n;            % Received signal
x = r(1+D:ntr+D);               % Input signal (received signal)
d = s(1:ntr);                   % Desired signal (delayed QPSK signal)
mu = 0.1;                       % Step size
po = 4;                         % Projection order
offset = 0.05;                  % Offset for covariance matrix
apf = dsp.AffineProjectionFilter('Length', 32, ...
    'StepSize', mu, 'ProjectionOrder', po, ...
```

```
    'InitialOffsetCovariance',offset);
[y,e] = apf(x,d);

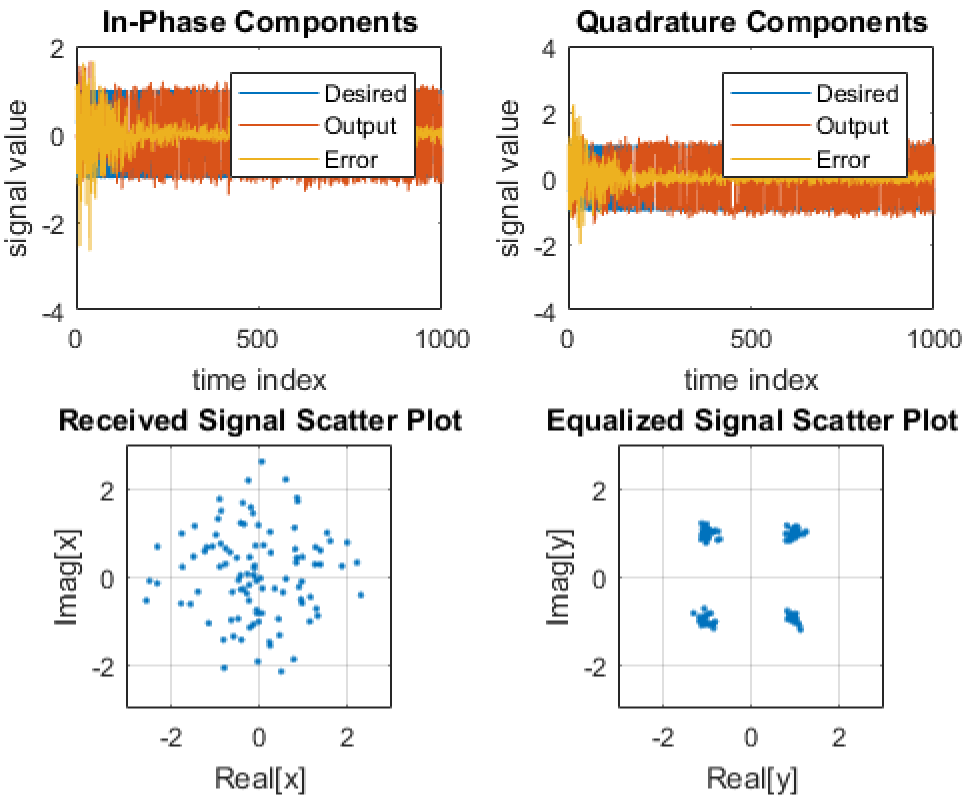
xlabel('Real[x]'); ylabel('Imag[x]'); grid on;
subplot(2,2,4); plot(y(ntr-100:ntr),'.'); axis([-3 3 -3 3]);
title('Equalized Signal Scatter Plot'); axis('square');
xlabel('Real[y]'); ylabel('Imag[y]'); grid on;
```



Algorithms

The affine projection algorithm (APA), is an adaptive scheme that estimates an unknown system based on multiple input vectors [1]. It is designed to improve the performance of other adaptive algorithms, mainly those that are LMS-based. The affine projection algorithm reuses old data resulting in fast convergence when the input signal is highly correlated, leading to a family of algorithms that can make trade-offs between computation complexity with convergence speed [2].

The following equations describe the conceptual algorithm used in designing AP filters:

$$\mathbf{U}_{ap}(n) = \begin{pmatrix} u(n) & \dots & u(n-L) \\ \vdots & \ddots & \vdots \\ u(n-N) & \cdots & u(n-L-N) \end{pmatrix} = \begin{pmatrix} \mathbf{u}(n) & \mathbf{u}(n-1) & \cdots & \mathbf{u}(n-L) \end{pmatrix}$$

$$\mathbf{y}_{ap}(n) = \mathbf{U}^T{}_{ap}(n)\mathbf{w}(n) = \begin{pmatrix} y(n) \\ \bullet \\ \bullet \\ \bullet \\ y(n-L) \end{pmatrix}$$

$$\mathbf{d}_{ap}(n) = \begin{pmatrix} d(n) \\ \bullet \\ \bullet \\ \bullet \\ d(n-L) \end{pmatrix}$$

$$\mathbf{e}_{ap}(n) = \mathbf{d}_{ap}(n) - \mathbf{y}_{ap}(n) = \begin{pmatrix} e(n) \\ \bullet \\ \bullet \\ \bullet \\ e(n-L) \end{pmatrix}$$

$$\mathbf{w}(n) = \mathbf{w}(n-1) + \mu \mathbf{U}_{ap}(n)(\mathbf{U}_{ap}{}^H(n)\mathbf{U}_{ap}(n) + \mathbf{C})^{-1}\mathbf{e}_{ap}$$

where **C** is either ε**I** if the initial offset covariance is a scalar ε, or **R** if the initial offset covariance is a matrix **R**. The variables are as follows:

Variable	Description
n	The current time index
u(n)	The input sample at step n
$\mathbf{U}_{ap}$(n)	The matrix of the last L+1 input signal vectors

Variable	Description
w(n)	The adaptive filter coefficients vector
y(n)	The adaptive filter output
d(n)	The desired signal
e(n)	The error at step n
L	The projection order
N	The filter order (i.e., filter length = N+1)
μ	The step size

msesim

System object: dsp.AffineProjectionFilter
Package: dsp

Mean-square error for Affine Projection filter

Syntax

```
MSE = msesim(sysObj,X,D)
[MSE,MEANW,W,TRACEK] = msesim(sysObj,X,D)
[...] = msesim(sysObj,X,D,M)
```

Description

`MSE = msesim(sysObj,X,D)` returns a sequence of mean-square errors. This column vector contains estimates of the mean-square error of the adaptive filter at each time instant. The length of `MSE` is equal to `SIZE(X,1)`. The columns of the matrix `X` contain individual input signal sequences, and the columns of the matrix `D` contain corresponding desired response signal sequences.

`[MSE,MEANW,W,TRACEK] = msesim(sysObj,X,D)` calculates three parameters corresponding to the simulated behavior of the adaptive filter defined by `sysObj`. `MEANW` is a sequence of coefficient vector means. The columns of this matrix contain estimates of the mean values of the adaptive filter coefficients at each time instant. The dimensions of `MEANW` are `(SIZE(X,1))` by `(sysObj.length)`. `W` is an estimate of the final values of the adaptive filter coefficients for the algorithm corresponding to `sysObj`. `TRACEK` is a sequence of total coefficient error powers. This column vector contains estimates of the total coefficient error power of the adaptive filter at each time instant. The length of `TRACEK` is equal to `SIZE(X,1)`.

`[...] = msesim(sysObj,X,D,M)` specifies an optional decimation factor for computing `MSE`, `MEANW`, and `TRACEK`. If `M` > `1`, every M^{th} predicted value of each of these sequences is saved. If omitted, the value of `M` is the default, which is 1.

System Identification of an FIR Filter Using Affine Projection Filter

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

```
ha = fir1(31,0.5);
fir = dsp.FIRFilter('Numerator',ha); % FIR system to be identified
iir = dsp.IIRFilter('Numerator',sqrt(0.75),...
        'Denominator',[1 -0.5]);
x = iir(sign(randn(2000,25)));
n = 0.1*randn(size(x));              % Observation noise signal
d = fir(x)+n;                    % Desired signal
l = 32;                              % Filter length
mu = 0.008;                          % Affine Projection filter Step size.
m  = 5;                              % Decimation factor for analysis
                                     % and simulation results
apf = dsp.AffineProjectionFilter(l,'StepSize',mu);
[simmse,meanWsim,Wsim,traceKsim] = msesim(apf,x,d,m);
plot(m*(1:length(simmse)),10*log10(simmse));
xlabel('Iteration'); ylabel('MSE (dB)');

reset

System object: dsp.AffineProjectionFilter
Package: dsp

Reset the internal states of a System object

Syntax

`reset(apf)`

Description

`reset(apf)` resets the internal states of the System object, `apf`, to their initial values.

For many System objects, this method is nonoperational. Objects that have internal states describe in their **help** what the reset method does for that object. The `reset` method is always nonoperational for unlocked System objects, as states may not be allocated when the object is not locked.

step

System object: dsp.AffineProjectionFilter
Package: dsp

Process inputs using the affine projection filter algorithm

Syntax

```
Y = step(apf,x)
[Y1,...,YN] = step(apf,x)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(apf,x)` processes the input data, `x`, to produce the output, `Y`, for the System object, `apf`. `[Y1,...,YN] = step(apf,x)` produces N outputs.

Every System object has a `step` method. The `step` method processes the input data according to the object algorithm. The number of the input and the output arguments depends on the algorithm, and may depend also on one or more property settings. The step method for some objects accepts fixed-point (fi) inputs.

Calling `step` on an object puts that object into a locked state. When locked, you cannot change nontunable properties or any input characteristics (size, data type and complexity) without reinitializing (unlocking and relocking) the object.

dsp.AllpassFilter System object

Package: dsp

Single section or cascaded allpass filter

Note: MATLAB code with `LatticeCoefficients`, `AllpassCoefficients`, and `WDFCoefficients` properties set to cell arrays will error in a future release. Set these properties to array values instead.

Description

The `AllpassFilter` object filters each channel of the input using Allpass filter implementations. This System object supports code generation. To import this object into Simulink, use the MATLAB System block.

To filter each channel of the input:

1. Define and set up your Allpass filter. See "Construction" on page 4-29.
2. Call step to filter each channel of the input according to the properties of `dsp.AllpassFilter`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`Allpass = dsp.AllpassFilter` returns an Allpass filter System object, `Allpass`, that filters each channel of the input signal independently using an allpass filter, with the default structure and coefficients.

`Allpass = dsp.AllpassFilter('PropertyName',PropertyValue, ...)` returns an Allpass filter System object, `Allpass`, with each property set to the specified value.

Properties

`Structure`

Internal allpass filter structure

You can specify the internal allpass filter implementation structure as one of `| Minimum multiplier | Lattice | Wave Digital Filter`. The default is `Minimum multiplier`. Each structure uses a different set of coefficients, independently stored in the corresponding object property.

`AllpassCoefficients`

Allpass polynomial coefficients

Specify the real allpass polynomial filter coefficients. This property is applicable only when the `Structure` property is set to `Minimum multiplier`. Specify this property as either an *N*-by-`1` or *N*-by-`2` matrix of *N* first-order or second-order allpass sections. The default value of this property is `[-2^(-1/2) 0.5]`. The default value defines a stable second-order allpass filter with poles and zeros located at $\pm\pi/3$ in the Z plane. This property is tunable.

`WDFCoefficients`

Wave Digital Filter allpass coefficients

Specify the real allpass coefficients in the Wave Digital Filter form. This property is only applicable when the `Structure` property is set to `Wave Digital Filter`. Specify this property as either a *N*-by-`1` or *N*-by-`2` matrix of *N* first-order or second-order allpass sections. All elements must have absolute values less than or equal to `1`. The default value for this property is [`1/2, -2^(1/2)/3`]. This value is a transformed version of the default value of `AllpassCoefficients`, computed using `allpass2wdf(AllpassCoefficients)`. These coefficients define the same stable second-order allpass filter as when `Structure` is set to `'Minimum multiplier'`. This property is tunable.

`LatticeCoefficients`

Lattice allpass coefficients

Specify the real or complex allpass coefficients as lattice reflection coefficients. This property is applicable only if the `Structure` property is set to `Lattice`. Specify this property as either a row vector (single-section configuration) or a column vector. The default is `[-2^(1/2)/3, 1/2]`. This value is a transformed and transposed version of the default value of `AllpassCoefficients`, computed using `transpose(tf2latc([1 h.AllpassCoefficients]))`. These coefficients define the same stable second-order allpass filter as when `Structure` is set to `'Lattice'`. This property is tunable.

TrailingFirstOrderSection

Indicate if last section is first order

Indicate if last section is first order or second order. When you set `TrailingFirstOrderSection` to `true`, the last section is considered to be first-order, and the second element of the last row of the N-by-2 matrix is ignored. When you set `TrailingFirstOrderSection` to `false`, the last section is considered to be second-order. The default is `false`.

Methods

reset	Reset internal states of a System object
step	Process inputs using allpass filter

For additional methods, see "Analysis Methods for Filter System Objects" on page 3-2.

For a complete list of analysis methods supported for the `dsp.AllpassFilter` object, enter `dsp.AllpassFilter.helpFilterAnalysis` at the MATLAB command prompt.

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Lowpass Filtering using Two Allpass Filters

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

Construct the Allpass Filters

```
Fs  = 48000;    % in Hz
FL = 1024;
APF1 = dsp.AllpassFilter('AllpassCoefficients',...
    [-0.710525516540603   0.208818210000029]);
APF2 =  dsp.AllpassFilter('AllpassCoefficients',...
    [-0.940456403667957   0.6;...
    -0.324919696232907   0],...
    'TrailingFirstOrderSection',true);
```

Construct the Transfer Function Estimator to estimate the transfer function between the random input and the Allpass filtered output

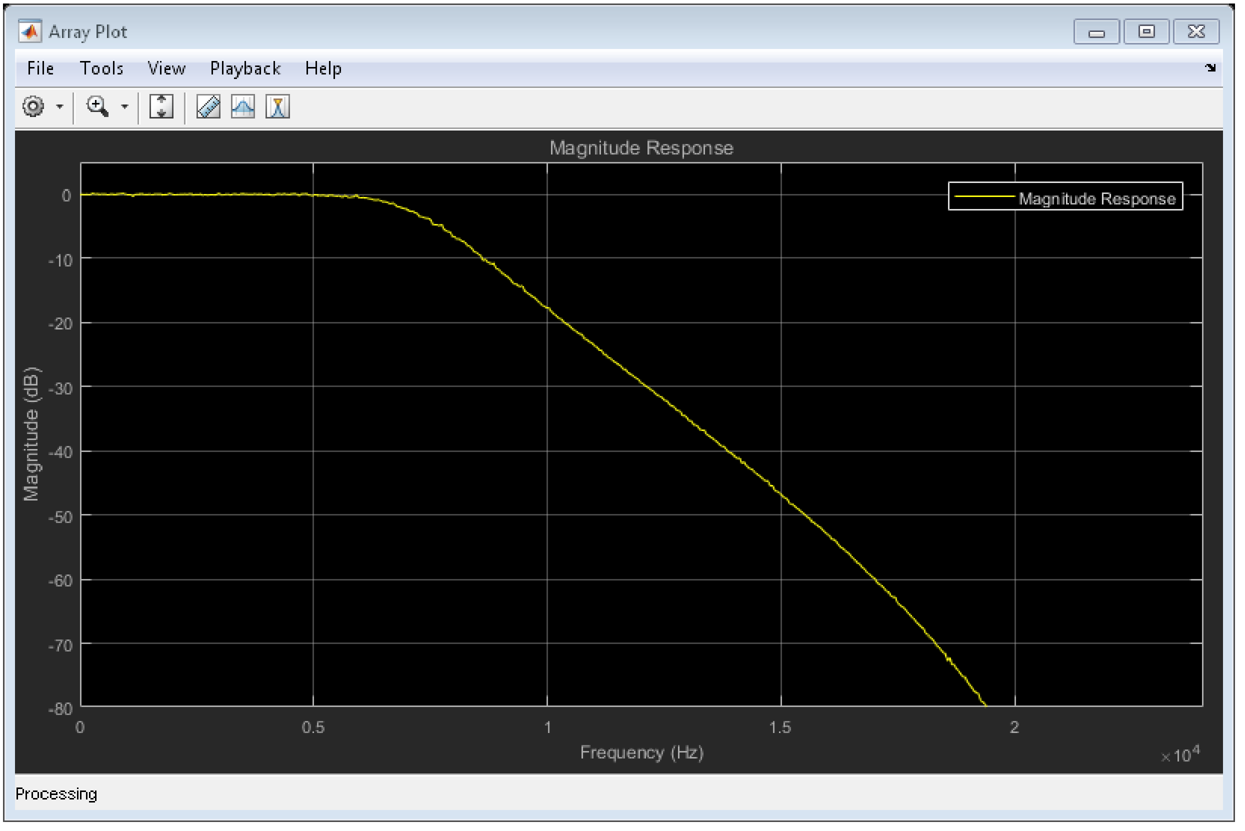
```
TFE = dsp.TransferFunctionEstimator('FrequencyRange',...
    'onesided','SpectralAverages',2);
```

Construct the ArrayPlot to plot the magnitude response

```
AP = dsp.ArrayPlot('PlotType','Line','YLimits', [-80 5],...
    'YLabel','Magnitude (dB)','SampleIncrement', Fs/FL,...
    'XLabel','Frequency (Hz)','Title','Magnitude Response',...
    'ShowLegend', true,'ChannelNames',{'Magnitude Response'});
```

Filter the Input and show the magnitude response of the estimated transfer function between the input and the filtered output

```
tic;
while toc < 5
    in  = randn(FL,1);
    out = 0.5.*(APF1(in) + APF2(in));
    A = TFE(in, out);
    AP(db(A));
end
```



Algorithms

The transfer function of an allpass filter is given by

$$H(z)=\frac{c(n)+c(n-1)z^{-1}+\ldots+z^{-n}}{1+c(1)z^{-1}+\ldots+c(n)z^{-n}}.$$

c is allpass polynomial coefficients vector. The order, n, of the transfer function is the length of vector c.

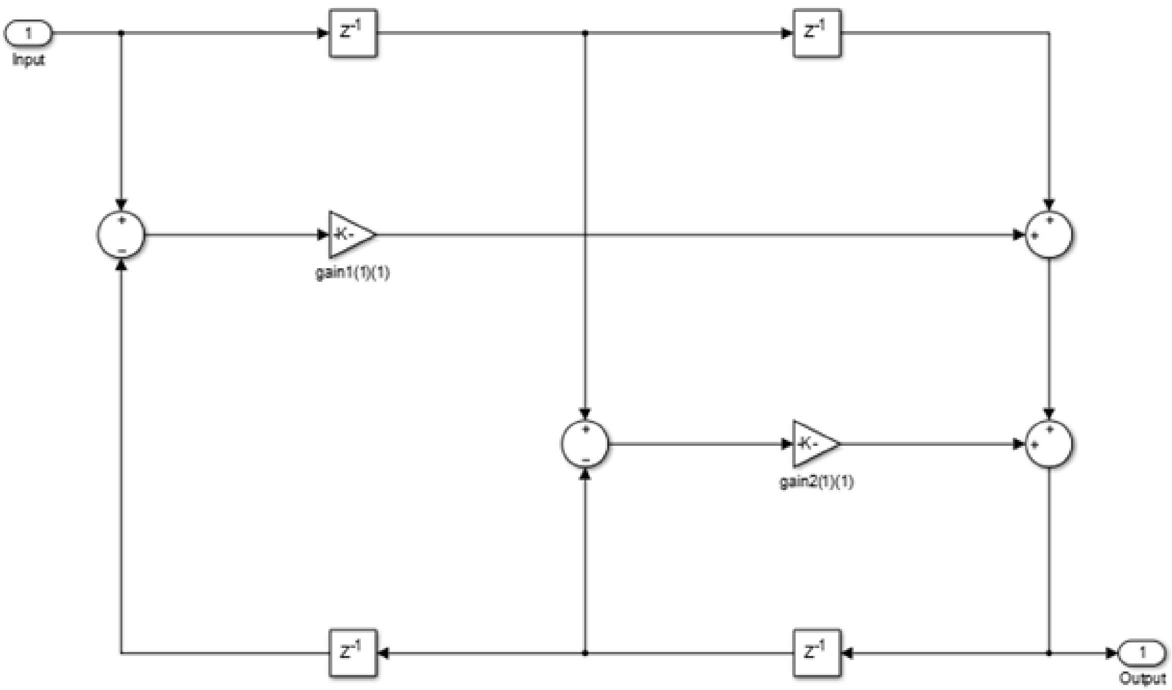
In the minimum multiplier form and wave digital form, the allpass filter is implemented as a cascade of either second-order (biquad) sections or first-order sections. When the coefficients are specified as an N-by-2 matrix, each row of the matrix specifies the coefficients of a second-order filter. The last element of the last row can be ignored based on the trailing first-order setting. When the coefficients are specified as an N-by-1 matrix, each element in the matrix specifies the coefficient of a first-order filter. The cascade of all the filter sections forms the allpass filter.

In the lattice form, the coefficients are specified as a vector.

These structures are computationally more economical and structurally more stable compared to the generic IIR filters, such as df1, df1t, df2, df2t. For all structures, the allpass filter can be a single-section or a multiple-section (cascaded) filter. The different sections can have different orders, but they are all implemented according to the same structure.

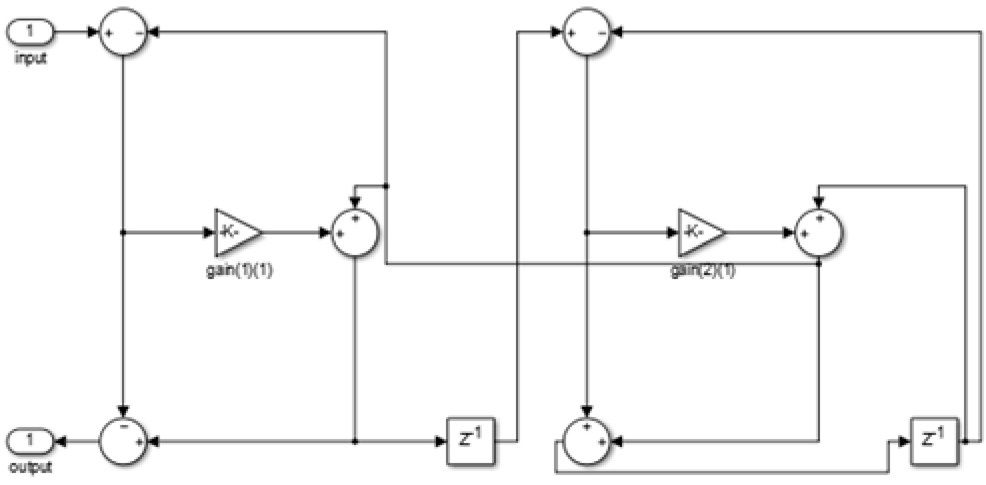
Minimum Multiplier

This structure realizes the allpass filter with the minimum number of required multipliers, equal to the order `n`. It also uses `2n` delay units and `2n` adders. The multipliers uses the specified coefficients, which are equal to the polynomial vector c in the allpass transfer function. In this second-order section of the minimum multiplier structure, the coefficients vector, c, is equal to [`0.1 -0.7`].



Wave Digital Filter

This structure uses `n` multipliers, but only `n` delay units, at the expense of requiring `3n` adders. To use this structure, specify the coefficients in wave digital filter (WDF) form. Obtain the WDF equivalent of the conventional allpass coefficients using `allpass2wdf(allpass_coefficients)`. To convert WDF coefficients into the equivalent allpass polynomial form, use `wdf2allpass(WDF coefficients)`. In this second-order section of the WDF structure, the coefficients vector w is equal to `allpass2wdf([0.1 -0.7])`.



Lattice

This lattice structure uses `2n` multipliers, `n` delay units, and `2n` adders. To use this structure, specify the coefficients as a vector.

You can obtain the lattice equivalent of the conventional allpass coefficients using `transpose(tf2latc(1, [1 allpass_coefficients]))`. In the following second-order section of the lattice structure, the coefficients vector is computed using `transpose(tf2latc(1, [1 0.1 -0.7]))`. Use these coefficients for a filter that is functionally equivalent to the minimum multiplier structure with coefficients [0.1 -0.7].

dsp.BiquadFilter | dsp.IIRFilter

Introduced in R2013a

reset

System object: dsp.AllpassFilter
Package: dsp

Reset internal states of a System object

Syntax

`reset(OBJ)`

Description

`reset(OBJ)` resets the internal states of the System object, `OBJ`, to their initial values.

For many System objects, this method is equivalent to no operation being executed. The `reset` method is always nonoperational for unlocked System objects, as states may not be allocated when the object is not locked.

step

System object: dsp.AllpassFilter
Package: dsp

Process inputs using allpass filter

Syntax

```
Y = step(OBJ,x)
[Y1,...,YN]= step(OBJ,x)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(OBJ,x)` processes the input data, `x`, to produce the output, `Y`, for the System object, `OBJ`. `[Y1,...,YN]= step(OBJ,x)` produces N outputs.

Every System object has a `step` method. The `step` method processes the input data according to the object algorithm. The number of the input and the output arguments depends on the algorithm, and may depend also on one or more property settings. The step method for some objects accepts fixed-point (fi) inputs.

Calling `step` on an object puts that object into a locked state. When locked, you cannot change nontunable properties or any input characteristics (size, data type and complexity) without reinitializing (unlocking and relocking) the object.

dsp.AllpoleFilter System object

Package: dsp

IIR Filter with no zeros

Description

The `AllpoleFilter` object filters each channel of the input using Allpole filter implementations.

To filter each channel of the input:

1. Define and set up your Allpole filter. See "Construction" on page 4-41.
2. Call step to filter each channel of the input according to the properties of `dsp.AllpoleFilter`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`allpole = dsp.AllpoleFilter` returns an Allpole filter System object, `allpole`, which independently filters each channel of the input over successive calls to the `step` method. This System object uses a specified Allpole filter implementation, and it supports variable-size input.

`allpole = dsp.AllpoleFilter('`*`PropertyName`*`',`*`PropertyValue`*`, ...)` returns an Allpole filter System object, `allpole`, with each property set to the specified value.

Properties

`Structure`

Filter structure

Specify the filter structure.
You can specify the filter structure as one of | `Direct form` | `Direct form transposed` | `Lattice AR`. The default is `Direct form`. Analysis methods are not supported for fixed-point processing if the structure is `Direct form` or `Direct form transposed`. This property is nontunable.

Denominator

Filter denominator coefficients

Specify the denominator coefficients as a real or complex numeric row vector. This property is applicable when the Structure property is set to one of `Direct form` | `Direct form transposed`. The default value of this property is `[1 0.1]`. This property is tunable.

ReflectionCoefficients

Lattice filter coefficients

Specify the lattice filter coefficients as a real or complex numeric row vector. This property is applicable when the Structure property is set to `Lattice AR`. The default value of this property is `[0.2 0.4]`. This property is tunable.

InitialConditions

Initial conditions for the filter states

Specify the initial conditions of the filter states. The default value is `0`.

You can specify the initial conditions as a scalar, vector, or matrix. If you specify a scalar value, this System object initializes all delay elements in the filter to that value. You can also specify a vector whose length equals the number of delay elements in the filter. When you do so, each vector element specifies a unique initial condition for the corresponding delay element. The object applies the same vector of initial conditions to each channel of the input signal.

You can also specify a matrix with the same number of rows as the number of delay elements in the filter and one column for each channel of the input signal. In this case, each element specifies a unique initial condition for the corresponding delay element in the corresponding channel. This property is tunable.

CoefficientsDataType

Denominator coefficients word- and fraction-length designations

Specify the denominator coefficients fixed-point data type as one of `Same word length as input` | `Custom`. The default is `Same word length as input`. This property is nontunable.

`ReflectionCoefficientsDataType`

Reflection coefficients word- and fraction-length designations

Specify the reflection coefficients fixed-point data type as one of `Same word length as input` | `Custom`. The default is `Same word length as input`. This property is nontunable.

Fixed-Point Properties

`ProductDataType`

Product word- and fraction-length designations

Specify the product fixed-point data type as one of | `Full precision` | `Same as input` | `Custom` |. The default is `Full precision`. This property is nontunable.

`AccumulatorDataType`

Accumulator word- and fraction-length designations

Specify the accumulator fixed-point data type to one of | `Full precision` | `Same as input` | `Same as product` | `Custom` |. The default is `Full precision`. This property is nontunable.

`OutputDataType`

Output word- and fraction-length designations

Specify the output fixed-point data type as one of | `Same as accumulator` | `Same as input` | `Custom` |. The default is `Same as input`. This property is nontunable.

`StateDataType`

State word- and fraction-length designations

Specify the state fixed-point data type as one of | `Same as input` | `Same as accumulator` | `Custom`. The default is `Same as accumulator`. This property is nontunable.

CustomCoefficientsDataType

Custom denominator word- and fraction-lengths

Specify the denominator coefficients fixed-point type as an autosigned numerictype (Fixed-Point Designer) object. This property is applicable when the `CoefficientsDataType` on page 4-42 property is `Custom`. The default value of this property is numerictype ([],16,15). This property is nontunable.

CustomReflectionCoefficientsDataType

Custom reflection coefficients word- and fraction-lengths

Specify the denominator coefficients fixed-point type as an autosigned numerictype (Fixed-Point Designer) object. This property is applicable when the `ReflectionCoefficientsDataType` on page 4-43 property is `Custom`. The default value of this property is numerictype ([],16,15). This property is nontunable.

CustomProductDataType

Custom Product word- and fraction-lengths

Specify the product fixed-point type as an autosigned scaled `numerictype` object. This property applies when you set the `ProductDataType` on page 4-43 property to `Custom`. The default is `numerictype ([],32,30)`. This property is nontunable.

CustomAccumulatorDataType

Custom accumulator word- and fraction-lengths

Specify the accumulator fixed-point type as an autosigned scaled `numerictype` object. This property applies when you set the `AccumulatorDataType` on page 4-43 property to `Custom`. The default is `numerictype([],32,30)`. This property is nontunable.

CustomStateDataType

Custom state word- and fraction-lengths

Specify the state fixed-point type as an autosigned scaled `numerictype` object. This property applies when you set the `StateDataType` on page 4-43 property to `Custom`. The default is `numerictype([],16,15)`. This property is nontunable.

CustomOutputDataType

Custom output word- and fraction-lengths

Specify the output fixed-point type as an autosigned scaled `numerictype` object. This property applies when you set the `OutputDataType` on page 4-43 property to `Custom`. The default is `numerictype([],16,15)`. This property is nontunable.

Methods

freqz	Frequency response
fvtool	Open filter visualization tool
impz	Impulse response
phasez	Unwrapped phase response
reset	Reset internal states of Allpole filter
step	Filter input with Allpole filter object

More "Analysis Methods for Filter System Objects" on page 3-2.

Note: In AllpoleFilter, analysis methods are not supported for fixed-point processing if the structure is `Direct form` or `Direct form transposed`.

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Lowpass filtering a waveform with two frequencies

Use an Allpole filter to apply a lowpass filter to a waveform with two sinusoidal frequencies.

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

```
 t = (0:1000)./8e3;
 xin = sin(2*pi*1e3*t)+sin(2*pi*3e3*t);

 src = dsp.SignalSource(xin', 4);
 sink = dsp.SignalSink;
 allpole = dsp.AllpoleFilter;
 tt = (-25:25)';
 xsinc = 0.4*sinc(0.4*tt);
 asinc = lpc(xsinc,51);
 allpole.Denominator = asinc;

 sa = dsp.SpectrumAnalyzer('SampleRate',8e3,...
    'PlotAsTwoSidedSpectrum',false,...
    'OverlapPercent', 80,'PowerUnits','dBW',...
    'YLimits', [-150 50]);

while ~isDone(src)
      input = src();
      filteredOutput = allpole(input);
      sink(filteredOutput);
      sa(filteredOutput)
 end

 filteredResult = sink.Buffer;
 fvtool(allpole,'Fs',8000)
```

dsp.FIRFilter | dsp.BiquadFilter | dsp.IIRFilter

Introduced in R2012b

freqz

System object: dsp.AllpoleFilter
Package: dsp

Frequency response

Syntax

```
[h,w] = freqz(allpole)
[h,w] = freqz(allpole,n)
[h,w] = freqz(allpole,Name,Value)
freqz(allpole)
```

Description

`[h,w] = freqz(allpole)` returns the complex, 8192–element frequency response vector `h`, and the corresponding frequencies `w` in radians/sample.

`[h,w] = freqz(allpole,n)` returns the complex, n-element frequency response vector `h`, and the corresponding frequencies `w` in radians/sample, using `n` samples.

`[h,w] = freqz(allpole,Name,Value)` returns the frequency response and the corresponding frequencies, with additional options specified by one or more Name, Value pair arguments.

`freqz(allpole)` uses FVTool to plot the magnitude and unwrapped phase of the frequency response of the filter System object `allpole`.

fvtool

System object: dsp.AllpoleFilter
Package: dsp

Open filter visualization tool

Syntax

```
fvtool(allpole)
fvtool(allpole,'Arithmetic',ARITH,...)
```

Description

`fvtool(allpole)` performs an analysis and computes the magnitude response of the filter System object `allpole`.

`fvtool(allpole,'Arithmetic',ARITH,...)` analyzes the filter System object `allpole`, based on the arithmetic specified in the ARITH input. ARITH can be set to one of 'double', 'single', or 'fixed'. The analysis tool assumes a double precision filter when the arithmetic input is not specified and the filter System object is in an unlocked state. The 'Arithmetic' input is only relevant for the analysis of filter System objects.

impz

System object: dsp.AllpoleFilter
Package: dsp

Impulse response

Syntax

```
[h,t] = impz(allpole)
[h,t] = impz(allpole,Name,Value)
impz(allpole)
```

Description

`[h,t] = impz(allpole)` returns the impulse response `h`, and the corresponding time points `t` at which the impulse response of`allpole` is computed.

`[h,t] = impz(allpole,Name,Value)` returns the impulse response `h`, and the corresponding time points`t` , with additional options specified by one or more Name, Value pair arguments.

`impz(allpole)` uses FVTool to plot the impulse response of the filter System object `allpole`.

Note: You can use `impz` for both real and complex filters. When you omit the output arguments, `impz` plots only the real part of the impulse response.

---

phasez

System object: dsp.AllpoleFilter
Package: dsp

Unwrapped phase response

Syntax

```
[phi,w] = phasez(allpole)
[phi,w] = phasez(allpole,n)
[phi,w] = phasez(allpole,Name,Value)
phasez(allpole)
```

Description

`[phi,w] = phasez(allpole)` returns the 8192–element phase response vector `phi`, and the corresponding frequencies `w` in radians/sample.

`[phi,w] = phasez(allpole,n)` returns the n-element phase response vector `phi`, and the corresponding frequencies `w` in radians/sample, using `n` samples.

`[phi,w] = phasez(allpole,Name,Value)` returns the phase response and the corresponding frequencies, with additional options specified by one or more Name, Value pair arguments.

`phasez(allpole)` uses FVTool to plot the phase response of the filter System object `allpole`.

reset

System object: dsp.AllpoleFilter
Package: dsp

Reset internal states of Allpole filter

Syntax

```
reset(allpole)
```

Description

`reset(allpole)` resets the filter states of the Allpole filter object, `allpole`, to their initial values of 0. The initial filter state values correspond to the initial conditions for the difference equation defining the filter. After the `step` method applies the allpole filter object to nonzero input data, the states may be nonzero. Invoking the `step` method again without first invoking the `reset` method may produce different outputs for an identical input.

Reset an Allpole Filter

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

```
n = 0:100;
x = cos(0.2*pi*n)+sin(0.8*pi*n);
allpole = dsp.AllpoleFilter;
a = lpc(x,20);
allpole.Denominator = a;
y = allpole(x);
```

Filter states are nonzero. Filter the input again without resetting the filter states.

```
y1 = allpole(x);
isequal(y,y1)
```

```
ans =

  logical

   0
```

Now reset filter states to 0.

```
reset(allpole)
```

Filter the input.

```
y2 = allpole(x);
isequal(y,y2)
```

```
ans =

  logical

   1
```

step

System object: dsp.AllpoleFilter
Package: dsp

Filter input with Allpole filter object

Syntax

```
Y = step(allpole,X)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(allpole,X)` filters the real or complex input signal `X` using the Allpole filter, `allpole`, to produce the output `Y` . When the input data is of a fixed-point type, it must be signed. The Allpole filter object operates on each channel of the input signal independently over successive calls to step method.

Note: `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

dsp.AnalyticSignal System object

Package: dsp

Analytic signals of discrete-time inputs

Description

The `AnalyticSignal` object computes analytic signals of discrete-time inputs. The real part of the analytic signal in each channel is a replica of the real input in that channel, and the imaginary part is the Hilbert transform of the input. In the frequency domain, the analytic signal doubles the positive frequency content of the original signal while zeroing-out negative frequencies and retaining the DC component. The object computes the Hilbert transform using an equiripple FIR filter.

To compute the analytic signal of a discrete-time input:

1 Define and set up your analytic signal calculation. See "Construction" on page 4-57.
2 Call step to compute the analytic signal according to the properties of `dsp.AnalyticSignal`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`anaSig = dsp.AnalyticSignal` returns an analytic signal object, `anaSig`, that computes the complex analytic signal corresponding to each channel of a real M-by-N input matrix.

`anaSig = dsp.AnalyticSignal('PropertyName',PropertyValue,...)` returns an analytic signal object, `anaSig`, with each specified property set to the specified value.

`anaSig = dsp.AnalyticSignal(order,'PropertyName',PropertyValue,...)` returns an analytic signal object, `anaSig`, with the `FilterOrder` on page 4-58 property set to `order` and other specified properties set to the specified values.

Properties

`FilterOrder`

Filter order used to compute Hilbert transform

Specify the order of the equiripple FIR filter used in computing the Hilbert transform as an even integer scalar. The default is `100`.

Methods

reset	Reset internal states of analytic signal object
step	Analytic signal

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Compute The Analytic Signal

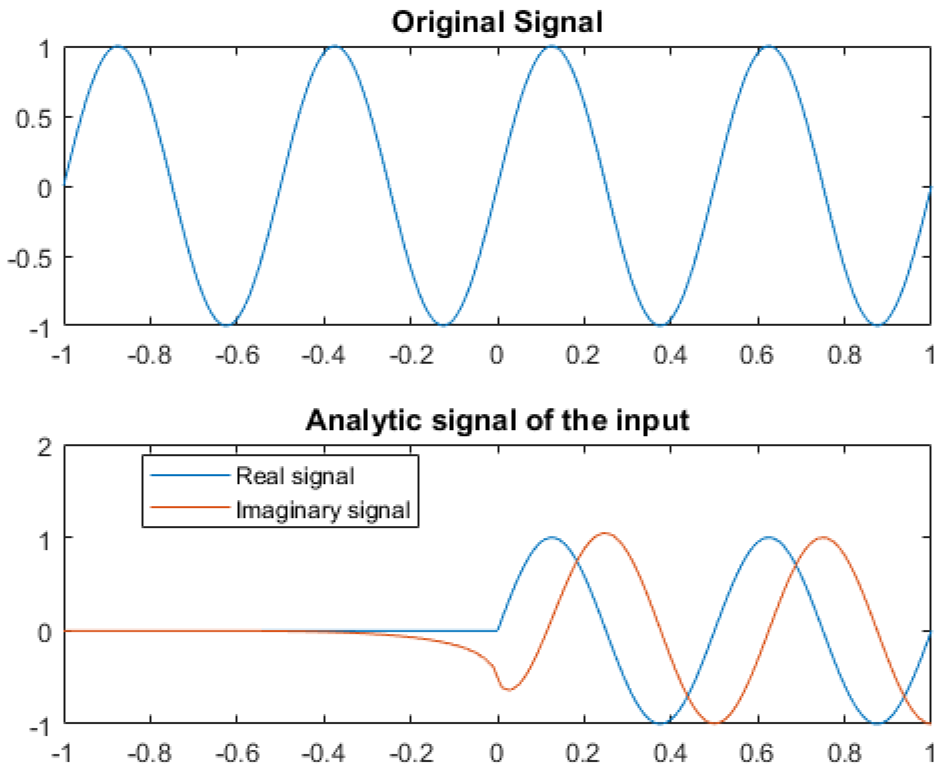
Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

Compute the analytic signal of a sinusoidal input.

```
t = (-1:0.01:1)';
x = sin(4*pi*t);
anaSig = dsp.AnalyticSignal(200);
y = anaSig(x);
```

View the analytic signal.

```
subplot(2,1,1), plot(t, x);
title('Original Signal');
subplot(2,1,2), plot(t, [real(y) imag(y)]);
title('Analytic signal of the input')
legend('Real signal','Imaginary signal',...
    'Location','best');
```



Algorithms

This object implements the algorithm, inputs, and outputs described on the `Analytic Signal` block reference page. The object properties correspond to the block parameters.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

dsp.IFFT | dsp.FFT

Introduced in R2012a

reset

System object: dsp.AnalyticSignal
Package: dsp

Reset internal states of analytic signal object

Syntax

`reset(anaSig)`

Description

`reset(anaSig)` sets the internal states of the `AnalyticSignal` object `anaSig` to their initial values.

step

System object: dsp.AnalyticSignal
Package: dsp

Analytic signal

Syntax

`Y = step(anaSig,X)`

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(anaSig,X)` computes the analytic signal, `Y`, of the M-by-N input matrix `X`, according to the equation

$$\mathbf{Y} = \mathbf{X} + jH\{\mathbf{X}\}$$

where j is the imaginary unit and $H\{\mathbf{X}\}$ denotes the Hilbert transform.

Each of the N columns in `X` contains M sequential time samples from an independent channel. The method computes the analytic signal for each channel.

Note: `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change

nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.ArrayPlot System object

Package: dsp

Display vectors or arrays

Description

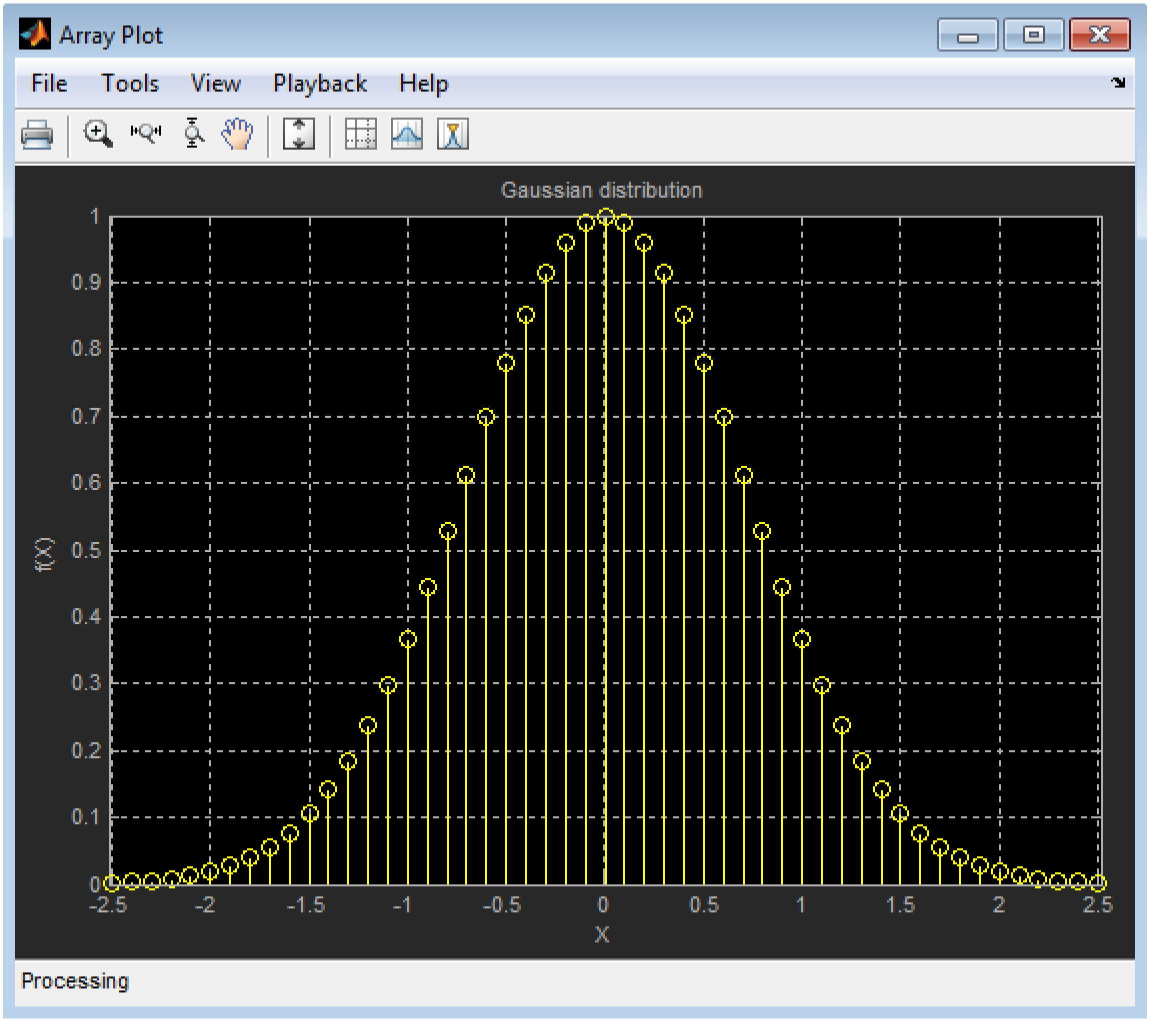
The `ArrayPlot` object displays vectors or arrays.

To display vectors or array in Array Plot:

1. Define and set up your Array Plot. See "Construction" on page 4-67.
2. Call step to display the vectors or arrays in the Array Plot figure. The behavior of `step` is specific to each object in the toolbox.

Use the MATLAB `clear` function to close the Array Plot figure window and clear its associated data. Use the hide method to hide the ArrayPlot window and the show method to make it visible.

Use the MATLAB `mcc` function to compile code containing an Array Plot.



See the following sections for more information on the Array Plot Graphical User Interface:

- "Signal Display" on page 4-76
- "Toolbar" on page 4-79
- "Measurements Panels" on page 4-83
- "Visuals — Array Plot Properties" on page 4-90

- “Style Dialog Box” on page 4-96
- “Tools — Plot Navigation Properties” on page 4-97

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`plot = dsp.ArrayPlot` creates an Array Plot System object, `plot`. This object displays vectors or arrays.

`plot = dsp.ArrayPlot('Name',Value,...)` creates an Array Plot System object, `plot`, with each specified property *`Name`* set to the specified value. You can specify *`Name`*–*`Value`* arguments in any order.

Properties

`ChannelNames`

Input channel names

Specify as a cell array of character vectors the input channels names to display in the legend, which is visible only when the `ShowLegend` property is `true`. The channel names are also used in the **Style** dialog, and in some **Measurements** panels. The default is an empty cell array, which labels the channels as `Channel 1`, `Channel 2`, etc. This property is Tunable (Simulink).

Default: empty cell array

`CustomXData`

X-data values

Specify the desired *x*-data values as a row or column vector of length equal to the frame length of the inputs. This property is used only if the `XDataMode` property is set to

'Custom'. If you use the default (empty vector) value, the x-data is uniformly spaced and set to (0:L-1), where L is the frame length.

An example of a Name-Value pair to specify logarithmic x-data scaling is 'CustomXData', logspace(0, log10(44100/2), 1024).

Default: empty vector

MaximizeAxes

Maximize axes control

Specify whether to display the scope in maximized axes mode. In this mode, each of the axes is expanded to fit into the entire display. To conserve space, labels do not appear in the display. Instead, tick-mark values appear on top of the plotted data. You can select one of the following options:

- Auto — In this mode, the axes appear maximized only if the Title and YLabel properties are empty. If you enter any value for either of these properties, the axes are not maximized.
- On — In this mode, the axes appear maximized. Any values entered into the Title and YLabel properties are hidden.
- Off — In this mode, none of the axes appear maximized.

This property is Tunable (Simulink).

Default: 'Auto'

Name

Caption to display on Scope window

Specify as a character vector the caption to display on the scope window. This property is Tunable (Simulink).

Default: 'Array Plot'

NumInputPorts

Number of input signals

Specify the number of input signals to display on the scope as a positive integer. You must invoke the `step` method with the same number of inputs as the value of this property.

Default: `1`

`PlotAsMagnitudePhase`

Plot signal as Magnitude-and-Phase

When you set this property to `true`, the scope plots the magnitude and phase of the input signal on two separate axes. When you set this property to `false`, the scope plots the real and imaginary parts of the input signal on two separate axes. This property is particularly useful for complex-valued input signals. When the input signal is real-valued and you select this check box, the phase will be 0 degrees when the amplitude of the input signal is nonnegative and 180 degrees when the input signal is negative. This property is Tunable (Simulink).

Default: `false`

`PlotType`

Option to control the type of plot

Specify the type of plot to use for all the input signals displayed in the scope window.

- When you set this property to `'Stem'` , the scope displays the input signal as circles with vertical lines extending down to the *x*-axis at each of the sampled values . This approach is similar to the functionality of the MATLAB `stem` function.
- When you set this property to `'Line'` , the scope displays the input signal as lines connecting each of the sampled values. This approach is similar to the functionality of the MATLAB `line` or `plot` function.
- When you set this property to `'Stairs'`, the scope displays the input signal as a *stairstep* graph. A stairstep graph is made up of only horizontal lines and vertical lines. Each horizontal line represents the signal value for a discrete sample period and is connected to two vertical lines. Each vertical line represents a change in values occurring at a sample. This approach is equivalent to the MATLAB `stairs` function. Stairstep graphs are useful for drawing time history graphs of digitally sampled data.

This property is Tunable (Simulink).

Default: `'Stem'`

Position

Scope window position in pixels

Specify, in pixels, the size and location of the scope window as a 4-element double vector of the form [left bottom width height]. You can place the scope window in a specific position on your screen by modifying the values to this property. This property is Tunable (Simulink).

Default: The default depends on your screen resolution. By default, the Scope window appears in the center of your screen with a width of `800` pixels and height of `450` pixels.

ReduceUpdates

Reduce updates to improve performance

When you set this property to `true`, the scope logs data for later use and updates the window periodically. When you set this property to `false`, the scope updates every time the `step` method is called. The simulation speed is faster when this property is set to `true`. This property is Tunable (Simulink).

You can also modify this property from the scope window. Opening the **Playback** menu and clearing the **Reduce Updates to Improve Performance** check box is the same as setting this property to `false`.

Default: `true`

SampleIncrement

Sample increment of input

Specify the spacing between samples along the *x*-axis as a finite numeric scalar. The input signal is only *y*-axis data. *x*-axis data is set automatically based on the `Xoffset` and `SampleIncrement` properties. For example, when `Xoffset` is 0 and `SampleIncrement` is 1, the x-data for the input signal is set to 0, 1, 2, 3, 4, etc. If you set `SampleIncrement` to 0.25, the x-axis data becomes 0, 0.25, 0.5, 0.75, 1, etc.

Default: `1`

ShowGrid

Option to enable or disable grid display

When you set this property to `true`, the grid appears. When you set this property to `false`, the grid is hidden. This property is Tunable (Simulink).

Default: `true`

`ShowLegend`

Source of legend

When you set this property to `true`, the scope displays a legend with the input channels labels. When you set this property to `false`, the scope does not display a legend. This property is Tunable (Simulink).

Default: `false`

`Title`

Display title

Specify the display title as a character vector. Enter `%<SignalLabel>` to use the signal labels in the Simulink Model as the axes titles. This property is Tunable (Simulink).

Default: `''`

`XDataMode`

Source of the *x*-data spacing

Specify whether to use the `SampleIncrement` and `XOffset` values, or specify your own custom spacing. Valid values are `'SampleIncrement and XOffset'` and `'Custom'`. If you specify `'Custom'`, you also must specify the `CustomXData` property values.

Default: `'SampleIncrement and XOffset'`

`XLabel`

The label for the *x*-axis

Specify the text for the scope to display below the *x*-axis. This property is Tunable (Simulink).

Default: `''`

XOffset

x-axis display offset

Specify the offset to apply to the *x*-axis. This property is a numeric scalar. This property is Tunable (Simulink).

Default: `0`

XScale

x-axis scale

Specify `'Linear'` or `'Log'` as the *x*-axis scale . If `XOffset` is a negative value, you cannot set `XScale` to `'Log'`. Tunable (Simulink)

Default: `'Linear'`

YLabel

The label for the *y*-axis

Specify the text for the scope to display to the left of the *y*-axis. Tunable (Simulink)

Default: `'Amplitude'`

YLimits

The limits for the *y*-axis

Specify the *y*-axis limits as a 2-element numeric vector, `[ymin ymax]`. This property is Tunable (Simulink).

Default: `[-10, 10]`

Methods

hide	Hide scope window

reset	Reset internal states of scope object
show	Make scope window visible
step	Display signal in scope figure

Examples

The following examples illustrate how to use the Array Plot object to view a variety of input signals.

Plot a Gaussian Distribution

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

View a *Gaussian*, or normal, distribution on the Array Plot figure.

Create a new Array Plot object.

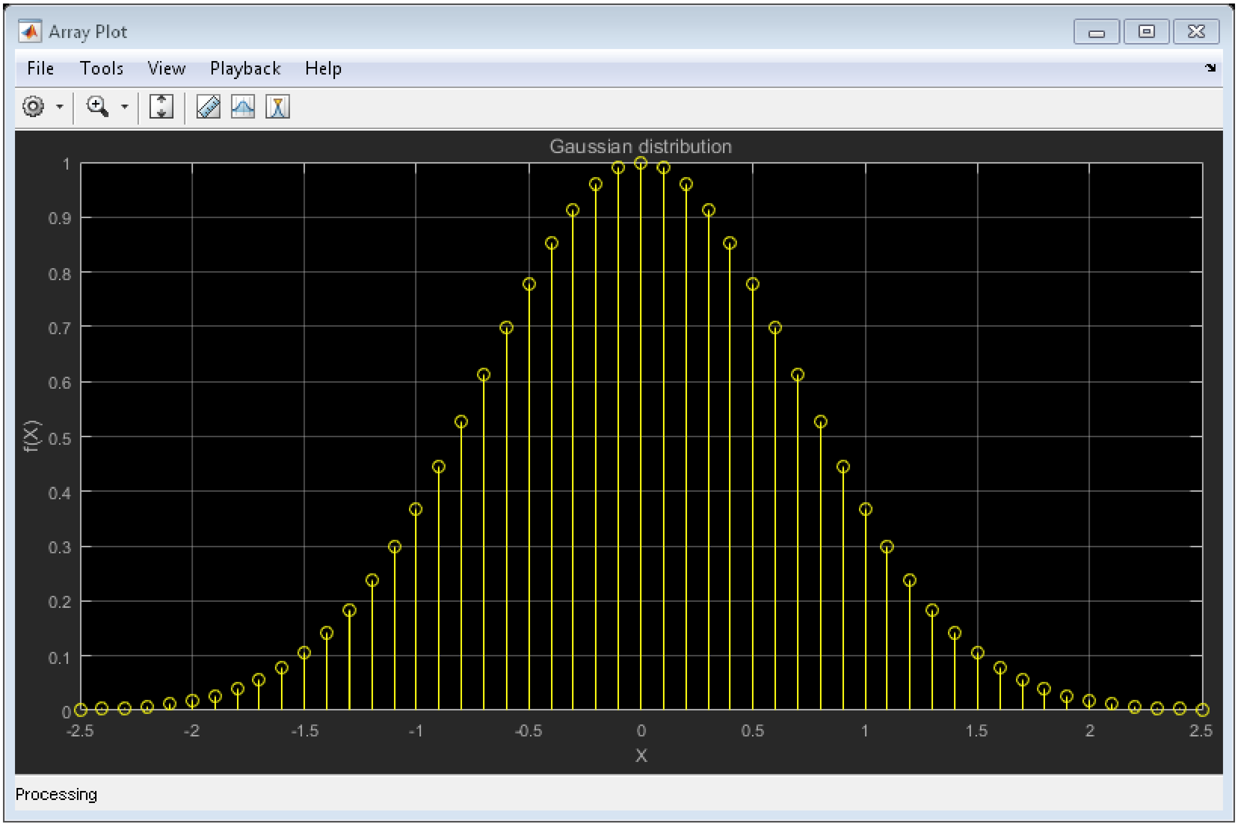
```
plot = dsp.ArrayPlot;
```

Configure the properties of the Array Plot object for a Gaussian distribution.

```
plot.YLimits = [0 1];
plot.XOffset = -2.5;
plot.SampleIncrement = 0.1;
plot.Title = 'Gaussian distribution';
plot.XLabel = 'X';
plot.YLabel = 'f(X)';
```

Call the `step (dsp.ArrayPlot)` method to plot a Gaussian distribution.

```
plot(exp(-(-2.5:.1:2.5).*(-2.5:.1:2.5))');
```



Plot Changing Filter Weights

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

View Least Mean Squares (LMS) adaptive filter weights on the Array Plot figure. Watch the filter weights change as they adapt to filter a noisy input signal.

Create an LMS adaptive filter System object.

```
lmsFilter = dsp.LMSFilter(40,'Method', 'Normalized LMS', 'StepSize', .002);
```

Create and configure an audio file reader System object to read the input signal from the specified audio file.

```
signalSource = dsp.AudioFileReader('dspafxf_8000.wav',  ...
    'SamplesPerFrame', 40, ...
    'PlayCount', Inf,...
    'OutputDataType', 'double');
```

Create and configure a fixed-point Finite Impulse Response (FIR) digital filter System object to filter random white noise, creating colored noise.

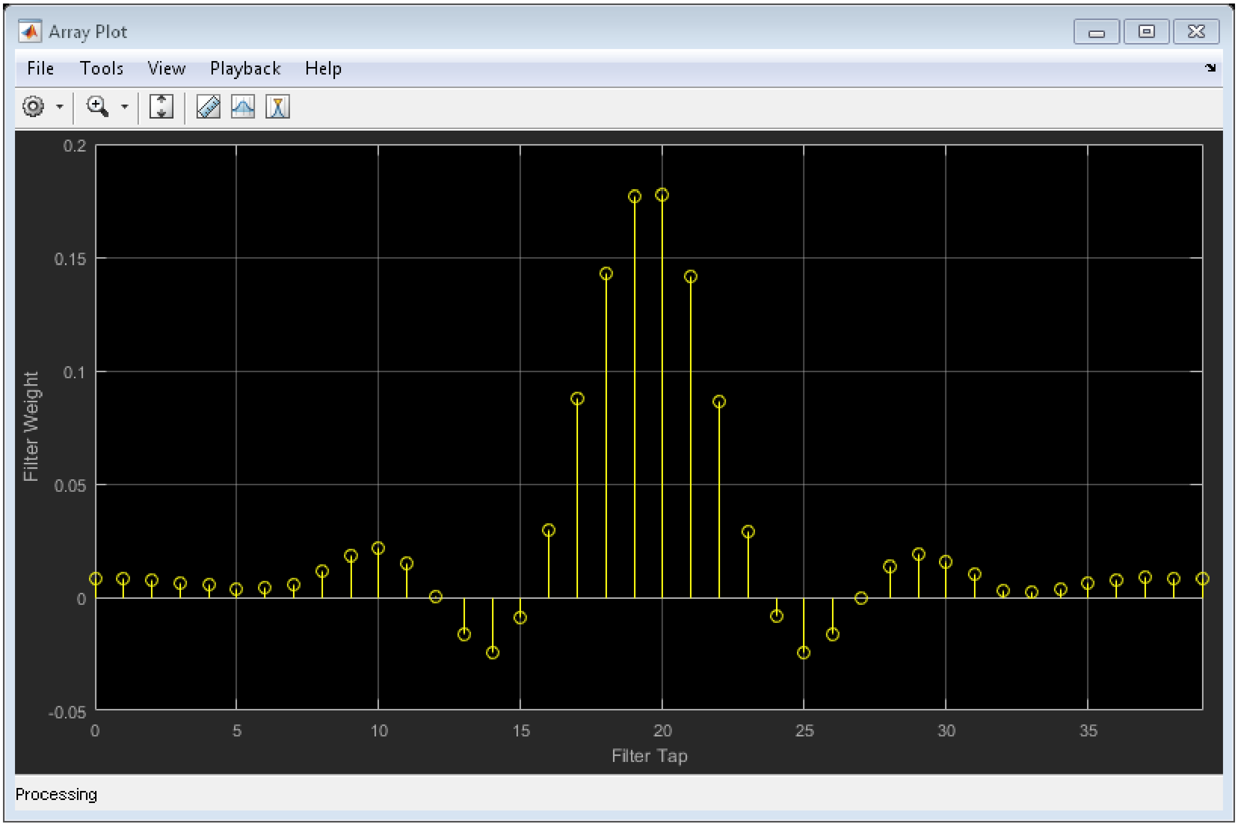
```
firFilter = dsp.FIRFilter('Numerator', fir1(39, .25));
```

Create and configure an Array Plot System object to display the adaptive filter weights.

```
plot = dsp.ArrayPlot('XLabel', 'Filter Tap', ...
    'YLabel', 'Filter Weight', ...
    'YLimits', [-.05 .2]');
```

Plot the LMS filter weights as they adapt to a desired signal. Read from the audio file, produce random data, and filter the random data. Update the filter weights and plot the filter weights.

```
numplays = 0;
while numplays < 3
    [y, eof]    = signalSource();
    noise       = rand(40,1);
    noisefilt   = firFilter(noise);
    desired     = y + noisefilt;
    [~, ~, wts] = lmsFilter(noise, desired);
    plot(wts);
    numplays = numplays + eof;
end
```

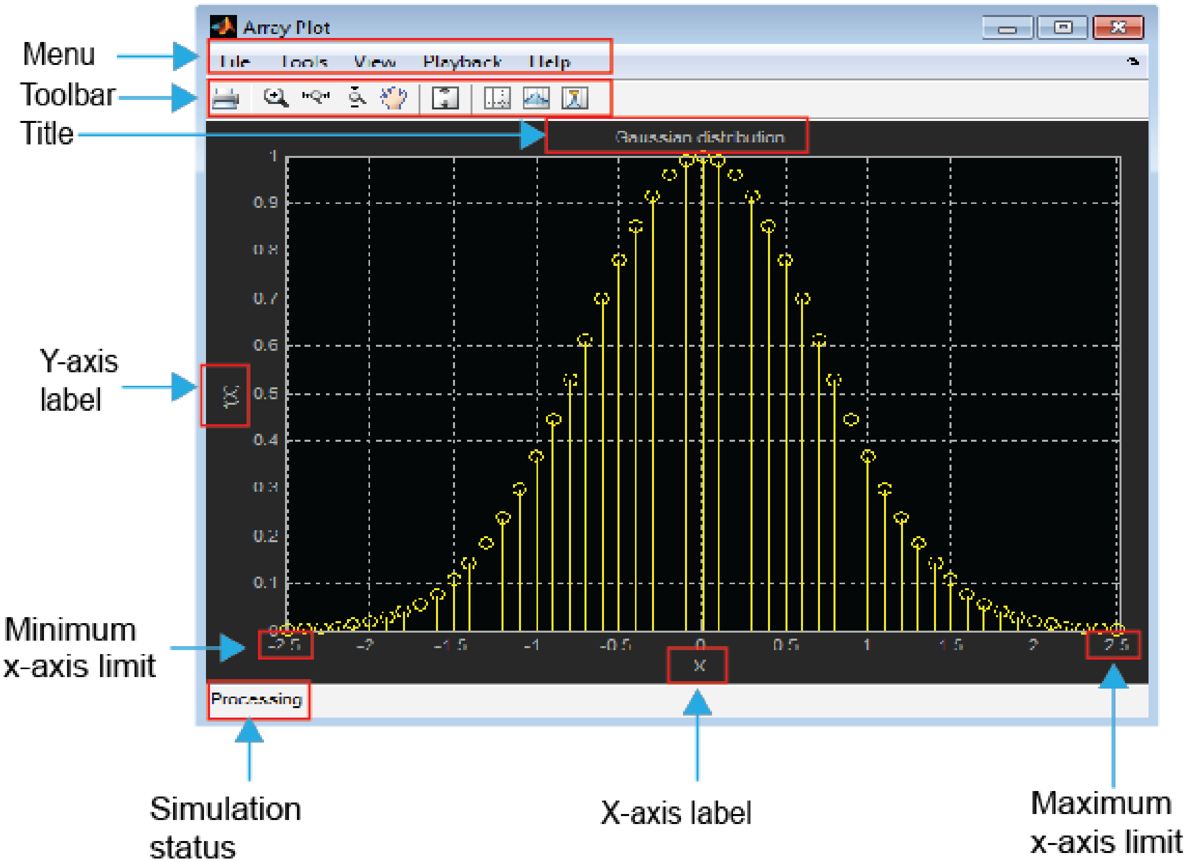


Signal Display

Array Plot uses the `XOffset` on page 4-72 and `SampleIncrement` on page 4-70 properties to determine the time range. To change the **X-offset** setting in the Array Plot figure, select **View** > **Configuration Properties**. The Visuals — Array Plot Properties dialog box appears. Go to the **Main** tab, and modify the value for the **X-offset**.

The span of the x-axis data is related to the `SampleIncrement` property by the equation $x_{span} = \texttt{SampleIncrement} \times (\text{length}(x) - 1)$. Suppose you set `SampleIncrement` on page 4-70 to `0.1` and the input signal data has 51 samples. The scope displays values on the x-axis from `0` to `5`. If you also set the **X-offset** to `–2.5`, the scope displays values on the x-axis from `-2.5` to `2.5`. The values on the x-axis of the scope display remain the same throughout simulation.

The following figure highlights the important aspects of the Array Plot window.



Indicators

- **Minimum x-axis limit** — Array Plot sets the minimum x-axis limit using the value of the **X-offset** parameter on the **Main** tab of the Visuals—Array Plot Properties dialog box.

- **Maximum x-axis limit** — Array Plot sets the maximum x-axis limit by summing the value of **X-offset** parameter with the span of x-axis values. The equation $x_{span} = \texttt{SampleIncrement} \times (\text{length}(x) - 1)$ defines the relationship of the span of the x-axis data to the `SampleIncrement` on page 4-70 property.

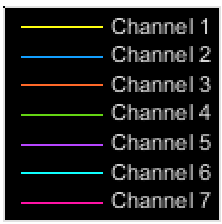
- *Simulation status* — Provides the current status of the model simulation. The status can be either of the following conditions:

  - `Processing` — Occurs after you run the `step` method and before you run the `release` method.
  - `Stopped` — Occurs after you construct the scope object and before you first run the `step` method. This status also occurs after you run the `release` method.

  The *Simulation status* is part of the *Status Bar* in the scope window. You can choose to hide or display the entire *Status Bar*. From the scope menu, select **View** > **Status Bar**.

Multiple Signal Names and Colors

By default, if the input signal has multiple channels, the scope uses an index number to identify each channel of that signal. For example, a 2-channel signal would have the following default names in the channel legend: `Channel 1`, `Channel 2`. To show the legend, select **View** > **Configuration Properties**, click the **Display** tab, and select the **Show Legend** check box. If there are a total of 7 input channels, the following legend appears in the display.



By default, the scope has a black axes background and chooses line colors for each channel in a manner similar to the Simulink Scope block. When the scope axes background is black, it assigns each channel of each input signal a line color in the order shown in the above figure.

If there are more than 7 channels, then the scope repeats this order to assign line colors to the remaining channels. To choose line colors for each channel, change the axes background color to any color except black. To change the axes background color to white, select **View** > **Style**, click the Axes background color button (), and select white from the color palette. Run the simulation again. The following legend appears in the display. This is the color order when the background is not black.

Toolbar

The Array Plot toolbar contains the following buttons.

Print, Settings, and Properties Buttons

Button	Menu Location	Shortcut Keys	Description
	**File** > **Print**	**Ctrl+P**	Print the current scope window. To print the current scope window to a figure rather than sending it to your printer, select **File** > **Print to figure**.

Zoom and Axes Control Buttons

Button	Menu Location	Shortcut Keys	Description
	**Tools** > **Zoom In**	N/A	When this tool is active, you can zoom in on the scope window. To do so, click in the center of your area of interest, or click and drag your cursor to draw a rectangular area of interest inside the scope window.

Button	Menu Location	Shortcut Keys	Description
	**Tools >** **Zoom X**	N/A	You access the Zoom X button from the menu under the Zoom In icon. When this tool is active, you can zoom in on the *x*-axis. To do so, click inside the scope window, or click and drag your cursor along the *x*-axis over your area of interest.
	**Tools >** **Zoom Y**	N/A	You access the Zoom Y button from the menu under the Zoom In icon. When this tool is active, you can zoom in on the *y*-axis. To do so, click inside the scope window, or click and drag your cursor along the *y*-axis over your area of interest.
	**Tools >** **Pan**	N/A	You access the Pan button from the menu under the Zoom In icon. When this tool is active, you can pan on the scope window. To do so, click in the center of your area of interest and drag your cursor to the left, right, up, or down, to move the position of the display.
	**Tools >** **Scale Y-Axis Limits**	**Ctrl+A**	Click this button to scale the axes in the active scope window. Alternatively, you can enable automatic axes scaling by selecting one of the following options from the **Tools** menu: • **Automatically Scale Axes Limits** — When you select this option, the scope scales the axes as needed during simulation. • **Scale Axes Limits after 10 Updates** — When you select this option, the scope scales the axes after 10 updates. The scope does not scale the axes again during the simulation. • **Scale Axes Limits at Stop** — When you select this option, the scope scales the axes each time the simulation is stopped.

Button	Menu Location	Shortcut Keys	Description
	**Tools > Scale X-Axis Limits**	N/A	You access the Scale X-Axis Limits button from the menu under the current Axis Limits icon. Click this button to scale the axes in the X direction in the active scope window. Alternatively, you can enable automatic axes scaling by selecting one of the following options from the **Tools** menu: • **Automatically Scale Axes Limits** — When you select this option, the scope scales the axes as needed during simulation. • **Scale Axes Limits after 10 Updates** — When you select this option, the scope scales the axes after 10 updates. The scope does not scale the axes again during the simulation. • **Scale Axes Limits at Stop** — When you select this option, the scope scales the axes each time the simulation is stopped.

Button	Menu Location	Shortcut Keys	Description
	**Tools** > **Scale X & Y Axes Limits**	N/A	You access the Scale X & Y Axes Limits button from the menu under the current Axis Limits icon. Click this button to scale the axes in both the X and Y directions in the active scope window. Alternatively, you can enable automatic axes scaling by selecting one of the following options from the **Tools** menu: • **Automatically Scale Axes Limits** — When you select this option, the scope scales the axes as needed during simulation. • **Scale Axes Limits after 10 Updates** — When you select this option, the scope scales the axes after 10 updates. The scope does not scale the axes again during the simulation. • **Scale Axes Limits at Stop** — When you select this option, the scope scales the axes each time the simulation is stopped.

Measurements Buttons

	**Tools** > **Measurements** > **Cursor Measurements**	N/A	Open or close the **Cursor Measurements** panel. This panel puts screen cursors on the display. See the "Cursor Measurements Panel" on page 4-85 section for more information.
	**Tools** > **Measurements** > **Signal Statistics**	N/A	Open or close the **Signal Statistics** panel. This panel displays the maximum, minimum, peak-to-peak difference, mean, median, RMS values of a selected signal, and the times at which the maximum and minimum occur. See the "Signal Statistics Panel" on page 4-86 section for more information.

	**Tools** > **Measurements** > **Peak Finder**	N/A	Open or close the **Peak Finder** panel. This panel displays maxima and the frequencies at which they occur, allowing the settings for peak threshold, maximum number of peaks, and peak excursion to be modified. See the "Peak Finder Panel" on page 4-88 section for more information.

Note: The zoom buttons do not change the settings related to span for the scope. These buttons are purely graphical.

You can control whether this toolbar appears in the Array Plot window. From the menu, select **View** > **Toolbar**.

Measurements Panels

The Measurements panels are the panels that appear to the right side of the Array Plot figure. These panels are labeled **Trace selection**, **Cursor Measurements**, **Signal Statistics**, and **Peak Finder**.

Measurements Panel Buttons

Each of the Measurements panels contains the following buttons that enable you to modify the appearance of the current panel.

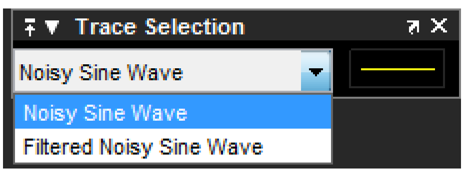
Button	Description
	Move the current panel to the top. When you are displaying more than one panel, this action moves the current panel above all the other panels.
	Collapse the current panel. When you first enable a panel, by default, it displays one or more of its panes. Click this button to hide all of its panes to conserve space. After you click this button, it becomes the expand button .
	Expand the current panel. This button appears after you click the collapse button to hide the panes in the current panel. Click this button to display

Button	Description
	the panes in the current panel and show measurements again. After you click this button, it becomes the collapse button again.
	Undock the current panel. This button lets you move the current panel into a separate window that can be relocated anywhere on your screen. After you click this button, it becomes the dock button in the new window.
	Dock the current panel. This button appears only after you click the undock button. Click this button to put the current panel back into the right side of the Scope window. After you click this button, it becomes the undock button again.
	Close the current panel. This button lets you remove the current panel from the right side of the Scope window.

Some panels have their measurements separated by category into a number of panes. Click the pane expand button to show each pane that is hidden in the current panel. Click the pane collapse button to hide each pane that is shown in the current panel.

Trace Selection Panel

When you use the scope to view multiple signals, the Trace Selection panel appears if you have more than one signal displayed and you click any of the other Measurements panels. The Measurements panels display information about only the signal chosen in this panel. Choose the signal name for which you would like to display time domain measurements. See the following figure.



You can choose to hide or display the **Trace Selection** panel. In the Scope menu, select **Tools** > **Measurements** > **Trace Selection**.

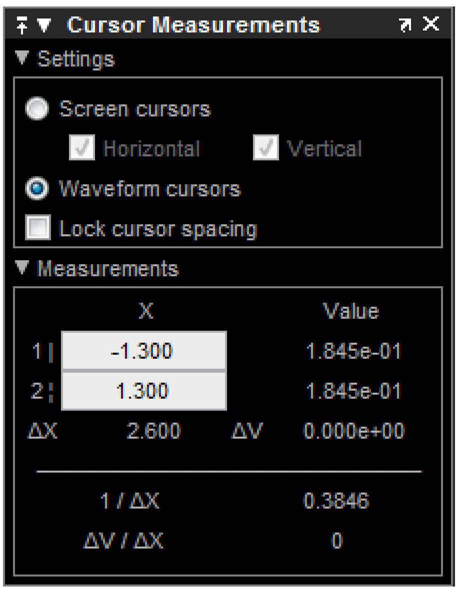
Cursor Measurements Panel

The **Cursor Measurements** panel displays screen cursors. The panel provides two types of cursors for measuring signals. Waveform cursors are vertical cursors that track along the signal. Screen cursors are both horizontal and vertical cursors that you can place anywhere in the display.

Note: If a data point in your signal has more than one value, the cursor measurement at that point is undefined and no cursor value is displayed.

In the Scope menu, select **Tools** > **Measurements** > **Cursor Measurements**.

Alternatively, in the Scope toolbar, click the Cursor Measurements  button.



The **Cursor Measurements** panel is separated into two panes, labeled **Settings** and **Measurements**. You can expand each pane to see the available options.

You can use the mouse or the left and right arrow keys to move vertical or waveform cursors and the up and down arrow keys for horizontal cursors.

Settings Pane

The **Settings** pane enables you to modify the type of screen cursors used to calculate *x*-axis and *y*-axis value measurements.

- **Screen Cursors**— Shows screen cursors.
- **Horizontal**— Shows horizontal screen cursors.
- **Vertical**— Shows vertical screen cursors.
- **Waveform Cursors**— Shows cursors that attach to the input signals.
- **Lock Cursor Spacing**— Locks the time difference between the two cursors.

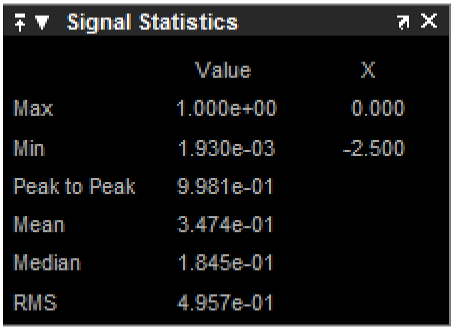
Measurements Pane

The **Measurements** pane shows the time and value measurements.

- **1 |**— Shows or enables you to modify the time or value at cursor number one, or both.
- **2 :**— Shows or enables you to modify the time or value at cursor number two, or both.
- **ΔX**— Shows the absolute value of the difference in the*x*-axis values between cursor number one and cursor number two.
- **ΔV**— Shows the absolute value of the difference in the *y*-axis values, or signal amplitudes, between cursor number one and cursor number two.
- **1/ΔX**— Shows the rate, the reciprocal of the absolute value of the difference in the *x*-axis values between cursor number one and cursor number two.
- **ΔV/ΔX**— Shows the slope, the ratio of the absolute value of the difference in the *y*-axis values between cursors to the absolute value of the difference in the *x*-axis values between cursors.

Signal Statistics Panel

The **Signal Statistics** panel displays the maximum, minimum, peak-to-peak difference, mean, median, and RMS values of a selected signal. It also shows the *x*-axis indices at which the maximum and minimum values occur. You can choose to hide or display the **Signal Statistics** panel. In the scope menu, select **Tools** > **Measurements** > **Signal Statistics**. Alternatively, in the scope toolbar, click the Signal Statistics  button.



Signal Statistics Measurements

The **Signal Statistics** panel shows statistics about the portion of the input signal within the *x*-axis and *y*-axis limits of the active display. The statistics shown are:

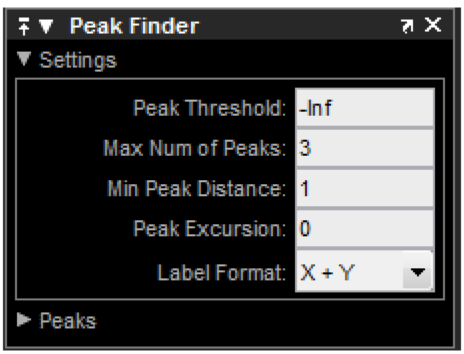
- **Max** — Shows the maximum or largest value within the displayed portion of the input signal. For more information on the algorithm this measurement uses, see the MATLAB `max` function reference.
- **Min** — Shows the minimum or smallest value within the displayed portion of the input signal. For more information on the algorithm this measurement uses, see the MATLAB `min` function reference.
- **Peak to Peak** — Shows the difference between the maximum and minimum values within the displayed portion of the input signal. For more information on the algorithm this measurement uses, see the Signal Processing Toolbox `peak2peak` function reference.
- **Mean** — Shows the average or mean of all the values within the displayed portion of the input signal. For more information on the algorithm this measurement uses, see the MATLAB `mean` function reference.
- **Median** — Shows the median value within the displayed portion of the input signal. For more information on the algorithm this measurement uses, see the MATLAB `median` function reference.
- **RMS** — Shows the difference between the maximum and minimum values within the displayed portion of the input signal. For more information on the algorithm this measurement uses, see the Signal Processing Toolbox `rms` function reference.

When you use the zoom options in the scope, the Signal Statistics measurements automatically adjust to the time range shown in the display. In the scope toolbar, click the **Zoom In** or **Zoom X** button to constrict the *x*-axis range of the display, and the statistics shown reflect this time range. For example, you can zoom in on one pulse to make the **Signal Statistics** panel display information about only that particular pulse.

The Signal Statistics measurements are valid for any units of the input signal. The letter after the value associated with each measurement represents the appropriate International System of Units (SI) prefix, such as *m* for *milli-*. For example, if the input signal is measured in volts, an *m* next to a measurement value indicates that this value is in units of millivolts.

Peak Finder Panel

The **Peak Finder** panel displays the maxima, showing the *x*-axis values at which they occur. Peaks are defined as a local maximum where lower values are present on both sides of a peak. Endpoints are not considered to be peaks. This panel allows you to modify the settings for peak threshold, maximum number of peaks, and peak excursion. You can choose to hide or display the **Peak Finder** panel. In the scope menu, select **Tools** > **Measurements** > **Peak Finder**. Alternatively, in the scope toolbar, select the Peak Finder button.

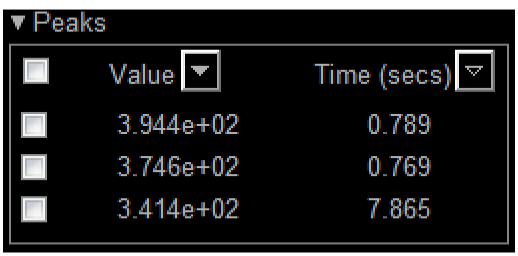


The **Peak finder** panel is separated into two panes, labeled **Settings** and **Peaks**. You can expand each pane to see the available options.

The **Settings** pane enables you to modify the parameters used to calculate the peak values within the displayed portion of the input signal. For more information on the algorithms this pane uses, see the Signal Processing Toolbox `findpeaks` function reference.

- **Peak Threshold** — The level above which peaks are detected. This setting is equivalent to the `MINPEAKHEIGHT` parameter, which you can set when you run the `findpeaks` function.
- **Max Num of Peaks** — The maximum number of peaks to show. The value you enter must be a scalar integer from 1 through 99. This setting is equivalent to the `NPEAKS` parameter, which you can set when you run the `findpeaks` function.
- **Min Peaks Distance** — The minimum number of samples between adjacent peaks. This setting is equivalent to the `MINPEAKDISTANCE` parameter, which you can set when you run the `findpeaks` function.
- **Peak Excursion** — The minimum height difference between a peak and its neighboring samples The peak excursion setting is equivalent to the `THRESHOLD` parameter, which you can set when you run the `findpeaks` function.
- **Label Format** — The coordinates to display next to the calculated peak values on the plot. To see peak values, expand the **Peaks** pane and select the check boxes associated with individual peaks of interest. By default, both *x*-axis and *y*-axis values are displayed on the plot. Select which axes values you want to display next to each peak symbol on the display.
  - `X+Y` — Display both *x*-axis and *y*-axis values.
  - `X` — Display only *x*-axis values.
  - `Y` — Display only *y*-axis values.

The **Peaks** pane displays all of the largest calculated peak values. It also shows the coordinates at which the peaks occur, using the parameters you define in the **Settings** pane. You set the **Max Num of Peaks** parameter to specify the number of peaks shown in the list.



The numerical values displayed in the **Value** column are equivalent to the `pks` output argument returned when you run the `findpeaks` function. The numerical values

displayed in the second column are similar to the `locs` output argument returned when you run the `findpeaks` function.

The Peak Finder displays the peak values in the **Peaks** pane. By default, the **Peak Finder** panel displays the largest calculated peak values in the **Peaks** pane in decreasing order of peak height. Use the sort descending button () to rearrange the category and order by which Peak Finder displays peak values. Click this button again to sort the peaks in ascending order instead. When you do so, the arrow changes direction to become the sort ascending button (). A filled sort button indicates that the peak values are currently sorted in the direction of the button arrow. If the sort button is not filled (), then the peak values are sorted in the opposite direction of the button arrow. The **Max Num of Peaks** parameter still controls the number of peaks listed.

Use the check boxes to control which peak values are shown on the display. By default, all check boxes are cleared and the **Peak Finder** panel hides all the peak values. To show all the peak values on the display, select the check box in the top-left corner of the **Peaks** pane. To hide all the peak values on the display, clear this check box. To show an individual peak, select the check box directly to the left of its **Value** listing. To hide an individual peak, clear the check box directly to the left of its **Value** listing.

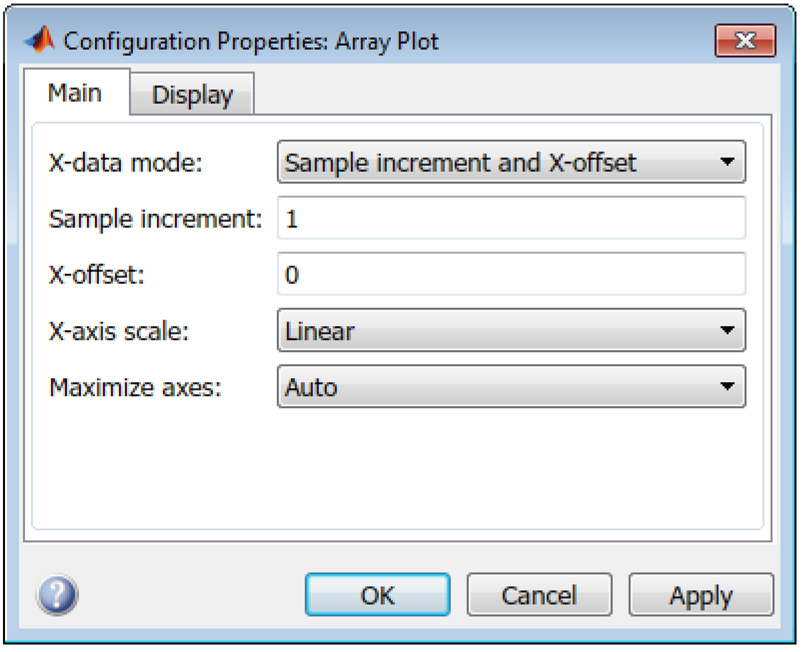
The Peaks are valid for any units of the input signal. The letter after the value associated with each measurement indicates the abbreviation for the appropriate International System of Units (SI) prefix, such as *m* for *milli-*. For example, if the input signal is measured in volts, an *m* next to a measurement value indicates that this value is in units of millivolts.

Visuals — Array Plot Properties

The Visuals—Array Plot Properties dialog box controls various properties about the Array Plot display. From the Array Plot menu, select **View** > **Configuration Properties** to open this dialog box.

Main Pane

The **Main** pane of the Visuals—Array Plot Properties dialog box appears as follows.



Sample increment

Specify the spacing between samples along the *x*-axis as a finite numeric scalar value.

X-offset

Specify the offset to apply to the *x*-axis. This property is a numeric scalar. This property is Tunable (Simulink).

X-axis scale

Specify `'Linear'` or `'Log'` as the *x*-axis scale . If `XOffset` is a negative value, you cannot set `XScale` to `'Log'`. Tunable (Simulink)

Maximize axes

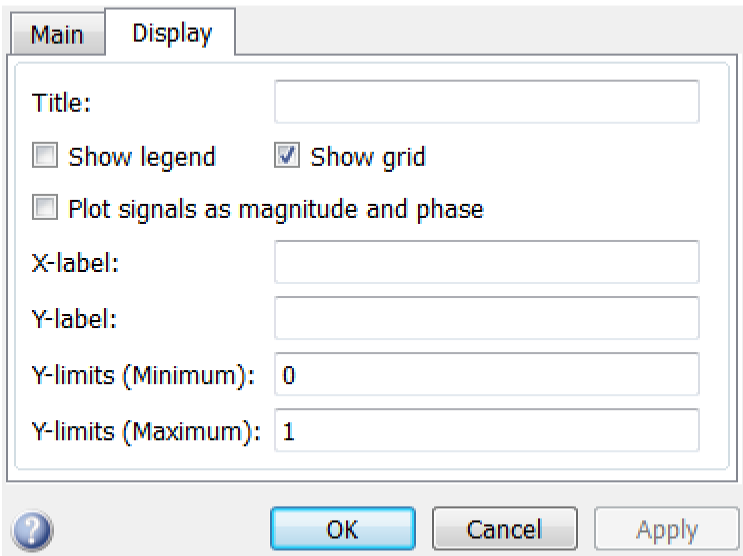
Specify whether to display the scope in maximized axes mode. In this mode, each of the axes is expanded to fit into the entire display. To conserve space, labels do not appear in the display. Instead, tick-mark values appear on top of the plotted data. You can select one of the following options:

- Auto — In this mode, the axes appear maximized only if the Title and YLabel properties are empty. If you enter any value for either of these properties, the axes are not maximized.
- On — In this mode, the axes appear maximized. Any values entered into the Title and YLabel properties are hidden.
- Off — In this mode, none of the axes appear maximized.

This property is Tunable (Simulink).

Display Pane

The **Display** pane of the Visuals—Array Plot Properties dialog box appears as follows.



Title

Specify the display title as a character vector. Enter %<SignalLabel> to use the signal labels in the Simulink Model as the axes titles. This property is Tunable (Simulink).

Show legend

Select this check box to show the legend in the display. The channel legend displays a name for each channel of each input signal. When the legend appears, you can place it anywhere inside the scope window. To turn off the legend, clear the **Show legend** check box. If the signal has multiple channels, the scope uses an index number to identify each signal channel.

You can use the legend to show and hide signals. Right-clicking a signal name toggles the signal visibility, shown or hidden. Clicking a signal name shows only the selected signal and hides the other signal.

You can edit the name of any channel by double-clicking the current channel name and entering a new name.

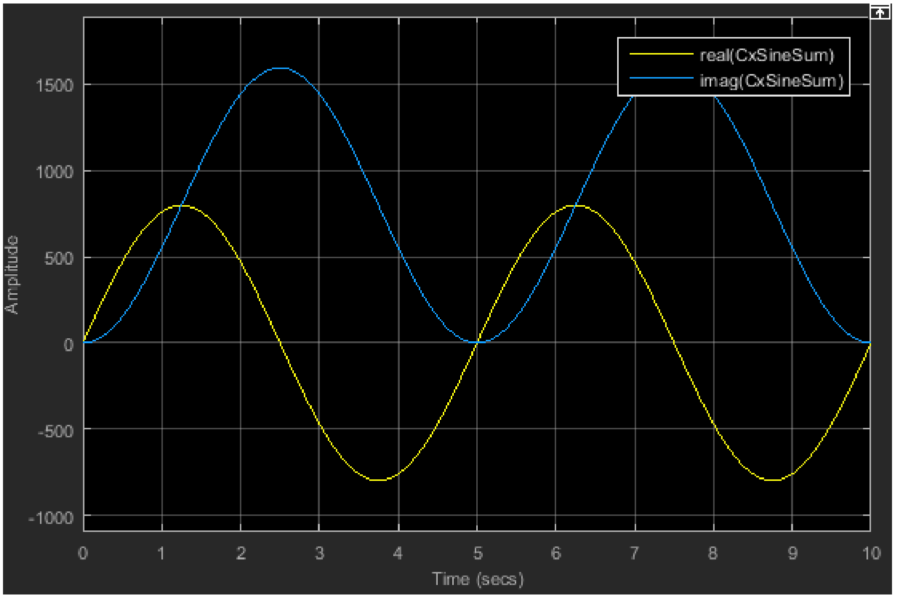
Tunable (Simulink)

Show grid

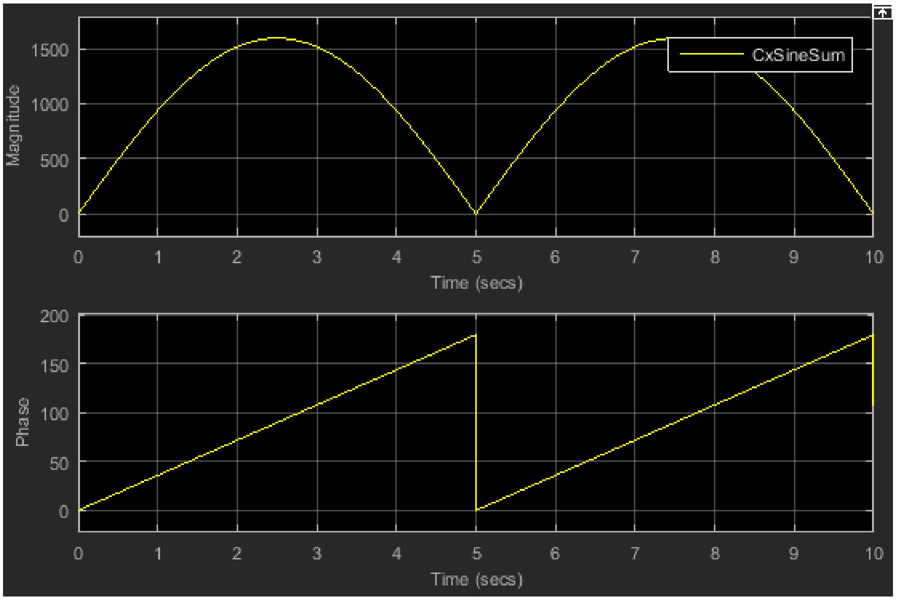
When you select this check box, a grid appears in the display of the scope figure. To hide the grid, clear this check box. Tunable (Simulink)

Plot signals as magnitude and phase

When you select this check box, the scope splits the display into a magnitude plot and a phase plot. By default, this check box is cleared. If the input signal has complex values, the scope plots the real and imaginary portions on the same axes. These real and imaginary portions appear as different-colored lines on the same axes, as shown in the following figure.



Selecting this check box and clicking the **Apply** or **OK** button changes the display. The magnitude of the input signal appears on the top axes and its phase, in degrees, appears on the bottom axes. See the following figure.



This feature is useful for complex-valued input signals. If the input is a real-valued signal, selecting this check box returns the absolute value of the signal for the magnitude. The phase is 0 degrees for nonnegative input and 180 degrees for negative input. Tunable (Simulink)

X-label

Specify the text for the scope to display below the *x*-axis. This property is Tunable (Simulink).

Y-label

Specify the text for the scope to display to the left of the *y*-axis. Tunable (Simulink)

Y-limits (Minimum)

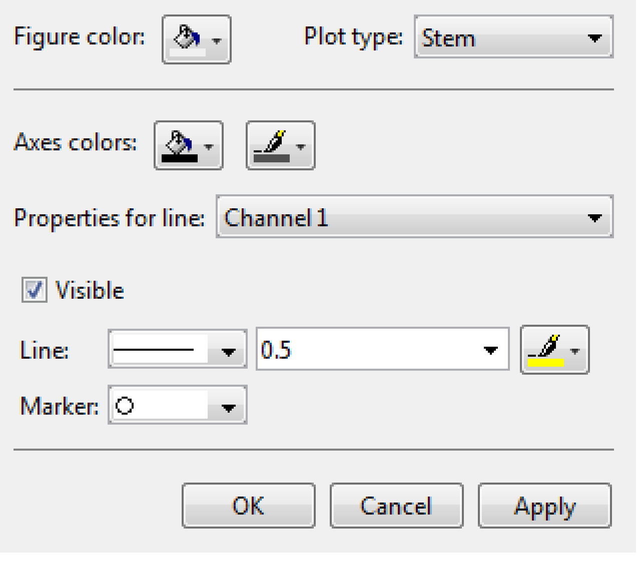
Specify the minimum value of the *y*-axis. Tunable (Simulink)

Y-limits (Maximum)

Specify the maximum value of the *y*-axis. Tunable (Simulink)

Style Dialog Box

In the **Style** dialog box, you can customize the style of displays. You are able to change the color of the figure containing the displays, the background and foreground colors of display axes, and properties of lines in a display. From the scope menu, select **View** > **Style** to open this dialog box.



Properties

The **Style** dialog box allows you to modify the following properties of the scope figure:

Figure color

Specify the color that you want to apply to the background of the scope figure. By default, the figure color is gray.

Plot type

Specify the type of plot to use for all the input signals displayed in the scope window.

- When you set this property to `'Stem'` , the scope displays the input signal as circles with vertical lines extending down to the x-axis at each of the sampled values . This approach is similar to the functionality of the MATLAB `stem` function.

- When you set this property to `'Line'` , the scope displays the input signal as lines connecting each of the sampled values. This approach is similar to the functionality of the MATLAB `line` or `plot` function.
- When you set this property to `'Stairs'`, the scope displays the input signal as a *stairstep* graph. A stairstep graph is made up of only horizontal lines and vertical lines. Each horizontal line represents the signal value for a discrete sample period and is connected to two vertical lines. Each vertical line represents a change in values occurring at a sample. This approach is equivalent to the MATLAB `stairs` function. Stairstep graphs are useful for drawing time history graphs of digitally sampled data.

This property is Tunable (Simulink).

The default setting is `Stem`.

Axes colors

Specify the color that you want to apply to the background of the axes.

Properties for line

Specify the channel for which you want to modify the visibility, line properties, and marker properties.

Visible

Specify whether the selected channel should be visible. If you clear this check box, the line disappears.

Line

Specify the line style, line width, and line color for the selected channel.

Marker

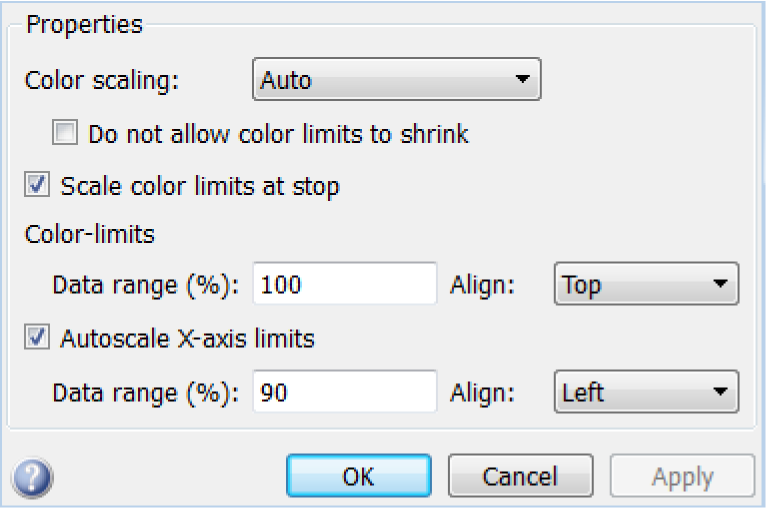
Specify marks for the selected channel to show at its data points. This parameter is similar to the `Marker` property for plot objects. You can choose any of the marker symbols from the dropdown.

Tools — Plot Navigation Properties

The Tools—Plot Navigation Properties dialog box allows you to automatically zoom in on and zoom out of your data. You can also scale the axes of the scope. In the scope menu, select **Tools > Axes Scaling Properties** to open this dialog box.

Properties

The Tools—Plot Navigation Properties dialog box appears as follows.



Axes Scaling

Specify when the scope automatically scales the axes. You can select one of the following options:

- `Manual` — When you select this option, the scope does not automatically scale the axes. You can manually scale the axes in any of the following ways:
  - Select **Tools** > **Axes Scaling Properties**.
  - Press one of the **Scale Axis Limits** toolbar buttons.
  - When the scope figure is the active window, press **Ctrl** and **A** simultaneously.
- `Auto` — When you select this option, the scope scales the axes as needed, both during and after simulation. Selecting this option shows the **Do not allow Y-axis limits to shrink** check box.
- `After N Updates` — Selecting this option causes the scope to scale the axes after a specified number of updates. This option is useful and more efficient when your scope display starts with one axis scale, but quickly reaches a different steady state axis scale. Selecting this option shows the **Number of updates** edit box.

By default, this property is set to `Auto`. This property is Tunable (Simulink).

By default, this parameter is set to `Manual`.

Do not allow Y-axis limits to shrink

When you select this property, the *y*-axis is allowed only to grow during axes scaling operations. If you clear this check box, the *y*-axis or color limits may shrink during axes scaling operations.

This property appears only when you select `Auto` for the **Axis scaling** property. When you set the **Axes scaling** property to `Manual` or `After N Updates`, the *y*-axis or color limits are allowed to shrink. Tunable (Simulink).

Number of updates

Specify as a positive integer the number of updates after which to scale the axes, or for the spectrogram, the color. This property appears only when you select `After N Updates` for the **Axes scaling** or **Color scaling** property. Tunable (Simulink).

Scale axes limits at stop

Select this check box to scale the axes when the simulation stops. The *y*-axis is always scaled. The *x*-axis limits are only scaled if you also select the **Scale X-axis limits** check box.

Y-axis Data range (%)

Set the percentage of the *y*-axis that the scope uses to display the data when scaling the axes. Valid values are from 1 through 100. For example, if you set this property to `100`, the Scope scales the *y*-axis limits such that your data uses the entire *y*-axis range. If you then set this property to `30`, the scope increases the *y*-axis range such that your data uses only 30% of the *y*-axis range. Tunable (Simulink).

Y-axis Align

Specify where the scope aligns your data along the *y*-axis when it scales the axes. You can select `Top`, `Center`, or `Bottom`. Tunable (Simulink).

Autoscale X-axis limits

Check this box to allow the scope to scale the *x*-axis limits when it scales the axes. If **Axes scaling** is set to `Auto`, checking **Autoscale X-axis limits** only scales the data currently within the axes, not the entire signal in the data buffer. If **Autoscale X-axis limits** is on and the resulting axis is greater than the span of the scope, trigger position markers will not be displayed. Triggers are controlled using the Trigger Measurements panel. Tunable (Simulink).

X-axis Align

Specify how the scope aligns your data along the *x*-axis: `Left`, `Center`, or `Right`. This property appears only when you select the **Scale X-axis limits** check box. Tunable (Simulink).

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- Supports MEX code generation by treating the calls to the object as extrinsic. Does not support code generation for standalone applications.
- See “System Objects in MATLAB Code Generation” (MATLAB Coder).

hide

System object: dsp.ArrayPlot
Package: dsp

Hide scope window

Syntax

`hide(plot)`

Description

`hide(plot)` hides the scope window associated with System object, `plot`.

See Also

dsp.ArrayPlot.show

reset

System object: dsp.ArrayPlot
Package: dsp

Reset internal states of scope object

Syntax

```
reset(plot)
```

Description

`reset(plot)` sets the internal states of the scope object `plot` to their initial values.

You should call the `reset` method after calling the `step` method when you want to clear the scope figure displays, prior to releasing system resources. This action enables you to start a simulation from the beginning. When you call the `reset` method, the displays will become blank again. In this sense, its functionality is similar to that of the MATLAB `clf` function. Do not call the `reset` method after calling the `release` method.

Algorithms

In operation, the `reset` method is similar to a consecutive execution of the `mdlTerminate` function and the `mdlInitializeConditions` function.

step

System object: dsp.ArrayPlot
Package: dsp

Display signal in scope figure

Syntax

```
step(plot,sig1)
step(plot,sig1,sig2,...,sigN)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`step(plot,sig1)` displays the signal, `sig1`, in the Array Plot.

`step(plot,sig1,sig2,...,sigN)` displays the signals `sig1`, `sig2`, ... ,`sigN` in the Array Plot `plot`. You must set the `NumInputPorts` property to `N` to enable more than one input signal. Each of the input signal matrices must have the same number of rows and cannot be scalars.

dsp.ArrayVectorAdder System object

Package: dsp

Add array to vector along specified dimension

Description

The `ArrayVectorAdder` object adds an N-D array to a vector along a specified dimension. The length of the vector must equal the size of the N-D array along the specified dimension.

To add an N-D array to a vector along a specified dimension:

1 Define and set up your array-vector addition object. See “Construction” on page 4-105.
2 Call step to add the N-D array according to the properties of `dsp.ArrayVectorAdder`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`ava = dsp.ArrayVectorAdder` returns an array-vector addition object, `ava`, that adds a vector to an N-D array along the first dimension.

`ava = dsp.ArrayVectorAdder('`*`PropertyName`*`',`*`PropertyValue`*`, ...)` returns an array-vector addition object, `ava`, with each property set to the specified value.

Properties

`Dimension`

Dimension along which to add vector elements to input

Specify the dimension along which to add the input array to the elements of the vector as a positive integer. The length of the vector must match the size of the N-D array along the specified dimension. The default is `1`.

`VectorSource`

Source of vector

Specify the source of the vector values as `|Input port | Property |`. The default is `Input port`.

`Vector`

Vector values

Specify the vector values. This property applies only when you set the `VectorSource` on page 4-106 property to `Property`. The default is `[0.5 0.25]`. This property is tunable.

Fixed-Point Properties

`FullPrecisionOverride`

Full precision override for fixed-point arithmetic

Specify whether to use full precision rules. If you set `FullPrecisionOverride` to `true`, which is the default, the object computes all internal arithmetic and output data types using full precision rules. These rules provide the most accurate fixed-point numerics. It also turns off the display of other fixed-point properties because they do not apply individually. These rules guarantee that no quantization occurs within the object. Bits are added, as needed, to ensure that no roundoff or overflow occurs. If you set `FullPrecisionOverride` to `false`, fixed-point data types are controlled through individual fixed-point property settings. For more information, see “Full Precision for Fixed-Point System Objects”.

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as | `Ceiling` | `Convergent` | `Floor` | `Nearest` | `Round` | `Simplest` | `Zero` |. The default is `Floor`. This property applies only if the object is not in full precision mode.

OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as | `Wrap` | `Saturate` |. The default is `Wrap`. This property applies only if the object is not in full precision mode.

VectorDataType

Vector word and fraction lengths

Specify the vector fixed-point data type as | `Same word length as input` | `Custom` |. This property applies when you set the `VectorSource` on page 4-106 property to `Property`. The default is `Same word length as input`.

CustomVectorDataType

Vector word and fraction lengths

Specify the vector fixed-point type as a `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `VectorSource` on page 4-106 property to `Property` and the `VectorDataType` on page 4-107 property to `Custom`. The default is `numerictype([],16,15)`.

AccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point data type as | `Full precision` | `Same as first input` | `Custom` |. The default is `Full precision`.

CustomAccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when the `AccumulatorDataType` on page 4-107 property is `Custom`. The default is `numerictype([],32,30)`.

`OutputDataType`

Output word and fraction lengths

Specify the output fixed-point data type as | `Same as accumulator` | `Same as first input` | `Custom` |.

`CustomOutputDataType`

Output word and fraction lengths

Specify the output fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when the `OutputDataType` on page 4-108 property is `Custom`. The default is `numerictype([],16,15)`.

Methods

step	Add vector to N-D array

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Add a Vector To a Matrix

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

Add a 2-by-1 vector to a 2-by-2 matrix along the first dimension of the array.

```
ava = dsp.ArrayVectorAdder;
a = ones(2);
x = [1 2]';
y = ava(a, x);
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the `Array-Vector Add` block reference page. The object properties correspond to the block parameters, except:

The array-vector addition object does not have **Minimum** or **Maximum** options for data output.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

dsp.ArrayVectorMultiplier | dsp.ArrayVectorDivider | dsp.ArrayVectorSubtractor

Introduced in R2012a

step

System object: dsp.ArrayVectorAdder
Package: dsp

Add vector to N-D array

Syntax

```
Y = step(ava,A)
Y = step(ava,A,V)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(ava,A)` returns `Y` , the result of adding the input array `A` to the elements of the vector specified in the `Vector` property along the specified dimension when the `VectorSource` property is `Property`. The length of the vector specified in the `Vector` property must equal the length of the specified dimension of `A`.

`Y = step(ava,A,V)` returns `Y` , the result of adding the input array `A` to the elements of the input vector `V` along the specified dimension when the `VectorSource` property is `Input port`. The length of the input `V` must equal the length of the specified dimension of `A`.

Note: `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change

nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.ArrayVectorDivider System object

Package: dsp

Divide array by vector along specified dimension

Description

The `ArrayVectorDivider` object divides an array by a vector along a specified dimension.

To divide an array by a vector along a specified dimension:

1. Define and set up your array-vector division object. See "Construction" on page 4-112.
2. Call step to divide the array according to the properties of `dsp.ArrayVectorDivider`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`avd = dsp.ArrayVectorDivider` returns an array-vector division object, `avd`, that divides an input array by the elements of a vector along the first dimension of the array.

`avd = dsp.ArrayVectorDivider('`*`PropertyName`*`',`*`PropertyValue`*`,...)` returns an array-vector division object, `avd`, with each property set to the specified value.

Properties

`Dimension`

Dimension along which to divide input by vector elements

Specify the dimension along which to divide the input array by the elements of a vector as a positive integer. The default is `1`.

`VectorSource`

Source of vector

Specify the source of the vector values as | `Input port` | `Property` |. The default is `Input port`.

`Vector`

Vector values

Specify the vector values. This property applies when you set the `VectorSource` on page 4-113 property to `Property`. The default is `[0.5 0.25]`. This property is tunable.

Fixed-Point Properties

`RoundingMethod`

Rounding method for fixed-point operations

Specify the rounding method as | `Ceiling` | `Convergent` | `Floor` | `Nearest` | `Round` | `Simplest` | `Zero` |. The default is `Floor`.

`OverflowAction`

Overflow action for fixed-point operations

Specify the overflow action as | `Wrap` | `Saturate` |. The default is `Wrap`.

`VectorDataType`

Vector word and fraction lengths

Specify the vector fixed-point mode as | `Same word length as input` | `Custom` |. This property applies when you set the `VectorSource` on page 4-113 property to `Property`. The default is `Same word length as input`.

`CustomVectorDataType`

Vector word and fraction lengths

Specify the vector fixed-point data type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `VectorSource` on page 4-113 property to `Property` and the `VectorDataType` on page 4-113 property to `Custom`. The default is `numerictype([],16,15)`.

`OutputDataType`

Output word and fraction lengths

Specify the output fixed-point data type as | `Same as first input` | `Custom` |. The default is `Same as first input`.

`CustomOutputDataType`

Output word and fraction lengths

Specify the output fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `OutputDataType` on page 4-114 property to `Custom`. The default is `numerictype([],16,15)`.

Methods

step	Divide array by vector

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Divide a Matrix By a Vector

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

```
avd = dsp.ArrayVectorDivider;
a = ones(2)
x = [2 3]'
y = avd(a, x)

a =

     1     1
     1     1

x =

     2
     3

y =

    0.5000    0.5000
    0.3333    0.3333
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the `Array-Vector Divide` block reference page. The object properties correspond to the block parameters, except:

The array-vector division object does not have **Minimum** or **Maximum** options for data output.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.ArrayVectorMultiplier System object

Package: dsp

Multiply array by vector along specified dimension

Description

The `ArrayVectorMultiplier` object multiplies an array by a vector along a specified dimension.

To multiply an array by a vector along a specified:

1. Define and set up your array-vector multiplication object. See "Construction" on page 4-119.
2. Call step to multiply the array according to the properties of `dsp.ArrayVectorMultiplier`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`avm = dsp.ArrayVectorMultiplier` returns an array-vector multiplication object, `avm`, that multiplies an input N-D array by the elements of a vector along the second dimension.

`avm = dsp.ArrayVectorMultiplier('`*`PropertyName`*`',`*`PropertyValue`*`,...)` returns an array-vector multiplication object, `avm`, with each property set to the specified value.

Properties

Dimension

Dimension along which to multiply input by vector elements

Specify the dimension along which to multiply the input array by the elements of vector as a positive integer. The default is `2`.

VectorSource

Source of vector

Specify the source of the vector values as one of `Input port` or `Property`. The default is `Input port`.

Vector

Vector to multiply array

Specify the vector by which to multiply the array. This property applies when you set the `VectorSource` on page 4-127 property to `Property`. The default is `[0.5 0.25]`. This property is tunable.

Fixed-Point Properties

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as `Ceiling`, `Convergent`, `Floor` , `Nearest`, `Round`, Simplest', `Zero`. The default is `floor`.

OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as `Wrap` or `Saturate`. The default is `Wrap`.

VectorDataType

Vector word and fraction lengths

Specify the vector fixed-point data type as `Same word length as input` , `Custom`. This property applies when you set the `VectorSource` on page 4-120 property to `Property`. The default is `Same word length as input`.

CustomVectorDataType

Vector word and fraction lengths

Specify the vector fixed-point type as a `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `VectorSource` on page 4-120 property to `Property` and the `VectorDataType` on page 4-120 property to `Custom`. The default is `numerictype([],16,15)`.

ProductDataType

Product word and fraction lengths

Specify the product fixed-point data type as `Full precision` , `Same as first input`, or `Custom`. The default is `Full precision`.

CustomProductDataType

Product word and fraction lengths

Specify the product fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `ProductDataType` on page 4-121 property to `Custom`. The default is `numerictype([],32,30)`.

AccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point data type as `Full precision` , `Same as product`, `Same as first input`, or `Custom`. The default is `Full precision`.

CustomAccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `AccumulatorDataType` on page 4-121 property to `Custom`. The default is `numerictype([],32,30)`.

OutputDataType

Output word and fraction lengths

Specify the output fixed-point data type as `Same as product`, `Same as first input`, or `Custom`. The default is `Same as product`.

CustomOutputDataType

Output word and fraction lengths

Specify the output fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `OutputDataType` on page 4-122 property to `Custom`. The default is `numerictype([],16,15)`.

Methods

step	Multiply array by vector

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Multiply a Matrix by a Vector

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

```
avm = dsp.ArrayVectorMultiplier;
a = ones(2);
```

```
x = [2 3]';
y = avm(a, x);
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the `Array-Vector Multiply` block reference page. The object properties correspond to the block parameters, except:

- The array-vector multiplication object does not have **Minimum** or **Maximum** options for data output.

If you change a nontunable property or an input specification, the System object issues an error. To change

nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.ArrayVectorSubtractor System object

Package: dsp

Subtract vector from array along specified dimension

Description

The `ArrayVectorSubtractor` object subtracts a vector from an N-D array along a specified dimension.

To subtract a vector from an N-D array along a specified dimension:

1. Define and set up your array-vector subtraction object. See "Construction" on page 4-126.
2. Call step to subtract the vector according to the properties of `dsp.ArrayVectorSubtractor`. The behavior of `step` is specified to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`avs = dsp.ArrayVectorSubtractor` returns an array-vector subtraction object, `avs`, that subtracts the elements of a vector from an N-D input array along the first dimension.

`avs = dsp.ArrayVectorSubtractor('`*`PropertyName`*`',`*`PropertyValue`*`,...)` returns an array-vector subtraction object, `avs`, with each property set to the specified value.

Properties

`Dimension`

Dimension along which to subtract vector elements from input

Specify the dimension along which to subtract the elements of the vector from the input array as an integer-valued scalar greater than `0`. The default is `1`.

`VectorSource`

Source of vector

Specify the source of the vector values as one of `Input port` or `Property`. The default is `Input port`.

`Vector`

Vector values

Specify the vector values. This property applies when you set the `VectorSource` on page 4-127 property to `Property`. The default is `[0.5 0.25]`. This property is tunable.

Fixed-Point Properties

`FullPrecisionOverride`

Full precision override for fixed-point arithmetic

Specify whether to use full precision rules. If you set `FullPrecisionOverride` to `true`, which is the default, the object computes all internal arithmetic and output data types using full precision rules. These rules provide the most accurate fixed-point numerics. It also turns off the display of other fixed-point properties because they do not apply individually. These rules guarantee that no quantization occurs within the object. Bits are added, as needed, to ensure that no roundoff or overflow occurs. If you set `FullPrecisionOverride` to `false`, fixed-point data types are controlled through individual fixed-point property settings. For more information, see “Full Precision for Fixed-Point System Objects”.

`RoundingMethod`

Rounding method for fixed-point operations

Specify the rounding method as `Ceiling`, `Convergent`, `Floor` , `Nearest`, `Round`, `Simplest`, or `Zero`. This property applies only if the object is not in full precision mode.

OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as one of `Wrap` or `Saturate`. The default is `Wrap`. This property applies only if the object is not in full precision mode.

VectorDataType

Vector word and fraction lengths

Specify the vector fixed-point data type as `Same word length as input` or `Custom`. This property applies when you set the `VectorSource` on page 4-127 property to `Property`. The default is `Same word length as input`.

CustomVectorDataType

Vector word and fraction lengths

Specify the vector fixed-point type as a `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `VectorSource` on page 4-127 property to `Property` and the `VectorDataType` on page 4-128 property to `Custom`. The default is `numerictype([],16,15)`.

AccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point data type as one of `Full precision` , `Same as first input`, or `Custom`. The default is `Full precision`.

CustomAccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `AccumulatorDataType` on page 4-128 property to `Custom`. The default is `numerictype([],32,30)`.

OutputDataType

Output word and fraction lengths

Specify the output fixed-point data type as `Same as accumulator`, `Same as first input`, or `Custom`. The default is `Same as accumulator`.

CustomOutputDataType

Output word and fraction lengths

Specify the output fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `OutputDataType` on page 4-129 property to `Custom`. The default is `numerictype([],16,15)`.

Methods

step	Subtract vector from array along specified dimension

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Subtract Vector From Matrix

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

```
avs = dsp.ArrayVectorSubtractor;
```

```
a = ones(2);
x = [1 2]';
y = avs(a, x)
```

```
y =

     0     0
    -1    -1
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the `Array-Vector Subtract` block reference page. The object properties correspond to the block parameters, except:

The array-vector subtraction object does not have **Minimum** or **Maximum** options for data output.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

step

System object: dsp.ArrayVectorSubtractor
Package: dsp

Subtract vector from array along specified dimension

Syntax

```
Y = step(avs,A,V)
Y = step(avs,A)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(avs,A,V)` returns `Y`. The value of `Y` results from subtracting the elements of input vector `V` from the input array `A` along the specified dimension when the `VectorSource` property is `Input port`. The length of the input `V` must equal the length of the specified dimension of `A`.

`Y = step(avs,A)` returns `Y`. The value of `Y` results from subtracting the elements of the vector specified in the `Vector` property from the input array `A` along the specified dimension when the `VectorSource` property is `Property`. The length of the vector specified in the `Vector` property must equal the length of the specified dimension of `A`.

Note: `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change

nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.AsyncBuffer System object

Package: dsp

FIFO buffer

Description

The `dsp.AsyncBuffer` System object writes samples to and reads samples from a first-in, first-out (FIFO) buffer. The `write` method writes data to the buffer and the `read` method reads data from the buffer. When creating the object, you can set the number of samples (rows) of the buffer using the `Capacity` property. The number of channels (columns) is set during the first call to `write`. Initialize the buffer by calling `write` or `setup` before the first call to `read`.

The data that you write occupies the next available space in the buffer. If the buffer is full and all the data within it is unread, that is, if `asyncBuff.NumUnreadSamples == asyncBuff.Capacity`, the object overwrites the oldest data with any new data that comes in. The buffer removes data only when the data is overwritten, so you can reread data from the past. The `dsp.AsyncBuffer` object supports writing and reading variable frame size signals. For examples, see “Read Variable Frame Sizes from Buffer” on page 4-135 and “Write Variable Frame Sizes to Buffer” on page 4-137.

To write and read samples from a FIFO buffer:

1 Create a `dsp.AsyncBuffer` object and set the properties of the object.
2 Call write to write samples to the buffer.
3 Call read to read samples from the buffer.

Construction

`asyncBuff = dsp.AsyncBuffer` returns an `AsyncBuffer` object, `asyncBuff`, using the default properties.

`asyncBuff = dsp.AsyncBuffer(cap)` sets the `Capacity` property to `cap`.

`asyncBuff = dsp.AsyncBuffer(Name,Value)` specifies properties using `Name,Value` pairs. Unspecified properties have default values.

Example:

```
asyncBuff = dsp.AsyncBuffer(200000);
```

Properties

`Capacity` — Number of writable/readable rows in buffer

`192000` (default) | positive integer greater than or equal to 2

Number of writable/readable rows in buffer. The number of rows during each write to the buffer must not exceed the capacity of the buffer. If the buffer is full and all the data within is unread, the object overwrites the oldest data with any new data that comes in. The `CumulativeOverrun` property returned by the `info` method gives the number of samples overrun per channel since the last call to `reset`. The number of samples overrun is the number of unread samples overwritten.

`NumUnreadSamples` — Number of unread samples in each channel

`0` (default) | scalar greater than or equal to 0

This property is read-only.

Number of unread samples in each channel (column) of the buffer. The total number of unread samples in the buffer is `NumUnreadSamples` × `numChann`, where `numChann` is the number of channels in the buffer.

The `CumulativeUnderrun` property returned by the `info` method gives the number of samples underrun per channel since the last call to `reset`. Underrun occurs if you attempt to read more samples than available.

Limitations

Before calling the `read` method, you must initialize the buffer by calling either the `write` or `setup` method. For an example, see “Why Does the dsp.AsyncBuffer Object Error When You Call read Before write?”

Methods

info	Get cumulative overrun and underrun

read	Read data from buffer
reset	Reset internal states of System object
write	Write data to buffer

Common to All System Objects	
clone	Create System object with same property values
getNumInpu	Expected number of inputs to a System object
getNumOutp	Expected number of outputs of a System object
isLocked	Check locked states of a System object (logical)
release	Allow System object property value changes

Examples

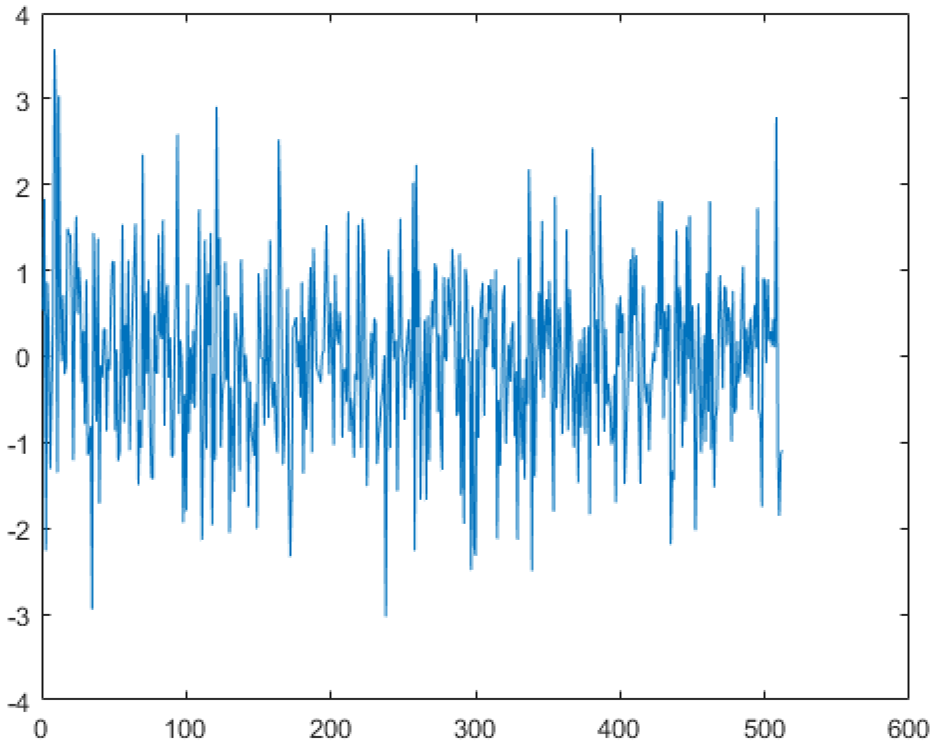
Read Variable Frame Sizes from Buffer

The `dsp.AsyncBuffer` System object™ supports reading variable frame sizes from the buffer.

Create a `dsp.AsyncBuffer` System object. The input is white Gaussian noise with zero mean, a standard deviation of 1, and a frame size of 512 samples. Write the input to the buffer using the `write` method. Store the data that is read from the buffer in `outTotal`.

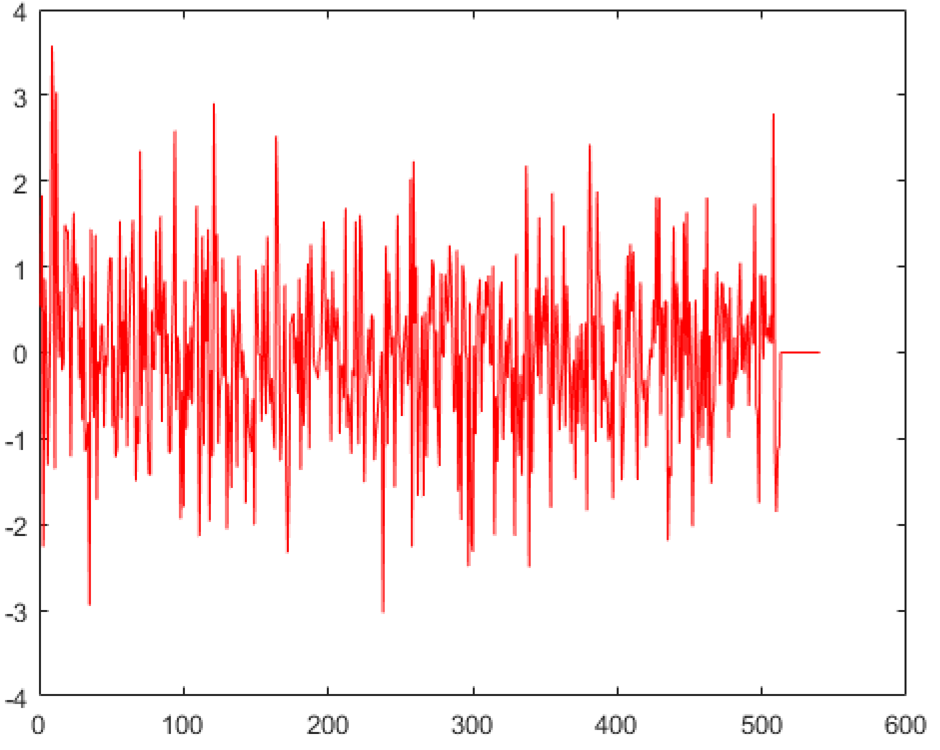
```
asyncBuff = dsp.AsyncBuffer;
input = randn(512,1);
write(asyncBuff,input);

outTotal = [];
plot(input)
hold on
```



Plot the input signal and data that is read from the buffer in the same plot. Read data from the buffer until all samples are read. In each loop of iteration, `randi` determines the number of samples to read. Therefore, the signal is read in as a variable-size signal.

```
while asyncBuff.NumUnreadSamples ~= 0
    numToRead = randi([1,64]);
    out = read(asyncBuff,numToRead);
    outTotal = [outTotal;out];
    plot(outTotal,'r');
    pause(0.2)
end
hold off
```



Write Variable Frame Sizes to Buffer

Write a sine wave of variable frame size to the buffer. Compute the FFT of the sine wave and visualize the result on an array plot.

Initialize the `dsp.AsyncBuffer`, `dsp.ArrayPlot`, and `dsp.FFT` System objects.

```
asynBuff = dsp.AsyncBuffer;
plotter = dsp.ArrayPlot;
fftObj = dsp.FFT('FFTLengthSource','Property','FFTLength',256);
```

The sine wave is generated using the `sin` function in MATLAB®. The `start` and `finish` variables mark the start and finish indices of each frame. If enough data is cached, read from the buffer and perform the FFT. View the FFT on an array plot.

```
start = 1;

for Iter = 1 : 2000
    numToWrite = randi([200,800]);
    finish = start + numToWrite;

    inputData = sin(start:finish)';
    start = finish + 1;

    write(asynBuff,inputData);
    while asynBuff.NumUnreadSamples >= 256
        x = read(asynBuff,256);
        X = abs(fftObj(x));
        plotter(log(X));
    end
end
```

Introduced in R2017a

info

System object: dsp.AsyncBuffer
Package: dsp

Get cumulative overrun and underrun

Syntax

```
S = info(asyncBuff)
```

Description

`S = info(asyncBuff)` returns a structure, `S`, containing the cumulative overrun and underrun information of the `dsp.AsyncBuffer` System object, `asyncBuff`.

The `CumulativeOverrun` property gives the number of samples overrun per channel since the last call to `reset`. The number of samples overrun is the number of unread samples overwritten. The `CumulativeUnderrun` property gives the number of samples underrun per channel since the last call to `reset`. Underrun occurs if you attempt to read more samples than available.

Introduced in R2017a

read

System object: dsp.AsyncBuffer
Package: dsp

Read data from buffer

Syntax

```
out = read(asyncBuff)
out = read(asyncBuff,NumRows)
out = read(asyncBuff,NumRows,Overlap)
[out,nUnderrun] = read(asyncBuff,___)
```

Description

`out = read(asyncBuff)` returns all unread samples from the buffer, `asyncBuff`.

`out = read(asyncBuff,NumRows)` returns `NumRows` samples from each channel (column) of the buffer. If the requested number of samples is greater than the number of unread samples, the output is zero-padded.

`out = read(asyncBuff,NumRows,Overlap)` returns `NumRows` samples from each channel and overlaps previously read samples by `Overlap`. The total number of samples read is `NumRows` × `NumChann`, where `NumChann` is the number of channels in the buffer. The total number of new samples read is (`NumRows` – `Overlap`) × `NumChann`. If the overlap portion contains samples that are overwritten, and are therefore not contiguously written, the output is zero-padded.

`[out,nUnderrun] = read(asyncBuff,___)` additionally returns the number of rows zero-padded if underrun occurred, using any of the previous arguments. `Underrun` occurs if you attempt to read more samples than available. Samples that are zero-padded in overlapped portions are not counted as underrun.

Introduced in R2017a

reset

System object: dsp.AsyncBuffer
Package: dsp

Reset internal states of System object

Syntax

`reset(asyncBuff)`

Description

`reset(asyncBuff)` returns the buffer to its initial condition, and resets the `CumulativeOverrun` and `CumulativeUnderrun` properties.

Introduced in R2017a

write

System object: dsp.AsyncBuffer
Package: dsp

Write data to buffer

Syntax

```
nOverrun = write(asyncBuff,x)
```

Description

`nOverrun = write(asyncBuff,x)` writes the input array, `x`, to the buffering object, `asyncBuff`. The object returns the number of samples overrun in the current call to `write`. The number of samples overrun is the number of unread samples overwritten. If `x` is a multichannel input, then `nOverrun` is the number of rows of data overrun.

Introduced in R2017a

audioDeviceWriter System object

Play to sound card

Description

The `audioDeviceWriter` System object writes audio samples to an audio output device. See "Audio Device Writer System Interaction" on page 4-152 for a visualization of how the `audioDeviceWriter` System object plays audio samples.

To stream data to an audio device:

1. Define and set up your audio device writer. See "Construction" on page 4-145.
2. Call step or play to stream data to an audio device.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`aDW = audioDeviceWriter` returns a System object, `aDW` that writes audio samples to an audio output device in real time.

`aDW = audioDeviceWriter(sampleRateValue)` sets the `SampleRate` property to `sampleRateValue`.

`aDW = audioDeviceWriter(Name,Value)` sets each property `Name` to the specified `Value`. Unspecified properties have default values.

Example: `aDW = audioDeviceWriter(12000,'BitDepth','8-bit integer')` creates a System object, `aDW`, with the `SampleRate` property set to `12000` and the `BitDepth` property set to `'8-bit integer'`.

Properties

`Driver` — Driver used to access audio device (Windows only)

`'DirectSound'` (default) | `'ASIO'` | `'WASAPI'`

Driver used to access your audio device, specified as `'DirectSound'`, `'ASIO'`, or `'WASAPI'`.

- ASIO drivers do not come pre-installed on Windows machines. To use the `'ASIO'` driver option, install an ASIO driver outside of MATLAB.

  Note: If `Driver` is specified as `'ASIO'`, open the ASIO UI outside of MATLAB to set the sound card buffer size to the `BufferSize` value of your `audioDeviceWriter` System object. See the documentation of your ASIO driver for more information.

- WASAPI drivers are supported for exclusive-mode only.

ASIO and WASAPI drivers do not provide sample rate conversion. For ASIO and WASAPI drivers, set `SampleRate` to a sample rate supported by your audio device.

This property applies only on Windows machines. Linux machines always use the ALSA driver. Mac machines always use the CoreAudio driver.

To specify nondefault `Driver` values, you must install Audio System Toolbox. If the toolbox is not installed, specifying nondefault `Driver` values returns an error.

`Device` — Device used to play audio samples

default audio device (default) | character vector

Device used to play audio samples, specified as a character vector. Use the `getAudioDevices` method to list available devices.

`SampleRate` — Sample rate of signal sent to audio device (Hz)

`44100` (default) | positive integer

Sample rate of signal sent to audio device, in Hz, specified as a positive integer. The range of `SampleRate` depends on your audio hardware.

`BitDepth` — Data type used by the device

`'16-bit integer'` (default) | `'8-bit integer'` | `'24-bit integer'` | `'32-bit float'`

Data type used by the device, specified as a character vector. Before performing digital-to-analog conversion, the input data is cast to a data type specified by `BitDepth`.

To specify a nondefault `BitDepth`, you must install Audio System Toolbox. If the toolbox is not installed, specifying a nondefault `BitDepth` returns an error.

`SupportVariableSizeInput` — Option to support variable frame size
`false` (default) | `true`

Option to support variable frame size, specified as `true` or `false`.

- `false` — If the `audioDeviceWriter` object is locked, the input must have the same frame size at each call to `step` or `play`. The buffer size of your audio device is the same as the input frame size.
- `true` — If the `audioDeviceWriter` object is locked, the input frame size can change at each call to `step` or `play`. The buffer size of your audio device is specified through the `BufferSize` property.

`BufferSize` — Buffer size of audio device
`4096` (default) | positive integer

Buffer size of audio device, specified as a positive integer.

Note: If `Driver` is specified as `'ASIO'`, open the ASIO UI to set the sound card buffer size to the `BufferSize` value of your `audioDeviceWriter` System object.

This property is available when you set `SupportVariableSizeInput` to `true`.

`ChannelMappingSource` — Source of mapping between columns of input matrix and channels of output device
`'Auto'` (default) | `'Property'`

Source of mapping between columns of input matrix and channels of audio output device, specified as `'Auto'` or `'Property'`.

- `'Auto'` — Default settings determine the mapping between columns of input matrix and channels of audio output device. For example, suppose that your input is a matrix with four columns, and your audio device has four channels available. Column 1 of your input data writes to channel 1 of your device, column 2 of your input data writes to channel 2 of your device, and so on.

- `'Property'` — The `ChannelMapping` property determines the mapping between columns of input matrix and channels of audio output device.

`ChannelMapping` — Nondefault mapping between columns of input matrix and channels of output device
`[1:MaximumOutputChannels]` (default) | scalar | vector

Nondefault mapping between columns of input matrix and channels of output device, specified as a scalar or vector of valid channel indices.

This property is available when you set `ChannelMappingSource` to `'Property'`.

To selectively map between columns of the input matrix and your sound card's output channels, you must install Audio System Toolbox. If the toolbox is not installed, specifying a nondefault `ChannelMapping` returns an error.

Methods

getAudioDevices	List available audio input devices
info	Get information about selected device
play	Stream audio data to output device
step	Stream audio data to output device

Examples

Read from File and Write to Audio Device

Read an MP3 audio file and play it through your default audio output device.

Create a `dsp.AudioFileReader` System object™ with default settings. Use the `audioinfo` function to return a structure containing information about the audio file.

```
fileReader = dsp.AudioFileReader('speech_dft.mp3');
fileInfo = audioinfo('speech_dft.mp3');
```

Create an `audioDeviceWriter` System object and specify the sample rate. Call `setup` to reduce the computational load of initialization in an audio stream loop.

```
deviceWriter = audioDeviceWriter(...
```

```
    'SampleRate',fileInfo.SampleRate);
setup(deviceWriter,...
    zeros(fileReader.SamplesPerFrame,fileInfo.NumChannels));
```

In an audio stream loop, read an audio signal frame from the file, and write the frame to your device.

```
while ~isDone(fileReader)
    audioData = fileReader();
    deviceWriter(audioData);
end
```

Close the input file and release the device.

```
release(fileReader);
release(deviceWriter);
```

Reduce Latency due to Output Device Buffer

Modify default properties of your `audioDeviceWriter` System object™ to reduce latency due to device buffer size.

Create a `dsp.AudioFileReader` System object to read an audio file with default settings.

```
fileReader = dsp.AudioFileReader('speech_dft.mp3');
```

Create an `audioDeviceWriter` System object and specify the sample rate to match that of the audio file reader.

```
deviceWriter = audioDeviceWriter(...
    'SampleRate',fileReader.SampleRate);
```

Calculate the latency due to your device buffer, in seconds.

```
bufferLatency = fileReader.SamplesPerFrame/deviceWriter.SampleRate
```

```
bufferLatency =

    0.0464
```

Set the `SamplesPerFrame` property of your `dsp.AudioFileReader` System object to 256. Calculate the buffer latency in seconds.

```
fileReader.SamplesPerFrame = 256;
bufferLatency = fileReader.SamplesPerFrame/deviceWriter.SampleRate
```

```
bufferLatency =

    0.0116
```

Determine and Decrease Underrun

Underrun refers to output signal silence, which occurs when the audio stream loop does not keep pace with the output device. Determine the underrun of an audio stream loop, add artificial computational load to the audio stream loop, and then modify properties of your `audioDeviceWriter` System object™ to decrease underrun. Your results depend on your computer.

Create a `dsp.AudioFileReader` System object, and specify the file to read. Use the `audioinfo` function to return a structure containing information about the audio file.

```
fileReader = dsp.AudioFileReader('speech_dft.mp3');
fileInfo = audioinfo('speech_dft.mp3');
```

Create an `audioDeviceWriter` System object. Use the `SampleRate` of the file reader as the `SampleRate` of the device writer. Call `setup` to reduce the computational load of initialization in an audio stream loop.

```
deviceWriter = audioDeviceWriter(...
    'SampleRate',fileReader.SampleRate);
setup(deviceWriter,...
    zeros(fileReader.SamplesPerFrame,fileInfo.NumChannels));
```

Run your audio stream loop with input from file and output to device. Print the total samples underrun and the underrun in seconds.

```
totalUnderrun = 0;
while ~isDone(fileReader)
    input = fileReader();
    numUnderrun = deviceWriter(input);
    totalUnderrun = totalUnderrun + numUnderrun;
end
fprintf('Total samples underrun: %d.\n',...
    totalUnderrun);
fprintf('Total seconds underrun: %d.\n',...
```

```
    double(totalUnderrun)/double(deviceWriter.SampleRate));
```

```
Total samples underrun: 0.
Total seconds underrun: 0.
```

Release your `dsp.AudioFileReader` and `audioDeviceWriter` System objects and set your counter variable to zero.

```
release(fileReader);
release(deviceWriter);
totalUnderrun = 0;
```

Use a pause to mimic an algorithm that takes 0.075 seconds to process. The pause causes the audio stream loop to go slower than the device, which results in periods of silence in the output audio signal.

```
while ~isDone(fileReader)
    input = fileReader();
    numUnderrun = deviceWriter(input);
    totalUnderrun = totalUnderrun + numUnderrun;
    pause(0.075)
end
fprintf('Total samples underrun: %d.\n',...
    totalUnderrun);
fprintf('Total seconds underrun: %d.\n',...
    double(totalUnderrun)/double(deviceWriter.SampleRate));
```

```
Total samples underrun: 70656.
Total seconds underrun: 3.204354e+00.
```

Release your `audioDeviceReader` and `dsp.AudioFileWriter` and set the counter variable to zero.

```
release(fileReader);
release(deviceWriter);
totalUnderrun = 0;
```

Set the frame size of your audio stream loop to 2048. Because the `SupportVariableSizeInput` property of your `audioDeviceWriter` System object is set to `false`, the buffer size of your audio device is the same size as the input frame size. Increasing your device buffer size decreases underrun.

```
fileReader = dsp.AudioFileReader('speech_dft.mp3');
fileReader.SamplesPerFrame = 2048;
fileInfo = audioinfo('speech_dft.mp3');
```

```
deviceWriter = audioDeviceWriter(...
    'SampleRate',fileReader.SampleRate);
setup(deviceWriter,...
    zeros(fileReader.SamplesPerFrame,fileInfo.NumChannels));
```

Calculate the total underrun.

```
while ~isDone(fileReader)
    input = fileReader();
    numUnderrun = deviceWriter(input);
    totalUnderrun = totalUnderrun + numUnderrun;
    pause(0.075)
end
fprintf('Total samples underrun: %d.\n',...
    totalUnderrun);
fprintf('Total seconds underrun: %d.\n',...
    double(totalUnderrun)/double(deviceWriter.SampleRate));
```

```
Total samples underrun: 0.
Total seconds underrun: 0.
```

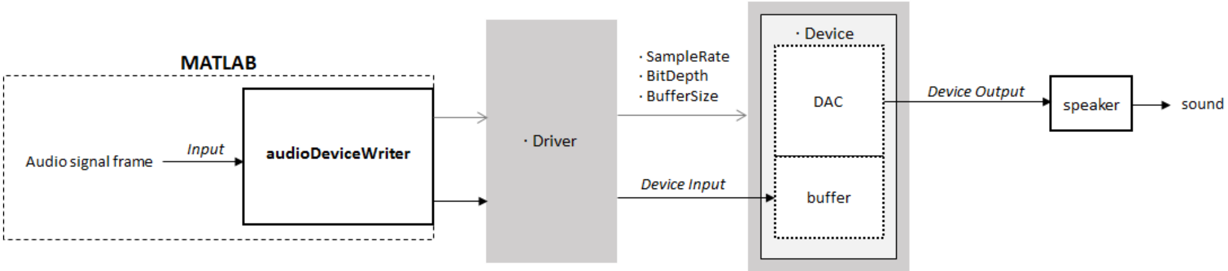
The increased frame size reduces the total underrun of your audio stream loop. However, increasing the frame size also increases latency. Other approaches to reduce underrun include:

- Increase the buffer size independent of input frame size. To increase buffer size independent of input frame size, you must first set `SupportVariableSizeInput` to `true`. This approach also increases latency.
- Decrease the sample rate. Decreasing the sample rate reduces both latency and underrun at the cost of signal resolution.
- Choose an optimal driver and device for your system.

More About

Audio Device Writer System Interaction

Properties of the audio device writer specify the driver, the device, and device attributes such as sample rate, bit depth, and buffer size.



Data Flow of Audio Device Writer

- Call `step` or `play` to input an audio signal frame to the `audioDeviceWriter`.
- The `audioDeviceWriter` uses the specified driver to pass the frame (device input) to the buffer of your specified audio device.
- The audio device performs digital-to-analog conversion at the specified sample rate and bit depth.
- The audio device outputs an analog chunk to your speaker.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- "System Objects in MATLAB Code Generation" (MATLAB Coder)
- The executable generated from this System object relies on prebuilt dynamic library files (`.dll` files) included with MATLAB. Use the `packNGo` function to package the code generated from this object and all the relevant files in a compressed zip file. Using this zip file, you can relocate, unpack, and rebuild your project in another development environment where MATLAB is not installed. For more details, see "How To Run a Generated Executable Outside MATLAB".

Blocks

`Audio Device Writer`

System Objects

dsp.AudioFileWriter | dsp.AudioFileReader

Topics

“How To Run a Generated Executable Outside MATLAB”

Introduced in R2016a

getAudioDevices

System object: audioDeviceWriter

List available audio input devices

Syntax

```
devices = getAudioDevices(aDW)
```

Description

`devices = getAudioDevices(aDW)` returns a cell array listing available audio output devices. The list of available output devices depends on the specified `Driver` property of your `audioDeviceWriter` object.

Introduced in R2016a

info

System object: audioDeviceWriter

Get information about selected device

Syntax

```
aDWInfo = info(aDW)
```

Description

`aDWInfo = info(aDW)` returns a structure containing information about your `audioDeviceWriter` System object. The structure contains information about the driver, device, and maximum number of input channels for your `audioDeviceWriter` System object.

Introduced in R2016a

play

System object: audioDeviceWriter

Stream audio data to output device

Syntax

`numUnderrun = play(aDW,x)`

Description

`numUnderrun = play(aDW,x)` writes one frame of audio samples, `x`, to the audio output device specified by the audio device writer System object, `aDW`. The number of samples underrun since the last call to `play` is returned.

If `x` is of data type `'double'` or `'single'`, the audio device writer clips values outside the range [–1, 1]. For other data types, the allowed input range is [min, max] of the specified data type.

When you call the `play` method of an `audioDeviceWriter` System object, the audio device specified by the `Device` property is locked. An audio device can be locked by only one `audioDeviceWriter` at a time. Call the `release` method of the `audioDeviceWriter` System object to release the audio device.

Note: The System object performs an internal initialization the first time you execute `play`. This initialization locks nontunable properties and input specifications, such as the dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Introduced in R2016a

step

System object: audioDeviceWriter

Stream audio data to output device

Syntax

```
numUnderrun = step(aDW,x)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`numUnderrun = step(aDW,x)` writes one frame of audio samples, `x`, to the audio output device specified by the audio device writer System object, `aDW`. The number of samples underrun since the last call to `step` is returned.

If `x` is of data type `'double'` or `'single'`, the audio device writer clips values outside the range [–1, 1]. For other data types, the allowed input range is [min, max] of the specified data type.

When you call the `step` method of an `audioDeviceWriter` System object, the audio device specified by the `Device` property is locked. An audio device can be locked by only one `audioDeviceWriter` at a time. Call the `release` method of the `audioDeviceWriter` System object to release the audio device.

Note: The System object performs an internal initialization the first time you execute `step`. This initialization locks nontunable properties and input specifications, such as the dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change

nontunable properties or inputs, you must first call the `release` method to unlock the object.

Introduced in R2016a

dsp.AudioFileReader System object

Package: dsp

Stream from audio file

Description

The `AudioFileReader` object reads audio samples from an audio file.

To read audio samples from an audio file:

1. Define and set up your audio file reader object. See “Construction” on page 4-160.
2. Call step to read audio samples according to the properties of `dsp.AudioFileReader`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj)` and `y = obj()` perform equivalent operations.

Construction

`afr = dsp.AudioFileReader` returns an audio file reader System object, `afr` that reads audio from an audio file.

`afr = dsp.AudioFileReader('`*`PropertyName`*`',`*`PropertyValue`*`,...)` returns an audio file reader System object, `afr`, with each specified property set to the specified value.

`afr = dsp.AudioFileReader(Filename,'`*`PropertyName`*`',`*`PropertyValue`*`,...)` returns an audio file reader object, `afr`, with `Filename` property set to *`FILENAME`* and other specified properties set to the specified values.

Properties

Filename

Name of audio file from which to read

Specify the name of an audio file as a character vector. Specify the full path for the file only if the file is not on the MATLAB path. The default is `speech_dft.mp3`.

PlayCount

Number of times to play file

Specify a positive integer as the number of times to play the file. The default is `1`.

SampleRate

Sampling rate of the audio file

This read-only property displays the sampling rate, in Hz, of the audio file.

SamplesPerFrame

Number of samples in audio frame

Specify the number of samples in an audio frame as a positive, scalar integer value. The default value is `1024`.

OutputDataType

Data type of output

Set the data type of the audio data output from the audio file reader object. Specify the data type as `double| single | int16 | uint8`. The default is `double`.

Supported Platforms and File Types

The following table lists the supported audio file formats:

Platforms	File Name Extensions
Windows	`.wav`, `.wma`, `.avi`, `.aif`, `.aifc`, `.aiff`, `.mp3`, `.au`, `.snd, .mp4, .m4a, .flac, .ogg`

Platforms	File Name Extensions
Non-Windows	`.avi, .mp3, .mp4, .m4a, .wav, .flac, .ogg, .aif, .aifc, .aiff,`

Methods

info	Information about specific audio file
isDone	End-of-file status (logical)
reset	Reset internal states of audio file reader to read from beginning of file
step	Read audio samples from audio file

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Read and Play back an Audio File

This example shows how to read and play back an audio file using the standard audio output device.

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For `dsp.AudioFileReader` System object™, myObject() becomes step(myObject). For all other objects, myObject(x) becomes step(myObject,x).

```
afr = dsp.AudioFileReader('speech_dft.mp3');
adw = audioDeviceWriter('SampleRate', afr.SampleRate);

while ~isDone(afr)
```

```
    audio = afr();
    adw(audio);
end
release(afr);
release(adw);
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the `From Multimedia File` block reference page. The object properties correspond to the block parameters, except:

- The object has no corresponding property for the **Inherit sample time from file** block parameter. The object always inherits the sample time from the file.
- The object has no corresponding property for the **Output end-of-file indicator** parameter. The object always outputs `EOF` as the last output.
- The object has no corresponding property for the **Multimedia Outputs** parameter because audio is the only supported output.
- The object has no corresponding property for the **Image signal** block parameter.
- The object has no corresponding property for the **Output color format** parameter.
- The object has no corresponding property for the **Video output data type** parameter.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- See “System Objects in MATLAB Code Generation” (MATLAB Coder).
- The executable generated from this System object relies on prebuilt dynamic library files (`.dll` files) included with MATLAB. Use the `packNGo` function to package the code generated from this object and all the relevant files in a compressed zip file.

Using this zip file, you can relocate, unpack, and rebuild your project in another development environment where MATLAB is not installed. For more details, see “How To Run a Generated Executable Outside MATLAB”.

Topics
“How To Run a Generated Executable Outside MATLAB”

Introduced in R2012a

info

System object: dsp.AudioFileReader
Package: dsp

Information about specific audio file

Syntax

```
S = info(afr)
```

Description

`S = info(afr)` returns a MATLAB structure, `S`, with information about the audio file specified in the `Filename` property. The number of fields in `S` varies depending on the audio content of the file. For possible fields and values for the structure `S`, see the following table.

Field	Value
SampleRate	Audio sampling rate of the audio file in Hz.
NumBits	Number of bits used to encode the audio stream.
NumChannels	Number of audio channels.

isDone

System object: dsp.AudioFileReader
Package: dsp

End-of-file status (logical)

Syntax

```
STATUS = isDone(afr)
```

Description

`STATUS = isDone(afr)` returns a logical value, `STATUS` , when the file is read `PlayCount` number of times. If you set the `PlayCount` property to a value greater than `1` , `STATUS` is `true` when `EOF` is reached `PlayCount` number of times, and it is `false` otherwise. `STATUS` is the same as the `PlayCount` output value in the `step` method syntax.

reset

System object: dsp.AudioFileReader
Package: dsp

Reset internal states of audio file reader to read from beginning of file

Syntax

```
reset(afr)
```

Description

`reset(afr)` resets the `AudioFileReader` object to read from the beginning of the file.

step

System object: dsp.AudioFileReader
Package: dsp

Read audio samples from audio file

Syntax

```
AUDIO = step(afr)
[AUDIO,EOF] = step(afr)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj)` and `y = obj()` perform equivalent operations.

`AUDIO = step(afr)` outputs one frame of audio samples, `AUDIO`. You can specify the number of times to play the file using the `PlayCount` property. After playing the file for the number of times you specify, `AUDIO` contains silence.

`[AUDIO,EOF] = step(afr)` returns an end-of-file indicator, `EOF`. `EOF` is true each time the output `AUDIO` contains the last audio sample in the file.

Note: `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

dsp.AudioFileWriter System object

Package: dsp

Stream to audio file

Description

The `AudioFileWriter` object writes audio samples to an audio file.

To write audio samples to an audio file:

1. Define and set up your audio file writer object. See "Construction" on page 4-169.
2. Call step to write audio samples according to the properties of `dsp.AudioFileWriter`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`afw = dsp.AudioFileWriter` returns an audio file writer System object, `afw`. This object writes audio samples to an audio file.

The following platform-specific restrictions apply when writing these files:

Windows 7	Mac OS X
• Only sample rates of `44,100` Hz and `48,000` Hz are supported for MPEG-4 AAC file format. For other file formats, there is no restriction on the sample rate.	• Only mono or stereo outputs are allowed for MPEG-4 AAC file format. For all other formats, more than two audio output channels are allowed.
• Only mono or stereo outputs are allowed for MPEG-4 AAC file format. For all	

Windows 7	Mac OS X
other formats, more than two audio output channels are allowed.	
• The output data is padded on both the front and back of the signal, with extra samples of silence. Windows AAC encoder places sharp fade-in and fade-out on audio signal, causing signal to be slightly longer in samples when written to disk.	• Not all sampling rates are supported, although the Mac Audio Toolbox API do not explicitly specify a restriction.
• A minimum of 1025 samples per channel must be written to the MPEG-4 AAC file.	

`afw = dsp.AudioFileWriter('`*`PropertyName`*`',`*`PropertyValue`*`,...)` returns an audio file writer System object, `afw`, with each specified property set to the specified value.

`afw = dsp.AudioFileWriter(`*`FILENAME`*`,'`*`PropertyName`*`',`*`PropertyValue`*`,...)` returns an audio file writer System object, `afw`. This object has the `Filename` property set to *`FILENAME`* and other specified properties set to the specified values.

Properties

`Filename`

Name of audio file to which to write

Specify the name of the audio file as a character vector. The default is `output.wav`.

`FileFormat`

Audio file format

Specify which audio file format the object writes. On Microsoft platforms, select one of `AVI | WAV | FLAC | OGG | MPEG4 | WMA`. On Linux platforms, select one of `AVI | WAV | FLAC | OGG`. On Mac OS X platforms, select one of `AVI | WAV | FLAC | OGG | MPEG4`. These abbreviations correspond to the following file formats:

- `AVI`: Audio-Video Interleave
- `WAV`: Microsoft WAVE Files
- `WMA`: Windows Media Audio
- `FLAC`: Free Lossless Audio Codec
- `OGG`: Ogg/Vorbis Compressed Audio File
- `MPEG4`: MPEG-4 AAC File — You can use both `.m4a` and `.mp4` extensions

The default is `WAV`.

SampleRate

Sampling rate of audio data stream

Specify the sampling rate of the input audio data as a positive, numeric scalar value. The default is `44100`.

Compressor

Algorithm that compresses audio data

Specify the type of compression algorithm the audio file writer uses to compress the audio data. Compression reduces the size of the audio file. Select `None (uncompressed)` to save uncompressed audio data to the file. The other options available reflect the audio compression algorithms installed on your system. You can use tab completion to query valid `Compressor` options for your computer by typing `H.Compressor = '` and then pressing the tab key. This property applies when writing `WAV` or `AVI` files on Windows platforms.

DataType

Data type of the uncompressed audio

Specify the type of uncompressed audio data written to the file as one of `inherit`, `int16`, `int24`, `single`, or `uint8`. This property only applies when writing uncompressed `WAV` files. The default value of this property is `int16`.

Methods

step	Write one frame of audio output samples

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Write an Audio Signal to a WAV File

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

Decimate an audio signal, and write it to disk as a WAV file.

```
afr = dsp.AudioFileReader('OutputDataType',...
   'double');
firdec = dsp.FIRDecimator; % decimate by 2
afw = dsp.AudioFileWriter...
   ('speech_dft.wav', ...
   'SampleRate', afr.SampleRate/2);

while ~isDone(afr)
     audio = afr();
     audiod = firdec(audio);
     afw(audiod);
end

release(afr);
release(afw);
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the `To Multimedia File` block reference page. The object properties correspond to the block parameters, except:

- The object `FileFormat` property does not support video-only file formats.
- The object has no corresponding property for the **Write** parameter. The object writes only audio content to files.
- The object has no corresponding property for the **Video compressor** parameter.
- The object has no corresponding property for the **File color format** parameter.
- The object has no corresponding property for the **Image signal** parameter.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- See "System Objects in MATLAB Code Generation" (MATLAB Coder).
- The executable generated from this System object relies on prebuilt dynamic library files (`.dll` files) included with MATLAB. Use the `packNGo` function to package the code generated from this object and all the relevant files in a compressed zip file. Using this zip file, you can relocate, unpack, and rebuild your project in another development environment where MATLAB is not installed. Topics

"How To Run a Generated Executable Outside MATLAB"

Introduced in R2012a

step

System object: dsp.AudioFileWriter
Package: dsp

Write one frame of audio output samples

Syntax

`step(afw,AUDIO)`

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`step(afw,AUDIO)` writes one frame of audio samples, `AUDIO` , to the output file. `AUDIO` is either a vector or an M-by-N matrix for mono or N-channel audio inputs respectively.

Note: `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

dsp.AudioPlayer System object

Package: dsp

Play audio data using computer's audio device

Note: The `dsp.AudioPlayer` object will be removed in a future release. Existing instances of the object continue to run. For new code, use the audioDeviceWriter object instead.

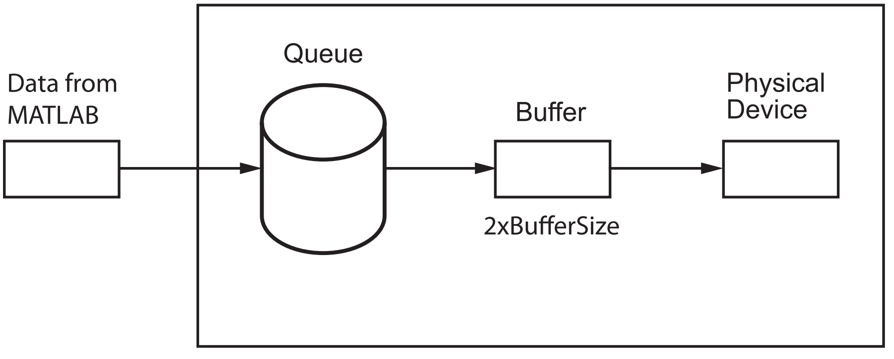
Description

The `AudioPlayer` object plays audio data using the computer's audio device.

To play audio data using the computer's audio device:

1. Define and set up your audio player object. See "Construction" on page 4-176.
2. Call step to play audio data according to the properties of `dsp.AudioPlayer`. The behavior of `step` is specific to each object in the toolbox.

This System object buffers the data from the audio device using the process illustrated by the following figure.



Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = dsp.AudioPlayer` returns an audio player object, `H`, that plays audio samples using an audio output device in real-time.

`H = dsp.AudioPlayer('PropertyName',PropertyValue, ...)` returns an audio player object, `H`, with each property set to the specified value.

`H = dsp.AudioPlayer(SAMPLERATE,'PropertyName',PropertyValue, ...)` returns an audio player object, `H`, with the `SampleRate` property set to `SAMPLERATE` and other specified properties set to the specified values. This System object supports variable-size input. If you use variable-size signals with this System object, you may experience sound dropouts when the size of the input frame increases. To avoid this behavior, use a signal of maximum expected size when you first call `step` to start running through this System object.

Properties

`DeviceName`

Device to which to send audio data

Specify the device to which to send the audio data. The default is `Default`, which is the computer's standard output device. You can use tab completion to query valid `DeviceName` assignments for your computer by typing `H.DeviceName = '` and then pressing the tab key.

`SampleRate`

Number of samples per second sent to audio device

Specify the number of samples per second in the signal as an integer. The default is `44100`. This property is tunable.

DeviceDataType

Data type used by device

Specify the data type used by the audio device to acquire audio data as `Determine from input data type`, `8-bit integer`, `16-bit integer`, `24-bit integer`, or `32-bit float`. The default is `Determine from input data type`.

BufferSizeSource

Source of Buffer Size

Specify how to determine the buffer size as `Auto` or `Property`. The default is `Auto`. When this property is set to `Auto`, an appropriate buffer size based on the `SampleRate` gets computed.

BufferSize

Buffer size

Specify the size of the buffer that the audio player object uses to communicate with the audio device as an integer. `BufferSize` is half the size of the sound card buffer. A frame of data cannot be passed to the queue until the device empties the buffer, which introduces *latency*. Latency is the time it takes the device to empty the queue and the buffer. `BufferSize` has to be smaller than the effective queue duration. This property is tunable. Tuning this property involves a balance between device latency and the possibility of dropping data (buffer underrun).

This property applies when you set the `BufferSizeSource` property to `Property`. The default is `4096`. To set the `BufferSize` to a value other than the default, first change the `BufferSizeSource` to `'Property'`. You can select `BufferSize` in the list of properties.

QueueDuration

Size of queue in seconds

Specify the length of the audio queue, in seconds. The default is `1.0`. This property is tunable. The purpose of the queue is to control the trade-off between latency and data dropout. Latency is calculated by the following equation:

$$latency = \frac{QueueDuration \times SampleRate + 2 \times BufferSize}{SampleRate}.$$

To minimize latency, lower the `QueueDuration` or set it to `0`. However, be aware that data dropouts or loss of system robustness may result. The `QueueDuration` property specifies the duration of the signal, in seconds, that can be buffered during the simulation. This value is the maximum length of time that the System object's data supply can lag the device's data demand. If the MATLAB data throughput rate is lower than the device throughput rate, a buffer underrun occurs. You can use `OutputNumUnderrunSamples` to monitor underrun. To correct the underrun, make the queue duration larger than the buffer. If the MATLAB data throughput rate is higher than the device throughput rate, a buffer overrun occurs, causing the System object to wait before writing data to the queue. To minimize the chance of dropouts, the System object checks to verify the queue duration is at least as large as the maximum of the buffer size and the frame size. If it is not, the queue duration is automatically set to this maximum value. At the start of the simulation, the queue is filled with silence. At each time step, the System object sends a buffer of samples from the top of the queue to the audio device. If the queue does not contain enough data to completely fill the buffer, the System object fills the remaining portion of the buffer with zeros.

OutputNumUnderrunSamples

Enable output of underrun count

Set to `true` to output the number of zero samples inserted due to queue underrun since the last call to the `step` method. The default is `false`.

ChannelMappingSource

Source of device channel mapping

Specify whether to determine the channel mapping as `'Auto'` or as `'Property'`. If you set the value of `ChannelMappingSource` to `'Auto'`, the `ChannelMapping` field is rendered inactive. If you set this property to `'Property'`, the vector specified in the `ChannelMapping` field is used to route the output.

ChannelMapping

Data-to-device channel mapping

Vector of valid channel indices to represent the mapping between data and device output channels. The term *Channel Mapping* refer to a 1-to-1 mapping that associates channels on the selected audio device to channels of the data. When you play audio, channel mapping allows you to specify which channel of the audio data to output a specific channel of audio data. By default, the `ChannelMapping` field is [1:MAXOUTPUTCHANNELS], where MAXOUTPUTCHANNELS depends upon the selected device.

Methods

step	Write audio to audio output device

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Read and Play an Audio File

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

Read in an AVI audio file, and play the file back using the standard audio output device.

```
AFR = dsp.AudioFileReader; % points to a default audio file
AP = audioDeviceWriter('SampleRate',AFR.SampleRate);
while ~isDone(AFR)
  audio = AFR();
  nUnderrun = AP(audio);
  if nUnderrun > 0
    fprintf('Audio player queue underrun by %d samples.\n'...
      ,nUnderrun);
  end
end
release(AFR);            % close the input file
```

```
release(AP);                % close the audio output device
```

Troubleshooting

Running an Executable Outside MATLAB

To run your generated standalone executable application in Shell, you need to set your environment to the following:

Platform	Command

Mac	`setenv DYLD_LIBRARY_PATH $LD_LIBRARY_PATH: $MATLABROOT/bin/maci64 (csh/tcsh)`
	
	`export DYLD_LIBRARY_PATH $LD_LIBRARY_PATH: $MATLABROOT/bin/maci64 (Bash)`

Linux	`setenv LD_LIBRARY_PATH $LD_LIBRARY_PATH: $MATLABROOT/bin/glnxa64 (csh/tcsh)`
	
	`export LD_LIBRARY_PATH $LD_LIBRARY_PATH: $MATLABROOT/bin/glnxa64 (Bash)`

Windows	`set PATH = $MATLABROOT\bin\win64;%PATH%`

Algorithms

This object implements the algorithm, inputs, and outputs described on the `To Audio Device` block reference page. The object properties correspond to the block parameters.

Topics

Set the Audio Hardware API on page 2-1730

Introduced in R2012a

step

System object: dsp.AudioPlayer
Package: dsp

Write audio to audio output device

Note: The `dsp.AudioPlayer` object will be removed in a future release. Existing instances of the object continue to run. For new code, use the audioDeviceWriter object instead.

Syntax

```
step(H,AUDIO)
Underrun = step(H,AUDIO)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`step(H,AUDIO)` writes one frame of `AUDIO` samples to the audio output device.

`Underrun = step(H,AUDIO)` writes one frame of `AUDIO` samples to the audio output device. The output `Underrun` indicates the number of zero samples inserted due to queue underrun since the last call to the `step` method. This syntax applies when you set the `OutputNumUnderrunSamples` on page 4-178 property to `true`.

Note: `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.AudioRecorder System object

Package: dsp

Record audio data using computer's audio device

Note: The `dsp.AudioRecorder` object will be removed in a future release. Existing instances of the object continue to run. For new code, use the `audioDeviceReader` object from Audio System Toolbox instead.

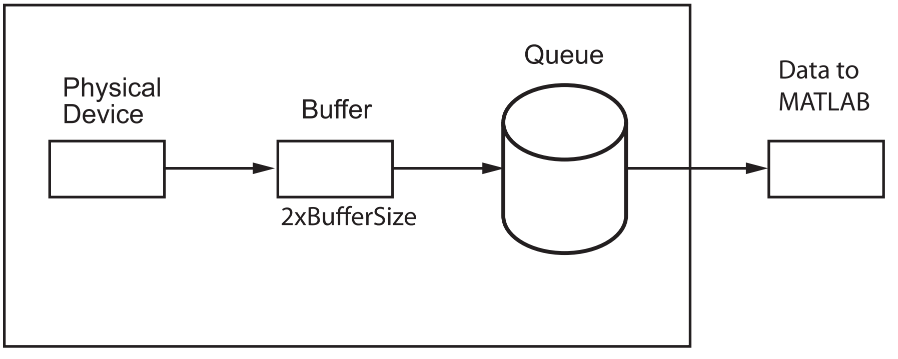
Description

The `AudioRecorder` object records audio data using the computer's audio device.

To record audio data using the computer’s audio device:

1. Define and set up your audio recorder object. See “Construction” on page 4-185.
2. Call step to record audio data according to the properties of `dsp.AudioRecorder`. The behavior of `step` is specific to each object in the toolbox.

This System object buffers the data from a frame of data using the process illustrated by the following figure.



Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = dsp.AudioRecorder` returns an audio recorder object, `H`, that records audio samples using an audio input device in real-time.

`H = dsp.AudioRecorder('PropertyName',PropertyValue, ...)` returns an audio recorder object, `H`, with each property set to the specified value.

Properties

`DeviceName`

Device from which to acquire audio data

Specify the device from which to acquire audio data. The default is `Default`, which is the computer's standard input device. You can use tab completion to query valid `DeviceName` assignments for your computer by typing `H.DeviceName = '` and then pressing the tab key. The tab completion functionality shows all valid audio device names for your computer.

`SampleRate`

Number of samples per second read from audio device

Specify the number of samples per second in the signal as an integer. The default is 44100. This property is tunable.

`NumChannels`

Number of audio channels

Specify the number of audio channels as an integer. The default is 2.

DeviceDataType

Data type used by device

Specify the data type used by the device to acquire audio data as `Determine from output data type` , `8-bit integer`, `16-bit integer`, `24-bit integer`, or `32-bit float`. The default is `Determine from output data type`.

BufferSizeSource

Source of Buffer Size

Specify how to determine the buffer size as `Auto` or `Property`. The default is `Auto`.

BufferSize

Buffer size

Specify as an integer the size of the buffer that the audio recorder object uses to communicate with the audio device. This property applies when you set the `BufferSizeSource` property to `Property`. The default is `4096`. This property is tunable. Tuning this property involves a balance between device latency and the possibility of dropping data (buffer underrun). The instant you receive the buffer from a device, you have samples that are relatively new and samples that are at least as old as the size of the buffer. Therefore, the buffer size introduces *latency*, which is the time required for the device to fill the queue and the buffer. `BufferSize` is half the size of the sound card buffer. The size of the buffer processed in each interrupt from the audio device affects the performance of the system. A frame of data cannot pass through the queue until the buffer is filled by the device, thus introducing latency. `BufferSize` has to be smaller than the effective queue duration. To set the `BufferSize` to a value other than the default, first change the `BufferSizeSource` to 'Property'. You can select `BufferSize` from the list of properties.

QueueDuration

Size of queue in seconds

Specify the length of the audio queue, in seconds. The default is `1.0`. This property is tunable. The purpose of the queue is to control the trade-off between latency and data dropout. Latency is calculated by the following equation:

$$latency = \frac{QueueDuration \times SampleRate + 2 \times BufferSize}{SampleRate}.$$

To minimize latency, lower the `QueueDuration` or set it to 0. However, be aware that data dropouts or loss of system robustness may result. The `QueueDuration` property specifies the duration of the signal, in seconds, that can be buffered during the simulation. This value is the maximum length of time that the System object's data supply can lag the device's data demand. If the MATLAB data throughput rate is lower than the device throughput rate, a buffer overrun occurs. You can use `OutputNumOverrunSamples` to monitor overrun. To correct the overrun, make the queue duration larger than the buffer. If the MATLAB data throughput rate is higher than the device throughput rate, a buffer underrun occurs, causing the System object to wait for new samples to become available. To minimize the chance of dropouts, the System object checks to verify the queue duration is at least as large as the maximum of the buffer size and the frame size. If it is not, the queue duration is automatically set to this maximum value. At the start of the simulation, the queue is filled with silence. At each time step, the audio device sends a buffer of samples to the top of the queue.

SamplesPerFrame

Number of samples in the output signal

Specify the number of samples in the audio recorder's output as an integer. The default is 1024.

OutputDataType

Data type of the output

Select the output data type as `uint8`, `int16`, `int32` , `single` , or `double`. The default is `double`.

OutputNumOverrunSamples

Enable output of overrun count

Set to `true` to output the number of samples dropped due to queue overrun since the last call to the `step` method. The default is `false`.

ChannelMappingSource

Source of device channel mapping

Specify whether to determine the channel mapping as `'Auto'` or as `'Property'`. If you set the value of `ChannelMappingSource` to `'Auto'`, the `ChannelMapping` field is rendered inactive. If you set this property to `'Property'`, the vector specified in the ChannelMapping field is used to route the input. Additionally, the `NumChannels` field is rendered inactive, because the channel map contains information about the number of data channels that the user is attempting to read.

ChannelMapping

Device-to-data channel mapping

Vector of valid channel indices to represent the mapping between device input channels and the data. The term *Channel Mapping* refers to a 1-to-1 mapping that associates channels on the selected audio device to channels of the data. When you record audio, channel mapping allows you to specify which channel of the audio data directs input to a specific channel of audio. By default, the `ChannelMapping` field is [1:MAXNUMINPUTCHANNELS], where MAXNUMINPUTCHANNELS depends upon the selected device.

Methods

step	Record audio from recording device

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Troubleshooting

Running an Executable Outside MATLAB

To run your generated standalone executable application in Shell, you need to set your environment to the following:

Platform	Command

Mac	`setenv DYLD_LIBRARY_PATH $LD_LIBRARY_PATH: $MATLABROOT/bin/maci64 (csh/tcsh)`
	
	`export DYLD_LIBRARY_PATH $LD_LIBRARY_PATH: $MATLABROOT/bin/maci64 (Bash)`

Linux	`setenv LD_LIBRARY_PATH $LD_LIBRARY_PATH: $MATLABROOT/bin/glnxa64 (csh/tcsh)`
	
	`export LD_LIBRARY_PATH $LD_LIBRARY_PATH: $MATLABROOT/bin/glnxa64 (Bash)`

Windows	`set PATH = $MATLABROOT\bin\win64;%PATH%`

Algorithms

This object implements the algorithm, inputs, and outputs described on the `From Audio Device` block reference page. The object properties correspond to the block parameters.

Autocorrelation sequence

Description

The `Autocorrelator` object returns the autocorrelation sequence for a discrete-time, deterministic input, or the autocorrelation sequence estimate for a discrete-time, wide-sense stationary (WSS) random process at positive lags.

To obtain the autocorrelation sequence:

1. Define and set up your autocorrelator. See "Construction" on page 4-191.
2. Call step to compute the autocorrelation sequence according to the properties of `dsp.Autocorrelator`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`ac = dsp.Autocorrelator` returns an autocorrelator, `ac`, that computes the autocorrelation along the first dimension of an N-D array. By default, the autocorrelator computes the autocorrelation at lags from zero to $N-1$, where N is the length of the input vector or the row dimension of the input matrix. Inputting a row vector results in a row of zero-lag autocorrelation sequence values, one for each column of the row vector. The default autocorrelator returns the unscaled autocorrelation and performs the computation in the time domain.

`ac = dsp.Autocorrelator('PropertyName',PropertyValue, ...)` returns an autocorrelator, `ac`, with each property set to the specified value.

Properties

`MaximumLagSource`

Source of maximum lag

Specify how to determine the range of lags for the autocorrelation as `Auto` or `Property`. If the value of `MaximumLagSource` is `Auto`, the autocorrelator computes the autocorrelation over all nonnegative lags in the interval `[0, N-1]`, where N is the length of the first dimension of the input. Otherwise, the object computes the autocorrelation using lags in the range `[0,MaximumLag on page 4-192]`. The default is `Auto`.

`MaximumLag`

Maximum positive lag

Specify the maximum lag as a positive integer. This property applies only when the `MaximumLagSource` on page 4-192 property is `Property`. The `MaximumLag` must be less than the length of the input data. The default is `1`.

`Scaling`

Autocorrelation function scaling

Specify the scaling to apply to the output as `None`, `Biased`, `Unbiased`, or `Unity at zero-lag`. Set this property to `None` to generate the autocorrelation function without scaling. This option is appropriate if you are computing the autocorrelation of a nonrandom (deterministic) input.

The `Biased` option scales the autocorrelation by $1/N$, where N is the length of the input data. Scaling by $1/N$ yields a biased, finite-sample approximation to the theoretical autocorrelation of a WSS random process. In spite of the bias, scaling by $1/N$ has the desirable property that the sample autocorrelation matrix is nonnegative definite, a property possessed by the theoretical autocorrelation matrices of all wide-sense stationary random processes. The Fourier transform of the biased autocorrelation estimate is the *periodogram*, a widely used estimate of the power spectral density of a WSS process.

The `Unbiased` option scales the estimate of the autocorrelation by 1/N-1. Scaling by $N-1$ produces an unbiased estimate of the theoretical autocorrelation. However, using the unbiased option, you can obtain an estimate of the autocorrelation function that fails to have the nonnegative definite property.

Use the `Unity at zero-lag` option to normalize the autocorrelation estimate as identically one at lag zero. The default is `None`.

`Method`

Domain for computing autocorrelations

Specify the domain for computing autocorrelations as `Time Domain` or `Frequency Domain`. You must set this property to `Time Domain` for fixed-point signals. The default is `Time Domain`.

Fixed-Point Properties

`FullPrecisionOverride`

Full precision override for fixed-point arithmetic

Specify whether to use full precision rules. If you set `FullPrecisionOverride` to `true`, which is the default, the object computes all internal arithmetic and output data types using full precision rules. These rules provide the most accurate fixed-point numerics. It also turns off the display of other fixed-point properties because they do not apply individually. These rules guarantee that no quantization occurs within the object. Bits are added, as needed, to ensure that no roundoff or overflow occurs. If you set `FullPrecisionOverride` to `false`, fixed-point data types are controlled through individual fixed-point property settings. For more information, see "Full Precision for Fixed-Point System Objects".

`RoundingMethod`

Rounding method for fixed-point operations

Specify the rounding method as `Ceiling`, `Convergent`, `Floor`, `Nearest`, `Round`, `Simplest`, or `Zero`. This property applies only when you set the `Method` on page 4-193 property to `Time Domain`. The default is `Floor`. This property applies only if the object is not in full precision mode.

`OverflowAction`

Overflow action for fixed-point operations

Specify the overflow action as `Wrap` or `Saturate`. This property applies only when you set the `Method` on page 4-193 property to `Time Domain`. The default is `Wrap`. This property applies only if the object is not in full precision mode.

ProductDataType

Product word and fraction lengths

Specify the product fixed-point data type as one of `Full precision`, `Same as input`, or `Custom`. This property applies only when you set the `Method` on page 4-193 property to `Time Domain`. The default is `Full precision`

CustomProductDataType

Product word and fraction lengths

Specify the product fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when you set the `Method` on page 4-193 property to `Time Domain` and the `ProductDataType` on page 4-194 property to `Custom`. The default is `numerictype([],32,30)`.

AccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point data type as one of `Full precision`, `Same as product`, `Same as input`, or `Custom`. This property applies only when the `Method` on page 4-193 property is `Time Domain`. The default is `Full precision`.

CustomAccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when you set the `Method` on page 4-193 property to `Time Domain` and the `AccumulatorDataType` on page 4-194 property to `Custom`. The default is`numerictype([],32,30)`.

OutputDataType

Output word and fraction lengths

Specify the output fixed-point data type as `Same as accumulator`, `Same as product`, `Same as input`, or `Custom`. This property applies only when the `Method` on page 4-193 property is `Time Domain`. The default is `Same as accumulator`.

CustomOutputDataType

Output word and fraction lengths

Specify the output fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when you set the `Method` on page 4-193 property to `Time Domain` and the `OutputDataType` on page 4-194 property to `Custom`. The default is `numerictype([],16,15)`.

Methods

step	Autocorrelation sequence

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Autocorrelation Of a Number Sequence

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

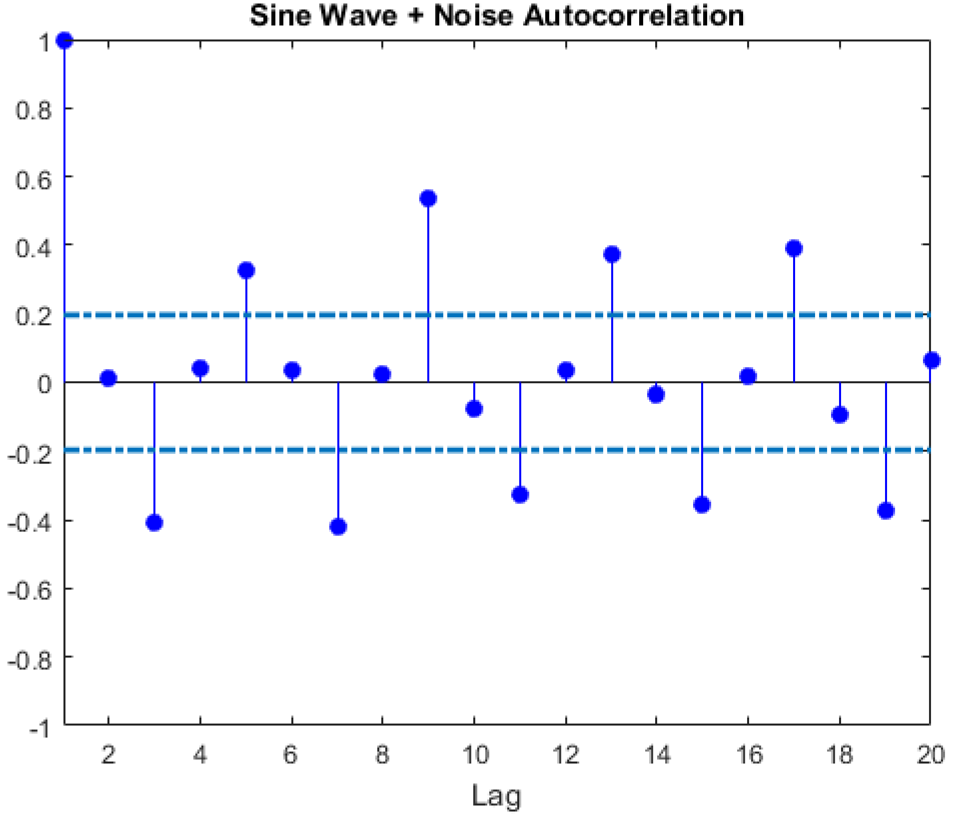
```
ac1 = dsp.Autocorrelator;
% x is a column vector
x = (1:100)';
y = ac1(x);
```

Autocorrelation of a Noisy Sine Wave

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

Compute the autocorrelation of a sine wave in white Gaussian noise with approximate 95% upper and lower confidence limits.

```
S = rng('default');
% Sine wave with period N=4
x = 1.4*cos(pi/2*(1:100))'+randn(100,1);
MaxLag = 20;
ac = dsp.Autocorrelator('MaximumLagSource',...
'Property','MaximumLag',MaxLag,'Scaling','Unity at zero-lag');
SigAutocorr = ac(x);
stem(SigAutocorr,'b','markerfacecolor',[0 0 1]);
line(1:MaxLag+1,1.96/sqrt(100)*ones(MaxLag+1,1),...
     'linestyle','-.','linewidth',2);
line(1:MaxLag+1,-1.96/sqrt(100)*ones(MaxLag+1,1),...
     'linestyle','-.','linewidth',2);
axis([1 20 -1 1]);
title('Sine Wave + Noise Autocorrelation'); xlabel('Lag');
```



As this figure shows, the autocorrelation estimate demonstrates the four sample periodic sine wave with excursions outside the 95% white Gaussian noise confidence limits every two samples.

Definitions

Autocorrelation

Autocorrelation is the correlation of a signal with itself at different points in time.

For a deterministic discrete-time sequence, *x(n)*, the autocorrelation is computed using the following relationship:

$$r_x(h) = \sum_{n=0}^{N-h-1} x^*(n)x(n+h) \quad h = 0,1,\ldots,N-1$$

where h is the lag and * denotes the complex conjugate. If the input is a length N realization of a WSS stationary random process, $r_x(h)$ is an estimate of the theoretical autocorrelation:

$$\rho_x(h) = E\{x^*(n)x(n+h)\}$$

where E{ } is the expectation operator. The `Unity at zero-lag` normalization divides each sequence value by the autocorrelation or autocorrelation estimate at zero lag.

$$\frac{\rho_x(h)}{\rho_x(0)} = \frac{E\{x^*(n)x(n+h)\}}{E\{|x(0)|^2\}}$$

The most commonly used estimate of the theoretical autocorrelation of a WSS random process is the biased estimate:

$$\hat{\rho}_x(h) = \frac{1}{N}\sum_{k=0}^{N-h-1} x^*(n)x(n+h)$$

Algorithms

Time domain Computation

When you set the computation domain to time, the algorithm computes the autocorrelation of the input signal in the time domain. The input signal can be a fixed-point signal in this domain.

The autocorrelation sequence, y, is computed using this equation:

$$y_{i,j} = \sum_{k=0}^{M-l-1} u_{k,j}^{*} u_{(k+i),j} \qquad 0 \le i \le l$$

- $y_{0,j}$ is the zero-lag element in the jth column of the input.
- i is the index of the lag.
- j is the index of the input data column.
- * denotes the complex conjugate.
- M is the number of elements in each column.
- l is the maximum positive lag for autocorrelation. When you choose to compute the autocorrelation with all nonnegative lags, l=M–1. Otherwise, l is the maximum nonnegative integer lag value specified.
- u is an M-by-N input matrix.

Frequency Domain Computation

When you set the computation domain to frequency, the algorithm computes the autocorrelation in the frequency domain.

In this domain, the algorithm computes the autocorrelation sequence by taking the Fourier transform of the input signal, multiplying the Fourier transform with its complex conjugate, and taking the inverse Fourier transform of the product. In this domain, depending on the input length, the algorithm can require fewer computations.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

dsp.Crosscorrelator

Introduced in R2012a

step

System object: dsp.Autocorrelator
Package: dsp

Autocorrelation sequence

Syntax

```
Y = step(ac,X)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(ac,X)` computes the autocorrelation sequence `Y` for the columns of the input `X`.

Note: `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

dsp.BinaryFileReader System object

Package: dsp

Read data from binary file

Description

The `dsp.BinaryFileReader` System object reads multichannel signal data from a binary file. If the header is not empty, then the header precedes the signal data. The System object specifies the prototype of the header, and the type, size, and complexity of the data. The first time you read the file, the reader reads the header, followed by the data. On subsequent calls, the reader reads the remaining data. Once the end of file is reached, the reader returns zeros of the specified data type, size, and complexity. The reader can read signal data from a binary file that is not created by the dsp.BinaryFileWriter System object.

The object accepts floating-point data or integer data. To read character data and fixed-point data, see the "Write and Read Character Data" on page 4-212 and "Write and Read Fixed-Point Data" on page 4-210 examples. The input data can be real or complex. When the data is complex, the object reads the data as interleaved real and imaginary components. For an example, see "Read Complex Data" on page 4-209. The reader assumes the default endianness of the host machine. To change the endianness, you can use the `swapbytes` function. For an example, see "Change the Endianness of the Data" on page 4-213.

This object supports C and C++ code generation.

To read data from a binary file:

1 Create a `dsp.BinaryFileReader` object and set the properties of the object.
2 Call step to read the binary file.

Note: Alternatively, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj)` and `y = obj()` perform equivalent operations.

Construction

`reader = dsp.BinaryFileReader` creates a binary file reader object, `reader`, using the default properties.

`reader = dsp.BinaryFileReader(fname)` sets the `Filename` property to `fname`.

`reader = dsp.BinaryFileReader(fname, Name, Value, ...)` with `Filename` set to `fname`, and each property `Name` set to the specified `Value`. Unspecified properties have default values.

Example:

```
reader = dsp.BinaryFileReader('myFilename.bin','SamplesPerFrame',1000,'NumChannels',2);
```

Properties

`Filename` — Name of the file

`'Untitled.bin'` (default) | character vector

Name of the file from which the object reads the data, specified as a character vector. If the file is not on the MATLAB path, then specify the full path for the file.

`HeaderStructure` — Size of the header

`struct('Field1',[])` (default) | structure

Size of the structure, specified as a structure. The structure specifies the prototype of the file header, that is, the size of the header and the data type of the field values. The structure can have an arbitrary number of fields. Each field of the structure must be a real matrix of a built-in type. For example, if `HeaderStructure` is set to `struct('field1',1:10,'field2',single(1))`, the object assumes that the header is formed by 10 real double-precision values followed by 1 single-precision value. If the file contains no header, you can set this property to an empty structure, `struct([])`. To retrieve the file header, call the `readHeader` method on the reader object.

`SamplesPerFrame` — Number of samples per output frame

`1024` (default) | positive integer

Number of samples per output frame, specified as a positive integer. `SamplesPerFrame` specifies the number of rows of the output matrix that the object returns. The size of the data is `SamplesPerFrame`-by-`NumChannels`. Once the end of file is reached, the reader returns zeros of the specified data type, size, and complexity.

`NumChannels` — Number of channels

`1` (default) | positive integer

Number of channels, specified as a positive integer. `NumChannels` specifies the number of columns of the output matrix that the object returns. This property defines the number of consecutive interleaved data samples stored in the file for each time instant. The size of the data is `SamplesPerFrame`-by-`NumChannels`. Once the end of file is reached, if the output matrix is not full, the object fills the matrix with zeros to make it a full-sized matrix.

`DataType` — Storage class of data in file

`'double'` (default) | `'single'` | `'int8'` | `'int16'` | `'int32'` | `'int64'` | `'uint8'` | `'uint16'` | `'uint32'` | `'uint64'`

Storage class of data in file, specified as a character vector. This property defines the data type of the matrix returned by the `step` method.

`IsDataComplex` — Specify data complexity

`false` (default) | `true`

Option to specify data complexity, specified as false or true. When this property is set to `true`, the reader treats the data as being complex. The object reads the data as interleaved real and imaginary components. Consider a reader object configured to read the data as a 2-by-2 matrix. The object reads `[1 5 2 6 3 7 4 8]` as `[1 2; 3 4]+1j*[5 6; 7 8]`. If this property is set to `false`, the same object reads the data as `[1 5; 2 6]`.

Methods

isdone	End-of-file status (logical)
readheader	Read file header
reset	Reset internal states of System object
step	Read data from binary file

Common to All System Objects	
`clone`	Create System object with same property values

Common to All System Objects	
getNumInpu	Expected number of inputs to a System object
getNumOutp	Expected number of outputs of a System object
isLocked	Check locked states of a System object (logical)
release	Allow System object property value changes

Examples

Write and Read Binary Files

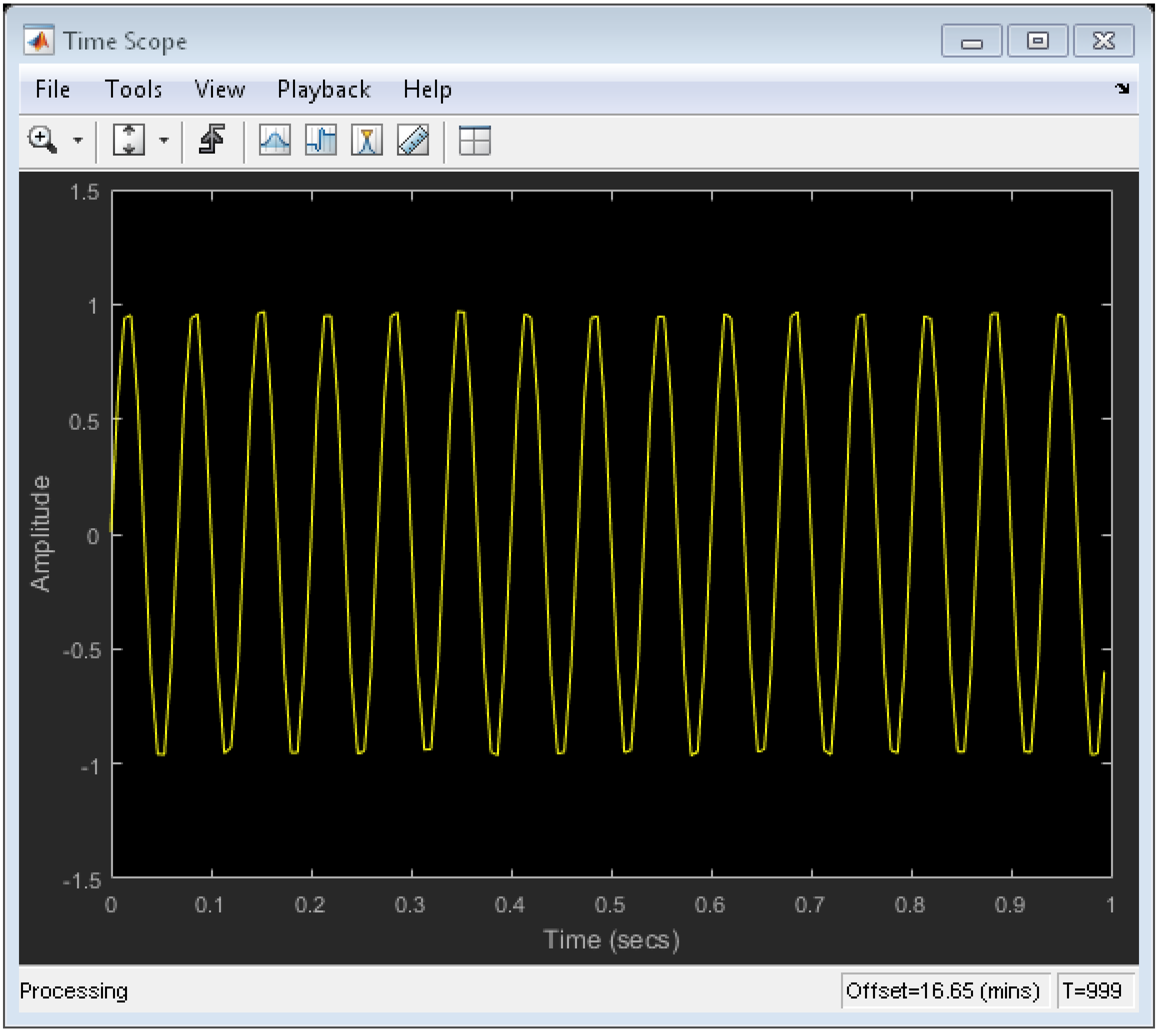
Create a binary file with a custom header using the `dsp.BinaryFileWriter` System object™. Write data to this file. Read the header and data using the `dsp.BinaryFileReader` System object.

Write the Data

Specify the file header and create a `dsp.BinaryFileWriter` object. The object writes the header first, followed by the data, to the `ex_file.bin` file. The data is a noisy sine wave signal. View the data in a time scope.

```
header = struct('A',[1 2 3 4],'B','x7');
writer = dsp.BinaryFileWriter('ex_file.bin','HeaderStructure',header);
L = 150;
sine = dsp.SineWave('SamplesPerFrame',L);
scopewriter = dsp.TimeScope(1,'YLimits',[-1.5 1.5],'SampleRate',...
    L,'TimeSpan',1);

for i = 1:1000
    data = sine()+0.01*randn(L,1);
    writer(data);
    scopewriter(data);
end
```



Release the writer so that the reader can access the data from this file.

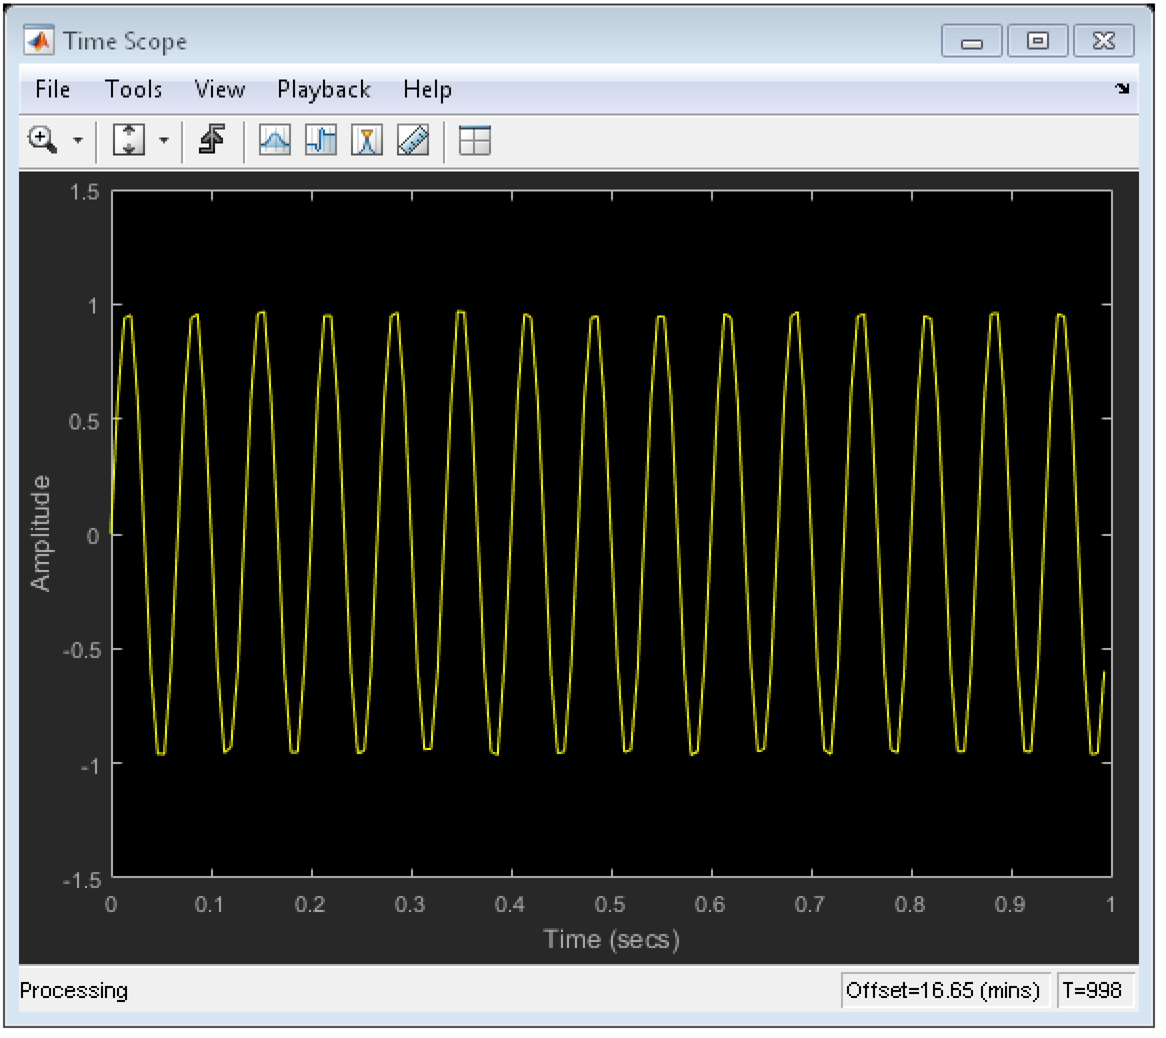
```
release(writer);
```

Read the Data

Specify the header using the `HeaderStructure` property of the reader object. If the exact header is not known, you must at least specify the prototype of the header, that is, its size and data type. The dsp.BinaryFileReader object reads the binary data from ex_file.bin until the end of file is reached. The data is read into a single channel (column) containing multiple frames, where each frame has 300 samples. View the data in a time scope.

```
headerPrototype = struct('A',[0 0 0 0],'B','-0');

reader = dsp.BinaryFileReader(...
    'ex_file.bin',...
    'HeaderStructure',headerPrototype,...
    'NumChannels',1,'SamplesPerFrame',300);
scopereader = dsp.TimeScope(1,'YLimits',[-1.5 1.5],'SampleRate',...
    L,'TimeSpan',1);
while ~isDone(reader)
    out = reader();
    scopereader(out);
end
release(reader);
```



Even when the reader reads data with a different frame size, the output in both time scopes matches exactly.

Write and Read Matrix Data

Use a `dsp.BinaryFileReader` System object™ to read data from a binary file in a row-major format.

Write the Data

Write the matrix A to the binary file Matdata.bin using a dsp.BinaryFileWriter object. The object writes the specified header followed by the data.

```
A = [1 2 3 8; 4 5 6 10; 7 8 9 11];
header = struct('A',[1 2],'B','x7');
writer = dsp.BinaryFileWriter('Matdata.bin','HeaderStructure',header);
writer(A);
```

Release the writer so that the reader can access the data.

```
release(writer);
```

Read the Data

Specify the header using the HeaderStructure property of the reader object. If the exact header is not known, you must at least specify the prototype of the header, that is, its size and data type. The dsp.BinaryFileReader object reads the binary file Matdata.bin until the end of file is reached. Specify the System object to read the data into 4 channels, with each channel containing 5 samples. Each loop of the iteration reads a channel (or frame) of data.

```
headerPrototype = struct('A',[0 0],'B','-0');
reader = dsp.BinaryFileReader('Matdata.bin','HeaderStructure',header,...
    'NumChannels',4,'SamplesPerFrame',5);
while ~isDone(reader)
    out = reader();
    display(out)
end
```

```
out =

     1     2     3     8
     4     5     6    10
     7     8     9    11
     0     0     0     0
     0     0     0     0
```

Each frame of out contains frames of the matrix A, followed by zeros to complete the frame. The original matrix A contains 4 channels with 3 samples in each channel. The reader is specified to read data into 4 channels, with each channel containing 5 samples.

Because there are not enough samples to complete the frame, the reader object appends zeros at the end of each frame.

Read Header Data

Read the header data from a binary file using the `readHeader` method.

Write a header, followed by the data to a binary file named `myfile.dat`. The header is a 1-by-4 matrix of double precision values, followed by a 5-by-1 vector of single-precision values. The data is a sequence of 1000 double-precision values.

```
fid = fopen('myfile.dat','w');
fwrite(fid,[1 2 3 4],'double');
fwrite(fid,single((1:5).'),'single');
fwrite(fid,(1:1000).','double');
fclose(fid);
```

Read the header using a `dsp.BinaryFileReader` object. Specify the expected header structure. This structure specifies only the format of the expected binary file header and does not contain the exact values.

```
reader = dsp.BinaryFileReader('myfile.dat');
s = struct('A',zeros(1,4),'B',ones(5,1,'single'));
reader.HeaderStructure = s;
```

Read the header using the `readHeader` method of the `dsp.BinaryFileReader` object.

```
H = readHeader(reader);
fprintf('H.A: ')
fprintf('%d ',H.A);
fprintf('\nH.A datatype: %s\n',class(H.A))
fprintf('H.B: ')
fprintf('%d ',H.B);
fprintf('\nH.B datatype: %s\n',class(H.B))
```

```
H.A: 1 2 3 4
H.A datatype: double
H.B: 1 2 3 4 5
H.B datatype: single
```

Read Complex Data

Read complex data from a binary file using the `dsp.BinaryFileReader` object.

Write a sequence of numbers to a binary file named `myfile.dat`. There is no header. The data is a 2-by-4 matrix of double-precision values. `fwrite` writes the data in a column-major format. That is, the 2-by-4 matrix `[1 2 3 4; 9 10 11 12]` is written as `[1 9 2 10 3 11 4 12]` in the binary file.

```
fid = fopen('myfile.dat','w');
fwrite(fid,[1 2 3 4; 9 10 11 12],'double');
fclose(fid);
```

Specify the data to be complex using the `IsDataComplex` property. The object reads the data as interleaved real and imaginary components. The `SamplesPerFrame` and `NumChannel` properties specify the number of rows and columns of the output data. The header structure is specified as empty.

```
reader = dsp.BinaryFileReader('myfile.dat','SamplesPerFrame',2,...
    'NumChannels',2, 'IsDataComplex',true);
s = struct([]);
reader.HeaderStructure = s;
data = reader();
display(data);
release(reader);
```

```
data =

   1.0000 + 9.0000i   2.0000 +10.0000i
   3.0000 +11.0000i   4.0000 +12.0000i
```

Alternatively, if you do not specify the data to be complex, the reader reads the data as a `SamplesPerFrame`-by- `NumChannel` matrix of real values.

```
reader.IsDataComplex = false;
data = reader();
display(data);
release(reader);
```

```
data =

     1     9
     2    10
```

Write and Read Fixed-Point Data

The `dsp.BinaryFileWriter` and `dsp.BinaryFileReader` System objects do not support writing and reading fixed-point data. As a workaround, you can write the stored integer portion of the `fi` data, read the data, and use this value to reconstruct the `fi` data.

Write the Fixed-Point Data

Create a `fi` object to represent 100 signed random numbers with a word length of 14 and a fraction length of 12. Write the stored integer portion of the `fi` object to the data file `myFile.dat`. The built-in data type is `int16`, which can be computed using `class(storeIntData)`.

```
data = randn(100,1);
fiDataWriter = fi(data,1,14,12);
storeIntData = storedInteger(fiDataWriter);

writer = dsp.BinaryFileWriter('myFile.dat');
writer(storeIntData);
```

Release the writer so that the reader can access the data.

```
release(writer);
```

Read the Fixed-Point Data

Specify the reader to read the stored integer data as `int16` data with 100 samples per data frame. The real-world value of the fixed-point number can be represented using $2^{(-fractionLength)*(storedInteger)}$. If you know the signedness, word length, and fraction length of the fixed-point data, you can reconstruct the `fi` data using $fi(realValue, signedness, wordLength, fractionLength)$. In this example, the data is signed with a word length of 14 and a fraction length of 12.

```
reader = dsp.BinaryFileReader('Filename','myFile.dat','SamplesPerFrame',100,...
    'DataType','int16');
data = reader();
fractionLength = 12;
wordLength = 14;
realValue = 2^(-fractionLength)*double(data);

fiDataReader = fi(realValue,1,wordLength,fractionLength);
```

Verify that the writer data is the same as the reader data.

```
isequal(fiDataWriter,fiDataReader)
```

```
ans =

  logical

   1
```

Write and Read Character Data

The `dsp.BinaryFileWriter` and `dsp.BinaryFileReader` System objects do not support writing and reading characters. As a workaround, cast character data to one of the built-in data types and write the integer data. After the reader reads the data, convert the data to a character using the `char` function.

Write the Character Data

Cast a character into `uint8` using the `cast` function. Write the cast data to the data file `myFile.dat`.

```
data = 'binary_file';
castData = cast(data,'uint8');
writer = dsp.BinaryFileWriter('myFile.dat');
writer(castData);
```

Release the writer so that the reader can access the data.

```
release(writer);
```

Read the `uint8` Data

Specify the reader to read the cast data as `uint8` data.

```
reader = dsp.BinaryFileReader('myFile.dat','DataType','uint8','SamplesPerFrame',11);
readerData = reader();
charData = char(readerData);
```

Verify that the writer data is the same as the reader data. By default, the reader returns the data in a column-major format.

```
strcmp(data,charData.')
```

```
ans =

  logical
```

```
    1
```

Change the Endianness of the Data

By default, the `dsp.BinaryFileReader` System object™ uses the endianness of the host machine. To change the endianness, such as when the host machine that writes the data does not have the same endianness as the host machine that reads the data, use the `swapbytes` function.

Write a numeric array into `myfile.dat` in big endian format. Read the data using the `dsp.BinaryFileReader` object. The reader object reads the data in little endian format.

```
fid = fopen('myfile.dat','w','b');
fwrite(fid,[1 2 3 4 5 6 7 8],'double');
fclose(fid);
reader = dsp.BinaryFileReader('myfile.dat','SamplesPerFrame',8);
x = reader();
display(x);
```

```
x =

  1.0e-318 *

    0.3039
    0.0003
    0.0104
    0.0206
    0.0256
    0.0307
    0.0357
    0.0408
```

`x` does not match the original data. Change the endianness of `x` using the `swapbytes` function.

```
y = swapbytes(x);
display(y);
```

```
y =
```

y matches the original data.

System Objects
dsp.BinaryFileWriter

Blocks
`Binary File Reader` | `Binary File Writer`

Introduced in R2016b

isdone

System object: dsp.BinaryFileReader
Package: dsp

End-of-file status (logical)

Syntax

```
status = isDone(reader)
```

Description

`status = isDone(reader)` returns true if the source System object, `obj`, has reached the end of the file.

Introduced in R2016b

readheader

System object: dsp.BinaryFileReader
Package: dsp

Read file header

Syntax

```
header = readHeader(reader)
```

Description

`header = readHeader(reader)` returns the header structure, `header`, from the file specified by the binary file reader, `reader`.

Introduced in R2016b

reset

System object: dsp.BinaryFileReader
Package: dsp

Reset internal states of System object

Syntax

```
reset(reader)
```

Description

`reset(reader)` resets to the beginning of the file and skips the header bytes.

Introduced in R2016b

step

System object: dsp.BinaryFileReader
Package: dsp

Read data from binary file

Syntax

`data = step(reader)`

Description

Note: Alternatively, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj)` and `y = obj()` perform equivalent operations.

`data = step(reader)` reads data from the binary file in row-major format. The data type, size, and complexity of the data are determined by the properties of the `reader` object. Once end of file is reached, the `step` method returns zeros of the specified data type, size, and complexity.

Introduced in R2016b

dsp.BinaryFileWriter System object

Package: dsp

Write data to binary files

Description

The `dsp.BinaryFileWriter` System object writes multichannel signal data to a binary file. If the header is not empty, then the header precedes the signal data. The object specifies the file name and the structure of the header. The first time you write to the file, the object writes the header, followed by the data. On subsequent calls, the object writes the remaining data. If the header is empty, then no header is written.

The object can write floating-point data and integer data. To write character data and fixed-point data, see "Write and Read Character Data" on page 4-228 and "Write and Read Fixed-Point Data" on page 4-226. The input data can be real or complex. When the data is complex, the object writes the data as interleaved real and imaginary components. For an example, see "Write and Read Fixed-Point Data" on page 4-226. The writer assumes the default endianness of the host machine. To change the endianness, you can use the `swapbytes` function. For an example, see "Change the Endianness of the Data Before Writing the Data" on page 4-229 .

The object writes the data in row-major format. For example if the input array is [`1 2 4 5; 8 7 9 2`], the object writes the data as [`1 2 4 5 8 7 9 2`].

The object supports C and C++ code generation.

To write data to a binary file:

1. Create a `dsp.BinaryFileWriter` object and set the properties of the object.
2. Call step to write to the binary file. In the first call to `step`, the object writes the header before the data. In subsequent calls, the object writes the data to the end of the file.

Note: Alternatively, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj)` and `y = obj()` perform equivalent operations.

Construction

`writer = dsp.BinaryFileWriter` creates a binary file writer object, `writer`, using the default properties.

`writer = dsp.BinaryFileWriter(fname)` sets the `Filename` property to `fname`.

`writer = dsp.BinaryFileWriter(fname,Name,Value, ...)` with `Filename` set to `fname`, and each property `Name` set to the specified `Value`. Unspecified properties have default values.

Example:

```
writer = dsp.BinaryFileWriter('myFilename.bin','HeaderStructure',struct('field1',1:10,
```

Properties

`Filename` — Name of the file

`'untitled.bin'` (default) | character vector

Name of the file to which the object writes the data, specified as a character vector. You must specify the full path for the file.

`HeaderStructure` — Header to write at the beginning of the file

`struct([])` (default) | structure

Header to write at the beginning of the file, specified as a structure. The structure can have an arbitrary number of fields. Each field of the structure must be a real matrix of a built-in type. For example, if `HeaderStructure` is set to `struct('field1',1:10,'field2',single(1))`, the object writes a header formed by 10 double-precision values, `(1:10)`, followed by one single precision value, `single(1)`. If you do not specify a header, the object sets this property to an empty structure, `struct([])`.

Methods

reset	Reset internal states of System object

step	Write data to the binary file

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Write and Read Binary Files

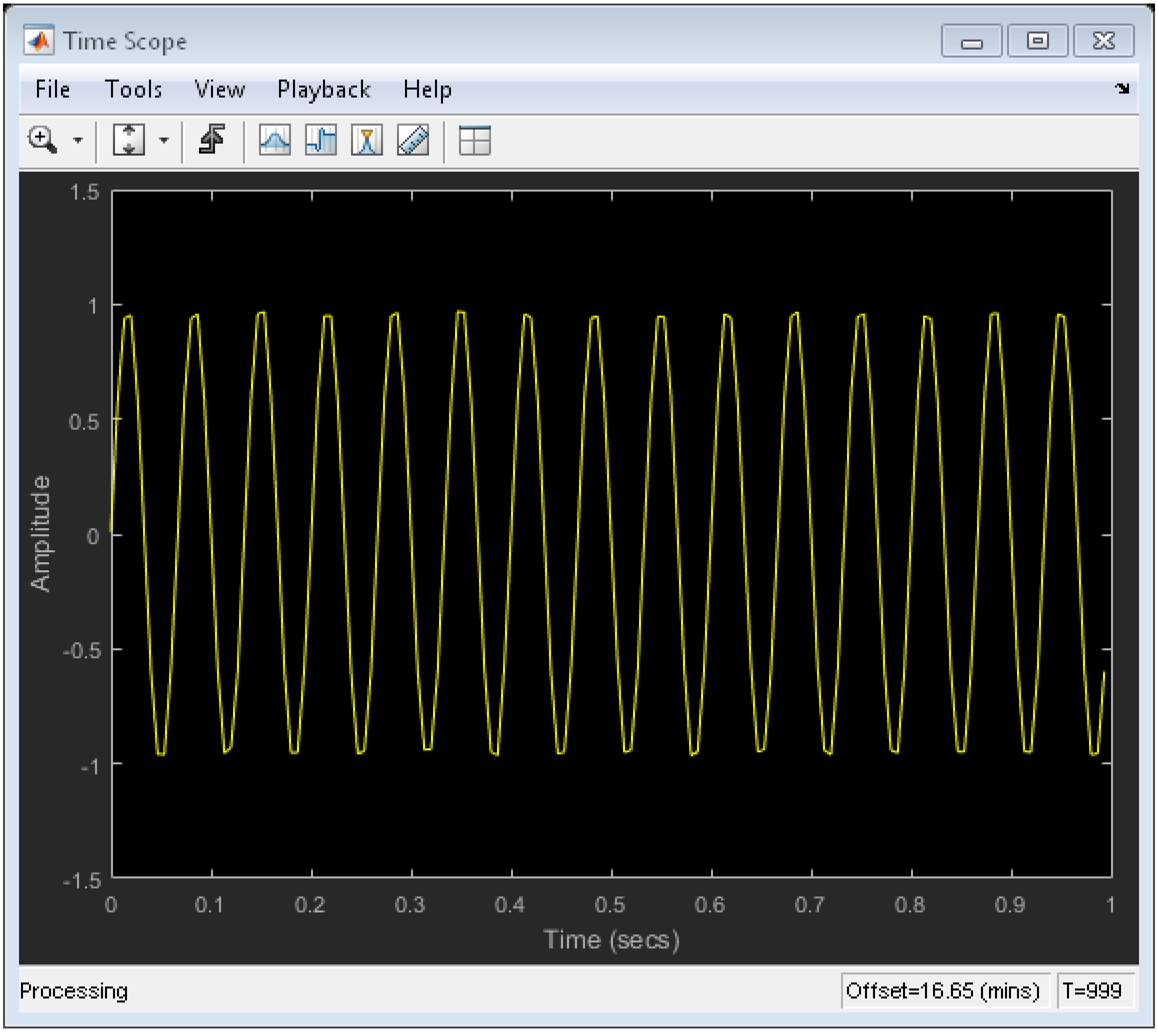
Create a binary file with a custom header using the `dsp.BinaryFileWriter` System object™. Write data to this file. Read the header and data using the `dsp.BinaryFileReader` System object.

Write the Data

Specify the file header and create a `dsp.BinaryFileWriter` object. The object writes the header first, followed by the data, to the `ex_file.bin` file. The data is a noisy sine wave signal. View the data in a time scope.

```
header = struct('A',[1 2 3 4],'B','x7');
writer = dsp.BinaryFileWriter('ex_file.bin','HeaderStructure',header);
L = 150;
sine = dsp.SineWave('SamplesPerFrame',L);
scopewriter = dsp.TimeScope(1,'YLimits',[-1.5 1.5],'SampleRate',...
    L,'TimeSpan',1);

for i = 1:1000
    data = sine()+0.01*randn(L,1);
    writer(data);
    scopewriter(data);
end
```



Release the writer so that the reader can access the data from this file.

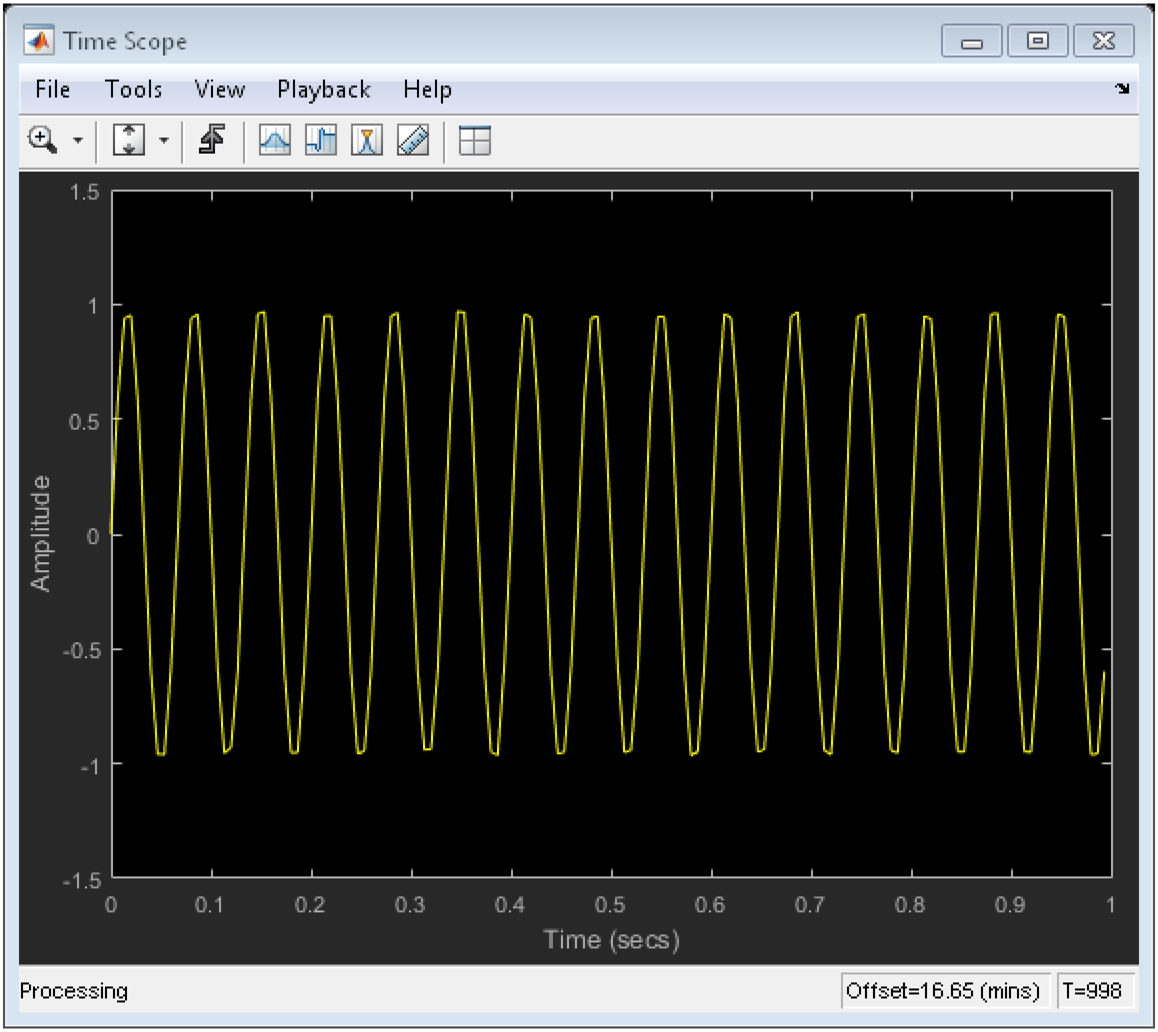
```
release(writer);
```

Read the Data

Specify the header using the `HeaderStructure` property of the reader object. If the exact header is not known, you must at least specify the prototype of the header, that is, its size and data type. The `dsp.BinaryFileReader` object reads the binary data from `ex_file.bin` until the end of file is reached. The data is read into a single channel (column) containing multiple frames, where each frame has 300 samples. View the data in a time scope.

```
headerPrototype = struct('A',[0 0 0 0],'B','-0');

reader = dsp.BinaryFileReader(...
    'ex_file.bin',...
    'HeaderStructure',headerPrototype,...
    'NumChannels',1,'SamplesPerFrame',300);
scopereader = dsp.TimeScope(1,'YLimits',[-1.5 1.5],'SampleRate',...
    L,'TimeSpan',1);
while ~isDone(reader)
    out = reader();
    scopereader(out);
end
release(reader);
```



Even when the reader reads data with a different frame size, the output in both time scopes matches exactly.

Write and Read Matrix Data

Use a `dsp.BinaryFileReader` System object™ to read data from a binary file in a row-major format.

Write the Data

Write the matrix A to the binary file Matdata.bin using a dsp.BinaryFileWriter object. The object writes the specified header followed by the data.

```
A = [1 2 3 8; 4 5 6 10; 7 8 9 11];
header = struct('A',[1 2],'B','x7');
writer = dsp.BinaryFileWriter('Matdata.bin','HeaderStructure',header);
writer(A);
```

Release the writer so that the reader can access the data.

```
release(writer);
```

Read the Data

Specify the header using the HeaderStructure property of the reader object. If the exact header is not known, you must at least specify the prototype of the header, that is, its size and data type. The dsp.BinaryFileReader object reads the binary file Matdata.bin until the end of file is reached. Specify the System object to read the data into 4 channels, with each channel containing 5 samples. Each loop of the iteration reads a channel (or frame) of data.

```
headerPrototype = struct('A',[0 0],'B','-0');
reader = dsp.BinaryFileReader('Matdata.bin','HeaderStructure',header,...
    'NumChannels',4,'SamplesPerFrame',5);
while ~isDone(reader)
    out = reader();
    display(out)
end
```

```
out =

     1     2     3     8
     4     5     6    10
     7     8     9    11
     0     0     0     0
     0     0     0     0
```

Each frame of out contains frames of the matrix A, followed by zeros to complete the frame. The original matrix A contains 4 channels with 3 samples in each channel. The reader is specified to read data into 4 channels, with each channel containing 5 samples.

Because there are not enough samples to complete the frame, the reader object appends zeros at the end of each frame.

Write Complex Data

This example shows how the `dsp.BinaryFileWriter` object writes complex data.

Create a `dsp.BinaryFileWriter` object which writes to a file named 'myfile.dat'. There is no header. The data is complex.

```
writer = dsp.BinaryFileWriter('myfile.dat');
data = [1 2 3 4]+1i*[5 6 7 8];
writer(data);
release(writer);
```

Read the data using the `dsp.BinaryFileReader` System object™. To view data in the format it is written to the file, set the `IsDataComplex` property to `false`. The reader object reads the data as a sequence of numbers in a row major format. Set `SamplesPerFrame` to 1 and `NumChannels` to 8.

```
reader = dsp.BinaryFileReader('myfile.dat','SamplesPerFrame',1,...
    'NumChannels',8);
s = struct([]);
reader.HeaderStructure = s;
dataRead = reader();
```

You can see that the real and imaginary components of the original data are sample interleaved.

```
display(dataRead);
```

```
dataRead =

     1     5     2     6     3     7     4     8
```

Write and Read Fixed-Point Data

The `dsp.BinaryFileWriter` and `dsp.BinaryFileReader` System objects do not support writing and reading fixed-point data. As a workaround, you can write the stored integer portion of the `fi` data, read the data, and use this value to reconstruct the `fi` data.

Write the Fixed-Point Data

Create a `fi` object to represent 100 signed random numbers with a word length of 14 and a fraction length of 12. Write the stored integer portion of the `fi` object to the data file `myFile.dat`. The built-in data type is `int16`, which can be computed using `class(storeIntData)`.

```
data = randn(100,1);
fiDataWriter = fi(data,1,14,12);
storeIntData = storedInteger(fiDataWriter);

writer = dsp.BinaryFileWriter('myFile.dat');
writer(storeIntData);
```

Release the writer so that the reader can access the data.

```
release(writer);
```

Read the Fixed-Point Data

Specify the reader to read the stored integer data as `int16` data with 100 samples per data frame. The real-world value of the fixed-point number can be represented using $2^{(-fractionLength)*(storedInteger)}$. If you know the signedness, word length, and fraction length of the fixed-point data, you can reconstruct the `fi` data using $fi(realValue, signedness, wordLength, fractionLength)$. In this example, the data is signed with a word length of 14 and a fraction length of 12.

```
reader = dsp.BinaryFileReader('Filename','myFile.dat','SamplesPerFrame',100,...
    'DataType','int16');
data = reader();
fractionLength = 12;
wordLength = 14;
realValue = 2^(-fractionLength)*double(data);

fiDataReader = fi(realValue,1,wordLength,fractionLength);
```

Verify that the writer data is the same as the reader data.

```
isequal(fiDataWriter,fiDataReader)
```

```
ans =

  logical
```

```
     1
```

Write and Read Character Data

The `dsp.BinaryFileWriter` and `dsp.BinaryFileReader` System objects do not support writing and reading characters. As a workaround, cast character data to one of the built-in data types and write the integer data. After the reader reads the data, convert the data to a character using the `char` function.

Write the Character Data

Cast a character into `uint8` using the `cast` function. Write the cast data to the data file `myFile.dat`.

```
data = 'binary_file';
castData = cast(data,'uint8');
writer = dsp.BinaryFileWriter('myFile.dat');
writer(castData);
```

Release the writer so that the reader can access the data.

```
release(writer);
```

Read the `uint8` Data

Specify the reader to read the cast data as `uint8` data.

```
reader = dsp.BinaryFileReader('myFile.dat','DataType','uint8','SamplesPerFrame',11);
readerData = reader();
charData = char(readerData);
```

Verify that the writer data is the same as the reader data. By default, the reader returns the data in a column-major format.

```
strcmp(data,charData.')
```

```
ans =

  logical

   1
```

Change the Endianness of the Data Before Writing the Data

By default, the `dsp.BinaryFileWriter` System object™ uses the endianness of the host machine. To change the endianness, use the `swapbytes` function.

Write a numeric array into `myfile.dat` using the `dsp.BinaryFileWriter` object. Before writing the data, change the endianness of the data using the `swapbytes` function.

```
data = [1 2 3 4 2 2];
swapData = swapbytes(data);
writer = dsp.BinaryFileWriter('myfile.dat');
writer(swapData);
```

System Objects

dsp.BinaryFileReader

Blocks

`Binary File Reader` | `Binary File Writer`

Introduced in R2016b

reset

System object: dsp.BinaryFileWriter
Package: dsp

Reset internal states of System object

Syntax

`reset(writer)`

Description

`reset(writer)` resets the position in the file at which the writer object writes the data. Upon calling reset, the writer object starts writing the data where the header data ends.

Introduced in R2016b

step

System object: dsp.BinaryFileWriter
Package: dsp

Write data to the binary file

Syntax

`step(writer,data)`

Description

Note: Alternatively, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj)` and `y = obj()` perform equivalent operations.

`step(writer,data)` writes data to the binary file in row-major format. Each call to `step` writes the elements of `data` at the end of the file. At the first call to `step`, the object writes the header first, followed by the data. If the header is empty, then no header is written.

The input data can be real or complex. For complex data, real and imaginary parts are interleaved. For example, if `data = [1 2; 3 4]+1j*[5 6; 7 8]`, then the object writes the elements as `1 5 2 6 3 7 4 8`.

Introduced in R2016b

dsp.BiquadFilter System object

Package: dsp

IIR filter using biquadratic structures

Description

The `BiquadFilter` object implements an IIR filter structure using biquadratic or second–order sections (SOS).

To implement an IIR filter structure using biquadratic or SOS:

1. Define and set up your biquadratic IIR filter. See “Construction” on page 4-232.
2. Call step to implement the IIR filter according to the properties of `dsp.BiquadFilter`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`biquad = dsp.BiquadFilter` returns a default biquadratic IIR filter, `biquad`, which independently filters each channel of the input over successive calls to the `step` method using the SOS section`[1 0.3 0.4 1 0.1 0.2]` with a direct-form II transposed structure.

`biquad = dsp.BiquadFilter('`*`PropertyName`*`',`*`PropertyValue`*`, ...)` returns a biquadratic filter object, `biquad`, with each property set to the specified value.

Properties

`Structure`

Filter structure

Specify the filter structure as one of | Direct form I | Direct form I transposed | Direct form II | Direct form II transposed |. The default is Direct form II transposed.

SOSMatrixSource

SOS matrix source

Specify the source of the SOS matrix as one of | Property | Input port|. The default is Property.

SOSMatrix

SOS matrix

Specify the second-order section (SOS) matrix as an N-by-6 matrix, where N is the number of sections in the filter. The default is [1 0.3 0.4 1 0.1 0.2]. Each row of the SOS matrix contains the numerator and denominator coefficients of the corresponding section of the filter. The system function, *H(z)*, of a biquad filter is:

$$H(z) = \frac{\sum_{k=0}^{2} b_k z^{-k}}{1 - \sum_{l=1}^{2} a_l z^{-l}}$$

The coefficients are ordered in the rows of the SOS matrix as (b_0, b_1,b_2, 1, $-a_1$, $-a_2$). You can use coefficients of real or complex values. This property applies only when you set the SOSMatrixSource on page 4-233 property to Property. The leading denominator coefficient of the biquad filter, a_0, equals 1 for each filter section, regardless of the specified value.

ScaleValues

Scale values for each biquad section

Specify the scale values to apply before and after each section of a biquad filter. ScaleValues must be either a scalar or a vector of length N+1, where N is the number of sections. If you set this property to a scalar, the scalar value is used as the gain value only before the first filter section. The remaining gain values are set to 1. If you set this property to a vector of N+1values, each value is used for a separate section of the filter.

This property applies only when you set the SOSMatrixSource on page 4-233 property to Property. The default is 1.

InitialConditions

Initial conditions for direct form II structures

Specify the initial conditions of the filter states when the Structure on page 4-232 property is one of | Direct form II | Direct form II transposed |. The number of states or delay elements (zeros and poles) in a direct-form II biquad filter equals twice the number of filter sections. You can specify the initial conditions as a scalar, vector, or matrix.

When you specify a scalar value, the biquad filter initializes all delay elements in the filter to that value. When you specify a vector of length equal to the number of delay elements in the filter, each vector element specifies a unique initial condition for the corresponding delay element.

The biquad filter applies the same vector of initial conditions to each channel of the input signal. When you specify a vector of length equal to the product of the number of input channels and the number of delay elements in the filter, each element specifies a unique initial condition for the corresponding delay element in the corresponding channel. When you specify a matrix with the same number of rows as the number of delay elements in the filter, and one column for each channel of the input signal, each element specifies a unique initial condition for the corresponding delay element in the corresponding channel. The default is the scalar 0.

NumeratorInitialConditions

Initial conditions on zeros side

Specify the initial conditions of the filter states on the side of the filter structure with the zeros. This property applies only when you set the Structure on page 4-232 property to one of | Direct form I | Direct form I transposed |. The number of states or delay elements in the numerator of a direct-form I biquad filter equals twice the number of filter sections. You can specify the initial conditions as a scalar, vector, or matrix. When you specify a scalar, the biquad filter initializes all delay elements on the zeros side in the filter to that value. When you specify a vector of length equal to the number of delay elements on the zeros side in the filter, each vector element specifies a unique initial condition for the corresponding delay element on the zeros side.

The biquad filter applies the same vector of initial conditions to each channel of the input signal. When you specify a vector of length equal to the product of the number of input channels and the number of delay elements on the zeros side in the filter, each element specifies a unique initial condition for the corresponding delay element on the zeros side in the corresponding channel. When you specify a matrix with the same number of rows as the number of delay elements on the zeros side in the filter, and one column for each channel of the input signal, each element specifies a unique initial condition for the corresponding delay element on the zeros side in the corresponding channel. The default is the scalar `0`.

`DenominatorInitialConditions`

Initial conditions on poles side

Specify the initial conditions of the filter states on the side of the filter structure with the poles. This property only applies when you set the `Structure` on page 4-232 property to one of `| Direct form I | Direct form I transposed |`. The number of denominator states, or delay elements, in a direct-form I (noncanonic) biquad filter equals twice the number of filter sections. You can specify the initial conditions as a scalar, vector, or matrix. When you specify a scalar, the biquad filter initializes all delay elements on the poles side of the filter to that value. When you specify a vector of length equal to the number of delay elements on the poles side in the filter, each vector element specifies a unique initial condition for the corresponding delay element on the poles side.

The object applies the same vector of initial conditions to each channel of the input signal. When you specify a vector of length equal to the product of the number of input channels and the number of delay elements on the poles side in the filter, each element specifies a unique initial condition for the corresponding delay element on the poles side in the corresponding channel. When you specify a matrix with the same number of rows as the number of delay elements on the poles side in the filter, and one column for each channel of the input signal, each element specifies a unique initial condition for the corresponding delay element on the poles side in the corresponding channel. The default is the scalar `0`.

`OptimizeUnityScaleValues`

Optimize unity scale values

When this Boolean property is set to `true`, the biquad filter removes all unity scale gain computations. This reduces the number of computations and increases the fixed-point accuracy. This property applies only when you set the `SOSMatrixSource` on page 4-233 property to `Property`. The default is `true`.

`ScaleValuesInputPort`

How to specify scale values

Select how to specify scale values. This property applies only when the `SOSMatrixSource` on page 4-233 property is `Input port`. By default, this property is `true`, and the scale values are specified via the input port. When this property is `false`, all scale values are 1.

Fixed-Point Properties

`RoundingMethod`

Rounding method for fixed-point operations

Specify the rounding method as one of `| Ceiling | Convergent | Floor | Nearest | Round | Simplest | Zero |`. The default is `Floor`.

`OverflowAction`

Overflow action for fixed-point operations

Specify the overflow action as one of `| Wrap | Saturate |`. The default is `Wrap`.

`MultiplicandDataType`

Multiplicand word and fraction lengths

Specify the multiplicand fixed-point data type as one of `| Same as output | Custom |`. This property applies only when you set the `Structure` on page 4-232 property to `Direct form I transposed`. The default is `Same as output`.

`CustomMultiplicandDataType`

Custom multiplicand word and fraction lengths

Specify the multiplicand fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when you set the

`MultiplicandDataType` on page 4-236 property to `Custom`. The default is `numerictype([],32,30)`.

SectionInputDataType

Section input word and fraction lengths

Specify the section input fixed-point data type as one of | `Same as input` | `Custom` |. The default is `Same as input`.

CustomSectionInputDataType

Custom section input word and fraction lengths

Specify the section input fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when you set the `SectionInputDataType` on page 4-237 property to `Custom`. The default is `numerictype([],16,15)`.

SectionOutputDataType

Section output word and fraction lengths

Specify the section output fixed-point data type as one of | `Same as section input` | `Custom` |. The default is `Same as section input`.

CustomSectionOutputDataType

Custom section output word and fraction lengths

Specify the section output fixed-point type as a signed, scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when you set the `SectionOutputDataType` on page 4-237 property to `Custom`. The default is `numerictype([],16,15)`.

NumeratorCoefficientsDataType

Numerator coefficients word and fraction lengths

Specify the numerator coefficients fixed-point data type as one of | `Same word length as input` | `Custom` |. This property applies only when you set the `SOSMatrixSource` on page 4-233 property to `Property`. Setting this property also sets the `DenominatorCoefficientsDataType` on page 4-238 and `ScaleValuesDataType` on page 4-238 properties to the same value. The default is `Same word length as input`.

CustomNumeratorCoefficientsDataType

Custom numerator coefficients word and fraction lengths

Specify the numerator coefficients fixed-point type as a `numerictype` object with a `Signedness` of `Auto`. This property applies only when you set the `SOSMatrixSource` on page 4-233 property to `Property` and the `NumeratorCoefficientsDataType` on page 4-237 property to `Custom`. The word length of the `CustomNumeratorCoefficientsDataType` on page 4-238, `CustomDenominatorCoefficientsDataType` on page 4-238, and `CustomScaleValuesDataType` on page 4-239 properties must be the same. The default is `numerictype([],16,15)`.

DenominatorCoefficientsDataType

Denominator coefficients word and fraction lengths

Specify the denominator coefficients fixed-point data type as one of `| Same word length as input | Custom |`. This property applies only when you set the `SOSMatrixSource` on page 4-233 property to `Property`. Setting this property also sets the `NumeratorCoefficientsDataType` on page 4-237 and `ScaleValuesDataType` on page 4-238 properties to the same value. The default is `Same word length as input`.

CustomDenominatorCoefficientsDataType

Custom denominator coefficients word and fraction lengths

Specify the denominator coefficients fixed-point type as a `numerictype` object with a `Signedness` of `Auto`. This property applies only when you set the `SOSMatrixSource` on page 4-233 property to `Property` and the `DenominatorCoefficientsDataType` on page 4-238 property to `Custom`. The `CustomNumeratorCoefficientsDataType` on page 4-238, `CustomDenominatorCoefficientsDataType` on page 4-238, and `CustomScaleValuesDataType` on page 4-239 properties must have the same word lengths. The default is `numerictype([],16,15)`.

ScaleValuesDataType

Scale values word and fraction lengths

Specify the scale values fixed-point data type as one of | Same word length as input | Custom |. This property applies only when you set the SOSMatrixSource on page 4-233 property to Property. Setting this property also sets the NumeratorCoefficientsDataType on page 4-237 and DenominatorCoefficientsDataType on page 4-238 properties to the same value. The default is Same word length as input.

CustomScaleValuesDataType

Custom scale values word and fraction lengths

Specify the scale values fixed-point type as a numerictype object with a Signedness of Auto. This property applies only when you set the SOSMatrixSource on page 4-233 property to Property and the ScaleValuesDataType on page 4-238 property to Custom. The CustomNumeratorCoefficientsDataType on page 4-238, CustomDenominatorCoefficientsDataType on page 4-238, and CustomScaleValuesDataType on page 4-239 properties must have the same word lengths. The default is numerictype([],16,15).

NumeratorProductDataType

Numerator product word and fraction lengths

Specify the mode to determine the numerator product fixed-point data type as:

- Same as input (default) — The numerator product word and fraction lengths are same as that of the input.
- Custom — Enables the CustomNumeratorProductDataType property, which you can use to specify the custom numerator product data type. Specify the data type as a numerictype object.
- Full precision — Use full-precision rules to specify the data type. These rules provide the most accurate fixed-point numerics. The rules prevent quantization from occurring within the object. Bits are added, as needed, so that no roundoff or overflow occurs. For more information, see “Full Precision for Fixed-Point System Objects”.

Setting this property also sets the DenominatorProductDataType on page 4-240 property to the same value.

CustomNumeratorProductDataType

Custom numerator product word and fraction lengths

Specify the product fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when you set the `NumeratorProductDataType` on page 4-239 property to `Custom`. The `CustomNumeratorProductDataType` on page 4-239 and `CustomDenominatorProductDataType` on page 4-240 properties must have the same word lengths. The default is `numerictype([],32,30)`.

DenominatorProductDataType

Denominator product word and fraction lengths

Specify the mode to determine the denominator product fixed-point data type as:

- `Same as input` (default) — The denominator product word and fraction lengths are same as that of the input.
- `Custom` — Enables the `CustomDenominatorProductDataType` property, which you can use to specify the custom denominator product data type. Specify the data type as a `numerictype` object.
- `Full precision` — Use full-precision rules to specify the data type. These rules provide the most accurate fixed-point numerics. The rules prevent quantization from occurring within the object. Bits are added, as needed, so that no roundoff or overflow occurs. For more information, see "Full Precision for Fixed-Point System Objects".

Setting this property also sets the `NumeratorProductDataType` on page 4-239 property to the same value.

CustomDenominatorProductDataType

Custom denominator product word and fraction lengths

Specify the product fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when you set the `DenominatorProductDataType` on page 4-240 to `Custom`. The `CustomNumeratorProductDataType` on page 4-239 and `CustomDenominatorProductDataType` on page 4-239 properties must have the same word lengths. The default is `numerictype([],32,30)`.

NumeratorAccumulatorDataType

Numerator accumulator word and fraction lengths

Specify the numerator accumulator fixed-point data type as one of `| Same as input | Same as product | Custom |`. Setting this property also sets the

`DenominatorAccumulatorDataType` on page 4-241 property to the same value. The default is `Same as product`.

CustomNumeratorAccumulatorDataType

Custom numerator accumulator word and fraction lengths

Specify the numerator accumulator fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when you set the `NumeratorAccumulatorDataType` on page 4-240 property to `Custom`. The `CustomNumeratorAccumulatorDataType` on page 4-241 and `CustomDenominatorAccumulatorDataType` on page 4-241 properties must have the same word lengths. The default is `numerictype([],32,30)`.

DenominatorAccumulatorDataType

Denominator accumulator word and fraction lengths

Specify the denominator accumulator fixed-point data type as one of `| Same as input | Same as product | Custom|`. Setting this property also sets the `NumeratorAccumulatorDataType` on page 4-240 property to the same value. The default is `Same as product`.

CustomDenominatorAccumulatorDataType

Custom denominator accumulator word and fraction lengths

Specify the denominator accumulator fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when you set the `DenominatorAccumulatorDataType` on page 4-241 property to `Custom`. The `CustomNumeratorAccumulatorDataType` on page 4-241 and `CustomDenominatorAccumulatorDataType` on page 4-241 properties must have the same word lengths. The default is `numerictype([],32,30)`.

StateDataType

State word and fraction lengths

Specify the state fixed-point data type as one of `| Same as input | Same as accumulator | Custom|`. This property applies when you set the `Structure` on page 4-232 property to `Direct form II` or `Direct form II transposed`. The default is `Same as accumulator`.

CustomStateDataType

Custom state word and fraction lengths

Specify the state fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when you set the `StateDataType` on page 4-241 property to `Custom`. The default is `numerictype([],16,15)`.

NumeratorStateDataType

Numerator state word and fraction lengths

Specify the numerator state fixed-point data type as one of `| Same as input | Same as accumulator | Custom |`. Setting this property also sets the `DenominatorStateDataType` on page 4-242 property to the same value. This property applies only when you set the `Structure` on page 4-232 property to `Direct form I transposed`. The default is `Same as accumulator`.

CustomNumeratorStateDataType

Custom numerator state word and fraction lengths

Specify the numerator state fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when you set the `StateDataType` on page 4-241 property to `Custom`. The `CustomNumeratorProductDataType` on page 4-239 and `CustomDenominatorProductDataType` on page 4-240 properties must have the same word lengths. The default is `numerictype([],16,15)`.

DenominatorStateDataType

Denominator state word and fraction lengths

Specify the denominator state fixed-point data type as one of `| Same as input | Same as accumulator | Custom |`. Setting this property also sets the `NumeratorStateDataType` on page 4-242 property to the same value. This property applies only when you set the `Structure` on page 4-232 property to `Direct form I transposed`. The default is `Same as accumulator`.

CustomDenominatorStateDataType

Custom denominator state word and fraction lengths

Specify the denominator state fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when you set the `StateDataType` on page 4-241 property to `Custom`. The `CustomNumeratorStateDataType` on page 4-242 and `CustomDenominatorStateDataType` on page 4-242 properties must have the same word lengths. The default is `numerictype([],16,15)`.

`OutputDataType`

Output word and fraction lengths

Specify the output fixed-point data type as one of `| Same as input | Same as accumulator | Custom |`. The default is `Same as accumulator`.

`CustomOutputDataType`

Custom output word and fraction lengths

Specify the output fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when you set the `OutputDataType` on page 4-243 property to `Custom`. The default is `numerictype([],16,15)`.

Methods

freqz	Frequency response
fvtool	Open filter visualization tool
impz	Impulse response
phasez	Unwrapped phase response
reset	Reset states of biquad filter object
step	Filter input with biquad filter object

More "Analysis Methods for Filter System Objects" on page 3-2.

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)

Common to All System Objects	
`release`	Allow System object property value changes

Examples

Filter a Signal Using Biquadratic Filter

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

Use a fourth order, lowpass biquadratic filter object with a normalized cutoff frequency of 0.4 to filter high frequencies from an input signal. Display the result as a power spectrum using the Spectrum Analyzer.

```
t = (0:1000)'/8e3;
xin = sin(2*pi*0.3e3*t)+sin(2*pi*3e3*t); % Input is 0.3 &amp;
                                        % 3kHz sinusoids
src = dsp.SignalSource(xin, 100);
sink = dsp.SignalSink;

[z,p,k] = ellip(4,1,60,.4);    % Set up the filter
[s,g] = zp2sos(z,p,k);
biquad = dsp.BiquadFilter('Structure','Direct form I', ...
   'SOSMatrix',s,'ScaleValues',g);

sa = dsp.SpectrumAnalyzer('SampleRate',8e3,...
    'PlotAsTwoSidedSpectrum',false,...
    'OverlapPercent', 80,'PowerUnits','dBW',...
    'YLimits', [-160 -10]);

while ~isDone(src)
     input = src();
     filteredOutput = biquad(input);
     sink(filteredOutput);
     sa(filteredOutput)
end

filteredResult = sink.Buffer;
fvtool(biquad,'Fs',8000)
```

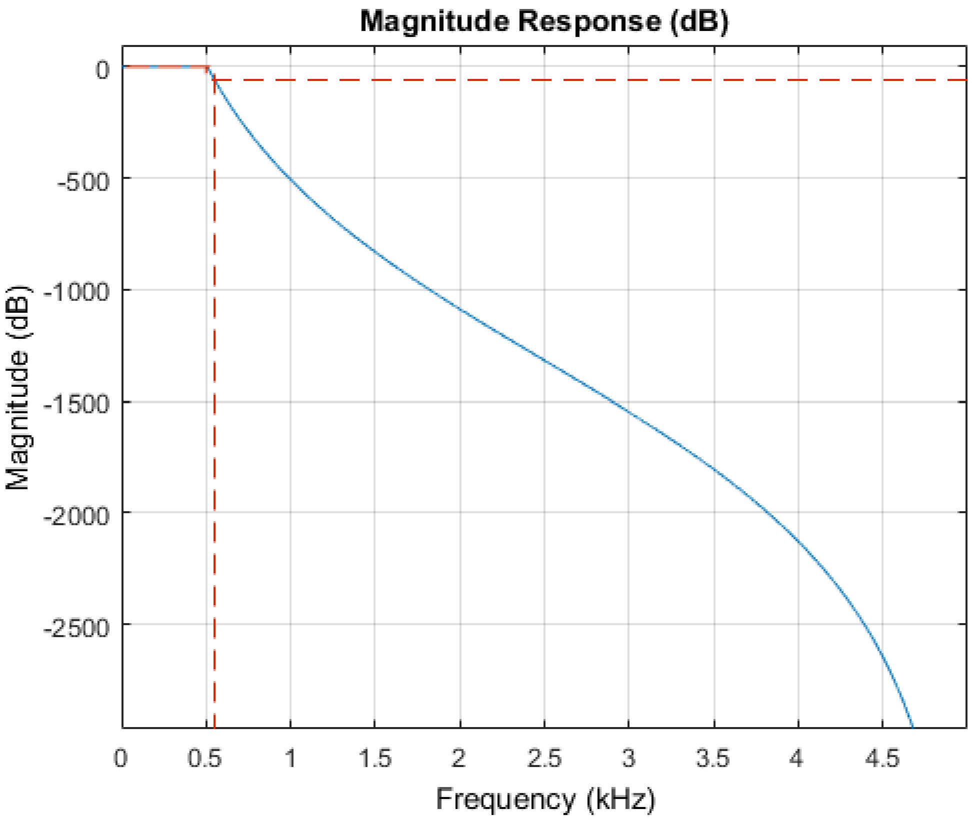
lpfilter =

  dsp.BiquadFilter with properties:

                 Structure: 'Direct form II'
           SOSMatrixSource: 'Property'
                 SOSMatrix: [42×6 double]
```

```
              ScaleValues: [43×1 double]
        InitialConditions: 0
 OptimizeUnityScaleValues: true

Use get to show all properties
```



Algorithm

This object implements the algorithm, inputs, and outputs described on the `Biquad Filter` block reference page. The object properties correspond to the block parameters, except:

- **Coefficient source**
- **Action when the a0 values of the SOS matrix are not one** – the biquad filter object assumes the zero-th-order denominator coefficient equals 1 regardless of the specified value. The biquad filter object does not support the `Error` or `Warn` options found in the corresponding block.

Both this object and its corresponding block support variable-size input. This means that the step method can handle an input which is changing in size.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See "System Objects in MATLAB Code Generation" (MATLAB Coder).

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

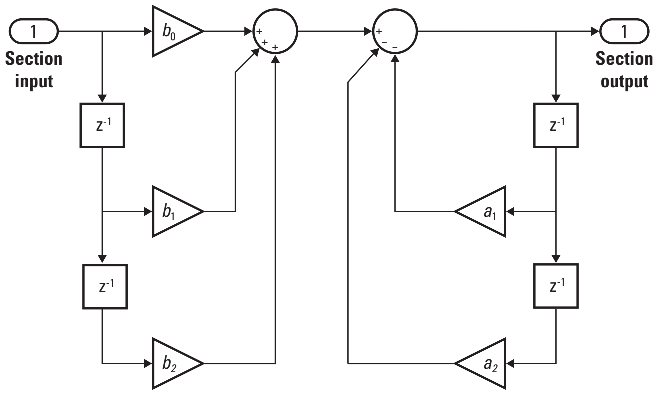
This object supports HDL code generation if you have the HDL Coder installed. HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

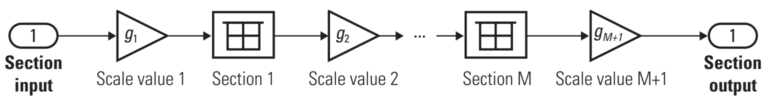
Fixed-Point Conversion

Design and simulate fixed-point algorithms using Fixed-Point Designer™.

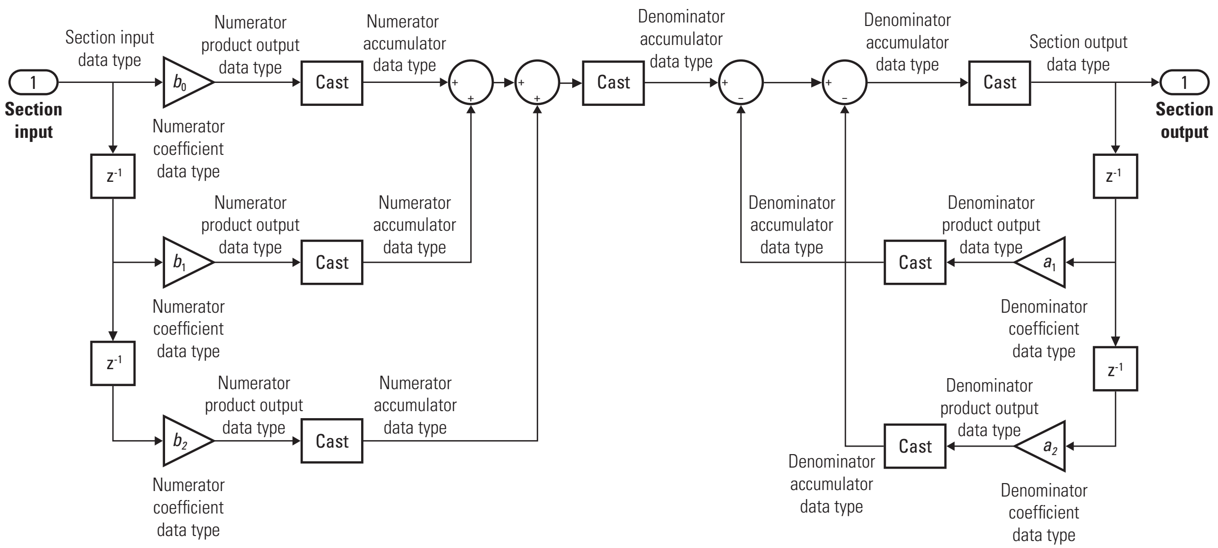
The following diagrams show the data types used in the `dsp.BiquadFilter` object when the input is fixed-point. For each filter structure the object supports, the data types shown in the diagrams can be set through the respective fixed-point properties of the object.

Direct Form I



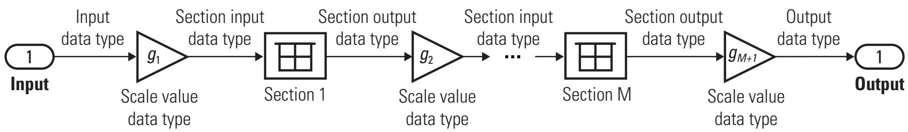


The following diagram shows the data types for one section of the filter for fixed-point signals.

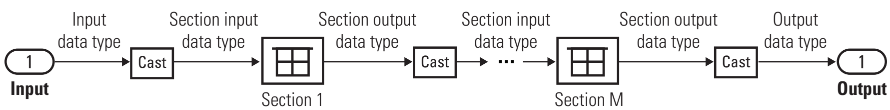


The following diagrams show the fixed-point data types between filter sections.

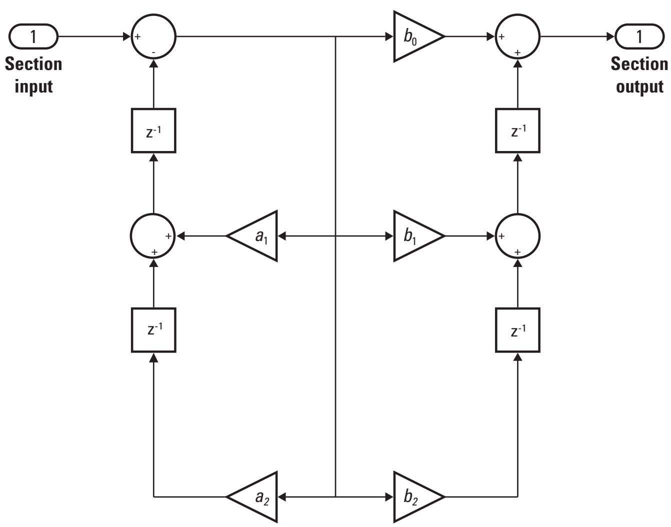
When the data is not optimized:

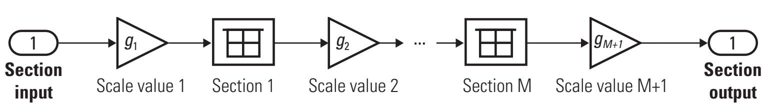


When you specify `OptimizeUnityScaleValues` to `true`, and scale values to 1:

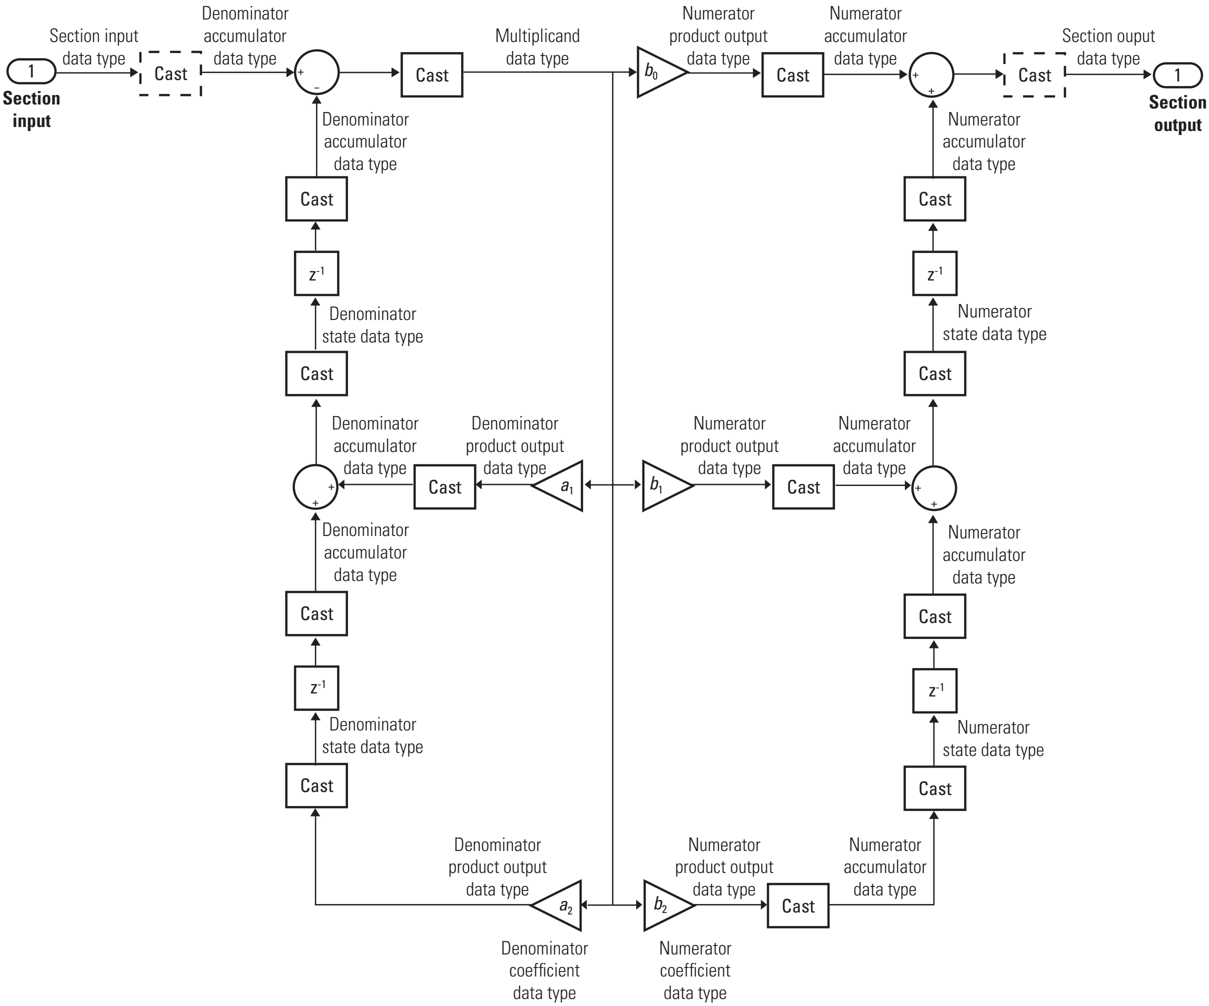


Direct Form I Transposed





The following diagram shows the data types for one section of the filter for fixed-point signals.



The dashed casts are omitted when you specify `OptimizeUnityScaleValues` to `true`, and scale values to 1.

System Objects

dsp.FIRFilter | dsp.IIRFilter

Blocks

`Biquad Filter`

Introduced in R2012a

freqz

System object: dsp.BiquadFilter
Package: dsp

Frequency response

Syntax

```
[h,w] = freqz(biquad)
[h,w] = freqz(biquad,n)
[h,w] = freqz(biquad,Name,Value)
freqz(biquad)
```

Description

`[h,w] = freqz(biquad)` returns the complex, 8192–element frequency response vector `h`, and the corresponding frequencies `w` in radians/sample.

`[h,w] = freqz(biquad,n)` returns the complex, n-element frequency response vector `h`, and the corresponding frequencies `w` in radians/sample, using `n` samples.

`[h,w] = freqz(biquad,Name,Value)` returns the frequency response and the corresponding frequencies, with additional options specified by one or more Name, Value pair arguments.

`freqz(biquad)` uses FVTool to plot the magnitude and unwrapped phase of the frequency response of the filter System object `biquad`.

fvtool

System object: dsp.BiquadFilter
Package: dsp

Open filter visualization tool

Syntax

```
fvtool(biquad)
fvtool(biquad,'Arithmetic',ARITH,...)
```

Description

`fvtool(biquad)` performs an analysis and computes the magnitude response of the filter System object `biquad`.

`fvtool(biquad,'Arithmetic',ARITH,...)` analyzes the filter System object `biquad`, based on the arithmetic specified in the ARITH input. ARITH can be set to one of 'double', 'single', or 'fixed'. The analysis tool assumes a double precision filter when the arithmetic input is not specified and the filter System object is in an unlocked state. The 'Arithmetic' input is only relevant for the analysis of filter System objects.

impz

System object: dsp.BiquadFilter
Package: dsp

Impulse response

Syntax

```
[h,t] = impz(biquad)
[h,t] = impz(biquad,Name,Value)
impz(biquad)
```

Description

`[h,t] = impz(biquad)` returns the impulse response `h`, and the corresponding time points `t` at which the impulse response of`biquad` is computed.

`[h,t] = impz(biquad,Name,Value)` returns the impulse response `h`, and the corresponding time points`t` , with additional options specified by one or more Name, Value pair arguments.

`impz(biquad)` uses FVTool to plot the impulse response of the filter System object `biquad`.

Note: You can use `impz` for both real and complex filters. When you omit the output arguments, `impz` plots only the real part of the impulse response.

---

phasez

System object: dsp.BiquadFilter
Package: dsp

Unwrapped phase response

Syntax

```
[phi,w] = phasez(biquad)
[phi,w] = phasez(biquad,n)
[phi,w] = phasez(biquad,Name,Value)
phasez(biquad)
```

Description

`[phi,w] = phasez(biquad)` returns the 8192–element phase response vector `phi`, and the corresponding frequencies `w` in radians/sample.

`[phi,w] = phasez(biquad,n)` returns the n-element phase response vector `phi`, and the corresponding frequencies `w` in radians/sample, using `n` samples.

`[phi,w] = phasez(biquad,Name,Value)` returns the phase response and the corresponding frequencies, with additional options specified by one or more Name, Value pair arguments.

`phasez(biquad)` uses FVTool to plot the phase response of the filter System object `biquad`.

reset

System object: dsp.BiquadFilter
Package: dsp

Reset states of biquad filter object

Syntax

```
reset(biquad)
```

Description

`reset(biquad)` resets the filter states of the biquad filter object,`biquad`, to the specified initial conditions. After the `step` method applies the biquad filter object to nonzero input data, the states may change. Invoking the `step` method again without first invoking the `reset` method may produce different outputs for an identical input.

Reset a Biquad Filter

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

```
n =0:20;
x = cos(pi/4*n)+sin(pi/2*n);
biquad = dsp.BiquadFilter;
y = biquad(x');
```

Call the biquad filter without invoking reset.

```
y1 = biquad(x');
isequal(y,y1)
```

```
ans =

  logical
```

```
   0
```

Reset filter states to zero.

```
reset(biquad);
```

Call the biquad filter again.

```
y2 = biquad(x');
isequal(y,y2)
```

```
ans =

  logical

   1
```

step

System object: dsp.BiquadFilter
Package: dsp

Filter input with biquad filter object

Syntax

```
Y = step(biquad,X)
Y = step(biquad,X,NUM,DEN)
Y = step(biquad,X,NUM,DEN,G)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(biquad,X)` filters the real or complex input signal `X` , and outputs the filtered values, `Y`. The biquad filter object filters each channel of the input signal over successive calls to the `step` method.

`Y = step(biquad,X,NUM,DEN)` filters the input using `NUM` as the numerator coefficients, and `DEN` as the denominator coefficients of the biquad filter. `NUM` must be a 3-by-N numeric matrix and `DEN` must be a 2-by-N numeric matrix, where N is the number of biquad filter sections. The object assumes that the first denominator coefficient of each section is 1. This configuration applies when the `SOSMatrixSource` property is `Input port` and the `ScaleValuesInputPort` property is `false`.

`Y = step(biquad,X,NUM,DEN,G)` specifies the scale values, `G`, of the biquad filter. `G` must be a 1-by-(N+1) numeric vector, where `N` is the number of biquad filter sections. This configuration applies when the `SOSMatrixSource` property is `Input Port` and the `ScaleValuesInputPort` property is true.

Note: `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

dsp.BlockLMSFilter System object

Package: dsp

Compute output, error, and weights using Block LMS adaptive algorithm

Description

The `BlockLMSFilter` object computes output, error, and weights using the Block LMS adaptive algorithm.

To compute the output, error, and weights:

1. Define and set up your adaptive FIR filter. See "Construction" on page 4-265.
2. Call step to compute the output, error, and weights according to the properties of `dsp.BlockLMSFilter`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`blms = dsp.BlockLMSFilter` returns an adaptive FIR filter, `blms`, that filters the input signal and computes filter weights based on the Block Least Mean Squares (LMS) algorithm.

`blsm = dsp.BlockLMSFilter('`*`PropertyName`*`',`*`PropertyValue`*`,...)` returns an adaptive FIR filter, `blms`, with each specified property set to the specified value.

`blms = dsp.BlockLMSFilter(length,blocksize,'`*`PropertyName`*`',...`
`PropertyValue``,...)` returns an adaptive FIR filter, `blms`, with the `Length` property set to `length`, the `BlockSize` property set to `blocksize`, and other specified properties set to the specified values.

Properties

Length

Length of FIR filter weights vector

Specify the length of the FIR filter weights vector as a positive integer scalar. The default is 32.

BlockSize

Number of samples acquired before weight adaptation

Specify the number of samples of the input signal to acquire before the object updates the filter weights. The input frame length must be an integer multiple of the block size. The default is 32.

StepSizeSource

Source of adaptation step size

Choose to specify the adaptation step size factor as Property or Input port. The default is Property.

StepSize

Adaptation step size

Specify the adaptation step size factor as a scalar, nonnegative numeric value. The default is 0.1. This property applies only when you set the StepSizeSource on page 4-266 property to 'Property'. This property is tunable.

LeakageFactor

Leakage factor used in Leaky LMS algorithm

Specify the leakage factor used in Leaky LMS algorithm as a scalar numeric value between 0 and 1, both inclusive. When the value is less than 1, the System object implements a leaky LMS algorithm. The default is 1, providing no leakage in the adapting algorithm. This property is tunable.

InitialWeights

Initial values of filter weights

Specify the initial values of the filter weights as a scalar or a vector of length equal to the `Length` on page 4-266 property value. The default is `0`.

AdaptInputPort

Additional input to enable adaptation of filter weights.

Specify when the object should adapt the filter weights. By default, the value of this property is `false`, and the filter continuously updates the filter weights. When this property is set to `true`, an adaptation control input is provided to the `step` method. If the value of this input is nonzero, the filter continuously updates the filter weights. If the input is zero, the filter weights remain at their current value.

WeightsResetInputPort

Additional input to enable weights reset

Specify whether the FIR filter can reset the filter weights. By default, the value of this property is `false`, and the object does not reset the weights. When this property is set to `true`, a reset control input is provided to the `step` method, and the `WeightsResetCondition` on page 4-267 property applies. The object resets the filter weights based on the values of the `WeightsResetCondition` on page 4-267 property and the reset input to the `step` method.

WeightsResetCondition

Condition that triggers the resetting of filter weights

Specify the event to reset the filter weights as one of `Rising edge`, `Falling edge`, `Either edge`, or `Non-zero`. The object resets the filter weights based on the values of this property and the reset input to the `step` method. This property applies only when you set the `WeightsResetInputPort` on page 4-267 property to `true`. The default is `Non-zero`.

WeightsOutputPort

Output filter weights

Set this property to `true` to output the adapted filter weights. The default is `true`.

Methods

msesim	Mean-square error for Block LMS filter
reset	Reset internal states of adaptive FIR filter object
step	Filter inputs using Block LMS algorithm

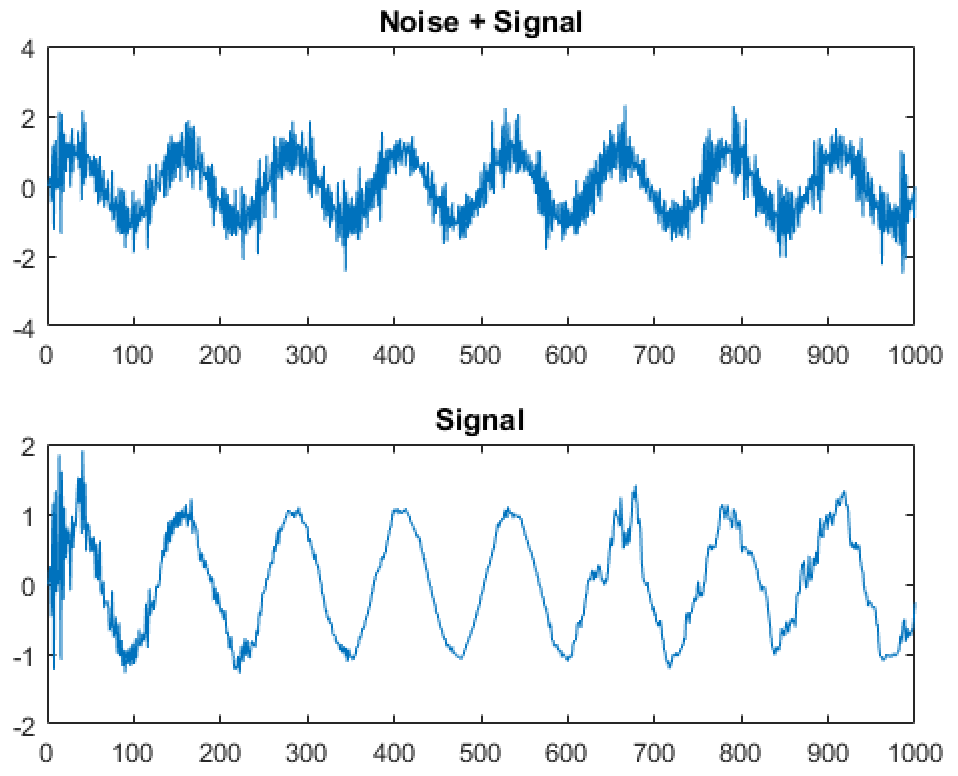
Common to All System Objects	
clone	Create System object with same property values
getNumInpu	Expected number of inputs to a System object
getNumOutp	Expected number of outputs of a System object
isLocked	Check locked states of a System object (logical)
release	Allow System object property value changes

Examples

Remove Noise Using Block LMS Adaptive Algorithm

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

```
blms = dsp.BlockLMSFilter(10,5);
blms.StepSize = 0.01;
blms.WeightsOutputPort = false;
filt = dsp.FIRFilter;
filt.Numerator = fir1(10,[.5, .75]);
x = randn(1000,1); % Noise
d = filt(x) + sin(0:.05:49.95)'; % Noise + Signal
[y, err] = blms(x, d);
subplot(2,1,1);
plot(d);
title('Noise + Signal');
subplot(2,1,2);
plot(err);
title('Signal');
```



Algorithms

This object implements the algorithm, inputs, and outputs described on the `Block LMS Filter` block reference page. The object properties correspond to the block parameters.

See Also

dsp.FIRFilter | dsp.LMSFilter

Introduced in R2012a

msesim

System object: dsp.BlockLMSFilter
Package: dsp

Mean-square error for Block LMS filter

Syntax

```
MSE = msesim(sysObj,X,D)
[MSE,MEANW,W,TRACEK] = msesim(sysObj,X,D)
[...] = msesim(sysObj,X,D,M)
```

Description

`MSE = msesim(sysObj,X,D)` returns a sequence of mean-square errors. This column vector contains estimates of the mean-square error of the adaptive filter at each time instant. The length of `MSE` is equal to `SIZE(X,1)`. The columns of the matrix `X` contain individual input signal sequences, and the columns of the matrix `D` contain corresponding desired response signal sequences.

`[MSE,MEANW,W,TRACEK] = msesim(sysObj,X,D)` calculates three parameters corresponding to the simulated behavior of the adaptive filter defined by `sysObj`. `MEANW` is a sequence of coefficient vector means. The columns of this matrix contain estimates of the mean values of the adaptive filter coefficients at each time instant. The dimensions of `MEANW` are `(SIZE(X,1))` by `(sysObj.length)`. `W` is an estimate of the final values of the adaptive filter coefficients for the algorithm corresponding to `sysObj`. `TRACEK` is a sequence of total coefficient error powers. This column vector contains estimates of the total coefficient error power of the adaptive filter at each time instant. The length of `TRACEK` is equal to `SIZE(X,1)`.

`[...] = msesim(sysObj,X,D,M)` specifies an optional decimation factor for computing `MSE`, `MEANW`, and `TRACEK`. If `M > 1`, every M^{th} predicted value of each of these sequences is saved. If omitted, the value of `M` is the default, which is 1.

System Identification of an FIR Filter Using Block LMS Filter

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

```
fir = fir1(31,0.5);
firFilter = dsp.FIRFilter('Numerator',fir); % FIR system to be identified
iirFilter = dsp.IIRFilter('Numerator',sqrt(0.75),...
        'Denominator',[1 -0.5]);
x = iirFilter(sign(randn(2000,25)));
n = 0.1*randn(size(x));            % Observation noise signal
d = firFilter(x)+n;                  % Desired signal
l = 32;                            % Filter length
mu = 0.008;                        % Block LMS Step size.
m  = 32;                           % Decimation factor for analysis
                                   % and simulation results
fir = dsp.BlockLMSFilter(l,'StepSize',mu);
[simmse,meanWsim,Wsim,traceKsim] = msesim(fir,x,d,m);
plot(m*(1:length(simmse)),10*log10(simmse));

reset

System object: dsp.BlockLMSFilter
Package: dsp

Reset internal states of adaptive FIR filter object

Syntax

```
reset(blms)
```

Description

`reset(blms)` sets the internal states of the `BlockLMSFilter` object `blms` to their initial values.

step

System object: dsp.BlockLMSFilter
Package: dsp

Filter inputs using Block LMS algorithm

Syntax

```
[Y,ERR,WTS] = step(blms,X,D)
[Y,ERR] = step(blms,X,D)
[...] = step(blms,X,D,MU)
[...] = step(blms,X,D,A)
[...] = step(blms,X,D,R)
[Y,ERR,WTS] = step(blms,X,D,MU,A,R)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`[Y,ERR,WTS] = step(blms,X,D)` filters the input `X`, using `D` as the desired signal, and returns the filtered output in `Y`. The filter error is in `ERR`, and the estimated filter weights is in `WTS`. The filter weights update once for every block of data that the object processes.

`[Y,ERR] = step(blms,X,D)` returns only the filtered output in `Y` and the filter error in `ERR`, when the `WeightsOutputPort` property is `false`.

`[...] = step(blms,X,D,MU)` uses `MU` as the step size, when you set the `StepSizeSource` property to `Input port`.

`[...] = step(blms,X,D,A)` uses `A` as the adaptation control, when you set the `AdaptInputPort` property to `true`. When `A` is nonzero, the filter continuously updates the filter weights. When `A` is zero, the filter weights remain constant.

`[...] = step(blms,X,D,R)` uses `R` as a reset signal, when you set the `WeightsResetInputPort` property to `true`. Use the `WeightsResetCondition` property to set the reset trigger condition. If a reset event occurs, the filter resets the filter weights to their initial values.

`[Y,ERR,WTS] = step(blms,X,D,MU,A,R)` filters input `X`, using `D` as the desired signal, `MU` as the step size, `A` as the adaptation control, and `R` as the reset signal. The objects returns the filtered output in `Y`, the filter error in `ERR`, and the adapted filter weights in `WTS`. Set the properties appropriately to provide all possible inputs.

Note: `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

dsp.Buffer System object

Package: dsp

Buffer input signal

Description

The `Buffer` object buffers an input signal. The number of samples per channel in the input must equal the difference between the output buffer size and buffer overlap (i.e., `Length` - `OverlapLength`).

To buffer an input signal:

1. Define and set up your buffer System object. See "Construction" on page 4-276.
2. Call step to buffer the input according to the properties of `dsp.Buffer`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`buff = dsp.Buffer` returns a buffer System object, `buff`, used to buffer input signals with overlap.

`buff = dsp.Buffer('`*`PropertyName`*`',`*`PropertyValue`*`,...)` returns a buffer object, `buff`, with each specified property set to the specified value.

`buff = dsp.Buffer(LEN,OVRLAP,ICS,'`*`PropertyName`*`',...`
`PropertyValue``,...)` returns a buffer object, `buff`, with `Length` on page 4-277 property set to `LEN`, `OverlapLength` on page 4- property set to `OVRLAP`, `InitialConditions` on page 4-277 property set to `ICS` and other specified properties set to the specified values.

Properties

`Length`

Number of samples to buffer

Specify the number of consecutive samples from each input channel to buffer. You can set this property to any scalar integer greater than `0` of MATLAB built-in numeric data type. The default is `64`.

`OverlapLength`

Amount of overlap between outputs

Specify the number of samples by which consecutive output frames overlap. You can set this property to any scalar integer greater than or equal to `0` of MATLAB built-in numeric data type. The default is `0`.

`InitialConditions`

Initial output

Specify the value of the object's initial output for cases of nonzero latency as a scalar, vector, or matrix. The default is `0`.

Methods

reset	Reset the internal states of a System object
step	Buffer input signal based on past values

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Create a Buffer

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

Create a buffer of 256 samples with 128 sample overlap.

```
reader = dsp.SignalSource(randn(1024,1),128);
buff = dsp.Buffer(256,128);

for i = 1:8
    y = buff(reader());
end
```

y is of length 256 with 128 samples from previous input.

Algorithms

This object implements the algorithm, inputs, and outputs described on the `Buffer` block reference page. The object properties correspond to the block properties, except as noted.

See Also

dsp.Delay | dsp.DelayLine

Introduced in R2012a

reset

System object: dsp.Buffer
Package: dsp

Reset the internal states of a System object

Syntax

```
reset(buff)
```

Description

`reset(buff)` resets the internal states of buffer to their initial values.

For many System objects, this method is a no-op. Objects that have internal states will describe in their help what the reset method does for that object.

The reset method is always a no-op for unlocked System objects, as the states may not be allocated when the object is not locked.

step

System object: dsp.Buffer
Package: dsp

Buffer input signal based on past values

Syntax

`Y = step(buff,X)`

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(buff,X)` creates output `Y` based on current input and stored past values of `X` . Output length equals the `Length` property.

Note: `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

dsp.BurgAREstimator System object

Package: dsp

Estimate of autoregressive (AR) model parameters using Burg method

Description

The `BurgAREstimator` object computes the estimate of the autoregressive (AR) model parameters using the Burg method.

To compute the estimate of the AR model parameters:

1. Define and set up your System object. See "Construction" on page 4-281.
2. Call step to compute the estimate according to the properties of `dsp.BurgAREstimator`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`burgarest = dsp.BurgAREstimator` returns a Burg `BurgAREstimator` System object, `burgarest`, that performs parametric AR estimation using the Burg maximum entropy method.

`burgarest = dsp.BurgAREstimator('`*`PropertyName`*`',`*`PropertyValue`*`,...)` returns a Burg AR estimator object, `burgarest`, with each specified property set to the specified value.

Properties

`AOutputPort`

Enable output of polynomial coefficients

Set this property to `true` to output the polynomial coefficients, `A`, of the AR model the object computes. The default is `true`. Either the `AOutputPort` property, the `KOutputPort on page 4-282` property, or both must be `true`.

`KOutputPort`

Enable output of reflection coefficients

Set this property to `true` to output the reflection coefficients, `K`, for the AR model that the object computes. The default is `false`. Either the `AOutputPort on page 4-282` property, the `KOutputPort` property, or both must be `true`.

`EstimationOrderSource`

Source of estimation order

Specify how to determine estimator order as `Auto` or `Property`. When you set this property to `Auto`, the object assumes the estimation order is one less than the length of the input vector. When you set this property to `Property`, the value in EstimationOrder on page 4-282 is used. The default is `Auto`.

`EstimationOrder`

Order of AR model

Set the AR model estimation order to a real positive integer. This property applies when you set the `EstimationOrderSource on page 4-282` to `Property`. The default is `4`.

Methods

step	Normalized estimate of AR model parameter

Common to All System Objects	
clone	Create System object with same property values
getNumInpu	Expected number of inputs to a System object
getNumOutp	Expected number of outputs of a System object
isLocked	Check locked states of a System object (logical)
release	Allow System object property value changes

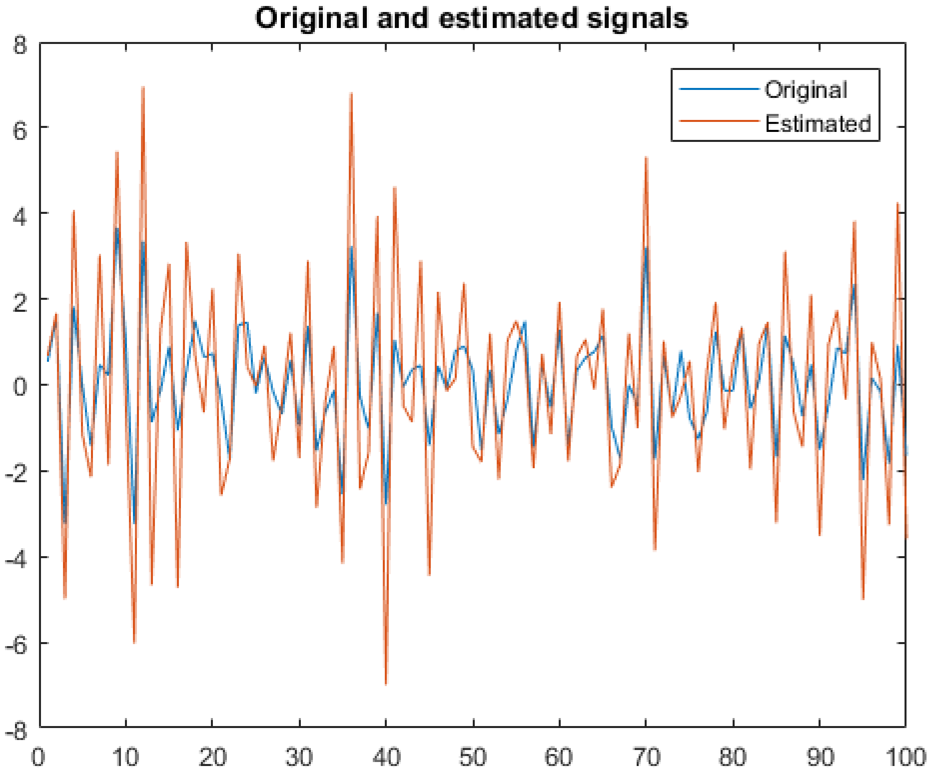
Examples

Estimate the parameters of an AR model

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

Use the `dsp.BurgAREstimator` System object™ to estimate the parameters of an AR model.

```
rng default; % Use default random number generator and seed
noise = randn(100,1); % Normalized white Gaussian noise
x = filter(1,[1 1/2 1/3 1/4 1/5],noise);
burgarest = dsp.BurgAREstimator(...
    'EstimationOrderSource', 'Property', ...
    'EstimationOrder', 4);
[a, g] = burgarest(x);
x_est = filter(g, a, x);
plot(1:100,[x x_est]);
title('Original and estimated signals');
legend('Original', 'Estimated');
```



Algorithms

This object implements the algorithm, inputs, and outputs described on the `Burg AR Estimator` block reference page. The object properties correspond to the block parameters, except:

Output(s) block parameter corresponds to the `AOutputPort` and the `KOutputPort` object properties.

dsp.LevinsonSolver

Introduced in R2012a

step

System object: dsp.BurgAREstimator
Package: dsp

Normalized estimate of AR model parameter

Syntax

```
[A,G] = step(burgarest,X)
[K,G] = step(burgarest,X)
[A,K,G] = step(burgarest,X)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`[A,G] = step(burgarest,X)` computes the normalized estimate of the `AR` model parameters to fit the input, `X`, in the least square sense. The input `X` must be a column vector. Output `A` is a column vector that contains the normalized estimate of the `AR` model polynomial coefficients in descending powers of z. The scalar `G` is the `AR` model gain.

`[K,G] = step(burgarest,X)` returns `K`, a column vector containing the `AR` model reflection coefficients when you set the `KOutputPort` property to `true` and the `AOutputPort` property to `false`.

`[A,K,G] = step(burgarest,X)` returns the `AR` model polynomial coefficients `A`, reflection coefficients `K`, and the scalar gain `G` when the `AOutputPort` and `KOutputPort` properties are both `true`.

Note: `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.BurgSpectrumEstimator System object

Package: dsp

Parametric spectral estimate using Burg method

Description

The `BurgSpectrumEstimator` object computes a parametric spectral estimate of the input using the Burg method. The object fits an autoregressive (AR) model to the signal by minimizing the forward and backward prediction errors (via least-squares). The AR parameters are constrained to satisfy the Levinson-Durbin recursion.

To compute the parametric spectral estimate of the input:

1. Define and set up your System object. See “Construction” on page 4-288.
2. Call step to compute the estimate according to the properties of `dsp.BurgSpectrumEstimator`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`burgspecest = dsp.BurgSpectrumEstimator` returns an object, `burgspecest`, that estimates the power spectral density (PSD) of the input frame using the Burg method.

`burgspecest = dsp.BurgSpectrumEstimator('`*`PropertyName`*`',`*`PropertyValue`*`,...)` returns a spectrum estimator, `burgspecest`, with each specified property set to the specified value.

Properties

`EstimationOrderSource`

Source of estimation order

Specify the source of the estimation order as `Auto` or `Property`. If you set this property to `Auto`, the object assumes the estimation order is one less than the length of the input vector. The default value is `Property`.

`EstimationOrder`

Order of AR model

Specify the order of AR model as a real positive integer. This property applies only when you set the `EstimationOrderSource` property to `Property`. The default value is `6`.

`FFTLengthSource`

Source of FFT length

Specify the source of the FFT length as `Auto` or `Property`. When you set this property to `Auto`, the objects assumes the FFT length is one more than the estimation order. When you set this property to `Property`, the `FFTLength` on page 4-289 property value must be an integer power of two.

`FFTLength`

FFT length as power-of-two integer value

Specify the FFT length as a power-of-two numeric scalar. This property applies when you set the `FFTLengthSource` on page 4-289 property to `Property`. The default value is `256`.

`SampleRate`

Sample rate of input time series

Specify the sampling rate of the original input time series as a positive numeric scalar in hertz. The default value is `1`.

Methods

step	Estimate of power spectral density

Common to All System Objects	
clone	Create System object with same property values
getNumInpu	Expected number of inputs to a System object
getNumOutp	Expected number of outputs of a System object
isLocked	Check locked states of a System object (logical)
release	Allow System object property value changes

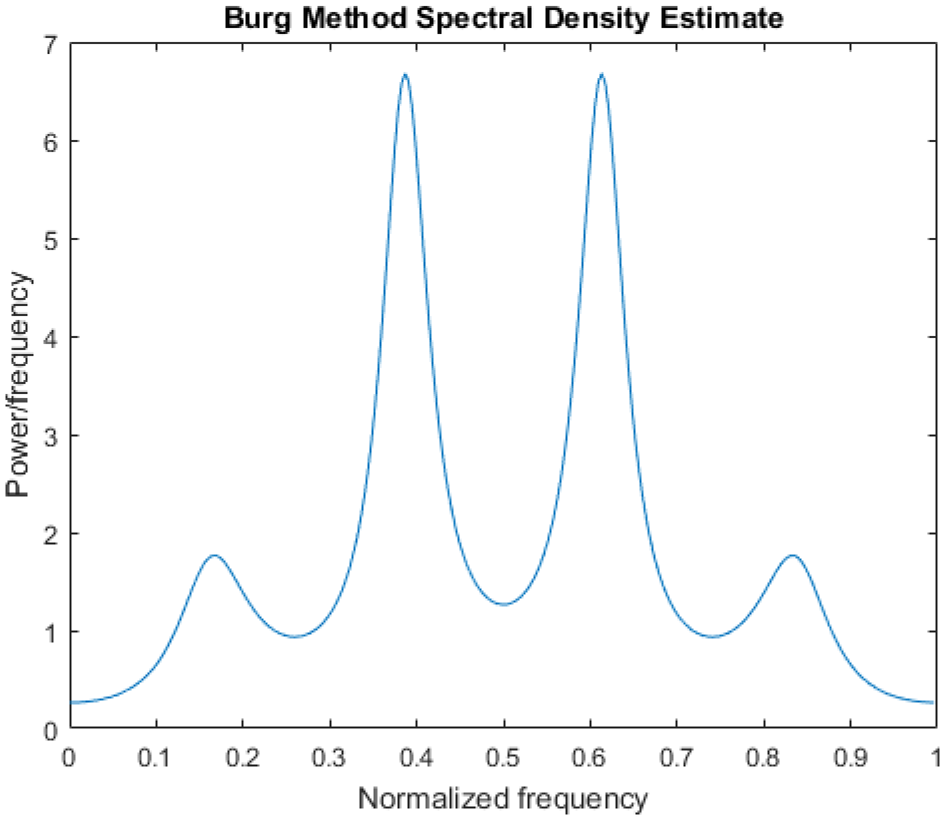
Examples

Estimate PSD Using the Burg Method

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

```
x = randn(100,1);
burgspecest = dsp.BurgSpectrumEstimator('EstimationOrder', 4);
y = filter(1,[1 1/2 1/3 1/4 1/5],x); % Fourth order AR filter
p = burgspecest(y); % Uses default FFT length of 256

plot((0:255)/256, p);
title('Burg Method Spectral Density Estimate');
xlabel('Normalized frequency'); ylabel('Power/frequency');
```



Algorithms

This object implements the algorithm, inputs, and outputs described on the `Burg Method` block reference page. The object properties correspond to the block properties.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- “System Objects in MATLAB Code Generation” (MATLAB Coder)
- When the FFT length is not a power of two, the executable generated from this System object relies on prebuilt dynamic library files (`.dll` files) included with MATLAB. Use the `packNGo` function to package the code generated from this object and all the relevant files in a compressed zip file. Using this zip file, you can relocate, unpack, and rebuild your project in another development environment where MATLAB is not installed. For more details, see “How To Run a Generated Executable Outside MATLAB”.
- When the FFT length is a power of two, you can generate standalone C and C++ code from this System object.

Estimate of power spectral density

Syntax

`Y = step(burgspecest,X)`

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(burgspecest,X)` outputs `Y`, a spectral estimate of input `X`, using the Burg method.

Note: `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

dsp.CepstralToLPC System object

Package: dsp

Convert cepstral coefficients to linear prediction coefficients

Description

The `CepstralToLPC` object converts cepstral coefficients to linear prediction coefficients (LPC).

To convert cepstral coefficients to LPC:

1. Define and set up your System object. See "Construction" on page 4-294.
2. Call step to convert the coefficients according to the properties of `dsp.CepstralToLPC`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`cc2lpc = dsp.CepstralToLPC` returns a System object, `cc2lpc`, that converts the cepstral coefficients(CCs) to linear prediction coefficients (LPCs).

`cc2lpc = dsp.CepstralToLPC('`*`PropertyName`*`',`*`PropertyValue`*`,...)` returns a `Cepstral to LPC` object, `cc2lpc`, with each specified property set to the specified value.

Properties

`PredictionErrorOutputPort`

Enable prediction error power output

Set this property to `true` to output the prediction error power. The prediction error power is the power of the error output of an FIR analysis filter represented by the LPCs for a given input signal. The default is `false`.

Methods

step	LPC coefficients from column of cepstral coefficients

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Convert Cepstral To LPC Coefficients

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

Convert cepstral coefficients to linear prediction coefficients.

```
cc = [0 0.9920 0.4919 0.3252 0.2418 , ...
    0.1917 0.1583 0.1344 0.1165 0.0956]';
cc2lpc = dsp.CepstralToLPC;
a = cc2lpc(cc)
```

step

System object: dsp.CepstralToLPC
Package: dsp

LPC coefficients from column of cepstral coefficients

Syntax

```
A = step(cc2lpc,CC)
[A,P]=step(cc2lpc,CC)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`A = step(cc2lpc,CC)` computes the linear prediction coefficients (LPC) coefficients, `A` , from the columns of cepstral coefficients, `CC`.

`[A,P]=step(cc2lpc,CC)` converts the columns of the cepstral coefficients `CC` to the LPCs and returns the prediction error power `P` when the `PredictionErrorOutputPort` property is `true`.

Note: `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

dsp.Channelizer System object

Package: dsp

Polyphase FFT analysis filter bank

Description

The `dsp.Channelizer` System object separates a broadband input signal into multiple narrow subbands using an FFT-based analysis filter bank. The filter bank uses a prototype lowpass filter and is implemented using a polyphase structure. You can specify the filter coefficients directly or through design parameters.

The number of rows in the input signal, `x`, must be a multiple of the number of frequency bands of the filter bank. Each column of `x` corresponds to a separate channel. If M is the number of frequency bands, and `x` is an L-by-1 matrix, then the output signal, `y`, has dimensions L/M-by-M. Each narrowband signal forms a column in the `y`. If `x` has more than one channel, that is, it has dimensions L-by-N, then `y` has dimensions L/M-by-M-by-N. The input `x` can be complex and supports single and double data types.

This object also accepts variable-size inputs. That is, once the object is locked, you can change the size of each input channel. The number of channels cannot change. This object supports C and C++ code generation.

To separate a broadband signal into multiple narrow subbands:

1 Create a `dsp.Channelizer` object and set the properties of the object.
2 Call step to do the signal analysis.

Note: Alternatively, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`channelizer = dsp.Channelizer` creates a channelizer object, using the default properties.

`channelizer = dsp.Channelizer(num)` sets the `NumFrequencyBands` property to `num`.

`channelizer = dsp.Channelizer(Name,Value)` specifies additional properties using `Name,Value` pairs. Unspecified properties have default values.

Example:

```
channelizer = dsp.Channelizer('NumTapsPerBand',20,'StopbandAttenuation',140);
```

Properties

`NumFrequencyBands` — Number of frequency bands

`8` (default) | positive integer greater than 1

Number of frequency bands into which the object separates the input broadband signal, specified as a positive integer greater than 1. This property indicates the FFT length and the decimation factor used by the algorithm.

`Specification` — Filter design parameters or coefficients

`'Number of taps per band and stopband attenuation'` (default) | `'Coefficients'`

Filter design parameters or filter coefficients, specified as one of these options:

- `'Number of taps per band and stopband attenuation'` — Specify the filter design parameters through the `NumTapsPerBand` and `StopbandAttenuation` properties.
- `'Coefficients'` — Specify the filter coefficients directly using `LowpassCoefficients`.

`NumTapsPerBand` — Number of filter coefficients per frequency band

`12` (default) | positive integer

Number of filter coefficients each polyphase branch uses, specified as a positive integer. The number of polyphase branches matches the number of frequency bands. The total number of filter coefficients for the prototype lowpass filter is given by `NumFrequencyBands×NumTapsPerBand`. For a given stopband attenuation, increasing the number of taps per band narrows the transition width of the filter. As a result, there is more usable bandwidth for each frequency band at the expense of increased computation.

This property applies when you set `Specification` to `'Number of taps per band and stopband attenuation'`.

`StopbandAttenuation` — Stopband attenuation
`80` (default) | positive real scalar

Stopband attenuation of the lowpass filter, specified as a positive real scalar in dB. This value controls the maximum amount of aliasing from one frequency band to the next. Larger is the stopband attenuation, smaller is the passband ripple.

This property applies when you set `Specification` to `'Number of taps per band and stopband attenuation'`.

`LowpassCoefficients` — Coefficients of the prototype lowpass filter
`[1×49 double]` (default) | row vector

Coefficients of the prototype lowpass filter, specified as a row vector. There must be at least one coefficient per frequency band. If the length of the lowpass filter is less than the number of frequency bands, the object zero-pads the coefficients.

This property applies when you set `Specification` to `'Coefficients'`.

This property is tunable. You can change its value even after the object is locked.

Methods

coeffs	Coefficients of prototype lowpass filter
polyphase	Polyphase matrix
reset	Reset internal states of System object
step	Separate broadband signal into narrow bands
tf	Transfer function

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object

Common to All System Objects	
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Quadrature Mirror Filter Bank

The quadrature mirror filter bank (QMF) contains an analysis filter bank section and a synthesis filter bank section. `dsp.Channelizer` implements the analysis filter bank. `dsp.ChannelSynthesizer` implements the synthesis filter bank using the efficient polyphase implementation that is based on a prototype lowpass filter.

Initialization

Initialize the `dsp.Channelizer` and `dsp.ChannelSynthesizer` System objects. Each object is set up with 8 frequency bands, 8 polyphase branches in each filter, 12 coefficients per polyphase branch, and a stopband attenuation of 140 dB. Use a sine wave with multiple frequencies as the input signal. View the input spectrum and the output spectrum using a spectrum analyzer.

```
offsets = [-40,-30,-20,10,15,25,35,-15];
sinewave = dsp.SineWave('ComplexOutput',true,'Frequency',...
    offsets+(-375:125:500),'SamplesPerFrame',800);

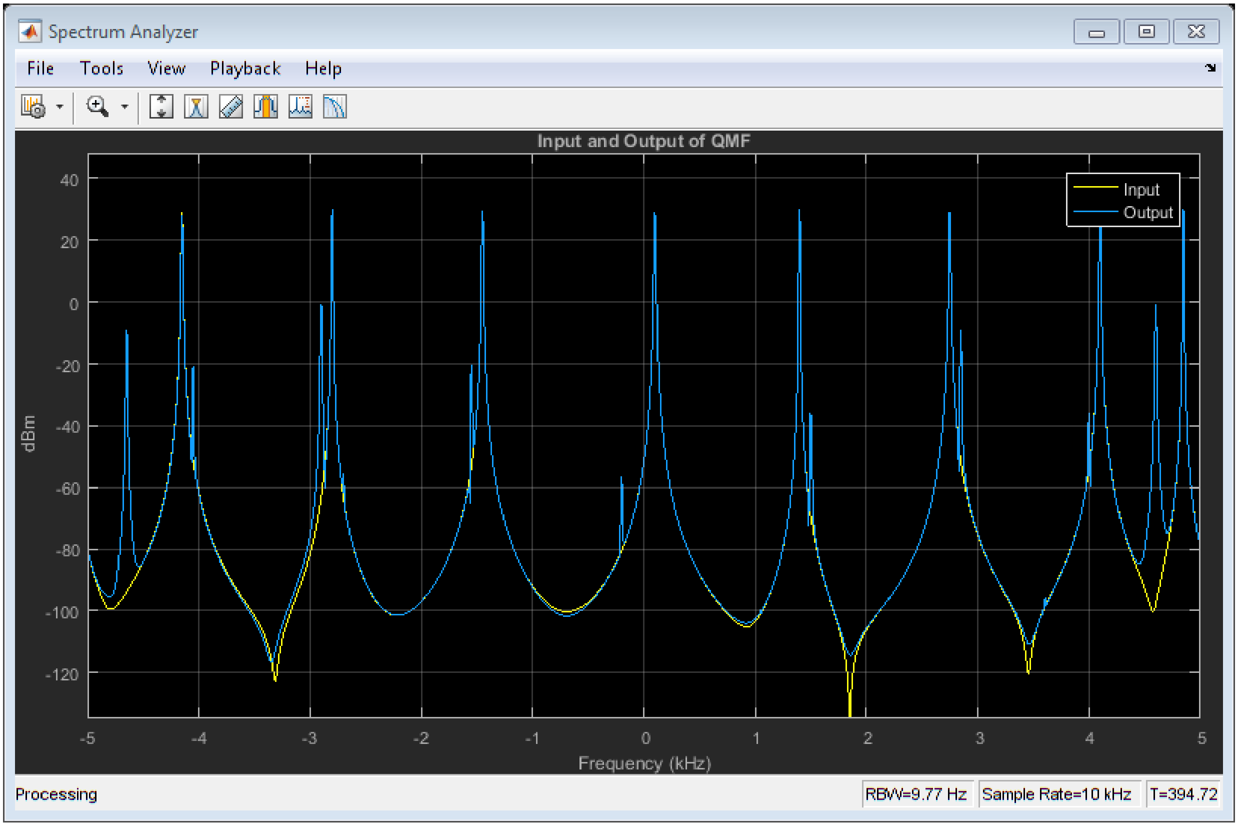
channelizer = dsp.Channelizer('StopbandAttenuation',140);
synthesizer = dsp.ChannelSynthesizer('StopbandAttenuation',140);
spectrumAnalyzer =  dsp.SpectrumAnalyzer('ShowLegend',true,'NumInputPorts',...
    2,'ChannelNames',{'Input','Output'},'Title','Input and Output of QMF');
```

Streaming

Use the channelizer to split the broadband input signal into multiple narrow bands. Then pass the multiple narrowband signals into the synthesizer, which merges these signals to form the broadband signal. Compare the spectra of the input and output signals.

```
for i = 1:5000
    x = sum(sinewave(),2);
    y = channelizer(x);
    v = synthesizer(y);
```

```
    spectrumAnalyzer(x,v);
end
```

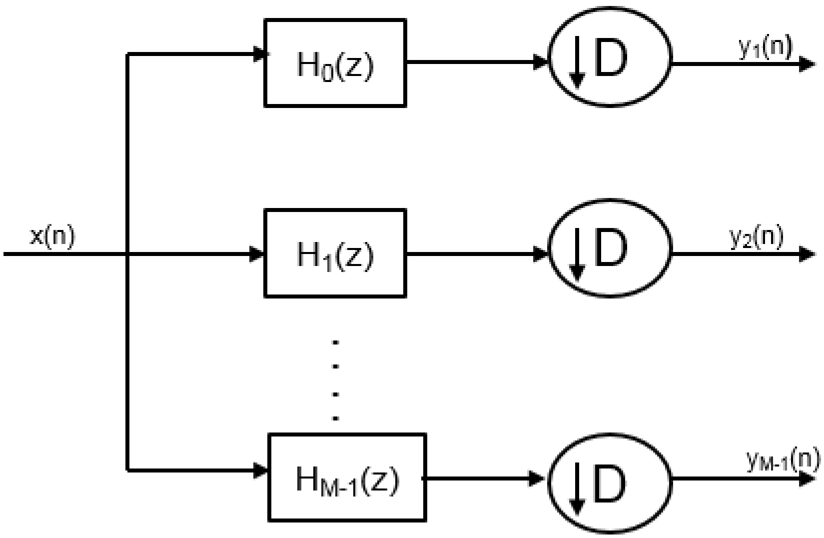


The input and output spectra match very closely.

Definitions

Analysis Filter Bank

The analysis filter bank consists of a series of parallel bandpass filters that split an input broadband signal, x(n), into a series of narrow subbands. Each bandpass filter retains a different portion of the input signal. After the bandwidth is reduced by one of the bandpass filters, the signal is downsampled to a lower sampling rate commensurate with the new bandwidth.



Prototype Lowpass Filter

To implement the analysis filter bank efficiently, the channelizer uses a prototype lowpass filter. This filter has an impulse response of h[n], a normalized two-sided bandwidth of $2\pi/M$, and a cutoff frequency of π/M. M is the number of frequency bands, that is, the branches of the analysis filter bank. This value corresponds to the FFT length that the filter bank uses. M can be high, in the order of 2048 or more. The stopband attenuation determines the minimum level of interference (aliasing) from one frequency band to another. The passband ripple must be small so that the input signal is not distorted in the passband.

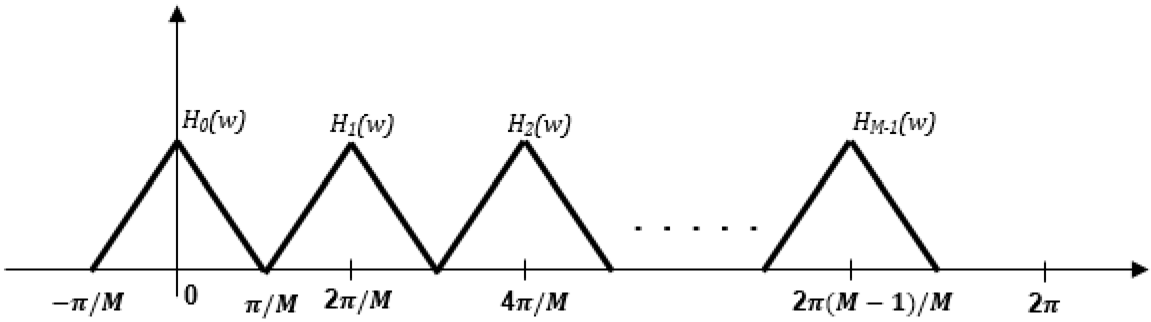
The prototype lowpass filter models the first branch of the filter bank. The other $M-1$ branches are modeled by filters that are modulated versions of the prototype filter. The modulation factor is given by $e^{-jw_k n}, \quad w_k = 2\pi k / M, \quad k = 0, 1, \ldots, M-1$.

Using Prototype Lowpass Filter

The transfer function of the modulated kth bandpass filter is given by:

$$H_k(z) = H_0(ze^{-jw_k}), \quad w_k = 2\pi k / M, \quad k = 1,2,\ldots,M-1$$

This figure shows the frequency response of *M* filters.

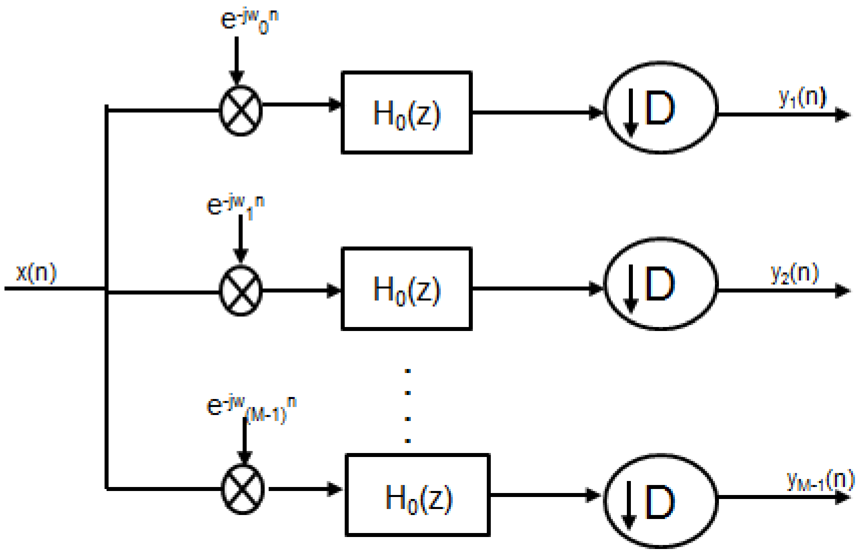


To obtain the frequency response characteristics of the filter $H_k(z)$, where $k = 1,\ldots,M-1$, uniformly shift the frequency response of the prototype filter, $H_0(z)$, by multiples of $2\pi/M$. Each subband filter, H_k(z), $\{k = 1,\ldots,M-1\}$, is derived from the prototype filter.

Shift Narrow Subbands to Baseband

The frequency components in the input signal, *x(n)*, are translated in frequency to baseband by multiplying *x(n)* with the complex exponentials, $e^{-jw_k n}, \quad where \quad w_k = 2\pi k / M, and\ k = 1,2,..,M-1$, where, $w_k = 2\pi k / M$, and $k = 1,2,\ldots,M-1$. The resulting product signals are passed through the lowpass filters, $H_0(z)$. The output of the lowpass filter is relatively narrow in bandwidth. Downsample the signal commensurate with the new bandwidth. Choose a decimation factor, $D \le M$, the number of branches of the analysis filter bank.

The figure shows an analysis filter bank that uses the prototype lowpass filter.



$y_1(n)$, $y_2(n)$, ..., $y_{M-1}(n)$ are narrow subband signals translated into baseband.

Algorithm

Polyphase Implementation

The analysis filter bank can be implemented efficiently using the polyphase structure.

To derive the polyphase structure, start with the transfer function of the prototype lowpass filter.

$$H_0(z) = b_0 + b_1 z^{-1} + \ldots + b_N z^{-N}$$

N+1 is the length of the prototype filter.

You can rearrange this equation as follows:

$$H_0(z) = \begin{array}{l} \left(b_0 + b_M z^{-M} + b_{2M} z^{-2M} + .. + b_{N-M+1} z^{-(N-M+1)}\right) + \\ z^{-1}\left(b_1 + b_{M+1} z^{-M} + b_{2M+1} z^{-2M} + .. + b_{N-M+2} z^{-(N-M+1)}\right) + \\ \vdots \\ z^{-(M-1)}\left(b_{M-1} + b_{2M-1} z^{-M} + b_{3M-1} z^{-2M} + .. + b_N z^{-(N-M+1)}\right) \end{array}$$

M is the number of polyphase components.

You can write this equation as:

$$H_0(z) = E_0(z^M) + z^{-1} E_1(z^M) + ... + z^{-(M-1)} E_{M-1}(z^M)$$

$E_0(z^M)$, $E_1(z^M)$, ..., $E_{M-1}(z^M)$ are polyphase components of the prototype lowpass filter, H_0(z).

The other filters in the filter bank, H_k(z), where k = 1, ..., M-1, are modulated versions of this prototype filter.

You can write the transfer function of the kth modulated bandpass filter as $H_k(z) = H_0(ze^{-jw_k})$. Replacing z with ze^{-jw_k},

$$H_k(z) = h_0 + h_1 e^{-jwk} z^{-1} + h_2 e^{-j2wk} z^{-2} ... + h_N e^{-jNwk} z^{-N}$$

N+1 is the length of the kth filter.

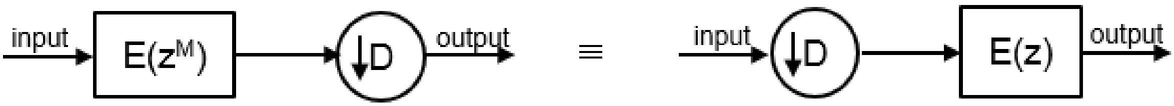
In polyphase form, the equation is as follows:

$$H_k(z) = \begin{bmatrix} 1 & e^{-jw_k} & e^{-j2w_k} & ... & e^{-j(M-1)w_k} \end{bmatrix} \begin{bmatrix} E_0(z^M) \\ z^{-1} E_1(z^M) \\ \vdots \\ z^{-(M-1)} E_{M-1}(z^M) \end{bmatrix}$$

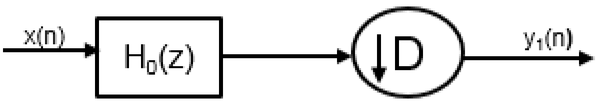
For all M channels in the filter bank, the MIMO transfer function, H(z), is given by:

$$H(z)=\begin{bmatrix} 1 & 1 & 1 & \cdots & 1 \\ 1 & e^{-jw_1} & e^{-j2w_1} & \cdots & e^{-j(M-1)w_1} \\ & & \vdots & & \\ 1 & e^{-jw_{M-1}} & e^{-j2w_{M-1}} & \cdots & e^{-j(M-1)w_{M-1}} \end{bmatrix}\begin{bmatrix} E_0(z^M) \\ z^{-1}E_1(z^M) \\ \vdots \\ z^{-(M-1)}E_{M-1}(z^M) \end{bmatrix}$$

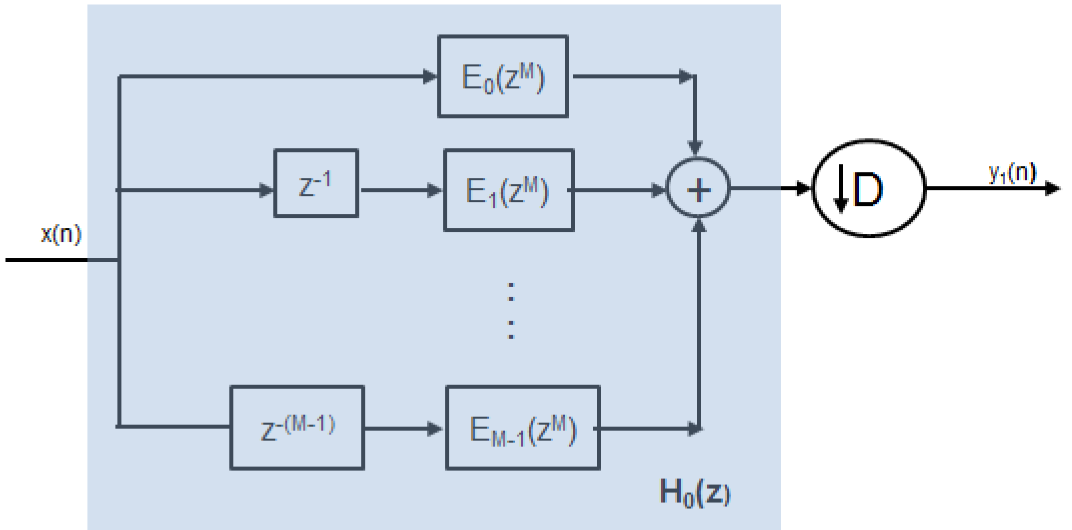
Here is the multirate noble identity for decimation.



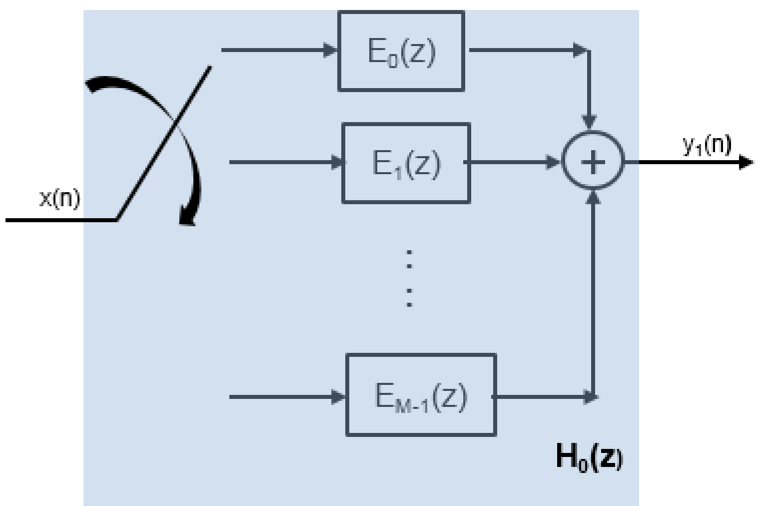
For illustration, consider the first branch of the filter bank that contains the lowpass filter.



Replace H_0(z) with its polyphase representation.



After applying the noble identity for decimation, you can replace the delays and the decimation factor with a commutator switch.



For all *M* channels in the filter bank, the MIMO transfer function, *H*(z), is given by:

$$H(z) = \begin{bmatrix} 1 & 1 & 1 & \dots & 1 \\ 1 & e^{-jw_1} & e^{-j2w_1} & \dots & e^{-j(M-1)w_1} \\ & & \vdots & & \\ 1 & e^{-jw_{M-1}} & e^{-j2w_{M-1}} & \dots & e^{-j(M-1)w_{M-1}} \end{bmatrix} \begin{bmatrix} E_0(z) \\ E_1(z) \\ \vdots \\ E_{M-1}(z) \end{bmatrix}$$

The matrix on the left is a DFT matrix. With the DFT matrix, the efficient implementation of the lowpass prototype based filter bank looks like the following.

coeffs

System object: dsp.Channelizer
Package: dsp

Coefficients of prototype lowpass filter

Syntax

```
c = coeffs(channelizer)
```

Description

`c = coeffs(channelizer)` returns a structure that contains the coefficients of the prototype lowpass filter. The value, `c`, equals the number of frequency bands times the number of coefficients per band. These values are given by the `NumFrequencyBands` and `NumTapsPerBand` properties of the channelizer respectively.

Introduced in R2016b

polyphase

System object: dsp.Channelizer
Package: dsp

Polyphase matrix

Syntax

```
p = polyphase(channelizer)
```

Description

`p = polyphase(channelizer)` returns the polyphase matrix used by the filter bank. Each row in the matrix corresponds to a polyphase branch. The number of columns in *p* corresponds to the number of filter taps per polyphase branch.

Introduced in R2016b

reset

System object: dsp.Channelizer
Package: dsp

Reset internal states of System object

Syntax

`reset(channelizer)`

Description

`reset(channelizer)` resets the states of the input object to their initial values. The initial state values correspond to the initial conditions for the difference equation defining the object. After you call the object using nonzero input data, the filter might have nonzero states. If you continue to pass nonzero input data to the object without first calling `reset`, the object might produce different outputs for an identical input.

Introduced in R2016b

step

System object: dsp.Channelizer
Package: dsp

Separate broadband signal into narrow bands

Syntax

```
y = step(channelizer,x)
```

Description

Note: Alternatively, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`y = step(channelizer,x)` separates the broadband input signal `x` into narrow band signals. Each signal forms a column in output signal `y`. The number of rows in `x` must be a multiple of the number of frequency bands. Each column of `x` corresponds to a separate channel. If M is the number of frequency bands, and `x` is a L-by-1 matrix, then `y` has dimensions, L/M-by-M. If `x` has more than one channel, that is, it has dimensions L-by-N, then `y` has dimensions L/M-by-M-by-N. The input `x` can be complex and supports single and double data types.

Introduced in R2016b

tf

System object: dsp.Channelizer
Package: dsp

Transfer function

Syntax

```
[b,a] = tf(channelizer)
```

Description

`[b,a] = tf(channelizer)` returns the vector of numerator coefficients, `b`, and the vector of denominator coefficients, `a`, of the prototype lowpass filter.

Introduced in R2016b

dsp.HDLChannelizer System object

Package: dsp

Polyphase filter bank and fast Fourier transform—optimized for HDL code generation

Description

The `HDLChannelizer` System object separates a broadband input signal into multiple narrowband output signals. It provides hardware speed and area optimization for streaming data applications. The object accepts scalar or vector input of real or complex data, provides hardware-friendly control signals, and has optional output frame control signals. You can achieve giga-sample-per-second (GSPS) throughput using vector input. The object implements a polyphase filter, with one subfilter per input vector element. The hardware implementation interleaves the subfilters, which results in sharing each filter multiplier (*FFT Length* / *Input Size*) times. The object implements the same pipelined Radix 2^2 FFT algorithm as the dsp.HDLFFT System object.

To process input data with an HDL-optimized channelizer:

1. Create and configure a `dsp.HDLChannelizer` System object. See “Construction” on page 4-316.
2. Call the step method to channelize the input data according to the properties of the `dsp.HDLChannelizer` object.

Note: Alternatively, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`channelize = dsp.HDLChannelizer` returns a System object, `channelize`, that implements a raised-cosine filter and an 8-point FFT.

`channelize = dsp.HDLChannelizer(Name,Value)` returns a System object, `channelize`, with additional options specified by one or more `Name,Value` pair arguments.

Properties

`NumFrequencyBands` — FFT length
`8` (default) | integer power of two

For HDL code generation, the FFT length must be a power of 2 from 2^3 to 2^{16}.

`FilterCoefficients` — Polyphase filter coefficients
`[ -0.032, 0.121, 0.318, 0.482, 0.546, 0.482, 0.318, 0.121, -0.032 ]` (default) | vector of numeric values

If the number of coefficients is not a multiple of `NumFrequencyBands`, the object pads this vector with zeros. The default filter specification is a raised-cosine FIR filter, `rcosdesign(0.25,2,4,'sqrt')`. You can specify a vector of coefficients or a call to a filter design function that returns the coefficient values. Complex coefficients are not supported. By default, the object casts the coefficients to the same data type as the input.

`ComplexMultiplication` — HDL implementation of complex multipliers
`'Use 3 multipliers and 5 adders'` (default) | `'Use 4 multipliers and 2 adders'`

Each multiplication is implemented with either 3 multipliers and 5 adders, or 4 multipliers and 2 adders. Which option is faster or smaller depends on your synthesis tool and target device.

`OutputSize` — Size and order of output data
`'Same as number of frequency bands'` (default) | `'Same as input size'`

- `'Same as number of frequency bands'` — Output data is a 1-by-M vector, where M is the FFT length. The output order is bit natural.
- `'Same as input size'` — Output data is an M-by-1 vector, where M is the input vector size. The output order is bit reversed.

`Normalize` — FFT scaling
`true` (default) | `false`

When you set this property to `true`, the FFT implements an overall 1/N scale factor by scaling the result of each pipeline stage by 2. This adjustment keeps the output of the FFT in the same amplitude range as its input. If scaling is disabled, the FFT avoids overflow by increasing the word length by 1 bit at each stage.

`RoundingMethod` — Rounding method used for internal fixed-point calculations
`'Floor'` (default) | `'Ceiling'` | `'Convergent'` | `'Nearest'` | `'Round'` | `'Zero'`

See “Rounding Modes”. The object uses fixed-point arithmetic for internal calculations when the input is any integer or fixed-point data type. This option does not apply when the input is `single` or `double`. Each FFT stage rounds after the twiddle factor multiplication but before the butterflies. Rounding can also occur when casting the coefficients and the output of the polyphase filter to the data types you specify.

`OverflowAction` — Overflow handling for internal fixed-point calculations
`'Wrap'` (default) | `'Saturate'`

See “Overflow Handling”. The object uses fixed-point arithmetic for internal calculations when the input is any integer or fixed-point data type. This option does not apply when the input is `single` or `double`. This option applies to casting the coefficients and the output of the polyphase filter to the data types you specify.

The FFT algorithm avoids overflow by either scaling the output of each stage (`Normalize` enabled), or by increasing the word length by 1 bit at each stage (`Normalize` disabled).

`CoefficientsDataType` — Data type of the filter coefficients
`'Same word length as input'` (default) | `numerictype` object

The object casts the polyphase filter coefficients to this data type, using the rounding and overflow settings you specify. When you select `Inherit: Same word length as input` (default), the object selects the binary point using `fi()` best-precision rules.

`FilterOutputDataType` — Data type of the output of the polyphase filter
`'Same word length as input'` (default) | `numerictype` object

The object casts the output of the polyphase filter (the input to the FFT) to this data type, using the rounding and overflow settings you specify. When you select `Inherit: Same word length as input` (default), the object selects a best-precision binary point by considering the values of your filter coefficients and the range of your input data type.

By default, the FFT logic does not change the data type. When you disable `Normalize`, the FFT increases the word length by 1 bit at each stage to avoid overflow.

`ResetInputPort` — Optional reset signal
`false` (default) | `true`

When you enable this property, the object expects an extra argument, `reset`. When the `reset` input is `true`, the object stops calculation and clears all internal state.

`StartOutputPort` — Optional control signal indicating start of data

`false` (default) | `true`

When you enable this property, the object returns an extra value, `startOut`. The `startOut` signal is true for the first cycle of output data in a frame.

`EndOutputPort` — Optional control signal indicating end of data

`false` (default) | `true`

When you enable this property, the object returns an extra value, `endOut`. The `endOut` signal is true for the last cycle of output data in a frame.

Methods

getLatency	Latency of channelizer operation
step	Filter and compute FFT

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Create Channelizer for HDL Generation

Create a function that contains the channelizer object and supports HDL code generation.

Create the specifications and input signal. The signal has 8 frequency channels.

```
N = 8;
loopCount = 1024;
```

```
offsets = [-40 -30 -20 10 15 25 35 -15];
sinewave = dsp.SineWave('ComplexOutput',true,'Frequency', ...
     offsets+(-375:125:500),'SamplesPerFrame',loopCount);
spectrumAnalyzer = dsp.SpectrumAnalyzer('ShowLegend',true, ...
     'SampleRate',sinewave.SampleRate/N);
```

Write a function that creates and calls the channelizer System object™. You can generate HDL from this function.

```
function [yOut,validOut] = HDLChannelizer8(yIn,validIn)
%HDLChannelizer8
% Process one sample of data using the dsp.HDLChannelizer System object
% yIn is a fixed-point scalar or column vector.
% validIn is a logical scalar value.
% You can generate HDL code from this function.

  persistent channelize8;
  if isempty(channelize8)
    % Use filter coeffs from non-HDL channelizer, or supply your own.
    channelizer = dsp.Channelizer('NumFrequencyBands',8);
    channelize8 = dsp.HDLChannelizer('NumFrequencyBands',8,'FilterCoefficients',tf(char
  end
  [yOut,validOut] = channelize8(yIn,validIn);
end
```

Channelize the input data by calling the object for each data sample.

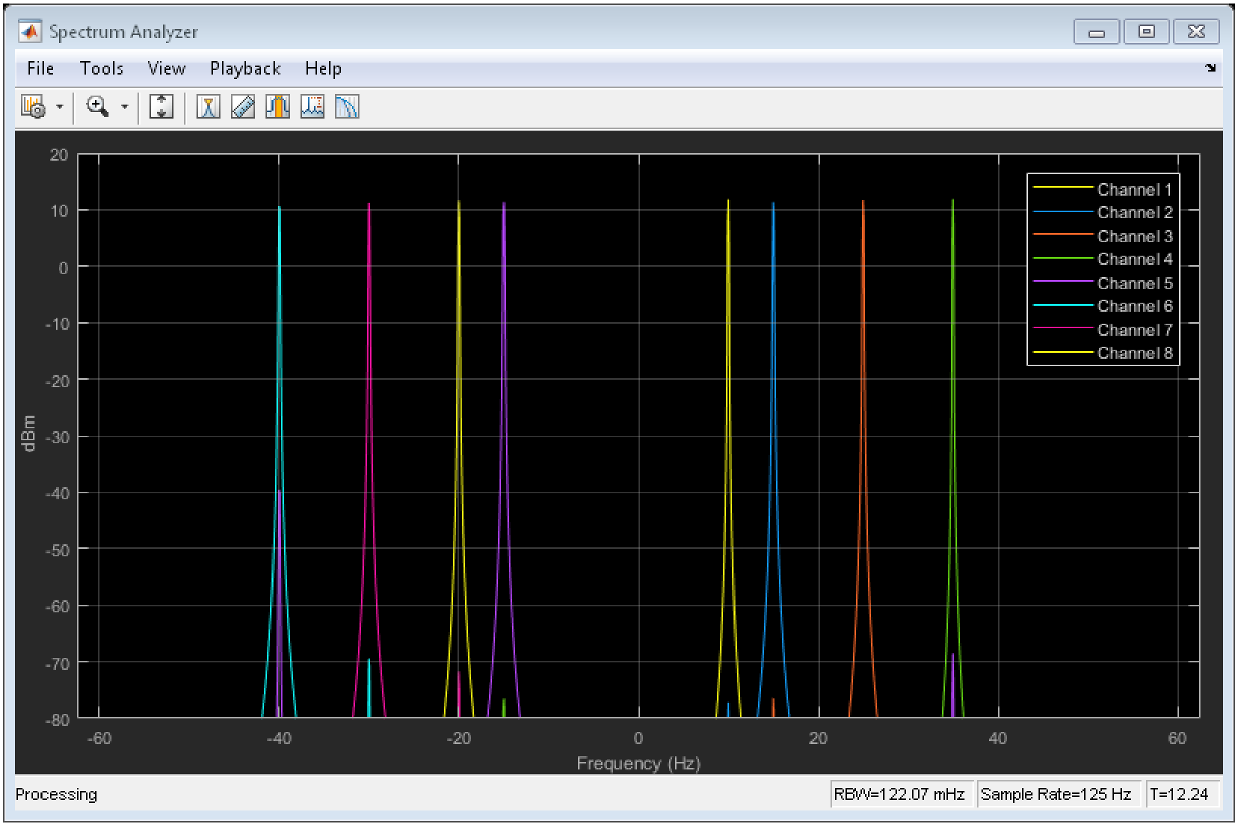
```
y = zeros(loopCount/N,N);
validOut = false(loopCount/N,1);
yValid = zeros(loopCount/(N*N),N);
for loop2=1:20
   x = sum(sinewave(),2);
   for loop=1:length(x)
      [y(loop,:),validOut(loop)]= HDLChannelizer8(complex(x(loop)),true);
   end
   yValid = y(validOut == 1,:);
   spectrumAnalyzer(yValid);
end
```

```
channelize8 =
```

```
dsp.HDLChannelizer with properties:

      NumFrequencyBands: 8
     FilterCoefficients: [1×96 double]
  ComplexMultiplication: 'Use 4 multipliers and 2 adders'
             OutputSize: 'Same as number of frequency bands'
              Normalize: true

Use get to show all properties
```



Explore Latency of the HDL Channelizer Object

The latency of the object varies with the FFT length and the vector size. Use the `getLatency` method to find the latency of a particular configuration. The latency is measured as the number of cycles between the first valid input and the first valid output, assuming the input is contiguous. The number of filter coefficients does not affect the latency. Setting the output size equal to the input size reduces the latency because the samples are not saved and reordered.

Create a new `dsp.HDLChannelizer` object and request the latency.

```
channelize = dsp.HDLChannelizer('NumFrequencyBands',512);
L512 = getLatency(channelize)
```

```
L512 =

        1118
```

Request hypothetical latency information about a similar object with a different number of frequency bands (FFT length). The properties of the original object do not change.

```
L256 = getLatency(channelize,256)
N = channelize.NumFrequencyBands
```

```
L256 =

   592

N =

   512
```

Request hypothetical latency information of a similar object that accepts eight-sample vector input.

```
L256v8 = getLatency(channelize,256,8)
```

```
L256v8 =

   132
```

Set `Normalize` to `true`. The latency does not change.

```
channelize.Normalize = true;
L512n = getLatency(channelize)
```

```
L512n =

        1118
```

Change the `OutputSize` to match the input size. The latency decreases because the object does not need to store and reorder the data before output. The default input size is scalar.

```
channelize.OutputSize = 'Same as input size';
L512r = getLatency(channelize)
```

```
L512r =

   605
```

Check the latency of a vector input implementation with the output size the same as the input size. Specify the current value of the FFT length, and a vector size of 8 samples. The latency decreases because the object computes results in parallel when the input is a vector.

```
L256rv8 = getLatency(channelize,channelize.NumFrequencyBands,8)
```

```
L256rv8 =

   145
```

Algorithm

This object implements the algorithm described on the `Channelizer HDL Optimized` block reference page.

Latency

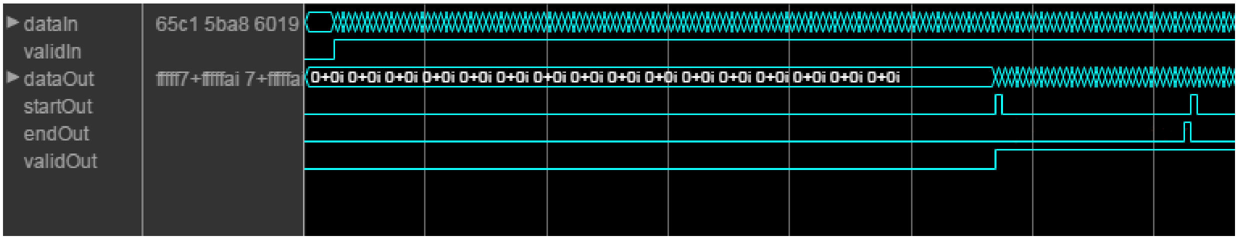
The latency varies with the FFT length and the vector size. Use the getLatency method to find the latency of a particular configuration. The latency is the number of cycles between the first valid input and the first valid output, assuming that the input is contiguous. The filter coefficients do not affect the latency. Setting the output size equal to the input size reduces the latency, because the samples are not saved and reordered.

Control Signals

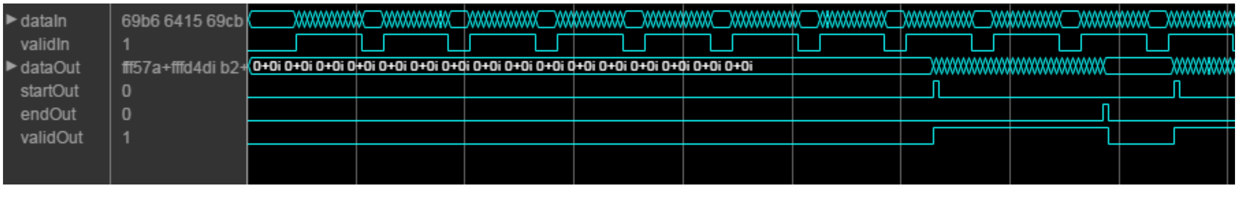
This diagram shows `validIn` and `validOut` signals for contiguous input data with a vector size of 16 and an FFT length of 512.

The diagram also shows the optional `startOut` and `endOut` signals that indicate frame boundaries. If you enable `startOut`, it pulses for one cycle with the first `validOut` of the frame. If you enable `endOut`, it pulses for one cycle with the last `validOut` of the frame.

If you apply continuous input frames, the output will also be continuous, after the initial latency.



The `validIn` signal can be noncontiguous. Data accompanied by a `validIn` signal is stored until a frame is filled, and output in a contiguous frame of *N* (FFT length) cycles. This diagram shows noncontiguous input and contiguous output for an FFT length of 512 and a vector size of 16 samples.



Performance

These resource and performance data are the place-and-route results from the generated HDL targeted to a Xilinx Virtex 6 (XC6VLX240-1ff784) FPGA. The three examples in the tables use this configuration:

- FFT length — 8
- Filter length — 96 coefficients
- 16-bit complex input data
- Coefficient and filter output data types same word length as input data (default)
- Complex multiplication (default) — 4 multipliers, 2 adders
- Output scaling — Enabled
- Minimize clock enables (HDL Coder parameter)

Performance of the synthesized HDL code varies with your target and synthesis options.

For scalar input, the design achieves a clock frequency of 346 MHz. The latency is 53 cycles. The subfilters share each multiplier eight (*N*) times. The design uses these resources.

Resource	Uses
LUT	1591
FFS	2681
Xilinx LogiCORE DSP48	16

For four-sample vector input, the design achieves a clock frequency of 333 MHz. The latency is 31 cycles. The subfilters share each multiplier twice (*N*/*M*). The design uses these resources.

Resource	Uses
LUT	1912
FFS	3986
Xilinx LogiCORE DSP48	56

For eight-sample vector input, the design achieves a clock frequency of 292 MHz. The latency is 20 cycles. When the input size is the same as the FFT length, the subfilters do not share any multipliers. The design uses these resources.

Resource	Uses
LUT	1388
FFS	2302
Xilinx LogiCORE DSP48	110

getLatency

System object: dsp.HDLChannelizer
Package: dsp

Latency of channelizer operation

Syntax

```
Y = getLatency(channelize)
Y = getLatency(channelize,N)
Y = getLatency(channelize,N,V)
```

Description

`Y = getLatency(channelize)` returns the number of cycles, `Y`, that the object takes to calculate the first channel analysis results from an input sample. The latency depends on the input vector size and the FFT length. The filter coefficients do not affect the latency.

`Y = getLatency(channelize,N)` returns the latency, `Y`, that an object with FFT Length `N` would take to channelize scalar input data. This method does not change the properties of `channelize`.

`Y = getLatency(channelize,N,V)` returns the latency, `Y`, that an object with FFT Length `N` would take to channelize vector input data of size `V`. This method does not change the properties of `channelize`.

Examples

Explore Latency of the HDL Channelizer Object

The latency of the object varies with the FFT length and the vector size. Use the `getLatency` method to find the latency of a particular configuration. The latency is measured as the number of cycles between the first valid input and the first valid output, assuming the input is contiguous. The number of filter coefficients does not affect the latency. Setting the output size equal to the input size reduces the latency because the samples are not saved and reordered.

Create a new `dsp.HDLChannelizer` object and request the latency.

```
channelize = dsp.HDLChannelizer('NumFrequencyBands',512);
L512 = getLatency(channelize)
```

```
L512 =

        1118
```

Request hypothetical latency information about a similar object with a different number of frequency bands (FFT length). The properties of the original object do not change.

```
L256 = getLatency(channelize,256)
N = channelize.NumFrequencyBands
```

```
L256 =

   592

N =

   512
```

Request hypothetical latency information of a similar object that accepts eight-sample vector input.

```
L256v8 = getLatency(channelize,256,8)
```

```
L256v8 =

   132
```

Set `Normalize` to `true`. The latency does not change.

```
channelize.Normalize = true;
```

```
L512n = getLatency(channelize)
```

```
L512n =

        1118
```

Change the `OutputSize` to match the input size. The latency decreases because the object does not need to store and reorder the data before output. The default input size is scalar.

```
channelize.OutputSize = 'Same as input size';
L512r = getLatency(channelize)
```

```
L512r =

   605
```

Check the latency of a vector input implementation with the output size the same as the input size. Specify the current value of the FFT length, and a vector size of 8 samples. The latency decreases because the object computes results in parallel when the input is a vector.

```
L256rv8 = getLatency(channelize,channelize.NumFrequencyBands,8)
```

```
L256rv8 =

   145
```

Input Arguments

`channelize` — Channelizer

`dsp.HDLChannelizer` System object

Specify a `dsp.HDLChannelizer` System object that you created and configured.

`N` — FFT length

integer power of two

Use this argument to request the latency of a similar object with FFT length `N`.

V — vector size
integer

Use this argument to request the latency of a similar object with `V`-sample vector input. When you do not specify this argument, the function assumes scalar input.

Output Arguments

Y — Cycles of latency
integer

Cycles of latency that the object takes to channelize the input data. The latency is the number of cycles between the first valid input and the first valid output, assuming the input is contiguous. Each call to the object simulates one cycle.

Introduced in R2017a

step

System object: dsp.HDLChannelizer
Package: dsp

Filter and compute FFT

Syntax

```
[dataOut,validOut] = step(obj,dataIn,validIn)
[dataOut,validOut] = step(obj,dataIn,validIn,reset)
[dataOut,startOut,endOut,validOut] = step(obj,___)
```

Description

Note: Alternatively, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`[dataOut,validOut] = step(obj,dataIn,validIn)` filters and computes a fast Fourier transform, and returns the frequency channels, `dataOut`, detected in the input signal, `dataIn`, when `validIn` is `true`. The `validIn` and `validOut` arguments are logical scalars that indicate the validity of the input and output signals, respectively.

`[dataOut,validOut] = step(obj,dataIn,validIn,reset)` returns the frequency channels, `dataOut`, detected in the input signal, `dataIn`, when `validIn` is `true` and `reset` is `false`. When `reset` is `true`, the object stops the current calculation and clears all internal state. To use this syntax, set the `ResetInputPort` property to `true`.

`[dataOut,startOut,endOut,validOut] = step(obj,___)` returns the frequency channels, `dataOut`, computed from the input arguments of any of the previous syntaxes. `startOut` is `true` on the first sample of a frame of output data. `endOut` is `true` for the last sample of a frame of output data. To use this syntax, set the `StartOutputPort` and `EndOutputPort` properties to `true`.

Note: `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Input Arguments

`obj` — Channelizer

`dsp.HDLChannelizer` System object

Specify a `dsp.HDLChannelizer` System object that you created and configured.

`dataIn` — Input data

scalar or column vector of real or complex values

The vector size must be a power of 2 between 1 and 64, that is not greater than the number of channels (FFT length). `double` and `single` are allowed for simulation but not for HDL code generation.

The object does not accept `uint64` data.

Data Types: `fi` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `single` | `double`
Complex Number Support: Yes

`validIn` — Indicates valid input data

scalar

When `validIn` is `true`, the object captures the value on `dataIn`.

Data Types: `logical`

`reset` — Reset control signal (optional)

scalar

When `reset` is `true`, the object stops the current calculation and clears internal state.

Dependencies

To enable this argument, set `ResetInputPort` to `true`.

Data Types: `logical`

Output Arguments

`dataOut` — Frequency channel output data
row vector

- If you set `OutputSize` to `'Same as number of frequency bands'` (default), the output data is a 1-by-M vector, where M is the FFT length. The output order is bit natural.
- If you set `OutputSize` to `'Same as input size'`, the output data is an M-by-1 vector, where M is the input vector size. The output order is bit reversed.

The data type is a result of the `FilterOutputDataType` and the bit growth in the FFT necessary to avoid overflow.

`validOut` — Indicates valid output data
scalar

The object sets `validOut` to `true` with each valid sample on `dataOut`.

Data Types: `logical`

`startOut` — Indicates the first valid cycle of output data (optional)
scalar

The object sets `startOut` to `true` during the first valid sample on `dataOut`.

Dependencies

To enable this argument, set `StartOutputPort` to `true`.

Data Types: `logical`

`endOut` — Indicates the last valid cycle of output data (optional)
scalar

The object sets `endOut` to `true` during the last valid sample on `dataOut`.

Dependencies

To enable this argument, set `EndOutputPort` to `true`.

Data Types: `logical`

Introduced in R2017a

dsp.ChannelSynthesizer System object

Package: dsp

Polyphase FFT synthesis filter bank

Description

The `dsp.ChannelSynthesizer` System object merges multiple narrowband signals into a broadband signal by using an FFT based synthesis filter bank. The filter bank uses a prototype lowpass filter and is implemented using a polyphase structure. You can specify the filter coefficients directly or through design parameters.

Each narrowband signal is stored as a column in the input signal, `x`. The number of columns in `x` corresponds to the number of frequency bands of the filter bank. If `x` is three-dimensional, each matrix corresponds to a separate channel. If M is the number of frequency bands, and `x` is an L-by-M matrix, then the output signal, `y`, has dimensions $L \times M$-by-1. If `x` has more than one channel, that is, it has dimensions L-by-M-by-N, then `y` has dimensions $L \times M$-by-N. The input `x` can be complex and supports single and double data types.

This object also accepts variable-size inputs. That is, once the object is locked, you can change the size of each input channel. The number of channels cannot change. This object supports C and C++ code generation.

To merge multiple narrowband signals into a broadband signal:

1. Create a `dsp.ChannelSynthesizer` object and set the properties of the object.
2. Call step to synthesize the signal.

Note: Alternatively, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`synthesizer = dsp.ChannelSynthesizer` creates a synthesizer object, using the default properties.

`synthesizer = dsp.ChannelSynthesizer(Name,Value)` specifies additional properties using `Name,Value` pairs. Unspecified properties have default values.

Example:

```
synthesizer = dsp.ChannelSynthesizer('NumTapsPerBand',20,'StopbandAttenuation',140);
```

Properties

`Specification` — Filter design parameters or coefficients

`'Number of taps per band and stopband attenuation'` (default) | `'Coefficients'`

Filter design parameters or filter coefficients, specified as one of these options:

- `'Number of taps per band and stopband attenuation'` — Specify the filter design parameters through the `NumTapsPerBand` and `StopbandAttenuation` properties.
- `'Coefficients'` — Specify the filter coefficients directly using `LowpassCoefficients`.

`NumTapsPerBand` — Number of filter coefficients per frequency band

`12` (default) | positive integer

Number of filter coefficients each polyphase branch uses, specified as a positive integer. The number of polyphase branches matches the number of frequency bands. The total number of filter coefficients for the prototype lowpass filter is given by product of the number of frequency bands and `NumTapsPerBand`. For a given stopband attenuation, increasing the number of taps per band narrows the transition width of the filter. As a result, there is more usable bandwidth for each frequency band at the expense of increased computation.

This property applies when you set `Specification` to `'Number of taps per band and stopband attenuation'`.

`StopbandAttenuation` — Stopband attenuation

`80` (default) | positive real scalar

Stopband attenuation of the lowpass filter, specified as a positive real scalar in dB. This value controls the maximum amount of aliasing from one frequency band to the next. Larger is the stopband attenuation, smaller is the passband ripple.

This property applies when you set `Specification` to `'Number of taps per band and stopband attenuation'`.

`LowpassCoefficients` — Coefficients of the prototype lowpass filter
`[1×49 double]` (default) | row vector

Coefficients of the prototype lowpass filter, specified as a row vector. There must be at least one coefficient per frequency band. If the length of the lowpass filter is less than the number of frequency bands, the object zero-pads the coefficients.

This property applies when you set `Specification` to `'Coefficients'`.

This property is tunable. You can change its value even after the object is locked.

Methods

coeffs	Coefficients of prototype lowpass filter
polyphase	Polyphase matrix
reset	Reset internal states of System object
step	Merge narrowband signals into a broadband signal
tf	Transfer function

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Quadrature Mirror Filter Bank

The quadrature mirror filter bank (QMF) contains an analysis filter bank section and a synthesis filter bank section. `dsp.Channelizer` implements the analysis filter bank.

`dsp.ChannelSynthesizer` implements the synthesis filter bank using the efficient polyphase implementation that is based on a prototype lowpass filter.

Initialization

Initialize the `dsp.Channelizer` and `dsp.ChannelSynthesizer` System objects. Each object is set up with 8 frequency bands, 8 polyphase branches in each filter, 12 coefficients per polyphase branch, and a stopband attenuation of 140 dB. Use a sine wave with multiple frequencies as the input signal. View the input spectrum and the output spectrum using a spectrum analyzer.

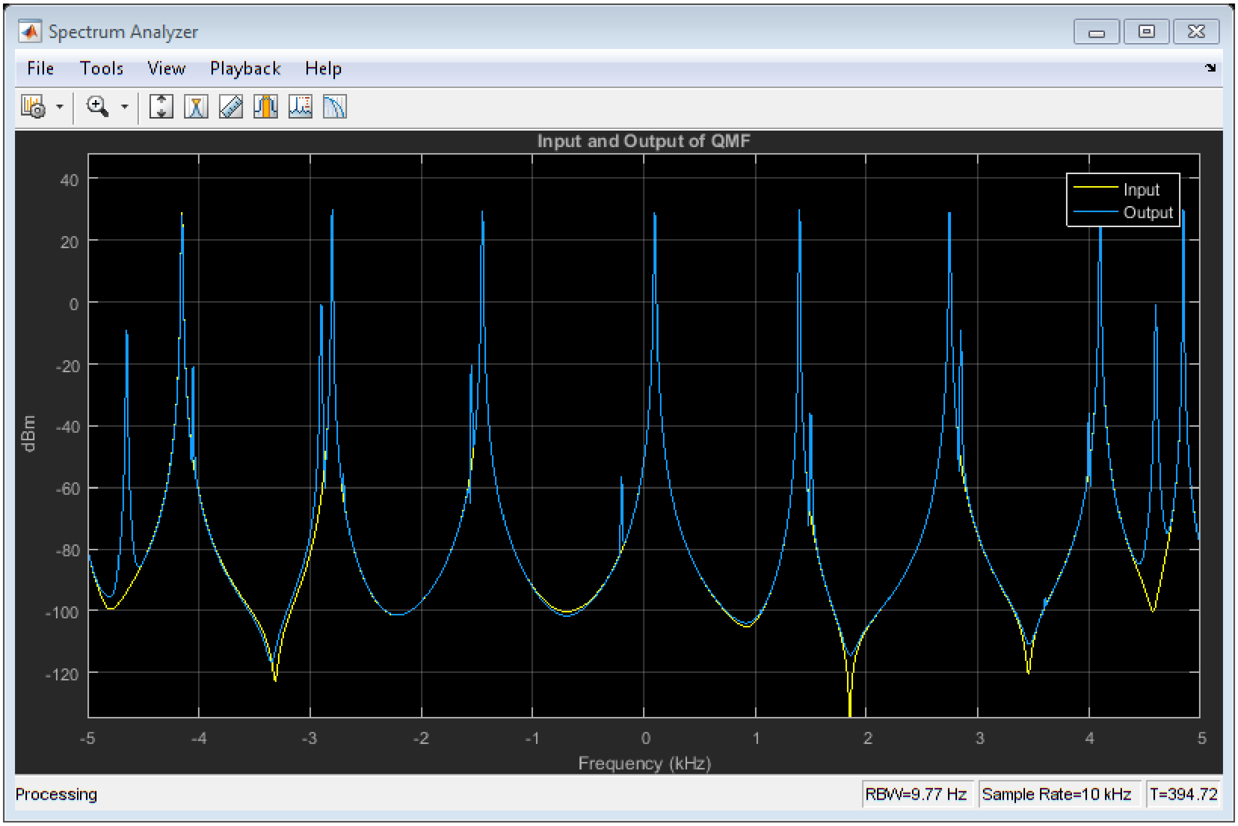
```
offsets = [-40,-30,-20,10,15,25,35,-15];
sinewave = dsp.SineWave('ComplexOutput',true,'Frequency',...
    offsets+(-375:125:500),'SamplesPerFrame',800);

channelizer = dsp.Channelizer('StopbandAttenuation',140);
synthesizer = dsp.ChannelSynthesizer('StopbandAttenuation',140);
spectrumAnalyzer =  dsp.SpectrumAnalyzer('ShowLegend',true,'NumInputPorts',...
    2,'ChannelNames',{'Input','Output'},'Title','Input and Output of QMF');
```

Streaming

Use the channelizer to split the broadband input signal into multiple narrow bands. Then pass the multiple narrowband signals into the synthesizer, which merges these signals to form the broadband signal. Compare the spectra of the input and output signals.

```
for i = 1:5000
    x = sum(sinewave(),2);
    y = channelizer(x);
    v = synthesizer(y);
    spectrumAnalyzer(x,v);
end
```

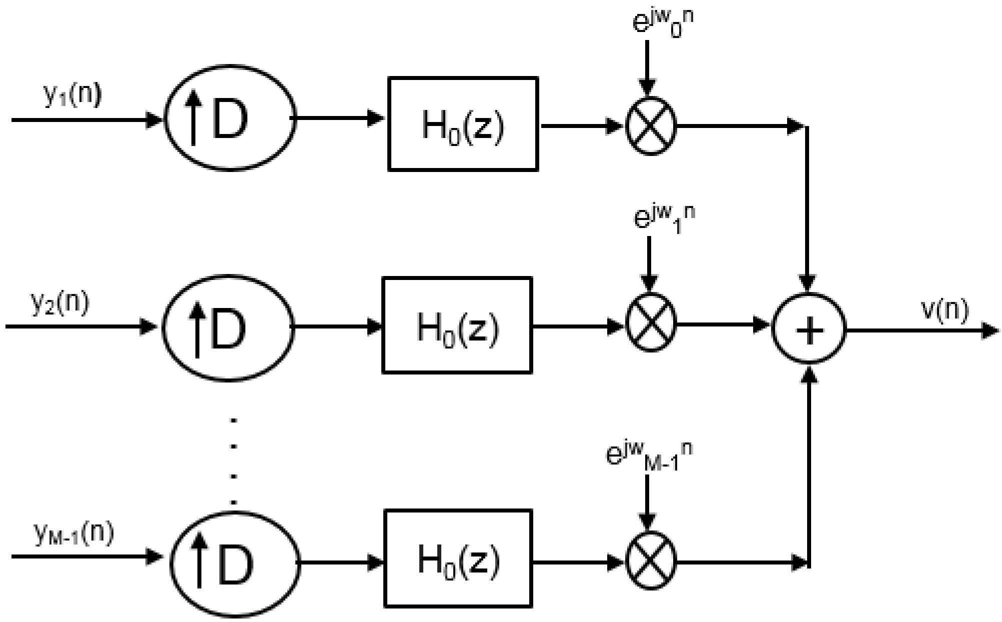


The input and output spectra match very closely.

Definitions

Synthesis Filter Bank

The synthesis filter bank consists of a set of parallel bandpass filters that merge multiple input narrowband signals, y_1(n), y_2(n),..., y_{M-1}(n) into a single broadband signal, *v(n)*. The input narrowband signals are in the baseband. Each narrowband signal is interpolated to a higher sampling rate by using the upsampler, and then filtered by the lowpass filter. A complex exponential that follows the lowpass filter centers the baseband signal around w_k.



Prototype Lowpass Filter

To implement the synthesis filter bank efficiently, the synthesizer uses a prototype lowpass filter. This filter has an impulse response of h[n], a normalized two-sided bandwidth of $2\pi/M$, and a cutoff frequency of π/M. M is the number of frequency bands, that is, the branches of the synthesis filter bank. This value corresponds to the FFT length that the filter bank uses. M can be high, in the order of 2048 or more. The stopband attenuation determines the minimum level of interference (aliasing) from one frequency band to another. The passband ripple must be small so that the input signal is not distorted in the passband.

The prototype lowpass filter models the first branch of the filter bank. The other $M - 1$ branches are modeled by filters that are modulated versions of the prototype filter. The modulation factor is given by $e^{jw_k n}, \quad w_k = 2\pi k / M, \quad k = 0,1,\ldots,M-1$.

The output of each bandpass filter forms a specific portion of the broadband signal. The output of all the branches are added to form the broadband signal, *v(n)*.

Algorithm

Polyphase Implementation

The synthesis filter bank can be implemented efficiently using the polyphase structure.

To derive the polyphase structure, start with the transfer function of the prototype lowpass filter.

$$H_0(z) = b_0 + b_1 z^{-1} + \ldots + b_N z^{-N}$$

N+1 is the length of the prototype filter.

You can rearrange this equation as follows:

$$\begin{aligned} H_0(z) = \; & \left(b_0 + b_M z^{-M} + b_{2M} z^{-2M} + .. + b_{N-M+1} z^{-(N-M+1)}\right) + \\ & z^{-1}\left(b_1 + b_{M+1} z^{-M} + b_{2M+1} z^{-2M} + .. + b_{N-M+2} z^{-(N-M+1)}\right) + \\ & \vdots \\ & z^{-(M-1)}\left(b_{M-1} + b_{2M-1} z^{-M} + b_{3M-1} z^{-2M} + .. + b_N z^{-(N-M+1)}\right) \end{aligned}$$

M is the number of polyphase components.

You can write this equation as:

$$H_0(z) = E_0(z^M) + z^{-1} E_1(z^M) + \ldots + z^{-(M-1)} E_{M-1}(z^M)$$

$E_0(z^M)$, $E_1(z^M)$,..., $E_{M-1}(z^M)$ are polyphase components of the prototype lowpass filter, H_0(z).

The other filters in the filter bank, H_k(z), where k = 1, ..., M-1, are modulated versions of this prototype filter.

You can write the transfer function of the kth modulated bandpass filter as $H_k(z) = H_0(ze^{jw_k})$. Replacing z with ze^{jw_k},

$$H_k(z) = h_0 + h_1 e^{jwk} z^{-1} + h_2 e^{j2wk} z^{-2} \ldots + h_N e^{jNwk} z^{-N}$$

N+1 is the length of the kth filter.

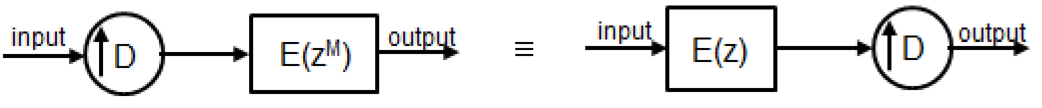
In polyphase form, the equation is as follows:

$$H_k(z) = \begin{bmatrix} 1 & e^{jw_k} & e^{j2w_k} & \ldots & e^{j(M-1)w_k} \end{bmatrix} \begin{bmatrix} E_0(z^M) \\ z^{-1}E_1(z^M) \\ \vdots \\ z^{-(M-1)}E_{M-1}(z^M) \end{bmatrix}$$

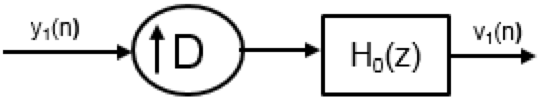
For all M channels in the filter bank, the MIMO transfer function, H(z), is given by:

$$H(z) = \begin{bmatrix} 1 & 1 & 1 & \ldots & 1 \\ 1 & e^{jw_1} & e^{j2w_1} & \ldots & e^{j(M-1)w_1} \\ & & \vdots & & \\ 1 & e^{jw_{M-1}} & e^{j2w_{M-1}} & \ldots & e^{j(M-1)w_{M-1}} \end{bmatrix} \begin{bmatrix} E_0(z^M) \\ z^{-1}E_1(z^M) \\ \vdots \\ z^{-(M-1)}E_{M-1}(z^M) \end{bmatrix}$$

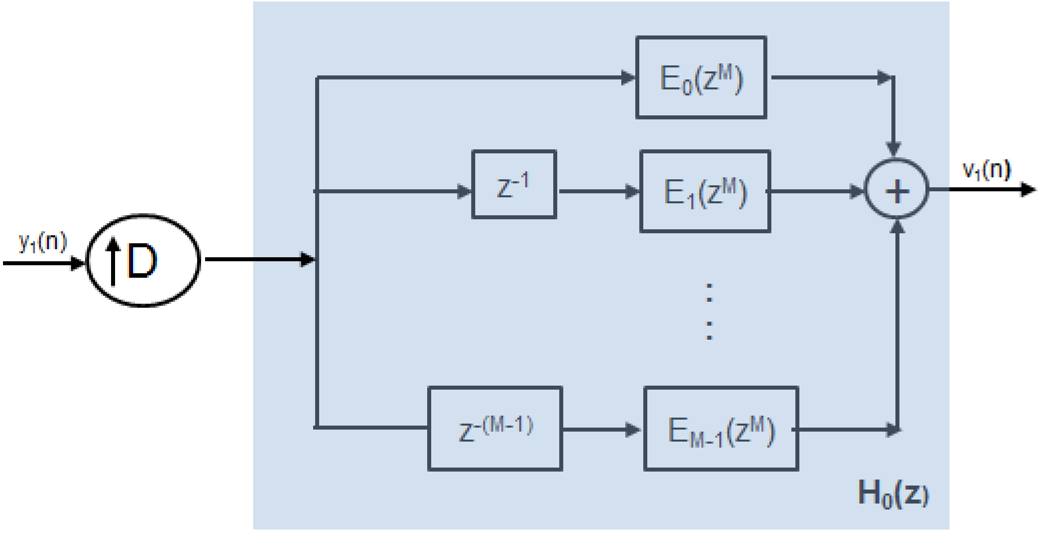
Here is the multirate noble identity for interpolation:



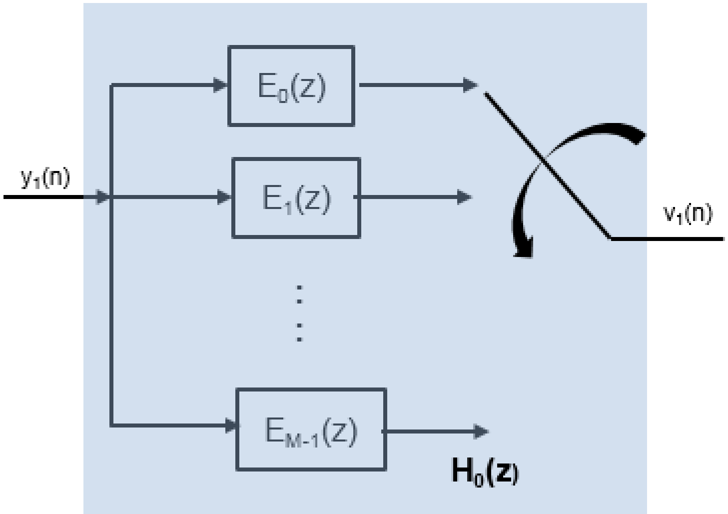
For illustration, consider the first branch of the filter bank that contains the lowpass filter.



Replace H_0(z) with its polyphase representation.



After applying the noble identity for interpolation, you can replace the delays, interpolation factor, and the adder with a commutator switch.



For all the M channels in the filter bank, the MIMO transfer function, $H(z)$, is given by:

$$H(z) = \begin{bmatrix} 1 & 1 & 1 & \dots & 1 \\ 1 & e^{jw_1} & e^{j2w_1} & \cdots & e^{j(M-1)w_1} \\ & & \vdots & & \\ 1 & e^{jw_{M-1}} & e^{j2w_{M-1}} & \cdots & e^{j(M-1)w_{M-1}} \end{bmatrix} \begin{bmatrix} E_0(z) \\ E_1(z) \\ \vdots \\ E_{M-1}(z) \end{bmatrix}$$

The matrix on the left is an IDFT matrix. With the IDFT matrix, the efficient implementation of the lowpass prototype based filter bank looks like the following.

coeffs

System object: dsp.ChannelSynthesizer
Package: dsp

Coefficients of prototype lowpass filter

Syntax

```
c = coeffs(synthesizer)
```

Description

`c = coeffs(synthesizer)` returns a structure that contains the coefficients of the prototype lowpass filter. This value is equal to the number of frequency bands times the number of coefficients per band. Number of frequency bands or the number of narrow band signals is given by the number of columns in the input signal. You can run `coeffs` on the synthesizer object only after the object is locked, that is, after you pass the input signal to the object.

Introduced in R2016b

polyphase

System object: dsp.ChannelSynthesizer
Package: dsp

Polyphase matrix

Syntax

```
p = polyphase(synthesizer)
```

Description

`p = polyphase(synthesizer)` returns the polyphase matrix used by the filter bank. Each row in the matrix corresponds to a polyphase branch. The number of columns in *p* corresponds to the number of filter taps per polyphase branch.

Introduced in R2016b

reset

System object: dsp.ChannelSynthesizer
Package: dsp

Reset internal states of System object

Syntax

```
reset(synthesizer)
```

Description

`reset(synthesizer)` resets the states of the input object to their initial values. The initial state values correspond to the initial conditions for the difference equation defining the object. After you call the object using nonzero input data, the filter might have nonzero states. If you continue to pass nonzero input data to the object without first calling `reset`, the object might produce different outputs for an identical input.

Introduced in R2016b

step

System object: dsp.ChannelSynthesizer
Package: dsp

Merge narrowband signals into a broadband signal

Syntax

```
y = step(synthesizer,x)
```

Description

Note: Alternatively, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`y = step(synthesizer,x)` merges the narrowband input signals contained as columns in `x` into broadband signal, `y`. The number of columns in `x` corresponds to the number of frequency bands. If `x` is three dimensional, each matrix corresponds to a separate channel. If M is the number of frequency bands, and `x` is a L-by-M matrix, then `y` has dimensions, $L*M$-by-1. If `x` has more than one channel, that is, L-by-M-by-N, then `y` has dimensions $L*M$-by-N. The input `x` can be complex and supports single and double data types.

Introduced in R2016b

tf

System object: dsp.ChannelSynthesizer
Package: dsp

Transfer function

Syntax

`[b,a] = tf(synthesizer)`

Description

`[b,a] = tf(synthesizer)` returns the vector of numerator coefficients, `b`, and the vector of denominator coefficients, `a`, of the prototype lowpass filter.

Introduced in R2016b

dsp.Chirp System object

Package: dsp

Generate swept-frequency cosine (chirp) signal

Description

The `Chirp` object generates a swept-frequency cosine (chirp) signal.

To generate the chirp signal:

1. Define and set up your chirp signal. See "Construction" on page 4-352.
2. Call step to generate the signal according to the properties of `dsp.Chirp`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj)` and `y = obj()` perform equivalent operations.

Construction

`chirp = dsp.Chirp` returns a chirp signal, `chirp`, with unity amplitude.

`chirp = dsp.Chirp('`*`PropertyName`*`',`*`PropertyValue`*`,...)` returns a chirp signal, `chirp`, with each specified property set to the specified value.

Properties

`Type`

Frequency sweep type

Specify the frequency sweep type as `Swept cosine`, `Linear`, `Logarithmic`, or `Quadratic`. This property specifies how the output instantaneous frequency sweep varies over time. The default value is `Linear`.

SweepDirection

Sweep direction

Specify the sweep direction as either `Unidirectional` or `Bidirectional`. The default value is `Unidirectional`.

InitialFrequency

Initial frequency (hertz)

When you set the `Type` on page 4-352 property to `Linear`, `Quadratic`, or `Logarithmic`, this property specifies the initial instantaneous frequency in hertz of the output chirp signal. When you set the `Type` on page 4-352 property to `Logarithmic`, the value of this property is one less than the actual initial frequency of the sweep. Also, when the sweep is logarithmic, the initial frequency must be less than the target frequency, specified by the `TargetFrequency` on page 4-353 property. This property is tunable. The default value is `1000`.

TargetFrequency

Target frequency (hertz)

When you set the `Type` on page 4-352 property to `Linear`, `Quadratic`, or `Logarithmic`, this property specifies the instantaneous frequency of the output signal in hertz at the target time. When you set the `Type` on page 4-352 property to `Swept Cosine`, the target frequency is the instantaneous frequency of the output at half the target time. Also, when the sweep is logarithmic, the target frequency must be greater than the initial frequency, specified by the `InitialFrequency` on page 4-353 property. This property is tunable. The default value is `4000`.

TargetTime

Target time

When you set the `Type` on page 4-352 property to `Linear`, `Quadratic`, or `Logarithmic`, this property specifies the target time in seconds at which the target frequency is reached. When you set the `Type` on page 4-352 property to `Swept cosine`, this property specifies the time at which the sweep reaches $2f_{tgt} - f_{init}$ Hz, where f_{tgt} is the `TargetFrequency` on page 4-353 and f_{init} is the `InitialFrequency` on page 4-353. The target time should not be greater than the sweep time, specified by the `SweepTime` on page 4-354 property. This property is tunable. The default value is `1`.

SweepTime

Sweep time

When you set the `SweepDirection` on page 4-353 property to `Unidirectional`, the sweep time in seconds is the period of the output frequency sweep. When you set the `SweepDirection` on page 4-353 property to `Bidirectional`, the sweep time is half the period of the output frequency sweep. The sweep time should be no less than the target time, specified by the `TargetTime` on page 4-353. This property must be a positive numeric scalar and is tunable. The default value is `1`.

InitialPhase

Initial phase

Specify initial phase of the output in radians at time $t = 0$. This property is tunable. The default value is `0`.

SampleRate

Sample rate

Specify the sampling rate of the output in hertz as a positive numeric scalar. The default value is `8000`.

SamplesPerFrame

Samples per output frame

Specify the number of samples to buffer into each output as a positive integer. The default value is `1`.

OutputDataType

Output data type

Specify the output data type as `double` or `single`. The default value is `double`.

Methods

reset	Reset internal states of chirp object

step	Generate chirp signal

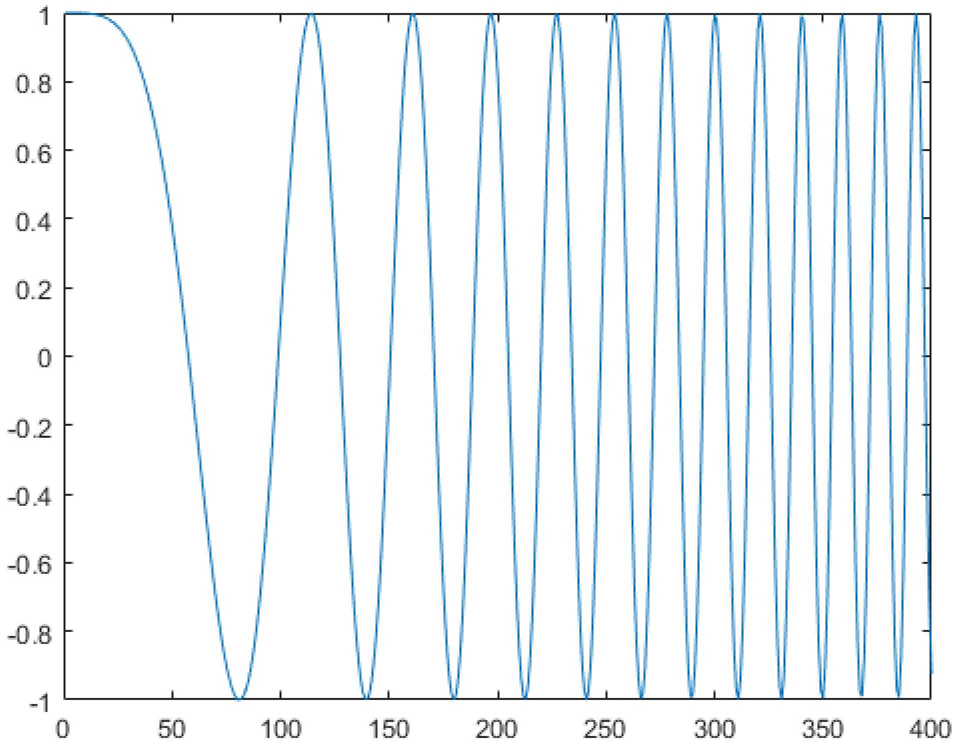
Common to All System Objects	
clone	Create System object with same property values
getNumInpu	Expected number of inputs to a System object
getNumOutp	Expected number of outputs of a System object
isLocked	Check locked states of a System object (logical)
release	Allow System object property value changes

Examples

Generate a Bidirectional Swept Chirp Signal

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject() becomes step(myObject).

```
chirp = dsp.Chirp(...
    'SweepDirection', 'Bidirectional', ...
    'TargetFrequency', 25, ...
    'InitialFrequency', 0,...
    'TargetTime', 1, ...
    'SweepTime', 1, ...
    'SamplesPerFrame', 400, ...
    'SampleRate', 400);
plot(chirp());
```



Algorithms

This object implements the algorithm, inputs, and outputs described on the `Chirp` block reference page. The object properties correspond to the block parameters.

See Also

dsp.SineWave

Introduced in R2012a

reset

System object: dsp.Chirp
Package: dsp

Reset internal states of chirp object

Syntax

```
reset(chirp)
```

Description

`reset(chirp)` sets the internal states of the `Chirp` object `chirp` to their initial values. After you reset `chirp`, the frequency sweep restarts from the beginning.

step

System object: dsp.Chirp
Package: dsp

Generate chirp signal

Syntax

`Y = step(chirp)`

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj)` and `y = obj()` perform equivalent operations.

`Y = step(chirp)` returns a swept-frequency cosine output, `Y`.

Note: `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.CICCompensationDecimator System object

Package: dsp

Compensate for CIC decimation filter using FIR decimator

Description

You can compensate for the shortcomings of a CIC decimator, namely its passband droop and wide transition region, by following it with a compensation decimator. This System object lets you design and use such a filter. `dsp.CICCompensationDecimator` supports fixed-point operations and ARM Cortex code generation.

To compensate for the shortcomings of a CIC filter using an FIR decimator:

1. Define and set up your CIC compensation decimator. See “Construction” on page 4-359.
2. Call step to compensate for the passband droop and wide transition region of the CIC filter according to the properties of `dsp.CICCompensationDecimator`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`ciccompdec = dsp.CICCompensationDecimator` returns a System object, `ciccompdec`, that applies an FIR decimator to each channel of an input signal. Using the properties of the object, the decimation filter can be designed to compensate for a preceding CIC filter.

`ciccompdec = dsp.CICCompensationDecimator(Name,Value)` returns a CIC compensation decimator System object, `ciccompdec`, with properties and options specified by one or more `Name,Value` pair arguments.

`ciccompdec = dsp.CICCompensationDecimator(decim,Name,Value)` returns a CIC compensation decimator System object, `ciccompdec`, with the `DecimationFactor` property set to `decim` and additional properties and options specified by one or more `Name,Value` pair arguments.

`ciccompdec = dsp.CICCompensationDecimator(cic,Name,Value)` returns a CIC compensation decimator System object, `ciccompdec`, with the `CICRateChangeFactor`, `CICNumSections`, and `CICDifferentialDelay` properties specified in the `dsp.CICDecimator` System object `cic` and additional properties and options specified by one or more `Name,Value` pair arguments.

`ciccompdec = dsp.CICCompensationDecimator(cic,decim,Name,Value)` returns a CIC compensation decimator System object, `ciccompdec`, with the `CICRateChangeFactor`, `CICNumSections`, and `CICDifferentialDelay` properties specified in the `dsp.CICDecimator` System object `cic`, the `DecimationFactor` property set to `decim`, and additional properties and options specified by one or more `Name,Value` pair arguments.

Properties

`CICDifferentialDelay` — Differential delay of the CIC filter being compensated

1 (default) | positive integer scalar

Specify the differential delay of the CIC filter being compensated as a positive integer scalar. The default is 1.

`CICNumSections` — Number of sections of the CIC filter being compensated

2 (default) | positive integer scalar

Specify the number of sections of the CIC filter being compensated as a positive integer scalar. The default is 2.

`CICRateChangeFactor` — Rate-change factor of the CIC filter being compensated

2 (default) | positive integer scalar

Specify the rate-change factor of the CIC filter being compensated as a positive integer scalar. The default is 2.

`DecimationFactor` — Decimation factor of compensator

2 (default) | positive integer scalar

Specify the decimation factor of the compensator System object as a positive integer scalar. The default is 2.

`DesignForMinimumOrder` — Design filter of minimum order or of specified order
`true` (default) | logical value

Specify whether to design a filter of minimum order or a filter of specified order as a logical scalar. The default is `true`, which corresponds to a filter of minimum order.

`FilterOrder` — Order of decimation compensator filter
12 (default) | positive integer scalar

Specify the order of the decimation compensator filter as a positive integer scalar. This property applies only when you set the `DesignForMinimumOrder` property to `false`. The default is 12.

`PassbandFrequency` — Passband edge frequency in hertz
100 kHz (default) | positive real scalar

Specify the passband edge frequency as a positive real scalar expressed in hertz. `PassbandFrequency` must be less than $F_s/2$, where F_s is the input sample rate. The default is 100 kHz.

`PassbandRipple` — Filter passband ripple in decibels
0.1 dB (default) | positive real scalar

Specify the filter passband ripple as a positive real scalar expressed in decibels. The default is 0.1 dB.

`SampleRate` — Input sample rate in hertz
600 kHz (default) | positive real scalar

Specify the input sample rate as a positive real scalar expressed in hertz. The default is 1200 kHz.

`StopbandAttenuation` — Filter stopband attenuation in decibels
60 dB (default) | positive real scalar

Specify the filter stopband attenuation as a positive real scalar expressed in decibels. The default is 60 dB

`StopbandFrequency` — Stopband edge frequency in hertz
400 kHz (default) | positive real scalar

Specify the stopband edge frequency as a positive real scalar expressed in hertz. `StopbandFrequency` must be less than $F_s/2$, where F_s is the input sample rate. The default is 400 kHz.

Fixed-Point Properties

`CoefficientsDataType` — Word and fraction lengths of coefficients
`numerictype(1,16)` (default) | `numerictype` object

Word and fraction lengths of coefficients, specified as a signed or unsigned `numerictype` object. The default, `numerictype(1,16)` corresponds to a signed numeric type object with 16-bit coefficients and a fraction length determined based on the coefficient values, to give the best possible precision.

This property is not tunable.

Word length of the output is same as the word length of the input. Fraction length of the output is computed such that the entire dynamic range of the output can be represented without overflow. For details on how the fraction length of the output is computed, see "Fixed-Point Precision Rules for Avoiding Overflow in FIR Filters".

`RoundingMethod` — Rounding method for output fixed-point operations
`'Floor'` (default) | `'Ceiling'` | `'Convergent'` | `'Nearest'` | `'Round'` | `'Simplest'` | `'Zero'`

Rounding method for output fixed-point operations, specified as a character vector. For more information on the rounding modes, see "Precision and Range".

Methods

reset	Reset internal states of CIC compensation decimator
step	Compensate for preceding CIC filter

Examples

Impulse and Frequency Response of CIC Compensation Decimator

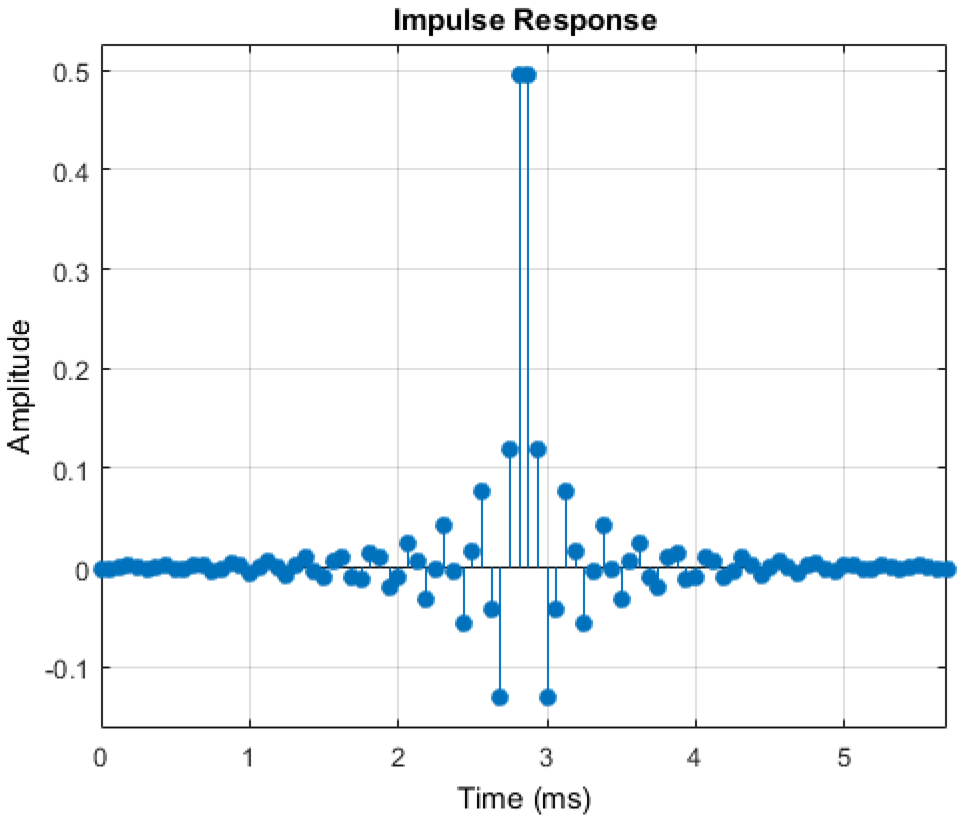
Design an CIC compensation decimator. Specify the decimation factor to be 2, passband frequency to be 4 kHz, stopband frequency to be 4.5 kHz, and the input sample rate to be 16 kHz.

```
fs = 16e3;
fPass = 4e3;
fStop = 4.5e3;

CICCompDecim = dsp.CICCompensationDecimator('DecimationFactor',2,'PassbandFrequency',fP
    'StopbandFrequency',fStop,'SampleRate',fs);
```

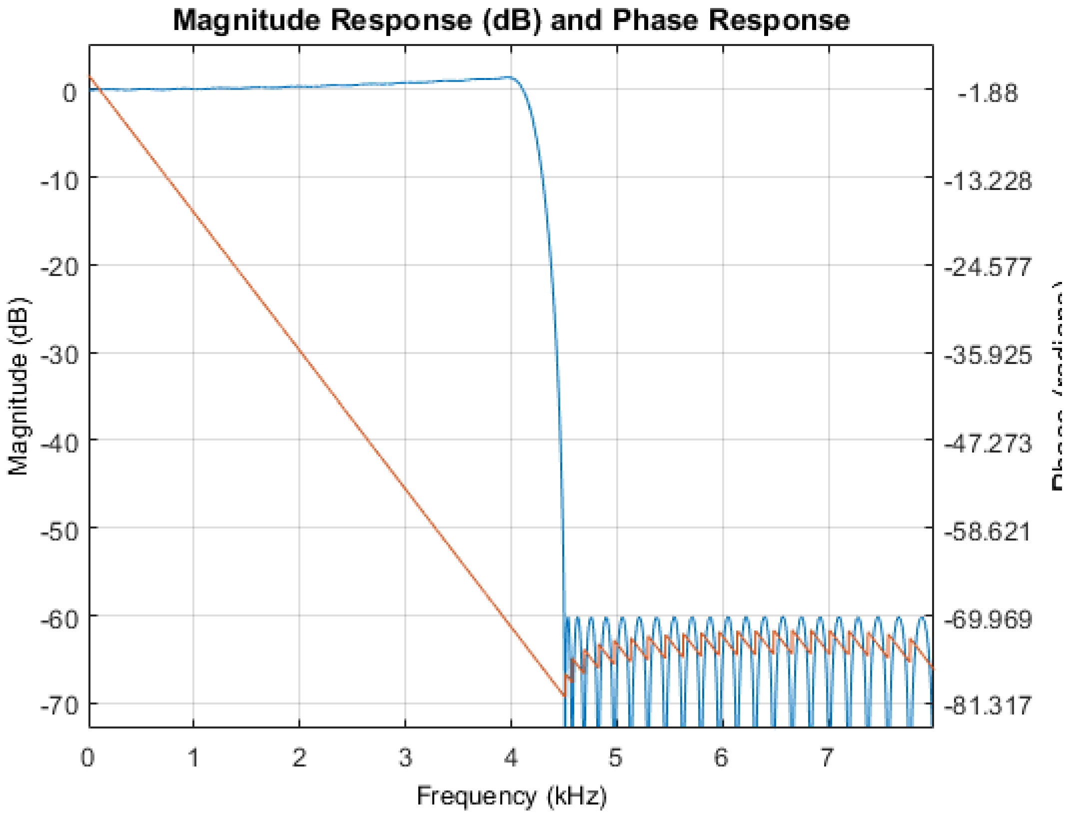
Plot the impulse response. The group delay of the filter is 45.5.

```
fvtool(CICCompDecim,'Analysis','impulse')
```



Plot the magnitude and Phase response.

```
fvtool(CICCompDecim,'Analysis','freq')
```



Compensation Decimator Design

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

Design a compensation decimator for an existing CIC decimator having six sections and a decimation factor of 6.

```
CICDecim = dsp.CICDecimator('DecimationFactor',6, ...
    'NumSections',6);
```

Construct the compensation decimator. Specify a decimation factor of 2, an input sample rate of 16 kHz, a passband frequency of 4 kHz, and a stopband frequency of 4.5 kHz.

```
fs = 16e3;
fPass = 4e3;
fStop = 4.5e3;

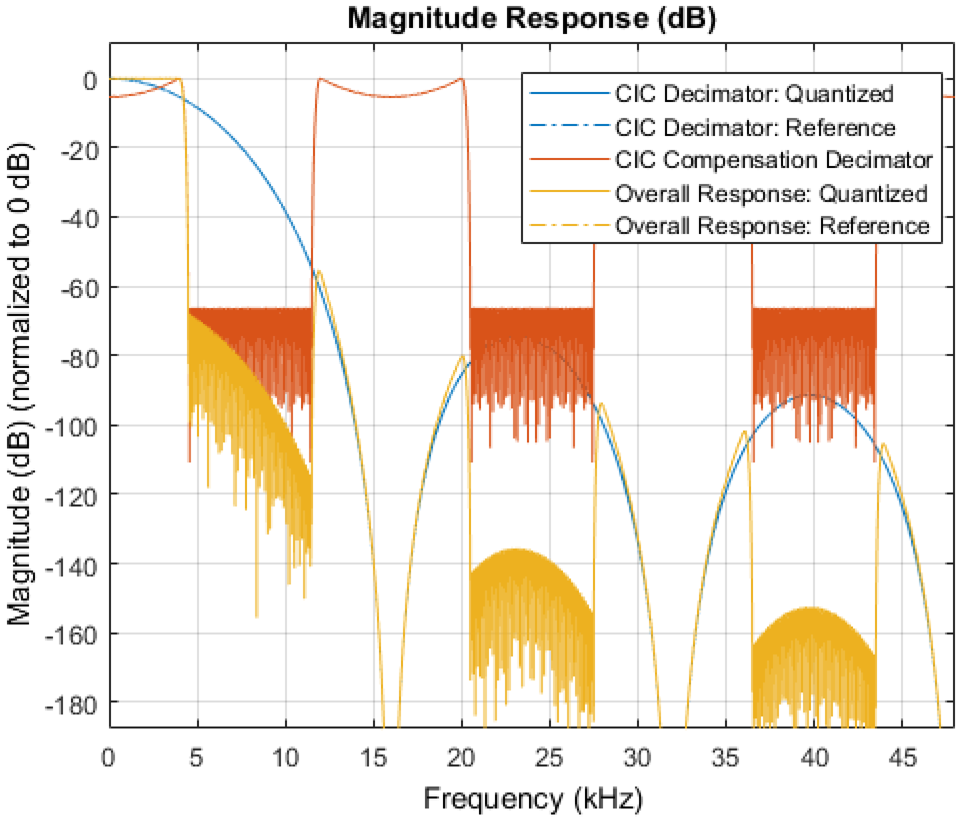
CICCompDecim = dsp.CICCompensationDecimator(CICDecim, ...
    'DecimationFactor',2,'PassbandFrequency',fPass, ...
    'StopbandFrequency',fStop,'SampleRate',fs);
```

Visualize the frequency response of the cascade. Normalize all magnitude responses to 0 dB.

```
filtCasc = dsp.FilterCascade(CICDecim,CICCompDecim);

f = fvtool(CICDecim, CICCompDecim, filtCasc, ...
    'Fs', [fs*6 fs fs*6]);

f.NormalizeMagnitudeto1 = 'on';
legend(f,'CIC Decimator','CIC Compensation Decimator', ...
    'Overall Response');
```



Apply the design to a 1200-sample random input signal.

```
x = dsp.SignalSource(fi(rand(1200,1),1,16,15),'SamplesPerFrame',120);

y = fi(zeros(0,1),1,32,20);
for ind = 1:10
    x2 = CICDecim(x());
    y = [y;CICCompDecim(x2)];
```

```
end
```

dsp.CICCompensationInterpolator | dsp.CICDecimator | dsp.CICInterpolator

Introduced in R2014b

reset

System object: dsp.CICCompensationDecimator
Package: dsp

Reset internal states of CIC compensation decimator

Syntax

`reset(ciccompdec)`

Description

`reset(ciccompdec)` resets the internal states of a `CICCompensationDecimator` System object, `ciccompdec`, to their initial values.

Input Arguments

`ciccompdec` — CIC compensation decimator

`CICCompensationDecimator` System object

CIC compensation decimator, specified as a `CICCompensationDecimator` System object.

step

System object: dsp.CICCompensationDecimator
Package: dsp

Compensate for preceding CIC filter

Syntax

```
y = step(ciccompdec,x)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`y = step(ciccompdec,x)` returns the filtered and downsampled values, `y`, of the input signal, `x`. The System object treats a $K_i \times N$ input matrix as N independent channels, decimating each channel over the first dimension. The result is a $K_o \times N$ output matrix, where $K_o = K_i / M$ and M is the decimation factor. The object supports any real or complex floating-point or fixed-point input, with the exception of complex unsigned fixed-point data.

Input Arguments

`ciccompdec` — CIC compensation decimator

`CICCompensationDecimator` System object

CIC compensation decimator, specified as a `CICCompensationDecimator` System object.

`x` — Input signal

vector | matrix

Input signal, specified as a vector or matrix.

Output Arguments

y — Filtered and downsampled signal

vector | matrix

Filtered and downsampled signal, returned as a vector or matrix.

dsp.CICCompensationInterpolator

dsp.CICCompensationInterpolator System object

Package: dsp

Compensate for CIC interpolation filter using FIR interpolator

Description

You can compensate for the shortcomings of a CIC interpolator, namely its passband droop and wide transition region, by preceding it with a compensation interpolator. This System object lets you design and use such a filter. `dsp.CICCompensationInterpolator` supports fixed-point operations and ARM Cortex code generation.

To compensate for the shortcomings of a CIC filter using an FIR interpolator:

1. Define and set up your CIC compensation interpolator. See “Construction” on page 4-372.
2. Call step to compensate for the passband droop and wide transition region of the CIC filter according to the properties of `dsp.CICCompensationInterpolator`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`ciccompint = dsp.CICCompensationInterpolator` returns a System object, `ciccompint`, that applies an FIR interpolator to each channel of an input signal. Using the properties of the object, the interpolation filter can be designed to compensate for a subsequent CIC filter.

`ciccompint = dsp.CICCompensationInterpolator(Name,Value)` returns a CIC compensation interpolator System object, `ciccompint`, with properties and options specified by one or more `Name,Value` pair arguments.

`ciccompint = dsp.CICCompensationInterpolator(interp,Name,Value)` returns a CIC compensation interpolator System object, `ciccompint`, with the `InterpolationFactor` property set to `interp` and additional properties and options specified by one or more `Name,Value` pair arguments.

`ciccompint = dsp.CICCompensationInterpolator(cic,Name,Value)` returns a CIC compensation interpolator System object, `ciccompint`, with the `CICRateChangeFactor`, `CICNumSections`, and `CICDifferentialDelay` properties specified in the `dsp.CICInterpolator` System object `cic` and additional properties and options specified by one or more `Name,Value` pair arguments.

`ciccompint = dsp.CICCompensationInterpolator(cic,interp,Name,Value)` returns a CIC compensation interpolator System object, `ciccompint`, with the `CICRateChangeFactor`, `CICNumSections`, and `CICDifferentialDelay` properties specified in the `dsp.CICInterpolator` System object `cic`, the `InterpolationFactor` property set to `interp`, and additional properties and options specified by one or more `Name,Value` pair arguments.

Properties

`CICDifferentialDelay` — Differential delay of the CIC filter being compensated

1 (default) | positive integer scalar

Specify the differential delay of the CIC filter being compensated as a positive integer scalar. The default is 1.

`CICNumSections` — Number of sections of the CIC filter being compensated

2 (default) | positive integer scalar

Specify the number of sections of the CIC filter being compensated as a positive integer scalar. The default is 2.

`CICRateChangeFactor` — Rate-change factor of the CIC filter being compensated

2 (default) | positive integer scalar

Specify the rate-change factor of the CIC filter being compensated as a positive integer scalar. The default is 2.

`DesignForMinimumOrder` — Design filter of minimum order or of specified order

`true` (default) | logical value

Specify whether to design a filter of minimum order or a filter of specified order as a logical scalar. The default is `true`, which corresponds to a filter of minimum order.

`FilterOrder` — Order of interpolation compensator filter

12 (default) | positive integer scalar

Specify the order of the interpolation compensator filter as a positive integer scalar. This property applies only when you set the `DesignForMinimumOrder` property to `false`. The default is 12.

`InterpolationFactor` — Interpolation factor of compensator

2 (default) | positive integer scalar

Specify the interpolation factor of the compensator System object as a positive integer scalar. The default is 2.

`PassbandFrequency` — Passband edge frequency in hertz

100 kHz (default) | positive real scalar

Specify the passband edge frequency as a positive real scalar expressed in hertz. `PassbandFrequency` must be less than $F_s/2$, where F_s is the output sample rate. The default is 100 kHz.

`PassbandRipple` — Filter passband ripple in decibels

0.1 dB (default) | positive real scalar

Specify the filter passband ripple as a positive real scalar expressed in decibels. The default is 0.1 dB.

`SampleRate` — Input sample rate in hertz

600 kHz (default) | positive real scalar

Specify the input sample rate as a positive real scalar expressed in hertz. The default is 600 kHz.

`StopbandAttenuation` — Filter stopband attenuation in decibels

60 dB (default) | positive real scalar

Specify the filter stopband attenuation as a positive real scalar expressed in decibels. The default is 60 dB

`StopbandFrequency` — Stopband edge frequency in hertz

400 kHz (default) | positive real scalar

Specify the stopband edge frequency as a positive real scalar expressed in hertz. StopbandFrequency must be less than $F_s/2$, where F_s is the output sample rate. The default is 400 kHz.

Fixed-Point Properties

CoefficientsDataType — Word and fraction lengths of coefficients
numerictype(1,16) (default) | numerictype object

Word and fraction lengths of coefficients, specified as a signed or unsigned numerictype object. The default, numerictype(1,16) corresponds to a signed numeric type object with 16-bit coefficients and a fraction length determined based on the coefficient values, to give the best possible precision.

This property is not tunable.

Word length of the output is same as the word length of the input. Fraction length of the output is computed such that the entire dynamic range of the output can be represented without overflow. For details on how the fraction length of the output is computed, see "Fixed-Point Precision Rules for Avoiding Overflow in FIR Filters".

RoundingMethod — Rounding method for output fixed-point operations
'Floor' (default) | 'Ceiling' | 'Convergent' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'

Rounding method for output fixed-point operations, specified as a character vector. For more information on the rounding modes, see "Precision and Range".

Methods

reset	Reset internal states of CIC compensation interpolator
step	Compensate for subsequent CIC filter

More "Analysis Methods for Filter System Objects" on page 3-2.

You can also type dsp.CICCompensationInterpolator.helpFilterAnalysis at the command line to obtain a list of multirate discrete-time filter analysis methods supported for dsp.CICCompensationInterpolator objects.

Examples

Impulse and Frequency Response of CIC Compensation Interpolator

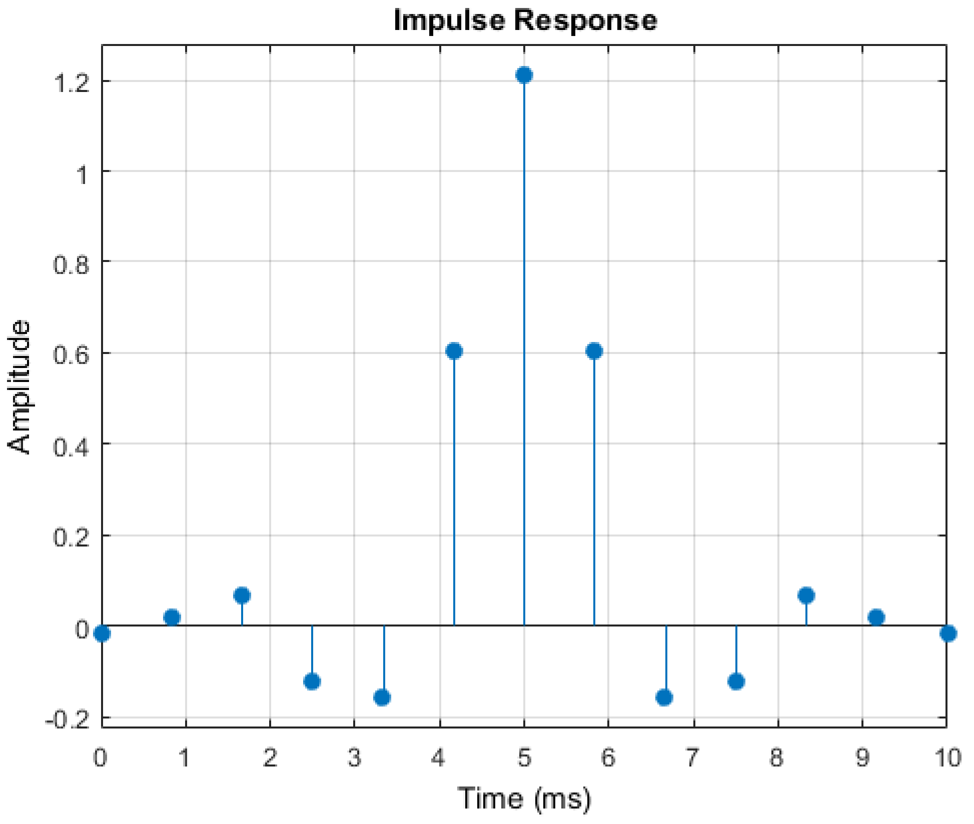
Design an CIC compensation interpolator. Specify the interpolation factor to be 2, passband frequency to be 200 Hz, stopband frequency to be 500 Hz, and the input sample rate to be 600 Hz.

```
fs = 600;
fPass = 200;
fStop = 500;

CICCompInterp = dsp.CICCompensationInterpolator('InterpolationFactor',2,'PassbandFreque
    'StopbandFrequency',fStop,'SampleRate',fs);
```

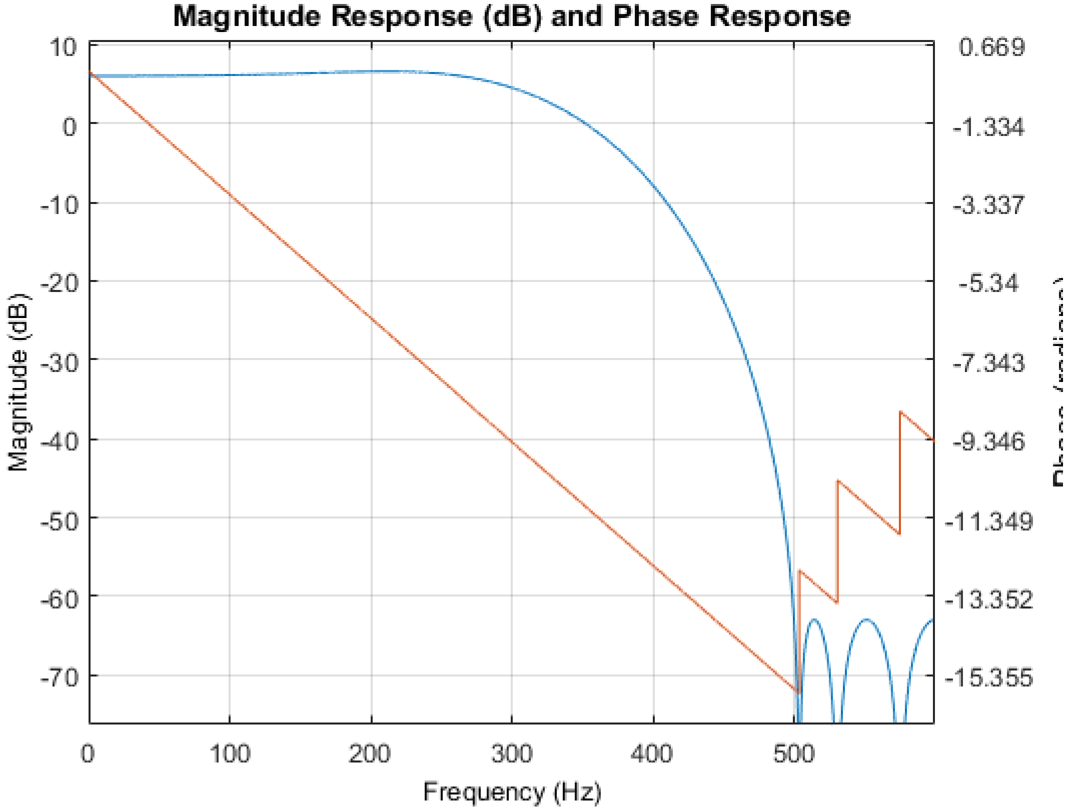
Plot the impulse response. The zeroth order coefficient is delayed 6 samples, which is equal to the group delay of the filter.

```
fvtool(CICCompInterp,'Analysis','impulse')
```



Plot the magnitude and Phase response.

```
fvtool(CICCompInterp,'Analysis','freq')
```



Compensation Interpolator Design

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

Design a compensation interpolator for an existing CIC interpolator having six sections and an interpolation factor of 16.

```
CICInterp = dsp.CICInterpolator('InterpolationFactor',16, ...
    'NumSections',6);
```

Construct the compensation interpolator. Specify an interpolation factor of 2, an input sample rate of 600 Hz, a passband frequency of 100 Hz, and a stopband frequency of 250

Hz. Set the minimum attenuation of alias components in the stopband to be at least 80 dB.

```
fs = 600;
fPass = 100;
fStop = 250;
ast = 80;

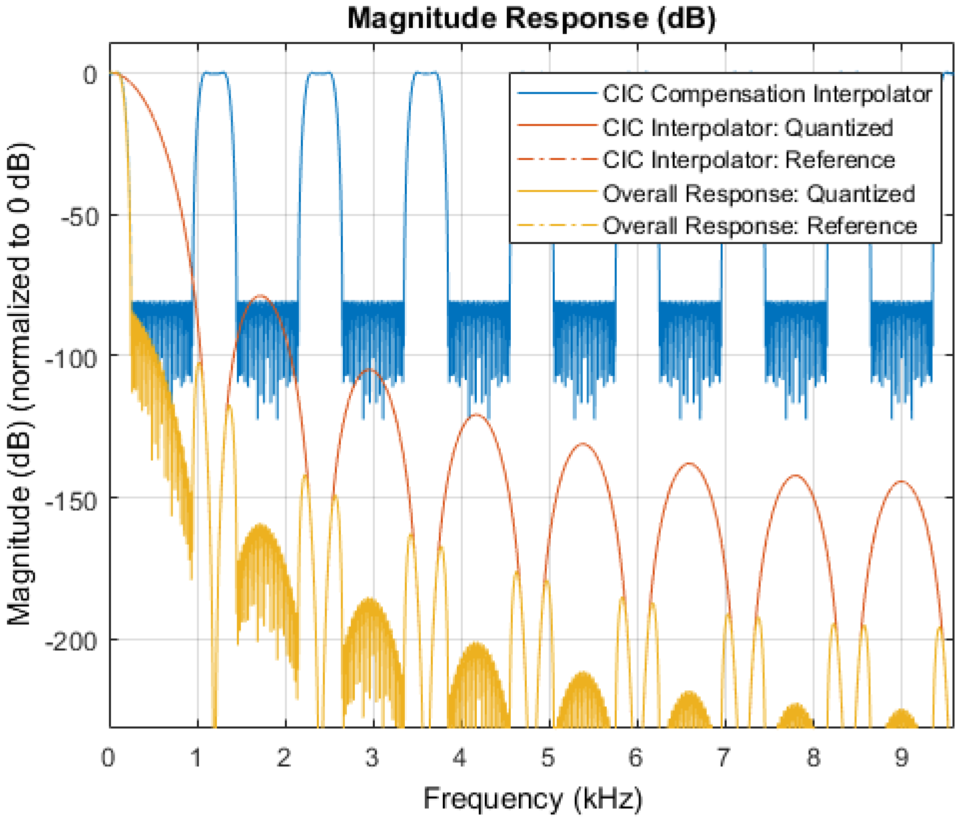
CICCompInterp = dsp.CICCompensationInterpolator(CICInterp, ...
    'InterpolationFactor',2,'PassbandFrequency',fPass, ...
    'StopbandFrequency',fStop,'StopbandAttenuation',ast, ...
    'SampleRate',fs);
```

Visualize the frequency response of the cascade. Normalize all magnitude responses to 0 dB.

```
FC = dsp.FilterCascade(CICCompInterp, CICInterp);

f = fvtool(CICCompInterp,CICInterp,FC, ...
    'Fs', [fs*2 fs*16*2 fs*16*2]);

f.NormalizeMagnitudeto1 = 'on';
legend(f,'CIC Compensation Interpolator','CIC Interpolator', ...
    'Overall Response');
```



Apply the design to a 1000-sample random input signal.

```
x = dsp.SignalSource(fi(rand(1000,1),1,16,15),'SamplesPerFrame',100);

y = fi(zeros(0,1),1,32,20);
for ind = 1:10
    x2 = CICCompInterp(x());
    y = [y;CICInterp(x2)];
```

```
end
```

dsp.CICDecimator System object

Package: dsp

Decimate input using Cascaded Integrator-Comb filter

Description

The `CICDecimator` object decimates inputs using a Cascaded Integrator-Comb filter. Fixed-point inputs and outputs to the object have signed fixed-point data types. To use fixed-point data types, you must have a Fixed-Point Designer license. Inputs and outputs to the System object can be single or double data types, in addition to the fixed-point data type. Property settings related to fixed-point data types are ignored for single or double data types.

Note: To use the filter analysis methods on `dsp.CICDecimator` System object, you must have the Fixed-Point Designer license. To get a list of the filter analysis methods this object supports, type `dsp.CICDecimator.helpFilterAnalysis` in the MATLAB command prompt.

To decimate inputs using a CIC filter:

1. Define and set up your System object. See “Construction” on page 4-386.
2. Call step to decimate the input according to the properties of `dsp.CICDecimator`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`cicdecim= dsp.CICDecimator` returns a `CICDecimator` System object, `cicdecim`, that you can use to decimate the input with a cascaded integrator-comb (CIC) decimation filter.

`cicdecim = dsp.CICDecimator('`*`PropertyName`*`',`*`PropertyValue`*`,...)` returns a `CICDecimator` object, `cicdecim`, with each specified property set to the value you specify.

`cicdecim = dsp.CICDecimator(`*`R`*`,`*`M`*`,`*`N`*`,'`*`PropertyName`*`',` *`PropertyValue`*`, ...)` returns a `CICDecimator` object, `cicdecim`, with the `DecimationFactor` on page 4-386 property set to *R*, the `DifferentialDelay` on page 4-386 property set to *M*, the `NumSections` on page 4-386 property set to *N*, and any other specified properties set to the values you specify.

Properties

`DecimationFactor`

Decimation factor of filter

Specify a positive integer amount by which the object decimates the input. The default is `2`.

`DifferentialDelay`

Differential delay of filter comb sections

Specify a positive integer delay value for the object to use in each comb section of the filter. The default is `1`.

`NumSections`

Number of integrator and comb sections

Specify the number of integrator and comb sections in the CIC filter as a positive integer value. The default is `2`.

FixedPointDataType

Fixed-point property setting

Specify the fixed-point data type as one of | `Full precision` | `Minimum section word lengths` | `Specify word lengths` | `Specify word and fraction lengths` |. The default is `Full precision`. When you set this property to:

- `Full precision` – the `CICDecimator` object automatically determines the word and fraction lengths of the filter sections and output.
- `Minimum section word length` – the object automatically determines the word and fraction lengths of the filter sections and the fraction length of the output. You must specify the `OutputWordLength` on page 4-388.
- `Specify word lengths` – the object automatically determines the fraction lengths of the filter sections and the output. You must specify values for the `OutputWordLength` and the `SectionWordLengths` on page 4-387 properties.
- `Specify word and fraction lengths`, – the object does not automatically determine word and fraction lengths for the filter sections or the output. You must specify them using the `OutputFractionLength` on page 4-388, `OutputWordLength`, `SectionFractionLengths` on page 4-387, and `SectionWordLengths` properties.

SectionWordLengths

Word length of each filter section

Specify the fixed-point word length for each section of the CIC filter as a scalar or a vector of length `2*NumSections` on page 4-386. This property applies only when you set the `FixedPointDataType` on page 4-387 property to either `Specify word lengths` or `Specify word and fraction lengths`. The default is `[16 16 16 16]`.

SectionFractionLengths

Fraction length of each filter section

Specify the fixed-point fraction length for each section of the CIC filter as a scalar or a vector of length `2*NumSections` on page 4-386. This property applies only when you set the `FixedPointDataType` on page 4-387 property to `Specify word and fraction lengths`. The default is `0`.

OutputWordLength

Word length of filter output

Specify the fixed-point word length for the filter output. This property applies only when you set the FixedPointDataType on page 4-387 property to Minimum section word lengths, Specify word lengths, orSpecify word and fraction lengths. The default is 32.

OutputFractionLength

Fraction length of filter output

Specify the fixed-point fraction length for the output of the CIC filter. This property applies only when you set the FixedPointDataType on page 4-387 property to Specify word and fraction lengths. The default is 0.

Methods

freqz	Frequency response
fvtool	Open filter visualization tool
impz	Impulse response
phasez	Unwrapped phase response
reset	Reset filter states of CIC decimator object
step	Decimate input using Cascaded Integrator-Comb filter

More “Analysis Methods for Filter System Objects” on page 3-2.

Common to All System Objects	
clone	Create System object with same property values
getNumInpu	Expected number of inputs to a System object
getNumOutp	Expected number of outputs of a System object

Examples

Decimate a Signal Using CICDecimator Object

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

Decimate signal by a factor of 4 (i.e., downsample the signal from 44.1 kHz to 11.025 kHz).

```
cicdec = dsp.CICDecimator(4);
cicdec.FixedPointDataType = 'Minimum section word lengths';
cicdec.OutputWordLength = 16;
```

Create fixed-point sinusoidal input signal

```
Fs = 44.1e3;              % Original sampling frequency
n = (0:1023)';            % 1024 samples, 0.0232 sec signal
x = fi(sin(2*pi*1e3/Fs*n),true,16,15);
```

Create SignalSource System object

```
src = dsp.SignalSource(x, 64);
```

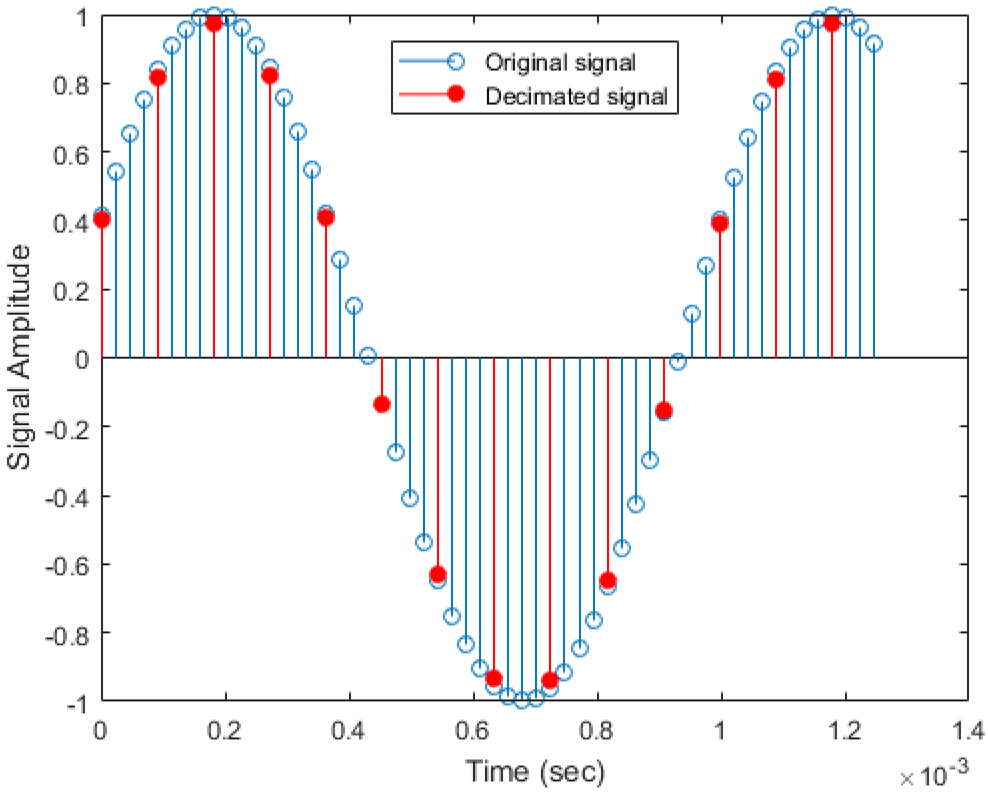
Decimate output with 16 samples per frame

```
y = zeros(16,16);
for ii=1:16
     y(ii,:) = cicdec(src());
end
```

Plot first frame of original and decimated signals. Output latency is 2 samples.

```
gainCIC = ...
   (cicdec.DecimationFactor*cicdec.DifferentialDelay)^cicdec.NumSections;
stem(n(1:56)/Fs, double(x(4:59))); hold on;
stem(n(1:14)/(Fs/cicdec.DecimationFactor),double(y(1,3:end))/gainCIC,'r','filled');
xlabel('Time (sec)');ylabel('Signal Amplitude');
legend('Original signal', 'Decimated signal', 'location', 'north');
```

```
hold off;
```



Algorithms

A Cascaded Integrator-Comb (CIC) decimation filter with comb and integrator sections is implemented when the input is fixed-point data type. When the input data type is double or single the `dsp.CICDecimator` object implements an *N*-section CIC interpolation filter as an FIR filter with a response that corresponds to a cascade of *N* boxcar filters.

This object implements the algorithm, inputs, and outputs described on the `CIC Decimation` block reference page. The object properties correspond to the block properties, except:

- The **Rate options** block parameter is not supported by the `dsp.CICDecimator` object.

dsp.FIRDecimator | dsp.CICInterpolator | dsp.CICCompensationInterpolator | dsp.CICCompensationDecimator

Introduced in R2012a

freqz

System object: dsp.CICDecimator
Package: dsp

Frequency response

Syntax

```
[h,w] = freqz(cicdecim)
[h,w] = freqz(cicdecim,n)
[h,w] = freqz(cicdecim,Name,Value)
freqz(cicdecim)
```

Description

`[h,w] = freqz(cicdecim)` returns the complex, 8192–element frequency response vector `h`, and the corresponding frequencies `w` in radians/sample.

`[h,w] = freqz(cicdecim,n)` returns the complex, n-element frequency response vector `h`, and the corresponding frequencies `w` in radians/sample, using `n` samples.

`[h,w] = freqz(cicdecim,Name,Value)` returns the frequency response and the corresponding frequencies, with additional options specified by one or more Name, Value pair arguments.

`freqz(cicdecim)` uses FVTool to plot the magnitude and unwrapped phase of the frequency response of the filter System object `cicdecim`.

fvtool

System object: dsp.CICDecimator
Package: dsp

Open filter visualization tool

Syntax

```
fvtool(cicdecim)
fvtool(cicdecim,'Arithmetic',ARITH,...)
```

Description

`fvtool(cicdecim)` performs an analysis and computes the magnitude response of the filter System object `cicdecim`.

`fvtool(cicdecim,'Arithmetic',ARITH,...)` analyzes the filter System object `cicdecim`, based on the arithmetic specified in the ARITH input. ARITH can be set to one of 'double', 'single', or 'fixed'. The analysis tool assumes a double precision filter when the arithmetic input is not specified and the filter System object is in an unlocked state. The 'Arithmetic' input is only relevant for the analysis of filter System objects.

impz

System object: dsp.CICDecimator
Package: dsp

Impulse response

Syntax

```
[h,t] = impz(cicdecim)
[h,t] = impz(cicdecim,Name,Value)
impz(cicdecim)
```

Description

`[h,t] = impz(cicdecim)` returns the impulse response `h`, and the corresponding time points `t` at which the impulse response of`cicdecim` is computed.

`[h,t] = impz(cicdecim,Name,Value)` returns the impulse response `h`, and the corresponding time points`t` , with additional options specified by one or more Name, Value pair arguments.

`impz(cicdecim)` uses FVTool to plot the impulse response of the filter System object `cicdecim`.

Note: You can use `impz` for both real and complex filters. When you omit the output arguments, `impz` plots only the real part of the impulse response.

phasez

System object: dsp.CICDecimator
Package: dsp

Unwrapped phase response

Syntax

```
[phi,w] = phasez(cicdecim)
[phi,w] = phasez(cicdecim,n)
[phi,w] = phasez(cicdecim,Name,Value)
phasez(cicdecim)
```

Description

`[phi,w] = phasez(cicdecim)` returns the 8192–element phase response vector `phi`, and the corresponding frequencies `w` in radians/sample.

`[phi,w] = phasez(cicdecim,n)` returns the n-element phase response vector `phi`, and the corresponding frequencies `w` in radians/sample, using `n` samples.

`[phi,w] = phasez(cicdecim,Name,Value)` returns the phase response and the corresponding frequencies, with additional options specified by one or more Name, Value pair arguments.

`phasez(cicdecim)` uses FVTool to plot the phase response of the filter System object `cicdecim`.

reset

System object: dsp.CICDecimator
Package: dsp

Reset filter states of CIC decimator object

Syntax

```
reset(cicdecim)
```

Description

`reset(cicdecim)` resets the filter states of the `CICDecimator` System object `cicdecim` to zero.

step

System object: dsp.CICDecimator
Package: dsp

Decimate input using Cascaded Integrator-Comb filter

Syntax

`Y = step(cicdecim,X)`

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(cicdecim,X)` decimates the fixed-point input `X` to produce a fixed-point output `Y` using the `CICDecimator` System object `cicdecim`.

Note: `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.CICInterpolator System object

Package: dsp

Interpolate signal using Cascaded Integrator-Comb filter

Description

The `CICInterpolator` object interpolates inputs using a Cascaded Integrator-Comb filter. Fixed-point inputs and outputs to the object have signed fixed-point data types. To use fixed-point data types, you must have a Fixed-Point Designer license. Inputs and outputs to the System object can be single or double data types, in addition to the fixed-point data type. Property settings related to fixed-point data types are ignored for single or double data types.

Note: To use the filter analysis methods on `dsp.CICInterpolator` System object, you must have the Fixed-Point Designer license. To get a list of the filter analysis methods this object supports, type `dsp.CICInterpolator.helpFilterAnalysis` in the MATLAB command prompt.

To interpolate inputs using a CIC filter:

1. Define and set up your System object. See "Construction" on page 4-399.
2. Call step to interpolate the input according to the properties of `dsp.CICInterpolator`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`cicinterp = dsp.CICInterpolator` returns a System object, `cicinterp`, that you can use to interpolate the input with a cascaded integrator-comb (CIC) interpolation filter.

`cicinterp = dsp.CICInterpolator('`*`PropertyName`*`',`*`PropertyValue`*`,...)` returns a `CIC` interpolation object, `cicinterp`, with each specified property set to the value you specify.

`cicinterp = dsp.CICInterpolator(`*`R`*`,`*`M`*`,`*`N`*`,'`*`PropertyName`*`',`*`PropertyValue`*`,...)` returns a `CICInterpolator` object, `cicinterp`, with the `InterpolationFactor` on page 4-399 property set to *`R`*, the `DifferentialDelay` on page 4-399 property set to *`M`*, the `NumSections` on page 4-399 property set to *`N`*, and other specified properties set to the values you specify.

Properties

`InterpolationFactor`

Interpolation factor of filter

Specify a positive integer amount by which the object interpolates the input signal. The default is `2`.

`DifferentialDelay`

Differential delay of filter comb sections

Specify a positive integer delay value for the object to use in each comb section of the filter. The default is `1`.

`NumSections`

Number of integrator and comb sections

Specify the number of integrator and comb sections in the CIC filter as a positive integer value. The default is `2`.

FixedPointDataType

Fixed-point property setting

Specify the fixed-point data type as one of | `Full precision` | `Minimum section word lengths` | `Specify word lengths` | `Specify word and fraction lengths` |. The default is `Full precision`. When you set this property to:

- `Full precision` – the `CICInterpolator` object automatically determines the word and fraction lengths of the filter sections and output.
- `Minimum section word length` – the object automatically determines the word and fraction lengths of the filter sections and the fraction length of the output. You must specify the `OutputWordLength` on page 4-401.
- `Specify word lengths` – the object automatically determines the fraction lengths of the filter sections and the output. You must specify values for the `OutputWordLength` and the `SectionWordLengths` on page 4-400 properties.
- `Specify word and fraction lengths` – the object does not automatically determine word and fraction lengths for the filter sections or the output. You must specify them using the `OutputFractionLength` on page 4-401, `OutputWordLength`, `SectionFractionLengths` on page 4-400, and `SectionWordLengths` properties.

SectionWordLengths

Word length of each filter section

Specify the fixed-point word length for each section of the CIC filter as a scalar or a vector of length `2*NumSections` on page 4-386. This property applies only when you set the `FixedPointDataType` on page 4-400 property to `Specify word lengths` or `Specify word and fraction lengths`. The default is `[16 16 16 16]`.

SectionFractionLengths

Fraction length of each filter section

Specify the fixed-point fraction length for each section of the CIC filter as a scalar or a vector of length `2*NumSections` on page 4-386. This property applies only when you set the `FixedPointDataType` on page 4-400 property to `Specify word and fraction lengths`. The default is `0`.

OutputWordLength

Word length of filter output

Specify the fixed-point word length for the filter output. This property applies only when you set the `FixedPointDataType` on page 4-400 property to `Minimum section word lengths`, `Specify word lengths`, or`Specify word and fraction lengths`. The default is `32`.

OutputFractionLength

Fraction length of filter output

Specify the fixed-point fraction length for the output of the CIC filter. This property applies only when you set the `FixedPointDataType` on page 4-400 property to `Specify word and fraction lengths`. The default is `0`.

Methods

freqz	Frequency response
fvtool	Open filter visualization tool
impz	Impulse response
phasez	Unwrapped phase response
reset	Reset internal states of CIC Interpolator object
step	Interpolate signal using Cascaded Integrator-Comb filter

More “Analysis Methods for Filter System Objects” on page 3-2.

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object

Common to All System Objects	
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Interpolate a Signal Using CICInterpolator Object

Interpolate signal by a factor of 2 (upsample the signal from 22.05 kHz to 44.1 kHz).

```
cicint = dsp.CICInterpolator(2);
```

Create fixed-point sinusoidal input signal

```
Fs = 22.05e3;      % Original sampling frequency
n = (0:511)';      % 512 samples, 0.0113 sec signal
x = fi(sin(2*pi*1e3/Fs*n),true,16,15);
```

Create SignalSource System object (TM).

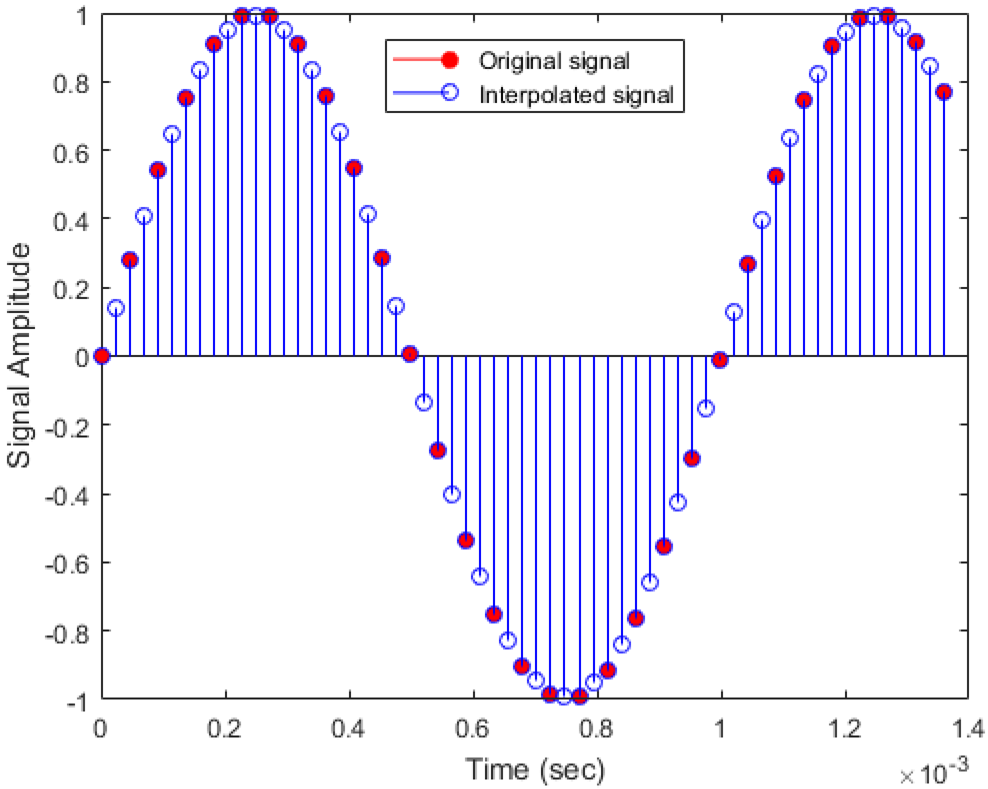
```
src = dsp.SignalSource(x, 32);
```

Interpolate output with 64 samples per frame

```
y = zeros(16,64);
for ii=1:16
     y(ii,:) = cicint(src());
end
```

Plot first frame of original and interpolated signals. Output latency is 2 samples.

```
gainCIC = ...
   (cicint.InterpolationFactor*cicint.DifferentialDelay)...
   ^cicint.NumSections/cicint.InterpolationFactor;
stem(n(1:31)/Fs, double(x(1:31)),'r','filled'); hold on;
stem(n(1:61)/(Fs*cicint.InterpolationFactor), ...
   double(y(1,4:end))/gainCIC,'b');
xlabel('Time (sec)');ylabel('Signal Amplitude');
legend('Original signal', 'Interpolated signal',...
   'location', 'north');
hold off;
```



Algorithms

A Cascaded Integrator-Comb (CIC) interpolation filter with comb and integrator sections is implemented when the input is fixed-point data type. When the input data type is double or single the `dsp.CICInterpolator` object implements an *N*-section CIC interpolation filter as an FIR filter with a response that corresponds to a cascade of *N* boxcar filters.

This object implements the algorithm, inputs, and outputs described on the `CIC Interpolation` block reference page. The object properties correspond to the block properties, except:

- The **Framing** block parameter is not supported by the `dsp.CICInterpolation` object. The object always maintains the input frame rate.
- The **Rate options** block parameter is not supported by the `dsp.CICInterpolation` object.
- The **Input processing** block parameter is not supported by the `dsp.CICInterpolation` object.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See "System Objects in MATLAB Code Generation" (MATLAB Coder).

dsp.FIRInterpolator | dsp.CICDecimator | dsp.CICCompensationInterpolator | dsp.CICCompensationDecimator

Introduced in R2012a

freqz

System object: dsp.CICInterpolator
Package: dsp

Frequency response

Syntax

```
[h,w] = freqz(cicinterp)
[h,w] = freqz(cicinterp,n)
[h,w] = freqz(cicinterp,Name,Value)
freqz(cicinterp)
```

Description

`[h,w] = freqz(cicinterp)` returns the complex, 8192–element frequency response vector `h`, and the corresponding frequencies `w` in radians/sample.

`[h,w] = freqz(cicinterp,n)` returns the complex, n-element frequency response vector `h`, and the corresponding frequencies `w` in radians/sample, using `n` samples.

`[h,w] = freqz(cicinterp,Name,Value)` returns the frequency response and the corresponding frequencies, with additional options specified by one or more Name, Value pair arguments.

`freqz(cicinterp)` uses FVTool to plot the magnitude and unwrapped phase of the frequency response of the filter System object `cicinterp`.

fvtool

System object: dsp.CICInterpolator
Package: dsp

Open filter visualization tool

Syntax

```
fvtool(cicinterp)
fvtool(cicinterp,'Arithmetic',ARITH,...)
```

Description

`fvtool(cicinterp)` performs an analysis and computes the magnitude response of the filter System object `cicinterp`.

`fvtool(cicinterp,'Arithmetic',ARITH,...)` analyzes the filter System object `cicinterp`, based on the arithmetic specified in the ARITH input. ARITH can be set to one of 'double', 'single', or 'fixed'. The analysis tool assumes a double precision filter when the arithmetic input is not specified and the filter System object is in an unlocked state. The 'Arithmetic' input is only relevant for the analysis of filter System objects.

impz

System object: dsp.CICInterpolator
Package: dsp

Impulse response

Syntax

```
[h,t] = impz(cicinterp)
[h,t] = impz(cicinterp,Name,Value)
impz(cicinterp)
```

Description

`[h,t] = impz(cicinterp)` returns the impulse response `h`, and the corresponding time points `t` at which the impulse response of`cicinterp` is computed.

`[h,t] = impz(cicinterp,Name,Value)` returns the impulse response `h`, and the corresponding time points`t` , with additional options specified by one or more Name, Value pair arguments.

`impz(cicinterp)` uses FVTool to plot the impulse response of the filter System object `cicinterp`.

Note: You can use `impz` for both real and complex filters. When you omit the output arguments, `impz` plots only the real part of the impulse response.

---

phasez

System object: dsp.CICInterpolator
Package: dsp

Unwrapped phase response

Syntax

```
[phi,w] = phasez(cicinterp)
[phi,w] = phasez(cicinterp,n)
[phi,w] = phasez(cicinterp,Name,Value)
phasez(cicinterp)
```

Description

`[phi,w] = phasez(cicinterp)` returns the 8192–element phase response vector `phi`, and the corresponding frequencies `w` in radians/sample.

`[phi,w] = phasez(cicinterp,n)` returns the n-element phase response vector `phi`, and the corresponding frequencies `w` in radians/sample, using `n` samples.

`[phi,w] = phasez(cicinterp,Name,Value)` returns the phase response and the corresponding frequencies, with additional options specified by one or more Name, Value pair arguments.

`phasez(cicinterp)` uses FVTool to plot the phase response of the filter System object `cicinterp`.

reset

System object: dsp.CICInterpolator
Package: dsp

Reset internal states of CIC Interpolator object

Syntax

`reset(cicinterp)`

Description

`reset(cicinterp)` resets the internal states of the `CICInterpolator` System object `cicinterp` to zero.

step

System object: dsp.CICInterpolator
Package: dsp

Interpolate signal using Cascaded Integrator-Comb filter

Syntax

```
Y = step(cicinterp,X)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(cicinterp,X)` interpolates the fixed-point input `X` to produce a fixed-point output `Y` using the `CICInterpolator` System object `cicinterp`.

Note: `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

dsp.ColoredNoise System object

Package: dsp

Colored noise generator

Description

The `ColoredNoise` object generates pink noise and other colored noise signals. The form of the PSD is $1/|f|^{\alpha}$ with the exponent, α, a real number in the interval [-2,2].

To generate a colored noise signal:

1. Define and set up your colored noise generator. See "Construction" on page 4-411.
2. Call step to generate the colored noise signal according to the properties of `dsp.ColoredNoise`. The signal is an array with the number of rows given by the `SamplesPerFrame` property. The number of columns is given by the `NumChannels` property.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj)` and `y = obj()` perform equivalent operations.

Construction

`cn = dsp.ColoredNoise` returns a colored noise generator, `cn`, with default settings. Calling step with the default property settings generates a pink noise signal.

`cn = dsp.ColoredNoise('`*`PropertyName`*`',`*`PropertyValue`*`, ...)` returns a colored noise generator, `cn`, with each specified property set to the specified value.

`cn = dsp.ColoredNoise(POW,SAMP,CHAN,'`*`PropertyName`*`',`*`PropertyValue`*`)` returns a colored noise generator, `cn`, with `InverseFrequencyPower` equal to `POW`, `SamplesPerFrame` equal to `SAMP`, and `NumChannels` equal to `CHAN`. Other specified properties are set to the specified values.

Properties

`Color`

Noise color

Specify the color of the noise as one of `'pink'` | `'white'` | `'brown'` | `'blue'` | `'purple'` | `'custom'`. Each color is associated with an inverse frequency power of the generated noise sequence.

- For pink noise, set `Color` to `'pink'`. The inverse frequency power of pink noise is equal to `1`.
- For white noise, set `Color` to `'white'`. The inverse frequency power of white noise is equal to `0`.
- For brown noise (also known as red or Brownian noise), set `Color` to `'brown'`. The inverse frequency power of brown noise is equal to `2`.
- For blue noise (also known as azure noise), set `Color` to `'blue'`. The inverse frequency power of blue noise is equal to `-1`.
- For purple noise (also known as violet noise), set `Color` to `'purple'`. The inverse frequency power of purple noise is equal to `-2`.
- For noise with a custom inverse frequency power, set `Color` to `'custom'`. In this case, the inverse frequency power is equal to the value specified in `InverseFrequencyPower`. This is the default value.

  `InverseFrequencyPower` can be any value in the interval [`-2,2`]. `InverseFrequencyPower` is applicable only when `Color` is set to `'custom'`.

`InverseFrequencyPower`

Inverse PSD exponent

Specify the inverse PSD exponent, a, as a real number in the interval `[-2 2]`. The inverse exponent defines the PSD of the random process by $1/|f|^{\alpha}$. The default value of this property is `1`. Values of `InverseFrequencyPower` greater than 0 generate lowpass noise with a singularity (pole) at f=0. These processes exhibit long memory. Values of `InverseFrequencyPower` less than 0 generate highpass noise with increments that are negatively correlated. These processes are referred to as anti-persistent. Special cases include:

- An `InverseFrequencyPower` value of 1 generates a pink noise. This is the default value.
- An `InverseFrequencyPower` value of 2 generates a Brownian process.
- An `InverseFrequencyPower` value of 0 generates a white noise process with a flat PSD.
- An `InverseFrequencyPower` value of -1 generates a blue noise process.
- An `InverseFrequencyPower` value of -2 generates a violet (purple) noise process.

This property is applicable only when `Color` is set to `'custom'`.

In a log-log plot of power as a function of frequency, processes generated by `dsp.ColoredNoise` exhibit an approximate linear relationship with slope equal to -α.

NumChannels

Number of output channels

Specify the number of output channels as a positive integer. This property determines the number of columns of the signal. The default value of this property is 1.

SamplesPerFrame

Samples per frame

Specify the number of samples per frame as a positive integer. This property determines the number of rows of the signal. The default value of this property is 1024.

RandomStream

Source of random number stream

Specify the source of the random number stream as `'Global Stream'` or `'mt19937ar with seed'`. If you set `RandomStream` to `'Global Stream'`, the current random number generator settings are used. The current settings of the random number generator are returned by `rng`. The default value of this property is `'Global Stream'`.

Seed

Initial seed

Specify the initial seed of the mt19937ar random number generator as a nonnegative integer. This property only applies when `RandomStream` is `'mt19937ar with seed'`. The default value of this property is 67.

`OutputDataType`

Output data type

Specify the output data type as `'double'` or `'single'`. The default value of this property is `'double'`.

Methods

reset	Reset random number generator seed
step	Generate colored noise signal

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Measure Pink Noise Power in Octave Bands

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject() becomes step(myObject).

This example shows how pink noise has approximately equal power in octave bands.

Generate a single-channel signal of pink noise that is 44100 samples in length. Set the random number generator to the default settings for reproducible results.

```
pinkNoise = dsp.ColoredNoise(1,44.1e3,1);
```

```
rng default;
x = pinkNoise();
```

Assume the sampling frequency is 44.1 kHz. Measure the power in octave bands beginning with 100-200 Hz and ending with 6.400-12.8 kHz. Display the results in a table.

```
beginfreq = 100;
endfreq = 200;
count = 1;
while(endfreq<=44.1e3/2)
    freqinterval(count,:) = [beginfreq endfreq];
    Pwr(count) = bandpower(x,44.1e3,[beginfreq endfreq]);
    beginfreq = endfreq;
    endfreq = 2*endfreq;
    count = count+1;
end
Pwr = Pwr(:);
table(freqinterval,Pwr)
```

```
ans =

  7×2 table

    freqinterval       Pwr
    _____________    _______

     100      200    0.19436
     200      400    0.18472
     400      800    0.20873
     800     1600     0.2177
    1600     3200    0.21887
    3200     6400    0.23617
    6400    12800    0.23526
```

The pink noise has roughly equal power in octave bands. Repeat the preceding example with `'InverseFrequencyPower'` equal to 0, which generates a white noise signal. A white noise signal has a flat power spectral density, or equal power per unit frequency. Set the random number generator to the default settings for reproducible results.

```
whiteNoise = dsp.ColoredNoise(0,44.1e3,1);
rng default;
x = whiteNoise();
```

Assume the sampling frequency is 44.1 kHz. Measure the power in octave bands beginning with 100-200 Hz and ending with 6.400-12.8 kHz. Display the results in a table.

```
beginfreq = 100;
endfreq = 200;
count = 1;
while(endfreq<=44.1e3/2)
    freqinterval(count,:) = [beginfreq endfreq];
    Pwr(count) = bandpower(x,44.1e3,[beginfreq endfreq]);
    beginfreq = endfreq;
    endfreq = 2*endfreq;
    count = count+1;
end
Pwr = Pwr(:);
table(freqinterval,Pwr)
```

```
ans =

  7×2 table

    freqinterval        Pwr
    _____________    _________

     100      200    0.0031417
     200      400    0.0073833
     400      800     0.017421
     800     1600     0.035926
    1600     3200     0.071139
    3200     6400      0.15183
    6400    12800      0.28611
```

White noise has approximately equal power per unit frequency. Therefore, you expect octave bands to have an unequal distribution of power. Because the width of an octave band increases with increasing frequency, the power per octave band increases for a white noise.

PSD of Pink Noise Realization

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject() becomes step(myObject).

Generate a pink noise signal 2048 samples in length. Assume a sampling rate of 1 Hz. Obtain an estimate of the power spectral density using Welch's overlapped segment averaging.

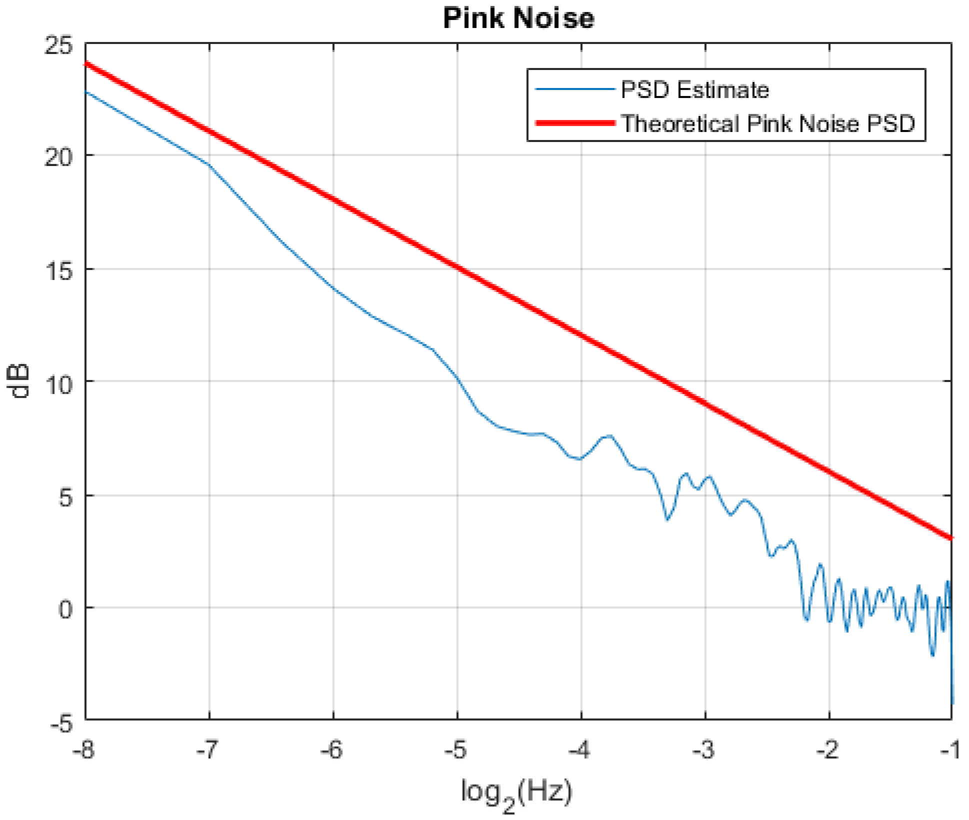
```
cn = dsp.ColoredNoise('Color','pink','SamplesPerFrame',2048);
x = cn();
Fs = 1;
[Pxx,F] = pwelch(x,hamming(128),[],[],Fs,'psd');
```

Construct the theoretical PSD of the pink noise process.

```
PSDPink = 1./F(2:end);
```

Display the Welch PSD estimate of the noise along with the theoretical PSD on a log-log plot. Plot the frequency axis as the logarithm to the base 2 to clearly show the octaves. Plot the PSD estimate in dB, $10\log_{10}$.

```
plot(log2(F(2:end)),10*log10(Pxx(2:end)));
hold on;
plot(log2(F(2:end)),10*log10(PSDPink),'r','linewidth',2)
xlabel('log_2(Hz)'); ylabel('dB');
title('Pink Noise');
grid on;
legend('PSD Estimate','Theoretical Pink Noise PSD');
```



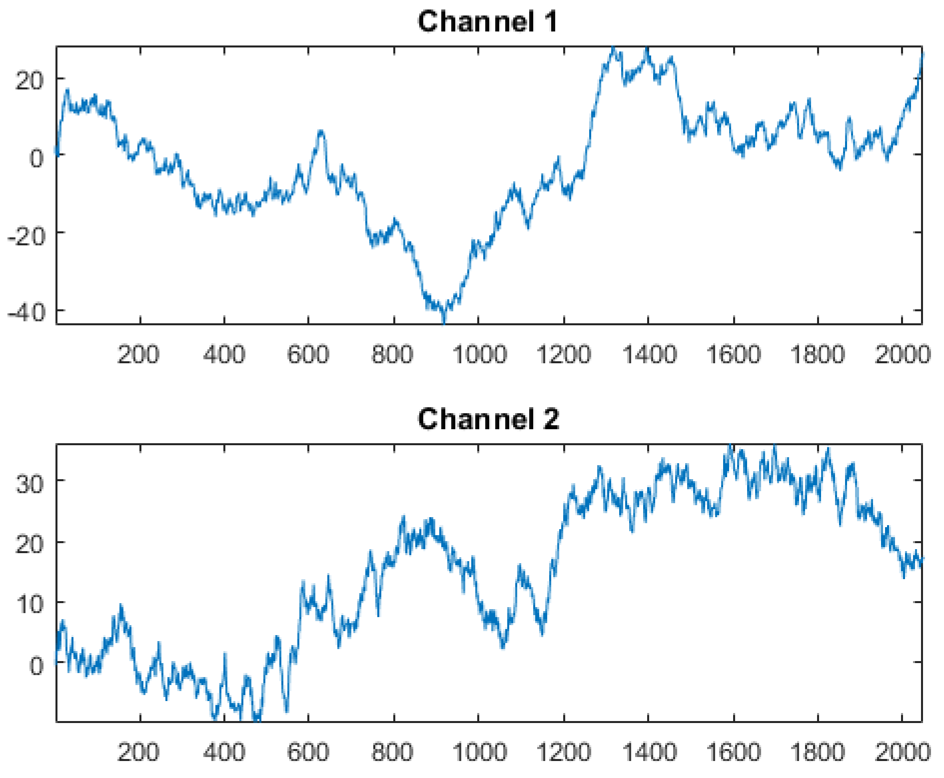
Two-Channel Brownian Noise

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject() becomes step(myObject).

Generate two channels of Brownian noise by setting `Color` to `brown` and `NumChannels` to 2.

```
cn = dsp.ColoredNoise('Color','brown','SamplesPerFrame',2048,...
    'NumChannels',2);
x = cn();
subplot(2,1,1)
plot(x(:,1)); title('Channel 1'); axis tight;
```

```
subplot(2,1,2)
plot(x(:,2)); title('Channel 2'); axis tight;
```

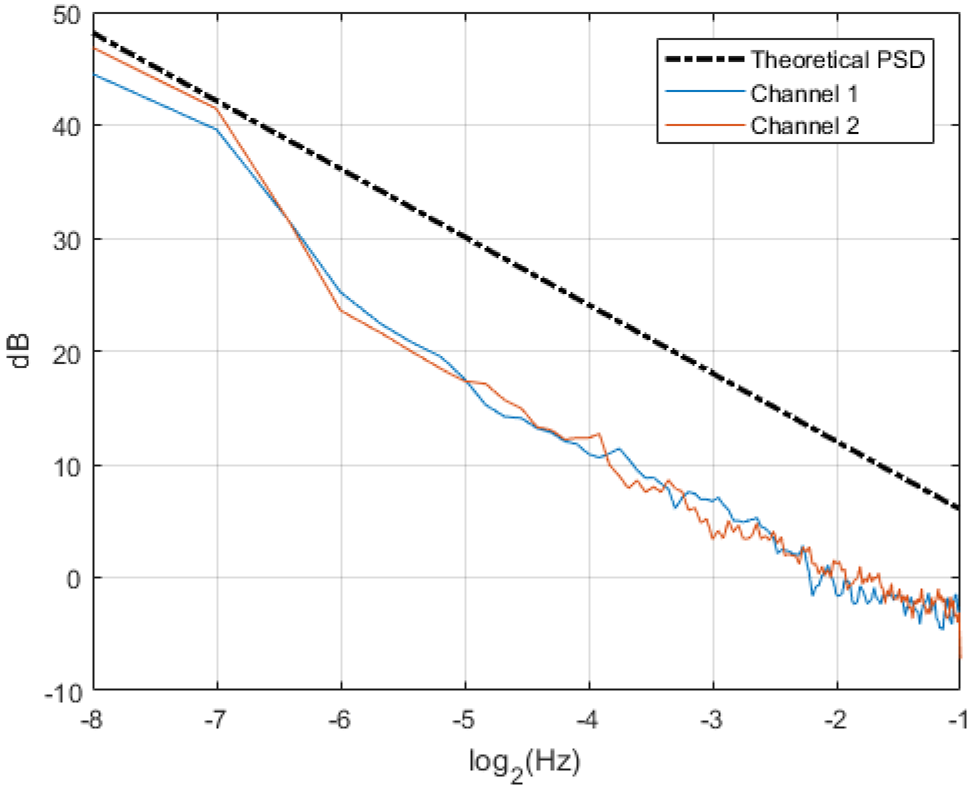


Assume a sampling frequency of 1 Hz. Obtain Welch PSD estimates for both channels.

```
Fs = 1;
for nn = 1:size(x,2)
[Pxx(:,nn),F] = pwelch(x(:,nn),hamming(128),[],[],Fs,'psd');
end
```

Construct the theoretical PSD of a Brownian process. Plot the theoretical PSD along with both realizations on a log-log plot. Use the logarithm to the base 2 for the frequency axis and plot the power spectral densities in dB.

```
PSDBrownian = 1./F(2:end).^2;
figure;
plot(log2(F(2:end)),10*log10(PSDBrownian),'k-.','linewidth',2);
hold on;
plot(log2(F(2:end)),10*log10(Pxx(2:end,:)));
xlabel('log_2(Hz)'); ylabel('dB');
grid on;
legend('Theoretical PSD','Channel 1', 'Channel 2');
```



Add Pink Noise at 0 dB SNR

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For `dsp.ColoredNoise` System object™, myObject() becomes step(myObject). For all other objects, myObject(x) becomes step(myObject,x).

This example shows how to stream in an audio file and add pink noise at a 0 dB SNR. The example reads in frames of an audio file 1024 samples in length, measures the RMS value of the audio frame, and adds pink noise with the same RMS value as the audio frame.

Set up the System objects. Set the number of `'SamplesPerFrame'` for both the file reader and the colored noise generator to 1024 samples. Set `Color` to `pink` to generate pink noise with a $1/|f|$ power spectral density.

```
N = 1024;
afr = dsp.AudioFileReader('Filename','speech_dft.mp3','SamplesPerFrame',N);
adw = audioDeviceWriter('SampleRate',afr.SampleRate);
cn = dsp.ColoredNoise('Color','pink','SamplesPerFrame',N);
rms = dsp.RMS;
```

Stream the audio file in 1024 samples at a time. Measure the signal RMS value for each frame, generate a frame of pink noise equal in length, and scale the RMS value of the pink noise to match the signal. Add the scaled noise to the signal and play the output.

```
while ~isDone(afr)
    audio = afr();
    speechRMS = rms(audio);
    noise = cn();
    noiseRMS = rms(noise);
    noise = noise*(speechRMS/noiseRMS);
    sigPlusNoise = audio+noise;
    adw(sigPlusNoise);
end

release(afr);
release(adw);
```

Averaged Power Spectrum of Pink Noise

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For `dsp.ColoredNoise` System object™, myObject() becomes step(myObject). For all other objects, myObject(x) becomes step(myObject,x).

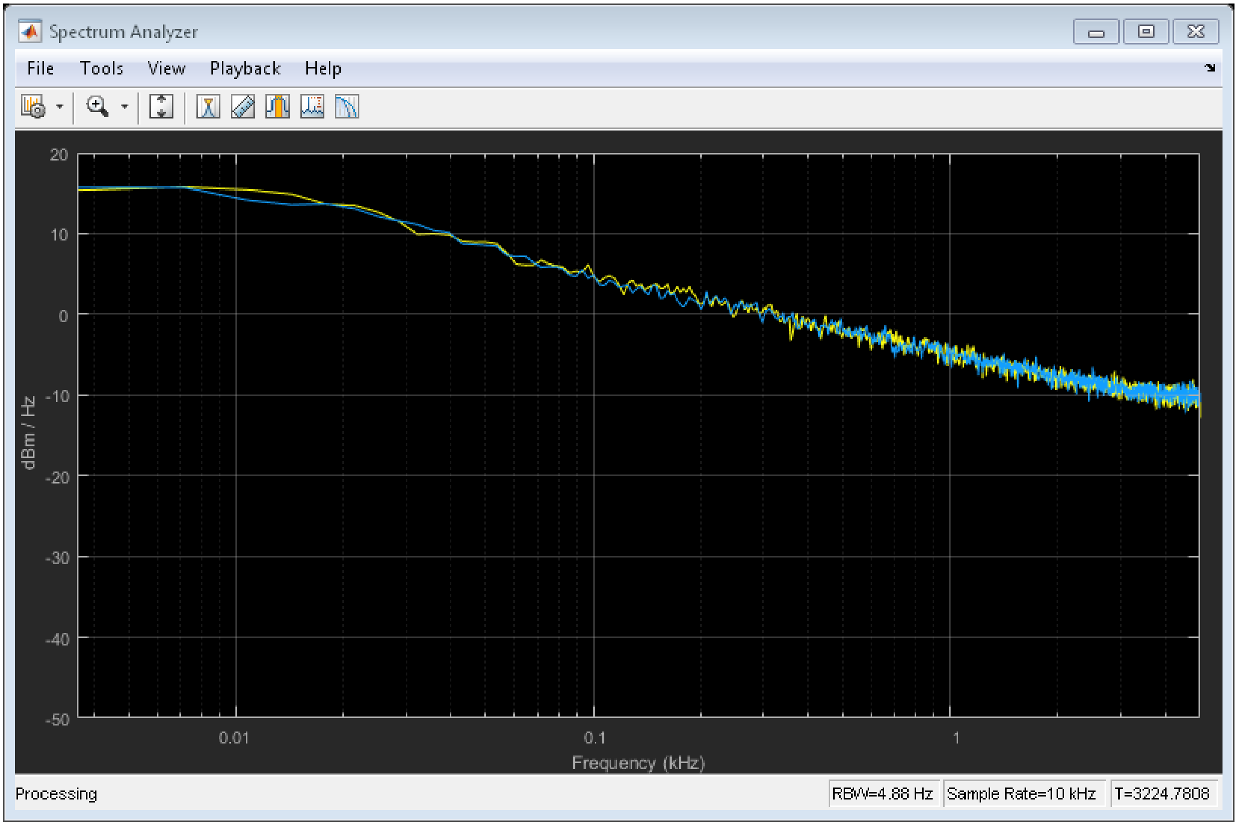
This example shows how to generate two-channels of pink noise and compute the power spectrum based on a running average of 50 PSD estimates.

Set up the colored noise generator to generate two-channels of pink noise with 1024 samples. Set up the spectrum analyzer to compute modified periodograms using a Hamming window and 50% overlap. Obtain a running average of the PSD using 50 spectral averages.

```
pinkNoise = dsp.ColoredNoise(1,1024,2);
sa = dsp.SpectrumAnalyzer('SpectrumType','Power density', ...
    'OverlapPercent',50,'Window','Hamming', ...
    'SpectralAverages',50,'PlotAsTwoSidedSpectrum',false, ...
    'FrequencyScale','log','YLimits',[-50 20]);
```

Run the simulation for 30 seconds.

```
tic
while toc < 30
    pink = pinkNoise();
    sa(pink);
end
```



Algorithms

AR Generation Method

`dsp.ColoredNoise` generates colored noise using a white noise input in an autoregressive model (AR) of order 63.

$$\sum_{k=0}^{63} a_k y(n-k) = w(n)$$

where a_0=1 and w(n) is a zero-mean white noise process.

The AR coefficients for k≥1 are generated according to the following recursive formula with α the inverse PSD exponent

$$a_k = (k - 1 - \tfrac{\alpha}{2})\frac{a_{k-1}}{k} \quad k = 1, 2, \ldots$$

The AR method used in `dsp.ColoredNoise` is detailed on pp. 820–822 in [2].

Definitions

Colored Noise Processes

Many phenomena in diverse fields such as hydrology and finance produce time series with power spectral density (PSD) functions that follow a power law of the form

$$S(f) = \frac{L(f)}{|f|^{\alpha}}$$

where α is a real number in the interval [-2,2] and $L(f)$ is a positive slowly-varying or constant function. Plotting the power spectral density of such processes on a log-log plot displays an approximate linear relationship between the log frequency and log PSD with slope equal to -α

$$\ln S(f) = -\alpha \ln|f| + \ln L(f).$$

It is often convenient to plot the PSD in dB as function of the log frequency to base 2 in order to characterize the slope in dB/octave. Rewriting the preceding equation, you obtain

$$10 \log S(f) = -10\alpha \frac{\ln(2)\log_2(f)}{\ln(10)} + 10\frac{\ln(L(f))}{\ln(10)}$$

with the slope in dB/octave given by

$$-10\alpha \frac{\ln(2)\log_2(f)}{\ln(10)}$$

If α>0, *S(f)* goes to infinity as the frequency, *f*, approaches 0. Stochastic processes with power spectral densities of this form exhibit long memory. Long-memory processes have autocorrelations that persist for a long time as opposed to decaying exponentially like many common time-series models. If α<0, the process is antipersistent and exhibits negative correlation between increments [1].

Special examples of $\frac{1}{|f|^{\alpha}}$ processes include:

- α=0 — white noise where *L(f)* is a constant proportional to the process variance.
- α=1 — pink, or flicker noise. Pink noise has equal energy per octave. See "Measure Pink Noise Power in Octave Bands" on page 4-414 for a demonstration. Accordingly, the power spectral density of pink noise decreases 3 dB per octave.
- α=2 — brown noise, or Brownian motion. Brownian motion is a nonstationary process with stationary increments. You can think of Brownian motion as the integral of a white noise process. Even though Brownian motion is nonstationary, you can still define a generalized power spectrum, which behaves like $\frac{1}{|f|^{2}}$. Accordingly, power in a brown noise decreases 6 dB per octave.
- α= -1 — blue noise. The power spectral density of blue noise increases 3 dB per octave.
- α= -2 — violet, or purple noise. The power spectral density of violet noise increases 6 dB per octave. You can think of violet noise as the derivative of white noise process.

`randn` | `Colored Noise`

Introduced in R2014a

reset

System object: dsp.ColoredNoise
Package: dsp

Reset random number generator seed

Syntax

```
reset(cn)
```

Description

`reset(cn)` resets the random number generator stream if the `RandomStream` property is set to `'mt19937ar with seed'`. The seed of the random number generator is the value of the `Seed` property.

step

System object: dsp.ColoredNoise
Package: dsp

Generate colored noise signal

Syntax

```
x = step(cn)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj)` and `y = obj()` perform equivalent operations.

`x = step(cn)` generates a colored noise signal for the number of channels specified by the `NumChannels` property. If the value of `NumChannels` is 1, `x` is a column vector. If the value of `NumChannels` is M >1, `x` is a matrix with M columns. The number of samples (rows) in `x` is equal to the value of `SamplesPerFrame` .

Note: `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Examples

Two Channels of Pink Noise

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For `dsp.ColoredNoise` System object™, myObject() becomes step(myObject). For all other objects, myObject(x) becomes step(myObject,x).

Generate two channels of pink noise 1000 samples in length.

```
NumChannels = 2;
NumSamples = 1000;
cn = dsp.ColoredNoise('InverseFrequencyPower',1,'NumChannels',2,...
    'SamplesPerFrame',NumSamples);
x = cn();
subplot(2,1,1)
plot(x(:,1)); title('Channel 1');
subplot(2,1,2)
plot(x(:,2)); title('Channel 2');
```

dsp.Convolver System object

Package: dsp

Convolution of two inputs

Description

The `Convolver` computes the convolution of two inputs.

To compute the convolution of two inputs:

1 Define and set up your convolver. See “Construction” on page 4-431.
2 Call step to compute the convolution according to the properties of `dsp.Convolver`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`conv = dsp.Convolver` returns a convolver object, `conv`, that convolves two inputs. For N-D arrays, the convolver computes the convolution column-wise. For arrays, the inputs must have an equal number of columns. If one input is a vector and the other is an N-D array, the convolver computes the convolution of the vector with each column of the N-D array. Convolving inputs of length N and M results in a sequence of length N+M–1. Convolving matrices of size M-by-N and P-by-N results in a matrix of size (M+P–1)-by-N.

`conv = dsp.Convolver('`*`PropertyName`*`',`*`PropertyValue`*`, ...)` returns a convolver object, `conv`, with each property set to the specified value.

Properties

`Method`

Domain for computing convolutions

Specify the domain in which the convolver performs the convolutions as `Time Domain`, `Frequency Domain`, or `Fastest`. Computing convolutions in the time domain minimizes memory use. Computing convolutions in the frequency domain may require fewer computations depending on the input length. If the value of this property is `Fastest`, the object computes convolutions in the domain which minimizes the number of computations. The default is `Time Domain`.

Fixed-Point Properties

`FullPrecisionOverride`

Full precision override for fixed-point arithmetic

Specify whether to use full precision rules. If you set `FullPrecisionOverride` to `true`, which is the default, the object computes all internal arithmetic and output data types using full precision rules. These rules provide the most accurate fixed-point numerics. It also turns off the display of other fixed-point properties because they do not apply individually. These rules guarantee that no quantization occurs within the object. Bits are added, as needed, to ensure that no roundoff or overflow occurs. If you set `FullPrecisionOverride` to `false`, fixed-point data types are controlled through individual fixed-point property settings. For more information, see "Full Precision for Fixed-Point System Objects".

`RoundingMethod`

Rounding method for fixed-point operations

Specify the rounding method as `Ceiling`, `Convergent`, `Floor`, `Nearest`, `Round`, `Simplest`, or `Zero`. The default is `Floor`. This property applies only if the object is not in full precision mode.

`OverflowAction`

Overflow action for fixed-point operations

Specify the overflow action as `Wrap` or `Saturate`. The default is `Wrap`. This property applies only if the object is not in full precision mode.

ProductDataType

Product word and fraction lengths

Specify the product fixed-point data type as `Full precision`, `Same as first input`, or `Custom`. The default is `Full precision`.

CustomProductDataType

Product word and fraction lengths

Specify the product fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when the `ProductDataType` on page 4-433 property is `Custom`. The default is `numerictype([],32,30)`.

AccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point data type as `Full precision`, `Same as product`, `Same as first input`, or `Custom`. The default is `Full precision`.

CustomAccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when the `AccumulatorDataType` on page 4-433 property is `Custom`. The default is `numerictype([],32,30)`.

OutputDataType

Output word and fraction lengths

Specify the output fixed-point data type as `Same as accumulator`, `Same as product`, `Same as first input`, or `Custom`. The default is `Same as accumulator`.

CustomOutputDataType

Output word and fraction lengths

Specify the output fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when the `OutputDataType` on page 4-433 property is `Custom`. The default is `numerictype([],16,15)`.

Methods

step	Convolution of inputs

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

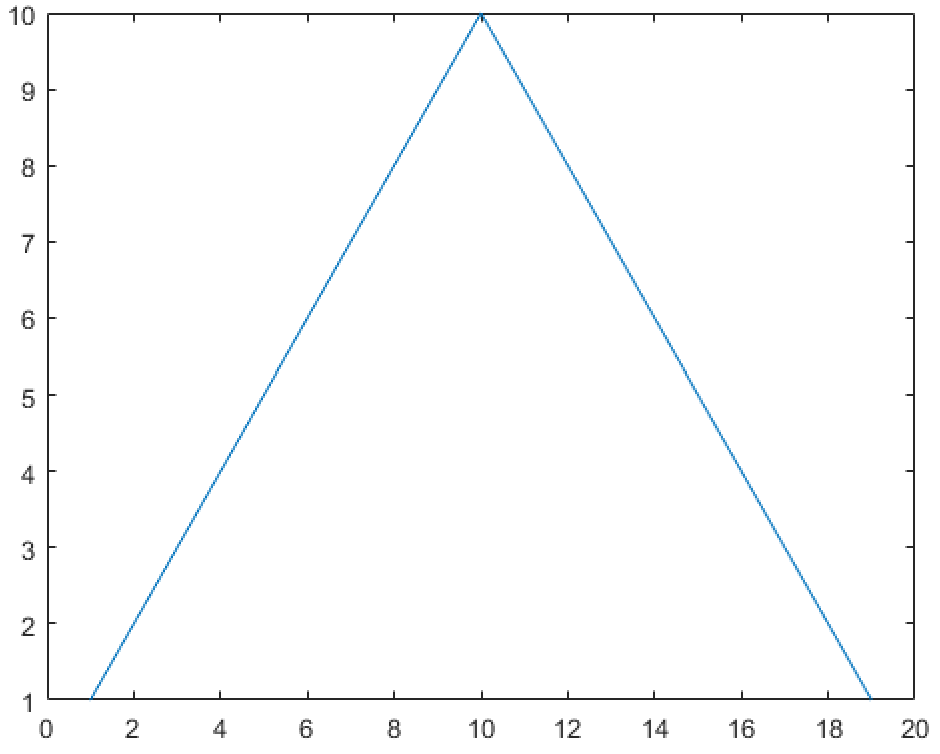
Convolve Two Rectangular Sequences

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

```
conv = dsp.Convolver;
x = ones(10,1);
y = conv(x, x);
```

Result is a triangular sequence

```
plot(y);
```



Algorithms

This object implements the algorithm, inputs, and outputs described on the `Convolution` block reference page. The object properties correspond to the block parameters.

Extended Capabilities

step

System object: dsp.Convolver
Package: dsp

Convolution of inputs

Syntax

```
Y = step(conv,A,B)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(conv,A,B)` convolves the inputs `A` and `B`.

Note: `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

dsp.DCBlocker System object

Package: dsp

Remove DC component

Description

The `DCBlocker` object filters or blocks the DC component of an incoming signal.

To filter the DC component of a signal:

1. Define and set up your DC blocker object. See “Construction” on page 4-438.
2. Call step to filter the DC component of a signal according to the properties of `dsp.DCBlocker`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`dcblker = dsp.DCBlocker` creates a DC blocker System object, `dcblker`, that removes the DC component of each channel, i.e., column, of an input signal.

`dcblker = dsp.DCBlocker(Name,Value)` creates a DC blocker object, `dcblker`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

Properties

`Algorithm`

DC offset algorithm type

Specify the DC offset estimating algorithm as one of `IIR | FIR | CIC | Subtract mean`. You can visualize the IIR, FIR, and CIC responses using the `fvtool` method. The default is `IIR`.

- `IIR` uses a recursive estimate based on a narrow, lowpass elliptic filter. You specify the filter order using the `Order` property and you set the bandwidth using the `NormalizedBandwidth` property. This algorithm typically uses less memory than FIR and is more efficient.
- `FIR` uses a non-recursive, moving-average estimate based on a finite number of past input samples that is set using the `Length` property. This algorithm typically uses more memory than IIR and is less efficient.
- `CIC` uses a lowpass filter that does not employ any multipliers. You specify the bandwidth of the filter using the `NormalizedBandwidth` property. If the `Algorithm` property is `CIC`, then fixed-point data must be input to the `step` function.
- `Subtract mean` computes the means of the columns of the input matrix and subtracts the means from the input. This method does not retain state between inputs.

NormalizedBandwidth

Normalized bandwidth of the lowpass IIR elliptic filter or the lowpass CIC filter

Specify the normalized bandwidth of the IIR or CIC filter used to estimate the DC component of the input signal as a real scalar greater than 0 and less than 1. This property applies when the `Algorithm` property is set to `IIR` or `CIC`. The default value is `0.001`.

Order

Order of the lowpass IIR elliptic filter

Specify the order of the IIR elliptic filter used to estimate the DC level. This property applies when the `Algorithm` property is set to `IIR`. Use an integer greater than 3. The default value is `6`.

Length

Number of past input samples for the FIR algorithm

Specify the number of past inputs used to estimate the running mean. This property applies when the `Algorithm` property is set to `FIR`. Use a positive integer. The default value is `50`.

Methods

fvtool	Show the frequency response of the filter used by the `DCBlocker` System object
reset	Reset states of the `DCBlocker` System object
step	Blocks DC components of input signal

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Remove DC Component and Display Results

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

This example shows how to use the DC Blocker System object to remove an input signal's DC component using three of the estimation algorithms.

Create a signal composed of a 15 Hz tone, a 25 Hz tone, and a DC offset.

```
t = (0:0.001:100)';
x = sin(30*pi*t) + 0.33*cos(50*pi*t) + 1;
```

Create three DC Blocker objects for the `IIR`, `FIR`, and `Subtract mean` estimation algorithms.

```
dc1 = dsp.DCBlocker('Algorithm','IIR','Order', 6);
```

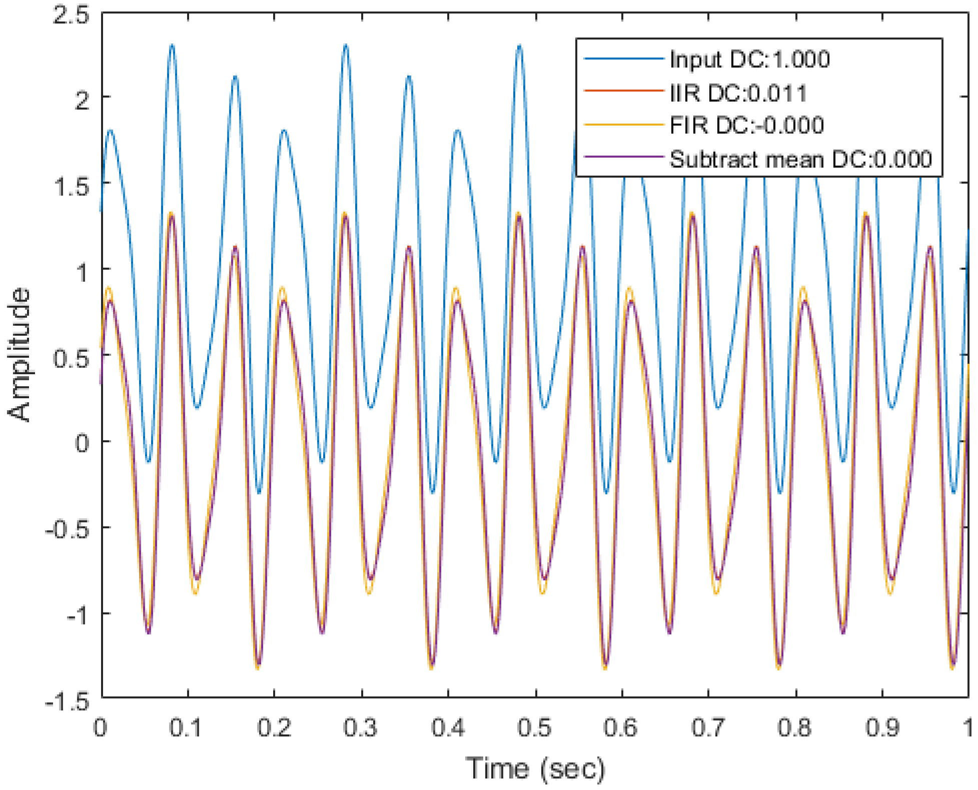
```
dc2 = dsp.DCBlocker('Algorithm','FIR','Length', 100);
dc3 = dsp.DCBlocker('Algorithm','Subtract mean');
```

For each second of time, pass the input signal through the DC blockers. By implementing the DC blockers in 1 second increments, you can observe differences in the convergence times.

```
for idx = 1 : 100
    range = (1:1000) + 1000*(idx-1);
    y1 = dc1(x(range));          % IIR estimate
    y2 = dc2(x(range));          % FIR estimate
    y3 = dc3(x(range));          % Subtract mean
end
```

Plot the input and output data for the three DC blockers for the first second of time and show the mean value for each signal. Looking at the mean values for the three algorithm types, you can see that the `FIR` and `Subtract mean` algorithms converge more quickly.

```
plot(t(1:1000),x(1:1000),...
    t(1:1000),y1, ...
    t(1:1000),y2, ...
    t(1:1000),y3);
xlabel('Time (sec)')
ylabel('Amplitude')
legend(sprintf('Input DC:%.3f',mean(x)), ...
    sprintf('IIR DC:%.3f',mean(y1)), ...
    sprintf('FIR DC:%.3f',mean(y2)), ...
    sprintf('Subtract mean DC:%.3f',mean(y3)));
```



Frequency Response Before and After DC Blocker

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

This example shows a comparison of the spectrum of an input signal with a DC offset to the spectrum of the same signal after application of a DC blocker using the `FIR` estimation algorithm.

Create an input signal composed of three tones and a DC offset of 1. Set the sampling frequency to 1 kHz and set the signal duration to 100 seconds.

```
fs = 1000;
```

```
t = (0:1/fs:100)';
x = sin(30*pi*t) + 0.67*sin(40*pi*t) + 0.33*sin(50*pi*t) + 1;
```

Create a DC blocker object with the `Algorithm` property set to `FIR`.

```
dcblk = dsp.DCBlocker('Algorithm','FIR','Length',100);
```

Create a `SpectrumAnalyzer` System object with power units set to `dBW` and a frequency range of `[-30 30]` to display the frequency response of the input signal. Using the `clone` method, create a second spectrum analyzer to display the response of the output. Then, use the `Name` property to label the two objects.

```
hsa = dsp.SpectrumAnalyzer('SampleRate',fs, ...
    'PowerUnits','dBW','FrequencySpan','Start and stop frequencies',...
    'StartFrequency',-30,'StopFrequency',30);

hsb = clone(hsa);

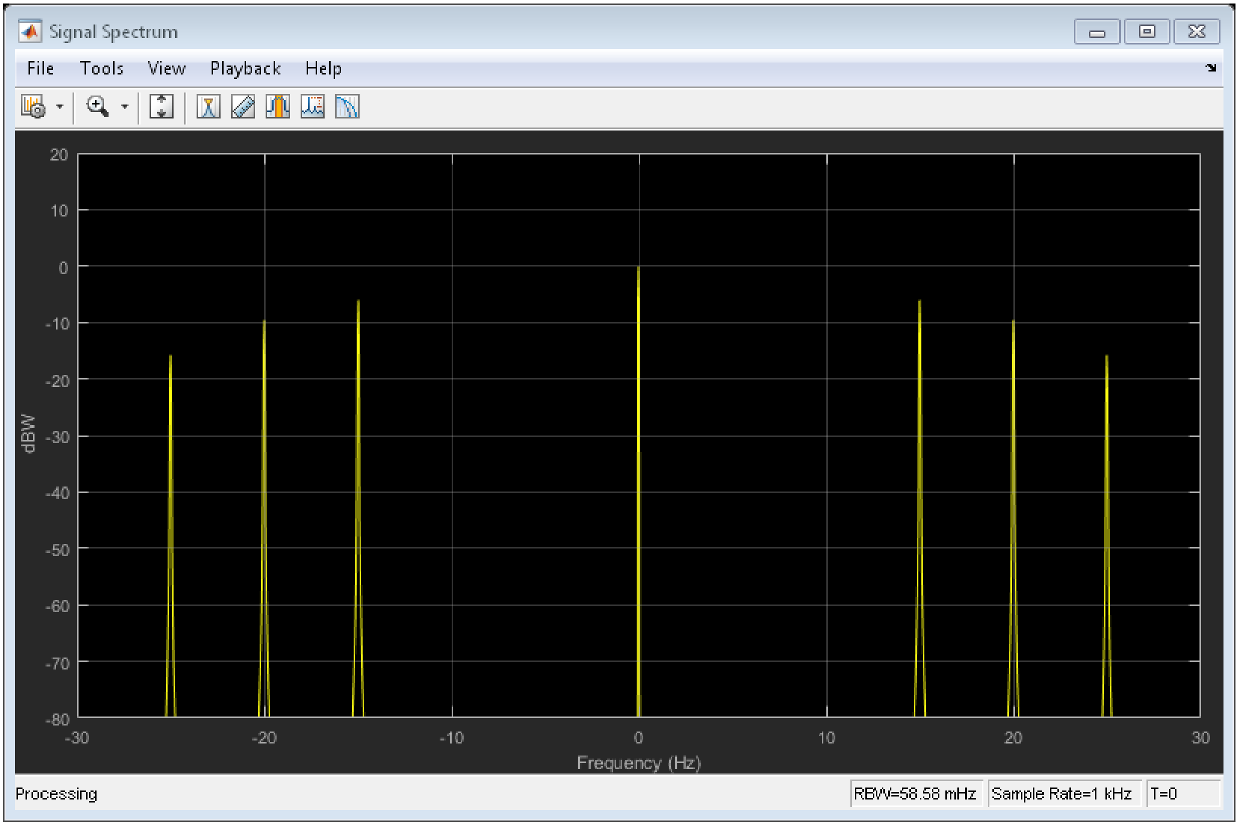
hsa.Name = 'Signal Spectrum';
hsb.Name = 'Signal Spectrum after DC Blocker';
```

Pass the input signal, `x`, through the DC blocker to generate the output signal, `y`.

```
y = dcblk(x);
```

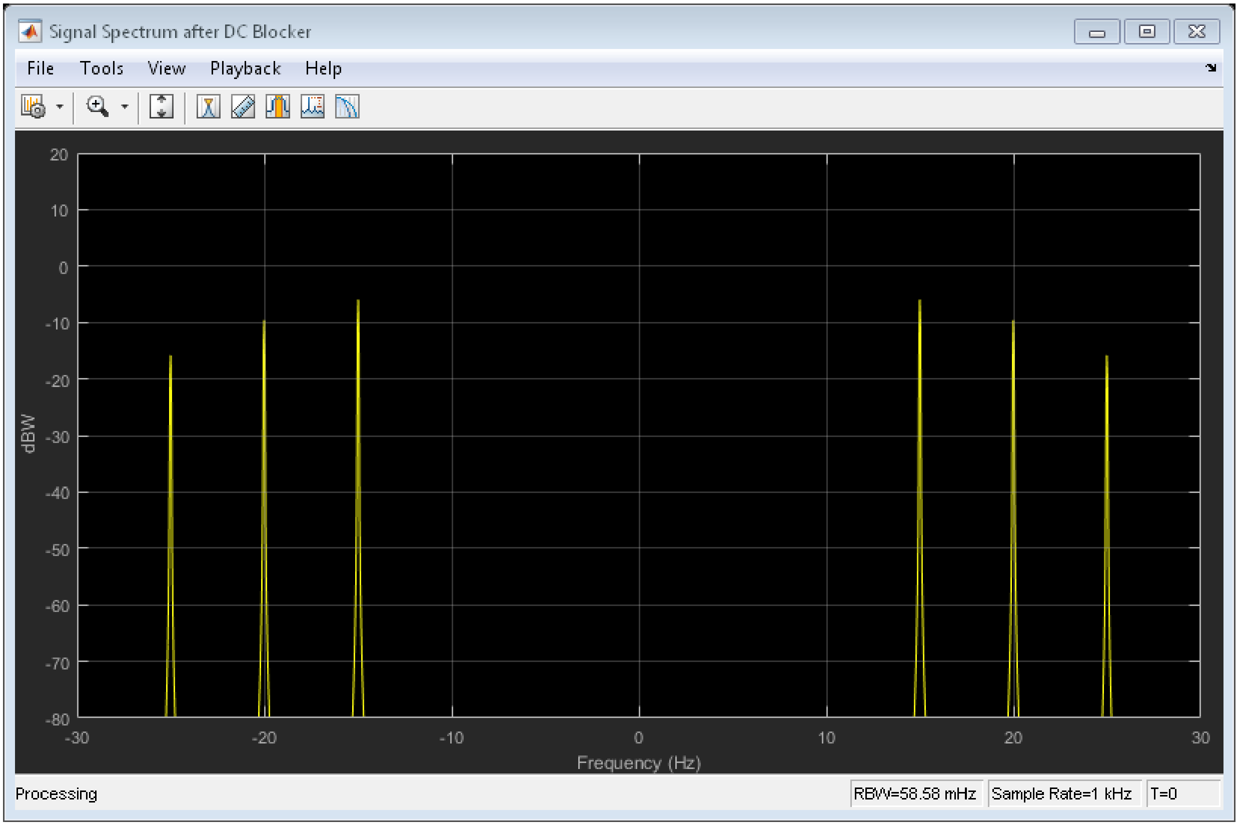
Use the spectrum analyzer, `hsa`, to display the frequency characteristics of the input signal. Note that the tones at 15 Hz, 20 Hz, and 25 Hz, and the DC component are clearly visible.

```
hsa(x)
```



Use the second spectrum analyzer, `hsb`, to display the frequency characteristics of the output signal. Note that the DC component has been removed.

```
hsb(y)
```



Remove DC Offset from Fixed-Point Data

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

This example shows how to use the DC Blocker to remove a DC offset from a fixed-point signal. The DC Blocker uses the CIC lowpass filtering method to estimate the DC offset.

Generate random binary data.

```
data = randi([0 1],1.2e5,1);
```

Modulate the data by creating a 64-QAM modulator System object and running its algorithm.

```
mod = comm.RectangularQAMModulator('ModulationOrder',64, ...
                                    'BitInput',true);
modOut = mod(data);
```

Determine the constellation reference points for the modulator.

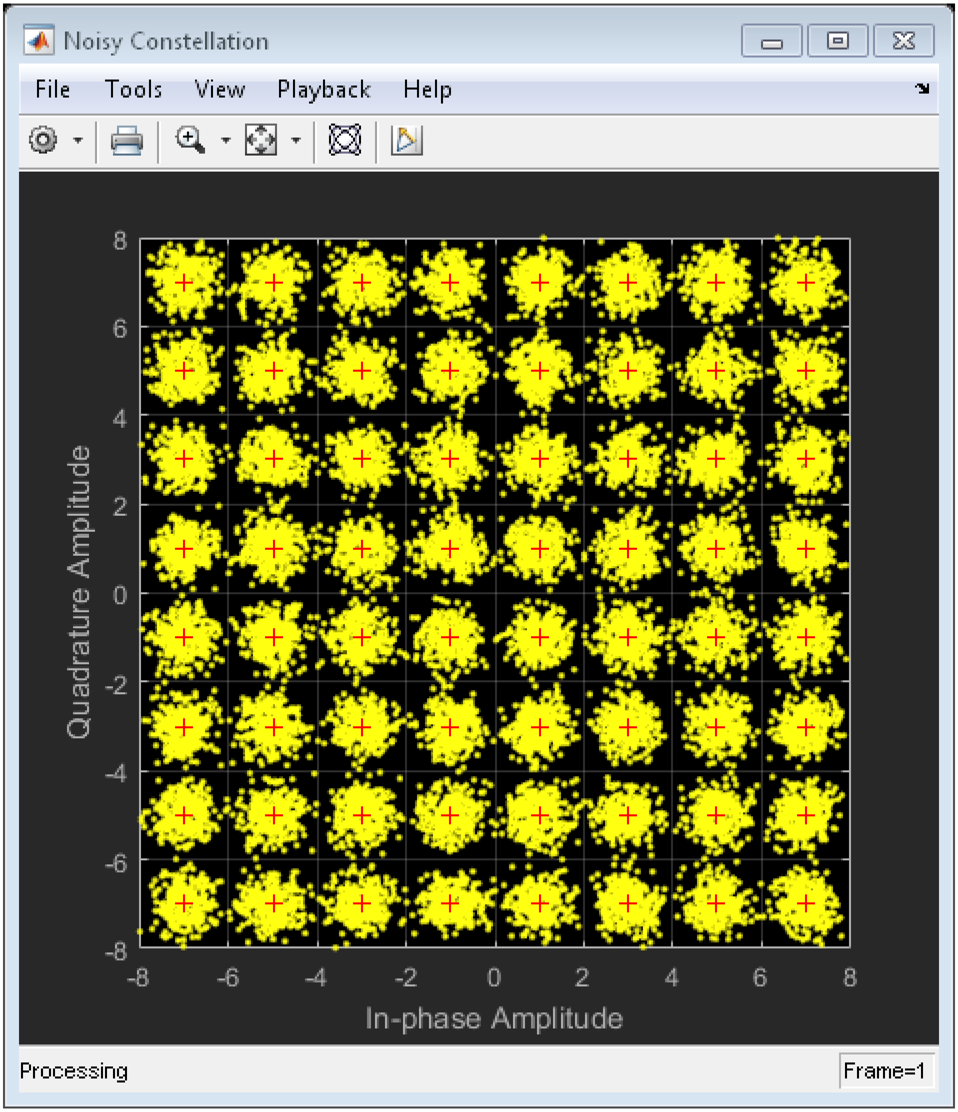
```
cRefPts = constellation(mod);
```

Add AWGN to the modulated signal using the appropriate System object and running its algorithm.

```
noise = comm.AWGNChannel('EbNo', 14.75, ...
                          'BitsPerSymbol', 6, ...
                          'SignalPower', 42, ...
                          'SamplesPerSymbol', 1);
noisyOut = noise(modOut);
```

Display the scatter plot of the noisy signal by using a Constellation Diagram object. The red '+' markers show the ideal symbol locations.

```
constDiag = comm.ConstellationDiagram('Name','Noisy Constellation',...
    'ReferenceConstellation',cRefPts, ...
    'XLimits',[-8 8],'YLimits',[-8 8]);
constDiag(noisyOut)
```

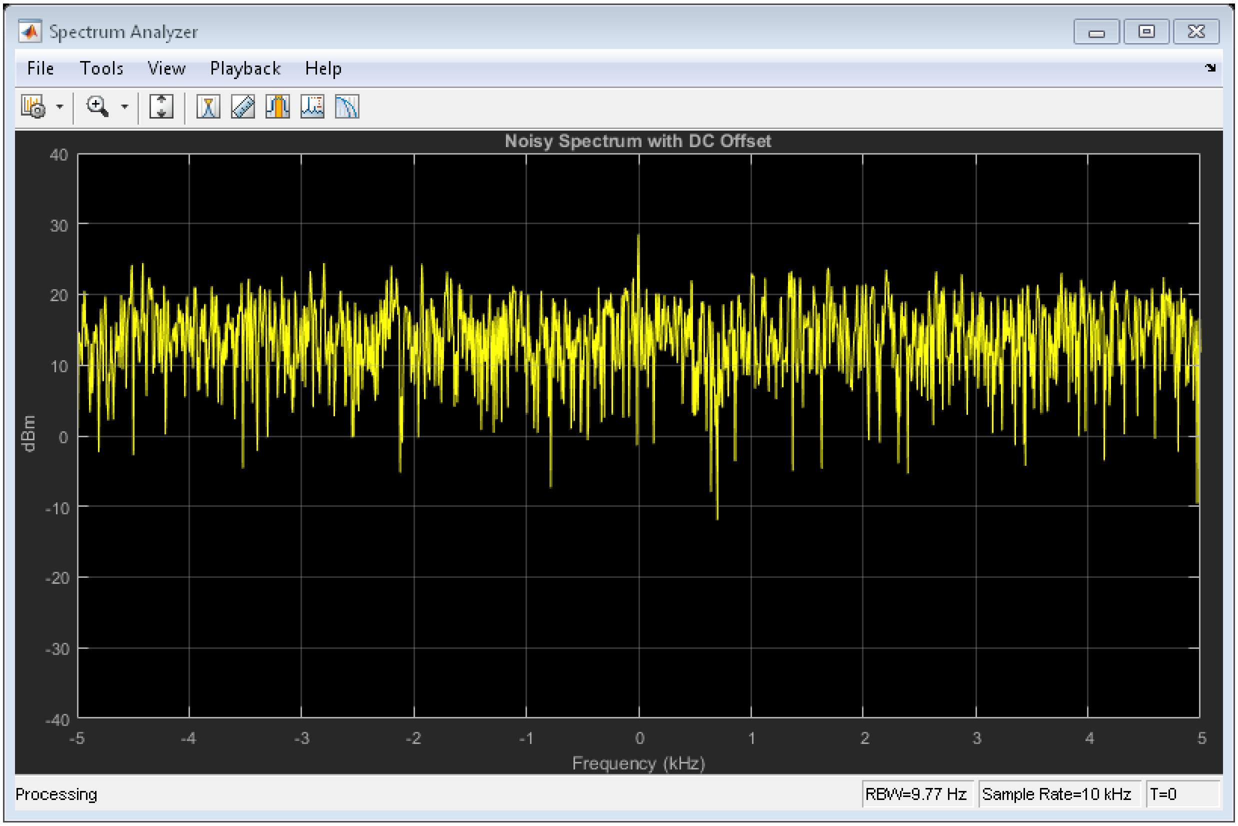


Add a DC offset of 1 to the modulated signal.

```
noisyOut = noisyOut + 1;
```

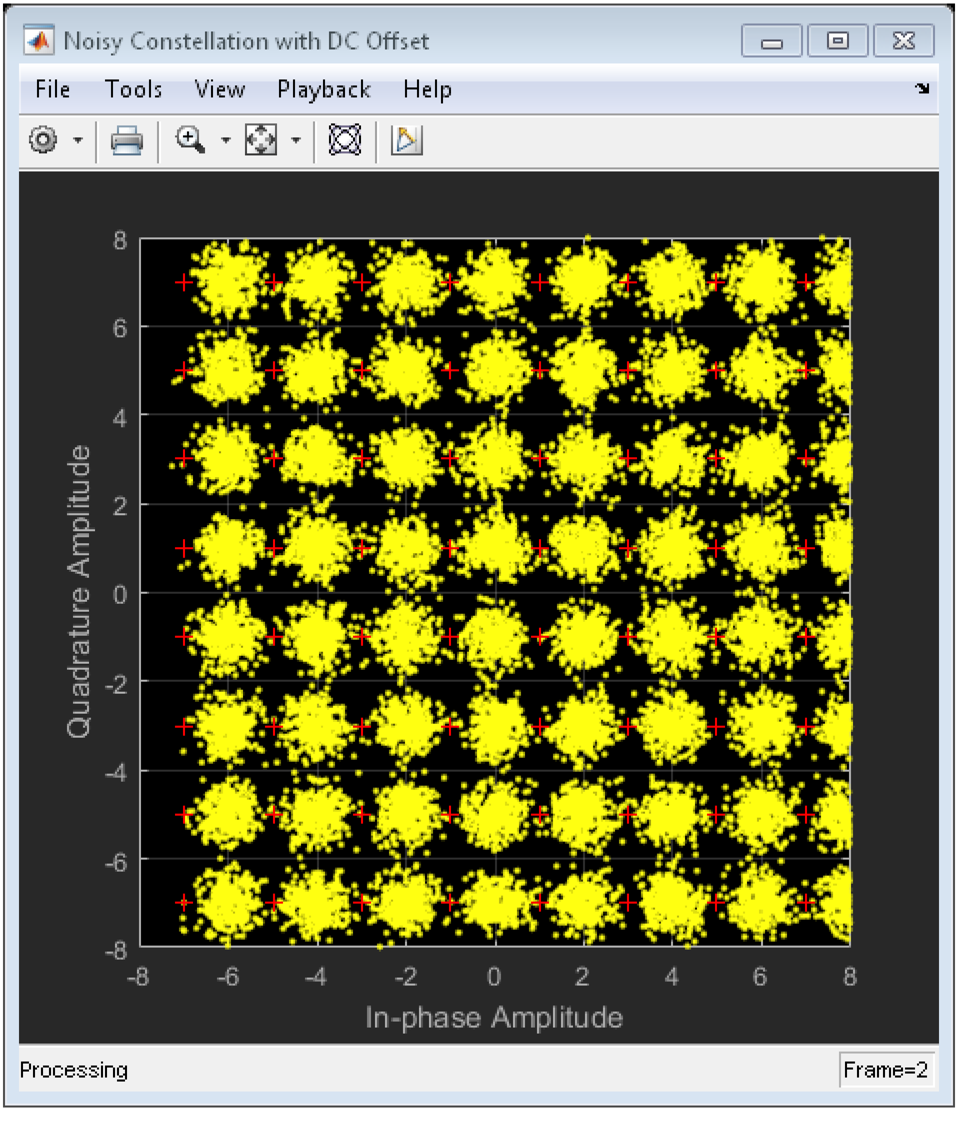
Display the spectrum of the signal. The spike at 0 kHz is due to the introduced offset.

```
specAna = dsp.SpectrumAnalyzer(...
  'YLimits',[-40,40], ...
  'Title','Noisy Spectrum with DC Offset');
specAna(noisyOut);
```



View the effect of the DC offset on the constellation. Observe that the constellation has shifted one unit to the right.

```
constDiag(noisyOut)
constDiag.Name = 'Noisy Constellation with DC Offset';
```



Convert the noisy signal to a signed, fixed-point object that has a 16-bit word length and an 11-bit fraction length.

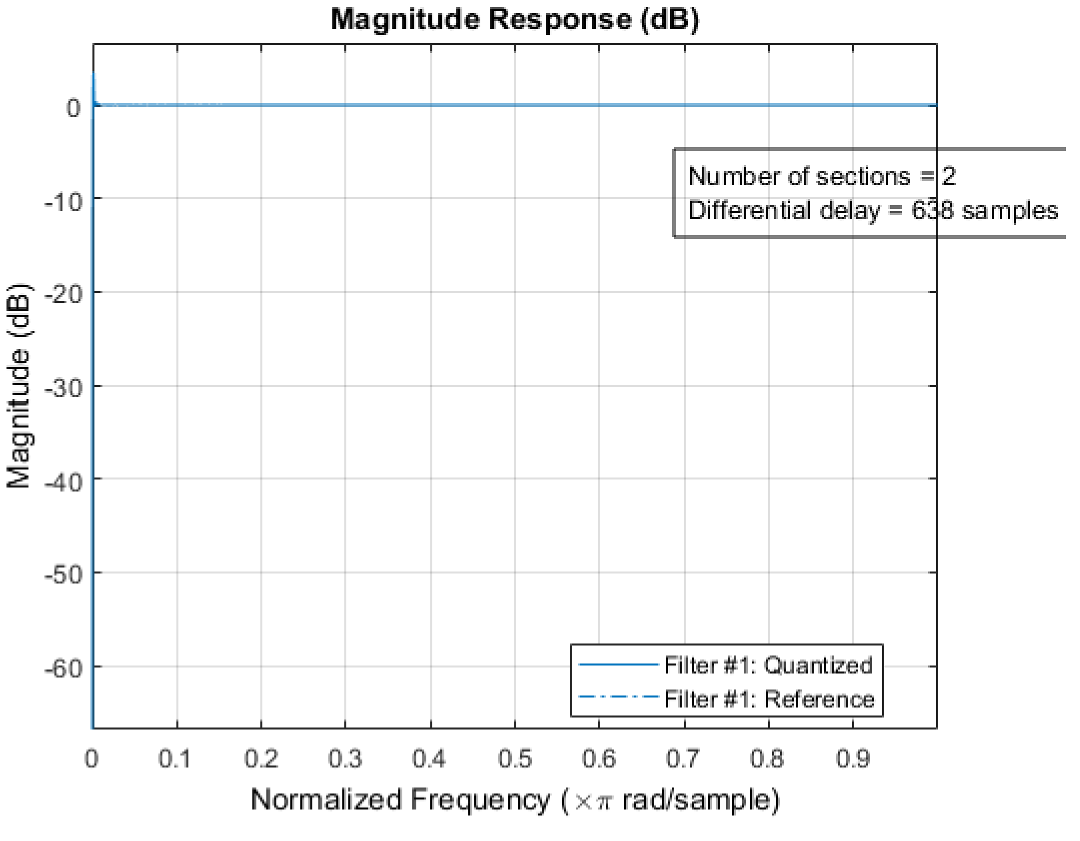
```
noisyOut = fi(noisyOut,1,16,11);
```

Remove the offset by creating a DC Blocker object. Set the `Algorithm` property of the object to `CIC`.

```
dcblk = dsp.DCBlocker('Algorithm','CIC');
```

Visualize the frequency response of the CIC estimating filter.

```
fvtool(dcblk)
```

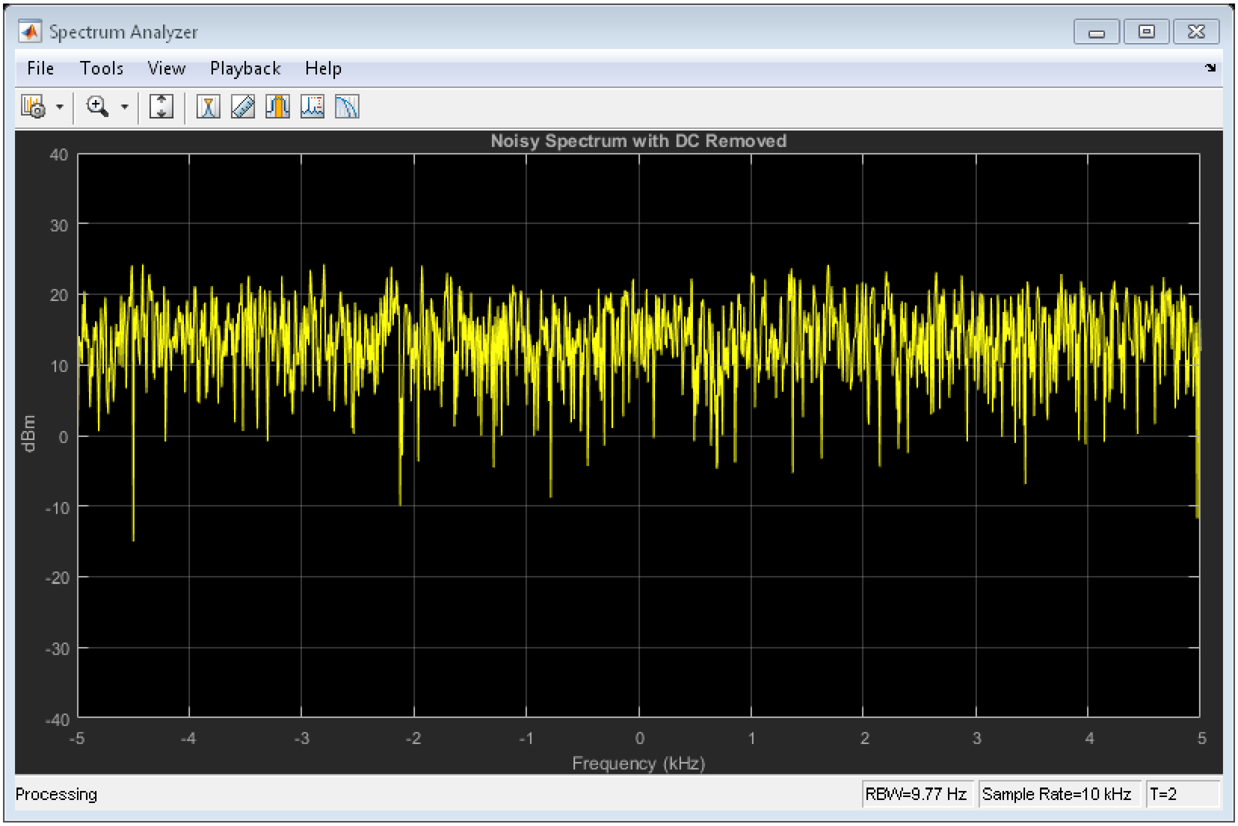


Pass the offset, noisy signal through the DC Blocker and convert its output to a double.

```
dcBlockerOutFxP = dcblk(noisyOut);
dcBlockerOut = double(dcBlockerOutFxP);
```

Plot the signal spectrum to show the effect of removing the DC offset. The spike at 0 kHz has been removed.

```
specAna(dcBlockerOut);
specAna.Title = 'Noisy Spectrum with DC Removed';
```



Plot the constellation and verify that the signal shifted back to the left.

```
constDiag(dcBlockerOut)
constDiag.Name = 'Noisy Constellation with DC Removed';
```

To see the effects of removing a DC offset, vary the value of the `NormalizedBandwidth` property.

Algorithms

The `DCBlocker` System object subtracts the DC component from the input signal. The DC component is estimated by one of the following:

- Passing the input signal through an IIR lowpass elliptical filter
- Passing the input signal through an FIR filter that uses a non-recursive, moving average from a finite number of past input samples
- Passing the input signal through a CIC filter. Because the CIC filter amplifies the signal, the filter gain is estimated and subtracted from the DC estimate.
- Computing the mean value of the input signal

The elliptical IIR filter has a passband ripple of 0.1 dB and a stopband attenuation of 60 dB. You specify the normalized bandwidth and filter order.

The FIR filter coefficients are given as `ones(1,Length)/Length`, where you specify the `Length` parameter. The FIR filter structure is a direct form 1 transposed.

The Cascaded Integrator-Comb (CIC) filter consists of two integrator-comb pairs. This helps to ensure that the peak of the first sidelobe of the filter response is attenuated by at least 25 dB relative to the peak of the main lobe. The normalized 3-dB bandwidth is used to calculate the differential delay. The delay is used to determine the gain of the CIC filter. The inverse of the filter gain is used as a multiplier which is applied to the output of the CIC filter. This ensures that the aggregate gain of the DC estimate is 0 dB.

The aggregate magnitude response of the filter and the multiplier is characterized by the following equation:

$$\left|H(e^{j\omega})\right| = \left|\frac{\sin(M\frac{\pi}{2}B_{norm})}{M\sin(\frac{\pi}{2}B_{norm})}\right|^N$$

- B_{norm} is the normalized bandwidth such that $0 < B_{norm} < 1$.
- M is the differential delay in samples.
- N is the number of sections, equal to 2.

The differential delay is found by setting M to the smallest integer such that $|H(e^{j\omega})| < 1/\sqrt{2}$. Once M is known, the gain of the CIC filter is calculated as M^N. Therefore, to precisely compensate for the filter gain, the multiplier is set to $(1/M)^N$.

dsp.BiquadFilter | dsp.FIRFilter | `DC Blocker` | dsp.CICDecimator

Introduced in R2014a

fvtool

System object: dsp.DCBlocker
Package: dsp

Show the frequency response of the filter used by the `DCBlocker` System object

Syntax

```
fvtool(dcblker)
```

Description

`fvtool(dcblker)` visualizes the frequency response of the DC blocker object, `dcblker`. With the fvtool, you can visualize the magnitude response, phase response, group delay, impulse response, pole-zero plot, and even view the coefficients of `dcblker`.

reset

System object: dsp.DCBlocker
Package: dsp

Reset states of the `DCBlocker` System object

Syntax

`reset(dcblker)`

Description

`reset(dcblker)` resets the states of the `DCBlocker` object, `dcblker`.

step

System object: dsp.DCBlocker
Package: dsp

Blocks DC components of input signal

Syntax

```
Y = step(dcblker,X)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(dcblker,X)` removes the DC component from the input signal, `X`, and returns the output, `Y`. The input signal is a numeric, signed matrix, with time samples recorded in rows and independent channels of data recorded in columns.

dsp.Counter System object

Package: dsp

Count up or down through specified range of numbers

Description

The `Counter` object counts up or down through a specified range of numbers.

To count up or down through a specified range of numbers:

1. Define and set up your counter. See "Construction" on page 4-458.
2. Call step to count up or down according to the properties of `dsp.Counter`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`count = dsp.Counter` returns a counter System object, `count`, that counts up when the input is nonzero.

`count = dsp.Counter('`*`PropertyName`*`',`*`PropertyValue`*`,...)` returns a counter System object, `count`, with each specified property set to the specified value.

Properties

`Direction`

Count up or down

Specify the counter direction as `Up` or `Down`. The default is `Up`. This property is tunable.

CountEventInputPort

Add input to specify a count event

Set this property to `true` to enable a count event input for the internal counter. The internal counter increments or decrements whenever the count event input satisfies the condition you specify in the `CountEventCondition on page 4-459` property. When you set this property to `false`, the internal counter is free running, that is, the counter increments or decrements on every call to the `step` method. The default is `true`.

CountEventCondition

Condition that increments, decrements, or resets internal counter

Specify the event at the count event input that increments or decrements the counter as `Rising edge`, `Falling edge`, `Either edge` or `Non-zero`.

If you set the `ResetInputPort on page 4-460` and `CountEventInputPort on page 4-459` properties to `true`, the counter is reset when the event you specify for the `CountEventCondition` occurs. This property applies only when you set the `CountEventInputPort on page 4-459` property to `true`.

CounterSizeSource

Source of counter size data type

Specify the source of the counter size data type as `Property` or `Input port`. The default is `Property`.

CounterSize

Range of integer values to count through

Specify the range of integer values to count through before recycling to zero as `8 bits`, `16 bits`, `32 bits` or `Maximum`. The default is `Maximum`.

MaximumCount

Counter's maximum value

Specify the counter's maximum value as a numeric scalar value. This property applies only when you set the `CounterSizeSource on page 4-` property to `Property` and the `CounterSize on page 4-` property to `Maximum`. The default is `255`. This property is tunable.

`InitialCount`

Counter initial value

Specify the initial value for the counter. The default is `0`. This property is tunable.

`CountOutputPort`

Output count

Set this property to `true` to enable output of the internal count. The default is `true`. You cannot set both `CountOutputPort` and `HitOutputPort on page 4-460` to `false` at the same time.

`HitOutputPort`

Output hit events

Set this property to `true` to enable output of the hit events. You cannot set both `CountOutputPort` on page 4-460 and `HitOutputPort` to `false` at the same time. The default is `true`.

`HitValues`

Values whose occurrence in count produce a true hit output

Specify an integer scalar or a vector of integers, whose occurrences in the count you want flagged as a hit. This property applies only when you set the `HitOutputPort on page 4-460` property to `true`.

`ResetInputPort`

Add input to enable internal counter reset

When you set this property to `true`, specify a reset input to the `step` method. When the reset input receives the event you specify for the `CountEventCondition on page 4-459` property, the counter resets. If you set the `CountEventInputPort on page 4-459` property to `false`, the counter resets whenever the reset input is not zero.

`SamplesPerFrame`

Number of samples in each output frame

Specify the number of samples in each output frame. This property applies only when you set the `CountEventInputPort on page 4-459` property to `false`, indicating a free-running counter. The default is `1`.

`CountOutputDataType`

Data type of count output

Specify the data type of the count output, CNT, as `double`, `single`, `int8`, `uint8`, `int16`, `uint16`, `int32` or `uint32`. This property applies when you set the `CountOutputPort on page 4-460` property to `true`. The default is `double`.

Methods

reset	Reset internal states of Counter object
step	Increment or decrement the internal counter

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Count the Rising Edges

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

Use `dsp.Counter` System object™ to count at every rising edge of the input signal.

```
count = dsp.Counter('MaximumCount', 5, ...
```

```
    'CountOutputPort', true, ...
    'HitOutputPort', false, ...
    'ResetInputPort', false);
sgnl = [0 1 0 1 0 1 0 1 0 1 0 1 ];
for ii = 1:length(sgnl)
    cnt(ii) = count(sgnl(ii));
end
display(cnt);
```

```
cnt =

     0     1     1     2     2     3     3     4     4     5     5     0
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the `Counter` block reference page. The object properties correspond to the block parameters.

- The `CountEventCondition` object property does not have a free-running option. Set the `CountEventInputPort` property to `false` to obtain the free-running option.
- The `CounterSizeSource` and `CounterSize` object properties correspond to the **Counter size** block parameter.
- The `CountOutputPort` and `HitOutputPort` correspond to the **Output** block parameter.
- There is no object property that corresponds to the **Hit data type** block parameter. The output type is logical in MATLAB. (This logical is different from the popup logical in the block. For the object, logical corresponds to Boolean in the block.)

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

Introduced in R2012a

reset

System object: dsp.Counter
Package: dsp

Reset internal states of Counter object

Syntax

`reset(count)`

Description

`reset(count)` resets the internal states of the counter object `count` to their initial values.

step

System object: dsp.Counter
Package: dsp

Increment or decrement the internal counter

Syntax

```
[CNT,HIT] = step(count,EVENT,RESET)
CNT = step(count,EVENT,RESET)
HIT = step(count,EVENT,RESET)
[...] = step(count)
[...] = step(count,EVENT)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`[CNT,HIT] = step(count,EVENT,RESET)` increments, decrements, or resets the internal counter as specified by the values of the `EVENT` and `RESET` inputs. The output argument `CNT` denotes the present value of the counter. A trigger event at the `EVENT` input causes the counter to increment or decrement. A trigger event at the `RESET` input resets the counter to its initial state.

`CNT = step(count,EVENT,RESET)` returns the current value of the count when you set the `CountOutputPort` property to `true`, and the `HitOutputPort` property to `false`.

`HIT = step(count,EVENT,RESET)` returns a Boolean value indicating whether the count has reached any of the values specified by the `HitValues` property. This condition applies when you set the `HitOutputPort` property to `true` and the `CountOutputPort` property to `false`.

`[...] = step(count)` increments or decrements the free-running internal counter when you set the `CountEventInputPort` property to `false` and the `ResetInputPort` property to `false`.

`[...] = step(count,EVENT)` increments or decrements the internal counter when the `EVENT` input matches the event you specify for the `CountEventCondition` property and you set the `ResetInputPort` property to `false`.

Note: `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

dsp.CoupledAllpassFilter System object

Package: dsp

Coupled allpass IIR filter

Description

The `CoupledAllpassFilter` object implements a coupled allpass filter structure composed of two allpass filters connected in parallel. Each allpass branch can contain multiple sections. The overall filter output is computed by adding the output of the two respective branches. An optional second output can also be returned, which is power complementary to the to the first. For example, from the frequency domain perspective, if the first output implements a lowpass filter, the second output implements the power complementary highpass filter. For real signals, the power complementary output is computed by subtracting the output of the second branch from the first. `CoupledAllpassFilter` supports double- and single-precision floating point and allows you to choose between different realization structures. This System object also supports complex coefficients, multichannel variable length input, and tunable filter coefficient values.

To filter each channel of the input:

1. Define and set up your Coupled Allpass Filter. See “Construction” on page 4-468.
2. Call step to filter each channel of the input according to the properties of `dsp.CoupledAllpassFilter`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`caf = dsp.CoupledAllpassFilter` returns a coupled allpass filter System object, `caf`, that filters each channel of the input signal independently. The coupled allpass filter uses the default inner structures and coefficients.

`caf = dsp.CoupledAllpassFilter('PropertyName',PropertyValue, ...)` returns a Coupled allpass filter System object, `caf`, with each property set to the specified value.

`caf = CoupledAllpassFilter(AllpassCoefficients1,AllpassCoefficients2)` returns a coupled allpass filter System object, `caf`, with `Structure` set to `'Minimum multiplier'`. The allpass coefficients for each of the two branches are set to their two corresponding specified values.

`caf = CoupledAllpassFilter(Structure,AllpassCoefficients1,AllpassCoefficients2)` returns a coupled allpass filter System object, `caf`, with `Structure` set to a specified value. This value can be `'Minimum multiplier'` | `'Wave Digital Filter'` | `'Lattice'`. The coefficients relevant to the specified structure are set to the values provided.

Properties

`Structure`

Internal structure of allpass branches

Specify the internal structure of allpass branches as one of `'Minimum multiplier'` | `'Wave Digital Filter'` | `'Lattice'`. Each structure uses a different pair of coefficient values, independently stored in the relevant object property.

`AllpassCoefficients1`

Allpass polynomial coefficients of branch 1

Specify the polynomial filter coefficients for the first allpass branch. This property is applicable only if you set the `Structure` property to `'Minimum multiplier'`. This property can accept values either in the form of a row vector (single-section configuration) or a cell array with as many cells as filter sections. The default value is `[0 0.5]`. This property is tunable.

WDFCoefficients1

Wave Digital Filter coefficients of branch 1

Specify the Wave Digital Filter coefficients for the first allpass branch. This property is applicable only if you set the `Structure` property to `'Wave Digital Filter'`. This property can accept values either in the form of a row vector (single-section configuration) or a cell array with as many cells as filter sections. The default value is `[0.5 0]`. This property is tunable.

LatticeCoefficients1

Lattice coefficients of branch 1

Specify the allpass lattice coefficients for the first allpass branch. This property is applicable only if you set the `Structure` property to `'Lattice'`. This property can accept values either in the form of a row vector (single-section configuration) or a cell array with as many cells as filter sections. The default value is `[0.5 0]`. This property is tunable.

Delay

length in samples for branch 1

`Delay` is the integer number of the delay taps in the top branch. This property is applicable only if you set the `PureDelayBranch` property to `true`. This property is a scalar positive integer, and is tunable.

Gain1

Independent Branch 1 Phase Gain

`Gain1` is the individual branch phase gain. This property can accept only values equal to `'1'`, `'-1'`, `'0+i'`, or `'0-i'`. The default value is `1`. This property is nontunable.

AllpassCoefficients2

Allpass polynomial coefficients of branch 2

Specify the polynomial filter coefficients for the second allpass branch. This property is applicable only if you set the `Structure` property to `'Minimum Multiplier'`.

This property can accept values either in the form of a row vector (single-section configuration) or a cell array with as many cells as filter sections. The default value is [ ]. This property is tunable.

WDFCoefficients2

Wave Digital Filter coefficients of branch 2

This property is applicable only if you set the `Structure` property to `'Wave Digital Filter'`. This property can accept values either in the form of a row vector (single-section configuration) or a cell array with as many cells as filter sections. The default value is [ ]. This property is tunable.

LatticeCoefficients2

Lattice coefficients of branch 2

Specify the allpass lattice coefficients for the second allpass branch. This property is applicable only if you set the `Structure` property to `'Lattice'`. This property can accept values either in the form of a row vector (single-section configuration) or a cell array with as many cells as filter sections. The default value is [ ]. This property is tunable.

Gain2

Independent Branch 2 Phase Gain

Specify the value of the independent phase gain applied to branch 2. This property can accept only values equal to `'1', '–1', '0+1i'` or `'0–1i'`. The default value is `1`. This property is nontunable.

Beta

Coupled phase gain

Specify the value of the phasor gain in complex conjugate form, in each of the two branches, and in complex coefficient configuration. This property is applicable only when the selected `Structure` property supports complex coefficients. The absolute value of this property should be `1` and its default value is `1`. This property is tunable.

PureDelayBranch

Replace allpass filter in first branch with pure delay

If you set `PureDelayBranch` to true, the property holding the coefficients for the first allpass branch is disabled and Delay becomes enabled. You can use this property to improve performance, when one of the two allpass branches is known to be a pure delay (e.g. for halfband filter designs)

ComplexConjugateCoefficients

Allow inferring coefficients of second allpass branch as complex conjugate of first

When the input signal is real, this property triggers the use of an optimized structural realization. This property is only enabled if the currently selected structure supports complex coefficients. Use it only if the filter coefficients are actually complex.

Methods

getBranches	Return internal allpass branches
reset	Reset internal states of Coupled Allpass filter
step	Filter input with CoupledAllpas filter object

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

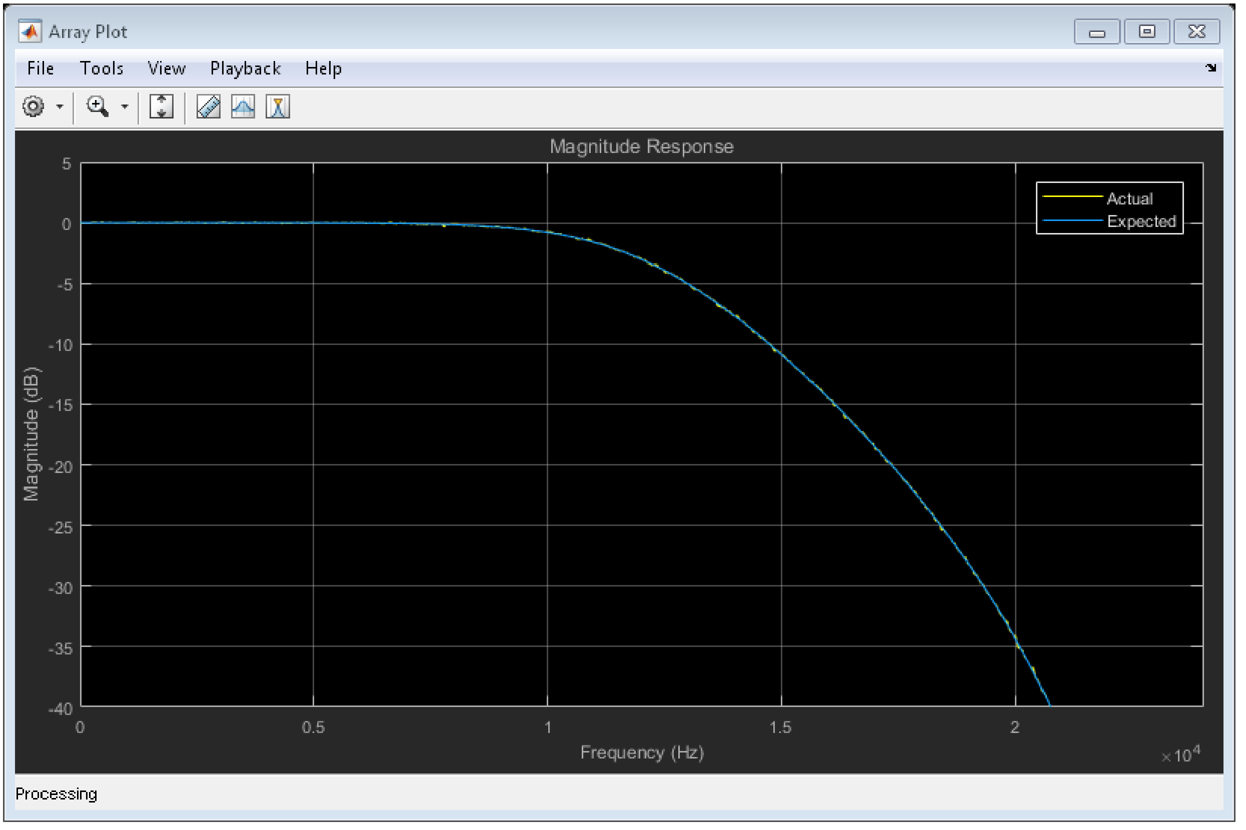
Examples

Allpass Realization of a Butterworth Lowpass Filter

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

Realize a Butterworth lowpass filter of order 3. Use a coupled allpass structure with inner minimum multiplier structure.

```
Fs = 48000;    % in Hz
Fc = 12000;    % in Hz
frameLength = 1024;
[b, a] = butter(3,2*Fc/Fs);
AExp = [freqz(b,a,frameLength/2); NaN];
[c1, c2] = tf2ca(b,a);
caf = dsp.CoupledAllpassFilter(c1(2:end),c2(2:end));
tfe = dsp.TransferFunctionEstimator('FrequencyRange', 'onesided',...
    'SpectralAverages', 2);
aplot = dsp.ArrayPlot('PlotType', 'Line',...
    'YLimits', [-40 5],...
    'YLabel', 'Magnitude (dB)',...
    'SampleIncrement', Fs/frameLength,...
    'XLabel', 'Frequency (Hz)',...
    'Title', 'Magnitude Response',...
    'ShowLegend', true,'ChannelNames',{'Actual','Expected'});
Niter = 200;
for k = 1:Niter
    in = randn(frameLength,1);
    out = caf(in);
    A = tfe(in,out);
    aplot(db([A,AExp]));
end
```



Allpass Realization of an Elliptic Highpass Filter

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

Remove a low-frequency sinusoid using an elliptic highpass filter design implemented through a coupled allpass structure.

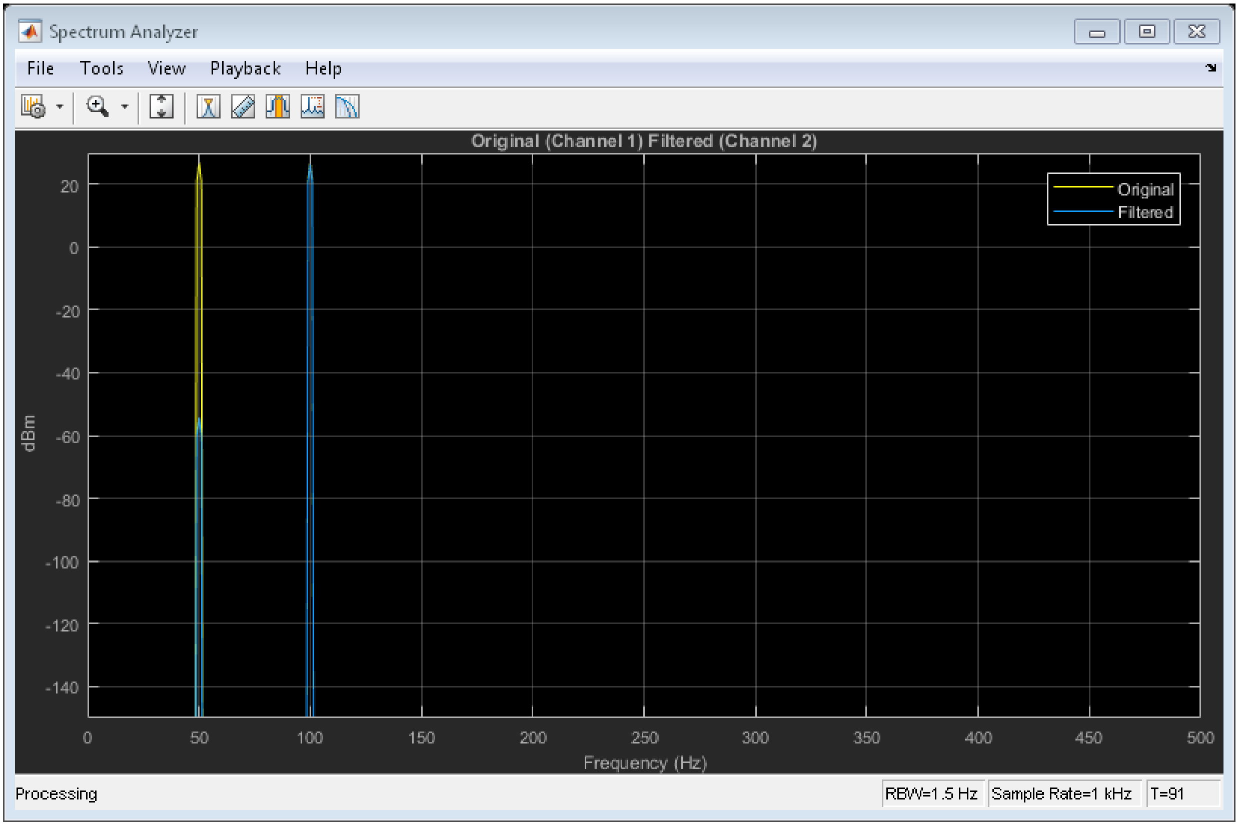
Initialize

```
Fs = 1000;
f1 = 50; f2 = 100;
Fpass = 70; Apass = 1;
```

```
Fstop = 60; Astop = 80;
filtSpecs = fdesign.highpass(Fstop,Fpass,Astop,Apass,Fs);
hpSpec = design(filtSpecs,'ellip','FilterStructure','cascadeallpass',...
    'SystemObject',true);
frameLength = 1000;
nFrames = 100;
sine   = dsp.SineWave('Frequency',[f1,f2],'SampleRate',Fs,...
  'SamplesPerFrame',frameLength); % Input composed of two sinusoids.
sa = dsp.SpectrumAnalyzer('SampleRate',Fs,'YLimits',[-150 30],...
  'PlotAsTwoSidedSpectrum',false,'ShowLegend',true,...
  'FrequencyResolutionMethod', 'WindowLength','WindowLength',1000,...
  'FFTLengthSource', 'Property','FFTLength', 1000,...
  'Title','Original (Channel 1) Filtered (Channel 2)',...
  'ChannelNames',{'Original','Filtered'});
```

Simulate

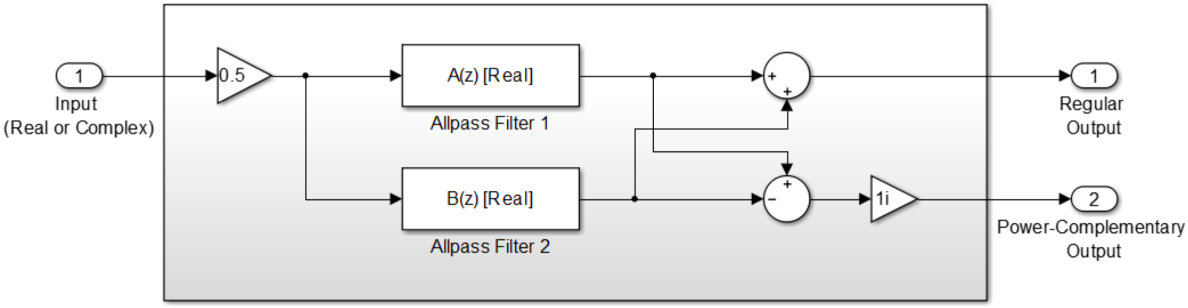
```
for k = 1:nFrames
  original = sum(sine(),2); % Add the two sinusoids together
  filtered = hpSpec(original);
  sa([original,filtered]);
end
```



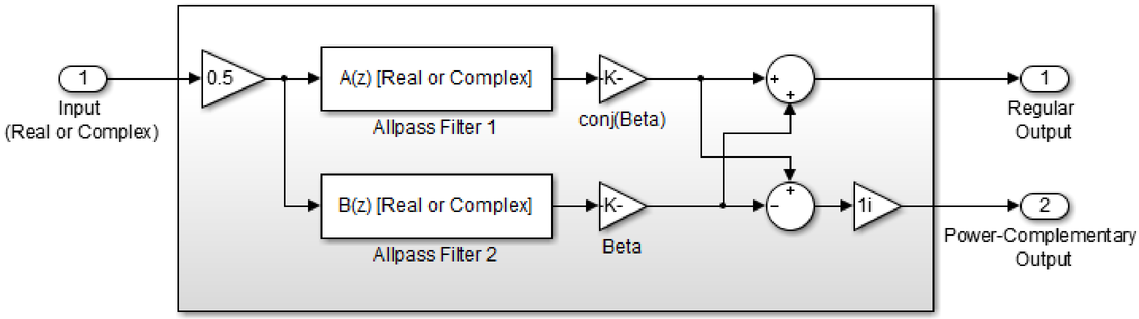
Algorithms

The following three figures summarize the main structures supported by `dsp.CoupledAllpassFilter`.

- Minimum Multiplier and WDF



- Lattice



- Lattice with Complex Conjugate Coefficients

dsp.AllpassFilter | dsp.IIRFilter | dsp.BiquadFilter

Introduced in R2013b

getBranches

System object: dsp.CoupledAllpassFilter
Package: dsp

Return internal allpass branches

Syntax

```
getBranches(caf)
```

Description

`getBranches(caf)` returns copies of the internal allpass branches, as a two-field structure. Each branch is an instance of dsp.AllpassFilter.

reset

System object: dsp.CoupledAllpassFilter
Package: dsp

Reset internal states of Coupled Allpass filter

Syntax

```
reset(caf)
```

Description

`reset(caf)` resets the internal states of the Coupled Allpass filter object, `caf`, to their initial values. The reset method is always a no-op for unlocked System objects, as the states may not be allocated when the object is not locked.

step

System object: dsp.CoupledAllpassFilter
Package: dsp

Filter input with CoupledAllpas filter object

Syntax

```
Y = step(caf,X)
[Y1,...,YN] = step(caf,X)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(caf,X)` processes the input data, `X` to produce the output, `Y`, for System object, `caf`.

`[Y1,...,YN] = step(caf,X)` produces `N` outputs.

Every System object has a step method. The step method processes the input data according to the object algorithm. The number of input and output arguments depends on the algorithm, and may depend also on one or more property settings. The step method for some objects accepts fixed-point (fi) inputs (but not for this object).

Note: `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change

nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.CrossSpectrumEstimator System object

Package: dsp

Estimate cross-spectral density

Description

The `dsp.CrossSpectrumEstimator` computes the cross- spectrum density of a signal, using the Welch algorithm and the Periodogram method.

To implement the cross-spectrum estimation object:

1. Define and set up your cross-spectrum estimator object. See “Construction” on page 4-482.
2. Call step to implement the estimator according to the properties of `dsp.CrossSpectrumEstimator`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`cse = dsp.CrossSpectrumEstimator` returns a System object, `cse`, that computes the cross-power spectrum of real or complex signals using the periodogram method and Welch’s averaged, modified periodogram method.

`cse = dsp.CrossSpectrumEstimator('`*`PropertyName`*`',` *`PropertyValue`*`,...)` returns a `Cross-Spectrum Estimator` System object, `cse`, with each specified property name set to the specified value. You can specify additional name-value pair arguments in any order as (Name1,Value1,...,NameN,ValueN).

Properties

SampleRate

Sample rate of input

Specify the sample rate of the input, in hertz, as a finite numeric scalar. The default value is `1 Hz`. The sample rate is the rate at which the signal is sampled in time.

SpectralAverages

Number of spectral averages

Specify the number of spectral averages as a positive, integer scalar. The Cross-Spectrum Estimator computes the current cross-spectral estimate by averaging the last `N` estimates. `N` is the number of spectral averages defined in the `SpectralAverages` property. The default is `8`.

FFTLengthSource

Source of the FFT length value

Specify the source of the FFT length value as one of `'Auto' | 'Property'`. The default is `'Auto'`. If you set this property to `'Auto'`, the Cross-Spectrum Estimator sets the FFT length to the input frame size. If you set this property to `'Property'`, then you specify the number of FFT points using the `FFTLength` property.

FFTLength

FFT Length

Specify the length of the FFT that the Cross-Spectrum Estimator uses to compute cross-spectral estimates as a positive, integer scalar. This property applies when you set the `FFTLengthSource` property to `'Property'`. The default value is `128`.

Window

Window function

Specify a window function for the cross-spectral estimator as one of `'Rectangular' | 'Chebyshev' | 'Flat Top' | 'Hamming' | 'Hann' | 'Kaiser'`. The default value is `'Hann'`.

SidelobeAttenuation

Side lobe attenuation of window

Specify the side lobe attenuation of the window as a real, positive scalar, in decibels (dB). This property applies when you set the `Window` property to `'Chebyshev'` or `'Kaiser'`. The default is `60 dB`.

FrequencyRange

Frequency range of the cross-spectrum estimate

Specify the frequency range of the cross-spectrum estimator as one of `'twosided' | 'onesided' | 'centered'`.

If you set the `FrequencyRange` to `'onesided'`, the cross-spectrum estimator computes the onesided spectrum of real input signals, `x` and `y`. If the FFT length, NFFT, is even, the length of the cross-spectrum estimate is `NFFT/2+1` and is computed over the interval `[0,SampleRate/2]`. If NFFT is odd, the length of the cross-spectrum estimate is equal to `(NFFT+1)/2` and the interval is `[0,SampleRate/2]`.

If you set the `FrequencyRange` to `'twosided'`, the cross-spectrum estimator computes the twosided spectrum of complex or real input signals, `x` and `y`. The length of the cross-spectrum estimate is equal to NFFT. This value is computed over `[0, SampleRate]`.

If you set the `FrequencyRange` to `'centered'`, the cross-spectrum estimator computes the centered twosided spectrum of complex or real input signals, `x` and `y`. The length of the cross-spectrum estimate is equal to NFFT and it is computed between `[-SampleRate/2, SampleRate/2]` and `(-SampleRate/2, SampleRate/2)` for even and odd lengths, respectively. The default value is `'Twosided'`.

Methods

getFrequencyVector	Get the vector of frequencies at which the cross-spectrum is estimated
getRBW	Get the resolution bandwidth of the cross-spectrum
reset	Reset the internal states of the cross-spectrum estimator

step	Estimate the cross-spectrum of a signal

Common to All System Objects	
clone	Create System object with same property values
getNumInpu	Expected number of inputs to a System object
getNumOutp	Expected number of outputs of a System object
isLocked	Check locked states of a System object (logical)
release	Allow System object property value changes

Examples

Compute the Cross-Power Spectrum of Two Noisy Sine Waves

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

Generate two sine waves.

```
sin1 = dsp.SineWave('Frequency',200, 'SampleRate', 1000);
sin1.SamplesPerFrame = 1000;
sin2 = dsp.SineWave('Frequency',100, 'SampleRate', 1000);
sin2.SamplesPerFrame =  1000;
```

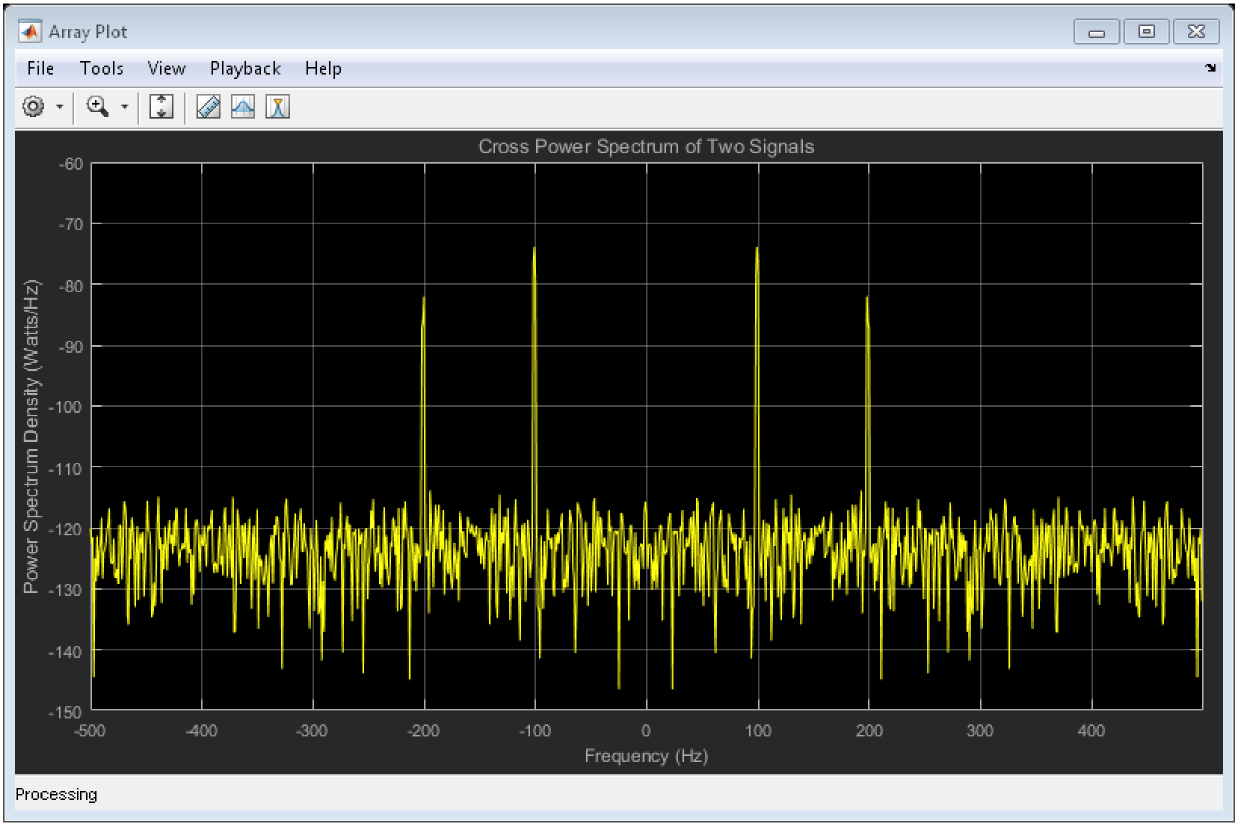
Use the Cross-Spectrum Estimator to compute the cross-spectrum of the signals. Also, use the Array Plot to display the spectra.

```
cse = dsp.CrossSpectrumEstimator('SampleRate', sin1.SampleRate,...
    'FrequencyRange','centered');
aplot = dsp.ArrayPlot('PlotType','Line','XOffset',-500,'YLimits',...
    [-150 -60],'YLabel','Power Spectrum Density (Watts/Hz)',...
    'XLabel','Frequency (Hz)',...
    'Title','Cross Power Spectrum of Two Signals');
```

Add random noise to the sine waves. Stream in the data, and plot the cross-power spectrum of the two signals.

```
for ii = 1:10
```

```
x = sin1() + 0.05*randn(1000,1);
y = sin2() + 0.05*randn(1000,1);
Pxy = cse(x, y);
aplot(20*log10(abs(Pxy)));
end
```



Algorithms

Given two signals `x` and `y` as inputs. We first window the two inputs, and scale them by the window power. We then take FFT of the signals, calling them `X` and `Y`. This is followed by taking the cross correlation of the FFT, i.e., `Z = X*conj(Y)`. We average the last N number of `Z`'s, and scale the answer by the sample rate.

For further information, refer to the “Algorithms” on page 2-1592 section in Spectrum Analyzer, which uses the same algorithm.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- “System Objects in MATLAB Code Generation” (MATLAB Coder)
- When the FFT length is not a power of two, the executable generated from this System object relies on prebuilt dynamic library files (`.dll` files) included with MATLAB. Use the `packNGo` function to package the code generated from this object and all the relevant files in a compressed zip file. Using this zip file, you can relocate, unpack, and rebuild your project in another development environment where MATLAB is not installed. For more details, see “How To Run a Generated Executable Outside MATLAB”.
- When the FFT length is a power of two, you can generate standalone C and C++ code from this System object.

Blocks

`Cross Spectrum Estimator`

Introduced in R2013b

getFrequencyVector

System object: dsp.CrossSpectrumEstimator
Package: dsp

Get the vector of frequencies at which the cross-spectrum is estimated

Syntax

`getFrequencyVector(cse)`

Description

`getFrequencyVector(cse)` returns the vector of frequencies at which the cross-spectrum is estimated.

If you set the `FrequencyRange` to `'onesided'` and the FFT length, `NFFT`, is even, the frequency vector is of length `NFFT/2+1`, and covers the interval `[0,SampleRate/2]`. If you set the `FrequencyRange` to `'onesided'` and `NFFT` is odd, the frequency vector is of length `(NFFT+1)/2` and covers the interval `[0,SampleRate/2]`. If you set the `FrequencyRange` to `'twosided'`, the frequency vector is of length `NFFT` and covers the interval `[0, SampleRate]`. If you set the `FrequencyRange` to `'centered'`, the frequency vector is of length `NFFT` and covers the range `[-SampleRate/2, SampleRate/2]` and `[-SampleRate/2, SampleRate/2]` for even and odd length `NFFT`, respectively.

getRBW

System object: dsp.CrossSpectrumEstimator
Package: dsp

Get the resolution bandwidth of the cross-spectrum

Syntax

```
getRBW(cse)
```

Description

`getRBW(cse)` returns the resolution bandwidth of the cross-spectrum.

The resolution bandwidth, `RBW`, is the smallest positive frequency, or frequency interval, that can be resolved. It is equal to `ENBW*SampleRate/ L`, where `L` is the input length, and `ENBW` is the two-sided equivalent noise bandwidth of the window (in Hz). For example, if `SampleRate=100`, `L=1024`, and `Window='Hann'`, `RBW=enbw(hann(1024))*100/1024`.

reset

System object: dsp.CrossSpectrumEstimator
Package: dsp

Reset the internal states of the cross-spectrum estimator

Syntax

`reset(sysObj)`

Description

`reset(sysObj)` resets the internal states of the System object, `sysObj`, to their initial values. The reset method is always a no-op for unlocked System objects, as the states may not be allocated when the object is not locked.

step

System object: dsp.CrossSpectrumEstimator
Package: dsp

Estimate the cross-spectrum of a signal

Syntax

```
Y = step(sysObj,x)
[Y1,...,YN] = step(sysObj,x)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(sysObj,x)` processes the input data, `x`, to produce the output, `Y`, from the System object, `sysObj`. `[Y1,...,YN] = step(sysObj,x)` produces `N` outputs.

The columns of `x` are treated as independent channels.

Every System object has a step method. The step method processes the input data according to the object algorithm. The number of input and output arguments depends on the algorithm, and may depend also on one or more property settings. The step method for some objects accepts fixed-point (fi) inputs.

Calling step on an object puts that object into a locked state. When locked, you cannot change nontunable properties or any input characteristics (size, data type and complexity) without reinitializing (unlocking and relocking) the object.

Note: `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.Crosscorrelator System object

Package: dsp

Cross-correlation of two inputs

Description

The `Crosscorrelator` returns the cross-correlation sequence for two discrete-time deterministic inputs. This object can also return the cross-correlation sequence estimate for two discrete-time, jointly wide-sense stationary (WSS), random processes.

To obtain the cross-correlation for two discrete-time deterministic inputs:

1. Define and set up your cross-correlator. See “Construction” on page 4-494.
2. Call step to compute the cross-correlation according to the properties of `dsp.Crosscorrelator`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`xcorr = dsp.Crosscorrelator` returns a cross-correlator object, `xcorr`, that computes the cross-correlation of two inputs. For N-D arrays, the cross-correlator computes the correlation column-wise. The inputs must have an equal number of columns. If one input is a vector and the other is an N-D array, the cross-correlator computes the cross-correlation of the vector with each column of the N-D array. Cross correlating inputs of length N and M results in a cross-correlation sequence of length $N+M-1$. Cross correlating matrices of size M-by-N and P-by-N results in a matrix of cross-correlation sequences of size $M+P-1$-by-N.

`xcorr = dsp.Crosscorrelator('`*`PropertyName`*`',`*`PropertyValue`*`, ...)` returns a cross-correlator, `xcorr`, with each property set to the specified value.

Properties

Method

Domain for computing correlations

Specify the domain for computing correlation as `Time Domain`, `Frequency Domain`, or `Fastest`. Computing correlations in the time domain minimizes memory use. Computing correlations in the frequency domain may require fewer computations than computing in the time domain depending on the input length. If the value of this property is `Fastest`, the cross-correlator operates in the domain which minimizes the number of computations. The default is `Time Domain`.

Fixed-Point Properties

FullPrecisionOverride

Full precision override for fixed-point arithmetic

Specify whether to use full precision rules. If you set `FullPrecisionOverride` to `true`, which is the default, the object computes all internal arithmetic and output data types using full precision rules. These rules provide the most accurate fixed-point numerics. It also turns off the display of other fixed-point properties because they do not apply individually. These rules guarantee that no quantization occurs within the object. Bits are added, as needed, to ensure that no roundoff or overflow occurs. If you set `FullPrecisionOverride` to `false`, fixed-point data types are controlled through individual fixed-point property settings. For more information, see “Full Precision for Fixed-Point System Objects”.

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as one of `Ceiling`, `Convergent`, `Floor`, `Nearest`, `Round`, `Simplest`, or `Zero`. The default is `Floor`. This property applies only if the object is not in full precision mode.

OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as one of Wrap or Saturate. The default is Wrap. This property applies only if the object is not in full precision mode.

ProductDataType

Product word and fraction lengths

Specify the product fixed-point data type as one of Full Precision, Same as first input, or Custom. The default is Full Precision.

CustomProductDataType

Product word and fraction lengths

Specify the product fixed-point type as a scaled numerictype object with a Signedness of Auto. This property applies only when the ProductDataType on page 4-496 property is Custom. The default is numerictype([],32,30).

AccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point data type as Full Precision, Same as product, Same as first input, or Custom. The default is Full Precision.

CustomAccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled numerictype object with a Signedness of Auto. This property applies only when the AccumulatorDataType on page 4-496 property is Custom. The default is numerictype([],32,30).

OutputDataType

Output word and fraction lengths

Specify the output fixed-point data type as one of Same as accumulator, Same as product, Same as first input, or Custom. The default is Same as accumulator.

CustomOutputDataType

Output word and fraction lengths

Specify the output fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when the `OutputDataType` on page 4-496 property is `Custom`. The default is `numerictype([],16,15)`.

Methods

step	Cross-correlation sequence

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Compute Correlation Between Two Signals

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

```
xcorr = dsp.Crosscorrelator;
t = 0:0.001:1;
x1 = sin(2*pi*2*t)+0.05*sin(2*pi*50*t);
x2 = sin(2*pi*2*t);
y = xcorr(x1,x2); %computes cross-correlation of x1 and x2
figure,plot(t,x1,'b',t, x2, 'g');
legend('Input signal 1',' Input signal 2')
figure, plot(y); title('Correlated output')
```

Cross-Correlation of Input Noise and Delayed Version

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

Use cross-correlation to detect delay in jointly stationary white Gaussian noise inputs.

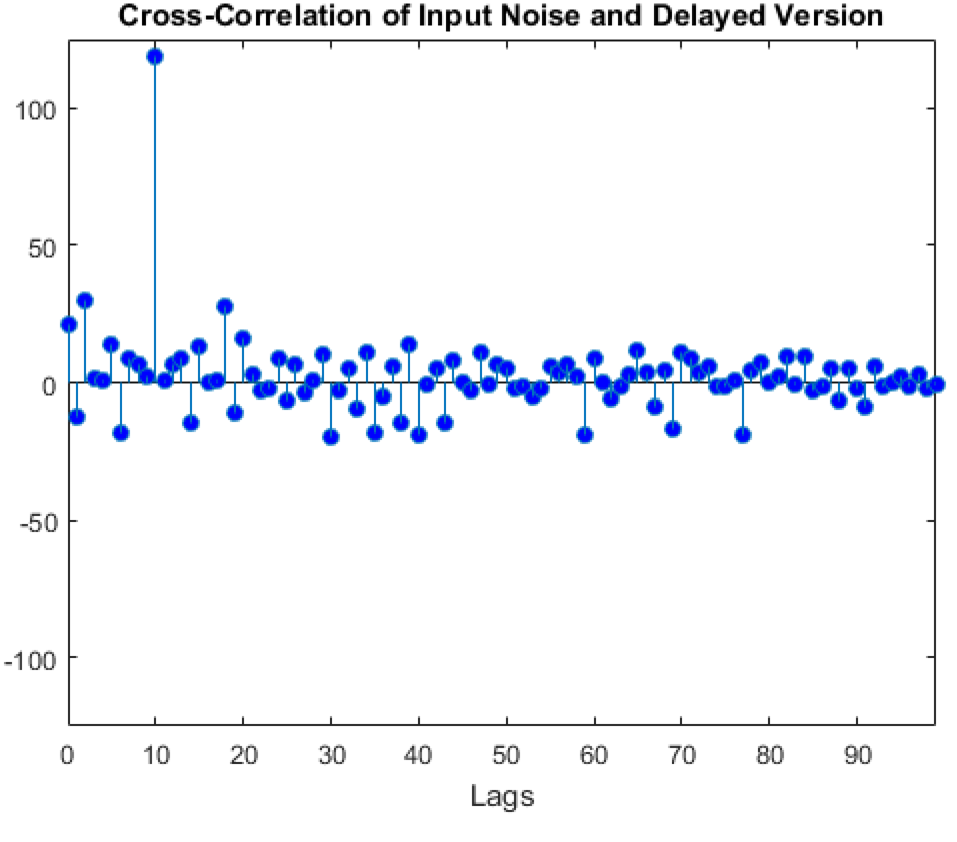
```
S = rng('default');
```

white Gaussian noise input

```
x = randn(100,1);
```

Create copy delayed by 10 samples x1[n] = x[n-10]

```
delay = dsp.Delay(10);
x1 = delay(x);
xcorr = dsp.Crosscorrelator;
y = xcorr(x1,x);
lags = 0:99; %Positive lags
stem(lags,y(100:end),'markerfacecolor',[0 0 1]);
axis([0 99 -125 125]);
xlabel('Lags');
title('Cross-Correlation of Input Noise and Delayed Version');
```



The theoretical cross-correlation sequence is identically zero except at lag 10. Note this is not true in the sample cross-correlation sequence, but the estimate demonstrates a peak at the correct lag.

Definitions

Cross-Correlation

Cross-correlation is the measure of similarity of two discrete-time sequences as a function of the lag of one relative to the other.

For two length N deterministic inputs, or realizations of jointly WSS random processes, x and y, the cross-correlation is computed using the following relationship:

$$r_{xy}(h) = \begin{cases} \sum_{n=0}^{N-h-1} x(n+h)y^*(n) & 0 \le h \le N-1 \\ r_{yx}^*(h) & -(N-1) \le h \le 0 \end{cases}$$

where h is the lag and * denotes the complex conjugate. If the inputs are realizations of jointly WSS stationary random processes, $r_{xy}(h)$ is an unnormalized estimate of the theoretical cross-correlation:

$$\rho_{xy}(h) = E\{x(n+h)y^*(n)\}$$

where E{ } is the expectation operator.

Algorithms

Time domain Computation

When you set the computation domain to time, the algorithm computes the cross-correlation of two signals in the time domain. The input signals can be fixed-point signals in this domain.

Correlate Two 2-D Arrays

When the inputs are two 2-D arrays, the jth column of the output, $y_{u,v}$, has these elements:

$$y_{uv(i,j)} = \sum_{k=0}^{\max(M_u,M_v)-1} u^{*}_{k,j} v_{(k+i),j} \qquad 0 \le i < M_v$$

$$y_{uv(i,j)} = y^{*}_{vu(-i,j)} \qquad -M_u < i < 0$$

- * denotes the complex conjugate.
- u is an M_u-by-N input matrix.
- v is an M_v-by-N input matrix.
- $y_{u,v}$ is an $(M_u + M_v - 1)$-by-N matrix.

Inputs u and v are zero when indexed outside their valid ranges.

Correlate a Column Vector with a 2-D Array

When one input is a column vector and the other input is a 2-D array, the algorithm independently cross-correlates the input vector with each column of the 2-D array. The jth column of the output, $y_{u,v}$, has these elements:

$$y_{uv(i,j)} = \sum_{k=0}^{\max(M_u,M_v)-1} u^{*}_{k} v_{(k+i),j} \qquad 0 \le i < M_v$$

$$y_{uv(i,j)} = y^{*}_{vu(-i,j)} \qquad -M_u < i < 0$$

- * denotes the complex conjugate.
- u is an M_u-by-1 column vector.
- v is an M_v-by-N matrix.
- $y_{u,v}$ is an $(M_u + M_v - 1)$-by-N matrix.

Inputs u and v are zero when indexed outside their valid ranges.

Correlate Two Column Vectors

When the inputs are two column vectors, the jth column of the output, $y_{u,v}$, has these elements:

$$y_{uv(i)} = \sum_{k=0}^{\max(M_u,M_v)-1} u_k^* v_{(k+i)} \qquad 0 \le i < M_v$$

$$y_{uv(i)} = y_{vu(-i)}^* \qquad -M_u < i < 0$$

- * denotes the complex conjugate.
- u is an M_u-by-1 column vector.
- v is an M_v-by-1 column vector.
- $y_{u,v}$ is an $(M_u + M_v - 1)$-by-1 column vector.

Inputs u and v are zero when indexed outside their valid ranges.

Frequency Domain Computation

When you set the computation domain to frequency, the algorithm computes the cross-correlation in the frequency domain.

To compute the cross-correlation, the algorithm:

1. Takes the Fourier transform of both input signals, U and V.
2. Multiplies U and V^*, where * denotes the complex conjugate.
3. Computes the inverse Fourier transform of the product.

In this domain, depending on the input length, the algorithm can require fewer computations.

dsp.Convolver | dsp.Autocorrelator

Introduced in R2012a

step

System object: dsp.Crosscorrelator
Package: dsp

Cross-correlation sequence

Syntax

```
Y = step(xcorr,A,B)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(xcorr,A,B)` computes the cross-correlation of `A` and `B` and returns the result in `Y`.

Note: `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

dsp.CumulativeProduct System object

Package: dsp

Cumulative product of channel, column, or row elements

Description

The `CumulativeProduct` object computes the cumulative product of channel, column, or row elements.

To compute the cumulative product of channel, column, or row elements:

1. Define and set up your cumulative product object. See "Construction" on page 4-506.
2. Call step to compute the cumulative product according to the properties of `dsp.CumulativeProduct`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`cprod = dsp.CumulativeProduct` returns a cumulative product object, `cprod`, that computes the cumulative product of input matrix or input vector elements along the default Dimension on page 4-507.

`cprod = dsp.CumulativeProduct('PropertyName',PropertyValue,...)` returns a cumulative product object, `cprod`, with each specified property set to the specified value.

Properties

Dimension

Computation dimension for cumulative product

Specify the computation dimension as one of | `Channels (running product)` | `Rows` | `Columns` |. The default is `Channels (running product)`.

ResetInputPort

Enable resetting cumulative product via input port

Set this property to `true` to enable resetting the cumulative product. When you set this property to `true`, specify a reset signal to the `step` method to reset the cumulative product. You can access this property when the `Dimension on page 4-507` property is set to `Channels (running product)`. The default is `false`.

ResetCondition

Reset condition for cumulative product

Specify the event on the reset input port that causes resetting the cumulative product to one of | `Rising edge` | `Falling edge` | `Either edge` | `Non-zero` |. This property applies when you set the `ResetInputPort on page 4-507` property to `true` and the `Dimension on page 4-507` property to `Channels (running product)`. The default is `Rising edge`.

Fixed-Point Properties

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as one of | `Ceiling` | `Convergent` | `Floor` | `Nearest`, | `Round` | `Simplest` | `Zero` |. The default is `Floor`.

OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as one of | `Wrap` | `Saturate` |. The default is `Wrap`.

IntermediateProductDataType

Intermediate product word and fraction lengths

Specify the intermediate product fixed-point data type as one of `| Same as input | Custom |`. The default is `Same as input`.

CustomIntermediateProductDataType

Intermediate product word and fraction lengths

Specify the intermediate product fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `IntermediateProductDataType on page 4-508` property to `Custom`. The default is `numerictype([], 16, 15)`.

ProductDataType

Product output word and fraction lengths

Specify the product output fixed-point data type as one of `| Same as input | Custom |`. The default is `Same as input`.

CustomProductDataType

Custom product output word and fraction lengths

Specify the product output fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `ProductDataType on page 4-508` property to `Custom`. The default is `numerictype([], 32, 30)`.

AccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point data type as one of `| Same as product output | Same as input | Custom |`. The default is `Same as input`.

CustomAccumulatorDataType

Custom accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `AccumulatorDataType on page 4-508` property to `Custom`. The default is `numerictype([], 32, 30)`.

OutputDataType

Output word and fraction lengths

Specify the output fixed-point data type as one of | Same as product output | Same as input | Custom |. The default is Same as input.

CustomOutputDataType

Custom output word and fraction lengths

Specify the output fixed-point type as a scaled numerictype object with a Signedness of Auto. This property applies when you set the OutputDataType on page 4-509 property to Custom. The default is numerictype([], 16, 15).

Methods

reset	Reset running cumulative product
step	Cumulative product of input along specified dimension for input

Common to All System Objects	
clone	Create System object with same property values
getNumInpu	Expected number of inputs to a System object
getNumOutp	Expected number of outputs of a System object
isLocked	Check locked states of a System object (logical)
release	Allow System object property value changes

Examples

Cumulative Product of a Matrix

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent step syntax. For example, myObject(x) becomes step(myObject,x).

Use the dsp.CumulativeProduct object to compute the cumulative product of a matrix.

```
cprod = dsp.CumulativeProduct;
x = magic(2)
y = cprod(x)
```

```
x =

     1     3
     4     2

y =

     1     3
     4     6
```

The cumulative product is computed column-wise along each channel.

Algorithms

This object implements the algorithm, inputs, and outputs described on the Cumulative Product block reference page. The object properties correspond to the block parameters, except:
The **Reset port** block parameter corresponds to both the ResetCondition and ResetInputPort object properties.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See "System Objects in MATLAB Code Generation" (MATLAB Coder).

dsp.CumulativeSum

Introduced in R2012a

reset

System object: dsp.CumulativeProduct
Package: dsp

Reset running cumulative product

Syntax

```
reset(cprod)
```

Description

`reset(cprod)` resets the running cumulative product for object `cprod` to zero.

step

System object: dsp.CumulativeProduct
Package: dsp

Cumulative product of input along specified dimension for input

Syntax

```
Y = step(cprod,X)
Y = step(cprod,X,R)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(cprod,X)` computes the cumulative product along the specified dimension for the input `X`.

`Y = step(cprod,X,R)` resets the cumulative product object's state based on the `ResetCondition` property value and the value of the reset signal, `R` when the `ResetInputPort` property is `true`.

Note: `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

dsp.CumulativeSum System object

Package: dsp

Cumulative sum of channel, column, or row elements

Description

The `CumulativeSum` object computes the cumulative sum of channel, column, or row elements.

To compute the cumulative sum of channel, column, or row elements:

1. Define and set up your cumulative sum object. See "Construction" on page 4-514.
2. Call step to compute the cumulative sum according to the properties of `dsp.CumulativeSum`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`csum = dsp.CumulativeSum` returns a cumulative sum System object, `csum`, which computes the running cumulative sum for each channel in the input.

`csum = dsp.CumulativeSum('PropertyName',PropertyValue,...)` returns a cumulative sum object, `csum`, with each specified property set to the specified value.

Properties

`Dimension`

Computation dimension for cumulative sum

Specify the computation dimension as one of | `Channels (running sum)` | `Rows` | `Columns` |. The default is `Channels (running sum)`.

ResetInputPort

Enable resetting cumulative sum via input port.

Set this property to `true` to enable resetting the cumulative sum. When you set this property to `true`, you also specify a reset input to the `step` method to reset the cumulative sum. The default is `false`.

ResetCondition

Reset condition for cumulative sum

Specify the event on the reset input port that resets the cumulative sum as one of | `Rising edge` | `Falling edge` | `Either edge` | `Non-zero` |. This property applies when you set the `ResetInputPort on page 4-515` property to `true`. The default is `Rising edge`.

Fixed-Point Properties

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as one of | `Ceiling` | `Convergent` | `Floor`, `Nearest`, `Round`, `Simplest` | `Zero` |. The default is `Floor`.

OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as one of | `Wrap` | `Saturate` |. The default is `Wrap`.

AccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point data type as one of | `Same as input` | `Custom` |. The default is `Same as input`.

CustomAccumulatorDataType

Custom accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `AccumulatorDataType on page 4-515` property to `Custom`. The default is `numerictype([], 32, 30)`.

OutputDataType

Output word and fraction lengths

Specify the output fixed-point data type as one of one of `| Same as accumulator | Same as input | Custom |`. The default is `Same as accumulator`.

CustomOutputDataType

Custom output word and fraction lengths

Specify the output fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `OutputDataType on page 4-516` property to `Custom`. The default is `numerictype([], 16, 15)`.

Methods

reset	Reset internal states of cumulative sum object to zero
step	Cumulative sum along specified dimension for input

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)

Common to All System Objects	
`release`	Allow System object property value changes

Examples

Cumulative Sum of a Matrix

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

Use the `dsp.CumulativeSum` object to compute the cumulative sum of a matrix.

```
csum = dsp.CumulativeSum;
x = magic(2)
y = csum(x)
```

```
x =

     1     3
     4     2

y =

     1     3
     5     5
```

The cumulative sum is computed column-wise along each channel.

Algorithms

This object implements the algorithm, inputs, and outputs described on the `Cumulative Sum` block reference page. The object properties correspond to the block properties, except:
The **Reset port** block parameter corresponds to both the `ResetCondition` and the `ResetInputPort` object properties

Extended Capabilities

dsp.CumulativeProduct

Introduced in R2012a

reset

System object: dsp.CumulativeSum
Package: dsp

Reset internal states of cumulative sum object to zero

Syntax

```
reset(csum)
```

Description

`reset(csum)` sets the states for the running cumulative sum object, `csum`, to zero when the `Dimension` property is set to `Channels (running sum)`.

step

System object: dsp.CumulativeSum
Package: dsp

Cumulative sum along specified dimension for input

Syntax

```
Y = step(csum,X)
Y = step(csum,X,R)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(csum,X)` computes the cumulative sum along the specified dimension for the input `X`.

`Y = step(csum,X,R)` resets the System object state based on the `ResetCondition` property value and the value of the reset signal, `R`. You can only reset the state if the `ResetInputPort` property is `true`.

Note: `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

dsp.DCT System object

Package: dsp

Discrete cosine transform (DCT)

Description

The `DCT` object computes the discrete cosine transform (DCT) of input.

To compute the DCT of input:

1. Define and set up your DCT object. See “Construction” on page 4-521.
2. Call step to compute the DCT according to the properties of `dsp.DCT`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`dct = dsp.DCT` returns a discrete cosine transform (DCT) object, `dct`, used to compute the DCT of a real or complex input signal.

`dct = dsp.DCT('`*`PropertyName`*`',`*`PropertyValue`*`, ...)` returns a DCT object, `dct`, with each property set to the specified value.

Properties

`SineComputation`

Method to compute sines and cosines

Specify how the DCT object computes the trigonometric values as `Trigonometric function` or `Table lookup`. This property must be set to `Table lookup` for fixed-point inputs. The default is `Table lookup`.

Fixed-Point Properties

`RoundingMethod`

Rounding method for fixed-point operations

Specify the rounding method as one of `Ceiling`, `Convergent`, `Floor` , `Nearest`, `Round`, `Simplest`, or `Zero`. This property applies when you set the `SineComputation` on page 4-521 property to `Table lookup`.

`OverflowAction`

Overflow action for fixed-point operations

Specify the overflow action as one of `Wrap` or `Saturate`. This property applies when you set the `SineComputation` on page 4-521 property to `Table lookup`.

`SineTableDataType`

Sine table word-length designation

Specify the sine table fixed-point data type as one of `Same word length as input` or `Custom`. This property applies when you set the `SineComputation` on page 4-521 property to `Table lookup`.

`CustomSineTableDataType`

Sine table word length

Specify the sine table fixed-point type as an unscaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `SineComputation` on page 4-521 property to `Table lookup` and the `SineTableDataType` on page 4-522 property to `Custom`. The default is `numerictype([],16)`.

`ProductDataType`

Product word and fraction lengths

Specify the product fixed-point data type as one of `Full precision` , `Same as input`, `Custom`. This property applies when you set the `SineComputation` on page 4-521 property to `Table lookup`.

`CustomProductDataType`

Product word and fraction lengths

Specify the product fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `SineComputation` on page 4-521 property to `Table lookup` and the `ProductDataType` on page 4-522 property to `Custom`. The default is `numerictype([],32,30)`.

`AccumulatorDataType`

Accumulator word and fraction lengths

Specify the accumulator fixed-point data type as one of `Full precision`, `Same as input`, `Same as product`, or `Custom`. This property applies when you set the `SineComputation` on page 4-521 property to `Table lookup`.

`CustomAccumulatorDataType`

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `SineComputation` on page 4-521 property to `Table lookup` and the `AccumulatorDataType` on page 4-523 property to `Custom`. The default is `numerictype([],32,30)`.

`OutputDataType`

Output word and fraction lengths

Specify the output fixed-point data type as one of `Full precision` , `Same as input`, `Custom`. This property applies when you set the `SineComputation` on page 4-521 property to `Table lookup`. The default is `Full precision`.

`CustomOutputDataType`

Output word and fraction lengths

Specify the output fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `SineComputation` on page 4-521 property to `Table lookup` and the `OutputDataType` on page 4-523 property to `Custom`. The default is `numerictype([],16,15)`.

Methods

step	Discrete cosine transform (DCT) of input

Common to All System Objects	
clone	Create System object with same property values
getNumInpu	Expected number of inputs to a System object
getNumOutp	Expected number of outputs of a System object
isLocked	Check locked states of a System object (logical)
release	Allow System object property value changes

Examples

Analyze the Energy Content in a Sequence

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

Use DCT to analyze the energy content in a sequence:

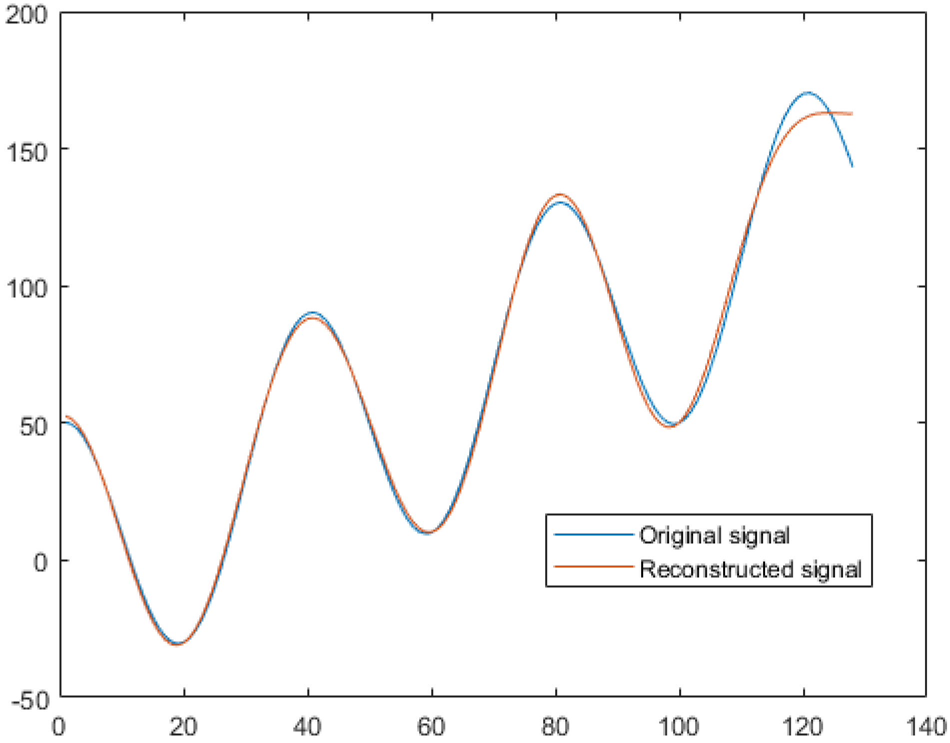
```
x = (1:128).' + 50*cos((1:128).'*2*pi/40);
dct = dsp.DCT;
X = dct(x);
```

Set the DCT coefficients which represent less than 0.1% of the total energy to 0 and reconstruct the sequence using IDCT.

```
[XX, ind] = sort(abs(X),1,'descend');
ii = 1;
while (norm([XX(1:ii);zeros(128-ii,1)]) <= 0.999*norm(XX))
    ii = ii+1;
end
disp(['Number of DCT coefficients that represent 99.9%',...
    'of the total energy in the sequence: ',num2str(ii)]);
XXt = zeros(128,1);
```

```
XXt(ind(1:ii)) = X(ind(1:ii));
idct = dsp.IDCT;
xt = idct(XXt);
plot(1:128,[x xt]);
legend('Original signal','Reconstructed signal',...
    'location','best');
```

```
Number of DCT coefficients that represent 99.9%of the total energy in the sequence: 10
```



Algorithms

This object implements the algorithm, inputs, and outputs described on the `DCT` block reference page. The object properties correspond to the block parameters.

dsp.FFT | dsp.IDCT | dsp.IFFT

Introduced in R2012a

step

System object: dsp.DCT
Package: dsp

Discrete cosine transform (DCT) of input

Syntax

`Y = step(dct,X)`

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(dct,X)` computes the `DCT` of the input `X`.

Note: `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.Delay System object

Package: dsp

Delay input by specified number of samples or frames

Description

Note: Certain features of this object will be removed in future releases. See "Functionality being removed or replaced for blocks and System objects".

The `Delay` object delays an input by a specified number of samples or frames.

To delay an input by a specified number of samples or frames:

1. Define and set up your delay object. See "Construction" on page 4-528.
2. Call step to delay the input according to the properties of `dsp.Delay`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`delay = dsp.Delay` returns a delay object, `delay`, to delay the input by one sample.

`delay = dsp.Delay('`*`PropertyName`*`',` *`PropertyValue`*`, ...)` returns a delay object, `delay`, with each property set to the specified value.

`delay = dsp.Delay(LEN,'`*`PropertyName`*`',`*`PropertyValue`*`, ...)` returns a delay object, `delay`, with the `Length` on page 4-529 property set to `LEN` and other specified properties set to the specified values.

Properties

`Units`

Delay units as samples or frames

Specify the delay units as one of | `Samples` | `Frames` . The default is `Samples`.

`Length`

Amount of delay

Specify amount of delay to apply to the input signal. The value of this property can be one of the following:

- A scalar non-negative integer by which to delay all channels equally.
- A vector of non-negative integers whose length is equal to the number of input columns (channels).

The default is 1.

`InitialConditionsPerChannel`

Enable different initial conditions per channel

Set this property to `true` to specify different initial conditions per channel. The default value is `false`.

`InitialConditionsPerSample`

Enable different initial conditions per sample

Set this property to `true` to specify different initial conditions per sample. The default value is `false`.

`InitialConditions`

Initial output of delay object

Specify the initial output(s) of the delay object. You can set this property to a scalar, vector, matrix, or a cell array depending on the values of the `InitialConditionsPerChannel` on page 4-529, `InitialConditionsPerSample` on page 4-529, and `Units` on page 4-529 properties. The default is `0`.

If the input is an *M*-by-*N* matrix, the dimensions of this property value must be as follows:

- If the `InitialConditionsPerChannel` and `InitialConditionsPerSample` properties are both `false`, the property value must be a scalar.
- If the `InitialConditionsPerChannel` property is `true` and the `InitialConditionsPerSample` property is `false`, the value must be a vector of length *N*.
- If the `InitialConditionsPerChannel` property is `false`, the `InitialConditionsPerSample` property is `true`, and the `Units` property is `Frames`, the value must be a vector of length equal to the product of *M* and the `Length` property value.
- If the `InitialConditionsPerChannel` property is `false`, the `InitialConditionsPerSample` property is `true`, and the `Units` property is `Samples`, the value must be a vector of length equal to the `Length` property value.
- If the `InitialConditionsPerChannel` and `InitialConditionsPerChannel` properties are both `true`, the property value must be a cell array of size *N*. Each cell of the cell array contains the delay values for one channel.
- If the `Units` property is `Frames`, each cell must be a vector of length equal to the product of *M* and the `Length` property value.
- If the `Units` property is `Samples`, each cell must be a vector of length equal to the `Length` property value.

ResetInputPort

Enable resetting delay states

Specify when the delay object should reset the delay states. By default, the value of this property is `false`, and the object does not reset the delay states. When this property is set to `true`, a reset control input is provided to the `step` method, and the `ResetCondition` on page 4-530 property applies. The object resets the delay states based on the values of the `ResetCondition` property and the reset input to the `step` method.

ResetCondition

Reset trigger setting for delay

Specify the event to reset the delay as one of | `Rising edge` | `Falling edge` | `Either edge` | `Non-zero` |. The delay object resets the delay based on the values of this property and the reset input to the `step` method. This property applies when you set the `ResetInputPort` on page 4-530 property to `true`. The default is `Non-zero`.

Methods

reset	Reset delay states
step	Apply delay to input

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Delay Input

Delay input by five samples using the `dsp.Delay` System object™.

```
delay = dsp.Delay(5);
y = delay((1:10)');
display(y);
```

```
y =

     0
     0
     0
     0
     0
     1
     2
     3
     4
```

```
5
```

The output `y` is delayed by 5 samples.

Algorithms

This object implements the algorithm, inputs, and outputs described on the `Delay` block reference page. The object properties correspond to the block parameters.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

dsp.VariableIntegerDelay | dsp.VariableFractionalDelay. | Delay

Introduced in R2012a

reset

System object: dsp.Delay
Package: dsp

Reset delay states

Syntax

```
reset(delay)
```

Description

`reset(delay)` resets the states of the delay object `delay` to the values specified in the `InitialConditions` property.

After you invoke the `step` method for a nonzero input, the delay object states may change and invoking the `step` method again without invoking the `reset` method may produce different outputs for identical inputs.

Reset the States of the Delay Object

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

Delay input by 5 samples.

```
delay = dsp.Delay(5);
y = delay((1:10)')
```

```
y =

     0
     0
     0
     0
     0
```

```
     1
     2
     3
     4
     5
```

Delay the input without calling reset.

```
y1 = delay((1:10)')
```

```
y1 =

     6
     7
     8
     9
    10
     1
     2
     3
     4
     5
```

Reset states.

```
reset(delay);
y2 = delay((1:10)')
```

```
y2 =

     0
     0
     0
     0
     0
     1
     2
     3
     4
     5
```

step

System object: dsp.Delay
Package: dsp

Apply delay to input

Syntax

```
Y = step(delay,X)
Y = step(delay,X,R)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(delay,X)` adds delay to input `X` to return output `Y`.

`Y = step(delay,X,R)` adds delay to `X` , and selectively resets the delay object's state based on the value of reset input `R` and the value of the `ResetCondition` property. You can use this option only when you set the `ResetInputPort` property to `true`.

Note: `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

dsp.DelayLine System object

Package: dsp

Rebuffer sequence of inputs with one-sample shift

Description

The `DelayLine` object rebuffers a sequence of inputs with one-sample shift.

To rebuffer a sequence of inputs with one-sample shift:

1. Define and set up your delay line object. See "Construction" on page 4-536.
2. Call step to rebuffer the sequence of inputs according to the properties of `dsp.DelayLine`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`dline = dsp.DelayLine` returns a delay line System object, `dline`, that buffers the input samples into a sequence of overlapping or underlapping matrix outputs.

`dline = dsp.DelayLine('`*`PropertyName`*`',`*`PropertyValue`*`,...)` returns a delay line System object, `dline`, with each specified property set to the specified value.

`dline = dsp.DelayLine(DELAYSIZE,INITIAL,'`*`PropertyName`*`',`*`PropertyValue`*`,...)` returns a delay line System object, `dline`, with the `Length` property set to `DELAYSIZE`, `InitialConditions` property set to `INITIAL` and other specified properties set to the specified values.

Properties

`Length`

Number of rows in output matrix

Specify the number of rows in the output matrix as a scalar positive integer. The default is `64`.

`InitialConditions`

Initial delay line output

Set the value of the object's initial output as one of `| scalar | vector | matrix |`.

For vector outputs, the following selections apply for the `InitialConditions` property:

- A vector of the same size
- A scalar value that you want repeated across all elements of the initial output

For matrix outputs, the following selections apply for the `InitialConditions` property:

- A matrix of the same size
- A vector (equal to the length of the number of matrix rows) that repeats across all columns of the initial output
- A scalar that repeats across all elements of the initial output

The default is `0`.

`DirectFeedthrough`

Enable passing input data to output without extra frame delay

When you set this property to `true`, there is no input data delay by an extra frame before it is available at the output buffer. Instead, the input data is available immediately at the output. When you set this property to `false`, there is one frame delay on the output. The default is `false`.

`EnableOutputInputPort`

Enable selective output linearization

The object internally uses a circular buffer, even though the output is linear. To obtain a valid output, the object must linearize the circular buffer. When this property is `true`, the object uses an additional Boolean input to determine if a valid output calculation is needed. If Boolean the input value is `1`, the object's output is linearized and thus valid. If Boolean the input value is `0`, the output is not linearized and is invalid. This allows the object to be more efficient when each step does not require the tapped delay line output. When you set this property to `false`, the output is always linearized and valid. The default is `false`.

`HoldPreviousValue`

Hold previous valid value for invalid output

If you set this property to `true`, the most recent, valid value is held on the output. If you set this property to `false`, the signal on the output is invalid data. This property applies only when you set the `EnableOutputInputPort on page 4-537` property to `true`. The default is `false`.

Methods

reset	Reset internal states of delay line object
step	Delayed version of input

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Delay Line

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

Use a delay line object with a delay line size of 4 samples.

```
delayline = dsp.DelayLine( ...
    'Length', 4, ...
    'DirectFeedthrough', true, ...
    'InitialConditions', -2, ...
    'EnableOutputInputPort', true, ...
    'HoldPreviousValue', true);
en = logical([1 1 0 1 0]);
y = zeros(4,5);
for ii = 1:5
    y(:,ii) = delayline(ii, en(ii));
end
display(y);
```

```
y =

    -2    -2    -2     1     1
    -2    -2    -2     2     2
    -2     1     1     3     3
     1     2     2     4     4
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the `Delay Line` block reference page. The object properties correspond to the block properties, except as noted.

This object processes inputs as separate channels (frames). The corresponding block has a temporary **Treat Mx1 and unoriented sample-based signals as** parameter with a `One channel` option for frame-based behavior and an `M channels` option for sample-based behavior. See the Delay Line block reference page for more information.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

See Also

dsp.Delay

Introduced in R2012a

reset

System object: dsp.DelayLine
Package: dsp

Reset internal states of delay line object

Syntax

```
reset(dline)
```

Description

`reset(dline)` sets the internal delay buffers of the `DelayLine` object `dline` to their initial conditions.

step

System object: dsp.DelayLine
Package: dsp

Delayed version of input

Syntax

```
Y = step(dline,X)
Y = step(dline,X,EN)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(dline,X)` returns the delayed version of input `X`. `Y` is an output matrix with the same number of rows as the delay line size. Each column of `X` is treated as a separate channel.

The System object rebuffers a sequence of *Mi*-by-*N* matrix inputs into a sequence of *Mo*-by-*N* matrix outputs, where *Mo* is the output frame size specified by the `Length` property. Depending on whether *Mo* is greater than, less than, or equal to the input frame size, *Mi*, the output frames can be underlapped or overlapped. Each of the *N* input channels is rebuffered independently:

- When*Mo* > *Mi*, the output frame overlap is the difference between the output and input frame size, *Mo*–*Mi*.
- When *Mo* < *Mi*, the output is underlapped; the object discards the first *Mi*–*Mo* samples of each input frame so that only the last *Mo* samples are buffered into the corresponding output frame.
- When *Mo* = *Mi*, the output data is identical to the input data, but is delayed by the latency of the object.

`Y = step(dline,X,EN)` selectively outputs the delayed version of input `X` depending on the Boolean input `EN`. This occurs only when you set the `EnableOutputInputPort` property to `true`. If `EN` is `false`, use the `HoldPreviousValue` property to specify if the object should hold the previous output value(s).

Note: `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

dsp.Differentiator System object

Package: dsp

Direct form FIR fullband differentiator filter

Description

`dsp.Differentiator` applies a fullband differentiator filter on the input signal to differentiate all its frequency components. This object uses an FIR equiripple filter design to design the differentiator filter. The ideal frequency response of the differentiator is $D(\omega) = j\omega$ for $-\pi \leq \omega \leq \pi$. You can design the filter with minimum order with a specified order. This object supports fixed-point operations.

To filter each channel of your input:

1. Define and set up your differentiator. See "Construction" on page 4-544.
2. Call step to filter each channel of the input signal according to the properties of `dsp.Differentiator`. The input signal can be a real-valued or complex-valued column vector or matrix. If the input signal is a matrix, each column of the matrix is treated as an independent channel. The number of rows in the input signal denotes the channel length. The data type of the input can be double, single, or fixed-point data type. The number of channels cannot change between calls to the `step` method. The data type characteristics (double, single, or fixed-point) and the real-complex characteristics (real or complex valued) must be the same for the input data and output data.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`DF = dsp.Differentiator` returns a differentiator, `DF`, with the default settings. Calling `step` with the default property settings filters the input data with a minimum-order filter that has a passband ripple of 0.1 dB.

`DF = dsp.Differentiator(Name,Value)` sets each property Name to the specified Value. Unspecified properties have default values.

Properties

`DesignForMinimumOrder` — Design minimum order filter

`true` (default) | `false`

Option to design a minimum-order filter, specified as a logical scalar. The filter has 2 degrees of freedom. When you set this property to

- `true` — The object designs the filter with the minimum order that meets the `PassbandRipple` value.
- `false` — The object designs the filter with order that you specify in the `FilterOrder` property.

This property is not tunable.

`FilterOrder` — Order of the filter

31 (default) | odd positive integer

Order of the filter, specified as an odd positive integer. You can specify the filter order only when `'DesignForMinimumOrder'` is set to `false`.

This property is not tunable.

`PassbandRipple` — Maximum passband ripple

0.1 (default) | positive real scalar

Maximum passband ripple in dB, specified as a positive real scalar. You can specify the passband ripple only when `'DesignForMinimumOrder'` is set to `true`.

This property is not tunable.

`ScaleCoefficients` — Scale filter coefficients

false (default) | true

Option to scale the filter coefficients, specified as a logical scalar. When you set this property to `true`, the object scales the filter coefficients to preserve the input dynamic range.

This property is not tunable.

Fixed-Point Properties

`CoefficientsDataType` — Word and fraction lengths of coefficients

`numerictype(1,16)` (default) | `numerictype` object

Word and fraction lengths of coefficients, specified as a signed or unsigned `numerictype` object. The default, `numerictype(1,16)`, corresponds to a signed numeric type object with 16-bit coefficients. To give the best possible precision, the fraction length is computed based on the coefficient values.

This property is not tunable.

The word length of the output is the same as the word length of the input. The object computes the fraction length of the output such that the entire dynamic range of the output can be represented without overflow. For details on how the object computes the fraction length of the output, see "Fixed-Point Precision Rules for Avoiding Overflow in FIR Filters".

`RoundingMethod` — Rounding method for output fixed-point operations

`'Floor'` (default) | `'Ceiling'` | `'Convergent'` | `'Nearest'` | `'Round'` | `'Simplest'` | `'Zero'`

Rounding method for output fixed-point operations, specified as a character vector. For more information on the rounding modes, see "Precision and Range".

This property is not tunable.

Examples

Group Delay Estimation

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

Estimate the group delay of a linear phase FIR filter using a `dsp.TransferFunctionEstimator` object followed by `dsp.PhaseExtractor` and `dsp.Differentiator` objects. The group delay of a linear phase FIR filter is given by $GD = -(d\theta(\omega)/d\omega) = -\frac{N}{2}$, where $\theta(\omega)$ is the phase information of the filter, ω is the frequency vector, and N is the order of the filter.

Set Up the Objects

Create a linear phase FIR lowpass filter. Set the order to 200, the passband frequency to 255 Hz, the passband ripple to 0.1 dB, and the stopband attenuation to 80 dB. Specify a sample rate of 512 Hz.

```
Fs = 512;
LPF = dsp.LowpassFilter('SampleRate',Fs,'PassbandFrequency',255,...
    'DesignForMinimumOrder',false,'FilterOrder',200);
```

To estimate the transfer function of the lowpass filter, create a transfer function estimator. Specify the window to be `Hann`. Set the FFT length to 1024 and the number of spectral averages to 200.

```
TFE = dsp.TransferFunctionEstimator('FrequencyRange','twosided',...
    'SpectralAverages',200,'FFTLengthSource','Property',...
    'FFTLength',1024);
```

To extract the unwrapped phase from the frequency response of the filter, create a phase extractor.

```
PE = dsp.PhaseExtractor;
```

To differentiate the phase θ, create a differentiator filter. This value is used in computing the group delay.

```
DF = dsp.Differentiator;
```

To smoothen the inputm create a variable bandwidth FIR filter.

```
Gain1 = 512/pi;
Gain2 = -1;
VBFilter = dsp.VariableBandwidthFIRFilter('CutoffFrequency',10,...
    'SampleRate',Fs);
```

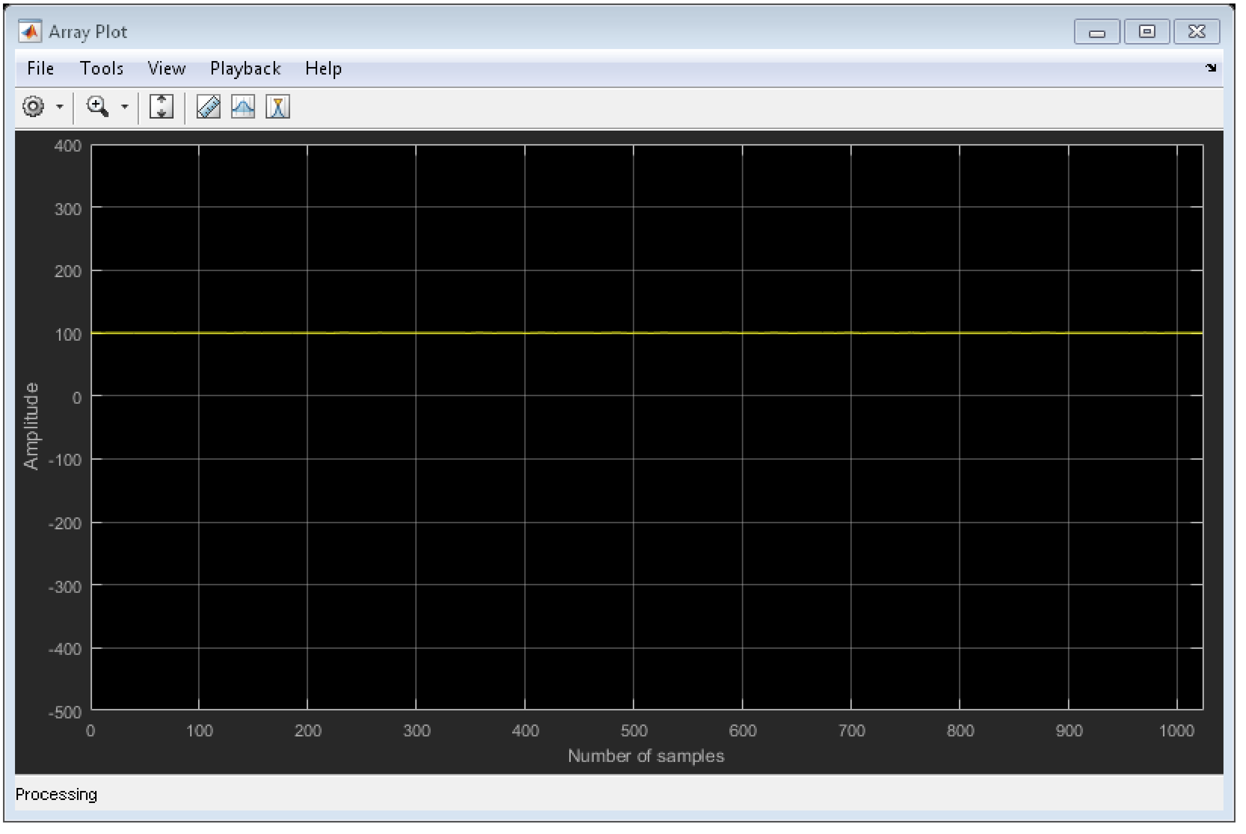
To view the group delay of the filter, create an array plot object.

```
AP = dsp.ArrayPlot('PlotType','Line','YLimits',[-500 400],...
    'YLabel','Amplitude','XLabel','Number of samples');
```

Run the Algorithm

The `for`-loop is the streaming loop that estimates the group delay of the filter. In the loop, the algorithm filters the input signal, estimates the transfer function of the filter, and differentiates the phase of the filter to compute the group delay.

```
Niter = 1000; % Number of iterations
for k = 1:Niter
        x = randn(512,1);  % Input signal = white Gaussian noise
        y = LPF(x);   % Filter noise with Lowpass FIR filter
        H = TFE(x,y); % Compute transfer function estimate
        Phase = PE(H); % Extract the Unwrapped phase
        phaseaftergain1 = Gain1*Phase;
        DiffOut = DF(phaseaftergain1); % Differentiate the phase
        phaseaftergain2 = Gain2 * DiffOut;
        VBFOut = VBFilter(phaseaftergain2); % Smooth the group delay
        AP(VBFOut); % Display the group delay
end
```



As you can see, the group delay of the lowpass filter is 100.

Methods

step	Differentiate input signal with respect to time
getFilter	Get underlying FIR filter
reset	Reset internal states of differentiator

For additional methods, see "Analysis Methods for Filter System Objects" on page 3-2.

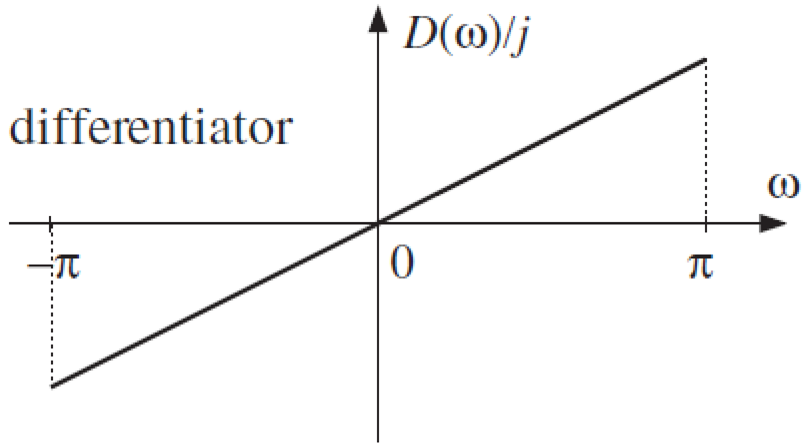
For a complete list of analysis methods supported for the `dsp.Differentiator` object, enter `dsp.Differentiator.helpFilterAnalysis` at the MATLAB command prompt.

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Algorithms

Differentiator Filter

Differentiator computes the derivative of a signal. The frequency response of an ideal differentiator filter is given by $D(\omega) = j\omega$, defined over the Nyquist interval $-\pi \leq \omega \leq \pi$.



The frequency response is antisymmetric and is linearly proportional to the frequency.

`dsp.Differentiator` object acts as a differentiator filter. This object condenses the two-step process into one. For the minimum order design, the object uses generalized Remez FIR filter design algorithm. For the specified order design, the object uses the Parks-McClellan optimal equiripple FIR filter design algorithm. The filter is designed as a linear phase Type-IV FIR filter with a Direct form structure.

The ideal differentiator has an antisymmetric impulse response given by $d(n) = -d(-n)$. Hence $d(0) = 0$. The differentiator must have zero response at zero frequency.

Linear-Phase FIR Differentiator Filter

The impulse response of an antisymmetric linear-phase FIR filter is given by $h(n) = -h(M-1-n)$, where M is the length of the filter. Because the filter is antisymmetric, you can use this type of FIR filter to design the linear-phase FIR differentiators.

Consider the design of linear-phase FIR differentiators based on the Chebyshev approximation criterion.

If M is odd, the real-valued frequency response of the FIR filter, $H_r(\omega)$, has the characteristics that $H_r(0) = 0$ and $H_r(\pi) = 0$. This filter satisfies the condition of zero response at zero frequency. However, it is not fullband because $H_r(\pi) = 0$. This differentiator has a linear response over the limited frequency range $[0\ 2\pi f_p]$, where f_p is the bandwidth of the differentiator. The absolute error between the desired response and the Chebyshev approximation increases as ω increases from 0 to $2\pi f_p$.

If M is even, the real-valued frequency response of the FIR filter, $H_r(\omega)$, has the characteristics that $H_r(0) = 0$ and $H_r(\pi) \neq 0$. This filter satisfies the condition of zero response at zero frequency. It is fullband and this design results in a significantly smaller approximation error than comparable odd-length differentiators. Hence, even-length (odd order) differentiators are preferred in practical systems.

Introduced in R2016a

step

System object: dsp.Differentiator
Package: dsp

Differentiate input signal with respect to time

Syntax

`Y = step(DF,X)`

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(DF,X)` filters the real or complex input signal, `X`, using the differentiator filter, `DF`. `Y` is a differentiated version of `X`. The input `X` must be a column vector or matrix. If `X` is a matrix, each column is treated as an independent channel. `X` can be a floating point or a fixed-point input.

Input Arguments

DF — Differentiator filter

`dsp.Differentiator` System object

Differentiator filter, specified as a `dsp.Differentiator` System object.

X — Input signal

vector | matrix

Input signal, specified as a vector or matrix with floating point or fixed-point precision. The row length of `X` is the frame size, that is, the channel length. Each column of `X` is treated as a separate channel. The column length of `X` is the number of channels.

Output Arguments

Y — Differentiated signal

vector | matrix

Differentiated signal, returned as a vector or matrix of the same size, data type, and complexity as the input signal, X.

Examples

Convert FM Signal to AM Signal

Create an FM wave on a 100 Hz carrier signal sampled at 1.5 kHz.

```
Fc = 1e2;   % Carrier
Fs = 1.5e3; % Sample rate
sinewave = dsp.SineWave('Frequency',10,...
                            'SamplesPerFrame',1e3,...
                            'SampleRate',Fs);
```

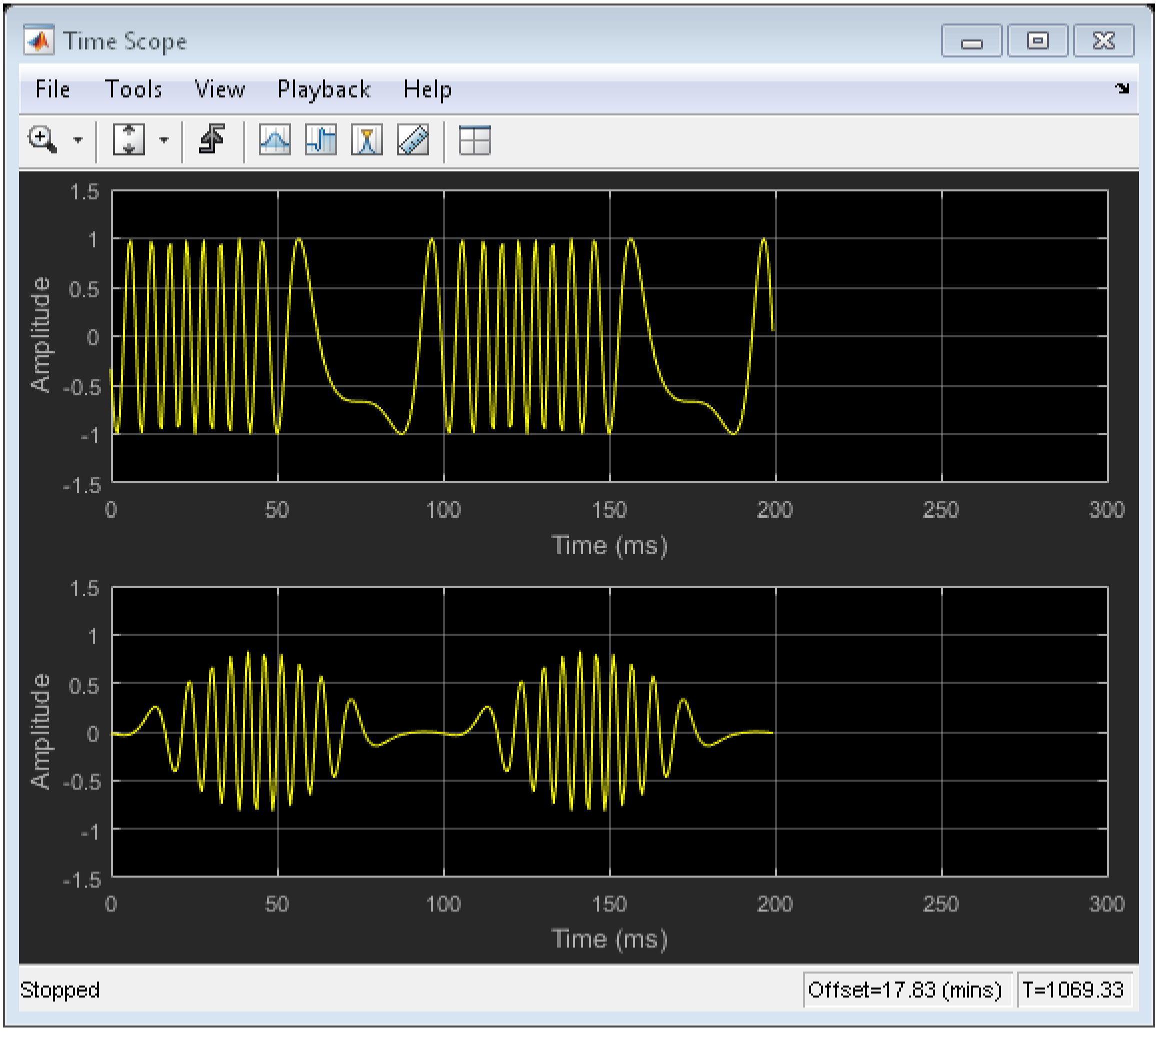
Convert the FM signal to an AM signal.

```
ts = dsp.TimeScope(2,...
                      'TimeSpan',0.3,...
                      'BufferLength',10*Fs,...
                      'SampleRate',Fs,...
                      'ShowGrid',true,...
                      'YLimits',[-1.5 1.5],...
                      'LayoutDimensions',[2 1]);

df = dsp.Differentiator;

tic
while toc<2.2
    x = step(sinewave);
    fm_y = modulate(x,Fc,Fs,'fm');
    am_y = step(df,fm_y);
    step(ts,fm_y,am_y);
end

release(df);
release(ts);
```



Introduced in R2016a

getFilter

System object: dsp.Differentiator
Package: dsp

Get underlying FIR filter

Syntax

```
filter = getFilter(DF)
```

Description

`filter = getFilter(DF)` returns the underlying FIR filter, `filter`, used to implement the differentiator, `DF`.

Input Arguments

DF — Differentiator filter

`dsp.Differentiator` System object

Differentiator filter, specified as a `dsp.Differentiator` System object.

Examples

Get the Underlying FIR Filter of the Differentiator

Create a `dsp.Differentiator` System object with default properties.

```
DF = dsp.Differentiator;
```

Use `getFilter` to get the underlying FIR filter, `filter`, which implements the differentiator, `DF`.

```
filter = getFilter(DF)
```

```
filter =

  dsp.FIRFilter with properties:

            Structure: 'Direct form'
      NumeratorSource: 'Property'
            Numerator: [1×60 double]
    InitialConditions: 0

  Use get to show all properties
```

Introduced in R2016a

reset

System object: dsp.Differentiator
Package: dsp

Reset internal states of differentiator

Syntax

```
reset(DF)
```

Description

`reset(DF)` resets the filter states of the differentiator, `DF`, to their initial values. The initial filter state values correspond to the initial conditions for the difference equation defining the filter. After the `step` method applies the differentiator to nonzero input data, the filter might have nonzero states. If you call `step` again without first calling `reset`, the object might produce different outputs for an identical input.

Input Arguments

DF — Differentiator filter

`dsp.Differentiator` System object

Differentiator filter, specified as a `dsp.Differentiator` System object.

Examples

Reset Differentiator

Create a differentiator with default properties.

```
DF = dsp.Differentiator;
```

Create a two-channel random signal. Call the `step` method twice on the signal.

```
x = randn(10,2);

y1 = step(DF,x);
y2 = step(DF,x);

no = all(y2==y1)
```

```
no =

  1×2 logical array

   0   0
```

The output is different because the internal states of `DF` have changed. Use `reset` to reset the differentiator. Call `step` again, and verify that the output is unchanged.

```
reset(DF)

y3 = step(DF,x);

yes = all(y3==y1)
```

```
yes =

  1×2 logical array

   1   1
```

Introduced in R2016a

dsp.DigitalDownConverter System object

Package: dsp

Translate digital signal from Intermediate Frequency (IF) band to baseband and decimate it

Description

The `DigitalDownConverter` object translates digital signal from Intermediate Frequency (IF) band to baseband, and decimates it.

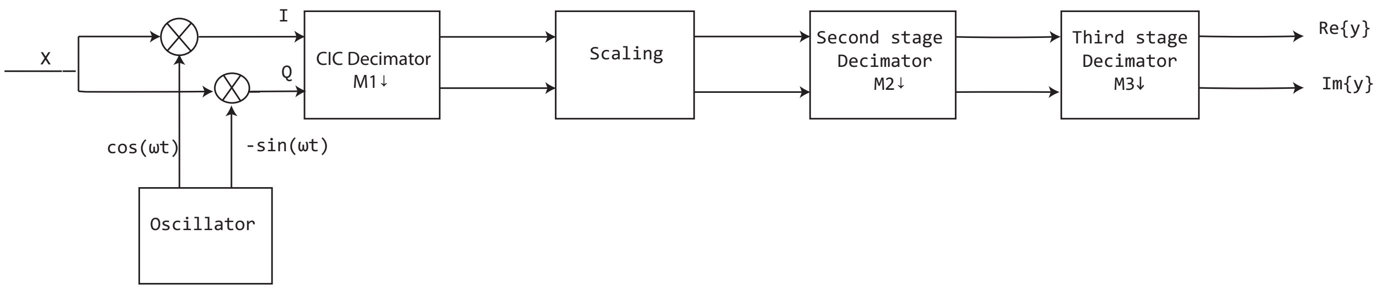
To digitally downconvert the input signal:

1. Define and set up your digital down converter. See “Construction” on page 4-559.
2. Call step to downconvert the input according to the properties of `dsp.DigitalDownConverter`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

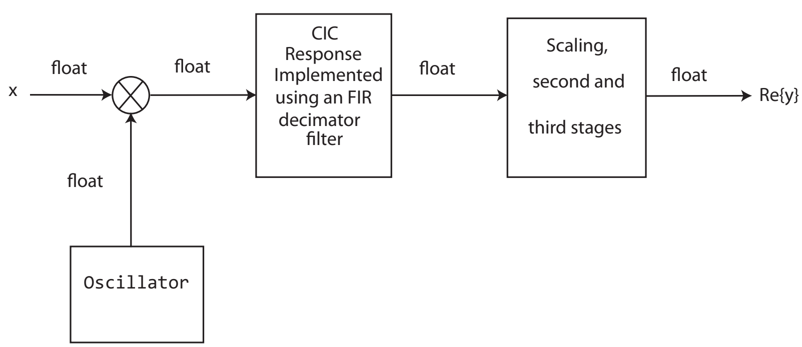
Construction

`dwnConv = dsp.DigitalDownConverter` returns a digital down-converter (DDC) System object, `dwnConv`. The object downconverts the input signal by multiplying it with a complex exponential with center frequency equal to the value in the `CenterFrequency` property. The object downsamples the frequency down-converted signal using a cascade of three decimation filters. In this case, the filter cascade consists of a CIC decimator, a CIC compensator, and a third FIR decimation stage. The following block diagram shows the architecture of the digital down converter.

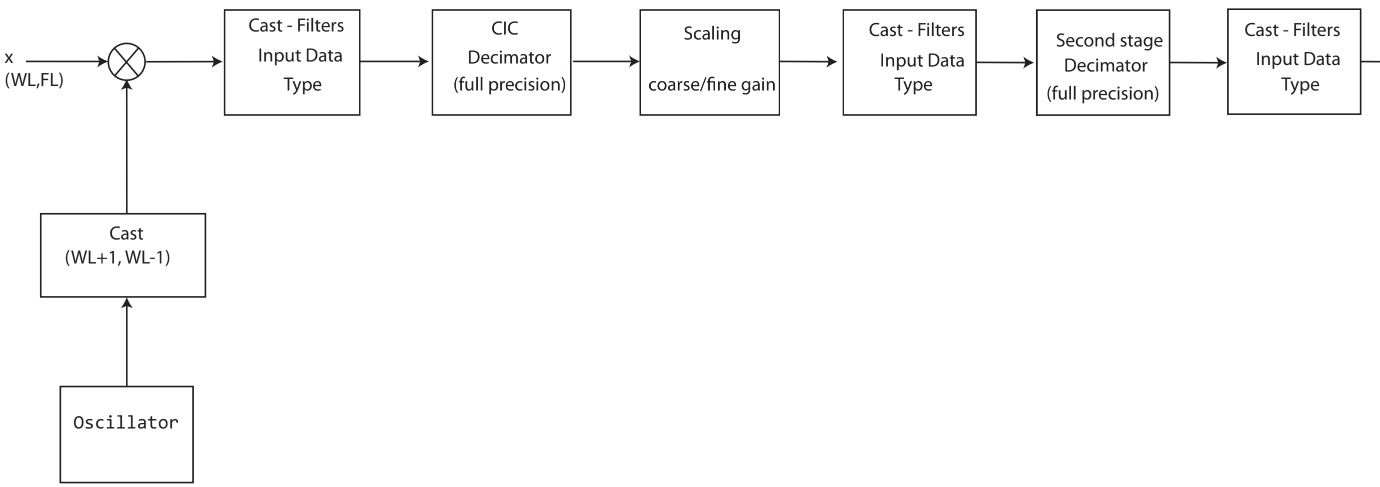


The scaling section normalizes the CIC gain and the oscillator power. It may also contain a correction factor to achieve the desired ripple specification. When you set the **Oscillator** property to `InputPort`, the normalization factor does not include the oscillator power factor. Depending on the setting of the **DecimationFactor** property, you may be able to bypass the third filter stage. When the input data type is double or single, the object implements an *N*-section CIC decimation filter as an FIR filter with a response that corresponds to a cascade of *N* boxcar filters. A true CIC filter with actual comb and integrator sections is implemented when the input data is of a fixed-point type. The CIC filter is emulated with an FIR filter so that you can run simulations with floating-point data.

The following block diagram represents the DDC arithmetic with single or double-precision, floating-point inputs.

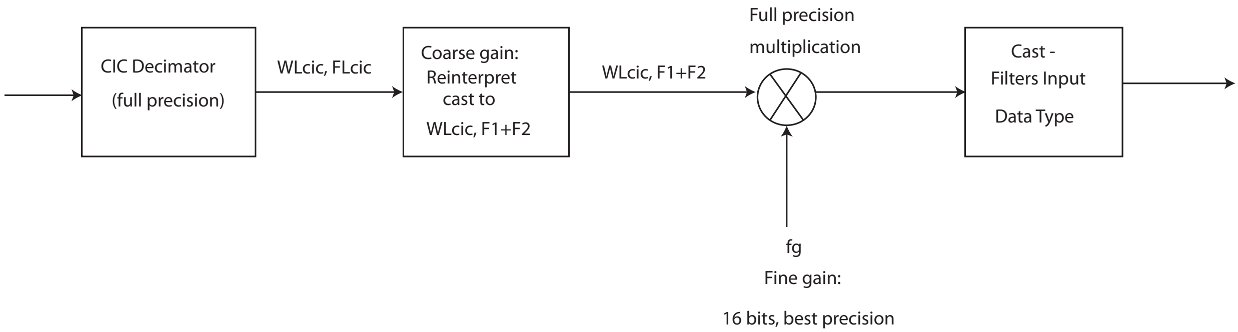


The following block diagram represents the DDC arithmetic with signed fixed-point inputs.



- `WL` is the word length of the input, and `FL` is the fraction length of the input.
- The input of each filter is cast to the data type specified in the **FiltersInputDataType** and **CustomFiltersInputDataType** properties.
- The oscillator output is cast to a word length equal to the input word length plus one. The fraction length is equal to the input word length minus one.
- The scaling at the output of the CIC decimator consists of coarse- and fine-gain adjustments. The coarse gain is achieved using the `reinterpretcast` function on the CIC decimator output. The fine gain is achieved using full-precision multiplication.

The following figure depicts the coarse- and fine-gain operations.



If the normalization gain is G (where `0<G≦1`), then:

- `WLcic` is the word length of the CIC decimator output and `FLcic` is the fraction length of the CIC decimator output
- `F1 = abs(nextpow2(G))`, indicating the part of G achieved using bit shifts (coarse gain)
- `F2` = fraction length specified by the **FiltersInputDataType** and **CustomFiltersInputDataType** properties
- `fg = fi((2^F1)*G, true, 16)`, indicating that the remaining gain cannot be achieved with a bit shift (fine gain)

`dwnConv = dsp.DigitalDownConverter(Name,Value)` returns a DDC object, `dwnConv`, with the specified property `Name` set to the specified `Value`. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

Properties

`SampleRate`

Sample rate of input signal

Set this property to a positive scalar value, greater than or equal to twice the value of the `CenterFrequency` property. The default is `30` MHz.

DecimationFactor

Decimation factor

Set this property to a positive integer scalar, or to a 1-by-2 or 1-by-3 vector of positive integers.

When you set this property to a scalar, the object automatically chooses the decimation factors for each of the three filtering stages.

When you set this property to a 1-by-2 vector, the object bypasses the third filter stage and sets the decimation factor of the first and second filtering stages to the values in the first and second vector elements respectively. Both elements of the `DecimationFactor` vector must be greater than one.

When you set this property to a 1-by-3 vector, the *i* th element of the vector specifies the decimation factor for the *i*th filtering stage. The first and second elements of the `DecimationFactor` vector must be greater than one, and the third element must be 1 or 2. The default is 100.

MinimumOrderDesign

Minimum order filter design

When you set this property to `true`, the object designs filters with the minimum order that meets the passband ripple, stopband attenuation, passband frequency, and stopband frequency specifications that you set using the `PassbandRipple`, `StopbandAttenuation`, `Bandwidth`, `StopbandFrequencySource`, and `StopbandFrequency` properties.

When you set this property to `false`, the object designs filters with orders that you specify in the `NumCICSections`, `SecondFilterOrder`, and `ThirdFilterOrder` properties. The filter designs meet the passband and stopband frequency specifications that you set using the `Bandwidth`, `StopbandFrequencySource`, and `StopbandFrequency` properties. The default is `true`.

NumCICSections

Number of sections of CIC decimator

Set this property to a positive integer scalar. This property applies when you set the `MinimumOrderDesign` property to `false`. The default is `3`.

SecondFilterOrder

Order of CIC compensation filter stage

Set this property to a positive integer scalar. This property applies when you set the MinimumOrderDesign property to false. The default is 12.

ThirdFilterOrder

Order of third filter stage

Set this property to an even positive integer scalar. When you set the DecimationFactor property to a 1-by-2 vector, the object ignores the ThirdFilterOrder property because the third filter stage is bypassed. This property applies when you set the MinimumOrderDesign property to false. The default is 10.

Bandwidth

Two-sided bandwidth of input signal in Hz

Set this property to a positive integer scalar. The object sets the passband frequency of the cascade of filters to one-half of the value that you specify in the Bandwidth property. Set the value of this property to less than SampleRate/DecimationFactor. The default is 200 kHz.

StopbandFrequencySource

Source of stopband frequency

Specify the source of the stopband frequency as one of Auto | Property. The default is Auto. When you set this property to Auto, the object places the cutoff frequency of the cascade filter response at approximately F_c = SampleRate/M/2 Hz, where M is the total decimation factor that you specify in the DecimationFactor property. The object computes the stopband frequency as $F_{stop} = F_c + TW/2$. TW is the transition bandwidth of the cascade response computed as $2\times(F_c–F_p)$, and the passband frequency, F_p, equals Bandwidth/2.

StopbandFrequency

Stopband frequency in Hz

Set this property to a double-precision positive scalar. This property applies when you set the StopbandFrequencySource property to Property. The default is 150 kHz.

PassbandRipple

Passband ripple of cascade response in dB.

Set this property to a double-precision positive scalar. When you set the `MinimumOrderDesign` property to `true`, the object designs the filters so that the cascade response meets the passband ripple that you specify in the `PassbandRipple` property. This property applies when you set the `MinimumOrderDesign` property to `true`. The default is `0.1` dB.

StopbandAttenuation

Stopband attenuation of cascade response in dB

Set this property to a double-precision positive scalar. When you set the `MinimumOrderDesign` property to `true`, the object designs the filters so that the cascade response meets the stopband attenuation that you specify in the `StopbandAttenuation` property. This property applies when you set the `MinimumOrderDesign` property to `true`. The default is `60` dB.

Oscillator

Type of oscillator

Specify the oscillator as one of `Sine wave` | `NCO` | `Input port` | `None`. The default is `Sine wave`. When you set this property to `Sine wave`, the object frequency down converts the input signal using a complex exponential obtained from samples of a sinusoidal trigonometric function. When you set this property to `NCO`, the object performs frequency down conversion with a complex exponential obtained using a numerically controlled oscillator (NCO). When you set this property to `Input port`, the object performs frequency down conversion using the complex signal that you set as an input to the step method. When you set this property to `None`, the mixer stage in the object is not present and the object acts as three stage cascaded decimator.

CenterFrequency

Center frequency of input signal in Hz

Specify this property as a double-precision positive scalar that is less than or equal to half the value of the `SampleRate` property. The object down converts the input signal from the passband center frequency you specify in the `CenterFrequency` property, to `0`

Hz. This property applies when you set the `Oscillator` property to `Sine wave` or `NCO`. The default is `14` MHz.

`NumAccumulatorBits`

Number of NCO accumulator bits

Specify this property as an integer scalar in the range `[1 128]`. This property applies when you set the `Oscillator` property to `NCO`. The default is `16`.

`NumQuantizedAccumulatorBits`

Number of NCO quantized accumulator bits

Specify this property as an integer scalar in the range `[1 128]`. The value you specify in this property must be less than the value you specify in the `NumAccumulatorBits` property. This property applies when you set the Oscillator property to `NCO`. The default is `12`.

`Dither`

Dither control for NCO

When you set this property to `true`, a number of dither bits specified in the `NumDitherBits` property will be used to apply dither to the NCO signal. This property applies when you set the `Oscillator` property to `NCO`. The default is `true`.

`NumDitherBits`

Number of NCO dither bits

Specify this property as an integer scalar smaller than the number of accumulator bits that you specify in the `NumAccumulatorBits` property. This property applies when you set the `Oscillator` property to `NCO` and the Dither property to `true`. The default is `4`.

Fixed-Point Properties

`FiltersInputDataType`

Data type of input of each filter stage

Specify the data type at the input of the first, second, and third (if it has not been bypassed) filter stages as one of `Same as input | Custom`. The default is `Same as` input. The object casts the data at the input of each filter stage according to the value you set in this property.

CustomFiltersInputDataType

Fixed-point data type of input of each filter stage

Specify the filters input fixed-point type as a scaled numerictype object with a Signedness of Auto. This property applies when you set the FiltersInputDataType property to Custom. The default is numerictype([],16,15).

OutputDataType

Data type of output

Specify the data type of output as Same as input | Custom. The default is Same as input.

CustomOutputDataType

Fixed-point data type of output

Specify the output fixed-point type as a scaled numerictype object with a Signedness of Auto. This property applies when you set the OutputDataType property to Custom. The default is numerictype([],16,15).

Methods

fvtool	Visualize response of filter cascade
getDecimationFactors	Get decimation factors of each filter stage
getFilters	Get handles to decimation filter objects
getFilterOrders	Get orders of decimation filters
groupDelay	Group delay of filter cascade
step	Digitally down convert input signal
visualizeFilterStages	Display response of filter stages

Common to All System Objects	
clone	Create System object with same property values

Common to All System Objects	
getNumInpu	Expected number of inputs to a System object
getNumOutp	Expected number of outputs of a System object
isLocked	Check locked states of a System object (logical)
release	Allow System object property value changes

Examples

Upconvert and Downconvert a Sine Wave Signal

Create a digital up converter object that up samples a 1 KHz sinusoidal signal by a factor of 20 and up converts it to 50 KHz. Create a digital down converter object that down converts the signal to 0 Hz and down samples it by a factor of 20.

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

Create a sine wave generator to obtain the 1 KHz sinusoidal signal with a sample rate of 6 KHz.

```
Fs = 6e3; % Sample rate
sine = dsp.SineWave('Frequency',1000,'SampleRate',...
Fs,'SamplesPerFrame',1024);
x = sine(); % generate signal
```

Create a `DigitalUpConverter` object. Use minimum order filter designs and set passband ripple to 0.2 dB and the stopband attenuation to 55 dB. Set the double sided signal bandwidth to 2 KHz.

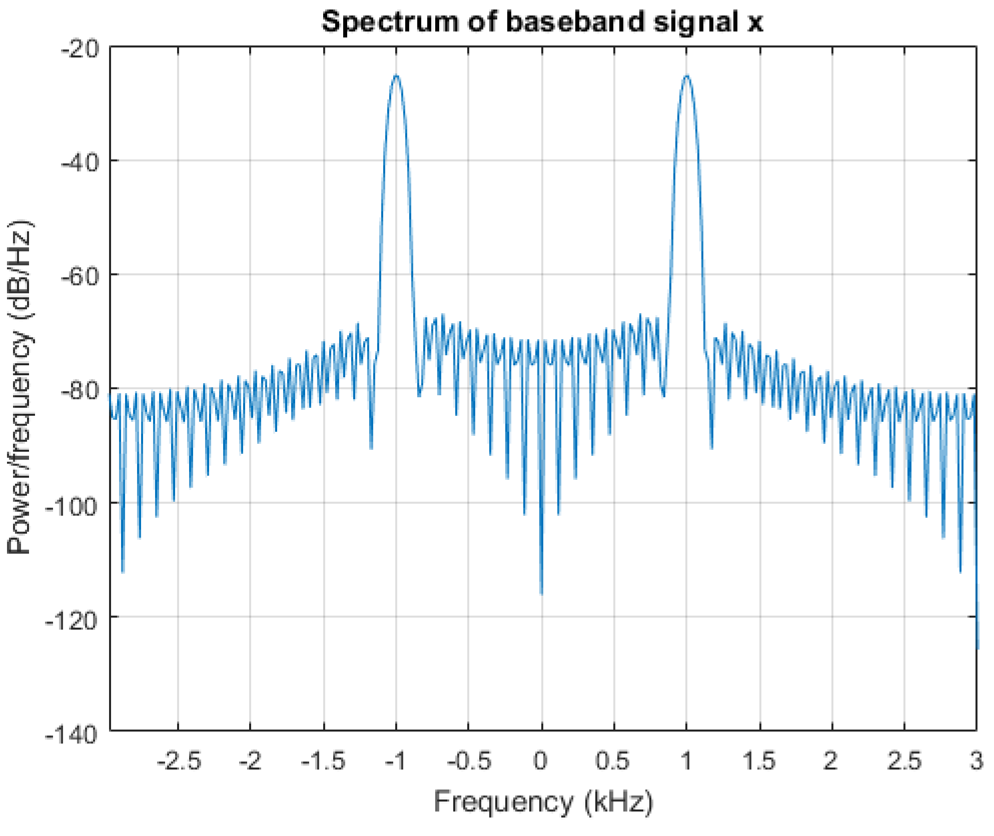
```
upConv = dsp.DigitalUpConverter(...
 'InterpolationFactor', 20,...
 'SampleRate', Fs,...
 'Bandwidth', 2e3,...
 'StopbandAttenuation', 55,...
 'PassbandRipple',0.2,...
 'CenterFrequency',50e3);
```

Create a `DigitalDownConverter` object. Use minimum order filter designs and set the passband ripple to 0.2 dB and the stopband attenuation to 55 dB.

```
dwnConv = dsp.DigitalDownConverter(...
  'DecimationFactor',20,...
  'SampleRate', Fs*20,...
  'Bandwidth', 3e3,...
  'StopbandAttenuation', 55,...
  'PassbandRipple',0.2,...
  'CenterFrequency',50e3);
```

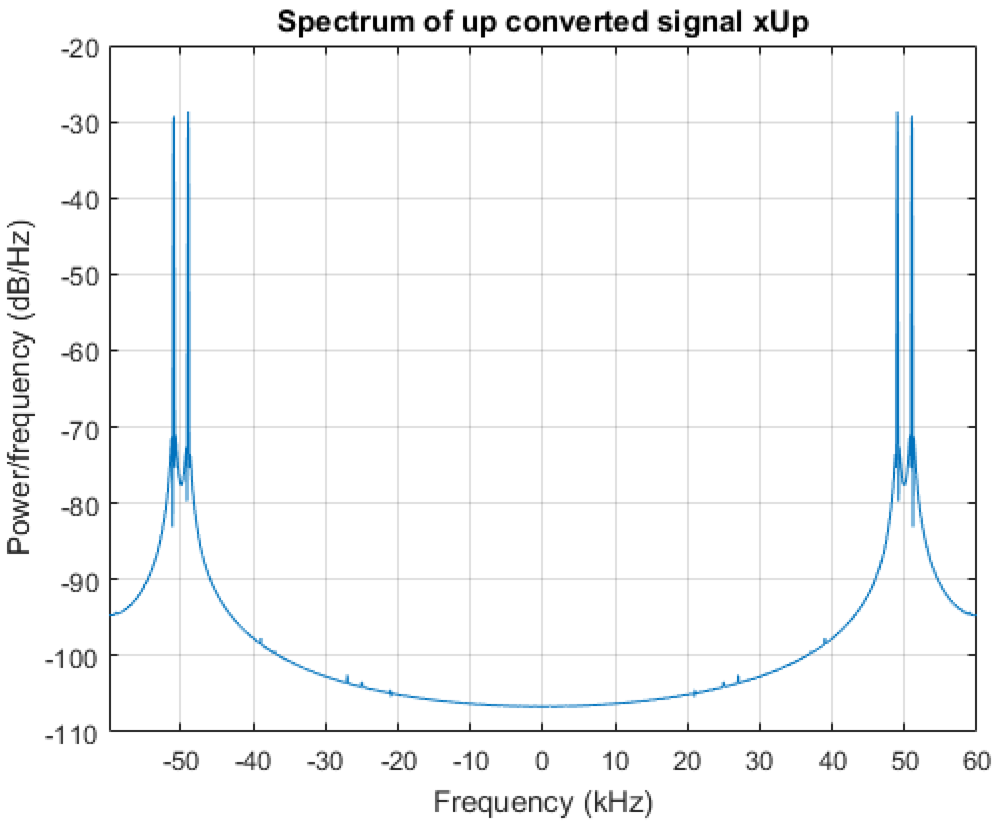
Create a spectrum estimator to visualize the signal spectrum before up converting, after up converting, and after down converting.

```
window = hamming(floor(length(x)/10));
figure; pwelch(x,window,[],[],Fs,'centered')
title('Spectrum of baseband signal x')
```



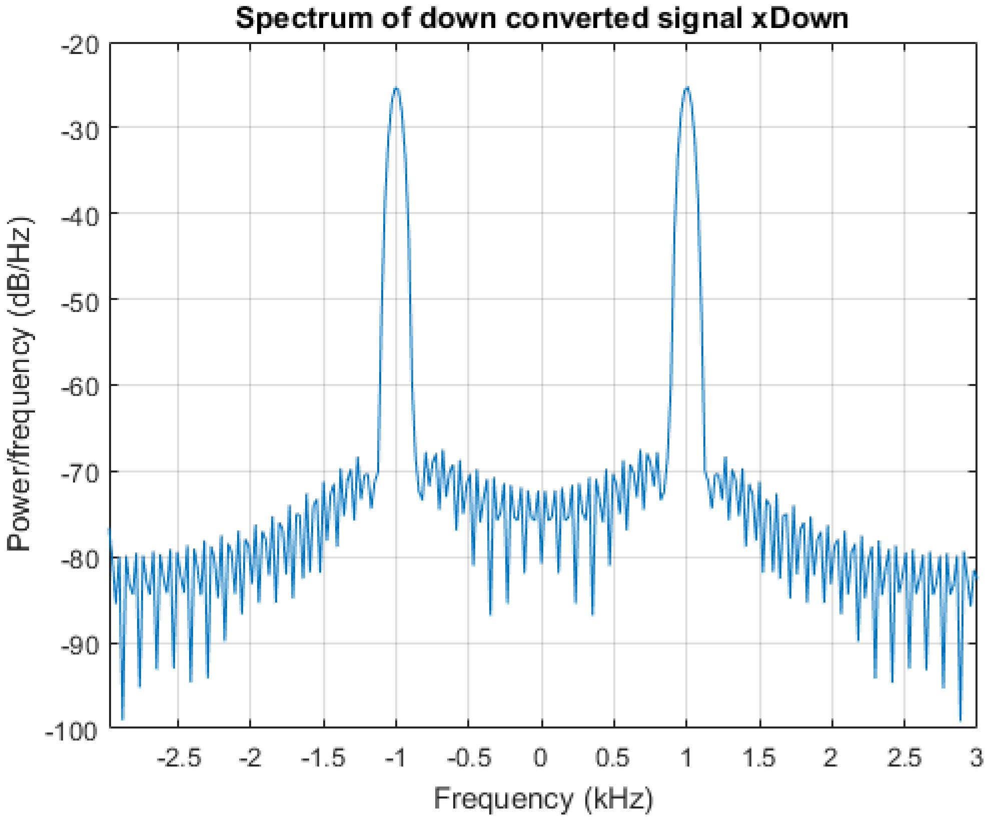
Up convert the signal and visualize the spectrum

```
xUp = upConv(x); % up convert
window = hamming(floor(length(xUp)/10));
figure; pwelch(xUp,window,[],[],20*Fs,'centered');
title('Spectrum of up converted signal xUp')
```



Down convert the signal and visualize the spectrum

```
xDown = dwnConv(xUp); % down convert
window = hamming(floor(length(xDown)/10));
figure; pwelch(xDown,window,[],[],Fs,'centered')
title('Spectrum of down converted signal xDown')
```



Visualize the response of the decimation filters

```
visualizeFilterStages(dwnConv)
```

fvtool

System object: dsp.DigitalDownConverter
Package: dsp

Visualize response of filter cascade

Syntax

```
fvtool(dwnConv)
fvtool(dwnConv,..,'Arithmetic',ARITH,...)
fvtool(dwnConv,..., PROP1, VALUE1,PROP2,VALUE2,...)
```

Description

`fvtool(dwnConv)` plots the magnitude response of the cascade of filters. By default, the object plots the cascade response up to the second CIC null frequency (or to the first when only one CIC null exists). When you set the `FilterSpecification` property to `Design parameters` the method plots a mask based on the filter specifications.

`fvtool(dwnConv,..,'Arithmetic',ARITH,...)` specifies the arithmetic of the filter cascade. You set input `ARITH` to `double`, `single`, or `fixed-point`. When object `dwnConv` is in an unlocked state you must specify the arithmetic. When object `dwnConv` is in a locked state the arithmetic input is ignored.

`fvtool(dwnConv,..., PROP1, VALUE1,PROP2,VALUE2,...)` launches FVTool and sets the specified FVTool properties to the specified values.

getDecimationFactors

System object: dsp.DigitalDownConverter
Package: dsp

Get decimation factors of each filter stage

Syntax

`M = getDecimationFactors(dwnConv)`

Description

`M = getDecimationFactors(dwnConv)`) returns a vector, `M`, with the decimation factors of each filter stage. If the third filter stage is bypassed, then `M` is a 1-by-2 vector containing the decimation factors of the first and second filter stages in the first and second elements respectively. If the third filter stage is not bypassed then `M` is a 1-by-3 vector containing the decimation factors of the first, second and third filter stages.

getFilters

System object: dsp.DigitalDownConverter
Package: dsp

Get handles to decimation filter objects

Syntax

```
S = getFilters(dwnConv)
getFilters(dwnConv,'Arithmetic',ARITH)
```

Description

`S = getFilters(dwnConv)` returns a structure, `S`, with copies of the filter System objects and the CIC normalization factor that form the decimation filter cascade. The `ThirdFilterStage` structure field is empty if the third filter stage has been bypassed. The CIC normalization factor equals the inverse of the CIC filter gain. In some cases, this gain includes a correction factor to ensure that the cascade response meets the ripple specifications.

`getFilters(dwnConv,'Arithmetic',ARITH)` specifies the arithmetic of the filter stages. You can set `ARITH` to `double`, `single`, or `fixed-point`. When object `dwnConv` is in an unlocked state, you must specify the arithmetic input. When object `dwnConv` is in a locked state, the arithmetic input is ignored.

When `dwnConv` is in an unlocked state, and you specify the arithmetic as `fixed-point`, the `getFilters` method returns filter System objects. The custom coefficient data type properties of these System objects are set to the values that the `dsp.DigitalDownConverter` System object uses to process data when you call the `step` method. All other fixed-point properties are set to their default values.

When `dwnConv` is in a locked state, and the input to the step method is of a fixed-point data type, the `getFilters` method returns filter System objects. All fixed-point properties of these System objects are set to the exact values that the `dsp.DigitalDownConverter` System object uses to process the data.

getFilterOrders

System object: dsp.DigitalDownConverter
Package: dsp

Get orders of decimation filters

Syntax

```
S = getFilterOrders(dwnConv)
```

Description

`S = getFilterOrders(dwnConv)` returns a structure, `S`, that contains the orders of the interpolation filter stages. The `ThirdFilterOrder` structure field will be empty if the third filter stage has been bypassed.

groupDelay

System object: dsp.DigitalDownConverter
Package: dsp

Group delay of filter cascade

Syntax

```
D = groupDelay(dwnConv,N)
[D,F] = groupDelay(dwnConv,N)
```

Description

`D = groupDelay(dwnConv,N)` returns a vector of group delays, `D`, evaluated at `N` frequency points equally spaced around the upper half of the unit circle. If you don't specify `N`, it defaults to `8192`.

`[D,F] = groupDelay(dwnConv,N)` returns a vector of frequencies, `F`, at which the group delay has been computed.

step

System object: dsp.DigitalDownConverter
Package: dsp

Digitally down convert input signal

Syntax

```
Y = step(dwnConv,X)
Y = step(dwnConv,X,Z)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(dwnConv,X)` takes a real or complex input column vector `X` and outputs a frequency down converted and down sampled signal `Y`. The length of input `X` must be a multiple of the decimation factor. `X` can be of data type double, single, signed integer, or signed fixed point (fi objects). The length of Y is equal to the length of `X` divided by the `DecimationFactor`. When the data type of `X` is double or single precision, the data type of `Y` is the same as that of `X`. When the data type of `X` is of a fixed point type, the data type of `Y` is defined by the `OutputDataType` on page 4-605 property.

`Y = step(dwnConv,X,Z)` uses the complex input, `Z`, as the oscillator signal used to frequency down convert input `X`, when you set the `Oscillator` on page 4-603 property to `Input port`. The length of `Z` must be equal to the length of `X`. `Z` can be of data type double, single, signed integer, or signed fixed point (fi objects).

visualizeFilterStages

System object: dsp.DigitalDownConverter
Package: dsp

Display response of filter stages

Syntax

```
visualizeFilterStages(dwnConv)
visualizeFilterStages(dwnConv,'Arithmetic',ARITH)
fvt = visualizeFilterStages(dwnConv)
```

Description

`visualizeFilterStages(dwnConv)` plots the magnitude response of the filter stages and of the cascade response. When you set the `FilterSpecification` property to `Design parameters` the method plots a mask based on the filter specifications. By default, the object plots the response of the filters up to the second CIC null frequency (or to the first when only one CIC null exists).

`visualizeFilterStages(dwnConv,'Arithmetic',ARITH)` specifies the arithmetic of the filter stages. You set input `ARITH` to `double`, `single`, or `fixed-point`. When object `dwnConv` is in an unlocked state you must specify the arithmetic. When object `dwnConv` is in a locked state the arithmetic input is ignored.

`fvt = visualizeFilterStages(dwnConv)` returns the handle to the FVTool object.

dsp.DigitalFilter System object

Package: dsp

Static or time-varying digital filter

Description

Note: `dsp.DigitalFilter` has been removed. For FIR filter structures, use dsp.FIRFilter. For Biquad (SOS) structures, use dsp.BiquadFilter. For non-SOS IIR filter structures, use dsp.IIRFilter. For All pole structures, use dsp.AllpoleFilter. For more details, see “Functionality being removed or replaced for blocks and System objects”.

The `DigitalFilter` object filters each channel of the input using static or time-varying digital filter implementations.

To filter each channel of the input using digital filter implementation:

1. Define and set up your IIR digital filter. See “Construction” on page 4-581.
2. Call step to filter each channel according to the properties of `dsp.DigitalFilter`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = dsp.DigitalFilter` returns a default IIR digital filter object, `H`, which independently filters each channel of the input over successive calls to the `step` method, using a specified digital filter implementation. The default numerator coefficients are `[1 2]` and denominator coefficients are `[1 0.1]`.

`H = dsp.DigitalFilter('`*`PropertyName`*`',`*`PropertyValue`*`, ...)` returns a digital filter object, `H`, with each property set to the specified value.

Properties

TransferFunction

Type of filter transfer function

Specify the type of digital filter transfer function as one of | IIR (poles & zeros) | IIR (all poles) | FIR (all zeros) |. The default is IIR (poles & zeros).

Structure

Filter structure

Specify the filter structure.
When you set the TransferFunction on page 4-582 property to FIR (all zeros), you can specify the filter structure as one of | Direct form | Direct form symmetric | Direct form antisymmetric | Direct form transposed | Lattice MA |. The default is Direct form.
When you set the TransferFunction property to IIR (all poles), you can specify the filter structure as Direct form, Direct form transposed, or Lattice AR. The default is Direct form.
When you set the TransferFunction to IIR (poles & zeros), you can specify the filter structure as Direct form I, Direct form I transposed, Direct form II, Direct form II transposed, Biquad direct form I (SOS), Biquad direct form I transposed (SOS), Biquad direct form II (SOS), or Biquad direct form II transposed (SOS). The biquad filter structure does not apply when you set the CoefficientsSource on page 4-582 property to Input port. The default is Direct form II transposed.

CoefficientsSource

Source of filter coefficients

Specify the source of the filter coefficients as one of | Property | Input port |. The default is Property. When you specify Input port, the digital filter object updates the time-varying filter once every frame.

Numerator

Numerator coefficients

Specify the filter numerator coefficients as a real or complex numeric vector. This property applies when you set the TransferFunction on page 4-582 property to FIR (all zeros), the CoefficientsSource on page 4-582 property to Property, and the Structure on page 4-582 property is not set to Lattice MA. This property also applies when you set the TransferFunction property to IIR (poles & zeros), the CoefficientsSource on page 4-582 to Property, and the TransferFunction property to Direct form, Direct form symmetric, Direct form antisymmetric, or Direct form transposed. The default is [1 2]. This property is tunable.

Denominator

Denominator coefficients

Specify the filter denominator coefficients as a real or complex numeric vector. This property applies when you set the TransferFunction on page 4-582 property to IIR (all poles), the CoefficientsSource on page 4-582 property to Property and the Structure on page 4-582 property is not set to Lattice AR. This property also applies when you set the TransferFunction on page 4-582 property to IIR (poles & zeros), the CoefficientsSource on page 4-582 to Property, and the TransferFunction on page 4-582 property to Direct form, Direct form symmetric, Direct form antisymmetric, or Direct form transposed. When the TransferFunction on page 4-582 property is IIR (poles & zeros), the numerator and denominator must have the same complexity. The default is [1 0.1]. This property is tunable.

ReflectionCoefficients

Reflection coefficients of lattice filter structure

Specify the reflection coefficients of a lattice filter as a real or complex numeric vector. This property applies when you set the TransferFunction on page 4-582 property to FIR (all zeros), the Structure on page 4-582 property to Lattice MA, and the CoefficientsSource on page 4-582 property to Property. This property also applies when you set the TransferFunction on page 4-582 property to IIR (all poles), the Structure property to Lattice AR, and the CoefficientsSource property to Property. The default is [0.2 0.4]. This property is tunable.

SOSMatrix

SOS matrix of biquad filter structure

Specify the second-order section (SOS) matrix of a biquad filter as an M-by-6 matrix, where M is the number of sections in the filter. Each row of the SOS matrix contains the numerator and denominator coefficients of the corresponding filter section. The first three elements of each row are the numerator coefficients and the last three elements are the denominator coefficients. You can use real or complex coefficients. This property applies when you set the `TransferFunction` on page 4-582 property to `IIR (poles and zeros)`, the `CoefficientsSource` on page 4-582 property to `Property`, and the `Structure` on page 4-582 property to `Biquad direct form I (SOS)`, `Biquad direct form I transposed (SOS)`, `Biquad direct form II (SOS)`, or `Biquad direct form II transposed (SOS)`. The default is `[1 0.3 0.4 1 0.1 0.2]`. This property is tunable.

ScaleValues

Scale values of biquad filter structure

Specify the scale values to apply before and after each section of a biquad filter. `ScaleValues` must be a scalar or a vector of length M+1, where$M$ is the number of sections. If you specify a scalar value, that value is used as the gain value before the first section of the second-order filter and the rest of the gain values are set to 1. If you specify a vector of M+1 values, each value is used for a separate section of the filter. This property applies when you set the `TransferFunction` on page 4-582 property to `IIR (poles & zeros)`, the `CoefficientsSource` on page 4-582 property to `Property`, and the `Structure` on page 4-582 property to `Biquad direct form I (SOS)`, `Biquad direct form I transposed (SOS)`, `Biquad direct form II (SOS)`, or `Biquad direct form II transposed (SOS)`. The default is `1`. This property is tunable.

IgnoreFirstDenominatorCoefficient

Assume first denominator coefficient is 1

Setting this Boolean property to `true` reduces the number of computations to produce the digital filter output by omitting the first denominator term, *a0*, (poles side) in the filter structure. The object output is invalid when you set this property to `true` when the first denominator coefficient is not always 1 for your time-varying filter. The object ignores this property for fixed-point inputs, because this object does not support nonunity *a0* coefficients for fixed-point inputs.

This property applies when you set the `CoefficientsSource` on page 4-582 property to `Input port`, the `TransferFunction` on page 4-582 property to `IIR (all poles)`, and the `Structure` on page 4-582 property is not set to `Lattice AR`. This property also applies when you set the `CoefficientsSource` on page 4-582 property to `Input port`, the `TransferFunction` on page 4-582 property to `IIR (poles & zeros)`, and the `Structure` property to `Direct form`, `Direct form symmetric`, `Direct form antisymmetric`, or `Direct form transposed`. The default is `true`.

InitialConditions

Initial conditions for all poles or all zeros filter

Specify the initial conditions of the filter states. When the `TransferFunction` on page 4-582 property is `FIR (all zeros)` or `IIR (all poles)`, the number of states or delay elements equals the number of reflection coefficients for the lattice structure, or the number of filter coefficients–1 for the other direct form structures. When the `TransferFunction` property is `IIR (poles & zeros)`, the number of states for direct form II and direct form II transposed structures equals the `max(N,M)`–1, where `N` and `M` are the number of poles and zeros, respectively.

You can specify the initial conditions as a scalar, vector, or matrix. If you specify a scalar value, the digital filter object initializes all delay elements in the filter to that value. If you specify a vector whose length equals the number of delay elements in the filter, each vector element specifies a unique initial condition for the corresponding delay element. The object applies the same vector of initial conditions to each channel of the input signal.

If you specify a vector whose length equals the product of the number of input channels and the number of delay elements in the filter, each element specifies a unique initial condition for the corresponding delay element in the corresponding channel.

If you specify a matrix with the same number of rows as the number of delay elements in the filter, and one column for each channel of the input signal, each element specifies a unique initial condition for the corresponding delay element in the corresponding channel. This property applies when you do not set the `Structure` on page 4-582 property to `Direct Form I`, `Direct Form I transposed`, `Biquad direct form I (SOS)`, or `Biquad direct form I transposed (SOS)`. The default is 0.

NumeratorInitialConditions

Initial conditions on zeros side

Specify the initial conditions of the filter states on the side of the filter structure with the zeros. This property applies when you set the `TransferFunction` on page 4-582 property to `IIR (poles & zeros)` and the `Structure` on page 4-582 property is `Direct form I`, `Direct form I transposed`, `Biquad direct form`

I (SOS), or Biquad direct form I transposed (SOS). The default is 0. See the InitialConditions on page 4-585 property for information on setting initial conditions.

DenominatorInitialConditions

Initial conditions on poles side

Specify the initial conditions of the filter states on the side of the direct form I (noncanonic) filter structure with the poles. This property applies when you set the TransferFunction on page 4-582 property to IIR (poles & zeros) and the Structure on page 4-582 property to Direct form I, Direct form I transposed, Biquad direct form I (SOS), or Biquad direct form I transposed (SOS). The default is 0. See the InitialConditions on page 4-585 property for information on setting initial conditions.

Fixed-Point Properties

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as one of | Ceiling | Convergent | Floor | Nearest | Round | Simplest | Zero |. The default is Floor.

OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as one of | Wrap | Saturate |. The default is Wrap.

TapSumDataType

Tap sum word and fraction lengths

Specify the tap sum fixed-point data type as one of | Same as input | Custom |. This property applies when you set the TransferFunction on page 4-582 property to FIR (all zeros) and the Structure on page 4-582 property to either Direct form symmetric or Direct form antisymmetric. The default is Same as input.

CustomTapSumDataType

Custom tap sum word and fraction lengths

Specify the tap sum fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `TapSumDataType` on page 4-586 property to `Custom`. The default is `numerictype([],32,30)`.

`MultiplicandDataType`

Multiplicand word and fraction lengths

Specify the multiplicand fixed-point data type as one of `| Same as output | Custom |`. This property applies when you set the `Structure` on page 4-582 property to either `Direct form I transposed` or `Biquad direct form I transposed (SOS)`. The default is `Same as output`.

`CustomMultiplicandDataType`

Custom multiplicand word and fraction lengths

Specify the multiplicand fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `MultiplicandDataType` property to `Custom`. The default to `numerictype([],32,30)`.

`SectionInputDataType`

Section input word and fraction lengths

Specify the section input fixed-point data type as one of `| Same as input | Custom |`. Setting this property also sets the `SectionOutputDataType` on page 4-587 property to the same value. This property applies when you set the `TransferFunction` on page 4-582 property to `IIR (poles & zeros)` and the `Structure` on page 4-582 property to one of the biquad filter structures. The default is `Same as input`.

`CustomSectionInputDataType`

Custom section input word and fraction lengths

Specify the section input fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `SectionInputDataType` on page 4-587 property to `Custom`. The `CustomSectionInputDataType` on page 4-587 and `CustomSectionOutputDataType` on page 4-588 property values must have equal word lengths. The default is `numerictype([],16,15)`.

`SectionOutputDataType`

Section output word and fraction lengths

Specify the section output fixed-point data type as one of | `Same as input` | `Custom` |. Setting this property also sets the `SectionInputDataType` on page 4-587 property to the same value. This property applies when you set the `TransferFunction` on page 4-582 property to `IIR (poles & zeros)` and the `Structure` on page 4-582 property to one of the biquad filter structures. The default is `Same as input`.

CustomSectionOutputDataType

Custom section output word and fraction lengths

Specify the section output fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `SectionOutputDataType` on page 4-587 property to `Custom`. The `CustomSectionInputDataType` on page 4-587 and `CustomSectionOutputDataType` on page 4-588 property values must have equal word lengths. The default is `numerictype([],16,15)`.

NumeratorCoefficientsDataType

Numerator coefficients word and fraction lengths

Specify the numerator coefficients fixed-point data type as one of | `Same word length as input` | `Custom` |. Setting this property also sets the `DenominatorCoefficientsDataType` on page 4-588 and the `ScaleValuesDataType` on page 4-589 properties, if applicable, to the same value. This property applies when you set the `CoefficientsSource` on page 4-582 property to `Property` and the `TransferFunction` on page 4-582 property is not set to `IIR (all poles)`. The default is `Same word length as input`.

CustomNumeratorCoefficientsDataType

Custom numerator coefficients word and fraction lengths

Specify the numerator coefficients fixed-point type as a `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `NumeratorCoefficientsDataType` on page 4-588 property to `Custom`. The `CustomNumeratorCoefficientsDataType` on page 4-588, `CustomDenominatorCoefficientsDataType` on page 4-589 and `ScaleValuesDataType` on page 4-589 properties, if applicable, must have equal word lengths. The default is `numerictype([],16,15)`.

DenominatorCoefficientsDataType

Denominator coefficients word and fraction lengths

Specify the denominator coefficients fixed-point data type as one of | `Same word length as input` | `Custom` |. Setting this property also sets the `NumeratorCoefficientsDataType` on page 4-588 and `ScaleValuesDataType` on page 4-589 properties, if applicable, to the same value. This property applies when you set the `CoefficientsSource` on page 4-582 property to `Property` and the `TransferFunction` on page 4-582 property is not set to `FIR (all zeros)`. The default is `Same word length as input`.

CustomDenominatorCoefficientsDataType

Custom denominator coefficients word and fraction lengths

Specify the denominator coefficients fixed-point type as a `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `DenominatorCoefficientsDataType` property to `Custom`. The `CustomNumeratorCoefficientsDataType` on page 4-588, `CustomDenominatorCoefficientsDataType` and `CustomScaleValuesDataType` on page 4-589 properties, if they apply, must have equal word lengths. The default is `numerictype([],16,15)`.

ScaleValuesDataType

Scale values word and fraction lengths

Specify the scale values fixed-point data type as one of | `Same word length as input` | `Custom` |. Setting this property also sets the `NumeratorCoefficientsDataType` on page 4-588 and the `DenominatorCoefficientsDataType` on page 4-588 properties, if they apply, to the same value. This property applies when you set the `CoefficientsSource` on page 4-582 property to `Property`, the `TransferFunction` on page 4-582 property to `IIR (poles & zeros)`, and the `Structure` on page 4-582 property to one of the biquad filter structures. The default is `Same word length as input`.

CustomScaleValuesDataType

Custom scale values word and fraction lengths

Specify the scale values fixed-point type as a `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `CoefficientsSource` on page 4-582 property to `Property` and the `ScaleValuesDataType` on page 4-589 property to `Custom`. The `CustomNumeratorCoefficientsDataType` on page 4-588, `CustomDenominatorCoefficientsDataType` on page 4-589, and the

CustomScaleValuesDataType on page 4-589 properties, if applicable, must have equal word lengths. The default is numerictype([],16,15).

ProductDataType

Product word and fraction lengths

Specify the product fixed-point data type as one of | Same as input | Custom |. The default is Same as input.

CustomProductDataType

Custom product word and fraction lengths

Specify the product fixed-point type as a scaled numerictype object with a Signedness of Auto. This property applies when you set the ProductDataType on page 4-590 property to Custom. The default is numerictype([],32,30).

AccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point data type to one of | Same as input | Same as product | Custom |. The default is Same as product.

CustomAccumulatorDataType

Custom accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled numerictype object with a Signedness of Auto. This property applies when you set the AccumulatorDataType on page 4-590 property to Custom. The default is numerictype([],32,30).

StateDataType

State word and fraction lengths

Specify the state fixed-point data type as one of | Same as input | Same as accumulator | Custom |. This property does not apply to any of the direct form or direct form I filter structures. The default is Same as accumulator.

CustomStateDataType

Custom state word and fraction lengths

Specify the state fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `StateDataType` on page 4-590 property to `Custom`. The default is `numerictype([],16,15)`.

`OutputDataType`

Output word and fraction lengths

Specify the output fixed-point data type as one of | `Same as input` | `Same as accumulator` | `Custom` |. The default is `Same as accumulator`.

`CustomOutputDataType`

Custom output word and fraction lengths

Specify the output fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `OutputDataType` on page 4-591 property to `Custom`. The default is `numerictype([],16,15)`.

Methods

reset	Reset internal states of digital filter
step	Filter input with digital filter object

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Use an FIR filter to apply a low pass filter to a waveform with two sinusoidal components:

```
 t = [0:63]./32e3;
 xin = (sin(2*pi*4e3*t)+sin(2*pi*12e3*t)) / 2;

hSR = dsp.SignalSource(xin', 4);
 hLog = dsp.SignalSink;
 hFilt = dsp.DigitalFilter;
 hFilt.TransferFunction = 'FIR (all zeros)';
 hFilt.Numerator = fir1(10,0.5);

 while ~isDone(hSR)
      input = step(hSR);
      filteredOutput = step(hFilt,input);
      step(hLog,filteredOutput);
 end

 filteredResult = hLog.Buffer;
 periodogram(filteredResult,[],[],32e3)
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the `Digital Filter` block reference page. The object properties correspond to the block parameters.

This object processes inputs only as frames of data. The block lets you specify whether to process inputs as individual samples or as frames of data . You use the **Input processing** parameter on the block.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The `SOSMatrix` and `Scalevalues` properties are not supported for code generation.
- See “System Objects in MATLAB Code Generation” (MATLAB Coder).

dsp.FIRFilter | dsp.IIRFilter | dsp.BiquadFilter | dsp.AllpoleFilter

Introduced in R2012a

reset

System object: dsp.DigitalFilter
Package: dsp

Reset internal states of digital filter

Syntax

```
reset(H)
```

Description

`reset(H)` resets the filter states of the digital filter object,`H`, to their initial values of 0. The initial filter state values correspond to the initial conditions for the difference equation defining the filter. After the `step` method applies the digital filter object to nonzero input data, the states may be nonzero. Invoking the `step` method again without first invoking the`reset` method may produce different outputs for an identical input.

For example:

```
H = dsp.DigitalFilter;
H.TransferFunction = 'FIR (all zeros)';
H.Numerator = fir1(20,0.25);
n = 0:100;
x = cos(0.2*pi*n)+sin(0.8*pi*n);
y = step(H,x);
% Filter states are nonzero
% Invoke step method again without resetting states
y1 = step(H,x);
isequal(y,y1) % returns 0
% Now reset filter states to 0
reset(H)
% Invoke step method
y2 = step(H,x);
isequal(y,y2) % returns a 1
```

step

System object: dsp.DigitalFilter
Package: dsp

Filter input with digital filter object

Syntax

```
Y = step(HFILT,X)
Y = step(HFILT,X,COEFF)
Y = step(HFILT,X,NUM,DEN)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(HFILT,X)` filters the real or complex input signal `X` using the digital filter, `H`, to produce the output `Y` . The digital filter object operates on each channel of the input signal independently over successive calls to step method.

`Y = step(HFILT,X,COEFF)` uses the time-varying numerator or denominator coefficients, `COEFF` , to filter the input signal `X` and produce the output `Y` . You can use this option when you set the `TransferFunction` property to either `FIR (all zeros)` or `IIR (all poles)` and the `CoefficientsSource` property to `Input port`.

`Y = step(HFILT,X,NUM,DEN)` uses the time-varying numerator coefficients `NUM` and the time-varying denominator coefficients `DEN` to filter the input signal `X` and produce the output `Y` . You can use this option when you set the `TransferFunction` property to `IIR (poles and zeros)` and the `CoefficientsSource` property to `Input port`.

Note: `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.DigitalUpConverter System object

Package: dsp

Interpolate digital signal and translate it from baseband to Intermediate Frequency (IF) band

Description

The `DigitalUpConverter` object interpolates digital signal, and translates it from baseband to Intermediate Frequency (IF) band.

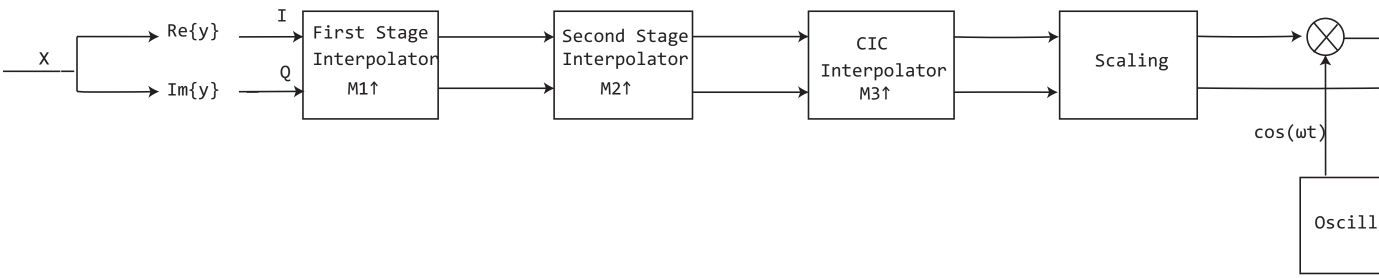
To digitally up convert the input signal:

1. Define and set up your digital up converter. See "Construction" on page 4-597.
2. Call step to upconvert the input according to the properties of `dsp.DigitalUpConverter`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

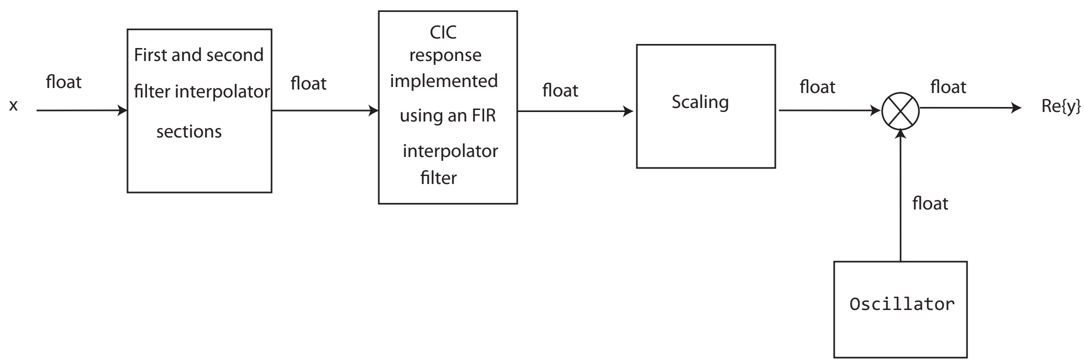
Construction

`upConv = dsp.DigitalUpConverter` returns a digital up-converter (DUC) System object, `upConv`. The object up samples the input signal using a cascade of three interpolation filters. This object frequency upconverts the up sampled signal by multiplying it with a complex exponential with center frequency equal to the value in the `CenterFrequency` property. In this case, the filter cascade consists of a first FIR interpolation stage, a CIC compensator, and a CIC interpolator. The following block diagram shows the architecture of the digital up converter.

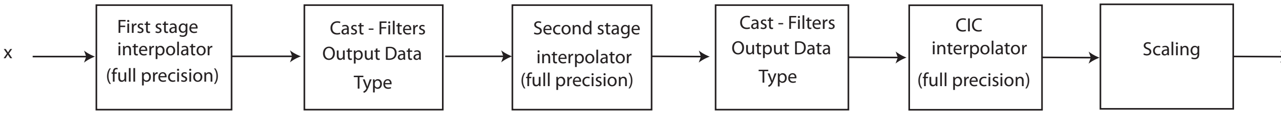


The scaling section normalizes the CIC gain and the oscillator power. It may also contain a correction factor to achieve the desired ripple specification. Depending on the setting of the **InterpolationFactor** property, you may be able to bypass the first filter stage. When the input data type is double or single, the object implements an N-section CIC interpolation filter as an FIR filter with a response that corresponds to a cascade of *N* boxcar filters. A true CIC filter with actual comb and integrator sections is implemented when the input data is of a fixed-point type. The CIC filter is emulated with an FIR filter so that you can run simulations with floating-point data.

The following diagram represents the DUC arithmetic with single or double-precision, floating-point inputs.

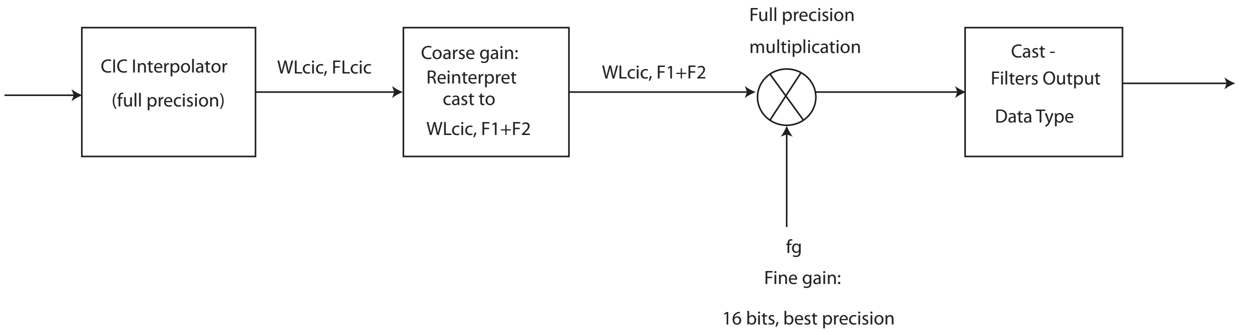


The following block diagram represents the DUC arithmetic with signed fixed-point inputs.



- `WL` is the word length of the input, and `FL` is the fraction length of the input.
- The output of each filter is cast to the data type specified in the **FiltersOutputDataType** and **CustomFiltersOutputDataType** properties. The casting of the CIC output occurs after the scaling factor is applied.
- The oscillator output is cast to a word length equal to the **FiltersOutputDataType** word length plus one. The fraction length is equal to the **FiltersOutputDataType** word length minus one.
- The scaling at the output of the CIC interpolator consists of coarse- and fine-gain adjustments. The coarse gain is achieved using the `reinterpretcast` function on the CIC interpolator output. The fine gain is achieved using full-precision multiplication.

The following figure depicts the coarse- and fine-gain operations.



If the normalization gain is G (where $0<G\leqq 1$), then:

- `WLcic` is the word length of the CIC interpolator output and `FLcic` is the fraction length of the CIC interpolator output
- `F1 = abs(nextpow2(G))`, indicating the part of G achieved using bit shifts (coarse gain)
- `F2` = fraction length specified by the **FiltersOutputDataType** and **CustomFiltersOutputDataType** properties
- `fg = fi((2^F1)*G, true, 16)`, indicating that the remaining gain cannot be achieved with a bit shift (fine gain)

`upConv = dsp.DigitalUpConverter('PropertyName','PropertyValue')` returns a DUC object, `upConv`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as (`Name1`,`Value1`,...,`NameN`,`ValueN`).

Properties

`SampleRate`

Sample rate of input signal

Set this property to a positive scalar. The value of this property multiplied by the total interpolation factor must be greater than or equal to twice the value of the `CenterFrequency` property. The default is `30` MHz.

InterpolationFactor

Interpolation factor

Set this property to a positive, integer scalar, or to a 1-by-2 or 1-by-3 vector of positive integers.

When you set this property to a scalar the object automatically chooses the interpolation factors for each of the three filtering stages.

When you set this property to a 1-by-2 vector, the object bypasses the first filter stage and sets the interpolation factor of the second and third filtering stages to the values in the first and second vector elements respectively. Both elements of the `InterpolationFactor` vector must be greater than one.

When you set this property to a 1-by-3 vector, the *i*th element of the vector specifies the interpolation factor for the *i*th filtering stage. The second and third elements of the `InterpolationFactor` vector must be greater than one and the first element must be `1` or `2`. The default is `100`.

MinimumOrderDesign

Minimum order filter design.

When you set this property to `true`, the object designs filters with the minimum order that meets the passband ripple, stopband attenuation, passband frequency, and stopband frequency specifications that you set using the `PassbandRipple`, `StopbandAttenuation`, `Bandwidth`, `StopbandFrequencySource`, and `StopbandFrequency` properties. When you set this property to`false`, the object designs filters with orders that you specify in the `FirstFilterOrder`, `SecondFilterOrder`, and `NumCICSections` properties. The filter designs meet the passband and stopband frequency specifications that you set using the `Bandwidth`, `StopbandFrequencySource`, and `StopbandFrequency` properties. The default is `true`.

SecondFilterOrder

Order of CIC compensation filter stage

Set this property to a positive, integer scalar. This property applies when you set the `MinimumOrderDesign` property to `false`. The default is `12`.

FirstFilterOrder

Order of first filter stage

Set this property to a positive, integer, even scalar. When you set the `InterpolationFactor` property to a 1-by-2 vector, the object ignores the `FirstFilterOrder` property because the first filter stage is bypassed. This property applies when you set the `MinimumOrderDesign` property to `false`. The default is `10`.

NumCICSections

Number of sections of CIC interpolator

Set this property to a positive, integer scalar. This property applies when you set the `MinimumOrderDesign` property to `false`. The default is `3`.

Bandwidth

Two-sided bandwidth of input signal in Hz .

Set this property to a positive, integer scalar. The object sets the passband frequency of the cascade of filters to one-half of the value that you specify in the `Bandwidth` property. The default is 200 kHz.

StopbandFrequencySource

Source of stopband frequency.

Specify the source of the stopband frequency as one of `Auto | Property`. The default is `Auto`. When you set this property to `Auto`, the object places the cutoff frequency of the cascade filter response at approximately F_c = `SampleRate`/2 Hz, and computes the stopband frequency as $F_{stop} = F_c + TW/2$. TW is the transition bandwidth of the cascade response, computed as $2\times(F_c–F_p)$, and the passband frequency, F_p, equals `Bandwidth`/2.

StopbandFrequency

Stopband frequency in Hz.

Set this property to a double precision positive scalar. This property applies when you set the `StopbandFrequencySource` property to `Property`. The default is `150` kHz.

PassbandRipple

Passband ripple of cascade response in dB.

Set this property to a double precision, positive scalar. When you set the MinimumOrderDesign property to true, the object designs the filters so that the cascade response meets the passband ripple that you specify in the PassbandRipple property. This property applies when you set the MinimumOrderDesign property to true. The default is 0.1 dB.

StopbandAttenuation

Stopband attenuation of cascade response in dB.

Set this property to a double precision, positive scalar. When you set the MinimumOrderDesign property to true, the object designs the filters so that the cascade response meets the stopband attenuation that you specify in the StopbandAttenuation property. This property applies when you set the MinimumOrderDesign property to true. The default is 60 dB.

Oscillator

Type of oscillator.

Specify the oscillator as one of Sine wave | NCO. The default is Sine wave. When you set this property to Sine wave, the object frequency up converts the output of the interpolation filter cascade using a complex exponential signal obtained from samples of a sinusoidal trigonometric function. When you set this property to NCO the object performs frequency up conversion with a complex exponential obtained using a numerically controlled oscillator (NCO).

CenterFrequency

Center frequency of output signal in Hz.

Specify this property as a double precision, positive scalar. The value of this property must be less than or equal to half the product of the SampleRate property times the total interpolation factor. The object up converts the input signal so that the output spectrum centers at the frequency you specify in the CenterFrequency property. The default is 14 MHz.

NumAccumulatorBits

Number of NCO accumulator bits

Specify this property as an integer scalar in the range [1 128]. This property applies when you set the Oscillator property to NCO. The default is 16.

See also dsp.NCO.

NumQuantizedAccumulatorBits

Number of NCO quantized accumulator bits.

Specify this property as an integer scalar in the range`[1 128]`. The value you specify for this property must be less than the value you specify in the `NumAccumulatorBits` property. This property applies when you set the `Oscillator` property to `NCO`. The default is `12`.

See also dsp.NCO.

Dither

Dither control for NCO.

When you set this property to `true`, the object uses the number of dither bits specified in the `NumDitherBits` property when applying dither to the NCO signal. This property applies when you set the `Oscillator` property to `NCO`. The default is `true`.

See also dsp.NCO.

NumDitherBits

Number of NCO dither bits.

Specify this property as an integer scalar smaller than the number of accumulator bits that you specify in the `NumAccumulatorBits` property. This property applies when you set the `Oscillator` property to `NCO` and the Dither property to `true`. The default is `4`.

See also dsp.NCO.

Fixed-Point Properties

FiltersOutputDataType

Data type of output of each filter stage

Specify the data type at the output of the first (if it has not been bypassed), second, and third filter stages as one of `Same as input` | `Custom`. The default is `Same as input`.

The object casts the data at the output of each filter stage according to the value you set in this property. For the CIC stage, the casting is done after the signal has been scaled by the normalization factor.

CustomFiltersOutputDataType

Fixed-point data type of output of each filter stage

Specify the filters output fixed-point type as a scaled numerictype object with a Signedness of `Auto`. This property applies when you set the `FiltersOutputDataType` property to `Custom`. The default is `numerictype([],16,15)`.

OutputDataType

Data type of output

Specify the data type of output as `Same as input` | `Custom`. The default is `Same as input`.

CustomOutputDataType

Fixed-point data type of output

Specify the output fixed-point type as a scaled numerictype object with a Signedness of `Auto`. This property applies when you set the `OutputDataType` property to `Custom`. The default is `numerictype([],16,15)`.

Methods

fvtool	Visualize response of filter cascade
getFilters	Get handles to interpolation filter objects
getFilterOrders	Get orders of interpolation filters
getInterpolationFactors	Get interpolation factors of each filter stage
groupDelay	Group delay of filter cascade
step	Process inputs using the digital up converter
visualizeFilterStages	Display response of filter stages

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Upconvert a Sine Wave Signal

Create a digital up converter object that upsamples a 1 KHz sinusoidal signal by a factor of 20, and up converts it to 50 KHz.

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

Initialization

Create a sine wave generator to obtain the 1 KHz sinusoidal signal with a sample rate of 6 KHz.

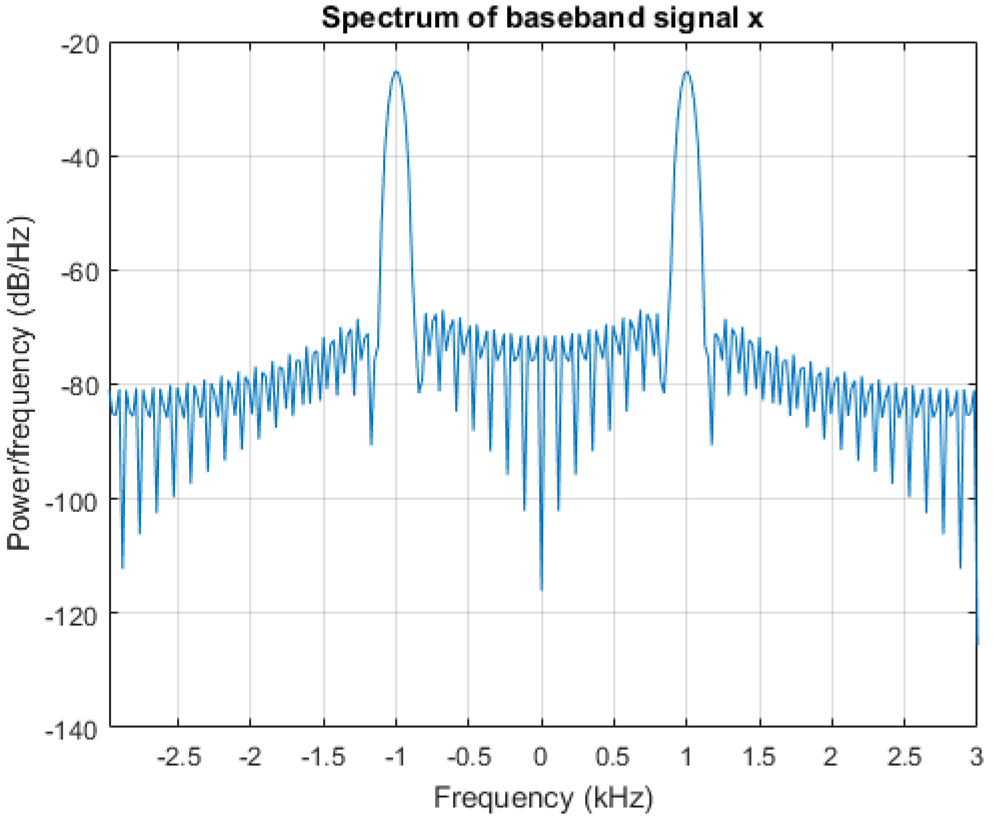
```
Fs = 6e3; % Sample rate
sine = dsp.SineWave('Frequency',1000,'SampleRate', Fs,'SamplesPerFrame',1024);
x = sine(); % generate signal
```

Create a DUC object. Use minimum order filter designs and set the passband ripple to 0.2 dB and the stopband attenuation to 55 dB. Set the double sided signal bandwidth to 2 KHz.

```
upConv = dsp.DigitalUpConverter(...
     'InterpolationFactor', 20,...
     'SampleRate', Fs,...
     'Bandwidth', 2e3,...
     'StopbandAttenuation', 55,...
     'PassbandRipple',0.2,...
     'CenterFrequency',50e3);
```

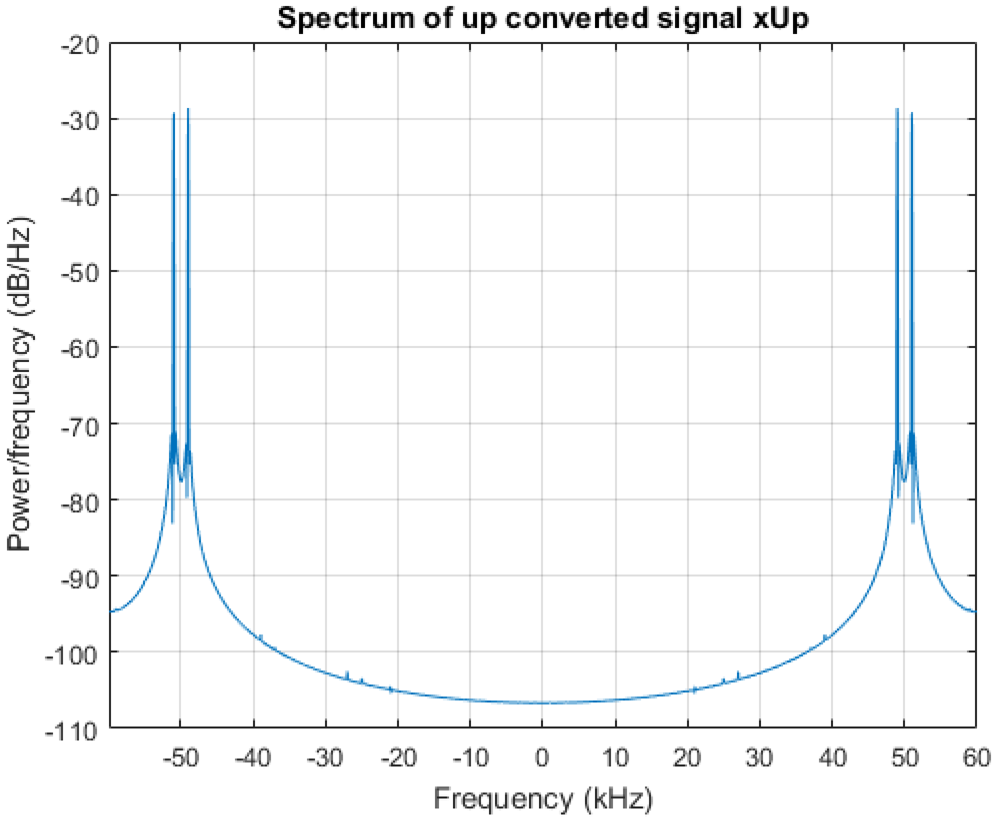
Create a spectrum estimator to visualize the signal spectrum before and after up converting.

```
window = hamming(floor(length(x)/10));
figure; pwelch(x,window,[],[],Fs,'centered')
title('Spectrum of baseband signal x')
```



Upconvert the Signal and Visualize the Spectrum

```
xUp = upConv(x); % up convert
window = hamming(floor(length(xUp)/10));
figure; pwelch(xUp,window,[],[],20*Fs,'centered')
title('Spectrum of up converted signal xUp')
```



Visualize the response of the interpolation filters

```
visualizeFilterStages(upConv)
```

dsp.DigitalDownConverter | `Digital Up-Converter` | `Digital Down-Converter`

Introduced in R2012a

fvtool

System object: dsp.DigitalUpConverter
Package: dsp

Visualize response of filter cascade

Syntax

```
fvtool(upConv)
fvtool(upConv,..,'Arithmetic',ARITH,...)
fvtool(upConv,..., PROP1, VALUE1,PROP2,VALUE2)
```

Description

`fvtool(upConv)` plots the magnitude response of the cascade of filters. By default, the object plots the cascade response up to the second CIC null frequency (or to the first when only one CIC null exists). When you set the `FilterSpecification` property to `Design parameters` the method plots a mask based on the filter specifications.

`fvtool(upConv,..,'Arithmetic',ARITH,...)` specifies the arithmetic of the filter cascade. You set input `ARITH` to `double`, `single`, or `fixed-point`. When object `upConv` is in an unlocked state you must specify the arithmetic. When object `upConv` is in a locked state the arithmetic input is ignored.

`fvtool(upConv,..., PROP1, VALUE1,PROP2,VALUE2)` launches FVTool and sets the specified FVTool properties to the specified values.

getFilters

System object: dsp.DigitalUpConverter
Package: dsp

Get handles to interpolation filter objects

Syntax

```
S = getFilters(upConv)
getFilters(upConv,'Arithmetic',ARITH)
```

Description

`S = getFilters(upConv)` returns a structure, `S`, with copies of the filter System objects and the CIC normalization factor that form the interpolation filter cascade. The `FirstFilterStage` structure field is empty if the first filter stage has been bypassed. The CIC normalization factor equals the inverse of the CIC filter gain. In some cases, this gain includes a correction factor to ensure that the cascade response meets the ripple specifications.

`getFilters(upConv,'Arithmetic',ARITH)` specifies the arithmetic of the filter stages. You set `ARITH` to `double`, `single`, or `fixed-point`. When object `upConv` is in an unlocked state, you must specify the arithmetic input. When object `upConv` is in a locked state, the arithmetic input is ignored.

When `upConv` is in an unlocked state, and you specify the arithmetic as `fixed-point`, the `getFilters` method returns filter System objects. The custom coefficient data type properties of these System objects are set to the values that the `dsp.DigitalUpConverter` System object uses to process data when you call the `step` method. All other fixed-point properties are set to their default values.

When `upConv` is in a locked state, and the input to the step method is of a fixed-point data type, the `getFilters` method returns filter System objects. All fixed-point properties of these System objects are set to the exact values that the `dsp.DigitalUpConverter` System object uses to process the data.

getFilterOrders

System object: dsp.DigitalUpConverter
Package: dsp

Get orders of interpolation filters

Syntax

```
S = getFilterOrders(upConv)
```

Description

`S = getFilterOrders(upConv)` returns a structure, `S`, that contains the orders of the interpolation filter stages. The `FirstFilterOrder` structure field will be empty if the first filter stage has been bypassed.

getInterpolationFactors

System object: dsp.DigitalUpConverter
Package: dsp

Get interpolation factors of each filter stage

Syntax

```
M = getInterpolationFactors(upConv)
```

Description

`M = getInterpolationFactors(upConv)` returns a vector, `M`, with the interpolation factors of each filter stage. If the first filter stage is bypassed, then `M` is a 1-by-2 vector containing the interpolation factors of the second and third stages in the first and second elements respectively. If the first filter stage is not bypassed then `M` is a 1-by-3 vector containing the interpolation factors of the first, second and third filter stages.

groupDelay

System object: dsp.DigitalUpConverter
Package: dsp

Group delay of filter cascade

Syntax

```
D = groupDelay(upConv,N)
[D,F] = groupDelay(upConv,N)
```

Description

`D = groupDelay(upConv,N)` returns a vector of group delays, `D`, evaluated at `N` frequency points equally spaced around the upper half of the unit circle. If you don't specify `N`, it defaults to `8192`.

`[D,F] = groupDelay(upConv,N)` returns a vector, `F`, of frequencies at which the group delay has been computed.

step

System object: dsp.DigitalUpConverter
Package: dsp

Process inputs using the digital up converter

Syntax

`Y = step(upConv,X)`

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(upConv,X)` takes a real or complex input column vector `X` and outputs an up sampled and frequency up converted signal `Y`. `X` can be of data type double, single, signed integer, or signed fixed point (fi objects). The length of `Y` is equal to the length of `X` multiplied by the `InterpolationFactor` on page 4-601. When the data type of `X` is double or single precision, the data type of `Y` is the same as that of `X`. When the data type of `X` is of a fixed point type, the data type of Y is defined by the `OutputDataType` on page 4-605 property.

visualizeFilterStages

System object: dsp.DigitalUpConverter
Package: dsp

Display response of filter stages

Syntax

```
visualizeFilterStages(upConv)
visualizeFilterStages(upConv,'Arithmetic',ARITH)
fvt = visualizeFilterStages(upConv)
```

Description

`visualizeFilterStages(upConv)` plots the magnitude response of the filter stages and of the cascade response. When the `FilterSpecification` property is set to `Design parameters` the method plots a mask based on the filter specifications. By default, the object plots the response of the filters up to the second CIC null frequency (or to the first when only one CIC null exists).

`visualizeFilterStages(upConv,'Arithmetic',ARITH)` specifies the arithmetic of the filter stages. You set input ARITH to 'double', 'single', or 'fixed-point'. When object `upConv` is in an unlocked state you must specify the arithmetic. When object `upConv` is in a locked state the arithmetic input is ignored.

`fvt = visualizeFilterStages(upConv)` returns the handle to the FVTool object.

dsp.DyadicAnalysisFilterBank System object

Package: dsp

Dyadic analysis filter bank

Description

The `DyadicAnalysisFilterBank` object uses a series of highpass and lowpass FIR filters to provide approximate octave band frequency decompositions of the input. Each filter output is downsampled by a factor of two. With the appropriate analysis filters and tree structure, the dyadic analysis filter bank is a discrete wavelet transform (DWT) or discrete wavelet packet transform (DWPT).

To obtain approximate octave band frequency decompositions of the input:

1. Define and set up your dyadic analysis filter bank. See "Construction" on page 4-618.
2. Call step to get the octave half band frequency decompositions of the input according to the properties of `dsp.DyadicAnalysisFilterBank`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`dydan = dsp.DyadicAnalysisFilterBank` constructs a dyadic analysis filter bank object, `dydan`, that computes the level-two discrete wavelet transform (DWT) of a column vector input. For a 2-D matrix input, the object transforms the columns using the Daubechies third-order extremal phase wavelet. The length of the input along the first dimension must be a multiple of 4.

```
dydan =
dsp.DyadicAnalysisFilterBank('PropertyName',PropertyValue, ...)
```

returns a dyadic analysis filter bank object, `dydan`, with each property set to the specified value.

Properties

`Filter`

Type of filter used in subband decomposition

Specify the type of filter used to determine the high and lowpass FIR filters in the dyadic analysis filter bank as `Custom` , `Haar`, `Daubechies`, `Symlets`, `Coiflets`, `Biorthogonal`, `Reverse Biorthogonal`, or `Discrete Meyer`. All property values except `Custom` require Wavelet Toolbox software. If the value of this property is `Custom`, the filter coefficients are specified by the values of the `CustomLowpassFilter` on page 4-619 and `CustomHighpassFilter` on page 4-620 properties. Otherwise, the dyadic analysis filter bank object uses the Wavelet Toolbox function `wfilters` to construct the filters. The following table lists supported wavelet filters and example syntax to construct the filters:

Filter	Example Setting	Syntax for Analysis Filters
Haar	N/A	`[Lo_D,Hi_D]=wfilters('haar');`
Daubechies extremal phase	`WaveletOrder=3;`	`[Lo_D,Hi_D]=wfilters('db3');`
Symlets (Daubechies least-asymmetric)	`WaveletOrder=4;`	`[Lo_D,Hi_D]=wfilters('sym4');`
Coiflets	`WaveletOrder=1;`	`[Lo_D,Hi_D]=wfilters('coif1');`
Biorthogonal	`FilterOrder='[3/1]';`	`[Lo_D,Hi_D,Lo_R,Hi_R]=...` `wfilters('bior3.1');`
Reverse biorthogonal	`FilterOrder='[3/1]';`	`[Lo_D,Hi_D,Lo_R,Hi_R]=...` `wfilters('rbior3.1');`
Discrete Meyer	N/A	`[Lo_D,Hi_D]=wfilters('dmey');`

`CustomLowpassFilter`

Lowpass FIR filter coefficients

Specify a vector of lowpass FIR filter coefficients, in powers of z^{-1}. Use a half-band filter that passes the frequency band stopped by the filter specified in the `CustomHighpassFilter` on page 4-620 property. This property applies when you set the `Filter` on page 4-619 property to `Custom`. The default specifies a Daubechies third-order extremal phase scaling (lowpass) filter.

`CustomHighpassFilter`

Highpass FIR filter coefficients

Specify a vector of highpass FIR filter coefficients, in powers of z^{-1}. Use a half-band filter that passes the frequency band stopped by the filter specified in the `CustomLowpassFilter` on page 4-619 property. This property applies when you set the `Filter` on page 4-619 property to `Custom`. The default specifies a Daubechies 3rd-order extremal phase wavelet (highpass) filter.

`WaveletOrder`

Order for orthogonal wavelets

Specify the order of the wavelet selected in the `Filter` on page 4-619 property. This property applies when you set the `Filter` property to an orthogonal wavelet: `Daubechies` (Daubechies extremal phase), `Symlets` (Daubechies least-asymmetric), or `Coiflets`. The default is `2`.

`FilterOrder`

Analysis and synthesis filter orders for biorthogonal filters

Specify the order of the analysis and synthesis filter orders for biorthogonal filter banks as `1 / 1`, `1 / 3`, `1 / 5`, `2 / 2`, `2 / 4`, `2 / 6`, `2 / 8`, `3 / 1`, `3 / 3`, `3 / 5`, `3 / 7`, `3 / 9`, `4 / 4`, or `5 / 5`, `6 / 8`. Unlike orthogonal wavelets, biorthogonal wavelets require different filters for the analysis (decomposition) and synthesis (reconstruction) of an input. The first number indicates the order of the synthesis (reconstruction) filter. The second number indicates the order of the analysis (decomposition) filter. This property applies when you set the `Filter` on page 4-619 property to `Biorthogonal` or `Reverse Biorthogonal`. The default is `1 / 1`.

`NumLevels`

Number of filter bank levels used in analysis (decomposition)

Specify the number of filter bank analysis levels a positive integer. A level-N asymmetric structure produces N+1 output subbands. A level-N symmetric structure produces 2^N output subbands. The default is 2. The size of the input along the first dimension must be a multiple of 2^N, where N is the number of levels.

TreeStructure

Structure of filter bank

Specify the structure of the filter bank as `Asymmetric` or `Symmetric`. The asymmetric structure decomposes only the lowpass filter output from each level. The symmetric structure decomposes the highpass and lowpass filter outputs from each level. If the analysis filters are scaling (lowpass) and wavelet (highpass) filters, the asymmetric structure is the discrete wavelet transform, while the symmetric structure is the discrete wavelet packet transform.

When this property is `Symmetric`, the output has 2^N subbands each of size $M/2^N$. In this case, M is the length of the input along the first dimension and N is the value of the `NumLevels` on page 4-620 property. When this property is `Asymmetric`, the output has N+1 subbands. The following equation gives the length of the output in the kth subband in the asymmetric case:

$$M_k = \begin{cases} \dfrac{M}{2^k} & 1 \le k \le N \\ \dfrac{M}{2^N} & k = N+1 \end{cases}$$

The default is `Asymmetric`.

Methods

reset	Reset filter states
step	Decompose input with dyadic filter bank

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object

Common to All System Objects	
getNumOutp	Expected number of outputs of a System object
isLocked	Check locked states of a System object (logical)
release	Allow System object property value changes

Examples

Filter Square Wave Using Dyadic Filter Banks

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

Denoise square wave input using dyadic analysis and synthesis filter banks.

```
t = 0:.0001:.0511;
x= square(2*pi*30*t);
xn = x' + 0.08*randn(length(x),1);
dydanl = dsp.DyadicAnalysisFilterBank;
```

The filter coefficients correspond to a `haar` wavelet.

```
dydanl.CustomLowpassFilter = [1/sqrt(2) 1/sqrt(2)];
dydanl.CustomHighpassFilter = [-1/sqrt(2) 1/sqrt(2)];
dydsyn = dsp.DyadicSynthesisFilterBank;
dydsyn.CustomLowpassFilter = [1/sqrt(2) 1/sqrt(2)];
dydsyn.CustomHighpassFilter = [1/sqrt(2) -1/sqrt(2)];
C = dydanl(xn);
```

Subband outputs.

```
C1 = C(1:256); C2 = C(257:384); C3 = C(385:512);
```

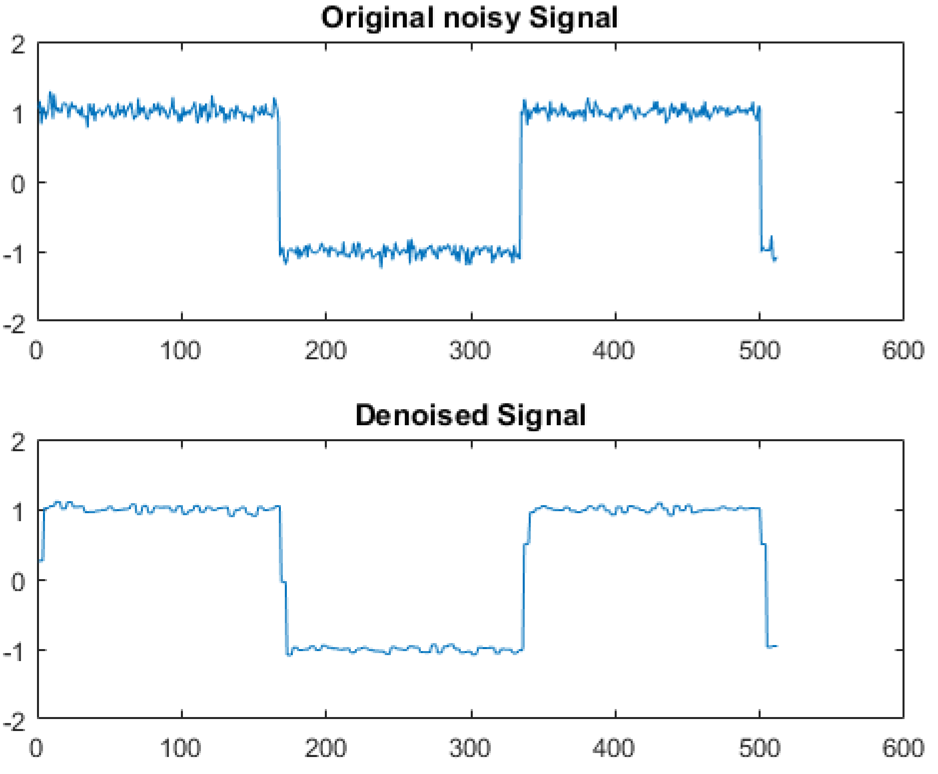
Set higher frequency coefficients to zero to remove the noise.

```
x_den = dydsyn([zeros(length(C1),1);...
    zeros(length(C2),1);C3]);
```

Plot the original and denoised signals.

```
subplot(2,1,1), plot(xn); title('Original noisy Signal');
```

```
subplot(2,1,2), plot(x_den); title('Denoised Signal');
```



Algorithms

This object implements the algorithm, inputs, and outputs described on the `Dyadic Analysis Filter Bank` block reference page. The object properties correspond to the block parameters, except:
The dyadic analysis filter bank object always concatenates the subbands into a single column vector for a column vector input, or into the columns of a matrix for a matrix input. This behavior corresponds to the block's behavior when you set the **Output** parameter to `Single port`.

dsp.DyadicSynthesisFilterBank | dsp.SubbandAnalysisFilter

Introduced in R2012a

reset

System object: dsp.DyadicAnalysisFilterBank
Package: dsp

Reset filter states

Syntax

```
reset(dydan)
```

Description

`reset(dydan)` resets the filter states of the dyadic analysis filter bank object, `dydan`, to their initial values of zero. After the `step` method applies the dyadic analysis filter bank to nonzero input data, the filter states may change. Invoking the `step` method again without first invoking the `reset` method may produce different outputs for an identical input.

Reset a Dyadic Analysis Filter Bank

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

```
X = [1 1 7 9 2 8 8 6]';
dydan = dsp.DyadicAnalysisFilterBank('NumLevels',1);
```

Filter states are zero.

```
y = dydan(X);
```

Invoke step method again without resetting states.

```
y1 = dydan(X);
isequal(y,y1)
```

```
ans =
```

```
  logical

   0
```

Reset the filter states.

```
reset(dydan); % Reset filter states to zero
y2 = dydan(X);
isequal(y,y2)
```

```
ans =

  logical

   1
```

step

System object: dsp.DyadicAnalysisFilterBank
Package: dsp

Decompose input with dyadic filter bank

Syntax

`Y = step(dydan,X)`

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(dydan,X)` computes the subband decomposition of the input `X` and outputs the dyadic subband decomposition in `Y` as a single concatenated column vector or matrix of coefficients. Each column of `X` is treated as an independent input, and the number of rows of `X` must be a multiple of 2^N, where N is the value of the `NumLevels` property. The elements of `Y` are ordered with the highest frequency subband first followed by subbands in decreasing frequency

Examples

Subband Ordering For Asymmetric Tree Structure Using Dyadic Analysis Filter Bank

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

Sampling frequency 1 kHz input length 1024

```
t = 0:.001:1.023;
x = square(2*pi*30*t);
xn = x' + 0.08*randn(length(x),1);
```

Default asymmetric structure with Daubechies order 3 extremal phase wavelet

```
dydan = dsp.DyadicAnalysisFilterBank;
Y = dydan(xn);
```

Level 2 yields 3 subbands (two detail-one approximation) Nyquist frequency is 500 Hz

```
D1 = Y(1:512); % subband approx. [250, 500] Hz
D2 = Y(513:768); % subband approx. [125, 250] Hz
Approx = Y(769:1024); % subband approx. [0,125] Hz
```

Subband Ordering For Symmetric Tree Structure Using Dyadic Analysis Filter Bank

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

Sampling frequency 1 kHz input length 1024.

```
t = 0:.001:1.023;
x = square(2*pi*30*t);
xn = x' + 0.08*randn(length(x),1);
```

symmetric structure with Daubechies order 3 extremal phase wavelets.

```
dydan = dsp.DyadicAnalysisFilterBank('TreeStructure',...
'Symmetric');
Y = dydan(xn);
D1 = Y(1:256); % subband approx. [375,500] Hz
D2 = Y(257:512); % subband approx. [250,375] Hz
D3 = Y(513:768); % subband approx. [125,250] Hz
Approx = Y(769:1024); % subband approx. [0, 125] Hz
```

dsp.DyadicSynthesisFilterBank System object

Package: dsp

Reconstruct signals from subbands

Description

The `DyadicSynthesisFilterBank` object reconstructs signals from subbands with smaller bandwidths and lower sample rates. The filter bank uses a series of highpass and lowpass FIR filters to repeatedly reconstruct the signal.

To reconstruct signals from subbands with smaller bandwidths and lower sample rates:

1 Define and set up your synthesis filter bank. See "Construction" on page 4-629.
2 Call step to reconstruct the signal according to the properties of `dsp.DyadicSynthesisFilterBank`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`dydsyn = dsp.DyadicSynthesisFilterBank` returns a synthesis filter bank, `dydsyn`, that reconstructs a signal from its subbands with smaller bandwidths and smaller sample rates.

`dydsyn =`
`dsp.DyadicSynthesisFilterBank('`*`Propertyname`*`',`*`PropertyValue`*`,...)` returns a synthesis filter bank, `dydsyn`, with each specified property set to the specified value.

Properties

`Filter`

Type of filter used in filter bank

Specify the type of filter used to determine the highpass and lowpass FIR filters in the filter bank as one of `Custom`, `Haar`, `Daubechies`, `Symlets`, `Coiflets`, `Biorthogonal`, `Reverse Biorthogonal`, or `Discrete Meyer`. If you set this property to `Custom`, the `CustomLowpassFilter` on page 4-630 and `CustomHighpassFilter` on page 4-631 properties specify the filter coefficients. Otherwise, the object uses the Wavelet Toolbox `wfilters` function to construct the filters. Depending on the filter, the `WaveletOrder` on page 4-631 or `FilterOrder` on page 4-631 property might apply. For a list of the supported wavelets, see the following table.

Filter	Sample Setting for Related Filter Specification Properties	Corresponding Wavelet Toolbox Function Syntax
`Haar`	None	`wfilters('haar')`
`Daubechies`	`H.WaveletOrder = 4`	`wfilters('db4')`
`Symlets`	`H.WaveletOrder = 3`	`wfilters('sym3')`
`Coiflets`	`H.WaveletOrder = 1`	`wfilters('coif1')`
`Biorthogonal`	`H.FilterOrder = '[3/1]'`	`wfilters('bior3.1')`
`Reverse Biorthogonal`	`H.FilterOrder = '[3/1]'`	`wfilters('rbior3.1')`
`Discrete Meyer`	None	`wfilters('dmey')`

In order to automatically design wavelet-based filters, install the Wavelet Toolbox product. Otherwise, use the `CustomLowpassFilter` on page 4-630 and `CustomHighpassFilter` on page 4-631 properties to specify lowpass and highpass FIR filters.

`CustomLowpassFilter`

Lowpass FIR filter coefficients

Specify a vector of lowpass FIR filter coefficients, in descending powers of z. Use a half-band filter that passes the frequency band stopped by the filter specified in the

`CustomHighpassFilter` on page 4-631 property. This property applies only when you set the `Filter` on page 4-630 property to `Custom`. To perfectly reconstruct a signal decomposed by the `DyadicAnalysisFilterBank` on page 4-618, design the filters in the synthesis filter bank to perfectly reconstruct the outputs of the analysis filter bank. Otherwise, the reconstruction is imperfect. The default values of this property specify a perfect reconstruction filter for the default settings of the analysis filter bank (based on a third-order Daubechies wavelet).

CustomHighpassFilter

Highpass FIR filter coefficients

Specify a vector of highpass FIR filter coefficients, in descending powers of z. Use a half-band filter that passes the frequency band stopped by the filter specified in the `CustomLowpassFilter` on page 4-630 property. This property applies only when you set the `Filter` on page 4-630 property to `Custom`. To perfectly reconstruct a signal decomposed by the `DyadicAnalysisFilterBank` on page 4-618, design the filters in the synthesis filter bank to perfectly reconstruct the outputs of the analysis filter bank. Otherwise, the reconstruction is imperfect. The default values of this property specify a perfect reconstruction filter for the default settings of the analysis filter bank (based on a third-order Daubechies wavelet).

WaveletOrder

Wavelet order

Specify the order of the wavelet selected in the `Filter` on page 4-630 property. This property applies only when you set the `Filter` on page 4-630 property to `Daubechies`, `Symlets` or `Coiflets`. The default is `2`.

FilterOrder

Wavelet order for synthesis filter stage

Specify the order of the wavelet for the synthesis filter stage as:

- First order: `'[1/1]'`, `'[1/3]'`, or `'[1/5]'`.
- Second order: `'[2/2]'`, `'[2/4]'`, `'[2/6]'`, or `'[2/8]'`.
- Third order: `'[3/1]'`, `'[3/3]'`, `'[3/5]'`, `'[3/7]'`, or `'[3/9]'`.
- Fourth order: `'[4/4]'`.

- Fifth order: `'[5/5]'`.
- Sixth order: `'[6/8]'`.

This property applies only when you set the `Filter` on page 4-630 property to `Biorthogonal` or `Reverse Biorthogonal`. The default is `'[1/1]'`.

`NumLevels`

Number of filter bank levels

Specify the number of filter bank levels as a scalar integer. An N-level asymmetric structure has $N + 1$ input subbands, and an N-level symmetric structure has 2^N input subbands. The default is `2`.

rg

`TreeStructure`

Structure of filter bank

Specify the structure of the filter bank as `Asymmetric` or `Symmetric`. In the asymmetric structure, the low-frequency subband input to each level is the output of the previous level, while the high-frequency subband input to each level is an input to the filter bank. In the symmetric structure, both the low- and high-frequency subband inputs to each level are outputs from the previous level. The default is `Asymmetric`.

Methods

step	Reconstruct signal from high- and low-frequency subbands

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)

Common to All System Objects	
`release`	Allow System object property value changes

Examples

Filter Square Wave Using Dyadic Filter Banks

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

Denoise square wave input using dyadic analysis and synthesis filter banks.

```
t = 0:.0001:.0511;
x= square(2*pi*30*t);
xn = x' + 0.08*randn(length(x),1);
dydanl = dsp.DyadicAnalysisFilterBank;
```

The filter coefficients correspond to a `haar` wavelet.

```
dydanl.CustomLowpassFilter = [1/sqrt(2) 1/sqrt(2)];
dydanl.CustomHighpassFilter = [-1/sqrt(2) 1/sqrt(2)];
dydsyn = dsp.DyadicSynthesisFilterBank;
dydsyn.CustomLowpassFilter = [1/sqrt(2) 1/sqrt(2)];
dydsyn.CustomHighpassFilter = [1/sqrt(2) -1/sqrt(2)];
C = dydanl(xn);
```

Subband outputs.

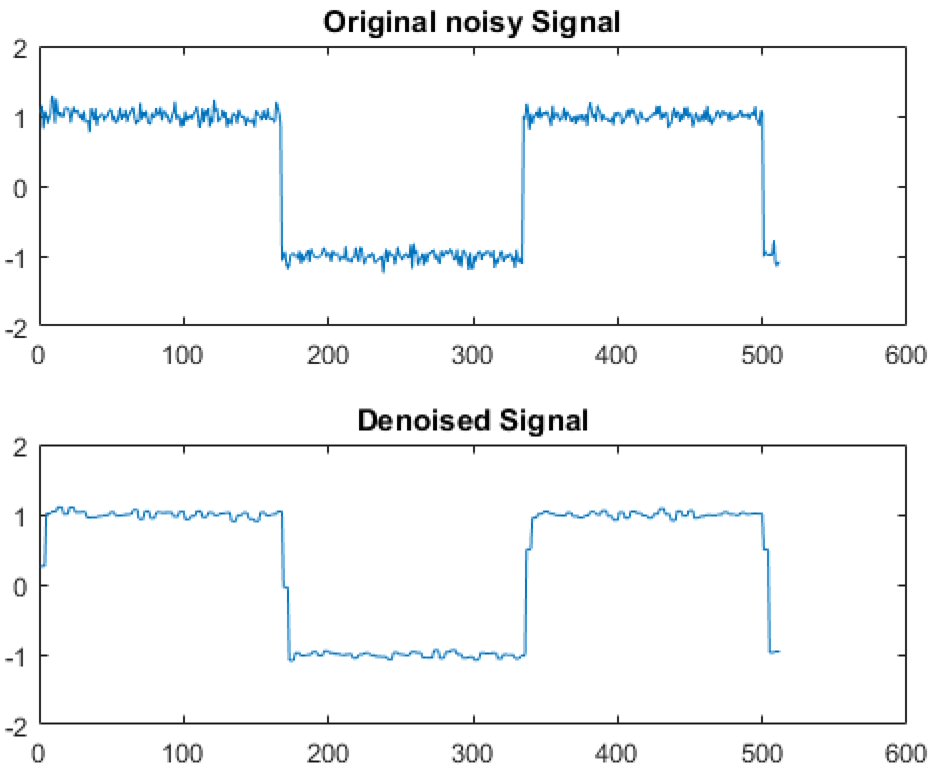
```
C1 = C(1:256); C2 = C(257:384); C3 = C(385:512);
```

Set higher frequency coefficients to zero to remove the noise.

```
x_den = dydsyn([zeros(length(C1),1);...
    zeros(length(C2),1);C3]);
```

Plot the original and denoised signals.

```
subplot(2,1,1), plot(xn); title('Original noisy Signal');
subplot(2,1,2), plot(x_den); title('Denoised Signal');
```



Algorithms

This object implements the algorithm, inputs, and outputs described on the `Dyadic Synthesis Filter Bank` block reference page. The object properties correspond to the block parameters, except:
The object only receives data as a vector or matrix of concatenated subbands, as specified using the `step` method.

dsp.DyadicAnalysisFilterBank | dsp.SubbandSynthesisFilter

Introduced in R2012a

step

System object: dsp.DyadicSynthesisFilterBank
Package: dsp

Reconstruct signal from high- and low-frequency subbands

Syntax

`X = step(dydsyn,S)`

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`X = step(dydsyn,S)` reconstructs the concatenated subband input `S` to output `X`. Each column of input `S` contains the subbands for an independent signal. Upper rows contain the high-frequency subbands, and lower rows contain the low-frequency subbands. The number of rows of `S` must be a multiple of 2^N, where N is the value of the `NumLevels` property.

Note: `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

dsp.FarrowRateConverter System object

Package: dsp

Polynomial sample rate converter with arbitrary conversion factor

Description

The `FarrowRateConverter` System object implements an efficient polynomial-fit sample rate conversion filter using a Farrow structure. You can use this object to convert the sample rate of a signal up or down by an arbitrary factor. This object supports fixed-point operations.

To convert the sample rate of a signal:

1. Define and set up your sample rate converter. See "Construction" on page 4-637.
2. Call step to convert the sample rate according to the properties of `dsp.FarrowRateConverter`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`src = dsp.FarrowRateConverter` creates a polynomial filter-based sample rate converter System object, `src`. For each channel of an input signal, `src` converts the input sample rate to the output sampling rate.

`src = dsp.FarrowRateConverter(Name,Value)` uses additional rate and filter properties, specified by one or more `Name,Value` pair arguments.

`src = dsp.FarrowRateConverter(FSIN,FSOUT,TOL,NP)` returns a sample rate converter object, `src`, with `InputSampleRate` property set to `FSIN`, OutputSampleRate property set to FSOUT, OutputRateTolerance property set to TOL, and PolynomialOrder property set to NP.

Properties

InputSampleRate — Sample rate of input signal

44100 Hz (default) | positive scalar in Hz

Sample rate of the input signal, specified as a positive scalar in Hz. The input sample rate must be greater than the bandwidth of interest. The default is 44.1 kHz.

OutputSampleRate — Sample rate of output signal

48000 Hz (default) | positive scalar in Hz

Sample rate of the output signal, specified as a positive scalar in Hz. The output sample rate can be higher or lower than the input sample rate. The default is 48 kHz.

OutputRateTolerance — Maximum allowed tolerance for output sample rate

0 (default) | positive scalar

Maximum allowed tolerance for the sample rate of the output signal, specified as a positive scalar from 0 through 0.5, inclusive. The default is 0.

The actual output sample rate varies but is within the specified range. For example, if OutputRateTolerance is specified as 0.01, then the actual output sample rate is in the range given by OutputSampleRate ± 1%. This flexibility allows for a simpler filter design often.

Specification — Polynomial specification

'Polynomial order' (default) | 'Coefficients'

Method used to specify the polynomial interpolator coefficients, specified as one of the following:

- 'Polynomial order' — Specify the order of the Lagrange interpolation filter polynomial through the PolynomialOrder property.
- 'Coefficients' — Specify the polynomial coefficients directly through the Coefficients property.

PolynomialOrder — Order of filter polynomial

3 (default) | positive integer less than or equal to 4

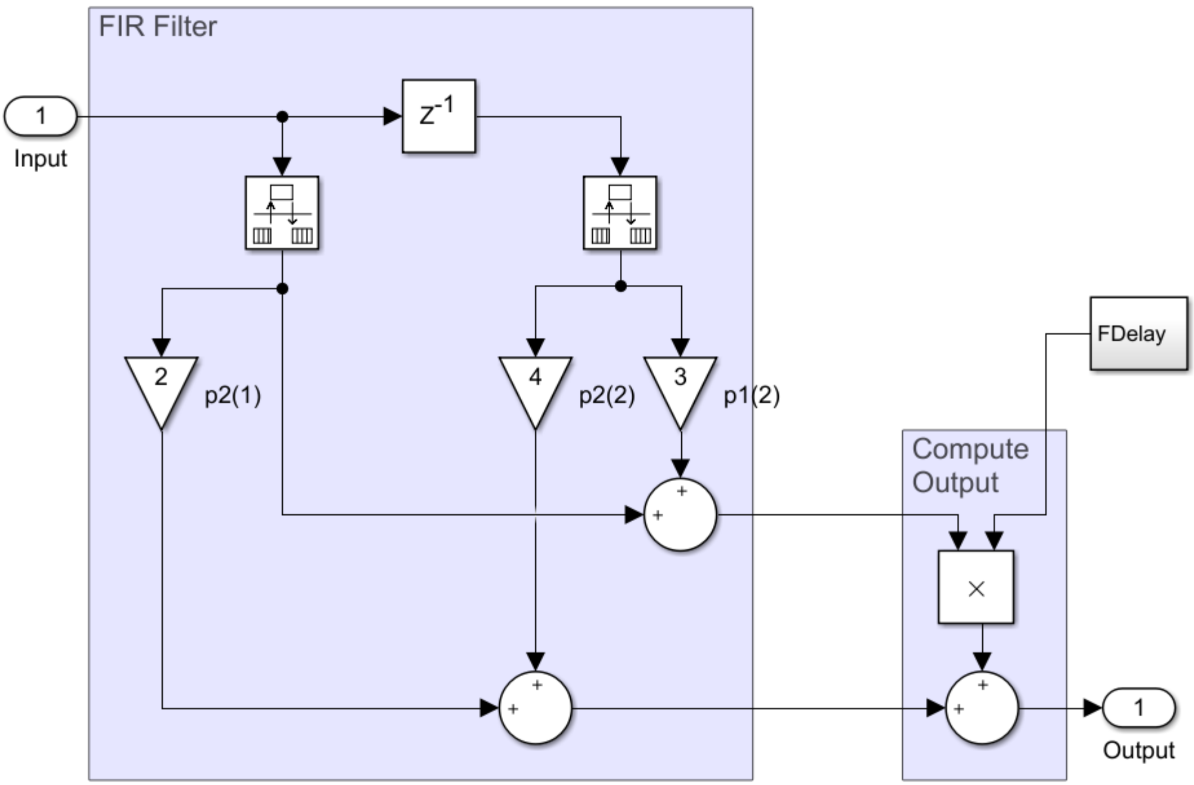
Order of the Lagrange interpolation filter polynomial, specified as a positive integer less than or equal to 4. The default is 3. This property applies only when you set `Specification` to `'Polynomial order'`.

`Coefficients` — Filter polynomial coefficients

`[-1 1; 1 0]` (default) | real-valued square matrix

Filter polynomial coefficients, specified as a real-valued square matrix. The default is `[-1 1; 1 0]`. This property applies only when you set `Specification` to `'Coefficients'`.

Here is the signal flow graph for farrow rate converter with coefficients set to `[1 2; 3 4]`.



Each branch of the FIR filter corresponds to each row of the coefficients matrix.

Fixed-Point Properties

`RoundingMethod` — Rounding method for fixed-point operations

`'Ceiling'` | `'Convergent'` | `'Floor'` | `'Nearest'` | `'Round'` | `'Zero'`

Rounding method, specified as a character vector. For more information on the rounding modes, see “Precision and Range”.

This property is not tunable.

`OverflowAction` — Overflow action for fixed-point operations

`'Wrap'` | `'Saturate'`

Overflow action, specified as `Wrap|Saturate`. For more details on the overflow modes, see the 'Overflow Handling' section of “Precision and Range”.

This property is not tunable.

`CoefficientsDataType` — Data type of the filter coefficients

`numerictype(1,16)` | `numerictype(1,16,3)`

Data type of the filter coefficients, specified as a signed `numerictype` object. The default, `numerictype(1,16)` corresponds to a signed numeric type object with 16-bit coefficients. To give the best possible precision, the fraction length of this data type is determined based on the coefficient values.

This property is not tunable.

`FractionalDelayDataType` — Data type of the fractional delay

`numerictype(0,8)` | `numerictype(0,16)`

Data type of the fractional delay, specified as an unsigned `numerictype` object. The default, `numerictype(0,8)` corresponds to an unsigned fixed-point fractional delay data type object with 8-bit word length. To give the best possible precision, the fraction length of this data type is determined based on the fractional delay values.

This property is not tunable.

`MultiplicandDataType` — Data type of the multiplicand

`numerictype(1,16,13)`

Data type of the multiplicand, specified as a signed `numerictype` object. The default, `numerictype(1,16,13)` corresponds to a signed fixed-point multiplicand data type with 16-bit word length and 13-bit fraction length.

This property is not tunable.

`OutputDataType` — Data type of the farrow rate converter output

`'Same word length as input'` | `'Same as accumulator'` | `numerictype(1,16)` | `numerictype(1,16,0)`

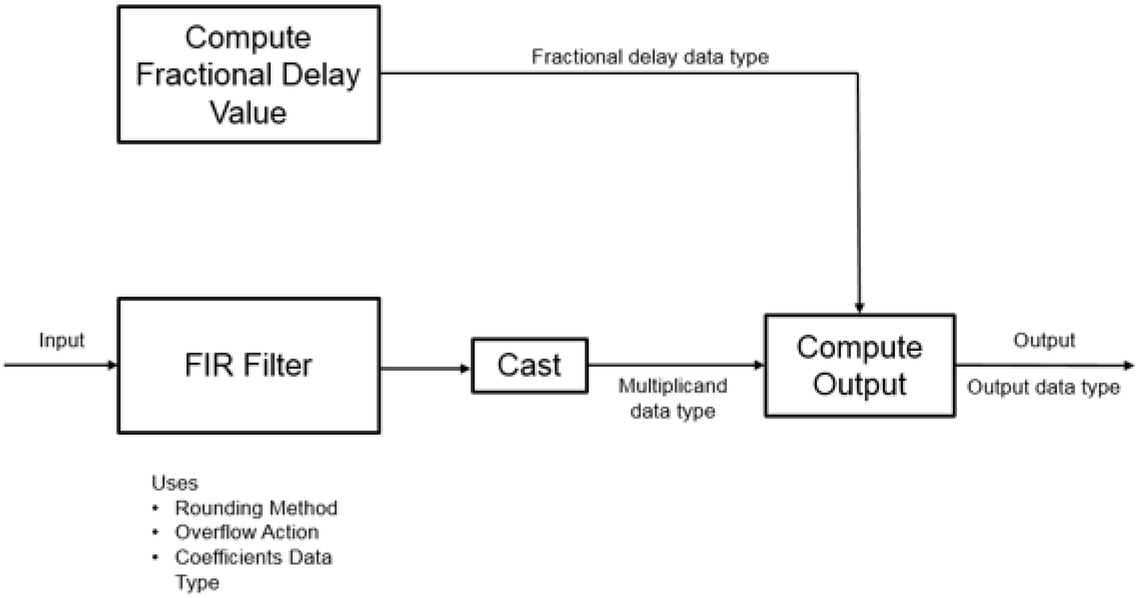
Data type of the output data type, specified as one of the following:

- `Same word length as input` (default) — Output word length and fraction lengths are the same as the input.
- `Same as accumulator` — Output word length and fraction lengths are the same as the accumulator.
- `numerictype(1,16)` — Signed fixed-point output data type with 16-bit word length. To give the best possible precision, the fraction length is computed based on the input range. The dynamic range of the input is preserved.
- `numerictype(1,16,0)` — Signed fixed-point output data type with 16-bit word length and zero fraction length.

This property is not tunable.

Fixed-Point Data Types

The signal flow diagram shows the data types used within the farrow rate converter for fixed-point signals and floating-point signals. You can specify these data types in the Farrow rate converter. If the input is floating point, all the data types with in the signal flow diagram have the same data type as the input, which can be single or double.



If the input is fixed point, the FIR filter uses the rounding mode, overflow mode, and the coefficients data type data you provide to the Farrow rate converter. The accumulator data type and the product data type in the signal flow are full precision.

Methods

cost	Implementation cost
freqz	Frequency response
getPolynomialCoefficients	Polynomial filter coefficients
getActualOutputRate	Actual output rate, accounting for tolerance
getRateChangeFactors	Overall interpolation and decimation factors
info	Filter implementation details
reset	Reset internal states of polynomial sample rate converter
step	Convert sample rate of signal

Common to All System Objects	
clone	Create System object with same property values
getNumInpu	Expected number of inputs to a System object
getNumOutp	Expected number of outputs of a System object
isLocked	Check locked states of a System object (logical)
release	Allow System object property value changes

Examples

Upsample an Audio Signal Using Farrow Sample Rate Converter

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

Create a Farrow rate converter object to convert an audio signal from 44.1 kHz to 96 kHz. Set the polynomial order for the Farrow filter.

```
fs1 = 44.1e3;
fs2 = 96e3;
LagrangeOrder = 2; % 1 = linear interpolation
frc = dsp.FarrowRateConverter('InputSampleRate',fs1,...
                              'OutputSampleRate',fs2,...
                              'PolynomialOrder',LagrangeOrder);
ar = dsp.AudioFileReader('guitar10min.ogg','SamplesPerFrame',14700);
aw = dsp.AudioFileWriter('guitar10min_96kHz.wav','SampleRate',fs2);
```

Check the resulting interpolation (L) and decimation (M) factors.

```
[L,M] = getRateChangeFactors(frc)
```

```
L =

   320

M =

   147
```

Display the polynomial the object uses to fit the input samples.

```
coeffs = getPolynomialCoefficients(frc)
```

```
coeffs =

    0.5000   -0.5000         0
   -1.0000         0    1.0000
    0.5000    0.5000         0
```

Convert 100 frames of the audio signal. Write the result to a file.

```
for n = 1:1:100
   x = ar();
   y = frc(x);
   aw(y);
end
```

Release the `AudioFileWriter` object to complete creation of the output file.

```
release(aw)
release(ar)
```

Plot the input and output signals of the 100th frame of data. Delay the input to compensate for the latency introduced by the filter.

```
t1 = 0:1/fs1:1/30-1/fs1;
t2 = 0:1/fs2:1/30-1/fs2;

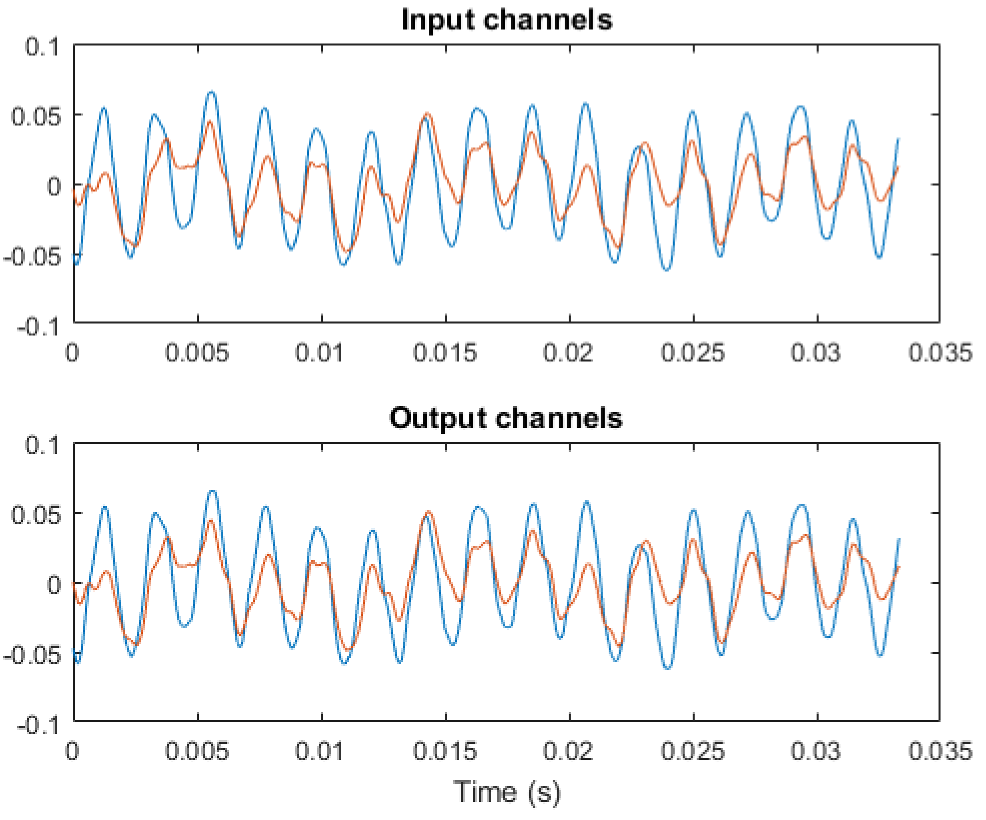
delay = ceil((LagrangeOrder+1)/2)/fs1;
el1 = 1:length(t1)-delay;
el2 = 1:length(t2);
el2(1:delay) = [];

figure

subplot(2,1,1)
plot(t1(1:length(el1)),x(el1,1))
hold on
plot(t1(1:length(el1)),x(el1,2))
title('Input channels')

subplot(2,1,2)
plot(t2(1:length(el2)),y(el2,1))
```

```
hold on
plot(t2(1:length(el2)),y(el2,2))
xlabel('Time (s)')
title('Output channels')
```



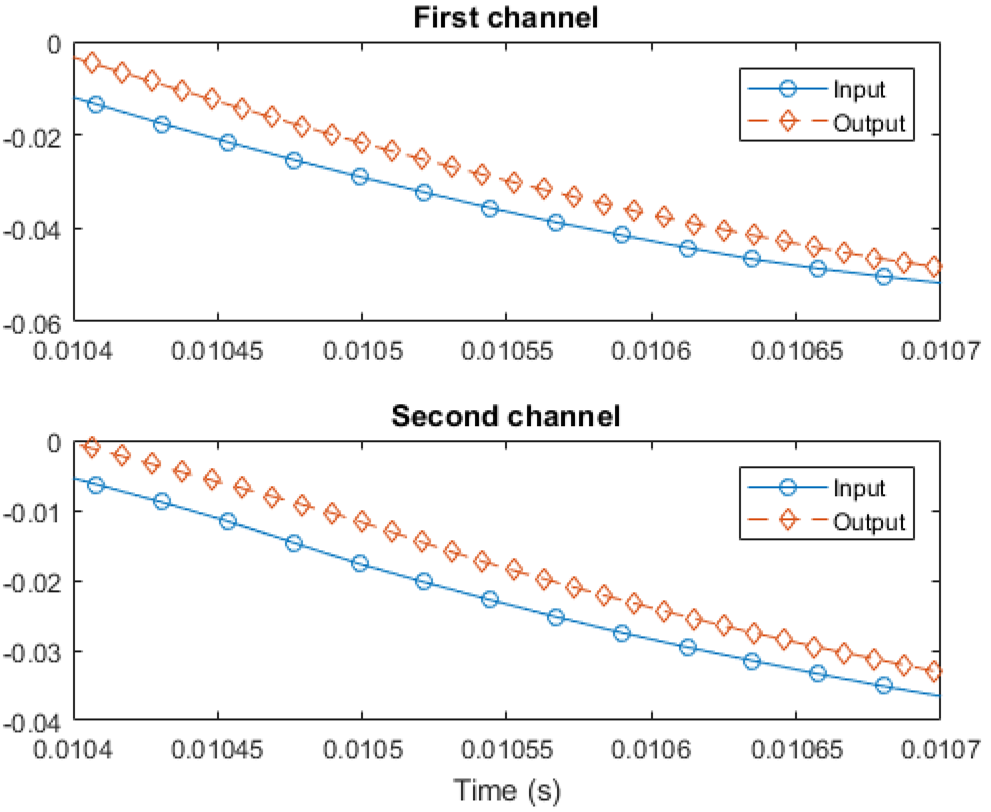
Zoom in to see the difference in sample rates.

```
figure

subplot(2,1,1)
plot(t1(1:length(el1)),x(el1,1),'o-')
hold on
plot(t2(1:length(el2)),y(el2,1),'d--')
xlim([0.0104 0.0107])
title('First channel')
```

```
legend('Input','Output')

subplot(2,1,2)
plot(t1(1:length(el1)),x(el1,2),'o-')
hold on
plot(t2(1:length(el2)),y(el2,2),'d--')
xlim([0.0104 0.0107])
xlabel('Time (s)')
title('Second channel')
legend('Input','Output')
```



Using Output Tolerance To Reduce Input Size Restriction

Create a Farrow rate converter with 0% tolerance. The output rate matches `OutputSampleRate` exactly. However, the input size must be a multiple of the decimation factor, M. In this case M is 320.

```
frc = dsp.FarrowRateConverter('InputSampleRate', 96e3,'OutputSampleRate',44.1e3);
FsOut = getActualOutputRate(frc)
[L,M] = getRateChangeFactors(frc)
```

```
FsOut =

       44100
```

```
L =

   147

M =

   320
```

Allow a 1% tolerance on the output rate and observe the difference in decimation factor. M is now only 13. The lower decimation factor allows more flexibility in input size. The output rate is within the range `OutputSampleRate` ± 1%.

```
frc.OutputRateTolerance = 0.01;
FsOut = getActualOutputRate(frc)
[Le,Me] = getRateChangeFactors(frc)
```

```
FsOut =

   4.4308e+04

Le =

     6

Me =

    13
```

Algorithm

Farrow filters implement piecewise polynomial interpolation using Horner's rule to compute samples from the polynomial. The polynomial coefficients used to fit the input samples correspond to the Lagrange interpolation coefficients.

Once a polynomial is fitted to the input data, the value of the polynomial can be calculated at any point. Therefore, a polynomial filter allows for interpolation at arbitrary locations between input samples.

You can use a polynomial of any order to fit to the existing samples. However, since large order polynomials oscillate a lot, polynomials of order 1, 2, 3, or 4 are used in practice.

The block computes interpolated values at the desired locations by varying only the fractional interval, μ. This interval is the distance between the previous input sample and the current output sample. All filter coefficients remain constant.

- The input samples, x, are filtered using $M + 1$ FIR filters, where M is the polynomial order.
- The outputs of these filters are multiplied by the fractional delay, μ.
- The output, y, is the sum of the multiplication results.

Topics

"Efficient Sample Rate Conversion Between Arbitrary Factors"

Introduced in R2014b

cost

System object: dsp.FarrowRateConverter
Package: dsp

Implementation cost

Syntax

`c = cost(src)`

Description

`c = cost(src)` returns a structure, `c`, whose fields contain information about the computational cost of implementing a polynomial sample rate converter, `src`.

Input Arguments

`src` — Polynomial sample rate converter

`FarrowRateConverter` System object

Polynomial sample rate converter, specified as a `FarrowRateConverter` System object.

Output Arguments

`c` — Output structure

structure

Output structure containing information about the computational cost of `src`, including the number of:

- Coefficients
- States
- Multiplications per unit sample

- Additions per unit sample

Examples

Computational Cost of Farrow Rate Converter

Create a polynomial sample rate converter with default values. Determine its computational cost: the number of coefficients, states, multiplications per unit sample, and additions per unit sample.

```
frc = dsp.FarrowRateConverter;
cst = cost(frc)
```

```
cst = 

  struct with fields:

                  NumCoefficients: 16
                        NumStates: 3
    MultiplicationsPerInputSample: 13.0612
          AdditionsPerInputSample: 11.9728
```

Repeat the computation, allowing for a 10% tolerance in the output sample rate.

```
frc.OutputRateTolerance = 0.1;
ctl = cost(frc)
```

```
ctl = 

  struct with fields:

                  NumCoefficients: 16
                        NumStates: 3
    MultiplicationsPerInputSample: 12
          AdditionsPerInputSample: 11
```

freqz

System object: dsp.FarrowRateConverter
Package: dsp

Frequency response

Syntax

```
[h,fout] = freqz(src,n,range)
[h,fout] = freqz(src,fin)
```

Description

`[h,fout] = freqz(src,n,range)` returns the complex frequency response, `h`, of the polynomial sample rate converter, `src`, evaluated at the `n` frequencies returned in `fout`. `range` is the frequency range over which the response is computed. The sample rate is taken to be the largest of `InputSampleRate` and `OutputSampleRate`.

`[h,fout] = freqz(src,fin)` returns the complex frequency response evaluated at the frequency points specified in the vector `fin`. `fin` is assumed to be expressed in hertz.

Input Arguments

`src` — Polynomial sample rate converter

`FarrowRateConverter` System object

Polynomial sample rate converter, specified as a `FarrowRateConverter` System object.

`n` — Number of evaluation points

512 (default) | positive integer

Number of frequencies for response evaluation, specified as a positive integer scalar. If not specified, `n` defaults to 512.

`range` — Range of frequencies

`'half'` (default) | `'whole'`

Range of frequencies considered when computing the frequency response, specified as either `'half'` (from 0 to π) or `'whole'` (from 0 to 2π). If not specified, `range` defaults to `'half'`.

`fin` — Frequencies
vector

Frequencies at which the response is evaluated, specified as a vector.

Output Arguments

`h` — Complex frequency response
vector

Complex frequency response, returned as a vector.

`fout` — Frequencies
vector

Frequencies at which the response is evaluated, returned as a vector.

Examples

Frequency Response of Farrow Rate Converter

Create a polynomial sample rate converter with default properties. Compute and display the frequency response.

```
frc = dsp.FarrowRateConverter;
[h,f] = freqz(frc);
plot(f,20*log10(abs(h)))

getPolynomialCoefficients

System object: dsp.FarrowRateConverter
Package: dsp

Polynomial filter coefficients

Syntax

```
[c] = getPolynomialCoefficients(src)
```

Description

`[c] = getPolynomialCoefficients(src)` returns the polynomial coefficients that the polynomial filter sample rate converter, `src`, uses to achieve the requested rate conversion.

Input Arguments

`src` — Polynomial filter sample rate converter

`FarrowRateConverter` System object

Polynomial sample rate converter, specified as a `FarrowRateConverter` System object.

Output Arguments

`c` — Polynomial filter coefficients

matrix

Polynomial filter coefficients, returned as a matrix.

Examples

Polynomial Coefficients of the Default Farrow Rate Converter

Create a default Farrow Rate Converter object to convert a signal from 44.1 kHz to 48 kHz.

```
FRC = dsp.FarrowRateConverter()
```

```
FRC =

  dsp.FarrowRateConverter with properties:

   Main
        InputSampleRate: 44100
       OutputSampleRate: 48000
    OutputRateTolerance: 0
          Specification: 'Polynomial order'
        PolynomialOrder: 3

  Use get to show all properties
```

Check the self-designed polynomial.

```
coeffs = getPolynomialCoefficients(FRC)
```

```
coeffs =

   -0.1667    0.5000   -0.3333         0
    0.5000   -1.0000   -0.5000    1.0000
   -0.5000    0.5000    1.0000         0
    0.1667         0   -0.1667         0
```

getActualOutputRate

System object: dsp.FarrowRateConverter
Package: dsp

Actual output rate, accounting for tolerance

Syntax

```
fsout = getActualOutputRate(src)
```

Description

`fsout = getActualOutputRate(src)` returns the actual output sample rate yielded by a `FarrowRateConverter` System object, accounting for the `OutputRateTolerance` parameter.

Input Arguments

`src` — Polynomial filter sample rate converter

`FarrowRateConverter` System object

Polynomial sample rate converter, specified as a `FarrowRateConverter` System object.

Output Arguments

`fsout` — Actual output sample rate

scalar

Actual output sample rate, returned as a scalar expressed in hertz.

Examples

Output Sample Rate of Farrow Rate Converter with Given Tolerance

Get the actual output sample rate for conversion between 44.1 kHz and 48 kHz, given a tolerance of 1%.

```
frc = dsp.FarrowRateConverter();
frc.OutputRateTolerance = 0.01;
FsOut = getActualOutputRate(frc)
```

```
FsOut =

   4.8109e+04
```

getRateChangeFactors

System object: dsp.FarrowRateConverter
Package: dsp

Overall interpolation and decimation factors

Syntax

```
[L,M] = getRateChangeFactors(src)
```

Description

`[L,M] = getRateChangeFactors(src)` returns the overall interpolation factor, `L`, and the overall decimation factor, `M`, corresponding to the polynomial filter sample rate converter, `src`. The overall decimation factor affects the allowable frame size of the input signal, which must be an integer multiple of `M`.

Input Arguments

`src` — Polynomial sample rate converter

`FarrowRateConverter` System object

Polynomial sample rate converter, specified as a `FarrowRateConverter` System object.

Output Arguments

`L` — Overall interpolation factor

scalar

Overall interpolation factor, returned as a scalar.

`M` — Overall decimation factor

scalar

Overall decimation factor, returned as a scalar.

Examples

Resampling Factors of Farrow Rate Converter

Create a default Farrow rate converter object to convert a signal from 44.1 kHz to 48 kHz. Determine its overall interpolation (L) and decimation (M) factors.

```
frc = dsp.FarrowRateConverter
[L,M] = getRateChangeFactors(frc)
```

```
frc = 

  dsp.FarrowRateConverter with properties:

   Main
        InputSampleRate: 44100
       OutputSampleRate: 48000
    OutputRateTolerance: 0
          Specification: 'Polynomial order'
        PolynomialOrder: 3

  Use get to show all properties

L =

   160

M =

   147
```

info

System object: dsp.FarrowRateConverter
Package: dsp

Filter implementation details

Syntax

`info(src)`

Description

`info(src)` displays information about the `FarrowRateConverter` System object, `src`.

Input Arguments

`src` — Polynomial sample rate converter
`FarrowRateConverter` System object

Polynomial sample rate converter, specified as a `FarrowRateConverter` System object.

Examples

Displaying Filter Information for Farrow Rate Converter

Use the `info` method to display the filter implementation details of a Farrow rate converter object.

```
frc = dsp.FarrowRateConverter;
info(frc)
```

```

reset

System object: dsp.FarrowRateConverter
Package: dsp

Reset internal states of polynomial sample rate converter

Syntax

`reset(src)`

Description

`reset(src)` resets the internal states of a polynomial `FarrowRateConverter` System object, `src`, to their initial values.

Input Arguments

`src` — Polynomial sample rate converter
`FarrowRateConverter` System object

Polynomial sample rate converter, specified as a `FarrowRateConverter` System object.

step

System object: dsp.FarrowRateConverter
Package: dsp

Convert sample rate of signal

Syntax

`y = step(src,x)`

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`y = step(src,x)` resamples input `x` to create output `y` according to the rate conversion defined by `src`.

Input Arguments

`src` — Polynomial sample rate converter

`FarrowRateConverter` System object

Polynomial sample rate converter, specified as a `FarrowRateConverter` System object.

`x` — Input signal

vector | matrix

Input signal, specified as a vector or matrix. The row length of `x` must be a multiple of the overall decimation factor. Each column of `x` is treated as a separate channel.

Output Arguments

y — Resampled signal

vector | matrix

Resampled signal, returned as a vector or matrix.

Examples

Upsample an Audio Signal Using Farrow Sample Rate Converter

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

Create a Farrow rate converter object to convert an audio signal from 44.1 kHz to 96 kHz. Set the polynomial order for the Farrow filter.

```
fs1 = 44.1e3;
fs2 = 96e3;
LagrangeOrder = 2; % 1 = linear interpolation
frc = dsp.FarrowRateConverter('InputSampleRate',fs1,...
                              'OutputSampleRate',fs2,...
                              'PolynomialOrder',LagrangeOrder);
ar = dsp.AudioFileReader('guitar10min.ogg','SamplesPerFrame',14700);
aw = dsp.AudioFileWriter('guitar10min_96kHz.wav','SampleRate',fs2);
```

Check the resulting interpolation (L) and decimation (M) factors.

```
[L,M] = getRateChangeFactors(frc)
```

```
L =

   320

M =

   147
```

Display the polynomial the object uses to fit the input samples.

```
coeffs = getPolynomialCoefficients(frc)
```

```
coeffs =

    0.5000   -0.5000         0
   -1.0000         0    1.0000
    0.5000    0.5000         0
```

Convert 100 frames of the audio signal. Write the result to a file.

```
for n = 1:1:100
   x = ar();
   y = frc(x);
   aw(y);
end
```

Release the `AudioFileWriter` object to complete creation of the output file.

```
release(aw)
release(ar)
```

Plot the input and output signals of the 100th frame of data. Delay the input to compensate for the latency introduced by the filter.

```
t1 = 0:1/fs1:1/30-1/fs1;
t2 = 0:1/fs2:1/30-1/fs2;

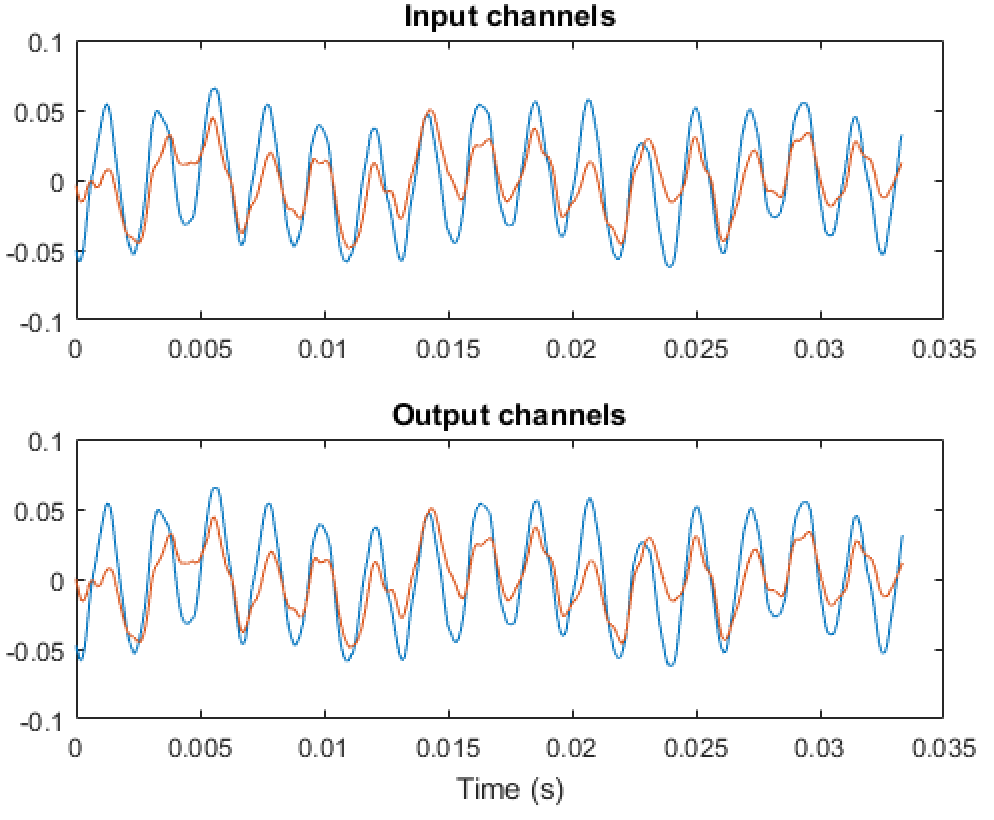
delay = ceil((LagrangeOrder+1)/2)/fs1;
el1 = 1:length(t1)-delay;
el2 = 1:length(t2);
el2(1:delay) = [];

figure

subplot(2,1,1)
plot(t1(1:length(el1)),x(el1,1))
hold on
plot(t1(1:length(el1)),x(el1,2))
title('Input channels')

subplot(2,1,2)
```

```
plot(t2(1:length(el2)),y(el2,1))
hold on
plot(t2(1:length(el2)),y(el2,2))
xlabel('Time (s)')
title('Output channels')
```



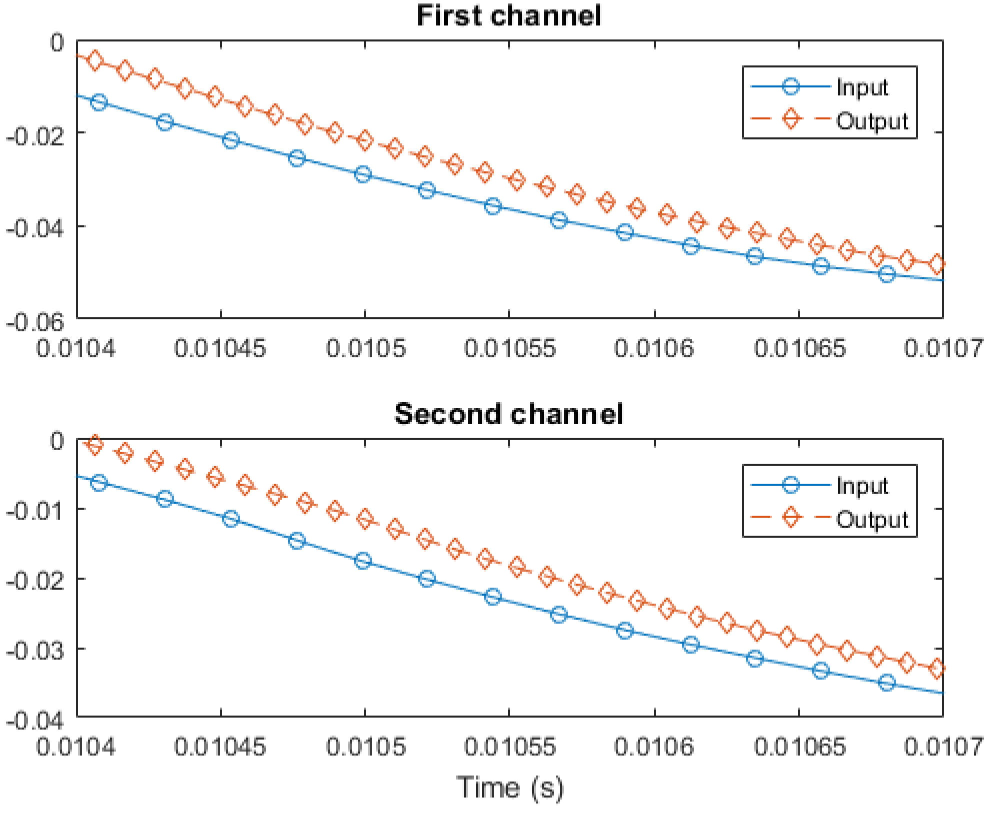
Zoom in to see the difference in sample rates.

```
figure

subplot(2,1,1)
plot(t1(1:length(el1)),x(el1,1),'o-')
hold on
plot(t2(1:length(el2)),y(el2,1),'d--')
```

```
xlim([0.0104 0.0107])
title('First channel')
legend('Input','Output')

subplot(2,1,2)
plot(t1(1:length(el1)),x(el1,2),'o-')
hold on
plot(t2(1:length(el2)),y(el2,2),'d--')
xlim([0.0104 0.0107])
xlabel('Time (s)')
title('Second channel')
legend('Input','Output')
```



dsp.FastTransversalFilter System object

Package: dsp

Fast Transversal filter

Description

The `dsp.FastTransversalFilter` computes output, error and coefficients using a fast transversal least-squares FIR adaptive filter.

To implement the adaptive FIR filter object:

1. Define and set up your adaptive FIR filter object. See “Construction” on page 4-670.
2. Call step to implement the filter according to the properties of `dsp.FastTransversalFilter`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`ftf = dsp.FastTransversalFilter` returns a System object, `ftf`, which is a fast transversal, least-squares FIR adaptive filter. This System object is used to compute the filtered output and the filter error for a given input and desired signal.

`ftf = dsp.FastTransversalFilter('`*`PropertyName`*`',` *`PropertyValue`*`,...)` returns a `FastTransversalFilter` System object, `ftf`, with each specified property set to the specified value.

`ftf =`
`dsp.FastTransversalFilter(LEN,'`*`PropertyName`*`',`*`PropertyValue`*`,...)`

returns a `FastTrasversalFilter` System object, `ftf`. In this case, the Length property set to `LEN`, and other specified properties set to the specified values.

Properties

`Method`

Method to calculate filter coefficients

Specify the method used to calculate filter coefficients as one of `'Fast transversal least-squares'` |`'Sliding-window fast transversal least-squares'`. The default value is `'Fast transversal least-squares'`. For algorithms used to implement these three different methods, refer to [1]. This property is nontunable.

`Length`

Length of filter coefficients vector

Specify the length of the FIR filter coefficients vector as a positive integer value. This property is nontunable.

The default value is 32.

`SlidingWindowBlockLength`

Width of sliding window

Specify the width of the sliding window as a positive integer value greater than or equal to the `Length` property value. This property applies only if the `Method` property is set to `'Sliding-window fast transversal least-squares'`. The default vale is the value of the `Length` property. This property is nontunable.

`ForgettingFactor`

Fast transversal filter forgetting factor

Specify the fast transversal filter forgetting factor as a positive numeric value. Setting this value to 1 denotes infinite memory while adaptation. Setting this property value to 1 denotes infinite memory while adapting to find the new filter. For best results, set this property to a value that lies in the range `[1-0.5/L, 1]`, where `L` is the Length property value. This property applies only if the Method property is set to `'Fast transversal least-squares'`. The default value is `1`. This property is tunable.

InitialPredictionErrorPower

Initial prediction error power

Specify the initial value of the forward and backward prediction error vectors as a positive numeric scalar. This scalar should be sufficiently large to maintain stability and prevent an excessive number of Kalman gain rescues. The default value is `10`.

This property is tunable.

InitialConversionFactor

Initial conversion factor (gamma)

Specify the initial value of the conversion factor of the fast transversal filter. If the `Method` property is set to `'Fast transversal least-squares'`, this property must be a positive numeric value less than or equal to `1`. In this case, the default value is `1`. If the `Method` property is set to `'Sliding-window fast transversal least-squares'`, this property must be a 2-element numeric vector. The first element of this vector must lie within the range `[0,1]`, and the second element must be less than or equal to `-1`. In this case, the default value is `[1, -1]`.

This property is tunable.

InitialCoefficients

Initial coefficients of the filter

Specify the initial values of the FIR adaptive filter coefficients as a scalar or a vector of length equal to the value of the `Length` property. The default value is `0`.

This property is tunable.

LockCoefficients

Locked status of the coefficient updates

Specify whether to lock the filter coefficient values. By default, the value of this property is `false`, and the object continuously updates the filter coefficients. If this property is set to `true`, the filter coefficients do not update and their values remain the same.

This property is tunable.

Methods

msesim	Mean-square error for Fast Transversal filter
reset	Reset filter states for Fast Transversal filter
step	Apply Fast Transversal filter to input

Common to All System Objects	
clone	Create System object with same property values
getNumInpu	Expected number of inputs to a System object
getNumOutp	Expected number of outputs of a System object
isLocked	Check locked states of a System object (logical)
release	Allow System object property value changes

Examples

System Identification Using Fast Transversal Filter

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

```
ftf1 = dsp.FastTransversalFilter(11,'ForgettingFactor',0.99);
filt = dsp.FIRFilter;
filt.Numerator = fir1(10,.25);
x = randn(1000,1);
d = filt(x) + 0.01*randn(1000,1);
[y,e] = ftf1(x,d);
w = ftf1.Coefficients;
subplot(2,1,1);
plot(1:1000,[d,y,e]);
title('System Identification of an FIR filter');
```

```
legend('Desired','Output','Error');
xlabel('time index');
ylabel('signal value');
subplot(2,1,2);
stem([filt.Numerator; w].');
legend('Actual','Estimated');
xlabel('coefficient #');
ylabel('coefficient value');
```

msesim

System object: dsp.FastTransversalFilter
Package: dsp

Mean-square error for Fast Transversal filter

Syntax

```
MSE = msesim(sysObj,X,D)
[MSE,MEANW,W,TRACEK] = msesim(sysObj,X,D)
[...] = msesim(sysObj,X,D,M)
```

Description

`MSE = msesim(sysObj,X,D)` returns a sequence of mean-square errors. This column vector contains estimates of the mean-square error of the adaptive filter at each time instant. The length of `MSE` is equal to `SIZE(X,1)`. The columns of the matrix `X` contain individual input signal sequences, and the columns of the matrix `D` contain corresponding desired response signal sequences.

`[MSE,MEANW,W,TRACEK] = msesim(sysObj,X,D)` calculates three parameters corresponding to the simulated behavior of the adaptive filter defined by `sysObj`. `MEANW` is a sequence of coefficient vector means. The columns of this matrix contain estimates of the mean values of the adaptive filter coefficients at each time instant. The dimensions of `MEANW` are `(SIZE(X,1))` by `(sysObj.length)`. `W` is an estimate of the final values of the adaptive filter coefficients for the algorithm corresponding to `sysObj`. `TRACEK` is a sequence of total coefficient error powers. This column vector contains estimates of the total coefficient error power of the adaptive filter at each time instant. The length of `TRACEK` is equal to `SIZE(X,1)`.

`[...] = msesim(sysObj,X,D,M)` specifies an optional decimation factor for computing `MSE`, `MEANW`, and `TRACEK`. If `M` > `1`, every M^{th} predicted value of each of these sequences is saved. If omitted, the value of `M` is the default, which is 1.

reset

System object: dsp.FastTransversalFilter
Package: dsp

Reset filter states for Fast Transversal filter

Syntax

`reset(sysObj)`

Description

`reset(sysObj)` resets the internal states of the System object, `sysObj`, to their initial values. The reset method is always a no-op for unlocked System objects, as the states may not be allocated when the object is not locked.

step

System object: dsp.FastTransversalFilter
Package: dsp

Apply Fast Transversal filter to input

Syntax

```
[Y, ERR] = step(sysObj, x, D)
Y = step(sysObj,x)
[Y1,...,YN] = step(sysObj,x)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`[Y, ERR] = step(sysObj, x, D)` filters the input `x`, using D as the desired signal, and returns the filtered output in `Y` and the filter error in `ERR`. The System object estimates the filter weights needed to minimize the error between the output signal and the desired signal.

`Y = step(sysObj,x)` processes the input data, `x`, to produce the output, `Y`, from the System object, `sysObj`. `[Y1,...,YN] = step(sysObj,x)` produces `N` outputs.

Every System object has a step method. The step method processes the input data according to the object algorithm. The number of input and output arguments depends on the algorithm, and may depend also on one or more property settings. The step method for some objects accepts fixed-point (fi) inputs.

Calling step on an object puts that object into a locked state. When locked, you cannot change nontunable properties or any input characteristics (size, data type and complexity) without reinitializing (unlocking and relocking) the object.

Note: `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.FFT System object

Package: dsp

Discrete Fourier transform

Description

The `FFT` object computes the discrete Fourier transform (DFT) of an input. The object uses one or more of the following fast Fourier transform (FFT) algorithms depending on the complexity of the input and whether the output is in linear or bit-reversed order:

- Double-signal algorithm
- Half-length algorithm
- Radix-2 decimation-in-time (DIT) algorithm
- Radix-2 decimation-in-frequency (DIF) algorithm
- An algorithm chosen by FFTW ,

To compute the DFT of an input:

1. Define and set up your `FFT` object. See "Construction" on page 4-680.
2. Call step to compute the DFT of the input according to the properties of `dsp.FFT`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`fft = dsp.FFT` returns a `FFT` object, `H`, that computes the DFT of an *N*-D array. For column vectors or multidimensional arrays, the `FFT` object computes the DFT along the first dimension. If the input is a row vector, the `FFT` object computes a row of single-sample DFTs and issues a warning.

`H = dsp.FFT('PropertyName',PropertyValue, ...)` returns a `FFT` object, `H`, with each property set to the specified value.

Properties

`FFTImplementation`

FFT implementation

Specify the implementation used for the FFT as one of `Auto | Radix-2 | FFTW`. When you set this property to `Radix-2`, the FFT length must be a power of two.

`BitReversedOutput`

Order of output elements relative to input elements

Designate order of output channel elements relative to order of input elements. Set this property to `true` to output the frequency indices in bit-reversed order. The default is `false`, which corresponds to a linear ordering of frequency indices.

`Normalize`

Divide butterfly outputs by two

Set this property to `true` if the output of the FFT should be divided by the FFT length. This option is useful when you want the output of the FFT to stay in the same amplitude range as its input. This is particularly useful when working with fixed-point data types.

The default value of this property is `false` with no scaling.

`FFTLengthSource`

Source of FFT length

Specify how to determine the FFT length as `Auto` or `Property`. When you set this property to `Auto`, the FFT length equals the number of rows of the input signal. The default is `Auto`.

`FFTLength`

FFT length

Specify the FFT length. This property applies when you set the `FFTLengthSource` on page 4-681 property to `Property`. The default is `64`.

This property must be a power of two when the input is a fixed-point data type, or when you set the `BitReversedOutput` on page 4-681 property to `true`, or when you set the `FFTImplementation` on page 4-681 property to `Radix-2`.

`WrapInput`

Boolean value of wrapping or truncating input

Wrap input data when FFT length is shorter than input length. If this property is set to true, modulo-length data wrapping occurs before the FFT operation, given FFT length is shorter than the input length. If this property is set to false, truncation of the input data to the FFT length occurs before the FFT operation. The default is `true`.

Fixed-Point Properties

`RoundingMethod`

Rounding method for fixed-point operations

Specify the rounding method as one of `Ceiling`, `Convergent`, `Floor`, `Nearest`, `Round`, `Simplest`, `Zero`. The default is `Floor`.

`OverflowAction`

Overflow action for fixed-point operations

Specify the overflow action as `Wrap` or `Saturate`. The default is `Wrap`.

`SineTableDataType`

Sine table word and fraction lengths

Specify the sine table data type as `Same word length as input` or `Custom`. The default is `Same word length as input`.

`CustomSineTableDataType`

Sine table word and fraction lengths

Specify the sine table fixed-point type as an unscaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `SineTableDataType` on page 4-682 property to `Custom`. The default is `numerictype([],16)`.

`ProductDataType`

Product word and fraction lengths

Specify the product data type as `Full precision`, `Same as input`, or `Custom`. The default is `Full precision`.

`CustomProductDataType`

Product word and fraction lengths

Specify the product fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `ProductDataType` on page 4-683 property to `Custom`. The default is `numerictype([],32,30)`.

`AccumulatorDataType`

Accumulator word and fraction lengths

Specify the accumulator data type as `Full precision`, `Same as input`, `Same as product`, or `Custom`. The default is `Full precision`.

`CustomAccumulatorDataType`

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `AccumulatorDataType` on page 4-683 property to `Custom`. The default is `numerictype([],32,30)`.

`OutputDataType`

Output word and fraction lengths

Specify the output data type as one of `Full precision`, `Same as input`, `Custom`. The default is `Full precision`.

`CustomOutputDataType`

Output word and fraction lengths

Specify the output fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `OutputDataType` on page 4-683 property to `Custom`. The default is `numerictype([],16,15)`.

Methods

step	Discrete Fourier transform of input

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Single-Sided Amplitude Spectrum Of a Signal

Find frequency components of a signal in additive noise.

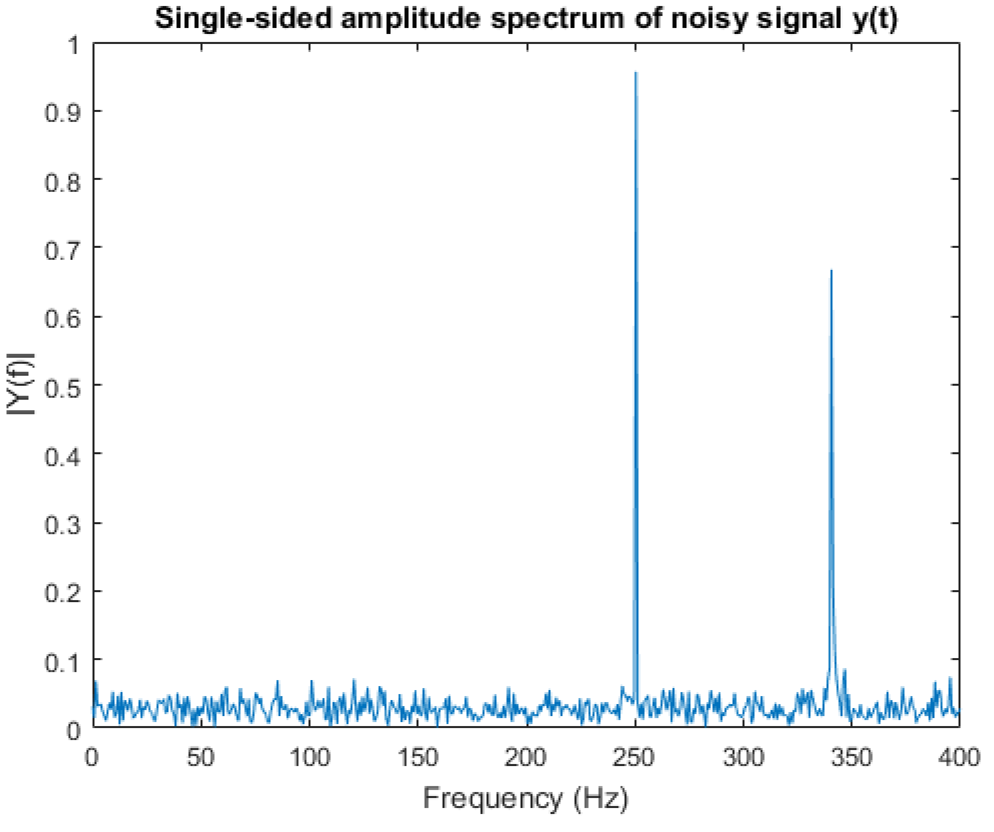
Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

```
Fs = 800; L = 1000;
t = (0:L-1)'/Fs;
x = sin(2*pi*250*t) + 0.75*cos(2*pi*340*t);
y = x + .5*randn(size(x)); % noisy signal
ft = dsp.FFT('FFTLengthSource', 'Property', ...
    'FFTLength', 1024);
Y = ft(y);
```

Plot the single-sided amplitude spectrum

```
plot(Fs/2*linspace(0,1,512), 2*abs(Y(1:512)/1024));
```

```
title('Single-sided amplitude spectrum of noisy signal y(t)');
xlabel('Frequency (Hz)'); ylabel('|Y(f)|');
```



Algorithms

This object implements the algorithm, inputs, and outputs described on the FFT block reference page. The object properties correspond to the block parameters.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- "System Objects in MATLAB Code Generation" (MATLAB Coder).
- When the following conditions apply, the executable generated from this System object relies on prebuilt dynamic library files (`.dll` files) included with MATLAB:
  - `FFTImplementation` is set to `'FFTW'`.
  - `FFTImplementation` is set to `'Auto'`, `FFTLengthSource` is set to `'Property'`, and `FFTLength` is not a power of two.

  Use the `packNGo` function to package the code generated from this System object and all the relevant files in a compressed zip file. Using this zip file, you can relocate, unpack, and rebuild your project in another development environment where MATLAB is not installed. For more details, see "How To Run a Generated Executable Outside MATLAB".
- When the FFT length is a power of two, you can generate standalone C and C++ code from this System object.

Introduced in R2012a

step

System object: dsp.FFT
Package: dsp

Discrete Fourier transform of input

Syntax

`Y = step(ft,X)`

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(ft,X)` computes the FFT, `Y` , of the input `X` along the first dimension of `X`. When the `FFTLengthSource` property is `Auto`, the length of `X` along the first dimension must be a positive integer power of two. This length is also the FFT length . When the `FFTLengthSource` property is `Property`, the `FFTLength` property must be a positive integer power of two.

dsp.FilterCascade System object

Package: dsp

Create a cascade of filter System objects

Description

The `dsp.FilterCascade` object creates a multistage System object that enables cascading of filter System objects, delays, and scalar gains. To see the System objects you can assign, at the MATLAB command prompt, enter:

```
dsp.FilterCascade.helpSupportedSystemObjects
```

You can use the cascaded filter for filtering a signal, and for generating the filtering code. You can pass the `dsp.FilterCascade` System object as a stage to another `dsp.FilterCascade` System object. You can also pass `dsp.FilterCascade` System object as an input to the `cascade` function. This object supports variable-size signals if the stages within support variable-size signals.

To filter a signal using the cascaded filter:

1 Define and set up your `dsp.FilterCascade` System object. See “Construction” on page 4-689.
2 Call step to filter each channel of the input signal using the stages in the cascade. The size, data type, and complexity of the input signal must be supported by the stages in the filter cascade.
3 Run the dsp.FilterCascade.generateFilteringCode method to generate MATLAB code using the design specified through the System objects.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`filtCasc = dsp.FilterCascade` returns a System object, `filtCasc`. This System object has a single stage of the dsp.FIRFilter object.

`filtCasc = dsp.FilterCascade(`*`Filter_1`*`,`*`Filter_2`*`,...)` returns a multistage System object, `filtCasc`, with the first stage set to *`Filter_1`*, the second stage set to *`Filter_2`*, and so on. *`Filter_1`*, *`Filter_2`*, etc. can be a filter System object, a `dsp.FilterCascade` System object, delay, or a scalar gain.

`filtCasc = cascade(`*`Filter_1`*`,`*`Filter_2`*`,...)` returns a `dsp.FilterCascade` System object, `filtCasc`, with the first stage set to *`Filter_1`*, the second stage set to *`Filter_2`*, and so on. *`Filter_1`*, *`Filter_2`*, etc. can be a filter System object, a `dsp.FilterCascade` System object, or a scalar gain. `cascade` function does not support delay as a filter stage.

Properties

`Stage`*`i`* `(Stage1, Stage2,...)`

Specify the *`i`*th stage of the `dsp.FilterCascade` System object. You can assign any of the filter System objects, delay, or a scalar gain to this property. To see the System objects you can assign, at the MATLAB command prompt, enter:

```
dsp.FilterCascade.helpSupportedSystemObjects
```

The default value of this property is `dsp.FIRFilter`. For more information, see dsp.FIRFilter.

Methods

addStage	Add a new filter stage to the cascade
generateFilteringCode	Generate MATLAB code to filter using cascade
getNumStages	Get the number of stages in the cascade object

releaseStages	Release the locked state of all stages in the cascade
removeStage	Remove a stage from filter cascade
step	Process inputs using the filter cascade

More "Analysis Methods for Filter System Objects" on page 3-2.

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Filter a Signal Using Cascaded Lowpass and Highpass Filters

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Design a bandpass filter by cascading:

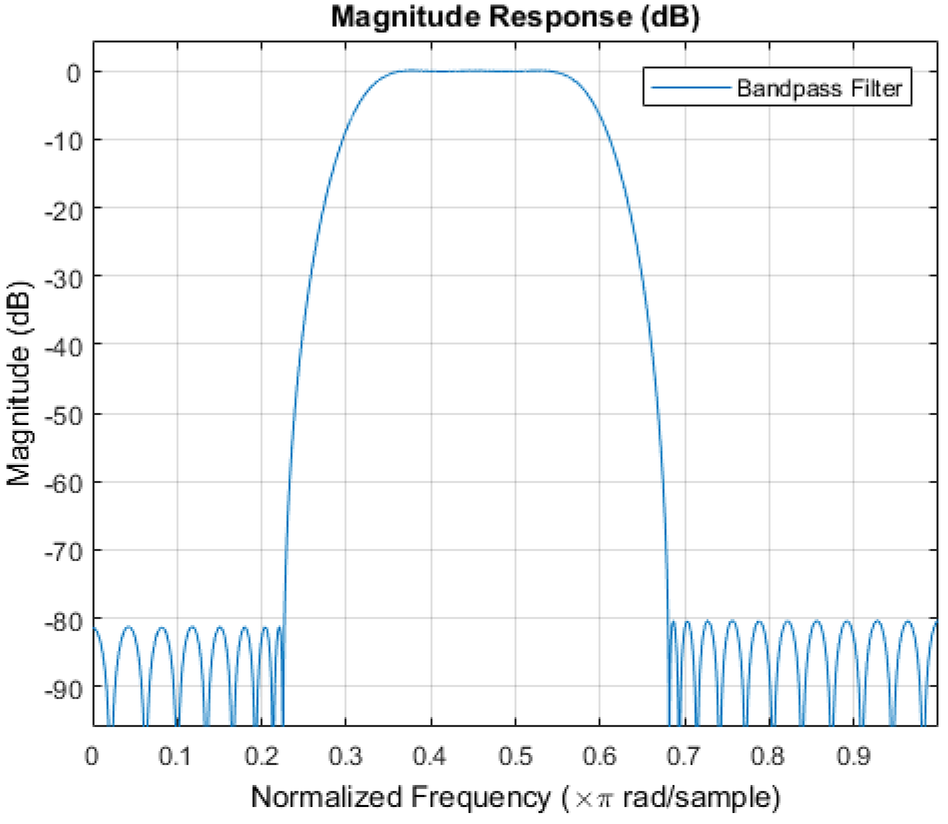
- A highpass filter with a stopband frequency of 5000 Hz and a passband frequency of 8000 Hz.
- A lowpass filter with a passband frequency of 12,000 Hz and a stopband frequency of 15,000 Hz.

Visualize the frequency response using `fvtool`.

```
lpFilt = dsp.LowpassFilter('StopbandFrequency',15000,...
    'PassbandFrequency',12000);
hpFilt = dsp.HighpassFilter('StopbandFrequency',5000,...
    'PassbandFrequency',8000);

bpFilt = dsp.FilterCascade(lpFilt,hpFilt);
```

```
fvtool(bpFilt);
legend('Bandpass Filter');
```



Pass a noisy sine wave as the input to the bandpass filter. The input is a sum of three sine waves with frequencies at 3 kHz, 10 kHz, and 15 kHz. The sampling frequency is 48 kHz. View the input and the filtered output on a spectrum analyzer.

```
Sine1 = dsp.SineWave('Frequency',3e3,'SampleRate',48e3,'SamplesPerFrame',6000);
Sine2 = dsp.SineWave('Frequency',10e3,'SampleRate',48e3,'SamplesPerFrame',6000);
Sine3 = dsp.SineWave('Frequency',15e3,'SampleRate',48e3,'SamplesPerFrame',6000);

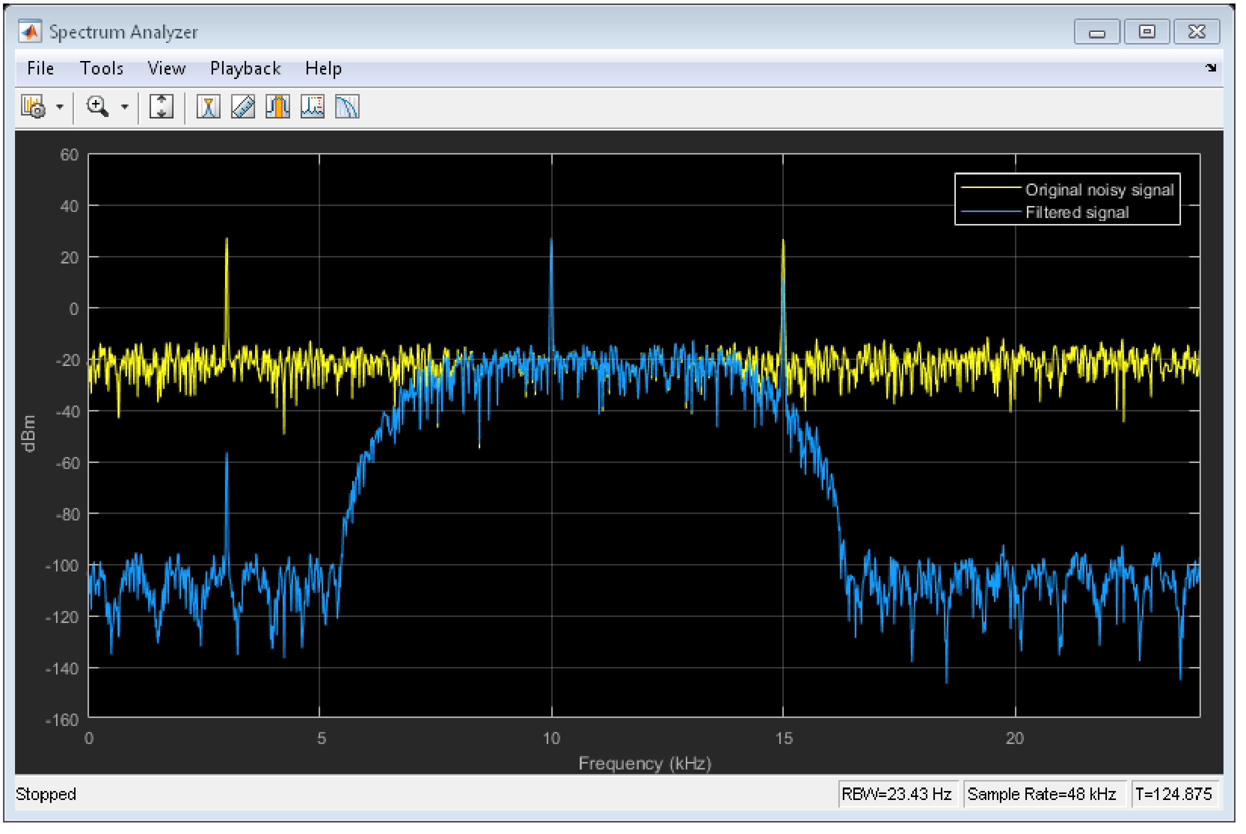
SpecAna = dsp.SpectrumAnalyzer('PlotAsTwoSidedSpectrum',false, ...
    'SampleRate',Sine1.SampleRate, ...
    'NumInputPorts',2,...
```

```
    'ShowLegend',true, ...
    'YLimits',[-160,60]);

SpecAna.ChannelNames = {'Original noisy signal','Filtered signal'};

for i = 1 : 1000
    x = Sine1()+Sine2()+Sine3()+0.1.*randn(Sine1.SamplesPerFrame,1);
    y = bpFilt(x);
    SpecAna(x,y);

end
release(SpecAna)
```



The tones at 3 kHz and 15 kHz are attenuated, and the tone at 10 kHz is preserved by the bandpass filter.

Design a Compensation Decimator for a CIC Decimator

Create a CIC decimator. Cascade the decimator with a gain.

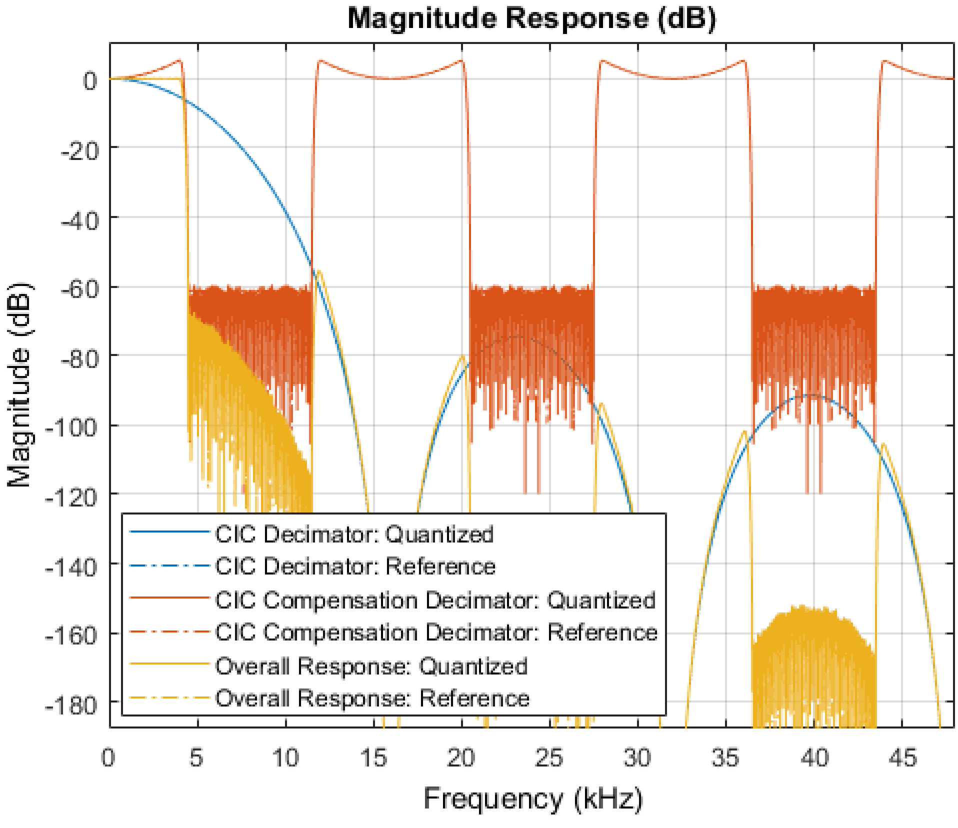
```
cicdecim = dsp.CICDecimator('DecimationFactor', 6, ...
    'NumSections', 6);
decimcasc = dsp.FilterCascade(cicdecim, 1/gain(cicdecim));
```

Design a compensation decimator and cascade it with the filter cascade, `decimcasc`.

```
fs = 16e3;     % Sampling frequency of input of compensation decimator
fPass = 4e3;   % Passband frequency
fStop = 4.5e3; % Stopband frequency
ciccomp = dsp.CICCompensationDecimator(cicdecim, ...
    'DecimationFactor', 2, ...
    'PassbandFrequency', fPass, ...
    'StopbandFrequency', fStop, ...
    'SampleRate', fs);
filtchain = dsp.FilterCascade(decimcasc, ciccomp);
```

Visualize the frequency response of the cascade of cascades.

```
f = fvtool(decimcasc, ciccomp, filtchain, 'Fs',[fs*6,fs,fs*6],...
    'Arithmetic', 'fixed');
legend(f,'CIC Decimator','CIC Compensation Decimator', ...
    'Overall Response');
```



The CIC compensation decimator has an inherent gain, `gain(cicdecim)`. By cascading with a factor of `1/gain(cicdecim)`, the filter cascade compensates for this gain.

Generate Code to Filter Using Cascade

Design a two-stage decimator with a 100 Hz transition width, a 2 kHz sampling frequency, and 60 dB attenuation in the stopband. The decimator needs to downsample by a factor of 4.

```
decimSpec = fdesign.decimator(4, 'Nyquist', 4, 'Tw,Ast', 100,60,2000);
filtCasc = design(decimSpec, 'multistage', 'SystemObject', true);
```

Verify your design using `fvtool`.

```
info(filtCasc)
fvtool(filtCasc)
```

```
ans =

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- You cannot generate code directly from `dsp.FilterCascade`. You can use the `generateFilteringCode` method to generate a MATLAB function. You can generate C/C++ code from this MATLAB function, if the filters in each stage support code generation.
- See "System Objects in MATLAB Code Generation" (MATLAB Coder).

System Objects
dsp.CICCompensationDecimator | dsp.CICDecimator | dsp.FIRFilter

Introduced in R2014b

addStage

System object: dsp.FilterCascade
Package: dsp

Add a new filter stage to the cascade

Syntax

```
addStage(FC, FILTERSYSOBJ)
addStage(FC, FILTERSYSOBJ, STAGEID)
```

Description

`addStage(FC, FILTERSYSOBJ)` adds `FILTERSYSOBJ` at the end of the filter cascade stored in the `dsp.FilterCascade` object `FC`. To see the System objects you can assign to `FILTERSYSOBJ`, at the MATLAB command prompt, enter

```
dsp.FilterCascade.helpSupportedSystemObjects
```

`addStage(FC, FILTERSYSOBJ, STAGEID)` adds `FILTERSYSOBJ` at stage position `STAGEID` of the filter cascade stored in the `dsp.FilterCascade` object `FC`. All existing filters from `STAGEID` to end of the cascade are shifted down in the cascade.

`FILTERSYSOBJ` can be any of the filter System objects provided by the DSP System Toolbox.

Examples

Add Stage to Cascade End

Add a stage at the end of the filter cascade:

```
FC = dsp.FilterCascade;
addStage(FC, dsp.IIRFilter);
```

Add Stage inside Cascade

Add a filter at the second stage of a filter cascade consisting of three filters:

```
FC = dsp.FilterCascade(dsp.CICDecimator,dsp.FIRDecimator,dsp.FIRFilter);
addStage(FC, dsp.IIRFilter, 2);
```

generateFilteringCode

System object: dsp.FilterCascade
Package: dsp

Generate MATLAB code to filter using cascade

Syntax

```
generateFilteringCode(FC)
generateFilteringCode(FC, FNAME)
```

Description

`generateFilteringCode(FC)` creates a MATLAB function in the editor that contains code to create stages of the cascade and calls `step` method on each stage in sequence.

`generateFilteringCode(FC, FNAME)` generates code and saves it to the file specified in the string `FNAME`.

Examples

Create a filter cascade object and generate code from it:

```
FC = dsp.FilterCascade(dsp.FIRFilter('Numerator',ones(1,5)),...
                           dsp.FIRDecimator);
fName = 'filterCascade.m';  % The code will be saved in this
                                % file in the current directory
generateFilteringCode(FC, fName);
```

getNumStages

System object: dsp.FilterCascade
Package: dsp

Get the number of stages in the cascade object

Syntax

`getNumStages(FC)`

Description

`getNumStages(FC)` returns the number of stages in the `dsp.FilterCascade` object, `FC`.

Examples

Get the number of stages in a filter cascade object:

```
FC = cascade(dsp.FIRFilter, dsp.IIRFilter);
N = getNumStages(FC);    % This will return 2
```

releaseStages

System object: dsp.FilterCascade
Package: dsp

Release the locked state of all stages in the cascade

Syntax

`releaseStages(FC)`

Description

`releaseStages(FC)` calls the `release` method of individual stages in the `dsp.FilterCascade` object `FC`.

For instance, if a `dsp.FilterCascade` object consists of a `dsp.FIRFilter` object and a `dsp.FIRInterpolator` object, the `releaseStages` method calls the:

- `release` method of the dsp.FIRFilter object.
- `release` method of the dsp.FIRInterpolator object.

Examples

Release Stages of a Filter Cascade

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

Create and release stages of a filter cascade.

```
firfilt = dsp.FIRFilter;
y = firfilt(randn);
FC = dsp.FilterCascade(dsp.FIRInterpolator, firfilt);
isLocked(FC.Stage2) % Returns 1
```

```
releaseStages(FC);
isLocked(FC.Stage2) % Returns 0
```

```
ans =

  logical

   1

ans =

  logical

   0
```

removeStage

System object: dsp.FilterCascade
Package: dsp

Remove a stage from filter cascade

Syntax

```
removeStage(FC)
removeStage(FC, STAGEID)
```

Description

`removeStage(FC)` removes a stage from the end of the filter cascade stored in the `dsp.FilterCascade` object `FC`.

`removeStage(FC, STAGEID)` removes the stage from the stage position `STAGEID` of the filter cascade stored in the `dsp.FilterCascade` object `FC`. All existing filters from `STAGEID` to end of the cascade are shifted up in the cascade.

Examples

Remove Stage from Cascade End

Remove a stage from the end of a filter cascade:

```
FC = dsp.FilterCascade(dsp.FIRFilter, dsp.IIRFilter);
removeStage(FC);
```

Remove Stage from Inside Cascade

Remove a filter from the third stage of a cascade consisting of four stages:

```
FC = cascade(dsp.FIRInterpolator, dsp.FIRInterpolator, ...
                dsp.FIRDecimator, dsp.FIRDecimator);
```

```
removeStage(FC, 3);
```

step

System object: dsp.FilterCascade
Package: dsp

Process inputs using the filter cascade

Syntax

```
y = step(filtCasc,x)
```

Description

Note: Alternatively, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`y = step(filtCasc,x)` runs the input `x` through the filter cascade, `filtCasc`, and returns the filtered output, `y`. The size, data type, and complexity of the input signal must be supported by the stages in the filter cascade.

Introduced in R2017a

dsp.FilteredXLMSFilter System object

Package: dsp

Filtered XLMS filter

Description

The `dsp.FilteredXLMSFilter` computes output, error and coefficients using Filtered-X Least Mean Squares FIR adaptive filter.

To implement the adaptive FIR filter object:

1. Define and set up your adaptive FIR filter object. See “Construction” on page 4-708.
2. Call step to implement the filter according to the properties of `dsp.FilteredXLMSFilter`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`fxlms = dsp.FilteredXLMSFilter` returns a filtered-x Least Mean Square FIR adaptive filter System object, `fxlms`. This System object is used to compute the filtered output and the filter error for a given input and desired signal.

`fxlms = dsp.FilteredXLMSFilter('`*`PropertyName`*`',` *`PropertyValue`*`,...)` returns a `FilteredXLMSFilter` System object, `fxlms`, with each specified property set to the specified value.

`fxlms= dsp.FilteredXLMSFilter(LEN,'`*`PropertyName`*`',`*`PropertyValue`*`,...)` returns a `FilteredXLMSFilter` System object, `fxlms`, with the Length property set to

LEN, and other specified properties set to the specified values. For the algorithm on how to implement this filter, refer to [1], [2].

Properties

Length

Length of filter coefficients vector

Specify the length of the FIR filter coefficients vector as a positive integer value. This property is nontunable.

The default value is 10.

StepSize

Adaptation step size

Specify the adaptation step size factor as a positive numeric scalar. The default value is 0.1. This property is tunable.

LeakageFactor

Adaptation leakage factor

Specify the leakage factor used in a leaky adaptive filter as a numeric value between 0 and 1, both inclusive. When the value is less than 1, the System object implements a leaky adaptive algorithm. The default value is 1, providing no leakage in the adapting method. This property is tunable.

SecondaryPathCoefficients

Coefficients of the secondary path filter model

Specify the coefficients of the secondary path filter model as a numeric vector. The secondary path connects the output actuator and the error sensor. The default value is a vector that represents the coefficients of a 10th-order FIR lowpass filter. This property is tunable.

SecondaryPathEstimate

An estimate of the secondary path filter model

Specify the estimate of the secondary path filter model as a numeric vector. The secondary path connects the output actuator and the error sensor. The default value equals to the SecondayPathCoefficients property value. This property is not tunable.

InitialCoefficients

Initial coefficients of the filter

Specify the initial values of the FIR adaptive filter coefficients as a scalar or a vector of length equal to the value of the Length property. The default value is 0.

This property is tunable.

LockCoefficients

Locked status of the coefficient updates

Specify whether to lock the filter coefficient values. By default, the value of this property is false, and the object continuously updates the filter coefficients. If this property is set to true, the filter coefficients do not update and their values remain the same.

This property is tunable.

Methods

msesim	Mean-square error for Filtered-X LMS filter
reset	Reset filter states for Filtered-X LMS filter
step	Apply Filtered-X LMS filter to input

Common to All System Objects	
clone	Create System object with same property values
getNumInpu	Expected number of inputs to a System object
getNumOutp	Expected number of outputs of a System object
isLocked	Check locked states of a System object (logical)
release	Allow System object property value changes

Examples

Active Noise Control of a Random Noise Signal

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

Generate noise, create FIR primary path system model, generate observation noise, filter the primary path system model output with added noise, and create FIR secondary path system model.

```
x  = randn(1000,1);
g  = fir1(47,0.4);
n  = 0.1*randn(1000,1);
d  = filter(g,1,x) + n;
b  = fir1(31,0.5);
```

Use the Filtered-X LMS Filter to compute the filtered output and the filter error for the input and the signal to be cancelled.

```
mu = 0.008;
fxlms = dsp.FilteredXLMSFilter(32, 'StepSize', mu, 'LeakageFactor', ...
     1, 'SecondaryPathCoefficients', b);
[y,e] = fxlms(x,d);
```

Plot the results.

```
plot(1:1000,d,'b',1:1000,e,'r');
title('Active Noise Control of a Random Noise Signal');
legend('Original','Attenuated');
xlabel('Time Index'); ylabel('Signal Value');  grid on;
```

dsp.LMSFilter | dsp.AffineProjectionFilter | dsp.FrequencyDomainAdaptiveFilter | dsp.RLSFilter | dsp.AdaptiveLatticeFilter | dsp.FIRFilter

Introduced in R2013b

msesim

System object: dsp.FilteredXLMSFilter
Package: dsp

Mean-square error for Filtered-X LMS filter

Syntax

```
MSE = msesim(sysObj,X,D)
[MSE,MEANW,W,TRACEK] = msesim(sysObj,X,D)
[...] = msesim(sysObj,X,D,M)
```

Description

`MSE = msesim(sysObj,X,D)` returns a sequence of mean-square errors. This column vector contains estimates of the mean-square error of the adaptive filter at each time instant. The length of `MSE` is equal to `SIZE(X,1)`. The columns of the matrix `X` contain individual input signal sequences, and the columns of the matrix `D` contain corresponding desired response signal sequences.

`[MSE,MEANW,W,TRACEK] = msesim(sysObj,X,D)` calculates three parameters corresponding to the simulated behavior of the adaptive filter defined by `sysObj`. `MEANW` is a sequence of coefficient vector means. The columns of this matrix contain estimates of the mean values of the adaptive filter coefficients at each time instant. The dimensions of `MEANW` are `(SIZE(X,1))` by `(sysObj.length)`. `W` is an estimate of the final values of the adaptive filter coefficients for the algorithm corresponding to `sysObj`. `TRACEK` is a sequence of total coefficient error powers. This column vector contains estimates of the total coefficient error power of the adaptive filter at each time instant. The length of `TRACEK` is equal to `SIZE(X,1)`.

`[...] = msesim(sysObj,X,D,M)` specifies an optional decimation factor for computing `MSE`, `MEANW`, and `TRACEK`. If `M > 1`, every M^{th} predicted value of each of these sequences is saved. If omitted, the value of `M` is the default, which is 1.

System Identification of an FIR Filter Using Filtered XLMS Filter

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

```
ha = fir1(31,0.5);
fir = dsp.FIRFilter('Numerator',ha); % FIR system to be identified
iir = dsp.IIRFilter('Numerator',sqrt(0.75),...
        'Denominator',[1 -0.5]);
x = iir(sign(randn(2000,25)));
n = 0.1*randn(size(x));            % Observation noise signal
d = fir(x)+n;                   % Desired signal
l = 32;                            % Filter length
mu = 0.008;                        % Filtered-X LMS filter Step size.
m  = 5;                            % Decimation factor for analysis
                                   % and simulation results
fxlms = dsp.FilteredXLMSFilter(l,'StepSize',mu);
[simmse,meanWsim,Wsim,traceKsim] = msesim(fxlms,x,d,m);
plot(m*(1:length(simmse)),10*log10(simmse));
xlabel('Iteration'); ylabel('MSE (dB)');

reset

System object: dsp.FilteredXLMSFilter
Package: dsp

Reset filter states for Filtered-X LMS filter

Syntax

`reset(sysObj)`

Description

`reset(sysObj)` resets the internal states of the System object, `sysObj`, to their initial values. The reset method is always a no-op for unlocked System objects, as the states may not be allocated when the object is not locked.

step

System object: dsp.FilteredXLMSFilter
Package: dsp

Apply Filtered-X LMS filter to input

Syntax

```
[Y, ERR] = step(sysObj, x, D)
Y = step(sysObj,x)
[Y1,...,YN] = step(sysObj,x)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`[Y, ERR] = step(sysObj, x, D)` filters the input `x`, using D as the desired signal, and returns the filtered output in `Y` and the filter error in `ERR`. The System object estimates the filter weights needed to minimize the error between the output signal and the desired signal.

`Y = step(sysObj,x)` processes the input data, `x`, to produce the output, `Y`, from the System object, `sysObj`. `[Y1,...,YN] = step(sysObj,x)` produces `N` outputs.

Every System object has a step method. The step method processes the input data according to the object algorithm. The number of input and output arguments depends on the algorithm, and may depend also on one or more property settings. The step method for some objects accepts fixed-point (fi) inputs.

Calling step on an object puts that object into a locked state. When locked, you cannot change nontunable properties or any input characteristics (size, data type and complexity) without reinitializing (unlocking and relocking) the object.

Note: `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.FIRDecimator System object

Package: dsp

Polyphase FIR decimator

Description

The `FIRDecimator` object resamples vector or matrix inputs along the first dimension. The object reseamples at a rate *M* times slower than the input sampling rate, where *M* is the integer-valued downsampling factor. The decimation combines an FIR anti-aliasing filter with downsampling. The FIR decimator object uses a polyphase implementation of the FIR filter.

To resample vector or matrix inputs along the first dimension:

1 Define and set up your FIR decimator. See “Construction” on page 4-720.
2 Call step to resample the vector or matrix inputs according to the properties of `dsp.FIRDecimator`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`firdecim = dsp.FIRDecimator` returns an FIR decimator, `firdecim`, which applies an FIR filter with a cutoff frequency of `0.4*pi` radians/sample to the input and downsamples the filter output by factor of 2. This System object supports variable-size input.

`firdecim = dsp.FIRDecimator ('`*`PropertyName`*`',`*`PropertyValue`*`, ...)` returns an FIR decimator, `firdecim`, with each property set to the specified value.

`firdecim = dsp.FIRDecimator(DECIM, NUM, '`*`PropertyName`*`',`*`PropertyValue`*`, ...)` returns an FIR decimator, `firdecim`, with the integer-valued DecimationFactor property set to DECIM, the Numerator property set to NUM, and other specified properties set to the specified values.

Properties

DecimationFactor

Decimation factor

Specify the downsampling factor as a positive integer. The FIR decimator reduces the sampling rate of the input by this factor. The size of the input along the first dimension must be a multiple of the decimation factor. The default is 2.

NumeratorSource

FIR filter coefficient source

Specify the source of the numerator coefficients as one of 'Property' (default) or 'Input port'. When you specify 'Input port', the filter object requires the numerator coefficients to be specified as the third argument to every step.

Numerator

FIR filter coefficients

Specify the numerator coefficients of the FIR filter in powers of z^{-1}. The following equation defines the system function for a filter of length L:

$$H(z) = \sum_{l=0}^{L-1} b_l z^{-l}$$

To prevent aliasing as a result of downsampling, the filter transfer function should have a normalized cutoff frequency no greater than 1/DecimationFactor. You can specify the filter coefficients as a vector in the supported data types. The default is fir1(35,0.4).

Structure

Filter structure

Specify the implementation of the FIR filter as either `Direct form` or `Direct form transposed`. The default is `Direct form`.

Fixed-Point Properties

`FullPrecisionOverride`

Full precision override for fixed-point arithmetic

Specify whether to use full precision rules. If you set `FullPrecisionOverride` to `true`, which is the default, the object computes all internal arithmetic and output data types using full precision rules. These rules provide the most accurate fixed-point numerics. It also turns off the display of other fixed-point properties because they do not apply individually. These rules guarantee that no quantization occurs within the object. Bits are added, as needed, to ensure that no roundoff or overflow occurs. If you set `FullPrecisionOverride` to `false`, fixed-point data types are controlled through individual fixed-point property settings. For more information, see “Full Precision for Fixed-Point System Objects”.

`RoundingMethod`

Rounding method for fixed-point operations

Specify the rounding method as one of `| Ceiling | Convergent | Floor | Nearest | Round | Simplest | Zero |`. The default is `Floor`. This property applies only if the object is not in full precision mode.

`OverflowAction`

Overflow action for fixed-point operations

Specify the overflow action as one of `Wrap` or `Saturate`. This property applies only if the object is not in full precision mode.

`CoefficientsDataType`

Coefficients word and fraction lengths

Specify the coefficients fixed-point data type as `Same word length as input` or `Custom`. The default is `Same word length as input`.

`CustomCoefficientsDataType`

Coefficients word and fraction lengths

Specify the coefficients fixed-point type as a `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `CoefficientsDataType` on page 4-722 property to `Custom`. The default is `numerictype([],16,15)`.

ProductDataType

Product word and fraction lengths

Specify the product fixed-point data type as one of | `Full precision` | `Same as input` | `Custom` |. The default is `Full precision`.

CustomProductDataType

Product word and fraction lengths

Specify the product fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `ProductDataType` on page 4-723 property to `Custom`. The default is `numerictype([],32,30)`.

AccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point data type as one of | `Full precision` | `Same as product` | `Same as input` | `Custom` |. The default is `Full precision`.

CustomAccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `AccumulatorDataType` on page 4-723 property to `Custom`. The default is `numerictype([],32,30)`.

OutputDataType

Output word and fraction lengths

Specify the output fixed-point data type as one of | `Same as accumulator` | `Same as product` | `Same as input` | `Custom` |. The default is `Same as accumulator`.

CustomOutputDataType

Output word and fraction lengths

Specify the output fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `OutputDataType` on page 4-723 property to `Custom`. The default is `numerictype([]1,16,15)`.

Methods

freqz	Frequency response
fvtool	Open filter visualization tool
impz	Impulse response
phasez	Unwrapped phase response
reset	Reset filter states of FIR decimator
step	Decimate input by integer factor

More "Analysis Methods for Filter System Objects" on page 3-2.

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Decimate a Sum of Sine Waves

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

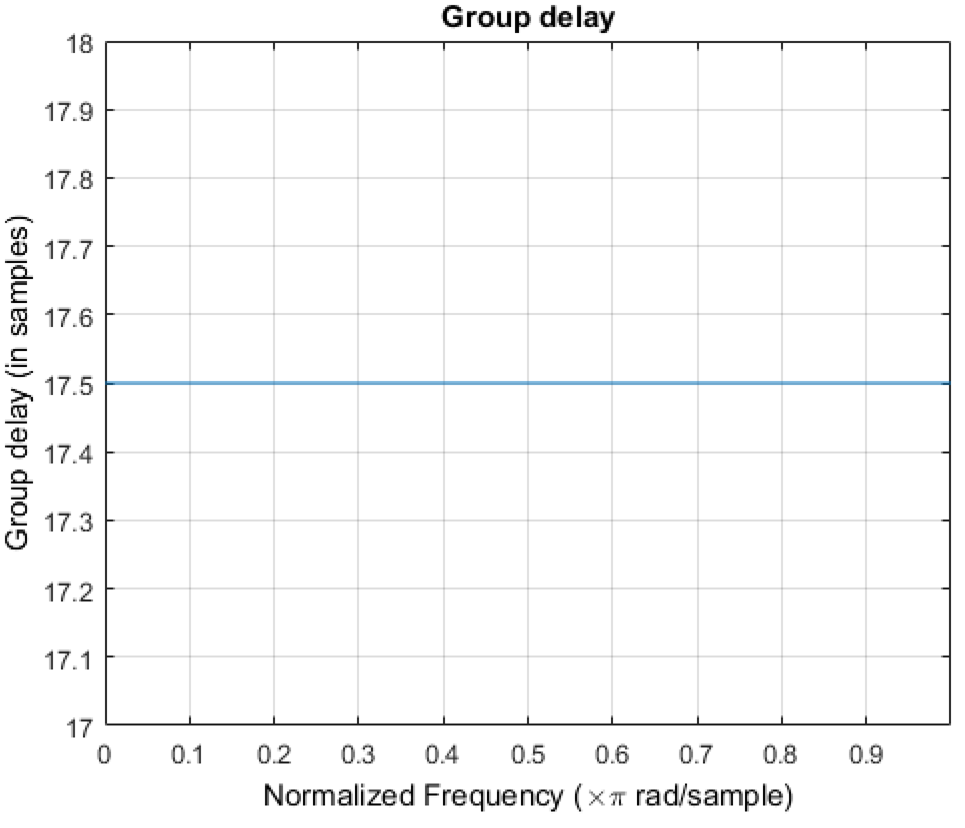
This example shows how to decimate a sum of sine waves with angular frequencies of pi/4 and 2pi/3 radians/sample by a factor of two. To prevent aliasing, the FIR decimator filters out the 2pi/3 radians/sample component before downsampling.

```
x = cos(pi/4*[0:95]')+sin(2*pi/3*[0:95]');
```

```
firdecim = dsp.FIRDecimator;
y = firdecim(x);
```

View group delay of default FIR filter

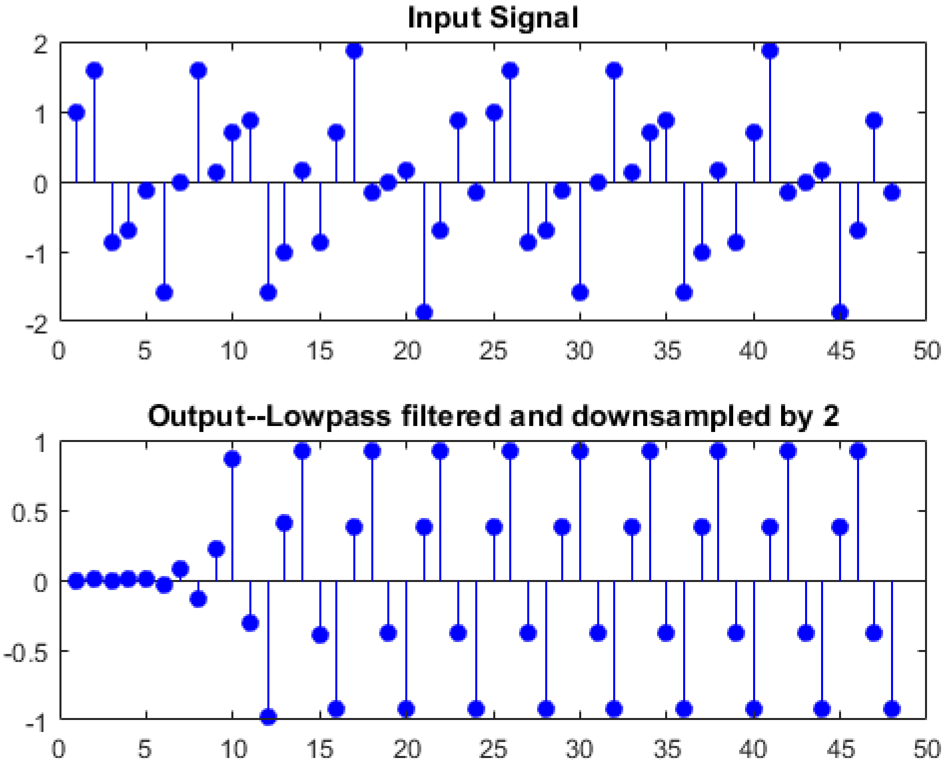
```
fvtool(fir1(35,0.4),1,'analysis','grpdelay');
```



Group delay of the default linear-phase FIR filter is 17.5 samples. Downsampling by a factor of two expect an approx. 8.75 sample delay in the output y with the initial filter states of zero

```
subplot(211);
stem(x(1:length(x)/2),'b','markerfacecolor',[0 0 1]);
title('Input Signal');
```

```
subplot(212);
stem(y,'b','markerfacecolor',[0 0 1]);
title('Output--Lowpass filtered and downsampled by 2');
```



Reduce the Sample Rate of an Audio Signal

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

This example shows how to reduce the sampling rate of an audio signal by 1/2 and plays it.

```
afr = dsp.AudioFileReader('OutputDataType',...
```

```
  'single');
adw = audioDeviceWriter(22050/2);
firdecim = dsp.FIRDecimator;

while ~isDone(afr)
     frame = afr();
     y = firdecim(frame);
     adw(y);
end

release(afr);
pause(0.5);
release(adw);
```

Definitions

Polyphase Subfilters

A polyphase implementation of an FIR decimator *splits* the lowpass FIR filter impulse response into M different subfilters, where M is the downsampling, or decimation factor. Let $h(n)$ denote the FIR filter impulse response of length L and $u(n)$ the input signal. Decimating the filter output by a factor of M is equivalent to the downsampled convolution:

$$y(n) = \sum_{l=0}^{L-1} h(l)u(nM - l)$$

The key to the efficiency of polyphase filtering is that specific input values are only multiplied by select values of the impulse response in the downsampled convolution. For example, letting $M=2$, the input values $u(0),u(2),u(4),$ ... are only combined with the filter coefficients $h(0),h(2),h(4),$..., and the input values $u(1),u(3),u(5),$ ... are only combined with the filter coefficients $h(1),h(3),h(5),$.... By splitting the filter coefficients into two polyphase subfilters, no unnecessary computations are performed in the convolution. The outputs of the convolutions with the polyphase subfilters are interleaved and summed to yield the filter output. The following MATLAB code demonstrates how to construct the two polyphase subfilters for the default order 35 filter in the `Numerator` on page 4-721 property and the default `DecimationFactor` on page 4-721 property value of two:

```
M = 2;
```

```
Num = fir1(35,0.4);
FiltLength = length(Num);
Num = flipud(Num(:));

if (rem(FiltLength, M) ~= 0)
     nzeros = M - rem(FiltLength, M);
     Num = [zeros(nzeros,1); Num];  % Appending zeros
end

len = length(Num);
nrows = len / M;
PolyphaseFilt = flipud(reshape(Num, M, nrows).');
```

The columns of `PolyphaseFilt` are subfilters containing the two *phases* of the filter in `Num`. For a general downsampling factor of M , there are M phases and therefore M subfilters.

Algorithms

This object implements the algorithm, inputs, and outputs described on the `FIR Decimation` block reference page. The object properties correspond to the block parameters, except:

- **Framing** – The FIR decimator object only supports `Maintain input frame rate`
- **Output buffer initial conditions** – The FIR decimator object does not support this parameter.
- **Rate options** – The FIR decimator object does not support this parameter.
- **Input processing** The FIR decimator object does not support this parameter.

dsp.FIRRateConverter | dsp.FIRInterpolator

Introduced in R2012a

freqz

System object: dsp.FIRDecimator
Package: dsp

Frequency response

Syntax

```
[h,w] = freqz(firdecim)
[h,w] = freqz(firdecim,n)
[h,w] = freqz(firdecim,Name,Value)
freqz(firdecim)
```

Description

`[h,w] = freqz(firdecim)` returns the complex, 8192–element frequency response vector `h`, and the corresponding frequencies `w` in radians/sample.

`[h,w] = freqz(firdecim,n)` returns the complex, n-element frequency response vector `h`, and the corresponding frequencies `w` in radians/sample, using `n` samples.

`[h,w] = freqz(firdecim,Name,Value)` returns the frequency response and the corresponding frequencies, with additional options specified by one or more Name, Value pair arguments.

`freqz(firdecim)` uses FVTool to plot the magnitude and unwrapped phase of the frequency response of the filter System object `firdecim`.

fvtool

System object: dsp.FIRDecimator
Package: dsp

Open filter visualization tool

Syntax

```
fvtool(firdecim)
fvtool(firdecim,'Arithmetic',ARITH,...)
```

Description

`fvtool(firdecim)` performs an analysis and computes the magnitude response of the filter System object `firdecim`.

`fvtool(firdecim,'Arithmetic',ARITH,...)` analyzes the filter System object `firdecim`, based on the arithmetic specified in the ARITH input. ARITH can be set to one of 'double', 'single', or 'fixed'. The analysis tool assumes a double precision filter when the arithmetic input is not specified and the filter System object is in an unlocked state. The 'Arithmetic' input is only relevant for the analysis of filter System objects.

impz

System object: dsp.FIRDecimator
Package: dsp

Impulse response

Syntax

```
[h,t] = impz(firdecim)
[h,t] = impz(firdecim,Name,Value)
impz(firdecim)
```

Description

`[h,t] = impz(firdecim)` returns the impulse response `h`, and the corresponding time points `t` at which the impulse response of`firdecim` is computed.

`[h,t] = impz(firdecim,Name,Value)` returns the impulse response `h`, and the corresponding time points`t` , with additional options specified by one or more Name, Value pair arguments.

`impz(firdecim)` uses FVTool to plot the impulse response of the filter System object `firdecim`.

Note: You can use `impz` for both real and complex filters. When you omit the output arguments, `impz` plots only the real part of the impulse response.

---

phasez

System object: dsp.FIRDecimator
Package: dsp

Unwrapped phase response

Syntax

```
[phi,w] = phasez(firdecim)
[phi,w] = phasez(firdecim,n)
[phi,w] = phasez(firdecim,Name,Value)
phasez(firdecim)
```

Description

`[phi,w] = phasez(firdecim)` returns the 8192–element phase response vector `phi`, and the corresponding frequencies `w` in radians/sample.

`[phi,w] = phasez(firdecim,n)` returns the n-element phase response vector `phi`, and the corresponding frequencies `w` in radians/sample, using `n` samples.

`[phi,w] = phasez(firdecim,Name,Value)` returns the phase response and the corresponding frequencies, with additional options specified by one or more Name, Value pair arguments.

`phasez(firdecim)` uses FVTool to plot the phase response of the filter System object `firdecim`.

reset

System object: dsp.FIRDecimator
Package: dsp

Reset filter states of FIR decimator

Syntax

```
reset(firdecim)
```

Description

`reset(firdecim)` resets the filter states of the FIR decimator object,`firdecim`, to the initial values of zero. After the `step` method applies the FIR decimator to nonzero input data, the filter states may change. Invoking the `step` method again without first invoking the `reset` method may produce different outputs for an identical input.

Reset an FIR Decimator

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

```
firdecim = dsp.FIRDecimator;
x = cos(pi/8*(0:1023)')+sin(pi/4*(0:1023)');
y = firdecim(x);
```

Call the FIR decimator again without reset.

```
y1 = firdecim(x);
isequal(y,y1)
```

```
ans =

  logical

   0
```

Reset filter states.

```
reset(firdecim);
```

Call the FIR decimator again.

```
y2 = firdecim(x);
isequal(y,y2)
```

```
ans =

  logical

   1
```

step

System object: dsp.FIRDecimator
Package: dsp

Decimate input by integer factor

Syntax

```
Y = step(firdecim,X)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(firdecim,X)` outputs the filtered and downsampled values, `Y`, of the input signal, `X`. A Ki-by-N input matrix is treated as N independent channels. The length of each column must be a multiple of the `DecimationFactor` property value. The FIR decimator operates on each channel separately and generates a Ko-by-N output matrix where $Ko = Ki/M$ with M the decimation factor. The object supports real and complex floating-point and fixed-point inputs, except for complex unsigned fixed-point inputs.

Note: `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.FIRFilter System object

Package: dsp

Static or time-varying FIR filter

Description

The `FIRFilter` object filters each channel of the input using static or time-varying FIR filter implementations.

To filter each channel of the input:

1. Define and set up your FIR filter. See "Construction" on page 4-737.
2. Call step to filter each channel of the input according to the properties of `dsp.FIRFilter`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`fir = dsp.FIRFilter` returns a default FIR filter object, `fir`, which independently filters each channel of the input over successive calls to the `step` method, using a specified FIR filter implementation. This System object supports variable-size input.

`fir = dsp.FIRFilter('`*`PropertyName`*`',`*`PropertyValue`*`, ...)` returns an FIR filter system object, `fir`, with each property set to the specified value.

Properties

`Structure`

Filter structure

Specify the filter structure.
You can specify the filter structure as one of | `Direct form` | `Direct form symmetric` | `Direct form antisymmetric` | `Direct form transposed` | `Lattice MA` |. The default is `Direct form`.

`NumeratorSource`

Source of filter coefficients

Specify the source of the filter coefficients as one of | `Property` | `Input port` |. The default is `Property`. When you specify `Input port`, the filter object updates the time-varying filter once every frame.

This applies when you set the `Structure` to `Direct form` | `Direct form symmetric` | `Direct form antisymmetric` | `Direct form transposed`.

`ReflectionCoefficientsSource`

Source of filter coefficients

Specify the source of the Lattice filter coefficients as one of | `Property` | `Input port` |. The default is `Property`. When you specify `Input port`, the filter object updates the time-varying filter once every frame.

This applies when you set the `Structure` to `Lattice MA` .

`Numerator`

Numerator coefficients

Specify the filter coefficients as a real or complex numeric row vector. This property applies when you set the `NumeratorSource` on page 4-738 property to `Property`, and the `Structure` on page 4-737 property is set to `Direct form`, `Direct form symmetric`, `Direct form antisymmetric`, or `Direct form transposed`. The default is `[0.5 0.5]`. This property is tunable.

`ReflectionCoefficients`

Reflection coefficients of lattice filter structure

Specify the reflection coefficients of a lattice filter as a real or complex numeric row vector. This property applies when you set the `Structure` on page 4-737 property to

`Lattice MA`, and the `ReflectionCoefficientsSource` on page 4-738 property to `Property`. The default is `[0.5 0.5]`. This property is tunable.

InitialConditions

Initial conditions for the FIR filter

Specify the initial conditions of the filter states. The number of states or delay elements equals the number of reflection coefficients for the lattice structure, or the number of filter coefficients–1 for the other direct form structures.

You can specify the initial conditions as a scalar, vector, or matrix. If you specify a scalar value, the FIR filter object initializes all delay elements in the filter to that value. If you specify a vector whose length equals the number of delay elements in the filter, each vector element specifies a unique initial condition for the corresponding delay element. The object applies the same vector of initial conditions to each channel of the input signal.

If you specify a vector whose length equals the product of the number of input channels and the number of delay elements in the filter, each element specifies a unique initial condition for the corresponding delay element in the corresponding channel.

If you specify a matrix with the same number of rows as the number of delay elements in the filter, and one column for each channel of the input signal, each element specifies a unique initial condition for the corresponding delay element in the corresponding channel. The default is 0.

This property is tunable.

Fixed-Point Properties

FullPrecisionOverride

Full precision override for fixed-point arithmetic

Specify whether to use full precision rules. If you set `FullPrecisionOverride` to `true`, which is the default, the object computes all internal arithmetic and output data types using full precision rules. These rules provide the most accurate fixed-point numerics. It also turns off the display of other fixed-point properties because they do not apply individually. These rules guarantee that no quantization occurs within the object. Bits are added, as needed, to ensure that no roundoff or overflow occurs. If you set `FullPrecisionOverride` to `false`, fixed-point data types are controlled through individual fixed-point property settings. For more information, see "Full Precision for Fixed-Point System Objects".

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as one of | `Ceiling` | `Convergent` | `Floor` | `Nearest` | `Round` | `Simplest` | `Zero` |. The default is `Floor`. This property applies only if the object is not in full precision mode.

OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as one of | `Wrap` | `Saturate` |. The default is `Wrap`. This property applies only if the object is not in full precision mode.

CoefficientsDataType

Coefficients word and fraction lengths

Specify the coefficients fixed-point data type as one of | `Same word length as input` | `Custom` |. This property applies when you set the `NumeratorSource` on page 4-738 property to `Property`. The default is `Same word length as input`.

CustomCoefficientsDataType

Custom coefficients word and fraction lengths

Specify the coefficients fixed-point type as a signed or unsigned `numerictype` object. This property applies when you set the `CoefficientsDataType` on page 4-740 property to `Custom`. The default is `numerictype(true,16,15)`.

ReflectionCoefficientsDataType

Reflection coefficients word and fraction lengths

Specify the reflection coefficients fixed-point data type as one of | `Same word length as input` | `Custom` |. This property applies when you set the `ReflectionCoefficientsSource` on page 4-738 property to `Property`. The default is `Same word length as input`.

CustomReflectionCoefficientsDataType

Custom reflection coefficients word and fraction lengths

Specify the reflection coefficients fixed-point type as a signed or unsigned `numerictype` object. This property applies when you set the `ReflectionCoefficientsDataType` on page 4-740 property to `Custom`. The default is `numerictype(true,16,15)`.

ProductDataType

Product word and fraction lengths

Specify the product fixed-point data type as one of | `Full precision` | `Same as input` | `Custom` |. The default is `Full precision`.

CustomProductDataType

Custom product word and fraction lengths

Specify the product fixed-point type as a signed or unsigned scaled `numerictype` object. This property applies when you set the `ProductDataType` on page 4-741 property to `Custom`. The default is `numerictype(true,32,30)`.

AccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point data type to one of | `Full precision` | `Same as input` | `Same as product` | `Custom` |. The default is `Full precision`.

CustomAccumulatorDataType

Custom accumulator word and fraction lengths

Specify the accumulator fixed-point type as a signed or unsigned scaled `numerictype` object. This property applies when you set the `AccumulatorDataType` on page 4-741 property to `Custom`. The default is `numerictype(true,32,30)`.

StateDataType

State word and fraction lengths

Specify the state fixed-point data type as one of | Same as input | Same as accumulator | Custom |. This property does not apply to any of the direct form or direct form I filter structures. The default is Same as accumulator.

CustomStateDataType

Custom state word and fraction lengths

Specify the state fixed-point type as a signed or unsigned scaled numerictype object. This property applies when you set the StateDataType on page 4-741 property to Custom. The default is numerictype(true,16,15).

OutputDataType

Output word and fraction lengths

Specify the output fixed-point data type as one of | Same as input | Same as accumulator | Custom |. The default is Same as accumulator.

CustomOutputDataType

Custom output word and fraction lengths

Specify the output fixed-point type as a signed or unsigned scaled numerictype object. This property applies when you set the OutputDataType on page 4-742 property to Custom. The default is numerictype(true,16,15).

Methods

freqz	Frequency response
fvtool	Open filter visualization tool
impz	Impulse response
phasez	Unwrapped phase response
reset	Reset internal states of FIR filter
step	Filter input with FIR filter object

isLocked	Check locked states of a System object (logical)
release	Allow System object property value changes

Examples

Lowpass Filter a Sinusoid Signal Using FIRFilter object

Use an FIR filter to apply a low pass filter to a waveform with two sinusoidal components.

```
 t = (0:1000)'/8e3;
 xin = sin(2*pi*0.3e3*t)+sin(2*pi*3e3*t);

 sr = dsp.SignalSource;
 sr.Signal = xin;
 sink = dsp.SignalSink;

 fir = dsp.FIRFilter;
 fir.Numerator = fir1(10,0.5);

sa = dsp.SpectrumAnalyzer('SampleRate',8e3,...
    'PlotAsTwoSidedSpectrum',false,...
    'OverlapPercent', 80, 'PowerUnits','dBW',...
    'YLimits', [-150 -10]);

 while ~isDone(sr)
      input = sr();
      filteredOutput = fir(input);
      sink(filteredOutput);
      sa(filteredOutput)
 end

 filteredResult = sink.Buffer;
 fvtool(fir,'Fs',8000)

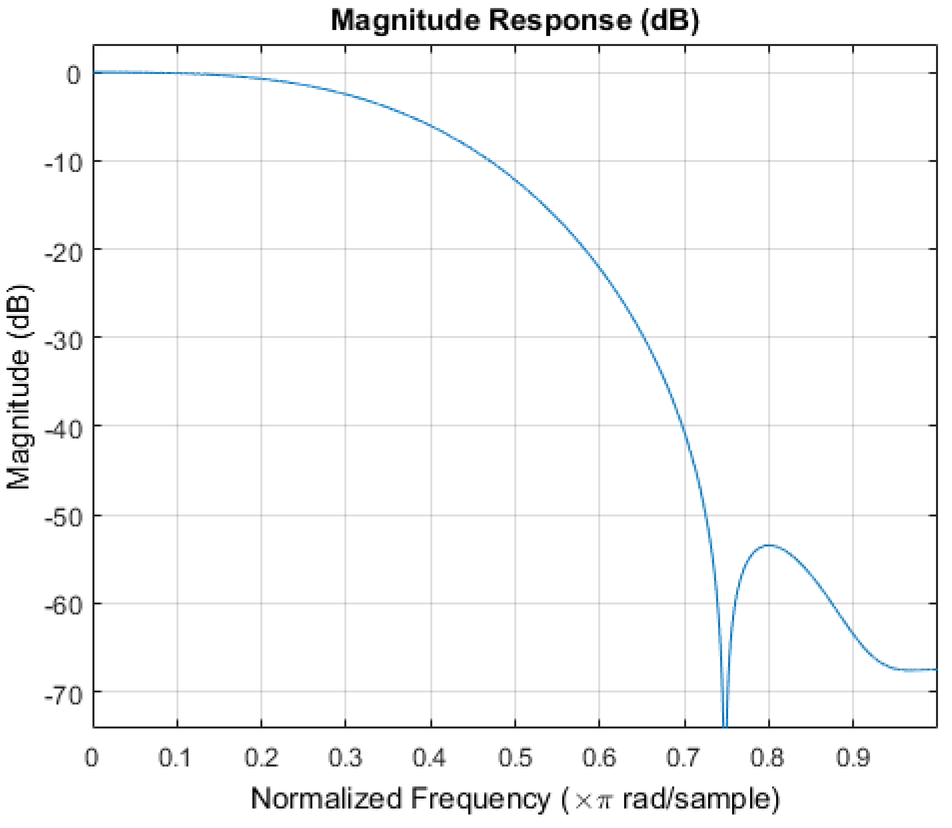
Design an FIR filter as a System object.

```
N = 10;
Fc = 0.4;
B = fir1(N,Fc);
fir1 = dsp.FIRFilter('Numerator',B);
fvtool(fir1)
```



This can also be achieved by using `fdesign` as a constructor and `design` to design the filter.

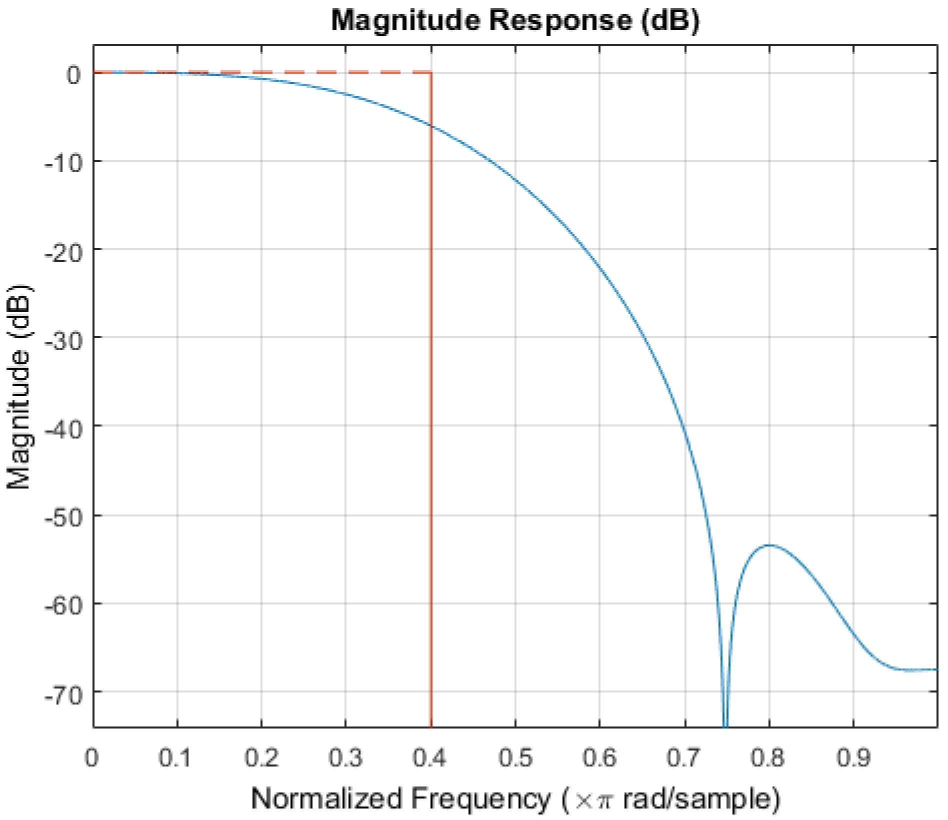
```
N = 10;
Fc = 0.4;
specLowpass = fdesign.lowpass('N,Fc',N,Fc);
fir2 = design(specLowpass,'systemobject',true)
fvtool(fir2);
```

```
fir2 =

  dsp.FIRFilter with properties:
```

```
          Structure: 'Direct form'
    NumeratorSource: 'Property'
          Numerator: [1×11 double]
  InitialConditions: 0

Use get to show all properties
```



Algorithms

This object implements the algorithm, inputs, and outputs described on the `Discrete FIR Filter` block reference page. The object properties correspond to the block parameters.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- Only the `Numerator` property is tunable for code generation.
- See “System Objects in MATLAB Code Generation” (MATLAB Coder).

Introduced in R2012a

freqz

System object: dsp.FIRFilter
Package: dsp

Frequency response

Syntax

```
[h,w] = freqz(fir)
[h,w] = freqz(fir,n)
[h,w] = freqz(fir,Name,Value)
freqz(fir)
```

Description

`[h,w] = freqz(fir)` returns the complex, 8192–element frequency response vector `h`, and the corresponding frequencies `w` in radians/sample.

`[h,w] = freqz(fir,n)` returns the complex, n-element frequency response vector `h`, and the corresponding frequencies `w` in radians/sample, using `n` samples.

`[h,w] = freqz(fir,Name,Value)` returns the frequency response and the corresponding frequencies, with additional options specified by one or more Name, Value pair arguments.

`freqz(fir)` uses FVTool to plot the magnitude and unwrapped phase of the frequency response of the filter System object `fir`.

fvtool

System object: dsp.FIRFilter
Package: dsp

Open filter visualization tool

Syntax

```
fvtool(fir)
fvtool(fir,'Arithmetic',ARITH,...)
```

Description

`fvtool(fir)` performs an analysis and computes the magnitude response of the filter System object `fir`.

`fvtool(fir,'Arithmetic',ARITH,...)` analyzes the filter System object `fir`, based on the arithmetic specified in the ARITH input. ARITH can be set to one of 'double', 'single', or 'fixed'. The analysis tool assumes a double precision filter when the arithmetic input is not specified and the filter System object is in an unlocked state. The 'Arithmetic' input is only relevant for the analysis of filter System objects.

impz

System object: dsp.FIRFilter
Package: dsp

Impulse response

Syntax

```
[h,t] = impz(fir)
[h,t] = impz(fir,Name,Value)
impz(fir)
```

Description

`[h,t] = impz(fir)` returns the impulse response `h`, and the corresponding time points `t` at which the impulse response of`fir` is computed.

`[h,t] = impz(fir,Name,Value)` returns the impulse response `h`, and the corresponding time points`t` , with additional options specified by one or more Name, Value pair arguments.

`impz(fir)` uses FVTool to plot the impulse response of the filter System object `fir`.

Note: You can use `impz` for both real and complex filters. When you omit the output arguments, `impz` plots only the real part of the impulse response.

phasez

System object: dsp.FIRFilter
Package: dsp

Unwrapped phase response

Syntax

```
[phi,w] = phasez(fir)
[phi,w] = phasez(fir,n)
[phi,w] = phasez(fir,Name,Value)
phasez(fir)
```

Description

`[phi,w] = phasez(fir)` returns the 8192–element phase response vector `phi`, and the corresponding frequencies `w` in radians/sample.

`[phi,w] = phasez(fir,n)` returns the n-element phase response vector `phi`, and the corresponding frequencies `w` in radians/sample, using `n` samples.

`[phi,w] = phasez(fir,Name,Value)` returns the phase response and the corresponding frequencies, with additional options specified by one or more Name, Value pair arguments.

`phasez(fir)` uses FVTool to plot the phase response of the filter System object `fir`.

reset

System object: dsp.FIRFilter
Package: dsp

Reset internal states of FIR filter

Syntax

`reset(fir)`

Description

`reset(fir)` resets the filter states of the FIR filter object,`fir`, to their initial values of 0. The initial filter state values correspond to the initial conditions for the difference equation defining the filter. After the `step` method applies the FIR filter object to nonzero input data, the states may be nonzero. Invoking the `step` method again without first invoking the`reset` method may produce different outputs for an identical input.

Reset an FIR Filter

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

```
fir = dsp.FIRFilter;
fir.Numerator = fir1(20,0.25);
n = 0:100;
x = cos(0.2*pi*n)+sin(0.8*pi*n);
y = fir(x);
```

Filter states are nonzero. Invoke step method again without resetting states

```
y1 = fir(x);
isequal(y,y1)
```

```
ans =
```

```
  logical

   0
```

Now reset filter states to 0

```
reset(fir)
```

Invoke step method

```
y2 = fir(x);
isequal(y,y2)
```

```
ans =

  logical

   1
```

step

System object: dsp.FIRFilter
Package: dsp

Filter input with FIR filter object

Syntax

```
Y = step(fir,X)
Y = step(fir,X,COEFF)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(fir,X)` filters the real or complex input signal `X` using the FIR filter, `fir`, to produce the output `Y` . When the input data is of a fixed-point type, it must be signed when the structure is set to `Direcform symmetric` or `Direct form antisymmetric`. The FIR filter object operates on each channel of the input signal independently over successive calls to step method.

`Y = step(fir,X,COEFF)` uses the time-varying coefficients, `COEFF` , to filter the input signal `X` and produce the output `Y` . You can use this option when you set the `NumeratorSource` or `ReflectionCoefficientsSource` property to `Input port`.

Note: `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change

nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.HDLFIRFilter System object

Package: dsp

Finite impulse response filter—optimized for HDL code generation

Description

The `HDLFIRFilter` System object models FIR filter architectures optimized for HDL code generation. The object is sample based, accepting one scalar at a time. It provides a hardware-friendly interface with optional input and output flow control signals.

The object implements a direct-form systolic FIR filter architecture based on multiply-accumulate operations with pipeline registers. The choice of architecture makes the object well-suited for high-throughput HDL code generation targeted for FPGAs with dedicated DSP blocks. The generated HDL code runs at a high clock rate and can filter new input data on every cycle.

The object provides flexible and efficient resource sharing options. This property results in tradeoffs between throughput and resource utilization. A sharing factor of *N* indicates that the object reduces overall DSP resource utilization by a factor of *N*. In this case, the object can process only input samples that are at least *N* time steps apart. To determine when the object is ready for new input data, use the optional `readyPort` property.

To provide a cycle-accurate simulation of the generated HDL code, the object models pipeline registers and resource sharing. These operations cause a delay between valid input data and the corresponding valid output data. The actual latency depends on the number of coefficients and the sharing factor.

To process input data with an HDL-optimized FIR filter:

1. Create and configure a `dsp.HDLFIRFilter` System object. See “Construction” on page 4-759.
2. Call the step method to filter the input data according to the properties of the `dsp.HDLFIRFilter` object.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as

dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Note: Alternatively, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`firFilt = dsp.HDLFIRFilter` creates an HDL-optimized discrete FIR filter System object, `firFilt`, with default filter properties.

`firFilt = dsp.HDLFIRFilter(num)` creates the filter with the Numerator property set to `num`.

`firFilt = dsp.HDLFIRFilter(___,Name,Value)` creates the filter with optional `Name,Value` pair arguments, in addition to any of the input arguments in previous syntaxes. Name is a property name from the list of "Properties" on page 4-759 and `Value` is the corresponding value. `Name` must appear inside single quotes (`''`). You can specify several name-value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`. Properties not specified retain their default values.

Properties

Main

`Numerator` — Discrete FIR filter coefficients

`[0.5 0.5]` (default) | vector of numeric values

Discrete FIR filter coefficients, specified as a vector of numeric values. You can also specify the vector as a workspace variable, or as a call to a filter design function. Complex coefficients are not supported. When the input data type is floating point, the object casts the coefficients to the same data type as the input. When the input data type is integer or fixed point, you can modify coefficient type casting details using the `CoefficientsDataType` property.

Example: `'Numerator',firpm(30,[0 .1 .2 .5]*2,[1 1 0 0])` defines the coefficients using a linear-phase filter design function.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32`

`Sharing` — Resource sharing option
`false` (default) | `true`

Resource sharing option, specified as a logical value. To reduce the overall DSP resource utilization on the FPGA, set this property to `true`. Then set the `SharingFactor` property to the value by which you want to reduce the number of DSPs.

`SharingFactor` — Factor by which the number of DSPs is reduced
`2` (default) | positive integer

Factor by which the number of DSPs is reduced, specified as a positive integer. A sharing factor of *N* indicates that the object reduces DSP resource utilization by a factor of *N*. In this case, the object can process only input samples that are at least *N* time steps apart.

Dependencies

To enable this property, set the `Sharing` property to `true`.

Data Types

`RoundingMethod` — Rounding method for type casting
`'Floor'` (default) | `'Ceiling'` | `'Convergent'` | `'Nearest'` | `'Round'` | `'Zero'`

Rounding method for type casting, specified as `'Floor'`, `'Ceiling'`, `'Convergent'`, `'Nearest'`, `'Round'`, or `'Zero'`. The rounding method is used when casting the output to the data type specified by the `OutputDataType` property. When the input data type is floating point, the `RoundingMethod` property has no effect. See “Rounding Modes” for more details.

`OverflowAction` — Overflow handling for type casting
`'Wrap'` (default) | `'Saturate'`

Overflow handling for type casting, specified as `'Wrap'` or `'Saturate'`. Overflow handling is used when casting the output to the data type specified by the `OutputDataType` property. When the input data type is floating point, the `OverflowAction` property has no effect. See "Overflow Handling" for more details.

`CoefficientsDataType` — Data type of discrete FIR filter coefficients

`'Same word length as input'` (default) | `numerictype` object

Data type of discrete FIR filter coefficients, specified as `'Same word length as input'`. Alternatively, you can specify the coefficients data type as a `numerictype` object by calling `numerictype(s,w,f)`. `s` is 1 for signed and 0 for unsigned, `w` is the word length in bits, and `f` is the number of fractional bits. The object casts the filter coefficients of the discrete FIR filter to the specified data type. The quantization uses nearest rounding and saturate overflow modes. When the input data type is floating point, the `Coefficients` property has no effect.

`OutputDataType` — Data type of discrete FIR filter output

`'Same word length as input'` (default) | `'Full precision'` | `numerictype` object

Data type of discrete FIR filter output, specified as `'Same word length as input'` or `'Full precision'`. Alternatively, you can specify the output data type as a `numerictype` object by calling `numerictype(s,w,f)`. `s` is 1 for signed and 0 for unsigned, `w` is the word length in bits, and `f` is the number of fractional bits. The object casts the output of the discrete FIR filter to the specified data type. The quantization uses the settings of `RoundingMethod` and `OverflowAction`. When the input data type is floating point, the `OutputDataType` property has no effect.

Control Ports

`ValidInPort` — Enable optional valid input control signal

`true` (default) | `false`

Option to enable valid input control signal, specified as `true` or `false`. When `ValidInPort` is `true`, you must call the object with an extra argument, `validIn`. The first argument of the object, `dataIn`, is treated as valid only when `validIn` is `true`. The extra argument is mandatory when DSP resources are shared. In this case, the object ignores the value of `ValidInPort`.

`ReadyPort` — Enable optional `ready` output control signal

`false` (default) | `true`

Option to enable `ready` output control signal, specified as `true` or `false`. When you set `ReadyPort` to `true`, the object returns an extra value, `ready`. The object sets `ready` to `true` to indicate that it is ready to accept new input data on the next time step.

Methods

step	Filter input with HDL-optimized FIR filter object

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Use HDL FIR Filter System Object with Default Settings

Create an HDL FIR Filter System object with default settings.

```
firFilt = dsp.HDLFIRFilter;
```

Create an input signal of some random noise, and allocate memory for outputs.

```
L = 100;
dataIn = randn(L,1);
dataOut = zeros(L,1);
validOut = false(L,1);
```

Call the object on the input signal, asserting that the input data is always valid. The object processes one data sample at a time.

```
for k=1:L
```

```
    [dataOut(k),validOut(k)] = firFilt(dataIn(k),true);
end
```

Use HDL FIR Filter System Object with Resource Sharing

Operate a 31-tap low pass filter with resource sharing.

Design the filter coefficients. Then create an HDL FIR Filter System object. Enable resource sharing and the `ready` output port.

```
numerator = firpm(30,[0 .1 .2 .5]*2,[1 1 0 0]);
sharingFactor = 10;
firFilt = dsp.HDLFIRFilter('Numerator',numerator, ...
    'Sharing',true,'SharingFactor',sharingFactor,'ReadyPort',true);
```

The specified `sharingFactor` indicates that the filter requires 10 time steps to calculate each output. Create input signals `dataIn` and `validIn` such that new data is applied only every `sharingFactor` time steps.

```
L = 16;
x = fi(randn(L,1),1,16);
dataIn = zeros(L*sharingFactor,1,'like',x);
dataIn(1:sharingFactor:end) = x;
validIn = false(L*sharingFactor,1);
validIn(1:sharingFactor:end) = true;
```

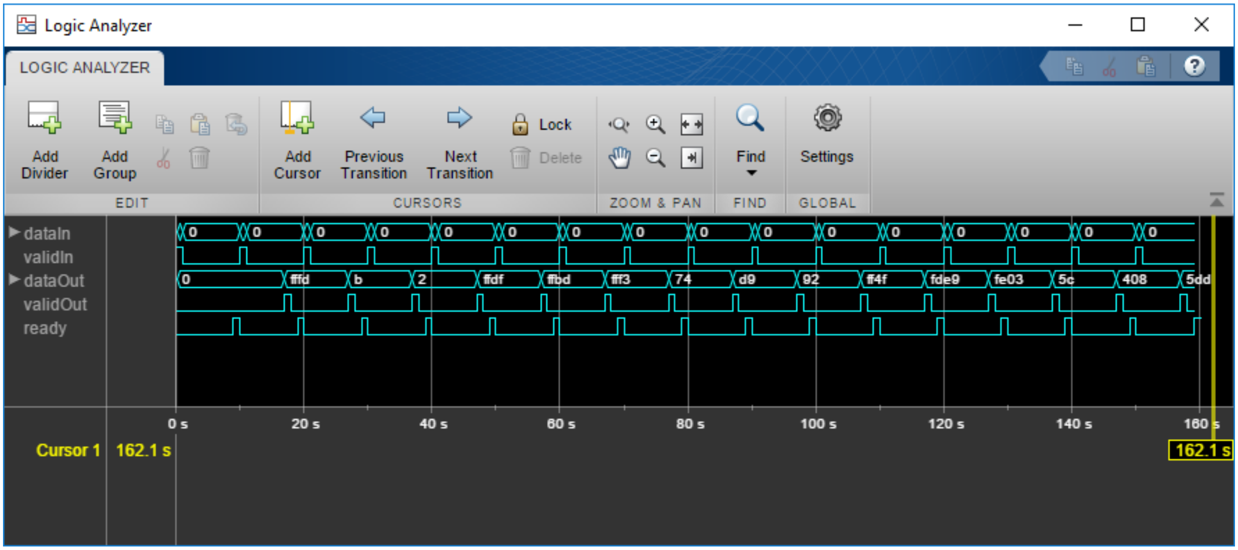
Create a `LogicAnalyzer` object to view the inputs and outputs

```
la = dsp.LogicAnalyzer('NumInputPorts',5, ...
    'SampleTime',1,'TimeSpan',length(dataIn));
tags = getDisplayChannelTags(la);
modifyDisplayChannel(la,tags{1},'Name','dataIn');
modifyDisplayChannel(la,tags{2},'Name','validIn');
modifyDisplayChannel(la,tags{3},'Name','dataOut');
modifyDisplayChannel(la,tags{4},'Name','validOut');
modifyDisplayChannel(la,tags{5},'Name','ready');
```

Call the filter System object on the input signals, and view the results in the **Logic Analyzer**.

```
for k=1:length(dataIn)
    [dataOut,validOut,ready] = firFilt(dataIn(k),validIn(k));
    la(dataIn(k),validIn(k),dataOut,validOut,ready)
```

```
end
```



The object models HDL pipeline registers and resource sharing. Therefore, there is an initial delay before valid output samples are returned by the object.

Create HDL FIR Filter System Object for HDL Code Generation

Use a function containing the HDL FIR filter System object which supports HDL code generation.

Create Function

Write a function that creates and calls an 11-tap HDL FIR Filter System object. You can generate HDL from this function.

```
function [dataOut,validOut] = HDLFIR11Tap(dataIn)
%HDLFIR11TAP
% Process one sample of data using the dsp.HDLFIRFilter System
% object.
% dataIn is a fixed-point scalar value.
% You can generate HDL code from this function.
    persistent fir
    if isempty(fir)
```

```
        Numerator = firpm(10,[0,0.1,0.5,1],[1,1,0,0]);
        fir = dsp.HDLFIRFilter(Numerator,'ValidInPort',false);
    end
    [dataOut,validOut] = fir(dataIn);
end
```

Create Test Bench for the Function

Clear the workspace, create an input signal of some random noise, and allocate memory for outputs.

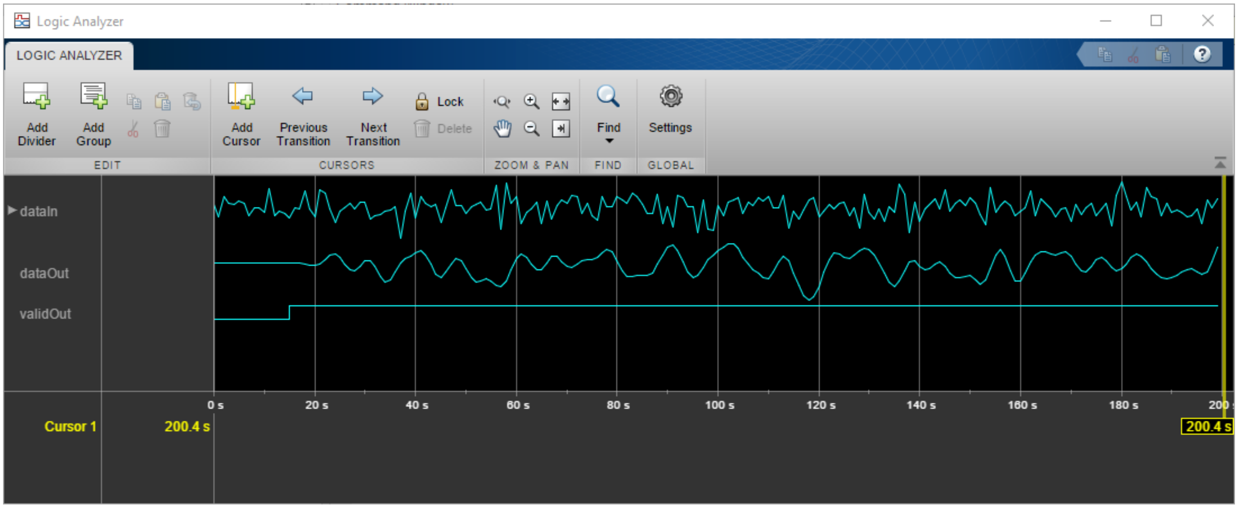
```
clear variables
clear HDLFIR11Tap
L = 200;
dataIn = fi(randn(L,1),1,16);
dataOut = zeros(L,1);
validOut = false(L,1);
```

Call the function on the input signal.

```
for k = 1:L
    [dataOut(k),validOut(k)] = HDLFIR11Tap(dataIn(k));
end
```

Plot the signals with the **Logic Analyzer**.

```
la = dsp.LogicAnalyzer('NumInputPorts',3,'SampleTime',1,'TimeSpan',L);
tags = getDisplayChannelTags(la);
modifyDisplayChannel(la,tags{1},'Name','dataIn','Format','Analog','Height',50);
modifyDisplayChannel(la,tags{2},'Name','dataOut','Format','Analog','Height',50);
modifyDisplayChannel(la,tags{3},'Name','validOut');
la(dataIn,dataOut,validOut)
```



Algorithms

This object implements the algorithms described on the `Discrete FIR Filter HDL Optimized` block reference page.

step

System object: dsp.HDLFIRFilter
Package: dsp

Filter input with HDL-optimized FIR filter object

Syntax

```
[dataOut,validOut] = step(firFilt,dataIn)
[dataOut,validOut] = step(firFilt,dataIn,validIn)
[dataOut,validOut,ready] = step(firFilt,dataIn,validIn)
```

Description

`[dataOut,validOut] = step(firFilt,dataIn)` filters the input data, `dataIn`, using the specified `firFilt` filter object. The returned output data, `dataOut`, is valid only when `validOut` is `true`.

`[dataOut,validOut] = step(firFilt,dataIn,validIn)` filters the input data only when `validIn` is true. This argument is required when `Sharing` is set to `true`. Otherwise, it is required only when the `ValidInPort` property of `firFilt` is set to `true`.

`[dataOut,validOut,ready] = step(firFilt,dataIn,validIn)` filters the input data when `validIn` is true, and sets `ready` to `true`, indicating that the object is ready to accept new input data on the next time step. To return `ready`, set the `ReadyPort` property of `firFilt` to `true`.

Note: Alternatively, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Input Arguments

`firFilt` — Discrete FIR filter
`dsp.HDLFIRFilter` System object

Discrete FIR filter, specified as a `dsp.HDLFIRFilter` System object.

`dataIn` — Input data
real or complex scalar

Input data, specified as a real or complex scalar. When the input data type is integer or fixed point, the object uses fixed-point arithmetic for internal calculations. `double` and `single` are accepted for simulation but not for HDL code generation.

Data Types: `fi` | `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32`
Complex Number Support: Yes

`validIn` — Indicate valid input data
logical scalar

Indicator of whether input data is valid, specified as a logical scalar. The first argument, `dataIn`, is treated as valid only when `validIn` is `true`. `validIn` is required when `Sharing` is set to `true`. Otherwise, it is required only when `ValidInPort` property is set to `true`.

Data Types: `logical`

Output Arguments

`dataOut` — Filtered output data
real or complex scalar

Filtered output data, returned as a real or complex scalar. When the input data is floating point, the output data inherits the data type of the input data. When the input data is integer or fixed point, the `OutputDataType` property determines the output data type.

Data Types: `fi` | `single` | `double`
Complex Number Support: Yes

`validOut` — Indicates valid output data
logical scalar

Indicator of whether output data is valid, returned as a logical scalar. The object sets `validOut` to `true` with each valid output data on `dataOut`.

Data Types: `logical`

`ready` — Indicates that the object is ready for new input data
logical scalar

Indicator of whether the object is ready for new input data, returned as a logical scalar. The object sets `ready` to `true` to indicate that it is ready to accept new input data on the next time step. The object returns this value only when the `ReadyPort` property is set to `true`.

Data Types: `logical`

dsp.FIRHalfbandDecimator System object

Package: dsp

Halfband decimator

Description

`dsp.FIRHalfbandDecimator` performs an efficient polyphase decimation of the input signal by a factor of two. You can use `dsp.FIRHalfbandDecimator` to implement the analysis portion of a two-band filter bank to filter a signal into lowpass and highpass subbands. `dsp.FIRHalfbandDecimator` uses an FIR equiripple design to construct the halfband filters and a polyphase implementation to filter the input. This object supports fixed-point operations and ARM Cortex code generation.

To filter and downsample your data:

1. Define and set up your halfband decimator. See “Construction” on page 4-770.
2. Call step to filter the input signal according to the properties of `dsp.FIRHalfbandDecimator`. The input signal can be a real- or complex-valued column vector or matrix. If the input signal is a matrix, each column of the matrix is treated as an independent channel. The number of rows in the input signal must be a multiple of 2.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`firhalfbanddecim = dsp.FIRHalfbandDecimator` returns a halfband decimator, `firhalfbanddecim`, with the default settings. Calling `step` with the default property settings filters and downsamples the input data with a halfband frequency of 11025 Hz, a transition width of 4.1 kHz, and a stopband attenuation of 80 dB.

`firhalfbanddecim = dsp.FIRHalfbandDecimator(Name,Value)` returns a halfband decimator, with additional properties specified by one or more `Name,Value` pair arguments. `Name` is the property name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name-value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Properties

`Specification` — Filter design parameters

`'Transition width and stopband attenuation'` (default) | `'Filter order and stopband attenuation'` | `'Filter order and transition width'`

Filter design parameters, specified as a character vector. Valid options are `'Transition width and stopband attenuation'` (default), `'Filter order and stopband attenuation'`, or `'Filter order and transition width'`. The filter design has only two degrees of freedom so you can only specify two of the following: filter order, transition width, or stopband attenuation. Setting a filter design specification without additionally specifying values for the design parameters results in default values for the specifications.

`FilterOrder` — Filter order

52 (default) | even positive integer

Filter order, specified as the comma-separated pair of `'FilterOrder'` and an even positive integer. Specifying a filter order is only valid when the value of `‘Specification’` is `'Filter order and stopband attenuation'` or `'Filter order and transition width'`.

`StopbandAttenuation` — Stopband attenuation

80 (default) | positive real scalar

Stopband attenuation in dB, specified as the comma-separated pair of `'StopbandAttenuation'` and a positive real scalar. Specifying the stopband attenuation is only valid when the value of `‘Specification’` is `'Filter order and stopband attenuation'` or `'Transition width and stopband attenuation'`.

`TransitionWidth` — Transition width

4100 (default) | positive real scalar

Transition width in Hz, specified as the comma-separated pair of `'TransitionWidth'` and a positive real scalar. The value of the transition width in Hz must be less than

1/2 the input sample rate. Specifying the transition width is valid only when the value of `‘Specification’` is `'Transition width and stopband attenuation'` or `'Filter order and transition width'`.

`SampleRate` — Input sample rate

44100 (default) | positive real scalar

Input sample rate in Hz, specified as a comma-separated pair of `'SampleRate'` and a positive real scalar. The input sample rate defaults to 44100 Hz. If you specify a transition width as one of your filter design parameters, the transition width cannot exceed 1/2 the input sample rate.

Fixed-Point Properties

`CoefficientsDataType` — Word and fraction lengths of coefficients

`numerictype(1,16)` (default) | `numerictype` object

Word and fraction lengths of coefficients, specified as a signed or unsigned `numerictype` object. The default, `numerictype(1,16)` corresponds to a signed numeric type object with 16-bit coefficients and a fraction length determined based on the coefficient values, to give the best possible precision.

This property is not tunable.

Word length of the output is same as the word length of the input. Fraction length of the output is computed such that the entire dynamic range of the output can be represented without overflow. For details on how the fraction length of the output is computed, see “Fixed-Point Precision Rules for Avoiding Overflow in FIR Filters”.

`RoundingMethod` — Rounding method for output fixed-point operations

`'Floor'` (default) | `'Ceiling'` | `'Convergent'` | `'Nearest'` | `'Round'` | `'Simplest'` | `'Zero'`

Rounding method for output fixed-point operations, specified as a character vector. For more information on the rounding modes, see “Precision and Range”.

Methods

reset	Reset internal states of FIR halfband decimator

step	Filter input with FIR halfband decimator

For additional methods, see "Analysis Methods for Filter System Objects" on page 3-2.

For a complete list of analysis methods supported for the `dsp.FIRHalfbandDecimator` object, enter `dsp.FIRHalfbandDecimator.helpFilterAnalysis` at the MATLAB command prompt.

Common to All System Objects	
clone	Create System object with same property values
getNumInpu	Expected number of inputs to a System object
getNumOutp	Expected number of outputs of a System object
isLocked	Check locked states of a System object (logical)
release	Allow System object property value changes

Examples

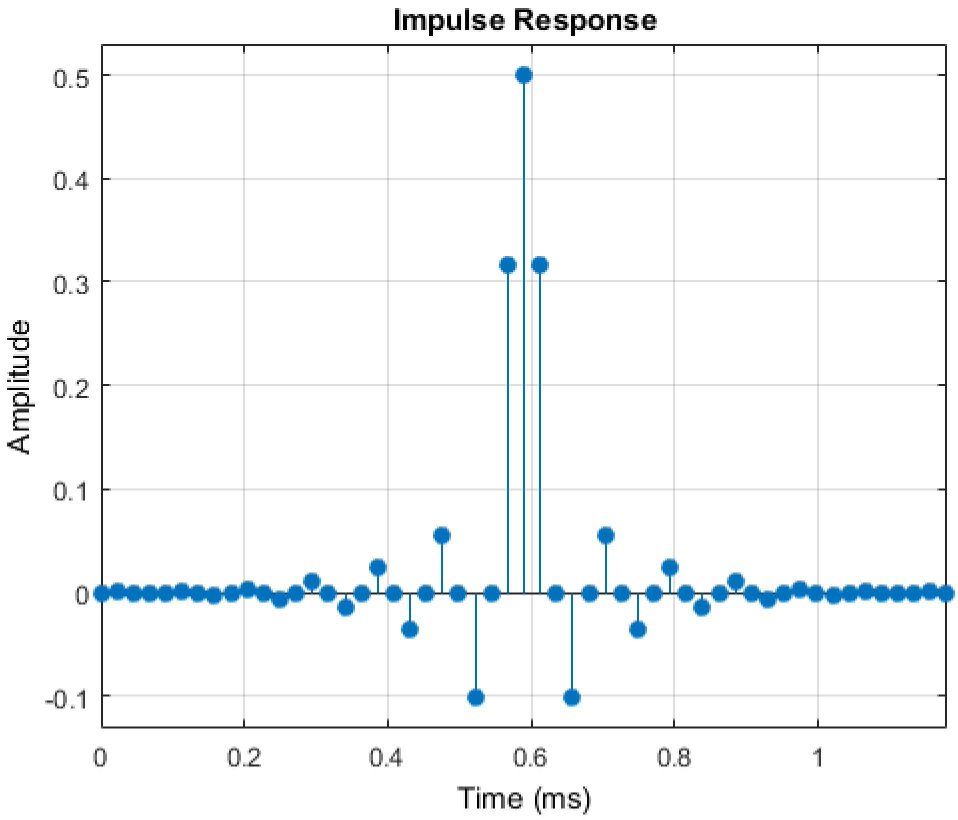
Impulse and Frequency Response of Half-band Decimation Filter

Create a lowpass half-band decimation filter for data sampled at 44.1 kHz. The output data rate is 1/2 the input sampling rate, or 22.05 kHz. Specify the filter order to be 52 with a transition width of 4.1 kHz.

```
Fs = 44.1e3;
filterspec = 'Filter order and transition width';
Order = 52;
TW = 4.1e3;
firhalfbanddecim =dsp.FIRHalfbandDecimator('Specification',filterspec,...
                                            'FilterOrder',Order,...
                                            'TransitionWidth',TW,...
                                            'SampleRate',Fs);
```

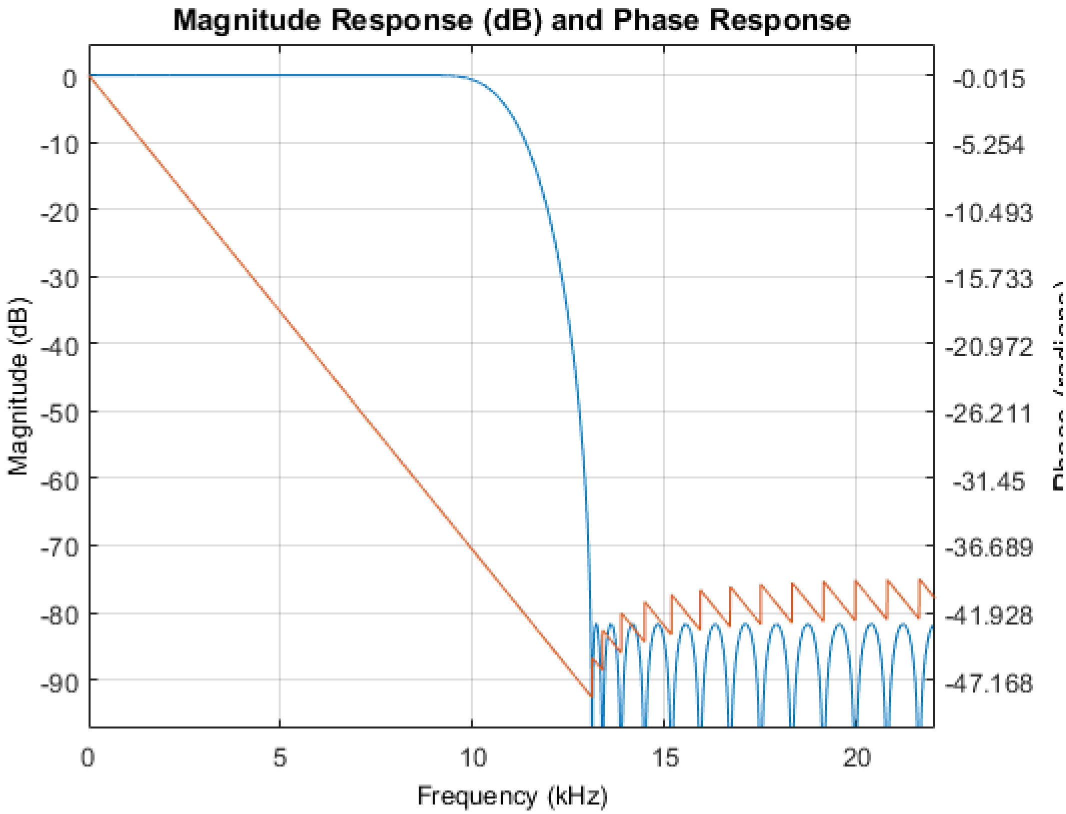
Plot the impulse response. The zero-th order coefficient is delayed 26 samples, which is equal to the group delay of the filter. This yields a causal half-band filter.

```
fvtool(firhalfbanddecim,'Analysis','impulse')
```



Plot the magnitude and phase response.

```
fvtool(firhalfbanddecim,'Analysis','freq')
```



Extract Low Frequency Subband From Speech

Use a halfband analysis filter bank and interpolation filter to extract the low frequency subband from a speech signal.

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

Set up the audio file reader, the analysis filter bank, audio device writer, and interpolation filter. The sampling rate of the audio data is 22050 Hz. The order of the halfband filter is 52, with a transition width of 2 kHz.

```
afr = dsp.AudioFileReader('speech_dft.mp3','SamplesPerFrame',1024);
```

```
filterspec = 'Filter order and transition width';
Order = 52;
TW = 2000;

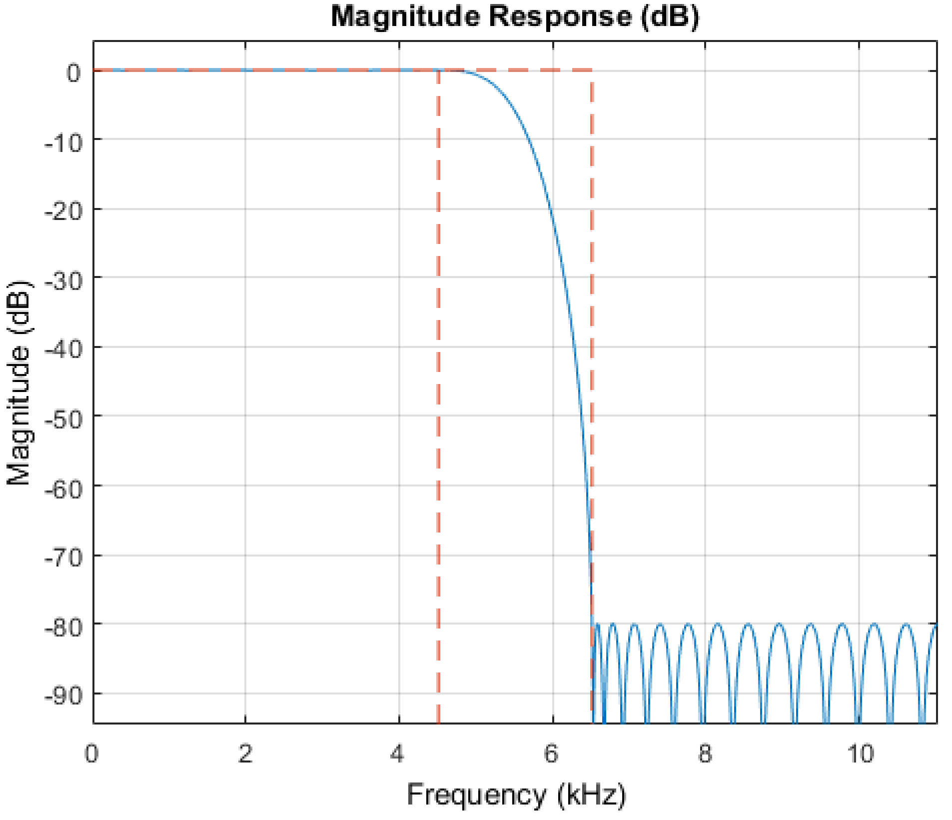
firhalfbanddecim = dsp.FIRHalfbandDecimator(...
    'Specification',filterspec,'FilterOrder',Order,...
    'TransitionWidth',TW,'SampleRate',afr.SampleRate);

firhalfbandinterp = dsp.FIRHalfbandInterpolator(...
    'Specification',filterspec,'FilterOrder',Order,...
    'TransitionWidth',TW,'SampleRate',afr.SampleRate/2);

adw = audioDeviceWriter('SampleRate',afr.SampleRate);
```

View the magnitude response of the halfband filter.

```
fvtool(firhalfbanddecim)
```



Read the speech signal from the audio file in frames of 1024 samples. Filter the speech signal into lowpass and highpass subbands with a halfband frequency of 5512.5 Hz. Reconstruct a lowpass approximation of the speech signal by interpolating the lowpass subband. Play the filtered output.

```
while ~isDone(afr)
  audioframe = afr();
  xlo = firhalfbanddecim(audioframe);
  ylow = firhalfbandinterp(xlo);
  adw(ylow);
end
```

Wait until the audio file is played to the end, then close the input file and release the audio output resource.

```
release(afr);
release(adw);
```

Two-Channel Filter Bank

Use a halfband decimator and interpolator to implement a two-channel filter bank. This example uses an audio file input and shows that the power spectrum of the filter bank output does not differ significantly from the input.

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

Set up the audio file reader and device writer. Construct the FIR halfband decimator and interpolator. Finally, set up the spectrum analyzer to display the power spectra of the filter-bank input and output.

```
AF = dsp.AudioFileReader('speech_dft.mp3','SamplesPerFrame',1024);
AP = audioDeviceWriter('SampleRate',AF.SampleRate);

filterspec = 'Filter order and transition width';
Order = 52;
TW = 2000;

firhalfbanddecim = dsp.FIRHalfbandDecimator(...
    'Specification',filterspec,'FilterOrder',Order,...
    'TransitionWidth',TW,'SampleRate',AF.SampleRate);

firhalfbandinterp = dsp.FIRHalfbandInterpolator(...
    'Specification',filterspec,'FilterOrder',Order,...
    'TransitionWidth',TW,'SampleRate',AF.SampleRate/2,...
    'FilterBankInputPort',true);

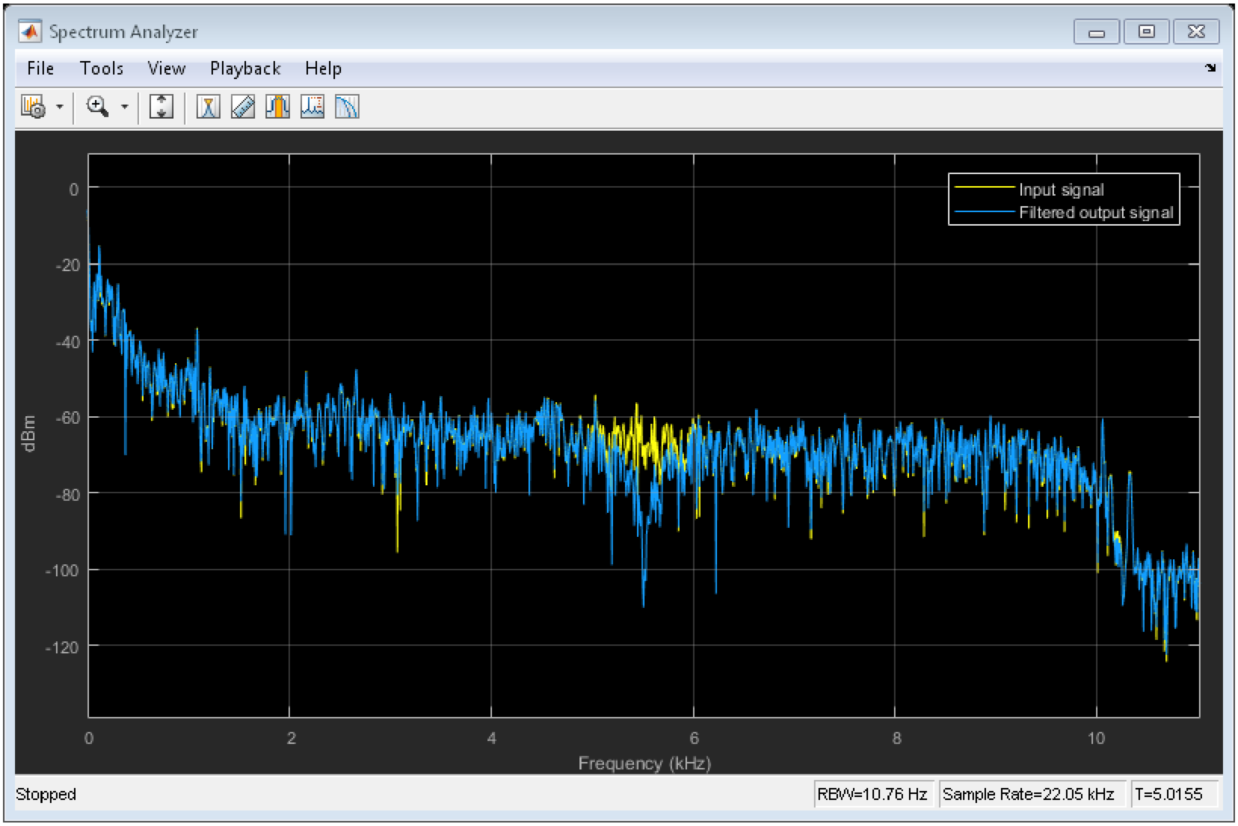
SpecAna = dsp.SpectrumAnalyzer('SampleRate',AF.SampleRate,...
    'PlotAsTwoSidedSpectrum',false,'ReducePlotRate',false,...
    'ShowLegend',true,...
    'ChannelNames',{'Input signal','Filtered output signal'});
```

Read the audio 1024 samples at a time. Filter the input to obtain the lowpass and highpass subband signals decimated by a factor of two. This is the analysis filter bank. Use the halfband interpolator as the synthesis filter bank. Display the running power spectrum of the audio input and the output of the synthesis filter bank. Play the output.

```
while ~isDone(AF)
    audioInput = AF();
```

```
    [xlo,xhigh] = firhalfbanddecim(audioInput);
    audioOutput = firhalfbandinterp(xlo,xhigh);
    spectrumInput = [audioInput audioOutput];
    SpecAna(spectrumInput);
    AP(audioOutput);
end

release(AF);
release(AP);
release(SpecAna);
```



Definitions

Halfband Filters

The ideal lowpass halfband filter is given by

$$h(n) = \frac{1}{2\pi}\int_{-\pi/2}^{\pi/2} e^{j\omega n}\, d\omega = \frac{\sin(\frac{\pi}{2} n)}{\pi n}.$$

The ideal filter is not realizable because the impulse response is noncausal and not absolutely summable. However, the impulse response of the ideal lowpass filter possesses some important properties that are required of a realizable approximation. Specifically, the ideal lowpass halfband filter's impulse response is:

- equal to 0 for all even-indexed samples
- equal to 1/2 at n=0. You can see this by using L'Hopital's rule on the continuous-valued equivalent of the discrete-time impulse response.

The ideal highpass halfband filter is given by

$$g(n) = \frac{1}{2\pi}\int_{-\pi}^{-\pi/2} e^{j\omega n}\, d\omega + \frac{1}{2\pi}\int_{\pi/2}^{\pi} e^{j\omega n}\, d\omega.$$

Evaluating the preceding integral gives the following impulse response

$$g(n) = \frac{\sin(\pi n)}{\pi n} - \frac{\sin(\frac{\pi}{2} n)}{\pi n}.$$

The ideal highpass halfband filter's impulse is:

- equal to 0 for all even-indexed samples
- equal to 1/2 at n=0.

`dsp.FIRHalfbandDecimator` uses a causal FIR approximation to the ideal halfband response, which is based on minimizing the ℓ^∞ norm of the error (minimax). See "Algorithms" on page 4-781 for more details.

Algorithms

Halfband Equiripple Design

`dsp.FIRHalfbandDecimator` uses a minimax FIR design to design a fullband linear phase filter with the desired specifications. The fullband filter is upsampled so that the even-indexed samples of the filter are replaced with zeros. The upsampling of the filter produces a halfband filter. Finally, the filter tap corresponding to the group delay of the filter in samples is set equal to 1/2. This yields a causal linear-phase FIR filter approximation to the ideal halfband filter defined in "Halfband Filters" on page 4-780. See [1] for a description of this filter design method using the Remez exchange algorithm.

Polyphase Implementation with Halfband Filters

`dsp.FIRHalfbandDecimator` uses an efficient polyphase implementation for halfband filters when you call step to filter your signal. The chief advantage of the polyphase implementation is that you can downsample the signal prior to filtering. This allows you to filter at the lower sampling rate.

Splitting a filter's impulse response, *h(n)*, into two polyphase components results in an even polyphase component with *z*-transform

$$H_0(z) = \sum_n h(2n) z^{-n}.$$

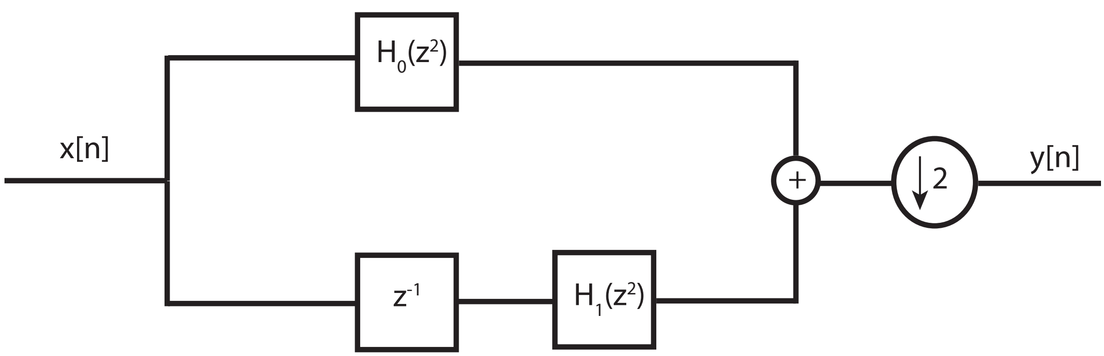
and an odd polyphase component with *z*-transform

$$H_1(z) = \sum_n h(2n+1) z^{-n}.$$

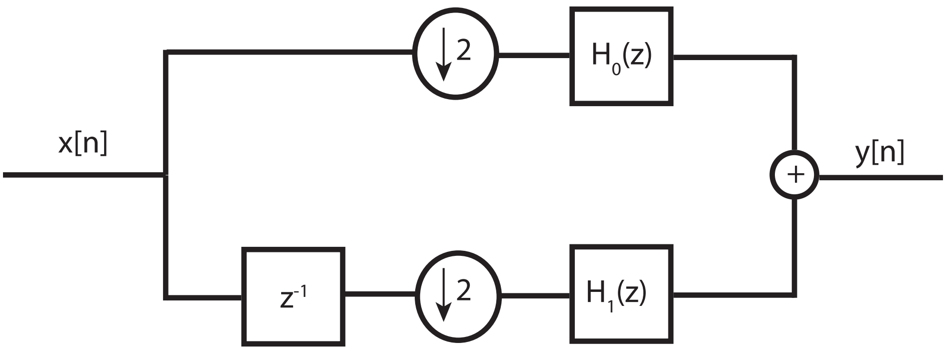
The *z*-transform of the filter can be written in terms of the even and odd polyphase components as

$$H(z) = H_0(z^2) + z^{-1} H_1(z^2).$$

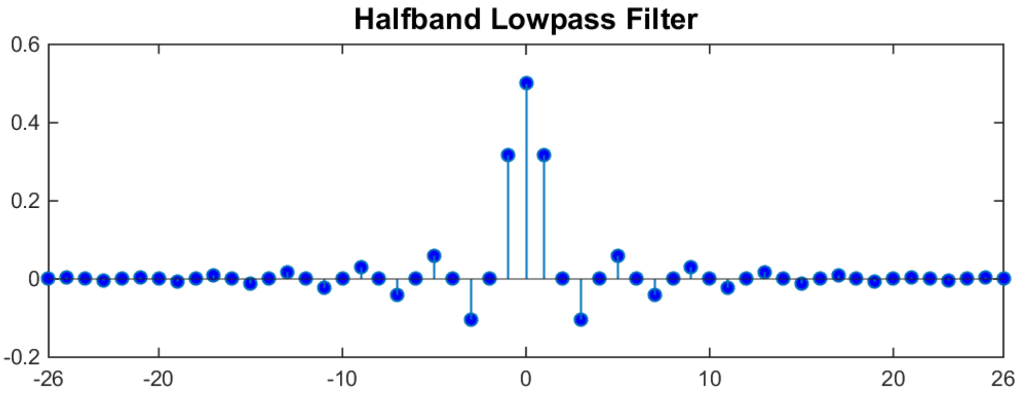
Graphically, you can represent filtering and input followed by downsampling by two with the following figure

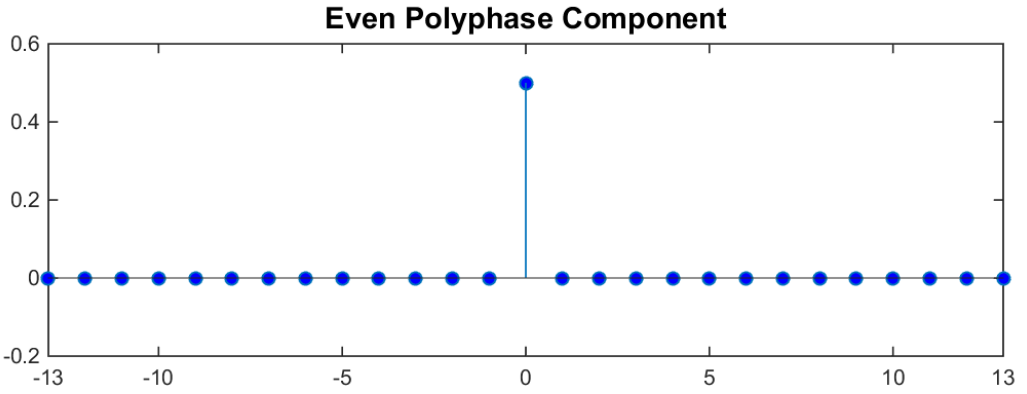


Using the multirate noble identity for downsampling, you can move the downsampling operation before filtering. This allows you to filter at the lower rate.



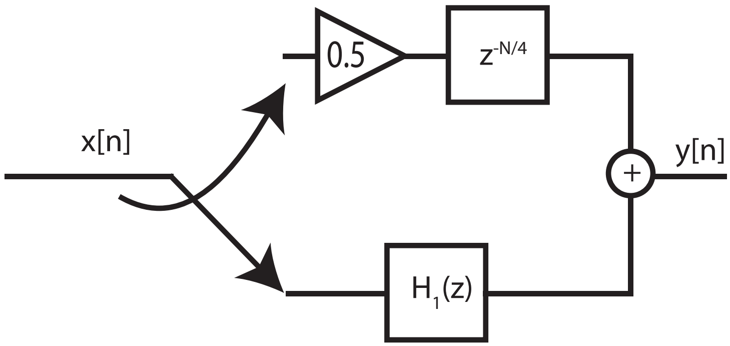
For a halfband filter, the only nonzero coefficient in the even polyphase component is the coefficient corresponding to z^0. Implementing the halfband filter as a causal FIR filter shifts the nonzero coefficient to approximately $z^{-N/4}$ where N is the number of filter taps. This process is illustrated in the following figure.





The top plot shows a halfband filter of order 52. The bottom plot shows the even polyphase component. Both of these filters are noncausal. Delaying the even polyphase component by 13 samples creates a causal FIR filter.

To efficiently implement the halfband decimator, `dsp.FIRHalfbandDecimator` replaces the delay block and downsampling operator with a commutator switch. This is illustrated in the following figure where one polyphase component is replaced by a gain and delay.



The commutator switch takes input samples from a single branch and supplies every other sample to one of the two polyphase components for filtering. This halves the sampling rate of the input signal. Which polyphase component reduces to a simple delay depends on whether the half order of the filter is even or odd. This is because the delay required to make the even polyphase component causal can be odd or even depending on the filter half order. You can see this by inspecting the polyphase components of the following filters.

```
filterspec = 'Filter order and stopband attenuation' ;
halfOrderEven = dsp.FIRHalfbandDecimator('Specification',filterspec,...
    'FilterOrder',64,'StopbandAttenuation',80);
halfOrderOdd = dsp.FIRHalfbandDecimator('Specification',filterspec,...
    'FilterOrder', 54,'StopbandAttenuation',80);
polyphase(halfOrderEven)
polyphase(halfOrderOdd)
```

To summarize, `dsp.FIRHalfbandDecimator`

- decimates the input prior to filtering and filters the even and odd polyphase components of the input separately with the even and odd polyphase components of the filter.
- exploits the fact that one filter polyphase component is a simple delay for a halfband filter.

reset

System object: dsp.FIRHalfbandDecimator
Package: dsp

Reset internal states of FIR halfband decimator

Syntax

```
reset(firhalfbanddecim)
```

Description

`reset(firhalfbanddecim)` resets the filter states of the FIR halfband decimator, `firhalfbanddecim`, to their initial values of 0. The initial filter state values correspond to the initial conditions for the difference equation defining the filter. After the `step` method applies the half-band decimator to nonzero input data, the states may be nonzero. Invoking the `step` method again without first invoking the`reset` method may produce different outputs for an identical input.

step

System object: dsp.FIRHalfbandDecimator
Package: dsp

Filter input with FIR halfband decimator

Syntax

```
Y = step(firhalfbanddecim,X)
[Ylow,Yhigh] = step(firhalfbanddecim,X)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(firhalfbanddecim,X)` filters the real or complex input signal `X` using the FIR halfband filter, `firhalfbanddecim`, and downsamples the output by a factor of 2 . `Y` is a lowpass halfband filtered and downsampled version of the input `X`. The input `X` must be a column vector or matrix with an even number of rows. If `X` is a matrix, each column is treated as an independent channel. The input `X` supports single, double, and fixed-point data types.

`[Ylow,Yhigh] = step(firhalfbanddecim,X)` outputs the lowpass, `Ylow`, and highpass, `Yhigh`, subbands.

Examples

Filter Input into Lowpass and Highpass Subbands

Create a halfband decimator for data sampled at 44.1 kHz. Use a minimum-order design with a transition width of 2 kHz and a stopband attenuation of 60 dB.

```
hfirhalfbanddecim = dsp.FIRHalfbandDecimator(...
    'Specification','Transition width and stopband attenuation',...
    'TransitionWidth',2000,'StopbandAttenuation',60,'SampleRate',44.1e3);
```

Filter a two-channel input into low and highpass subbands

```
x = randn(1024,2);
[ylow,yhigh] = step(hfirhalfbanddecim,x);
```

dsp.FIRHalfbandInterpolator System object

Package: dsp

Halfband interpolator

Description

`dsp.FIRHalfbandInterpolator` performs efficient polyphase interpolation of the input signal using an upsampling factor of two. You can use `dsp.FIRHalfbandInterpolator` to implement the synthesis portion of a two-band filter bank to synthesize a signal from lowpass and highpass subbands. `dsp.FIRHalfbandInterpolator` uses an FIR equiripple design to construct the halfband filters and a polyphase implementation to filter the input. This object supports fixed-point operations and ARM Cortex code generation.

To upsample and interpolate your data:

1. Define and set up your halfband interpolator. See “Construction” on page 4-790.
2. Call step to filter the input signal according to the properties of `dsp.FIRHalfbandInterpolator`. The input signal can be a real- or complex-valued column vector or matrix. If the input signal is a matrix, each column of the matrix is treated as an independent channel.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`firhalfbandinterp = dsp.FIRHalfbandInterpolator` returns a FIR halfband interpolation filter, `firhalfbandinterp`, with the default settings. Calling `step` with the default property settings upsamples and interpolates the input data using a halfband frequency of 11025 Hz, a transition width of 4.1 kHz, and a stopband attenuation of 80 dB.

`firhalfbandinterp = dsp.FIRHalfbandInterpolator(Name,Value)` returns a halfband interpolator, with additional properties specified by one or more `Name,Value` pair arguments. `Name` is the property name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name-value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Properties

`Specification` — Filter design parameters

`'Transition width and stopband attenuation'` (default) | `'Filter order and stopband attenuation'` | `'Filter order and transition width'`

Filter design parameters, specified as a character vector. Valid options are `'Transition width and stopband attenuation'` (default), `'Filter order and stopband attenuation'`, or `'Filter order and transition width'`. The filter design has only two degrees of freedom, so you can specify only two of the following: filter order, transition width, or stopband attenuation. Setting a filter design specification without additionally specifying values for the design parameters results in default values for the specifications.

`FilterOrder` — Filter order

52 (default) | even positive integer

Filter order, specified as the comma-separated pair of `'FilterOrder'` and an even positive integer. Specifying a filter order is valid only when the value of `‘Specification’` is `'Filter order and stopband attenuation'` or `'Filter order and transition width'`.

`StopbandAttenuation` — Stopband attenuation

80 (default) | positive real scalar

Stopband attenuation in dB, specified as the comma-separated pair of `'StopbandAttenuation'` and a positive real scalar. Specifying the stopband attenuation is valid only when the value of `‘Specification’` is `'Filter order and stopband attenuation'` or `'Transition width and stopband attenuation'`.

`TransitionWidth` — Transition width

4100 (default) | positive real scalar

Transition width in Hz, specified as the comma-separated pair of `'TransitionWidth'` and a positive real scalar. The value of the transition width in Hz must be less than 1/2 the output sample rate. Specifying the transition width is valid only when the value of ‘Specification’ is 'Transition width and stopband attenuation' or 'Filter order and transition width'.

SampleRate — Input sample rate
44100 (default) | positive real scalar

Input sample rate in Hz, specified as a comma-separated pair of 'SampleRate' and a positive real scalar. The input sample rate defaults to 44100 Hz. If you specify a transition width as one of your filter design parameters, the transition width cannot exceed 1/2 the input sample rate.

FilterBankInputPort — Synthesis filter bank
false (default) | true

Synthesis filter bank, specified as a comma-separated pair consisting of 'FilterBankInputPort' and a logical value. If this property is false, dsp.FIRHalfbandInterpolator is an interpolation filter for a single vector- or matrix-valued input when you use step. If this property is true, dsp.FIRHalfbandInterpolator is a synthesis filter bank and step accepts two inputs, the lowpass and highpass subbands to synthesize.

Fixed-Point Properties

CoefficientsDataType — Word and fraction lengths of coefficients
numerictype(1,16) (default) | numerictype object

Word and fraction lengths of coefficients, specified as a signed or unsigned numerictype object. The default, numerictype(1,16) corresponds to a signed numeric type object with 16-bit coefficients and a fraction length determined based on the coefficient values, to give the best possible precision.

This property is not tunable.

Word length of the output is same as the word length of the input. Fraction length of the output is computed such that the entire dynamic range of the output can be represented without overflow. For details on how the fraction length of the output is computed, see “Fixed-Point Precision Rules for Avoiding Overflow in FIR Filters”.

RoundingMethod — Rounding method for output fixed-point operations
'Floor' (default) | 'Ceiling' | 'Convergent' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'

Rounding method for output fixed-point operations, specified as a character vector. For more information on the rounding modes, see “Precision and Range”.

Methods

reset	Reset internal states of FIR halfband interpolator
step	Filter input with FIR halfband interpolator

For additional methods, see “Analysis Methods for Filter System Objects” on page 3-2.

For a complete list of analysis methods supported for the `dsp.FIRHalfbandInterpolator` object, enter `dsp.FIRHalfbandInterpolator.helpFilterAnalysis` at the MATLAB command prompt.

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Impulse and Frequency Response of Halfband Interpolation Filter

Create a lowpass halfband interpolation filter for upsampling data to 44.1 kHz. Specify a filter order of 52 and a transition width of 4.1 kHz.

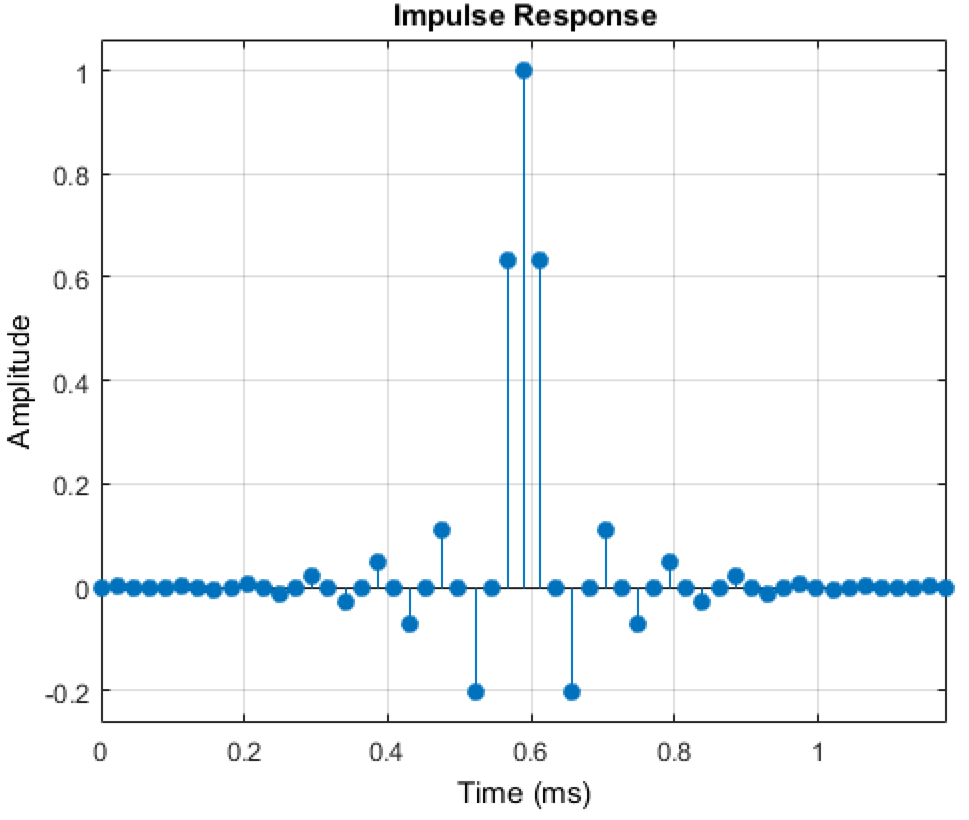
```
Fs = 44.1e3;
InputSampleRate = Fs/2;
Order = 52;
```

```
TW = 4.1e3;
filterspec = 'Filter order and transition width';

firhalfbandinterp = dsp.FIRHalfbandInterpolator(...
    'Specification',filterspec,'FilterOrder',Order,...
    'TransitionWidth',TW,'SampleRate',InputSampleRate);
```

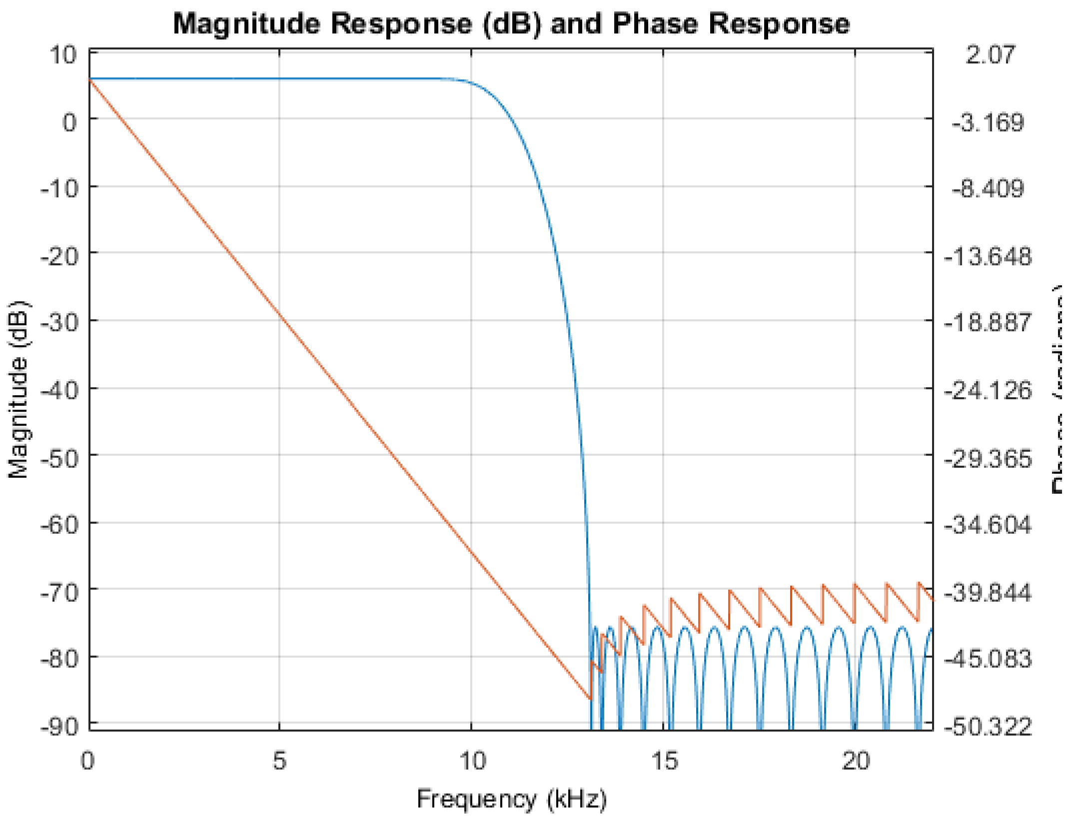
Plot the impulse response. The 0th order coefficient is delayed 26 samples, which is equal to the group delay of the filter. This yields a causal halfband filter.

```
fvtool(firhalfbandinterp,'Analysis','Impulse');
```



Plot the magnitude and phase response.

```
fvtool(firhalfbandinterp,'Analysis','freq');
```



Extract Low Frequency Subband From Speech

Use a halfband analysis filter bank and interpolation filter to extract the low frequency subband from a speech signal.

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

Set up the audio file reader, the analysis filter bank, audio device writer, and interpolation filter. The sampling rate of the audio data is 22050 Hz. The order of the halfband filter is 52, with a transition width of 2 kHz.

```
afr = dsp.AudioFileReader('speech_dft.mp3','SamplesPerFrame',1024);

filterspec = 'Filter order and transition width';
Order = 52;
TW = 2000;

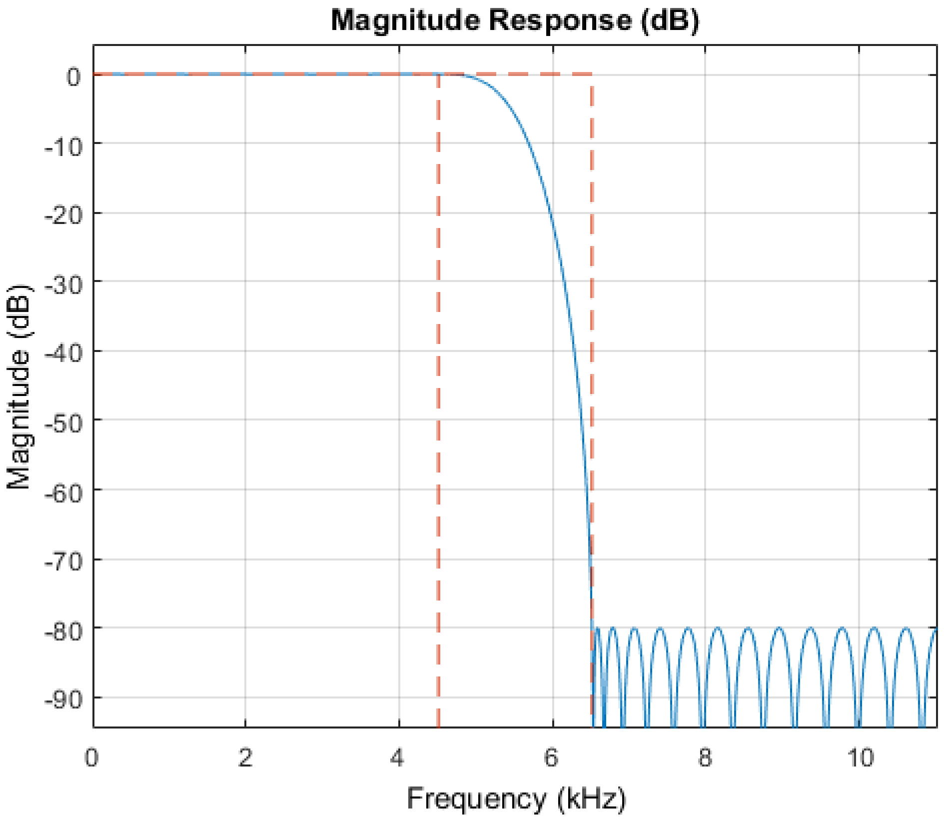
firhalfbanddecim = dsp.FIRHalfbandDecimator(...
    'Specification',filterspec,'FilterOrder',Order,...
    'TransitionWidth',TW,'SampleRate',afr.SampleRate);

firhalfbandinterp = dsp.FIRHalfbandInterpolator(...
    'Specification',filterspec,'FilterOrder',Order,...
    'TransitionWidth',TW,'SampleRate',afr.SampleRate/2);

adw = audioDeviceWriter('SampleRate',afr.SampleRate);
```

View the magnitude response of the halfband filter.

```
fvtool(firhalfbanddecim)
```



Read the speech signal from the audio file in frames of 1024 samples. Filter the speech signal into lowpass and highpass subbands with a halfband frequency of 5512.5 Hz. Reconstruct a lowpass approximation of the speech signal by interpolating the lowpass subband. Play the filtered output.

```
while ~isDone(afr)
  audioframe = afr();
  xlo = firhalfbanddecim(audioframe);
  ylow = firhalfbandinterp(xlo);
  adw(ylow);
end
```

Wait until the audio file is played to the end, then close the input file and release the audio output resource.

```
release(afr);
release(adw);
```

Two-Channel Filter Bank

Use a halfband decimator and interpolator to implement a two-channel filter bank. This example uses an audio file input and shows that the power spectrum of the filter bank output does not differ significantly from the input.

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

Set up the audio file reader and device writer. Construct the FIR halfband decimator and interpolator. Finally, set up the spectrum analyzer to display the power spectra of the filter-bank input and output.

```
AF = dsp.AudioFileReader('speech_dft.mp3','SamplesPerFrame',1024);
AP = audioDeviceWriter('SampleRate',AF.SampleRate);

filterspec = 'Filter order and transition width';
Order = 52;
TW = 2000;

firhalfbanddecim = dsp.FIRHalfbandDecimator(...
    'Specification',filterspec,'FilterOrder',Order,...
    'TransitionWidth',TW,'SampleRate',AF.SampleRate);

firhalfbandinterp = dsp.FIRHalfbandInterpolator(...
    'Specification',filterspec,'FilterOrder',Order,...
    'TransitionWidth',TW,'SampleRate',AF.SampleRate/2,...
    'FilterBankInputPort',true);

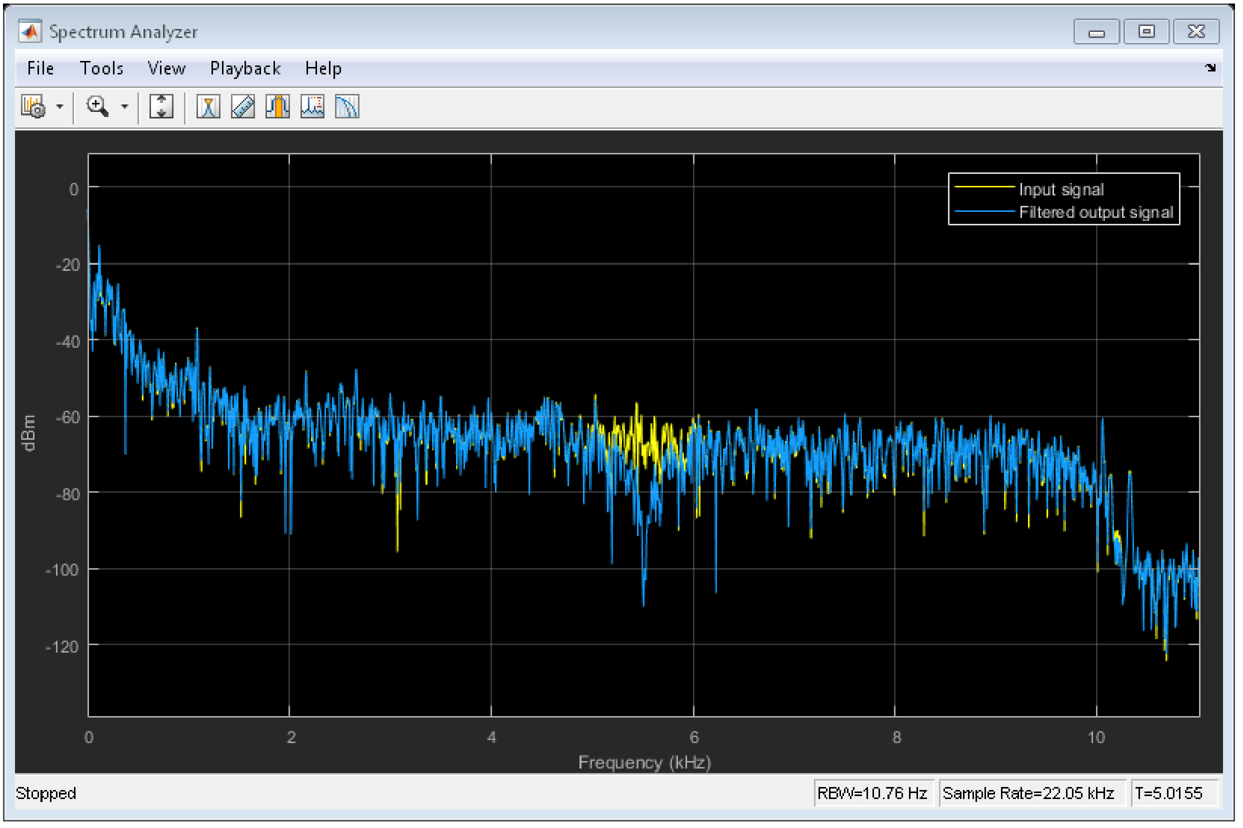
SpecAna = dsp.SpectrumAnalyzer('SampleRate',AF.SampleRate,...
    'PlotAsTwoSidedSpectrum',false,'ReducePlotRate',false,...
    'ShowLegend',true,...
    'ChannelNames',{'Input signal','Filtered output signal'});
```

Read the audio 1024 samples at a time. Filter the input to obtain the lowpass and highpass subband signals decimated by a factor of two. This is the analysis filter bank. Use the halfband interpolator as the synthesis filter bank. Display the running power spectrum of the audio input and the output of the synthesis filter bank. Play the output.

```
while ~isDone(AF)
    audioInput = AF();
```

```
    [xlo,xhigh] = firhalfbanddecim(audioInput);
    audioOutput = firhalfbandinterp(xlo,xhigh);
    spectrumInput = [audioInput audioOutput];
    SpecAna(spectrumInput);
    AP(audioOutput);
end

release(AF);
release(AP);
release(SpecAna);
```



Definitions

Halfband Filters

The ideal lowpass halfband filter is given by

$$h(n)=\frac{1}{2\pi}\int_{-\pi/2}^{\pi/2} e^{j\omega n}\,d\omega=\frac{\sin(\frac{\pi}{2}n)}{\pi n}.$$

The ideal filter is not realizable because the impulse response is noncausal and not absolutely summable. However, the impulse response of the ideal lowpass filter possesses some important properties that are required of a realizable approximation. Specifically, the ideal lowpass halfband filter's impulse response is:

- equal to 0 for all even-indexed samples
- equal to 1/2 at n=0. You can see this by using L'Hopital's rule on the continuous-valued equivalent of the discrete-time impulse response.

The ideal highpass halfband filter is given by

$$g(n) = \frac{1}{2\pi}\int_{-\pi}^{-\pi/2} e^{j\omega n}\, d\omega + \frac{1}{2\pi}\int_{\pi/2}^{\pi} e^{j\omega n}\, d\omega.$$

Evaluating the preceding integral gives the following impulse response

$$g(n) = \frac{\sin(\pi n)}{\pi n} - \frac{\sin(\frac{\pi}{2} n)}{\pi n}.$$

The ideal highpass halfband filter's impulse is:

- Equal to 0 for all even-indexed samples
- Equal to 1/2 at n=0.

`dsp.FIRHalfbandInterpolator` uses a causal FIR approximation to the ideal halfband response, which is based on minimizing the ℓ^{∞} norm of the error (minimax). See "Algorithms" on page 4-801 for more details.

Algorithms

Halfband Equiripple Design

`dsp.FIRHalfbandInterpolator` uses a minimax FIR design to design a fullband linear phase filter with the desired specifications. The fullband filter is upsampled so that the even-indexed samples of the filter are replaced with zeros. The upsampling of the filter produces a halfband filter. Finally, the filter tap corresponding to the group delay of the filter in samples is set equal to 1/2. This yields a causal linear-phase FIR filter approximation to the ideal halfband filter defined in "Halfband Filters" on page 4-800. See [1] for a description of this filter design method using the Remez exchange algorithm.

The coefficients of the halfband interpolation filter are scaled by the interpolation factor, two, to preserve the output power of the signal.

Polyphase Implementation with Halfband Filters

`dsp.FIRHalfbandInterpolator` uses an efficient polyphase implementation for halfband filters when you call step to filter your signal. You can use a polyphase implementation to move the upsampling operation after filtering. This allows you to filter at the lower sampling rate.

Splitting a filter's impulse response, *h(n)*, into two polyphase components results in an even polyphase component with *z*-transform

$$H_0(z) = \sum_n h(2n) z^{-n}.$$

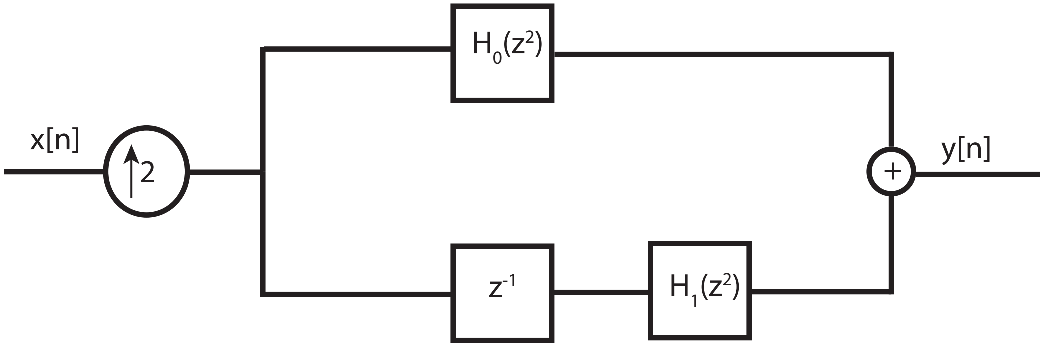
and an odd polyphase component with *z*-transform

$$H_1(z) = \sum_n h(2n+1) z^{-n}.$$

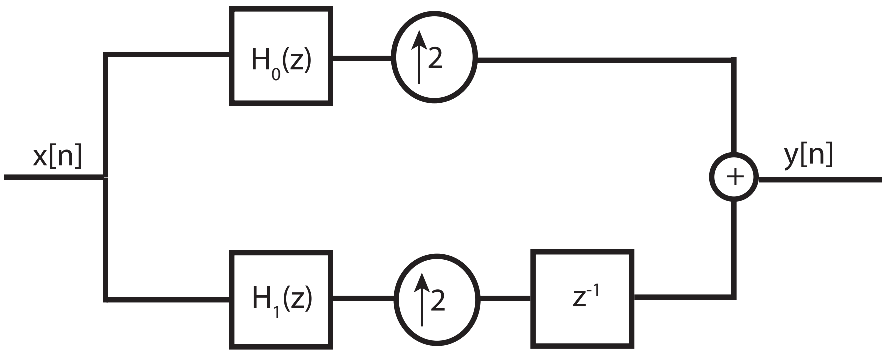
The *z*-transform of the filter can be written in terms of the even and odd polyphase components as

$$H(z) = H_0(z^2) + z^{-1} H_1(z^2).$$

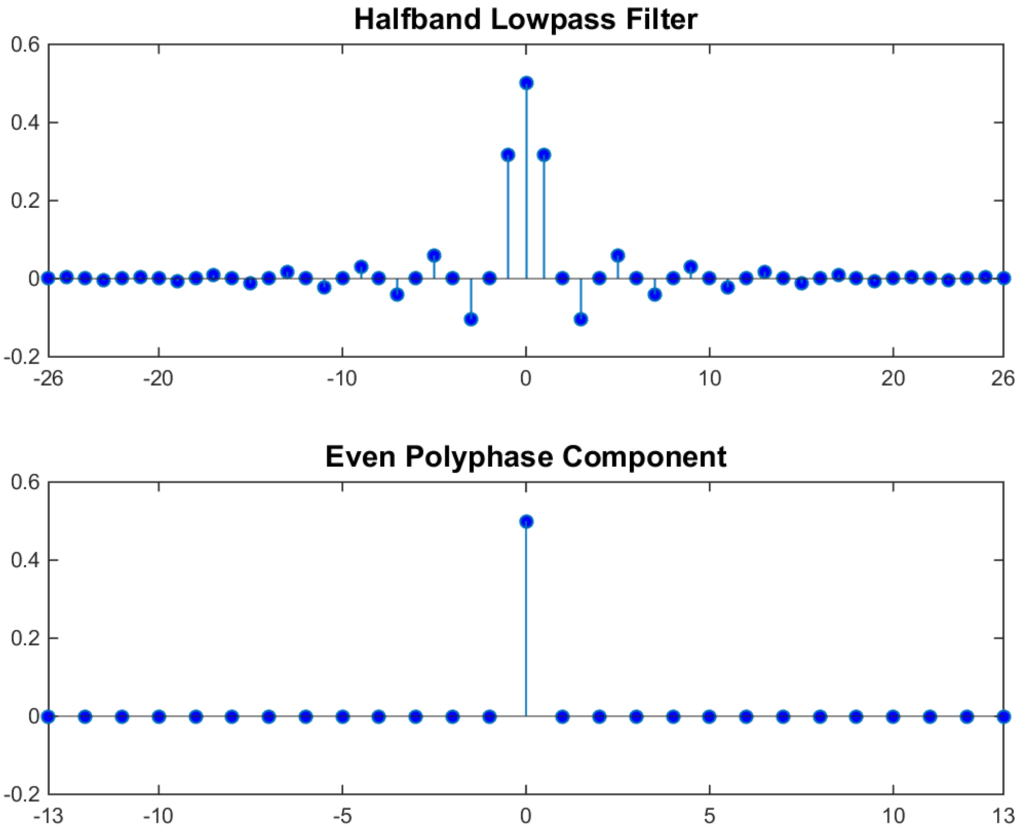
Graphically, you can represent upsampling by two followed by filtering with the following figure



Using the multirate noble identity for upsampling, you can move the upsampling operation after filtering. This enables you to filter at the lower rate.

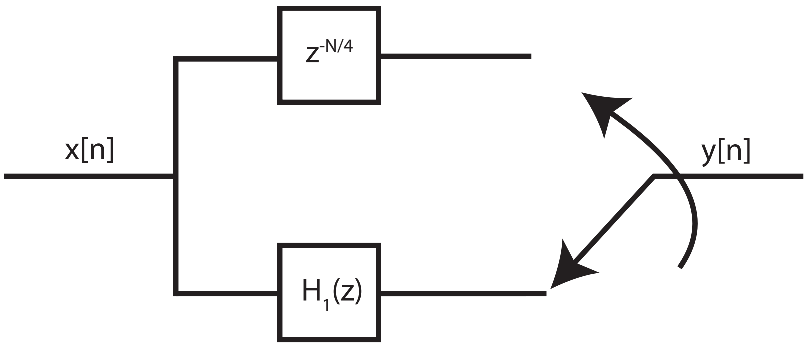


For a halfband filter, the only nonzero coefficient in the even polyphase component is the coefficient corresponding to z^0. Implementing the halfband filter as a causal FIR filter shifts the nonzero coefficient to approximately $z^{-N/4}$, where N is the number of filter taps. This process is shown in the following figure.



The top plot shows a halfband filter of order 52. The bottom plot shows the even polyphase component. Both of these filters are noncausal. Delaying the even polyphase component by 13 samples creates a causal FIR filter.

To efficiently implement the halfband interpolator, `dsp.FIRHalfbandInterpolator` replaces the upsampling operator, delay block, and adder with a commutator switch. This is shown in the following figure, where one polyphase component is replaced by a delay.



The commutator switch takes input samples from the two branches alternately, one sample at a time. This doubles the sampling rate of the input signal. The polyphase component that reduces to a simple delay depends on whether the half order of the filter is even or odd. This is because the delay required to make the even polyphase component causal can be odd or even, depending on the filter half order. For an example of this behavior, inspect the polyphase components of the following filters.

```
filterspec = 'Filter order and stopband attenuation';
halfOrderEven = dsp.FIRHalfbandInterpolator('Specification',filterspec,...
    'FilterOrder',64,'StopbandAttenuation',80);
halfOrderOdd = dsp.FIRHalfbandInterpolator('Specification',filterspec,...
    'FilterOrder', 54,'StopbandAttenuation',80);
polyphase(halfOrderEven)
polyphase(halfOrderOdd)
```

One of the polyphase components has a single nonzero coefficient indicating that it is a simple delay. To preserve the output power of the signal, the coefficients are scaled by the interpolation factor, two. To see this scaling, compare the polyphase components of a halfband interpolator with the coefficients of a halfband decimator.

```
hfirinterp = dsp.FIRHalfbandInterpolator;
hfirdecim = dsp.FIRHalfbandDecimator;
polyphase(hfirdecim)
polyphase(hfirinterp)
```

To summarize, `dsp.FIRHalfbandInterpolator`

- Filters the input before upsampling with the even and odd polyphase components of the filter.
- Exploits the fact that one filter polyphase component is a simple delay for a halfband filter.

Reset internal states of FIR halfband interpolator

Syntax

`reset(firhalfbandinterp)`

Description

`reset(firhalfbandinterp)` resets the filter states of the FIR halfband interpolator, `firhalfbandinterp`, to their initial values of 0. The initial filter state values correspond to the initial conditions for the difference equation defining the filter. After the `step` method applies the halfband interpolator to nonzero input data, the states may be nonzero. Invoking the `step` method again without first invoking the`reset` method may produce different outputs for an identical input.

step

System object: dsp.FIRHalfbandInterpolator
Package: dsp

Filter input with FIR halfband interpolator

Syntax

```
Y = step(firhalfbandinterp,X)
Y = step(firhalfbandinterp,X1,X2)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(firhalfbandinterp,X)` upsamples by two and interpolates the real or complex input signal `X` using the FIR halfband interpolator, `firhalfbandinterp`. The input `X` must be a column vector or matrix. If `X` is a matrix, each column is treated as an independent channel. The input `X` supports single, double, and fixed-point data types.

`Y = step(firhalfbandinterp,X1,X2)` implements a halfband synthesis filter bank for the inputs `X1` and `X2`. `X1` is the lowpass output of a halfband analysis filter bank and `X2` is the highpass output of a halfband analysis filter bank. `dsp.FIRHalfbandInterpolator` implements a synthesis filter bank only when the `'FilterBankInputPort'` property is `true`.

Examples

Upsample and Interpolate Multichannel Input

Create a half-band interpolation filter for data sampled at 44.1 kHz. The filter order is 52 with a transition width of 4.1 kHz. Use the filter to upsample and interpolate a multichannel input.

```
Fs = 44.1e3;
filterspec = 'Filter order and transition width';
Order = 52;
TW = 4.1e3;
firhalfbandinterp = dsp.FIRHalfbandInterpolator(...
                                               'Specification',filterspec,...
                                               'FilterOrder',Order,...
                                               'TransitionWidth',TW,...
                                                'SampleRate',Fs);

x = randn(1024,4);
y = step(firhalfbandinterp,x);
```

dsp.FIRInterpolator System object

Package: dsp

Polyphase FIR interpolator

Description

The `FIRInterpolator` object upsamples an input by the integer upsampling factor, *L*, followed by an FIR anti-imaging filter. The filter coefficients are scaled by the interpolation factor. A polyphase interpolation structure implements the filter. The resulting discrete-time signal has a sampling rate *L* times the original sampling rate.

To upsample an input:

1. Define and set up your FIR interpolator. See "Construction" on page 4-810.
2. Call step to upsample the input according to the properties of `dsp.FIRInterpolator`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`firinterp = dsp.FIRInterpolator` returns an FIR interpolator, `firinterp`, which upsamples an input signal by a factor of 3 and applies an FIR filter to interpolate the output.

`firinterp = dsp.FIRInterpolator('`*`PropertyName`*`',`*`PropertyValue`*`, ...)` returns an FIR interpolator, `firinterp`, with each property set to the specified value.

`firinterp = dsp.FIRInterpolator(INTERP, NUM,'`*`PropertyName`*`',`*`PropertyValue`*`, ...)` returns an FIR interpolation object, firinterp, with the InterpolationFactor property set to INTERP, the Numerator property set to NUM, and other properties set to the specified values.

Properties

InterpolationFactor

Interpolation factor

Specify the integer factor, L, by which to increase the sampling rate of the input signal. The polyphase implementation uses L polyphase subfilters to compute convolutions at the lower sample rate. The FIR interpolator delays and interleaves these lower-rate convolutions to obtain the higher-rate output. The property value defaults to 3.

NumeratorSource

FIR filter coefficient source

Specify the source of the numerator coefficients as one of 'Property' (default) or 'Input port'. When you specify 'Input port', the filter object requires the numerator coefficients to be specified as the third argument to every step.

Numerator

FIR filter coefficients

Specify the numerator coefficients of the FIR anti-imaging filter as the coefficients of a polynomial in z^{-1}. Indexing from zero, the filter coefficients are:

$$H(z) = \sum_{n=0}^{N-1} b(n) z^{-n}$$

To act as an effective anti-imaging filter, the coefficients must correspond to a lowpass filter with a normalized cutoff frequency no greater than the reciprocal of the InterpolationFactor on page 4-811. The filter coefficients are scaled by the value of the InterpolationFactor property before filtering the signal. To form the L polyphase subfilters, Numerator is appended with zeros if necessary. The default is the output of fir1(15,0.25). This property is valid only when the NumeratorSource on page 4-811 property is 'Property'.

Fixed-Point Properties

`FullPrecisionOverride`

Full precision override for fixed-point arithmetic

Specify whether to use full precision rules. If you set `FullPrecisionOverride` to `true`, which is the default, the object computes all internal arithmetic and output data types using full precision rules. These rules provide the most accurate fixed-point numerics. It also turns off the display of other fixed-point properties because they do not apply individually. These rules guarantee that no quantization occurs within the object. Bits are added, as needed, to ensure that no roundoff or overflow occurs. If you set `FullPrecisionOverride` to `false`, fixed-point data types are controlled through individual fixed-point property settings. For more information, see “Full Precision for Fixed-Point System Objects”.

`RoundingMethod`

Rounding method for fixed-point operations

Specify the rounding method as one of `| Ceiling | Convergent | Floor | Nearest | Round | Simplest | Zero |`. The default is `Floor`. This property applies only if the object is not in full precision mode.

`OverflowAction`

Overflow action for fixed-point operations

Specify the overflow action as one of `| Wrap | Saturate |`. The default is `Wrap`. This property applies only if the object is not in full precision mode.

`CoefficientsDataType`

Coefficient word and fraction lengths

Specify the coefficients fixed-point data type as one of `| Same word length as input | Custom |`. The default is `Same word length as input`.

`CustomCoefficientsDataType`

Coefficient word and fraction lengths

Specify the coefficients fixed-point type as a `numerictype` object with a `Signedness` of `Auto`. This property applies only when the `CoefficientsDataType` on page 4-812 property is `Custom`. The default is `numerictype([],16,15)`.

ProductDataType

Product word and fraction lengths

Specify the product fixed-point data type as one of | `Full precision` | `Same as input` | `Custom` |. The default is `Full precision`.

CustomProductDataType

Product word and fraction lengths

Specify the product fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when the `ProductDataType` on page 4-813 property is `Custom`. The default is `numerictype([],32,30)`.

AccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point data type as one of | `Full precision` | `Same as product` | `Same as input` | `Custom` |. The default is `Full precision`.

CustomAccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when the `AccumulatorDataType` on page 4-813 property is `Custom`. The default is `numerictype([],32,30)`.

OutputDataType

Output word and fraction lengths

Specify the output fixed-point data type as one of | `Same as accumulator` | `Same as product` | `Same as input` | `Custom` |. The default is `Same as accumulator`.

CustomOutputDataType

Output word and fraction lengths

Specify the output fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when the `OutputDataType` on page 4-813 property is `Custom`. The default is `numerictype([],16,15)`.

Methods

freqz	Frequency response
fvtool	Open filter visualization tool
impz	Impulse response
phasez	Unwrapped phase response
reset	Reset FIR interpolator filter states
step	Upsample and interpolate input

More “Analysis Methods for Filter System Objects” on page 3-2.

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Double the Sample Rate Using FIR Intepolator

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

This example shows how to double the sampling rate of an audio signal from 22.05 kHz to 44.1 kHz, and play the audio.

```
afr = dsp.AudioFileReader('OutputDataType',...
   'single');
```

```
adw = audioDeviceWriter(44100);
firinterp = dsp.FIRInterpolator(2, ...
   firpm(30, [0 0.45 0.55 1], [1 1 0 0]));

while ~isDone(afr)
     frame = afr();
     y = firinterp(frame);
     adw(y);
end

pause(1);
release(afr);
release(adw);
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the `FIR Interpolation` block reference page. The object properties correspond to the block parameters, except:

- The `FIRInterpolator` object does not have a property that corresponds to the **Input processing** parameter of the FIR Interpolation block.
- The **Rate options** block parameter is not supported by the `FIRInterpolator` object.

dsp.FIRRateConverter | dsp.FIRDecimator

Introduced in R2012a

freqz

System object: dsp.FIRInterpolator
Package: dsp

Frequency response

Syntax

```
[h,w] = freqz(firinterp)
[h,w] = freqz(firinterp,n)
[h,w] = freqz(firinterp,Name,Value)
freqz(firinterp)
```

Description

`[h,w] = freqz(firinterp)` returns the complex, 8192–element frequency response vector `h`, and the corresponding frequencies `w` in radians/sample.

`[h,w] = freqz(firinterp,n)` returns the complex, n-element frequency response vector `h`, and the corresponding frequencies `w` in radians/sample, using `n` samples.

`[h,w] = freqz(firinterp,Name,Value)` returns the frequency response and the corresponding frequencies, with additional options specified by one or more Name, Value pair arguments.

`freqz(firinterp)` uses FVTool to plot the magnitude and unwrapped phase of the frequency response of the filter System object `firinterp`.

fvtool

System object: dsp.FIRInterpolator
Package: dsp

Open filter visualization tool

Syntax

```
fvtool(firinterp)
fvtool(firinterp,'Arithmetic',ARITH,...)
```

Description

`fvtool(firinterp)` performs an analysis and computes the magnitude response of the filter System object `firinterp`.

`fvtool(firinterp,'Arithmetic',ARITH,...)` analyzes the filter System object `firinterp`, based on the arithmetic specified in the ARITH input. ARITH can be set to one of 'double', 'single', or 'fixed'. The analysis tool assumes a double precision filter when the arithmetic input is not specified and the filter System object is in an unlocked state. The 'Arithmetic' input is only relevant for the analysis of filter System objects.

impz

System object: dsp.FIRInterpolator
Package: dsp

Impulse response

Syntax

```
[h,t] = impz(firinterp)
[h,t] = impz(firinterp,Name,Value)
impz(firinterp)
```

Description

`[h,t] = impz(firinterp)` returns the impulse response `h`, and the corresponding time points `t` at which the impulse response of`firinterp` is computed.

`[h,t] = impz(firinterp,Name,Value)` returns the impulse response `h`, and the corresponding time points`t` , with additional options specified by one or more Name, Value pair arguments.

`impz(firinterp)` uses FVTool to plot the impulse response of the filter System object `firinterp`.

Note: You can use `impz` for both real and complex filters. When you omit the output arguments, `impz` plots only the real part of the impulse response.

phasez

System object: dsp.FIRInterpolator
Package: dsp

Unwrapped phase response

Syntax

```
[phi,w] = phasez(firinterp)
[phi,w] = phasez(firinterp,n)
[phi,w] = phasez(firinterp,Name,Value)
phasez(firinterp)
```

Description

`[phi,w] = phasez(firinterp)` returns the 8192–element phase response vector `phi`, and the corresponding frequencies `w` in radians/sample.

`[phi,w] = phasez(firinterp,n)` returns the n-element phase response vector `phi`, and the corresponding frequencies `w` in radians/sample, using `n` samples.

`[phi,w] = phasez(firinterp,Name,Value)` returns the phase response and the corresponding frequencies, with additional options specified by one or more Name, Value pair arguments.

`phasez(firinterp)` uses FVTool to plot the phase response of the filter System object `firinterp`.

reset

System object: dsp.FIRInterpolator
Package: dsp

Reset FIR interpolator filter states

Syntax

`reset(firinterp)`

Description

`reset(firinterp)` resets the filter states of the FIR filter in the interpolator object, `firinterp`, to their initial values of 0. The initial filter state values correspond to the initial conditions for the constant coefficient linear difference equation defining the FIR filter. After the `step` method applies the interpolator to nonzero input data, the states may be nonzero. Invoking the `step` method again without first invoking the `reset` method may produce different outputs for an identical input.

Reset an FIR Interpolator

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

Reset filter states to 0 to produce consistent output.

```
firinterp = dsp.FIRInterpolator(2);
x =[1 -1]'; x = repmat(x,8,1);
y = firinterp(x); % Filter states are nonzero
```

Use reset method to set states to zero.

```
reset(firinterp);
```

Apply FIR interpolator to input x

```
y1 = firinterp(x);
```

```
isequal(y,y1)
```

```
ans =

  logical

   1
```

step

System object: dsp.FIRInterpolator
Package: dsp

Upsample and interpolate input

Syntax

```
Y = step(firinterp,X)
Y = step(firinterp,X,Num)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(firinterp,X)` outputs the upsampled and interpolated values, `Y` , of the input signal `X` . A K-by-N input matrix is treated as N independent channels. The FIR interpolator object interpolates each channel over the first dimension and generates a M-by-N output matrix, where M is the product of K and the upsampling factor, L.

`Y = step(firinterp,X,Num)` uses the FIR filter, `Num`, to interpolate the input signal. This configuration is valid only when the `'NumeratorSource'` property is `'Input port'`.

Note: `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change

nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.FIRRateConverter System object

Package: dsp

Sample rate converter

Description

The `FIRRateConverter` performs sampling rate conversion by a rational factor on a vector or matrix input. The FIR rate convertor cascades an interpolator with a decimator. The interpolator upsamples the input by the upsampling factor, *L*, followed by a lowpass FIR filter. The FIR filter acts both as an anti-imaging filter and an anti-aliasing filter prior to decimation. The decimator downsamples the output of upsampling and FIR filtering by the downsampling factor *M*. You must use upsampling and downsampling factors that are relatively prime, or coprime. The resulting discrete-time signal has a sampling rate *L*/*M* times the original sampling rate.

To perform sampling rate conversion:

1 Define and set up your FIR sample rate converter. See “Construction” on page 4-825.
2 Call step to perform sampling rate conversion according to the properties of `dsp.FIRRateConverter`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`firrc = dsp.FIRRateConverter` returns a FIR sample rate converter, `firrc`, that resamples an input signal at a rate 3/2 times the original sampling rate.

`firrc = dsp.FIRRateConverter('`*`PropertyName`*`',`*`PropertyValue`*`, ...)` returns an FIR sample rate converter, `firrc`, with each property set to the specified value.

firrc = dsp.FIRRateConverter(L,M,NUM,'*PropertyName*', *PropertyValue*, ...) returns an FIR sample rate converter, firrc, with the InterpolationFactor property set to L, the DecimationFactor property set to M, the Numerator property set to NUM, and other specified properties set to the specified values.

Properties

InterpolationFactor

Interpolation factor

Specify the integer upsampling factor. The default is 3.

DecimationFactor

Decimation factor

Specify the integer downsampling factor. The default is 2.

Numerator

FIR filter coefficients

Specify the FIR filter coefficients in powers of z^{-1}. The length of filter coefficients must exceed the interpolation factor. Use a lowpass with normalized cutoff frequency no greater than min(1/InterpolationFactor, 1/DecimationFactor). All initial filter states are zero. The default is firpm(70,[0 0.28 0.32 1],[1 1 0 0]).

Fixed-Point Properties

FullPrecisionOverride

Full precision override for fixed-point arithmetic

Specify whether to use full precision rules. If you set FullPrecisionOverride to true, which is the default, the object computes all internal arithmetic and output data types using full precision rules. These rules provide the most accurate fixed-point numerics. It also turns off the display of other fixed-point properties because they do not apply individually. These rules guarantee that no quantization occurs within the object. Bits are added, as needed, to ensure that no roundoff or overflow occurs. If you set `FullPrecisionOverride` to `false`, fixed-point data types are controlled through individual fixed-point property settings. For more information, see “Full Precision for Fixed-Point System Objects”.

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as one of | `Ceiling` | `Convergent` | `Floor` | `Nearest` | `Round` | `Simplest` | `Zero` |. The default is `Floor`. This property applies only if the object is not in full precision mode.

OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as one of | `Wrap` | `Saturate` |. The default is `Wrap`. This property applies only if the object is not in full precision mode.

CoefficientsDataType

Word and fraction lengths of filter coefficients

Specify the filter coefficient fixed-point data type as one of | `Same word length as input` | `Custom` |. The default is `Same word length as input`.

CustomCoefficientsDataType

Word and fraction lengths of filter coefficients

Specify the filter coefficient fixed-point type as a `numerictype` object with a `Signedness` of `Auto`. This property applies only when the `CoefficientsDataType` on page 4-827 property is `Custom`. The default is `numerictype([],16,15)`.

ProductDataType

Product word and fraction lengths

Specify the product fixed-point data type as one of | `Full precision` | `Same as input` | `Custom` |. The default is `Full precision`.

CustomProductDataType

Product word and fraction lengths

Specify the product fixed-point type as a scaled numerictype object with a Signedness of Auto. This property applies only when the ProductDataType on page 4-827 property is Custom. The default is numerictype([],32,30).

AccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point data type as one of | Full precision | Same as product | Same as input | Custom |. The default is Full precision.

CustomAccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled numerictype object with a Signedness of Auto. This property applies only when the AccumulatorDataType on page 4-828 property is Custom. The default is numerictype([],32,30).

OutputDataType

Output word and fraction lengths

Specify the output fixed-point data type as one of | Same as accumulator | Same as product | Same as input | Custom |. The default is Same as accumulator.

CustomOutputDataType

Output word and fraction lengths

Specify the output fixed-point type as a scaled numerictype object with a Signedness of Auto. This property applies only when the OutputDataType on page 4-828 property is Custom. The default is numerictype([],16,15).

Methods

reset	Reset states of FIR sample rate converter

step	Resample input with FIR rate converter

Common to All System Objects	
clone	Create System object with same property values
getNumInpu	Expected number of inputs to a System object
getNumOutp	Expected number of outputs of a System object
isLocked	Check locked states of a System object (logical)
release	Allow System object property value changes

Examples

Resample a Signal using FIR Rate Converter

This example shows how to resample a 100 Hz sine wave signal by a factor of 3:2.

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

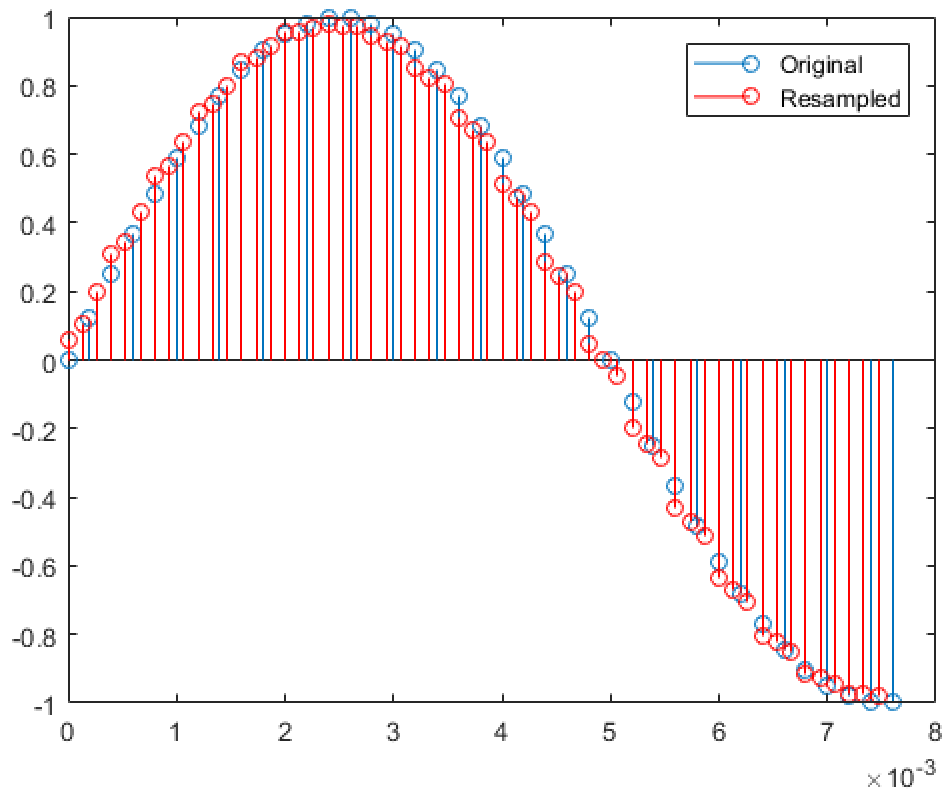
```
sine = dsp.SineWave(1, 100,'SampleRate', 5000,'SamplesPerFrame', 50);
```

Create a FIR rate converter filter. The default interpolation factor is 3 and decimation factor is 2.

```
firrc = dsp.FIRRateConverter;
input = sine();
output = firrc(input);
```

Plot the original and resampled signals.

```
ndelay = round(length(firrc.Numerator)/2/firrc.DecimationFactor);
indx = ndelay+1:length(output);
x = (0:length(indx)-1)/sine.SampleRate*firrc.DecimationFactor/firrc.InterpolationFacto
stem((0:38)/sine.SampleRate, input(1:39)); hold on;
stem(x, firrc.InterpolationFactor*output(indx),'r');
legend('Original','Resampled');
```



Resample and Play an Audio Signal

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

This example shows how to resample and play an audio signal from 48 kHz to 32 kHz on a Windows® platform.

```
afr = dsp.AudioFileReader('audio48kHz.wav', ...
    'OutputDataType', 'single', ...
    'SamplesPerFrame', 300);
adw = audioDeviceWriter(32000);
```

Create an FIRRateConverter System object with interpolation factor = 2, decimation factor = 3. Default FIR filter coefficients define a lowpass filter with normalized cutoff frequency of 1/3.

```
firrc = dsp.FIRRateConverter(2,3);

while ~isDone(afr)
    audio1 = afr();
    audio2 = firrc(audio1);
    adw(audio2);
end

release(afr);
release(adw);
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the `FIR Rate Conversion` block reference page. The object properties correspond to the block parameters.

Reset states of FIR sample rate converter

Syntax

```
reset(firrc)
```

Description

`reset(firrc)` resets the filter states of the FIR filter in the sample rate converter, `firrc`, to their initial values of 0. The initial filter state values correspond to the initial conditions for the constant coefficient linear difference equation defining the FIR filter. After the `step` method applies the FIR rate converter to nonzero input data, the states may be nonzero. Invoking the `step` method again without first invoking the `reset` method may produce different outputs for an identical input.

Reset an FIR Rate Converter

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

Reset filter states to 0 to produce consistent output.

```
firrc = dsp.FIRRateConverter(2,4);
x =[1 -1]'; x = repmat(x,8,1);
y = firrc(x); % Filter states are nonzero
```

Use reset method to set states to zero.

```
reset(firrc);
```

Apply sampling rate converter to input x

```
y1 = firrc(x);
```

```
isequal(y,y1)

ans =

  logical

   1
```

step

System object: dsp.FIRRateConverter
Package: dsp

Resample input with FIR rate converter

Syntax

```
Y = step(firrc,X)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(firrc,X)` resamples the input `X` and returns the resampled signal `Y` . An *M*-by-*N* matrix input is treated as *N* independent channels.

dsp.HDLFIRRateConverter System object

Package: dsp

Upsample, filter, and downsample—optimized for HDL code generation

Description

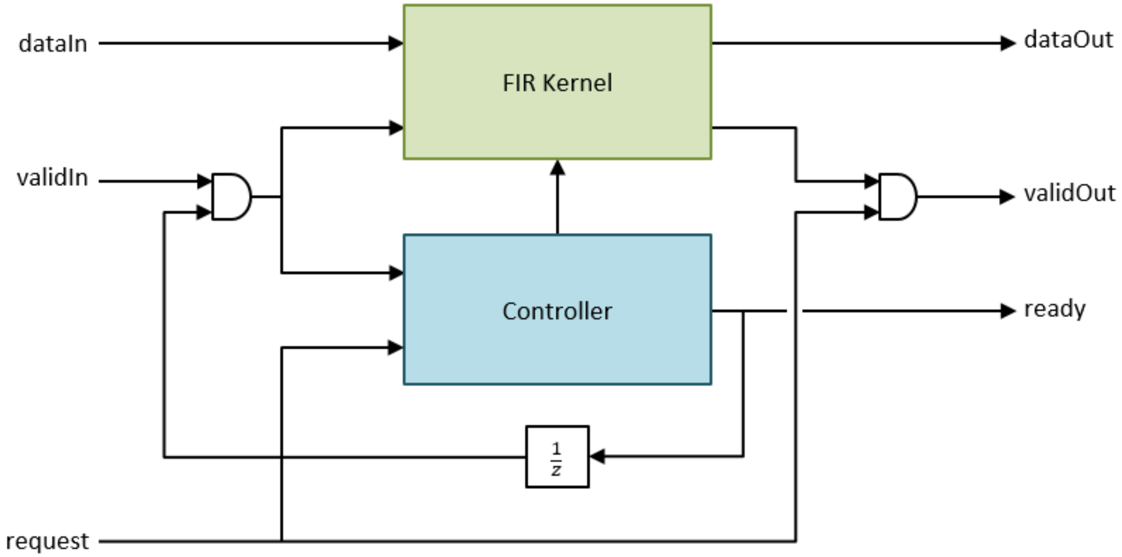
The `HDLFIRRateConverter` System object upsamples, filters, and downsamples input signals. It is optimized for HDL code generation and operates on one sample of each channel at a time. The object implements an efficient polyphase architecture to avoid unnecessary arithmetic operations and high intermediate sample rates.

The object upsamples by an integer factor of L, applies an FIR filter, and downsamples by an integer factor of M.

To resample and filter input data:

1. Define and configure a FIR rate converter System object. See "Construction" on page 4-837.
2. Call the step method to compute each output data sample according to the "Properties" on page 4-837 of the object you created. The object models HDL pipeline latency, so there is an initial delay of several `step` calls before the object returns the first valid output sample. The behavior of `step` is specific to each System object.

The `step` method accepts and returns control signal arguments for pacing the flow of samples in and out of the System object. The `step` method uses `validIn` and `validOut` control signals by default. You can also enable a `ready` output signal and a `request` input signal.



The `ready` output from the `step` method indicates that the object can accept a new input data sample on the next call to `step`. When $L \geq M$, you can use the `ready` argument to achieve continuous output data samples. If you apply a new input sample after each time the `step` method returns `ready` = `true`, each call to `step` returns a data output sample with `validOut` = `true`.

When you do not enable the `ready` argument, you can apply a valid data sample only every `ceil(L/M)` calls to `step`. For example:

- L/M = 4/5 — You can apply a new input sample on every call to `step`.
- L/M = 3/2— You can apply a new input sample on every other call to `step`.

When you enable the `request` input to the `step` method, the object returns the next output sample when `request` is `true` and a valid output sample is available. When you do not use `request`, the object returns output samples when they are available. Calls to `step` that do not return a new sample return `validOut` = `false`.

You can connect `request` to the `ready` output of a downstream object.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`HDLFIRRC = dsp.HDLFIRRateConverter` returns a System object, `HDLFIRRC`, which resamples each channel of the input. The object upsamples by an integer factor of L, applies an FIR filter, and downsamples by an integer factor of M. The default L/M is 3/2.

`HDLFIRRC = dsp.HDLFIRRateConverter(Name,Value)` returns a System object, `HDLFIRRC`, with additional options specified by one or more `Name,Value` pair arguments. `Name` is a property name and `Value` is the corresponding value. `Name` must appear inside single quotes (`''`). You can specify several name-value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`. Properties not specified retain their default values.

`HDLFIRRC = dsp.HDLFIRRateConverter(L,M,NUM,Name,Value)` returns a System object, `HDLFIRRC`, with the `InterpolationFactor` property set to `L`, the `DecimationFactor` property set to `M`, the `Numerator` property set to `NUM`, and other specified properties set to the specified values.

Properties

`InterpolationFactor`

Upsampling factor, L, specified as a scalar positive integer.

Default: 3

`DecimationFactor`

Downsampling factor, M, specified as a scalar positive integer.

Default: 2

`Numerator`

FIR filter coefficients, specified as a vector in descending powers of z^{-1}.

You can generate filter coefficients using the Signal Processing Toolbox filter design functions (such as `fir1`). Design a lowpass filter with normalized cutoff frequency no greater than `min(1/L,1/M)`. The object initializes internal filter states to zero.

Default: `firpm(70,[0 .28 .32 1],[1 1 0 0])`

`ReadyPort`

Set `ReadyPort` to `true` to return a logical scalar value, `ready`, from the `step` method. This value indicates whether the object will be ready for a new input sample the next time you call the `step` method.

Default: `false`

`RequestPort`

Set `RequestPort` to `true` to enable a `request` argument to the `step` method. This argument is a logical scalar value that requests a new output sample on the current call to the `step` method.

Default: `false`

`RoundingMethod`

Rounding mode used for fixed-point operations. This property does not apply when the input is single or double type. '`Simplest`' mode is not supported.

Default: `Floor`

`OverflowAction`

Overflow mode used for fixed-point operations. This property does not apply when the input is single or double type.

Default: `Wrap`

CoefficientsDataType

Data type of the FIR filter coefficients, specified as a `numerictype(s,wl,fl)` object with `signedness`, `word length`, and `fractional length` properties.

Default: `numerictype(1,16,16)`

OutputDataType

Data type of the output data samples, specified as one of `'Same word length as input'`, `'Full precision'`, or as a `numerictype(s,wl,fl)` object.

Default: `'Same word length as input'`

Methods

step	Resample and filter input sample

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Downsample Signal

Convert a signal from 48 kHz to 32 kHz using the HDL FIR Rate Converter System object™.

Define the sample rate and length of the input signal, and a 2 kHz cosine waveform. Set `validIn` = `true` for every sample.

```
Fs = 48e3;
Ns = 100;
t = (0:Ns-1).'/Fs;
dataIn = cos(2*pi*2e3*t);
validIn = true(Ns,1);
```

Preallocate `dataOut` and `validOut` signals for faster simulation.

```
dataOut = zeros(Ns,1);
validOut = false(Ns,1);
```

Create the System object. Configure it to perform rate conversion by a factor of 2/3, using an equiripple filter.

```
Numerator = firpm(70, [0,.25,.32,1], [1,1,0,0]);
firrc = dsp.HDLFIRRateConverter(2,3,Numerator);
```

Call the System object to perform the rate conversion and obtain each output sample.

Note: This object syntax runs only in R2016b or later. If you are using an earlier release, replace each call of an object with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

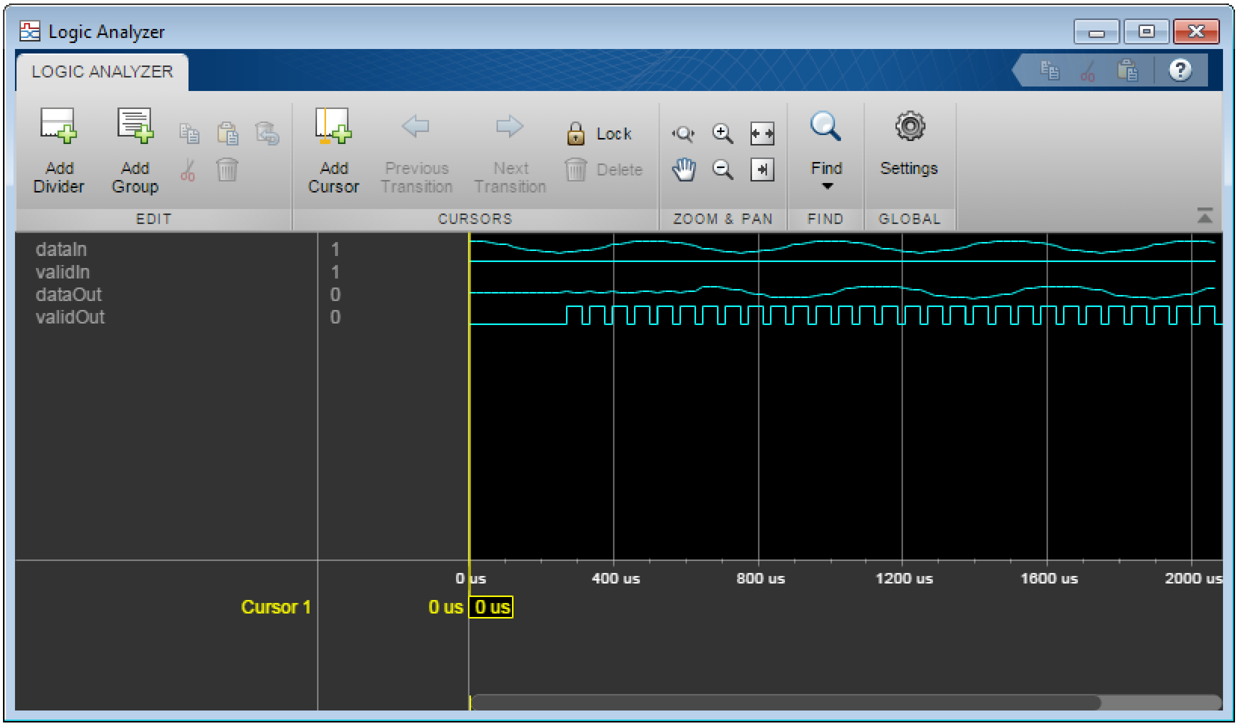
```
for k = 1:Ns
    [dataOut(k),validOut(k)] = firrc(dataIn(k),validIn(k));
end
```

Because the input sample rate is higher than the output sample rate, not every member of `dataOut` is valid. Use `validOut` to extract the valid samples from `dataOut`.

```
y = dataOut(validOut);
```

View the input and output signals with the **Logic Analyzer**.

```
la = dsp.LogicAnalyzer('NumInputPorts',4,'SampleTime',1/Fs,'TimeSpan',Ns/Fs);
modifyDisplayChannel(la,1,'Name','dataIn','Format','Analog','Height',8)
modifyDisplayChannel(la,2,'Name','validIn')
modifyDisplayChannel(la,3,'Name','dataOut','Format','Analog','Height',8)
modifyDisplayChannel(la,4,'Name','validOut')
la(dataIn,validIn,dataOut,validOut)
```



Upsample Signal

Convert a signal from 40 MHz to 100 MHz using the HDL FIR Rate Converter System object™. To avoid overrunning the object as the signal is upsampled, control the input rate manually.

Define the sample rate and length of the input signal, and a fixed-point cosine waveform.

```
Fs = 40e6;
Ns = 50;
t = (0:Ns-1).'/Fs;
x = fi(cos(2*pi*1.2e6*t), 1, 16, 14);
```

Define the rate conversion parameters. Use an interpolation factor of 5 and a decimation factor of 2. Calculate how often the object can accept a new input sample.

```
L = 5;
M = 2;
```

```
stepsPerInput = ceil(L/M);
numSteps = stepsPerInput*Ns;
```

Generate `dataIn` and `validIn` based on how often the object can accept a new sample.

```
dataIn = zeros(numSteps,1,'like',x);
dataIn(1:stepsPerInput:end) = x;
validIn = false(numSteps,1);
validIn(1:stepsPerInput:end) = true;
```

Create the System object. Configure it to perform rate conversion using the specified factors and an equiripple FIR filter.

```
Numerator = firpm(70, [0,.15,.25,1], [1,1,0,0]);
rateConverter = dsp.HDLFIRRateConverter(L,M,Numerator);
```

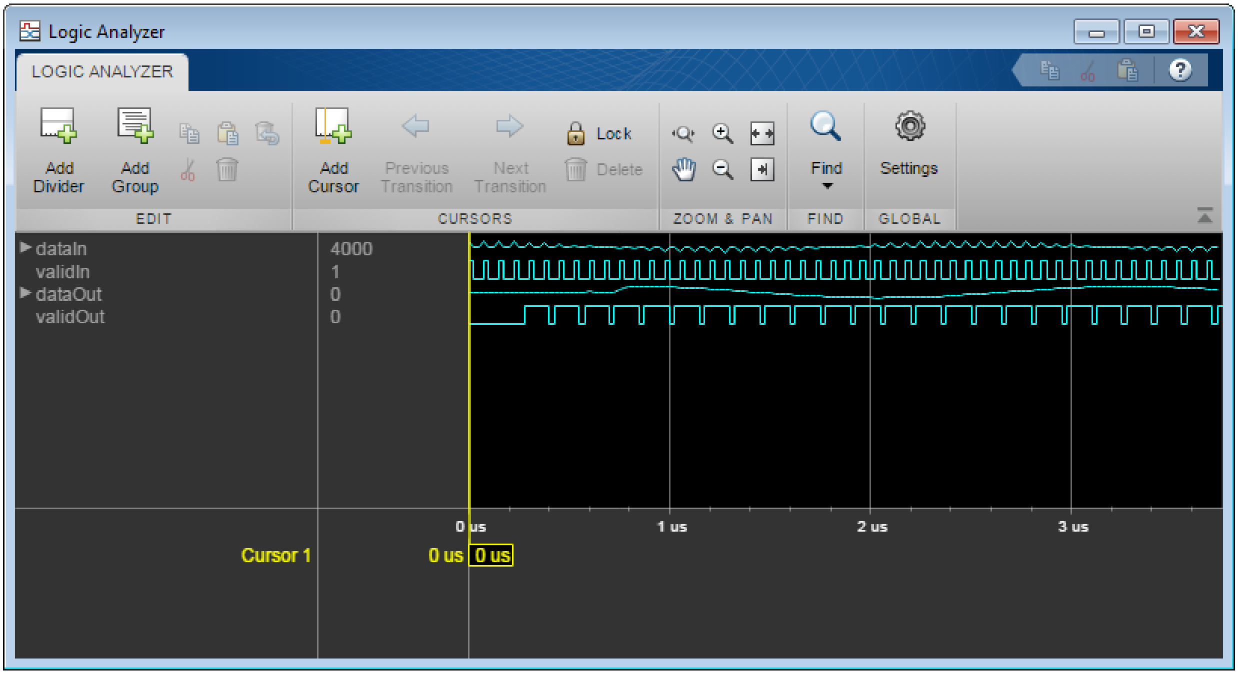
Create a **Logic Analyzer** to capture and view the input and output signals.

```
la = dsp.LogicAnalyzer('NumInputPorts',4,'SampleTime',1/Fs,'TimeSpan',numSteps/Fs);
modifyDisplayChannel(la,1,'Name','dataIn','Format','Analog','Height',8)
modifyDisplayChannel(la,2,'Name','validIn')
modifyDisplayChannel(la,3,'Name','dataOut','Format','Analog','Height',8)
modifyDisplayChannel(la,4,'Name','validOut')
```

Call the System object to perform the rate conversion and obtain each output sample. Call the Logic Analyzer to add each sample to the waveform display.

Note: This object syntax runs only in R2016b or later. If you are using an earlier release, replace each call of an object with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

```
for k = 1:numSteps
    [dataOut,validOut] = rateConverter(dataIn(k),validIn(k));
    la(dataIn(k),validIn(k),dataOut,validOut)
end
```



Control Input Rate When Upsampling

Convert a signal from 40 MHz to 100 MHz using the HDL FIR Rate Converter System object™. Use the optional `ready` output signal to avoid overrunning the object as the data is upsampled. The `ready` signal indicates the object can accept a new data sample on the next call to the object.

Define the sample rate and length of the input signal, and a fixed-point cosine waveform. Create a `SignalSource` object to provide data samples on demand.

```
Fs = 40e6;
Ns = 50;
t = (0:Ns-1).'/Fs;
x = fi(cos(2*pi*1.2e6*t),1,16,14);
inputSource = dsp.SignalSource(x);
```

Define the rate conversion parameters. Use an interpolation factor of 5 and a decimation factor of 2. Determine the number of calls to the object needed to convert *Ns* samples.

```
L = 5;
```

```
M = 2;
numSteps = floor(Ns*L/M);
```

Create the System object and configure it to perform rate conversion using the desired factors and an equiripple FIR filter. Enable the optional `ready` output port.

```
Numerator = firpm(70, [0,.15,.25,1], [1,1,0,0]);
rateConverter = dsp.HDLFIRRateConverter(L,M,Numerator,'ReadyPort',true);
```

Create a **Logic Analyzer** to capture and view the input and output signals.

```
la = dsp.LogicAnalyzer('NumInputPorts',5,'SampleTime',1/Fs,'TimeSpan',numSteps/Fs);
modifyDisplayChannel(la,1,'Name','dataIn','Format','Analog','Height',8)
modifyDisplayChannel(la,2,'Name','validIn')
modifyDisplayChannel(la,3,'Name','dataOut','Format','Analog','Height',8)
modifyDisplayChannel(la,4,'Name','validOut')
modifyDisplayChannel(la,5,'Name','ready')
```

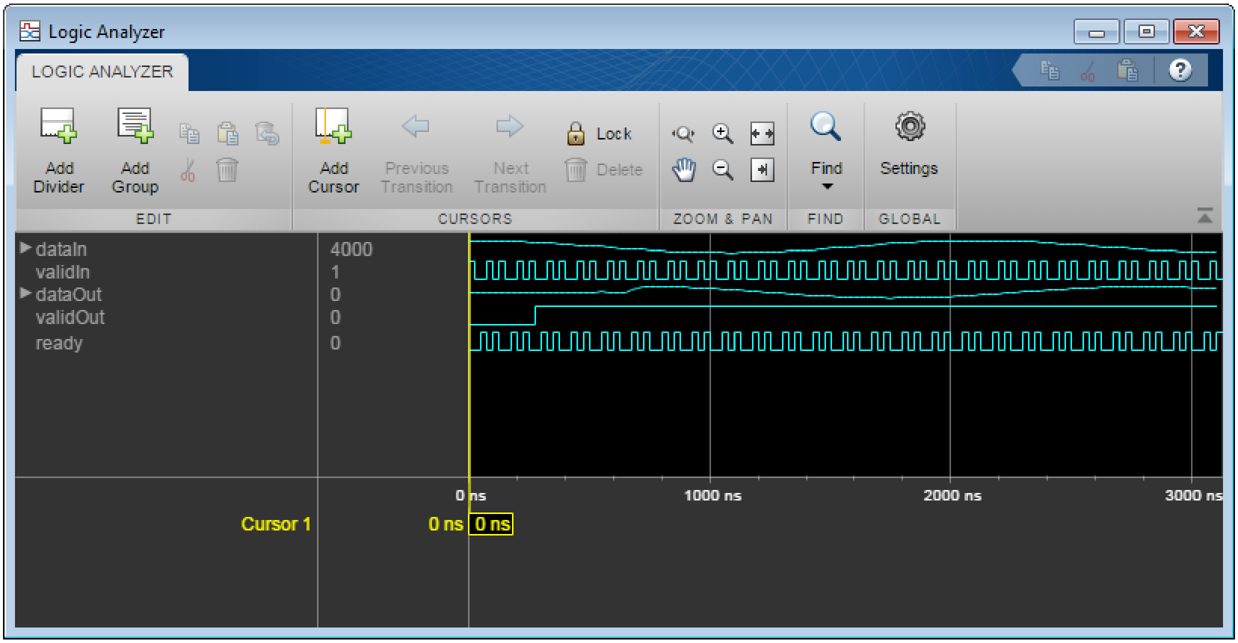
Initialize the `ready` signal. The object is always ready for input data on the first call.

```
ready = true;
```

Call the System object to perform the rate conversion and obtain each output sample. Apply a new input sample when the object indicates it is ready. Otherwise, set `validIn` to `false`.

Note: This object syntax runs only in R2016b or later. If you are using an earlier release, replace each call of an object with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

```
for k = 1:numSteps
    if ready
        dataIn = inputSource();
    end
    validIn = ready;
    [dataOut,validOut,ready] = rateConverter(dataIn,validIn);
    la(dataIn,validIn,dataOut,validOut,ready)
end
```



Control Output Rate When Upsampling

Convert a signal from 40 MHz to 100 MHz using the HDL FIR Rate Converter System object™. Use the optional `request` input signal to control the output data rate. When the object receives the `request` signal, it returns a new output data sample. This example models a clock rate of 200 MHz by requesting an output sample every second call to the object.

Define the sample rate and length of the input signal, and a fixed-point cosine waveform. Create a `SignalSource` object to provide data samples on demand.

```
Fs = 40e6;
Ns = 50;
t = (0:Ns-1).'/Fs;
x = fi(cos(2*pi*1.2e6*t),1,16,14);
inputSource = dsp.SignalSource(x);
```

Define the rate conversion parameters. Use an interpolation factor of 5 and a decimation factor of 2. Determine the number of calls to the object needed to convert *Ns* samples.

```
L = 5;
```

```
M = 2;
numSteps = floor(2*Ns*L/M);
```

Create the System object and configure it to perform rate conversion using the specified factors and an equiripple FIR filter. Enable the optional `ready` and `request` ports.

```
Numerator = firpm(70, [0,.15,.25,1], [1,1,0,0]);
rateConverter = dsp.HDLFIRRateConverter(L,M,Numerator,...
                                        'ReadyPort',true,...
                                        'RequestPort',true);
```

Create a **Logic Analyzer** to capture and view the input and output signals.

```
la = dsp.LogicAnalyzer('NumInputPorts',6,'SampleTime',1/Fs,'TimeSpan',numSteps/Fs);
modifyDisplayChannel(la,1,'Name','dataIn','Format','Analog','Height',8)
modifyDisplayChannel(la,2,'Name','validIn')
modifyDisplayChannel(la,3,'Name','request')
modifyDisplayChannel(la,4,'Name','dataOut','Format','Analog','Height',8)
modifyDisplayChannel(la,5,'Name','validOut')
modifyDisplayChannel(la,6,'Name','ready')
```

Generate a signal that requests a new output sample every second call to the object.

```
request = false(numSteps,1);
request(1:2:end) = true;
```

Initialize the `ready` signal. The object is always ready for input data on the first call.

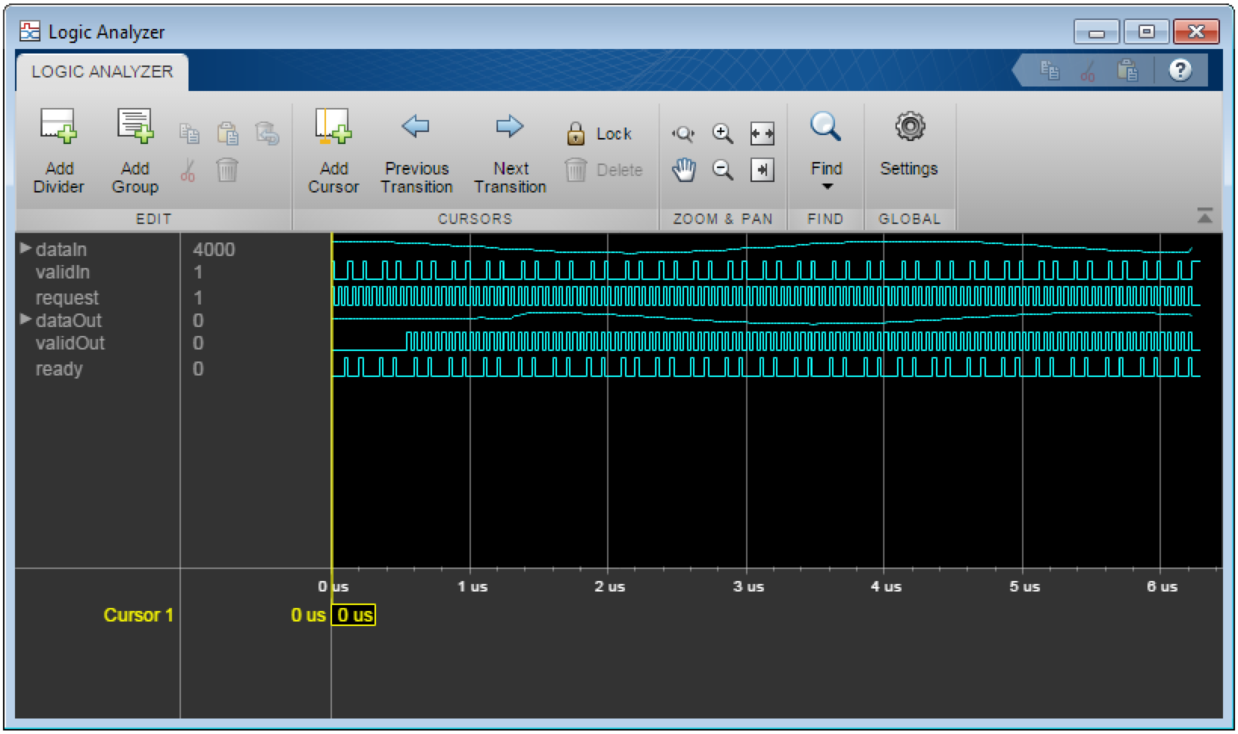
```
ready = true;
```

Call the System object to perform the rate conversion and obtain each output sample. Apply a new input sample when the object indicates it is ready. Otherwise, set `validIn` to `false`. The object returns valid output samples when `request` is set to `true`.

Note: This object syntax runs only in R2016b or later. If you are using an earlier release, replace each call of an object with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

```
for k = 1:numSteps
    if ready
        dataIn = inputSource();
    end
    validIn = ready;
    [dataOut,validOut,ready] = rateConverter(dataIn,validIn,request(k));
```

```
    la(dataIn,validIn,request(k),dataOut,validOut,ready)
end
```



Design for HDL Code Generation from HDL FIR Rate Converter

Create a rate conversion function targeted for HDL code generation, and a test bench to exercise it. The function converts a signal from 40 MHz to 100 MHz. To avoid overrunning the object, the test bench manually controls the input rate.

Define the sample rate and length of the input signal, and a fixed-point cosine waveform.

```
Fs = 40e6;
Ns = 50;
t = (0:Ns-1).'/Fs;
x = fi(cos(2*pi*1.2e6*t), 1, 16, 14);
```

Define the rate conversion parameters. Use an interpolation factor of 5 and a decimation factor of 2. Calculate how often the object can accept a new data sample.

```
L = 5;
M = 2;
stepsPerInput = ceil(L/M);
numSteps = stepsPerInput*Ns;
```

Generate `dataIn` and `validIn` based on how often the object can accept a new sample.

```
dataIn = zeros(numSteps,1,'like',x);
dataIn(1:stepsPerInput:end) = x;
validIn = false(numSteps,1);
validIn(1:stepsPerInput:end) = true;
```

Create a **Logic Analyzer** to capture and view the input and output signals.

```
la = dsp.LogicAnalyzer('NumInputPorts',4,'SampleTime',1/Fs,'TimeSpan',numSteps/Fs);
modifyDisplayChannel(la,1,'Name','dataIn','Format','Analog','Height',8)
modifyDisplayChannel(la,2,'Name','validIn')
modifyDisplayChannel(la,3,'Name','dataOut','Format','Analog','Height',8)
modifyDisplayChannel(la,4,'Name','validOut')
```

Write a function that instantiates and calls the System object.

Note: This object syntax runs only in R2016b or later. If you are using an earlier release, replace each call of an object with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

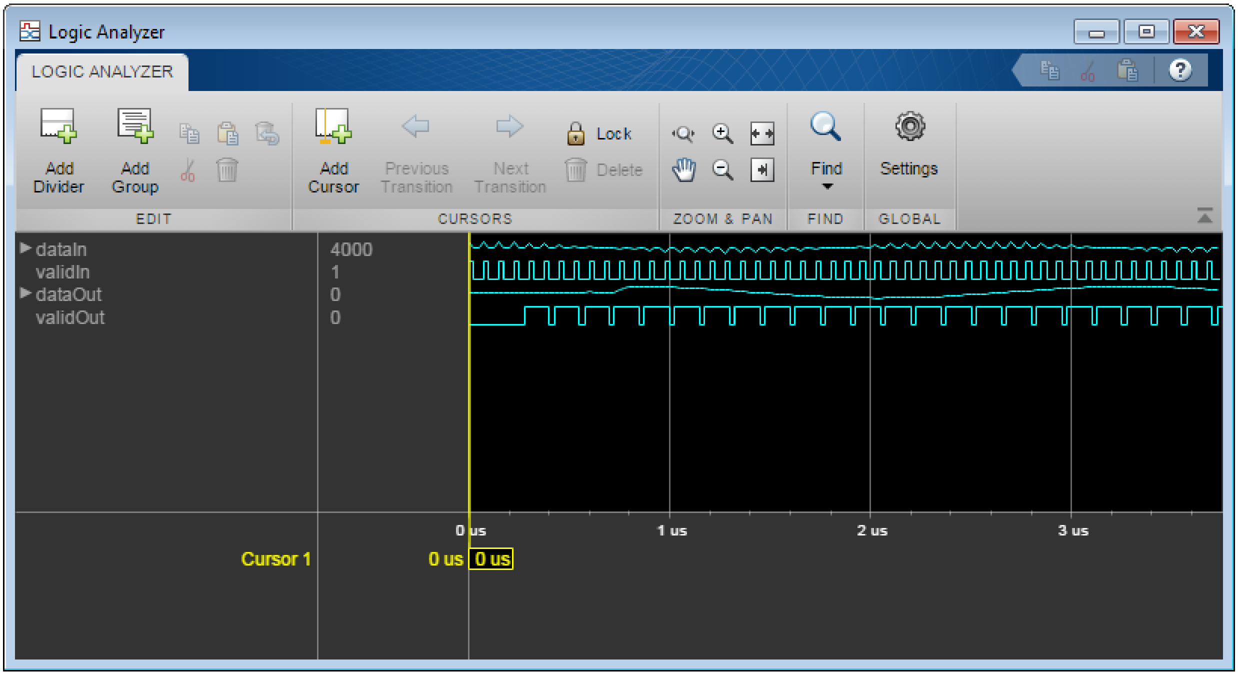
```
function [dataOut,validOut] = HDLFIRRC5_2(dataIn,validIn)
%HDLFIRRC5_2
% Processes one sample of data using the dsp.HDLFIRRateConverter System
% object. dataIn is a fixed-point scalar value. validIn is a logical scalar value.
% You can generate HDL code from this function.

  persistent firrc5_2;
  if isempty(firrc5_2)
    Numerator = firpm(70,[0,.15,.25,1],[1,1,0,0]);
    firrc5_2 = dsp.HDLFIRRateConverter(5,2,Numerator);
  end
  [dataOut,validOut] = firrc5_2(dataIn,validIn);
end
```

Resample the signal by calling the function for each data sample.

```
for k = 1:numSteps
```

```
    [dataOut,validOut] = HDLFIRRC5_2(dataIn(k),validIn(k));
    la(dataIn(k),validIn(k),dataOut,validOut)
end
```



Algorithm

This object implements the algorithms described on the `FIR Rate Conversion HDL Optimized` block reference page.

dsp.FIRRateConverter | `FIR Rate Conversion HDL Optimized`

Introduced in R2015b

step

System object: dsp.HDLFIRRateConverter
Package: dsp

Resample and filter input sample

Syntax

```
[dataOut,validOut] = step(HDLFIRRC,dataIn,validIn)
[dataOut,ready,validOut] = step(HDLFIRRC,dataIn,validIn)
[dataOut,ready,validOut] = step(HDLFIRRC,dataIn,validIn,request)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`[dataOut,validOut] = step(HDLFIRRC,dataIn,validIn)` resamples `dataIn` according to the `InterpolationFactor` (*L*) and `DecimationFactor` (*M*) properties. To avoid dropped samples when using this syntax, apply new valid input samples, with `validIn` set to `true`, only every `ceil(L/M)` calls to the `step` method. The object sets `validOut` to `true` when `dataOut` is a new valid sample.

`[dataOut,ready,validOut] = step(HDLFIRRC,dataIn,validIn)` resamples the input data and returns `ready` to indicate whether the object can accept a new sample on the next call to the `step` method. This syntax applies when you set the `ReadyPort` property to `true`.

`[dataOut,ready,validOut] = step(HDLFIRRC,dataIn,validIn,request)` resamples the input data, indicates whether the object can accept a new sample, and, if `request` is `true`, returns the next available sample . This syntax applies when you set the `RequestPort` property to `true`.

You can connect the `ready` output of a downstream object to the `request` input of an upstream object.

Note: The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Input Arguments

`dataIn` must be a scalar value or a row vector in which each element represents an independent channel. `validIn` and `validOut` are logical scalars that indicate the validity of the input and output signals respectively.

HDLFIRRC

`dsp.HDLFIRRateConverter` System object.

dataIn

Data sample, specified as a scalar, or as a row vector where each element represents an independent channel.

The data can be real or complex. Supported data types:

- `fixdt()`
- `uint`8/16/32, `int`8/16/32
- `double` and `single` are allowed for simulation but not for HDL code generation.

validIn

Qualification of the `dataIn` value, specified as a `logical` scalar.

When `validIn` is `true`, the object captures the value on `dataIn`. You can apply a valid data sample every `ceil(L/M)` calls to `step`. You can use the optional `ready` output signal to indicate when the object can accept a new sample.

request

Request for a new output sample, specified as a logical scalar.

When request is true, and a new output data sample is available, the object returns the sample with validOut set to true. If there is no sample available, the object returns validOut set to false. The object accepts this argument when you set the RequestPort property to true.

Output Arguments

dataOut

Resampled and filtered data sample, returned as a scalar, or as a vector in which each element represents an independent channel.

Supported data types:

- fixdt()
- uint8/16/32, int8/16/32
- double and single are allowed for simulation but not for HDL code generation.

validOut

Qualification of the dataOut value, returned as a logical scalar.

When validOut is true, the data output is valid. When validOut is false, the data output is not valid.

ready

Indication that the object is ready for a new input sample, returned as a logical scalar.

The object returns ready = true to indicate that the object can accept a new input data sample on the next call to step. The object returns this additional output when you set the ReadyPort property to true.

dsp.FrequencyDomainAdaptiveFilter System object

Package: dsp

Frequency Domain Adaptive filter

Description

The `dsp.FrequencyDomainAdaptiveFilter` computes output, error, and coefficients using a frequency domain FIR adaptive filter.

To implement the adaptive FIR filter object:

1. Define and set up your adaptive FIR filter object. See "Construction" on page 4-853.
2. Call step to implement the filter according to the properties of `dsp.FrequencyDomainAdaptiveFilter`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`fdaf = dsp.FrequencyDomainAdaptiveFilter` returns a frequency domain FIR adaptive filter System object, `fdaf`. This System object is used to compute the filtered output and the filter error for a given input and desired signal.

`fdaf = dsp.FrequencyDomainAdaptiveFilter('`*`PropertyName`*`',` *`PropertyValue`*`,...)` returns an `FrequencyDomainAdaptiveFilter` System object, `fdaf`, with each specified property set to the specified value.

`fdaf =`
`dsp.FrequencyDomainAdaptiveFilter(LEN,'`*`PropertyName`*`',`*`PropertyValue`*`,...)` returns an `FrequencyDomainAdaptiveFilter` System object, `fdaf`, with the Length property set to `LEN` and other specified properties set to the specified values.

Properties

`Method`

Method to calculate filter coefficients

Specify the method used to calculate filter coefficients as one of `'Constrained FDAF'` |`'Unconstrained FDAF'`. The default is `'Constrained FDAF'`. For algorithms on how to implement this filter and its three methods, refer to [1]. This property is nontunable.

`Length`

Length of filter coefficients vector

Specify the length of the FIR filter coefficients vector as a positive integer value. This property is nontunable.

The default value is 32.

`BlockLength`

Block length for coefficient updates

Specify the block length of the coefficients updates as a positive integer value. The length of the input vectors must be divisible by the `BlockLength` property value. For faster execution, the sum of the length property value and the `BlockLength` property value should be a power of two. The default value is the value of `Length`. This property is nontunable.

`StepSize`

Adaptation step size

Specify the adaptation step size factor as a positive numeric scalar less than or equal to `1`. Setting the `StepSize` property equal to `1` provides the fastest convergence during adaptation. The default is `1`. This property is tunable.

`LeakageFactor`

Adaptation leakage factor

Specify the leakage factor used in leaky adaptive filter as a scalar numeric value between 0 and 1, both inclusive. When the value is less than 1, the System object implements a leaky adaptive algorithm. The default is `1`, providing no leakage in the adapting method. This property is tunable.

AveragingFactor

Averaging factor of energy estimator

Specify the averaging factor used to compute the exponentially windowed FFT input signal powers for the coefficient updates as a scalar positive numeric value less than or equal to 1. The default value is `1`. This property is tunable.

Offset

Offset for normalization terms

Specify the offset for the normalization terms in the coefficient updates as a scalar nonnegative numeric value. Use this property to avoid divide by zero or divide by very small numbers. This situation occurs if any of the FFT input signal powers becomes very small. The default value is `0`. This property is tunable.

InitialPower

Initial FFT input signal power

Specify the initial common value of all of the FFT input signal powers as a scalar positive numeric value. The default is `1`. This property is tunable.

InitialCoefficients

Time-domain initial coefficients of the filter

Specify the initial time-domain coefficients of the adaptive filter as a scalar or a vector of length equal to the `Length` property value. The adaptive filter object uses these coefficients to compute the initial frequency-domain filter coefficients. The default is `0`. This property is tunable.

LockCoefficients

Locked status of coefficient updates

Specify whether to lock the filter coefficient values. By default, the value of this property is `false`, and the object continuously updates the filter coefficients. If this property is set to `true`, the filter coefficients do not update and their values remain the same.

This property is tunable.

FFTCoefficients

Current FFT coefficients of the filter

This property stores the current discrete Fourier transform of the filter coefficients as a row vector. The length of this vector is equal to the sum of the `Length` value and the `BlockLength` value. This property is initialized to the FFT values of the `InitialCoefficients` property. To get the discrete Fourier transform of the filter coefficients, call the object, and access the `FFTCoefficients` property of the object.

Methods

reset	Reset filter states for Frequency Domain Adaptive filter
step	Apply Frequency Domain Adaptive filter to input

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

QPSK Adaptive Equalization With FIR Filter

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

Generate QPSK and noise signals, filter to obtain the received signal, and delay the QPSK signal to obtain the desired signal.

```
D = 16;
```

```
b  = exp(1i*pi/4)*[-0.7 1];
a  = [1 -0.7];
ntr= 1024;
s  = sign(randn(1,ntr+D))+1i*sign(randn(1,ntr+D));
n  = 0.1*(randn(1,ntr+D) + 1i*randn(1,ntr+D));
r  = filter(b,a,s) + n;
x  = r(1+D:ntr+D);
d  = s(1:ntr);
```

Use the Frequency Domain Adaptive Filter to compute the filtered output and the filter error for the input and desired signal. To get the discrete Fourier transform of the filter coefficients, call the `fdaf` object, and access the FFTCoefficients property of this object.

```
mu  = 0.1;
fdaf = dsp.FrequencyDomainAdaptiveFilter('Length',32,'StepSize',mu);
[y,e] = fdaf(x,d);
fftCoeffs = fdaf.FFTCoefficients
```

```
fftCoeffs =

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- “System Objects in MATLAB Code Generation” (MATLAB Coder).
- When the sum of `BlockLength` and `Length` is not a power of two, the executable generated from this System object relies on prebuilt dynamic library files (`.dll` files) included with MATLAB. Use the `packNGo` function to package the code generated from this object and all the relevant files in a compressed zip file. Using this zip file, you can relocate, unpack, and rebuild your project in another development environment where MATLAB is not installed. For more details, see “How To Run a Generated Executable Outside MATLAB”.
- When the sum of `BlockLength` and `Length` is a power of two, you can generate standalone C and C++ code from this System object.

Introduced in R2013b

reset

System object: dsp.FrequencyDomainAdaptiveFilter
Package: dsp

Reset filter states for Frequency Domain Adaptive filter

Syntax

```
reset(sysObj)
```

Description

`reset(sysObj)` resets the internal states of the System object, `sysObj`, to their initial values. The reset method is always a no-op for unlocked System objects, as the states may not be allocated when the object is not locked.

step

System object: dsp.FrequencyDomainAdaptiveFilter
Package: dsp

Apply Frequency Domain Adaptive filter to input

Syntax

```
[y,err] = step(fdaf,x,d)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`[y,err] = step(fdaf,x,d)` filters the input *x*, using *d* as the desired signal, and returns the filtered output in *y* and the filter error in *err*. The System object estimates the filter weights needed to minimize the error between the output signal and the desired signal. You can obtain the FFT of these filter weights by accessing the `FFTCoefficients` property after calling the `step` method by `fdaf.FFTCoefficients`.

Note: `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.HDLComplexToMagnitudeAngle System object

Package: dsp

Compute magnitude and phase angle of complex signal—optimized for HDL code generation

Description

The HDL Complex To Magnitude Angle System object computes the magnitude and/or phase angle of a complex signal. It provides hardware-friendly control signal arguments for the step method. The object uses a pipelined Coordinate Rotation Digital Computer (CORDIC) algorithm to achieve an efficient HDL implementation.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`HCMA = dsp.HDLComplexToMagnitudeAngle()` returns a System object, HCMA, that computes the magnitude and phase angle of a complex input.

`HCMA = dsp.HDLComplexToMagnitudeAngle(Name,Value)` returns a System object, HCMA, with additional options specified by one or more `Name,Value` pair arguments.

Properties

`OutputValue`

Specifies which outputs the `step` method returns. You can set this property to `Magnitude`, `Angle`, or `Magnitude and angle`. The default is `Magnitude and angle`.

AngleFormat

Specifies the format of the Angle output of the `step` method. You can set this property to `Normalized` or `Radians`. `Normalized` is a fixed-point format that normalizes the angles in the range [–1,1]. `Radians` returns fixed-point values between π and −π. The default is `Normalized`.

ScaleOutput

Scales output by the inverse of the CORDIC gain factor when this property is `true`. The default is `true`.

Note: If you turn off output scaling, and apply the CORDIC gain elsewhere in your design, you must exclude the π/4 term. The quadrant mapping algorithm replaces the first CORDIC iteration by mapping inputs onto the angle range [0,π/4]. Therefore, the initial rotation does not contribute a gain term.

NumIterationsSource

Specifies the source of the `NumIterations` property for the CORDIC algorithm. You can set `NumIterations` to `Property` or `Auto`. `Property` uses the number of iterations from `NumIterations`. `Auto` sets the number of iterations to input vector word length – 1. If the input is `double` or `single`, `Auto` sets the number of iterations to 16. The default is `Auto`.

NumIterations

Specifies the number of CORDIC iterations the object executes. This value is used when `NumIterationsSource` is set to `Property`. The number of iterations must be less than or equal to the input data word length – 1.

Methods

step	Process complex input to produce magnitude and/or phase angle

Common to All System Objects	
`clone`	Create System object with same property values

Common to All System Objects	
getNumInpu	Expected number of inputs to a System object
getNumOutp	Expected number of outputs of a System object
isLocked	Check locked states of a System object (logical)
release	Allow System object property value changes

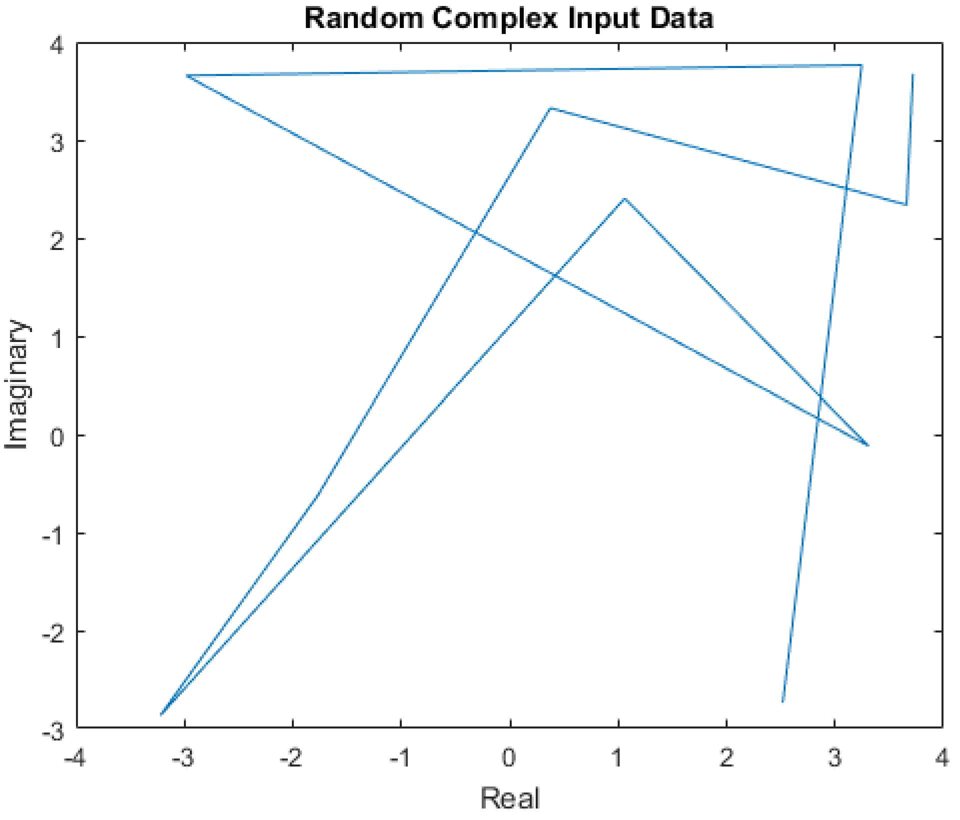
Examples

Convert Complex Data to Magnitude-Angle Data

This example shows how to use the `dsp.HDLComplextoMagnitudeAngle` object to compute magnitude and angle of a complex signal. The object uses a CORDIC algorithm for an efficient hardware implementation.

Choose word lengths and create random complex input data. Than, convert the input to fixed-point.

```
a = -4;
b = 4;
inputWL = 16;
inputFL = 12;
numSamples = 10;
reData = ((b-a).*rand(numSamples,1)+a);
imData = ((b-a).*rand(numSamples,1)+a);
dataIn = (fi(reData+imData*1i,1,inputWL,inputFL));
figure
plot(dataIn)
title('Random Complex Input Data')
xlabel('Real')
ylabel('Imaginary')
```



Write a function that creates and calls the System object™. You can generate HDL from this function.

Note: This object syntax runs only in R2016b or later. If you are using an earlier release, replace each call of an object with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

```
function [mag,angle,validOut] = Complex2MagAngle(yIn,validIn)
%Complex2MagAngle
% Converts one sample of complex data to magnitude and angle data.
% yIn is a fixed-point complex number.
% validIn is a logical scalar value.
% You can generate HDL code from this function.
```

```
  persistent cma;
  if isempty(cma)
    cma = dsp.HDLComplexToMagnitudeAngle('AngleFormat','Radians')
  end
  [mag,angle,validOut] = cma(yIn,validIn);
end
```

The object takes some latency to computer the answer for each input sample, depending on the number of CORDIC iterations. When you set `NumIterationsSource` to 'Auto', `NumIterations=inputWL-1`. The latency is `NumIterations+2`, so `latency=inputWL+1`.

```
latency = inputWL+1;
mag = zeros(1,numSamples+latency);
ang = zeros(1,numSamples+latency);
validOut = false(1,numSamples+latency);
```

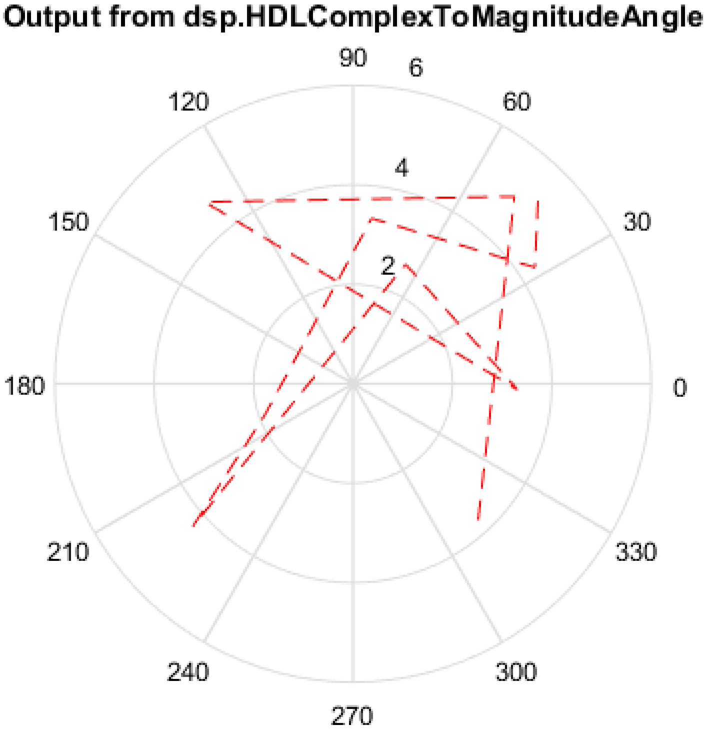
Call the function to convert each sample. After you apply all input samples, continue calling the function with invalid input to flush remaining output samples.

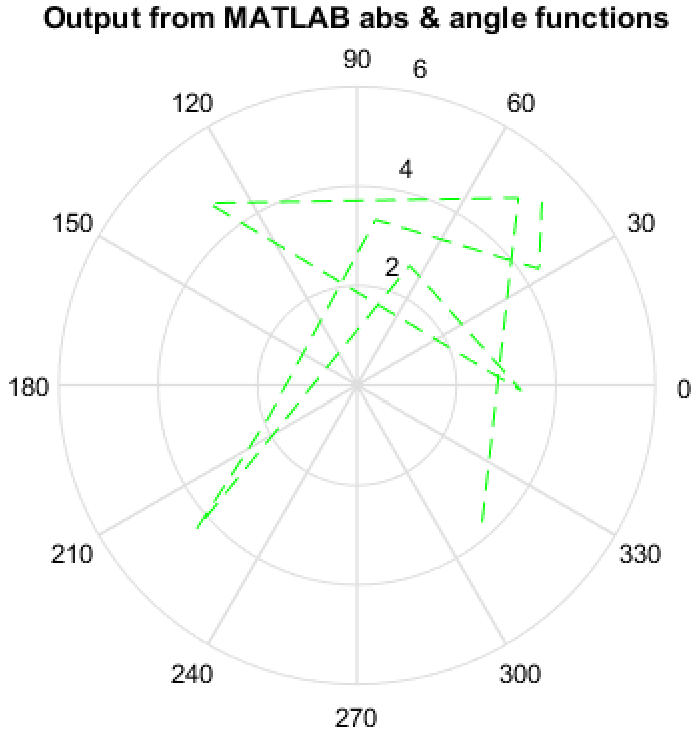
```
for ii = 1:1:numSamples
   [mag(ii),ang(ii),validOut] = Complex2MagAngle(dataIn(ii),true);
end
for ii = (numSamples+1):1:(numSamples+latency)
   [mag(ii),ang(ii),validOut(ii)] = Complex2MagAngle(fi(0+0*1i,1,inputWL,inputFL),false
end
% Strip non-valid out
mag = mag(validOut == 1);
ang = ang(validOut == 1);
figure
polar(ang,mag,'--r')   % Red is output from HDL-Optimized object
title('Output from dsp.HDLComplexToMagnitudeAngle')
magD = abs(dataIn);
angD = angle(dataIn);
figure
polar(angD,magD,'--g') % Green is output from MATLAB abs & angle
title('Output from MATLAB abs & angle functions')
```

```
cma =
```

```
dsp.HDLComplexToMagnitudeAngle with properties:

  NumIterationsSource: 'Auto'
         OutputFormat: 'Magnitude and angle'
          AngleFormat: 'Radians'
          ScaleOutput: true
```





Algorithm

This object implements the algorithm described on the `Complex to Magnitude-Angle HDL Optimized` block reference page.

Delay

The latency is `NumIterations` + 2 cycles from input to output. Each call to the step method models one clock cycle.

When you set `Number of Iterations Source` to `Auto`, the number of iterations is input word length − 1, and the latency is input word length + 1. If the input is `double` or `single` type, the number of iterations is 16, and the latency is 18.

Performance

When generated HDL code for the default configuration, with output scaling disabled and `fixdt(1,16,12)` input, is synthesized into a Xilinx Virtex–6 (XC6VLX240T-1FFG1156) FPGA, the design achieves 260 MHz clock frequency. It uses the following resources.

Resource	Uses
LUT	882
FFS	792
Xilinx LogiCORE DSP48	0
Block RAM (16K)	0

Performance of the synthesized HDL code varies depending on your target and synthesis options.

Introduced in R2014b

step

System object: dsp.HDLComplexToMagnitudeAngle
Package: dsp

Process complex input to produce magnitude and/or phase angle

Syntax

```
[Mag,Angle,validOut] = step(H,X,validIn)
[Mag,validOut] = step(H,X,validIn)
[Angle,validOut] = step(H,X,validIn)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`[Mag,Angle,validOut] = step(H,X,validIn)` converts complex scalar X into component magnitude and angle. `validIn` and `validOut` are logical scalars that indicate the validity of the input and output signals respectively. If `validOut` is high, the output is valid.

`[Mag,validOut] = step(H,X,validIn)` converts complex scalar X into component magnitude. Use this syntax when you set `OutputValue` to `'Magnitude'`. `validOut` is a logical scalar that indicates the validity of output signal. If `validOut` is high, the output is valid.

`[Angle,validOut] = step(H,X,validIn)` converts complex scalar X into component magnitude. Use this syntax when you set `OutputValue` to `'Angle'`. `validOut` is a logical scalar that indicates the validity of output signal. If `validOut` is high, the output is valid.

Note: `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.HDLFFT System object

Package: dsp

Fast Fourier transform—optimized for HDL code generation

Description

The HDL FFT System object implements a pipelined Radix 2^2 FFT algorithm which provides hardware speed and area optimization for streaming data applications. The object accepts scalar or vector real or complex input, provides hardware-friendly control signals, and has optional output frame control signals. You can achieve giga-sample-per-second (GSPS) throughput using vector input.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`HFFT = dsp.HDLFFT` returns an HDL FFT System object, `HFFT`, that performs a fast Fourier transform.

`HFFT = dsp.HDLFFT(Name,Value)` returns an HDL FFT System object, `HFFT`, with additional options specified by one or more `Name,Value` pair arguments.

Properties

`Architecture`

`'Streaming Radix 2^2'` (default) — An efficient architecture that has lower latency and uses fewer resources than the previous versions.

`'Streaming Radix 2 (this choice will be removed -see release notes).'` — Versions before R2016a use this architecture. Use only for backward-compatibility purposes.

`ComplexMultiplication`

Select the HDL implementation of complex multipliers. Choose to implement each multiplier with `'Use 4 multipliers and 2 adders'` or `'Use 3 multipliers and 5 adders'`. Which option is faster or smaller depends on your synthesis tool and target device. This option applies only if you use the Radix 2^2 architecture.

`BitReversedOutput`

Select the order of the output data.

- `true` (default) — The output channel elements are bit reversed relative to the input order.
- `false` — The output channel elements are in linear order.

The FFT algorithm calculates output in the reverse order to the input, and performs an extra reversal operation when required to provide output in the same order as the input. For vector data, input and output data must be in opposite orders so choose only one of `BitReversedOutput` or `BitReversedInput`. For more information on ordering of the output, see "Linear and Bit-Reversed Output Order".

`BitReversedInput`

Select the expected order of the input data.

- `true` — The input channel elements are in bit-reversed order.
- `false` (default) — The input channel elements are in linear order.

The FFT algorithm calculates output in the reverse order to the input, and performs an extra reversal operation when required to provide output in the same order as the input. For vector data, input and output data must be in opposite orders so choose only one of `BitReversedOutput` or `BitReversedInput`. For more information on ordering of the output, see "Linear and Bit-Reversed Output Order".

`Normalize`

Enable output scaling.

- `true` — The object implements an overall 1/N scale factor by scaling the result of each pipeline stage by 2. This adjustment keeps the output of the IFFT in the same amplitude range as its input.

- `false` (default) — The object avoids overflow by increasing the word length by one bit at each stage.

FFTLength

Number of data points used for one FFT calculation. The default value is 1024. The FFT length must be a power of 2 between 2^3 and 2^{16} for HDL code generation.

ResetInputPort

When you set `ResetInputPort` to `true`, the `step` method expects an additional argument, `reset`. When `reset` is `true`, the object stops calculation and clears all internal state. The default value of `ResetInputPort` is `false`.

StartOutputPort

If you set `StartOutputPort` to `true`, the `step` method returns an additional output signal that is `true` on the first cycle of each valid output frame. The default value of `StartOutputPort` is `false`.

EndOutputPort

If you set `EndOutputPort` to `true`, the step method returns an additional output signal that is `true` on the last cycle of each valid output frame. The default value of `EndOutputPort` is `false`.

RoundingMethod

Rounding mode used for fixed-point operations. The FFT object uses fixed-point arithmetic for internal calculations when the input is any integer or fixed-point data type. This option does not apply when the input is single or double type. The default `RoundingMethod` is `'Floor'`. Each stage rounds after the twiddle factor multiplication but before the butterflies.

Methods

getLatency	Latency of FFT operation
step	Process inputs using HDL optimized FFT (fast Fourier transform)

Common to All System Objects	
clone	Create System object with same property values
getNumInpu	Expected number of inputs to a System object
getNumOutp	Expected number of outputs of a System object
isLocked	Check locked states of a System object (logical)
release	Allow System object property value changes

Examples

Create an FFT for HDL Generation

Create the specifications and input signal.

```
N = 128;
Fs = 40;
t = (0:N-1)'/Fs;
x = sin(2*pi*15*t) + 0.75*cos(2*pi*10*t);
y = x + .25*randn(size(x));
y_fixed = sfi(y,32,24);
```

Write a function that creates and calls the System object™. You can generate HDL from this function.

Note: This object syntax runs only in R2016b or later. If you are using an earlier release, replace each call of an object with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

```
function [yOut,validOut] = HDLFFT128(yIn,validIn)
%HDLFFT128
% Processes one sample of FFT data using the dsp.HDLFFT System object(TM)
% yIn is a fixed-point scalar or column vector.
% validIn is a logical scalar value.
% You can generate HDL code from this function.

  persistent fft128;
  if isempty(fft128)
    fft128 = dsp.HDLFFT('FFTLength',128)
  end
```

```
  [yOut,validOut] = fft128(yIn,validIn);
end
```

Compute the FFT by calling the function for each data sample.

```
Yf = zeros(1,3*N);
validOut = false(1,3*N);
for loop = 1:1:3*N
    if (mod(loop, N) == 0)
        i = N;
    else
        i = mod(loop, N);
    end
    [Yf(loop),validOut(loop)] = HDLFFT128(complex(y_fixed(i)),(loop <= N));
end
```

```
fft128 =

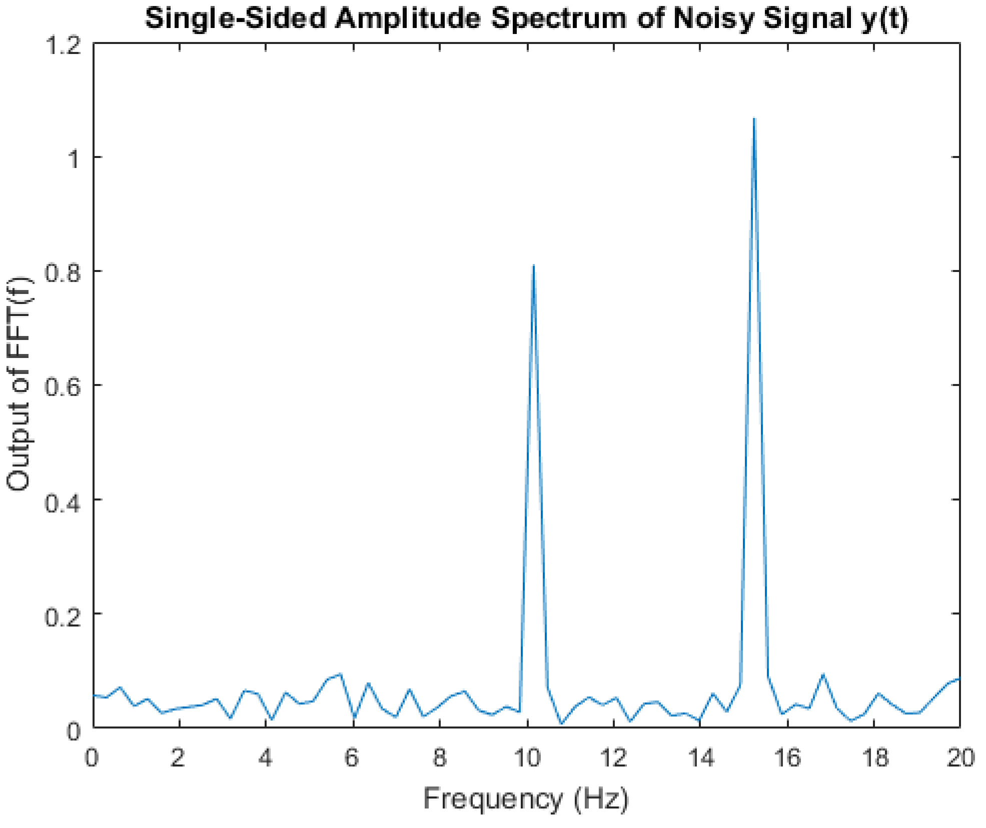
  dsp.HDLFFT with properties:

              FFTLength: 128
           Architecture: 'Streaming Radix 2^2'
    ComplexMultiplication: 'Use 4 multipliers and 2 adders'
       BitReversedOutput: true
        BitReversedInput: false
               Normalize: false

  Use get to show all properties
```

Discard invalid data samples. Then plot the frequency channel results from the FFT.

```
Yf = Yf(validOut == 1);
Yr =  bitrevorder(Yf);
plot(Fs/2*linspace(0,1,N/2), 2*abs(Yr(1:N/2)/N))
title('Single-Sided Amplitude Spectrum of Noisy Signal y(t)')
xlabel('Frequency (Hz)')
ylabel('Output of FFT(f)')
```



Create a Vector-Input FFT for HDL Generation

Create specifications and input signal. This example uses a 128-point FFT and computes the transform over 16 samples at a time.

```
N = 128;
V = 16;
Fs = 40;
t = (0:N-1)'/Fs;
x = sin(2*pi*15*t) + 0.75*cos(2*pi*10*t);
y = x + .25*randn(size(x));
y_fixed = sfi(y,32,24);
y_vect = reshape(y_fixed,V,N/V);
```

Write a function that instantiates and calls the System object™. The function does not need to know the vector size. The object saves the size of the input signal the first time you call it.

Note: This object syntax runs only in R2016b or later. If you are using an earlier release, replace each call of an object with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

```
function [yOut,validOut] = HDLFFT128V16(yIn,validIn)
%HDLFFT128V16
% Processes 16-sample vectors of FFT data
% yIn is a fixed-point column vector.
% validIn is a logical scalar value.
% You can generate HDL code from this function.

  persistent fft128v16;
  if isempty(fft128v16)
    fft128v16 = dsp.HDLFFT('FFTLength',128)
  end
  [yOut,validOut] = fft128v16(yIn,validIn);
end
```

Compute the FFT by passing 16-element vectors to the object. Use the `getLatency` method to find out when the first output data sample will be ready. Then, add the frame length to determine how many times to call the object. Because the object instance is in the function, use a dummy instance of the object to call the method. Use the loop counter to flip `validIn` to false after N input samples.

```
tempfft = dsp.HDLFFT;
loopCount = getLatency(tempfft,N,V)+N/V;
Yf = zeros(V,loopCount);
validOut = false(V,loopCount);
for loop = 1:1:loopCount
    if ( mod(loop,N/V) == 0 )
        i = N/V;
    else
        i = mod(loop,N/V);
    end
    [Yf(:,loop),validOut(loop)] = HDLFFT128V16(complex(y_vect(:,i)),(loop<=N/V));
end
```

```
fft128v16 =

  dsp.HDLFFT with properties:

                FFTLength: 128
             Architecture: 'Streaming Radix 2^2'
    ComplexMultiplication: 'Use 4 multipliers and 2 adders'
        BitReversedOutput: true
         BitReversedInput: false
                Normalize: false

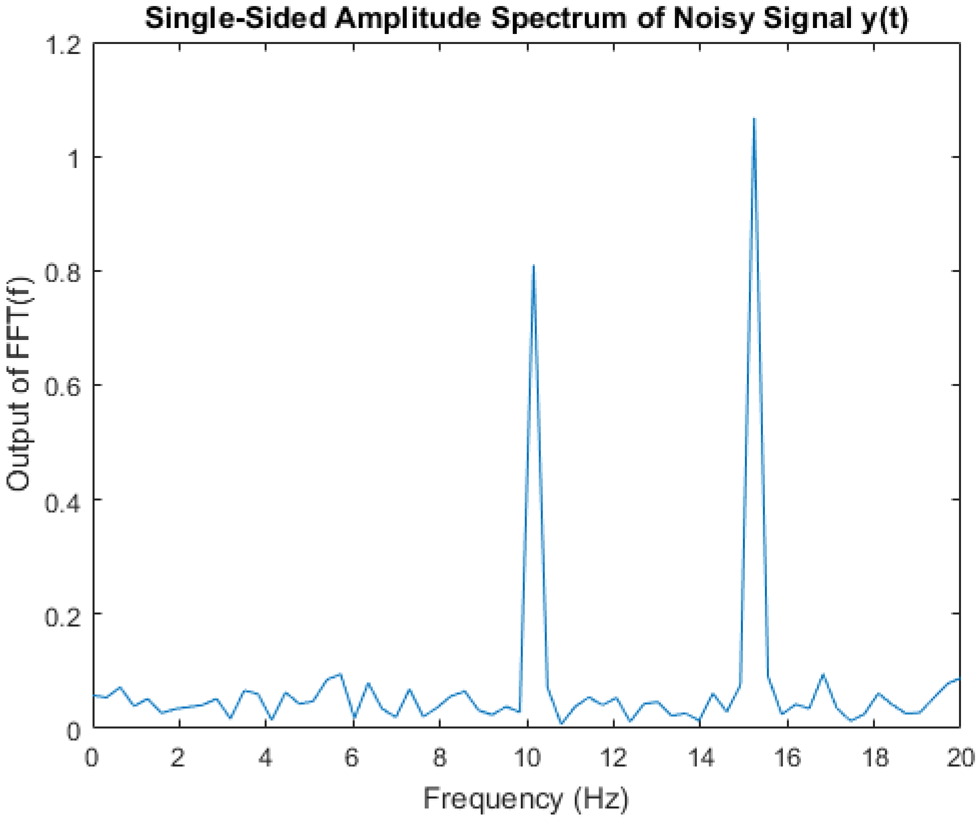
  Use get to show all properties
```

Discard invalid output samples.

```
C = Yf(:,validOut==1);
Yf_flat = C(:);
```

Plot the frequency channel data from the FFT. The FFT output is in bit-reversed order. Reorder it before plotting.

```
Yr =  bitrevorder(Yf_flat);
plot(Fs/2*linspace(0,1,N/2),2*abs(Yr(1:N/2)/N))
title('Single-Sided Amplitude Spectrum of Noisy Signal y(t)')
xlabel('Frequency (Hz)')
ylabel('Output of FFT(f)')
```



Explore Latency of HDL FFT Object

The latency of the object varies with the FFT length and the vector size. Use the `getLatency` method to find the latency of a particular configuration. The latency is the number of cycles between the first valid input and the first valid output, assuming the input is contiguous.

Create a new `dsp.HDLFFT` object and request the latency.

```
hdlfft = dsp.HDLFFT('FFTLength',512);
L512 = getLatency(hdlfft)
```

```
L512 =
```

```
   599
```

Request hypothetical latency information about a similar object with a different FFT length. The properties of the original object do not change.

```
L256 = getLatency(hdlfft,256)
N = hdlfft.FFTLength
```

```
L256 =

   329

N =

   512
```

Request hypothetical latency information of a similar object that accepts eight-sample vector input.

```
L256v8 = getLatency(hdlfft,256,8)
```

```
L256v8 =

    93
```

Set `Normalize` to `true`. The latency does not change.

```
hdlfft.Normalize = true;
L512n = getLatency(hdlfft)
```

```
L512n =

   599
```

Set `BitReversedOutput` to `false`. The latency increases because the object must collect the output before reordering.

```
hdlfft.BitReversedOutput = false;
L512r = getLatency(hdlfft)
```

```
L512r =

        1078
```

Algorithm

This object implements the algorithms described on the `FFT HDL Optimized` block reference page.

Latency

The latency varies with the FFT length and the vector size. Use the getLatency method to find the latency of a particular configuration. The latency is the number of cycles between the first valid input and the first valid output, assuming the input is contiguous.

Performance

These resource and performance data are the synthesis results from the generated HDL targeted to a Xilinx Virtex-6 (XC6VLX75T-1FF484) FPGA. The three examples in the tables have this configuration:

- FFT length (default) — 1024
- Complex multiplication — 4 multipliers, 2 adders
- Output scaling — Enabled
- 16-bit complex input data
- Minimize clock enables (HDL Coder parameter)

Performance of the synthesized HDL code varies with your target and synthesis options. For instance, natural order output uses more RAM than bit-reversed output, and real input uses less RAM than complex input.

For a scalar input Radix 2^2 configuration, the design achieves 326 MHz clock frequency. The latency is 1116 cycles. The design uses these resources.

Resource	Uses
LUT	4597
FFS	5353
Xilinx LogiCORE DSP48	12
Block RAM (16K)	6

When you vectorize the same Radix 2^2 implementation to process two 16-bit input samples in parallel, the design achieves 316 MHz clock frequency. The latency is 600 cycles. The design uses these resources.

Resource	Uses
LUT	7653
FFS	9322
Xilinx LogiCORE DSP48	24
Block RAM (16K)	8

The Radix 2 implementation is supported with scalar input data only. The Radix 2 design achieves 295 MHz clock frequency. The latency is 1148 cycles. The design uses these resources.

Resource	Uses
LUT	4060
FFS	5160
Xilinx LogiCORE DSP48	16
Block RAM (16K)	6

dsp.FFT | dsp.HDLIFFT | dsp.HDLChannelizer | `FFT HDL Optimized`

Introduced in R2014b

getLatency

System object: dsp.HDLFFT
Package: dsp

Latency of FFT operation

Syntax

```
Y = getLatency(H)
Y = getLatency(H,N)
Y = getLatency(H,N,V)
```

Description

`Y = getLatency(H)` returns the number of cycles, `Y`, that the object takes to calculate the FFT of an input. The latency changes depending on the FFT length.

`Y = getLatency(H,N)` returns the latency, `Y`, that a hypothetical object with FFT Length `N`, and scalar input, would take to calculate the FFT of an input. This method does not change the properties of `H`.

`Y = getLatency(H,N,V)` returns the latency, `Y`, that a hypothetical object with FFT Length `N`, and vector input of size `V`, would take to calculate the FFT of an input. This method does not change the properties of `H`.

Examples

Explore Latency of HDL FFT Object

The latency of the object varies with the FFT length and the vector size. Use the `getLatency` method to find the latency of a particular configuration. The latency is the number of cycles between the first valid input and the first valid output, assuming the input is contiguous.

Create a new `dsp.HDLFFT` object and request the latency.

```
hdlfft = dsp.HDLFFT('FFTLength',512);
L512 = getLatency(hdlfft)
```

```
L512 =

   599
```

Request hypothetical latency information about a similar object with a different FFT length. The properties of the original object do not change.

```
L256 = getLatency(hdlfft,256)
N = hdlfft.FFTLength
```

```
L256 =

   329

N =

   512
```

Request hypothetical latency information of a similar object that accepts eight-sample vector input.

```
L256v8 = getLatency(hdlfft,256,8)
```

```
L256v8 =

    93
```

Set `Normalize` to `true`. The latency does not change.

```
hdlfft.Normalize = true;
L512n = getLatency(hdlfft)
```

```
L512n =
```

```
   599
```

Set `BitReversedOutput` to `false`. The latency increases because the object must collect the output before reordering.

```
hdlfft.BitReversedOutput = false;
L512r = getLatency(hdlfft)
```

```
L512r =

        1078
```

Input Arguments

H

HDLFFT System object

N

(optional) FFT length. Use this argument to request the latency of a similar object with FFT length `N`.

V

(optional) Vector size. Use this argument to request the latency of a similar object with `V`-sample vector input. When you do not specify this argument, the function assumes scalar input.

Output Arguments

Y

Cycles of latency that the object takes to calculate the FFT of an input. The latency is the number of cycles between the first valid input and the first valid output, assuming the input is contiguous. Each call to the step method simulates one cycle.

step

System object: dsp.HDLFFT
Package: dsp

Process inputs using HDL optimized FFT (fast Fourier transform)

Syntax

```
[Y,validOut] = step(H,X,validIn)
[Y,startOut,endOut,validOut] = step(H,X,validIn)
[Y,validOut] = step(H,X,validIn,resetIn)
[Y,startOut,endOut,validOut] = step(H,X,validIn,resetIn)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`[Y,validOut] = step(H,X,validIn)` returns the fast Fourier transform (FFT), `Y`, of the input, `X`, when `validIn` is `true`. `validIn` and `validOut` are logical scalars that indicate the validity of the input and output signals, respectively.

`[Y,startOut,endOut,validOut] = step(H,X,validIn)` returns the FFT, `Y`. `startOut` is `true` on the first sample of a frame of output data. `endOut` is `true` for the last sample of a frame of output data. To use this syntax, set the `StartOutputPort` and `EndOutputPort` properties to `true`.

`[Y,validOut] = step(H,X,validIn,resetIn)` returns the FFT, `Y`, when `validIn` is `true` and `resetIn` is `false`. When `resetIn` is `true`, the object stops the current calculation and clears all internal state. To use this syntax set the `ResetInputPort` property to `true`.

`[Y,startOut,endOut,validOut] = step(H,X,validIn,resetIn)` returns the FFT, `Y`, using all optional control signals. You can use any combination of the optional port syntaxes.

Note: `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Input Arguments

`H`

HDLFFT System object.

`X`

Scalar or vector of real or complex input data, in fixed-point or integer format. The vector size must be a power of 2 between 1 and 64, and not greater than the FFT length. `double`/`single` is supported for simulation but not for HDL code generation.

`validIn`

Logical scalar that indicates the validity of the input data.

`resetIn`

(optional) Logical scalar to reset the internal state.

Output Arguments

`Y`

Scalar or vector of real or complex output data, in the same format as the input data.

`startOut`

(optional) Logical scalar that is `true` for the first sample of a frame of output data.

`endOut`

(optional) Logical scalar that is `true` for the last sample of a frame of output data.

`validOut`

Logical scalar that indicates the validity of the output data.

dsp.HDLIFFT System object

Package: dsp

Inverse fast Fourier transform—optimized for HDL code generation

Description

The HDL IFFT System object implements a pipelined Radix 2^2 IFFT algorithm which provides hardware speed and area optimization for streaming data applications. The object accepts scalar or vector real or complex input, provides hardware-friendly control signals, and has optional output frame control signals. You can achieve giga-sample-per-second (GSPS) throughput using vector input.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`HIFFT = dsp.HDLIFFT` returns an HDL IFFT System object, `HIFFT`, that performs an inverse fast Fourier transform.

`HIFFT = dsp.HDLIFFT(Name,Value)` returns an HDL IFFT System object, `HIFFT`, with additional options specified by one or more `Name,Value` pair arguments.

Properties

`Architecture`

`'Streaming Radix 2^2'` (default) — An efficient architecture that has lower latency and uses fewer resources than the previous versions.

`'Streaming Radix 2 (this choice will be removed -see release notes).'` — Versions before R2016a use this architecture. Use only for backward-compatibility purposes.

ComplexMultiplication

Select the HDL implementation of complex multipliers. Choose to implement each multiplier with `'Use 4 multipliers and 2 adders'` or `Use 3 multipliers and 5 adders`. Which option is faster or smaller depends on your synthesis tool and target device. This option applies only if you use the Radix 2^2 architecture.

BitReversedOutput

Select the order of the output data.

- `true` (default) — The output channel elements are bit reversed relative to the input order.
- `false` — The output channel elements are in linear order.

The FFT algorithm calculates output in the reverse order to the input, and performs an extra reversal operation when required to provide output in the same order as the input. For vector data, input and output data must be in opposite orders so choose only one of `BitReversedOutput` or `BitReversedInput`. For more information on ordering of the output, see "Linear and Bit-Reversed Output Order".

BitReversedInput

Select the expected order of the input data.

- `true` — The input channel elements are in bit-reversed order.
- `false` (default) — The input channel elements are in linear order.

The FFT algorithm calculates output in the reverse order to the input, and performs an extra reversal operation when required to provide output in the same order as the input. For vector data, input and output data must be in opposite orders so choose only one of `BitReversedOutput` or `BitReversedInput`. For more information on ordering of the output, see "Linear and Bit-Reversed Output Order".

Normalize

Enable output scaling.

- `true` (default) — The object implements an overall 1/N scale factor by scaling the result of each pipeline stage by 2. This adjustment keeps the output of the IFFT in the same amplitude range as its input.

- `false` — The object avoids overflow by increasing the word length by one bit at each stage.

FFTLength

Number of data points used for one FFT calculation. The default value is 1024. The FFT length must be a power of 2 between 2^3 and 2^{16} for HDL code generation.

ResetInputPort

When you set `ResetInputPort` to `true`, the `step` method expects an additional argument, `reset`. When `reset` is `true`, the object stops calculation and clears all internal state. The default value of `ResetInputPort` is `false`.

StartOutputPort

If you set `StartOutputPort` to `true`, the `step` method returns an additional output signal that is `true` on the first cycle of each valid output frame. The default value of `StartOutputPort` is `false`.

EndOutputPort

If you set `EndOutputPort` to `true`, the step method returns an additional output signal that is `true` on the last cycle of each valid output frame. The default value of `EndOutputPort` is `false`.

RoundingMethod

Rounding mode used for fixed-point operations. The IFFT object uses fixed-point arithmetic for internal calculations when the input is any integer or fixed-point data type. This option does not apply when the input is single or double type. The default `RoundingMethod` is `Floor`. Each stage rounds after the twiddle factor multiplication but before the butterflies.

Methods

getLatency	Latency of IFFT operation
step	Process inputs using the HDL optimized IFFT (Inverse Fast Fourier Transform)

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Create an IFFT for HDL Code Generation

Create the specifications and input signal. This example uses a 128-point FFT.

```
N = 128;
Fs = 40;
t = (0:N-1)'/Fs;
x = sin(2*pi*15*t) + 0.75*cos(2*pi*10*t);
y = x + .25*randn(size(x));
y_fixed = sfi(y,32,16);
noOp = zeros(1,'like',y_fixed);
```

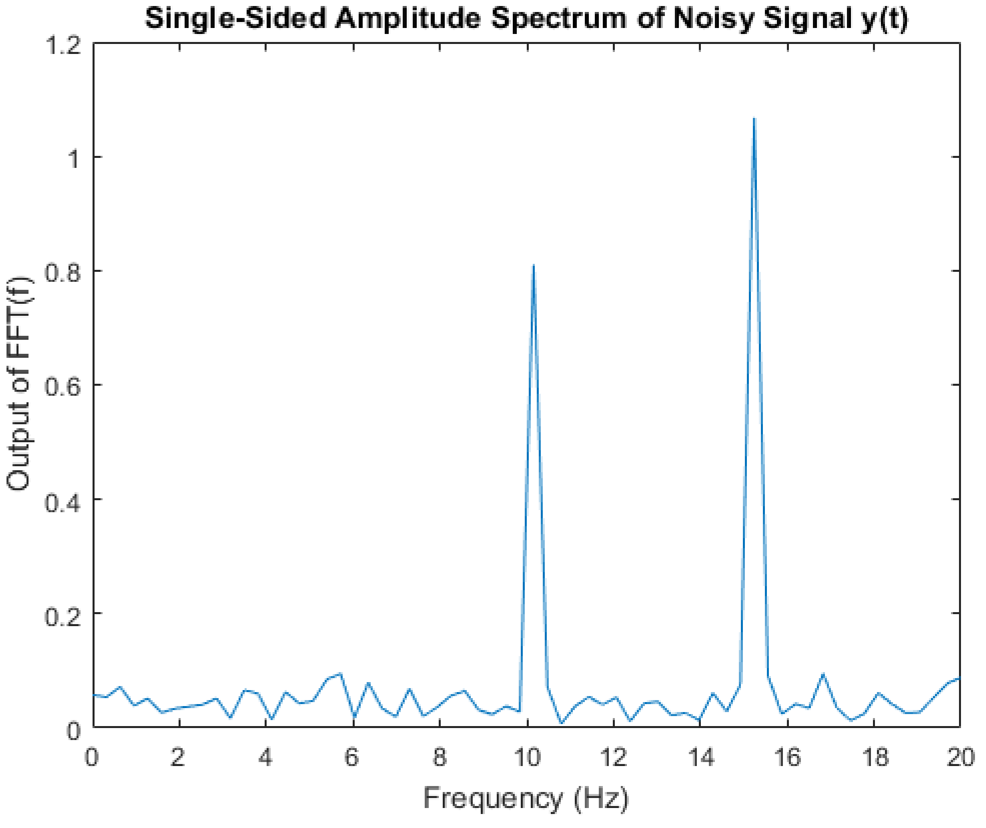
Compute the FFT of the signal to use as the input to the IFFT object.

Note: This object syntax runs only in R2016b or later. If you are using an earlier release, replace each call of an object with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

```
hdlfft = dsp.HDLFFT('FFTLength',N,'BitReversedOutput',false);
Yf = zeros(1,4*N);
validOut = false(1,4*N);
for loop = 1:1:N
      [Yf(loop),validOut(loop)] = hdlfft(complex(y_fixed(loop)),true);
end
for loop = N+1:1:4*N
   [Yf(loop),validOut(loop)] = hdlfft(complex(noOp),false);
end
Yf = Yf(validOut == 1);
```

Plot the single-sided amplitude spectrum.

```
plot(Fs/2*linspace(0,1,N/2),2*abs(Yf(1:N/2)/N))
title('Single-Sided Amplitude Spectrum of Noisy Signal y(t)')
xlabel('Frequency (Hz)')
ylabel('Output of FFT(f)')
```



Select frequencies that hold the majority of the energy in the signal. The `cumsum` function doesn't accept fixed-point arguments, so convert the data back to `double`.

```
[Ysort,i] = sort(abs(double(transpose(Yf(1:N)))),1,'descend');
Ysort_d = double(Ysort);
CumEnergy = sqrt(cumsum(Ysort_d.^2))/norm(Ysort_d);
j = find(CumEnergy > 0.9, 1);
     disp(['Number of FFT coefficients that represent 90% of the ', ...
```

```
     'total energy in the sequence: ', num2str(j)])
Yin = zeros(N,1);
Yin(i(1:j)) = Yf(i(1:j));
```

```
Number of FFT coefficients that represent 90% of the total energy in the sequence: 4
```

Write a function that instantiates and calls the IFFT System object™. You can generate HDL from this function.

```
function [yOut,validOut] = HDLIFFT128(yIn,validIn)
%HDLIFFT128
% Processes one sample of data using the dsp.HDLIFFT System object(TM)
% yIn is a fixed-point scalar or column vector.
% validIn is a logical scalar.
% You can generate HDL code from this function.

  persistent ifft128;
  if isempty(ifft128)
    ifft128 = dsp.HDLIFFT('FFTLength',128)
  end
  [yOut,validOut] = ifft128(yIn,validIn);
end
```

Compute the IFFT by calling the function for each data sample.

```
Xt = zeros(1,3*N);
validOut = false(1,3*N);
for loop = 1:1:N
    [Xt(loop),validOut(loop)] = HDLIFFT128(complex(Yin(loop)),true);
end
for loop = N+1:1:3*N
    [Xt(loop),validOut(loop)] = HDLIFFT128(complex(0),false);
end
```

```
ifft128 =

  dsp.HDLIFFT with properties:

              FFTLength: 128
           Architecture: 'Streaming Radix 2^2'
  ComplexMultiplication: 'Use 4 multipliers and 2 adders'
```

```
        BitReversedOutput: true
         BitReversedInput: false
                Normalize: true

  Use get to show all properties
```

Discard invalid output samples. Then inspect the output and compare it with the input signal. The original input is in green.

```
Xt = Xt(validOut==1);
Xt = bitrevorder(Xt);
norm(x-transpose(Xt(1:N)))
figure
stem(real(Xt))
figure
stem(real(x),'--g')
```

```
ans =

    0.7863
```

Create a Vector-Input IFFT for HDL Code Generation

Create the specifications and input signal. This example uses a 128-point FFT and computes the transform over 16 samples at a time.

```
N = 128;
V = 16;
Fs = 40;
t = (0:N-1)'/Fs;
x = sin(2*pi*15*t) + 0.75*cos(2*pi*10*t);
y = x + .25*randn(size(x));
y_fixed = sfi(y,32,24);
y_vect = reshape(y_fixed,V,N/V);
```

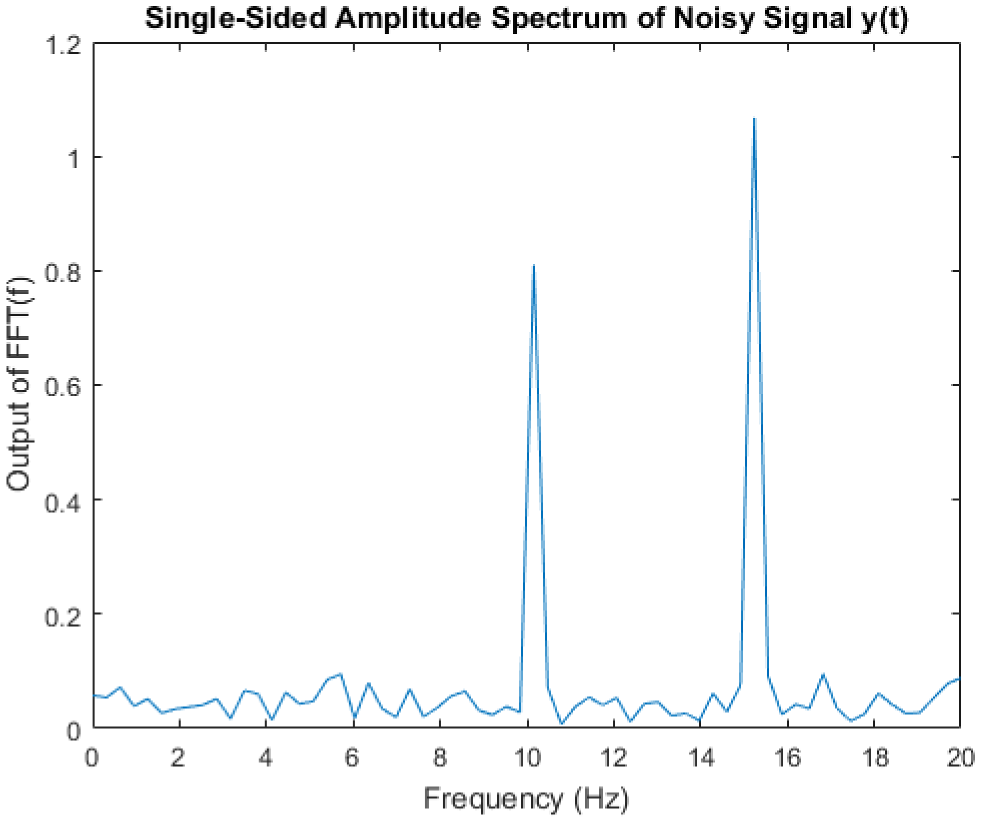
Compute the FFT of the signal, to use as the input to the IFFT object.

Note: This object syntax runs only in R2016b or later. If you are using an earlier release, replace each call of an object with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

```
hdlfft = dsp.HDLFFT('FFTLength',N);
loopCount = getLatency(hdlfft,N,V)+N/V;
Yf = zeros(V,loopCount);
validOut = false(V,loopCount);
for loop = 1:1:loopCount
    if ( mod(loop,N/V) == 0 )
        i = N/V;
    else
        i = mod(loop,N/V);
    end
    [Yf(:,loop),validOut(loop)] = hdlfft(complex(y_vect(:,i)),(loop<=N/V));
end
```

Plot the single-sided amplitude spectrum.

```
C = Yf(:,validOut==1);
Yf_flat = C(:);
Yr = bitrevorder(Yf_flat);
plot(Fs/2*linspace(0,1,N/2),2*abs(Yr(1:N/2)/N))
title('Single-Sided Amplitude Spectrum of Noisy Signal y(t)')
xlabel('Frequency (Hz)')
ylabel('Output of FFT(f)')
```



Select frequencies that hold the majority of the energy in the signal. The `cumsum` function doesn't accept fixed-point arguments, so convert the data back to `double`.

```
[Ysort,i] = sort(abs(double(Yr(1:N))),1,'descend');
CumEnergy = sqrt(cumsum(Ysort.^2))/norm(Ysort);
j = find(CumEnergy > 0.9, 1);
     disp(['Number of FFT coefficients that represent 90% of the ', ...
     'total energy in the sequence: ', num2str(j)])
Yin = zeros(N,1);
Yin(i(1:j)) = Yr(i(1:j));
YinVect = reshape(Yin,V,N/V);
```

```
Number of FFT coefficients that represent 90% of the total energy in the sequence: 4
```

Write a function that creates and calls the IFFT System object™. You can generate HDL from this function.

```
function [yOut,validOut] = HDLIFFT128V16(yIn,validIn)
%HDLFFT128V16
% Processes 16-sample vectors of FFT data
% yIn is a fixed-point column vector.
% validIn is a logical scalar value.
% You can generate HDL code from this function.

  persistent ifft128v16;
  if isempty(ifft128v16)
    ifft128v16 = dsp.HDLIFFT('FFTLength',128)
  end
  [yOut,validOut] = ifft128v16(yIn,validIn);
end
```

Compute the IFFT by calling the function for each data sample.

```
Xt = zeros(V,loopCount);
validOut = false(V,loopCount);
for loop = 1:1:loopCount
    if ( mod(loop,N/V) == 0 )
        i = N/V;
    else
        i = mod(loop,N/V);
    end
    [Xt(:,loop),validOut(loop)] = HDLIFFT128V16(complex(YinVect(:,i)),(loop<=N/V));
end
```

```
ifft128v16 =

  dsp.HDLIFFT with properties:

                FFTLength: 128
             Architecture: 'Streaming Radix 2^2'
    ComplexMultiplication: 'Use 4 multipliers and 2 adders'
        BitReversedOutput: true
         BitReversedInput: false
                Normalize: true
```

```
  Use get to show all properties
```

Discard invalid output samples. Then inspect the output and compare it with the input signal. The original input is in green.

Explore Latency of HDL IFFT Object

The latency of the object varies with the FFT length and the vector size. Use the `getLatency` method to find the latency of a particular configuration. The latency is the number of cycles between the first valid input and the first valid output, assuming the input is contiguous.

Create a new `dsp.HDLIFFT` object and request the latency.

```
hdlifft = dsp.HDLIFFT('FFTLength',512);
L512 = getLatency(hdlifft)
```

```
L512 =
```

```
   599
```

Request hypothetical latency information about a similar object with a different FFT length. The properties of the original object do not change. When you do not specify a vector length, the function assumes scalar input data.

```
L256 = getLatency(hdlifft,256)
N = hdlifft.FFTLength
```

```
L256 =

   329

N =

   512
```

Request hypothetical latency information of a similar object that accepts eight-sample vector input.

```
L256v8 = getLatency(hdlifft,256,8)
```

```
L256v8 =

    93
```

Set `Normalize` to `true`. The latency does not change.

```
hdlifft.Normalize = true;
L512n = getLatency(hdlifft)
```

```
L512n =

   599
```

Set `BitReversedOutput` to `false`. This setting increases the latency because the object must collect the output before reordering.

```
hdlifft.BitReversedOutput = false;
L512r = getLatency(hdlifft)

L512r =

        1078
```

Algorithm

This object implements the inverse function of the HDL FFT System object. The algorithm is described on the `FFT HDL Optimized` block reference page.

Latency

The latency varies with the FFT length and the vector size. Use the getLatency method to find the latency of a particular configuration. The latency is the number of cycles between the first valid input and the first valid output, assuming the input is contiguous.

Performance

These resource and performance data are the synthesis results from the generated HDL targeted to a Xilinx Virtex-6 (XC6VLX75T-1FF484) FPGA. The three examples in the tables have this configuration:

- FFT length (default) — 1024
- Complex multiplication — 4 multipliers, 2 adders
- Output scaling — Enabled
- 16-bit complex input data
- Minimize clock enables (HDL Coder parameter)

Performance of the synthesized HDL code varies with your target and synthesis options. For instance, natural order output uses more RAM than bit-reversed output, and real input uses less RAM than complex input.

For a scalar input Radix 2^2 configuration, the design achieves 326 MHz clock frequency. The latency is 1116 cycles. The design uses these resources.

Resource	Uses
LUT	4597
FFS	5353
Xilinx LogiCORE DSP48	12
Block RAM (16K)	6

When you vectorize the same Radix 2^2 implementation to process two 16-bit input samples in parallel, the design achieves 316 MHz clock frequency. The latency is 600 cycles. The design uses these resources.

Resource	Uses
LUT	7653
FFS	9322
Xilinx LogiCORE DSP48	24
Block RAM (16K)	8

The Radix 2 implementation is supported with scalar input data only. The Radix 2 design achieves 295 MHz clock frequency. The latency is 1148 cycles. The design uses these resources.

Resource	Uses
LUT	4060
FFS	5160
Xilinx LogiCORE DSP48	16
Block RAM (16K)	6

getLatency

System object: dsp.HDLIFFT
Package: dsp

Latency of IFFT operation

Syntax

```
Y = getLatency(H)
Y = getLatency(H,N)
Y = getLatency(H,N,V)
```

Description

`Y = getLatency(H)` returns the number of cycles, `Y`, that the object takes to calculate the IFFT of an input. The latency depends on the FFT length.

`Y = getLatency(H,N)` returns the latency, `Y`, that a hypothetical object with FFT Length `N`, and scalar input data, would take to calculate the IFFT of an input. This method does not change the properties of `H`.

`Y = getLatency(H,N,V)` returns the latency, `Y`, that a hypothetical object with FFT Length `N`, and vector input of size `V`, would take to calculate the IFFT of an input. This method does not change the properties of `H`.

Examples

Explore Latency of HDL IFFT Object

The latency of the object varies with the FFT length and the vector size. Use the `getLatency` method to find the latency of a particular configuration. The latency is the number of cycles between the first valid input and the first valid output, assuming the input is contiguous.

Create a new `dsp.HDLIFFT` object and request the latency.

```
hdlifft = dsp.HDLIFFT('FFTLength',512);
L512 = getLatency(hdlifft)
```

```
L512 =

   599
```

Request hypothetical latency information about a similar object with a different FFT length. The properties of the original object do not change. When you do not specify a vector length, the function assumes scalar input data.

```
L256 = getLatency(hdlifft,256)
N = hdlifft.FFTLength
```

```
L256 =

   329

N =

   512
```

Request hypothetical latency information of a similar object that accepts eight-sample vector input.

```
L256v8 = getLatency(hdlifft,256,8)
```

```
L256v8 =

    93
```

Set `Normalize` to `true`. The latency does not change.

```
hdlifft.Normalize = true;
L512n = getLatency(hdlifft)
```

```
L512n =
```

```
   599
```

Set `BitReversedOutput` to `false`. This setting increases the latency because the object must collect the output before reordering.

```
hdlifft.BitReversedOutput = false;
L512r = getLatency(hdlifft)
```

```
L512r =

        1078
```

Input Arguments

H

HDLIFFT System object

N

(optional) FFT length. Use this argument to request the latency of a similar object with FFT length `N`.

V

(optional) Vector size. Use this argument to request the latency of a similar object with `V`-sample vector input. When you do not specify this argument, the function assumes scalar input.

Output Arguments

Y

Cycles of latency that the object takes to calculate the IFFT of an input. The latency is the number of cycles between the first valid input and the first valid output, assuming the input is contiguous. Each call to the step method simulates one cycle.

step

System object: dsp.HDLIFFT
Package: dsp

Process inputs using the HDL optimized IFFT (Inverse Fast Fourier Transform)

Syntax

```
[Y,validOut] = step(H,X,validIn)
[Y,startOut,endOut,validOut] = step(H,X,validIn)
[Y,validOut] = step(H,X,validIn,resetIn)
[Y,startOut,endOut,validOut] = step(H,X,validIn,resetIn)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`[Y,validOut] = step(H,X,validIn)` returns the inverse fast Fourier transform (IFFT), `Y`, of the input, `X`, when `validIn` is `true`. `validIn` and `validOut` are logical scalars that indicate the validity of the input and output signals, respectively.

`[Y,startOut,endOut,validOut] = step(H,X,validIn)` returns the IFFT, `Y`. `startOut` is `true` on the first sample of a frame of output data. `endOut` is `true` for the last sample of a frame of output data. To use this syntax, set the `StartOutputPort` and `EndOutputPort` properties to `true`.

`[Y,validOut] = step(H,X,validIn,resetIn)` returns the IFFT, `Y`, when `validIn` is `true` and `resetIn` is `false`. When `resetIn` is `true`, the object stops the current calculation and clears all internal state. To use this syntax set the `ResetInputPort` property to `true`.

`[Y,startOut,endOut,validOut] = step(H,X,validIn,resetIn)` returns the IFFT, `Y`, using all optional control signals. You can use any combination of the optional port syntaxes.

Note: `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Input Arguments

`H`

HDLIFFT System object.

`X`

Scalar or vector of real or complex input data, in fixed-point or integer format. The vector size must be a power of 2 between 1 and 64, and not greater than the FFT length. `double`/`single` is supported for simulation but not for HDL code generation.

`validIn`

Logical scalar that indicates the validity of the input data.

`resetIn`

(optional) Logical scalar to reset the internal state.

Output Arguments

`Y`

Scalar or vector of real or complex output data, in the same format as the input data.

`startOut`

(optional) Logical scalar that is `true` for the first sample of a frame of output data.

`endOut`

(optional) Logical scalar that is `true` for the last sample of a frame of output data.

`validOut`

Logical scalar that indicates the validity of the output data.

dsp.HDLNCO System object

Package: dsp

Generate real or complex sinusoidal signals—optimized for HDL code generation

Description

The HDL NCO System object generates real or complex sinusoidal signals. In addition, the HDL NCO System object provides hardware-friendly control signals, optional reset signal, optional valid input signal, optional phase output signal, and an optional external dither input signal. It uses the same phase accumulation and lookup table technology as implemented in the NCO System object. You can use the lookup table compression option to significantly reduce the lookup table size with less than one LSB loss in precision. The System object does not support the property that allows the block to synthesize the LUT to a ROM on an FPGA.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj)` and `y = obj()` perform equivalent operations.

Construction

`HDLNCO = dsp.HDLNCO` returns a numerically controlled oscillator (NCO) System object, `HDLNCO`, that generates a real or complex sinusoidal signal. The amplitude of the generated signal is always 1.

`HDLNCO = dsp.HDLNCO(Name,Value)` returns an HDL NCO System object, `HDLNCO`, with additional options specified by one or more `Name,Value` pair arguments. `Name` is a property name and `Value` is the corresponding value. `Name` must appear inside single quotes (`''`). You can specify several name-value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`. Properties not specified retain their default values.

`HDLNCO = dsp.HDLNCO(Inc,'PhaseIncrementSource','Property')` returns an HDL NCO System object, `HDLNCO`, with the `PhaseIncrement` property set to `Inc`. `Inc` is an integer scalar. To use the `PhaseIncrement` property, set the `PhaseIncrementSource` property to `Property`. You can add other `Name,Value` pairs before or after `PhaseIncrementSource`.

Input Arguments

`Inc`

An integer scalar value for the `PhaseIncrement` property. To use this value, set the `PhaseIncrementSource` property to `Property`.

Default: 100

Properties

This object supports `double` for simulation but not for HDL code generation. When a data input is fixed point, or when no data input ports are enabled, the object computes the output waveform based on the fixed-point property settings. When a data input is floating-point, the object ignores `NumDitherBits`, `PhaseQuantization`, `NumQuantizerAccumulatorBits`, `LUTCompress`, and the fixed-point data type properties, and computes a double-precision output waveform.

`PhaseIncrementSource`

Select which phase increment the object uses. Set `PhaseIncrementSource` to `Property` to use the `PhaseIncrement` property. Set `PhaseIncrementSource` to `Input port` to use an input argument of the `step` method. The default is `Input port`.

```
hnco = dsp.HDLNCO(...,'PhaseIncrementSource','Property','PhaseIncrement',phIncr, ...)
```

`PhaseIncrement`

Specify the phase increment as an integer scalar. This property is applicable when you set the `PhaseIncrementSource` property to `Property`. The default value of this property is 100.

`PhaseOffsetSource`

Select which phase offset the object uses. Set `PhaseOffsetSource` property to `Property` to use the `PhaseOffset` property. Set `PhaseOffsetSource` property to `Input port` to use an input argument of the `step` method. The default is `Property`.

```
hnco = dsp.HDLNCO(...,'PhaseOffsetSource','Property','PhaseOffset',phOffset,...)
```

PhaseOffset

Specify the phase offset as an integer scalar. This property is applicable when you set the `PhaseOffsetSource` property to `Property`. The default value of `PhaseOffset` is 0.

DitherSource

Select which dither size the object uses. Set `DitherSource` property to `Property` to use the `NumDitherBits` property. Other options are `Input port` to use an input argument of the `step` method, or `None` to disable dithering. The default is `Property`.

```
hnco = dsp.HDLNCO(...,'DitherSource','Property','NumDitherBits',ditherBits,...)
```

NumDitherBits

Specify the number of dither bits as a positive integer. This property is applicable when you set the `DitherSource` property to `Property`. The default value of `NumDitherBits` is 4.

PhaseQuantization

Set this property to `true` to enable quantization of the accumulated phase. The default value of `PhaseQuantization` is `true`.

```
hnco = dsp.HDLNCO(...,'PhaseQuantization',true,'NumQuantizerAccumulatorBits',accumBits,...)
```

NumQuantizerAccumulatorBits

Specify the number of quantizer accumulator bits as an integer scalar greater than 1 and less than the accumulator word length. `NumQuantizerAccumulatorBits` determines the number of entries in the lookup table of sine values. This property is applicable when you set `PhaseQuantization` to `true`. The default value of this property is 12.

LUTCompress

Set this property to `true` to enable lookup table compression. The object uses the Sunderland compression method to reduce the size of the lookup table. The default value of this property is `false`.

Waveform

Choose whether the output of the object is `Sine`, `Cosine`, `Complex exponential`, or `Sine and cosine` signals. If you select `Complex exponential`, the output is of the form `sine + j*cosine`. If you select `Sine and cosine`, the `step` method returns an additional output. The default is `Sine`.

PhasePort

Set `PhasePort` to `true` to return the current phase along with the output from the `step` method. The default value of this property is `false`.

ResetAction

Set `ResetAction` to `true` to enable a reset argument to the `step` method. The default value of this property is `false`.

ValidInputPort

Set `ValidInputPort` to `false` to disable the `ValidIn` input argument to the `step` method. The default value is `true`.

OverflowAction

Overflow mode for fixed-point operations. `OverflowAction` is a constant property with value `Wrap`.

RoundingMethod

Rounding mode for fixed-point operations. `RoundingMethod` is a constant property with value `Floor`.

AccumulatorDataType

Accumulator data type description. This property is a constant with value `Binary point scaling`.

AccumulatorSigned

Select signed or unsigned accumulator data format. This property is a constant. All output is signed format.

AccumulatorWL

Accumulator word length. Default is 16 bits.

AccumulatorFL

Accumulator fraction length. This property is a constant with value 0 bits.

OutputDataType

Specify the output signal data type. Options are: `double`, `single`, and `Binary point scaling`. If this property is set to `Binary point scaling`, the output sign, word length, and fraction length are taken from the following three properties. The default is `Binary point scaling`.

OutputSigned

Select signed or unsigned output data. This property is a constant. All output is signed format.

OutputWL

Output data word length. The default is 16 bits.

OutputFL

Output data fraction length. The default is 14 bits.

Methods

step	Process inputs using the HDL optimized NCO (Numerically Controlled Oscillator)

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object

Common to All System Objects	
getNumOutp	Expected number of outputs of a System object
isLocked	Check locked states of a System object (logical)
release	Allow System object property value changes

Examples

Design a HDL-Compatible NCO Source

This example shows how to design an HDL-compatible NCO source.

```
F0 = 510;     % Output frequency = 510 Hz
df = 0.05;    % Frequency resolution = 0.05 Hz
minSFDR = 96; % Spurious free dynamic range >= 96 dB
Ts = 1/4000;  % Sample period = 1/4000 seconds
dphi = pi/2;  % Desired phase offset = pi/2;
```

Calculate the number of accumulator bits required for the frequency resolution, and the number of quantized accumulator bits to satisfy the SFDR requirement.

```
Nacc = ceil(log2(1/(df*Ts)));
actdf = 1/(Ts*2^Nacc); % Actual frequency resolution achieved
Nqacc = ceil((minSFDR-12)/6);
```

Calculate the phase increment and offset.

```
phIncr = round(F0*Ts*2^Nacc);
phOffset = 2^Nacc*dphi/(2*pi);
```

Construct a NCO HDL System object™. Set the properties to the values calculated. Call the object to generate data points in a sine wave. The input to the object is a valid signal.

Note: This object syntax runs only in R2016b or later. If you are using an earlier release, replace each call of an object with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

```
hdlnco = dsp.HDLNCO('PhaseIncrementSource','Property', ...
       'PhaseIncrement',phIncr,...
       'PhaseOffset',phOffset,...
```

```
        'NumDitherBits',4, ...
        'NumQuantizerAccumulatorBits',Nqacc,...
        'AccumulatorWL',Nacc)
for k = 1:1/Ts
   y(k) = hdlnco(true);
end
```

```
hdlnco =

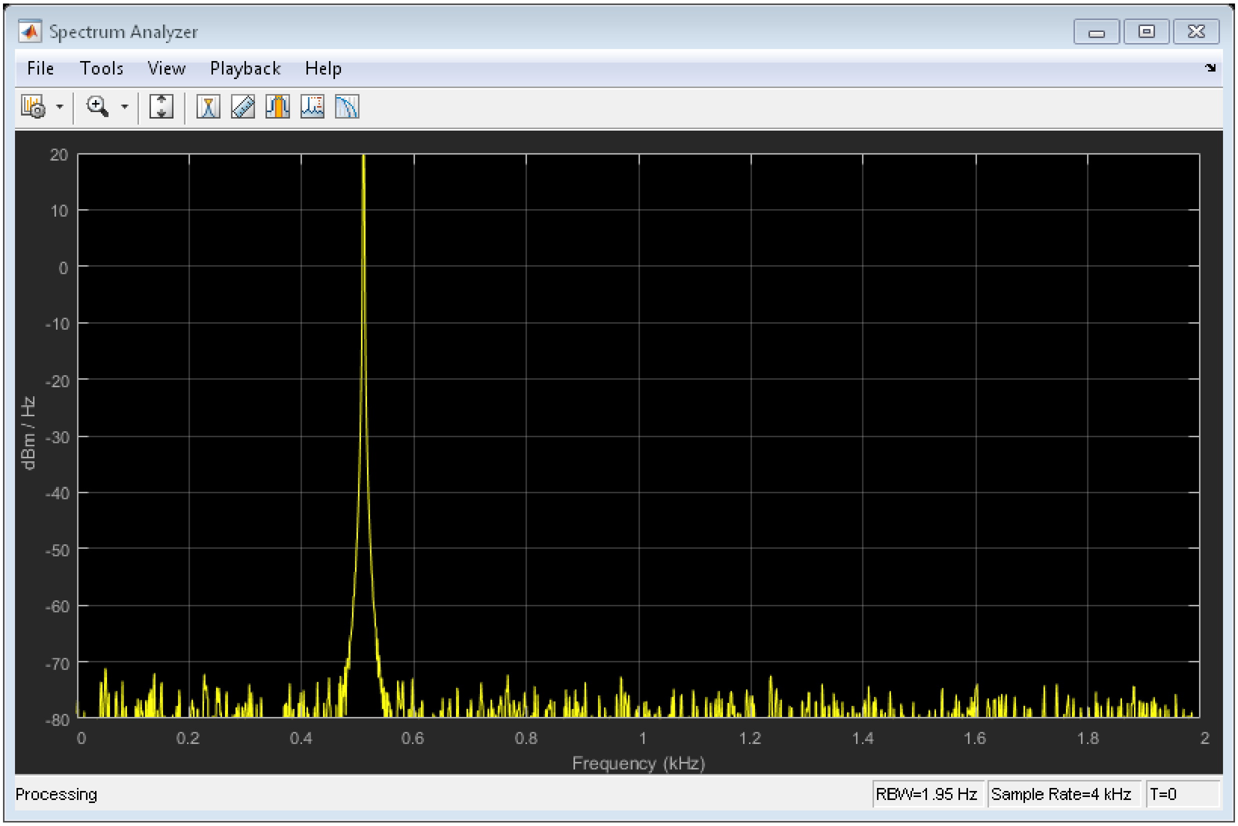
  dsp.HDLNCO with properties:

           PhaseIncrementSource: 'Property'
                 PhaseIncrement: 16712
              PhaseOffsetSource: 'Property'
                    PhaseOffset: 32768
                   DitherSource: 'Property'
                  NumDitherBits: 4
              PhaseQuantization: true
    NumQuantizerAccumulatorBits: 14
                    LUTCompress: false
                    ResetAction: false
                 ValidInputPort: true
                       Waveform: 'Sine'
                      PhasePort: false

  Use get to show all properties
```

Plot the mean-square spectrum of the 510 Hz sine wave generated by the NCO.

```
sa = dsp.SpectrumAnalyzer('SampleRate',1/Ts);
sa.SpectrumType = 'Power density';
sa.PlotAsTwoSidedSpectrum = false;
sa(y');
```



Algorithms

Lookup Table Algorithm

When you enable lookup table (LUT) compression, the HDL NCO System object applies the Sunderland compression method. Sunderland techniques use trigonometric identities to divide each phase of the quarter sine wave into three components and express it as:

$$\sin(A+B+C) = \sin(A+B)\cos C + \cos A \cos B \cos C - \sin A \sin B \sin C$$

If the phase has 12 bits, the components are defined as:

- A, the four most significant bits

  $(0 \le A \le \frac{\pi}{2})$

- B, the following four bits

  $(0 \le B \le \frac{\pi}{2} \times 2^{-4})$

- C, the four least significant bits

  $(0 \le C \le \frac{\pi}{2} \times 2^{-8})$

Because C is small enough that sin(C)≅1 and cos(C)≅0, the equation is approximated by:

$$\sin(A+B+C) \approx \sin(A+B) + \cos A \sin C$$

The HDL NCO System object implements this equation with one LUT for sin(A+B) and one LUT for cos(A)sin(C). The second term is a fine correction factor and can be truncated to fewer bits without losing precision. With the default accumulator size of 16 bits, and the example phase width of 12 bits, the LUTs use only 2^8×16 plus 2^8×4 bits (5kb). A quarter sine lookup table would use 2^{12}×16 bits (65kb). This approximation is accurate within 1 LSB which gives an SNR of at least 60 dB on the output. See L. Cordesses, "Direct Digital Synthesis: A Tool for Periodic Wave Generation (Part 1)", IEEE Signal Processing Magazine, DSP Tips & Tricks column, pp. 50–54, Vol. 21, No. 4 July 2004.

dsp.NCO | `NCO HDL Optimized`

Introduced in R2013a

step

System object: dsp.HDLNCO
Package: dsp

Process inputs using the HDL optimized NCO (Numerically Controlled Oscillator)

Syntax

```
[Y,ValidOut] = step(HDLNCO,Inc,ValidIn)
[Y,ValidOut] = step(HDLNCO)
[Y,ValidOut] = step(HDLNCO,Inc,Offset,Dither,ValidIn)
[Y,Phase,ValidOut]= step(HDLNCO,___)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj)` and `y = obj()` perform equivalent operations.

`[Y,ValidOut] = step(HDLNCO,Inc,ValidIn)` returns a sinusoidal signal, `Y`, generated by the HDLNCO System object, with the specified phase increment, `Inc`. When `ValidIn` is `true`, `Inc` is added to the accumulator.

`[Y,ValidOut] = step(HDLNCO)` returns a waveform, `Y`, when you set the `PhaseIncrementSource`, `PhaseOffsetSource`, and `DitherSource` properties to `Property`, and `ValidInputPort` to `false`. These properties are independent of each other. You can mix and match the activation of these arguments.

`[Y,ValidOut] = step(HDLNCO,Inc,Offset,Dither,ValidIn)` returns a waveform, `Y`, with phase increment, `Inc`, phase offset, `Offset`, and dither, `Dither`. This syntax applies when you set the `PhaseIncrementSource`, `PhaseOffsetSource`, and `DitherSource` properties to `Input port`. These properties are independent of each other. You can mix and match the activation of these arguments.

`[Y,Phase,ValidOut]= step(HDLNCO,___)` returns a waveform, `Y`, and output `Phase`, when the `PhasePort` property is `true`. The object returns the waveform value, Y, as a sine value, a cosine value, a complex exponential value, or a [Sine,Cosine] pair of values, depending on the Waveform property. This syntax can include any of the arguments from other syntaxes.

Note: obj specifies the System object on which to run this step method.

The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

Input Arguments

HDLNCO

dsp.HDLNCO System object.

Inc

Phase increment, specified as a scalar integer.

The object accepts this argument when you set the PhaseIncrementSource property to Input port.

Supported data types:

- fixdt([],N,0)
- int, uint
- double and single are allowed for simulation but not for HDL code generation.

ValidIn

Enable signal, specified as a logical scalar.

The object increments the phase when ValidIn input is high. When ValidIn is low, the phase is held. The object accepts this argument when you set the ValidInputPort property to true.

Offset

Phase offset, specified as a scalar integer.

The object accepts this argument when you set the `PhaseSource` property to `Input port`.

Supported data types:

- `fixdt([],N,0)`
- `int`, `uint`
- `double` and `single` are allowed for simulation but not for HDL code generation.

Dither

Dither, specified as a scalar integer.

The object accepts this argument when you set the `DitherSource` property to `Input port`.

Supported data types:

- `fixdt([],N,0)`
- `int`, `uint`
- `double` and `single` are allowed for simulation but not for HDL code generation.

Reset

Request reset of the accumulator, specified as a `logical` scalar value.

The object resets the accumulator to zero when `Reset` is high. The object accepts this argument when you set the `ResetAction` property to `true`.

Output Arguments

Y

Waveform, returned as a scalar fixed-point or floating-point value, or as a [`Sine,Cosine`] pair of values.

The type of the output waveform depends on the `Waveform` property.

- `Sine` (default) — returns a generated sine wave
- `Cosine` — returns a generated cosine wave
- `Complex exponential` — returns a wave in the form `sine + j*cosine`
- `Sine and cosine` — returns a pair of values representing corresponding sine and cosine waves

Supported data types:

- `fixdt()`
- `double` and `single` are allowed for simulation but not for HDL code generation.

ValidOut

Validity of the `Y` output, returned as a `logical` scalar.

When `ValidOut` is high, the data output is valid. When `ValidOut` is low, the data output is not valid.

Phase

Current phase of the NCO, returned as a scalar.

The object returns this additional output when you set the `PhasePort` property to `true`.

Supported data types:

- `fixdt(1,M,-Z)`, where *M* is the number of quantized accumulator bits, and *Z* is the accumulator word length.
- `double` and `single` are allowed for simulation but not for HDL code generation. The object returns `Phase` as floating point if the input to the `step` method is floating point.

dsp.HampelFilter System object

Package: dsp

Filter outliers using Hampel identifier

Description

The `dsp.HampelFilter` System object detects and removes the outliers of the input signal by using the Hampel identifier. The Hampel identifier is a variation of the three-sigma rule of statistics that is robust against outliers. For each sample of the input signal, the object computes the median of a window composed of the current sample and $\frac{Len-1}{2}$ adjacent samples on each side of current sample. *Len* is the window length you specify through the `WindowLength` property. The object also estimates the standard deviation of each sample about its window median by using the median absolute deviation. If a sample differs from the median by more than the threshold multiplied by the standard deviation, the filter replaces the sample with the median. For more information, see "Algorithms" on page 2-859.

The object accepts multichannel inputs, that is, m-by-n size inputs, where $m \geq 1$, and $n > 1$. m is the number of samples in each frame (channel), and n is the number of channels. The object also accepts variable-size inputs. After the object is locked, you can change the size of each input channel. However, the number of channels cannot change.

To filter the input signal using a Hampel identifier:

1. Create a `dsp.HampelFilter` object and set the properties of the object.
2. Call step to filter the signal using the Hampel identifier.

Note: Alternatively, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`hampFilt = dsp.HampelFilter` returns a Hampel filter object, `hampFilt`, using the default properties.

`hampFilt = dsp.HampelFilter(Len)` sets the `WindowLength` property to `Len`.

`hampFilt = dsp.HampelFilter(Len, Lim)` sets the `WindowLength` property to `Len` and the `Threshold` property to `Lim`.

`hampFilt = dsp.HampelFilter(Name,Value)` specifies properties using `Name,Value` pairs. Unspecified properties have default values.

Example:

```
hampFilt = dsp.HampelFilter(11,2);
```

Properties

If a property is listed as tunable, then you can change its value even when the object is locked.

`WindowLength` — Length of the sliding window

11 (default) | positive odd scalar integer

Length of the sliding window, specified as a positive odd scalar integer. The window of finite length slides over the data, and the object computes the median and median absolute deviation of the data in the window.

`Threshold` — Threshold for outlier detection

3 (default) | positive real scalar

Threshold for outlier detection, specified as a positive real scalar. For information on how this property is used to detect the outlier, see “Algorithms” on page 2-859.

Tunable: Yes

Methods

reset	Reset internal states of System object

step	Remove outliers from input

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Remove High-Frequency Noise Using Hampel Filter

Filter high-frequency noise from a noisy sine wave signal using a Hampel filter. Compare the performance of the Hampel filter with a median filter.

Initialization

Set up a `dsp.HampelFilter` and a `dsp.MedianFilter` object. These objects use the sliding window method with a window length of 7. Create a time scope for viewing the output.

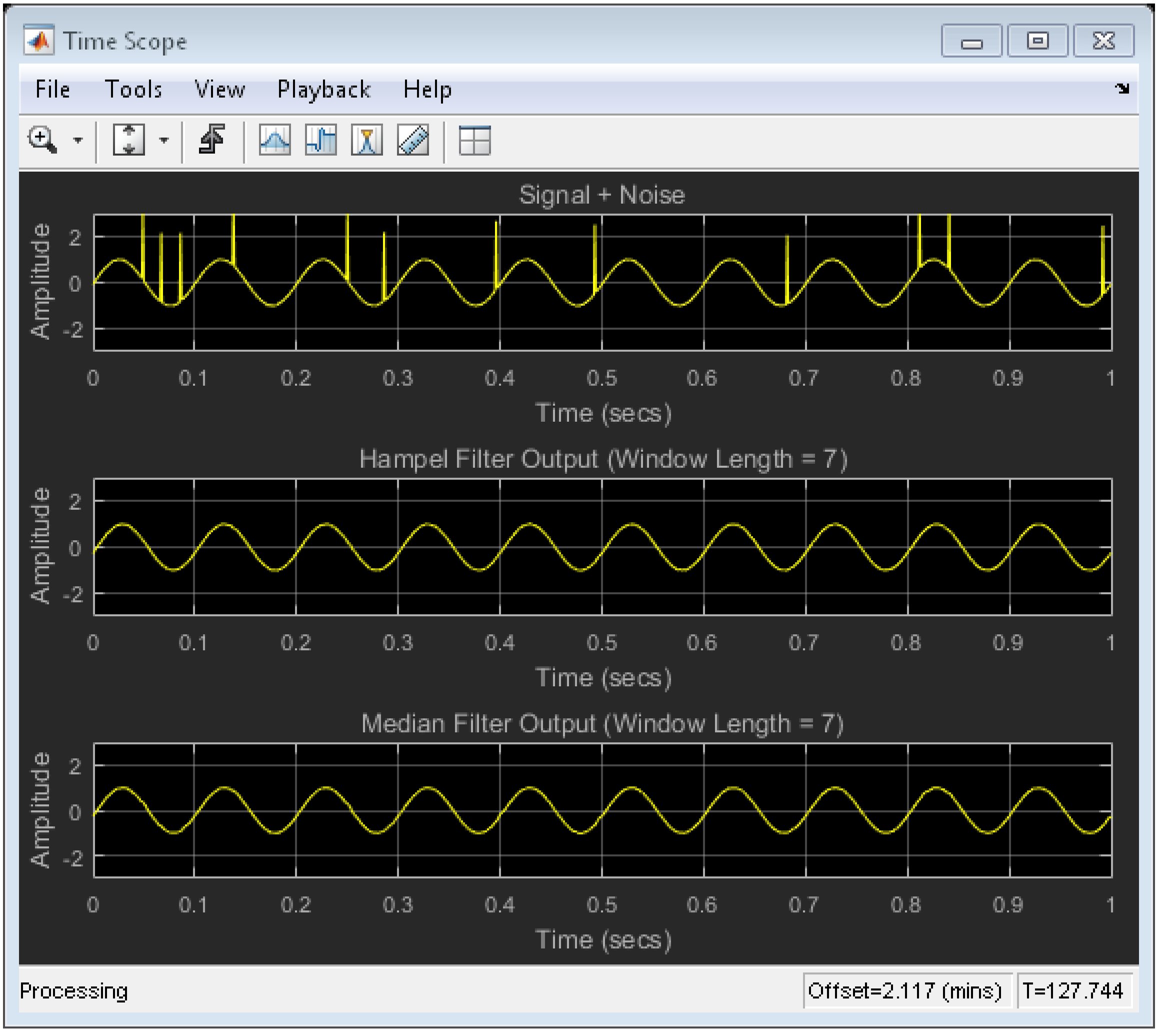
```
Fs = 1000;
hampFilt = dsp.HampelFilter(7);
medFilt = dsp.MedianFilter(7);
scope  = dsp.TimeScope('SampleRate',Fs, ...
    'TimeSpanOverrunAction','Scroll', ...
    'TimeSpan',1,'ShowGrid',true, ...
    'YLimits',[-3 3], ...
    'LayoutDimensions',[3 1], ...
    'NumInputPorts',3);
scope.ActiveDisplay = 1;
scope.Title = 'Signal + Noise';
scope.ActiveDisplay = 2;
scope.Title = 'Hampel Filter Output (Window Length = 7)';
scope.ActiveDisplay = 3;
scope.Title = 'Median Filter Output (Window Length = 7)';
```

Filter the Noisy Sine Wave Using a Window of Length 7

Generate a noisy sine wave signal with a frequency of 10 Hz. Apply the Hampel filter and the median filter object to the signal. View the output on the time scope.

```
FrameLength = 256;
sine = dsp.SineWave('SampleRate',Fs,'Frequency',10,...
    'SamplesPerFrame',FrameLength);

for i = 1:500
    hfn = 3 * (rand(FrameLength,1) < 0.02);
    x = sine() + 1e-2 * randn(FrameLength,1) + hfn;
    y1 = hampFilt(x);
    y2 = medFilt(x);
    scope(x,y1,y2);
end
```



Both filters remove the high-frequency noise. However, when you increase the window length, the Hampel filter is preferred. Unlike the median filter, the Hampel filter preserves the shape of the sine wave even with large window lengths.

Filter the Noisy Sine Wave Using a Window of Length 37

Increase the window length of both the filters to 37. Filter the noisy sine wave and view the filtered output on the time scope. To change the window length of the filters, you must release the filter objects at the start of the processing loop.

```
release(hampFilt);
release(medFilt);
hampFilt.WindowLength = 37;
medFilt.WindowLength = 37;
scope.ActiveDisplay = 1;
scope.Title = 'Signal + Noise';
scope.ActiveDisplay = 2;
scope.Title = 'Hampel Filter Output (Window Length = 37)';
scope.ActiveDisplay = 3;
scope.Title = 'Median Filter Output (Window Length = 37)';
for i = 1:500
    hfn = 3 * (rand(FrameLength,1) < 0.02);
    x = sine() + 1e-2 * randn(FrameLength,1) + hfn;
    y1 = hampFilt(x);
    y2 = medFilt(x);
    scope(x,y1,y2);
end
```

The median filter flattens the crests and troughs of the sine wave due to the median operation over a large window of data. The Hampel filter preserves the shape of the signal, in addition to removing the outliers.

Remove High-Frequency Noise from Gyroscope Data Using Hampel Filter

Remove the high-frequency outliers from a streaming signal using the `dsp.HampelFilter` System object™.

Use the `dsp.MatFileReader` System object to read the gyroscope MAT file. The file contains three columns of data, with each column containing 7140 samples. The three columns represent the *x*-axis, *y*-axis, and *z*-axis data from the gyroscope motion sensor. Choose a frame size of 714 samples so that each column of the data contains 10 frames. The `dsp.HampelFilter` System object uses a window length of 11. Create a `dsp.TimeScope` object to view the filtered output.

```
reader = dsp.MatFileReader('SamplesPerFrame',714,'Filename','LSM9DSHampelgyroData73.ma
    'VariableName','data');
hampFilt = dsp.HampelFilter(11);
scope = dsp.TimeScope('NumInputPorts',1,'SampleRate',119,'YLimits',[-300 300], ...
    'ChannelNames',{'Input','Filtered Output'},'TimeSpan',60,'ShowLegend',true);
```

Filter the gyroscope data using the `dsp.HampelFilter` System object. View the filtered *z*-axis data in the Time Scope.

```
for i = 1:10
    gyroData = reader();
    filteredData = hampFilt(gyroData);
    scope([gyroData(:,3),filteredData(:,3)]);
end
```

The Hampel filter removes all the outliers and preserves the shape of the signal.

Definitions

Hampel Identifier

The Hampel identifier is a variation of the three-sigma rule of statistics that is robust against outliers.

Given a sequence x_1, x_2, x_3, …, x_n and a sliding window of length k, define point-to-point median and standard-deviation estimates using:

- Local median — $m_i = \text{median}\left(x_{i-k}, x_{i-k+1}, x_{i-k+2}, \ldots, x_i, \ldots, x_{i+k-2}, x_{i+k-1}, x_{i+k}\right)$
- Standard deviation — $\sigma_i = \kappa\, \text{median}\left(\left|x_{i-k} - m_i\right|, \ldots, \left|x_{i+k} - m_i\right|\right)$, where

$$\kappa = \frac{1}{\sqrt{2}\,\text{erfc}^{-1}\,1/2} \approx 1.4826$$

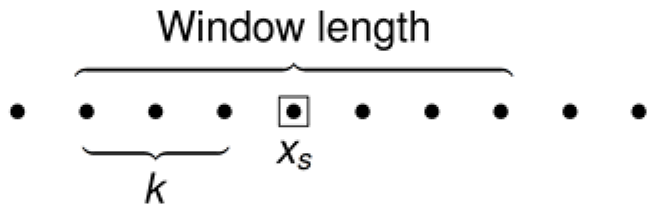
The quantity σ_i / κ is known as the median absolute deviation (MAD).

If a sample x_i is such that

$$\left|x_i - m_i\right| > n_\sigma \sigma_i$$

for a given threshold n_σ, then the Hampel identifier declares x_i an outlier and replaces it with m_i. If n_σ is 0, then the Hampel filter behaves as a regular median filter.

Algorithms



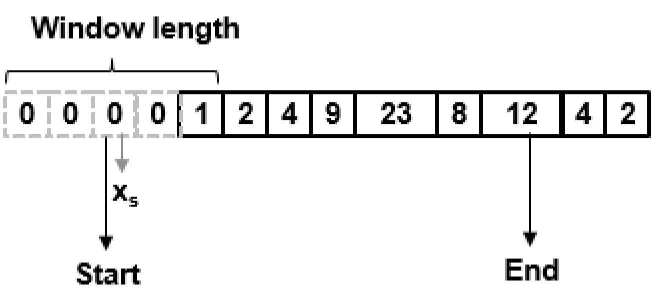
For a given sample of data, x_s, the algorithm:

- Centers the window of odd length at the current sample.
- Computes the local median, m_i, and standard deviation, σ_i, over the current window of data.
- Compares the current sample with $n_\sigma \times \sigma_i$, where n_σ is the threshold value. If $|x_s - m_i| > n_\sigma \times \sigma_i$, the filter identifies the current sample, x_s, as an outlier and replaces it with the median value, m_i.

Consider a frame of data that is passed into the Hampel filter.

1	2	4	9	23	8	12	4	2

In this example, the Hampel filter slides a window of length 5 (Len) over the data. The filter has a threshold value of 2 (n_σ). To have a complete window at the beginning of the frame, the filter algorithm prepends the frame with $Len - 1$ zeros. To compute the first sample of the output, the window centers on the $\left[\frac{Len-1}{2}+1\right]^{th}$ sample in the appended frame, the third zero in this case. The filter computes the median, median absolute deviation, and the standard deviation over the data in the local window.



- Current sample: $x_s = 0$.
- Window of data: win = [0 0 0 0 1].
- Local median: m_i = median([0 0 0 0 1]) = 0.

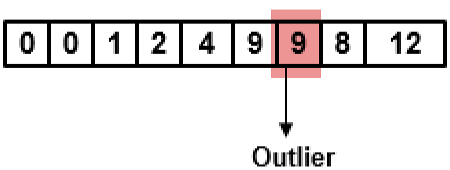
- Median absolute deviation: $mad_i = \text{median}\left(|x_{i-k} - m_i|, \ldots, |x_{i+k} - m_i|\right)$. For this window of data, $mad = \text{median}\left(|0-0|, \ldots, |1-0|\right) = 0$.
- Standard deviation: $\sigma_i = \kappa \times mad_i = 0$, where $\kappa = \frac{1}{\sqrt{2}\,\text{erfc}^{-1}\,1/2} \approx 1.4826$.
- The current sample, $x_s = 0$, does not obey the relation for outlier detection.

  $$\left[|x_s - m_i| = 0\right] > \left[(n_\sigma \times \sigma_i) = 0\right]$$

  Therefore, the Hampel filter outputs the current input sample, $x_s = 0$.

Repeat this procedure for every succeeding sample until the algorithm centers the window on the $\left[End - \frac{Len-1}{2}\right]^{th}$ sample, marked as `End`. Because the window centered on the last $\frac{Len-1}{2}$ samples cannot be full, these samples are processed with the next frame of input data.

Here is the first output frame the Hampel filter generates:



The seventh sample of the appended input frame, 23, is an outlier. The Hampel filter replaces this sample with the median over the local window [4 9 23 8 12].

Blocks
`Hampel Filter` | `Median Filter` | `Moving Average`

Introduced in R2017a

reset

System object: dsp.HampelFilter
Package: dsp

Reset internal states of System object

Syntax

`reset(hampFilt)`

Description

`reset(hampFilt)` resets the states of the input object to their initial values. The initial state values correspond to the initial conditions for the difference equation defining the object. After you call the object using nonzero input data, the filter might have nonzero states. If you continue to pass nonzero input data to the object without first calling `reset`, the object might produce different outputs for an identical input.

Introduced in R2017a

step

System object: dsp.HampelFilter
Package: dsp

Remove outliers from input

Syntax

```
y = step(hampFilt,x)
[y,isOutlier] = step(hampFilt,x)
```

Description

Note: Alternatively, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`y = step(hampFilt,x)` detects and removes the outliers of each channel of the input signal, `x`, independently over time using the input `dsp.HampelFilter` System object, `hampFilt`. The input `x` must be real, and it supports single and double data types.

`[y,isOutlier] = step(hampFilt,x)` returns a logical array, `IsOutlier`, where each element is `true` when the corresponding element in the input is an outlier. `isOutlier` is the same size as the input and output vectors.

Introduced in R2017a

dsp.HighpassFilter System object

Package: dsp

FIR or IIR highpass filter

Description

`dsp.HighpassFilter` independently filters each channel of the input over time using the given design specifications. You can set the `FilterType` property of `dsp.HighpassFilter` to `'FIR'` or `'IIR'` to implement the object as a FIR or IIR highpass filter. This object supports fixed-point operations, HDL code generation, and ARM Cortex code generation.

To filter each channel of your input:

1. Define and set up your highpass filter. See “Construction” on page 4-944.
2. Call step to filter each channel of the input signal according to the properties of `dsp.HighpassFilter`. The input signal can be a real- or complex-valued column vector or matrix, with floating point or fixed-point precision. If the input signal is a matrix, each column of the matrix is treated as an independent channel. The number of rows in the input signal denote the channel length.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`HPF = dsp.HighpassFilter` returns a minimum order FIR highpass filter, `HPF`, with the default filter settings. Calling `step` with the default property settings filters the input data with a stopband frequency of `8` kHz, a passband frequency of `12` kHz, a stopband attenuation of `80` dB, and a passband ripple of `0.1` dB.

`HPF = dsp.HighpassFilter(Name,Value)` returns a highpass filter, with additional properties specified by one or more `Name,Value` pair arguments. `Name` is the property name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name-value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Properties

`SampleRate` — Input sample rate

`44100` (default) | positive real scalar

Input sample rate in Hz, specified as the comma-separated pair consisting of `'SampleRate'` and a positive real scalar.

`FilterType` — Filter type

`'FIR'` (default) | `'IIR'`

Filter type, specified as one of the following options:

- `'FIR'` — The object designs an FIR highpass filter.
- `'IIR'` — The object designs an IIR highpass (biquad) filter.

`DesignForMinimumOrder` — Minimum order filter design

`true` (default) | `false`

Minimum order filter design, specified as the comma-separated pair consisting of `'DesignForMinimumOrder'` and a logical value. If this property is `true`, then `dsp.HighpassFilter` designs filters with the minimum order that meets the passband frequency, stopband frequency, passband ripple, and stopband attenuation specifications. Set these specifications using the corresponding properties. If this property is `false`, then the object designs filters with the order that you specify in the `FilterOrder` property. This filter design meets the passband frequency, passband ripple, and stopband attenuation specifications that you set using the respective properties.

`FilterOrder` — Order of the FIR or IIR filter

`50` (default) | positive integer scalar

Order of the FIR or IIR filter, specified as the comma-separated pair consisting of `'FilterOrder'` and a positive integer scalar. Specifying a filter order is only valid when the value of `'DesignForMinimumOrder'` is `false`.

`StopbandFrequency` — Filter stopband edge frequency

`8000` (default) | real positive scalar

Filter stopband edge frequency in Hz, specified as the comma-separated pair consisting of `'StopbandFrequency'` and a real positive scalar. The value of the stopband edge frequency in Hz must be less than the passband frequency. You can specify the stopband edge frequency only when `'DesignForMinimumOrder'` is `true`.

`PassbandFrequency` — Filter passband edge frequency
`12000` (default) | real positive scalar

Filter passband edge frequency in Hz, specified as the comma-separated pair consisting of `'PassbandFrequency'` and a real positive scalar. The value of the passband edge frequency in Hz must be less than half the `SampleRate` and greater than `StopbandFrequency`.

`StopbandAttenuation` — Minimum attenuation in the stopband
`80` (default) | real positive scalar

Minimum attenuation in the stopband in dB, specified as the comma-separated pair consisting of `'StopbandAttenuation'` and a real positive scalar. Minimum attenuation in the stopband defaults to `80` dB.

`PassbandRipple` — Maximum ripple of filter response in the passband
`0.1` (default) | real positive scalar

Maximum ripple of filter response in the passband, in dB, specified as the comma-separated pair consisting of `'PassbandRipple'` and a real positive scalar. Maximum ripple of filter response defaults to `0.1` dB.

Fixed-Point Properties

`RoundingMethod` — Rounding method for output fixed-point operations
`'Floor'` (default) | `'Ceiling'` | `'Convergent'` | `'Nearest'` | `'Round'` | `'Simplest'` | `'Zero'`

Rounding method for output fixed-point operations, specified as a character vector. For more information on the rounding modes, see “Precision and Range”.

`CoefficientsDataType` — Word and fraction lengths of coefficients
`numerictype([],16)` (default) | `numerictype` object

Word and fraction lengths of coefficients, specified as a `numerictype` object. The default, `numerictype(1,16)` corresponds to a signed numeric type object with 16-bit coefficients and a fraction length determined based on the coefficient values, to give the best possible precision.

This property is not tunable.

Word length of the output is same as the word length of the input. Fraction length of the output is computed such that the entire dynamic range of the output can be represented without overflow. For details on how the fraction length of the output is computed, see "Fixed-Point Precision Rules for Avoiding Overflow in FIR Filters".

Methods

measure	Measure frequency response characteristics of `dsp.HighpassFilter` System object.
reset	Reset internal states of highpass filter
step	Filter input using FIR or IIR highpass filter

For additional methods, see "Analysis Methods for Filter System Objects" on page 3-2.

For a complete list of analysis methods supported for the `dsp.HighpassFilter` object, enter `dsp.HighpassFilter.helpFilterAnalysis` at the MATLAB command prompt.

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Impulse and Frequency Response of FIR and IIR Highpass Filters

Create a minimum order FIR highpass filter for data sampled at 44.1 kHz. Specify a passband frequency of 12 kHz, a stopband frequency of 8 kHz, a passband ripple of 0.1 dB, and a stopband attenuation of 80 dB.

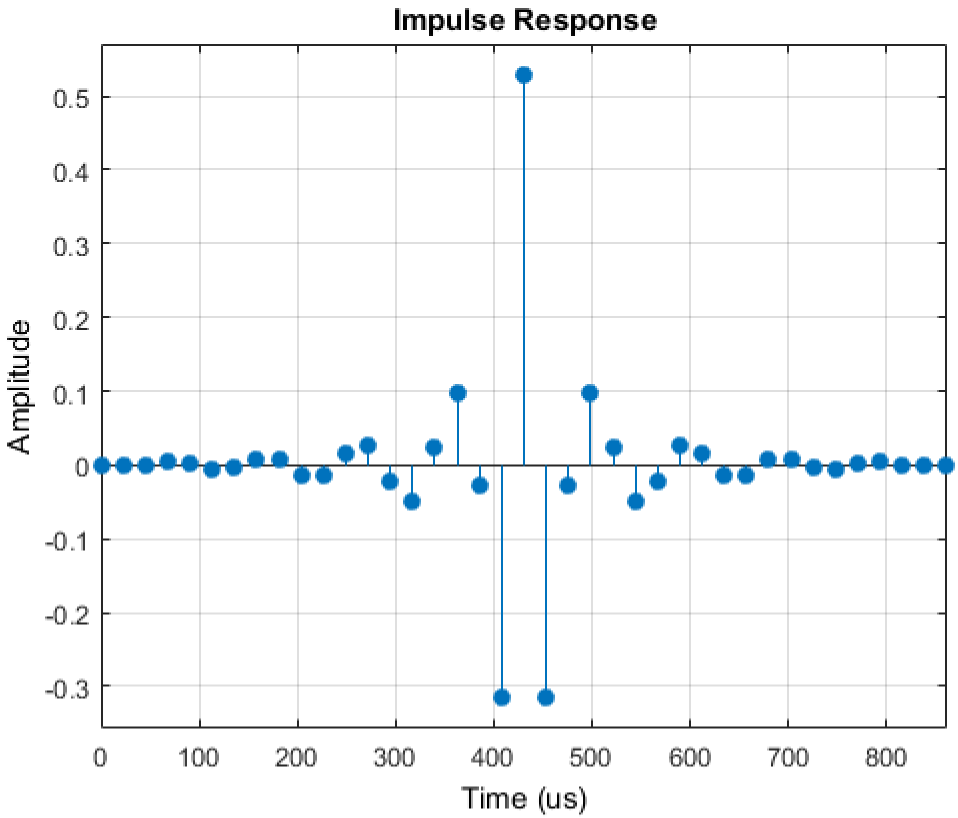
```
Fs = 44.1e3;
filtertype = 'FIR';
Fpass = 12e3;
Fstop = 8e3;
Rp = 0.1;
Astop = 80;
FIRHPF = dsp.HighpassFilter('SampleRate',Fs,...
                             'FilterType',filtertype,...
                             'PassbandFrequency',Fpass,...
                             'StopbandFrequency',Fstop,...
                             'PassbandRipple',Rp,...
                             'StopbandAttenuation',Astop);
```

Design a minimum order IIR highpass filter with the same properties as the FIR highpass filter. Use `clone` to create a system object with the same properties as the FIR Highpass filter. Change the `FilterType` property of the cloned filter to `IIR`.

```
IIRHPF = clone(FIRHPF);
IIRHPF.FilterType = 'IIR';
```

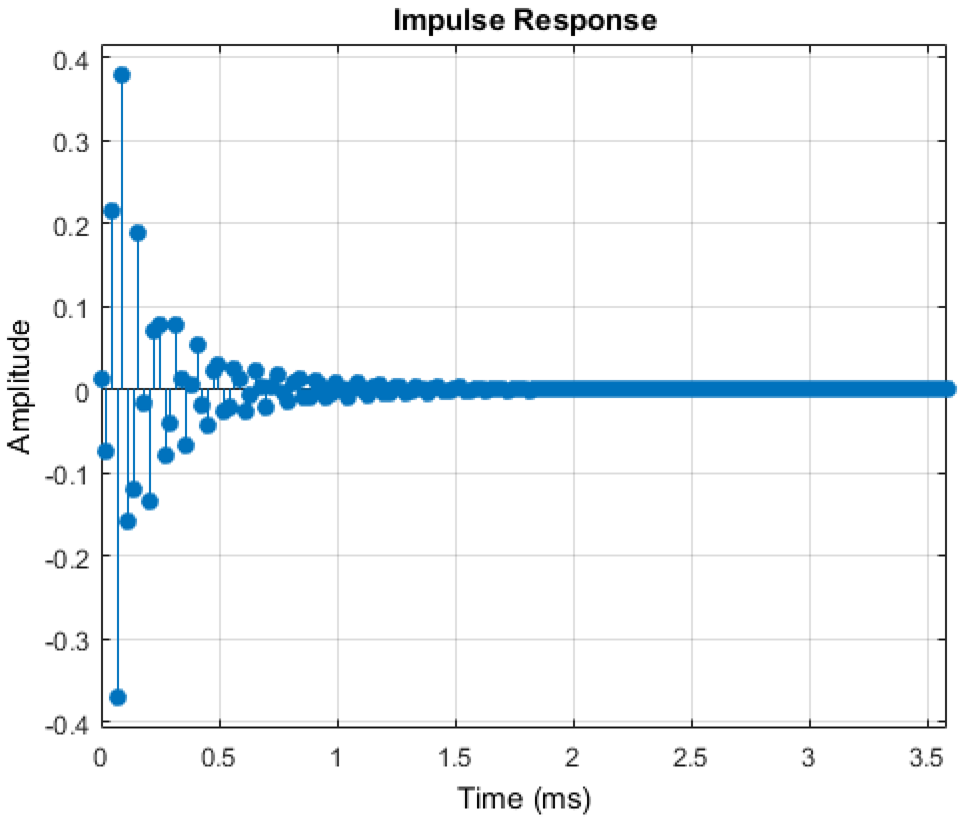
Plot the impulse response of the FIR highpass filter. The zeroth order coefficient is delayed by 19 samples, which is equal to the group delay of the filter. The FIR highpass filter is a causal FIR filter

```
fvtool(FIRHPF,'Analysis','impulse')
```



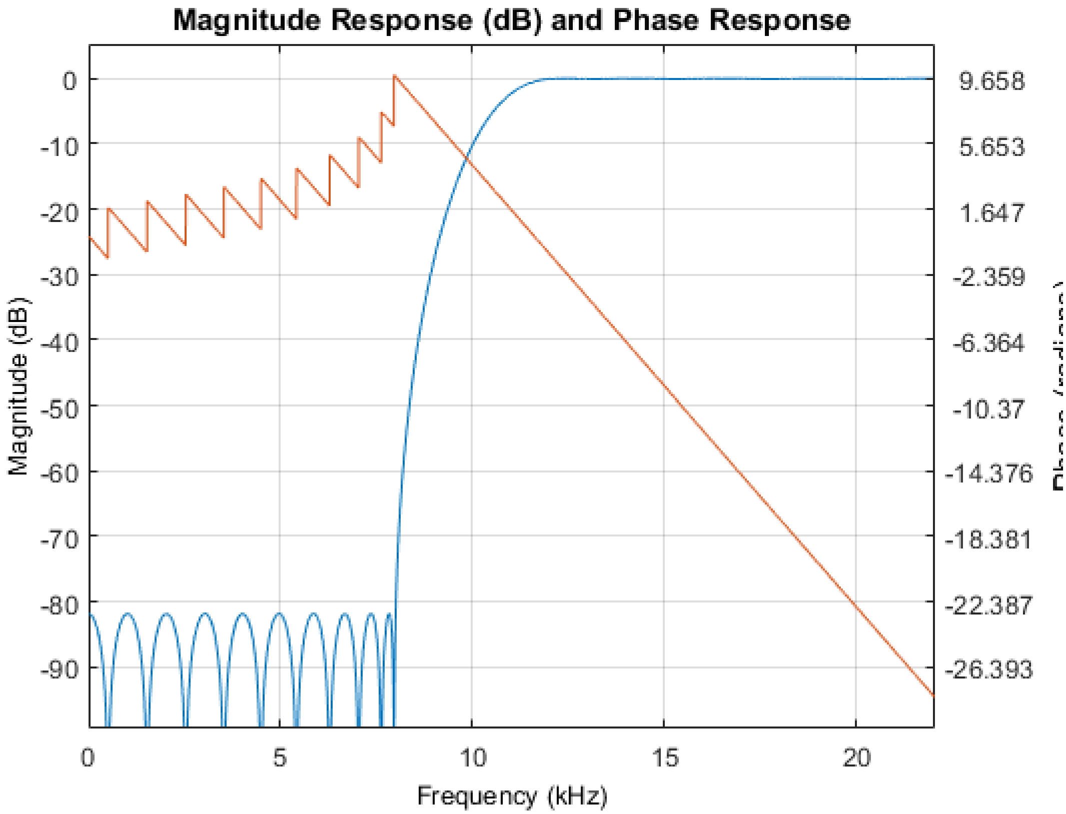
Plot the impulse response of the IIR highpass filter.

```
fvtool(IIRHPF,'Analysis','impulse')
```



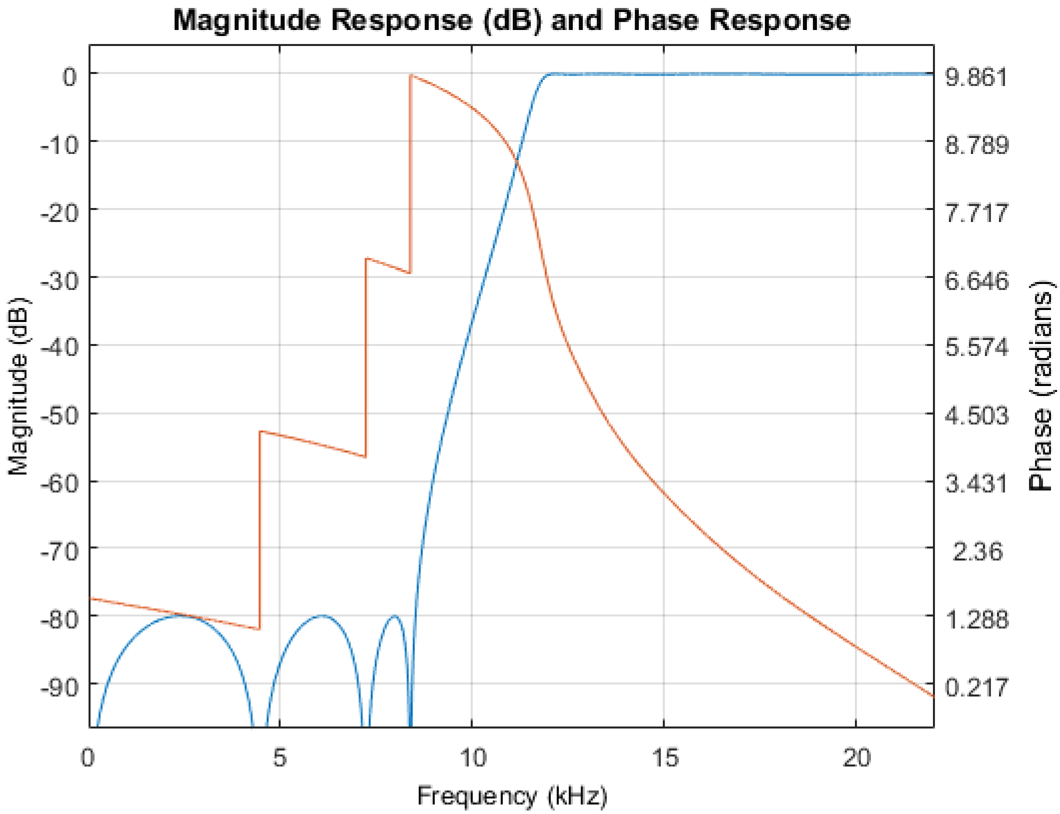
Plot the magnitude and phase response of the FIR highpass filter.

```
fvtool(FIRHPF,'Analysis','freq')
```



Plot the magnitude and phase response of the IIR highpass filter.

```
fvtool(IIRHPF,'Analysis','freq')
```



Calculate the cost of implementing the FIR highpass filter.

```
cost(FIRHPF)
```

```
ans = 

  struct with fields:

                NumCoefficients: 39
                      NumStates: 38
    MultiplicationsPerInputSample: 39
          AdditionsPerInputSample: 38
```

Calculate the cost of implementing the IIR highpass filter. The IIR filter is more efficient to implement than its FIR counterpart.

```
cost(IIRHPF)
```

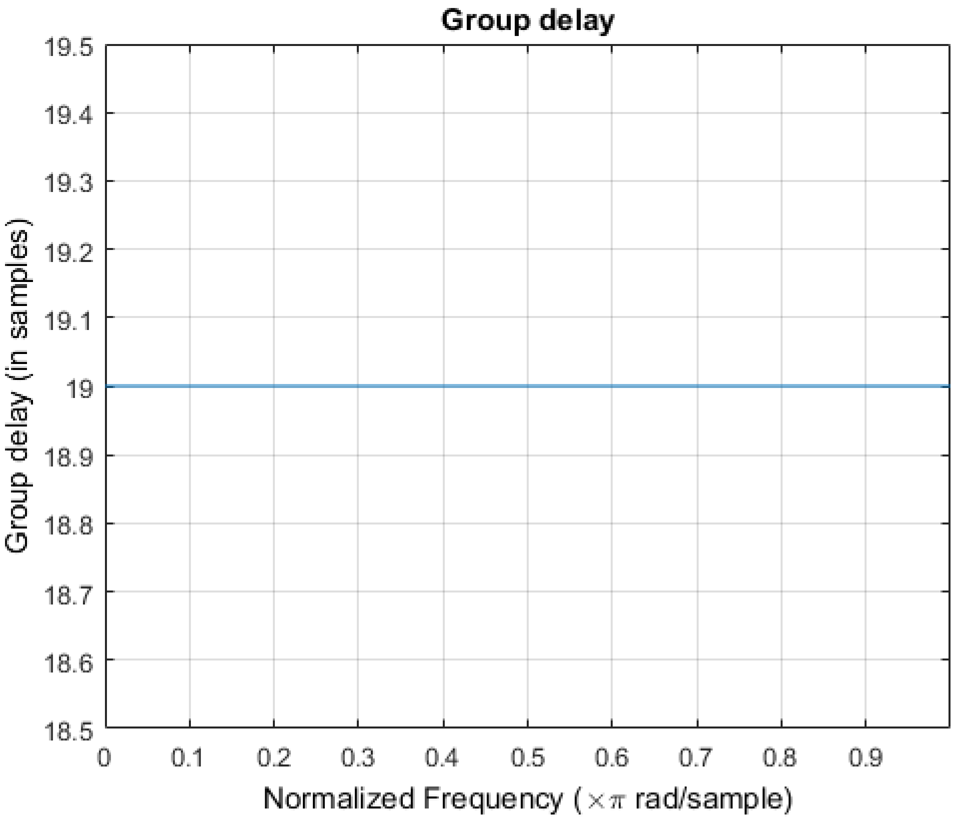
```
ans = 

  struct with fields:

                  NumCoefficients: 18
                        NumStates: 14
    MultiplicationsPerInputSample: 18
          AdditionsPerInputSample: 14
```

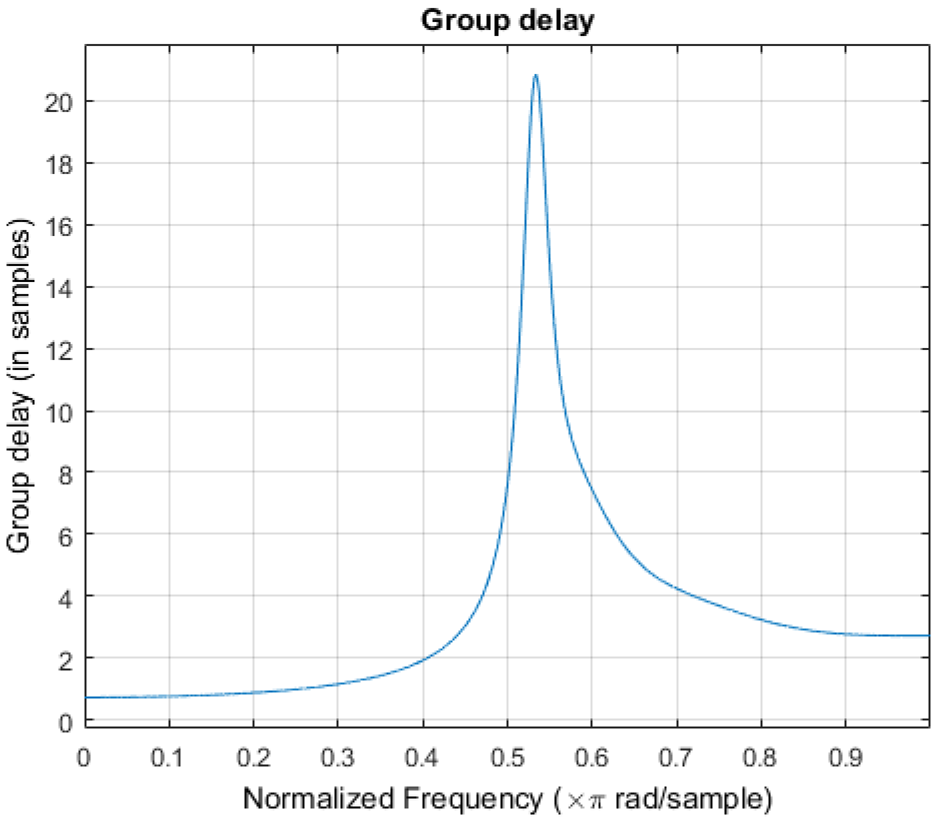
Calculate the group delay of the FIR highpass filter.

```
grpdelay(FIRHPF)
```



Calculate the group delay of the IIR highpass filter. The FIR filter has a constant group delay (linear phase) while its IIR counterpart does not.

```
grpdelay(IIRHPF)
```



Filter White Gaussian Noise with an IIR Highpass filter

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

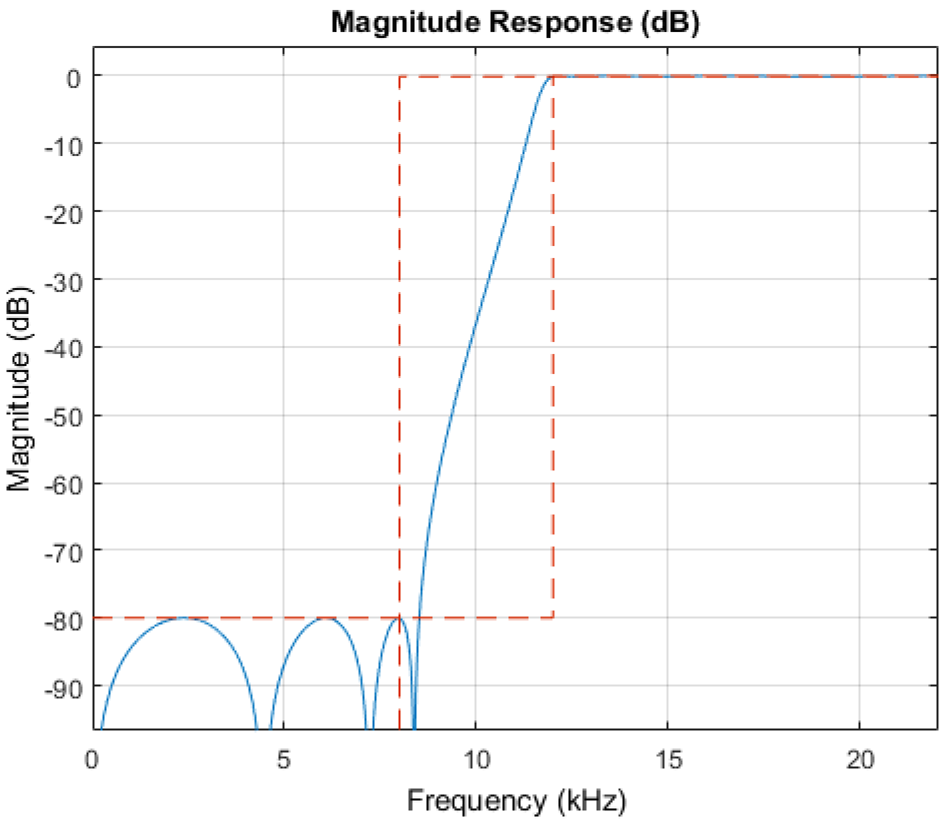
Set up the IIR highpass filter. The sampling rate of the white Gaussian noise is 44,100 Hz. The passband frequency of the filter is 12 kHz, the stopband frequency is 8 kHz, the passband ripple is 0.1 dB, and the stopband attenuation is 80 dB.

```
Fs = 44.1e3;
filtertype = 'IIR';
Fpass = 12e3;
Fstop = 8e3;
```

```
Rp = 0.1;
Astop = 80;
hpf = dsp.HighpassFilter('SampleRate',Fs,...
                             'FilterType',filtertype,...
                             'PassbandFrequency',Fpass,...
                             'StopbandFrequency',Fstop,...
                             'PassbandRipple',Rp,...
                             'StopbandAttenuation',Astop);
```

View the magnitude response of the highpass filter.

```
fvtool(hpf)
```

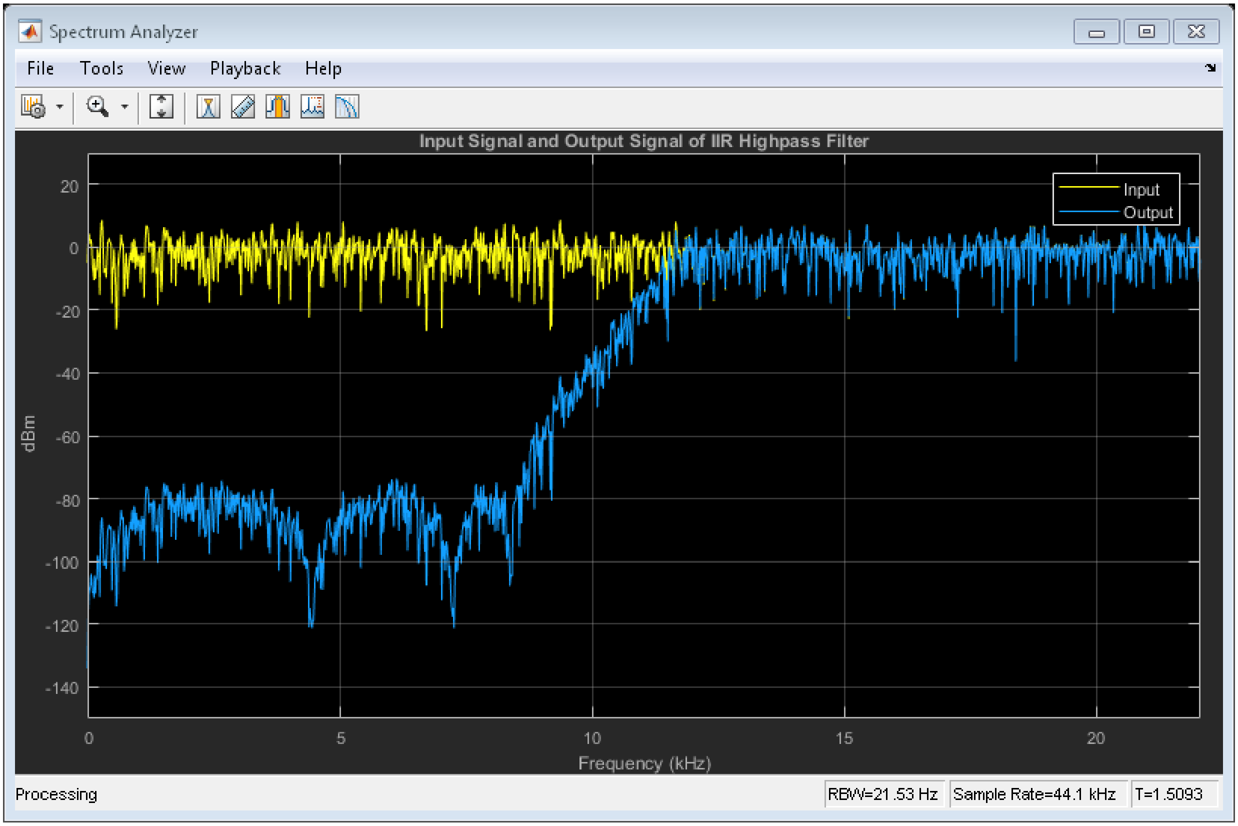


Create a spectrum analyzer object.

```
sa = dsp.SpectrumAnalyzer('SampleRate',44.1e3,...
    'PlotAsTwoSidedSpectrum',false,'ShowLegend',true,'YLimits',...
           [-150 30],...
           'Title',...
           'Input Signal and Output Signal of IIR Highpass Filter');
sa.ChannelNames = {'Input','Output'};
```

Filter the white Gaussian noisy input signal. View the input and output signals using the spectrum analyzer.

```
for k = 1:100
    Input = randn(1024,1);
    Output = hpf(Input);
    sa([Input,Output]);
end
```



Supported Data Types

Argument	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point • Fixed point
Output	• Double-precision floating point • Single-precision floating point • Fixed point

Algorithms

FIR Highpass Filter

When the `FilterType` property is set to `'FIR'`, the `dsp.HighpassFilter` object acts as a FIR highpass filter. In this configuration, `dsp.HighpassFilter` is an alternative to using `firceqrip` and `firgr` with `dsp.FIRFilter`. This object condenses the two-step process into one. For the minimum order design, the object uses generalized Remez FIR filter design algorithm. For the specified order design, the object uses constrained equiripple FIR filter design algorithm. The designed filter is then implemented as a linear phase Type-1 filter with a `Direct form` structure. You can use dsp.HighpassFilter.measure to verify that the design meets the prescribed specifications.

IIR Highpass Filter

When the `FilterType` property is set to `'IIR'`, the `dsp.HighpassFilter` object acts as an IIR highpass filter. In this configuration, this object uses the elliptic design method to compute the SOS and scale values required to meet the filter design specifications. The object uses the SOS and scale values to set up a `Direct form I` biquadratic IIR filter, which forms the basis of the IIR version of the `dsp.HighpassFilter` System object. You can use dsp.HighpassFilter.measure to verify that the design meets the prescribed specifications.

dsp.LowpassFilter

Introduced in R2015a

measure

System object: dsp.HighpassFilter
Package: dsp

Measure frequency response characteristics of `dsp.HighpassFilter` System object.

Syntax

```
HPFMeas = measure(HPF)
```

Description

`HPFMeas = measure(HPF)` measures the frequency response characteristics of the `dsp.HighpassFilter` System object, `HPF`.

Input Arguments

`HPF` — FIR or IIR highpass filter

`HighpassFilter` System object

FIR or IIR highpass filter, specified as a `HighpassFilter` System object.

Output Arguments

`HPFMeas` — Measurements of frequency response characteristics of the highpass filter

`HighpassFilter` System object

Measurements of frequency response characteristics of the highpass filter, returned as an `fdesign.highpassmeas` object.

Examples

Measure Frequency Response Characteristics of Highpass Filter

Measure the frequency response characteristics of a highpass filter. Create a `dsp.HighpassFilter` System object with default properties. Measure the frequency response characteristics of the filter.

```
HPF = dsp.HighpassFilter
HPFMeas = measure(HPF)
```

```
HPF =

  dsp.HighpassFilter with properties:

               FilterType: 'FIR'
    DesignForMinimumOrder: true
        StopbandFrequency: 8000
        PassbandFrequency: 12000
      StopbandAttenuation: 80
           PassbandRipple: 0.1000
               SampleRate: 44100

  Use get to show all properties

HPFMeas =

Sample Rate      : 44.1 kHz
Stopband Edge    : 8 kHz
6-dB Point       : 10.418 kHz
3-dB Point       : 10.8594 kHz
Passband Edge    : 12 kHz
Stopband Atten.  : 81.8558 dB
Passband Ripple  : 0.08066 dB
Transition Width : 4 kHz
```

Introduced in R2015a

reset

System object: dsp.HighpassFilter
Package: dsp

Reset internal states of highpass filter

Syntax

`reset(HPF)`

Description

`reset(HPF)` resets the filter states of the highpass filter, `HPF`, to their initial values. The initial filter state values correspond to the initial conditions for the difference equation defining the filter. After the `step` method applies the highpass filter to nonzero input data, the filter might have nonzero states. If you Invoke the `step` method again without first invoking the `reset` method, the object might produce different outputs for an identical input.

Input Arguments

`HPF` — FIR or IIR highpass filter

`HighpassFilter` System object

FIR or IIR highpass filter, specified as a `HighpassFilter` System object.

Examples

Reset a Highpass Filter

Create a highpass filter with default properties.

```
HPF = dsp.HighpassFilter;
```

Create a two-channel random signal. Apply the `step` method twice on the signal.

```
x = randn(10,2);

y1 = step(HPF,x);
y2 = step(HPF,x);

no = all(y2==y1)

no =

  1×2 logical array

   0   0
```

The output is different because the internal states of HPF have changed. Reset the highpass filter and apply step again. Verify that the output is unchanged.

```
reset(HPF)

y3 = step(HPF,x);

yes = all(y3==y1)

yes =

  1×2 logical array

   1   1
```

step

System object: dsp.HighpassFilter
Package: dsp

Filter input using FIR or IIR highpass filter

Syntax

`Y = step(HPF,X)`

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(HPF,X)` filters the real or complex input signal, `X`, using the highpass filter, `HPF`. `Y` is a highpass-filtered version of `X`. The input `X` must be a column vector or matrix. If `X` is a matrix, each column is treated as an independent channel. `X` can be a floating point or a fixed-point input.

Input Arguments

`HPF` — FIR or IIR highpass filter

`HighpassFilter` System object

FIR or IIR highpass filter, specified as a `HighpassFilter` System object.

`X` — Input signal

vector | matrix

Input signal, specified as a vector or matrix with floating point or fixed-point precision. The row length of `X` is the frame size, that is, channel length. Each column of `X` is treated as a separate channel. The column length of `X` is the number of channels.

Output Arguments

Y — Highpass-filtered signal

vector | matrix

Highpass-filtered signal, returned as a vector or matrix of the same size, data type, and complexity as the input signal, X.

Examples

Filter White Gaussian Noise Signal With a Highpass Filter

Create a highpass filter with default properties.

```
HPF = dsp.HighpassFilter;
```

Create a spectrum analyzer object.

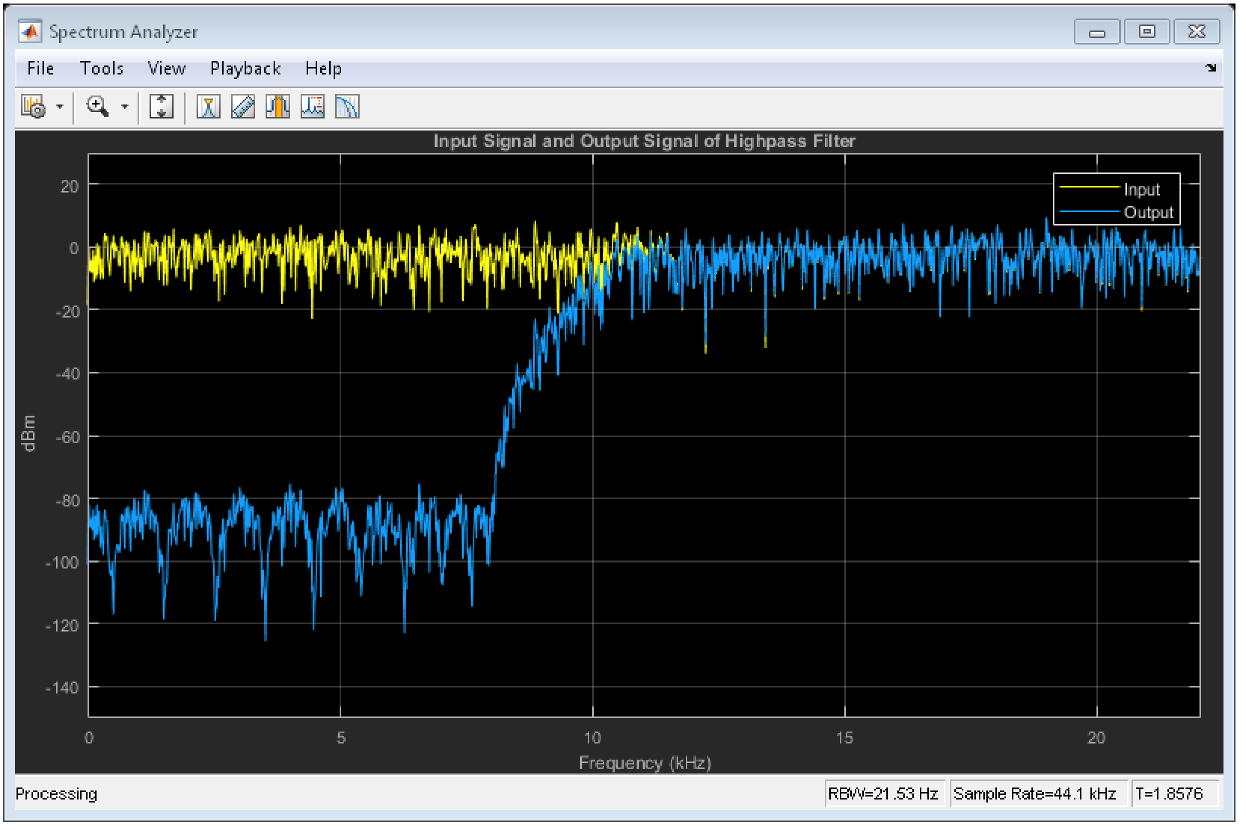
```
hSA = dsp.SpectrumAnalyzer('SampleRate',44.1e3,...
    'PlotAsTwoSidedSpectrum',false,'ShowLegend',true,'YLimits',...
           [-150 30],...
           'Title',...
           'Input Signal and Output Signal of Highpass Filter');
hSA.ChannelNames = {'Input','Output'};
```

Implement `step` on `HPF` to filter the white Gaussian noisy input signal. View the input and output signals using the spectrum analyzer.

```
for k = 1:100
    Input = randn(1024,1);

    Output = step(HPF,Input);

    step(hSA,[Input,Output]);
end
```



Introduced in R2015a

dsp.Histogram System object

Package: dsp

Histogram of input or sequence of inputs

Description

The `Histogram` object generates a histogram for an input or a sequence of inputs.

To generate a histogram for an input or a sequence of inputs:

1. Define and set up your histogram object. See "Construction" on page 4-968.
2. Call step to generate the histogram for an input according to the properties of `dsp.Histogram`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`hist = dsp.Histogram` returns a histogram object, `hist`, that computes the frequency distribution of the elements in each input matrix.

`hist = dsp.Histogram('`*`PropertyName`*`',`*`PropertyValue`*`, ...)` returns a histogram object, `hist`, with each specified property set to the specified value.

`hist =`
`dsp.Histogram(`*`MIN`*`,`*`MAX`*`,`*`NUMBINS`*`,'`*`PropertyName`*`',`*`PropertyValue`*`,...)` returns a histogram object, `hist`, with the `LowerLimit` property set to *`MIN`*, `UpperLimit` property set to *`MAX`*, `NumBins` property set to *`NUMBINS`* and other specified properties set to the specified values.

Properties

LowerLimit

Lower boundary

Specify the lower boundary of the lowest-valued bin as a real-valued scalar. `NaN` and `Inf` are not valid values for this property. The default is `0`. This property is tunable.

UpperLimit

Upper boundary

Specify the upper boundary of the highest-valued bin as a real-valued scalar. `NaN` and `Inf` are not valid values for this property. The default is `10`. This property is tunable.

NumBins

Number of bins in histogram

Specify the number of bins in the histogram. The default is `11`.

Dimension

Specify how the histogram calculation is performed over the data as one of `| All | Column |`. The default is `Column`.

Normalize

Enable output vector normalization

Specify whether the histogram object normalizes the output vector, v, so that $sum(v) = 1$. When you set this property to `true`, the output vector is normalized. When you set it to `false`, the object supports fixed-point operations and does not use this property for normalization. The default is `false`.

RunningHistogram

Enable calculation over successive `step` method calls

Set this property to `true` to enable running histogram calculations for the input elements over successive calls to the `step` method. Set this property to `false` to compute a histogram for the current input. The default is `false`.

ResetInputPort

Enable resetting in running histogram mode

Set this property to true to enable resetting the running histogram. When you set the property to true, specify a reset input to the step method that resets the running histogram. This property applies when you set the RunningHistogram on page 4-969 property to true. When this property is false, the histogram object does not reset. The default is false.

ResetCondition

Reset condition for running histogram mode

Specify the event that resets the running histogram as one of | Rising edge | Falling edge | Either edge | Non-zero |. This property applies when you set the ResetInputPort property to true. The default is Non-zero

Fixed-Point Properties

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as one of | Ceiling | Convergent | Floor | Nearest | Round | Simplest | Zero |. The default is Floor.

OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as one of | Wrap | Saturate |. The default is Wrap.

ProductDataType

Product word and fraction lengths

Specify the product fixed-point data type as one of | Same as input | Custom |. The default is Same as input.

CustomProductDataType

Custom product word and fraction lengths

Specify the product fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `ProductDataType on page 4-970` property to `Custom`. The default is `numerictype([],32,30)`.

`AccumulatorDataType`

Accumulator word and fraction lengths

Specify the accumulator fixed-point data type as one of `|` `Same as product` `|` `Same as input` `|` `Custom` `|`. The default is `Same as input`.

`CustomAccumulatorDataType`

Custom accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `AccumulatorDataType on page 4-971` property to `Custom`. The default is `numerictype([],32,30)`.

Methods

reset	Reset histogram bin values to zero
step	Histogram for input data

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Compute Histogram of a Sequence

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

Compute a histogram with four bins, for possible input values 1 through 4.

```
hist = dsp.Histogram(1,4,4);
y = hist([1 2 2 3 3 3 4 4 4 4]');
```

y is equal to [1; 2; 3; 4] - one ones, two twos, etc.

Algorithms

This object implements the algorithm, inputs, and outputs described on the `Histogram` block reference page. The object properties correspond to the block parameters, except:

- The **Reset port** block parameter corresponds to both the `ResetCondition` and the `ResetInputPort` object properties.
- The **Find histogram over** block parameter corresponds to the Dimension on page 4-969 property of the object.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- This object has no tunable properties for code generation.
- See "System Objects in MATLAB Code Generation" (MATLAB Coder).

See Also

dsp.Minimum | dsp.Maximum | dsp.Mean

Introduced in R2012a

reset

System object: dsp.Histogram
Package: dsp

Reset histogram bin values to zero

Syntax

```
reset(hist)
```

Description

`reset(hist)` sets the `Histogram` object bin values to zero when you set the `RunningHistogram` property to `true`.

step

System object: dsp.Histogram
Package: dsp

Histogram for input data

Syntax

```
Y = step(hist,X)
Y = step(hist,X,R)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(hist,X)` returns a histogram `Y` for the input data `X` . When the `RunningHistogram` property is `true`, `Y` corresponds to the histogram of the input elements over successive calls to the `step` method.

`Y = step(hist,X,R)` resets the histogram state based on the value of `R` and the object's `ResetCondition` property. You can reset the histogram state only when the `RunningHistogram` and the `ResetInputPort` properties are `true`.

Note: `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

dsp.IDCT System object

Package: dsp

Inverse discrete cosine transform (IDCT)

Description

The `IDCT` object computes the inverse discrete cosine transform (IDCT) of an input.

To compute the IDCT of an input:

1. Define and set up your IDCT object. See "Construction" on page 4-975.
2. Call step to compute the IDCT of an input according to the properties of `dsp.IDCT`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`idct = dsp.IDCT` returns a inverse discrete cosine transform (IDCT) object, `idct`. This object computes the IDCT of a real or complex input signal using the `Table lookup` method.

`idct = dsp.IDCT('PropertyName',PropertyValue,...)` returns an inverse discrete cosine transform (IDCT) object, `idct`, with each property set to the specified value.

Properties

`SineComputation`

Method to compute sines and cosines

Specify how the IDCT object computes the trigonometric function values as `Trigonometric function` or `Table lookup`. You must set this property to `Table lookup` for fixed-point inputs. The default is `Table lookup`.

Fixed-Point Properties

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as one of `Ceiling`, `Convergent`, `Floor` , `Nearest`, `Round`, `Simplest`, or `Zero`. This property applies when you set the `SineComputation` on page 4-975 property to `Table lookup`.

OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as one of `Wrap` or `Saturate`. This property applies when you set the `SineComputation` on page 4-975 property to `Table lookup`.

SineTableDataType

Sine table word-length designation

Specify the sine table fixed-point data type as one of `Same word length as input` or `Custom`. This property applies when you set the `SineComputation` on page 4-975 property to `Table lookup`.

CustomSineTableDataType

Sine table word length

Specify the sine table fixed-point type as a signed, unscaled `numerictype` object. This property applies when you set the `SineComputation` on page 4-975 property to `Table lookup` and the `SineTableDataType` on page 4-976 property to `Custom`. The default is `numerictype(true,16)`.

ProductDataType

Product word and fraction lengths

Specify the product fixed-point data type as one of `Full precision`, `Same as input`, `Custom`. This property applies when you set the `SineComputation` on page 4-975 property to `Table lookup`.

CustomProductDataType

Product word and fraction lengths

Specify the product fixed-point type as a signed, scaled `numerictype` object. This property applies when you set the `SineComputation` on page 4-975 property to `Table lookup` and the `ProductDataType` on page 4-976 property to `Custom`. The default is `numerictype(true,32,30)`.

AccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point data type as one of `Full precision`, `Same as input`, `Same as product`, or `Custom`. This property applies when you set the `SineComputation` on page 4-975 property to `Table lookup`.

CustomAccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a signed, scaled `numerictype` object. This property applies when you set the `SineComputation` on page 4-975 property to `Table lookup` and the `AccumulatorDataType` on page 4-977 property to `Custom`. The default is `numerictype(true,32,30)`.

OutputDataType

Output word and fraction lengths

Specify the output fixed-point data type as one of `Full precision` , `Same as input`, `Custom`. This property applies when you set the `SineComputation` on page 4-975 property to `Table lookup`. The default is `Full precision`.

CustomOutputDataType

Output word and fraction lengths

Specify the output fixed-point type as a signed, scaled `numerictype` object. This property applies when you set the `SineComputation` on page 4-975 property to `Table lookup` and the `OutputDataType` on page 4-977 property to `Custom`. The default is`numerictype(true,16,15)`.

Methods

step	Inverse discrete cosine transform (IDCT) of input

Common to All System Objects	
clone	Create System object with same property values
getNumInpu	Expected number of inputs to a System object
getNumOutp	Expected number of outputs of a System object
isLocked	Check locked states of a System object (logical)
release	Allow System object property value changes

Examples

Analyze the Energy Content in a Sequence

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

Use DCT to analyze the energy content in a sequence:

```
x = (1:128).' + 50*cos((1:128).'*2*pi/40);
dct = dsp.DCT;
X = dct(x);
```

Set the DCT coefficients which represent less than 0.1% of the total energy to 0 and reconstruct the sequence using IDCT.

dsp.DCT | dsp.IFFT. | dsp.FFT

Introduced in R2012a

step

System object: dsp.IDCT
Package: dsp

Inverse discrete cosine transform (IDCT) of input

Syntax

```
Y = step(idct,X)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(idct,X)` computes the inverse discrete cosine transform, `Y` , of input `X`.

Note: `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.IFFT System object

Package: dsp

Inverse discrete Fourier transform (IDFFT)

Description

The `IFFT` object computes the inverse discrete Fourier transform (IDFFT) of the input. The object uses one or more of the following fast Fourier transform (FFT) algorithms depending on the complexity of the input and whether the output is in linear or bit-reversed order:

- Double-signal algorithm
- Half-length algorithm
- Radix-2 decimation-in-time (DIT) algorithm
- Radix-2 decimation-in-frequency (DIF) algorithm
- An algorithm chosen by FFTW [1], [2]

To compute the IFFT of the input:

1. Define and set up your IFFT object. See "Construction" on page 4-982.
2. Call step to compute the IFFT of the input according to the properties of `dsp.IFFT`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`ift = dsp.IFFT` returns an `IFFT` object, `ift`, that computes the IDFT of a column vector or N-D array. For column vectors or N-D arrays, the `IFFT` object computes the IDFT along the first dimension of the array. If the input is a row vector, the `IFFT` object computes a row of single-sample IDFTs and issues a warning.

`ift = dsp.IFFT('PropertyName',PropertyValue, ...)` returns an `IFFT` object, `ift`, with each property set to the specified value.

Properties

`FFTImplementation`

FFT implementation

Specify the implementation used for the FFT as one of `Auto | Radix-2 | FFTW`. When you set this property to `Radix-2`, the FFT length must be a power of two.

`BitReversedInput`

Enable bit-reversed order interpretation of input elements

Set this property to`true` if the order of Fourier transformed input elements to the `IFFT` object are in bit-reversed order. This property applies only when the `FFTLengthSource` on page 4-983 property is `Auto`. The default is `false`, which denotes linear ordering.

`ConjugateSymmetricInput`

Enable conjugate symmetric interpretation of input

Set this property to `true` if the input is conjugate symmetric to yield real-valued outputs. The discrete Fourier transform of a real valued sequence is conjugate symmetric, and setting this property to `true` optimizes the IDFT computation method. Setting this property to `false` for conjugate symmetric inputs may result in complex output values with nonzero imaginary parts. This occurs due to rounding errors. Setting this property to `true` for nonconjugate symmetric inputs results in invalid outputs. This property applies only when the`FFTLengthSource` on page 4-983 property is `Auto`. The default is `false`.

`Normalize`

Enable dividing output by FFT length

Specify whether to divide the IFFT output by the FFT length. The default is `true` and each element of the output is divided by the FFT length.

`FFTLengthSource`

Source of FFT length

Specify how to determine the FFT length as `Auto` or `Property`. When you set this property to `Auto`, the FFT length equals the number of rows of the input signal. This property applies only when both the `BitReversedInput` on page 4-983 and `ConjugateSymmetricInput` on page 4-983 properties are `false`. The default is `Auto`.

FFTLength

FFT length

Specify the FFT length as a numeric scalar. This property applies when you set the `BitReversedInput` on page 4-983 and `ConjugateSymmetricInput` on page 4-983 properties to `false`, and the `FFTLengthSource` on page 4-983 property to `Property`. The default is `64`.

This property must be a power of two when the input is a fixed-point data type, or when you set the `FFTImplementation` on page 4-983 property to `Radix-2`.

When you set the `FFT implementation` property to `Radix-2`, or when you set the `BitReversedOutput` property to `true`, this value must be a power of two.

WrapInput

Boolean value of wrapping or truncating input

Wrap input data when `FFTLength` is shorter than input length. If this property is set to true, modulo-length data wrapping occurs before the FFT operation, given `FFTLength` is shorter than the input length. If this property is set to false, truncation of the input data to the `FFTLength` occurs before the FFT operation. The default is `true`.

Fixed-Point Properties

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as `Ceiling`, `Convergent`, `Floor`, `Nearest`, `Round`, `Simplest`, or `Zero`. The default is `Floor`.

OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as `Wrap` or `Saturate`. The default is `Wrap`.

SineTableDataType

Sine table word and fraction lengths

Specify the sine table data type as `Same word length as input` or `Custom`. The default is `Same word length as input`.

CustomSineTableDataType

Sine table word and fraction lengths

Specify the sine table fixed-point type as an unscaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `SineTableDataType` on page 4-985 property to `Custom`. The default is `numerictype([],16)`.

ProductDataType

Product word and fraction lengths

Specify the product data type as `Full precision`, `Same as input`, or `Custom`. The default is `Full precision`.

CustomProductDataType

Product word and fraction lengths

Specify the product fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `ProductDataType` on page 4-985 property to `Custom`. The default is `numerictype([],32,30)`.

AccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator data type as `Full precision`, `Same as input`, `Same as product`, or `Custom`. The default is `Full precision`.

CustomAccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `AccumulatorDataType` on page 4-985 property to `Custom`. The default is `numerictype([],32,30)`.

`OutputDataType`

Output word and fraction lengths

Specify the output data type as `Full precision`, `Same as input`, or `Custom`. The default is `Full precision`.

`CustomOutputDataType`

Output word and fraction lengths

Specify the output fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `OutputDataType` on page 4-986 property to `Custom`. The default is `numerictype([],16,15)`.

Methods

step	Inverse discrete Fourier transform of input

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Inverse Discrete Fourier Transform of a Signal

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

This example analyzes the energy content in a sequence.

```
Fs = 40; L = 128;
t = (0:L-1)'/Fs;
x = sin(2*pi*10*t) + 0.75*cos(2*pi*15*t);
y = x + .5*randn(size(x)); % noisy signal
ft = dsp.FFT;
ift = dsp.IFFT('ConjugateSymmetricInput', true);
X = ft(x);
[XX, ind] = sort(abs(X),1,'descend');
XXn = sqrt(cumsum(XX.^2))/norm(XX);
ii = find(XXn > 0.999, 1);
disp('Number of FFT coefficients that represent 99.9% ')
disp(['of the total energy in the sequence: ', num2str(ii)]);
XXt = zeros(128,1);
XXt(ind(1:ii)) = X(ind(1:ii));
xt = ift(XXt);
```

```
Number of FFT coefficients that represent 99.9%
of the total energy in the sequence: 4
```

Verify that the reconstructed signal matches the original signal.

```
norm(x-xt)
```

```
ans =

   1.2012e-13
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the `IFFT` block reference page. The object properties correspond to the block parameters, except: **Output sampling mode** parameter is not supported by `dsp.IFFT`.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- See “System Objects in MATLAB Code Generation” (MATLAB Coder).
- When the following conditions apply, the executable generated from this System object relies on prebuilt dynamic library files (`.dll` files) included with MATLAB:
  - `FFTImplementation` is set to `'FFTW'`.
  - `FFTImplementation` is set to `'Auto'`, `FFTLengthSource` is set to `'Property'`, and `FFTLength` is not a power of two.

  Use the `packNGo` function to package the code generated from this System object and all the relevant files in a compressed zip file. Using this zip file, you can relocate, unpack, and rebuild your project in another development environment where MATLAB is not installed. For more details, see “How To Run a Generated Executable Outside MATLAB”.
- When the FFT length is a power of two, you can generate standalone C and C++ code from this System object.

step

System object: dsp.IFFT
Package: dsp

Inverse discrete Fourier transform of input

Syntax

```
Y = step(ift,X)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(ift,X)` computes the inverse discrete Fourier transform (IDFT) , `Y` , of the input `X` along the first dimension of `X`. When the `FFTLengthSource` property is `Auto`, the length of `X` along the first dimension must be a positive integer power of two. When the `FFTLengthSource` property is `'Property'`, the length of `X` along the first dimension can be any positive integer and the `FFTLength` property must be a positive integer power of two.

Note: `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.IIRFilter System object

Package: dsp

Infinite Impulse Response (IIR) filter

Description

The `IIRFilter` object filters each channel of the input using IIR filter implementations.

To filter each channel of the input:

1. Define and set up your IIR filter. See "Construction" on page 4-990.
2. Call step to filter each channel of the input according to the properties of `dsp.IIRFilter`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`iir = dsp.IIRFilter` returns an IIR filter System object, `iir`, which independently filters each channel of the input over successive calls to the `step` method. This System object uses a specified IIR filter implementation.

`iir = dsp.IIRFilter('`*`PropertyName`*`',`*`PropertyValue`*`, ...)` returns an IIR filter System object, `iir`, with each property set to the specified value.

Properties

`Structure`

Filter structure

Specify the filter structure.
You can specify the filter structure as one of | `Direct form I` | `Direct form I transposed` | `Direct form II` | `Direct form II transposed`. The default is `Direct form II transposed`. This property is nontunable.

Numerator

Filter numerator coefficients

Specify the numerator coefficients as a real or complex numeric row vector. The default is `[1 1]`. This property is tunable.

Denominator

Filter denominator coefficients

Specify the denominator coefficients as a real or complex numeric row vector. The default value of this property is `[1 0.1]`. This property is tunable.

InitialConditions

Initial conditions for the IIR filter

Specify the initial conditions of the filter states. This property is applicable when the structure is one of `Direct form II` | `Direct form II transposed`. The default value is `0`. The number of states equals the `max(N,M)-1`, where `N` and `M` are the number of poles and zeros respectively.

You can specify the initial conditions as a scalar, vector, or matrix. If you specify a scalar value, this System object initializes all delay elements in the filter to that value. You can also specify a vector whose length equals the number of delay elements in the filter. When you do so, each vector element specifies a unique initial condition for the corresponding delay element. The object applies the same vector of initial conditions to each channel of the input signal.

You can also specify a matrix with the same number of rows as the number of delay elements in the filter and one column for each channel of the input signal. In this case, each element specifies a unique initial condition for the corresponding delay element in the corresponding channel. This property is tunable.

NumeratorInitialConditions

Initial conditions on zeros side

Specify the initial conditions of the filter states on the side of the filter structure with the zeros. This property is applicable when the Structure property is one of `Direct form I | Direct form I transposed`. The default value of this property is `0`. The number of states equals the `max(N,M)-1`, where `N` and `M` are the number of poles and zeros respectively.

You can specify the initial conditions as a scalar, vector, or matrix. When you specify a scalar, the IIR filter initializes all delay elements on the zeros side in the filter to that value. You can specify a vector of length equal to the number of delay elements on the zeros side in the filter. When you do so, each vector element specifies a unique initial condition for the corresponding delay element on the zeros side.

You can also specify a matrix with the same number of rows as the number of delay elements on the zeros side in the filter, and one column for each channel of the input signal. In this case, each element specifies a unique initial condition for the corresponding delay element on the zeros side in the corresponding channel. This property is tunable.

DenominatorInitialConditions

Initial conditions on poles side

Specify the initial conditions of the filter states on the side of the filter structure with the poles. This property is applicable when the Structure property is one of `Direct form I | Direct form I transposed`. The default value of this property is `0`. The number of states equals the `max(N,M)-1`, where `N` and `M` are the number of poles and zeros respectively.

You can specify the initial conditions as a scalar, vector, or matrix. When you specify a scalar, the IIR filter initializes all delay elements on the poles side of the filter to that value. You can specify a vector of length equal to the number of delay elements on the poles side in the filter. When you do so, each vector element specifies a unique initial condition for the corresponding delay element on the poles side.

You can also specify a matrix with the same number of rows as the number of delay elements on the poles side in the filter, and one column for each channel of the input signal. In this case, each element specifies a unique initial condition for the corresponding delay element on the poles side in the corresponding channel. This property is tunable.

NumeratorCoefficientsDataType

Numerator coefficients word- and fraction-length designations

Specify the numerator coefficients fixed-point data type as one of `Same word length as input` | `Custom`. The default is `Same word length as input`. This property is nontunable.

`DenominatorCoefficientsDataType`

Denominator coefficients word- and fraction-length designations

Specify the denominator coefficients fixed-point data type as one of `Same word length as input` | `Custom`. The default is `Same word length as input`. This property is nontunable.

Fixed-Point Properties

`NumeratorProductDataType`

Product word- and fraction-length designations on zeros side

Specify the numerator product fixed-point data type as one of | `Full precision` | `Same as input` | `Custom` |. The default is `Full precision`. This property is nontunable.

`DenominatorProductDataType`

Product word- and fraction-length designations on poles side

Specify the denominator product fixed-point data type as one of | `Full precision` | `Same as input` | `Custom` |. The default is `Full precision`. This property is nontunable.

`NumeratorAccumulatorDataType`

Accumulator word- and fraction-length designations on zeros side

Specify the numerator accumulator fixed-point data type to one of | `Full precision` | `Same as input` | `Same as product` | `Custom` |. The default is `Full precision`. This property is nontunable.

`DenominatorAccumulatorDataType`

Accumulator word- and fraction-length designations on poles side

Specify the denominator accumulator fixed-point data type to one of | `Full precision` | `Same as input` | `Same as product` | `Custom` |. The default is `Full precision`. This property is nontunable.

OutputDataType

Output word- and fraction-length designations

Specify the output fixed-point data type as one of | `Full precision` | `Same as input` | `Custom` |. The default is `Same as input`. This property is nontunable.

StateDataType

State word- and fraction-length designations

Specify the state fixed-point data type as one of | `Same as input` | `Custom` |. This property does not apply to `Direct form I` filter structure. The default is `Same as input`. This property is nontunable.

MultiplicandDataType

Multiplicand word- and fraction-length designations

Specify the multiplicand fixed-point data type as one of | `Same as input` | `Custom` |. This property is applicable only when the `Structure` property is `Direct form I transposed`. The default is `Same as input`. This property is nontunable.

CustomNumeratorCoefficientsDataType

Numerator coefficients word- and fraction-lengths

Specify the numerator coefficients fixed-point type as an autosigned numerictype (Fixed-Point Designer) object. This property is applicable when the `NumeratorCoefficientsDataType` on page 4-992 property is `Custom`. The default value of this property is numerictype ([],16,15). This property is nontunable.

CustomDenominatorCoefficientsDataType

Denominator coefficients word- and fraction-lengths

Specify the denominator coefficients fixed-point type as an autosigned numerictype (Fixed-Point Designer) object. This property is applicable when the

`DenominatorCoefficientsDataType` on page 4-993 property is `Custom`. The default value of this property is numerictype([], 16, 15) . This property is nontunable.

CustomNumeratorProductDataType

Custom product word- and fraction-lengths on zeros side

Specify the numerator product fixed-point type as an autosigned scaled `numerictype` object. This property applies when you set the `NumeratorProductDataType` on page 4-993 property to `Custom`. The default is `numerictype ([],32,30)`. This property is nontunable.

CustomDenominatorProductDataType

Custom product word- and fraction-lengths on poles side

Specify the denominator product fixed-point type as an autosigned scaled `numerictype` object. This property applies when you set the `DenominatorProductDataType` on page 4-993 property to `Custom`. The default is `numerictype ([],32,30)`. This property is nontunable.

CustomNumeratorAccumulatorDataType

Custom accumulator word- and fraction-lengths on zeros side

Specify the numerator accumulator fixed-point type as an autosigned scaled `numerictype` object. This property applies when you set the `NumeratorAccumulatorDataType` on page 4-993 property to `Custom`. The default is `numerictype([],32,30)`. This property is nontunable.

CustomDenominatorAccumulatorDataType

Custom accumulator word- and fraction-lengths on poles side

Specify the denominator accumulator fixed-point type as an autosigned scaled `numerictype` object. This property applies when you set the `DenominatorAccumulatorDataType` on page 4-993 property to `Custom`. The default is `numerictype([],32,30)`. This property is nontunable.

CustomStateDataType

Custom state word- and fraction-lengths

Specify the state fixed-point type as an autosigned scaled `numerictype` object. This property applies when you set the `StateDataType` on page 4-994 property to `Custom`. The default is `numerictype([],16,15)`. This property is nontunable.

CustomOutputDataType

Custom output word- and fraction-lengths

Specify the output fixed-point type as an autosigned scaled `numerictype` object. This property applies when you set the `OutputDataType` on page 4-994 property to `Custom`. The default is `numerictype([],16,15)`. This property is nontunable.

CustomMultiplicandDataType

Custom multiplicand word- and fraction-lengths

Specify the multiplicand fixed-point type as an autosigned scaled `numerictype` object. This property applies when you set the `MultiplicandDataType` on page 4-994 property to `Custom`. The default is `numerictype([],16,15)`. This property is nontunable.

Methods

freqz	Frequency response
fvtool	Open filter visualization tool
impz	Impulse response
phasez	Unwrapped phase response
reset	Reset internal states of IIR filter
step	Filter input with IIR filter object

More "Analysis Methods for Filter System Objects" on page 3-2.

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object

Common to All System Objects

`release`	Allow System object property value changes

Examples

Filter a Noisy Signal Using the IIRFilter System object

This example shows how to filter a noisy signal with a `dsp.IIRFilter` System object™. View the magnitude response of the IIR filter. Use the `Spectrum Analyzer` to display the power spectrum of the output signal.

Initialization

```
x = randn(2048,1);
x = x-mean(x);
src = dsp.SignalSource;
src.Signal = x;
sink = dsp.SignalSink;

N = 10;
Fc = 0.4;
[b,a] = butter(N,Fc);
iir = dsp.IIRFilter('Numerator',b,'Denominator',a);

sa = dsp.SpectrumAnalyzer('SampleRate',8e3,...
    'PlotAsTwoSidedSpectrum',false,...
    'OverlapPercent', 80,'PowerUnits','dBW',...
    'YLimits', [-220 -10]);
```

Filter the Signal

```
while ~isDone(src)
  input = src();
  output = iir(input);
  sa(output)
  sink(output);
end

Result = sink.Buffer;
fvtool(iir,'Fs',8000)
```

Design an IIR Filter

This example shows the two ways of designing an IIR Filter

Design the filter using `fdesign` and `design`.

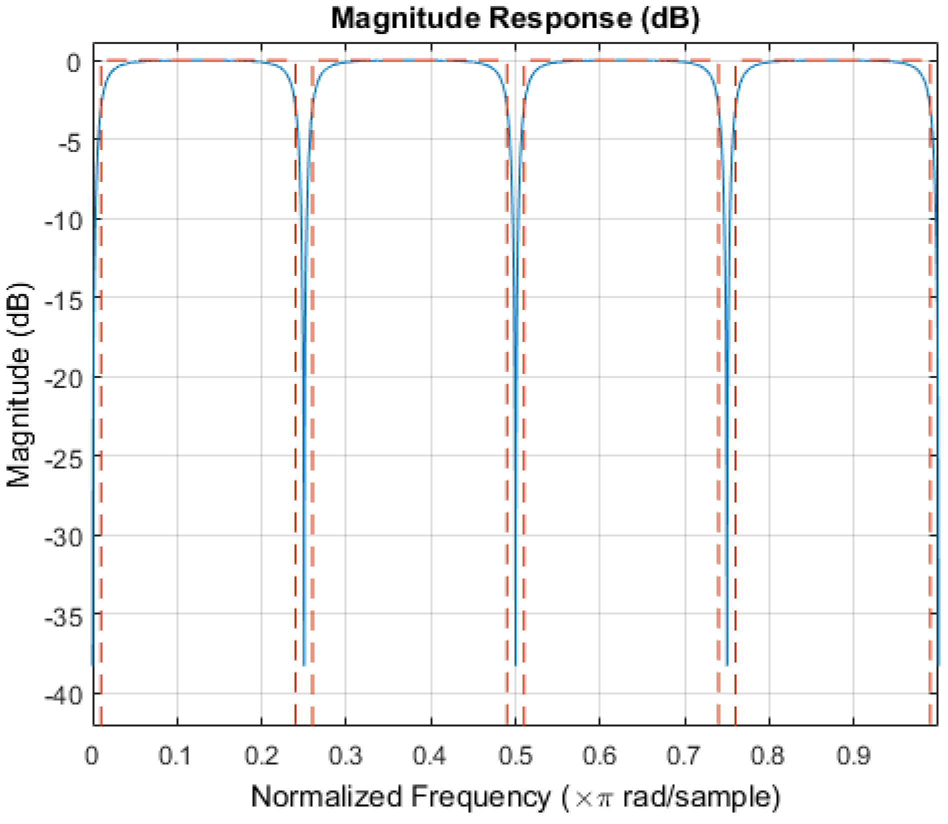
```
D = fdesign.comb('notch','N,BW',8,0.02);
iir = design(D,'systemobject',true)
fvtool(iir);
```

```
iir =

  dsp.IIRFilter with properties:
```

```
            Structure: 'Direct form II'
            Numerator: [0.8878 0 0 0 0 0 0 0 -0.8878]
          Denominator: [1 0 0 0 0 0 0 0 -0.7757]
    InitialConditions: 0

  Use get to show all properties
```



Design the filter using filter coefficients.

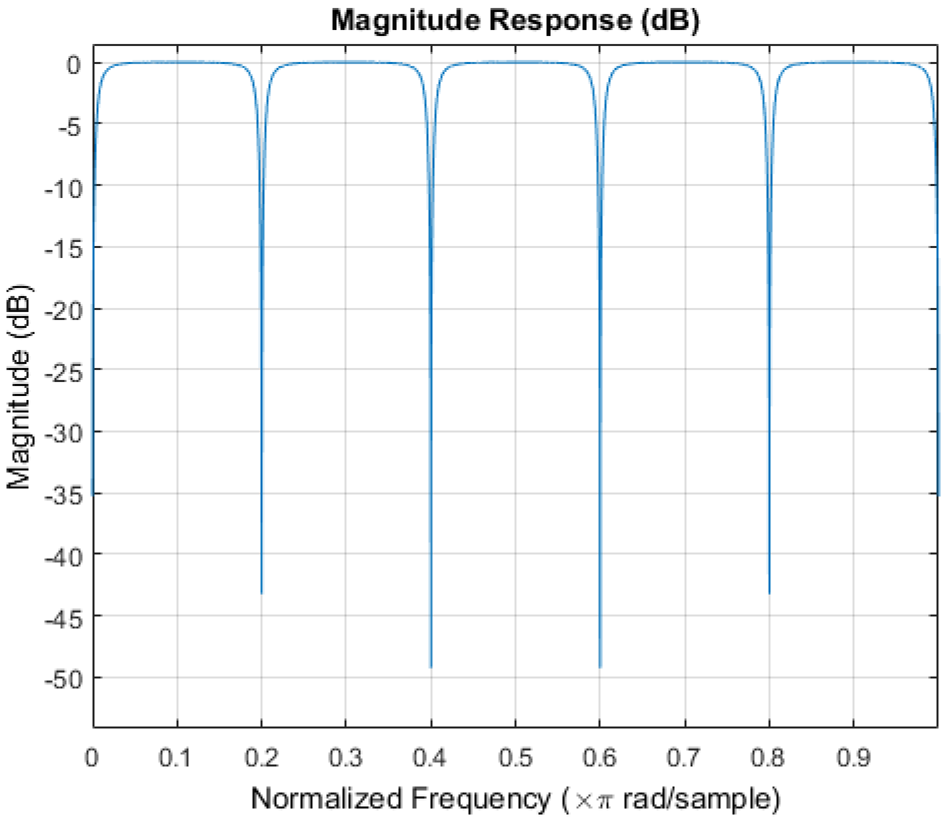
```
b = [0.9 zeros(9,1)' -0.9];
a = [1 zeros(9,1)' -0.8];
iir = dsp.IIRFilter('Numerator',b,'Denominator',a)
fvtool(iir);
```

```
iir =

  dsp.IIRFilter with properties:

            Structure: 'Direct form II transposed'
            Numerator: [0.9000 0 0 0 0 0 0 0 0 0 -0.9000]
          Denominator: [1 0 0 0 0 0 0 0 0 0 -0.8000]
    InitialConditions: 0

  Use get to show all properties
```



Algorithms

This object implements the algorithm, inputs, and outputs described on the Discrete Filter block reference page. The object properties correspond to the block parameters.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- Only the `Numerator` and `Denominator` properties are tunable for code generation.
- See "System Objects in MATLAB Code Generation" (MATLAB Coder).

dsp.FIRFilter | dsp.BiquadFilter | dsp.AllpoleFilter

Introduced in R2012b

freqz

System object: dsp.IIRFilter
Package: dsp

Frequency response

Syntax

```
[h,w] = freqz(iir)
[h,w] = freqz(iir,n)
[h,w] = freqz(iir,Name,Value)
freqz(iir)
```

Description

`[h,w] = freqz(iir)` returns the complex, 8192–element frequency response vector `h`, and the corresponding frequencies `w` in radians/sample.

`[h,w] = freqz(iir,n)` returns the complex, n-element frequency response vector `h`, and the corresponding frequencies `w` in radians/sample, using `n` samples.

`[h,w] = freqz(iir,Name,Value)` returns the frequency response and the corresponding frequencies, with additional options specified by one or more Name, Value pair arguments.

`freqz(iir)` uses FVTool to plot the magnitude and unwrapped phase of the frequency response of the filter System object `iir`.

fvtool

System object: dsp.IIRFilter
Package: dsp

Open filter visualization tool

Syntax

```
fvtool(iir)
fvtool(iir,'Arithmetic',ARITH,...)
```

Description

`fvtool(iir)` performs an analysis and computes the magnitude response of the filter System object `iir`.

`fvtool(iir,'Arithmetic',ARITH,...)` analyzes the filter System object `iir`, based on the arithmetic specified in the ARITH input. ARITH can be set to one of 'double', 'single', or 'fixed'. The analysis tool assumes a double precision filter when the arithmetic input is not specified and the filter System object is in an unlocked state. The 'Arithmetic' input is only relevant for the analysis of filter System objects.

impz

System object: dsp.IIRFilter
Package: dsp

Impulse response

Syntax

```
[h,t] = impz(iir)
[h,t] = impz(iir,Name,Value)
impz(iir)
```

Description

`[h,t] = impz(iir)` returns the impulse response `h`, and the corresponding time points `t` at which the impulse response of`iir` is computed.

`[h,t] = impz(iir,Name,Value)` returns the impulse response `h`, and the corresponding time points`t` , with additional options specified by one or more Name, Value pair arguments.

`impz(iir)` uses FVTool to plot the impulse response of the filter System object `iir`.

Note: You can use `impz` for both real and complex filters. When you omit the output arguments, `impz` plots only the real part of the impulse response.

phasez

System object: dsp.IIRFilter
Package: dsp

Unwrapped phase response

Syntax

```
[phi,w] = phasez(iir)
[phi,w] = phasez(iir,n)
[phi,w] = phasez(iir,Name,Value)
phasez(iir)
```

Description

`[phi,w] = phasez(iir)` returns the 8192–element phase response vector `phi`, and the corresponding frequencies `w` in radians/sample.

`[phi,w] = phasez(iir,n)` returns the n-element phase response vector `phi`, and the corresponding frequencies `w` in radians/sample, using `n` samples.

`[phi,w] = phasez(iir,Name,Value)` returns the phase response and the corresponding frequencies, with additional options specified by one or more Name, Value pair arguments.

`phasez(iir)` uses FVTool to plot the phase response of the filter System object `iir`.

reset

System object: dsp.IIRFilter
Package: dsp

Reset internal states of IIR filter

Syntax

```
reset(iir)
```

Description

`reset(iir)` resets the filter states of the IIR filter object, `iir`, to their initial values of 0. The initial filter state values correspond to the initial conditions for the difference equation defining the filter. After the `step` method applies the IIR filter object to nonzero input data, the states may be nonzero. Invoking the `step` method again without first invoking the`reset` method may produce different outputs for an identical input.

Reset an IIR Filter

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

```
iir = dsp.IIRFilter;
[b,a] = ellip(20, 0.5, 80, 0.25);
iir.Numerator = b;
iir.Denominator = a;
n = 0:100;
x = cos(0.2*pi*n)+sin(0.8*pi*n);
y = iir(x);
```

Filter states are nonzero. Call the IIR filter without resetting states.

```
y1 = iir(x);
isequal(y,y1)
```

```
ans =

  logical

   0
```

Now reset filter states to 0.

```
reset(iir)
```

Call the IIR filter again.

```
y2 = iir(x);
isequal(y,y2)
```

```
ans =

  logical

   1
```

step

System object: dsp.IIRFilter
Package: dsp

Filter input with IIR filter object

Syntax

```
Y = step(iir,X)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(iir,X)` filters the real or complex input signal `X` using the IIR filter, `iir`, to produce the output `Y` . When the input data is of a fixed-point type, it must be signed. The IIR filter object operates on each channel of the input signal independently over successive calls to step method.

Note: `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.IIRHalfbandDecimator System object

Package: dsp

Decimate by factor of two using polyphase IIR

Description

`dsp.IIRHalfbandDecimator` performs efficient polyphase decimation of the input signal by a factor of two. To design the halfband filter, you can specify the object to use an elliptic design or a quasi-linear phase design. The object uses these design methods to compute the filter coefficients. To filter the inputs, the object uses a polyphase structure. The allpass filters in the polyphase structure are in a minimum multiplier form.

Elliptic design introduces nonlinear phase and creates the filter using fewer coefficients than quasi linear design. Quasi-linear phase design overcomes phase nonlinearity at the cost of additional coefficients.

Alternatively, instead of designing the halfband filter using a design method, you can specify the filter coefficients directly. When you choose this option, the allpass filters in the two branches of the polyphase implementation can be in a minimum multiplier form or in a wave digital form.

You can also use the `dsp.IIRHalfbandDecimator` object to implement the analysis portion of a two-band filter bank to filter a signal into lowpass and highpass subbands. This object supports ARM Cortex code generation.

To filter and downsample your data:

1. Define and set up your halfband decimator. See "Construction" on page 4-1012.
2. Call step to filter the input signal according to the properties of `dsp.IIRHalfbandDecimator`. The input signal can be a real- or complex-valued column vector or matrix. If the input signal is a matrix, each column of the matrix is treated as an independent channel. The number of rows in the input signal must be a multiple of 2.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`IIRHalfbandDecim = dsp.IIRHalfbandDecimator` returns a halfband decimator, `IIRHalfbandDecim`, with the default settings. Calling `step` with the default property settings filters and downsamples the input data with a halfband frequency of `11025` Hz, a transition width of `4100` Hz, and a stopband attenuation of `80` dB.

`IIRHalfbandDecim = dsp.IIRHalfbandDecimator(Name,Value)` sets each property Name to the specified Value. Unspecified properties have default values.

Properties

`Specification` — Filter design parameters

`'Transition width and stopband attenuation'` (default) | `'Filter order and stopband attenuation'` | `'Filter order and transition width'` | `'Coefficients'`

Filter design parameters, specified as a character vector. When you set `Specification` to one of the filter design options, you can specify the filter design parameters using the corresponding `FilterOrder`, `StopbandAttenuation`, and `TransitionWidth` properties. Also, you can specify the design method using `DesignMethod`. When you set `Specification` to `'Coefficients'`, you can specify the coefficients directly.

`FilterOrder` — Order of the IIR halfband filter

9 (default) | positive scalar integer

Order of the IIR halfband filter, specified as a positive scalar integer. If you set `DesignMethod` to `'Elliptic'`, then `FilterOrder` must be an odd integer greater than one. If you set `DesignMethod` to `'Quasi-linear phase'`, then `FilterOrder` must be a multiple of four. This property applies when you set `Specification` to `'Filter order and stopband attenuation'` or `'Filter order and transition width'`.

`StopbandAttenuation` — Minimum attenuation needed in stopband

80 (default) | positive real scalar

Minimum attenuation needed in the stopband of the IIR halfband filter, specified as a positive real scalar. Units are in dB. This property applies only when you set `Specification` to `'Filter order and stopband attenuation'` or `'Transition width and stopband attenuation'`.

`TransitionWidth` — Transition width

4100 (default) | positive real scalar

Transition width of the IIR halfband filter, specified as a positive real scalar. Units are in Hz. The value of the transition width must be less than half the input sample rate. This property applies only when you set `Specification` to `'Transition width and stopband attenuation'` or `'Filter order and transition width'`.

`DesignMethod` — Design method

`'Elliptic'` (default) | `'Quasi-linear phase'`

Design method for the IIR halfband filter, specified as `'Elliptic'` or `'Quasi-linear phase'`. When the property is set to `'Quasi-linear phase'`, the first branch of the polyphase structure is a pure delay, which results in an approximately linear phase response. This property applies only when you set `Specification` to any accepted value except `'Coefficients'`.

`SampleRate` — Input sample rate

44100 (default) | positive real scalar

Input sample rate, specified as a positive real scalar. Units are in Hz. This property applies only when you set `Specification` to any accepted value except `'Coefficients'`.

`Structure` — Internal allpass filter implementation structure

`'Minimum multiplier'` (default) | `'Wave Digital Filter'`

Internal allpass filter implementation structure, specified as `'Minimum multiplier'` or `'Wave Digital Filter'`. This property applies only when you set `'Specification'` to `'Coefficients'`. Each structure uses a different coefficients set, independently stored in the corresponding object property.

This property is not tunable.

`AllpassCoefficients1` — Allpass polynomial filter coefficients of first branch

`[0.1284563; 0.7906755]` (default) | `[0.1284563 0.1534; 0.7906755 0.6745]`

Allpass polynomial filter coefficients of the first branch, specified as an N-by-1 or N-by-2 matrix. N is the number of first-order or second-order allpass sections. This property applies only when you set `Specification` to `'Coefficients'` and `Structure` to `'Minimum multiplier'`.

This property is tunable.

`AllpassCoefficients2` — Allpass polynomial filter coefficients of second branch

`[0.4295667]` (default) | `[0.7906755 0.1534]`

Allpass polynomial filter coefficients of the second branch, specified as an N-by-1 or N-by-2 matrix. N is the number of first-order or second-order allpass sections. This property applies only when you set `Specification` to `'Coefficients'` and `Structure` to `'Minimum multiplier'`.

This property is tunable.

`WDFCoefficients1` — Allpass filter coefficients of first branch in Wave Digital Filter form

`[0.1284563; 0.7906755]` (default) | `[0.1284563 0.1534; 0.7906755 0.6745]`

Allpass filter coefficients of the first branch in Wave Digital Filter form, specified as an N-by-1 or N-by-2 matrix. N is the number of first-order or second-order allpass sections. This property applies only when you set `Specification` to `'Coefficients'` and `Structure` to `'Wave Digital Filter'`. Each element must have an absolute value less than or equal to 1.

This property is not tunable.

`WDFCoefficients2` — Allpass filter coefficients of second branch in Wave Digital Filter form

`[0.4295667]` (default) | `[0.7906755 0.1534]`

Allpass filter coefficients of the second branch in Wave Digital Filter form, specified as the comma-separated pair consisting of `'WDFCoefficients2'` and a N-by-1 or N-by-2 matrix. N is the number of first-order or second-order allpass sections. This property applies only when you set `'Specification'` to `'Coefficients'` and `'Structure'` to `'Wave Digital Filter'`. Each element must have an absolute value less than or equal to 1.

This property is not tunable.

`HasPureDelayBranch` — Make first branch a pure delay

`false` (default) | `true`

Flag to make the first allpass branch a delay, specified as a logical scalar. This property applies only when you set `Specification` to `'Coefficients'`. When this property is true, the first branch is treated as a pure delay and the properties `AllpassCoefficients1` and `WDFCoefficients1` do not apply.

This property is not tunable.

`Delay` — Length of delay

`1` (default) | finite positive scalar

Length of the first branch delay, specified as a finite positive scalar. This property applies only when you set `Specification` to `'Coefficients'` and `HasPureDelayBranch` to 1. The value of this property specifies the number of samples by which you can delay the input to the first branch.

This property is not tunable.

`HasTrailingFirstOrderSection` — Treat the last section of the second branch as first order

`false` (default) | `true`

Option to treat the last section of the second branch as first order, specified as a logical scalar. This property applies only when you set `Specification` to `'Coefficients'`. When this property is 1 and the coefficients of the second branch are in an N-by-2 matrix, the object ignores the second element of the last row of the matrix. The last section of the second branch then becomes a first-order section. When this property is set to `0`, the last section of the second branch is a second-order section. When the coefficients of the second branch are in an N-by-1 matrix, this property is ignored.

This property is not tunable.

Methods

reset	Reset internal states of IIR halfband decimator
step	Filter input with IIR halfband decimator

For additional methods, see "Analysis Methods for Filter System Objects" on page 3-2.

For a complete list of analysis methods supported for the `dsp.IIRHalfbandDecimator` object, enter `dsp.IIRHalfbandDecimator.helpFilterAnalysis` at the MATLAB command prompt.

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Frequency Response of Quasi-Linear Phase IIR Halfband Decimator

Create a minimum-order lowpass IIR halfband decimation filter for data sampled at 44.1 kHz. The filter has a transition width of 4.1 kHz, and a stopband attenuation of 80 dB.

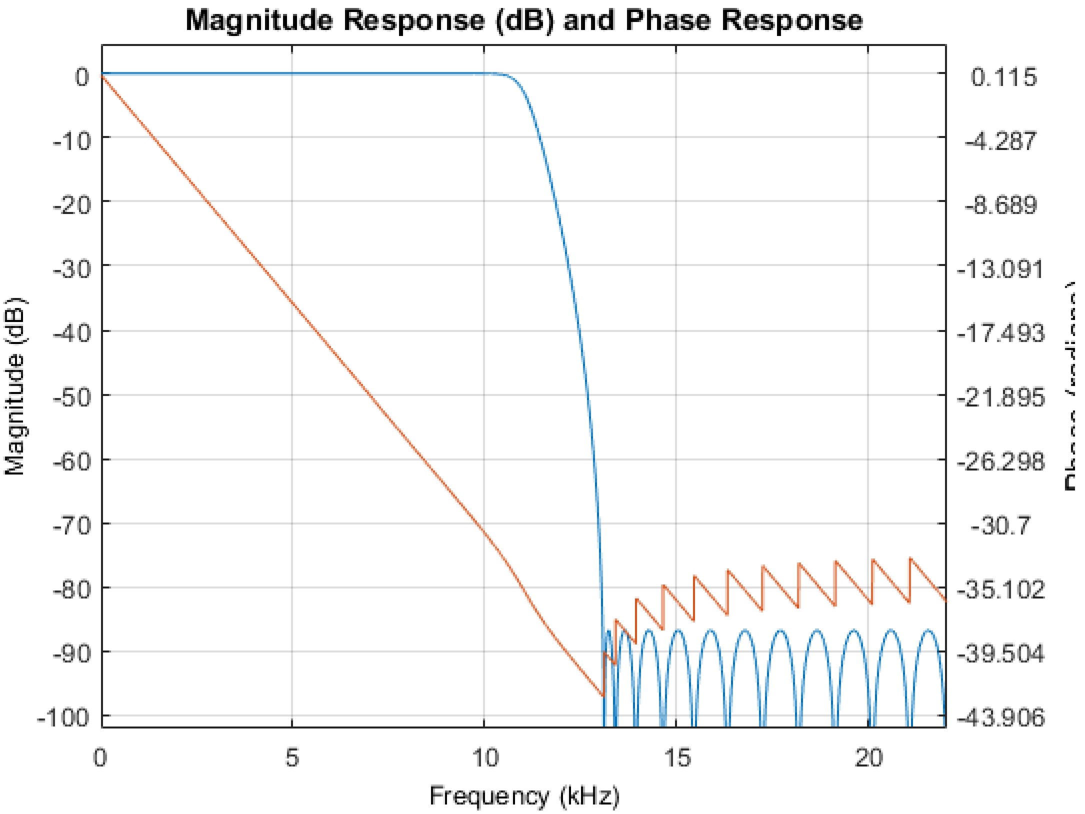
```
IIRHalfbandDecim = dsp.IIRHalfbandDecimator(...
                        'DesignMethod', 'Quasi-linear phase');
```

Obtain the filter coefficients.

```
c = coeffs(IIRHalfbandDecim);
```

Plot the magnitude and phase response.

```
fvtool(IIRHalfbandDecim,'Analysis','freq')
```



Extract Low Frequency Subband from Speech

Use a halfband analysis filter bank and interpolation filter to extract the low frequency subband from a speech signal.

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

Set up the audio file reader, the analysis filter bank, the audio device writer, and the interpolation filter. The sampling rate of the audio data is 22050 Hz. The halfband filter has an order of 21 and a transition width of 2 kHz.

```
afr = dsp.AudioFileReader('speech_dft.mp3','SamplesPerFrame',1024);
```

```
filterspec = 'Filter order and transition width';
Order = 21;
TW = 2000;

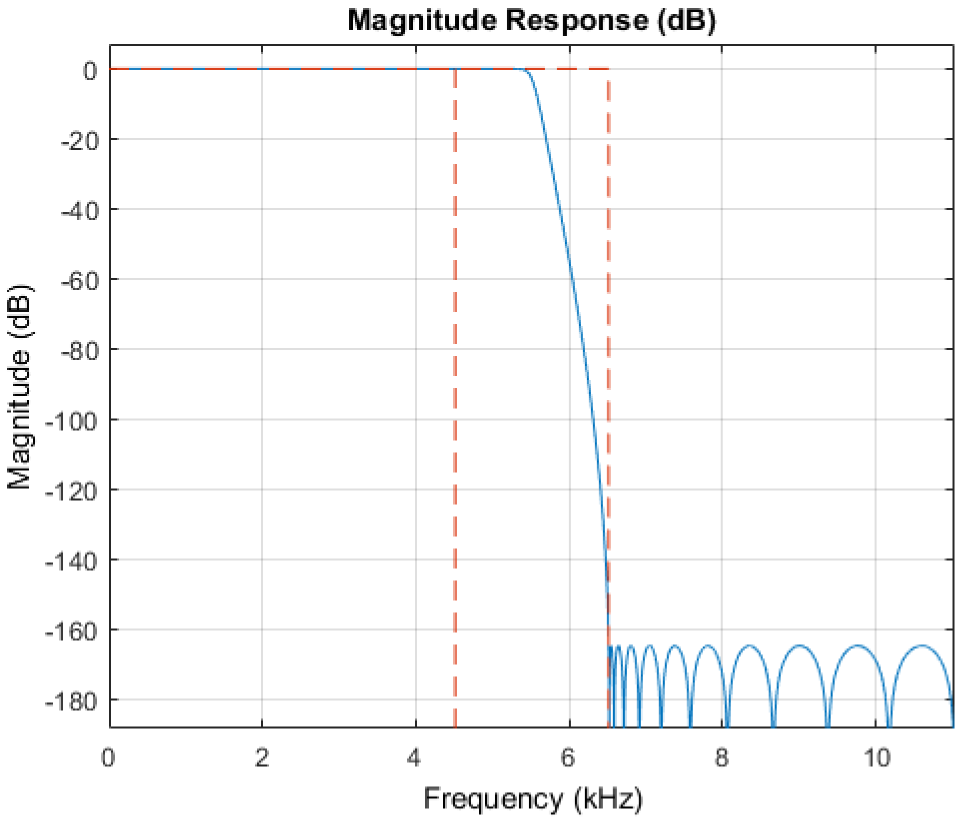
IIRHalfbandDecim = dsp.IIRHalfbandDecimator(...
    'Specification',filterspec,'FilterOrder',Order,...
    'TransitionWidth',TW,'SampleRate',afr.SampleRate);

IIRHalfbandInterp = dsp.IIRHalfbandInterpolator(...
    'Specification',filterspec,'FilterOrder',Order,...
    'TransitionWidth',TW,'SampleRate',afr.SampleRate/2);

ap = audioDeviceWriter('SampleRate',afr.SampleRate);
```

View the magnitude response of the halfband filter.

```
fvtool(IIRHalfbandDecim)
```



Read the speech signal from the audio file in frames of 1024 samples. Filter the speech signal into lowpass and highpass subbands with a halfband frequency of 5512.5 Hz. Reconstruct a lowpass approximation of the speech signal by interpolating the lowpass subband. Play the filtered output.

```
while ~isDone(afr)
  audioframe = afr();
  xlo = IIRHalfbandDecim(audioframe);
  ylow = IIRHalfbandInterp(xlo);
  ap(ylow);
end
```

Wait until the audio file ends, and then close the input file and release the audio output resource.

```
release(afr);
release(ap);
```

Two-Channel Filter Bank

Use a halfband decimator and interpolator to implement a two-channel filter bank. This example uses an audio file input and shows that the power spectrum of the filter bank output does not differ significantly from the input.

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

Set up the audio file reader and audio device writer. Construct the IIR halfband decimator and interpolator. Finally, set up the spectrum analyzer to display the power spectra of the filter-bank input and output.

```
AF = dsp.AudioFileReader('speech_dft.mp3','SamplesPerFrame',1024);
AP = audioDeviceWriter('SampleRate',AF.SampleRate);

filterspec = 'Filter order and transition width';
Order = 51;
TW = 2000;

IIRHalfbandDecim = dsp.IIRHalfbandDecimator(...
    'Specification',filterspec,'FilterOrder',Order,...
    'TransitionWidth',TW,'SampleRate',AF.SampleRate);

IIRHalfbandInterp = dsp.IIRHalfbandInterpolator(...
    'Specification',filterspec,'FilterOrder',Order,...
    'TransitionWidth',TW,'SampleRate',AF.SampleRate/2,...
    'FilterBankInputPort',true);

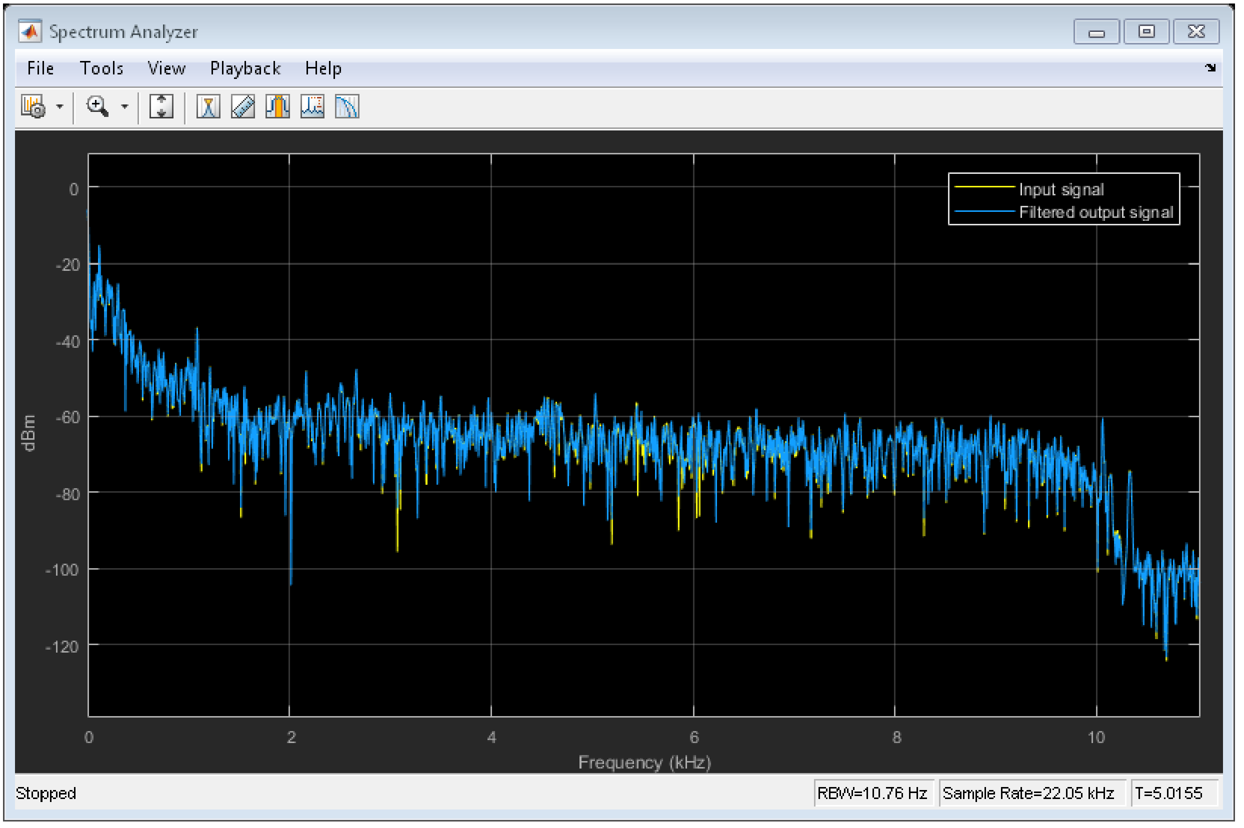
SpecAna = dsp.SpectrumAnalyzer('SampleRate',AF.SampleRate,...
    'PlotAsTwoSidedSpectrum',false,'ReducePlotRate',false,...
    'ShowLegend',true,...
    'ChannelNames',{'Input signal','Filtered output signal'});
```

Read the audio 1024 samples at a time. Filter the input to obtain the lowpass and highpass subband signals decimated by a factor of two. This is the analysis filter bank. Use the halfband interpolator as the synthesis filter bank. Display the running power spectrum of the audio input and the output of the synthesis filter bank. Play the output.

```
while ~isDone(AF)
    audioInput = AF();
```

```
    [xlo,xhigh] = IIRHalfbandDecim(audioInput);
    audioOutput = IIRHalfbandInterp(xlo,xhigh);
    spectrumInput = [audioInput audioOutput];
    SpecAna(spectrumInput);
    AP(audioOutput);
end

release(AF);
release(AP);
release(SpecAna);
```



Algorithms

Polyphase Implementation with Halfband Filters

When you call step to filter your signal, `dsp.IIRHalfbandDecimator` uses an efficient polyphase implementation for halfband filters. You can use the polyphase implementation to move the downsample operation before filtering. This change enables you to filter at the lower sampling rate.

IIR halfband filters are generally modeled using two parallel allpass filter branches.

$$H(z) = 0.5 * [A_1(z^2) + z^{-1} A_2(z^2)]$$

Elliptic Design

The allpass filters for elliptic IIR halfband filter are given as

$$A_1(z) = \prod_{k=1}^{K_1} \frac{a_k^{(1)} + z^{-1}}{1 + a_k^{(1)} z^{-1}}$$

$$A_2(z) = \prod_{k=1}^{K_2} \frac{a_k^{(2)} + z^{-1}}{1 + a_k^{(2)} z^{-1}}$$

Quasi-Linear Phase Design

To achieve a near-linear phase response for IIR halfband filters, make one of the branches a pure delay. In this design, the cost of the filter increases.

The allpass filters for the quasi-linear phase IIR halfband filter are

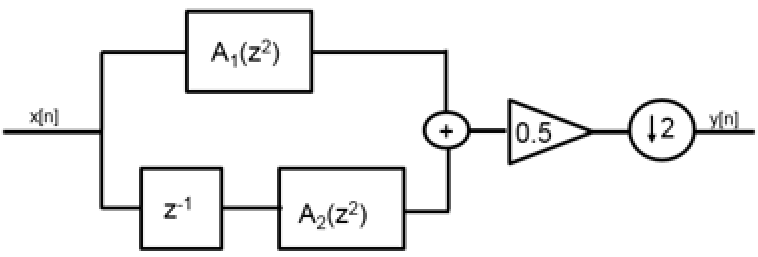
$$A_1(z) = z^{-k}$$

where k is the length of the delay.

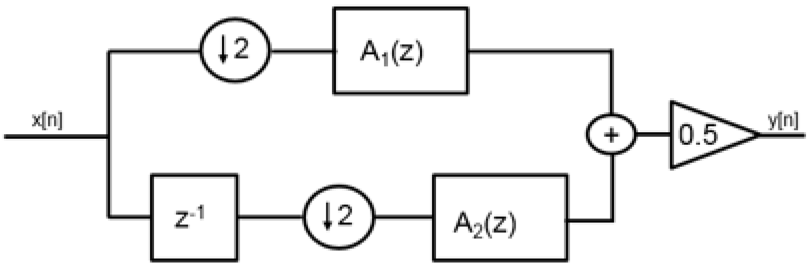
$$A_2(z) = \prod_{K=1}^{K_2^{(1)}} \frac{a_k + z^{-1}}{1 + a_k z^{-1}} \prod_{K=1}^{K_2^{(2)}} \frac{c_k + b_k z^{-1} + z^{-2}}{1 + b_k z^{-1} + c_k z^{-2}}$$

where N is the order of the IIR halfband filter.

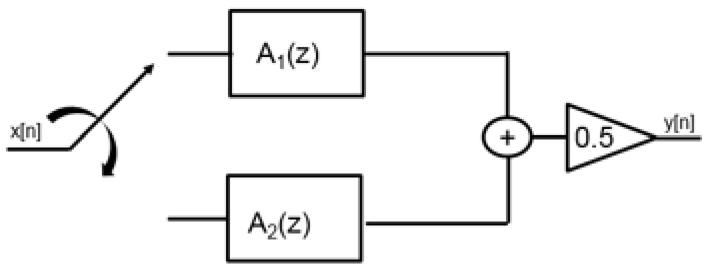
This figure represents filtering and downsampling the input by two.



Using the multirate noble identity for downsampling, you can move the downsampling operation before filtering. This change enables you to filter at the lower rate.



To implement the halfband decimator efficiently, `dsp.IIRHalfbandDecimator` replaces the delay block and downsampling operator with a commutator switch.

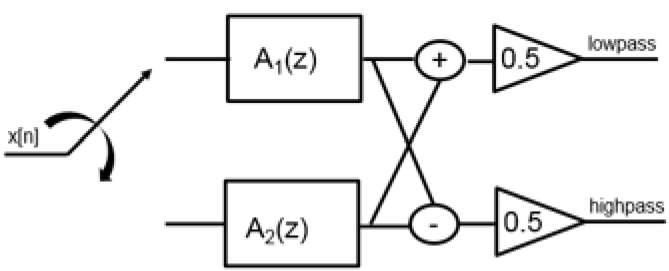


Analysis Filter Bank

The transfer function of the complementary highpass filter branch of the analysis filter bank is given by

$$G(z) = 0.5 * [A_1(z^2) - z^{-1} A_2(z^2)]$$

Graphically, you can represent the analysis filter bank as follows.



`dsp.IIRHalfbandDecimator` generates two power-complementary output signals by adding and subtracting the two polyphase branch outputs respectively.

To summarize, `dsp.IIRHalfbandDecimator`

- Decimates the input prior to filtering.
- Acts as an analysis filter bank.
- Has non-linear phase response and uses few coefficients with elliptic design method.
- Has near-linear phase response at the cost of additional coefficients with quasi-linear phase design method. One of the branches in this design is a pure delay.

Reset internal states of IIR halfband decimator

Syntax

`reset(IIRHalfbandDecim)`

Description

`reset(IIRHalfbandDecim)` resets the filter states of the IIR halfband decimator to their initial values of 0. The initial filter state values correspond to the initial conditions for the difference equation defining the filter. After the `step` method applies the halfband decimator to nonzero input data, the filter might have nonzero states. If you Invoke the `step` method again without first invoking the `reset` method, the object might produce different outputs for an identical input.

Input Arguments

`IIRHalfbandDecim` — IIR halfband decimator

`IIRHalfbandDecimator` System object

IIR halfband decimator, specified as an `IIRHalfbandDecimator` System object.

Examples

Reset an IIR Halfband Decimator

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

Create an IIR halfband decimator with default properties.

```
IIRHalfbandDecim = dsp.IIRHalfbandDecimator;
```

Create a two-channel random signal. Apply the `step` method twice on the signal.

```
x = randn(10,2);

y1 = IIRHalfbandDecim(x);
y2 = IIRHalfbandDecim(x);

no = all(y2==y1)
```

```
no =

  1×2 logical array

   0   0
```

The output is different because the internal states of `IIRHalfbandDecim` have changed. Use `reset` to reset the IIR halfband decimator and apply `step` again. Verify that the output is unchanged.

```
reset(IIRHalfbandDecim)

y3 = IIRHalfbandDecim,(x);

yes = all(y3==y1)
```

```
y3 =

  dsp.IIRHalfbandDecimator with properties:

          Specification: 'Transition width and stopband attenuation'

step

System object: dsp.IIRHalfbandDecimator
Package: dsp

Filter input with IIR halfband decimator

Syntax

```
Y = step(IIRHalfbanddecim,X)
[Ylow,Yhigh] = step(IIRHalfbanddecim,X)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(IIRHalfbanddecim,X)` filters the real or complex input signal, `X`, using the IIR halfband filter, `hiirhalfbanddecim`, and downsamples the output by a factor of 2. `Y` is a lowpass filtered and downsampled version of the input `X`. The input `X` must be a column vector or matrix with an even number of rows. If `X` is a matrix, each column is treated as an independent channel. The input `X` supports single and double data types.

`[Ylow,Yhigh] = step(IIRHalfbanddecim,X)` computes the `Ylow` and `Yhigh`, of the analysis filter bank, `IIRHalfbanddecim` for input `X`. A *Ki*-by-*N* input matrix is treated as *N* independent channels. The System object generates two power-complementary output signals by adding and subtracting the two polyphase branch outputs respectively. `Ylow` and `Yhigh` are of the same size (`Ko-by-N`) and data type. `Ko = Ki/2`, where `2` is the decimation factor.

Examples

Filter Input into Lowpass and Highpass Subbands

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

Create a halfband decimator for data sampled at 44.1 kHz. Use a minimum-order design with a transition width of 2 kHz and a stopband attenuation of 60 dB.

```
IIRHalfbanddecim = dsp.IIRHalfbandDecimator(...
    'Specification','Transition width and stopband attenuation',...
    'TransitionWidth',2000,'StopbandAttenuation',60,'SampleRate',44.1e3);
```

Filter a two-channel input into lowpass and highpass subbands.

```
x = randn(1024,2);
[ylow,yhigh] = IIRHalfbanddecim(x);
```

Introduced in R2015b

dsp.IIRHalfbandInterpolator System object

Package: dsp

Interpolate by a factor of two using polyphase IIR

Description

`dsp.IIRHalfbandInterpolator` performs efficient polyphase interpolation of the input signal by a factor of two. To design the halfband filter, you can specify the object to use an elliptic design or a quasi-linear phase design. The object uses these design methods to compute the filter coefficients. To filter the inputs, the object uses a polyphase structure. The allpass filters in the polyphase structure are in a minimum multiplier form.

Elliptic design introduces nonlinear phase and creates the filter using fewer coefficients than quasi linear design. Quasi-linear phase design overcomes phase nonlinearity at the cost of additional coefficients.

Alternatively, instead of designing the halfband filter using a design method, you can specify the filter coefficients directly. When you choose this option, the allpass filters in the two branches of the polyphase implementation can be in a minimum multiplier form or in a wave digital form.

You can also use `dsp.IIRHalfbandInterpolator` object to implement the synthesis portion of a two-band filter bank to synthesize a signal from lowpass and highpass subbands. This object supports ARM Cortex code generation.

To upsample and interpolate your data:

1. Define and set up your halfband interpolator. See “Construction” on page 4-1033.
2. Call step to filter the input signal according to the properties of `dsp.IIRHalfbandInterpolator`. The input signal can be a real- or complex-valued column vector or matrix. If the input signal is a matrix, each column of the matrix is treated as an independent channel.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`IIRHalfbandInterp = dsp.IIRHalfbandInterpolator` returns an IIR halfband interpolation filter, `IIRHalfbandInterp`, with the default settings. Calling `step` with the default property settings upsamples and interpolates the input data using a halfband frequency of `11025` Hz, a transition width of `4100` Hz, and a stopband attenuation of `80` dB.

`IIRHalfbandInterp = dsp.IIRHalfbandInterpolator(Name,Value)` sets each property Name to the specified Value. Unspecified properties have default values.

Properties

`Specification` — Filter design parameters

`'Transition width and stopband attenuation'` (default) | `'Filter order and stopband attenuation'` | `'Filter order and transition width'` | `'Coefficients'`

Filter design parameters, specified as a character vector. When you set `Specification` to one of the filter design options, you can specify the filter design parameters using the corresponding `FilterOrder`, `StopbandAttenuation`, and `TransitionWidth` properties. Also, you can specify the design method using `DesignMethod`. When you set `Specification` to `'Coefficients'`, you can specify the coefficients directly.

`FilterOrder` — Order of the IIR halfband filter

9 (default) | positive scalar integer

Order of the IIR halfband filter, specified as a positive scalar integer. If you set `DesignMethod` to `'Elliptic'`, then `FilterOrder` must be an odd integer greater than one. If you set `DesignMethod` to `'Quasi-linear phase'`, then `FilterOrder` must be a multiple of four. This property applies when you set `Specification` to `'Filter order and stopband attenuation'` or `'Filter order and transition width'`.

`StopbandAttenuation` — Minimum attenuation needed in stopband

80 (default) | positive real scalar

Minimum attenuation needed in the stopband of the IIR halfband filter, specified as a positive real scalar. Units are in dB. This property applies only when you set `Specification` to `'Filter order and stopband attenuation'` or `'Transition width and stopband attenuation'`.

`TransitionWidth` — Transition width

4100 (default) | positive real scalar

Transition width of the IIR halfband filter, specified as a positive real scalar. Units are in Hz. The value of the transition width must be less than half the input sample rate. This property applies only when you set `Specification` to `'Transition width and stopband attenuation'` or `'Filter order and transition width'`.

`DesignMethod` — Design method

`'Elliptic'` (default) | `'Quasi-linear phase'`

Design method for the IIR halfband filter, specified as `'Elliptic'` or `'Quasi-linear phase'`. When the property is set to `'Quasi-linear phase'`, the first branch of the polyphase structure is a pure delay, which results in an approximately linear phase response. This property applies only when you set `Specification` to any accepted value except `'Coefficients'`.

`SampleRate` — Input sample rate

44100 (default) | positive real scalar

Input sample rate, specified as a positive real scalar. Units are in Hz. This property applies only when you set `Specification` to any accepted value except `'Coefficients'`.

`FilterBankInputPort` — Option to use object as synthesis filter bank

`false` (default) | `true`

Option to use object as synthesis filter bank, specified as a logical value. If this property is `false`, `dsp.IIRHalfbandInterpolator` acts as an interpolator. If this property is `true`, then `dsp.IIRHalfbandInterpolator` acts as a synthesis filter bank and `step` accepts two inputs: the lowpass and highpass subbands. This property applies only when you set `Specification` to any accepted value except `'Coefficients'`.

`Structure` — Filter structure used in coefficient mode

`'Minimum multiplier'` (default) | `'Wave Digital Filter'`

Internal allpass filter implementation structure, specified as 'Minimum multiplier' or 'Wave Digital Filter'. This property applies only when you set 'Specification' to 'Coefficients'. Each structure uses a different coefficients set, independently stored in the corresponding object property.

This property is not tunable.

AllpassCoefficients1 — Allpass polynomial filter coefficients of first branch

[0.1284563; 0.7906755] (default) | [0.1284563 0.1534; 0.7906755 0.6745]

Allpass polynomial filter coefficients of the first branch, specified as an *N*-by-1 or *N*-by-2 matrix. *N* is the number of first-order or second-order allpass sections. This property applies only when you set Specification to 'Coefficients' and Structure to 'Minimum multiplier'.

This property is tunable.

AllpassCoefficients2 — Allpass polynomial filter coefficients of second branch

[0.4295667] (default) | [0.7906755 0.1534]

Allpass polynomial filter coefficients of the second branch, specified as an *N*-by-1 or *N*-by-2 matrix. *N* is the number of first-order or second-order allpass sections. This property applies only when you set Specification to 'Coefficients' and Structure to 'Minimum multiplier'.

This property is tunable.

WDFCoefficients1 — Allpass filter coefficients of first branch in Wave Digital Filter form

[0.1284563; 0.7906755] (default) | [0.1284563 0.1534; 0.7906755 0.6745]

Allpass filter coefficients of the first branch in Wave Digital Filter form, specified as an *N*-by-1 or *N*-by-2 matrix. *N* is the number of first-order or second-order allpass sections. This property applies only when you set Specification to 'Coefficients' and Structure to 'Wave Digital Filter'. All elements must have an absolute value less than or equal to 1.

This property is not tunable.

WDFCoefficients2 — Allpass filter coefficients of second branch in Wave Digital Filter form

[0.4295667] (default) | [0.7906755 0.1534]

Allpass filter coefficients of the second branch in Wave Digital Filter form, specified as an N-by-1 or N-by-2 matrix. N is the number of first-order or second-order allpass sections. This property applies only when you set `Specification` to `'Coefficients'` and `Structure` to `'Wave Digital Filter'`. All elements must have an absolute value less than or equal to `1`.

This property is not tunable.

`HasPureDelayBranch` — Make the first branch a pure delay

`false` (default) | `true`

Flag to make the first allpass branch a delay, specified as a logical scalar. This property applies only when you set `Specification` to `'Coefficients'`. When this property is true, the first branch is treated as a pure delay and the properties `AllpassCoefficients1` and `WDFCoefficients1` do not apply.

This property is not tunable.

`Delay` — Length of the delay

`1` (default) | finite positive scalar

Length of the first branch delay, specified as a finite positive scalar. This property is applicable only when you set `'Specification'` to `'Coefficients'` and `HasPureDelayBranch` to 1. The value of this property specifies the number of samples by which you can delay the input to the first branch.

This property is not tunable.

`HasTrailingFirstOrderSection` — Make the last section of the second branch as first order

`false` (default) | `true`

Option to treat the last section of the second branch as first order, specified as a logical scalar. This property applies only when you set `Specification` to `'Coefficients'`. When this property is 1 and the coefficients of the second branch are in an N-by-2 matrix, the object ignores the second element of the last row of the matrix. The last section of the second branch then becomes a first-order section. When this property is set to `0`, the last section of the second branch is a second-order section. When the coefficients of the second branch are in an N-by-1 matrix, this property is ignored.

This property is not tunable.

Methods

reset	Reset internal states of IIR halfband interpolator
step	Filter input with IIR halfband interpolator

For additional methods, see "Analysis Methods for Filter System Objects" on page 3-2.

For a complete list of analysis methods supported for the `dsp.IIRHalfbandInterpolator` object, enter `dsp.IIRHalfbandInterpolator.helpFilterAnalysis` at the MATLAB command prompt.

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Frequency response of Quasi-linear Phase IIR Halfband Interpolator

Create a minimum order lowpass IIR half-band interpolation filter for data sampled at 44.1 kHz. The filter has a transition width of 4.1 kHz, and a stopband attenuation of 80 dB.

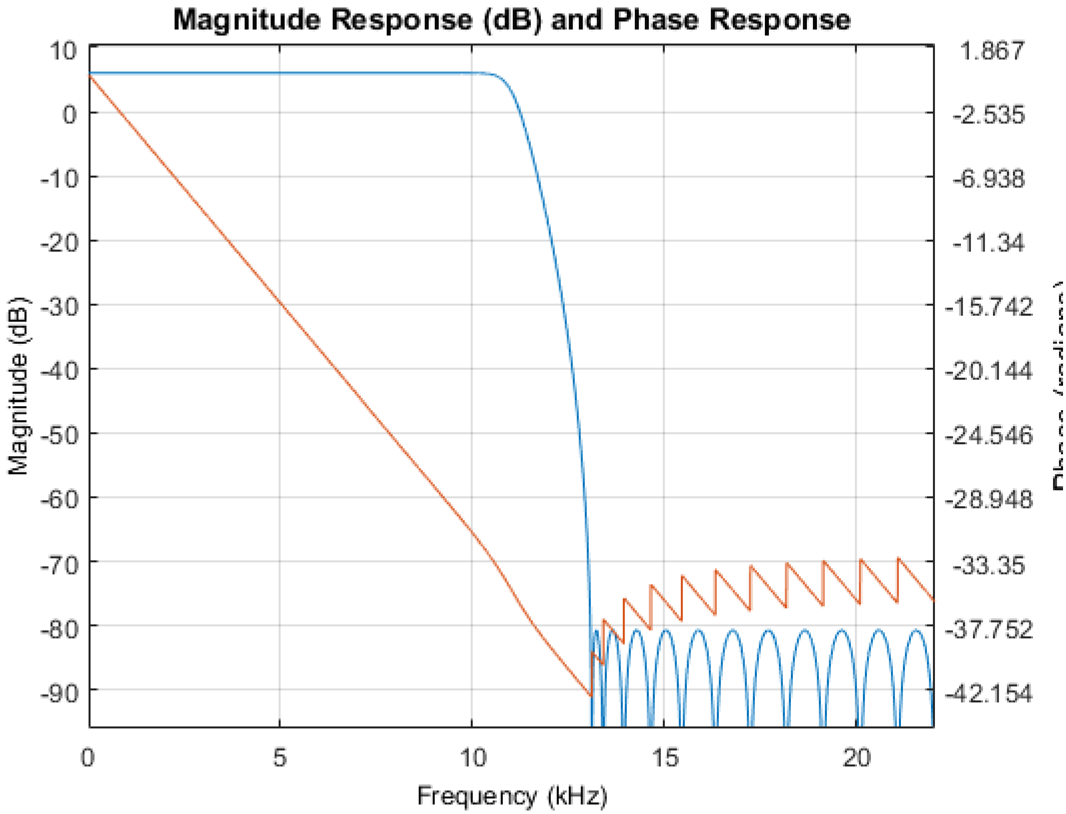
```
IIRHalfbandInterp = dsp.IIRHalfbandInterpolator(...
                        'DesignMethod', 'Quasi-linear phase');
```

Obtain filter coefficients

```
c = coeffs(IIRHalfbandInterp);
```

Plot the Magnitude and Phase response

```
fvtool(IIRHalfbandInterp,'Analysis','freq')
```



Extract Low Frequency Subband from Speech

Use a halfband analysis filter bank and interpolation filter to extract the low frequency subband from a speech signal.

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

Set up the audio file reader, the analysis filter bank, the audio device writer, and the interpolation filter. The sampling rate of the audio data is 22050 Hz. The halfband filter has an order of 21 and a transition width of 2 kHz.

```
afr = dsp.AudioFileReader('speech_dft.mp3','SamplesPerFrame',1024);

filterspec = 'Filter order and transition width';
Order = 21;
TW = 2000;

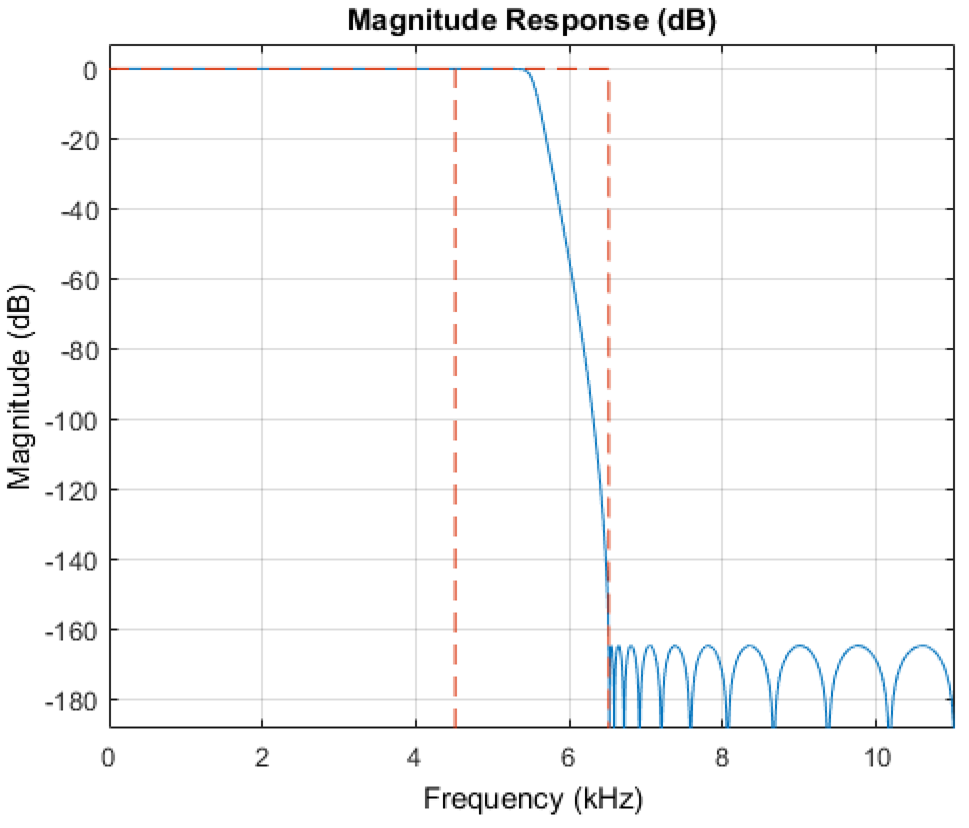
IIRHalfbandDecim = dsp.IIRHalfbandDecimator(...
    'Specification',filterspec,'FilterOrder',Order,...
    'TransitionWidth',TW,'SampleRate',afr.SampleRate);

IIRHalfbandInterp = dsp.IIRHalfbandInterpolator(...
    'Specification',filterspec,'FilterOrder',Order,...
    'TransitionWidth',TW,'SampleRate',afr.SampleRate/2);

ap = audioDeviceWriter('SampleRate',afr.SampleRate);
```

View the magnitude response of the halfband filter.

```
fvtool(IIRHalfbandDecim)
```



Read the speech signal from the audio file in frames of 1024 samples. Filter the speech signal into lowpass and highpass subbands with a halfband frequency of 5512.5 Hz. Reconstruct a lowpass approximation of the speech signal by interpolating the lowpass subband. Play the filtered output.

```
while ~isDone(afr)
  audioframe = afr();
  xlo = IIRHalfbandDecim(audioframe);
  ylow = IIRHalfbandInterp(xlo);
  ap(ylow);
end
```

Wait until the audio file ends, and then close the input file and release the audio output resource.

```
release(afr);
release(ap);
```

Two-Channel Filter Bank

Use a halfband decimator and interpolator to implement a two-channel filter bank. This example uses an audio file input and shows that the power spectrum of the filter bank output does not differ significantly from the input.

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

Set up the audio file reader and audio device writer. Construct the IIR halfband decimator and interpolator. Finally, set up the spectrum analyzer to display the power spectra of the filter-bank input and output.

```
AF = dsp.AudioFileReader('speech_dft.mp3','SamplesPerFrame',1024);
AP = audioDeviceWriter('SampleRate',AF.SampleRate);

filterspec = 'Filter order and transition width';
Order = 51;
TW = 2000;

IIRHalfbandDecim = dsp.IIRHalfbandDecimator(...
    'Specification',filterspec,'FilterOrder',Order,...
    'TransitionWidth',TW,'SampleRate',AF.SampleRate);

IIRHalfbandInterp = dsp.IIRHalfbandInterpolator(...
    'Specification',filterspec,'FilterOrder',Order,...
    'TransitionWidth',TW,'SampleRate',AF.SampleRate/2,...
    'FilterBankInputPort',true);

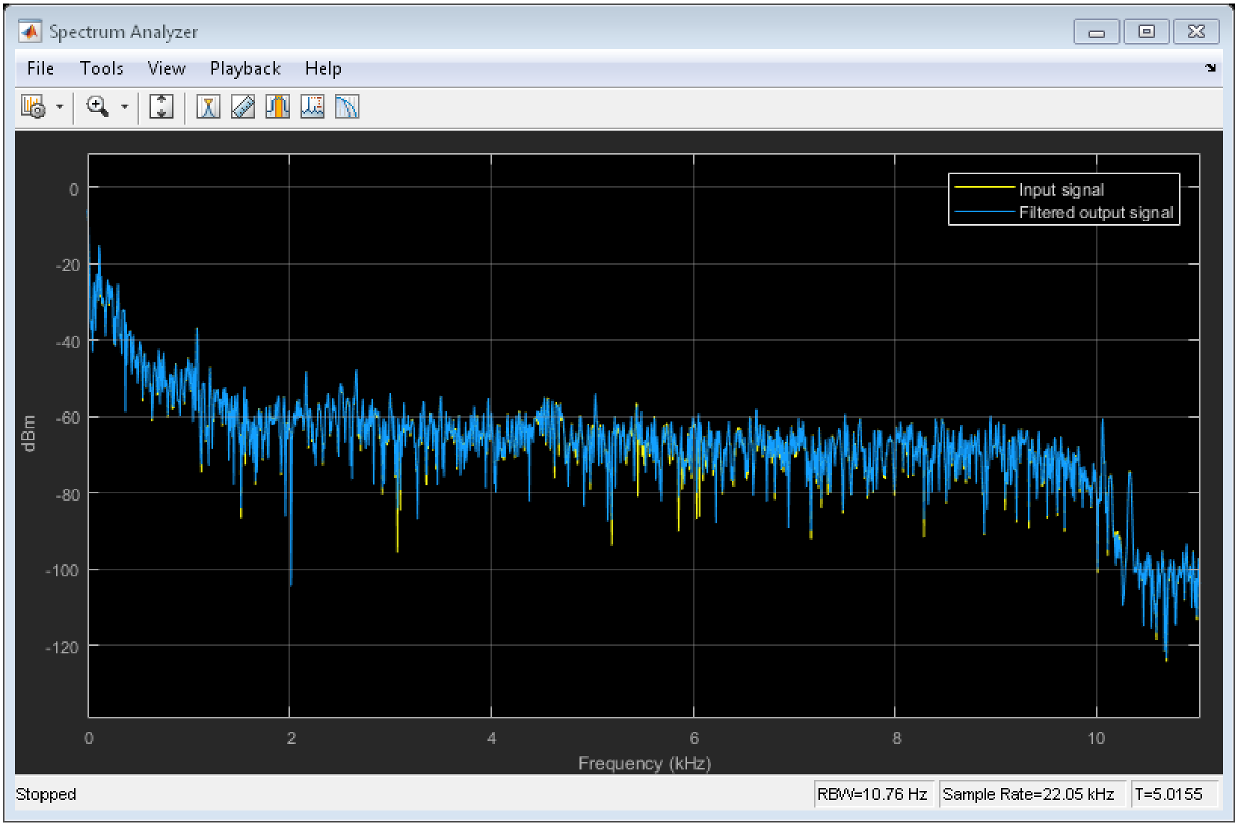
SpecAna = dsp.SpectrumAnalyzer('SampleRate',AF.SampleRate,...
    'PlotAsTwoSidedSpectrum',false,'ReducePlotRate',false,...
    'ShowLegend',true,...
    'ChannelNames',{'Input signal','Filtered output signal'});
```

Read the audio 1024 samples at a time. Filter the input to obtain the lowpass and highpass subband signals decimated by a factor of two. This is the analysis filter bank. Use the halfband interpolator as the synthesis filter bank. Display the running power spectrum of the audio input and the output of the synthesis filter bank. Play the output.

```
while ~isDone(AF)
    audioInput = AF();
```

```
    [xlo,xhigh] = IIRHalfbandDecim(audioInput);
    audioOutput = IIRHalfbandInterp(xlo,xhigh);
    spectrumInput = [audioInput audioOutput];
    SpecAna(spectrumInput);
    AP(audioOutput);
end

release(AF);
release(AP);
release(SpecAna);
```



Algorithms

Polyphase Implementation with Halfband Filters

When you call step to filter your signal, `dsp.IIRHalfbandInterpolator` uses an efficient polyphase implementation for halfband filters. You can use a polyphase implementation to move the upsampling operation after filtering. This change enables you to filter at the lower sampling rate.

IIR halfband filters are generally modeled using two parallel allpass filter branches.

$$H(z) = 0.5 * [A_1(z^2) + z^{-1} A_2(z^2)]$$

Elliptic Design

The allpass filters for elliptic IIR halfband filter are given as

$$A_1(z) = \prod_{k=1}^{K_1} \frac{a_k^{(1)} + z^{-1}}{1 + a_k^{(1)} z^{-1}}$$

$$A_2(z) = \prod_{k=1}^{K_2} \frac{a_k^{(2)} + z^{-1}}{1 + a_k^{(2)} z^{-1}}$$

Quasi-Linear Phase Design

A near-linear phase response for IIR halfband filters is achieved by making one of the branches a pure delay. In this design, the cost of the filter increases.

The allpass filters for quasi-linear phase IIR halfband filter are

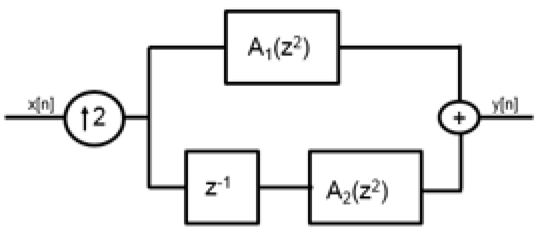
$$A_1(z) = z^{-k}$$

where, k is the length of the delay.

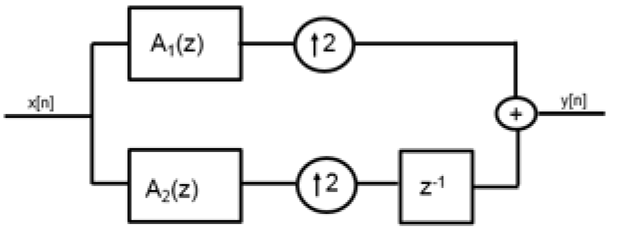
$$A_2(z) = \prod_{K=1}^{K_2^{(1)}} \frac{a_k + z^{-1}}{1 + a_k z^{-1}} \prod_{K=1}^{K_2^{(2)}} \frac{c_k + b_k z^{-1} + z^{-2}}{1 + b_k z^{-1} + c_k z^{-2}}$$

where N is the order of the IIR halfband filter.

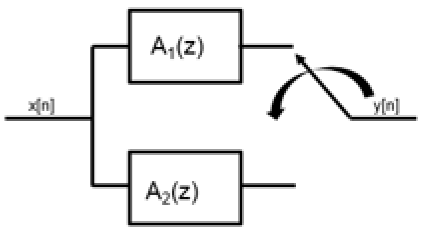
Graphically, you can represent upsampling by two followed by filtering with the following figure



Using the multirate noble identity for upsampling, you can move the upsampling operation after filtering. This enables you to filter at the lower rate.



To efficiently implement the halfband interpolator, `dsp.IIRHalfbandInterpolator` replaces the upsampling operator, delay block, and adder with a commutator switch. The commutator switch operates at twice the input sample rate. This is shown in the following figure:



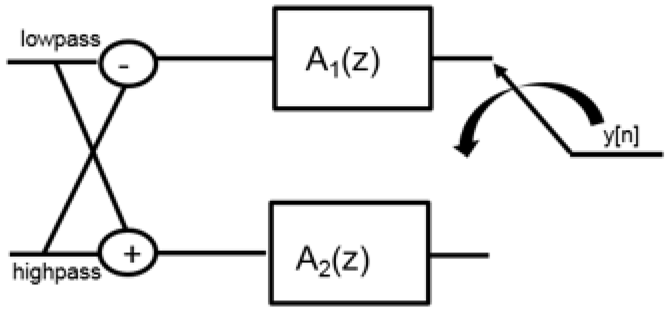
The commutator switch takes input samples from the two branches alternately, one sample at a time. This doubles the sampling rate of the input signal.

Synthesis Filter Bank

Transfer function of the complementary high-pass filter branch of the synthesis filter bank is given by

$$G(z) = 0.5 * [A_1(z^2) - z^{-1} A_2(z^2)]$$

Graphically, you can represent the synthesis filter bank as



`dsp.IIRHalfbandInterpolator` to implement the synthesis portion of a two-band filter bank to synthesize a signal from lowpass and highpass subbands.

To summarize, `dsp.IIRHalfbandInterpolator`

- Filters the input before upsampling
- acts as a synthesis filter bank
- has non-linear phase response and uses few coefficients with elliptic design method
- has near-linear phase response at the cost of additional coefficients with quasi-linear phase design method. One of the branches in this design is a pure delay.

dsp.FIRHalfbandDecimator | dsp.FIRHalfbandInterpolator | dsp.IIRHalfbandDecimator | `IIR Halfband Interpolator`

Introduced in R2015b

reset

System object: dsp.IIRHalfbandInterpolator
Package: dsp

Reset internal states of IIR halfband interpolator

Syntax

`reset(IIRHalfbandInterp)`

Description

`reset(IIRHalfbandInterp)` resets the filter states of the IIR halfband interpolator,`IIRHalfbandInterp`, to their initial values of 0. The initial filter state values correspond to the initial conditions for the difference equation defining the filter. After the `step` method applies the halfband interpolator to nonzero input data, the states may be nonzero. If you Invoke the `step` method again without first invoking the `reset` method, the object might produce different outputs for an identical input.

Input Arguments

`IIRHalfbandInterp` — IIR halfband interpolator
`dsp.IIRHalfbandInterpolator` System object

IIR halfband interpolator, specified as a `dsp.IIRHalfbandInterpolator` System object.

Examples

Reset an IIR Halfband Interpolator

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

Create an IIR halfband interpolator with default properties.

```
IIRHalfbandInterp = dsp.IIRHalfbandInterpolator;
```

Create a two-channel random signal. Apply the `step` method twice on the signal.

```
x = randn(10,2);

y1 = IIRHalfbandInterp(x);
y2 = IIRHalfbandInterp(x);

no = all(y2==y1)
```

```
no =

  1×2 logical array

   0   0
```

The output is different because the internal states of `IIRHalfbandInterp` have changed. Use `reset` to reset the IIR halfband interpolator and apply `step` again. Verify that the output is unchanged.

```
reset(IIRHalfbandInterp)

y3 = IIRHalfbandInterp(x);

yes = all(y3==y1)
```

```
yes =

  1×2 logical array

   1   1
```

step

System object: dsp.IIRHalfbandInterpolator
Package: dsp

Filter input with IIR halfband interpolator

Syntax

```
Y = step(IIRHalfbandInterp,X)
Y = step(hiirhalfbandinterp,X1,X2)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(IIRHalfbandInterp,X)` upsamples by two and interpolates the real or complex input signal `X` using the IIR halfband interpolator, `hfirhalfbandinterp`. The input `X` must be a column vector or matrix. If `X` is a matrix, each column is treated as an independent channel. The input `X` supports single, and double data types.

`Y = step(hiirhalfbandinterp,X1,X2)` implements a halfband synthesis filter bank for the inputs `X1` and `X2`. `X1` is the lowpass output of a halfband analysis filter bank and `X2` is the highpass output of a halfband analysis filter bank. `dsp.IIRHalfbandInterpolator` implements a synthesis filter bank only when the `FilterBankInputPort` property is `true`.

Examples

Upsample and Interpolate Multichannel Input with IIR Halfband Interpolator

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

Create a half-band interpolation filter for data sampled at 44.1 kHz. The filter order is 51 with a transition width of 4.1 kHz. Use the filter to upsample and interpolate a multichannel input.

```
Fs = 44.1e3;
filterspec = 'Filter order and transition width';
Order = 51;
TW = 4.1e3;
iirhalfbandinterp = dsp.IIRHalfbandInterpolator(...
                                               'Specification',filterspec,...
                                               'FilterOrder',Order,...
                                               'TransitionWidth',TW,...
                                                'SampleRate',Fs);

x = randn(1024,4);
y = iirhalfbandinterp(x);
```

dsp.Interpolator System object

Package: dsp

Linear or FIR interpolation

Description

The `Interpolator` object interpolates real-valued inputs using linear or polyphase FIR interpolation.

To interpolate real-valued inputs:

1. Define and set up your interpolation object. See "Construction" on page 4-1052.
2. Call step to interpolate the input according to the properties of `dsp.Interpolator`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`interp = dsp.Interpolator` returns a handle to an interpolation object, `interp`. The interpolation method defaults to `Linear` and the interpolation points default to a 5×1 vector.

`interp = dsp.Interpolator('`*`PropertyName`*`',`*`PropertyValue`*`,...)` returns an interpolation object, `interp`, with the specified property name and value pairs.

Properties

`InterpolationPointsSource`

Source of interpolation points

You can select a value of `Property` or `Input port`. If you set this property to `Input port`, you must provide the interpolation points as an input to the `step` method when you interpolate the input. The default is `Property`.

InterpolationPoints

Interpolation points

This property only applies when you set the `InterpolationPointsSource` on page 4-1052 property to `Property`. Specify the interpolation points as a column vector or a matrix with the same number of channels as the input.

The valid range of the values in the interpolation vector is from `1` to the number of samples in each channel of the input. If you specify interpolation points outside the valid range, the object *clips* the point to the nearest point in the valid range. For example, if the input is `[2 3.1 -2.1]`, the valid range of interpolation points is from `1` to `3`. If you specify the following vector of interpolation points `[-1 1.5 2 2.5 3 3.5]`, the interpolator object clips `-1` to `1` and `3.5` to `3`. This clipping results in the interpolation points `[1 1.5 2 2.5 3 3]`. The default is `[1.1;4.8;2.67;1.6;3.2]`. This property is tunable.

Method

Interpolation method

Specify the interpolation method as `Linear` or `FIR`. When this property is `Linear`, the interpolator object interpolates data values by assuming that the data varies linearly between adjacent samples. When this property is `FIR`, the interpolator object uses polyphase interpolation to replace filtering (convolution) at the upsampled rate with a series of convolutions at the lower rate. The interpolator object always performs linear interpolation if there are insufficient low-rate samples to perform FIR interpolation as explained in the description of the `FilterHalfLength` on page 4-1053 property. The default is `Linear`.

FilterHalfLength

Interpolation filter half length

This property applies only when you set the `Method` on page 4-1053 property to `FIR`. For a filter half length of P, the polyphase FIR subfilters have length $2P$. FIR interpolation always requires $2P$ low-rate samples for every interpolation point.

- If the interpolation point does not correspond to a low-rate sample, FIR interpolation requires P low-rate samples below and P low-rate samples above the interpolation point.
- If the interpolation point corresponds to a low-rate sample, the $2P$-sample requirement includes the low-rate sample.
- If there are less than $2P$ neighboring low-rate samples, the interpolator object uses linear interpolation.

For example, for an input `[1 4 1 4 1 4 1 4]`, upsampling by a factor of four results in the equally spaced interpolation points `InterP = 1:0.25:8;`. The points `InterP(9:12)` are `[3.0 3.25 3.5 3.75]`. Assuming a `FilterHalfLength` property equal to 2, interpolating at these points uses the four low-rate samples from the input with indices `(2,3,4,5)`. If you set the `FilterHalfLength` property to 4 in this case, the interpolator object uses linear interpolation because there are not enough low-rate samples to perform FIR interpolation.

The longer the `FilterHalfLength` property, the better the quality of the interpolation. However, the costs are increased computation and requiring more low-rate samples below and above the interpolation point. In general, setting the `FilterHalfLength` property between 4 and 6 provides reasonably accurate interpolation.

InterpolationPointsPerSample

Interpolation points per input sample

This property only applies when you set the `Method` on page 4-1053 property to `FIR` and indicates the upsampling factor, L. An upsampling factor of L inserts L–1 zeros between low-rate samples. Interpolation results from filtering the upsampled sequence with a lowpass anti-imaging filter. The interpolator object uses a polyphase FIR implementation with `InterpolationPointsPerSample` subfilters of length $2P$, where P is the `FilterHalfLength` on page 4-1053 property. Denoting the low-rate samples in the upsampled input by nL, $n=1,2,...$, the interpolator object uses exactly one of the `InterpolationPointsPerSample` subfilters, or filter arms, to interpolate at the points $nL+i/L$, where $i=0,1,2,...,L-1$.

If you specify interpolation points which do not correspond to a polyphase subfilter, the object rounds the point down to the nearest interpolation point associated with a polyphase subfilter. For example, you set the `InterpolationPointsPerSample` property to `4` and interpolate at the points `[3 3.2 3.4 3.6 3.8]`. The interpolator object uses the first polyphase subfilter for the points `[3.0 3.2]`, the second subfilter for the point `3.4`, the third subfilter for the point `3.6`, and the fourth subfilter for the point `3.8`.

Bandwidth

Normalized input bandwidth

This property applies only when you set the `Method` on page 4-1053 property to `FIR`. The normalized bandwidth is a real-valued scalar between 0 and 1, where 1 equals the Nyquist frequency, or 1/2 the sampling frequency (*Fs*). You may know that your input does not have frequency content above some cutoff frequency less than the Nyquist frequency. You can use this information to improve the FIR interpolation filters by relaxing the stopband requirements in frequency regions where the signal has no energy. For example, if the input signal does not have frequency content above *Fs/8*, you can specify a value of `0.25` for the `Bandwidth` property. The default value is `0.5`.

Methods

step	Linear or FIR interpolation

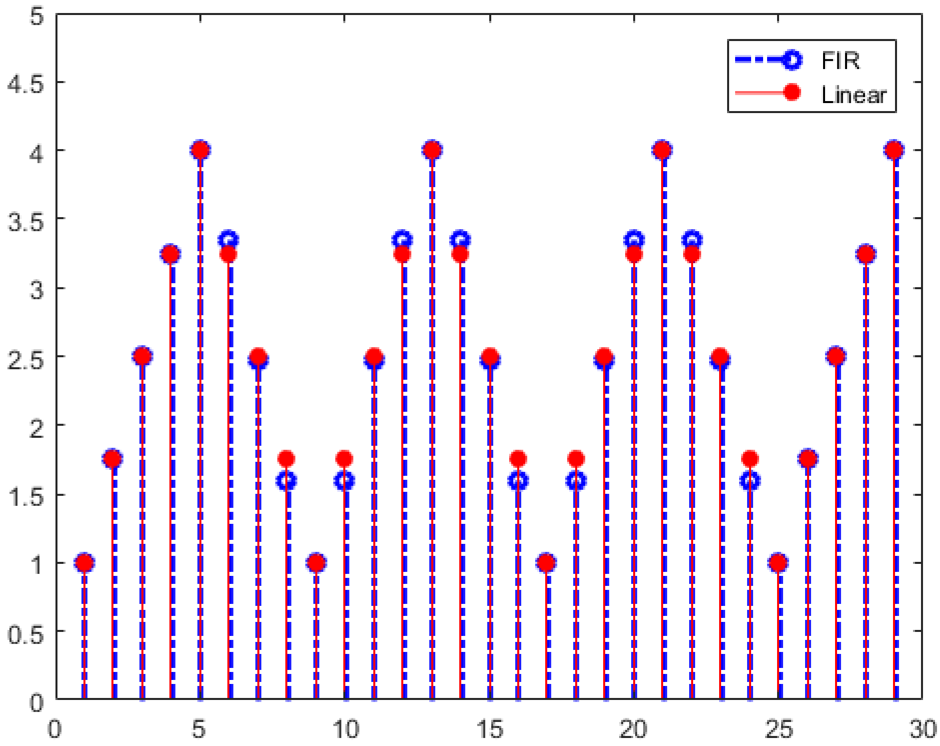
Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Compare Linear Interpolation With FIR Interpolation

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

```
x =[1 4];
x = repmat(x,1,4);
x1 = 1:0.25:8;
firInterp =dsp.Interpolator('Method','FIR','FilterHalfLength',2,...
'InterpolationPoints',x1','InterpolationPointsPerSample',4);
linInterp = dsp.Interpolator('InterpolationPoints',x1');
OutFIR = firInterp(x');
OutLin = linInterp(x');
stem(OutFIR,'b-.','linewidth',2); hold on;
stem(OutLin,'r','markerfacecolor',[1 0 0]);
axis([0 30 0 5]); legend('FIR','Linear','Location','Northeast');
```

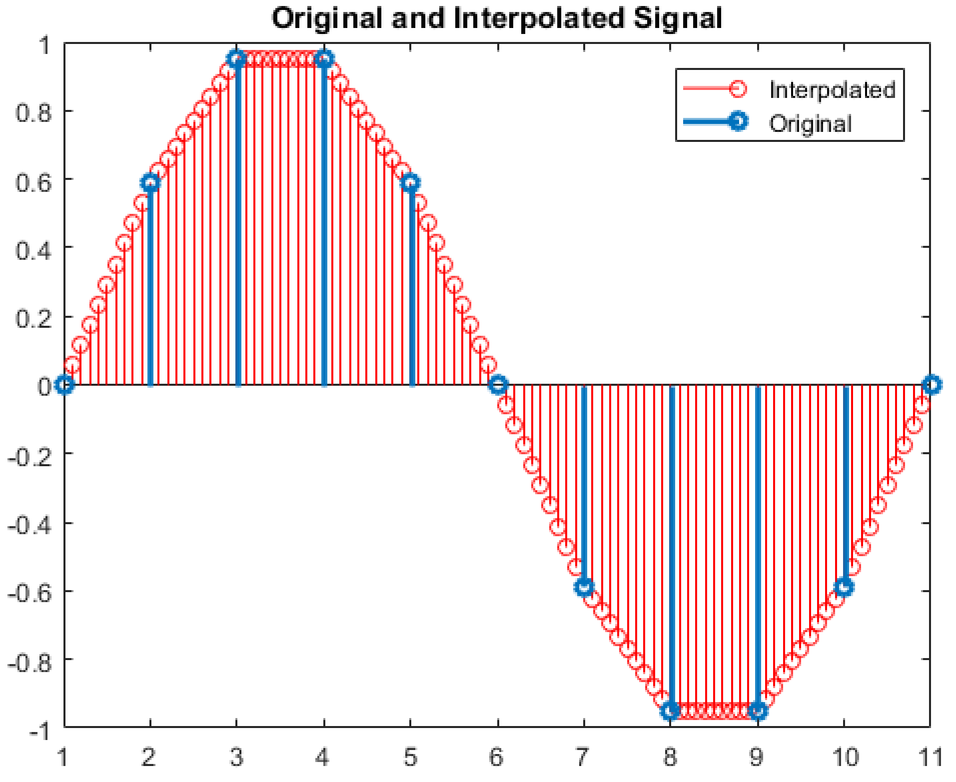


For the indices 1 to 5 and 25 to 29, the interpolator object uses linear interpolation in both cases. The reason for this is that there are not enough low-rate samples surrounding the interpolation points at those indices to use FIR interpolation with the specified filter length.

Interpolate a Sinusoid With Linear Interpolation

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

```
t = 0:.0001:.0511;
x = sin(2*pi*20*t);
x1 = x(1:50:end);
I = 1:0.1:length(x1);
interp = dsp.Interpolator('InterpolationPointsSource',...
    'Input port');
y = interp(x1',I');
stem(I',y, 'r');
title('Original and Interpolated Signal');
hold on; stem(x1, 'Linewidth', 2);
legend('Interpolated','Original');
```



Interpolate a Sum of Sinusoids

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

Interpolate a sum of sinusoids with FIR interpolation and `Input Port` as the source of interpolation points.

```
Fs = 1000;
t = 0:(1/Fs):0.1-(1/Fs);
x = cos(2*pi*50*t)+0.5*sin(2*pi*100*t);
x1 = x(1:4:end);
I = 1:(1/4):length(x1);
```

```
interp = dsp.Interpolator('Method','FIR',...
'FilterHalfLength',3,'InterpolationPointsSource','Input Port');
y = interp(x1',I');
stem(I,y,'r'); hold on;
axis([0 25 -2 2]);

Polyphase Implementation

A polyphase implementation of an FIR interpolation filter *splits* the lowpass FIR filter impulse response into a number of different subfilters.

Let L represent the number of interpolation points per sample, or the upsampling factor, and P the half length of the polyphase subfilters. Indexing from zero, if *h(n)* is the impulse response of the FIR filter, the k-th subfilter is:

$$h_k(n) = h(k + nL) \quad k = 0,1,\ldots,L-1 \quad n = 0,1,\ldots,2P-1$$

The following table describes the decomposition of an 18-coefficient FIR filter into 3 polyphase subfilters of length 6, the defaults for the FIR interpolator object:

Coefficients	Polyphase Subfilter
h(0),h(3),h(6), ..., h(15)	$h_0(n)$
h(1),h(4),h(7), ..., h(16)	$h_1(n)$
h(2),h(5),h(8), ..., h(17)	$h_2(n)$

The following code shows how to find the polyphase subfilters for the default FIR interpolator object:

```
interp = dsp.Interpolator('Method','FIR');
L = interp.InterpolationPointsPerSample;
P = interp.FilterHalfLength;
FiltCoeffs = intfilt(L,P,interp.Bandwidth);
% Returns filter of length 2*P*L-1
FiltLen=length(FiltCoeffs);
FiltCols = ceil(FiltLen/2/L);

% We need 2*P*L coefficients
% Prepending a zero does not affect the filter magnitude
FiltCoeffs = [zeros(FiltCols*2*L-FiltLen,1); FiltCoeffs(:)];

% Each column of PolyPhaseCoeffs is a polyphase subfilter
PolyPhaseCoeffs  = reshape(FiltCoeffs,FiltCols,2*L)';
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the `Interpolation` block reference page. The object properties correspond to the Simulink block parameters, except:

Out of range interpolation points — The interpolator object only has the `Clip` option. The Simulink block has the additional `Clip and warn` and `Error` options.

Extended Capabilities

`intfilt` | dsp.FIRInterpolator | dsp.VariableFractionalDelay

Introduced in R2012a

step

System object: dsp.Interpolator
Package: dsp

Linear or FIR interpolation

Syntax

```
Y = step(interp,X)
Y = step(interp,X,IPTS)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(interp,X)` outputs the interpolated sequence, `Y`, of the input vector or matrix `X` as specified in the `InterpolationPoints` property.

`Y = step(interp,X,IPTS)` outputs the interpolated sequence as specified by the input argument `IPTS` when the `InterpolationPointsSource` property is set to 'Input port'. `IPTS` a column vector or a matrix of interpolation points. If `IPTS` is a matrix, it must have the same number of channels as the input.

Note: `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

dsp.KalmanFilter System object

Package: dsp

Estimate system measurements and states using Kalman filter

Description

The `KalmanFilter` is an estimator used to recursively obtain a solution for linear optimal filtering. This estimation is made without precise knowledge of the underlying dynamic system. The Kalman filter implements the following linear discrete-time process with state, x, at the k^{th} time-step: $x(k) = Ax(k-1) + Bu(k-1) + w(k-1)$ (state equation). This measurement, z, is given as: $z(k) = Hx(k) + v(k)$ (measurement equation).

The Kalman filter algorithm computes the following two steps recursively:

- Prediction: Process parameters x (state) and P (state error covariance) are estimated using the previous state,
- Correction: The state and error covariance are corrected using the current measurement,

To filter each channel of the input:

1. Define and set up your Kalman filter. See “Construction” on page 4-1064.
2. Call step to filter each channel of the input according to the properties of `dsp.KalmanFilter`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`kalman = dsp.KalmanFilter` returns the Kalman filter System object, `kalman`, with default values for the parameters.

`kalman = dsp.KalmanFilter('`*`PropertyName`*`',`*`PropertyValue`*`, ...)` returns an Kalman filter System object, `kalman`, with each property set to the specified value.

`kalman = dsp.KalmanFilter(STMatrix, MMatrix, PNCovariance, MNCovariance, CIMatrix, 'PropertyName', PropertyValue, ...)` returns a Kalman filter System object, `kalman`. The `StateTransitionMatrix` property is set to `STMatrix`, and `MeasurementMatrix` property is set to `MMatrix`. In addition, the `ProcessNoiseCovariance` property set to `PNCovariance`, `MeasurementNoiseCovariance` property set to `MNCovariance`, `ControlInputMatrix` property set to `CIMatrix`. Other specified properties are set to the specified values.

Properties

`StateTransitionMatrix`

Model of state transition

Specify `A` in the state equation that relates the state at the previous time step to the state at current time step. `A` is a square matrix with each dimension equal to the number of states. The default value is `1`.

`ControlInputMatrix`

Model of relation between control input and states

Specify `B` in the state equation that relates the control input to the state. `B` is a matrix with a number of rows equal to the number of states. This property is activated only when the `ControlInputPort` property value is `true`. The default value is `1`.

`MeasurementMatrix`

Model of relation between states and measurement output

Specify `H` in the measurement equation that relates the states to the measurements. `H` is a matrix with the number of columns equal to the number of measurements. The default value is `1`.

`ProcessNoiseCovariance`

Covariance of process noise

Specify `Q` as a square matrix with each dimension equal to the number of states. This matrix, `Q`, is the covariance of the white Gaussian process noise, `w`, in the state equation. The default value is `0.1`.

`MeasurementNoiseCovariance`

Covariance of measurement noise

Specify `R` as a square matrix with each dimension equal to the number of states. This matrix, `R`, is the covariance of the white Gaussian process noise, `v`, in the measurement equation. The default value is `0.1`.

`InitialStateEstimate`

Initial value for states

Specify an initial estimate of the states of the model as a column vector with length equal to the number of states. The default value is `0`.

`InitialErrorCovarianceEstimate`

Initial value for state error covariance

Specify an initial estimate for covariance of the state error, as a square matrix with each dimension equal to the number of states. The default value is `0.1`.

`DisableCorrection`

Disable port for filters

Specify as a scalar logical value, disabling System object filters from performing the correction step after the prediction step in the Kalman filter algorithm. The default value is `false`.

`ControlInputPort`

Presence of a control input

Specify if the control input is present, using a scalar logical value. The default value is `true`.

Methods

reset	Reset internal states of Kalman filter

step	Filter input with Kalman filter object

Common to All System Objects	
clone	Create System object with same property values
getNumInpu	Expected number of inputs to a System object
getNumOutp	Expected number of outputs of a System object
isLocked	Check locked states of a System object (logical)
release	Allow System object property value changes

Examples

Estimate a Changing Scalar

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

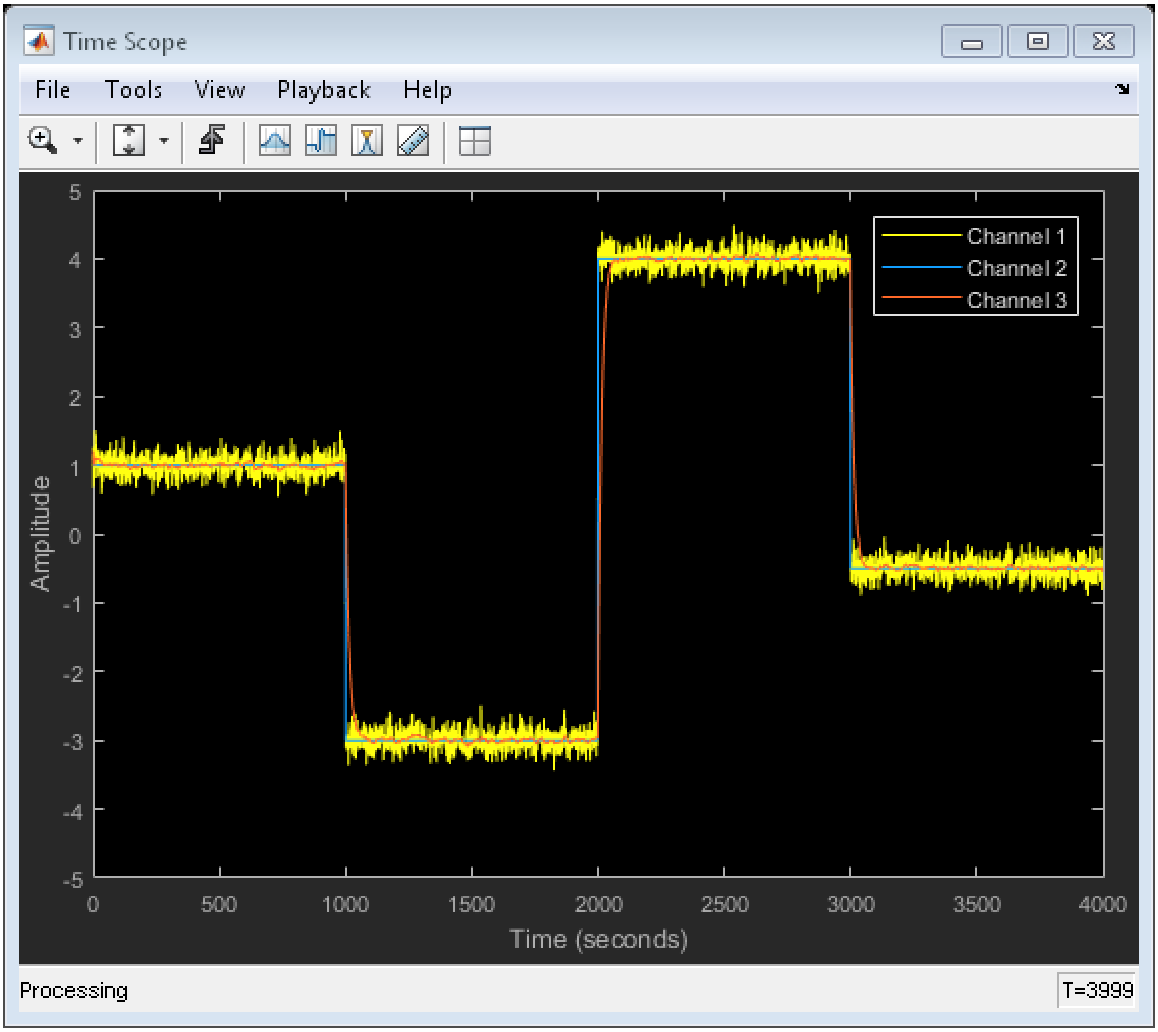
Create the System objects for the changing scalar input, the Kalman filter, and the scope (for plotting).

```
numSamples = 4000;
R = 0.02;
src = dsp.SignalSource;
src.Signal = [ones(numSamples/4,1);   -3*ones(numSamples/4,1);...
    4*ones(numSamples/4,1); -0.5*ones(numSamples/4,1)];
tScope = dsp.TimeScope('NumInputPorts', 3, 'TimeSpan', numSamples, ...
    'TimeUnits', 'Seconds', 'YLimits',[-5 5], ...
    'ShowLegend', true); % Create the Time Scope
kalman = dsp.KalmanFilter('ProcessNoiseCovariance', 0.0001,...
    'MeasurementNoiseCovariance', R,...
    'InitialStateEstimate', 5,...
    'InitialErrorCovarianceEstimate', 1,...
    'ControlInputPort',false); %Create Kalman filter
```

Add noise to the scalar, and pass the result to the Kalman filter. Stream the data, and plot the filtered signal.

```
while(~isDone(src))
   trueVal = src();
   noisyVal = trueVal + sqrt(R)*randn;
```

```
   estVal = kalman(noisyVal);
   tScope(noisyVal,trueVal,estVal);
end
```



Disable the Correction Step in the Kalman Filter Algorithm

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

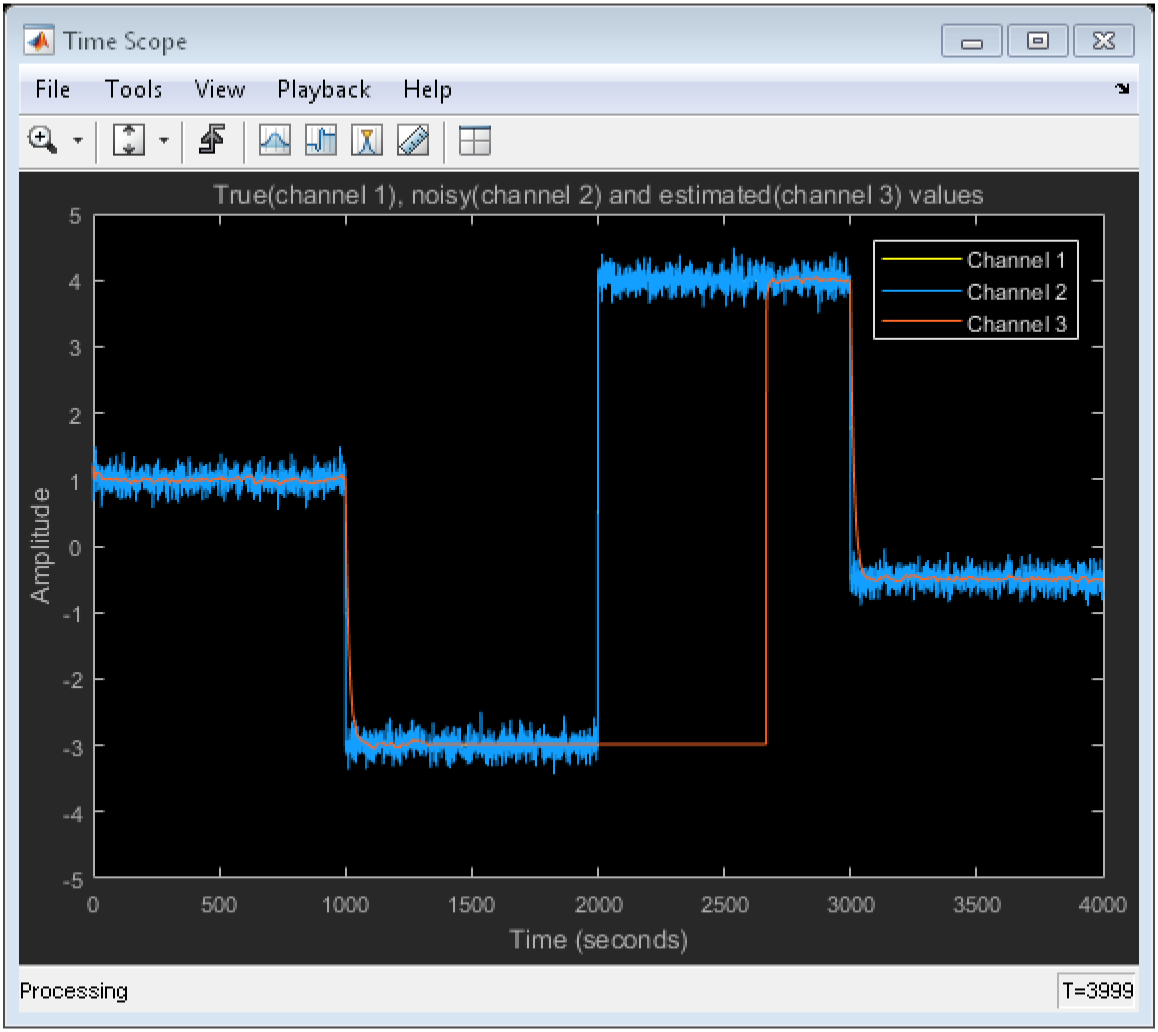
Create the signal, Kalman Filter, and Time Scope System objects.

```
numSamples = 4000;
R = 0.02;
src = dsp.SignalSource;
src.Signal = [  ones(numSamples/4,1);   -3*ones(numSamples/4,1);...
              4*ones(numSamples/4,1); -0.5*ones(numSamples/4,1)];
tScope = dsp.TimeScope('NumInputPorts', 3, 'TimeSpan', numSamples, ...
          'TimeUnits', 'Seconds', 'YLimits',[-5 5], ...
          'Title', ['True(channel 1), noisy(channel 2) and ',...
          'estimated(channel 3) values'], ...
          'ShowLegend', true);
kalman = dsp.KalmanFilter('ProcessNoiseCovariance', 0.0001,...
          'MeasurementNoiseCovariance', R,...
          'InitialStateEstimate', 5,...
          'InitialErrorCovarianceEstimate', 1,...
          'ControlInputPort',false);
ctr = 0;
```

Add noise to the signal. Stream the data, and plot the filtered signal.

```
while(~isDone(src))
    trueVal = src();
    noisyVal = trueVal + sqrt(R)*randn;
    estVal = kalman(noisyVal);
    tScope(trueVal,noisyVal,estVal);

    % Disabling the correction step of second filter for the middle
    % one-third of the simulation
    if ctr == floor(numSamples/3)
        kalman.DisableCorrection = true;
    end
    if ctr == floor(2*numSamples/3)
        kalman.DisableCorrection = false;
    end
    ctr = ctr + 1;
end
```



Use a Single System object to Track Multiple Scalar Values

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

Create the signal where the columns are the two scalar values to be tracked. Also create the Kalman Filter, and the Time Scopes.

```
numSamples = 4000;
R = 0.02;
src = dsp.SignalSource;
sig1 = [  ones(numSamples/4,1);   -3*ones(numSamples/4,1);...
         4*ones(numSamples/4,1); -0.5*ones(numSamples/4,1)];
sig2 = [-2*ones(numSamples/4,1);   4*ones(numSamples/4,1);...
        -3*ones(numSamples/4,1); 1.5*ones(numSamples/4,1)];

src.Signal = [sig1, sig2];

tScope1 = dsp.TimeScope('NumInputPorts', 3, 'TimeSpan', numSamples, ...
           'TimeUnits', 'Seconds', 'YLimits',[-5 5], ...
           'Title', ['True(channel 1), noisy(channel 2) and ',...
           'estimated(channel 3) values'], ...
           'ShowLegend', true);
tScope2 = clone(tScope1);
kalman = dsp.KalmanFilter('ProcessNoiseCovariance', 0.0001,...
    'MeasurementNoiseCovariance', R,...
    'InitialStateEstimate', -3,...
    'InitialErrorCovarianceEstimate', 1,...
    'ControlInputPort',false);
```

Add noise to the signal. Stream the data, and plot the filtered signal.

```
while(~isDone(src))
    trueVal = src();
    noisyVal = trueVal + sqrt(R)*randn(1,2);
    estVal = kalman(noisyVal);
           % Plot results of first channel on Time Scope
    tScope1(trueVal(:,1),noisyVal(:,1),estVal(:,1));
           % Plot results of second channel on Time Scope
    tScope2(trueVal(:,2),noisyVal(:,2),estVal(:,2));
end
```

Use a Unit Step To Track a Ramp Signal

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

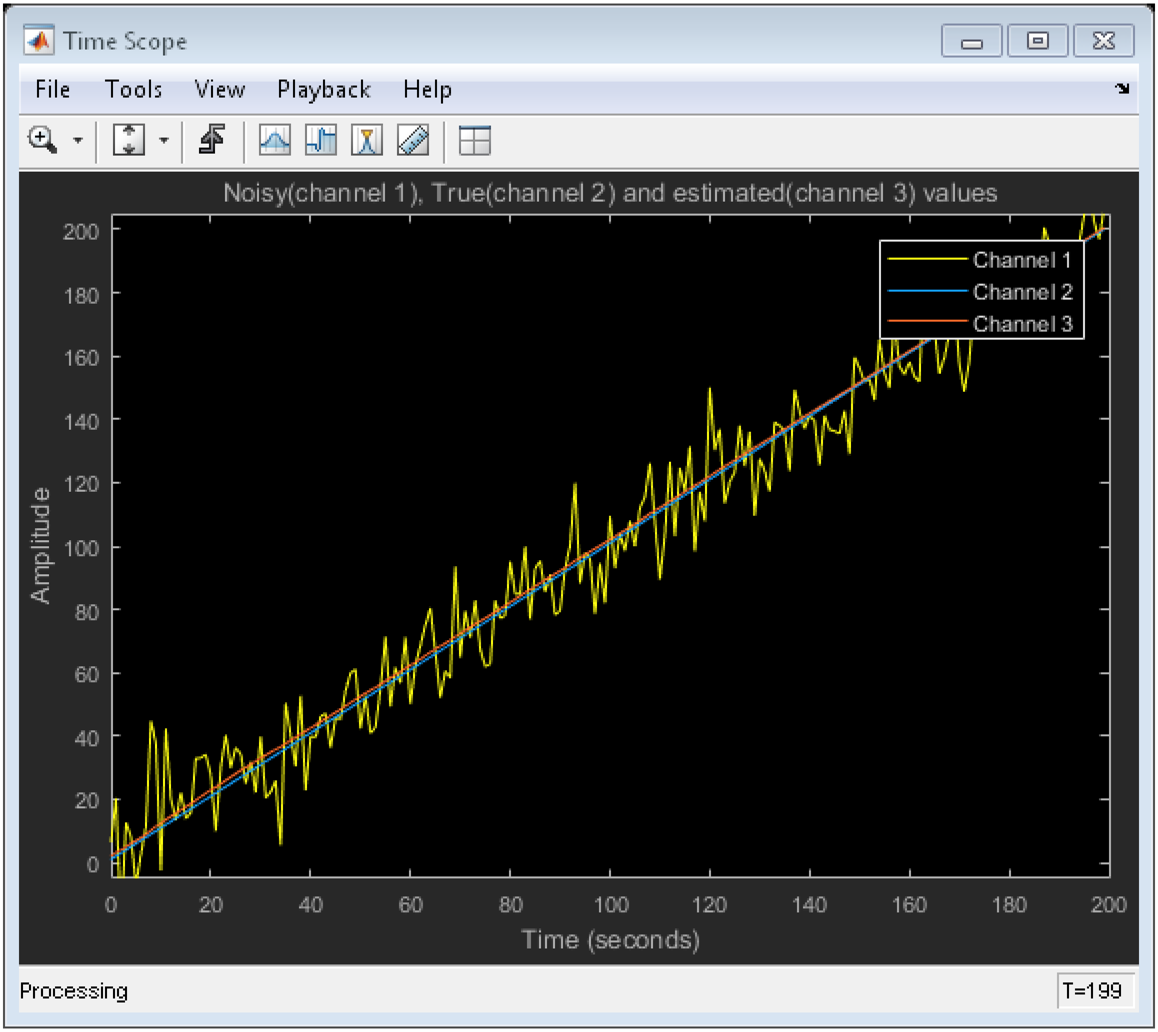
Use a unit step as the control input to track a ramp signal. Create the ramp signal to be tracked, the control input, the Time Scope, and the Kalman Filter.

```
numSamples = 200;
R = 100;
src = dsp.SignalSource;
src.Signal = (1:numSamples)';
control = dsp.SignalSource;
control.Signal = ones(numSamples,1);

tScope = dsp.TimeScope('NumInputPorts', 3, 'TimeSpan', numSamples, ...
    'TimeUnits', 'Seconds', 'YLimits',[-5 205], ...
    'Title', ['Noisy(channel 1), True(channel 2) and ',...
    'estimated(channel 3) values'], ...
    'ShowLegend', true);
kalman = dsp.KalmanFilter('ProcessNoiseCovariance', 0.0001,...
    'MeasurementNoiseCovariance', R,...
    'InitialStateEstimate', 1,...
    'InitialErrorCovarianceEstimate', 1);
```

Add noise to the signal. Filter the signal using kalman filter. View the output using time scope.

```
while(~isDone(src))
    trueVal = src();
    ctrl = control();
    noisyVal = trueVal + sqrt(R)*randn;
    estVal = kalman(noisyVal,ctrl);
    tScope(noisyVal,trueVal,estVal);
end
```



Algorithms

This object implements the algorithm, inputs, and outputs described on the `Kalman Filter` block reference page. The object properties correspond to the block parameters.

`Kalman Filter`

Introduced in R2013b

reset

System object: dsp.KalmanFilter
Package: dsp

Reset internal states of Kalman filter

Syntax

`reset(kalman)`

Description

`reset(kalman)` resets the internal states of the Kalman filter object, `kalman`, to their initial values. The reset method is always a no-op for unlocked System objects, as the states may not be allocated when the object is not locked.

step

System object: dsp.KalmanFilter
Package: dsp

Filter input with Kalman filter object

Syntax

```
Y = step(kalman,X)
[Y1,...,YN] = step(kalman,X)
[zEst, xEst, MSE_Est, zPred, xPred, MSE_Pred] = step(kalman, z, u)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(kalman,X)` processes the input data, `X` to produce the output, `Y`, for System object, `kalman`.

`[Y1,...,YN] = step(kalman,X)` produces `N` outputs.

`[zEst, xEst, MSE_Est, zPred, xPred, MSE_Pred] = step(kalman, z, u)` Carries out the iterative Kalman filter algorithm over measurements `z` and control inputs `u`. The columns in `z` and `u` are treated as inputs to separate parallel filters, whose correction (or update) step can be disabled by the `DisableCorrection` property. The values returned are estimated measurements `z_est`, estimated states `x_est`, MSE of estimated states `MSE_Est`, predicted measurements `zPred`, predicted states `xPred` and MSE of predicted states `MSE_Pred`.

Note: `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.LDLFactor System object

Package: dsp

Factor square Hermitian positive definite matrices into components

Description

The `LDLFactor` object factors square Hermitian positive definite matrices into lower, upper, and diagonal components. The object uses only the lower triangle of S.

To factor these matrices into lower, upper, and diagonal components:

1. Define and set up your LDL factor object. See "Construction" on page 4-1081.
2. Call step to factor the matrices according to the properties of `dsp.LDLFactor`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`ldl = dsp.LDLFactor` returns an LDL factor System object, `ldl`, that computes unit lower triangular `L` and diagonal `D` such that `S` = LDL for square, symmetric/Hermitian, positive definite input matrix `S`.

`ldl = dsp.LDLFactor('`*`PropertyName`*`',`*`PropertyValue`*`,...)` returns an `LDL` factor System object, `ldl`, with each specified property set to the specified value.

Properties

Fixed-Point Properties

AccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point data type as `Full precision`, `Same as input`, `Same as product` or `Custom`. The default is `Full precision`

CustomAccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `AccumulatorDataType on page 4-1082` property to `Custom`. The default is `numerictype([],32,30)`.

CustomIntermediateProductDataType

Intermediate product word and fraction lengths

Specify the intermediate product fixed-point type as a signed, scaled `numerictype` object. This property applies when you set the `IntermediateProductDataType on page 4-1083` property to `Custom`. The default is `numerictype(true,16,15)`.

CustomOutputDataType

Output word and fraction lengths

Specify the output fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `OutputDataType on page 4-1083` property to `Custom`. The default is `numerictype([],16,15)`.

CustomProductDataType

Product word and fraction lengths

Specify the product fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `ProductDataType on page 4-1083` property to `Custom`. The default is `numerictype([],32,30)`.

IntermediateProductDataType

Intermediate product word and fraction lengths

Specify the intermediate product fixed-point data type as `Same as input` or `Custom`. The default is `Same as input`.

OutputDataType

Output word and fraction lengths

Specify the output fixed-point data type as `Same as input` or `Custom`. The default is `Same as input`.

OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as one of `Wrap` or `Saturate`. The default is `Wrap`.

ProductDataType

Product word and fraction lengths

Specify the product fixed-point data type as `Full precision`, `Same as input` or `Custom`. The default is `Full precision`.

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as: `Ceiling`, `Convergent`, `Floor`, `Nearest`, `Round`, `Simplest` or `Zero`. The default is `Floor`.

Methods

step	Decompose matrix into components

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object

Common to All System Objects	
getNumOutp	Expected number of outputs of a System object
isLocked	Check locked states of a System object (logical)
release	Allow System object property value changes

Examples

Decompose a Matrix

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

Decompose a square Hermitian positive definite matrix using LDL factor.

```
A = gallery('randcorr',5);
ldl = dsp.LDLFactor;
y = ldl(A);
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the `LDL Factorization` block reference page. The object properties correspond to the block parameters, except:
No object property that corresponds to the **Non-positive definite input** block parameter. The object does not issue any alerts for nonpositive definite inputs. The output is not a valid factorization. A partial factorization is in the upper left corner of the output.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

dsp.LUFactor

Introduced in R2012a

step

System object: dsp.LDLFactor
Package: dsp

Decompose matrix into components

Syntax

`Y = step(ldl,S)`

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(ldl,S)` decomposes the matrix `S` into lower, upper, and diagonal components. The output `Y` is a composite matrix with the `L` as its lower triangular part and `D` as the diagonal and `L'` as its upper triangular part. If `S` is not positive definite the output `Y` is not a valid factorization.

Note: `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

dsp.LevinsonSolver System object

Package: dsp

Solve linear system of equations using Levinson-Durbin recursion

Description

The `LevinsonSolver` object solves linear systems of equations using Levinson-Durbin recursion.

To solve linear systems of equations using Levinson-Durbin recursion:

1. Define and set up your System object. See "Construction" on page 4-1087.
2. Call step to solve the system of equations according to the properties of `dsp.LevinsonSolver`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`levinson = dsp.LevinsonSolver` returns a System object, `levinson`, that solves a Hermitian Toeplitz system of equations using the Levinson-Durbin recursion.

`levinson = dsp.LevinsonSolver('PropertyName',PropertyValue,...)` returns a Levinson-Durbin object, `levinson`, with each specified property set to the specified value.

Properties

`AOutputPort`

Enable polynomial coefficients output

Set this property to `true` to output the polynomial coefficients *A*. Both `AOutputPort` and `KOutputPort on page 4-1088` properties cannot be `false` at the same time. For scalar inputs, set the `AOutputPort` property to `true`. The default is `false`.

KOutputPort

Enable reflection coefficients output

Set this property to `true` to output the reflection coefficients *K*. You cannot set both the `AOutputPort on page 4-1087` and `KOutputPort` properties to `false` at the same time. For scalar inputs, you must set the `KOutputPort` property to `false`. The default is `true`.

PredictionErrorOutputPort

Enable prediction error output

Set this property to `true` to output the prediction error. The default is `false`.

ZerothLagZeroAction

Action when value of lag zero is zero

Specify the output for an input with the first coefficient as zero. Select `Ignore` or `Use zeros`. The default is `Use zeros`.

Fixed-Point Properties

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as `Ceiling`, `Convergent`, `Floor`, `Nearest`, `Round`, `Simplest`, or `Zero`. The default is `Floor`.

OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as `Wrap`, `Saturate`. The default is `Wrap`.

ACoefficientDataType

A coefficient word and fraction lengths

This constant property has a value of `Custom`.

CustomACoefficientDataType

A coefficient word and fraction lengths

Specify the *A* coefficient fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. The default is `numerictype([],16,15)`.

KCoefficientDataType

K coefficient word and fraction lengths

This constant property has a value of `Custom`.

CustomKCoefficientDataType

K coefficient word and fraction lengths

Specify the *K* coefficient fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. The default is `numerictype([],16,15)`.

PredictionErrorDataType

Prediction error power word and fraction lengths

Specify the prediction error power fixed-point data type as `Same as input` or `Custom`. The default is `Same as input`.

CustomPredictionErrorDataType

Prediction error power word and fraction lengths

Specify the prediction error power fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when the `PredictionErrorDataType on page 4-1089` property is `Custom`. The default is `numerictype([],16,15)`.

ProductDataType

Product word and fraction lengths

Specify the product fixed-point data type as `Same as input` or `Custom`. The default is `Custom`

`CustomProductDataType`

Product word and fraction lengths

Specify the product fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when the `ProductDataType` on page 4-1089 property is `Custom`. The default is `numerictype([],32,30)`.

`AccumulatorDataType`

Accumulator word and fraction lengths

Specify the Accumulator fixed-point data type as `Same as input`, `Same as product`, or `Custom`. The default is `Custom`.

`CustomAccumulatorDataType`

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when the `AccumulatorDataType` on page 4-1090 property is `Custom`. The default is `numerictype([],32,30)`.

Methods

step	Reflection coefficients corresponding to columns of input

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Compute Polynomial Coefficients

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

Use the Levinson solver to compute polynomial coefficients from autocorrelation coefficients.

```
levinson = dsp.LevinsonSolver;
levinson.AOutputPort = true;
levinson.KOutputPort = false;
x = (1:100)';
ac = dsp.Autocorrelator(...
'MaximumLagSource', 'Property', ...
'MaximumLag', 10);
a = ac(x);
c = levinson(a); % Compute polynomial coefficients
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the `Levinson-Durbin` block reference page. The object properties correspond to the block parameters, except:
Output(s) block parameter corresponds to the `AOutputPort` and the `KOutputPort` object properties.

step

System object: dsp.LevinsonSolver
Package: dsp

Reflection coefficients corresponding to columns of input

Syntax

```
K = step(levinson,X)
A = step(levinson,X)
[A, K] = step(levinson,X)
[..., P] = step(levinson,X)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`K = step(levinson,X)` returns reflection coefficients `K` corresponding to the columns of input `X`. `X` is typically a column or matrix of autocorrelation coefficients with lag `0` as the first element.

`A = step(levinson,X)` returns polynomial coefficients `A` when the `AOutputPort` property is `true` and the `KOutputPort` property is `false`.

`[A, K] = step(levinson,X)` returns polynomial coefficients `A` and reflection coefficients `K` when both the `AOutputPort` and `KOutputPort` properties are `true`.

`[..., P] = step(levinson,X)` also returns the error power `P` when the `PredictionErrorOutputPort` property is `true`.

Note: `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.LMSFilter System object

Package: dsp

LMS adaptive filter

Description

The `LMSFilter` implements an adaptive FIR filter object that returns the filtered output, the error vector, and filter weights. The LMS filter uses one of five different LMS algorithms.

To implement the adaptive FIR filter object:

1. Define and set up your adaptive FIR filter object. See "Construction" on page 4-1095.
2. Call step to implement the filter according to the properties of `dsp.LMSFilter`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`lms = dsp.LMSFilter` returns an adaptive FIR filter object, `lms`, that computes the filtered output, filter error and the filter weights for a given input and desired signal using the Least Mean Squares (LMS) algorithm.

`lms = dsp.LMSFilter('`*`PropertyName`*`', `*`PropertyValue`*`,...)` returns an LMS filter object, `lms`, with each property set to the specified value.

`lms = dsp.LMSFilter(LEN,'`*`PropertyName`*`',`*`PropertyValue`*`,...)` returns an LMS filter object, `lms`, with the `Length` property set to `LEN`, and other specified properties set to the specified values.

Properties

Method

Method to calculate filter weights

Specify the method used to calculate filter weights as LMS, Normalized LMS, Sign-Error LMS, Sign-Data LMS, or Sign-Sign LMS. The default is LMS.

Length

Length of FIR filter weights vector

Specify the length of the FIR filter weights vector as a positive integer. The default is 32.

StepSizeSource

How to specify adaptation step size

Choose how to specify the adaptation step size factor as Property or Input port. The default is Property.

StepSize

Adaptation step size

Specify the adaptation step size factor as a nonnegative real number. For convergence of the normalized LMS method, set the step size greater than 0 and less than 2. This property only applies when the StepSizeSource on page 4-1096 property is Property. The default is 0.1. This property is tunable.

LeakageFactor

Leakage factor used in LMS filter

Specify the leakage factor as a real number between 0 and 1 inclusive. A leakage factor of 1 corresponds to no leakage in the adapting method. The default is 1. This property is tunable.

InitialConditions

Initial conditions of filter weights

Specify the initial values of the FIR filter weights as a scalar or vector of length equal to the `Length` property value. The default is `0`.

AdaptInputPort

Enable weight adaptation

Specify when the LMS filter should adapt the filter weights. By default, the value of this property is `false`, and the object continuously updates the filter weights. When this property is set to `true`, an adaptation control input is provided to the `step` method. If the value of this input is nonzero, the object continuously updates the filter weights. If the input is zero, the filter weights remain at their current value.

WeightsResetInputPort

Enable weight reset

Specify when the LMS filter should reset the filter weights. By default, the value of this property is `false`, and the object does not reset the weights. When this property is set to `true`, a reset control input is provided to the `step` method, and the `WeightsResetCondition` on page 4-1097 property applies. The object resets the filter weights based on the values of the `WeightsResetCondition` property and the `reset` input to the `step` method.

WeightsResetCondition

Reset trigger setting for filter weights

Specify the event to reset the filter weights as `Rising edge`, `Falling edge`, `Either edge`, or `Non-zero`. The LMS filter resets the filter weights based on the values of this property and the `reset` input to the `step` method. This property only applies when the `WeightsResetInputPort` on page 4-1097 property is `true`. The default is `Non-zero`.

WeightsOutput

Enable returning filter weights

Specify how to output the adapted filter weights as one of the following:

- `'Last'` (default) — The object returns a column vector of weights corresponding to the last sample of the data frame. The length of the weights vector is the value given by the `Length` property.

- 'All' — The object returns a *FrameLength*-by-*Length* matrix of weights. The matrix corresponds to the full sample-by-sample history of weights values for all *FrameLength* samples of the input values. Each row in the matrix corresponds to a set of LMS filter weights calculated for the corresponding input sample.
- 'None' — This setting disables the weights output.

Fixed-Point Properties

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as Ceiling, Convergent, Floor, Nearest, Round, Simplest, or Zero. The default is Floor.

OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as Wrap or Saturate. The default is Wrap.

StepSizeDataType

Step size word and fraction lengths

Specify the step size fixed-point data type as Same word length as first input or Custom. Setting this property also sets the LeakageFactorDataType on page 4-1098 property to the same value. This property only applies when the StepSizeSource on page 4-1096 property is Property. The default is Same word length as first input.

CustomStepSizeDataType

Step size word and fraction lengths

Specify the step size fixed-point type as a numerictype object with a Signedness of Auto. This property only applies when the StepSizeSource on page 4-1096 property is Property and the StepSizeDataType on page 4-1098 property is Custom. The default is numerictype([],16,15).

LeakageFactorDataType

Leakage factor word and fraction lengths

Specify the leakage factor fixed-point data type as `Same word length as first input` or `Custom`. Setting this property also sets the `StepSizeDataType` on page 4-1098 property to the same value. This property only applies when the `StepSizeSource` on page 4-1096 property is `Property`. The default is `Same word length as first input`.

CustomLeakageFactorDataType

Leakage factor word and fraction lengths

Specify the leakage factor fixed-point type as a `numerictype` object with a `Signedness` of `Auto`. This property only applies when the `StepSizeSource` on page 4-1096 property is `Property` and the `LeakageFactorDataType` on page 4-1098 property is `Custom`. The default is `numerictype([],16,15)`.

WeightsDataType

Weights word and fraction lengths

Specify the filter weights fixed-point data type as `Same as first input` or `Custom`. The default is `Same as first input`.

CustomWeightsDataType

Weights word and fraction lengths

Specify the filter weights fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property only applies when the `WeightsDataType` on page 4-1099 property is `Custom`. The default is `numerictype([],16,15)`.

EnergyProductDataType

Energy product word and fraction lengths

Specify the energy product fixed-point data type as `Same as first input` or `Custom`. This property only applies when the `Method` property is `Normalized LMS`. Setting this property also sets the `ConvolutionProductDataType` on page 4-1100, `StepSizeErrorProductDataType` on page 4-1101, `WeightsUpdateProductDataType` on page 4-1101, and `QuotientDataType` on page 4-1102 properties to the same value. The default is `Same as first input`.

CustomEnergyProductDataType

Energy product word and fraction lengths

Specify the energy product fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property only applies when the `Method` on page 4-1096 property is `Normalized LMS` and the `EnergyProductDataType` on page 4-1099 property is `Custom`. The default is `numerictype([],32,20)`.

EnergyAccumulatorDataType

Energy accumulator word and fraction lengths

Specify the energy accumulator fixed-point data type as `Same as first input` or `Custom`. This property only applies when the `Method` on page 4-1096 property is `Normalized LMS`. Setting this property also sets the `ConvolutionAccumulatorDataType` on page 4-1101 property to the same value. The default is `Same as first input`.

CustomEnergyAccumulatorDataType

Energy accumulator word and fraction lengths

Specify the energy accumulator fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property only applies when the `Method` on page 4-1096 property is `Normalized LMS` and the `EnergyAccumulatorDataType` on page 4-1100 property is `Custom`. The default is `numerictype([],32,20)`.

ConvolutionProductDataType

Convolution product word and fraction lengths

Specify the convolution product fixed-point data type as `Same as first input` or `Custom`. Setting this property also sets the `EnergyProductDataType` on page 4-1099, `StepSizeErrorProductDataType` on page 4-1101, `WeightsUpdateProductDataType` on page 4-1101 and `QuotientDataType` on page 4-1102 properties to the same value. The default is `Same as first input`.

CustomConvolutionProductDataType

Convolution product word and fraction lengths

Specify the convolution product fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property only applies when the `ConvolutionProductDataType` on page 4-1100 property is `Custom`. The default is `numerictype([],32,20)`.

ConvolutionAccumulatorDataType

Convolution accumulator word and fraction lengths

Specify the convolution accumulator fixed-point data type as `Same as first input` or `Custom`. Setting this property also sets the `EnergyAccumulatorDataType` on page 4-1100 property to the same value. The default is `Same as first input`.

CustomConvolutionAccumulatorDataType

Convolution accumulator word and fraction lengths

Specify the convolution accumulator fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property only applies when the `ConvolutionAccumulatorDataType` on page 4-1101 property is `Custom`. The default is`numerictype([],32,20)`.

StepSizeErrorProductDataType

Step size error product word and fraction lengths

Specify the step size error product fixed-point data type as `Same as first input` or `Custom`. Setting this property also sets the `ConvolutionProductDataType` on page 4-1100, `EnergyProductDataType` on page 4-1099, `WeightsUpdateProductDataType` on page 4-1101, and `QuotientDataType` on page 4-1102 properties to the same value. The default is `Same as first input`.

CustomStepSizeErrorProductDataType

Step size error product word and fraction lengths

Specify the step size error product fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property only applies when the `StepSizeErrorProductDataType` on page 4-1101 property is `Custom`. The default is `numerictype([],32,20)`.

WeightsUpdateProductDataType

Weight update product word and fraction lengths

Specify the weight update product fixed-point data type as `Same as first input` or`Custom`. Setting this property also sets the `ConvolutionProductDataType` on page 4-1100, EnergyProductDataType on page 4-1099, StepSizeErrorProductDataType on page 4-1101, and QuotientDataType on page 4-1102 properties to the same value. The default is Same as first input.

CustomWeightsUpdateProductDataType

Weight update product word and fraction lengths

Specify the weight update product fixed-point type as a scaled numerictype object with a Signedness of Auto. This property only applies when the WeightsUpdateProductDataType on page 4-1101 property is Custom. The default is numerictype([],32,20).

QuotientDataType

Quotient word and fraction lengths

Specify the quotient fixed-point data type as one of Same as first input or Custom. This property only applies when the Method on page 4-1096 property is Normalized LMS. Setting this property also sets the ConvolutionProductDataType on page 4-1100, EnergyProductDataType on page 4-1099, StepSizeErrorProductDataType on page 4-1101, and WeightsUpdateProductDataType on page 4-1101 properties to the same value. The default is Same as first input.

CustomQuotientDataType

Quotient word and fraction lengths

Specify the quotient fixed-point type as a scaled numerictype object with a Signedness of Auto. This property only applies when the Method on page 4-1096 property is Normalized LMS and the QuotientDataType on page 4-1102 property is Custom. The default is numerictype([],32,20).

Methods

maxstep	Maximum step size for LMS adaptive filter convergence

msepred	Predicted mean-square error for LMS filter
msesim	Mean-squared error for LMS filter
reset	Reset filter states for LMS filter
step	Apply LMS adaptive filter to input

Common to All System Objects	
clone	Create System object with same property values
getNumInpu	Expected number of inputs to a System object
getNumOutp	Expected number of outputs of a System object
isLocked	Check locked states of a System object (logical)
release	Allow System object property value changes

Examples

System Identification Using LMS Filter

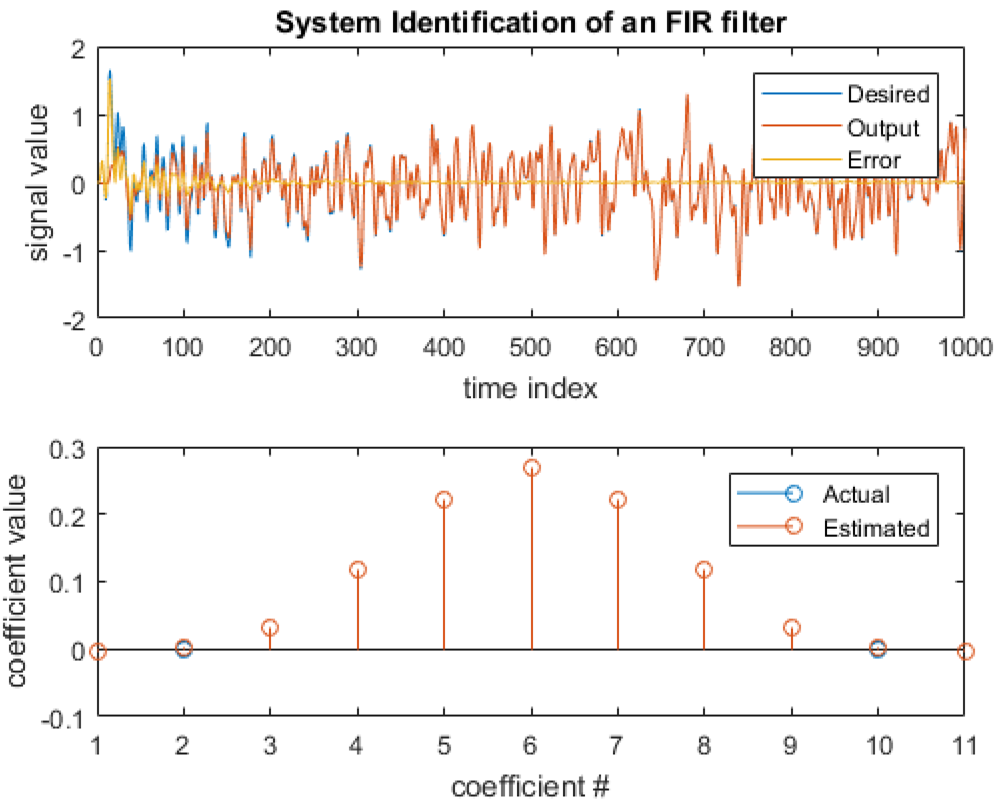
Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

```
lms1 = dsp.LMSFilter(11,'StepSize',0.01);
filt = dsp.FIRFilter; % System to be identified
filt.Numerator = fir1(10,.25);
x = randn(1000,1); % input signal

d = filt(x) + 0.01*randn(1000,1); % desired signal
[y,e,w] = lms1(x,d);

subplot(2,1,1);
plot(1:1000, [d,y,e]);
title('System Identification of an FIR filter');
legend('Desired', 'Output', 'Error');
xlabel('time index');
ylabel('signal value');
subplot(2,1,2);
stem([filt.Numerator.',w]);
```

```
legend('Actual','Estimated');
xlabel('coefficient #');
ylabel('coefficient value');
```



Cancel Noise Using LMS Filter

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

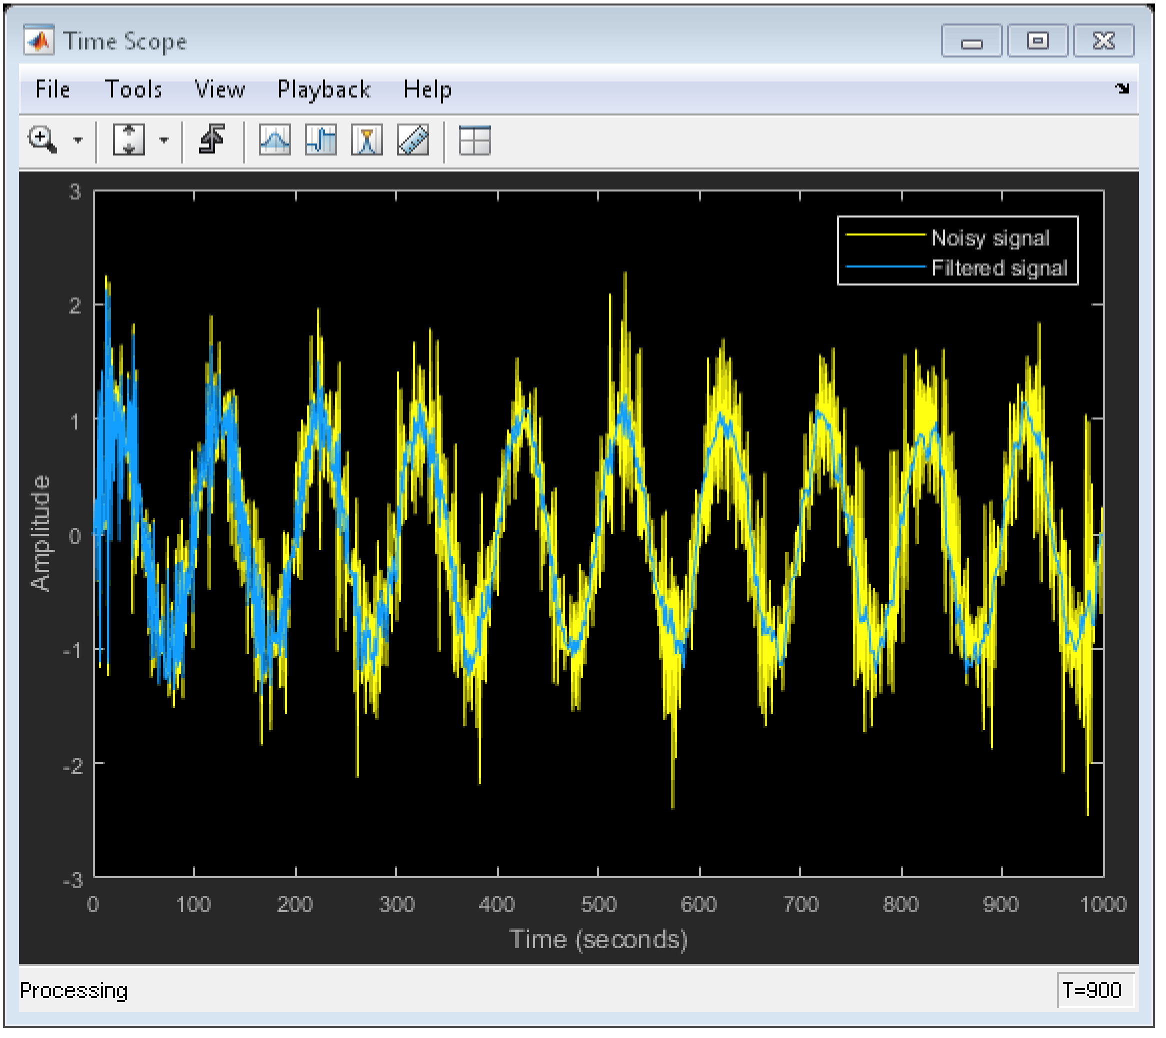
Initialize the LMS filter with a length of 11 and step size of 0.05.

```
FrameSize = 100; NIter = 10;
```

```
lmsfilt2 = dsp.LMSFilter('Length',11,'Method','Normalized LMS', ...
    'StepSize',0.05);
firfilt2 = dsp.FIRFilter('Numerator', fir1(10,[.5, .75]));
sinewave = dsp.SineWave('Frequency',0.01, ...
    'SampleRate',1,'SamplesPerFrame',FrameSize);
TS = dsp.TimeScope('TimeSpan',FrameSize*NIter,'TimeUnits','Seconds',...
    'YLimits',[-3 3],'BufferLength',2*FrameSize*NIter, ...
    'ShowLegend',true,'ChannelNames', ...
    {'Noisy signal', 'Filtered signal'});
```

Pass the noisy input signal into the LMS filter and view the filtered output in the time scope.

```
for k = 1:NIter
    x = randn(FrameSize,1);       % Input signal
    d = firfilt2(x) + sinewave(); % Noise + Signal
    [y,e,w] = lmsfilt2(x,d);
    TS([d,e]);          % Noisy = channel 1; Filtered = channel 2
end
```



Access the Full History of LMS Filter Weights

Note: This example runs only in R2017a or later. If you are using a release earlier than R2017a, the object does not output a full sample-by-sample history of filter weights. If you are using a release earlier than R2016b, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

Initialize the `dsp.LMSFilter` System object™ and set the `WeightsOutput` property to `'All'`. This setting enables the LMS filter to output a matrix of weights with dimensions `[FrameLength Length]`, corresponding to the full sample-by-sample history of weights for all `FrameLength` samples of input values.

```
FrameSize = 15000;
lmsfilt3 = dsp.LMSFilter('Length',63,'Method','LMS', ...
    'StepSize',0.001,'LeakageFactor',0.99999, ...
    'WeightsOutput','All'); % full Weights history

w_actual = fir1(64,[0.5 0.75]);
firfilt3 = dsp.FIRFilter('Numerator',w_actual);
sinewave = dsp.SineWave('Frequency',0.01, ...
    'SampleRate',1,'SamplesPerFrame',FrameSize);

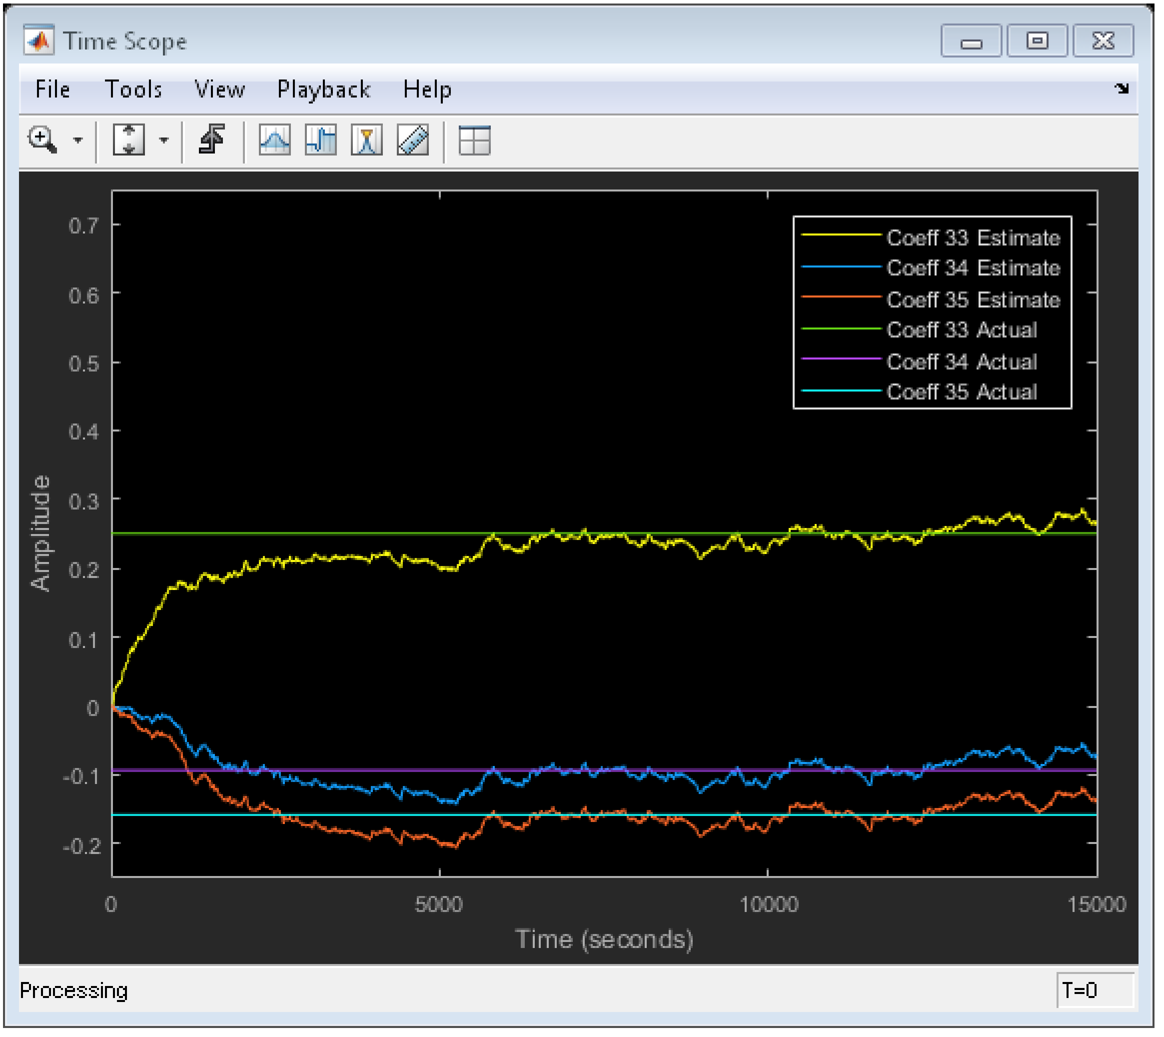
TS = dsp.TimeScope('TimeSpan',FrameSize,'TimeUnits','Seconds', ...
    'YLimits',[-0.25 0.75],'BufferLength',2*FrameSize, ...
    'ShowLegend',true,'ChannelNames', ...
    {'Coeff 33 Estimate','Coeff 34 Estimate','Coeff 35 Estimate', ...
    'Coeff 33 Actual','Coeff 34 Actual','Coeff 35 Actual'});
```

Run one frame and output the full adaptive weights history, `w`.

```
x = randn(FrameSize,1);       % Input signal
d = firfilt3(x) + sinewave(); % Noise + Signal
[~,~,w] = lmsfilt3(x,d);
```

Each row in `w` is a set of weights estimated for the respective input sample. Each column in `w` gives the complete history of a specific weight. Plot the actual weight and the entire history of the 33rd, 34th, and the 35th weight. In the plot, you can see that the estimated weight output eventually converges with the actual weight as the adaptive filter receives input samples and continues to adapt.

```
idxBeg = 33;
idxEnd = 35;
TS([w(:,idxBeg:idxEnd), repmat(w_actual(idxBeg:idxEnd),FrameSize,1)]);
```



Algorithms

This filter's algorithm is defined by the following equations.

$$y(n) = \mathbf{w}^T(n-1)\mathbf{u}(n)$$
$$e(n) = d(n) - y(n)$$
$$\mathbf{w}(n) = \alpha\mathbf{w}(n-1) + f(\mathbf{u}(n), e(n), \mu)$$

The various LMS adaptive filter algorithms available in this System object are defined as:

- LMS:

  $$f(\mathbf{u}(n), e(n), \mu) = \mu e(n)\mathbf{u}^*(n)$$

- Normalized LMS:

  $$f(\mathbf{u}(n), e(n), \mu) = \mu e(n)\frac{\mathbf{u}^*(n)}{\varepsilon + \mathbf{u}^H(n)\mathbf{u}(n)}$$

- Sign-Error LMS:

  $$f(\mathbf{u}(n), e(n), \mu) = \mu\, sign(e(n))\mathbf{u}^*(n)$$

- Sign-Data LMS:

  $$f(\mathbf{u}(n), e(n), \mu) = \mu e(n)\, sign(\mathbf{u}(n))$$

  where **u**(n) is real.
- Sign-Sign LMS:

  $$f(\mathbf{u}(n), e(n), \mu) = \mu\, sign(e(n))\, sign(\mathbf{u}(n))$$

  where **u**(n) is real.

The variables are as follows:

Variable	Description
n	The current time index
$\mathbf{u}(n)$	The vector of buffered input samples at step n

Variable	Description
u*(n)	The complex conjugate of the vector of buffered input samples at step n
w(n)	The vector of filter weight estimates at step n
$y(n)$	The filtered output at step n
$e(n)$	The estimation error at step n
$d(n)$	The desired response at step n
μ	The adaptation step size
α	The leakage factor ($0 < \alpha \leq 1$)

Blocks
`LMS Filter`

Introduced in R2012a

maxstep

System object: dsp.LMSFilter
Package: dsp

Maximum step size for LMS adaptive filter convergence

Syntax

```
MUMAX = maxstep(lms,X)
[MUMAX,MUMAXMSE] = maxstep(lms,X)
```

Description

`MUMAX = maxstep(lms,X)` predicts a bound on the step size to provide convergence of the mean values of the adaptive filter coefficients. The columns of the matrix X contain individual input signal sequences. The signal set is assumed to have zero mean or nearly so.

`[MUMAX,MUMAXMSE] = maxstep(lms,X)` predicts a bound on the adaptive filter step size to provide convergence of the adaptive filter coefficients in mean square.

Examples

Compute the Maximum Step of the LMS Adaptive Filter

Analyze and simulate a 32-coefficient (31st-order) LMS adaptive filter object. To demonstrate the adaptation process, run 2000 iterations and 50 trials.

Specify [numiterations,numexamples] = size(x);

```
x = zeros(2000,50);
d = x;
lp = fdesign.lowpass('n,fc',31,0.5);
FIRFilter = design(lp,'window','SystemObject',true);
coef = FIRFilter.Numerator;
```

Create input and desired response signal matrices.

```
for k=1:size(x,2)
% Set the kth input to the filter.
  x(:,k) = filter(sqrt(0.75),[1 -0.5],sign(randn(size(x,1),1)));
  n = 0.1*randn(size(x,1),1);  % (k)th observation noise signal.
  d(:,k) = filter(coef,1,x(:,k))+n; % (k)th desired signal end.
end
mu = 0.1;      % LMS step size.
LMSFilter = dsp.LMSFilter('Length',32,'StepSize',mu);
```

Compute the maximum step of the filter.

```
[mumax,mumaxmse] = maxstep(LMSFilter,x)
```

```
mumax =

    0.0628

mumaxmse =

    0.0536
```

msepred

System object: dsp.LMSFilter
Package: dsp

Predicted mean-square error for LMS filter

Syntax

```
[MMSE,EMSE] = msepred(sysObj,X,D)
[MMSE,EMSE,MEANW,MSE,TRACEK] = msepred(sysObj,X,D)
[MMSE,EMSE,MEANW,MSE,TRACEK] = msepred(sysObj,X,D,M)
```

Description

`[MMSE,EMSE] = msepred(sysObj,X,D)` predicts the steady-state values at convergence of the minimum mean-squared error (`MMSE`) and the excess mean-squared error (`EMSE`) given the input and desired response signal sequences in `X` and `D` and the quantities in the adaptive filter `sysObj`.

`[MMSE,EMSE,MEANW,MSE,TRACEK] = msepred(sysObj,X,D)` calculates three sequences corresponding to the analytical behavior of the adaptive filter defined by `sysObj`. `MEANW` is the sequence of coefficient vector means. The columns of this matrix contain predictions of the mean values of the adaptive filter coefficients at each time instant. The dimensions of `MEANW` are `(SIZE(X,1))` by `(H.length)`. `MSE` is the sequence of mean-square errors. This column vector contains predictions of the mean-square error of the adaptive filter at each time instant. The length of `MSE` is equal to `SIZE(X,1)`. `TRACEK` is a sequence of total coefficient error powers. This column vector contains predictions of the total coefficient error power of the adaptive filter at each time instant. The length of `TRACEK` is equal to `SIZE(X,1)`.

`[MMSE,EMSE,MEANW,MSE,TRACEK] = msepred(sysObj,X,D,M)` specifies an optional decimation factor for computing `MEANW`, `MSE`, and `TRACEK`. If `M > 1`, every M^{th} predicted value of each of these sequences is saved. If omitted, the value of `M` is the default, which is one.

Examples

Predict Mean Square Error for LMS Filter

```
x = zeros(2000,25); d = x;
firCoeff = fir1(31,0.5);
x = filter(sqrt(0.75),[1 -0.5],sign(randn(size(x))));
n = 0.1*randn(size(x));
d = filter(firCoeff,1,x)+n;
l = 32;
mu = 0.008;
m  = 5;

lms = dsp.LMSFilter('Length',l,'StepSize',mu);
[mmse,emse,meanW,mse,traceK] = msepred(lms,x,d,m);
[simmse,meanWsim,Wsim,traceKsim] = msesim(lms,x,d,m);
nn = m:m:size(x,1);
subplot(2,1,1);

msesim

System object: dsp.LMSFilter
Package: dsp

Mean-squared error for LMS filter

Syntax

```
MSE = msesim(sysObj,X,D)
[MSE,MEANW,W,TRACEK] = msesim(sysObj,X,D)
[...] = msesim(sysObj,X,D,M)
```

Description

`MSE = msesim(sysObj,X,D)` returns a sequence of mean-square errors. This column vector contains estimates of the mean-square error of the adaptive filter at each time instant. The length of `MSE` is equal to `SIZE(X,1)`. The columns of the matrix `X` contain individual input signal sequences, and the columns of the matrix `D` contain corresponding desired response signal sequences.

`[MSE,MEANW,W,TRACEK] = msesim(sysObj,X,D)` calculates three parameters corresponding to the simulated behavior of the adaptive filter defined by `sysObj`. `MEANW` is a sequence of coefficient vector means. The columns of this matrix contain estimates of the mean values of the adaptive filter coefficients at each time instant. The dimensions of `MEANW` are `(SIZE(X,1))` by `(sysObj.length)`. `W` is an estimate of the final values of the adaptive filter coefficients for the algorithm corresponding to `sysObj`. `TRACEK` is a sequence of total coefficient error powers. This column vector contains estimates of the total coefficient error power of the adaptive filter at each time instant. The length of `TRACEK` is equal to `SIZE(X,1)`.

`[...] = msesim(sysObj,X,D,M)` specifies an optional decimation factor for computing `MSE`, `MEANW`, and `TRACEK`. If $M > 1$, every M^{th} predicted value of each of these sequences is saved. If omitted, the value of `M` is the default, which is 1.

Examples

Predict Mean Square Error for LMS Filter

```
x = zeros(2000,25); d = x;
firCoeff = fir1(31,0.5);
x = filter(sqrt(0.75),[1 -0.5],sign(randn(size(x))));
n = 0.1*randn(size(x));
d = filter(firCoeff,1,x)+n;
l = 32;
mu = 0.008;
m  = 5;

lms = dsp.LMSFilter('Length',l,'StepSize',mu);
[mmse,emse,meanW,mse,traceK] = msepred(lms,x,d,m);
[simmse,meanWsim,Wsim,traceKsim] = msesim(lms,x,d,m);
nn = m:m:size(x,1);
subplot(2,1,1);
plot(nn,meanWsim(:,12),'b',nn,meanW(:,12),'r',nn,...
meanWsim(:,13:15),'b',nn,meanW(:,13:15),'r');
PlotTitle ={'Average Coefficient Trajectories for';...
            'W(12), W(13), W(14), and W(15)'};
title(PlotTitle);
legend('Simulation','Theory');

reset

System object: dsp.LMSFilter
Package: dsp

Reset filter states for LMS filter

Syntax

```
reset(lms)
```

Description

`reset(lms)` resets the filter states of the LMS FIR filter, `lms`, to their initial values specified in the `InitialConditions` property. The initial filter state values correspond to the initial conditions for difference equation defining the adaptive filter. After the `step` method applies the LMS filter to nonzero input data, the states may be different. Invoking the `step` method again without first invoking the`reset` method may produce different outputs for an identical input.

Reset an LMS Filter

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

```
lms1 = dsp.LMSFilter(11, 'StepSize', 0.01);
filt = dsp.FIRFilter; % System to be identified
filt.Numerator = fir1(10, .25);
x = randn(1000,1); % input signal
d = filt(x) + 0.01*randn(1000,1); % desired signal
[y,e,w] = lms1(x, d);
```

Call LMS algorithm again without resetting filter states.

```
[y1,e1,w1] = lms1(x,d);
isequal(y,y1)
```

```
ans =

  logical

   0
```

Now reset the filter states to zero.

```
reset(lms1)
```

Call the LMS algorithm.

```
[y2,e2,w2] = lms1(x,d);
isequal(y,y2)
```

```
ans =

  logical

   1
```

step

System object: dsp.LMSFilter
Package: dsp

Apply LMS adaptive filter to input

Syntax

```
[Y,ERR,WTS] = step(lms,X,D)
[Y, ERR] = step(lms,X,D)
[...] = step(lms,X,D,MU)
[...] = step(lms,X,D,A)
[...] = step(lms,X,D,R)
[Y,ERR,WTS] = step(lms,X,D,MU,A,R)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`[Y,ERR,WTS] = step(lms,X,D)` applies the LMS filter object, `lms` to the input `X` , using `D` as the desired signal. This approach returns the filtered output in `Y` , the filter error in `ERR` , and the estimated filter weights in `WTS` . The LMS filter estimates the filter weights needed to minimize the mean square error between the output and the desired signal.

`[Y, ERR] = step(lms,X,D)` filters the input `X` , using `D` as the desired signal. This approach returns the filtered output in `Y` and the filter error in `ERR` when the `WeightsOutputPort` property is `false`.

`[...] = step(lms,X,D,MU)` uses `MU` as the step size, when the `StepSizeSource` property is `'Input port'`.

[...] = step(lms,X,D,A) uses A as the adaptation control, when the AdaptInputPort property is true. When A is nonzero, the LMS filter continuously updates the filter weights. When A is zero, the filter weights remain constant.

[...] = step(lms,X,D,R) uses R as a reset signal when the WeightsResetInputPort property is true. The WeightsResetCondition property can be used to set the reset trigger condition. If a reset event occurs, the LMS filter resets the filter weights to their initial values.

[Y,ERR,WTS] = step(lms,X,D,MU,A,R) filters the input X using D as the desired signal, MU as the step size, A as the adaptation control, and R as the reset signal. This approach returns the filtered output in Y , the filter error in ERR , and the adapted filter weights in WTS.

Note: obj specifies the System object on which to run this step method.

The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

dsp.LogicAnalyzer System object

Package: dsp

Visualize, measure, and analyze transitions and states over time

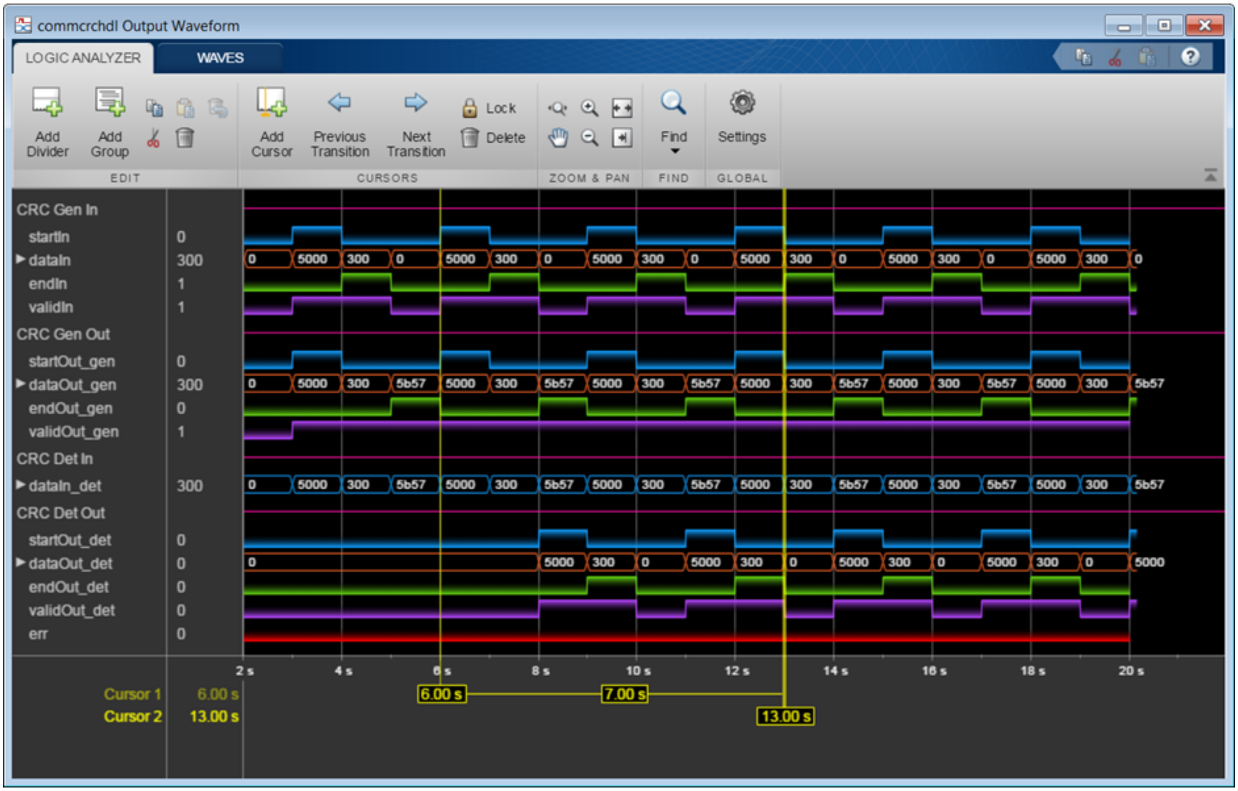
Description

The `LogicAnalyzer` System object displays the transitions in time-domain signals.

To display the transitions of signals in the Logic Analyzer:

1. Define and set up your Logic Analyzer. See "Construction" on page 4-1124.
2. Call step to display the transitions of the signals in the Logic Analyzer figure.

Use the MATLAB `clear` function to close the Logic Analyzer figure window and clear its associated data. Use the hide method to hide the Logic Analyzer window and the show method to make it visible.



Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`scope = dsp.LogicAnalyzer` creates a Logic Analyzer System object, `scope`.

`scope = dsp.LogicAnalyzer(Name,Value)` sets each property `Name` to the specified `Value`. Unspecified properties have default values.

Properties

If a property is listed as tunable, then you can change its value even when the object is locked.

`BackgroundColor` — Background color for display
'Black' (default) | 'White'

Background color of the display, specified as 'Black' or 'White'.

Tunable: Yes

Data Types: char

`DisplayChannelColor` — Color for channels in the display
[0.0588 1 1] (default) | RGB triplet

Color for channels in the display, specified as an RGB triplet.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0,1]; for example, [0.4 0.6 0.7].

Tunable: Yes

Data Types: double | single | uint8 | uint16 | uint32 | uint64 | int8 | int16 | int32 | int64

`DisplayChannelFontSize` — Font size for channels in the display (points)
10 (default) | nonnegative scalar integer

Font size for channels in the display, in points, specified as a nonnegative scalar integer.

Tunable: Yes

Data Types: double | single | uint8 | uint16 | uint32 | uint64 | int8 | int16 | int32 | int64

`DisplayChannelFormat` — Format for channels in the display
'Automatic' (default) | 'Analog' | 'Digital'

Format for channels in the display, specified as one of the following:

- 'Automatic' — Displays floating-point signals in Analog format and integer and fixed-point signals in Digital format. Boolean signals are displayed as zero or one.

- `'Analog'` — Shows values as an analog plot.
- `'Digital'` — Shows values as digital transitions.

Tunable: Yes

Data Types: `char`

`DisplayChannelHeight` — Channel height in the display (pixels)

`12` (default)

Channel height in the display, in pixels, specified as a positive real scalar in the range 8 to 200.

Tunable: Yes

Data Types: `double` | `single` | `uint8` | `uint16` | `uint32` | `uint64` | `int8` | `int16` | `int32` | `int64`

`DisplayChannelRadix` — Base of the enumeration used to display values

`'Hexadecimal'` (default) | `'Binary'` | `'Octal'` | `'Signed decimal'` | `'Unsigned decimal'`

Base of the enumeration used to display values, specified as one of the following:

- `'Hexadecimal'` — Displays values as symbols from zero to nine and A to F
- `'Binary'` — Displays values as zeros and ones
- `'Octal'` — Displays values as numbers from zero to seven
- `'Signed decimal'` — Displays the signed, stored integer value
- `'Unsigned decimal'` — Displays the stored integer value

This property applies only to fixed-point (`fi`) values.

Tunable: Yes

Data Types: `char`

`DisplayChannelSpacing` — Spacing between channels in display (pixels)

4 (default) | positive scalar integer

Spacing between channels in the display, in pixels, specified as a positive scalar integer.

Tunable: Yes

Data Types: `double` | `single` | `uint8` | `uint16` | `uint32` | `uint64` | `int8` | `int16` | `int32` | `int64`

`Name` — Caption to display on scope window

`'Logic Analyzer'` (default) | character vector

Caption to display on the scope window, specified as a character vector.

Tunable: Yes

Data Types: `char`

`NumInputPorts` — Number of input signals

`1` | positive scalar integer

Number of input signals, specified as a positive scalar integer. You must call the `step` method with the same number of inputs as the value of this property.

Data Types: `double` | `single` | `uint8` | `uint16` | `uint32` | `uint64` | `int8` | `int16` | `int32` | `int64`

`Position` — Scope window position (pixels)

`[left bottom width height]` vector

Position of the scope window on your screen, in pixels, specified as a `[left bottom width height]` vector. The default position depends on your screen resolution. By default, the scope window appears in the center of your screen, with a width of `800` pixels and height of `600` pixels.

Tunable: Yes

Data Types: `double` | `single` | `uint8` | `uint16` | `uint32` | `uint64` | `int8` | `int16` | `int32` | `int64`

`SampleTime` — Sample time of inputs (seconds)

`1` (default) | finite numeric scalar

Sample time of inputs in seconds, specified as a finite numeric scalar. The same sample time is used for all inputs.

Data Types: `double` | `single` | `uint8` | `uint16` | `uint32` | `uint64` | `int8` | `int16` | `int32` | `int64`

`TimeDisplayOffset` — Time display offset (seconds)

`0` (default) | nonnegative scalar

Time display offset in seconds, specified as a nonnegative scalar.

Tunable: Yes

Data Types: `double` | `single` | `uint8` | `uint16` | `uint32` | `uint64` | `int8` | `int16` | `int32` | `int64`

`TimeSpan` — Time span (seconds)
`10` | positive scalar

Time span in seconds, specified as a positive scalar. The *x*-axis limits are calculated as follows:

- Minimum *x*-axis limit = min(`TimeDisplayOffset`)
- Maximum *x*-axis limit = max(`TimeDisplayOffset`) + `TimeSpan`

`TimeDisplayOffset` and `TimeSpan` are the values of their respective properties.

Tunable: Yes

Data Types: `double` | `single` | `uint8` | `uint16` | `uint32` | `uint64` | `int8` | `int16` | `int32` | `int64`

Methods

addCursor	Add cursor to display
addDivider	Add divider to display
addWave	Add wave corresponding to specified input
deleteCursor	Delete specified cursor
deleteDisplayChannel	Delete specified display channel
getCursorInfo	Return settings for specified cursor
getCursorTags	Return all cursor tags
getDisplayChannelInfo	Return settings for specified display channel
getDisplayChannelTags	Return all display channel tags
hide	Hide scope window
modifyCursor	Modify properties of specified cursor

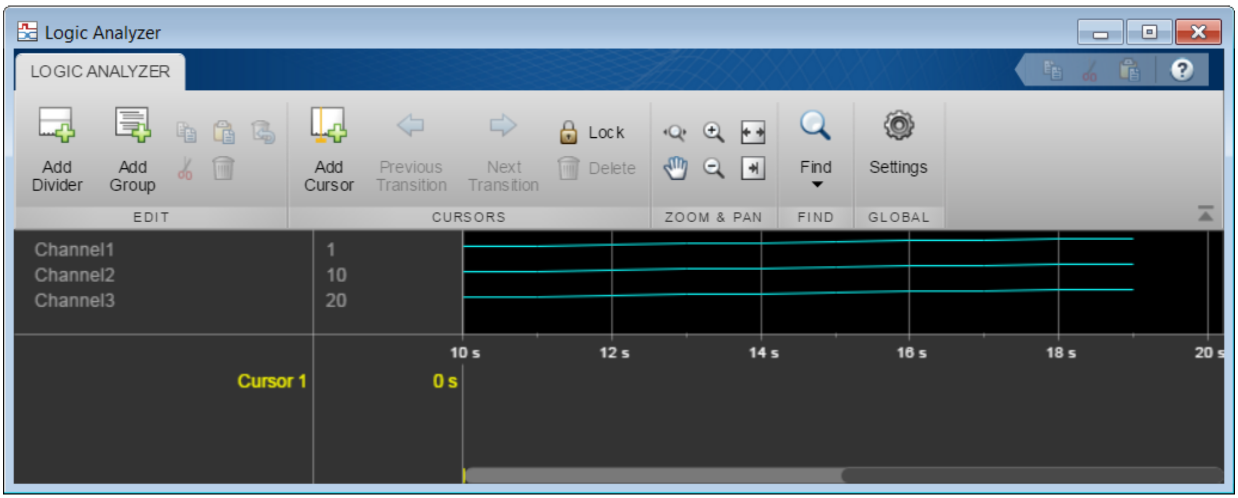
modifyDisplayChannel	Modify properties of specified display channel
moveDisplayChannel	Move position of specified display channel
reset	Reset internal states of scope object
show	Make scope window visible
step	Display signal in scope figure

Examples

Display Simple Ramp Signals

Create a `dsp.LogicAnalyzer` object. Call the scope in a loop to display the signals.

```
scope = dsp.LogicAnalyzer('NumInputPorts',3);
for ii = 1:20
    scope(ii,10*ii,20*ii);
end
```



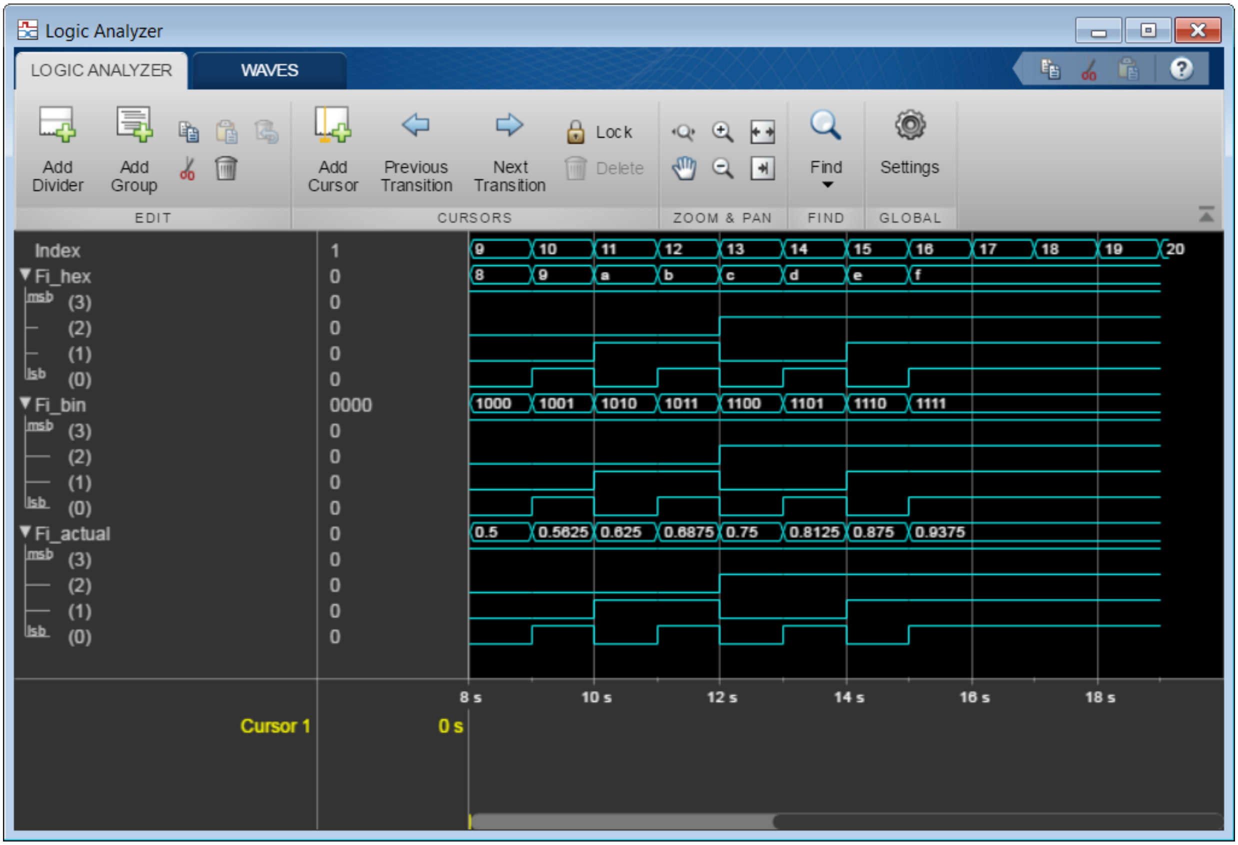
Display Fixed-Point Signals

Create a `dsp.LogicAnalyzer` object with four channels. Call `modifyDisplayChannel` to set the radix of each of the channels. Run the scope in a loop to display the waves.

```
scope = dsp.LogicAnalyzer('NumInputPorts',4,'DisplayChannelFormat','Digital');
scope.TimeSpan = 12;

modifyDisplayChannel(scope,1,'Name','Index','Radix','Unsigned decimal');
modifyDisplayChannel(scope,2,'Name','Fi_hex','Radix','Hexadecimal');
modifyDisplayChannel(scope,3,'Name','Fi_bin','Radix','Binary');
modifyDisplayChannel(scope,4,'Name','Fi_actual','Radix','Signed decimal');

for ii = 1:20
    fival = fi((ii-1)/16,0,4,4);
    scope(ii,fival,fival,fival);
end
```



Display Vector, Complex, and Enumerated Signals

Define a `WeekDaysInt` class to hold an enumerated list of weekday values. Create and save the following class definition file.

```
classdef WeekDaysInt < int32
  enumeration
    Monday(1), Tuesday(2), Wednesday(3), Thursday(4), Friday(5)
  end
end
```

Create and configure the vector, complex, and enumerated data signals.

```
s{1} = dsp.LogicAnalyzerWave('InputChannel',1,...
```

```
     'Name','Vector Digital');
s{2} = dsp.LogicAnalyzerWave('InputChannel',2,...
     'Name','Vector Analog', 'Format','Analog',...
     'Height',80);
s{3} = dsp.LogicAnalyzerWave('InputChannel',3,...
     'Name','Complex Digital');
s{4} = dsp.LogicAnalyzerWave('InputChannel',4,...
     'Name','Complex Analog', 'Format','Analog',...
     'Height',80,'Color','Green');
s{5} = dsp.LogicAnalyzerWave('InputChannel',5,...
     'Name','Enum Digital');
s{6} = dsp.LogicAnalyzerWave('InputChannel',6,...
     'Name','Enum Analog', 'Format','Analog',...
     'Height',80);
```

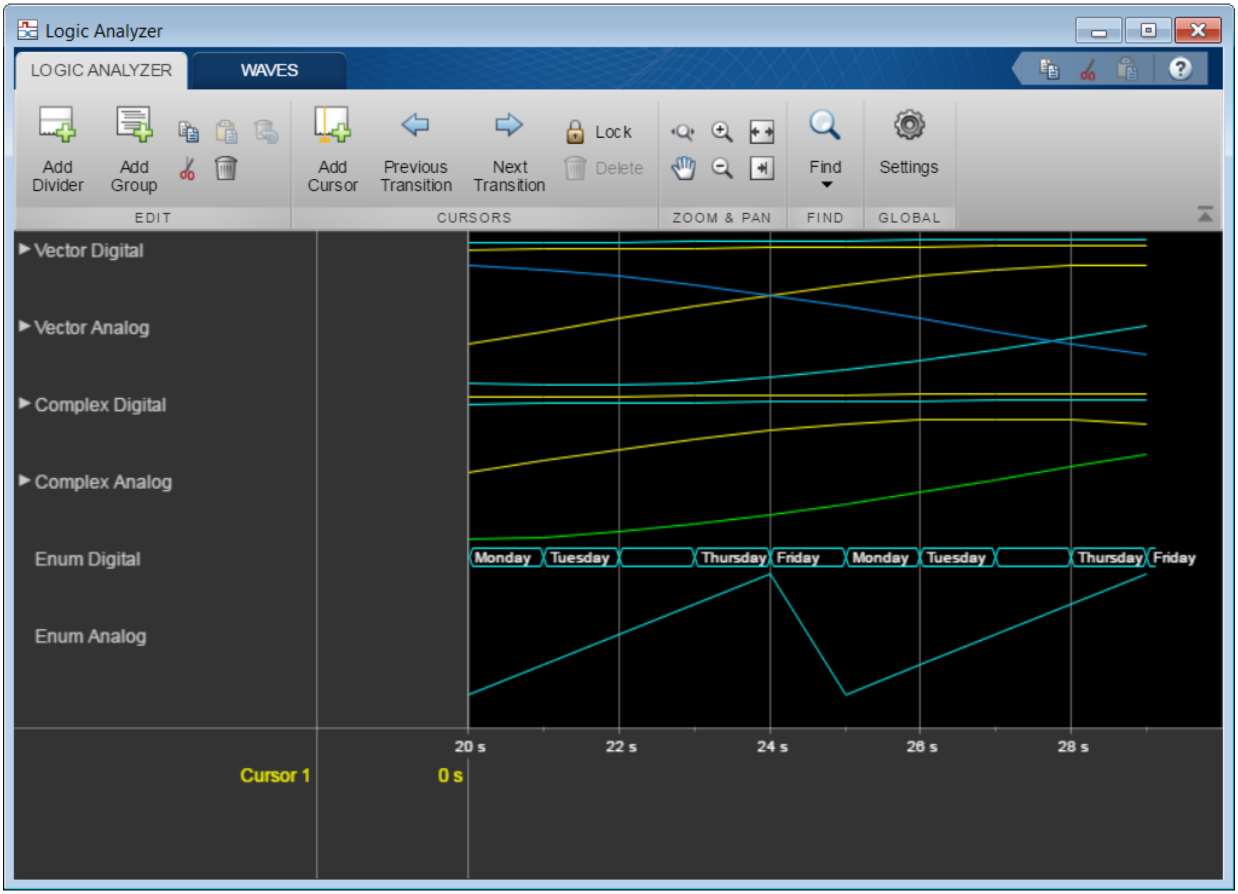
Create a `dsp.LogicAnalyzer` object. Call the object in a loop to display the signals.

```
scope = dsp.LogicAnalyzer('DisplayChannels',s,...
     'NumInputPorts',numel(s));

t = 30;
for c = 1:t
    sinValVec       = sin(c/t*2*pi);
    cosValVec       = cos(c/t*2*pi);
    cosValVecOffset = cos((c+10)/t*2*pi);
    sinValReal      = sin((c+2)/t*2*pi);
    cosValImag      = cos((c+2)/t*2*pi);

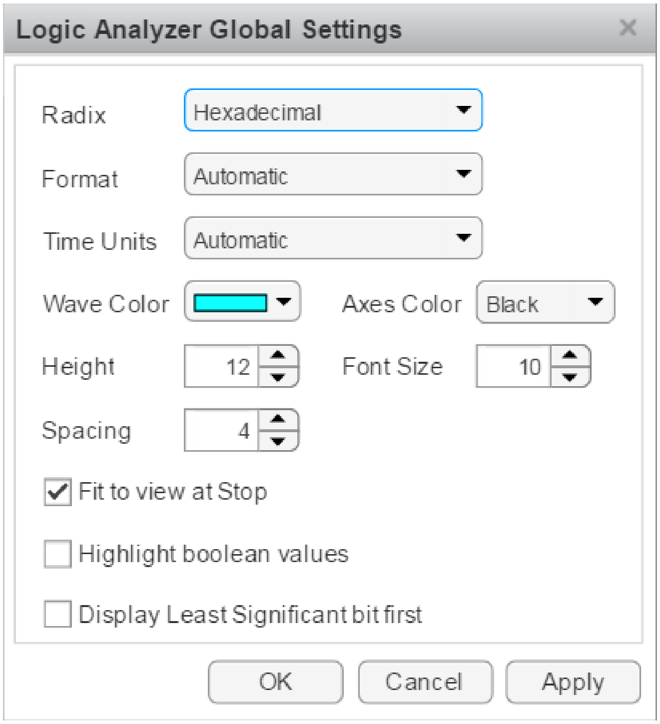
    % Create a weekday enumerated value by wrapping the index
    day = WeekDaysInt(1+mod(c-1,5));

    scope(...
          [c (c-(t/2))],...                          % digital vector
          [sinValVec cosValVec cosValVecOffset],... % analog vector
          complex((c-(t/2)),c),...                  % digital complex
          complex(sinValReal, cosValImag),...       % analog complex
          day,...                                    % digital enum
          day...                                     % analog enum
          )
end
```



Configure Visualization of Logic Analyzer

The Logic Analyzer Global Settings dialog box controls the default visual configuration of the Logic Analyzer display. From the Logic Analyzer toolstrip, select **Settings** to open this dialog box. Any settings made on individual signals supersede the global setting.



Set the display **Radix** of your signals as one of the following:

- `Hexadecimal` — Displays values as symbols from zero to nine and A to F
- `Octal` — Displays values as numbers from zero to seven
- `Binary` — Displays values as zeros and ones
- `Signed decimal` — Displays the signed, stored integer value
- `Unsigned decimal` — Displays the stored integer value

Set the display **Format** as one of the following:

- `Automatic` — Displays floating point signals in `Analog` format and integer and fixed-point signals in `Digital` format. Boolean signals are displayed as zero or one.
- `Analog` — Displays values as an analog plot
- `Digital` — Displays values as digital transitions

Set the display **Time Units** to one of the following:

- `Automatic` — Uses a time scale appropriate to the time range shown in the current plot
- `seconds`
- `milliseconds`
- `microseconds`
- `nanoseconds`
- `picoseconds`
- `femtoseconds`

You can expand fixed-point and integer signals and view individual bits. The **Display Least Significant bit first** option enables you to reverse the order of the displayed bits.

Inspect the graphic for an explanation of the global settings: **Wave Color**, **Axes Color**, **Height**, **Font Size**, and **Spacing**. **Font Size** applies only to the text within the axes.

Introduced in R2013a

addCursor

System object: dsp.LogicAnalyzer
Package: dsp

Add cursor to display

Syntax

```
cursorTag = addCursor(scope)
cursorTag = addCursor(scope,'Name',Value)
```

Description

`cursorTag = addCursor(scope)` adds in a cursor to the display. A tag value is returned, which can be used to modify and delete the cursor.

`cursorTag = addCursor(scope,'Name',Value)` adds in a cursor to the display with each specified property *`Name`* set to the specified value. You can specify *`Name`*–*`Value`* arguments in any order.

Input Arguments

`scope` — The Logic Analyzer object to which you want to add a cursor
`dsp.LogicAnalyzer` object

Example: `'addCursor(scope)'` adds a cursor with the default characteristics.

Example: `'scope.addCursor()'` adds a cursor with the default characteristics.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'Location',2,'Color','Blue'` specifies that a cursor should be moved to the 2-second mark and colored blue.

`'Color'` — Color of the cursor

`'Yellow'` (default) | character vector | three element vector

Color of the cursor, specified as an `[R G B]` value or one of the following:

- `'Black'`
- `'Blue'`
- `'Cyan'`
- `'Green'`
- `'Magenta'`
- `'White'`
- `'Yellow'`

Example: `'Color','Blue'`

Example: `'Color',[0,0,1]`

Data Types: `char` | `double`

`'Location'` — Location of the cursor

`0` (default) | numeric scalar

Specify as a numeric scalar value, in seconds, the cursor location.

Example: `'Location',1`

Data Types: `double`

`'Locked'` — Locked status of the cursor

`false` (default) | `true`

Locked status of the cursor, specified as `false` or `true`.

- `true` — the cursor's location cannot be changed. Logic Analyzer denotes this by assigning a default color of red.
- `false` — the cursor's location can be changed. Logic Analyzer denotes this by assigning a default color of yellow.

Example: `'Locked',true`

addDivider

System object: dsp.LogicAnalyzer
Package: dsp

Add divider to display

Syntax

```
dividerTag = addDivider(scope)
dividerTag = addDivider(scope,'Name',Value)
```

Description

`dividerTag = addDivider(scope)` adds a divider to the display. A tag value is returned, which can be used to modify and delete the divider.

`dividerTag = addDivider(scope,'Name',Value)` adds in a divider to the display with each specified property *`Name`* set to the specified value. You can specify *`Name`*–*`Value`* arguments in any order.

Input Arguments

`scope` — The Logic Analyzer object to which you want to add a divider

dsp.LogicAnalyzer object

Example: `addDivider(scope)` adds a divider with the default characteristics.

Example: `scope.addDivider()` adds a divider with the default characteristics.

Divider Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'DisplayChannel',2,'Name','MyDivider'` specifies that a divider should be added to display channel 2 and named “MyDivider”.

`'DisplayChannel'` — Channel on the display that shows this divider
`NumInputPorts` (default) | scalar numeric value in the range (1,`NumInputPorts`)

Specify as a scalar numeric value the display channel that shows this divider. By default, the divider is added to the end of the display.

Example: `'DisplayChannel',2`

Data Types: `double` | `single` | `uint8` | `uint16` | `uint32` | `uint64` | `int8` | `int16` | `int32` | `int64`

`'Height'` — Height of the divider
`0` (default) | scalar integer

Specify, in pixels, the height of the divider as a scalar integer in the range 8 to 200. If you choose 0, the value of the `DisplayChannelHeight` property in the Logic Analyzer is used.

Example: `'Height',2`

Data Types: `double`

`'Name'` — The name or label for the divider
`''` (default) | character vector

Specify as a character vector the name that you would like to set for the new divider.

Example: `'Name','MyDivider'`

Data Types: `char`

addWave

System object: dsp.LogicAnalyzer
Package: dsp

Add wave corresponding to specified input

Syntax

```
waveTag = addWave(scope)
waveTag = addWave(scope,'Name',Value)
```

Description

`waveTag = addWave(scope)` adds in a wave corresponding to the specified input channel. A tag value is returned back, which can be used to modify and delete the wave.

`waveTag = addWave(scope,'Name',Value)` adds in a wave with each specified property *`Name`* set to the specified value. You can specify *`Name`*–*`Value`* arguments in any order.

Input Arguments

`scope` — The Logic Analyzer object to which you want to add a wave
dsp.LogicAnalyzer object

Example: `'addWave(scope)'` adds a wave with the default characteristics.

Example: `'scope.addWave()'` adds a wave with the default characteristics.

Wave Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'InputChannel',2,'Color','Blue'` specifies that a wave should be added to input channel 1 and colored blue.

`'Color'` — Color of the wave

`'Default'` (default) | character vector

Color of the wave, specified as an `[R G B]` value or one of the following:

- `'Black'`
- `'Blue'`
- `'Cyan'`
- `'Default'`
- `'Green'`
- `'Magenta'`
- `'Red'`
- `'White'`
- `'Yellow'`

When you choose `'Default'`, the value of the `DisplayChannelColor` property in the Logic Analyzer is used.

Example: `'Color','Blue'`

Example: `'Color',[0,0,1]`

Data Types: `char` | `double` | `single` | `uint8` | `uint16` | `uint32` | `uint64` | `int8` | `int16` | `int32` | `int64`

`'DisplayChannel'` — Channel on the display that shows this wave

`NumInputPorts` (default) | scalar numeric value in the range (1,`NumInputPorts`)

Specify as a scalar numeric value the display channel that shows this wave. By default, the wave is added to the end of the display.

Example: `'DisplayChannel',2`

Data Types: `double` | `single` | `uint8` | `uint16` | `uint32` | `uint64` | `int8` | `int16` | `int32` | `int64`

`'FontSize'` — Font size for values in the wave

`0` (default) | scalar nonnegative integer

Specify as a scalar nonnegative integer the font size in points. When you choose 0, the value of the `DisplayChannelFontSize` property in the Logic Analyzer is used.

Example: `'FontSize',8`

Data Types: `double`

`'Format'` — Display format for the wave

`'Default'` (default) | character vector

`'Format'` must be one of the following.

- `'Analog'`
- `'Default'`
- `'Digital'`

When you choose `'Default'`, the value of the `DisplayChannelFormat` property in the Logic Analyzer is used.

Example: `'Format','Digital'`

Data Types: `char`

`'Height'` — Height of the wave

`0` (default) | scalar integer

Specify as a scalar integer the height of the wave in the display in units of 16 pixels. When you choose 0, the value of the `DisplayChannelHeight` property in the Logic Analyzer is used.

Example: `'Height',2`

Data Types: `double`

`'InputChannel'` — Input channel that corresponds to this wave

`1` (default) | scalar integer in the range (1,`NumInputPorts`)

This property specifies the input channel whose data is used for this wave. By default, it will connect the first input to this wave.

Example: `'InputChannel',2`

Data Types: `double` | `single` | `uint8` | `uint16` | `uint32` | `uint64` | `int8` | `int16` | `int32` | `int64`

`'Name'` — The name or label for the wave
`''` (default) | character vector

Specify as a character vector the name that you would like to set for the new wave.

Example: `'Name','MyWave'`

Data Types: `char`

`'Radix'` — Radix for the wave
`'Default'` (default) | character vector

`'Radix'` must be one of the following.

- `'Binary'`
- `'Default'`
- `'Hexadecimal'`
- `'Octal'`
- `'Signed decimal'`
- `'Unsigned decimal'`

When the input signals are of class double, single, or logical, you should not set this property. When you choose `'Default'`, the value of the `DisplayChannelRadix` property in the Logic Analyzer is used.

Example: `'Radix','Hexadecimal'`

Data Types: `char`

deleteCursor

System object: dsp.LogicAnalyzer
Package: dsp

Delete specified cursor

Syntax

```
deleteCursor(scope,tag)
deleteCursor(scope,'CursorTag',tag)
```

Description

`deleteCursor(scope,tag)` deletes the cursor specified by the input tag.

`deleteCursor(scope,'CursorTag',tag)` deletes the cursor specified by the input tag.

Input Arguments

`scope` — The Logic Analyzer object from which you want to delete a cursor

`dsp.LogicAnalyzer` object handle

The Logic Analyzer object from which you want to delete a cursor, specified as a handle to the `dsp.LogicAnalyzer` object.

`tag` — The tag identifying which cursor to delete

character vector, randomly assigned

The tag identifying which cursor to delete, specified as a randomly assigned character vector.

Example: `'deleteCursor(scope,tag)'` deletes a cursor from Logic Analyzer.

Example: `'scope.deleteCursor(tag)'` deletes a cursor from Logic Analyzer.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'CursorTag','C6'` specifies to delete the divider with tag `'C6'`.

`'CursorTag'` — The tag identifying which cursor to delete

character vector, randomly assigned

The tag identifying which cursor to delete, specified as a randomly assigned character vector.

Example: `'CursorTag','C6'`

Data Types: `char`

deleteDisplayChannel

System object: dsp.LogicAnalyzer
Package: dsp

Delete specified display channel

Syntax

```
deleteDisplayChannel(scope,tag)
deleteDisplayChannel(scope,'DisplayChannelTag',tag)
```

Description

`deleteDisplayChannel(scope,tag)` deletes the display channel, either a wave or a divider, specified by the input tag.

`deleteDisplayChannel(scope,'DisplayChannelTag',tag)` deletes the display channel, either a wave or a divider, specified by the input tag.

Input Arguments

`scope` — The Logic Analyzer object from which you want to delete a display channel

`dsp.LogicAnalyzer` object

The Logic Analyzer object from which you want to delete a display channel, specified as a handle to the `dsp.LogicAnalyzer` object.

`tag` — The tag identifying which display channel to delete

character vector

The tag identifying which display channel to delete, specified as a character vector.

Example: `'deleteDisplayChannel(scope,tag)'` deletes a display channel from Logic Analyzer.

Example: `'scope.deleteDisplayChannel(tag)'` deletes a display channel from Logic Analyzer.

Data Types: `char`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'DisplayChannelTag','C5'` specifies to delete the divider with tag `'C5'`.

`'DisplayChannelTag'` — The tag identifying which display channel to delete
character vector

The tag identifying which display channel to delete, specified as a character vector.

Example: `'DisplayChannelTag','C5'`

Data Types: `char`

getCursorInfo

System object: dsp.LogicAnalyzer
Package: dsp

Return settings for specified cursor

Syntax

```
getCursorInfo(scope,'CursorTag',tag)
```

Description

`getCursorInfo(scope,'CursorTag',tag)` returns the settings for the cursor or cursors, specified by the input tag.

Input Arguments

`scope` — The Logic Analyzer object from which you want to return cursor settings
dsp.LogicAnalyzer object

The Logic Analyzer object from which you want to return cursor settings, specified as a handle to the `dsp.LogicAnalyzer` object.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'CursorTag','C5'` specifies to return settings about the cursor with tag `'C5'`.

`'CursorTag'` — The tag or tags identifying the cursor or cursors about which to get information
character vector or cell array of character vectors

The tag or tags identifying the cursor or cursors about which to get information, specified as a character vector or cell array of character vectors.

Example: `'CursorTag','C5'`

Example: `'CursorTag',{'C4','C5'}`

Data Types: `char` | `cell`

Output Arguments

`cursorInfo` — Information about settings for the cursor or cursors

struct

The `cursorInfo` struct contains the following fields:

- `Location` — Location of the cursors
- `Color` — Color of the cursors
- `Locked` — Locked status of the cursors
- `Tag` — Tag identifying cursors

getCursorTags

System object: dsp.LogicAnalyzer
Package: dsp

Return all cursor tags

Syntax

```
T = getCursorTags(scope)
```

Description

`T = getCursorTags(scope)` returns all the cursor tags for the Logic Analyzer. You can use these tags to get information about a cursor using the dsp.LogicAnalyzer.getCursorInfo method, to modify a cursor using the dsp.LogicAnalyzer.modifyCursor method, or to delete a cursor using the dsp.LogicAnalyzer.deleteCursor method.

Input Arguments

`scope` — The Logic Analyzer object from which you want to return all cursor tags
`dsp.LogicAnalyzer` object

The Logic Analyzer object from which you want to return all cursor tags, specified as a handle to the `dsp.LogicAnalyzer` object.

Output Arguments

`T` — The cursor tags
cell array of character vectors

The cursor tags, specified as a cell array of character vectors.

Example: `{'C1'}`

Example: `{'C1','C2','C3'}`

Data Types: `cell`

getDisplayChannelInfo

System object: dsp.LogicAnalyzer
Package: dsp

Return settings for specified display channel

Syntax

`channelInfo = getDisplayChannelInfo(scope,'DisplayChannelTag',tag)`

Description

`channelInfo = getDisplayChannelInfo(scope,'DisplayChannelTag',tag)` returns the settings for the display channel or channels, specified by the input tag.

Input Arguments

`scope` — The Logic Analyzer object from which you want to return display channel settings
`dsp.LogicAnalyzer` object

The Logic Analyzer object from which you want to return display channel settings, specified as a handle to the `dsp.LogicAnalyzer` object.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'DisplayChannelTag','W5'` specifies to return display channel settings about the wave with tag `'W5'`.

`'DisplayChannelTag'` — The tag or tags identifying the display channel or channels about which to get information
character vector or cell array of character vectors

The tag or tags identifying the display channel or channels about which to get information, specified as a character vector or cell array of character vectors.

Example: `'DisplayChannelTag','W5'`

Example: `'DisplayChannelTag',{'W4','W5'}`

Data Types: `char` | `cell`

Output Arguments

`channelInfo` — Information about settings for the display channel or channels

struct

The `channelInfo` struct contains the following fields:

- `Color` — Color of the waves.
- `InputChannel` — Channel on the display that corresponds to the specified waves.
- `Radix` — Radix for the waves.
- `FontSize` — Font size for values in the waves. A value of `0` indicates that the waves inherit `FontSize` from the global `DisplayChannelColor` property.
- `Name` — The name or label for the waves.
- `Height` — Height of the wave. A value of `0` indicates that the waves inherit `Height` from the global `DisplayChannelHeight` property.
- `Tag` — Tag for the channel.

getDisplayChannelTags

System object: dsp.LogicAnalyzer
Package: dsp

Return all display channel tags

Syntax

```
T = getDisplayChannelTags(scope)
```

Description

`T = getDisplayChannelTags(scope)` returns all the display channel tags for the Logic Analyzer. These tags are particularly useful for getting information about a wave or divider using the dsp.LogicAnalyzer.getDisplayChannelInfo method, for modifying a wave or divider using the dsp.LogicAnalyzer.modifyDisplayChannel method, or for deleting a wave or divider using the dsp.LogicAnalyzer.deleteDisplayChannel method.

Input Arguments

`scope` — The Logic Analyzer object from which you want to return all display channel tags
`dsp.LogicAnalyzer` object

The Logic Analyzer object from which you want to return all display channel tags, specified as a handle to the `dsp.LogicAnalyzer` object.

Output Arguments

`T` — The display channel tags
cell array of character vectors

The display channel tags, returned as a cell array of character vectors.

Example: `{'W1'}`

Example: `{'W1','W2','W3'}`

Data Types: `cell`

hide

System object: dsp.LogicAnalyzer
Package: dsp

Hide scope window

Syntax

`hide(scope)`

Description

`hide(scope)` hides the window associated with System object, `scope`.

See Also

dsp.LogicAnalyzer.show

modifyCursor

System object: dsp.LogicAnalyzer
Package: dsp

Modify properties of specified cursor

Syntax

```
modifyCursor(scope,tag)
modifyCursor(scope,'CursorTag',tag)
modifyCursor(scope,tag,'Name',Value)
modifyCursor(scope,'CursorTag',tag,'Name',Value)
```

Description

`modifyCursor(scope,tag)` modifies the properties of the cursor specified by the input tag.

`modifyCursor(scope,'CursorTag',tag)` modifies the properties of the cursor specified by the input tag.

`modifyCursor(scope,tag,'Name',Value)` modifies the properties of the cursor specified by the input tag with each specified property *Name* set to the specified value. You can specify *Name*–*Value* arguments in any order.

`modifyCursor(scope,'CursorTag',tag,'Name',Value)` modifies the properties of the cursor specified by the input tag with each specified property *Name* set to the specified value. You can specify *Name*–*Value* arguments in any order.

Input Arguments

`scope` — The Logic Analyzer object for which you want to modify a cursor

`dsp.LogicAnalyzer` object

The Logic Analyzer object for which you want to modify a cursor specified, as a handle to the `dsp.LogicAnalyzer` object.

`tag` — The tag identifying which cursor to modify
character vector, randomly assigned

The tag identifying which cursor to modify specified, as a randomly assigned character vector.

Example: `modifyCursor(scope,tag)` modifies a cursor in Logic Analyzer.

Example: `scope.modifyCursor(tag)` modifies a cursor in Logic Analyzer.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'Location',2,'Color','Blue'` specifies that a cursor should be moved to the 2-second mark and colored blue.

`'Color'` — Color of the cursor
`'Yellow'` (default) | character vector | three element vector

Color of the cursor, specified as an `[R G B]` value or one of the following:

- `'Black'`
- `'Blue'`
- `'Cyan'`
- `'Green'`
- `'Magenta'`
- `'White'`
- `'Yellow'`

Example: `'Color','Blue'`

Example: `'Color',[0,0,1]`

Data Types: `char` | `double`

`'Location'` — Location of the cursor
`0` (default) | numeric scalar

Specify as a numeric scalar value, in seconds, the cursor location.

Example: `'Location',1`

Data Types: `double`

`'Locked'` — Locked status of the cursor

`false` (default) | `true`

Locked status of the cursor, specified as `false` or `true`.

- `true` — the cursor's location cannot be changed. Logic Analyzer denotes this by assigning a default color of red.
- `false` — the cursor's location can be changed. Logic Analyzer denotes this by assigning a default color of yellow.

Example: `'Locked',true`

modifyDisplayChannel

System object: dsp.LogicAnalyzer
Package: dsp

Modify properties of specified display channel

Syntax

```
modifyDisplayChannel(scope,tag,'Name',Value)
modifyDisplayChannel(scope,'DisplayChannelTag',tag,'Name',Value)
```

Description

`modifyDisplayChannel(scope,tag,'Name',Value)` modifies the properties of the display channel specified by the input tag with each specified property *Name* set to the specified value. You can specify *Name–Value* arguments in any order.

`modifyDisplayChannel(scope,'DisplayChannelTag',tag,'Name',Value)` modifies the properties of the display channel specified by the input tag with each specified property *Name* set to the specified value. You can specify *Name–Value* arguments in any order.

Input Arguments

`scope` — The Logic Analyzer object for which you want to modify a display channel
`dsp.LogicAnalyzer` object

The Logic Analyzer object for which you want to modify a display channel, specified as a handle to the `dsp.LogicAnalyzer` object.

`tag` — The tag identifying which display channel to modify
character vector, randomly assigned

The tag identifying which display channel to modify, specified as a randomly assigned character vector.

Example: `modifyDisplayChannel(scope,tag)` modifies a display channel in Logic Analyzer.

Example: `scope.modifyDisplayChannel(tag)` modifies a display channel in Logic Analyzer.

The first section on Name-Value Pair Arguments shows the properties you can set if the display channel contains a wave. The second section on Name-Value Pair Arguments shows the properties you can set if the display channel contains a divider.

Wave Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'InputChannel',2,'Color','Blue'` specifies that a wave should be added to input channel 1 and colored blue.

`'Color'` — Color of the wave
`'Default'` (default) | character vector

Color of the wave, specified as an `[R G B]` value or one of the following:

- `'Black'`
- `'Blue'`
- `'Cyan'`
- `'Default'`
- `'Green'`
- `'Magenta'`
- `'Red'`
- `'White'`
- `'Yellow'`

When you choose `'Default'`, the value of the `DisplayChannelColor` property in the Logic Analyzer is used.

Example: `'Color','Blue'`

Example: `'Color',[0,0,1]`

Data Types: `char` | `double` | `single` | `uint8` | `uint16` | `uint32` | `uint64` | `int8` | `int16` | `int32` | `int64`

`'DisplayChannel'` — Channel on the display that shows this wave
`NumInputPorts` (default) | scalar numeric value in the range (1,`NumInputPorts`)

Specify as a scalar numeric value the display channel that shows this wave. By default, the wave is added to the end of the display.

Example: `'DisplayChannel',2`

Data Types: `double` | `single` | `uint8` | `uint16` | `uint32` | `uint64` | `int8` | `int16` | `int32` | `int64`

`'FontSize'` — Font size for values in the wave
`0` (default) | scalar nonnegative integer

Specify as a scalar nonnegative integer the font size in points. When you choose 0, the value of the `DisplayChannelFontSize` property in the Logic Analyzer is used.

Example: `'FontSize',8`

Data Types: `double`

`'Format'` — Display format for the wave
`'Default'` (default) | character vector

`'Format'` must be one of the following.

- `'Analog'`
- `'Default'`
- `'Digital'`

When you choose `'Default'`, the value of the `DisplayChannelFormat` property in the Logic Analyzer is used.

Example: `'Format','Digital'`

Data Types: `char`

`'Height'` — Height of the wave
`0` (default) | scalar integer

Specify as a scalar integer the height of the wave in the display in units of 16 pixels. When you choose 0, the value of the `DisplayChannelHeight` property in the Logic Analyzer is used.

Example: `'Height',2`

Data Types: `double`

`'InputChannel'` — Input channel that corresponds to this wave

`1` (default) | scalar integer in the range (1,`NumInputPorts`)

This property specifies the input channel whose data is used for this wave. By default, it will connect the first input to this wave.

Example: `'InputChannel',2`

Data Types: `double` | `single` | `uint8` | `uint16` | `uint32` | `uint64` | `int8` | `int16` | `int32` | `int64`

`'Name'` — The name or label for the wave

`''` (default) | character vector

Specify as a character vector the name that you would like to set for the new wave.

Example: `'Name','MyWave'`

Data Types: `char`

`'Radix'` — Radix for the wave

`'Default'` (default) | character vector

`'Radix'` must be one of the following.

- `'Binary'`
- `'Default'`
- `'Hexadecimal'`
- `'Octal'`
- `'Signed decimal'`
- `'Unsigned decimal'`

When the input signals are of class double, single, or logical, you should not set this property. When you choose `'Default'`, the value of the `DisplayChannelRadix` property in the Logic Analyzer is used.

Example: 'Radix','Hexadecimal'

Data Types: char

Divider Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Example: 'DisplayChannel',2,'Name','MyDivider' specifies that a divider should be added to display channel 2 and named “MyDivider”.

'DisplayChannel' — Channel on the display that shows this divider

NumInputPorts (default) | scalar numeric value in the range (1,NumInputPorts)

Specify as a scalar numeric value the display channel that shows this divider. By default, the divider is added to the end of the display.

Example: 'DisplayChannel',2

Data Types: double | single | uint8 | uint16 | uint32 | uint64 | int8 | int16 | int32 | int64

'Height' — Height of the divider

0 (default) | scalar integer

Specify, in pixels, the height of the divider as a scalar integer in the range 8 to 200. If you choose 0, the value of the DisplayChannelHeight property in the Logic Analyzer is used.

Example: 'Height',2

Data Types: double

'Name' — The name or label for the divider

'' (default) | character vector

Specify as a character vector the name that you would like to set for the new divider.

Example: 'Name','MyDivider'

Data Types: char

moveDisplayChannel

System object: dsp.LogicAnalyzer
Package: dsp

Move position of specified display channel

Syntax

```
moveDisplayChannel(scope,tag,'DisplayChannel',displayChannelValue)
moveDisplayChannel(
scope,'DisplayChannelTag',tag,'DisplayChannel',displayChannelValue)
```

Description

`moveDisplayChannel(scope,tag,'DisplayChannel',displayChannelValue)` moves the display channel, either a wave or a divider, specified by the input `tag`, to the new location specified by the input `displayChannelValue`.

`moveDisplayChannel(`
`scope,'DisplayChannelTag',tag,'DisplayChannel',displayChannelValue)` moves the display channel, either a wave or a divider, specified by the input `tag`, to the new location specified by the input `displayChannelvValue`.

Input Arguments

`scope` — The Logic Analyzer object in which you want to move a display channel

`dsp.LogicAnalyzer` object

The Logic Analyzer object in which you want to move a display channel, specified as a handle to the `dsp.LogicAnalyzer` object.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'DisplayChannelTag','W1'` specifies to delete the divider with tag `'W1'`.

`'DisplayChannelTag'` — The tag identifying which display channel to move
character vector

The tag identifying which display channel to move, specified as a character vector.

Example: `'DisplayChannelTag','W1'`

Data Types: `char`

`'DisplayChannel'` — The location identifying where the display channel should be moved
scalar integer

The location identifying where the display channel should be moved, specified as a scalar integer.

Example: `'DisplayChannel',2`

Data Types: `double`

reset

System object: dsp.LogicAnalyzer
Package: dsp

Reset internal states of scope object

Syntax

```
reset(scope)
```

Description

`reset(scope)` sets the internal states of the scope object to their initial values.

You should call the `reset` method after calling the `step` method when you want to clear the scope figure displays, prior to releasing system resources. This action enables you to start a simulation from the beginning. When you call the `reset` method, the displays will become blank again. In this sense, its functionality is similar to that of the MATLAB `clf` function. Do not call the `reset` method after calling the `release` method.

Algorithms

In operation, the `reset` method is similar to a consecutive execution of the `mdlTerminate` function and the `mdlInitializeConditions` function.

See Also

dsp.LogicAnalyzer

show

System object: dsp.LogicAnalyzer
Package: dsp

Make scope window visible

Syntax

`show(scope)`

Description

`show(scope)` makes the window associated with System object, `scope`, visible.

See Also

dsp.LogicAnalyzer.hide

step

System object: dsp.LogicAnalyzer
Package: dsp

Display signal in scope figure

Syntax

```
step(scope,X)
step(scope,X1,X2,...,XN)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`step(scope,X)` displays the signal, `X`, in the scope figure.

`step(scope,X1,X2,...,XN)` displays the signals `X1`, `X2`,...,`XN` in the scope figure when you set the `NumInputPorts` property to `N`. In this case, `X1`, `X2`,...,`XN` can have different data types and dimensions.

dsp.LowerTriangularSolver System object

Package: dsp

Solve lower-triangular matrix equation

Description

The `LowerTriangularSolver` object solves $LX = B$ for X when L is a square, lower-triangular matrix with the same number of rows as B.

To solve $LX = B$ for X:

1. Define and set up your linear system solver. See “Construction” on page 4-1170.
2. Call step to solve the equation according to the properties of `dsp.LowerTriangularSolver`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`lowtriang = dsp.LowerTriangularSolver` returns a linear system solver, `lowtriang`, used to solve the linear system $LX = B$, where L is a lower (or unit-lower) triangular matrix.

`lowtriang = dsp.LowerTriangularSolver('`*`PropertyName`*`',`*`PropertyValue`*`,...)` returns a linear system solver, `lowtriang`, with each specified property set to the specified value.

Properties

OverwriteDiagonal

Replace diagonal elements of input with ones

When you set this property to `true`, the linear system solver replaces the elements on the diagonal of the input, *L*, with ones. Set this property to either `true` or `false`. The default is `false`.

RealDiagonalElements

Indicate that diagonal of complex input is real

When you set this property to `true`, the linear system solver optimizes computation speed if the diagonal elements of complex input, *L*, are real. This property applies only when you set the `OverwriteDiagonal` on page 4-1171 property to `false`. Set this property to either `true` or `false`. The default is `false`.

Fixed-Point Properties

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as `Ceiling`, `Convergent`, `Floor`, `Nearest`, `Round`, `Simplest`, or `Zero`. The default is `Floor`.

OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as `Wrap` or `Saturate`. The default is `Wrap`.

ProductDataType

Data type of product

Specify the product data type as `Full precision`, `Same as input`, or `Custom`. The default is `Full precision`.

CustomProductDataType

Product word and fraction lengths

Specify the product fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when you set the `ProductDataType` on page 4-1171 property to `Custom`. The default is `numerictype([],32,30)`.

AccumulatorDataType

Data type of accumulator

Specify the accumulator data type as `Full precision`, `Same as first input`, `Same as product`, or `Custom`. The default is `Full precision`.

CustomAccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when you set the `AccumulatorDataType` on page 4-1172 property to `Custom`. The default is `numerictype([],32,30)`.

OutputDataType

Data type of output

Specify the output data type as `Same as first input` or `Custom`. The default is `Same as first input`.

CustomOutputDataType

Output word and fraction lengths

Specify the output fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when you set the `OutputDataType` on page 4-1172 property to `Custom`. The default is `numerictype([],16,15)`.

Methods

step	Solve matrix equation for specified inputs

Common to All System Objects	
clone	Create System object with same property values
getNumInpu	Expected number of inputs to a System object
getNumOutp	Expected number of outputs of a System object
isLocked	Check locked states of a System object (logical)
release	Allow System object property value changes

Examples

Solve a Lower Triangular Matrix

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

```
lowtriang = dsp.LowerTriangularSolver;
u = tril(rand(4, 4));
b = rand(4, 1);
```

Check that result is the solution to the linear equations.

```
x1 = inv(u)*b
x = lowtriang(u, b)

x1 =

    0.5177
    4.5810
   -3.4853
    9.6147

x =

    0.5177
    4.5810
   -3.4853
    9.6147
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the `Forward Substitution` block reference page. The object properties correspond to the block parameters.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See "System Objects in MATLAB Code Generation" (MATLAB Coder).

See Also

dsp.UpperTriangularSolver

Introduced in R2012a

step

System object: dsp.LowerTriangularSolver
Package: dsp

Solve matrix equation for specified inputs

Syntax

`X = step(lowtriang,L,B)`

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`X = step(lowtriang,L,B)` computes the solution, X, of the matrix equation $LX = B$, where L is a square, lower-triangular matrix with the same number of rows as the matrix B.

Note: `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

dsp.LowpassFilter System object

Package: dsp

FIR or IIR lowpass filter

Description

`dsp.LowpassFilter` independently filters each channel of the input over time using the given design specifications. You can set the `FilterType` property of `dsp.LowpassFilter` to `'FIR'` or `'IIR'` to implement the object as a FIR or IIR lowpass filter. This object supports fixed-point operations, HDL code generation, and ARM Cortex code generation.

To filter each channel of your input:

1. Define and set up your lowpass filter. See "Construction" on page 4-1176.
2. Call step to filter each channel of the input signal according to the properties of `dsp.LowpassFilter`. The input signal can be a real- or complex-valued column vector or matrix, with floating point or fixed-point precision. If the input signal is a matrix, each column of the matrix is treated as an independent channel. The number of rows in the input signal denote the channel length.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`LPF = dsp.LowpassFilter` returns a minimum order FIR lowpass filter, `LPF`, with the default filter settings. Calling `step` with the default property settings filters the input data with a passband frequency of `8` kHz, a stopband frequency of `12` kHz, a passband ripple of `0.1` dB, and a stopband attenuation of `80` dB.

`LPF = dsp.LowpassFilter(Name,Value)` returns a lowpass filter, with additional properties specified by one, or more `Name,Value` pair arguments. `Name` is the property name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name-value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Properties

`SampleRate` — Input sample rate
`44100` (default) | real positive scalar

Input sample rate in Hz, specified as the comma-separated pair consisting of `'SampleRate'` and a real positive scalar.

`FilterType` — Filter type
`'FIR'` (default) | `'IIR'`

Filter type, specified as one of the following options:

- `'FIR'` — The object designs an FIR lowpass filter.
- `'IIR'` — The object designs an IIR lowpass (biquad) filter.

`DesignForMinimumOrder` — Minimum order filter design
`true` (default) | `false`

Minimum order filter design, specified as the comma-separated pair consisting of `'DesignForMinimumOrder'` and a logical value. If this property is `true`, then `dsp.LowpassFilter` designs filters with the minimum order that meets the passband frequency, stopband frequency, passband ripple, and stopband attenuation specifications. Set these specifications using the corresponding properties. If this property is `false`, then the object designs filters with the order that you specify in the `FilterOrder` property. This filter design meets the passband frequency, passband ripple, and stopband attenuation specifications that you set using the respective properties.

`FilterOrder` — Order of the FIR or IIR filter
`50` (default) | positive integer scalar

Order of the FIR or IIR filter, specified as the comma-separated pair consisting of `'FilterOrder'` and a positive integer scalar. Specifying a filter order is only valid when the value of `'DesignForMinimumOrder'` is `false`.

`PassbandFrequency` — Filter passband edge frequency
`8000` (default) | real positive scalar

Filter passband edge frequency in Hz, specified as the comma-separated pair of 'PassbandFrequency' and a real positive scalar. The value of the passband edge frequency in Hz must be less than half the SampleRate.

StopbandFrequency — Filter stopband edge frequency
12000 (default) | real positive scalar

Filter stopband edge frequency in Hz, specified as the comma-separated pair consisting of 'StopbandFrequency' and a real positive scalar. The value of the stopband edge frequency in Hz must be less than half the SampleRate. You can specify the stopband edge frequency only when 'DesignForMinimumOrder' is true.

PassbandRipple — Maximum ripple of filter response in the passband
0.1 (default) | real positive scalar

Maximum ripple of filter response in the passband, in dB, specified as the comma-separated pair consisting of 'PassbandRipple' and a real positive scalar. Maximum ripple of filter response defaults to 0.1 dB.

StopbandAttenuation — Minimum attenuation in the stopband
80 (default) | real positive scalar

Minimum attenuation in the stopband in dB, specified as the comma-separated pair consisting of 'StopbandAttenuation' and a real positive scalar. Minimum attenuation in the stopband defaults to 80 dB.

Fixed-Point Properties

RoundingMethod — Rounding method for output fixed-point operations
'Floor' (default) | 'Ceiling' | 'Convergent' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'

Rounding method for output fixed-point operations, specified as a character vector. For more information on the rounding modes, see "Precision and Range".

CoefficientsDataType — Word and fraction lengths of coefficients
numerictype(1,16) (default) | numerictype object

Word and fraction lengths of coefficients, specified as a numerictype object. The default, numerictype(1,16) corresponds to a signed numeric type object with 16-bit coefficients and a fraction length determined based on the coefficient values, to give the best possible precision.

This property is not tunable.

Word length of the output is same as the word length of the input. Fraction length of the output is computed such that the entire dynamic range of the output can be represented without overflow. For details on how the fraction length of the output is computed, see “Fixed-Point Precision Rules for Avoiding Overflow in FIR Filters”.

Methods

measure	Measure frequency response characteristics of `dsp.LowpassFilter` System object.
reset	Reset internal states of lowpass filter
step	Filter input using FIR or IIR lowpass filter

For additional methods, see “Analysis Methods for Filter System Objects” on page 3-2.

For a complete list of analysis methods supported for the `dsp.LowpassFilter` object, enter `dsp.LowpassFilter.helpFilterAnalysis` at the MATLAB command prompt.

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Impulse and Frequency Response of FIR and IIR Lowpass Filters

Create a minimum order FIR lowpass filter for data sampled at 44.1 kHz. Specify a passband frequency of 8 kHz, a stopband frequency of 12 kHz, a passband ripple of 0.1 dB, and a stopband attenuation of 80 dB.

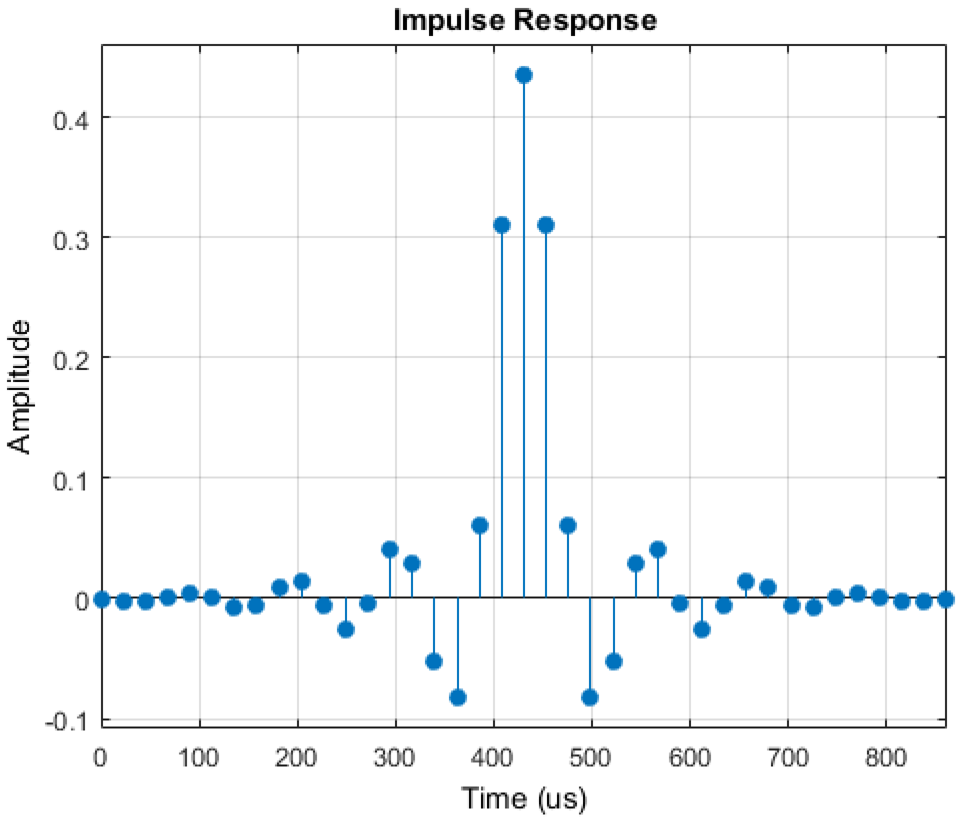
```
Fs = 44.1e3;
filtertype = 'FIR';
Fpass = 8e3;
Fstop = 12e3;
Rp = 0.1;
Astop = 80;
FIRLPF = dsp.LowpassFilter('SampleRate',Fs,...
                             'FilterType',filtertype,...
                             'PassbandFrequency',Fpass,...
                             'StopbandFrequency',Fstop,...
                             'PassbandRipple',Rp,...
                             'StopbandAttenuation',Astop);
```

Design a minimum order IIR lowpass filter with the same properties as the FIR lowpass filter. Use `clone` to create a system object with the same properties as the FIR lowpass filter. Change the `FilterType` property of the cloned filter to `IIR`.

```
IIRLPF = clone(FIRLPF);
IIRLPF.FilterType = 'IIR';
```

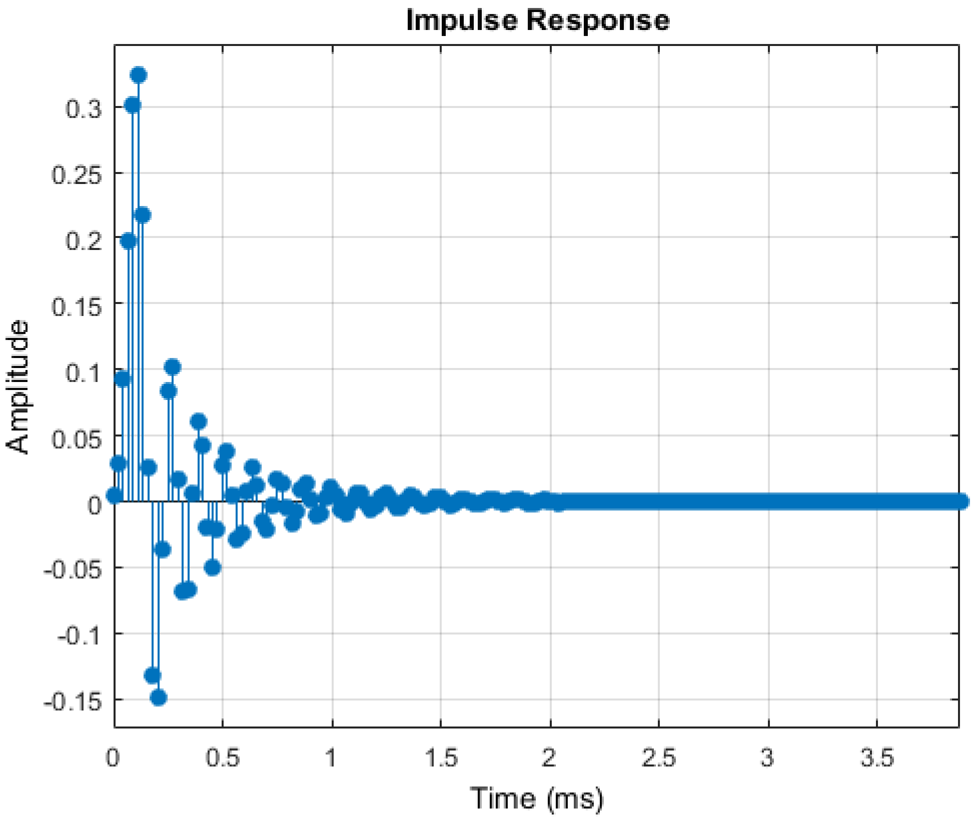
Plot the impulse response of the FIR lowpass filter. The zeroth order coefficient is delayed by 19 samples, which is equal to the group delay of the filter. The FIR lowpass filter is a causal FIR filter.

```
fvtool(FIRLPF,'Analysis','impulse')
```



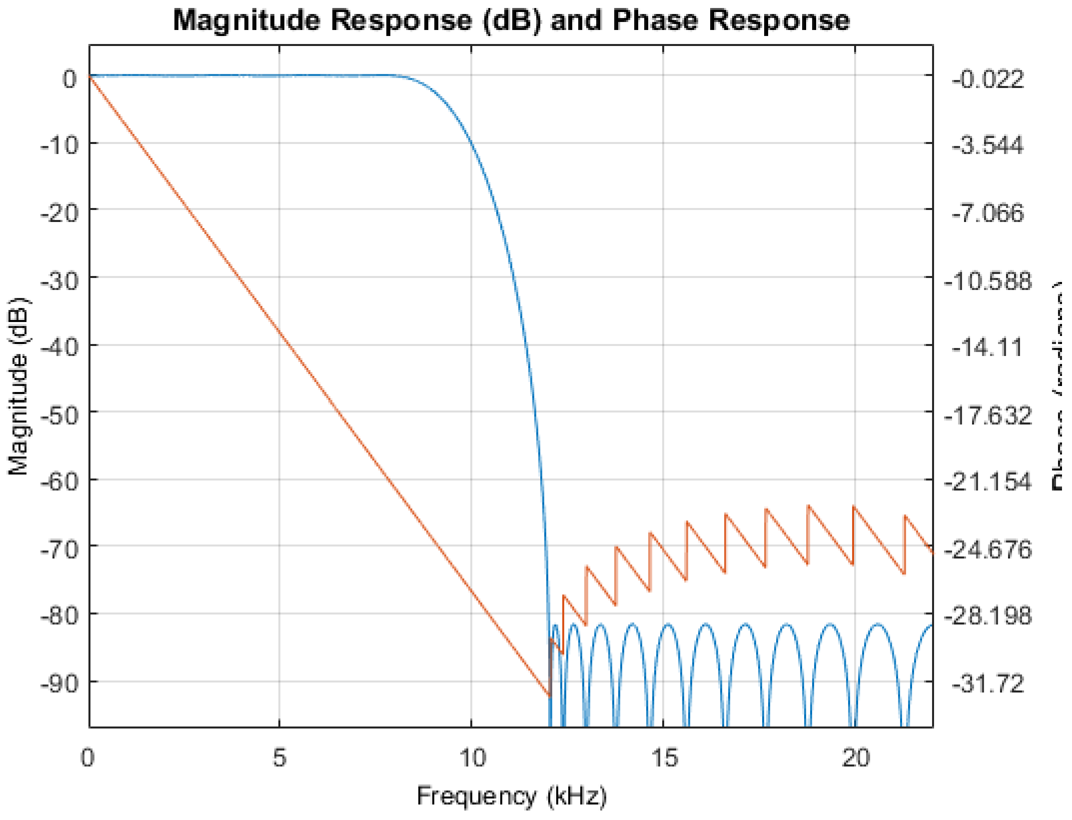
Plot the impulse response of the IIR lowpass filter.

```
fvtool(IIRLPF,'Analysis','impulse')
```



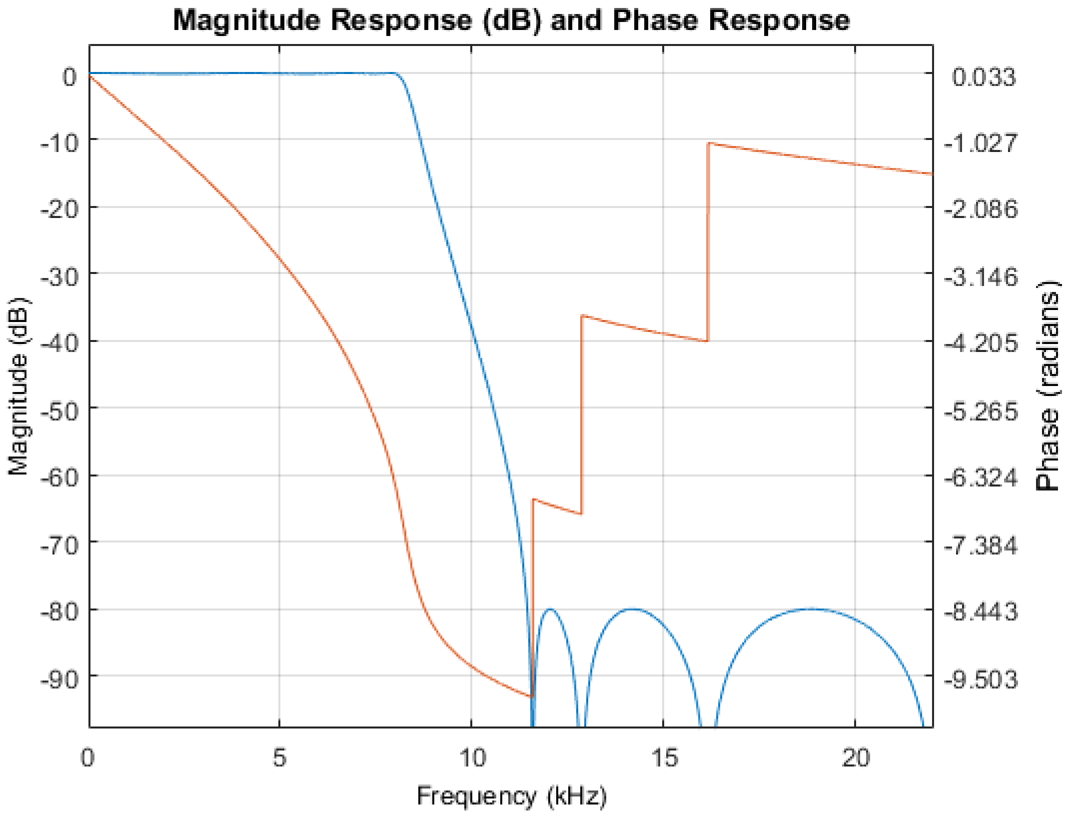
Plot the magnitude and phase response of the FIR lowpass filter.

```
fvtool(FIRLPF,'Analysis','freq')
```



Plot the magnitude and phase response of the IIR lowpass filter.

```
fvtool(IIRLPF,'Analysis','freq')
```



Calculate the cost of implementing the FIR lowpass filter.

```
cost(FIRLPF)
```

```
ans =

  struct with fields:

                NumCoefficients: 39
                      NumStates: 38
    MultiplicationsPerInputSample: 39
          AdditionsPerInputSample: 38
```

Calculate the cost of implementing the IIR lowpass filter. The IIR filter is more efficient to implement than its FIR counterpart.

```
cost(IIRLPF)
```

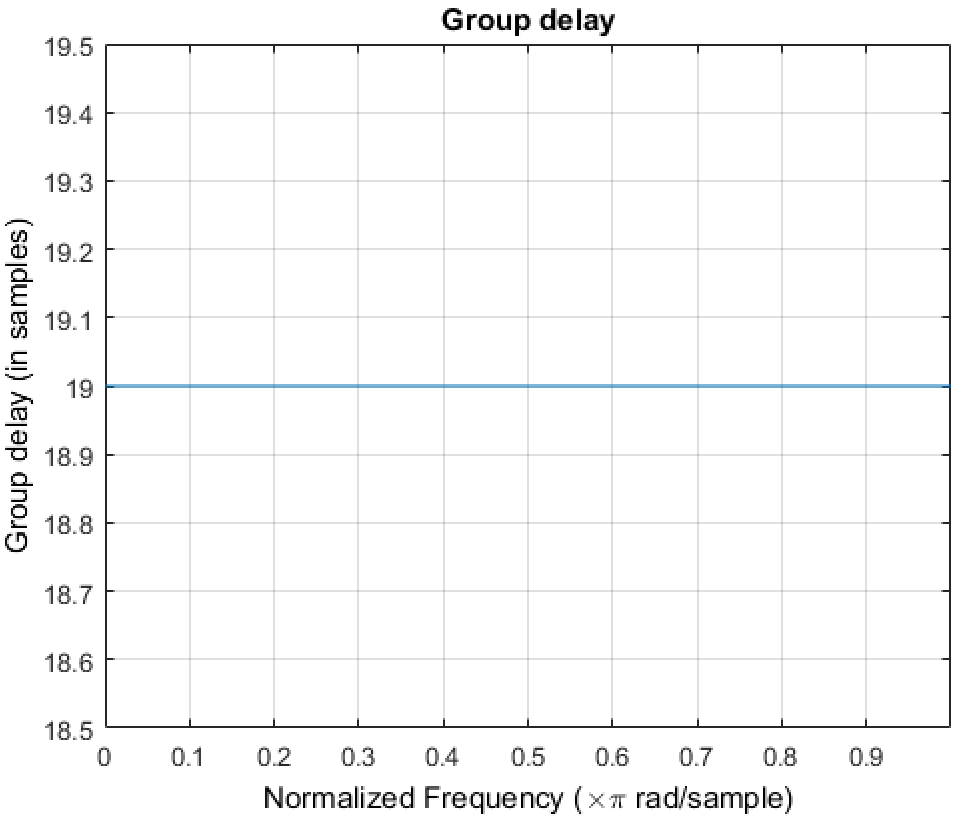
```
ans = 

  struct with fields:

                  NumCoefficients: 18
                        NumStates: 14
    MultiplicationsPerInputSample: 18
          AdditionsPerInputSample: 14
```

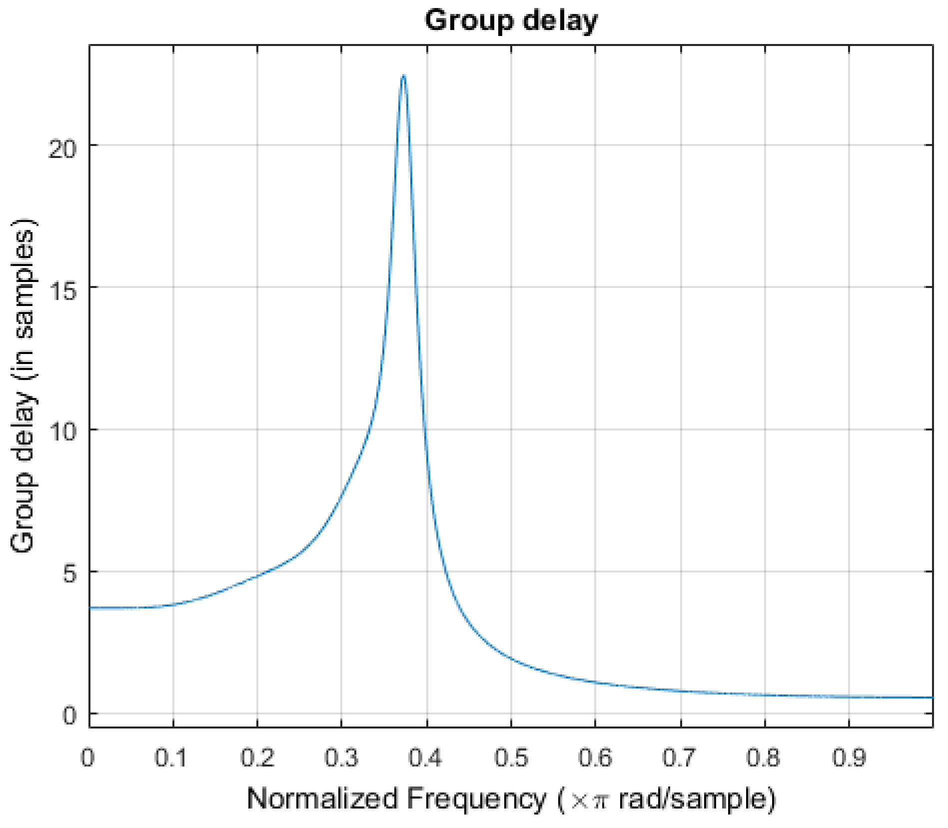
Calculate the group delay of the FIR lowpass filter.

```
grpdelay(FIRLPF)
```



Calculate the group delay of the IIR lowpass filter. The FIR filter has a constant group delay (linear phase), while its IIR counterpart does not.

```
grpdelay(IIRLPF)
```



Filter White Gaussian Noise

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

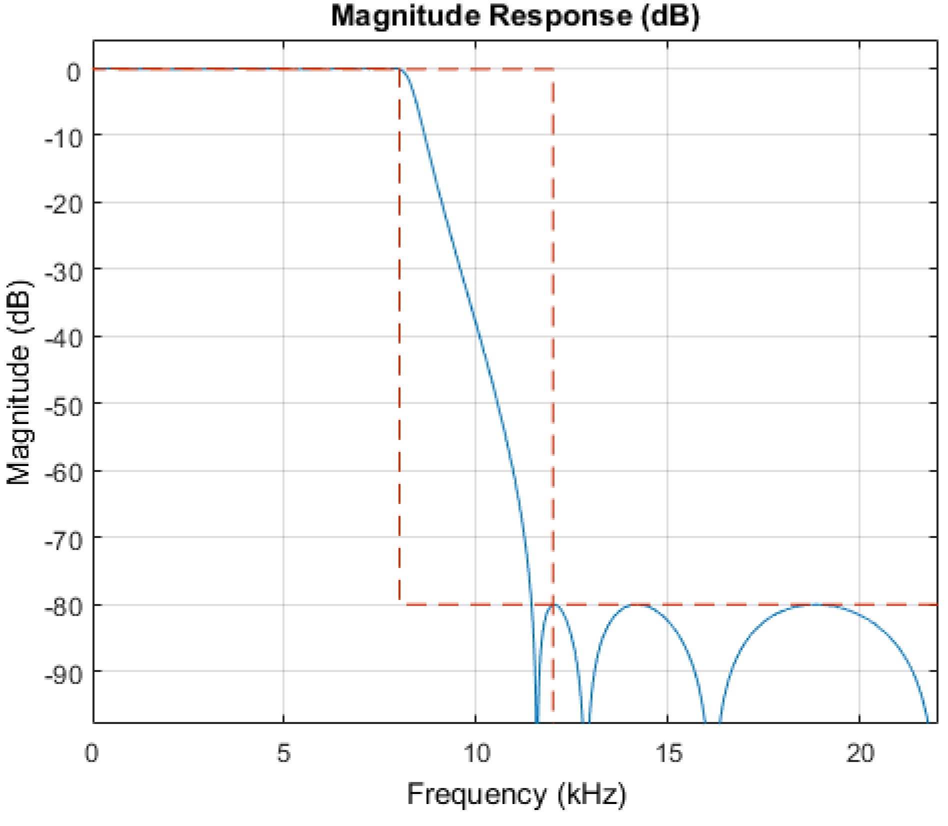
Set up the IIR lowpass filter. The sampling rate of the white Gaussian noise is 44,100 Hz. The passband frequency of the filter is 8 kHz, the stopband frequency is 12 kHz, the passband ripple is 0.1 dB, and the stopband attenuation is 80 dB.

```
Fs = 44.1e3;
filtertype = 'IIR';
Fpass = 8e3;
Fstop = 12e3;
```

```
Rp = 0.1;
Astop = 80;
LPF = dsp.LowpassFilter('SampleRate',Fs,...
                        'FilterType',filtertype,...
                        'PassbandFrequency',Fpass,...
                        'StopbandFrequency',Fstop,...
                        'PassbandRipple',Rp,...
                        'StopbandAttenuation',Astop);
```

View the magnitude response of the lowpass filter.

```
fvtool(LPF)
```



Create a spectrum analyzer object.

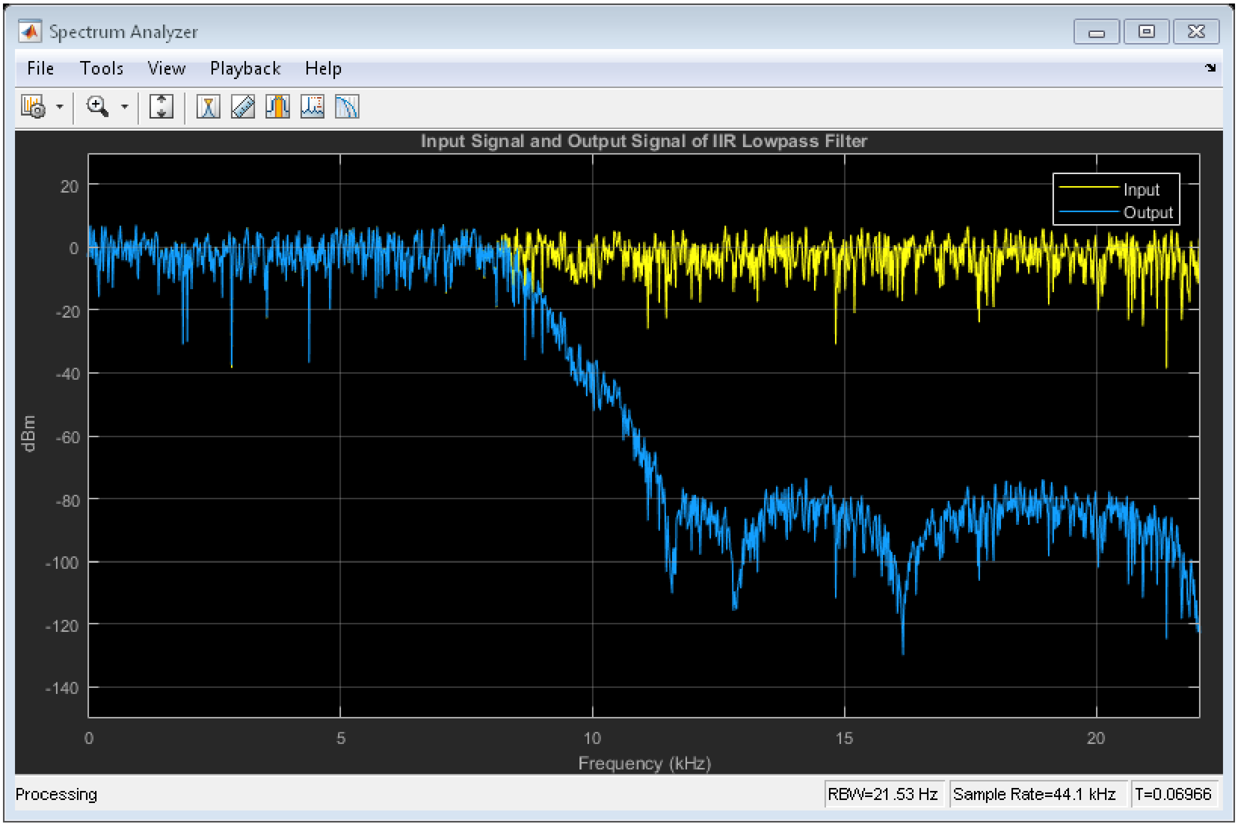
```
hSA = dsp.SpectrumAnalyzer('SampleRate',44.1e3,...
    'PlotAsTwoSidedSpectrum',false,'ShowLegend',true,'YLimits',...
           [-150 30],...
           'Title',...
           'Input Signal and Output Signal of IIR Lowpass Filter');
hSA.ChannelNames = {'Input','Output'};
```

Filter the white Gaussian noisy input signal. View the input and output signals using the spectrum analyzer.

```
for k = 1:100
    Input = randn(1024,1);

    Output = LPF(Input);

    hSA([Input,Output]);
end
```



Supported Data Types

Argument	Supported Data Types
Input	• Double-precision floating point • Single-precision floating point • Fixed point
Output	• Double-precision floating point • Single-precision floating point • Fixed point

Algorithms

FIR Lowpass Filter

When the `FilterType` property is set to `'FIR'`, the `dsp.LowpassFilter` object acts as a FIR lowpass filter.

In this configuration, `dsp.LowpassFilter` is an alternative to using `firceqrip` and `firgr` with `dsp.FIRFilter`. This object condenses the two-step process into one. For the minimum order design, the object uses generalized Remez FIR filter design algorithm. For the specified order design, the object uses the constrained equiripple FIR filter design algorithm. The designed filter is then implemented as a linear phase Type-1 filter with a `Direct form` structure. You can use dsp.LowpassFilter.measure to verify that the design meets the prescribed specifications.

IIR Lowpass Filter

When the `FilterType` property is set to `'IIR'`, the `dsp.LowpassFilter` object acts as an IIR lowpass filter. In this configuration, the object uses the elliptic design method to compute the SOS and scale values required to meet the filter design specifications. The object uses the SOS and scale values to setup a `Direct form I` biquadratic IIR filter, which forms the basis of the IIR version of the `dsp.LowpassFilter` System object. You can use dsp.LowpassFilter.measure to verify that the design meets the prescribed specifications.

dsp.HighpassFilter | “Lowpass Filter Design in MATLAB”

Introduced in R2015a

measure

System object: dsp.LowpassFilter
Package: dsp

Measure frequency response characteristics of `dsp.LowpassFilter` System object.

Syntax

`LPFMeas = measure(LPF)`

Description

`LPFMeas = measure(LPF)` measures the frequency response characteristics of the `dsp.LowpassFilter` System object, `LPF`.

Input Arguments

`LPF` — FIR or IIR lowpass filter

`LowpassFilter` System object

FIR or IIR lowpass filter, specified as a `LowpassFilter` System object.

Output Arguments

`LPFMeas` — Measurements of frequency response characteristics of the lowpass filter

`LowpassFilter` System object

Measurements of frequency response characteristics of the lowpass filter, returned as an `fdesign.lowpassmeas` object.

Examples

Measure Frequency Response Characteristics of Lowpass Filter

Measure the frequency response characteristics of a lowpass filter. Create a `dsp.LowpassFilter` System object with default properties. Measure the frequency response characteristics of the filter.

```
LPF = dsp.LowpassFilter
LPFMeas = measure(LPF)
```

```
LPF = 

  dsp.LowpassFilter with properties:

               FilterType: 'FIR'
    DesignForMinimumOrder: true
        PassbandFrequency: 8000
        StopbandFrequency: 12000
           PassbandRipple: 0.1000
      StopbandAttenuation: 80
               SampleRate: 44100

  Use get to show all properties

LPFMeas = 

Sample Rate      : 44.1 kHz
Passband Edge    : 8 kHz
3-dB Point       : 9.1311 kHz
6-dB Point       : 9.5723 kHz
Stopband Edge    : 12 kHz
Passband Ripple  : 0.08289 dB
Stopband Atten.  : 81.6141 dB
Transition Width : 4 kHz
```

Introduced in R2015a

reset

System object: dsp.LowpassFilter
Package: dsp

Reset internal states of lowpass filter

Syntax

`reset(LPF)`

Description

`reset(LPF)` resets the filter states of the lowpass filter, `LPF`, to their initial values. The initial filter state values correspond to the initial conditions for the difference equation defining the filter. After the `step` method applies the lowpass filter to nonzero input data, the filter might have nonzero states. If you Invoke the `step` method again without first invoking the `reset` method, the object might produce different outputs for an identical input.

Input Arguments

`LPF` — FIR or IIR lowpass filter

`LowpassFilter` System object

FIR or IIR lowpass filter, specified as a `LowpassFilter` System object.

Examples

Reset a Lowpass Filter

Create a lowpass filter with default properties.

```
LPF = dsp.LowpassFilter;
```

Create a two-channel random signal. Apply the `step` method twice on the signal.

```
x = randn(10,2);

y1 = step(LPF,x);
y2 = step(LPF,x);

no = all(y2==y1)

no =

  1×2 logical array

   0   0
```

The output is different because the internal states of `LPF` have changed. Use `reset` to reset the lowpass filter and apply `step` again. Verify that the output is unchanged.

```
reset(LPF)

y3 = step(LPF,x);

yes = all(y3==y1)

yes =

  1×2 logical array

   1   1
```

Introduced in R2015a

step

System object: dsp.LowpassFilter
Package: dsp

Filter input using FIR or IIR lowpass filter

Syntax

`Y = step(LPF,X)`

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(LPF,X)` filters the real or complex input signal, `X`, using the lowpass filter, `LPF`. `Y` is a lowpass-filtered version of `X`. The input `X` must be a column vector or matrix. If `X` is a matrix, each column is treated as an independent channel. `X` can be a floating point or a fixed-point input.

Input Arguments

`LPF` — FIR or IIR lowpass filter

`LowpassFilter` System object

FIR or IIR lowpass filter, specified as a `LowpassFilter` System object.

`X` — Input signal

vector | matrix

Input signal, specified as a vector or matrix with floating point or fixed-point precision. The row length of `X` is the frame size, that is, channel length. Each column of `X` is treated as a separate channel. The column length of `X` is the number of channels.

Output Arguments

Y — Lowpass-filtered signal

vector | matrix

Lowpass-filtered signal, returned as a vector or matrix of the same size, data type, and complexity as the input signal, X.

Examples

Filter White Gaussian Noise Signal With Lowpass Filter

Create a lowpass filter with default properties.

```
LPF = dsp.LowpassFilter;
```

Create a spectrum analyzer object.

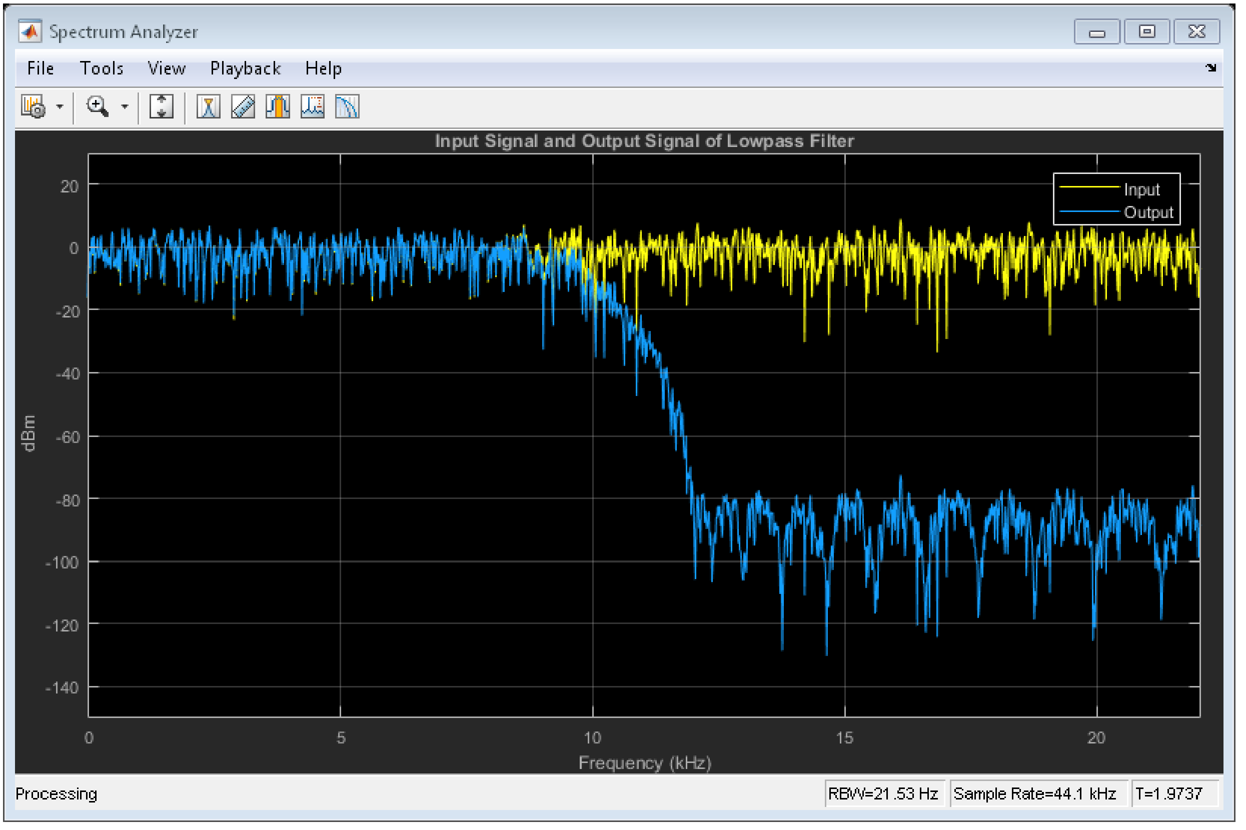
```
hSA = dsp.SpectrumAnalyzer('SampleRate',44.1e3,...
    'PlotAsTwoSidedSpectrum',false,'ShowLegend',true,'YLimits',...
           [-150 30],...
           'Title',...
           'Input Signal and Output Signal of Lowpass Filter');
hSA.ChannelNames = {'Input','Output'};
```

Implement step on LPF to filter the white Gaussian noisy input signal. View the input and output signals using the spectrum analyzer.

```
for k = 1:100
    Input = randn(1024,1);

    Output = step(LPF,Input);

    step(hSA,[Input,Output]);
end
```



Introduced in R2015a

dsp.LPCToAutocorrelation System object

Package: dsp

Convert linear prediction coefficients to autocorrelation coefficients

Description

The `LPCToAutocorrelation` System object converts linear prediction coefficients to autocorrelation coefficients.

To convert LPC to autocorrelation coefficients:

1 Define and set up your LPC to autocorrelation object. See "Construction" on page 4-1200.
2 Call step to convert LPC according to the properties of `dsp.LPCToAutocorrelation`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`lpc2ac = dsp.LPCToAutocorrelation` returns an LPC to autocorrelation System object, `lpc2ac`, that converts linear prediction coefficients (LPC) to autocorrelation coefficients.

`lpc2ac = dsp.LPCToAutocorrelation('`*`PropertyName`*`',`*`PropertyValue`*`,...)` returns an `LPC` to autocorrelation conversion object, `lpc2ac`, with each specified property set to the specified value.

Properties

`PredictionErrorInputPort`

Enable prediction error power input

Choose how to select the prediction error power. When you set this property to `true`, you must specify the prediction error power as a second input to the `step` method. When you set this property to `false`, the object assumes that the prediction error power is `1`. The default is `false`.

`NonUnityFirstCoefficientAction`

Action to take when first LPC coefficient is not `1`

Specify the action that the object takes when the first coefficient of each channel of the LPC input is not `1`. Select `Replace with 1` or `Normalize`. The default is `Replace with 1`.

Methods

step	Autocorrelation coefficients from LPC coefficients

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Convert LPC To Autocorrelation Coefficients

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

Convert the linear prediction coefficients to autocorrelation coefficients.

```
a = [1.0 -1.4978 1.4282 -1.3930 0.9076 -0.3855 0.0711].';
lpc2ac = dsp.LPCToAutocorrelation;
ac = lpc2ac(a);
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the `LPC/RC to Autocorrelation` block reference page. The object properties correspond to the block parameters, except:
The object does not have a property that corresponds to the **Type of Conversion** block parameter. The object's behavior corresponds to the block's behavior when you set the **Type of Conversion** parameter to `LPC to autocorrelation`.

Extended Capabilities

C/C++ Code Generation
Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

dsp.LPCToRC | dsp.LPCToLSF | dsp.LPCToCepstral | dsp.RCToAutocorrelation

Introduced in R2012a

step

System object: dsp.LPCToAutocorrelation
Package: dsp

Autocorrelation coefficients from LPC coefficients

Syntax

```
AC = step(lpc2ac,A)
AC = step(lpc2ac,A,P)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`AC = step(lpc2ac,A)` converts the columns of the linear prediction coefficients, `A`, to autocorrelation coefficients, `AC`. The object assumes a prediction error power of `1`.

`AC = step(lpc2ac,A,P)` when you set the `PredictionErrorInputPort` property to `true`, converts the columns of the linear prediction coefficients, `A`, to autocorrelation coefficients, `AC`. This conversion uses `P` as the prediction error power. `P` must be a row vector with same number of columns as `A`.

Note: `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

dsp.LPCToCepstral System object

Package: dsp

Convert linear prediction coefficients to cepstral coefficients

Description

The `LPCToCepstral` object converts linear prediction coefficients to cepstral coefficients.

To convert LPC to cepstral coefficients:

1. Define and set up your LPC to cepstral converter. See "Construction" on page 4-1204.
2. Call step to convert LPC according to the properties of `dsp.LPCToCepstral`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`lpc2cc = dsp.LPCToCepstral` returns an LPC to cepstral converter object, `lpc2cc`, that converts linear prediction coefficients (LPCs) to cepstral coefficients (CCs).

`lpc2cc = dsp.LPCToCepstral('`*`PropertyName`*`',`*`PropertyValue`*`,...)` returns an LPC to cepstral converter object, `lpc2cc`, with each specified property set to the specified value.

Properties

`PredictionErrorInputPort`

Enable prediction error power input

Choose how to set the prediction error power. When you set this property to `true`, you must specify the prediction error as a second input to the `step` method. When you set this property to `false`, the object assumes the prediction error power is 1. The default is `false`.

CepstrumLengthSource

Source of cepstrum length

Select how to specify the length of cepstral coefficients: `Auto` or `Property`. The default is `Auto`. When this property is set to `Auto`, the length of each channel of the cepstral coefficients output is the same as the length of each channel of the input LPC coefficients. The default is `Property`.

CepstrumLength

Number of output cepstral coefficients

Set the length of the output cepstral coefficients vector as a scalar numeric integer. This property applies when you set the `CepstrumLengthSource on page 4-` property to `Property`. The default is `10`.

NonUnityFirstCoefficientAction

LPC coefficient nonunity action

Specify the action that the object takes when the first coefficient of each channel of the LPC input is not `1`. Select `Replace with 1` or `Normalize`. The default is `Replace with 1`.

Methods

step	Cepstral coefficients from columns of input LPC coefficients

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object

Common to All System Objects	
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Convert LPC To Cepstral Coefficients

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

```
levinson = dsp.LevinsonSolver;
levinson.AOutputPort = true; % Output polynomial coefficients
ac = dsp.Autocorrelator;
ac.MaximumLagSource = 'Property';
ac.MaximumLag = 9; % Compute autocorrelation lags between [0:9]
lpc2cc = dsp.LPCToCepstral;
x = (1:100)';
a = ac(x);
```

Compute LPC coefficients.

```
A = levinson(a);
```

Convert LPC to CC.

```
CC = lpc2cc(A);
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the `LPC to/from Cepstral Coefficients` block reference page. The object properties correspond to the block parameters, except:
The object does not have a property that corresponds to the **Type of Conversion** block parameter. The object's behavior corresponds to the block's behavior when you set the **Type of Conversion** parameter to `LPCs to cepstral coefficients`.

step

System object: dsp.LPCToCepstral
Package: dsp

Cepstral coefficients from columns of input LPC coefficients

Syntax

```
CC = step(lpc2cc,A)
CC = step(lpc2cc,A,P)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`CC = step(lpc2cc,A)` computes the cepstral coefficients, `CC`, from the columns of input linear prediction coefficients, `A`. The object assumes the prediction error power is `1`.

`CC = step(lpc2cc,A,P)` when you set the `PredictionErrorInputPort` property to `true`, computes the cepstral coefficients, `CC`, from the columns of input linear prediction coefficients, `A`. This conversion uses `P` as the prediction error power.

Note: `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.LPCToLSF System object

Package: dsp

Convert linear prediction coefficients to line spectral frequencies

Description

The `LPCToLSF` object converts linear prediction coefficients to line spectral frequencies.

To convert LPC to LSF:

1 Define and set up your LPC to LSF converter. See "Construction" on page 4-1209.
2 Call step to convert LPC according to the properties of `dsp.LPCToLSF`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`lpc2lsf = dsp.LPCToLSF` returns a System object, `lpc2lsf`, that converts linear prediction coefficients (LPCs) to line spectral frequencies (LSFs).

`lpc2lsf = dsp.LPCToLSF('`*`PropertyName`*`',`*`PropertyValue`*`,...)` returns an LPC to LSF System object, `lpc2lsf`, with each specified property set to the specified value.

Properties

`NumCoarseGridPoints`

Number of coarse subintervals used for finding roots (LSP values)

Specify the number of coarse subintervals, `n`, used for finding line spectral pairs (LSP) values as a positive scalar integer. LSPs, which are the roots of two particular polynomials related to the input LPC polynomial, always lie in the range (–1, 1). The System object finds these roots using the Chebyshev polynomial root finding method. To compute LSF outputs, the object computes the arc cosine of the LSPs, outputting values ranging from 0 to pi radians. The object divides the interval (–1, 1) into n subintervals and looks for roots in each subinterval. If you set *n* too small in relation to the LPC polynomial order, the object can fail to find some of the roots. The default is `64`. This property is tunable.

NumBisects

Value of bisection refinement used for finding roots

Specify the root bisection refinement value, `k`, used in the Chebyshev polynomial root finding method, where each line spectral pair (LSP) output is within

$$\frac{1}{(n \cdot 2^k)}$$

of the actual LSP value. Here *n* is the value of the `NumCoarseGridPoints on page 4-` property, and the object searches a maximum of $k \cdot (n-1)$ points for finding the roots. You must set the `NumBisects` property value *k*, to a positive scalar integer. The default is `4`. This property is tunable.

ExceptionOutputPort

Produces output with validity status of LSF output

Set this property to `true` to return a second output that indicates whether the computed LSF values are valid. The output is a vector with a length equal to the number of channels. A logical value of `1` indicates valid output. A logical value of `0` indicates invalid output. The LSF outputs are invalid when the object fails to find all the LSF values or when the input LPCs are unstable. The default is `false`.

OverwriteInvalidOutput

Enable overwriting invalid output with previous output

Specify the action that the System object should take for invalid LSF outputs. When you set this property to `true`, the object overwrites the invalid output with the previous output. When you set this property to `false`, the object does not take any action on invalid outputs and ignores the outputs.

FirstOutputValuesSource

Source of values for first output when output is invalid

Specify the source of values for the first output when the output is invalid as `Auto` or `Property`. This property applies when you set the `OverwriteInvalidOutput on page 4-` property to `true`. The default is `Auto`. When you set this property to `Auto`, the object uses a default value for the first output. The default value corresponds to the LSF representation of an allpass filter.

FirstOutputValues

Value of the first output

Specify a numeric vector of LSF values for overwriting an invalid first output. The length of this vector must be one less than the length of the input LPC vector. For multichannel inputs, you can set this property to a matrix with the same number of channels as the input, or one vector that is applied to every channel. The default is an empty vector. This property applies when you set the `OverwriteInvalidOutput on page 4-` property to `true` and the `FirstOutputValuesSource on page 4-` property to `Property`.

NonUnityFirstCoefficientAction

Action to take when first LPC coefficient is not `1`

Specify the action the object takes when the first coefficient of each channel of the LPC input is not `1` as `Replace with 1` or `Normalize`. The default is `Replace with 1`.

Methods

reset	Reset values for overwriting invalid outputs to their initial values
step	Convert LPC coefficients to line spectral frequencies

Common to All System Objects	
`clone`	Create System object with same property values

Common to All System Objects	
getNumInpu	Expected number of inputs to a System object
getNumOutp	Expected number of outputs of a System object
isLocked	Check locked states of a System object (logical)
release	Allow System object property value changes

Examples

Convert LPC Coefficients To LSF Coefficients

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

Convert LPC to LSF coefficients

```
a = [1.0000 0.6149 0.9899 0.0000 0.0031 -0.0082]';
lpc2lsf = dsp.LPCToLSF;
y = lpc2lsf(a);
display(y);
```

```
y =

    0.7842
    1.5605
    1.8776
    1.8984
    2.3593
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the `LPC to LSF/LSP Conversion` block reference page. The object properties correspond to the block parameters, except:
There is no object property that corresponds to the **Output** block parameter. The object only supports LSF outputs in the range $(0, \Pi)$

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

See Also

dsp.LPCToLSP | dsp.LSFToLPC

Introduced in R2012a

reset

Reset values for overwriting invalid outputs to their initial values

Syntax

```
reset(lpc2lsf)
```

Description

`reset(lpc2lsf)` resets the values for overwriting the invalid outputs to their initial values.

step

System object: dsp.LPCToLSF
Package: dsp

Convert LPC coefficients to line spectral frequencies

Syntax

```
LSF = step(lpc2lsf,A)
[..., STATUS] = step(lpc2lsf,A)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`LSF = step(lpc2lsf,A)` converts the `LPC` coefficients, `A` , to line spectral frequencies, `LSF`, in the range (0 pi). The System object operates along the columns of the input `A`.

`[..., STATUS] = step(lpc2lsf,A)` also returns the status flag, `STATUS`, indicating if the current output is valid when the `ExceptionOutputPort` property is `true`.

Note: `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

dsp.LPCToLSP System object

Package: dsp

Convert linear prediction coefficients to line spectral pairs

Description

The `LPCToLSP` object converts linear prediction coefficients to line spectral pairs.

To convert LPC to LSP:

1. Define and set up your LPC to LSP converter. See "Construction" on page 4-1216.
2. Call step to convert LPC according to the properties of `dsp.LPCToLSP`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`lpc2lsp = dsp.LPCToLSP` returns a System object, `lpc2lsp`, that converts linear prediction coefficients (LPCs) to line spectral pairs (LSPs).

`lpc2lsp = dsp.LPCToLSP('`*`PropertyName`*`',`*`PropertyValue`*`,...)` returns an `LPC` to `LSF` System object, `lpc2lsp`, with each specified property set to the specified value.

Properties

`NumCoarseGridPoints`

Number of coarse subintervals used for finding roots (LSP values)

Specify the number of coarse subintervals, *n*, used for finding line spectral pairs (LSP) values, as a positive scalar integer. LSPs, which are the roots of two particular polynomials related to the input LPC polynomial, always lie in the range (–1, 1). The System object finds these roots using the Chebyshev polynomial root finding method. The object divides the interval (–1, 1) into *n* subintervals and looks for roots in each subinterval. If *n* is set to too small a number in relation to the LPC polynomial order, the object can fail to find some of the roots. The default is `64`. This property is tunable.

`NumBisects`

Value of bisection refinement used for finding roots

Specify the root bisection refinement value, *k*, that the Chebyshev polynomial uses in the root finding method. For each line spectral pair (LSP) the output is within

$$\frac{1}{\mathrm{n} \cdot 2^{\mathrm{k}}}$$

of the actual LSP value. Here *n* is the value of the `NumCoarseGridPoints` on page 4- property and the object searches a maximum of

$$\mathrm{k} \cdot (\mathrm{n}\text{-}1)$$

points for finding the roots. The `NumBisects` on page 4- property value *k*, must be a positive scalar integer. The default is `4`. This property is tunable.

`ExceptionOutputPort`

Produces output with validity status of LSP output

Set this property to `true` to return a second output that indicates whether the computed LSP values are valid. The object outputs a vector length equal to the number of channels. A logical value of `1` indicates the output is valid. A logical value of `0` indicates the output is invalid. The LSP outputs are invalid when the object fails to find all the LSP values or when the input LPCs are unstable. The default is `false`.

`OverwriteInvalidOutput`

Enable overwriting invalid output with previous output

Specify the action that the object takes for invalid LSP outputs. When you set this property to `true`, the object overwrites the invalid output with the previous output.

When you set this property to `false`, the object takes no action on invalid outputs and ignores the outputs.

`FirstOutputValuesSource`

Source of values for first output when output is invalid

Specify the source of values for the first output when the output is invalid as `Auto` or `Property`. This property applies only when you set the `OverwriteInvalidOutput on page 4-` property to `true`. The default is `Auto`. When this property is `Auto`, the object uses a default value for the first output. The default value corresponds to the LSP representation of an allpass filter.

`FirstOutputValues`

Value of first output

Specify a numeric vector of LSP values for overwriting an invalid first output. The length of this vector must be one less than the length of the input LPC vector. For multichannel inputs, set this property can to a matrix with the same number of channels as the input or one vector that you apply to every channel. The default is an empty vector. This property applies only when you set the `OverwriteInvalidOutput on page 4-` property to `true` and the `FirstOutputValuesSource on page 4-` property to `Property`.

`NonUnityFirstCoefficientAction`

First coefficient nonunity action

Specify the action that the object takes when the first coefficient of each channel of the LPC input is not equal to `1`. Specify as one of `Replace with 1` or `Normalize`. The default is `Replace with 1`.

Methods

reset	Reset values for overwriting invalid outputs to their initial values
step	Convert linear prediction coefficients to line spectral pairs

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Convert LPC To LSP Coefficients

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

Convert the linear prediction coefficients to line spectral pairs.

```
a = [1.0000 0.6149 0.9899 0.0000 0.0031 -0.0082]';
lpc2lsp = dsp.LPCToLSP;
y = lpc2lsp(a); % Convert to LSP coefficients
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the `LPC to LSF/LSP Conversion` block reference page. The object properties correspond to the block parameters, except:
No object property corresponds to the **Output** block parameter. The object only supports LSP outputs.

`reset(H)` resets the values for overwriting the invalid outputs to their initial values.

step

System object: dsp.LPCToLSP
Package: dsp

Convert linear prediction coefficients to line spectral pairs

Syntax

```
LSF = step(lpc2lsp,A)
[..., STATUS] = step(lpc2lsp,A)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`LSF = step(lpc2lsp,A)` converts the `LPC` coefficients, `A` , to line spectral pairs normalized in the range (–1 1), `LSP`. The object operates along the columns of the input `A`.

`[..., STATUS] = step(lpc2lsp,A)` also returns the status flag, `STATUS`, indicating if the current output is valid when the `ExceptionOutputPort` property is `true`.

Note: `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.LPCToRC System object

Package: dsp

Convert linear prediction coefficients to reflection coefficients

Description

The `LPCToRC` object converts linear prediction coefficients to reflection coefficients.

To convert LPC to reflection coefficients:

1. Define and set up your LPC to RC converter. See "Construction" on page 4-1223.
2. Call step to convert LPC according to the properties of `dsp.LPCToRC`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`lpc2rc = dsp.LPCToRC` returns an LPC to RC System object, `lpc2rc`, that converts linear prediction coefficients (LPC) to reflection coefficients (RC).

`lpc2rc = dsp.LPCToRC('`*`PropertyName`*`',`*`PropertyValue`*`,...)` returns an LPC to RC conversion object, `lpc2rc`, with each specified property set to the specified value.

Properties

`PredictionErrorOutputPort`

Enable normalized prediction error power output

Set this property to `true` to return the normalized error power as a vector with one element per input channel. Each element varies between zero and one. The default is `true`.

ExceptionOutputPort

Produces output with stability status of filter represented by LPC coefficients

Set this property to `true` to return the stability status of the filter. A logical value of `1` indicate a stable filter. A logical value of `0` indicate an unstable filter. The default is `false`.

NonUnityFirstCoefficientAction

Action to take when first LPC coefficient is not 1

Specify the action that the object takes when the first coefficient of each channel of the LPC input is not 1. Select `Replace with 1` or `Normalize`. The default is `Replace with 1`.

Methods

step	Convert columns of linear prediction coefficients to reflection coefficients

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Convert LPC Coefficients To RC Coefficients

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

Convert the linear prediction coefficients to reflection coefficients:

```
load mtlb

levinson = dsp.LevinsonSolver;
levinson.AOutputPort = true;
levinson.KOutputPort = false;

ac = dsp.Autocorrelator;
lpc2rc = dsp.LPCToRC;
ac.MaximumLagSource = 'Property';
```

Compute autocorrelation for lags between [0:10]

```
ac.MaximumLag = 10;
a = ac(mtlb);
A = levinson(a); % Compute LPC coefficients
[K, P] = lpc2rc(A); % Convert to RC
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the `LPC to/from RC` block reference page. The object properties correspond to the block parameters, except:

- There is no object property that corresponds to the **Type of conversion** block parameter. The object always converts LPC to RC.
- The `NonUnityFirstCoefficientAction` object property corresponds to the **If first input value is not 1** block parameter. There is neither a `Normalize and warn` nor an `Error` option for the object.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

dsp.RCToLPC | dsp.LPCToAutocorrelation

Introduced in R2012a

step

System object: dsp.LPCToRC
Package: dsp

Convert columns of linear prediction coefficients to reflection coefficients

Syntax

```
[K,P] = step(lpc2rc,A)
K = step(lpc2rc,A)
[..., S] = step(lpc2rc,A)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`[K,P] = step(lpc2rc,A)` converts the columns of linear prediction coefficients, `A`, to reflection coefficients `K` and outputs the normalized prediction error power, `P`.

`K = step(lpc2rc,A)` when you set the `PredictionErrorOutputPort` property to `false`, converts the columns of linear prediction coefficients, `A`, to reflection coefficients `K`.

`[..., S] = step(lpc2rc,A)` also outputs the `LPC` filter stability, `S`, when you set the `ExceptionOutputPort` property to `true`.

Note: `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.LSFToLPC System object

Package: dsp

Convert line spectral frequencies to linear prediction coefficients

Description

The `LSFToLPC` object converts line spectral frequencies to linear prediction coefficients.

To convert LSF to LPC:

1. Define and set up your LSF to LPC converter. See "Construction" on page 4-1229.
2. Call step to convert LSF according to the properties of `dsp.LSFToLPC`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`lsf2lpc = dsp.LSFToLPC` returns an LSF to LPC System object, `lsf2lpc`, which converts line spectral frequencies (LSFs) to linear prediction coefficients (LPCs).

Methods

step	Convert input line spectral frequencies to linear prediction coefficients

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object

Common to All System Objects	
getNumOutp	Expected number of outputs of a System object
isLocked	Check locked states of a System object (logical)
release	Allow System object property value changes

Examples

Convert LSF Coefficients to LPC Coefficients

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

```
a = [1.0000 0.6149 0.9899 0.0000 0.0031 -0.0082]'
lpc2lsf = dsp.LPCToLSF;
ylsf = lpc2lsf(a);
lsf2lpc = dsp.LSFToLPC;
ylpc = lsf2lpc(ylsf);
```

```
a =

    1.0000
    0.6149
    0.9899
         0
    0.0031
   -0.0082
```

Check if values in `ylpc` are the same as in `a`.

```
display(ylpc);
```

```
ylpc =

    1.0000
    0.6149
    0.9899
    0.0000
```

```
  0.0031
 -0.0082
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the `LSF/LSP to LPC Conversion` block reference page. The object properties correspond to the block parameters, except:
The object does not have a property that corresponds to the **Input** block parameter. The object's behavior corresponds to the block's behavior when you set the **Input** parameter to `LSF in range (0 pi)`.

Extended Capabilities

dsp.LSPToLPC System object

Package: dsp

Convert line spectral pairs to linear prediction coefficients

Description

The `LSPToLPC` object converts line spectral pairs to linear prediction coefficients.

To convert LSP to LPC:

1 Define and set up your LSP to LPC converter. See "Construction" on page 4-1233.
2 Call step to convert LSP according to the properties of `dsp.LSPToLPC`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = dsp.LSPToLPC` returns an LSP to LPC System object, `H`, which converts line spectral pairs (LSPs) to linear prediction coefficients (LPCs).

Methods

step	Convert input line spectral pairs to linear prediction coefficients

Common to All System Objects	
`clone`	Create System object with same property values

Common to All System Objects

dsp.LSFToLPC | dsp.LPCToLSP

Introduced in R2012a

step

System object: dsp.LSPToLPC
Package: dsp

Convert input line spectral pairs to linear prediction coefficients

Syntax

`A = step(lsp2lpc,LSP)`

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`A = step(lsp2lpc,LSP)` converts the input line spectral pairs in the range (–1,1), `LSP`, to linear prediction coefficients, `A`. The input can be a vector or a matrix, where each column of the matrix is treated as a separate channel.

Note: `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.LUFactor System object

Package: dsp

Factor square matrix into lower and upper triangular matrices

Description

The `LUFactor` object factors a square matrix into lower and upper triangular matrices.

To factor a square matrix into lower and upper triangular matrices:

1 Define and set up your System object. See "Construction" on page 4-1237.
2 Call step to factor the square matrix according to the properties of `dsp.LUFactor`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`lu = dsp.LUFactor` returns an `LUFactor` System object, `lu`, which factors a row permutation of a square input matrix `A` as $A_p = L \cdot U$, where `L` is the unit-lower triangular matrix, and `U` is the upper triangular matrix. The row-pivoted matrix A_p contains the rows of A permuted as indicated by the permutation index vector P. The equivalent MATLAB code is `Ap = A(P,:)`.

`lu = dsp.LUFactor('PropertyName',PropertyValue,...)` returns an `LUFactor` object, `lu`, with each specified property set to the specified value.

Properties

ExceptionOutputPort

Set to `true` to output singularity of input

Set this property to `true` to output the singularity of the input as logical data type values of `true` or `false`. An output of `true` indicates that the current input is singular, and an output of `false` indicates the current input is nonsingular.

Fixed-Point Properties

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as `|Ceiling|Convergent|Floor|Nearest |Round | Simplest | Zero|`. The default is `Floor`.

OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as `Wrap` or `Saturate`. The default is `Wrap`.

ProductDataType

Product word and fraction lengths

Specify the product fixed-point data type as `Full precision`, `Same as input` or `Custom`. The default is `Full precision`.

CustomProductDataType

Product word and fraction lengths

Specify the product fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `ProductDataType on page 4-1238` property to `Custom`. The default is `numerictype([],32,30)`.

AccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point data type as `Full precision`, `Same as input`, `Same as product` or `Custom`. The default is `Full precision`.

CustomAccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `AccumulatorDataType on page 4-1238` property to `Custom`. The default is `numerictype([],32,30)`.

OutputDataType

Output word and fraction lengths

Specify the output fixed-point data type as `Same as input` or `Custom`. The default is `Same as input`.

CustomOutputDataType

Output word and fraction lengths

Specify the output fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `OutputDataType on page 4-1239` property to `Custom`. The default is `numerictype([],16,15)`.

Methods

step	Decompose matrix into lower and upper triangular matrices

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Decompose a Square Matrix

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

Decompose a square matrix into the lower and upper components.

```
lu = dsp.LUFactor;
x = rand(4)
[LU, P] = lu(x);
L = tril(LU,-1)+diag(ones(size(LU,1),1));
U = triu(LU);
y = L*U
```

```
x =

    0.8147    0.6324    0.9575    0.9572
    0.9058    0.0975    0.9649    0.4854
    0.1270    0.2785    0.1576    0.8003
    0.9134    0.5469    0.9706    0.1419

y =

    0.9134    0.5469    0.9706    0.1419
    0.9058    0.0975    0.9649    0.4854
    0.8147    0.6324    0.9575    0.9572
    0.1270    0.2785    0.1576    0.8003
```

Check back whether `y` equals the permuted `x`

```
xp = x(P,:)
```

```
xp =

    0.9134    0.5469    0.9706    0.1419
    0.9058    0.0975    0.9649    0.4854
    0.8147    0.6324    0.9575    0.9572
```

```
    0.1270    0.2785    0.1576    0.8003
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the `LU Factorization` block reference page. The object properties correspond to the block parameters.

dsp.LDLFactor

Introduced in R2012a

step

System object: dsp.LUFactor
Package: dsp

Decompose matrix into lower and upper triangular matrices

Syntax

```
[LU,P] = step(lu,A)
[LU,P,S] = step(lu,A)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`[LU,P] = step(lu,A)` decomposes the matrix `A` into lower and upper triangular matrices. The output `LU` is a composite matrix with lower triangle elements from `L` and upper triangle elements from `U` . The permutation vector `P` is the second output.

`[LU,P,S] = step(lu,A)` returns an additional output `S` indicating if the input is singular when the `ExceptionOutputPort` property is set to `true`.

Note: `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

dsp.MatFileReader System object

Package: dsp

Read MAT file

Description

The `MatFileReader` object reads V7.3 MAT files.

To read V7.3 MAT files:

1. Define and set up your System object. See "Construction" on page 4-1243.
2. Call step to read the MAT file according to the properties of `dsp.MatFileReader`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj)` and `y = obj()` perform equivalent operations.

Construction

`mfr = dsp.MatFileReader` returns a System object, `mfr`, to read scalar stream data from a V7.3 MAT file.

`mfr = dsp.MatFileReader(`*`FILENAME`*`,`*`VARIABLENAME`*`,`*`FRAMESIZE`*`)` reads frames of MAT file data, using the specified file name, variable name, and frame size.

`mfr = dsp.MatFileReader('`*`PropertyName`*`',`*`PropertyValue`*`,...)` reads MAT file data with each specified property set to the specified value.

`mfr =`
`dsp.MatFileReader(`*`FILENAME`*`,`*`VARIABLENAME`*`,`*`FRAMESIZE`*`,'`*`PropertyName`*`',`*`PropertyValue`*
reads frames of MAT file data, using the specified file name, variable name, and frame size, and other specified properties set to the specified values.

Properties

`Filename`

Name of MAT file from which to read

Specify the name of a MAT file as a character vector. Specify the full path for the file only if the file is not on the MATLAB path.

Default: `Untitled.mat`

`VariableName`

Name of the variable to read

Name of the variable stored in and read from the MAT file.

Default: `x`

`SamplesPerFrame`

Number of samples per output frame

Specify the number of elements (samples per frame) to read from the MAT file each time the `step` method is called.

Default: 1

Methods

isDone	End-of-file status
reset	Reset internal states of multimedia file reader to read from beginning of file
step	Read data from a variable in the MAT file

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object

Common to All System Objects	
getNumOutp	Expected number of outputs of a System object
isLocked	Check locked states of a System object (logical)
release	Allow System object property value changes

Examples

Read a MAT File

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

Read a MAT file using the `MatFileReader` object.

```
filename = [tempname '.mat'];  % Create variable name
originalData = rand(40,2);
save(filename,'originalData','-v7.3'); % Write to MAT file

mfr = dsp.MatFileReader(filename,'VariableName',...
   'originalData','SamplesPerFrame', 4);
while ~isDone(mfr)          % Stream data into MATLAB
    finalData = mfr();
end
```

See Also

dsp.MatFileWriter

isDone

System object: dsp.MatFileReader
Package: dsp

End-of-file status

Syntax

```
STATUS = isDone(mfr)
```

Description

`STATUS = isDone(mfr)` returns a logical value, `STATUS`. When the `MatFileReader` object, `mfr` , reaches the end of the MAT file, `STATUS` is `true`.

reset

System object: dsp.MatFileReader
Package: dsp

Reset internal states of multimedia file reader to read from beginning of file

Syntax

`reset(mfr)`

Description

`reset(mfr)` resets the `MatFileReader` object to read from the beginning of the file.

step

System object: dsp.MatFileReader
Package: dsp

Read data from a variable in the MAT file

Syntax

```
X = step(mfr)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj)` and `y = obj()` perform equivalent operations.

`X = step(mfr)` reads data, `X`, from a variable stored in a MAT-file. The variable is assumed to be *N*-dimensional and a MATLAB built-in datatype. The data is read into MATLAB by reading along the first dimension.

Note: `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

dsp.MatFileWriter System object

Package: dsp

Write MAT file

Description

The `MatFileWriter` object writes data to a V7.3 MAT file.

To write data to a V7.3 MAT file:

1. Define and set up your System object. See “Construction” on page 4-1249.
2. Call step to write data according to the properties of `dsp.MatFileWriter`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`mfw = dsp.MatFileWriter` returns a MAT file writer System object, `mfw`, that writes data to a V7.3 MAT file.

`mfw = dsp.MatFileWriter('PropertyName',PropertyValue,...)` returns a MAT file writer System object, `mfw`, with each specified property set to the specified value.

`mfw = dsp.MatFileWriter(FILENAME,'PropertyName',PropertyValue,...)` returns a MAT file writer System object, `mfw`, with `Filename` property set to `FILENAME` and other specified properties set to the specified values.

Properties

`Filename`

Name of MAT file to write

Specify the name of a MAT file as a character vector. Specify the full path for the file only if the file is not on the MATLAB path. The default file name is `Untitled.mat`.

`VariableName`

Name of the variable to write

Name of the variable to which to write. This variable is stored in the MAT file. The default variable name is `x`. You cannot overwrite a variable that is already in an existing MAT file.

Methods

step	Write one frame of MAT file data

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Write Data Into a MAT File

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

First, create a variable name.

```
filename = [tempname '.mat'];
```

Next, write that variable to a MAT-file.

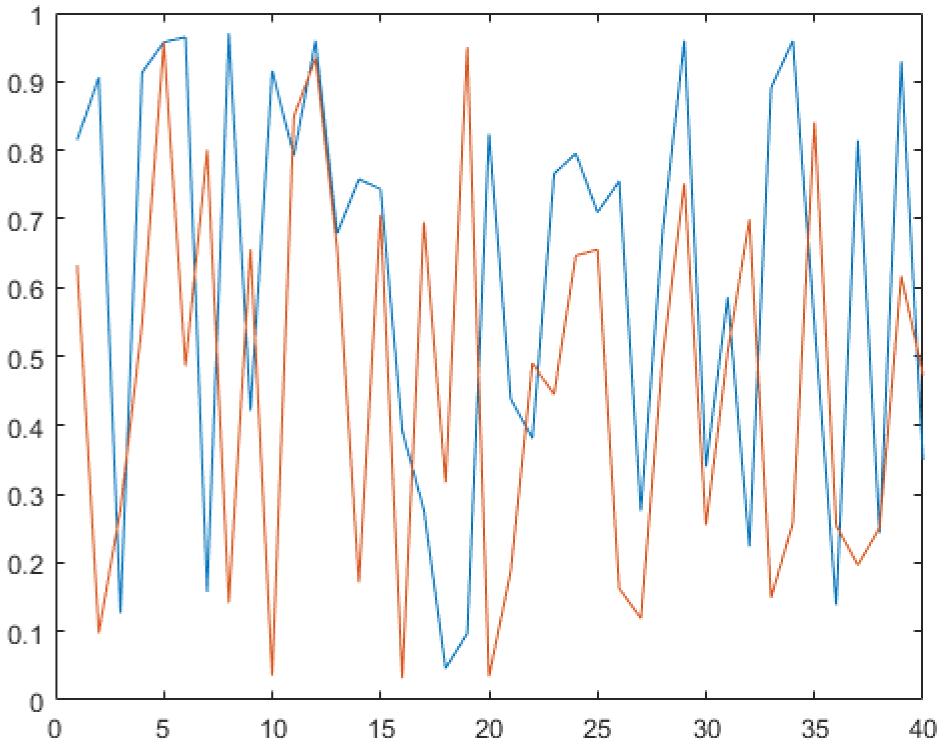
```
mfw = dsp.MatFileWriter(filename, 'VariableName', 'originalData');
for i = 1:10
    originalData = rand(4,2);
    mfw(originalData);
end
release(mfw); % This will close the MAT file
```

Finally, load the variable back into MATLAB.

```
data = load(filename, 'originalData');
```

Plot the data.

```
plot(data.originalData);
```



See Also

dsp.MatFileReader

Introduced in R2012b

step

System object: dsp.MatFileWriter
Package: dsp

Write one frame of MAT file data

Syntax

`step(mfw,X)`

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`step(mfw,X)` writes one frame of data, `X` , to the variable stored in the MAT file. The variable is assumed to be N-dimensional and a MATLAB built-in data type. The data is written to the file by concatenating along the first dimension.

Note: `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.Maximum System object

Package: dsp

Find maximum value of input or sequence of inputs

Description

The `dsp.Maximum` object finds the maximum values of an input or sequence of inputs.

To compute the maximum value of an input or sequence of inputs:

1. Define and set up your System object. See "Construction" on page 4-1254.
2. Call step to find the maximum according to the properties of `dsp.Maximum`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Note: The `Running` mode in the `dsp.Maximum` System object will be removed in a future release. To compute the running maximum in MATLAB, use the dsp.MovingMaximum System object instead.

Construction

`max = dsp.Maximum` returns an object, `max`, that computes the value and index of the maximum elements in an input or a sequence of inputs along the specified `Dimension` on page 4-1256.

`max = dsp.Maximum('`*`PropertyName`*`',`*`PropertyValue`*`,...)` returns a maximum-finding object, `max`, with each specified property set to the specified value.

Properties

ValueOutputPort

Output maximum value

Set this property to `true` in order to output the maximum of the input. This property applies only when you set the `RunningMaximum` on page 4-1255 property to false. The default is `true`.

RunningMaximum

Calculate over single input or multiple inputs

When you set this property to `true`, the object computes the maximum value over successive calls to the `step` method. When you set this property to `false`, the object computes the maximum value over the current input. The default is `false`.

IndexOutputPort

Output index of maximum value

Set this property to `true` to output the index of the maximum value of the input. This property applies only when you set the `RunningMaximum` on page 4-1255 property to `false`. The default is `true`.

ResetInputPort

Additional input to enable resetting of running maximum

Set this property to `true` to enable resetting the running maximum. When you set this property to `true`, you must specify a reset input to the `step` method to reset the running maximum. This property applies only when you set the `RunningMaximum` on page 4-1255 property to `true`. The default is `false`.

ResetCondition

Condition that triggers resetting of running maximum

Specify the event that resets the running maximum as one of `| Rising edge | Falling edge | Either edge | Non-zero |`. This property applies only when you set the `ResetInputPort` on page 4-1255 property to `true`. The default is `Non-zero`.

IndexBase

Numbering base for index of maximum value

Specify whether to start the index numbering from `One` or `Zero` when computing the index of the maximum value. This property applies only when you set the `IndexOutputPort` on page 4-1255 property to `true`. The default is `One`.

Dimension

Dimension to operate along

Specify how the maximum calculation is performed over the data as one of | `All` | `Row` | `Column` | `Custom` |. This property applies when you set the `RunningMaximum` on page 4-1255 property to `false`. The default is `Column`.

CustomDimension

Numerical dimension to calculate over

Specify the integer dimension of the input signal over which the object finds the maximum. The cannot exceed the number of dimensions in the input signal. This property only applies when you set the `Dimension` on page 4-1256 property to `Custom`. The default is `1`.

Fixed-Point Properties

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as one of | `Ceiling` | `Convergent` | `Floor` | `Nearest` | `Round` | `Simplest` | `Zero` |. The default is `Floor`.

OverflowAction

Action to take when integer input is out-of-range

Specify the overflow action as one of | `Wrap` | `Saturate` |. The default is `Wrap`.

ProductDataType

Data type of product

Specify the product fixed-point data type as one of | `Same as input` | `Custom` |. The default is `Same as input`.

`CustomProductDataType`

Product word and fraction lengths

Specify the product fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when you set the `AccumulatorDataType` on page 4-1257 property to `Custom`. The default is `numerictype([],32,30)`.

`AccumulatorDataType`

Data type of accumulator

Specify the accumulator fixed-point data type as one of | `Same as product` | `Same as input` | `Custom` |. The default is `Same as product`.

`CustomAccumulatorDataType`

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when you set the `AccumulatorDataType` on page 4-1257 property to `Custom`. The default is `numerictype([],32,30)`.

Methods

reset	Reset computation of running maximum
step	Maximum value

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object

Common to All System Objects	
getNumOutp	Expected number of outputs of a System object
isLocked	Check locked states of a System object (logical)
release	Allow System object property value changes

Examples

Compute the Maximum and Running Maximum of a Signal

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

Find a maximum value and its index.

```
max1 = dsp.Maximum;
x = randn(100,1);
[y, I] = max1(x)
```

```
y =

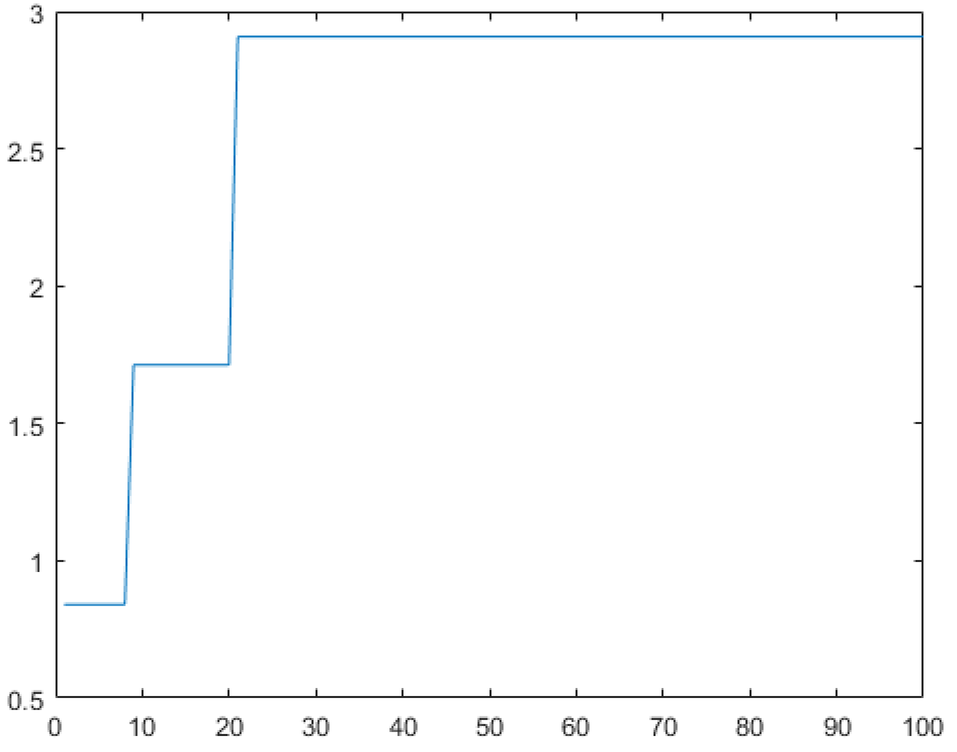
    3.5784

I =

     9
```

Compute a running maximum.

```
max2 = dsp.Maximum;
max2.RunningMaximum = true;
x = randn(100,1);
z = max2(x);
plot(z);
```



y(i) is the minimum of all values in the vector x(1:i).

Algorithms

This object implements the algorithm, inputs, and outputs described on the `Maximum` block reference page. The object properties correspond to the block parameters.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

Package: dsp

Reset computation of running maximum

Syntax

```
reset(max)
```

Description

`reset(max)` resets the computation of the running maximum for the `Maximum` object `max`.

step

System object: dsp.Maximum
Package: dsp

Maximum value

Syntax

```
[VAL,IND] = step(max,X)
VAL = step(max,X)
IND = step(max,X)
VAL = step(max,X,R)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`[VAL,IND] = step(max,X)` returns the maximum value, `VAL`, and the index or position of the maximum value, `IND`, along the specified `Dimension` of `X`.

`VAL = step(max,X)` returns the maximum value, `VAL`, of the input `X`. When the `RunningMaximum` property is `true`, `VAL` corresponds to the maximum value over successive calls to the `step` method.

`IND = step(max,X)` returns the zero- or one-based index `IND` of the maximum value. To enable this type of processing, set the `IndexOutputPort` property to `true` and the `ValueOutputPort` and `RunningMaximum` properties to `false`.

`VAL = step(max,X,R)` resets the state of `max` based on the value of reset signal, `R`, and the `ResetCondition` property. To enable this type of processing, set the `RunningMaximum` property to `true` and the `ResetInputPort` property to `true`.

Note: `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.Mean System object

Package: dsp

Find mean value of input or sequence of inputs

Description

The `dsp.Mean` object finds the mean of an input or sequence of inputs.

To compute the mean of an input or sequence of inputs:

1 Define and set up your System object. See "Construction" on page 4-1264.
2 Call step to compute the mean according to the properties of `dsp.Mean`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Note: The `Running` mode in the `dsp.Mean` System object will be removed in a future release. To compute the running mean in MATLAB, use the dsp.MovingAverage System object instead.

Construction

`mn = dsp.Mean` returns an object, `mn`, that computes the mean of an input or a sequence of inputs.

`mn = dsp.Mean('`*`PropertyName`*`',`*`PropertyValue`*`,...)` returns a mean-finding object, `mn`, with each specified property set to the specified value.

Properties

RunningMean

Calculate over single input or multiple inputs

When you set this property to `true`, the object calculates the mean over successive calls to the `step` method. When you set this property to `false`, the object computes the mean over the current input. The default is `false`.

ResetInputPort

Additional input to enable resetting of running mean

Set this property to `true` to enable resetting of the running mean. When you set this property to `true`, you must specify a reset input to the `step` method to reset the running mean. This property applies only when you set the `RunningMean` on page 4-1265 property to `true`. The default is `false`.

ResetCondition

Condition that triggers resetting of running mean

Specify the event that resets the running maximum as one of | `Rising edge` | `Falling edge` | `Either edge` | `Non-zero` |. This property applies only when you set the `ResetInputPort` on page 4-1265 property to `true`. The default is `Non-zero`.

Dimension

Dimension to operate along

Specify how the mean calculation is performed over the data as one of | `All` | `Row` | `Column` | `Custom` |. This property applies when you set the `RunningMean` on page 4-1265 property to `false`. The default is `Column`.

CustomDimension

Numerical dimension to calculate over

Specify the integer dimension, indexed from one, of the input signal over which the object calculates the mean. The value cannot exceed the number of dimensions in the input signal. This property only applies when you set the `Dimension` on page 4-1265 property to `Custom`. The default is `1`.

Fixed-Point Properties

`RoundingMethod`

Rounding method for fixed-point operations

Specify the rounding method as one of | `Ceiling` | `Convergent` | `Floor` | `Nearest` | `Round` | `Simplest` | `Zero` |. The default is `Floor`.

`OverflowAction`

Action to take when integer input is out-of-range

Specify the overflow action as one of | `Wrap` | `Saturate` |. The default is `Wrap`.

`AccumulatorDataType`

Data type of accumulator

Specify the accumulator fixed-point data type as one of | `Same as input` | `Custom` |. The default is `Same as input`.

`CustomAccumulatorDataType`

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when you set the `AccumulatorDataType` on page 4-1266 property to `Custom`. The default is `numerictype([],32,30)`.

`OutputDataType`

Data type of output

Specify the output fixed-point data type as one of | `Same as accumulator` | `Same as input` | `Custom` |. The default is `Same as accumulator`.

`CustomOutputDataType`

Output word and fraction lengths

Specify the output fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when you set the `OutputDataType` on page 4-1266 property to `Custom`. The default is `numerictype([],32,30)`.

Methods

reset	Reset internal states of mean-finding object
step	Mean value

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Compute the Mean and Running Mean of a Signal

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

Mean

```
mean1 = dsp.Mean;
x = randn(100,1);
y = mean1(x);
```

Running Mean

```
mean2 = dsp.Mean;
mean2.RunningMean = true;
x = randn(100,1);
```

```
yrmean = mean2(x);
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the `Mean` block reference page. The object properties correspond to the block parameters.

Reset internal states of mean-finding object

Syntax

```
reset(mn)
```

Description

`reset(mn)` sets the internal states of the `Mean` object `mn` to their initial values.

step

System object: dsp.Mean
Package: dsp

Mean value

Syntax

```
Y = step(mn,X)
Y = step(mn,X,R)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(mn,X)` computes the mean of `X`. When you set the `RunningMean` property to `true`, `Y` corresponds to the mean successive calls to the `step` method.

`Y = step(mn,X,R)` resets the computation of the running mean based on the value of the reset signal, `R`, and the `ResetCondition` property. To enable this type of processing, set the `RunningMean` property to `true` and the `ResetInputPort` property to `true`.

Note: `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.Median System object

Package: dsp

Median value of input

Description

The `Median` object computes the median value of the input. The object can compute the median along each dimension (row or column) of the input or of the entire input.

To compute the median of the input:

1. Define and set up your median System object. See "Construction" on page 4-1271.
2. Call step to compute the median according to the properties of `dsp.Median`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`med = dsp.Median` returns a median System object, `med`, that computes the median along the columns of the input using the `Quick sort` sorting method.

`med = dsp.Median('`*`PropertyName`*`',`*`PropertyValue`*`,...)` returns a median System object, `med`, with each property set to the value you specify.

Properties

`SortMethod`

Sort method

Specify the method the object should use to sort the data before computing the median. You can specify `Quick sort` or `Insertion sort`. The quick sort algorithm uses a recursive sort method and is faster at sorting more than 32 elements. The insertion sort algorithm uses a nonrecursive method and is faster at sorting less than 32 elements. If you are using the `Median` object to generate code, you should use the insertion sort algorithm to prevent recursive function calls in your generated code. The default is `Quick sort`.

Dimension

Dimension to operate along

Specify the dimension along which the object computes the median values. You can specify one of | `All` | `Row` | `Column` | `Custom` |. The default is `Column`.

CustomDimension

Numerical dimension to operate along

Specify the dimension of the input signal (as a one-based value), over which the object computes the median. The cannot exceed the number of dimensions in the input signal. This property applies only when you set the `Dimension` on page 4-1272 property to `Custom`. The default is `1`.

Fixed-Point Properties

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as one of | `Ceiling` | `Convergent` | `Floor` | `Nearest` | `Round` | `Simplest` | `Zero` |. The default is `Floor`.

OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as one of | `Wrap` | `Saturate` |. The default is `Wrap`.

ProductDataType

Product word and fraction lengths

Specify the product data type as one of | `Same as input` | `Custom` |. The default is `Same as input`.

`CustomProductDataType`

Product word and fraction lengths

Specify the product data type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when you set the `ProductDataType` on page 4-1272 property to `Custom`. The default is `numerictype([],32,30)`.

`AccumulatorDataType`

Accumulator word and fraction lengths

Specify the accumulator data type as one of | `Same as product` | `Same as input` | `Custom` |. The default is `Same as product`.

`CustomAccumulatorDataType`

Accumulator word and fraction lengths

Specify the fixed-point accumulator data type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when you set the `AccumulatorDataType` on page 4-1273 property to `Custom`. The default is `numerictype([],32,30)`.

`OutputDataType`

Output word and fraction lengths

Specify the output data type as one of | `Same as accumulator` | `Same as product` | `Same as input` | `Custom` |. The default is `Same as accumulator`.

`CustomOutputDataType`

Output word and fraction lengths

Specify the data type of the output as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies only when you set the `OutputDataType` on page 4-1273 property to `Custom`. The default is `numerictype([],16,15)`.

Methods

step	Median value

Common to All System Objects	
clone	Create System object with same property values
getNumInpu	Expected number of inputs to a System object
getNumOutp	Expected number of outputs of a System object
isLocked	Check locked states of a System object (logical)
release	Allow System object property value changes

Examples

Compute The Median

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

Compute the median value of the input column using the `dsp.Median` object.

```
med = dsp.Median;
x = [7 -9 0 -1 2 0 3 5 -9]';
y = med(x)
```

```
y =

     0
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the `Median` block reference page. The object properties correspond to the block properties, except:
Treat sample-based row input as a column block parameter is not supported by the `dsp.Median` System object.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

dsp.Minimum | dsp.Variance | dsp.Mean | dsp.Maximum

Introduced in R2012a

step

System object: dsp.Median
Package: dsp

Median value

Syntax

`Y = step(med,X)`

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(med,X)` computes the median value of the input `X` and returns the result in `Y`.

Note: `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

dsp.MedianFilter System object

Package: dsp

Median filter

Description

The `dsp.MedianFilter` System object computes the moving median of the input signal along each channel, independently over time. The object uses the sliding window method to compute the moving median. In this method, a window of specified length is moved over each channel, sample by sample, and the object computes the median of the data in the window. For more details, see "Algorithms" on page 4-1284.

The object accepts multichannel inputs, that is, m-by-n size inputs, where $m \geq 1$, and $n > 1$. m is the number of samples in each frame (or channel), and n is the number of channels. The object also accepts variable-size inputs. Once the object is locked, you can change the size of each input channel. However, the number of channels cannot change. This object supports C and C++ code generation.

To compute the moving median of the input:

1 Create a `dsp.MedianFilter` object and set the properties of the object.
2 Call step to compute the moving median.

Note: Alternatively, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`medFilt = dsp.MedianFilter` returns a median filter object, `medFilt`, using the default properties.

`medFilt = dsp.MedianFilter(Len)` sets the `WindowLength` property to `Len`.

`medFilt = dsp.MedianFilter(Name,Value)` specifies properties using `Name,Value` pairs. Unspecified properties have default values.

Example:

```
movMin = dsp.MedianFilter('WindowLength',5);
```

Properties

`WindowLength` — Length of the sliding window

5 (default) | positive scalar integer

Length of the sliding window, specified as a positive scalar integer.

Methods

reset	Reset internal states of System object
step	Moving median of input signal

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Remove High-Frequency Noise Using Median Filter

Filter high-frequency noise from a noisy sine wave signal using a median filter. Compare the performance of the median filter with an averaging filter.

Initialization

Set up a `dsp.MedianFilter` object, `medFilt`, and a `dsp.MovingAverage` object, `movavgWin`. These objects use the sliding window method with a window length of 7. Create a time scope for viewing the output.

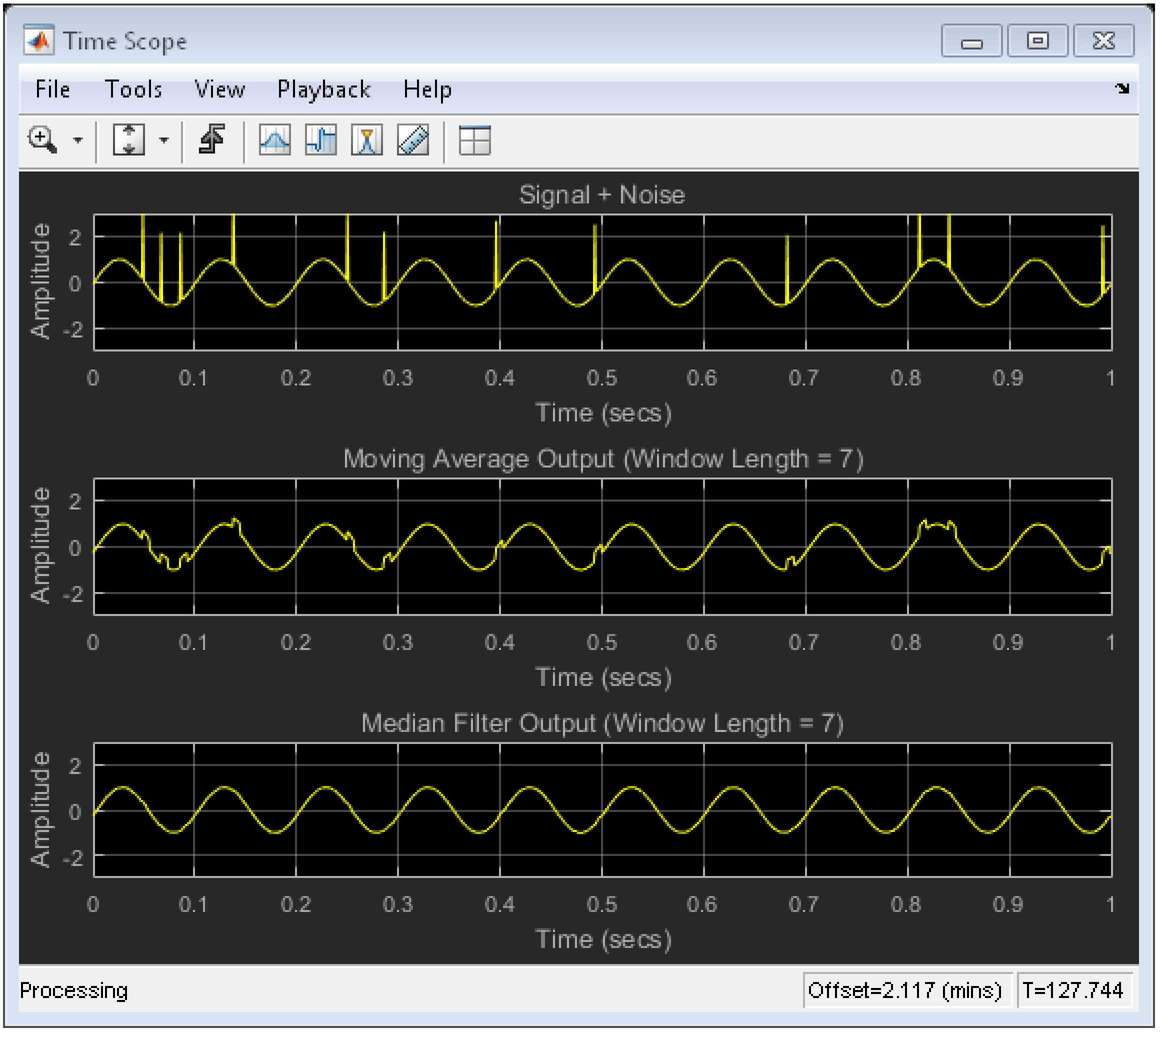
```
Fs = 1000;
medFilt = dsp.MedianFilter(7);
movavgWin = dsp.MovingAverage(7);
scope  = dsp.TimeScope('SampleRate',Fs,...
    'TimeSpanOverrunAction','Scroll',...
    'TimeSpan',1,'ShowGrid',true,...
    'YLimits',[-3 3],...
    'LayoutDimensions',[3 1],...
    'NumInputPorts',3);
scope.ActiveDisplay = 1;
scope.Title = 'Signal + Noise';
scope.ActiveDisplay = 2;
scope.Title = 'Moving Average Output (Window Length = 7)';
scope.ActiveDisplay = 3;
scope.Title = 'Median Filter Output (Window Length = 7)';

FrameLength = 256;
count = 1;
sine = dsp.SineWave('SampleRate',Fs,'Frequency',10,...
    'SamplesPerFrame',FrameLength);
```

Filter the Noisy Sine Wave

Generate a noisy sine wave signal with a frequency of 10 Hz. Apply the median filter and the moving average object to the signal. View the output on the time scope.

```
for i = 1:500
    hfn = 3 * (rand(FrameLength,1) < 0.02);
    x = sine() + 1e-2 * randn(FrameLength,1) + hfn;
    y1 = movavgWin(x);
    y2 = medFilt(x);
    scope(x,y1,y2);
end
```



The median filter removes the high-frequency noise more effectively than the moving average object does.

Remove High-Frequency Noise from Gyroscope Data

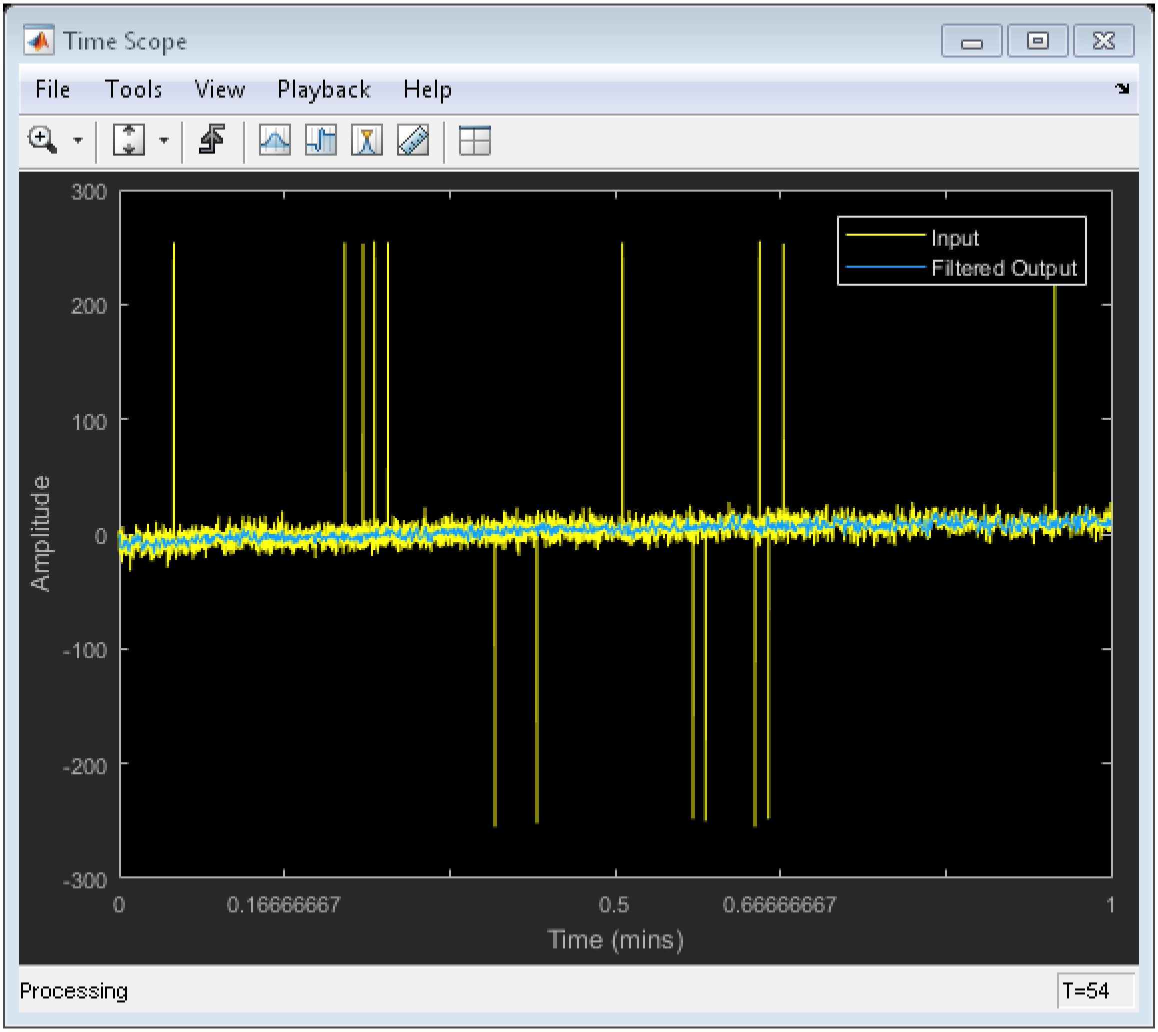
This example shows how to remove the high-frequency outliers from a streaming signal using the `dsp.MedianFilter` System object™.

Use the dsp.MatFileReader System object to read the gyroscope MAT file. The gyroscope MAT file contains 3 columns of data, with each column containing 7140 samples. The three columns represent the *X*-axis, *Y*-axis, and *Z*-axis data from the gyroscope motion sensor. Choose a frame size of 714 samples so that each column of the the data contains 10 frames. The dsp.MedianFilter System object uses a window length of 10. Create a dsp.TimeScope object to view the filtered output.

```
reader = dsp.MatFileReader('SamplesPerFrame',714,'Filename','LSM9DS1gyroData73.mat',...
    'VariableName','data');
medFilt = dsp.MedianFilter(10);
scope = dsp.TimeScope('NumInputPorts',1,'SampleRate',119,'YLimits',[-300 300],...
    'ChannelNames',{'Input','Filtered Output'},'TimeSpan',60,'ShowLegend',true);
```

Filter the gyroscope data using the dsp.MedianFilter System object. View the filtered *Z*-axis data in the time scope.

```
for i = 1:10
    gyroData = reader();
    filteredData = medFilt(gyroData);
    scope([gyroData(:,3),filteredData(:,3)]);
end
```



The original data contains several outliers. Zoom in on the data to confirm that the median filter removes all the outliers.

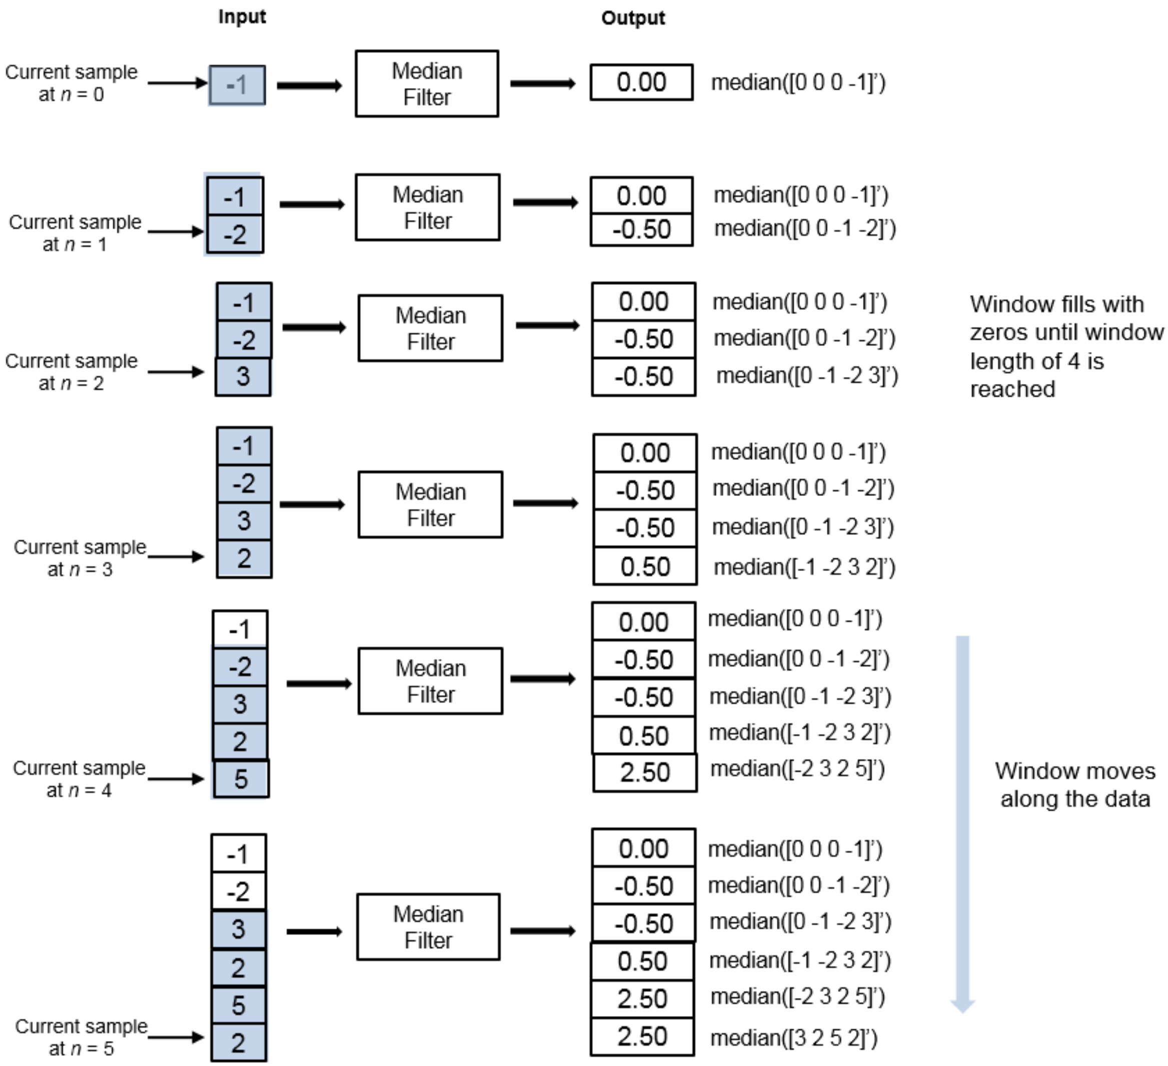
Algorithms

Sliding Window Method

In the sliding window method, the output for each input sample is the median of the current sample and the *Len* - 1 previous samples. *Len* is the length of the window. To compute the first *Len* - 1 outputs, when the window does not have enough data yet, the algorithm fills the window with zeros. As an example, to compute the median value when the second input sample comes in, the algorithm fills the window with *Len* - 2 zeros. The data vector, *x*, is then the two data samples followed by *Len* - 2 zeros. This object performs median filtering on the input data over time.

Consider an example of computing the moving median of a streaming input data using the sliding window method. The algorithm uses a window length of 4. With each input sample that comes in, the window of length 4 moves along the data.



Input

Introduced in R2016b

reset

System object: dsp.MedianFilter
Package: dsp

Reset internal states of System object

Syntax

`reset(medFilt)`

Description

`reset(medFilt)` resets the states of the input object to their initial values. The initial state values correspond to the initial conditions for the difference equation defining the object. After you call the object using nonzero input data, the filter might have nonzero states. If you continue to pass nonzero input data to the object without first calling `reset`, the object might produce different outputs for an identical input.

Introduced in R2016b

step

System object: dsp.MedianFilter
Package: dsp

Moving median of input signal

Syntax

`y = step(medFilt,x)`

Description

Note: Alternatively, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`y = step(medFilt,x)` computes the moving median of the input signal, `x`, using the sliding window method of the input `dsp.MedianFilter` System object, `medFilt`. The input `x` can be a row vector, a column vector, or a matrix. If `x` is a matrix, each column is treated as an independent channel. The moving median is computed along each channel. The input `x` can be complex and supports single and double data types.

Introduced in R2016b

dsp.Minimum System object

Package: dsp

Find minimum values of input or sequence of inputs

Description

The `dsp.Minimum` object finds the minimum value of an input or sequence of inputs.

To compute the minimum value of an input or sequence of inputs:

1. Define and set up your System object. See "Construction" on page 4-1289.
2. Call step to compute the minimum according to the properties of `dsp.Minimum`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Note: The `Running` mode in the `dsp.Minimum` System object will be removed in a future release. To compute the running minimum in MATLAB, use the dsp.MovingMinimum System object instead.

Construction

`min = dsp.Minimum` returns an object, `min`, that computes the value and/or index of the minimum elements in an input or a sequence of inputs over the specified `Dimension`.

`min = dsp.Minimum('`*`PropertyName`*`',`*`PropertyValue`*`,...)` returns a minimum-finding object, `min`, with each specified property set to the specified value.

Properties

ValueOutputPort

Output minimum value

Set this property to `true` in order to output the minimum value of the input. This property applies only when you set the `RunningMinimum` on page 4-1290 property to false. The default is `true`.

RunningMinimum

Calculate over single input or multiple inputs

When you set this property to `true`, the object computes the minimum value over successive calls to the `step` method. When you set this property to `false`, the object computes the minimum value over the current input. The default is `false`.

IndexOutputPort

Output index of minimum value

Set this property to `true` to output the index of the minimum value of the input. This property applies only when you set the `RunningMinimum` on page 4-1290 property to `false`. The default is `true`.

ResetInputPort

Additional input to enable resetting of running minimum

Set this property to `true` to enable resetting of the running minimum. When you set this property to `true`, you must specify a reset input to the `step` method to reset the running minimum. This property applies only when you set the `RunningMinimum` on page 4-1290 property to `true`. The default is `false`.

ResetCondition

Condition that triggers resetting of running minimum

Specify the event that resets the running minimum as one of `| Rising edge | Falling edge | Either edge | Non-zero |`. This property applies only when you set the `ResetInputPort` on page 4-1290 property to `true`. The default is `Non-zero`.

IndexBase

Numbering base for index of minimum value

Specify the numbering used when computing the index of the minimum value as starting from either `One` or `Zero`. This property applies only when you set the `IndexOutputPort` on page 4-1290 property to `true`. The default is `One`.

Dimension

Dimension to operate along

Specify how the minimum calculation is performed over the data as one of `| All | Row | Column | Custom |`. This property applies when you set the `RunningMinimum` on page 4-1290 property to `false`. The default is `Column`.

CustomDimension

Numerical dimension to calculate over

Specify the integer dimension of the input signal over which the object finds the minimum. The cannot exceed the number of dimensions in the input signal. This property only applies when you set the `Dimension` on page 4-1291 property to `Custom`. The default is `1`.

Fixed-Point Properties

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as one of `| Ceiling | Convergent | Floor | Nearest | Round | Simplest | Zero |`. The default is `Floor`.

OverflowAction

Action to take when integer input is out-of-range

Specify the overflow action as one of `| Wrap | Saturate |`. The default is `Wrap`.

ProductDataType

Data type of product

Specify the product fixed-point data type as one of | Same as input | Custom |. The default is Same as input.

CustomProductDataType

Product word and fraction lengths

Specify the product fixed-point type as a scaled numerictype object with a Signedness of Auto. This property applies only when you set the AccumulatorDataType on page 4-1292 property to Custom. The default is numerictype([],32,30).

AccumulatorDataType

Data type of accumulator

Specify the accumulator fixed-point data type as one of | Same as product | Same as input | Custom |. The default is Same as product.

CustomAccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled numerictype object with a Signedness of Auto. This property applies only when you set the AccumulatorDataType on page 4-1292 property to Custom. The default is numerictype([],32,30).

Methods

reset	Reset internal states of minimum-finding object
step	Operate on inputs to calculate outputs

Common to All System Objects	
clone	Create System object with same property values

Common to All System Objects	
getNumInpu	Expected number of inputs to a System object
getNumOutp	Expected number of outputs of a System object
isLocked	Check locked states of a System object (logical)
release	Allow System object property value changes

Examples

Compute the Minimum and Running Minimum of a Signal

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

Find a minimum value and its index.

```
min1 = dsp.Minimum;
x = randn(100,1);
[y, I] = min1(x)
```

```
y =

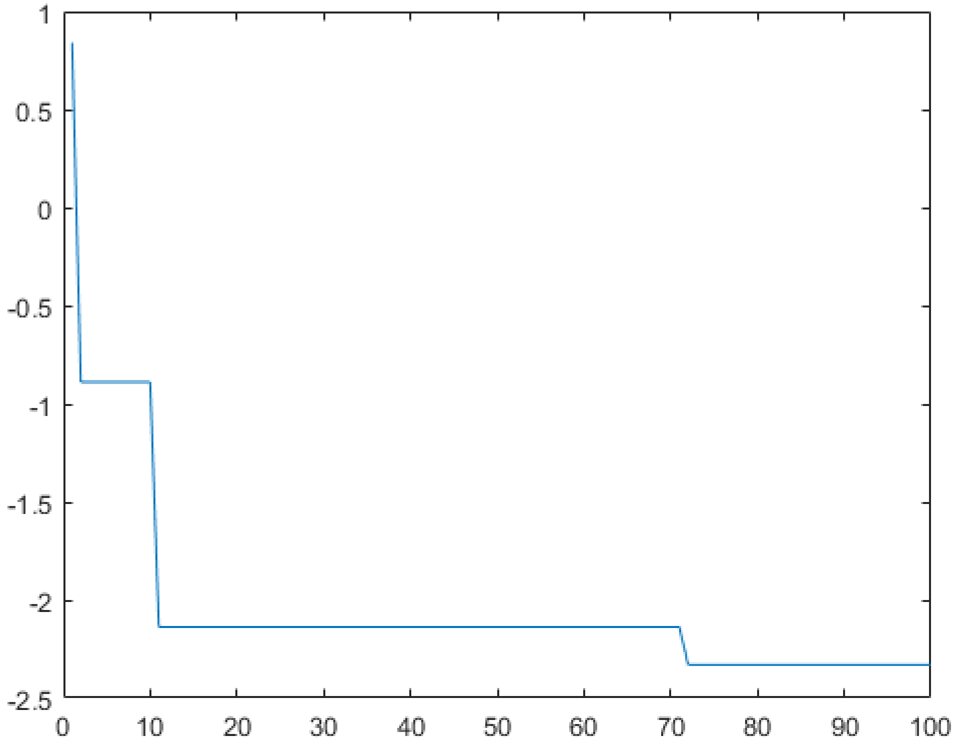
   -2.9443

I =

    35
```

Compute a running minimum.

```
min2 = dsp.Minimum;
min2.RunningMinimum = true;
x = randn(100,1);
y = min2(x);
plot(y);
```



y(i) is the minimum of all values in the vector x(1:i);

Algorithms

This object implements the algorithm, inputs, and outputs described on the `Minimum` block reference page. The object properties correspond to the block parameters.

Extended Capabilities

C/C++ Code Generation
Generate C and C++ code using MATLAB® Coder™.

dsp.MovingMinimum | dsp.Mean | dsp.Minimum

Blocks
`Minimum` | `Moving Minimum`

Introduced in R2012a

reset

System object: dsp.Minimum
Package: dsp

Reset internal states of minimum-finding object

Syntax

`reset(min)`

Description

`reset(min)` sets the internal states of the `Minimum` object `min` to their initial values.

step

System object: dsp.Minimum
Package: dsp

Operate on inputs to calculate outputs

Syntax

```
[VAL,IND] = step(min,X)
VAL = step(min,X)
IND = step(min,X)
VAL = step(min,X,R)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`[VAL,IND] = step(min,X)` returns the minimum value, `VAL`, and the index or position of the minimum value, `IND`, along the specified `Dimension` of `X`.

`VAL = step(min,X)` returns the minimum value, `VAL`, of the input `X`. When the `RunningMinimum` property is `true`, `VAL` corresponds to the minimum value over successive calls to the `step` method.

`IND = step(min,X)` returns the zero- or one-based index `IND` of the minimum value when the `IndexOutputPort` property is `true` and the `ValueOutputPort` property is `false`. You must set the `RunningMinimum` property to `false` to use this syntax.

`VAL = step(min,X,R)` resets the state of `min` based on the value of reset signal, `R`, and the `ResetCondition` property. To enable this type of processing, set the `RunningMinimum` property to `true` and the `ResetInputPort` property to `true`.

Note: `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

dsp.MovingAverage System object

Package: dsp

Moving average

Description

The `dsp.MovingAverage` System object computes the moving average of the input signal along each channel, independently over time. The object uses either the sliding window method or the exponential weighting method to compute the moving average. In the sliding window method, a window of specified length is moved over the data, sample by sample, and the average is computed over the data in the window. In the exponential weighting method, the object multiplies the data samples with a set of weighting factors. The average is computed by summing the weighted data. For more details on these methods, see "Algorithms" on page 2-1246.

The object accepts multichannel inputs, that is, m-by-n size inputs, where $m \geq 1$, and $n > 1$. The object also accepts variable-size inputs. Once the object is locked, you can change the size of each input channel. However, the number of channels cannot change. This object supports C and C++ code generation.

To compute the moving average of the input:

1. Create a `dsp.MovingAverage` object and set the properties of the object.
2. Call step to compute the moving average.

Note: Alternatively, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`movAvg = dsp.MovingAverage` returns a moving average object, `movAvg`, using the default properties.

`movAvg = dsp.MovingAverage(Len)` sets the `WindowLength` property to `Len`.

`movAvg = dsp.MovingAverage(Name,Value)` specifies additional properties using `Name,Value` pairs. Unspecified properties have default values.

Example:

```
movAvg = dsp.MovingAverage('Method','Exponential weighting','ForgettingFactor',0.9);
```

Properties

`Method` — Averaging method

`'Sliding window'` (default) | `'Exponential weighting'`

Averaging method, specified as `'Sliding window'` or `'Exponential weighting'`.

- `'Sliding window'` — A window of length specified by `SpecifyWindowLength` is moved over the input data along each channel. For every sample the window moves by, the object computes the average over the data in the window.
- `'Exponential weighting'` — The object multiplies the samples with a set of weighting factors. The magnitude of the weighting factors decreases exponentially as the age of the data increases, never reaching zero. To compute the average, the algorithm sums the weighted data.

For more details on these methods, see “Algorithms” on page 2-1246.

`SpecifyWindowLength` — Specify window length

true (default) | false

Flag to specify a window length, specified as a scalar boolean.

- `true` — The length of the sliding window is equal to the value you specify in the `WindowLength` property.
- `false` — The length of the sliding window is infinite. In this mode, the average is computed using the current sample and all the past samples.

This property applies when you set `Method` to `'Sliding window'`.

`WindowLength` — Length of the sliding window

4 (default) | positive scalar integer

Length of the sliding window, specified as a positive scalar integer. This property applies when you set `Method` to `'Sliding window'` and `SpecifyWindowLength` to `true`.

`ForgettingFactor` — Exponential weighting factor

0.9 (default) | positive real scalar in the range (0,1]

Exponential weighting factor, specified as a positive real scalar in the range (0,1]. This property applies when you set `Method` to `'Exponential weighting'`. A forgetting factor of 0.9 gives more weight to the older data than does a forgetting factor of 0.1. A forgetting factor of 1.0 indicates infinite memory. All the past samples are given an equal weight. This property is tunable. You can change its value even when the object is locked.

Methods

reset	Reset internal states of System object
step	Moving average of input signal

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Moving Average of Noisy Ramp Signal

Compute the moving average of a noisy ramp signal using the `dsp.MovingAverage` object.

Initialization

Set up `movavgWindow` and `movavgExp` objects. `movavgWindow` uses the sliding window method with a window length of 10. `movavgExp` uses the exponentially weighting method with a forgetting factor of 0.9. Create a time scope for viewing the output.

```
FrameLength = 1001;
Fs = 1000;
movavgWindow = dsp.MovingAverage(10);
movavgExp = dsp.MovingAverage('Method','Exponential weighting',...
    'ForgettingFactor',0.9);
scope  = dsp.TimeScope('SampleRate',Fs,...
    'TimeSpanOverrunAction','Scroll',...
    'TimeSpan',2,...
    'ShowGrid',true,...
    'YLimits',[-0.5 1.5]);
title = 'Sliding Window Average(blue) and Exponentially Weighted Average(red)';
scope.Title = title;
```

Compute the Average

Generate a ramp signal with an amplitude of 1.0 and a time span of 2 seconds. Apply the sliding window average and exponentially weighted average to the ramp. View the output on the time scope.

```
for i = 1:500
    t = (0:0.001:1)';
    unitstep = t>=0;
    ramp = t.*unitstep;
    x = ramp + 0.1 * randn(FrameLength,1);
    y1 = movavgWindow(x);
    y2 = movavgExp(x);
    scope([x,y1,y2]);
end
```

Algorithms

Sliding Window Method

In the sliding window method, the output for each input sample is the average of the current sample and the *Len* - 1 previous samples. *Len* is the length of the window. To compute the first *Len* - 1 outputs, when the window does not have enough data yet, the algorithm fills the window with zeros. As an example, to compute the average when the second input sample comes in, the algorithm fills the window with *Len* - 2 zeros. The data vector, x, is then the two data samples followed by *Len* - 2 zeros.

When you do not specify the window length, the algorithm chooses an infinite window length. In this mode, the output is the moving average of the current sample and all the previous samples in the channel.

For an example, see "Sliding Window Method and Exponential Weighting Method".

Exponential Weighting Method

In the exponential weighting method, the moving average is computed recursively using these formulas:

$$w_{N,\lambda} = \lambda w_{N-1,\lambda} + 1,$$

$$\bar{x}_{N,\lambda} = \left(1 - \frac{1}{w_{N,\lambda}}\right)\bar{x}_{N-1,\lambda} + \left(\frac{1}{w_{N,\lambda}}\right)x_N$$

- $\bar{x}_{N,\lambda}$ — Moving average at the current sample
- x_N — Current data input sample
- $\bar{x}_{N-1,\lambda}$ — Moving average at the previous sample
- λ — Forgetting factor
- $w_{N,\lambda}$ — Weighting factor applied to the current data sample
- $\left(1 - \frac{1}{w_{N,\lambda}}\right)\bar{x}_{N-1,\lambda}$ — Effect of the previous data on the average

For the first sample, where $N = 1$, the algorithm chooses $w_{N,\lambda} = 1$. For the next sample, the weighting factor is updated and used to compute the average, as per the recursive equation. As the age of the data increases, the magnitude of the weighting factor decreases exponentially and never reaches zero. In other words, the recent data has more influence on the current average than the older data.

The value of the forgetting factor determines the rate of change of the weighting factors. A forgetting factor of 0.9 gives more weight to the older data than does a forgetting factor of 0.1. A forgetting factor of 1.0 indicates infinite memory. All the previous samples are given an equal weight.

For an example, see “Sliding Window Method and Exponential Weighting Method”.

reset

System object: dsp.MovingAverage
Package: dsp

Reset internal states of System object

Syntax

`reset(movAvg)`

Description

`reset(movAvg)` resets the states of the input object to their initial values. The initial state values correspond to the initial conditions for the difference equation defining the object. After you call the object using nonzero input data, the filter might have nonzero states. If you continue to pass nonzero input data to the object without first calling `reset`, the object might produce different outputs for an identical input.

Introduced in R2016b

step

System object: dsp.MovingAverage
Package: dsp

Moving average of input signal

Syntax

```
y = step(movAvg,x)
```

Description

Note: Alternatively, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`y = step(movAvg,x)` computes the moving average of the input signal, `x`, using either the sliding window method or exponential weighting method of the input `dsp.MovingAverage` System object, `movAvg`. The input `x` can be a row vector, a column vector, or a matrix. If `x` is a matrix, each column is treated as an independent channel. The moving average is computed along each channel. The input `x` can be complex and supports single and double data types.

Introduced in R2016b

dsp.MovingMaximum System object

Package: dsp

Moving maximum

Description

The `dsp.MovingMaximum` System object determines the moving maximum of the input signal along each channel, independently over time. The object uses the sliding window method to determine the moving maximum. In this method, a window of specified length is moved over each channel, sample by sample, and the object determines the maximum of the data in the window. For more details, see "Algorithms" on page 4-1313.

The object accepts multichannel inputs, that is, m-by-n size inputs, where $m \geq 1$, and $n > 1$. The object also accepts variable-size inputs. Once the object is locked, you can change the size of each input channel. However, the number of channels cannot change. This object supports C and C++ code generation.

To determine the moving maximum of the input:

1. Create a `dsp.MovingMaximum` object and set the properties of the object.
2. Call step to compute the moving maximum.

Note: Alternatively, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`movMax = dsp.MovingMaximum` returns a moving maximum object, `movMax`, using the default properties.

`movMax = dsp.MovingMaximum(Len)` sets the `WindowLength` property to `Len`.

`movMax = dsp.MovingMaximum(Name,Value)` specifies additional properties using `Name,Value` pairs. Unspecified properties have default values.

Example:

```
movMax = dsp.MovingMaximum('SpecifyWindowLength',1,'WindowLength',10);
```

Properties

`SpecifyWindowLength` — Specify window length

true (default) | false

Flag to specify a window length, specified as a scalar boolean.

- `true` — The length of the sliding window is equal to the value you specify in the `WindowLength` property.
- `false` — The length of the sliding window is infinite. In this mode, the object determines the maximum of the current sample and all the past samples.

`WindowLength` — Length of the sliding window

4 (default) | positive scalar integer

Length of the sliding window, specified as a positive scalar integer. This property applies when you set `SpecifyWindowLength` to `true`.

Methods

reset	Reset internal states of System object
step	Moving maximum of input signal

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Moving Maximum of Sine Wave Signal

Compute the moving maximum of a sum of three sine waves with varying amplitude. Use a sliding window of length 30.

Initialization

Set up an input signal that is a sum of three sine waves with frequences at 2 Hz, 5 Hz, and 10 Hz. The sampling frequency is 100 Hz. Create a `dsp.MovingMaximum` object with a window length of 30. Create a time scope for viewing the output.

```
sin = dsp.SineWave('SampleRate',100,...
    'Frequency',[2 5 10],...
    'SamplesPerFrame',100);
movMax = dsp.MovingMaximum(30);
scope  = dsp.TimeScope('SampleRate',100,...
    'TimeSpanOverrunAction','Scroll',...
    'TimeSpan',10,'ShowGrid',true,...
    'YLimits',[-4.5 4.5]);
```

Compute the Moving Maximum

Each sine wave component of the input signal has a different amplitude that varies with the iteration. Use the `movMax` object to determine the maximum value of the current sample and the past 29 samples of the input signal.

```
for index = 1:100
    sin.Amplitude = rand(1,3);
    x = sum(sin(),2);
    xmax = movMax(x);
    scope([x,xmax])
end
```

Algorithms

Sliding Window Method

In the sliding window method, the output for each input sample is the maximum of the current sample and the *Len* - 1 previous samples. *Len* is the length of the window. When the algorithm computes the first *Len* - 1 outputs, the length of the window is the length of the data that is available.

When you do not specify the window length, the algorithm chooses an infinite window length. In this mode, the output is the maximum of the current sample and all the previous samples in the channel.

Consider an example of computing the moving maximum of a streaming input data using the sliding window method. The algorithm uses a window length of 4. With each input sample that comes in, the window of length 4 moves along the data.

Moving maximum of input signal

Syntax

`y = step(movMax,x)`

Description

Note: Alternatively, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`y = step(movMax,x)` determines the moving maximum of the input signal, `x`, using the sliding window method of the input `dsp.MovingMaximum` System object, `movMax`. The input `x` can be a row vector, a column vector, or a matrix. If `x` is a matrix, each column is treated as an independent channel. The moving maximum is determined along each channel. The input `x` can be complex and supports single and double data types.

Introduced in R2016b

dsp.MovingMinimum System object

Package: dsp

Moving minimum

Description

The `dsp.MovingMinimum` System object determines the moving minimum of the input signal along each channel, independently over time. The object uses the sliding window method to determine the moving minimum. In this method, a window of specified length is moved over each channel, sample by sample, and the object determines the minimum of the data in the window. For more details, see "Algorithms" on page 4-1322.

The object accepts multichannel inputs, that is, m-by-n size inputs, where $m \geq 1$, and $n > 1$. The object also accepts variable-size inputs. Once the object is locked, you can change the size of each input channel. However, the number of channels cannot change. This object supports C and C++ code generation.

To determine the moving minimum of the input:

1 Create a `dsp.MovingMinimum` object and set the properties of the object.
2 Call step to compute the moving minimum.

Note: Alternatively, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`movMin = dsp.MovingMinimum` returns a moving minimum object, `movMin`, using the default properties.

`movMin = dsp.MovingMinimum(Len)` sets the `WindowLength` property to `Len`.

`movMin = dsp.MovingMinimum(Name,Value)` specifies additional properties using `Name,Value` pairs. Unspecified properties have default values.

Example:

```
movMin = dsp.MovingMinimum('SpecifyWindowLength',1,'WindowLength',10);
```

Properties

`SpecifyWindowLength` — Specify window length

true (default) | false

Flag to specify a window length, specified as a scalar boolean.

- `true` — The length of the sliding window is equal to the value you specify in the `WindowLength` property.
- `false` — The length of the sliding window is infinite. In this mode, the object determines the minimum of the current sample and all the past samples.

`WindowLength` — Length of the sliding window

4 (default) | positive scalar integer

Length of the sliding window, specified as a positive scalar integer. This property applies when you set `SpecifyWindowLength` to `true`.

Methods

reset	Reset internal states of System object
step	Moving minimum of input signal

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Moving Minimum of Sine Wave Signal

Compute the moving minimum of a sum of three sine waves with varying amplitude. Use a sliding window of length 30.

Initialization

Set up an input signal that is a sum of three sine waves with frequences at 2 Hz, 5 Hz, and 10 Hz. The sampling frequency is 100 Hz. Create a `dsp.MovingMinimum` object with a window length of 30. Create a time scope for viewing the output.

```
sin = dsp.SineWave('SampleRate',100,...
    'Frequency',[2 5 10],...
    'SamplesPerFrame',100);
movMin = dsp.MovingMinimum(30);
scope  = dsp.TimeScope('SampleRate',100,...
    'TimeSpanOverrunAction','Scroll',...
    'TimeSpan',10,'ShowGrid',true,...
    'YLimits',[-4.5 4.5]);
```

Compute the Moving Minimum

Each sine wave component of the input signal has a different amplitude that varies with the iteration. Use the `movMin` object to determine the minimum value of the current sample and the past 29 samples of the input signal.

```
for index = 1:100
    sin.Amplitude = rand(1,3);
    x = sum(sin(),2);
    xmin = movMin(x);
    scope([x,xmin])
end
```

The input `x` can be complex and supports single and double data types.

Introduced in R2016b

dsp.MovingRMS System object

Package: dsp

Moving Root Mean Square

Description

The `dsp.MovingRMS` System object computes the moving Root Mean Square (RMS) of the input signal along each channel, independently over time. The object uses either the sliding window method or the exponential weighting method to compute the moving RMS. In the sliding window method, a window of specified length is moved over the data, sample by sample, and the RMS is computed over the data in the window. In the exponential weighting method, the object squares the data samples, multiplies them with a set of weighting factors, and sums the weighed data. The object then computes the RMS by taking the square root of the sum. For more details on these methods, see "Algorithms" on page 2-1261.

The object accepts multichannel inputs, that is, m-by-n size inputs, where $m \geq 1$, and $n > 1$. The object also accepts variable-size inputs. Once the object is locked, you can change the size of each input channel. However, the number of channels cannot change. This object supports C and C++ code generation.

To compute the moving RMS of the input:

1 Create a `dsp.MovingRMS` object and set the properties of the object.
2 Call step to compute the moving RMS.

Note: Alternatively, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`movRMS = dsp.MovingRMS` returns a moving RMS object, `movRMS`, using the default properties.

`movRMS = dsp.MovingRMS(Len)` sets the `WindowLength` property to `Len`.

`movRMS = dsp.MovingRMS(Name,Value)` specifies additional properties using `Name,Value` pairs. Unspecified properties have default values.

Example:

```
movRMS = dsp.MovingRMS('Method','Exponential weighting','ForgettingFactor',0.9);
```

Properties

`Method` — Moving RMS method

`'Sliding window'` (default) | `'Exponential weighting'`

Moving RMS method, specified as `'Sliding window'` or `'Exponential weighting'`.

- `'Sliding window'` — A window of length specified by `SpecifyWindowLength` is moved over the input data along each channel. For every sample the window moves by, the object computes the RMS over the data in the window.
- `'Exponential weighting'` — The object multiplies the squares of the samples with a set of weighting factors. The magnitude of the weighting factors decreases exponentially as the age of the data increases, never reaching zero. To compute the RMS, the algorithm sums the weighted data, and takes a square root of the sum.

For more details on these methods, see “Algorithms” on page 2-1261.

`SpecifyWindowLength` — Specify window length

true (default) | false

Flag to specify a window length, specified as a scalar Boolean.

- `true` — The length of the sliding window is equal to the value you specify in the `WindowLength` property.
- `false` — The length of the sliding window is infinite. In this mode, the RMS is computed using the current sample and all past samples.

This property applies when you set `Method` to `'Sliding window'`.

`WindowLength` — Length of the sliding window

4 (default) | positive scalar integer

Length of the sliding window, specified as a positive scalar integer. This property applies when you set `Method` to `'Sliding window'` and `SpecifyWindowLength` to `true`.

`ForgettingFactor` — Exponential weighting factor
0.9 (default) | positive real scalar in the range (0,1]

Exponential weighting factor, specified as a positive real scalar in the range (0,1]. This property applies when you set `Method` to `'Exponential weighting'`.

A forgetting factor of 0.9 gives more weight to the older data than does a forgetting factor of 0.1. A forgetting factor of 1.0 indicates infinite memory. All the past samples are given an equal weight.

This property is tunable. You can change its value even when the object is locked.

Methods

reset	Reset internal states of System object
step	Moving RMS of input signal

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Moving RMS of Noisy Square Wave Signal

Compute the moving RMS of a noisy square wave signal with varying amplitude using the `dsp.MovingRMS` object.

Initialization

Set up movrmsWin and movrmsExp objects. movrmsWin uses the sliding window method with a window length of 20. movrmsExp uses the exponential weighting method with a forgetting factor of 0.995. Create a time scope for viewing the output.

```
FrameLength = 10;
Fs = 100;
movrmsWin = dsp.MovingRMS(20);
movrmsExp = dsp.MovingRMS('Method','Exponential weighting',...
    'ForgettingFactor',0.995);
scope  = dsp.TimeScope('SampleRate',Fs,...
    'TimeSpanOverrunAction','Scroll',...
    'TimeSpan',100,...
    'ShowGrid',true,...
    'YLimits',[-1.0 5.5]);
title = 'Sliding Window RMS (blue) and Exponentially Weighted RMS (red)';
scope.Title = title;
```

Compute the RMS

Generate a noisy square wave signal. Vary the amplitude of the square wave after a given number of frames. Apply the sliding window method and the exponential weighting method on this signal. View the output on the time scope.

```
count = 1;
Vect = [1/8 1/2 1 2 3 4];
index = 1;
for index = 1:length(Vect)
    V = Vect(index);
    for i = 1:160
        x = V + 0.1 * randn(FrameLength,1);
        y1 = movrmsWin(x);
        y2 = movrmsExp(x);
        scope([x,y1,y2]);
    end
end
```

Algorithms

Sliding Window Method

In the sliding window method, the output for each input sample is the RMS of the current sample and the *Len* - 1 previous samples. *Len* is the length of the window. To compute the first *Len* - 1 outputs, when the window does not have enough data yet, the algorithm fills the window with zeros. As an example, to compute the RMS when the second input sample comes in, the algorithm fills the window with *Len* - 2 zeros. The data vector, x, is then the two data samples followed by *Len* - 2 zeros.

When you do not specify the window length, the algorithm chooses an infinite window length. In this mode, the output is the moving RMS of the current sample and all the previous samples in the channel.

Consider an example of computing the moving RMS of a streaming input data using the sliding window method. The algorithm uses a window length of 4. With each input sample that comes in, the window of length 4 moves along the data.

Exponential Weighting Method

In the exponential weighting method, the moving RMS is computed recursively using these formulas:

$$w_{N,\lambda} = \lambda w_{N-1,\lambda} + 1,$$

$$x\_rms_{N,\lambda} = \sqrt{\left(1 - \frac{1}{w_{N,\lambda}}\right) x\_rms_{N-1,\lambda} + \left(\frac{1}{w_{N,\lambda}}\right) x^2{}_N}$$

- $x\_rms_{N,\lambda}$ — Moving RMS at the current sample
- $x^2{}_N$ — Square of the current input data sample
- $x\_rms_{N-1,\lambda}$ — Moving RMS at the previous sample
- λ — Forgetting factor
- $w_{N,\lambda}$ — Weighting factor applied to the current data sample
- $\left(1 - \frac{1}{w_{N,\lambda}}\right) x\_rms_{N-1,\lambda}$ — Effect of the previous data on the RMS

For the first sample, where $N = 1$, the algorithm chooses $w_{N,\lambda}$ = 1. For the next sample, the weighting factor is updated and used to compute the RMS, as per the recursive equation. As the age of the data increases, the magnitude of the weighting factor decreases exponentially and never reaches zero. In other words, the recent data has more influence on the current RMS than the older data.

The value of the forgetting factor determines the rate of change of the weighting factors. A forgetting factor of 0.9 gives more weight to the older data than does a forgetting factor of 0.1. A forgetting factor of 1.0 indicates infinite memory. All the previous samples are given an equal weight.

Here is an example of computing the moving RMS using the exponential weighting method. The forgetting factor is 0.9.

reset

System object: dsp.MovingRMS
Package: dsp

Reset internal states of System object

Syntax

`reset(movRMS)`

Description

`reset(movRMS)` resets the states of the input object to their initial values. The initial state values correspond to the initial conditions for the difference equation defining the object. After you call the object using nonzero input data, the filter might have nonzero states. If you continue to pass nonzero input data to the object without first calling `reset`, the object might produce different outputs for an identical input.

Introduced in R2016b

step

System object: dsp.MovingRMS
Package: dsp

Moving RMS of input signal

Syntax

```
y = step(movRMS,x)
```

Description

Note: Alternatively, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`y = step(movRMS,x)` computes the moving RMS of the input signal, `x`, using either the sliding window method or exponential weighting method of the input `dsp.MovingRMS` System object, `movRMS`. The input `x` can be a row vector, a column vector, or a matrix. If `x` is a matrix, each column is treated as an independent channel. The moving RMS is computed along each channel. The input `x` can be complex and supports single and double data types.

Introduced in R2016b

dsp.MovingStandardDeviation System object

Package: dsp

Moving standard deviation

Description

The `dsp.MovingStandardDeviation` System object computes the moving standard deviation of the input signal along each channel, independently over time. The object uses either the sliding window method or the exponential weighting method to compute the moving standard deviation. In the sliding window method, a window of specified length is moved over the data, sample by sample, and the object computes the standard deviation over the data in the window. In the exponential weighting method, the object computes the exponentially weighted moving variance, and takes the square root. For more details on these methods, see “Algorithms” on page 2-1276.

The object accepts multichannel inputs, that is, m-by-n size inputs, where $m \geq 1$, and $n > 1$. The object also accepts variable-size inputs. Once the object is locked, you can change the size of each input channel. However, the number of channels cannot change. This object supports C and C++ code generation.

To compute the moving standard deviation of the input:

1. Create a `dsp.MovingStandardDeviation` object and set the properties of the object.
2. Call step to compute the moving standard deviation.

Note: Alternatively, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`MovStd = dsp.MovingStandardDeviation` returns a moving standard deviation object, `MovStd`, using the default properties.

`MovStd = dsp.MovingStandardDeviation(Len)` sets the `WindowLength` property to `Len`.

`MovStd = dsp.MovingStandardDeviation(Name,Value)` specifies additional properties using `Name,Value` pairs. Unspecified properties have default values.

Example:

```
MovStd = dsp.MovingStandardDeviation('Method','Exponential weighting','ForgettingFactor
```

Properties

`Method` — Moving standard deviation method

`'Sliding window'` (default) | `'Exponential weighting'`

- `'Sliding window'` — A window of length specified by `SpecifyWindowLength` is moved over the input data along each channel. For every sample the window moves by, the object computes the standard deviation over the data in the window.
- `'Exponential weighting'` — The object computes the exponentially weighted moving variance, and takes the square root.

For more details on these methods, see “Algorithms” on page 2-1276.

`SpecifyWindowLength` — Specify window length

true (default) | false

Flag to specify a window length, specified as a scalar boolean.

- `true` — The length of the sliding window is equal to the value you specify in the `WindowLength` property.
- `false` — The length of the sliding window is infinite. In this mode, the standard deviation is computed using the current sample and all the past samples.

This property applies when you set `Method` to `'Sliding window'`.

`WindowLength` — Length of the sliding window

4 (default) | positive scalar integer

Length of the sliding window, specified as a positive scalar integer. This property applies when you set `Method` to `'Sliding window'` and `SpecifyWindowLength` to `true`.

`ForgettingFactor` — Exponential weighting factor

0.9 (default) | positive real scalar in the range (0,1]

Exponential weighting factor, specified as a positive real scalar in the range (0,1].

This property applies when you set `Method` to `'Exponential weighting'`.

This property is tunable. You can change its value even when the object is locked.

Methods

reset	Reset internal states of System object
step	Moving standard deviation of input signal

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Moving Standard Deviation of Noisy Square Wave Signal

Compute the moving standard deviation of a noisy square wave signal with varying amplitude using the `dsp.MovingStandardDeviation` object.

Initialization

Set up `movstdWindow` and `movstdExp` objects. `movstdWindow` uses the sliding window method with a window length of 800. `movstdExp` uses the exponential weighting method with a forgetting factor of 0.999. Create a time scope for viewing the output.

```
FrameLength = 100;
Fs = 100;
movstdWindow = dsp.MovingStandardDeviation(800);
movstdExp = dsp.MovingStandardDeviation('Method','Exponential weighting',...
    'ForgettingFactor',0.999);
scope  = dsp.TimeScope('SampleRate',Fs,...
    'TimeSpanOverrunAction','Scroll',...
    'TimeSpan',1000,...
    'ShowGrid',true,...
    'BufferLength',1e7,...
    'YLimits',[0 3e-2]);
title = 'Actual (yellow) Sliding Window (blue) Exponentially Weighted (red) standard de
scope.Title = title;
```

Compute the Standard Deviation

Generate a noisy square wave signal. Vary the amplitude of the square wave after a given number of frames. Apply the sliding window method and the exponential weighting method on this signal. The actual standard deviation is `sqrt(np)`. This value is used while adding noise to the data. Compare the actual standard deviation with the computed standard deviation on the time scope.

```
count = 1;
noisepower = 1e-4 * [1 2 3 4];
index = 1;
for index = 1:length(noisepower)
    np = noisepower(index);
    yexp = sqrt(np)*ones(FrameLength,1);
    for i = 1:250
        x = sqrt(np) * randn(FrameLength,1);
        y1 = movstdWindow(x);
        y2 = movstdExp(x);
        scope([yexp,y1,y2]);
    end
end
```

Algorithms

Sliding Window Method

In the sliding window method, the output at the current sample is the standard deviation of the current sample with respect to the data in the window. To compute the first *Len* - 1 outputs, when the window does not have enough data yet, the algorithm fills the window with zeros. As an example, to compute the standard deviation when the second input sample comes in, the algorithm fills the window with *Len* - 2 zeros. *Len* is the length of the window. The data vector, *x*, is then the two data samples followed by *Len* - 2 zeros.

When you do not specify the window length, the algorithm chooses an infinite window length. In this mode, the output is the moving standard deviation of the current sample with respect to all the previous samples in the channel.

Consider an example of computing the moving standard deviation of a streaming input data using the sliding window method. The algorithm uses a window length of 4. With each input sample that comes in, the window of length 4 moves along the data.

Current sample at n = 5
1.414
std([3 2 5 2]')

Exponential Weighting Method

In the exponential weighting method, the moving standard deviation is computed recursively using these formulas:

$$s_{N,\lambda} = \sqrt{\frac{1}{v_{N,\lambda}} \sum_{k=1}^{N} \lambda^{N-k} \left[x_k - \bar{x}_{N,\lambda} \right]^2},$$

$$v_{N,\lambda} = \frac{2\lambda(1-\lambda^{N-1})}{(1-\lambda)(1+\lambda)}$$

- $s_{N,\lambda}$ — Moving standard deviation of the current data sample with respect to the rest of the data.
- $\left[x_k - \bar{x}_{N,\lambda} \right]^2$ — Difference between each data sample and the average of the data, squared.
- $\sum_{k=1}^{N} \lambda^{N-k} \left[x_k - \bar{x}_{N,\lambda} \right]^2$ — Difference between each data sample and the average of the data, squared and multiplied with the forgetting factor. All the squared terms are added.
- $\frac{1}{v_{N,\lambda}}$ — Weighting factor applied to the sum.
- λ — Forgetting factor.

As the age of the data increases, the magnitude of the weighting factor decreases exponentially and never reaches zero. In other words, the recent data has more influence on the current standard deviation than the older data.

The value of the forgetting factor determines the rate of change of the weighting factors. A forgetting factor of 0.9 gives more weight to the older data than does a forgetting factor of 0.1. A forgetting factor of 1.0 indicates infinite memory. All previous samples are given an equal weight.

Consider an example of computing the moving standard deviation using the exponential weighting method. The forgetting factor is 0.9.

The input `x` can be a row vector, a column vector, or a matrix. If `x` is a matrix, each column is treated as an independent channel. The moving standard deviation is computed along each channel. The input `x` can be complex and supports single and double data types.

Introduced in R2016b

dsp.MovingVariance System object

Package: dsp

Moving variance

Description

The `dsp.MovingVariance` System object computes the moving variance of the input signal along each channel, independently over time. The object uses either the sliding window method or the exponential weighting method to compute the moving variance. In the sliding window method, a window of specified length is moved over the data, sample by sample, and the variance is computed over the data in the window. In the exponential weighting method, the object subtracts each sample of the data from the average, squares the difference, and multiplies the squared result with a weighting factor. The object then computes the variance by adding all the weighted data. For more details on these methods, see "Algorithms" on page 2-1268.

The object accepts multichannel inputs, that is, m-by-n size inputs, where $m \geq 1$, and $n > 1$. The object also accepts variable-size inputs. Once the object is locked, you can change the size of each input channel. However, the number of channels cannot change. This object supports C and C++ code generation.

To compute the moving variance of the input:

1. Create a `dsp.MovingVariance` object and set the properties of the object.
2. Call step to compute the moving variance.

Note: Alternatively, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`MovVar = dsp.MovingVariance` returns a moving variance object, `MovVar`, using the default properties.

`MovVar = dsp.MovingVariance(Len)` sets the `WindowLength` property to `Len`.

`MovVar = dsp.MovingVariance(Name,Value)` specifies additional properties using `Name,Value` pairs. Unspecified properties have default values.

Example:

```
MovVar = dsp.MovingVariance('Method','Exponential weighting','ForgettingFactor',0.9);
```

Properties

`Method` — Method to compute the variance

`'Sliding window'` (default) | `'Exponential weighting'`

- `'Sliding window'` — A window of length specified by `SpecifyWindowLength` is moved over the input data along each channel. For every sample the window moves by, the object computes the variance over the data in the window.
- `'Exponential weighting'` — The object subtracts each sample of the data from the average, squares the difference, and multiplies the squared result with a weighting factor. The object then computes the variance by adding all the weighted data. The magnitude of the weighting factors decreases exponentially as the age of the data increases, never reaching zero.

For more details on these methods, see “Algorithms” on page 2-1268.

`SpecifyWindowLength` — Specify window length

true (default) | false

Flag to specify a window length, specified as a scalar Boolean.

- `true` — The length of the sliding window is equal to the value you specify in the `WindowLength` property.
- `false` — The length of the sliding window is infinite. In this mode, the variance is computed using the current sample and all past samples.

This property applies when you set `Method` to `'Sliding window'`.

`WindowLength` — Length of the sliding window

4 (default) | positive scalar integer

Length of the sliding window, specified as a positive scalar integer. This property applies when you set `Method` to `'Sliding window'` and `SpecifyWindowLength` to `true`.

`ForgettingFactor` — Exponential weighting factor
0.9 (default) | positive real scalar in the range (0,1]

Exponential weighting factor, specified as a positive real scalar in the range (0,1]. This property applies when you set `Method` to `'Exponential weighting'`.

A forgetting factor of 0.9 gives more weight to the older data than does a forgetting factor of 0.1. A forgetting factor of 1.0 indicates infinite memory. All the past samples are given an equal weight.

This property is tunable. You can change its value even when the object is locked.

Methods

reset	Reset internal states of System object
step	Moving Variance of input signal

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object

Examples

Moving Variance of Noisy Square Wave Signal

Compute the moving variance of a noisy square wave signal with varying amplitude using the `dsp.MovingVariance` object.

Initialization

Set up movvarWindow and movvarExp objects. movvarWindow uses the sliding window method with a window length of 800. movvarExp uses the exponentially weighting method with a forgetting factor of 0.999. Create a time scope for viewing the output.

```
FrameLength = 100;
Fs = 100;
movvarWindow = dsp.MovingVariance(800);
movvarExp = dsp.MovingVariance('Method','Exponential weighting',...
    'ForgettingFactor',0.999);
scope  = dsp.TimeScope('SampleRate',Fs,...
    'TimeSpanOverrunAction','Scroll',...
    'TimeSpan',1000,...
    'ShowGrid',true,...
    'BufferLength',1e7,...
    'YLimits',[0 7e-4]);
title = 'Actual (yellow) Sliding Window (blue) Exponentially Weighted (red) variance';
scope.Title = title;
```

Compute the Variance

Generate a noisy square wave signal. Vary the amplitude of the square wave after a given number of frames. Apply the sliding window method and the exponentially weighting method on this signal. The actual variance is *np*. This value is used while adding noise to the data. Compare the actual variance with the computed variances on the time scope.

```
count = 1;
noisepower = 1e-4 * [1 2 3 4];
index = 1;
for index = 1:length(noisepower)
    np = noisepower(index);
    yexp = np*ones(FrameLength,1);
    for i = 1:250
        x = 1 + sqrt(np) * randn(FrameLength,1);
        y1 = movvarWindow(x);
        y2 = movvarExp(x);
        scope([yexp,y1,y2]);
    end
end
```

Algorithms

Sliding Window Method

In the sliding window method, the output at the current sample is the variance of the current sample with respect to the data in the window. To compute the first *Len* - 1 outputs, when the window does not have enough data yet, the algorithm fills the window with zeros. As an example, to compute the variance when the second input sample comes in, the algorithm fills the window with *Len* - 2 zeros. *Len* is the length of the window. The data vector, *x*, is then the two data samples followed by *Len* - 2 zeros.

When you do not specify the window length, the algorithm chooses an infinite window length. In this mode, the output is the moving variance of the current sample with respect to all previous samples in the channel.

Consider an example of computing the moving variance of a streaming input data using the sliding window method. The algorithm uses a window length of 4. With each input sample that comes in, the window of length 4 moves along the data.

Current sample at n = 5
2.000
var([3 2 5 2]')

Exponential Weighting Method

In the exponential weighting method, the moving variance is computed recursively using these formulas:

$$s^2_{N,\lambda} = \frac{1}{v_{N,\lambda}} \sum_{k=1}^{N} \lambda^{N-k} \left[x_k - \bar{x}_{N,\lambda} \right]^2,$$

$$v_{N,\lambda} = \frac{2\lambda(1-\lambda^{N-1})}{(1-\lambda)(1+\lambda)}$$

To compute the moving variance, the algorithm implements these equations recursively.

- $s^2_{N,\lambda}$ — Moving variance of the current data sample with respect to the rest of the data in the channel.
- $\bar{x}_{N,\lambda}$ — Moving average at the current sample. For details on computing the moving average, see dsp.MovingAverage.
- $\left[x_k - \bar{x}_{N,\lambda} \right]^2$ — Difference between each data sample and the average of the data, squared.
- $\sum_{k=1}^{N} \lambda^{N-k} \left[x_k - \bar{x}_{N,\lambda} \right]^2$ — Difference between each data sample and the average of the data, squared and multiplied with the forgetting factor. All the squared terms are added.
- $\frac{1}{v_{N,\lambda}}$ — Weighting factor applied to the sum.
- λ — Forgetting factor you can specify through the `ForgettingFactor` property.

As the age of the data increases, the magnitude of the weighting factor decreases exponentially, and never reaches zero. In other words, the recent data has more influence on the current variance, than the older data.

The value of the forgetting factor determines the rate of change of the weighting factors. A forgetting factor of 0.9 gives more weight to the older data than does a forgetting factor of 0.1. A forgetting factor of 1.0 indicates infinite memory. All the past samples are given an equal weight.

Consider an example of computing the moving variance using the exponential weighting method. The forgetting factor is 0.9.

System object: dsp.MovingVariance
Package: dsp

Reset internal states of System object

Syntax

```
reset(movVar)
```

Description

`reset(movVar)` resets the states of the input object to their initial values. The initial state values correspond to the initial conditions for the difference equation defining the object. After you call the object using nonzero input data, the filter might have nonzero states. If you continue to pass nonzero input data to the object without first calling `reset`, the object might produce different outputs for an identical input.

Introduced in R2016b

step

System object: dsp.MovingVariance
Package: dsp

Moving Variance of input signal

Syntax

```
y = step(movVar,x)
```

Description

Note: Alternatively, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`y = step(movVar,x)` computes the moving variance of the input signal, `x`, using either the sliding window method or exponential weighting method of the input `dsp.MovingVariance` System object, `movVar`. The input `x` can be a row vector, a column vector, or a matrix. If `x` is a matrix, each column is treated as an independent channel. The moving variance is computed along each channel. The input `x` can be complex and supports single and double data types.

Introduced in R2016b

dsp.NCO System object

Package: dsp

Generate real or complex sinusoidal signals

Description

The numerically controlled oscillator, or `NCO`, object generates real or complex sinusoidal signals. The amplitude of the generated signal is always 1.

To generate real or complex sinusoidal signals:

1. Define and set up your NCO System object. See "Construction" on page 4-1363.
2. Call step to generate the signals according to the properties of `dsp.NCO`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj)` and `y = obj()` perform equivalent operations.

Construction

`nco = dsp.NCO` returns an NCO System object, `nco`, that generates a multichannel real or complex sinusoidal signal, with independent frequency and phase in each output channel.

`nco = dsp.NCO('`*`PropertyName`*`',`*`PropertyValue`*`,...)` returns an `NCO` System object, `nco`, with each specified property set to the specified value.

Properties

`PhaseIncrementSource`

Source of phase increment

Indicate how to specify the phase increment: `Property` or `Input port`. The default is `Input port`.

PhaseIncrement

Phase increment

Specify the phase increment as an integer scalar. This property applies only when you set the `PhaseIncrementSource on page 4-1363` property to `Property`. The default is `100`.

PhaseOffsetSource

Source of phase offset

Specify the phase offset as `Property` or `Input port`. The default is `Property`.

PhaseOffset

Phase offset

Specify the phase offset as an integer scalar. This property applies only when you set the `PhaseOffsetSource on page 4-1364` property to `Property`. The default is `0`.

Dither

Enable adding internal dithering to NCO algorithm

Set this property to `true` to add internal dithering to the NCO algorithm. Dithering is added using the PN Sequence Generator from the Communications System Toolbox product. The default is `true`.

NumDitherBits

Number of dither bits

Specify the number of dither bits as a positive integer. This property applies only when you set the `Dither` property to `true`. The default is `4`.

PhaseQuantization

Enable quantization of accumulated phase

Set this property to `true` to enable quantization of the accumulated phase. The default is `true`.

NumQuantizerAccumulatorBits

Number of quantizer accumulator bits

Specify the number of quantizer accumulator bits as an integer scalar greater than 1 and less than the accumulator word length. This property determines the number of entries in the lookup table of sine values. This property applies only when you set the `PhaseQuantization` on page 4-1364 property to `true`. The default is `12`.

PhaseQuantizationErrorOutputPort

Enable output of phase quantization error

Set this property to `true` to output the phase quantization error. This property applies only when you set the `PhaseQuantization` on page 4-1364 property to `true`. The default is `false`.

Waveform

Type of output signal

Specify the type of the output signal: `Sine`, `Cosine`, `Complex exponential` or `Sine and cosine`. The default is `Sine`.

SamplesPerFrame

Number of output samples per frame

Specify the number of samples per frame of the output signal. This property applies only when you set the `PhaseOffsetSource` on page 4-1364 property to `Property`. The default is `1`. When the `PhaseOffsetSource` property is `Input port`, and the `PhaseIncrementSource` on page 4-1363 property is `Property`, the number of rows or frame size of the phase offset input determines the number of samples per frame of the output signal. When you set both the `PhaseOffsetSource` on page 4-1364 and `PhaseIncrementSource` on page 4-1363 properties to `Input port`, the number of rows in the inputs must be 1, and the samples per frame of the output signal is 1.

OutputDataType

Output data type

Specify the output data type as `double`, `single` or `Custom`. The default is `Custom`. When you select `Custom` you must also set the `CustomOutputDataType` property.

You can find the CustomOutputDataType property described under Fixed-Point Properties on this page.

Fixed-Point Properties

RoundingMethod

Rounding method for fixed-point operations

This constant property has a value Floor.

OverflowAction

Overflow action for fixed-point operations

This constant property has a value Wrap.

AccumulatorDataType

Accumulator word and fraction lengths

This constant property has a value Custom.

CustomAccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as an unscaled numerictype object with a Signedness of Auto. The default is numerictype([],16).

CustomOutputDataType

Output word and fraction lengths

Specify the output fixed-point type as a scaled numerictype object with a Signedness of Auto. This property applies only when you set the OutputDataType on page 4-1365 property to Custom. The default is numerictype([],16,14).

Methods

info	Characteristic information about generated signal

reset	Reset accumulator of NCO object
step	Generate multichannel real or complex sinusoidal signal using NCO (Numerically Controlled Oscillator)

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Design an NCO Source

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject() becomes step(myObject).

Design an NCO source according to given specifications.

```
df = 0.05; % Frequency resolution = 0.05 Hz
minSFDR = 96; % Spurious free dynamic range >= 96 dB
Ts = 1/8000; % Sample period = 1/8000 sec
dphi = pi/2; % Desired phase offset = pi/2;
```

Calculate number of accumulator bits required for the given frequency resolution.

```
Nacc = ceil(log2(1/(df*Ts)));
```

Actual frequency resolution achieved.

```
actdf = 1/(Ts*2^Nacc);
```

Calculate number of quantized accumulator bits required from the SFDR requirement

```
Nqacc = ceil((minSFDR-12)/6);
```

Calculate the phase offset

```
phOffset = 2^Nacc*dphi/(2*pi);
```

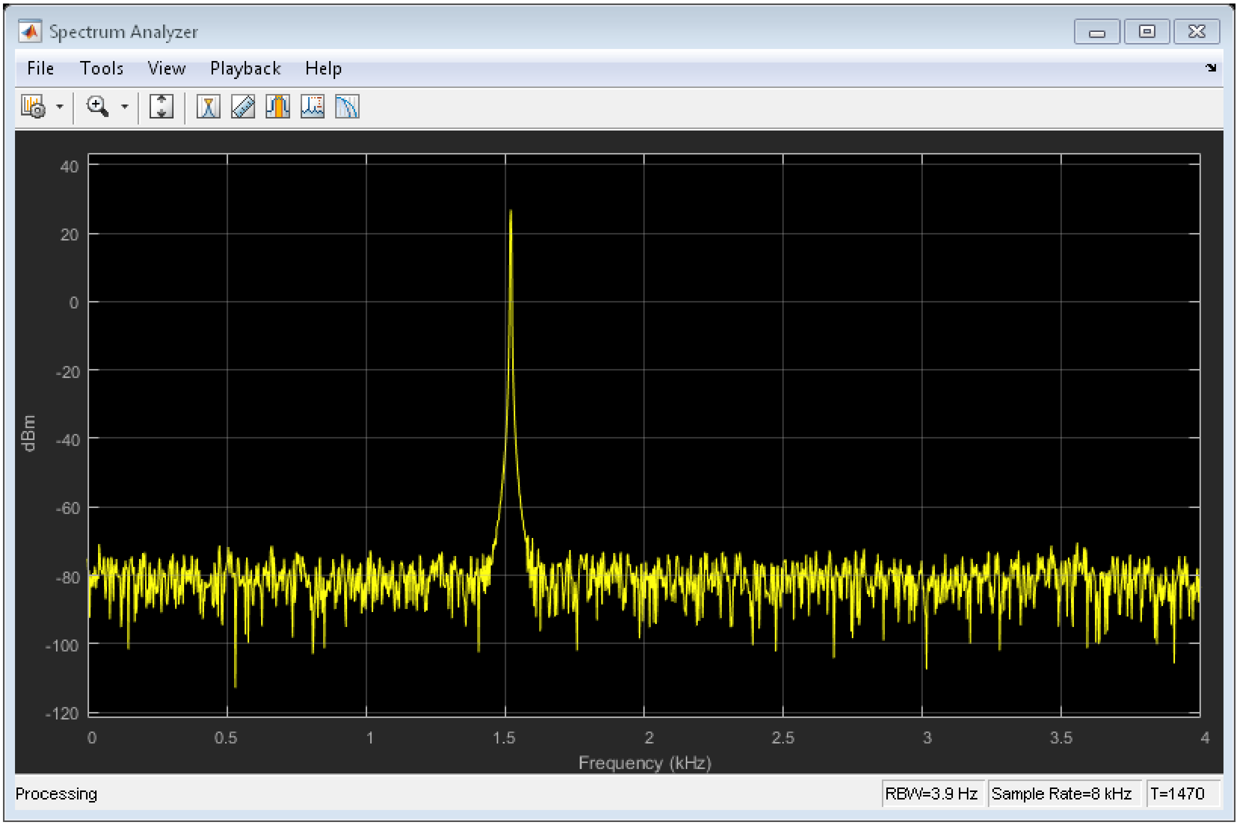
Design the NCO source.

```
nco = dsp.NCO('PhaseOffset', phOffset,...
    'NumDitherBits', 4, ...
    'NumQuantizerAccumulatorBits', Nqacc,...
    'SamplesPerFrame', 1/Ts, ...
    'CustomAccumulatorDataType', numerictype([],Nacc));
san = dsp.SpectrumAnalyzer('SampleRate', 1/Ts, ...
    'PlotAsTwoSidedSpectrum', false);
```

View the output of the NCO source on a spectrum analyzer. Change the output frequency in the middle of the simulation from 510 Hz to 1520 Hz.

```
tic;
while toc < 10

    if toc < 5
        F0 = 510;
    else
        F0 = 1520;
    end
    % Calculate the phase increment
    phIncr = int32(round(F0*Ts*2^Nacc));
    y = nco(phIncr);
    san(y);
end
```



Algorithms

This object implements the algorithm, inputs, and outputs described on the `NCO` block reference page. The object properties correspond to the block properties, except:
There is no object property that corresponds to the **Sample time** block parameter. The objects assumes a sample time of one second.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

See Also

dsp.SineWave

Introduced in R2012a

info

System object: dsp.NCO
Package: dsp

Characteristic information about generated signal

Syntax

```
S = info(nco)
```

Description

`S = info(nco)` returns a structure containing characteristic information, `S`, about the signal being generated by the `NCO` System object, `nco`. The number of fields of `S`, and their values vary depending on the property value settings of `nco`. For description of the possible fields and their values, see the following table.

Field	Value
`NumPointsLUT`	Number of data points for lookup table. The lookup table is implemented as a quarter-wave sine table.
`SineLUTSize`	Quarter-wave sine lookup table size in bytes.
`TheoreticalSFDR`	Theoretical spurious free dynamic range (SFDR) in dBc. This field applies when you set the `PhaseQuantization` property to `true`.
`FrequencyResolution`	Frequency resolution of the `NCO` in Hz. The sample time of the output signal is assumed to be `1` sec.

reset

System object: dsp.NCO
Package: dsp

Reset accumulator of NCO object

Syntax

```
reset(nco)
```

Description

`reset(nco)` resets the accumulator of the `NCO` System object, `nco`, to zero.

step

System object: dsp.NCO
Package: dsp

Generate multichannel real or complex sinusoidal signal using NCO (Numerically Controlled Oscillator)

Syntax

```
Y = step(nco,INC)
Y = step(nco)
Y = step(nco,OFFSET)
Y = step(nco,INC,OFFSET)
[Y,COSINE] = step(nco,___)
[Y,QERR] = step(nco,___)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj)` and `y = obj()` perform equivalent operations.

`Y = step(nco,INC)` returns a sinusoidal signal, `Y` , generated by the `NCO` with the specified phase increment, `INC`. `INC` must be a built-in integer or a fi object comprising either a scalar or a row vector, where each row element corresponds to a separate channel.

`Y = step(nco)` when the `PhaseIncrementSource` and `PhaseOffsetSource` properties are both `Property`, returns a sinusoidal signal, `Y`.

`Y = step(nco,OFFSET)` returns a sinusoidal signal, `Y`, with phase offset, `OFFSET`, when the `PhaseOffsetSource` property is `Input port`. `OFFSET` must be a built-in integer or a fi object. The number of rows of `OFFSET` determines the number of samples per frame of the output signal. The number of columns of the `OFFSET` determines the number of channels of the output signal.

Y = step(nco,INC,OFFSET) returns a sinusoidal signal, Y, with phase increment, INC, and phase offset, OFFSET, when the PhaseIncrementSource and the PhaseOffsetSource properties are both Input port. INC and OFFSET must both be row vectors of the same length, where the length determines the number of channels in the output signal.

[Y,COSINE] = step(nco,___) returns a sinusoidal signal, Y, and a cosinusoidal signal, COSINE, when the Waveform property is set to Sine and cosine. This syntax can include any of the input arguments in previous syntaxes.

[Y,QERR] = step(nco,___)when the PhaseQuantization and the PhaseQuantizationErrorOutputPort properties are both true, returns a sinusoidal signal, Y, and output quantization error, QERR.

Note: obj specifies the System object on which to run this step method.

The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

---

dsp.Normalizer System object

Package: dsp

Vector normalization along specified dimension

Description

The `Normalizer` object performs vector normalization along rows, columns, or specified dimension.

To perform vector normalization:

1. Define and set up your normalization object. See "Construction" on page 4-1375.
2. Call step to perform vector normalization according to the properties of `dsp.Normalizer`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`norm = dsp.Normalizer` returns a normalization object, `norm`, that normalizes the input over each column by the squared 2-norm of the column plus a bias term of 1e-10 used to protect against divide-by-zero.

`norm = dsp.Normalizer('`*`PropertyName`*`',`*`PropertyValue`*`, ...)` returns a normalization object, `norm`, with each property set to the specified value.

Properties

`Method`

Type of normalization to perform

Specify the type of normalization to perform as `2-norm` or `Squared 2-norm`. The `2-norm` mode supports floating-point signals only. The `Squared 2-norm` supports both fixed-point and floating-point signals. The default is `Squared 2-norm`.

Bias

Real number added in denominator to avoid division by zero

Specify the real number to add in the denominator to avoid division by zero. The default is 1e-10. This property is tunable.

Dimension

Dimension to operate along

Specify whether to normalize along `Column` , `Row`, or `Custom`. The default is `Column`.

CustomDimension

Numerical dimension to operate along

Specify the one-based value of the dimension over which to normalize. The value of this parameter cannot exceed the number of dimensions in the input signal. This property applies when `Dimension` on page 4-1376 property is `Custom`. The default is 1.

Fixed-Point Properties

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as one of `Ceiling`, `Convergent`, `Floor` , `Nearest`, `Round`, `Simplest`, or `Zero`. The default is `Floor`.

OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as one of `Wrap` or `Saturate`. The default is `Wrap`.

ProductDataType

Product word and fraction lengths

Specify the product fixed-point data type as one of `Same as input` or `Custom`.

CustomProductDataType

Product word and fraction lengths

Specify the product fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `ProductDataType` on page 4-1376 property to `Custom`. The default to `numerictype([],32,32)`.

AccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point data type as one of `Same as product`, `Same as input`, `Custom`. The default is `Same as product`.

CustomAccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `AccumulatorDataType` on page 4-1377 property to `Custom`. The default is `numerictype([],32,30)`.

OutputDataType

Output word and fraction lengths

Specify the output fixed-point data type as one of `Same as accumulator`, `Same as product` , `Same as input`, `Custom`. The default is `Same as product`.

CustomOutputDataType

Output word and fraction lengths

Specify the output fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`. This property applies when you set the `OutputDataType` on page 4-1377 property to `Custom`. The default is `numerictype([],32,32)`.

Methods

step	Normalize input along specified dimension

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Normalize a Matrix

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

```
norm = dsp.Normalizer;
x = magic(3);
y = norm(x);
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the `Normalization` block reference page. The object properties correspond to the block parameters, except:

- **Treat sample-based row input as column** — The block allows you to input a row vector and normalize the row vector as a column vector. The normalization object always normalizes along the value of the `Dimension` on page 4-1376 property.
- The normalization object does not support the **Minimum** and **Maximum** options for data output.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

See Also

dsp.ArrayVectorMultiplier

Introduced in R2012a

step

System object: dsp.Normalizer
Package: dsp

Normalize input along specified dimension

Syntax

`Y = step(norm,X)`

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(norm,X)` returns a normalized output`Y` . The input `X` must be floating-point for the `2-norm` mode, and either fixed-point and floating-point for the `Squared 2-norm` mode.

Note: `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

dsp.NotchPeakFilter System object

Package: dsp

Second-order tunable notching and peaking IIR filter

Description

The `NotchPeakFilter` object filters each channel of the input using IIR filter implementation.

To filter each channel of the input:

1. Define and set up your NotchPeak filter. See "Construction" on page 4-1381.
2. Call step to filter each channel of the input according to the properties of `dsp.NotchPeakFilter`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`npFilter = dsp.NotchPeakFilter` returns a second-order notching and peaking IIR filter which independently filters each channel of the input over time, using a specified center frequency and 3 dB bandwidth. Both of these properties are specified in Hz and are tunable. Both of these values must be scalars between `0` and half the sample rate.

`npFilter = dsp.NotchPeakFilter('`*`PropertyName`*`',`*`PropertyValue`*`, ...)` returns a notch filter with each specified property name set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1,Value1,...,NameN,ValueN)`.

`npFilter = dsp.NotchPeakFilter('specification','Quality factor and center frequency')` specifies the quality factor (Q factor) of the notch or peak filter instead of the 3 dB bandwidth. The Q factor is defined as the center frequency divided by the bandwidth. A higher Q factor corresponds to a narrower notch or peak. The Q factor should be a scalar value greater than 0. The Q factor is tunable.

`npFilter = dsp.NotchPeakFilter('Specification','Coefficients')` specifies the coefficient values that affect bandwidth and center frequency directly, rather than specifying the design parameters in Hz. This removes the trigonometry calculations involved when the properties are tuned. The `CenterFrequencyCoefficients` should be a scalar between `-1` and `1`, with `-1` corresponding to `0` Hz and `1` corresponding to the Nyquist frequency. The `BandwidthCoefficient` should be a scalar between `-1` and `1`, with `-1` corresponding to the largest `3` dB bandwidth and `1` corresponding to the smallest `3` dB bandwidth. Both coefficient values are tunable.

Properties

`Specification`

Filter specification

Set the specification as one of `'Bandwidth and center frequency'` | `'Quality factor and center frequency'` | `'Coefficients'`. The default is `'Bandwidth and center frequency'`.

`Bandwidth`

3 dB bandwidth

Specify the filter's `3` dB bandwidth as a finite positive numeric scalar in Hertz. This property is applicable only if `specification` is `'Bandwidth and center frequency'`. The default is `2205` Hz. This property is tunable.

`CenterFrequency`

Notch or Peak center frequency

Specify the filter's center frequency (for both the notch and the peak) as a finite positive numeric scalar in Hertz. This property is applicable only if `specification` is `'Bandwidth and center frequency'` | `'Quality factor and center frequency'`. The default is `11025` Hz. This property is tunable.

QualityFactor

Quality factor for notch or peak filter

Specify the quality factor (Q factor) for both the notch and the peak filters. The Q factor is defined as the center frequency divided by the bandwidth. This property is applicable only if `specification` is set to `'Quality factor and center frequency'`. The default value is `5`. This property is tunable.

SampleRate

Sample rate of input

Specify the sample rate of the input in Hertz as a finite numeric scalar. The default is `44100` Hz.

BandwidthCoefficient

Bandwidth coefficient

Specify the value that determines the filter's `3` dB bandwidth as a finite numeric scalar in the range `[-1 1]`. Where `-1` corresponds to the maximum `3` dB bandwidth (SampleRate/4), and `1` corresponds to the minimum `3` dB bandwidth (0 Hz, an allpass filter). The default is `0.72654`. This property is only applicable if `specification` is set to `'Coefficients'`. This property is tunable.

CenterFrequencyCoefficient

Center frequency coefficient

Specify the coefficient that determines the filter's center frequency as a finite numeric scalar between `-1` and `1`. Where `-1` corresponds to the minimum center frequency (0 Hz), and 1 corresponds to the maximum center frequency (`SampleRate/2` Hz). This property is only applicable if `specification` is set to `'Coefficients'`. The default is 0 which corresponds to `SampleRate/4` Hz. This property is tunable.

Methods

getBandwidth	Get 3 dB bandwidth

getCenterFrequency	Get center frequency
getOctaveBandwidth	Bandwidth in number of octaves
getQualityFactor	Get quality factor
reset	Reset the internal states of notch or peak filter
step	Process input using the notch or peak filter algorithm
tf	Transfer function

Common to All System Objects	
clone	Create System object with same property values
getNumInpu	Expected number of inputs to a System object
getNumOutp	Expected number of outputs of a System object
isLocked	Check locked states of a System object (logical)
release	Allow System object property value changes

Examples

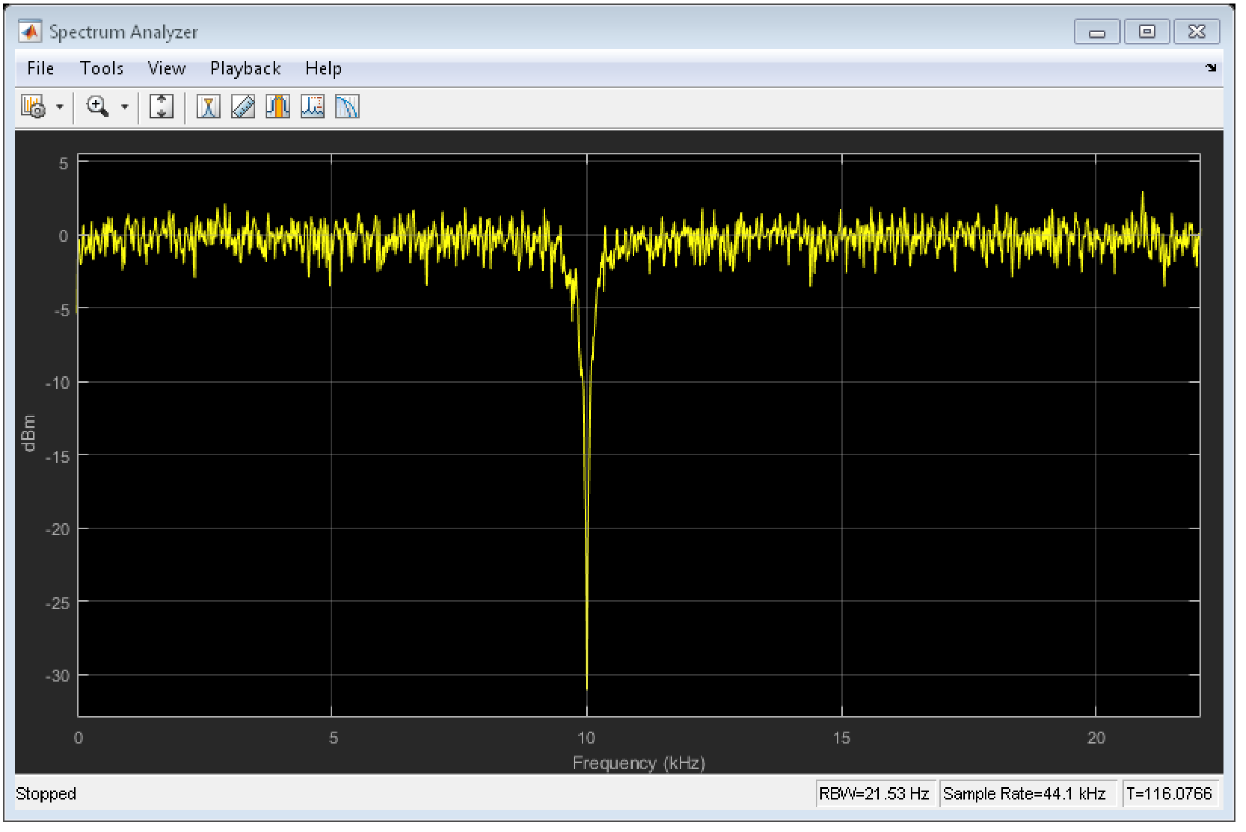
Notch filter

This example shows how to use dsp.NotchPeakFilter as a notch filter with center frequency of 5000 Hz and a 3 dB bandwidth of 500 Hz.

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

```
npFilter = dsp.NotchPeakFilter('CenterFrequency',5000,'Bandwidth',500);
sa =  dsp.SpectrumAnalyzer('SampleRate',44100,...
    'PlotAsTwoSidedSpectrum',false,'SpectralAverages',50);
for i=1:5000
    y = npFilter(randn(1024,1));
    sa(y);
    if (i==2500)
        % Tune center frequency to 10000
        npFilter.CenterFrequency = 10000;
```

```
    end
end
release(npFilter)
release(sa)
```



Algorithms

The design equations for this filter are:

$$H(z) = (1-b)\frac{1-z^{-2}}{1-2b\cos w_0 z^{-1} + (2b-1)z^{-2}}$$

The previous equation is for peak filter, and the following equation is for notch filter.

$$H(z) = b\frac{1 - 2\cos w_0 z^{-1} + z^{-2}}{1 - 2b\cos w_0 z^{-1} + (2b-1)z^{-2}}$$

With

$$b = \frac{1}{1 + \tan(\Delta w / 2)}$$

where $\omega_0 = 2\pi f_0/f_s$ is the center frequency in radians/sample (f_0 is the center frequency in Hz and f_s is the sampling frequency in Hz). $\Delta\omega = 2\pi\Delta f/f_s$ is the 3 dB bandwidth in radians/sample (Δf is the 3 dB bandwidth in Hz). Note that the two filters are complementary:

$$H_{notch}(z) + H_{peak}(z) = 1$$

they can be written as:

$$H_{peak}(z) = \frac{1}{2}[1 - A(z)]$$

$$H_{notch}(z) = \frac{1}{2}[1 + A(z)]$$

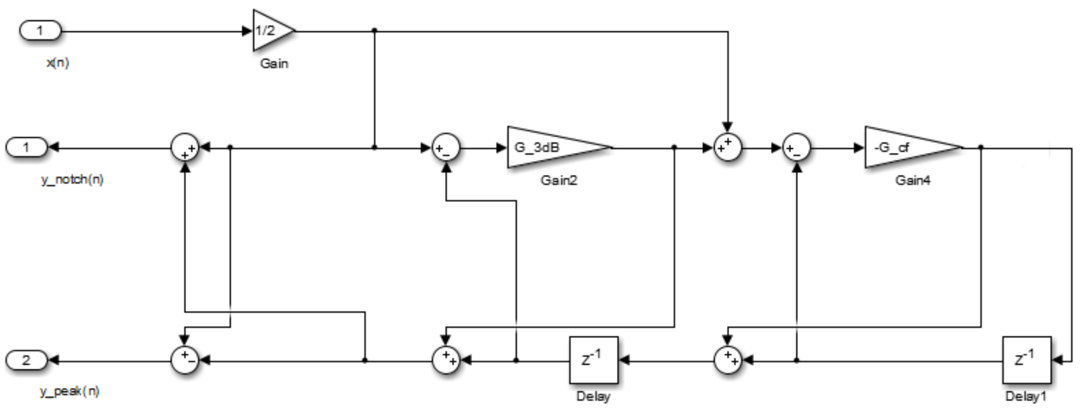
where A(z) is a 2^{nd} order allpass filter.

$$A(z) = \frac{a_2 + a_1 z^{-1} + z^{-2}}{1 + a_1 z^{-1} + a_2 z^{-2}}$$

and

$$a_1 = -2b\cos\omega_0$$
$$a_2 = 2b - 1$$

The filter is implemented as follows:



where

$$G_{3dB} = a_2 = 2b - 1$$

$$G_{cf} = \frac{a_1 - a_1 a_2}{1 - a_2{}^2} = -\cos w_0$$

Notice that G_{cf} depends only on the center frequency, and G_{3dB} depends only on the 3 dB bandwidth.

dsp.BiquadFilter | `iirnotch` | `iirpeak` | `Notch-Peak Filter`

Introduced in R2014a

getBandwidth

System object: dsp.NotchPeakFilter
Package: dsp

Get 3 dB bandwidth

Syntax

```
BW = getBandwidth(npFilter)
```

Description

`BW = getBandwidth(npFilter)` returns the 3 dB bandwidth for the notch or peak filter. If the `Specification` is set to `'Quality factor and center frequency'`, the 3 dB bandwidth is determined from the quality factor value. If the `Specification` property is set to `'Coefficients'`, the 3 dB bandwidth is determined from the `BandwidthCoefficient` value and the sample rate.

getCenterFrequency

System object: dsp.NotchPeakFilter
Package: dsp

Get center frequency

Syntax

```
CF= getCenterFrequency(npFilter)
```

Description

`CF= getCenterFrequency(npFilter)` returns the center frequency of the notch or peak filter. If the `Specification` property is set to `'Coefficients'`, the center frequency is determined from the `CenterFrequencyCoefficient` value and the sample rate.

getOctaveBandwidth

System object: dsp.NotchPeakFilter
Package: dsp

Bandwidth in number of octaves

Syntax

```
N = getOctaveBandwidth(npFilter)
```

Description

`N = getOctaveBandwidth(npFilter)` returns the bandwidth of the notch or peak filter, measured in number of octaves rather than Hz.

getQualityFactor

System object: dsp.NotchPeakFilter
Package: dsp

Get quality factor

Syntax

```
Q = getQualityFactor(npFilter)
```

Description

`Q = getQualityFactor(npFilter)` returns the quality factor (`Q` factor) for both the notch and the peak filters. The `Q` factor is defined as the center frequency divided by the bandwidth.

reset

System object: dsp.NotchPeakFilter
Package: dsp

Reset the internal states of notch or peak filter

Syntax

`reset(npFilter)`

Description

`reset(npFilter)` resets the internal states of System object, `npFilter`, to their initial values. System objects without states are unaffected by reset.

step

System object: dsp.NotchPeakFilter
Package: dsp

Process input using the notch or peak filter algorithm

Syntax

```
Y = step(npFilter,x)
[Yn,Yp] = step(npFilter,x)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(npFilter,x)` filters each channel of the input signal, `x`, using the notch peak filter, `npFilter`, to produce the notch filter output, `Y`.

`[Yn,Yp] = step(npFilter,x)` filters each channel of the input signal, `x`, using the notch peak filter, `npFilter`, to produce the notch filter output, `Yn`, and peak filter output, `Yp`.

Calling step on an object puts that object into a locked state. When locked, nontunable properties or any input characteristics (size, data type and complexity) cannot change without reinitializing (unlocking and relocking) the object.

tf

System object: dsp.NotchPeakFilter
Package: dsp

Transfer function

Syntax

```
[B,A] = tf(npFilter)
[B,A,B2,A2] = tf(npFilter)
```

Description

`[B,A] = tf(npFilter)` returns the vector of numerator coefficients, `B`, and the vector of denominators, `A`, for the equivalent transfer function corresponding to the notch filter.

In addition to `B` and `A`, `[B,A,B2,A2] = tf(npFilter)` returns the vector of numerator coefficients, `B2`, and the vector of denominator coefficients, `A2`, for the equivalent transfer function corresponding to the peak filter.

Examples

Determine the Transfer Function of Notch Peak Filter

Create a `dsp.NotchPeakFilter` System object™. Obtain the coefficients of the transfer function corresponding to the notch and peak filters.

```
notchpeak = dsp.NotchPeakFilter;
[Bnotch,Anotch,Bpeak,Apeak] = tf(notchpeak);
```

`Bnotch` and `Anotch` are the vector of numerator and denominator coefficients for the equivalent transfer function corresponding to the notch filter. `Bpeak` and `Apeak` are the vector of numerator and denominator coefficients for the equivalent transfer function corresponding to the peak filter.

dsp.ParametricEQFilter System object

Package: dsp

Tunable second-order parametric equalizer filter

Note: The `dsp.ParametricEQFilter` object will be removed in a future release. Existing instances of the object continue to run. For new code, use the `multibandParametricEQ` object from Audio System Toolbox instead.

Description

The `ParametricEQFilter` object is a tunable, second-order parametric equalizer filter.

To apply the filter to each channel of the input:

1. Define and set up your equalizer filter. See "Construction" on page 4-1395.
2. Call step to filter each channel according to the properties of `dsp.ParametricEQFilter`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = dsp.ParametricEQFilter` returns a second-order parametric equalizer filter that independently filters each channel of the input over time, using the default values for `Bandwidth`, `CenterFrequency`, and `PeakGaindB`. The `center frequency` and `bandwidth` are specified in Hz and are tunable. The `peak gain` (dip) is specified in dB and is also tunable. The `bandwidth` is measured at the arithmetic mean between the `peak gain` in absolute power units and one.

`H = dsp.ParametricEQFilter('Specification', 'Quality factor and center frequency')` specifies the quality factor (Q factor) of the filter. The `Q factor` is defined as the center frequency/bandwidth. A higher `Q factor` corresponds to a narrower peak/dip. The Q factor should be a scalar value greater than 0. The Q factor is tunable.

`H = dsp.ParametricEQFilter('Specification', 'Coefficients')` specifies the gain values for the bandwidth and center frequency. This removes the trigonometry calculations involved when the properties are tuned. The `CenterFrequencyCoefficient` should be a scalar between -1 and 1, with -1 corresponding to 0 Hz, and 1 corresponding to the Nyquist frequency. The `BandwidthCoefficient` should be a scalar between -1 and 1, with -1 corresponding to the largest bandwidth, and 1 corresponding to the smallest bandwidth. In this mode, the peak gain is specified in linear units rather than dB.

`H = dsp.ParametricEQFilter('Name', Value, ...)` returns a parametric equalizer filter with each specified property name set to the specified value. You can specify several name-value pair arguments in any order as `('Name1',Value1,...,'NameN',ValueN)`.

Properties

`Specification`

Design parameters or coefficients that specify the filter

Choose one of the following `Specification` values. Use the corresponding tunable properties to specify the filter:

- `Bandwidth and center frequency` — Use `Bandwidth`, `CenterFrequency`, and `PeakGaindB`.
- `Quality factor and center frequency` — Use `QualityFactor`, `CenterFrequency`, and `PeakGaindB`.
- `Coefficients` — Use `BandwidthCoefficient`, `CenterFrequencyCoefficient`, and `PeakGain`.

The default value is `Bandwidth and center frequency`.

Using `Coefficients` specifies gain values for the bandwidth and center frequency. This approach does not require the trigonometric calculations of the other two approaches where design parameters are specified in Hz.

Bandwidth

bandwidth of filter

Specify the bandwidth of the filter as a finite positive numeric scalar that is less than half the sample rate of the input signal, in Hz. This property is applicable if `Specification` is set to `Bandwidth and center frequency`. The default is 2205 Hz. This property is tunable.

BandwidthCoefficient

Coefficient for bandwidth of filter

Specify the value that determines the filter's bandwidth as a finite numeric scalar in the range `[-1 1]`:

- `-1` corresponds to the maximum bandwidth (`SampleRate`/4).
- `1` corresponds to the minimum bandwidth (0 Hz, that is, an allpass filter).

This property is only applicable if `Specification` is set to `Coefficients`. The default is 0.72654. This property is tunable.

CenterFrequency

Center frequency of the filter

Specify the filter's center frequency as a finite positive numeric scalar that is less than half the sample rate of the input signal, in Hz. This property is only applicable if `Specification` is set to `Bandwidth and center frequency` or `Quality factor and center frequency`. The default is `11025` Hz. This property is tunable.

CenterFrequencyCoefficient

Coefficient for center frequency of filter

Specify the value that determines the filter's center frequency as a finite numeric scalar between -1 and 1:

- -1 corresponds to the minimum center frequency (0 Hz).
- 1 corresponds to the maximum center frequency (`SampleRate`/2 Hz).

This property is only applicable if `Specification` is set to `Coefficients`. The default is `0`, which corresponds to `SampleRate`/4 Hz.

This property is tunable.

`PeakGain`

Peak or dip gain of the filter in linear units

Specify the filter's peak or dip gain in linear units. A value greater than one boosts the signal. A value less than one attenuates the signal. The default is 2 (6.0206 dB). This property is tunable.

`PeakGaindB`

Peak or dip gain of the filter in dB

Specify the filter's peak or dip gain in dB. A positive value boosts the signal. A negative value attenuates the signal. The default is `6.0206` dB. This property is tunable.

`QualityFactor`

Quality factor of the parametric EQ filter

Specify the Quality factor (Q factor) of the filter. The Q factor is defined as the center frequency divided by the bandwidth. A higher Q factor corresponds to a narrower peak or dip. This property is only applicable if `Specification` is set to `Quality factor and center frequency`. The default value is 5. This property is tunable.

`SampleRate`

Input sample rate

Specify the sample rate of the input as a finite numeric scalar, in Hz. The default is `44100` Hz.

Methods

getBandwidth	Convert quality factor or bandwidth coefficient to bandwidth in Hz
getCenterFrequency	Convert center frequency coefficient to frequency in Hz

getOctaveBandwidth	Measure bandwidth of parametric equalizer filter in octaves
getPeakGain	Convert peak or notch gain from dB to absolute units
getPeakGaindB	Convert peak or notch gain from absolute units to dB
getQualityFactor	Convert bandwidth to quality factor
reset	Reset states of `ParametricEQFilter` object
step	Filter input with `ParametricEQFilter` object
tf	Compute transfer function

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Tune Equalizer Filter

Create a `ParametricEQFilter` object where the center frequency and bandwidth of the equalizer filter are 5000 Hz and 500 Hz respectively. The sample rate for the filter is the default, 44,100 Hz.

```
h = dsp.ParametricEQFilter('CenterFrequency',5000,...
       'Bandwidth',500);
```

Create objects to estimate and display the transfer function of the filter.

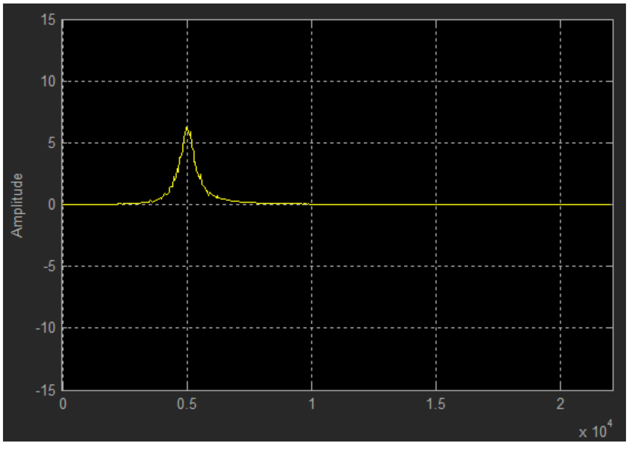
```
htf = dsp.TransferFunctionEstimator('FrequencyRange','onesided',...
         'SpectralAverages',50);
hplot = dsp.ArrayPlot('PlotType','Line','YLimits',[-15 15],...
       'SampleIncrement',44100/1024);
```

Generate a random signal and filter the signal.

```
for i=1:1000
   x = randn(1024,1);       % Random signal
   y = h(x);           % Filter signal
   H = htf(x,y);       % Estimate transfer function
   magdB = 20*log10(abs(H));% Convert to dB
   hplot(magdB);       % Display transfer function

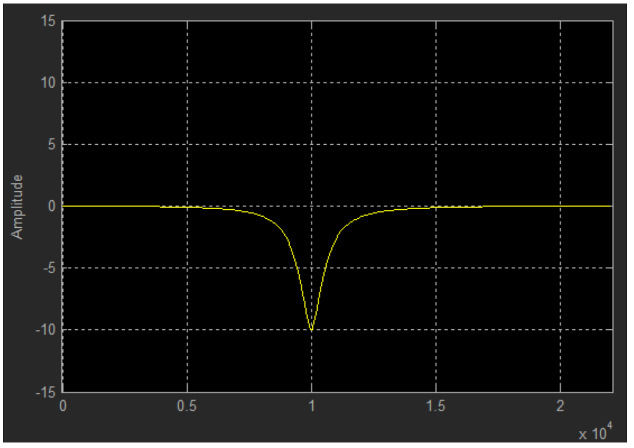
   if (i==1)                % Pause to display initial transfer function
      pause;
   end
   if (i==500)              % Tune filter
      h.CenterFrequency = 10000;
      h.Bandwidth = 2000;
      h.PeakGaindB = -10;
   end
 end
```

The software displays the initial transfer function estimate.



To continue, press any key.

At `i=500`, the filter is tuned. The center frequency, bandwidth, and peak gain of the filter now have different values. The software displays the new transfer function.

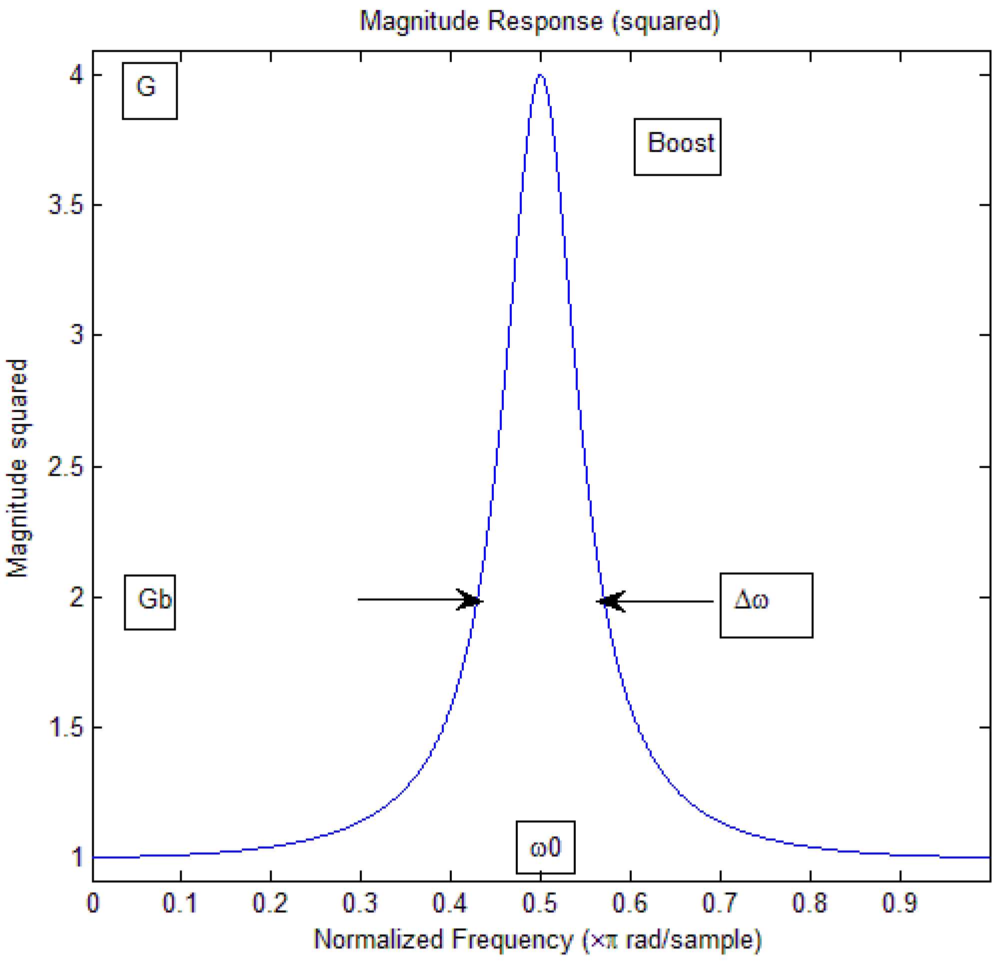


Algorithm

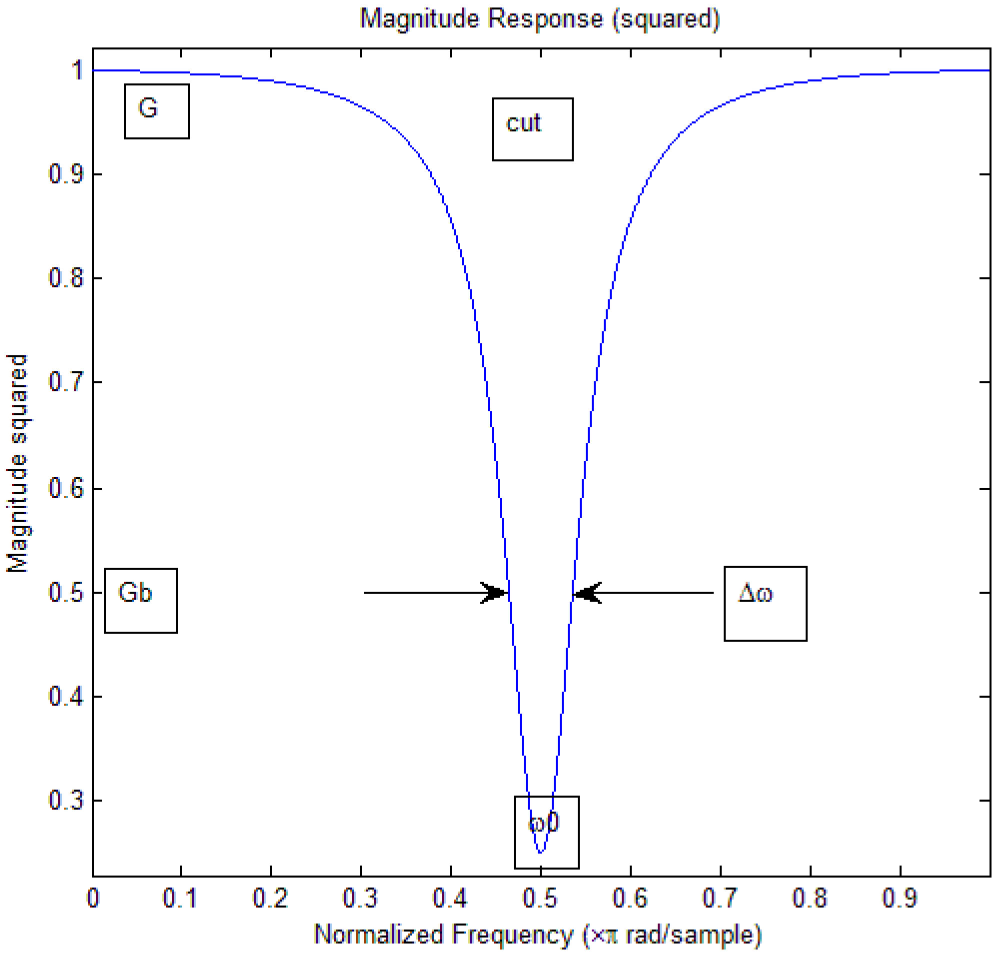
The parametric equalizer is formed by a linear combination of a peak and a notch filter. See the **Algorithm** section of dsp.NotchPeakFilter for details.

$$H(z) = H_{notch}(z) + GH_{peak}(z)$$

Here is a graph of the two cases (boost and cut) of the magnitude squared of the transfer functions:



Magnitude Response (squared)
G
Boost
Gb
Δω
ω0
Magnitude squared
Normalized Frequency (×π rad/sample)
4
3.5
3
2.5
2
1.5
1
0
0.1
0.2
0.3
0.4
0.5
0.6
0.7
0.8
0.9



The transfer function can be written as:

$$H(z) = \frac{(\frac{1+G_\gamma}{1+\gamma}) - 2(\frac{\cos\omega_0}{1+\gamma})z^{-1} + (\frac{1-G_\gamma}{1+\gamma})z^{-2}}{1 - 2(\frac{\cos\omega_0}{1+\gamma})z^{-1} + (\frac{1-\gamma}{1+\gamma})z^{-2}}$$

where

$$\gamma = \tan(\frac{\Delta\omega}{2})$$

and

$$G_B{}^2 = \frac{1+G^2}{2}$$

G is the parametric equalizer gain, and G_B is the bandwidth gain, that is, the gain level at which the bandwidth Δω is measured.

The dsp.NotchPeakFilter that does most of the work is implemented in a decoupled way so that the center frequency can be tuned independently from the bandwidth. Note that the Q factor is defined as center frequency/bandwidth.

`Parametric EQ Filter`	DSP System Toolbox
`iirparameq`	DSP System Toolbox

Introduced in R2014a

getBandwidth

System object: dsp.ParametricEQFilter
Package: dsp

Convert quality factor or bandwidth coefficient to bandwidth in Hz

---

Note: The `dsp.ParametricEQFilter` object will be removed in a future release. Existing instances of the object continue to run. For new code, use the `multibandParametricEQ` object from Audio System Toolbox instead.

Syntax

```
BW = getBandwidth(H)
```

Description

`BW = getBandwidth(H)` returns the bandwidth of the parametric equalizer filter. The bandwidth is measured halfway between 1 and the peak (or notch) gain of the filter. The gain is specified in absolute power units (filter magnitude squared). If the `Specification` property is set to `Quality factor and center frequency`, the bandwidth is determined from the quality factor of the filter. If the `Specification` property is set to `Coefficients`, the bandwidth is determined from the `BandwidthCoefficient` value and the sample rate of the filter.

getCenterFrequency

System object: dsp.ParametricEQFilter
Package: dsp

Convert center frequency coefficient to frequency in Hz

Note: The `dsp.ParametricEQFilter` object will be removed in a future release. Existing instances of the object continue to run. For new code, use the `multibandParametricEQ` object from Audio System Toolbox instead.

Syntax

```
CF = getCenterFrequency(H)
```

Description

`CF = getCenterFrequency(H)` returns the center frequency of the parametric equalizer filter. If the `Specification` property is set to `Coefficients`, the center frequency is determined from the `CenterFrequencyCoefficient` value and the sample rate of the filter.

getOctaveBandwidth

System object: dsp.ParametricEQFilter
Package: dsp

Measure bandwidth of parametric equalizer filter in octaves

Note: The `dsp.ParametricEQFilter` object will be removed in a future release. Existing instances of the object continue to run. For new code, use the `multibandParametricEQ` object from Audio System Toolbox instead.

Syntax

```
N = getOctaveBandwidth(H)
```

Description

`N = getOctaveBandwidth(H)` returns the bandwidth of the parametric equalizer filter in octaves instead of Hz.

getPeakGain

System object: dsp.ParametricEQFilter
Package: dsp

Convert peak or notch gain from dB to absolute units

Note: The `dsp.ParametricEQFilter` object will be removed in a future release. Existing instances of the object continue to run. For new code, use the `multibandParametricEQ` object from Audio System Toolbox instead.

Syntax

```
G = getPeakGain(H)
```

Description

`G = getPeakGain(H)` returns the peak or notch gain of the parametric equalizer filter in absolute units.

getPeakGaindB

System object: dsp.ParametricEQFilter
Package: dsp

Convert peak or notch gain from absolute units to dB

Note: The `dsp.ParametricEQFilter` object will be removed in a future release. Existing instances of the object continue to run. For new code, use the `multibandParametricEQ` object from Audio System Toolbox instead.

Syntax

```
G = getPeakGaindB(H)
```

Description

`G = getPeakGaindB(H)` returns the peak or notch gain of the parametric equalizer filter in dB.

getQualityFactor

System object: dsp.ParametricEQFilter
Package: dsp

Convert bandwidth to quality factor

Note: The `dsp.ParametricEQFilter` object will be removed in a future release. Existing instances of the object continue to run. For new code, use the `multibandParametricEQ` object from Audio System Toolbox instead.

Syntax

```
Q = getQualityFactor(H)
```

Description

`Q = getQualityFactor(H)` returns the quality factor (Q factor) for the parametric equalizer filter. The Q factor is defined as the center frequency divided by the bandwidth.

reset

System object: dsp.ParametricEQFilter
Package: dsp

Reset states of `ParametricEQFilter` object

Note: The `dsp.ParametricEQFilter` object will be removed in a future release. Existing instances of the object continue to run. For new code, use the `multibandParametricEQ` object from Audio System Toolbox instead.

Syntax

```
reset(H)
```

Description

`reset(H)` resets the filter states of the `ParametricEQFilter` object,`H`, to the specified initial conditions. After the `step` method applies the `ParametricEQFilter` object to nonzero input data, the states can change. Invoking the `step` method again without first invoking the `reset` method can produce different outputs for an identical input.

step

System object: dsp.ParametricEQFilter
Package: dsp

Filter input with `ParametricEQFilter` object

Note: The `dsp.ParametricEQFilter` object will be removed in a future release. Existing instances of the object continue to run. For new code, use the `multibandParametricEQ` object from Audio System Toolbox instead.

Syntax

```
Y = step(H, X)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H, X)` filters the real or complex input signal `X` using the specified filter to produce the equalized filter output `Y`. The filter processes each channel of the input signal (each column of `X`) independently over time.

Note: `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change

nontunable properties or inputs, you must first call the `release` method to unlock the object.

tf

System object: dsp.ParametricEQFilter
Package: dsp

Compute transfer function

Note: The `dsp.ParametricEQFilter` object will be removed in a future release. Existing instances of the object continue to run. For new code, use the `multibandParametricEQ` object from Audio System Toolbox instead.

Syntax

`[B,A] = tf(H)`

Description

`[B,A] = tf(H)` returns the vector of numerator coefficients `B` and the vector of denominator coefficients `A` for the equivalent transfer function of the parametric equalizer filter.

dsp.PeakFinder System object

Package: dsp

Determine extrema (maxima or minima) in input signal

Description

The `PeakFinder` object determines the extrema (maxima or minima) in the input signal.

To compute the extrema in the input signal:

1. Define and set up your peak finder. See "Construction" on page 4-1415.
2. Call step to compute the extrema according to the properties of `dsp.PeakFinder`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`pkFind = dsp.PeakFinder` returns a peak finder System object, `pkFind`, that compares the current signal value to the previous and next values to determine if the current value is an extremum.

`pkFind = dsp.PeakFinder('`*`PropertyName`*`',`*`PropertyValue`*`,...)` returns a peak finder System object, `pkFind`, with each specified property set to the specified value.

Properties

`PeakType`

Looking for maxima, minima, or both

Specify whether the object is looking for maxima, minima, or both. You can set this property to`Maxima`, `Minima`, or `Maxima and Minima`. The default is `Maxima and Minima`.

PeakIndicesOutputPort

Enable output of extrema indices

Set this property to `true` to output the extrema indices. The default is `false`.

PeakValuesOutputPort

Enable output of extrema values

Set this property to `true` to output the extrema values. The default is `false`.

MaximumPeakCount

Number of extrema to look for in each input signal

The object stops searching the input signal for extrema after the maximum number of extrema has been found. The value of this property must be an integer greater than or equal to one. The default is `10`.

IgnoreSmallPeaks

Enable ignoring peaks below threshold

Set this property to `true` if you want to eliminate the detection of peaks whose amplitudes are within a specified threshold of neighboring values. The default is `false`.

PeakThreshold

Threshold below which peaks are ignored

Specify the noise threshold value. This property defines the current input value as a maximum if:

- The current input value minus the previous input value is greater than the threshold, and
- The current input value minus next input value is greater than the threshold.

This property applies when you set the `IgnoreSmallPeaks on page 4-1416` property to `true`. The default is `0`.

Fixed-Point Properties

RoundingMethod

Rounding method for fixed-point operations

The rounding method is a constant property set to `Floor`.

OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as `Wrap` or `Saturate`. The default is `Wrap`.

Methods

step	Number of extrema in input signal

Common to All System Objects	
clone	Create System object with same property values
getNumInpu	Expected number of inputs to a System object
getNumOutp	Expected number of outputs of a System object
isLocked	Check locked states of a System object (logical)
release	Allow System object property value changes

Examples

Determine the local Maxima and Minima

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

Determine whether each value of an input signal is local maximum or minimum.

```
pkFind = dsp.PeakFinder;
pkFind.PeakIndicesOutputPort = true;
```

```
pkFind.PeakValuesOutputPort = true;
```

```
x1 = [9 6 10 3 4 5 0 12]';
```

Find the peaks of each input [prev;cur;next]: {[9;6;10],[6;10;3],...}

Peak Value For a Fixed-Point Signal

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

Determine peak values for a fixed-point input signal.

```
pkFind = dsp.PeakFinder('PeakType', 'Maxima', ...
    'PeakValuesOutputPort', true, ...
    'MaximumPeakCount', 2, ...
    'IgnoreSmallPeaks', true, ...
    'PeakThreshold', 0.25, ...
    'OverflowAction', 'Saturate');
x2 = fi([-1;0.5;0],true,16,15);
[cnt2, val2] = pkFind(x2)
```

```
cnt2 =

  uint32

   1

val2 =

    0.5000
```

```
          0

      DataTypeMode: Fixed-point: binary point scaling
        Signedness: Signed
        WordLength: 16
    FractionLength: 15
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the `Peak Finder` block reference page. The object properties correspond to the block parameters.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

See Also

dsp.Minimum | dsp.Maximum

Introduced in R2012a

step

System object: dsp.PeakFinder
Package: dsp

Number of extrema in input signal

Syntax

```
YCNT = step(pkFind,X)
[YCNT,IDX] = step(pkFind,X)
[..., VAL] = step(pkFind,X)
[..., POL] = step(pkFind,X)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`YCNT = step(pkFind,X)` returns the number of extrema (minima, maxima, or both) `YCNT` in input signal `X`.

`[YCNT,IDX] = step(pkFind,X)` when the `PeakIndicesOutputPort` property is `true`, returns the number of extrema `YCNT` and peak indices `IDX` in input signal `X`.

`[..., VAL] = step(pkFind,X)` also returns the peak values `VAL` in input signal `X` when the `PeakValuesOutputPort` property is `true`.

`[..., POL] = step(pkFind,X)` also returns the extrema polarity `POL` in input signal `X` when the `PeakType` property is `Maxima and Minima` and the `PeakIndicesOutputPort` property is `true`. The polarity is `1` for maxima and `0` for minima.

Note: `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.PeakToPeak System object

Package: dsp

Peak-to-peak value

Description

The `PeakToPeak` object computes the peak-to-peak value of an input.

To obtain the peak-to-peak value:

1. Define and set up your peak-to-peak calculation. See "Construction" on page 4-1423.
2. Call step to compute the peak-to-peak value for an input vector according to the properties of `dsp.PeakToPeak`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`ptp = dsp.PeakToPeak` creates a peak-to-peak System object, `ptp`, that computes the difference between the maximum and minimum value in an input or a sequence of inputs.

`ptp = dsp.PeakToPeak('`*`PropertyName`*`',`*`PropertyValue`*`,...)` returns an `PeakToPeak` System object, `ptp`, with each specified property set to the specified value.

Properties

CustomDimension

Dimension to operate along. Specify the dimension as a positive integer along which the peak-to-peak difference is computed. The value of this property cannot exceed the number of dimensions in the input signal. This property applies when the `Dimension` property is `'Custom'`.

Default: `1`

Dimension

Dimension to operate along. Specify the dimension along which to calculate the peak-to-peak ratio as one of `'All'`, `'Row'`, `'Column'`, or `'Custom'`. This property applies when the `RunningPeakToPeak` property is `false`. If you set this property to `'Custom'`, specify the dimension using the `CustomDimension` property.

Default: `'Column'`

ResetCondition

Reset condition for running peak-to-peak mode. Specify the event to reset the running peak-to-peak as one of `'Rising edge'`, `'Falling edge'`, `'Either edge'`, or `'Non-zero'`. This property applies when the `ResetInputPort` property is `true`.

ResetInputPort

Enables resetting in running peak-to-peak mode. Set this property to `true` to enable resetting the running peak-to-peak. When the property is set to `true`, a reset input must be specified to the call of step to reset the running peak-to-peak difference. This property applies when the `RunningPeakToPeak` property is `true`.

Default: `false`

RunningPeakToPeak

Calculation over successive calls to step. Set this property to `true` to enable the calculation of the peak-to-peak difference over successive calls to the `step`.

Default: `false`

Methods

reset	Reset the running peak-to-peak object
step	Compute peak-to-peak value

Common to All System Objects	
clone	Create System object with same property values
getNumInpu	Expected number of inputs to a System object
getNumOutp	Expected number of outputs of a System object
isLocked	Check locked states of a System object (logical)
release	Allow System object property value changes

Examples

Peak-to-Peak Value of Vector

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

Determine the peak-to-peak value for a vector input.

```
in = (1:10)';
ptp = dsp.PeakToPeak;
y = ptp(in)
```

```
y =

     9
```

Peak-to-Peak Value of Matrix Input

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

Determine the peak-to-peak value of a matrix input.

```
in = magic(4);
ptp = dsp.PeakToPeak;
ptp.Dimension = 'All';
y = ptp(in)
```

```
y =

    15
```

dsp.Maximum | dsp.PeakToRMS

Introduced in R2012a

reset

System object: dsp.PeakToPeak
Package: dsp

Reset the running peak-to-peak object

Syntax

`reset(ptp)`

Description

`reset(ptp)` resets the running peak-to-peak value for the object `ptp`.

step

System object: dsp.PeakToPeak
Package: dsp

Compute peak-to-peak value

Syntax

```
Y = step(ptp,X)
Y = step(ptp,X,R)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(ptp,X)` computes the peak-to-peak value, `Y`, of the floating-point input vector `X`. When the `RunningPeakToPeak` property is `true`, `Y` corresponds to the peak-to-peak value of the input elements over successive calls to the `step` method.

`Y = step(ptp,X,R)` computes the peak-to-peak value of the input elements over successive calls to the `step` method. The object optionally resets its state based on the reset input signal, `R`, and the value of the `ResetCondition` property. This is possible when you set both the `RunningPeakToPeak` and the `ResetInputPort` properties to `true`.

dsp.PeakToRMS System object

Package: dsp

Peak-to-root-mean-square value of vector

Description

The `PeakToRMS` object calculates the peak-to-root-mean-square ratio of a vector.

To compute the peak-to-root-mean-square ratio:

1 Define and set up your peak-to-root-mean-square calculation. See "Construction" on page 4-1429.
2 Call step to calculate the peak-to-root-mean-square value for an input vector according to the properties of `dsp.PeakToRMS`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`ptr = dsp.PeakToRMS` creates a peak-to-root-mean-square System object, `ptr`, that returns the ratio of the maximum magnitude (peak) to the root-mean-square (RMS) value in an input or a sequence of inputs.

`ptr = dsp.PeakToRMS('`*`PropertyName`*`',`*`PropertyValue`*`,...)` returns an `PeakToRMS` System object, `ptr`, with each specified property set to the specified value.

Properties

`CustomDimension`

Numerical dimension to operate along. Specify the dimension as a positive integer along which the peak-to-RMS ratio is computed. The value of this property cannot exceed the number of dimensions in the input signal. This property applies when `Dimension` property is `'Custom'`.

Default: `1`

`DecibelScaledOutput`

Report output in decibels (dB). Set this property to `true` to enable output in dB. Set this property to `false` to report output as a ratio.

Default: `true`

`Dimension`

Dimension to operate along. Specify the dimension along which to calculate the peak-to-RMS ratio as one of `'All'`, `'Row'`, `'Column'`, or `'Custom'`. This property applies when the `RunningPeakToRMS` property is `false`. If you set this property to `'Custom'`, specify the dimension using the `CustomDimension` property.

Default: `'Column'`

`ResetCondition`

Reset condition for running peak-to-RMS mode. Specify the event to reset the running peak-to-RMS as one of `'Rising edge'`, `'Falling edge'`, `'Either edge'`, or `'Non-zero'`. This property applies when the `ResetInputPort` property is `true`.

`ResetInputPort`

Enables resetting in running peak-to-RMS mode. Set this property to `true` to enable resetting. When the property is set to `true`, a reset input must be specified in the call to step to reset the running peak-to-RMS ratio. This property applies when the `RunningPeakToRMS` property is `true`.

Default: `false`

RunningPeakToRMS

Calculation over successive calls to step. Set this property to `true` to enable the calculation of the peak-to-RMS ratio over successive calls to the `step`.

Default: `false`

Methods

reset	Reset the running peak-to-root-mean-square object
step	Compute peak-to-RMS ratio

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Peak-to-RMS Ratio of Vector Input

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

Determine the peak-to-RMS ratio of a vector input.

```
in = (1:10)';
ptr = dsp.PeakToRMS;
y = ptr(in)
```

```
y =
```

```
    1.6116
```

Peak-to-RMS Ratio of Matrix Input

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

Determine the peak-to-RMS ratio of a matrix input.

```
in = magic(4);
ptr = dsp.PeakToRMS;
ptr.Dimension = 'All';
y = ptr(in)
```

```
y =

    1.6547
```

Definitions

Peak-magnitude-to-RMS Level

The peak-magnitude-to-RMS level is

$$\frac{||X||_\infty}{\sqrt{\frac{1}{N}\sum_{n=1}^{N}|X_n|^2}}$$

where the l-infinity norm and RMS values are computed along the specified dimension.

dsp.Maximum | dsp.PeakToPeak

Introduced in R2012a

reset

System object: dsp.PeakToRMS
Package: dsp

Reset the running peak-to-root-mean-square object

Syntax

`reset(ptr)`

Description

`reset(ptr)` resets the running peak-to-root-mean-square value for the object `ptr`.

step

System object: dsp.PeakToRMS
Package: dsp

Compute peak-to-RMS ratio

Syntax

```
Y = step(ptr,X)
Y = step(ptr,X,R)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(ptr,X)` computes the peak-to-RMS ratio, `Y`, of the floating-point input vector `X`. When the `RunningPeakToRMS` property is `true`, `Y` corresponds to the peak-to-RMS ratio of the input elements over successive calls to the `step` method.

`Y = step(ptr,X,R)` computes the peak-to-RMS ratio of the input elements over successive calls to the `step` method. The object optionally resets its state based on the reset input signal, `R`, and the value of the `ResetCondition` property. This is possible when you set both the `RunningPeakToRMS` and the `ResetInputPort` properties to `true`.

dsp.PhaseExtractor System object

Package: dsp

Extract the unwrapped phase of a complex input

Description

The `PhaseExtractor` object extracts the unwrapped phase of a complex input.

To extract the unwrapped phase of a signal input:

1. Define and set up your `dsp.PhaseExtractor` System object. See "Construction" on page 4-1436.
2. Call step with your input signal to extract the signal phase according to the properties of this System object. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`phase = dsp.PhaseExtractor` returns a System object, `phase`, that extracts the unwrapped phase of an input signal.

`phase = dsp.PhaseExtractor('`*`PropertyName`*`',`*`PropertyValue`*`,...)` returns a System object, `phase`, with each specified property set to the specified value.

Properties

`TreatFramesIndependently`

Specify if you want to reset the unwrapped phase at the end of a frame.

If you set this property to:

- `true`: The object treats each frame of data independently. It resets the initial cumulative unwrapped phase to zero each time a new input frame is received.
- `false`: The object ignores boundaries between frames when returning the unwrapped phase.

The default value is `false`.

Methods

reset	Reset internal states of object
step	Extract phase of signal input

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Plot Unwrapped Phase Of a Sine Wave

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

Create a `dsp.SineWave` System object™. Specify that the object generates an exponential output with a complex exponent.

```
sine = dsp.SineWave('Frequency',10,...
```

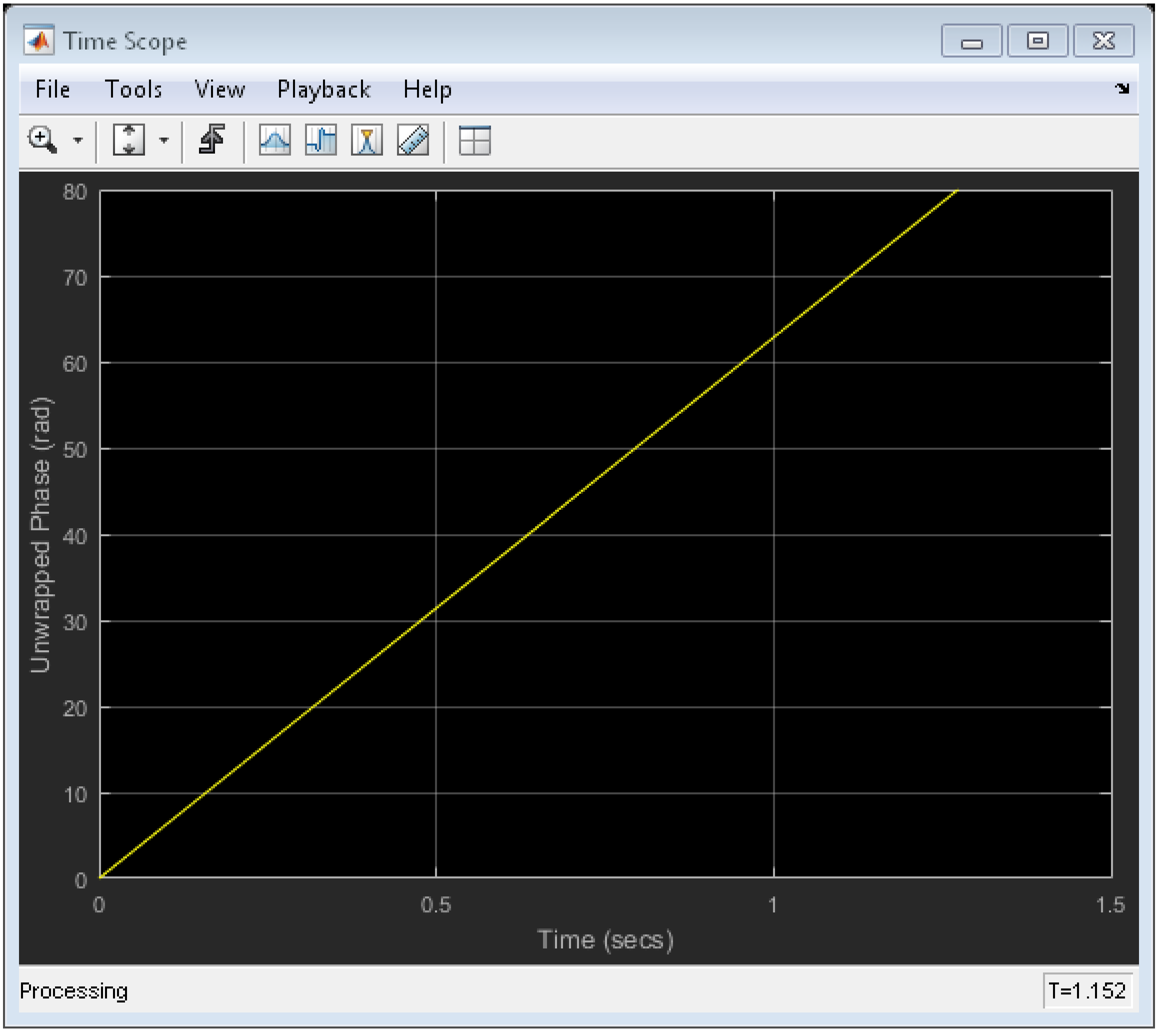
```
    'ComplexOutput',true,'SamplesPerFrame',128);
```

Create a `dsp.PhaseExtractor` System object™. Specify that the object ignores frame boundaries when returning the unwrapped phase.

```
phase = dsp.PhaseExtractor('TreatFramesIndependently',false);
```

Extract the unwrapped phase of a sine wave. Plot the phase versus time using a `dsp.TimeScope` System object™.

```
timeplot = dsp.TimeScope('PlotType','Line','SampleRate',1000,...
    'TimeSpan',1.5,'YLimits',[0 80],...
    'ShowGrid',true,...
    'YLabel','Unwrapped Phase (rad)');
for ii = 1:10
    sineOutput = sine();
    phaseOutput = phase(sineOutput);
    timeplot(phaseOutput)
end
```



Plot Phase Response of Third-Order IIR Filter

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

Create a `dsp.TransferFunctionEstimator` System object™.

```
tfe = dsp.TransferFunctionEstimator('FrequencyRange','centered');
```

Create a `dsp.PhaseExtractor` System object™. Specify that the object must treat each frame of data independently.

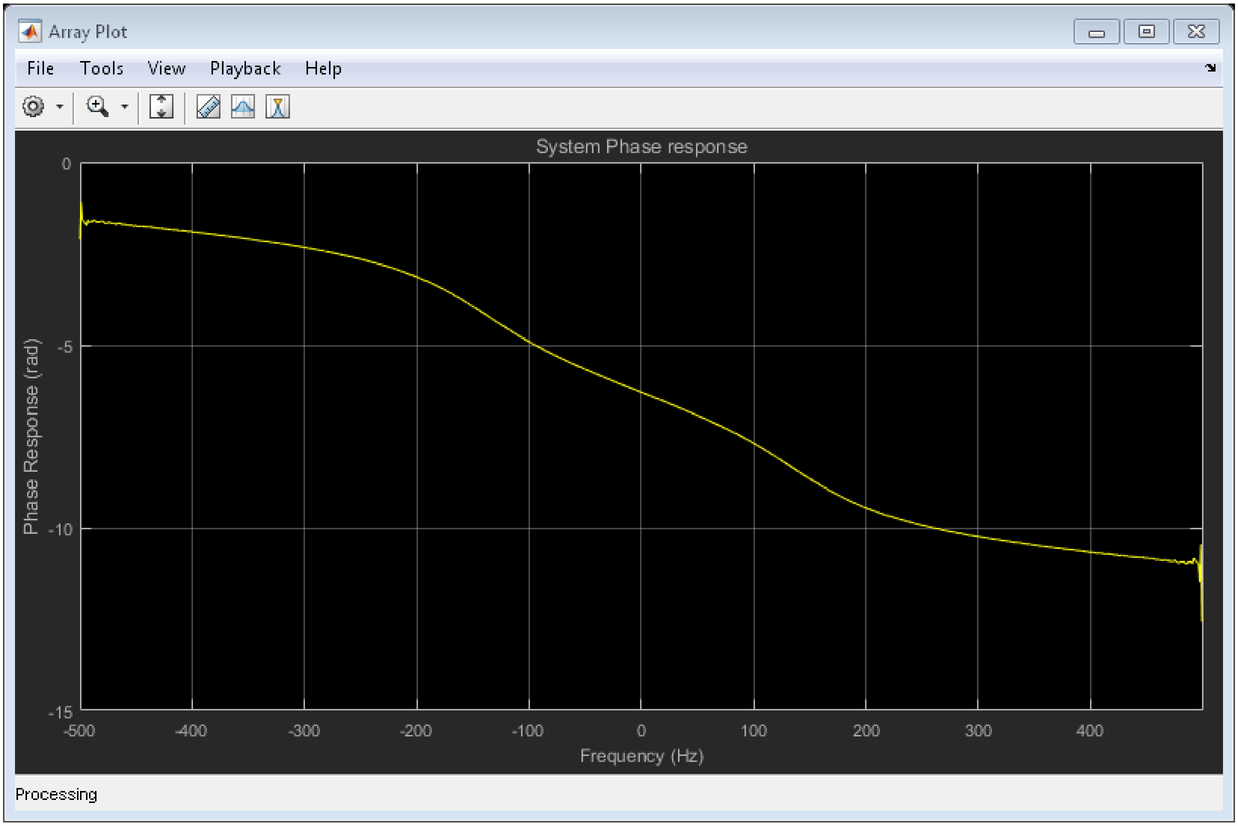
```
phase = dsp.PhaseExtractor('TreatFramesIndependently',true);
```

Create a `dsp.IIRFilter` System object™. Compute the transfer function of a third-order IIR filter. Use the `butter` function to generate coefficients for the filter.

```
[b,a] = butter(3,.3);
iir = dsp.IIRFilter('Numerator',b,'Denominator',a);
```

Extract the phase response of the transfer function. Plot using a `dsp.ArrayPlot` System object™.

```
sampleRate = 1e3;
phaseplot = dsp.ArrayPlot('PlotType','Line','XOffset',-sampleRate/2,...
    'YLimits',[-15 0],...
    'YLabel','Phase Response (rad)',...
    'XLabel','Frequency (Hz)',...
    'Title','System Phase response');
for ii = 1:100
    % Generate input
    input = 0.05*randn(1000,1);
    % Pass through IIR filter
    filterOutput = iir(input);
    % Estimate transfer function
    transferFunction = tfe(input,filterOutput);
    % Plot transfer function phase
    phaseOutput = phase(transferFunction);
    phaseplot(phaseOutput);
end
```



Algorithm

Consider an input frame of length N:

$$\begin{pmatrix} x_1 \\ x_2 \\ \vdots \\ x_N \end{pmatrix}$$

The `step` method acts on this frame and produces this output:

$$\begin{pmatrix} \Phi_1 \\ \Phi_2 \\ \vdots \\ \Phi_N \end{pmatrix}$$

where:

$$\Phi_i = \Phi_{i-1} + \text{angle}(x_{i-1}^* x_i)$$

Here, i runs from 1 to N. The `angle` function returns the phase angle in radians.

If the input signal consists of multiple frames:

- If you set `TreatFramesIndependently` to `true`, the `step` method treats each frame independently. Therefore, in each frame, the `step` method calculates the phase using the preceding formula where:
  - Φ_0 is 0.
  - x_0 is 1.
- If you set `TreatFramesIndependently` to `false`, the `step` method ignores boundaries between frames. Therefore, in each frame, the `step` method calculates the phase using the preceding formula where:
  - Φ_0 is the last unwrapped phase from the previous frame.
  - x_0 is the last sample from the previous frame.

Blocks

`Phase Extractor`

Introduced in R2014b

reset

System object: dsp.PhaseExtractor
Package: dsp

Reset internal states of object

Syntax

`reset(phase)`

Description

`reset(phase)` resets the values of internal variables Φ_0 to 0 and x_0 to 1. For more information on how the internal variables are used, see the algorithm used by the dsp.PhaseExtractor object.

step

System object: dsp.PhaseExtractor
Package: dsp

Extract phase of signal input

Syntax

`Y = step(phase,X)`

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(phase,X)` returns a vector containing the unwrapped phase of the input signal `X` in radians. The method treats each column of `X` as an independent channel. The data types of input signals must be either single or double-precision floating point.

If the property `TreatFramesIndependently` of the `dsp.PhaseExtractor` object `phase` is set to:

- `true`, the object treats each frame of data independently. It resets the initial cumulative unwrapped phase to zero each time a new input frame is received.
- `false`, the object ignores boundaries between frames when returning the unwrapped phase.

.

Note: `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as

dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.PhaseUnwrapper System object

Package: dsp

Unwrap signal phase

Description

The `PhaseUnwrapper` object unwraps the signal phase input specified in radians.

To unwrap the signal phase input:

1. Define and set up your System object. See "Construction" on page 4-1447.
2. Call step to unwrap the signal phase according to the properties of `dsp.PhaseUnwrapper`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`phUnwrap = dsp.PhaseUnwrapper` returns a System object, `phUnwrap`. This System object adds or subtracts appropriate multiples of 2π to each input element to remove phase discontinuities (unwrap).

`phUnwrap = dsp.PhaseUnwrapper('`*`PropertyName`*`',`*`PropertyValue`*`,...)` returns an unwrapped System object, `phUnwrap`, with each specified property set to the specified value.

Properties

`InterFrameUnwrap`

Enable unwrapping of phase discontinuities between successive frames

Set this property to `false` to unwrap phase discontinuities only within the frame. Set this property to `true` to also unwrap phase discontinuities between successive frames. The default is `true`.

`Tolerance`

Jump size as true phase discontinuity

Specify the jump size that the phase unwrapper recognizes as a true phase discontinuity. The default is set to π (rather than a smaller value) to avoid altering legitimate signal features. To increase the phase wrapper sensitivity, set the `Tolerance` property to a value slightly less than π.

Methods

reset	Reset internal states of Phase Unwrapper System object
step	Unwrap input phase signal input

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

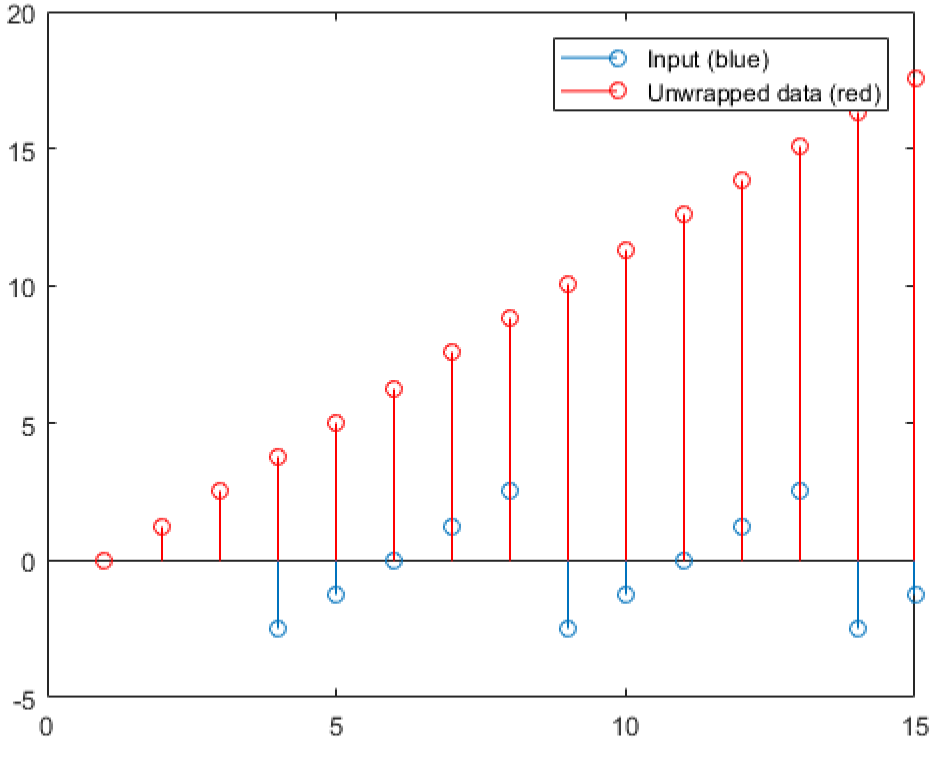
Unwrap input phase data

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

```
phUnwrap = dsp.PhaseUnwrapper;
p = [0 2/5 4/5 -4/5 -2/5 0 2/5 4/5 -4/5 -2/5 0 2/5 ...
    4/5 -4/5, -2/5]*pi;
```

```
y = phUnwrap(p');
figure,stem(p); hold
stem(y, 'r');
legend('Input (blue)','Unwrapped data (red)');
hold off;
```

```
Current plot held
```



Algorithms

This object implements the algorithm, inputs, and outputs described on the `Unwrap` block reference page. The object properties correspond to the Simulink block parameters.

Package: dsp

Reset internal states of Phase Unwrapper System object

Syntax

`reset(phUnwrap)`

Description

`reset(phUnwrap)` resets the 2π multiplier `k` to `0` for the phase unwrapper object `phUnwrap`. See "Frame-Based Processing" on page 2-1807 for details.

step

System object: dsp.PhaseUnwrapper
Package: dsp

Unwrap input phase signal input

Syntax

```
Y = step(phUnwrap,X)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(phUnwrap,X)` unwraps the input signal `X` in radians for the root mean square (RMS) object `phUnwrap`.

Note: `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

dsp.PulseMetrics System object

Package: dsp

Pulse metrics of bilevel waveforms

Description

The `PulseMetrics` object computes rise times, fall times, pulse widths, and cycle metrics including pulse period, pulse separation, and duty cycle for bilevel waveforms.

To obtain pulse metrics for a bilevel waveform:

1. Define and set up your pulse metrics. See "Construction" on page 4-1453.
2. Call step to compute the pulse metrics according to the properties of `dsp.PulseMetrics`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`pm = dsp.PulseMetrics` creates a pulse metrics System object, `pm`. The object computes the rise time, fall time, and width of a pulse. `dsp.PulseMetrics` also computes cycle metrics such as pulse separations, periods, and duty cycles. Because a pulse contains two transitions, the object contains a superset of the capability defined in dsp.TransitionMetrics.

`pm = dsp.PulseMetrics('`*`PropertyName`*`',`*`PropertyValue`*`,...)` returns a `PulseMetrics` System object, `pm`, with each specified property set to the specified value.

Properties

CycleOutputPort

Enable cycle metrics. If CycleOutputPort is true, cycle metrics are reported for each pulse period.

Default: false

MaximumRecordLength

Maximum samples to preserve between calls to step. This property requires a positive integer that specifies the maximum number of samples to save between calls to the step method. When the number of samples to be saved exceeds this length, the oldest excess samples are discarded. This property applies when the RunningMetrics property is true and is tunable.

Default: 1000

PercentReferenceLevels

Lower-, middle-, and upper-percent reference levels. This property contains a three-element numeric row vector that contains the lower-, middle-, and upper-percent reference levels. These reference levels are used as an offset between the lower and upper states of the waveform when computing the duration of each transition.

Default: [10 50 90]

PercentStateLevelTolerance

Tolerance of the state level (in percent). This property requires a scalar that specifies the maximum deviation from either the low or high state before it is considered to be outside that state. The tolerance is expressed as a percentage of the waveform amplitude.

Default: 2

Polarity

Polarity of pulse to extract. This property specifies the type of pulse to extract by the polarity of the leading transition. Valid values for this property are 'positive' or 'negative'.

Default: `'positive'`

PostshootOutputPort

Enable posttransition aberration metrics. If this property is set to `true`, overshoot and undershoot metrics are reported for a region defined immediately after each transition. The posttransition aberration region is defined as the waveform interval that begins at the end of each transition and whose duration is the value of `PostshootSeekFactor` times the computed transition duration. If a complete subsequent transition is detected before the interval is over, the region is truncated at the start of the subsequent transition. The metrics are computed for each transition that has a complete posttransition aberration region.

Default: `false`

PostshootSeekFactor

Corresponds to the duration of time to search for the overshoot and undershoot metrics immediately following each transition. The duration is expressed as a factor of the duration of the transition. This property is enabled only when the `PostshootOutputPort` property is set to `true` and is tunable.

Default: 3

PreshootOutputPort

Enable pretransition aberration metrics. If `PreshootOutputPort` is set to `true`, overshoot and undershoot metrics are reported for a region defined immediately before each transition. The pretransition aberration region is defined as the waveform interval that ends at the start of each transition and whose duration is `PreshootSeekFactor` times the computed transition duration.

Default: `'false'`

PreshootSeekFactor

Corresponds to the duration of time to search for the overshoot and undershoot metrics immediately preceding each transition. The duration is expressed as a factor of the duration of the transition. This property is enabled only when the `PreshootOutputPort` property is set to `true` and is tunable.

Default: 3

RunningMetrics

Enable metrics over all calls to step. If RunningMetrics is set to false, metrics are computed for each call to step independently. If RunningMetrics is set to true, metrics are computed across subsequent calls to step. If there are not enough samples to compute metrics associated with the last transition, posttransition aberration region, or settling seek duration in the current record, the object will defer reporting all transition, aberration, and settling metrics associated with the last transition until a subsequent call to step is made with enough data to compute all enabled metrics for that transition.

Default: false

SampleRate

Sampling rate of uniformly-sampled signal. Specify the sample rate in hertz as a positive scalar. This property is used to construct the internal time values that correspond to the input sample values. Time values start with zero. This property applies when the TimeInputPort property is set to false.

Default: 1

SettlingOutputPort

Enable settling metrics. If the SettlingOutputPort property is set to true, settling metrics are reported for each transition. The region used to compute the settling metrics starts at the midcrossing and lasts until the SettlingSeekDuration has elapsed. If an intervening transition occurs, or the signal has not settled within the PercentStateLevelTolerance of the final level, NaN is returned for each metric. If there are not enough samples after the last transition to complete the SettlingSeekDuration, no metrics are reported for the last transition. The metrics are reported for the transition the next time step is called if the RunningMetrics property is set to true.

Default: false

SettlingSeekDuration

Duration of time over which to search for settling. This property value is a scalar that specifies the amount of time to inspect from the mid-reference level crossing (in seconds). If the transition has not yet settled, or a subsequent complete transition is detected within this duration, the PulseMetrics object will report NaN for all settling metrics.

This property is tunable and applies only when you set the `SettlingOutputPort` property to `true`.

Default: `0.02`

StateLevels

Low- and high-state levels. This property is a 2–element numeric row vector that contains the low- and high-state levels respectively. These state levels correspond to the nominal logic low and high levels of the pulse waveform. This property is tunable.

Default: `[0 2.3]`

StateLevelsSource

Auto or manual state-level computation. If `StateLevelsSource` is set to `'Auto'`, the first record sent to `step` is sent to dsp.StateLevels with the default settings to determine the state levels of the incoming waveform. If this property is set to `'Property'`, the object uses the values the user specifies in the `StateLevels` property.

Default: `'Property'`

TimeInputPort

Add input to specify sample instants. Set `TimeInputPort` to `true` to enable an additional real input column vector to `step` to specify the sample instants that correspond to the sample values. If this property is `false`, the sample instants are built internally. The sample instants start at zero and increment by the reciprocal of the `SampleRate` property for subsequent samples. The sample instants continue to increment if the `RunningMetrics` property is set to `true` and no intervening calls to the `reset` or `release` methods are encountered.

Default: `false`

TransitionOutputPort

Enable transition metrics. If the `TransitionOutputPort` property is set to `true`, transition metrics are reported for the initial and final transitions of each pulse.

Default: `false`

Methods

plot	Plots signal and metrics computed in last call to `step`
reset	Reset the running pulse metrics object
step	Pulse metrics of bilevel waveforms

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Width, Period, and Duty Cycle

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

Determine the width, period, and duty cycle of a 5 V pulse sampled at 4 MHz.

```
load('pulseex.mat', 'x', 't');
```

Construct the `dsp.PulseMetrics` object. Set the `TimeInputPort` property to `true` to specify the sampling instants as an input. Set the `CycleOutputPort` property to `true` to obtain metrics for each pulse. Because the input is a 5V pulse, set the `StateLevels` property to `[0 5]`.

```
pm = dsp.PulseMetrics('TimeInputPort',true, ...
                      'CycleOutputPort', true, ...
                      'StateLevels',[0 5])
```

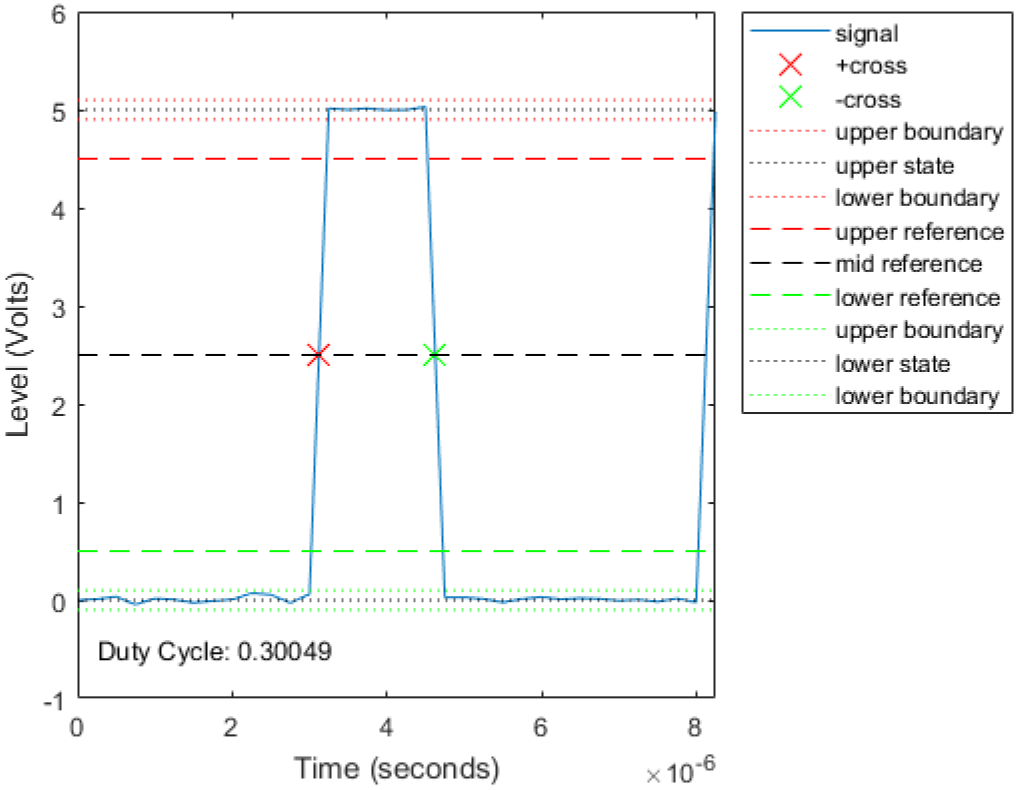
```
pm =

  dsp.PulseMetrics with properties:

                    Polarity: 'Positive'
           StateLevelsSource: 'Property'
                 StateLevels: [0 5]
   PercentStateLevelTolerance: 2
      PercentReferenceLevels: [10 50 90]
              RunningMetrics: false
               TimeInputPort: true
             CycleOutputPort: true
        TransitionOutputPort: false
          PreshootOutputPort: false
         PostshootOutputPort: false
          SettlingOutputPort: false
```

Call `step` to compute the cycle metrics and plot the result.

```
[pulse, cycle] = pm(x,t);
plot(pm)
text(t(2),-0.5,['Duty Cycle: ',num2str(cycle.DutyCycle)]);
```



Slew Rates for 2.3 V Digital Clock

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

Find the slew rates of the leading and trailing edges of a 2.3 V digital clock sampled at 4 MHz.

```
load('pulseex.mat', 'x', 't');
```

Construct the `dsp.PulseMetrics` object. Set the `TransitionOutputPort` property to `true` to report transition metrics for the initial and final transitions. Set the `StateLevelsSource` property to `'Auto'` to estimate the state levels from the data.

```
pm = dsp.PulseMetrics('SampleRate',4e6, ...
                      'TransitionOutputPort', true, ...
                      'StateLevelsSource','Auto');
```

Compute the pulse and transition metrics and plot the result.

```
[pulse, transition] = pm(x);
plot(pm);
```

dsp.StateLevels | dsp.TransitionMetrics

Introduced in R2012a

plot

System object: dsp.PulseMetrics
Package: dsp

Plots signal and metrics computed in last call to `step`

Syntax

`plot(pm)`

Description

`plot(pm)` plots the signal and metrics resulting from the last call of the step method.

By default `plot` displays

- the low and high state levels and the state-level boundaries defined by the `PercentStateLevelTolerance` property.
- the lower-, middle-, and upper-reference levels.
- the locations of the mid-reference level crossings of the positive (+) and negative (-) transitions of each detected pulse.

When the `TransitionOutputPort` property is set to `true`, the locations of the upper and lower crossings are also plotted. When the `PreshootOutputPort` or `PostShootOutputPort` properties are set to `true`, the corresponding overshoots and undershoots are plotted as inverted or noninverted triangles. When the `SettlingOutputPort` property is set to `true`, the locations where the signal enters and remains within the lower and upper state boundaries over the specified seek duration are plotted.

reset

System object: dsp.PulseMetrics
Package: dsp

Reset the running pulse metrics object

Syntax

`reset(pm)`

Description

`reset(pm)` clears information from previous calls to step.

step

System object: dsp.PulseMetrics
Package: dsp

Pulse metrics of bilevel waveforms

Syntax

```
PULSE = step(pm,X)
[PULSE,CYCLE] = step(pm,X)
[PULSE, TRANSITION] = step(pm,X)
[PULSE,PRESHOOT] = step(pm,X)
[PULSE,POSTSHOOT] = step(pm,X)
[PULSE,SETTLING] = step(pm,X)
[...] = step(pm,X,T)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`PULSE = step(pm,X)` returns a structure array, `PULSE`, whose fields contain real-valued column vectors. The number of rows of each field corresponds to the number of complete pulses found in the real-valued column vector input, `X`. Each pulse starts with a transition of the polarity specified by the `Polarity` property and ends with a transition of the opposite polarity.

`PULSE` fields:

- `PositiveCross` — Instants where the positive-going transitions cross the mid-reference level of each pulse
- `NegativeCross` — Instants where the negative-going transitions cross the mid-reference level of each pulse

- `Width` — Absolute difference between `PositiveCross` and `NegativeCross` of each pulse
- `RiseTime` — Duration between the linearly-interpolated instants when the positive-going (rising) transition of each pulse crosses the lower- and upper-reference levels
- `FallTime` — Duration between the linearly-interpolated instants when the negative-going (falling) transition of each pulse crosses the upper- and lower-reference levels

`[PULSE,CYCLE] = step(pm,X)` returns a structure array, `CYCLE`, whose fields contain real-valued column vectors when you set the `CycleOutputPort` property to `true`. The number of rows of each field corresponds to the number of complete pulse periods found in the real-valued column vector input, `X`. You need at least three consecutive alternating polarity transitions that start and end with the same polarity as the value of the `Polarity` property if you want to compute cycle metrics. If the last transition found in the input `X` does not match the polarity of the `Polarity` property, the pulse separation, period, frequency, and duty cycle are not reported for the last pulse. If the `RunningMetrics` property is set to `true` when this occurs, all pulse, cycle, transition, preshoot, postshoot, and settling metrics associated with the last pulse are deferred until a subsequent call to `step` detects the next transition.

`CYCLE` fields:

- `Period` — Duration between the first transition of the current pulse and the first transition of the next pulse
- `Frequency` — Reciprocal of the period
- `Separation` — Durations between the mid-reference level crossings of the second transition of each pulse and the first transition of the next pulse
- `Width` — Durations between the mid-reference level crossings of the first and second transitions of each pulse. This is equivalent to the width parameter of the `PULSE` structure.
- `DutyCycle` — Ratio of the width to the period for each pulse

`[PULSE, TRANSITION] = step(pm,X)` returns a structure array, `TRANSITION`, when you set the `TransitionOutputPort` property to `true`. The fields of `TRANSITION` contain real-valued matrices with two columns which correspond to the metrics of the first and second transitions. The number of rows corresponds to the number of pulses found in the input waveform.

`TRANSITION` fields:

- `Duration` — Amount of time between the interpolated instants where the transition crosses the lower- and upper-reference levels
- `SlewRate` — Ratio of absolute difference between the upper and lower reference levels to the transition duration
- `MiddleCross` — Linearly-interpolated instant in time where the transition first crosses the mid-reference level
- `LowerCross` — Linearly-interpolated instant where the signal crosses the lower-reference level
- `UpperCross` — Linearly-interpolated instant where the signal crosses the upper-reference level

`[PULSE,PRESHOOT] = step(pm,X)` returns a structure array, `PRESHOOT`, when you set the `PreshootOutputPort` property to `true`. The fields of `PRESHOOT` contain real-valued 2-column matrices whose row length corresponds to the number of transitions found in the input waveform. The field names are identical to those of the `POSTSHOOT` structure array.

`[PULSE,POSTSHOOT] = step(pm,X)` returns a structure, `POSTSHOOT`, when you set the `PostshootOutputPort` property to `true`. The fields of `POSTSHOOT` contain real-valued 2-column matrices whose row length corresponds to the number of transitions found in the input waveform.

`PRESHOOT` and `POSTSHOOT` fields:

- `Overshoot` — Overshoot of the region of interest expressed as a percentage of the waveform amplitude
- `Undershoot` — Undershoot of the region of interest expressed as a percentage of the waveform amplitude
- `OvershootLevel` — Level of the overshoot
- `UndershootLevel` — Level of the undershoot
- `OvershootInstant` — Instant that corresponds to the overshoot
- `UndershootInstant` — Instant that corresponds to the undershoot

`[PULSE,SETTLING] = step(pm,X)` returns a structure array, `SETTLING`, when you set the `SettlingOutputPort` property to `true`. The fields of `SETTLING` correspond to the settling metrics for each transition. Each field is a column vector whose elements correspond to the individual settling durations, levels, and instants.

SETTLING fields:

- Duration — Amount of time from when the signal crosses the mid-reference level to the time where the signal enters and remains within the specified PercentStateLevelTolerance of the waveform amplitude over the specified settling seek duration
- Instant — Instant in time where the signal enters and remains within the specified tolerance
- Level — Level of the waveform where it enters and remains within the specified tolerance

The above operations can be used simultaneously, provided the System object properties are set appropriately. One example of providing all possible inputs and returning all possible outputs is :

[PULSE,CYCLE,TRANSITION,PRESHOOT,POSTSHOOT,SETTLING] = step(pm,X) which returns the PULSE, CYCLE, TRANSITION, PRESHOOT, POSTSHOOT, and SETTLING structures when the CycleOutputPort, PreshootOutputPort, PostshootPort, and SettlingOutputPort properties are true. You may enable or disable any combination of output ports. However, the output arguments are defined in the order shown here.

[...] = step(pm,X,T) performs the above metrics with respect to a sampled signal, whose sample values, X, and sample instants, T, are real-valued column vectors of the same length. The additional input T applies only when you set the TimeInputPort property to true.

dsp.RCToAutocorrelation System object

Package: dsp

Convert reflection coefficients to autocorrelation coefficients

Description

The `RCToAutocorrelation` object converts reflection coefficients to autocorrelation coefficients.

To convert reflection coefficients to autocorrelation coefficients:

1. Define and set up your System object. See "Construction" on page 4-1469.
2. Call step to convert reflection coefficients according to the properties of `dsp.RCToAutocorrelation`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`rc2ac = dsp.RCToAutocorrelation` returns an `RCToAutocorrelation` System object, `rc2ac`. This object converts reflection coefficients to autocorrelation coefficients, assuming an error power of `1`.

`rc2ac = dsp.RCToAutocorrelation('`*`PropertyName`*`',`*`PropertyValue`*`,...)` returns an object, `rc2ac`, that converts reflection coefficients into autocorrelation coefficients, with each specified property set to the specified value.

Properties

PredictionErrorInputPort

Enable prediction error power input

Choose how to select the prediction error power. When you set this property to `true`, you must specify the prediction error power as a second input to the `step` method. When you set this property to `false`, the object assumes a prediction error power of `1`. The default is `false`.

Methods

step	Convert columns of reflection coefficients to autocorrelation coefficients

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Convert Reflection Coefficients to Autocorrelation Coefficients

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

```
k = [-0.8091 0.2525 -0.5044 0.4295 -0.2804 0.0711].';
rc2ac = dsp.RCToAutocorrelation;
```

```
ac = rc2ac(k);
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the `LPC/RC to Autocorrelation` block reference page. The object properties correspond to the block parameters, except:

- There is no object property that corresponds to the **Type of conversion** block parameter.
- **PredictionErrorInputPort** is a pop-up menu choice on the block. Setting the `PredictionErrorInputPort` object property to `false` corresponds to selecting `Assume P = 1` in the pop-up menu. Setting `PredictionErrorInputPort` to `true` corresponds to selecting `Via input port` from the pop-up menu.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

dsp.LPCToRC | dsp.LPCToLSF | dsp.LPCToCepstral | dsp.LPCToAutocorrelation

Introduced in R2012a

step

System object: dsp.RCToAutocorrelation
Package: dsp

Convert columns of reflection coefficients to autocorrelation coefficients

Syntax

```
AC = step(rc2ac,K)
AC = step(rc2ac,K,P)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`AC = step(rc2ac,K)` converts the columns of the reflection coefficients, `K`, to autocorrelation coefficients, `AC`.

`AC = step(rc2ac,K,P)` when you set the `PredictionErrorInputPort` property to `true`, converts the columns of the reflection coefficients, `K` , to autocorrelation coefficients, `AC`, using `P` as the prediction error power. `P` must be a row vector with same number of columns as in `K`.

Note: `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.RCToLPC System object

Package: dsp

Convert reflection coefficients to linear prediction coefficients

Description

The `RCToLPC` object converts reflection coefficients to linear prediction coefficients.

To convert reflection coefficients to LPC:

1. Define and set up your RC to LPC System object. See “Construction” on page 4-1473.
2. Call step to convert RC to LPC according to the properties of `dsp.RCToLPC`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`rc2lpc = dsp.RCToLPC` returns an RC to LPC System object, `rc2lpc`, that converts reflection coefficients (RC) to linear prediction coefficients (LPC).

`rc2lpc = dsp.RCToLPC('`*`PropertyName`*`',`*`PropertyValue`*`,...)` returns an RC to LPC conversion object, `rc2lpc`, with each specified property set to the specified value.

Properties

`PredictionErrorOutputPort`

Enable normalized prediction error power output

Set this property to `true` to return the normalized error power as a vector with one element per input channel. Each element varies between `0` and `1`. The default is `true`.

`ExceptionOutputPort`

Produce output with stability status of filter represented by LPC coefficients

Set this property to `true` to return the stability of the filter. The output is a vector of a length equal to the number of channels. A logical value of `1` indicates a stable filter. A logical value of `0` indicates an unstable filter. The default is `false`.

Methods

step	Convert columns of reflection coefficients to linear prediction coefficients

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Convert RC to LPC Coefficients

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

Convert reflection coefficients to linear prediction coefficients.

```
levinson = dsp.LevinsonSolver;
ac = dsp.Autocorrelator;
ac.MaximumLagSource = 'Property';
```

```
ac.MaximumLag = 10; % Compute autocorrelation
% lags between [0:10]
rc2lpc = dsp.RCToLPC;
x = (1:100)';
a = ac(x);
k = levinson(a); % Compute reflection coefficients
[A, P] = rc2lpc(k);
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the `LPC to/from RC` block reference page. The object properties correspond to the block parameters, except:
There is no object property that corresponds to the **Type of conversion** block parameter. The object always converts LPC to RC.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

step

System object: dsp.RCToLPC
Package: dsp

Convert columns of reflection coefficients to linear prediction coefficients

Syntax

```
[A,P] = step(rc2lpc,K)
A = step(rc2lpc,K)
[..., S] = step(rc2lpc,K)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`[A,P] = step(rc2lpc,K)` converts the columns of the reflection coefficients, `K`, to linear prediction coefficients, `A`, and outputs the normalized prediction error power, `P`.

`A = step(rc2lpc,K)` when the `PredictionErrorOutputPort` property is `false`, converts the columns of the reflection coefficients, `K`, to linear prediction coefficients, `A`.

`[..., S] = step(rc2lpc,K)` also outputs the `LPC` filter stability, `S`, when the `ExceptionOutputPort` property is `true`.

Note: `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change

nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.RLSFilter System object

Package: dsp

Compute output, error and coefficients using Recursive Least Squares (RLS) algorithm

Description

The `RLSFilter` object filters each channel of the input using RLS filter implementations.

To filter each channel of the input:

1. Define and set up your RLS filter. See “Construction” on page 4-1478.
2. Call step to filter each channel of the input according to the properties of `dsp.RLSFilter`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`rlsFilt = dsp.RLSFilter` returns an adaptive RLS filter System object, `rlsFilt`. This System object computes the filtered output, filter error and the filter weights for a given input and desired signal using the RLS algorithm.

`rlsFilt = dsp.RLSFilter('`*`PropertyName`*`',`*`PropertyValue`*`, ...)` returns an RLS filter System object, `rlsFilt`, with each specified property set to the specified value.

`rlsFilt = dsp.RLSFilter(LEN, '`*`PropertyName`*`', `*`PropertyValue`*`, ...)` returns an RLS filter System object, `rlsFilt`. This System object has the Length property set to `LEN`, and other specified properties set to the specified values.

Properties

`Method`

Method to calculate the filter coefficients

You can specify the method used to calculate filter coefficients as one of | `Conventional RLS` [1] [2] | `Householder RLS` [3] [4] | `Sliding-window RLS` [5][1][2] | `Householder sliding-window RLS` [4] | `QR decomposition` [1] [2]. The default value is `Conventional RLS`. This property is nontunable.

`Length`

Length of filter coefficients vector

Specify the length of the RLS filter coefficients vector as a scalar positive integer value. The default value is `32`. This property is nontunable.

`SlidingWindowBlockLength`

Width of the sliding window

Specify the width of the sliding window as a scalar positive integer value greater than or equal to the Length property value. This property is applicable only when the Method property is set to `Sliding-window RLS` or `Householder sliding-window RLS`. The default value is `48`. This property is nontunable.

`ForgettingFactor`

RLS forgetting factor

Specify the RLS forgetting factor as a scalar positive numeric value less than or equal to 1. Setting this property value to 1 denotes infinite memory, while adapting to find the new filter. The default value is `1`. This property is tunable.

`InitialCoefficients`

Initial coefficients of the filter

Specify the initial values of the FIR adaptive filter coefficients as a scalar or a vector of length equal to the `Length` property value. The default value is `0`. This property is tunable.

InitialInverseCovariance

Initial inverse covariance

Specify the initial values of the inverse covariance matrix of the input signal. This property must be either a scalar or a square matrix, with each dimension equal to the `Length` property value. If you set a scalar value, the `InverseCovariance` property is initialized to a diagonal matrix with diagonal elements equal to that scalar value. This property applies only when the `Method` property is set to `Conventional RLS` or `Sliding-window RLS`. The default value is `1000`. This property is tunable.

InitialSquareRootInverseCovariance

Initial square root inverse covariance

Specify the initial values of the square root inverse covariance matrix of the input signal. This property must be either a scalar or a square matrix with each dimension equal to the `Length` property value. If you set a scalar value, the `SquareRootInverseCovariance` property is initialized to a diagonal matrix with diagonal elements equal to that scalar value. This property applies only when the `Method` property is set to `Householder RLS` or `Householder sliding-window RLS`. The default value is `sqrt(1000)`. This property is tunable.

InitialSquareRootCovariance

Initial square root covariance

Specify the initial values of the square root covariance matrix of the input signal. This property must be either a scalar or a square matrix with each dimension equal to the `Length` property value. If you set a scalar value, the `SquareRootCovariance` property is initialized to a diagonal matrix with diagonal elements equal to the scalar value. This property applies only when the `Method` property is set to `QR-decomposition RLS`. The default value is `sqrt(1/1000)`. This property is tunable.

LockCoefficients

Lock coefficient updates

Specify whether the filter coefficient values should be locked. When you set this property to `true`, the filter coefficients are not updated and their values remain the same. The default value is `false` (filter coefficients continuously updated). This property is tunable.

Methods

msesim	Mean-square error for RLS filter
reset	Reset the internal states of a System object
step	Process inputs using RLS filter

Common to All System Objects	
clone	Create System object with same property values
getNumInpu	Expected number of inputs to a System object
getNumOutp	Expected number of outputs of a System object
isLocked	Check locked states of a System object (logical)
release	Allow System object property value changes

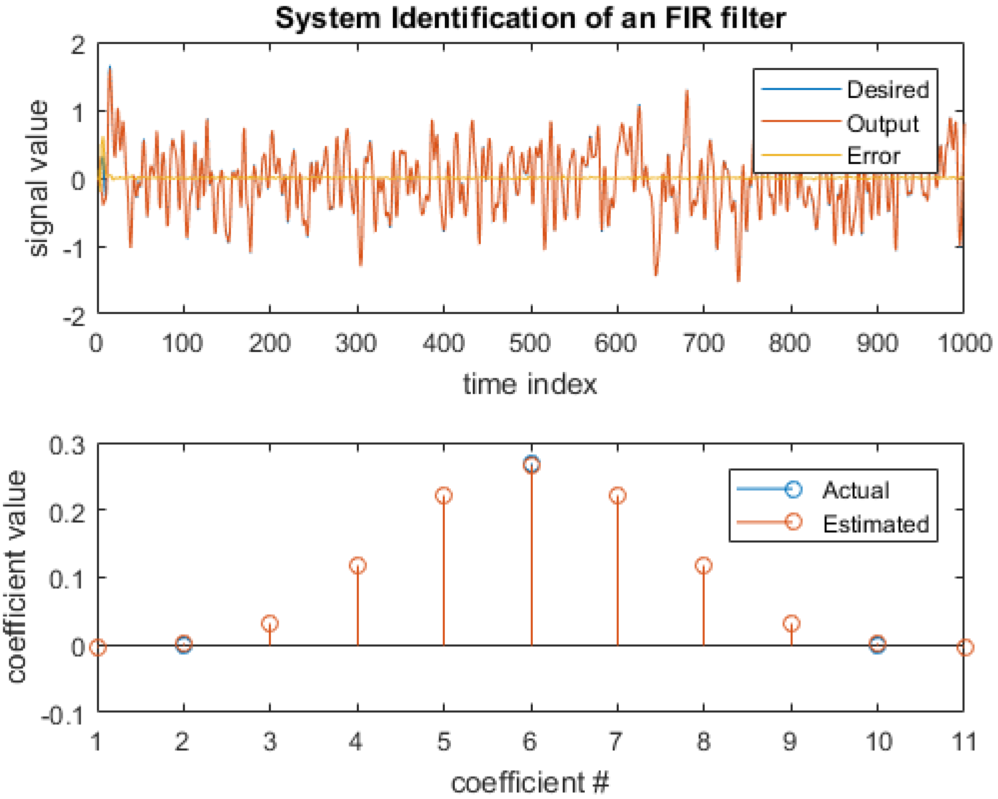
Examples

System Identification of an FIR Filter

Use the RLS filter System object™ to determine the signal value.

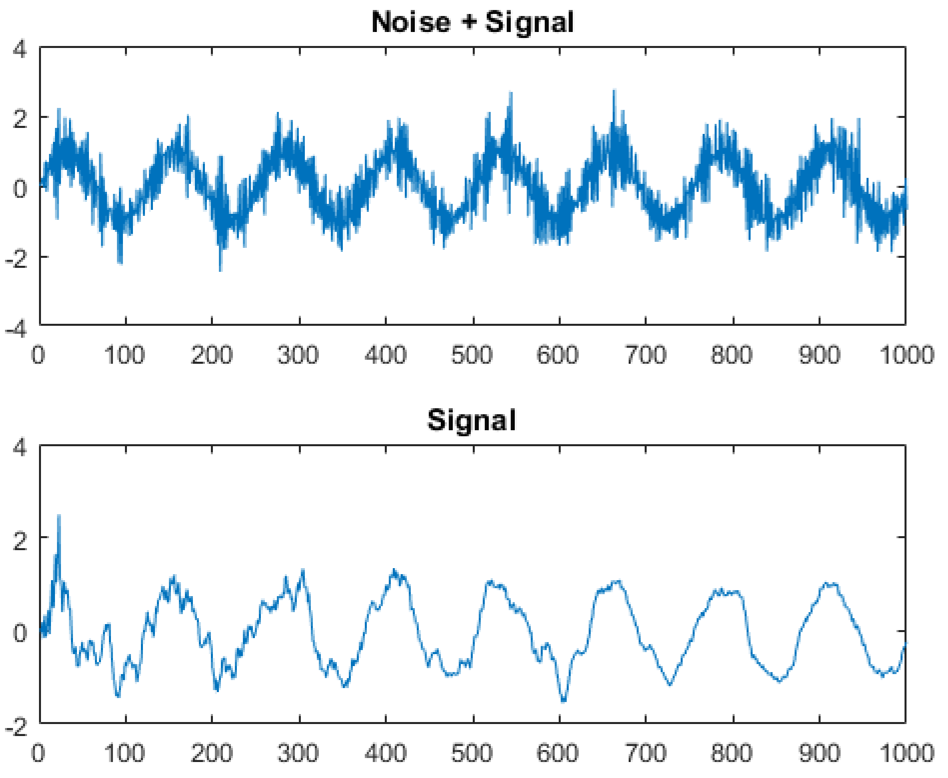
Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

```
rls1 = dsp.RLSFilter(11, 'ForgettingFactor', 0.98);
filt = dsp.FIRFilter('Numerator',fir1(10, .25)); % Unknown System
x = randn(1000,1);                               % input signal
d = filt(x) + 0.01*randn(1000,1); % desired signal
[y,e] = rls1(x, d);
w = rls1.Coefficients;
subplot(2,1,1), plot(1:1000, [d,y,e]);
title('System Identification of an FIR filter');
legend('Desired', 'Output', 'Error');
xlabel('time index'); ylabel('signal value');
subplot(2,1,2); stem([filt.Numerator; w].');
legend('Actual','Estimated');
xlabel('coefficient #'); ylabel('coefficient value');
```



Noise Cancellation

```
rls2 = dsp.RLSFilter('Length', 11, 'Method', 'Householder RLS');
filt2 = dsp.FIRFilter('Numerator',fir1(10, [.5, .75]));
x = randn(1000,1);                              % Noise
d = filt2(x) + sin(0:.05:49.95)';      % Noise + Signal
[y, err] = rls2(x, d);
subplot(2,1,1), plot(d), title('Noise + Signal');
subplot(2,1,2), plot(err), title('Signal');
```



Algorithms

The `dsp.RLSFilter` System object, when `Conventional RLS` is selected, recursively computes the least squares estimate (RLS) of the FIR filter weights. The System object estimates the filter weights or coefficients, needed to convert the input signal into the desired signal. The input signal can be a scalar or a column vector. The desired signal must have the same data type, complexity, and dimensions as the input signal. The corresponding RLS filter is expressed in matrix form as $\mathbf{P}(n)$:

$$\mathbf{k}(n) = \frac{\lambda^{-1}\mathbf{P}(n-1)\mathbf{u}(n)}{1+\lambda^{-1}\mathbf{u}^{H}(n)\mathbf{P}(n-1)\mathbf{u}(n)}$$

$$y(n) = \mathbf{w}^{T}(n-1)\mathbf{u}(n)$$

$$e(n) = d(n) - y(n)$$

$$\mathbf{w}(n) = \mathbf{w}(n-1) + \mathbf{k}(n)e(n)$$

$$\mathbf{P}(n) = \lambda^{-1}\mathbf{P}(n-1) - \lambda^{-1}\mathbf{k}(n)\mathbf{u}^{H}(n)\mathbf{P}(n-1)$$

where λ^{-1} denotes the reciprocal of the exponential weighting factor. The variables are as follows:

Variable	Description
n	The current time index
$\mathbf{u}(n)$	The vector of buffered input samples at step n
$\mathbf{P}(n)$	The inverse correlation matrix at step n
$\mathbf{k}(n)$	The gain vector at step n
$\mathbf{w}(n)$	The vector of filter tap estimates at step n
$y(\mathrm{n})$	The filtered output at step n
$e(n)$	The estimation error at step n
$d(n)$	The desired response at step n
λ	The forgetting factor

u, **w**, and **k** are all column vectors.

dsp.FIRFilter | dsp.AffineProjectionFilter | dsp.LMSFilter | “Adaptive Noise Cancellation Using RLS Adaptive Filtering”

Introduced in R2013a

msesim

System object: dsp.RLSFilter
Package: dsp

Mean-square error for RLS filter

Syntax

```
MSE = msesim(sysObj,X,D)
[MSE,MEANW,W,TRACEK] = msesim(sysObj,X,D)
[...] = msesim(sysObj,X,D,M)
```

Description

`MSE = msesim(sysObj,X,D)` returns a sequence of mean-square errors. This column vector contains estimates of the mean-square error of the adaptive filter at each time instant. The length of `MSE` is equal to `SIZE(X,1)`. The columns of the matrix `X` contain individual input signal sequences, and the columns of the matrix `D` contain corresponding desired response signal sequences.

`[MSE,MEANW,W,TRACEK] = msesim(sysObj,X,D)` calculates three parameters corresponding to the simulated behavior of the adaptive filter defined by `sysObj`. `MEANW` is a sequence of coefficient vector means. The columns of this matrix contain estimates of the mean values of the adaptive filter coefficients at each time instant. The dimensions of `MEANW` are `(SIZE(X,1))` by `(sysObj.length)`. `W` is an estimate of the final values of the adaptive filter coefficients for the algorithm corresponding to `sysObj`. `TRACEK` is a sequence of total coefficient error powers. This column vector contains estimates of the total coefficient error power of the adaptive filter at each time instant. The length of `TRACEK` is equal to `SIZE(X,1)`.

`[...] = msesim(sysObj,X,D,M)` specifies an optional decimation factor for computing `MSE`, `MEANW`, and `TRACEK`. If `M` > `1`, every M^{th} predicted value of each of these sequences is saved. If omitted, the value of `M` is the default, which is 1.

reset

System object: dsp.RLSFilter
Package: dsp

Reset the internal states of a System object

Syntax

`reset(rlsFilt)`

Description

`reset(rlsFilt)` resets the internal states of the System object, `rlsFilt`, to their initial values.

For many System objects, this method is nonoperational. Objects that have internal states describe in their **help** what the reset method does for that object. The `reset` method is always nonoperational for unlocked System objects, as states may not be allocated when the object is not locked.

step

System object: dsp.RLSFilter
Package: dsp

Process inputs using RLS filter

Syntax

```
y = step(rlsFilt,x,d)
[y,e] = step(rlsFilt,x,d)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`y = step(rlsFilt,x,d)` recursively adapts the reference input, `x`, to match the desired signal, `d`, using the System object, `rlsFilt`. The desired signal,`d` is the signal desired plus some undesired noise. `[y,e] = step(rlsFilt,x,d)` shows the output of the RLS filter along with the error, `e`, between the reference input and the desired signal. The filters adapts its coefficients until the error, `e` is minimized. You can access these coefficients by accessing the 'Coefficients' property of the object. You must access this property after calling the `step` method on the object. For example, you can access the optimized coefficients of `rlsFilt` filter object through `rlsFilt.Coefficients`, after calling the `step` method on this object.

dsp.RMS System object

Package: dsp

Root mean square of vector elements

Description

The RMS object computes the root mean square (RMS) value.

To compute the RMS value of your input:

1. Define and set up your RMS calculation. See “Construction” on page 4-1489.
2. Call step to compute the RMS value for an input according to the properties of `dsp.RMS`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Note: The `Running` mode in the `dsp.RMS` System object will be removed in a future release. To compute the running RMS in MATLAB, use the dsp.MovingRMS System object instead.

Construction

`rms = dsp.RMS` returns a System object, `rms`, that computes the root mean square (RMS) of an input or a sequence of inputs over the specified `Dimension`.

`rms = dsp.RMS('PropertyName',PropertyValue,...)` returns an RMS System object, `rms`, with each specified property set to the specified value.

Properties

`RunningRMS`

Enable calculating RMS over time

Set this property to `true` to enable calculating the RMS over successive calls to the `step` method.

Default: `false`

`ResetInputPort`

Enable resetting in running RMS mode

Set this property to `true` to enable resetting the running RMS. When the property is set to `true`, you must specify a reset input to the `step` method to reset the running RMS. This property applies when you set the `RunningRMS` on page 4- property to `true`.

Default: `false`

`ResetCondition`

Reset condition for running RMS mode

Specify the event to reset the running RMS as one of `Rising edge`, `Falling edge`, `Either edge`, or `Non-zero`. `Non-zero` resets the running RMS each time a nonzero sample is acquired. See "Rising and Falling Edges" on page 4-1493 for definitions of rising and falling edges. This property applies when you set the `ResetInputPort` on page 4- property to `true`.

Default: `Non-zero`

`Dimension`

Dimension to compute RMS value along

Specify the dimension along which to calculate the RMS as one of `All`, `Row`, `Column`, or `Custom`. This property applies only when you set the `RunningRMS` on page 4- property to `false`. Specifying the `Dimension` property as `All` computes the RMS value over the entire input.

Default: `Column`

`CustomDimension`

Numerical dimension to operate along

Specify the dimension (one-based scalar integer value) of the input signal, along which the RMS is computed. The cannot exceed the number of dimensions in the input signal. This property applies when you set the `Dimension` on page 4- property to `Custom`.

Default: `1`

Methods

reset	Reset the running root mean square object
step	Root mean square of input

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

RMS Value of Vector Input

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

Compute the RMS value of a vector consisting of the integers 1 to 10.

```
x = 1:10;
```

```
rms = dsp.RMS('Dimension','row');
rmsval = rms(x)

rmsval =

    6.2048
```

RMS Value of Matrix Input

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

Compute the RMS value of a matrix with the `Dimension` property set to `'All'`.

```
in2 = magic(4);
rms2d = dsp.RMS;
rms2d.Dimension = 'All';
y_rms2 = rms2d(in2)

y_rms2 =

    9.6695
```

The output is equivalent to reshaping the 4-by-4 matrix into a 16-by-1, or 1-by-16 vector and computing the RMS value for the vector.

Definitions

Root-Mean-Square Level

The root-mean-square level of a vector, X, is

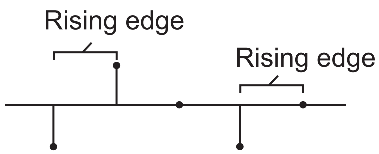
$$X_{\mathrm{RMS}} = \sqrt{\frac{1}{N}\sum_{n=1}^{N}|X_n|^2},$$

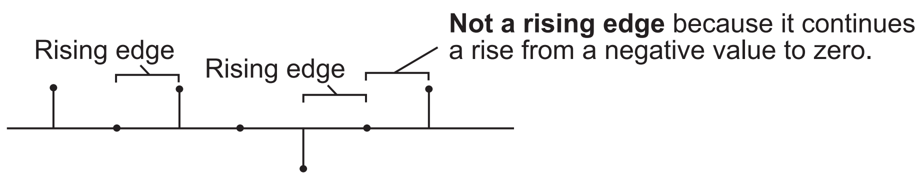
with the summation performed along the specified dimension.

Rising and Falling Edges

A rising edge:

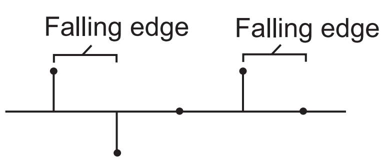
- Rises from a negative value to a positive value or zero.
- Rises from zero to a positive value, where the rise is not a continuation of a rise from a negative value to zero.

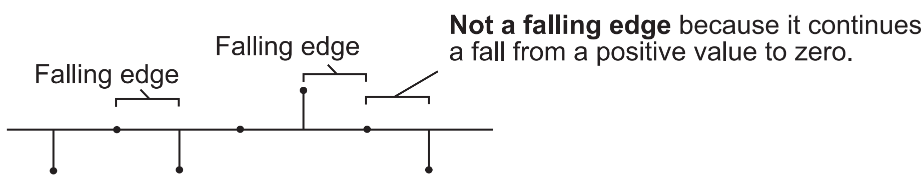




A falling edge:

- Falls from a positive value to a negative value or zero.
- Falls from zero to a negative value, where the fall is not a continuation of a fall from a positive value to zero.





Algorithms

This object implements the algorithm, inputs, and outputs described on the RMS block reference page. The object properties correspond to the Simulink block parameters, except:

- **Treat sample-based row input as a column** block parameter is not supported by the dsp.RMS object.
- **Reset Port** block parameter corresponds to both the ResetCondition and the ResetInputPort object properties.

reset

System object: dsp.RMS
Package: dsp

Reset the running root mean square object

Syntax

```
reset(rms)
```

Description

`reset(rms)` resets the running root mean square (RMS) for the object `rms`.

step

System object: dsp.RMS
Package: dsp

Root mean square of input

Syntax

```
Y = step(rms,X)
Y = step(rms,X,R)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(rms,X)` computes the root mean square (RMS) output, `Y` , of input vector `X`. When the `RunningRMS` property is true, `Y` corresponds to the `RMS` of the input elements over successive calls to the `step` method.

`Y = step(rms,X,R)` resets the running RMS state based on the value of `R`, the reset signal, and the `ResetCondition` property. This computation is possible when you set both the `RunningRMS` and the `ResetInputPort` properties to `true`.

Note: `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

dsp.SampleRateConverter System object

Package: dsp

Multistage sample rate converter

Description

The `SampleRateConverter` System object converts the sample rate of an incoming signal.

To convert the sample rate of a signal:

1. Define and set up your sample rate converter. See “Construction” on page 4-1497.
2. Call step to convert the sample rate according to the properties of `dsp.SampleRateConverter`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`src = dsp.SampleRateConverter` creates a multistage FIR sample rate converter System object, `src`, that converts the sample rate of each channel of an input signal.

`src = dsp.SampleRateConverter(Name,Value)` returns a multistage FIR sample rate converter System object, `src`, with properties and options specified by one or more `Name,Value` pair arguments.

Properties

`Bandwidth` — Two-sided bandwidth of interest

40 kHz (default) | positive scalar

Specify the two-sided bandwidth of interest (after rate conversion) as a positive scalar expressed in hertz. This property is the two-sided bandwidth of the information-carrying portion of the signal that you wish to retain. The default is 40 kHz.

`InputSampleRate` — Sample rate of input signal

192 kHz (default) | positive scalar

Specify the sample rate of the input signal as a positive scalar expressed in hertz. The input sample rate must be greater than the bandwidth of interest. The default is 192 kHz.

`OutputRateTolerance` — Maximum allowed tolerance for output sample rate

0 (default) | positive scalar

Specify the maximum allowed tolerance for the sample rate of the output signal as a positive scalar between 0 and 1. The default is 0.

The output rate tolerance allows for a simpler design in many cases. The actual output sample rate varies but is within the specified range. For example, if `OutputRateTolerance` is specified as 0.01, then the actual output sample rate is in the range given by `OutputSampleRate` ± 1%.

`OutputSampleRate` — Sample rate of output signal

44.1 kHz (default) | positive scalar

Specify the sample rate of the output signal as a positive scalar expressed in hertz. The output sample rate must be greater than the bandwidth of interest. The default is 44.1 kHz.

`StopbandAttenuation` — Minimum dB attenuation for aliased components

80 dB (default) | positive scalar

Specify the stopband attenuation as a positive scalar expressed in decibels. This property is the minimum amount by which any aliasing involved in the process is attenuated. The default is 80 dB.

Methods

cost	Compute implementation cost

freqz	Frequency response
getFilters	Obtain single-stage filters
getActualOutputRate	Get actual output rate
getRateChangeFactors	Overall interpolation and decimation factors
info	Display information about sample rate converter
reset	Reset internal states of multistage sample rate converter
step	Convert sample rate of signal
visualizeFilterStages	Visualize filter stages

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Convert Sample Rate of Audio Signal

Convert the sample rate of an audio signal from 44.1 kHz (CD quality) to 96 kHz (DVD quality).

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

```
fs1 = 44.1e3;
fs2 = 96e3;

SRC = dsp.SampleRateConverter('Bandwidth',40e3,...
    'InputSampleRate',fs1,'OutputSampleRate',fs2);
```

```
[L,M] = getRateChangeFactors(SRC);
FrameSize = 10*M;

AR = dsp.AudioFileReader('guitar10min.ogg', ...
    'SamplesPerFrame',FrameSize);
AW = dsp.AudioFileWriter('guitar10min_96k.wav', ...
    'SampleRate',fs2);
```

Run the system for 15 s. Release all objects.

```
tic
while toc < 15
    x = AR();
    y = SRC(x);
    AW(y);
end

release(AR);
release(AW);
release(SRC);
```

Plot the input and output signals. Use a different set of axes for each signal. Shift the output to compensate for the delay introduced by the filter.

```
t1 = 0:1/fs1:1/30-1/fs1;
t2 = 0:1/fs2:1/30-1/fs2;

delay = 114;

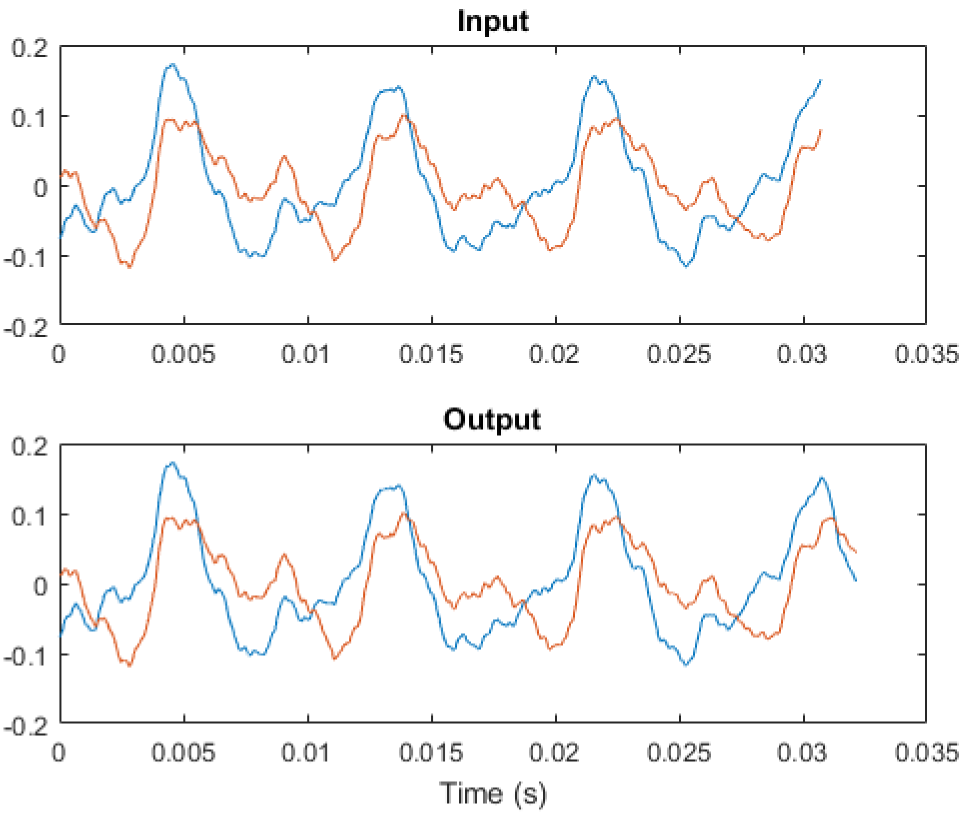
el1 = 1:length(t1)-delay;

el2 = 1:length(t2);
el2(1:delay) = [];

subplot(2,1,1)
plot(t1(1:length(el1)),x(el1,1))
hold on
plot(t1(1:length(el1)),x(el1,2))
title('Input')

subplot(2,1,2)
plot(t2(1:length(el2)),y(el2,1))
hold on
plot(t2(1:length(el2)),y(el2,2))
```

```
xlabel('Time (s)')
title('Output')
```

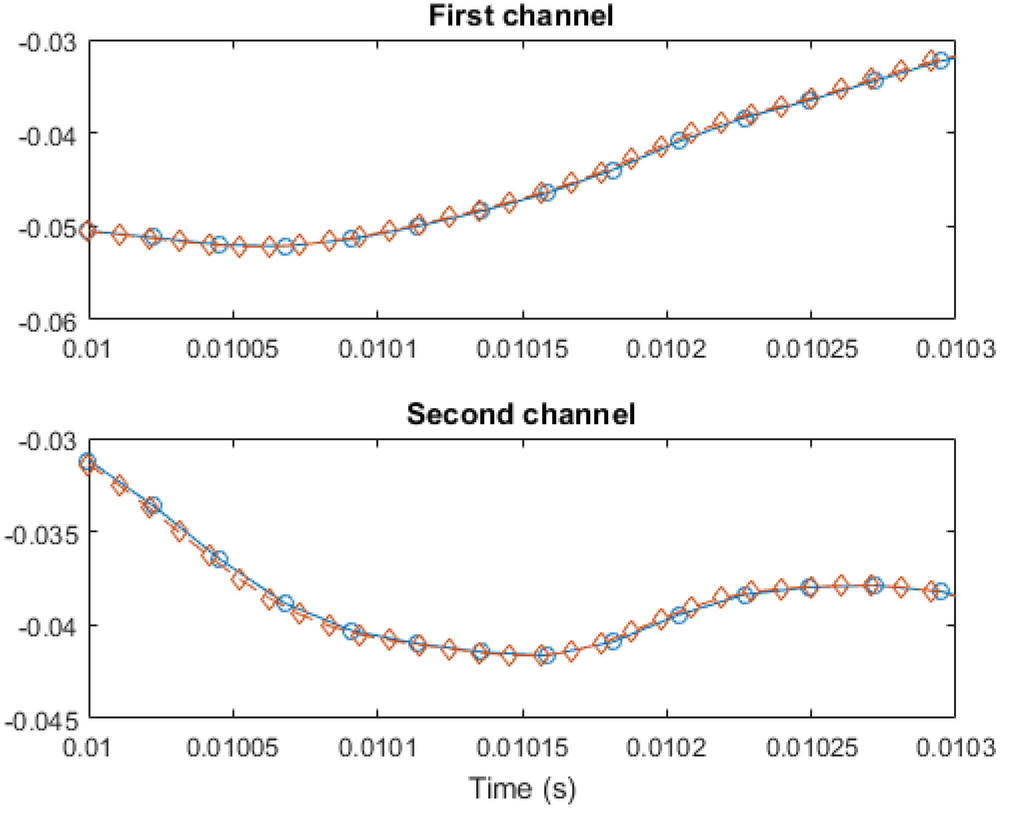


Zoom in to see the difference in sample rates. Use a different set of axes for each channel.

```
figure

subplot(2,1,1)
plot(t1(1:length(el1)),x(el1,1),'o-')
hold on
plot(t2(1:length(el2)),y(el2,1),'d--')
xlim([0.01 0.0103])
title('First channel')
```

```
subplot(2,1,2)
plot(t1(1:length(el1)),x(el1,2),'o-')
hold on
plot(t2(1:length(el2)),y(el2,2),'d--')
xlim([0.01 0.0103])
xlabel('Time (s)')
title('Second channel')
```



Tolerance Cost in Sample Rate Conversion

A signal output from an A/D converter is sampled at 98.304 MHz. The signal has a bandwidth of 20 MHz. Reduce the sample rate of the signal to 22 MHz, which is the bandwidth of 802.11 channels. Make the conversion exactly and then redo it with an output rate tolerance of 1%.

```
SRC1 = dsp.SampleRateConverter('Bandwidth',20e6, ...
    'InputSampleRate',98.304e6,'OutputSampleRate',22e6, ...
    'OutputRateTolerance',0);
SRC2 = dsp.SampleRateConverter('Bandwidth',20e6, ...
    'InputSampleRate',98.304e6,'OutputSampleRate',22e6, ...
    'OutputRateTolerance',0.01);
```

Use the `cost` method to determine the cost of each sample rate conversion. The zero-tolerance process requires more than 500 times as many coefficients as the 1% process.

```
c1 = cost(SRC1)
c2 = cost(SRC2)
```

```
c1 = 

  struct with fields:

                  NumCoefficients: 84779
                        NumStates: 133
    MultiplicationsPerInputSample: 27.0422
          AdditionsPerInputSample: 26.0684

c2 = 

  struct with fields:

                  NumCoefficients: 150

     9
```

Compute the actual sample rate of the output signal when the sample rate conversion has a tolerance of 1%.

```
getActualOutputRate(SRC2)
```

```
ans =

   2.1845e+07
```

Algorithms

- The general multistage sample rate converter performs a multistage decimation, a single-stage sample rate conversion, and a multistage interpolation, in that order. Actual designs include at most two of those steps.
- The procedure determines automatically the optimal number of decimation or interpolation stages. In special cases, the decimation or the interpolation can be performed in a single stage.
- The algorithm always attempts to start by reducing the sample rate. This decreases the amount of computation required. The decimation step is designed so that no intermediate sample rate goes below the bandwidth of interest. This ensures that no information is filtered out.
- Each individual stage uses halfband or Nyquist filters to minimize the number of nonzero coefficients.

- Transition-band aliasing is allowed because it decreases the implementation cost. The signal within the bandwidth of interest is kept alias free up to the value specified by the `StopbandAttenuation` property.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

Introduced in R2014b

cost

System object: dsp.SampleRateConverter
Package: dsp

Compute implementation cost

Syntax

```
c = cost(src)
```

Description

`c = cost(src)` returns a structure, `c`, whose fields contain information about the computational cost of implementing a multistage sample rate converter, `src`.

Input Arguments

`src` — Multistage sample rate converter

`SampleRateConverter` System object

Multistage sample rate converter, specified as a `SampleRateConverter` System object.

Output Arguments

`c` — Output structure

structure

Output structure with information about the computational cost of `src`:

- The number of coefficients,
- The number of states,
- The number of multiplications per unit sample, and
- The number of additions per unit sample.

Examples

Computational Cost of a Sample Rate Converter

Create `src`, a multistage sample rate converter with default values. `src` combines three filter stages to convert from 192 kHz to 44.1 kHz. Determine its computational cost: the number of coefficients, the number of states, the number of multiplications per unit sample, and the number of additions per unit sample.

```
src = dsp.SampleRateConverter;
cst = cost(src)
```

```
cst = 

  struct with fields:

                 NumCoefficients: 8631
                       NumStates: 138
    MultiplicationsPerInputSample: 27.6672
          AdditionsPerInputSample: 26.6875
```

Repeat the computation allowing a tolerance of 10% in the output sample rate.

```
src.OutputRateTolerance = 0.1;
ctl = cost(src)
```

```
ctl = 

  struct with fields:

                 NumCoefficients: 44
                       NumStates: 80
    MultiplicationsPerInputSample: 14.2500
          AdditionsPerInputSample: 13.5000
```

freqz

System object: dsp.SampleRateConverter
Package: dsp

Frequency response

Syntax

```
[h,f] = freqz(src,n,range)
[h,f] = freqz(src,f)
```

Description

`[h,f] = freqz(src,n,range)` returns the complex frequency response, `h`, of the multistage sample rate converter, `src`, evaluated at the `n` frequencies returned in `f`. `range` is the frequency range over which the response is computed. The sample rate is taken to be the largest of `InputSampleRate` and `OutputSampleRate`.

`[h,f] = freqz(src,f)` returns the complex frequency response evaluated at the frequency points specified in the vector `f`. `f` is assumed to be expressed in hertz.

Input Arguments

`src` — Multistage sample rate converter

`SampleRateConverter` System object

Multistage sample rate converter, specified as a `SampleRateConverter` System object.

`n` — Number of evaluation points

512 (default) | positive integer

Number of frequencies for response evaluation, specified as a positive integer scalar. If `n` is not specified, it defaults to 512.

`range` — Range of frequencies

`'half'` (default) | `'whole'`

Range considered when computing the frequency response, specified as either `'half'` (from 0 to π) or `'whole'` (from 0 to 2π). If `range` is not specified, it defaults to `'half'`.

Output Arguments

`h` — Complex frequency response

vector

Complex frequency response, returned as a vector.

`f` — Frequencies

vector

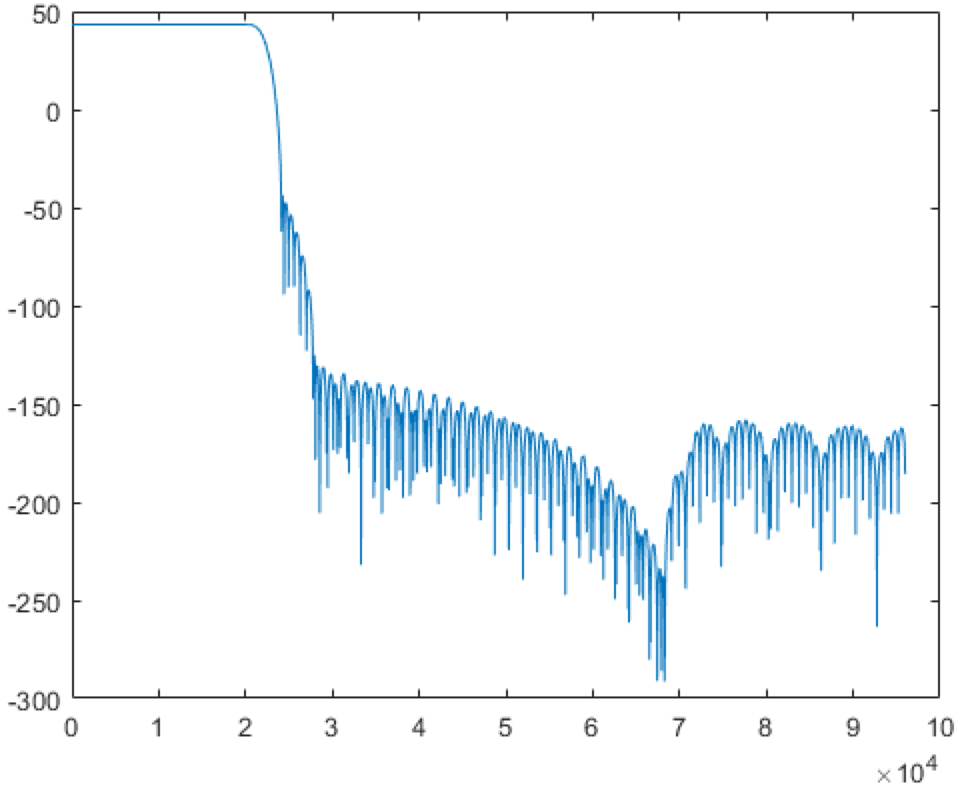
Frequencies at which the response is evaluated, returned as a vector.

Examples

Frequency Response of Default Converter

Create a multistage sample rate converter with default properties, corresponding to the combined three filter stages used to convert from 192 kHz to 44.1 kHz. Compute and display the frequency response.

```
src = dsp.SampleRateConverter;
[H,f] = freqz(src);
plot(f,20*log10(abs(H)))
```



Compute and display the frequency response over the range between 20 Hz and 44.1 kHz.

```
f = 20:10:44.1e3;
[H,f] = freqz(src,f);
plot(f,20*log10(abs(H)))

getFilters

System object: dsp.SampleRateConverter
Package: dsp

Obtain single-stage filters

Syntax

```
c = getFilters(src)
```

Description

`c = getFilters(src)` returns the multirate filters cascaded together in `src` to perform the overall sample rate conversion. The result is a `FilterCascade` structure, `c`. Each field of `c` holds the filter used at a particular stage and gives access to its coefficients and rate-change factors.

Input Arguments

`src` — Multistage sample rate converter

`SampleRateConverter` System object

Multistage sample rate converter, specified as a `SampleRateConverter` System object.

Output Arguments

`c` — Single-stage filters

`FilterCascade` structure

Single-stage filters, returned as a `FilterCascade` structure.

Examples

Single-Stage Filters

Create `src`, a multistage sample rate converter with default properties. `src` converts between 192 kHz and 44.1 kHz. Find the individual filters that are cascaded together to perform the conversion.

```
src = dsp.SampleRateConverter;
c = getFilters(src);
```

Visualize the frequency response of the decimator used in the first stage of the process.

```
m = c.Stage1;

[h,w] = freqz(m);
plot(w/pi,20*log10(abs(h)))

getActualOutputRate

System object: dsp.SampleRateConverter
Package: dsp

Get actual output rate

Syntax

```
fsout = getActualOutputRate(src)
```

Description

`fsout = getActualOutputRate(src)` returns the actual output sample rate yielded by a `SampleRateConverter` System object. The computation takes into account the `OutputRateTolerance` parameter.

Input Arguments

`src` — Multistage sample rate converter

`SampleRateConverter` System object

Multistage sample rate converter, specified as a `SampleRateConverter` System object.

Output Arguments

`fsout` — Actual output sample rate

scalar

Actual output sample rate, returned as a scalar expressed in hertz.

Examples

Output Sample Rate with Given Tolerance

Get the actual output sample rate for conversion between 192 kHz and 44.1 kHz when given a tolerance of 1%.

```
src = dsp.SampleRateConverter;
src.OutputRateTolerance = 0.01;
FsOut = getActualOutputRate(src)
```

```
FsOut =

   4.4308e+04
```

getRateChangeFactors

System object: dsp.SampleRateConverter
Package: dsp

Overall interpolation and decimation factors

Syntax

`[L,M] = getRateChangeFactors(src)`

Description

`[L,M] = getRateChangeFactors(src)` returns the overall interpolation factor, `L`, and the overall decimation factor, `M`, corresponding to the multistage sample rate converter, `src`. The overall decimation factor affects the allowable frame size of the input signal, which must be an integer multiple of `M`.

Input Arguments

`src` — Multistage sample rate converter

`SampleRateConverter` System object

Multistage sample rate converter, specified as a `SampleRateConverter` System object.

Output Arguments

`L` — Overall interpolation factor

scalar

Overall interpolation factor, returned as a scalar.

`M` — Overall decimation factor

scalar

Overall decimation factor, returned as a scalar.

Examples

Default Resampling Factors

Create `src`, a multistage sample rate converter with default properties. `src` combines three filter stages to convert from 192 kHz to 44.1 kHz. Determine its overall interpolation and decimation factors.

```
src = dsp.SampleRateConverter;
[L,M] = getRateChangeFactors(src)
```

```
L =

   147

M =

info

System object: dsp.SampleRateConverter
Package: dsp

Display information about sample rate converter

Syntax

`info(src)`

Description

`info(src)` displays information about the multistage `SampleRateConverter` System object, `src`.

Input Arguments

`src` — Multistage sample rate converter

`SampleRateConverter` System object

Multistage sample rate converter, specified as a `SampleRateConverter` System object.

Examples

Default Multistage Sample Rate Converter

Create a multistage sample rate converter with default properties, corresponding to the combined three filter stages used to convert from 192 kHz to 44.1 kHz. Display information about the design.

```
src = dsp.SampleRateConverter
info(src)
```

```
src =
```

```
  dsp.SampleRateConverter with properties:

     '
```

reset

System object: dsp.SampleRateConverter
Package: dsp

Reset internal states of multistage sample rate converter

Syntax

`reset(src)`

Description

`reset(src)` resets the internal states of a multistage `SampleRateConverter` System object, `src`, to their initial values.

Input Arguments

`src` — Multistage sample rate converter
`SampleRateConverter` System object

Multistage sample rate converter, specified as a `SampleRateConverter` System object.

Examples

Reset a Sample Rate Converter

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

Create a multistage sample rate converter with default properties, corresponding to the combined three filter stages used to convert from 192 kHz to 44.1 kHz. Determine its overall decimation and interpolation factors.

```
src = dsp.SampleRateConverter;
```

```
[L,M] = getRateChangeFactors(src);
```

Create a two-channel random signal. Specify a number of samples equal to the decimation factor. Apply the `step` method twice on the signal.

```
x = randn(M,2);

y1 = src(x);
y2 = src(x);

no = all(y2==y1)
```

```
no =

  1×2 logical array

   0   0
```

The output is different because the internal states of `src` have changed. Use `reset` to reset the converter and call the converter again. Verify that the output is unchanged.

```
reset(src)

y3 = src(x);

yes = all(y3==y1)
```

```
yes =

  1×2 logical array

   1   1
```

step

System object: dsp.SampleRateConverter
Package: dsp

Convert sample rate of signal

Syntax

`y = step(src,x)`

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`y = step(src,x)` returns a signal, `y`, corresponding to the input signal, `x`, with sample rate converted by `src`.

Input Arguments

`src` — Multistage sample rate converter

`SampleRateConverter` System object

Multistage sample rate converter, specified as a `SampleRateConverter` System object.

`x` — Input signal

vector | matrix

Input signal, specified as a vector or matrix. The row length of `x` must be a multiple of the overall decimation factor. Each column of `x` is treated as a separate channel.

Output Arguments

y — Resampled signal
vector | matrix

Resampled signal, returned as a vector or matrix.

Examples

Convert the Sample Rate of a Sinusoid

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

Create a multistage sample rate converter with default properties. The converter converts from 192 kHz to 44.1 kHz in three stages.

```
src = dsp.SampleRateConverter;
```

Use `src` to convert the sample rate of a noisy sinusoid. The sinusoid has a frequency of 20 kHz and is sampled for 0.1 s.

```
f = 20e3;

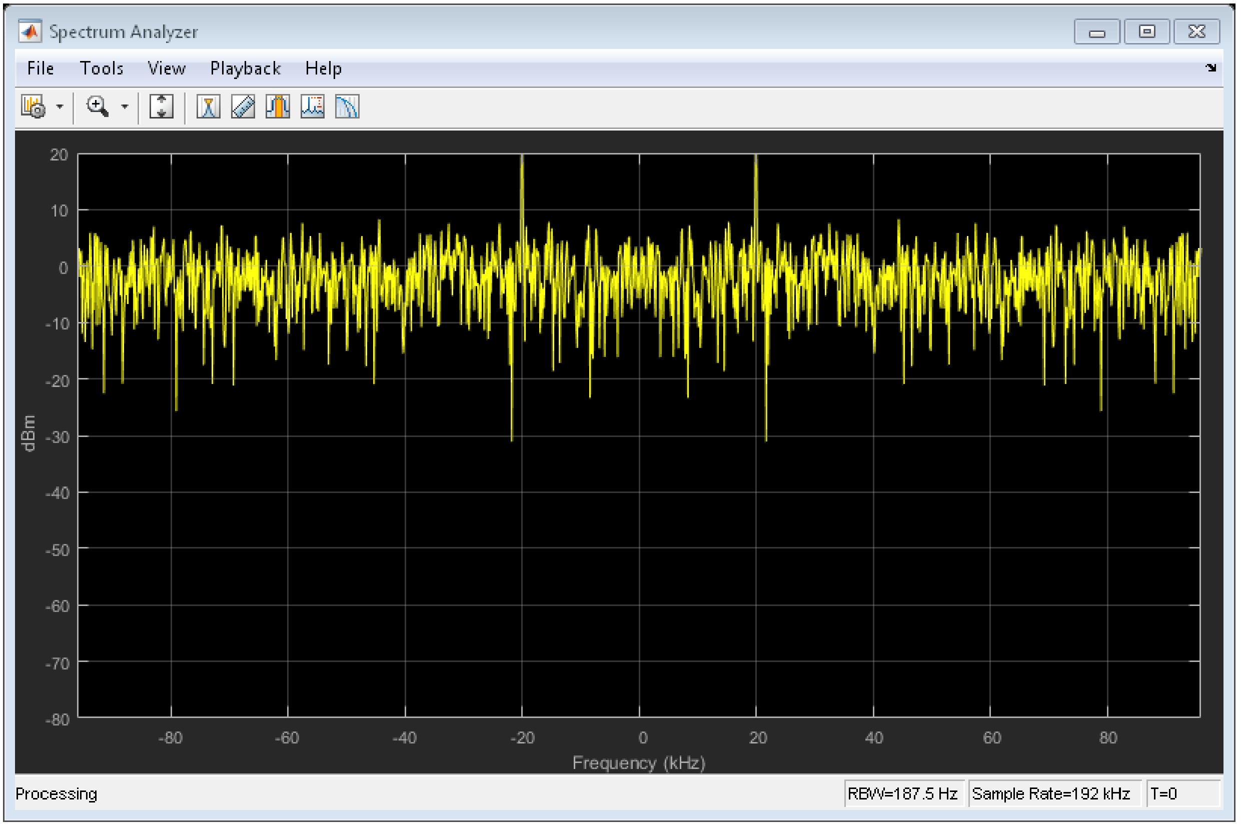
FsIn = src.InputSampleRate;
FsOut = src.OutputSampleRate;

t1 = (0:1/FsIn:0.1-1/FsIn)';

sIn = sin(2*pi*f*t1) + randn(size(t1));
```

Estimate the power spectral density of the input.

```
hsa = dsp.SpectrumAnalyzer('SampleRate',FsIn);
hsa(sIn)
```



Convert the sample rate of the signal. Estimate the power spectral density of the output.

```
sOut = src(sIn);

hsb = dsp.SpectrumAnalyzer('SampleRate',FsOut);
hsb(sOut)
```

Package: dsp

Visualize filter stages

Syntax

```
visualizeFilterStages(src)
```

Description

`visualizeFilterStages(src)` shows the response of each individual filter stage of `src` using `FVTool`.

Input Arguments

`src` — Multistage sample rate converter

`SampleRateConverter` System object

Multistage sample rate converter, specified as a `SampleRateConverter` System object.

Examples

Sample Rate Converter Stages

Create a multistage sample rate converter with default properties, corresponding to the combined three filter stages used to convert from 192 kHz to 44.1 kHz. Visualize the stages.

dsp.ScalarQuantizerDecoder System object

Package: dsp

Convert each index value into quantized output value

Description

The `ScalarQuantizerDecoder` object converts each index value into a quantized output value. The specified codebook defines the set of all possible quantized output values or codewords. Input index values less than 0 are set to 0 and index values greater $N-1$ are set to $N-1$. N is the length of the codebook vector.

To convert an index value into a quantized output value:

1. Define and set up your scalar quantizer decoder. See "Construction" on page 4-1529.
2. Call step to convert the index value according to the properties of `dsp.ScalarQuantizerDecoder`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`sqdec = dsp.ScalarQuantizerDecoder` returns a scalar quantizer decoder System object, `sqdec`, that transforms zero-based input index values into quantized output values.

`sqdec = dsp.ScalarQuantizerDecoder('`*`PropertyName`*`',`*`PropertyValue`*`,...)` returns a scalar quantizer decoder object, `sqdec`, with each specified property set to the specified value.

Properties

CodebookSource

How to specify codebook values

Specify how to determine the codebook values as `Property` or `Input port`. The default is `Property`.

Codebook

Codebook

Specify the codebook as a vector of quantized output values that correspond to each index value. The default is `1:10`. This property is tunable.

OutputDataType

Data type of codebook and quantized output

Specify the data type of the codebook and quantized output values as `Same as input`, `double`, `single` or `Custom`. The default is `double`.

Fixed-Point Properties

CustomOutputDataType

Output word and fraction lengths

Specify the output fixed-point type as a signed or unsigned `numerictype` object. This property applies only when you set the `OutputDataType` on page 4-1530 property to `Custom`. The default is `numerictype(true,16)`.

Methods

step	Decode using scalar quantization

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object

Common to All System Objects	
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

Examples

Quantize a Signal

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

Given a codebook and index values as inputs, determine the corresponding output quantized values.

```
codebook = single([-2.1655 -1.3238 -0.7365 -0.2249 0.2726, ...
    0.7844 1.3610 2.1599]);
indices = uint8([1 3 5 7 6 4 2 0]);
sqdec = dsp.ScalarQuantizerDecoder;
sqdec.CodebookSource = 'Input port';
qout = sqdec(indices, codebook);
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the `Scalar Quantizer Decoder` block reference page. The object properties correspond to the block parameters, except:
There is no object property that directly corresponds to the **Action for out of range index value** block parameter. The object sets any index values less than `0` to `0` and any index values greater than or equal to N to $N-1$.

dsp.ScalarQuantizerEncoder | dsp.VectorQuantizerDecoder

Introduced in R2012a

step

System object: dsp.ScalarQuantizerDecoder
Package: dsp

Decode using scalar quantization

Syntax

```
Q = step(sqdec, I)
Q = step(sqdec,I,C)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Q = step(sqdec, I)` returns the quantized output values `Q` corresponding to the input indices `I`. The data type of `I` can be `uint8`, `uint16`, `uint32`, `int8`, `int16`, or `int32`. The `OutputDataType` property determines the data type for `Q`.

`Q = step(sqdec,I,C)` uses input `C` as the codebook values when you set the `CodebookSource` property to `Input port`. The data type of `C` can be `double`, `single`, or `fixed-point`. The output `Q` has the same data type as the codebook input `C`.

dsp.ScalarQuantizerEncoder System object

Package: dsp

Associate input value with index value of quantization region

Description

The `ScalarQuantizerEncoder` object encodes each input value by associating that value with the index value of the quantization region. Then, the object outputs the index of the associated region.

To encode an input value by associating it with an index value of the quantization region:

1. Define and set up your scalar quantizer encoder. See "Construction" on page 4-1534.
2. Call step to encode the input value according to the properties of `dsp.ScalarQuantizerEncoder`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`sqenc = dsp.ScalarQuantizerEncoder` returns a scalar quantizer encoder System object, `sqenc`. This object maps each input value to a quantization region by comparing the input value to the user-specified boundary points.

`sqenc = dsp.ScalarQuantizerEncoder('`*`PropertyName`*`',`*`PropertyValue`*`,...)` returns a scalar quantizer encoder object, `sqenc`, with each specified property set to the specified value.

Properties

BoundaryPointsSource

Source of boundary points

Specify how to determine the boundary points and codebook values as `Property` or `Input port`. The default is `Property`.

Partitioning

Quantizer is bounded or unbounded

Specify the quantizer as `Bounded` or `Unbounded`. The default is `Bounded`.

BoundaryPoints

Boundary points of quantizer regions

Specify the boundary points of quantizer regions as a vector. The vector values must be in ascending order. Let `[p0 p1 p2 p3 ... pN]` denote the boundary points property in the quantizer. If the quantizer is bounded, the object uses this property to specify `[p0 p1 p2 p3 ... pN]`. If the quantizer is unbounded, the object uses this property to specify `[p1 p2 p3 ... p(N-1)]` and sets `p0 = -Inf` and `pN = +Inf`. This property applies when you set the `BoundaryPointsSource on page 4-1535` property to `Property`. The default is `1:10`. This property is tunable.

SearchMethod

Find quantizer index by linear or binary search

Specify whether to find the appropriate quantizer index using a linear search or a binary search as one of `Linear` or `Binary`. The computational cost of the linear search method is of the order P and the computational cost of the binary search method is of the order

$$\log_2(\mathrm{P})$$

where P is the number of boundary points. The default is `Linear`.

TiebreakerRule

Behavior when input equals boundary point

Specify whether the input value is assigned to the lower indexed region or higher indexed region when the input value equals boundary point by selecting `Choose the lower index` or `Choose the higher index`. The default is `Choose the lower index`.

CodewordOutputPort

Enable output of codeword value

Set this property to `true` to output the codeword values that correspond to each index value. The default is `false`.

QuantizationErrorOutputPort

Enable output of quantization error

Set this property to `true` to output the quantization error for each input value. The quantization error is the difference between the input value and the quantized output value. The default is `false`.

Codebook

Codebook

Specify the codebook as a vector of quantized output values that correspond to each region. If the `Partitioning` property is `Bounded` and the boundary points vector has length N, you must set this property to a vector of length N-1. If the `Partitioning` property is `Unbounded` and the boundary points vector has length N, you must set this property to a vector of length N+1. This property applies when you set the `BoundaryPointsSource on page 4-1535` property to `Property` and either the `CodewordOutputPort on page 4-1536` property or the `QuantizationErrorOutputPort on page 4-1536` property is `true`. The default is `1.5:9.5`. This property is tunable.

ClippingStatusOutputPort

Enable output of clipping status

Set this property to `true` to output the clipping status. The output is a 1 when an input value is outside the range defined by the `BoundaryPoints on page 4-1535` property.

When the value is inside the range, the exception output is a 0. This property applies when you set the `Partitioning on page 4-1535` property to `Bounded`. The default is `false`.

`OutputIndexDataType`

Data type of the index output

Specify the data type of the index output from the object as: `int8`, `uint8`, `int16`, `uint16`, `int32`, `uint32`. The default is `int32`.

Fixed-Point Properties

`RoundingMethod`

Rounding method for fixed-point operations

Specify the rounding method as `Ceiling`, `Convergent`, `Floor`, `Nearest`, `Round`, `Simplest` or `Zero`. The default is `Floor`.

`OverflowAction`

Overflow action for fixed-point operations

Specify the overflow action as `Wrap` or `Saturate`. The default is `Wrap`.

Methods

step	Encode using scalar quantization

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

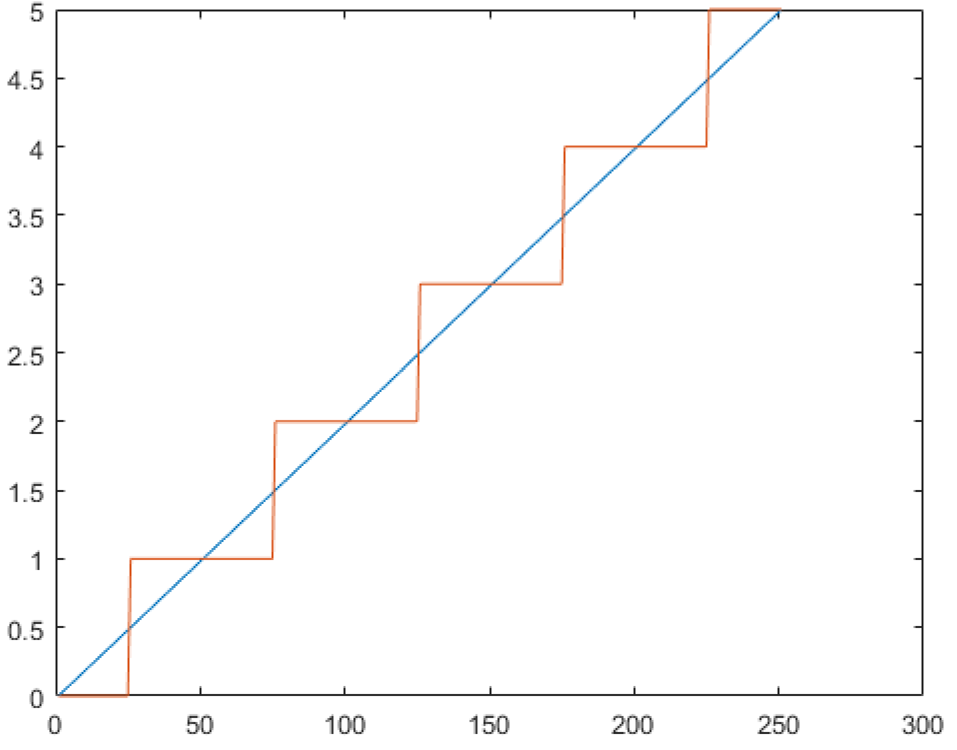
Examples

Quantize the Varying Fractional Inputs

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

Quantize the varying fractional inputs between zero and five to the closest integers, and then plot the results.

```
sqenc = dsp.ScalarQuantizerEncoder;
sqenc.BoundaryPoints = [-.001 .499 1.499 ...
    2.499 3.499 4.499 5.001];
sqenc.CodewordOutputPort = true;
sqenc.Codebook = [0 1 2 3 4 5];
input = (0:0.02:5)';
[index, quantizedValue] = sqenc(input);
plot(1:length(input), [input quantizedValue]);
```



Algorithms

This object implements the algorithm, inputs, and outputs described on the `Scalar Quantizer Encoder` block reference page. The object properties correspond to the block parameters.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See "System Objects in MATLAB Code Generation" (MATLAB Coder).

See Also

dsp.ScalarQuantizerDecoder | dsp.VectorQuantizerEncoder

Introduced in R2012a

step

System object: dsp.ScalarQuantizerEncoder
Package: dsp

Encode using scalar quantization

Syntax

```
INDEX= step(sqenc,INPUT)
[...] = step(sqenc,INPUT,BPOINTS)
[...] = step(sqenc,INPUT,BPOINTS,CODEBOOK)
[...,CODEWORD] = step(sqenc, ...)
[..., QERR] = step(sqenc, ...)
[...,CLIPSTATUS] = step(sqenc, ...)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`INDEX= step(sqenc,INPUT)` returns the `INDEX` of the quantization region to which the `INPUT` belongs. The input data, boundary points, codebook values, quantized output values, and the quantization error must have the same data type whenever they are present.

`[...] = step(sqenc,INPUT,BPOINTS)` when the `BoundaryPointsSource` property is `Input port`, uses input `BPOINTS` as the boundary points .

`[...] = step(sqenc,INPUT,BPOINTS,CODEBOOK)` uses input `BPOINTS` as the boundary points and input `CODEBOOK` as the codebook when the `BoundaryPointsSource` property is `Input port` and either the `CodewordOutputPort` property or the `QuantizationErrorOutputPort` property is `true`.

`[...,CODEWORD] = step(sqenc, ...)` outputs the `CODEWORD` values that corresponds to each index value when the `CodewordOutputPort` property is `true`.

`[..., QERR] = step(sqenc, ...)` outputs the quantization error `QERR` for each input value when the `QuantizationErrorOutputPort` property is `true`.

`[...,CLIPSTATUS] = step(sqenc, ...)` also returns output `CLIPSTATUS` as the clipping status output port for each input value when the `Partitioning` property is `Bounded` and the `ClippingStatusOutputPort` property is `true`. If an input value is outside the range defined by the `BoundaryPoints` property, `CLIPSTATUS` is `true`. If an input value is inside the range, `CLIPSTATUS` is `false`.

Note: `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.SignalSink System object

Package: dsp

Log simulation data in buffer

Description

The `SignalSink` object logs MATLAB simulation data. This object accepts any numeric data type.

To log MATLAB simulation data :

1. Define and set up your signal sink. See "Construction" on page 4-1543.
2. Call step to log the simulation data according to the properties of `dsp.SignalSink`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = dsp.SignalSink` returns a signal sink, `H`, that logs 2-D input data in the object.

`H = dsp.SignalSink('`*`PropertyName`*`',`*`PropertyValue`*`,...)` returns a signal sink, `H`, with each specified property set to the specified value.

Properties

`BufferLength`

Maximum number of input frames to log

Specify the maximum number of frames to log. The object always preserves the most recent data in the buffer. When you specify a buffer length that is greater than the input length, the object pads the end of the logged data with zeros. To capture all input data without extra padding, set the `BufferLength` property to `inf`. The default is `inf`.

`Decimation`

Decimation factor

Setting this property to any positive integer d causes the signal sink to write data at every dth sample. The default is `1`.

`FrameHandlingMode`

Output dimensionality for frame-based inputs

Set the dimension of the output array for frame-based inputs as `2-D array (concatenate)` or `3-D array (separate)`. Concatenation occurs along the first dimension for `2-D array (concatenate)`. The default is `2-D array (concatenate)`.

`Buffer`

Logged Data (read only)

The signal sink writes simulation data into a buffer. Specify the maximum length of the buffer with the `BufferLength` on page 4-1543 property.

Methods

reset	Reset internal states of signal logger object
step	Store signal in buffer

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)

Common to All System Objects	
`release`	Allow System object property value changes

Examples

Log Input Data

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject(x) becomes step(myObject,x).

```
hlog = dsp.SignalSink;
 for i=1:10
     y = sin(i);
     hlog(y);
 end
log = hlog.Buffer;
display(log);
```

```
log =

    0.8415
    0.9093
    0.1411
   -0.7568
   -0.9589
   -0.2794
    0.6570
    0.9894
    0.4121
   -0.5440
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the To Workspace block reference page. The object properties correspond to the block properties, except:

The object always generates fixed-point output for fixed-point input.

See Also

dsp.SignalSource

Introduced in R2012b

reset

System object: dsp.SignalSink
Package: dsp

Reset internal states of signal logger object

Syntax

`reset(H)`

Description

`reset(H)` sets the internal states of the `SignalSink` object `H` to their initial values.

step

System object: dsp.SignalSink
Package: dsp

Store signal in buffer

Syntax

`step(H,Y)`

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`step(H,Y)` buffers the signal `Y`. The buffer may be accessed at any time from the `Buffer` property of `H`.

Note: `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

---

dsp.SignalSource System object

Package: dsp

Import variable from workspace

Description

The `SignalSource` object imports a variable from the MATLAB workspace.

To import a variable from the MATLAB workspace:

1 Define and set up your signal source. See “Construction” on page 4-1549.
2 Call step to import the variable according to the properties of `dsp.SignalSource`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj)` and `y = obj()` perform equivalent operations.

Construction

`src = dsp.SignalSource` returns a signal source System object, `src`, that outputs the variable one sample or frame at a time.

`src = dsp.SignalSource('`*`PropertyName`*`',`*`PropertyValue`*`,...)` returns a signal source object, `src`, with each specified property set to the specified value.

`src = dsp.SignalSource(signal,spf,'`*`PropertyName`*`',`*`PropertyValue`*`,...)` returns a signal source object, `src`, with the `Signal` on page 4-1550 property set to `signal`, the `SamplesPerFrame` on page 4-1550 property set to `spf`, and other specified properties set to the specified values.

Properties

Signal

Variable or expression containing the signal

Specify the name of the workspace variable from which to import the signal, or a valid expression specifying the signal. The default is [1:10].

SamplesPerFrame

Number of samples per output frame

Specify the number of samples to buffer into each output frame. This property must be 1 when you specify a 3-D array in the Signal on page 4-1550 property. The default is 1.

SignalEndAction

Action after final signal values are generated

Specify the output after all of the specified signal samples have been generated as one of Set to zero, Hold final value, or Cyclic repetition. The default is Set to zero.

Methods

isDone	End-of-file status for signal reader object
reset	Reset internal states of signal reader object
step	Read one sample or frame of signal

Common to All System Objects	
clone	Create System object with same property values
getNumInpu	Expected number of inputs to a System object
getNumOutp	Expected number of outputs of a System object
isLocked	Check locked states of a System object (logical)
release	Allow System object property value changes

Examples

Create a Signal Source

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject() becomes step(myObject).

Create a signal source to output one sample at a time.

```
src1 = dsp.SignalSource;
src1.Signal = randn(1024, 1);
y1 = zeros(1024,1);
idx = 1;
while(~isDone(src1))
    y1(idx) = src1();
    idx = idx+1;
end
```

Create a signal source to output vectors.

```
src2 = dsp.SignalSource(randn(1024, 1), 128);
y2 = src2(); % y2 is a 128-by-1 frame of samples
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the `Signal From Workspace` block reference page. The object properties correspond to the block parameters, except:
The object does not have properties that correspond to the **Sample time** or **Warn when frame size does not evenly divide input length** block parameters.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

dsp.SignalSink

Introduced in R2012b

isDone

System object: dsp.SignalSource
Package: dsp

End-of-file status for signal reader object

Syntax

`isDone(src)`

Description

`isDone(src)` returns a logical value indicating whether or not the `SignalSource` object, `src`, has reached the end of the imported signal. If the `SignalEndAction` property is set to `Cyclic repetition`, this method will return `true` every time the reader reaches the end.

reset

System object: dsp.SignalSource
Package: dsp

Reset internal states of signal reader object

Syntax

`reset(src)`

Description

`reset(src)` resets the signal reader object `src`, to start reading from the beginning of the imported signal.

step

System object: dsp.SignalSource
Package: dsp

Read one sample or frame of signal

Syntax

```
Y = step(src)
```

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj)` and `y = obj()` perform equivalent operations.

`Y = step(src)` outputs one sample or frame of data, `Y`, from each column of the imported signal. The imported signal is the variable or expression you specify for the `Signal` property of the `SignalSource` System object `src`.

Note: `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties (MATLAB) and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.SineWave System object

Package: dsp

Discrete-time sinusoid

Description

The `SineWave` object generates a discrete-time sinusoid. The sine wave object generates a real–valued sinusoid or a complex exponential. A real-valued, discrete-time sinusoid is defined as:

$$y(n) = A\sin(2\pi fn + \phi)$$

where A is the amplitude, f is the frequency in hertz, and φ is the initial phase, or phase offset, in radians. A complex exponential is defined as:

$$y(n) = Ae^{j(2\pi fn+\phi)}$$

For both real and complex sinusoids, the amplitude, frequency, and phase offsets can be scalars or length-N vectors, where N is the desired number of channels in the output. When you specify at least one of these properties as a length-N vector, scalar values specified for the other properties are applied to each of the N channels.

To generate a discrete-time sinusoid:

1 Define and set up your sine wave. See “Construction” on page 4-1557.
2 Call step to generate the sinusoid according to the properties of `dsp.SineWave`. The behavior of `step` is specific to each object in the toolbox.

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj)` and `y = obj()` perform equivalent operations.

Construction

`sine = dsp.SineWave` returns a sine wave object, `sine`, that generates a real-valued sinusoid with an amplitude of 1, a frequency of 100 Hz, and a phase offset of 0. By default, the sine wave object only generates one sample.

`sine = dsp.SineWave('`*`PropertyName`*`',`*`PropertyValue`*`, ...)` returns a sine wave object, `sine`, with each property set to the specified value.

`sine = dsp.SineWave(AMP,FREQ,PHASE, '`*`PropertyName`*`',`*`PropertyValue`*`, ...)` returns a sine wave object, `sine`, with the `Amplitude` property set to `AMP`, the `Frequency` property set to `FREQ`, the `PhaseOffset` property set to `PHASE`, and the other specified properties set to the specified values.

Properties

`Amplitude`

Amplitude of the sine wave

Specify the amplitude as a length-*N* vector containing the amplitudes of the sine waves in each of *N* output channels, or a scalar to apply to all *N* channels. The vector length must equal that specified for the `Frequency` on page 4-1557 and `PhaseOffset` on page 4-1557 properties. The default value is 1. This property is tunable when `Method` on page 4-1558 property is `Differential` or `Trigonometric function`.

`Frequency`

Frequency of the sine wave

Specify a length-*N* vector containing frequencies, in hertz, of the sine waves in each of *N* output channels, or a scalar to apply to all *N* channels. The vector length must equal that specified for the `Amplitude` on page 4-1557 and `PhaseOffset` on page 4-1557 properties. You can specify positive, zero, or negative frequencies. The default is 100. This property is nontunable.

`PhaseOffset`

Phase offset of the sine wave in radians

A length-*N* vector containing the phase offsets, in radians, of the sine waves in each of *N* output channels, or a scalar to apply to all *N*channels. The vector length must equal that specified for the `Amplitude` on page 4-1557 and `Frequency` on page 4-1557 properties. The default value is 0. This property is nontunable.

ComplexOutput

Indicates whether the sine wave is complex or real

Set to `true` to output a complex exponential. The default value is `false`.

Method

Method used to generate sinusoids

The sinusoids are generated by either the `Trigonometric function` , `Table lookup`, or `Differential` methods . The `Trigonometric function` method computes the sinusoid by sampling the continuous-time sinusoid. The `table lookup` method precomputes the unique samples of every output sinusoid at the start of the simulation, and recalls the samples from memory as needed. The `differential` method uses an incremental algorithm. This algorithm computes the output samples based on the output values computed at the previous sample time and precomputed update terms. The default value is `Trigonometric function`.

TableOptimization

Optimizes the table of sine values for speed or memory

Optimizes the table of sine values for `Speed` or `Memory`. When optimized for speed, the table contains *k* elements, and when optimized for memory, the table contains *k/4* elements, where *k* is the number of input samples in one full period of the sine wave. This property applies only when the `Method` on page 4-1558 property is `Table lookup`. The default value is `Speed`.

SampleRate

Sampling rate for the sine wave

Specify the sampling rate of the output, in hertz, as a positive numeric scalar. The default is 1000.

SamplesPerFrame

Number of samples per frame

Specify the number of consecutive samples from each sinusoid to buffer into the output frame. The default is 1.

`OutputDataType`

Output data type

Specify the output data type as `double`, `single`, or `Custom`. The default value is `double`.

Fixed-Point Properties

`CustomOutputDataType`

Output word and fraction lengths

Specify the output fixed-point type as a `numerictype` object with a `Signedness` of `Auto`. This property applies only when the `OutputDataType` on page 4-1559 property is `Custom`. The default value is `numerictype([]1,16)`.

Methods

reset	Reset sine wave to the beginning
step	Discrete-time sine wave

Common to All System Objects	
`clone`	Create System object with same property values
`getNumInpu`	Expected number of inputs to a System object
`getNumOutp`	Expected number of outputs of a System object
`isLocked`	Check locked states of a System object (logical)
`release`	Allow System object property value changes

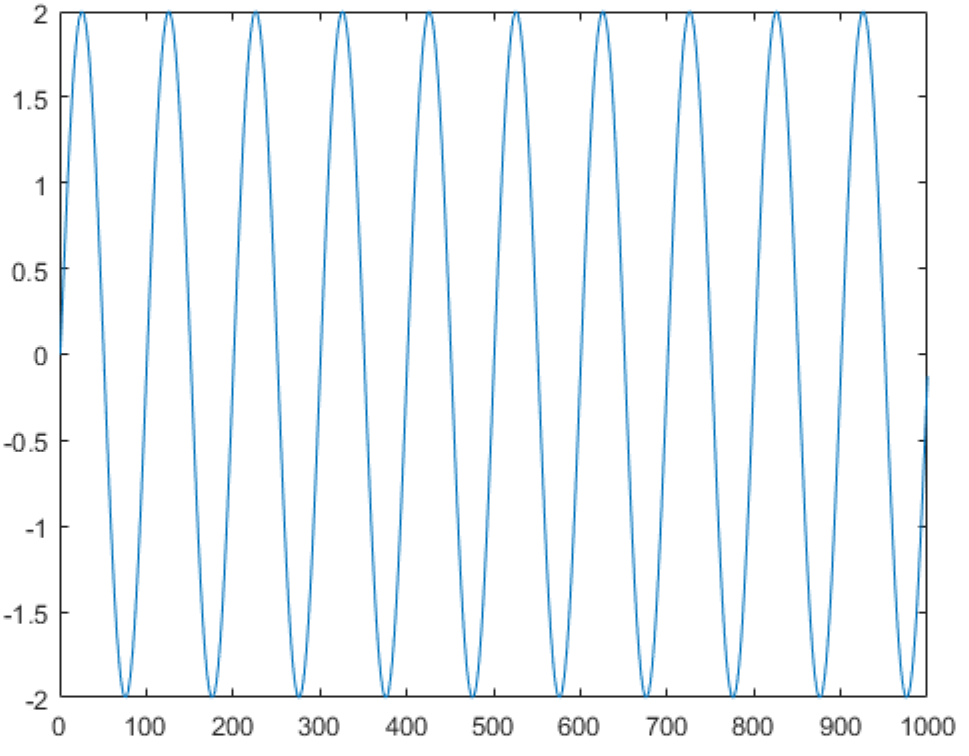
Examples

Generate a Sine Wave Signal

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, myObject() becomes step(myObject).

Generate a sine wave with an amplitude of 2, frequency of 10 Hz, and an initial phase of 0.

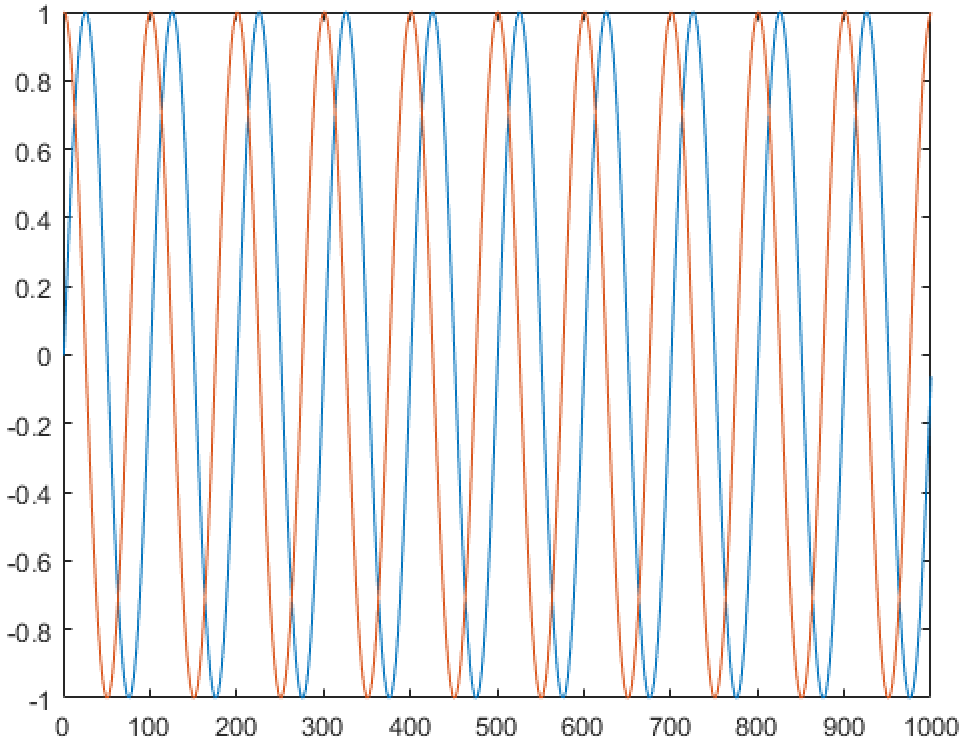
```
sine1 = dsp.SineWave(2, 10);
sine1.SamplesPerFrame = 1000;
y = sine1();
plot(y);
```



Generate two sine waves offset by a phase of pi/2 radians.

```
sine2 = dsp.SineWave;
sine2.Frequency = 10;
sine2.PhaseOffset = [0 pi/2];
```

```
sine2.SamplesPerFrame = 1000;
y = sine2();
plot(y);
```



Algorithms

This object implements the algorithm, inputs, and outputs described on the `Sine Wave` block reference page. The object properties correspond to the block parameters.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- This object has no tunable properties for code generation.
- See “System Objects in MATLAB Code Generation” (MATLAB Coder).

dsp.Chirp | dsp.NCO

Introduced in R2012a

reset

System object: dsp.SineWave
Package: dsp

Reset sine wave to the beginning

Syntax

`reset(sine)`

Description

`reset(sine)` resets the sine wave object to the beginning (*n=0*). If you invoke the `step` method without first invoking the `reset` method, the sine wave object generates additional samples of the original sinusoid.

Reset the SineWave Signal

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For `dsp.ColoredNoise` System object™, myObject() becomes step(myObject). For all other objects, myObject(x) becomes step(myObject,x).

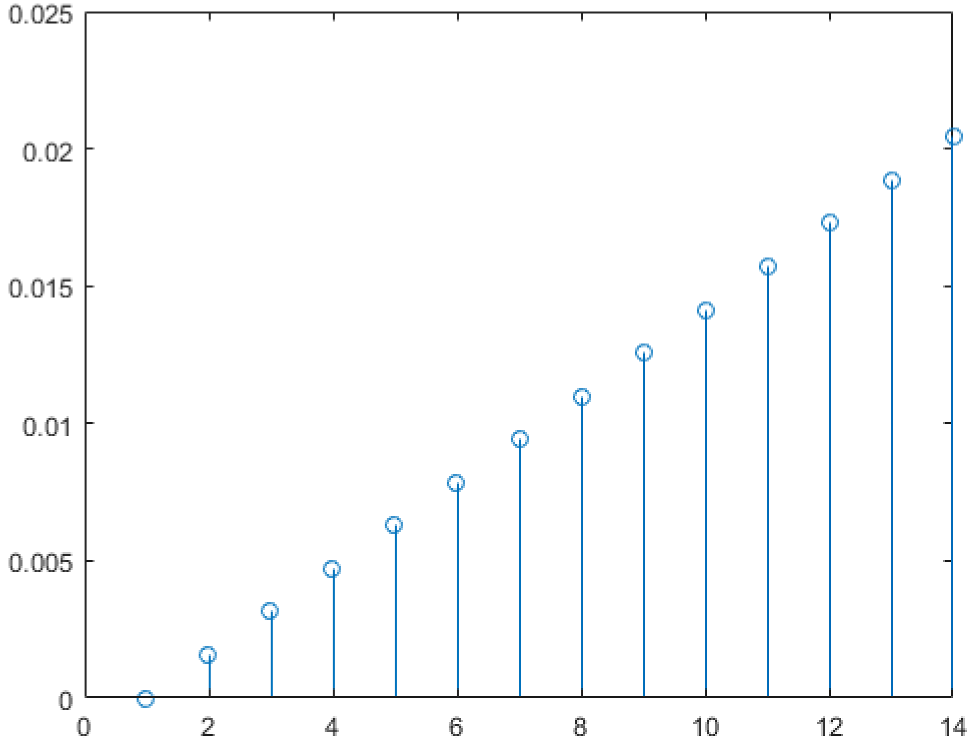
```
sine = dsp.SineWave('Amplitude',1,'Frequency',1/4,'SamplesPerFrame',7);
```

7 samples of a sine wave with frequency of 1/4 Hz

```
y = sine();
```

Call step method without reset

```
y1 = sine();
stem([y; y1])
```



y1 is a continuation of y. Now reset

```
reset(sine);
y2 = sine();
```

y2 starts at n = 0 and equals y

```
isequal(y,y2)
```

```
ans =

  logical
```

1

step

System object: dsp.SineWave
Package: dsp

Discrete-time sine wave

Syntax

`Y = step(sine)`

Description

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj)` and `y = obj()` perform equivalent operations.

`Y = step(sine)` produces the sine wave `Y` using the specifications in the object `sine`.

dsp.SpectrumAnalyzer System object

Package: dsp

Display frequency spectrum of time-domain signals

Description

The `SpectrumAnalyzer` object, referred to as the scope, displays the frequency spectrum of time-domain signals. This scope supports variable-size input, which allows the input frame size to change. Frame size is the first dimension of the input vector. The number of input channels must remain constant.

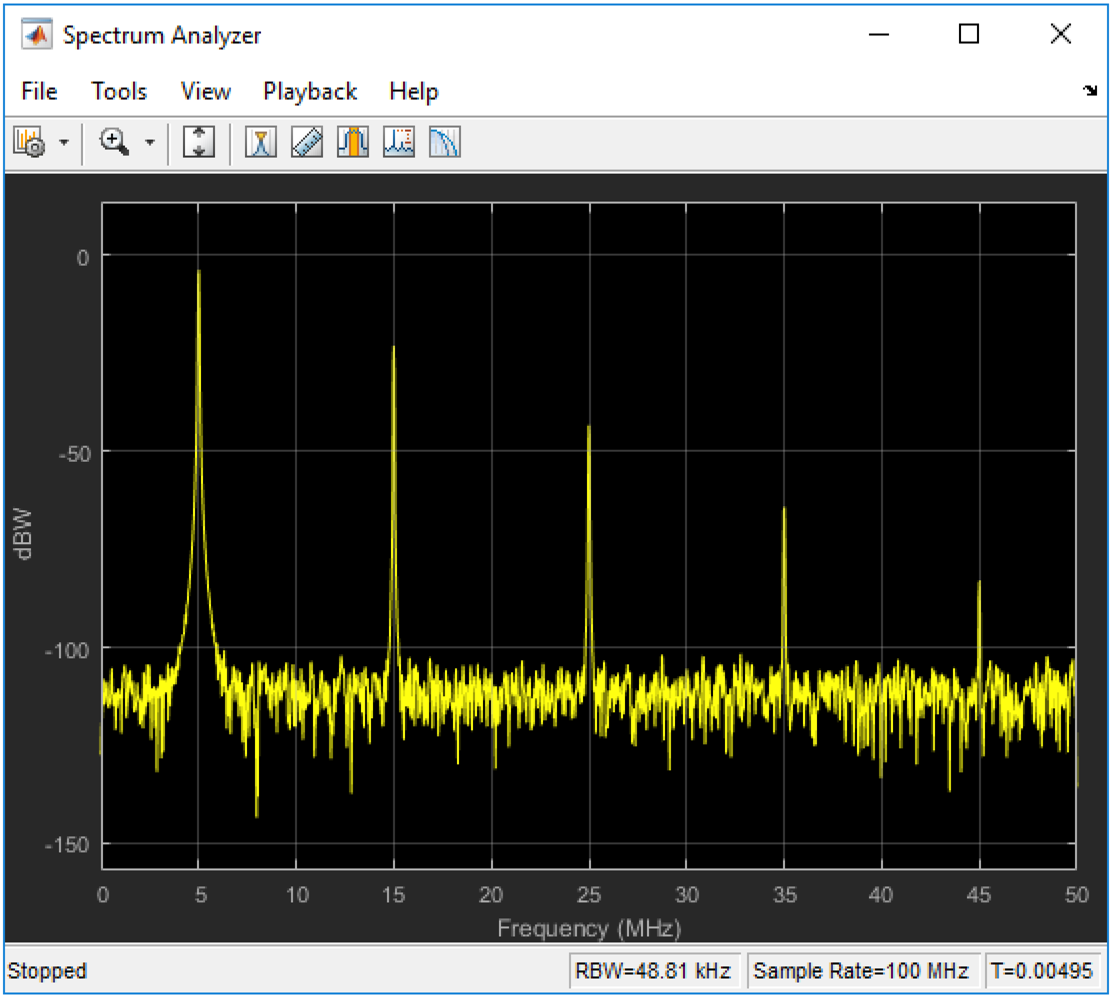
To display the spectra of signals in the Spectrum Analyzer:

1. Define and set up your Spectrum Analyzer. See "Construction" on page 4-1569.
2. Call step to display the frequency spectrum of the signals in the Spectrum Analyzer figure. The number of inputs to the step method must match the value of the NumInputPorts property. The input to every port must have same frame length, but can have a different number of channels. Each input is an individual channel of input data. For example, if the first input is a signal vector, it is Channel 1. If the second input is a two-column matrix, it is Channel 2 and Channel 3.

Use the MATLAB `clear` function to close the Spectrum Analyzer figure window and clear its associated data. Use the hide method to hide the Spectrum Analyzer window and the show method to make it visible.

Use the MATLAB `mcc` function to compile code containing a Spectrum Analyzer.

Note: You cannot open Spectrum Analyzer configuration dialogs if you have more than one compiled component in your application.



See the following sections for more information on the Spectrum Analyzer Graphical User Interface:

- "Signal Display" on page 4-1596
- "Spectrum Settings" on page 4-1601
- "Measurements Panels" on page 4-1608
- "Visuals — Spectrum Properties" on page 4-1623

- “Style Dialog Box” on page 2-1587
- “Tools — Axes Scaling Properties” on page 4-1627
- “Algorithms” on page 2-1592

Note: For information about the Spectrum Analyzer block, see `Spectrum Analyzer`.

Note: If you own the MATLAB Coder product, you can generate C or C++ code from MATLAB code in which an instance of this system object is created. When you do so, the scope system object is automatically declared as an *extrinsic* variable. In this manner, you are able to see the scope display in the same way that you would see a figure using the `plot` function, without directly generating code from it. For the full list of system objects supporting code generation, see “DSP System Toolbox” (MATLAB Coder).

Note: Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = dsp.SpectrumAnalyzer` creates a Spectrum Analyzer System object, `H`. This object displays the frequency spectrum of real- and complex-valued floating- and fixed-point signals.

`H = dsp.SpectrumAnalyzer(ports)` creates a Spectrum Analyzer with the specified number of input `ports`. This value is stored in the `NumInputPorts` property.

`H = dsp.SpectrumAnalyzer('`*`Name`*`',`*`Value`*`,...)` creates a Spectrum Analyzer System object, `H`, with each specified property *`Name`* set to the specified value. You can specify *`Name`*–*`Value`* arguments in any order.

Properties

`AxesLayout`

Orientation of the spectrum and spectrogram

Specify the layout type as one of `'Horizontal'` or `'Vertical'`. A vertical layout stacks the spectrum above the spectrogram. A horizontal layout puts the two views side-by-side. This property applies when the `ViewType` is set to `'Spectrum and spectrogram'`.

This property is Tunable (Simulink).

Default: `'Vertical'`

CenterFrequency

Frequency over which frequency span is centered

Specify as a real scalar the center frequency, in hertz, of the frequency span over which the Spectrum Analyzer computes and plots the spectrum. This property applies when you set the FrequencySpan property to `'Span and center frequency'`. The overall frequency span, defined by the Span and CenterFrequency properties, must fall within the Nyquist frequency interval. When the PlotAsTwoSidedSpectrum property is set to `true`, the interval is $\left[-\frac{SampleRate}{2}, \frac{SampleRate}{2}\right] + FrequencyOffset$ hertz. When the `PlotAsTwoSidedSpectrum` property is set to `false`, the interval is $\left[0, \frac{SampleRate}{2}\right] + FrequencyOffset$ hertz.

This property is Tunable (Simulink).

Default: `0`

ChannelNames

Channel names

Specify as a cell array of character vectors the input channels names to display in the legend, the Style dialog, and in some Measurements panels. The channel names only appear in the legend when the `ShowLegend` property is `true`. The default is an empty cell array, which labels the channels as `Channel 1`, `Channel 2`, etc.

This property is Tunable (Simulink).

FFTLength

FFT length

Specify as a positive, scalar integer the length of the FFT that the Spectrum Analyzer uses to compute spectral estimates. This property applies only when you set the FrequencyResolutionMethod property to `'WindowLength'` and the FFTLengthSource property to `'Property'`. The `FFTLength` must be greater than or equal to the WindowLength. You cannot control the FFT length when the FrequencyResolutionMethod property is `'RBW'`. In that case, the FFT length is set as the window length required to achieve the specified resolution bandwidth value or 1024, whichever is larger.

This property is Tunable (Simulink).

Default: `128`

`FFTLengthSource`

Source of the FFT length value

Specify the source of the FFT length value as one of `'Auto'` or `'Property'`.

- When you set this property to `'Auto'`, the Spectrum Analyzer sets the FFT length to the window length specified in the WindowLength property or to 1024, whichever is larger.
- When you set this property to `'Property'`, specify the number of FFT points using the FFTLength property. The `FFTLength` must be greater than the `WindowLength`.

This property applies only when you set the FrequencyResolutionMethod property to `'WindowLength'`.

`FFTLengthSource` property is Tunable (Simulink).

Default: `'Auto'`

`FrequencyOffset`

Frequency offset

Specify as a real, scalar value to apply the same frequency offset, in Hertz, to all channels. To apply a specific frequency offset for each channel, specify a vector of real, scalar values. The vector length must be equal to number of input channels. The *frequency*-axis values are offset by the values specified in this property. The overall span must fall within the *Nyquist* frequency interval. When the PlotAsTwoSidedSpectrum property is `true`, the Nyquist interval is $\left[-\frac{SampleRate}{2}, \frac{SampleRate}{2}\right] + FrequencyOffset$ hertz. When you set the `PlotAsTwoSidedSpectrum` property to `false`, the Nyquist interval is $\left[0, \frac{SampleRate}{2}\right] + FrequencyOffset$ hertz. You can control the overall span in different ways based on how you set the FrequencySpan property.

This property is Tunable (Simulink).

Default: `0`

`FrequencyResolutionMethod`

Frequency resolution method

Specify how to control the frequency resolution of the spectrum analyzer as either `'RBW'` or `'WindowLength'`. When you set this property to `'RBW'`, the RBWSource and RBW properties control the frequency resolution (in Hz) of the analyzer. When you set this property to `'WindowLength'`, the WindowLength property controls the frequency resolution.

In this case, the frequency resolution of the analyzer is defined as $\frac{NENBW * Fs}{N_{window}}$ where *NENBW* is the normalized effective noise bandwidth of the window currently specified in the Window property. You can control the number of FFT points only when the `FrequencyResolutionMethod` property is `'WindowLength'`. When the `FrequencyResolutionMethod` property is `'RBW'`, the FFT length is the window length that results from achieving the specified RBW value or 1024, whichever is larger.

This property is Tunable (Simulink).

Default: `'RBW'`

`FrequencyScale`

Frequency scale

Specify the frequency scale as either `'Linear'` or `'Log'`. When you set the `FrequencyScale` property to `'Log'`, the Spectrum Analyzer displays the frequencies on the *x*-axis on a logarithmic scale. To use the `'Log'` setting, you must also set the PlotAsTwoSidedSpectrum property to `false`. When the `PlotAsTwoSidedSpectrum` property is `true`, you must set this property to `'Linear'`.

This property is Tunable (Simulink).

Default: `'Linear'`

FrequencySpan

Frequency span mode

Specify the frequency span mode as one of `'Full'`, `'Span and center frequency'`, or `'Start and stop frequencies'`.

- When you set this property to `'Full'`, the Spectrum Analyzer computes and plots the spectrum over the entire *Nyquist* frequency interval. When the PlotAsTwoSidedSpectrum property is `true`, the Nyquist interval is $\left[-\frac{SampleRate}{2}, \frac{SampleRate}{2}\right] + FrequencyOffset$ hertz. If you set the `PlotAsTwoSidedSpectrum` property to `false`, the Nyquist interval is $\left[0, \frac{SampleRate}{2}\right] + FrequencyOffset$ hertz.
- When you set this property to `'Span and center frequency'`, the Spectrum Analyzer computes and plots the spectrum over the interval specified by the Span and CenterFrequency properties.
- When you set this property to `'Start and stop frequencies'`, the Spectrum Analyzer computes and plots the spectrum over the interval specified by the StartFrequency and StopFrequency properties.

This property is Tunable (Simulink).

Default: `'Full'`

Name

Caption to display on Spectrum Analyzer window

Specify as a character vector the caption to display on the scope window. This property is Tunable (Simulink).

Default: `'Spectrum Analyzer'`

`NumInputPorts`

Number of input ports

Number of input ports, specified as an integer. Each signal coming through an input port becomes a separate channel in the Spectrum Analyzer.

Default: `1`

`OverlapPercent`

Overlap percentage

Specify as a real, scalar value, the percentage overlap between the previous and current buffered data segments. The overlap creates a window segment that is used to compute a spectral estimate. The value must be greater than or equal to zero and less than 100. This property is Tunable (Simulink).

Default: `0`

`PlotAsTwoSidedSpectrum`

Two sided spectrum flag

Set this property to `true` to compute and plot two-sided spectral estimates. Set this property to `false` to compute and plot one-sided spectral estimates. If you set this property to `false`, then the input signal must be real valued. When the input signal is complex valued, you must set this property to `true`.

When this property is `false`, Spectrum Analyzer uses *power folding*. The *y*-axis values are twice the amplitude that they would be if this property were set to `true`, except at 0 and the Nyquist frequency. A one-sided PSD contains the total power of the signal in the frequency interval from DC to half of the Nyquist rate. For more information, see the `pwelch` function reference page.

Default: `true`

PlotMaxHoldTrace

Max-hold trace flag

Set this property to `true` to compute and plot the maximum-hold spectrum of each input channel. The maximum-hold spectrum at each frequency bin is computed by keeping the maximum value of all the power spectrum estimates. When you toggle this property, the Spectrum Analyzer resets its maximum-hold computations. This property applies only when you set the ViewType property to `'Spectrum'` or `'Spectrum and spectrogram'`.

This property is Tunable (Simulink).

See also: PlotMinHoldTrace and PlotNormalTrace.

Default: `false`

PlotMinHoldTrace

Min-hold trace flag

Set this property to `true` to compute and plot the minimum-hold spectrum of each input channel. The minimum-hold spectrum at each frequency bin is computed by keeping the minimum value of all the power spectrum estimates. When you toggle this property, the Spectrum Analyzer resets its minimum-hold computations. This property applies only when you set the ViewType property to `'Spectrum'` or `'Spectrum and spectrogram'`.

This property is Tunable (Simulink).

See also: PlotMaxHoldTrace andPlotNormalTrace.

Default: `false`

PlotNormalTrace

Normal trace flag

Set this property to `false` to remove the display of the normal traces. These traces display the free-running spectral estimates. Note that even when the traces are removed from the display, the Spectrum Analyzer continues its spectral computations. This property applies only when you set the ViewType property to `'Spectrum'` or `'Spectrum and spectrogram'`.

This property is Tunable (Simulink).

See also: PlotMaxHoldTrace and PlotMinHoldTrace.

Default: `true`

PlotType

Plot type for normal traces

Specify the type of plot to use for displaying normal traces as either `'Line'` or `'Stem'`. *Normal* traces are traces that display free-running spectral estimates. This property applies only when you set the ViewType property to `'Spectrum'` or `'Spectrum and spectrogram'` and the PlotNormalTrace property to `true`.

This property is Tunable (Simulink).

Default: `'Line'`

Position

Spectrum Analyzer window position in pixels

Specify, in pixels, the size and location of the scope window as a 4-element double vector of the form [left bottom width height]. You can place the scope window in a specific position on your screen by modifying the values to this property. This property is Tunable (Simulink).

Default: The default depends on your screen resolution. By default, the Spectrum Analyzer window appears in the center of your screen with a width of `800` pixels and height of `450` pixels.

RBW

Resolution bandwidth

Specify as a real, positive scalar the resolution bandwidth (RBW), in hertz. RBW controls the spectral resolution of Spectrum Analyzer. This property applies only when you set the FrequencyResolutionMethod property to `'RBW'` and the RBWSource property to `'Property'`. You must specify a value to ensure that there are at least two RBW intervals over the specified frequency span. Thus, the ratio of the overall span to RBW must be greater than two: $\frac{span}{RBW} > 2$. You can specify the overall span in different ways based on how you set the `FrequencySpan` on page 4-1573 property.

This property is Tunable (Simulink).

See also: RBWSource.

Default: `9.76`

RBWSource

Source of resolution bandwidth value

Specify the source of the resolution bandwidth (RBW) as either `'Auto'` or `'Property'`. This property is relevant only when you set the FrequencyResolutionMethod property to `'RBW'`.

- When you set this property to `'Auto'`, the Spectrum Analyzer adjusts the spectral estimation resolution to ensures that there are 1024 RBW intervals over the defined frequency span.
- When you set this property to `'Property'`, specify the resolution bandwidth directly using the RBW property.

This property is Tunable (Simulink).

See also: RBW.

Default: `'Auto'`

ReducePlotRate

Reduce plot rate to improve performance

When you set this property to `true`, the scope logs data for later use and updates the display at fixed intervals of time. Data occurring between these fixed intervals might not be plotted. When you set this property to `false`, the scope updates every time it computes the power spectrum. Use the `false` setting when you do not want to miss any spectral updates at the expense of slower simulation speed. The simulation speed is faster when this property is set to `true`. This property is Tunable (Simulink).

Default: `true`

`ReferenceLoad`

Reference load

Specify as a real, positive scalar the load, in ohms, that the Spectrum Analyzer uses as a reference to compute power values.

This property is Tunable (Simulink).

Default: `1`

`SampleRate`

Sample rate of input

Specify the sample rate, in hertz, of the input signals.

The sample rate must be a finite numeric scalar.

Default: `10e3`

`ShowGrid`

Option to enable or disable grid display
